ESHG Plenary Lectures

PL1.1
The Regulome - the Next Frontier in Human Genetics

***S. Mundlos**;*
Berlin, Germany.

No abstract received as per date of publication. Please check the programme planner at http://www.eshg.org/abstracts2012.0.html for possible updates.

PL1.2
Oncogenomics of pediatric brain tumors: From molecular profiling towards clinical Translation

***P. Lichter**;*
Heidelberg, Germany.

No abstract received as per date of publication. Please check the programme planner at http://www.eshg.org/abstracts2012.0.html for possible updates.

PL1.3
Myocardial infarction: common disease, common variants, common mechanisms

***H. Schunkert**;*
Lübeck, Germany.

The primary manifestation of coronary disease occurs often suddenly and unexpectedly in form of myocardial infarction. Thus, the prediction of silent atherosclerotic alterations in coronary arteries is a highly relevant medical need. Recent genomic research identified numerous genetic variants that associate with a higher prevalence of coronary disease. At present, association with coronary artery disease has been demonstrated at more than 40 chromosomal locations with risk alleles increasing relative risk by 8-25 % per allele. Moreover, genetic variants primarily affecting cardiovascular risk factors such as hypertension or LDL cholesterol were shown to affect the risk of coronary disease as well.

This enormous progress has been facilitated by genome-wide association studies. By nature, these studies focus on frequent alleles. Thus, the alleles that have been identified to increase the risk of coronary disease are also relatively frequent in our population, i.e. allele frequencies range between roughly 10-90%. As a consequence, virtually all individuals of our population carry a variable degree of genetic predisposition. More recently, the focus turned to rare variants with more profound effects. In this regard, the domain of human genetics, i.e. family based research and counseling, received more attention - once again. The presentation will address how this information can be utilized for a better understanding of disease mechanisms as well as for genomic prediction of coronary artery disease.

PL2.1
Genome sequencing of childhood medulloblastoma brain tumors links chromothripsis with TP53 mutations - a discovery with clinical implications

***J. O. Korbel**[1], P. Lichter[2], S. Pfister[2];*
[1]European Molecular Biology Laboratory, Heidelberg, Germany, [2]DKFZ, Heidelberg, Germany.

Somatic structural variations typically occur progressively during tumor development. Recent findings, however, suggest an alternative mechanism, involving chromosome shattering and reshuffling ('chromothripsis'), the underlying mechanistic basis of which is unknown. In the context of the International Cancer Genome Consortium (ICGC) Pediatric Brain Tumor Project (www.pedbraintumor.org), whole-genome sequencing of a Sonic-Hedgehog medulloblastoma (SHH-MB) brain tumor from a patient with a germline TP53 mutation (Li-Fraumeni syndrome) revealed massive, complex rearrangements resulting from chromothripsis. Integrating TP53 status with genomic rearrangement data in additional medulloblastomas revealed a striking association between TP53 mutation and chromothripsis in SHH-MBs. Unexpectedly, five seemingly sporadic SHH-MB patients with chromothripsis harbored TP53 germline mutation. Our analysis of additional tumor entities substantiated a link between TP53 mutation and chromothripsis, beyond general genomic instability. Among these, we observed a strong association between somatic TP53 mutations and chromothripsis in acute myeloid leukemia, and an increased occurrence of chromothripsis in Li Fraumeni Syndrome-associated malignancies other than medulloblastoma. Our findings implicate p53 in the initiation of, or cellular reaction to, chromothripsis - a novel role for the 'guardian of the genome'. In addition, our findings are of relevance for clinical management and personalized medicine, since TP53 germline mutations represent an "actionable" genetic variant. Regular cancer screening in TP53 germline mutation carriers can lead to a survival benefit. Furthermore, in patients with known Li-Fraumeni Syndrome, administration of high-dose radiotherapy or DNA-damaging chemotherapy has to be thoroughly weighed against the potential of these modalities of readily inducing secondary malignancies.

PL2.2
KLHL3 and Cullin-3 mutations cause Familial Hyperkalemic Hypertension by impairing ion transport in the distal nephron

***H. Louis dit Picard**[1,2,3], J. Barc[4], D. Trujillano[5], S. Miserey-Lenkei[6], N. Bouatia-Naji[1,2], O. Pylypenko[6], G. Beaurain[1], A. Bonnefond[7], C. Simian[3], E. Vidal-Petiot[1,2], C. Soukaseum[1,2], P. Bruneval[1], X. Estivill[5], P. Froguel[7], J. Hadchouel[1,2], J. Schott[4], X. Jeunemaitre[1,2,3];*
[1]INSERM UMRS970 ; Paris Cardiovascular Research Center PARCC, Paris, France, [2]Descartes University - Sorbonne Paris-Cité, Paris, France, [3]AP-HP, Département de Génétique, HEGP, Paris, France, [4]INSERM, UMR 1087, Institut du thorax, Université de Nantes, Nantes, France, [5]Genes and Disease Program, Center for Genomic Regulation and Universitat Pompeu Fabra, Barcelona, Spain, [6]CNRS UMR144, Institut Curie, Paris, France, [7]CNRS-UMR8199, Lille Pasteur Institute, Lille, France.

Familial Hyperkalemic Hypertension (FHHt), also known as Pseudohypoaldosteronism type 2, is a rare inherited disease which associates net positive Na^+ balance with renal K^+ retention. Only a minority of cases are caused by mutations in the genes encoding With No lysine (K) kinases 1 and 4.

We carried out linkage analysis combined with whole exome sequencing in two informative French families and identified mutations in the *KLHL3* gene. This gene encodes for an actin-binding protein that recruit substrates for the Cullin3-based ubiquitin-ligase complex. Direct sequencing of 47 additional cases revealed 11 inherited missense *KLHL3* mutations in 16 families with dominant or recessive transmission. Analysis of the *CUL3* gene revealed de novo splice-site mutations clustered around exon 9 and observed in younger and more severe cases. Three-dimensional structural modeling showed that the mutated KLHL3 residues are located within conserved motifs at the surface of the molecule, whereas all *CUL3* mutations lead to a loss of 57 residues corresponding to a segment linking BTB and RING-binding domains of the protein. KLHL3 is highly expressed in the distal nephron like the Na^+-Cl^- cotransporter (NCC) and its inhibition by RNA interference leads to an increase of NCC expression at the cell membrane. We further showed that KLHL3 and NCC co-immunoprecipitate in HEK293T cells, suggesting that KLHL3 directly mediates a negative regulation of NCC expression, probably through ubiquitination.

In conclusion, we identifies KLHL3 and CUL3 as members of a new pathway regulating ion transport in the distal nephron and thus blood pressure.

PL2.3
Duplications of *BHLHA9* are associated with ectrodactyly and tibia hemimelia inherited in non-Mendelian fashion

Split-hand/foot malformation (SHFM) is a congenital disorder characterized by severe malformations affecting the central rays of hands and/or feet. The combination of SHFM and long bone deficiency represents a distinct entity termed SHFLD. Although six different loci/mutations (SHFM1-6) have been associated with SHFM the underlying cause in a large number of cases is still unresolved.

We performed array CGH in a SHFM/SHFLD cohort which detected microduplications on chromosome 17p13.3; a locus previously associated with SHFLD. Detailed analysis of 17 families revealed that this CNV serves as a susceptibility factor for a highly variable phenotype with reduced penetrance, particularly in females. Compared to other known causes 17p duplications appear to be the most frequent cause of SHFLD. A ~11.8kb minimal critical region was identified encompassing a single gene, *BHLHA9*, a putative basic-helix-loop-helix transcription factor. Whole mount in situ hybridization showed expression restricted to the limb bud mesenchyme underlying the apical ectodermal ridge (AER) in mouse and zebrafish embryos. Mouse models suggest that a defect of the central AER leads to the SHFM phenotype. Knock-down of *bhlha9* in zebrafish resulted in shortening of the pectoral fins indicating a role of this gene in limb development. In summary, we demonstrate microduplications encompassing *BHLHA9* associated with SHFLD and non-Mendelian inheritance characterized by a high degree of non-penetrance with gender-bias. Our finding shows that rare CNVs can serve as a susceptibility factor for congenital disease, a mechanism which may explain increased recurrence risk in conditions otherwise considered to be sporadic.

PL2.4

A novel molecular and functional mechanism predisposing to ototoxicity

While our knowledge about molecular mechanisms underlying Mendelian forms of hearing loss tremendously increased over the last years, the genetic basis and pathogenesis for drug induced hearing impairment remains unclear. Aminoglycosides are the most commonly used antibiotics worldwide. Although highly effective, their use is restricted by side effects such as ototoxicity in a significant subset of patients. However, underlying pathogenesis and pharmacogenetic risk variants are largely unknown. Here we show that dysfunction of an actin remodeling protein (named here ARP) can result in a drug-inducible disturbance of actin dynamics and an irreversible hearing impairment in humans. By positional cloning, we identified a homozygous missense variant, p.L329P, in ARP as a cause of aminoglycoside-induced hearing impairment in a large consanguineous family from Turkey with 4 affected individuals. Complete ARP loss in knock out mice leads to hearing loss associated with shortened stereocilia. We demonstrate that the protein is a component of the tip complex that regulates stereocilia length and that it interacts with whirlin. The mutation severely impairs this interaction in vitro. Extensive biochemical studies showed that myosinXVa can stabilize the ARP-whirlin interaction complex, and we show for the first time that kanamycin has a negative effect on this complex formation, which is even more pronounced in mutant complexes, thereby explaining the development of hearing loss in affected individuals after aminoglycoside treatment. Taken together, we link ototoxicity after aminoglycoside treatment to actin dynamics and this finding will help in devising strategies to counteract this severe side-effect of aminoglycosides.

PL2.5

Genome-wide association and functional studies identify the DOT1L gene to be involved in cartilage thickness and hip osteoarthritis

M. C. Castano-Betancourt[1,2], *F. Cailotto*[3], *H. Kerkhof*[1,2], *F. M. Cornelis*[3], *S. A. Doherty*[4], *D. J. Hart*[5], *A. Hofman*[6], *F. P. Luyten*[3], *R. A. Maciewicz*[7], *M. Doherty*[4], *R. J. Lories*[3], *A. M. Valdes*[5], *J. B. Van Meurs*[1,2];

[1]Department of Internal Medicine, Erasmus MC, Rotterdam, Netherlands, [2]Netherlands Genomics Initiative-Sponsored by the Netherlands Consortium for Healthy Aging, Leiden, Netherlands, [3]Laboratory for Skeletal development and Joint disorders, Division of Rheumatology, K.U., Leuven, Belgium, [4]Academic Rheumatology, University of Nottingham, City Hospital Nottingham, Nottingham, United Kingdom, [5]Department of Twin Research and Genetic Epidemiology, St. Thomas' Hospital, King's College, London, United Kingdom, [6]Department of Epidemiology, Erasmus MC, Rotterdam, Netherlands, [7]Respiratory & Inflammation Research Area, AstraZeneca, Loughborough, United Kingdom, [8]Health Sciences Research Institute, Warwick Medical School University of Warwick, Coventry, United Kingdom, [9]Musculoskeletal Biomedical Research Unit, University of Oxford, Oxford, United Kingdom.

Hip osteoarthritis (HOA) is one of the most disabling and common joint disorders with a large genetic component which is, however, still ill defined. To date, genome-wide association studies (GWAS) in osteoarthritis (OA) and specifically in HOA have yielded only few loci, which is partly explained by the heterogeneity in OA definition. Therefore, we here focused on radiographically measured joint space width (JSW), a proxy for cartilage thickness and an important underlying intermediate trait for HOA. In a GWAS of 6,523 individuals on JSW of the hip, we identified the G-allele of rs12982744 on chromosome 19p13.3 to be associated with a 5% larger joint space width ($P= 4.8\times10^{-10}$). The association was replicated in 4,442 individuals from 3 UK-cohorts with an overall meta-analysis P value of 1.1×10^{-11}. The SNP was also strongly associated with a 12% reduced risk for HOA ($P =1\times10^{-4}$). The SNP is located in the *DOT1L* gene, which is an evolutionarily conserved histone methyltransferase. Immunohistochemical staining of DOT1L protein during mouse limb bud development supports a role for DOT1L in chondrogenic differentiation and adult articular cartilage. Silencing of *Dot1l* inhibited chondrogenesis. *Dot1l* knock-down reduces proteoglycan and collagen content, and mineralization during chondrogenesis. In the *in vitro* ATDC5 chondrogenesis model system, DOT1L interacts with TCF and Wnt signalling. These data are a further step to understand the role of Wnt-signaling during chondrogenesis and cartilage homeostasis. DOT1L may represent a therapeutic target for osteoarthritis.

PL2.6

Insights into tissue-specific mechanisms of gene regulation involving genetic variants and DNA methylation

M. Gutierrez-Arcelus[1,2], *S. B. Montgomery*[1,3], *T. Lappalainen*[1,2], *H. Ongen*[1,2], *A. Yurovsky*[1,2], *J. Bryois*[1,2], *A. Buil*[1,2], *T. Giger*[1], *L. Romano*[1,2], *A. Planchon*[1,2], *E. Falconnet*[1,2], *I. Padioleau*[1,2], *C. Borel*[1], *A. Letourneau*[1,2], *P. Makrythanasis*[1,2], *M. Guipponi*[1,2], *C. Gehrig*[1,2], *S. E. Antonarakis*[1,2], *E. T. Dermitzakis*[1];

[1]University of Geneva, Geneva, Switzerland, [2]Institute of Genetics and Genomics in Geneva (iGE3), Geneva, Switzerland, [3]Stanford University, Stanford, CA, United States.

Multiple studies have demonstrated the importance of genetic variants affecting gene expression (eQTLs) and initial limited studies have identified genetic variants affecting local DNA methylation levels (mQTLs). Moreover, DNA methylation is known to be associated with gene silencing, and more recently with active gene expression when present within the gene body. Yet the mechanisms by which genetic variation and DNA methylation affect gene expression and tissue specificity are not well understood. In this study, we use a cohort of 210 newborn Caucasian individuals who we genotyped (2.5 million SNPs) and for whom we measured mRNA levels through RNA-seq in three cell-types derived from cord blood and umbilical cord: lymphoblastoid cell lines, T-cells and fibroblasts. For ~110 samples of each of the three cell-types, we have assayed DNA methylation levels in more than 400,000 CpG sites through bisulfite conversion and bead chips. We characterized the tissue-specificity of eQTLs, allele-specific expression, mQTLs and eQTMs (methylation-expression associations). We identified genetic variants and a modest number of methylation sites affecting alternative splicing. Additionally, we tested the contribution of different mechanistic models. We provide evidence for synergistic interactions between SNPs and methylation sites. We found a significant number of cases in which the SNP effect on gene expression is mediated through methylation. Finally, we describe the mechanistic differences between patterns of methylation associated with increase and decrease of gene expression. Overall, our results provide insights into the genetics and epigenetics involved in gene regulation and tissue specificity, which is important for better understanding complex traits.

PL3.1

Found in Translation: New Insights into the Pathogenesis and Treatment of Marfan syndrome and related disorders

H. Dietz;

Johns Hopkins University School of Medicine, Baltimore, MD, United States.

Dysregulation of TGF signaling has been implicated in many disease states including Marfan syndrome (MFS), a condition caused by deficiency of the extracellular matrix protein fibrillin-1. Many manifestations of MFS can be attenuated in mouse models using interventions that antagonize TGF signaling. TGF can initiate both canonical (Smad-dependent) and noncanonical (prominently including the MAPKs ERK, JNK and p38) signaling cascades. Multiple lines of evidence will be presented that implicate ERK signaling as the primary TGF-dependent event that drives disease including the ability of ERK antagonists to achieve phenotypic rescue. Despite this progress, our understanding of how fibrillin-1 deficiency initiates altered TGF activity remains incomplete, as does knowledge regarding events that culminate in tissue failure or that that account for the wide intrafamilial variability in the severity of vascular disease. In attempt to refine our mechanistic understanding of disease pathogenesis (with a focus on aortic aneurysm), we have launched initiatives to identify environmental and genetic modifiers of MFS. Use of calcium channel blockers to mitigate hemodynamic stress resulted in a marked acceleration of aortic growth and rupture in mice with MFS and correlated with accentuation of ERK signaling. The deleterious consequences of this gene-by-environment interaction were abrogated using ERK antagonists. In a separate study, we identified a single major protective modifying locus for MFS coincident with the map position for MAP3K4 (a major JNK and p38 kinase). Taken together, these data reinforce the concept that noncanonical TGF signaling is central to disease progression. Insights regarding initiating events derived from our demonstration that a congenital presentation of skin fibrosis (scleroderma) is caused by mutations in fibrillin-1 that specifically impair integrin binding to its RGD sequence. Mice harboring a RGD to RGE mutation in fibrillin-1 (causing an obligate loss of integrin binding) show dense dermal fibrosis in association with increased expression of an integrin subtype (v3) known to activate TGFbeta and ERK, and are protected from fibrosis by manipulations that mimic the interaction between fibrillin-1 and other integrins (e.g. 51). When stimulated with TGF, scleroderma fibroblasts show unique and marked activation of ERK when compared to control cells. This effect is prevented by treatment with an integrin 1-activating or 3-blocking antibody. These data suggest that 3 integrin not only augments TGF signaling, but also specifically influences the choice between the Smad and ERK cascades (favoring ERK), perhaps through a direct potentiating interaction between αvβ3 and TβRII. RGE mice also develop aortic aneurysm, providing an ideal system to test the hypothesis that loss of matricellular integrin-ligand interaction is an inciting event in the MFS aorta and to test integrin-targeted therapies.

PL3.2

Molecularly Targeted Treatments in Tuberous Sclerosis Complex (TSC)

P. de Vries, *S. Struengmann;*
University of Cape Town, Child & Adolescent Psychiatry, Cape Town, South Africa.

Until recently, no targeted treatments were available to individuals with genetic syndromes such as TSC. The evidence emerging from an increasing number of genetic disorders has, however, begun to challenge this irreversibility assumption, and is showing how an understanding of the neurobiological mechanisms underlying a syndrome can lead to biologically- or molecularly-targeted treatments.

Advances in the molecular biology of tuberous sclerosis have shown that TSC is an mTOR (mammalian Target Of Rapamycin) overactivation syndrome, and phase III trials are currently underway for physical phenotypes of the disorder. The neuropsychiatric phenotype of TSC was presumed to be caused by the structural brain abnormalities and/or seizures seen in the disorder. However, over the last few years research has shown that there are also direct molecular pathways from genetic mutation to neurocognitive phenotypes.

Molecularly-targeted treatments using mTOR inhibitors are showing great promise for the physical and neurological features of the disorder. Intriguingly, pre-clinical and early-phase clinical studies of neuropsychiatric phenotypes are suggesting that specific aspects of cognition or neurodevelopment might also be reversible, even in adults with the disorder.

In this talk, we will follow the history of tuberous sclerosis complex from first description to molecularly targeted treatments.

PL3.3

Targeted treatments in Fragile X syndrome

S. Jacquemont[1], *A. Curie*[2], *V. des Portes*[2], *M. Torrioli*[3], *G. Neri*[4], *F. Gasparini*[5], *B. Gomez-Mancilla*[6]*;*
[1]*Service de Génétique Médicale, CHUV, Lausanne, Switzerland,* [2]*Hospices Civils de Lyon, Université de Lyon and CNRS UMR 5230 (L2C2), Lyon, France,* [3]*Università Cattolica del Sacro Cuore, Cattedra di Neuropsichiatria Infantile, Roma, Italy,* [4]*Università Cattolica del Sacro Cuore, Istituto di Genetica Medica, Rome, Italy,* [5]*Neuroscience Discovery, Novartis Pharma AG, Basel, Switzerland,* [6]*Neuroscience Translational Medicine, Novartis Institutes for Biomedical Research, Novartis Pharma AG, Basel, Switzerland.*

Fragile X syndrome (FXS) is caused by expansion of a CGG repeat in the 5‘ untranslated region of the fragile X mental retardation 1 (FMR1) gene. This mutation is associated with hypermethylation at the FMR1 promoter and subsequent transcriptional silencing. The absence of FMRP (FMR1 protein) at the synapse has many consequences, including up-regulation of metabotropic glutamate receptor 5 (mGluR5)-mediated signaling. It has been postulated that this increased mGluR5 signal may be responsible for many of the clinical manifestations observed in fragile X syndrome. mGluR5 receptor antagonists have repeatedly been shown to rescue many phenotypes and endophenotypes in animal models of the fragile X syndrome. Comprehensive phenotype correction also occurs when treatment is administered later in the adult KO mice. We examined whether a receptor subtype-selective inhibitor of mGluR5, AFQ056, improves the behavioral symptoms of FXS in a randomized, double-blind, two-treatment, two-period, crossover study of 30 male FXS patients aged 18 to 35 years. We detected no significant effects of treatment on the primary outcome measure, the Aberrant Behavior Checklist-Community Edition (ABC-C) score, at day 19 or 20 of treatment. In an exploratory analysis, however the patients with full FMR1 promoter methylation and no detectable FMR1 messenger RNA improved, as measured with the ABC-C, significantly more after AFQ056 treatment than with placebo ($P < 0.001$). If confirmed in larger and longer-term studies, these results suggest that blockade of the mGluR5 receptor in patients with full methylation at the FMR1 promoter may show improvement in the behavioral attributes of FXS.

Homing in on causative genes in GWAS-identified risk loci using eQTL information

***Y. Momozawa**, V. Deffontaine, B. Charloteaux, F. Crins, A. Gori, C. Lecut, M. Mni, C. Oury, C. Reenaers, E. Théâtre, E. Louis, M. Georges;*

University of Liege, Liege, Belgium.

GWAS have mapped hundreds of risk loci for tens of complex diseases, including inflammatory bowel disease (IBD). However, for most risk loci the causative genes amongst positional candidates remain unknown.

To aid in the identification of causative genes, we have generated transcriptome data for nine IBD-relevant cell-types in more than 200 healthy individuals. We have mapped cis- and trans-eQTL in all cell types. We first quantified tissular overlap between eQTL as well as their tissue-specific degree of coincidence with IBD risk loci.

We then used the ensuing eQTL information to pinpoint likely causative genes in known risk loci as follows. It is becoming increasingly apparent that a substantial proportion of inherited risk is due to regulatory variants that alter the expression profile of the causative genes. In such cases, and independently of the number of risk variants involved, disease association profile (i.e. the combination of p-values exhibited by all variants in a risk locus) and eQTL association profile are bound to be highly correlated in the disease-relevant tissue. We have devised and characterized the behavior of metrics that measure such correlations. These metrics are made independent of known disease-associated coding SNPs mapping to the risk loci of interest. We have used these metrics to prioritize candidate genes in the 118 known risk loci associated with Crohn's disease and/or Ulcerative Colitis. eQTL-informed high-throughput resequencing of candidates in large case-control cohorts to confirm their causality is in progress. Latest results will be presented.

Investigating Genomic Heterogeneity in Breast Cancer by Single-Cell Sequencing

***N. Navin**;*

Houston, TX, United States.

As a tumor evolves from a single cell, it acquires complex somatic mutations and diverges to form distinct lineages of clones. This intratumor heterogeneity confounds basic research and clinical diagnosis, because tools do not exist to resolve it. To address this problem, we developed a single-cell sequencing method to profile genomic copy number in individual tumor cells. We used this method to profile hundreds of single cells from two triple-negative (ER-, PR- and Her2-) breast cancer patients. Analysis of 100 single cells from a heterogeneous tumor revealed three distinct clonal subpopulations that represent sequential clonal expansions. Additional analysis of 100 single cells from a homogeneous primary tumor and its liver metastasis indicated that a single clonal expansion formed the primary tumor and seeded the metastasis. In both primary tumors, we also identified an unexpectedly abundant subpopulation of genetically diverse ‚pseudodiploid' cells that do not travel to the metastatic site. In contrast to the prevailing models of gradual tumor progression, our data suggest that these tumors grew by punctuated clonal expansions, in which hundreds of chromosomal rearrangements were acquired in short bursts of evolution. Recently, we have also developed a method to perform whole-genome sequencing of single cells. From this data we can detection many classes of chromosomal mutations (point mutations, indels and structural variants) at base-pair resolution in single cells. We are using this tool to investigate several major areas of cancer biology including invasion, metastasis and response to chemotherapy.

S02.3

Genomic instability in early stages of cancer development

*A. C. Bester, E. Ozeri-Galai, **B. Kerem**;*

Department of Genetics, The Life Sciences Institute, The Hebrew University, Jerusalem, Israel.

Chromosomal instability in early cancer stages is caused by stress on DNA replication. The molecular basis for this replication perturbation was unknown. We showed the replication dynamics in cells in which a regulator of S-the effect of other oncogenes and of micronutrients on the replication dynamics and genomic instability. These results will be presented and discussed.

The perturbed DNA replication in early stages of cancer development induces chromosomal instability preferentially at fragile sites. However, the molecular basis for this instability was unknown. We showed that already under normal conditions, replication fork progression along the fragile site, FRA16C, is slow and forks frequently stall at AT-rich sequences, leading to activation of additional origins. Under mild replication stress, the frequency of stalling at AT-rich sequences is further increased. Strikingly, unlike in the entire genome, in FRA16C additional origins are not activated, suggesting that all potential origins are already activated under normal conditions. We further studied the replication dynamics of another fragile site FRA16D. The results of this analysis will be presented and discussed. Altogether, our results provide a mechanism explaining the replication stress sensitivity of fragile sites and thus, the basis for genomic instability during early stages of cancer.

S03.3

Epigenetics of the impact of early trauma on behavior across generations

***J. Bohacek**;*

Brain Research Institute, University/ETH Zürich, Zurich, Switzerland.

The development and expression of behaviors in mammals are strongly influenced by environmental factors. When favorable and positive, these factors can facilitate appropriate responses and normal behaviors, but when aversive and stressful, they can lead to behavioral pathologies. Adverse and traumatic events early in life are particularly strong risk factors for behavioral and psychiatric conditions such as depression, personality and conduct disorders, and antisocial behaviors. Such disorders can not only affect the individuals directly exposed to trauma, but can also be transmitted and similarly expressed in the following generations[1]. The mechanisms underlying the etiology and inheritance of behavioral symptoms induced by traumatic stress early in life have been proposed to involve epigenetic processes, but remain undefined. This talk will discuss novel developments in transgenerational epigenetics, and introduce an experimental model of early traumatic stress in mice that provides initial evidence for the contribution of epigenetic processes to the inherited impact of stress on behavior. This model shows that chronic and unpredictable maternal separation causes depressive- and impulsive-like behaviors, social withdrawal and cognitive defects in adult mice, and that these symptoms are transmitted to the following offspring. It provides initial evidence that these alterations are associated with persistent changes in DNA methylation in the promoter-associated CpG island of several genes, in the brain of the offspring and in the germline of their stressed fathers[2-4]. These findings suggest that epigenetic mechanisms contribute to the impact of negative environmental conditions early in life on adult behavior and its inheritance[5-8]. Novel molecular candidate mechanisms thought to contribute to transgenerational epigenetic inheritance will also be discussed.

S04.1

Integrating clinical and genomic approaches to identify causative genetic loci for nonsyndromic orofacial clefting

***E. Mangold*;**
Institute of Human Genetics, University of Bonn, Bonn, Germany.

Formal genetic and epidemiological studies have indicated that the etiology of nonsyndromic orofacial clefts is multifactorial, with both genetic and environmental factors contributing to the phenotype. Improved understanding of the etiology of clefting may facilitate development of new preventative measures and therapeutic approaches, and could improve genetic counselling for families at risk.

In this talk the latest genetic findings for nonsyndromic orofacial clefts will be discussed as well as their biological and functional implications.

Most epidemiological and molecular genetic studies of nonsyndromic orofacial clefts have been performed in patients with nonsyndromic cleft lip with or without cleft palate (nsCL/P), which is the most common form of orofacial clefting. Nonsyndromic cleft palate only (nsCPO) is the second most common subtype, and only limited research has been conducted into the genetic factors underlying nsCPO.

For nsCL/P linkage and candidate gene studies have attempted to elucidate the underlying genetic architecture, however, only the interferon regulatory factor 6 (*IRF6*) gene has been identified as causative. Recent genome-wide association studies (GWAS) have substantially extended our knowledge of the underlying risk factors. Four GWAS of nsCL/P have been conducted, and these have identified five new chromosomal loci. One locus, located in an intergenic region of chromosome 8q24, has been implicated in all GWAS and constitutes a major susceptibility locus. Although there is considerable overlap between studies in terms of the regions identified (particularly for the loci at 8q24 and 10q25), the causative variants still await identification. With the exception of 8q24, each of the identified loci harbors candidate genes. However, proof of causality is still lacking in all cases.

S04.2

Dissecting Treacher Collins syndrome using the mouse as a model organism

***M. J. Dixon*[1], *P. A. Trainor*[2], *J. Dixon*[1];**
[1]University of Manchester, Manchester, United Kingdom, [2]Stowers Institute for Medical Research, Kansas City, MO, United States.

Treacher Collins syndrome (TCS) is an autosomal dominant disorder of craniofacial development that occurs with an estimated incidence of 1 in 50,000 live births. TCS is characterized by a combination of: bilateral downward slanting of the palpebral fissures; colobomas of the lower eyelids with a paucity of eyelashes medial to the defect; hypoplasia of the facial bones; cleft palate; malformation of the external ears; atresia of the external auditory canals; and bilateral conductive hearing loss. A high degree of inter- and intra-familial variation in the clinical phenotype is observed. The majority of TCS patients are heterozygous for a mutation in *TCOF1* which introduces a premature termination codon into the encoded protein Treacle. Treacle is a nucleolar phosphoprotein which co-localizes with upstream binding factor (Ubf) and RNA polymerase 1 in nucleolar organizing regions where it functions in ribosomal DNA (rDNA) gene transcription.

To investigate the developmental basis of TCS, we have generated a mouse model through germline mutation of *Tcof1*. Haploinsufficiency of *Tcof1* results in marked apoptosis in the neuroepithelium leading to a deficiency of migrating neural crest cells and resulting in severe craniofacial malformations. We have further demonstrated that Treacle is required cell autonomously for the formation and proliferation of neural crest cells and that Treacle elicits its role through regulating the production of mature ribosomes. Subsequently, we have demonstrated that haploinsufficiency of *Tcof1* induces nucleolar stress and p53 checkpoint activation which results in p53 stabilization and cyclin G1-mediated, cell-cycle arrest. Collectively, these perturbations underpin the tissue specificity of neuroepithelial apoptosis and neural crest cell hypoplasia characteristic of TCS. Importantly, chemical or genetic inhibition of p53 prevents cyclin G1-driven apoptotic elimination of neural crest cells and rescues the craniofacial abnormalities associated with mutations in *Tcof1*. Notably, recent evidence has indicated that a subset of TCS cases arise from mutations in two genes encoding subunits of RNA polymerases I and III, *POLR1D* and *POLR1C*, providing further evidence that TCS is a ribosomopathy.

S04.3

Human Facial Dysostoses

***D. Wieczorek*;**
Institut für Humangenetik, Universitätsklinikum Essen, Essen, Germany.

Human facial dysostoses can be subdivided into mandibulofacial (MFD) and acrofacial dysostoses (AFD). Both are characterized by hypoplasia of facial structures derived from the first and second branchial arches. In addition to facial findings AFDs include anomalies of the extremities.

The best known MFD is the Treacher Collins syndrome, a monogenic disease caused by mutations of the *TCOF1*, *POLR1D* or *POLR1C* genes (Dauwerse *et al.*, 2011), which are involved in rRNA transcription. MFD with microcephaly is another important form of MFD. Very recently, haploinsufficiency of a spliceosomal GTPase encoded by the *EFTUD2* gene was identified in these patients (Lines *et al.*, 2012). Other MFDs such as MFD type Toriello or Burn-McKeown syndrome are more rare and their molecular etiology has not been resolved so far.

AFDs fall into two groups: i) AFDs with postaxial malformations of extremities, e.g. Miller syndrome, and ii) AFDs with preaxial involvement, e.g. Nager syndrome. Miller syndrome is caused by mutations within the *DHODH* gene, involved in the pyrimidine biosynthesis pathway (Ng *et al.*, 2010). Haploinsufficiency of *SF3B4*, a component of the pre-mRNA spliceosomal complex, leads to Nager syndrome (Bernier *et al.*, 2012). In other, much rarer AFDs the molecular etiology is still unknown.

Schizophrenia Genetics

M. O'Donovan*;*
MRC Centre for Neuropsychiatric Genetics and Genomics, Institute of Psychological Medicine and Clinical Neurosciences, Cardiff University, Cardiff, United Kingdom.

It has long been known that schizophrenia has high heritability, but as for other complex disorders, identifying the specific genes responsible has been a major challenge. However, through the technological revolution in genomics, and by the deployment of very large samples through international collaboration, highly significant evidence for the involvement of around 15 common genetic variants has emerged, each making a small contribution to risk of the disorder. Replication studies suggest that of 81 independent variants surpassing p<10-5 in the largest schizophrenia GWAS, the vast majority are likely to be true risk variants but it is also clear from multi-locus tests that around a thousand or more risk variants exist. There is clear evidence that these common variants substantially overlap with risk variants for bipolar disorder, and emerging evidence that they also overlap with those conferring risk of other disorders, in particular ADHD. The same developments that have allowed GWAS have also identified a number of abnormalities of chromosome structure with clear evidence for their involvement in schizophrenia and that these occur as de novo mutations in about 5% of cases. Although rare, the CNVs confer a substantial increase in risk of schizophrenia to carriers as well as to other neurodevelopmental phenotypes including ADHD, Autism and Intellectual Disability. Although only a small amount of the total genetic variation that contributes to schizophrenia and bipolar disorder has been allocated to specific DNA variants, recent findings have strongly implicated specific aspects of neuronal function that are of importance in the pathogenesis of psychosis.

S06.1

Tailoring and implementing aCGH for prenatal diagnosis: experience from Hong Kong

R. K. W. Choy*;*
Chinese University of Hong Kong, Hong Kong, China.

Microarray analysis has been recognized as a powerful diagnostic tool for detection of chromosome copy number aberrations in infants and children with congenital malformations and neurodevelopmental disabilities. Although microarray-based comparative genomic hybridization (aCGH) was made available at the same time as the postnatal setting, in the prenatal setting it has had a slower adoption rate. Based on the CNVs abnormality rate detected from the recent NICHD sponsored multicentre trial and meta-analysis reported, aCGH is a more sensitive diagnostic test and adds incremental value to conventional karyotyping. There were also emerging evidences suggested that a targeted or lower resolution array appeared to be more appropriate for the detection of majority of clinically relevant chromosome copy number abnormalities while maintaining a low rate of results with unknown clinical significant. Our laboratory has been offering „one-stop" prenatal screening and diagnostic service using low resolution targeted array (aCGH; 4x44K) since 2009. In this study, we present a prospective follow-up survey of 500 pregnancies after prenatal screening and aCGH analysis with subsequent antenatal care in our unit. This is a prospective follow-up study, using pregnancy outcome as the end point to investigate the accuracy, efficacy, clinical advantages and shortcoming of prenatal diagnosis using targeted aCGH as compared to standard conventional chromosome analysis using microscopy and QF-PCR. A few cases neglected by aCGH but subsequently identified to have chromosomal or genetic abnormalities by other methods will be discussed.

S06.2

Prenatal diagnosis: Challenges in the interpretation of high resolution genetic screening tests

K. Devriendt*;*
Center for Human Genetics, UZ Leuven, Leuven, Belgium.

High resolution genetic screening tests based on array-CGH are being introduced in the prenatal setting. They significantly increase the detection of genetic variants with clinical implications. Several flow-charts exist for the interpretation of CNV's in postnatal setting. However, the clinical interpretation of CNV's in a prenatal setting is more challenging compared to a postnatal setting, since the clinical information needed to interpret CNV's is often incomplete, time is pressing and decisions taken are irreversible. In high risk pregnancies, e.g. (multiple) malformations detected on ultrasound, the added value of array-CGH often is limited, since decisions with regard to pregnancy management are already taken based on the detected anomalies. In contrast, array-CGH can have a major added value as a screening tool in low risk pregnancies, this has to be outweighed against the difficult issues such as CNV's with reduced penetrance, variable expressivity and pleiotropic effects, unclassified CNV's, incidental findings etc. The huge demand for pre-test counseling raised by these difficulties cannot be met by most genetic centers. Also, one can question to what extent parents can take truly informed decisions, not only on taking a prenatal array-CGH test, but also taking decisions regarding pregnancy management if a variant is detected.

S07.1

Pharmacogenomic biomarkers: growing promise and hype

W. Sadee*;*
The Ohio State University, Columbus, OH, United States.

Genomic sciences supported by ultra-high throughput technologies begin to change the landscape of medicine, disease prevention, and therapy. Development of genomic biomarkers guiding drug therapies has moved to the forefront of translation into clinical practice. The US FDA's Table of Pharmacogenomic Biomarkers in Drug Labels (1) now contains >120 drug entries where evidence of a genetic effect has been described. However, confidence in the presented evidence and effect size with regards to drug response or toxicity vary over a wide range - from definitive clinical recommendations to 'for information only'. While strong genetic factors predictive of adverse drug reactions move into clinical practice as biomarker tests, drug efficacy is typically multifactorial, with few tests capable of predicting outcomes - companion biomarker tests for targeted cancer chemotherapy a possible exception. Yet accurate prediction of positive response to therapy has the potential to improve drug therapy substantially, while much of the genetic variability in drug response genes has yet to be discovered. Our research focuses on expression genetics, based on the premise that regulatory variants (affecting transcription, RNA processing, and translation) are more prevalent than nonsynonymous SNPs that alter protein function directly. I will present specific examples and highlight emerging opportunities and hurdles to translation of genetics/genomics into therapeutic advances. Supported by NIH U01 GM092655.

S07.2

Clinical pharmagenomics: perspectives and limitations

M. Schwab[1,2]*;*
[1]*Dr Margarete Fischer-Bosch Institute of Clinical Pharmacology, Stuttgart, Germany,*
[2]*Department of Clinical Pharmacology, University Hospital, Tuebingen, Germany.*

Variation in drug disposition and response among patients is a major concern associated with many therapeutical agents used in all disciplines of medicine. The clinical relevance of variability is most evident with drugs that have a narrow therapeutic window (i.e., the dose used is close to the dose probably resulting in drug-related toxicity in most individuals). With increasingly information available from the Human Genome Project and the HapMap Project, pharmacogenomics aims to elucidate the genomic determinants of drug efficacy and toxicity. For instance, variants in genes that are relevant for ADME processes such as drug metabolizing enzymes, drug transporters and nuclear receptors have profound effects on patient outcome. Recent clinically important examples are pharmacogenomics of tamoxifen, a well established drug for treatment of postmenopausal breast cancer, and pharmacogenomics of clopidogrel, an antiplatelet drug. However, it is unlikely that one single gene will affect exclusively disease or treatment outcome, and therefore a more comprehensive approach will be to consider genetic polymorphisms in entire biological/ pharmacological pathways. Recently developed '-omics' appoaches (e.g. genomics, transcriptomics, proteomics, metabonomics) will be helpful to identify further putative targets for better prediction of drug response and will complement each other. Array technologies (e.g. cDNA arrays, GWA), next generation sequencing and metabonomics have shown to be helpful for identifying novel genes, redefining disease diagnosis and predicting therapy response to specific drugs. Finally, non-genetic factors as well as epigenetics (e.g. methylation, miRNA) have to be considered more intensively in the future. Experimental as well as computational approaches are required to obtain holistic, mechanistic information on disease networks and drug response. Thus, only systems pharmacology allows the integration of the systems-level understanding of drug response with genome medicine to promote the idea of personalized medicine.

S08.1

Research about psychological issues related to genetic counselling and genetic testing: a personal view on past, present and future

***G. Evers-Kiebooms**;*
Department of Human Genetics, University of Leuven, Leuven, Belgium.

Notwithstanding the complex psychological risks faced by individuals at increased risk for developing genetic disease or for having offspring with genetic disease, psychological issues related to genetic risk, genetic counselling and genetic testing were hardly studied before 1980. Thereafter the attention for the psychological dimension increased rather slowly and moreover most studies were descriptive and did not use adequate control groups . In several countries the success of the human genome project also stimulated research on other than technical or medical aspects of the new genetics. Unfortunately more attention and funding went to ELSI (Ethical, Legal, Social issues) than to Psychological issues. ELSI instead of PELSI…

The fact that the "teaching model" of genetic counselling dominated the "counselling model" for many years, resulted initially in psychological research that was mainly focused on cognitive aspects of genetic counseling (understanding of probabilistic information, recall of risks). Seymour Kessler played an important role in drawing the attention on genetic counseling as a complex communication process and on the factors involved in processing emotionally laden information, coping with genetic disease and communication about genetic issues within the family. The first part of the presentation is dedicated to a personal selection of research findings about the impact of genetic counselling as well as about directiveness versus non-directiveness.

The progress in diagnostic possibilities allowed the detection of more and more genetic diseases in adults or children, prenatally and even in the embryo. The second and major part of the presentation consists of a personal looking back on research about psychological aspects of prenatal testing, carrier testing and predictive testing. For each of the three types of genetic testing two major dimensions will be considered: decision making about testing and the psychological impact of testing. Where applicable in the context of predictive testing attention will also be paid to a third dimension: psychological issues involved in preventive health behavior or life style changes that may be induced by a genetic test result. The focus in this part of the presentation will be on predictive testing, prenatal testing and preimplantation genetic diagnosis for Huntington's disease, with special attention for longitudinal studies evaluating the impact of the test result on the psychological wellbeing of the tested person and his or her partner and on subsequent family planning.

So far psychological research to delineate the challenges as well as the pitfalls of whole genome sequencing for predicting future health problems is very limited. Based on relevant research in psychological decision making and health psychology, mainly on risk perception, the consequences of information overload and differences in coping style, a few comments will be formulated in the closing part of the presentation.

S08.2

Risk Communication and Behaviour Change: Exploring the Chasm

***T. Marteau**;*
London, United Kingdom.

There is a strong belief held by the public, health care practitioners and science funders that using biomarkers and in particular genotypes, will motivate behavior change to reduce the identified risks. This paper will present the result of a recently updated Cochrane Review which supports the conclusions of the original review (Marteau et al 2010) that communicating genetic risk information is unlikely to make much discernible impact upon the change in behaviour needed to reduce the high and rising rates of non-communicable diseases attributable to smoking, diet and physical inactivity. This is in keeping with recent evidence from neuroscience and psychology that highlights the finding that much behaviour taking place outside of awareness.

While the communication of genetic risk information is unlikely to form part of broader public health strategies to change health related behavior in order to improve population health, genetic and other biomarker-based risk information will continue to be given in some clinical contexts. The next generation of research in this latter context could usefully take as its starting points first, that there is nothing particularly motivating about biomarker risk information and second, that engagement in some programmes can change health-related behaviour.

S08.3

Psycho-onco-genetics: historical background and future challenges

***E. M. A. Bleiker**;*
The Netherlands Cancer Institute, Amsterdam, Netherlands.

'Psycho-onco-genetics' is the domain where psychology, oncology and genetics meet. A brief historical background of the three sciences is presented, followed by suggestions for future research.

Cancer is as old as mankind. In Western countries, first successful treatments for cancer were given between 1900 and 1950. In the 1960s, the taboo decreased and a cancer diagnosis was more openly communicated to the patient. At that time, psychology and psychiatry entered oncology. By the mid-seventies, the first psycho-oncological investigators studied issues like anxiety and depression. Questionnaires assessing 'quality of life' were developed in the 1980s and 1990s, to measure physical, social, and emotional wellbeing. In the 21st century, the screening of cancer patients for distress ('the 6th vital sign') is being advocated. Parallel to the developments in cancer treatment and psycho-oncology, the field of genetics developed. The hypothesis that a disease like breast cancer could be inherited was for the first time reported by Paul Broca in 1866. In 1953, Watson and Crick were among the first to report on the structure of DNA, and more important discoveries followed in the next decades. In the 1960s the first papers on genetic counseling for cancer appeared. A literature search on this topic revealed over 10.000 papers published since 1967, with a strong increase in the 1990s, when a number of genes associated with cancer syndromes were identified.

Concerns were raised about the possible negative psychosocial impact of genetic testing and preventive surgery for (breast) cancer. In general, results did not support this concern. However, a number of questions still need to be answered. For example: are the currently used distress-questionnaires sufficiently sensitive to assess the specific problems encountered by the counselees? Are those who do not request counseling psychologically more vulnerable? To what extent should counselors play an active role in the communication of genetic test results to distant relatives of mutation carriers? What will be the best use of SNP's in clinical practice, and how can we support counselees with coping with these small elevated risks for cancer? How can we improve psycho-education about reproductive decision making such as prenatal and pre-implantation genetic diagnosis? In addition, a number of questions need to be answered when commercial genetic testing will arrive in Europe, making genetic testing accessible without the intervention of a trained genetic counselor.

S09.1

Opposing roles for IL-23 and IL-12 in maintaining occult cancer in an equilibrium state

M. W. Teng[1,2], *M. D. Vessely*[3], *H. Duret*[1], *N. McLaughlin*[1], *J. E. Towne*[4], *R. D. Schreiber*[3], *M. J. Smyth*[1,2];

[1]Peter MacCallum Cancer Centre, Melbourne, Australia, [2]Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, Australia, [3]Department of Pathology and Immunology, Washington University School of Medicine, St Louis, MO, United States, [4]Inflammation Research, AMGEN Incorporated, Seattle, WA, United States.

The detailed mechanism controlling the equilibrium phase of cancer immunoediting that results in immune-mediated dormancy of cancer remains to be delineated. Here, we investigate the length of the equilibrium phase during immune control of methycholanthrene (MCA) induced cancers and extend these observations to aging, cancer prone p53 mutant mice. We also demonstrate, for the first time, the critical and opposing roles of IL-23 and IL-12 in maintaining cancer cells in a state of immune-mediated dormancy. Over a series of experiments, inhibition of IL-23p19 was shown to reduce the malignant potential of lesions established by MCA inoculation, while inhibition of IL-12/23p40 enhanced tumor outgrowth. Furthermore, agonistic anti-CD40 antibody treatment mimicked the effects of anti-IL-23p19 mAb treatment. Other cytokines such as IL-4, IL-17, TNF, and IFNαβ, which are known to play important roles either in MCA tumorigenesis or in the elimination phase of cancer immunoediting did not play critical roles in maintaining the equilibrium phase. Taken together, these data indicate opposing roles for IL-23 and IL-12 in determining the outgrowth versus dormancy of occult neoplasia and suggest a potential long-term danger in using IL-12/23p40 antibodies for treating human autoimmune inflammatory disorders.

S09.2

Paracrine and Autocrine Signals Induce and Maintain Mesenchymal and Stem-Cell States in the Breast

C. Scheel;

Helmholtz Center Munich, German Research Center, for Environmental Health, Neuherberg, Germany.

The epithelial-mesenchymal transition (EMT) has been associated with the acquisition of motility, invasiveness, and self- renewal traits. During both normal development and tumor pathogenesis, this change in cell phenotype is induced by contextual signals that epithelial cells receive from their microenvironment. The signals that are responsible for inducing an EMT and maintaining the resulting cellular state have been unclear.

We describe three signaling pathways, involving transforming growth factor (TGF)-beta and canonical and noncanonical Wnt signaling, that collaborate to induce activation of the EMT program and thereafter function in an autocrine fashion to maintain the resulting mesenchymal and stem cell-like state. Importantly, the downregulation of endogenously synthesized inhibitors of autocrine signals by epithelial cells enables the induction of the EMT program. Conversely, disruption of autocrine signaling by added inhibitors of these pathways inhibits migration and self-renewal in primary human mammary epithelial cells and reduces tumorigenicity and metastasis by their transformed derivatives.

Our results indicate that ongoing autocrine signaling is required for maintenance of mesenchymal and stem cell traits both in primary and transformed mammary epithelial cells. At the same time, given the appropriate signaling context, these factors act in a paracrine manner that allow the derivation of mesenchymal and stem cell-like cells in both primary and transformed populations of mammary epithelial cells that do not display these attributes.

In the longer term, our observations may provide the basis for efficiently inducing differentiated epithelial cells to pass through an EMT and enter into a SC state without relying on genetic alteration. Such an approach may eventually be of great utility in the area of regenerative medicine. Acting in the opposing direction, the tumor-initiating cells of certain carcinomas may be forced to exit the mesenchymal, stem cell-like state by therapeutically interrupting multiple autocrine signaling pathways required for their continued residence in this state.

S09.3

Microsatelite instability and cancers: From biology to clinics

A. Collura, *A. Duval*;

Inserm, Team ‚Microsatellite Instability and Cancer', Paris, France.

Recently, we identified a mutated form of HSP110 (HSP110DE9) in a subset of colorectal cancer (CRC), i.e. CRC displaying microsatellite instability (MSI) (Dorard et al., Nat. Med. 2011). The human tumour phenotype referred to as MSI is frequent, being associated with inherited neoplasms (Lynch syndrome) and with 10-15% of sporadic colon, gastric and endometrial cancers. Unpublished results we recently obtained show that HSP110 is frequently mutated in human MSI neoplasms regardless of their primary location.

Heat shock proteins (HSPs) are necessary for cancer cell survival. The HSP110DE9 mutant is the first HSP inhibitor produced endogenously by the cancer cell. It is generated from an aberrantly spliced mRNA and lacks the HSP110 substrate binding domain. HSP110DE9 expression is observed at variable levels in MSI cancer cells and tightly correlates with the size of allelic deletions in a T17 DNA repeat located in HSP110 intron 8. HSP110DE9 impaired both the normal cellular localization of HSP110 and its interaction with other HSPs, thus abrogating the chaperone activity and anti-apoptotic function of HSP110 in a dominant negative manner. Forced overexpression of HSP110ΔE9 causes the sensitization of cells to anticancer agents such as oxaliplatin and 5-fluorouracil regardless of their microsatellite status. Importantly, these in vitro results have clinical significance, since MSI CRC highly expressing HSP110DE9 due to large T17 deletions show significantly longer relapse-free survival and response to chemotherapy compared to those with a low ratio (Collura et al., Submitted). More generally, we suspect HSP110 mutation to constitute a first step towards understanding of the clinical behaviour of colorectal, gastric and endometrial MSI tumours that have been reported to show an improved prognosis and possibly a different response to chemotherapeutic agents.

S10.1

Estimation of the human mutation rate by whole-genome sequencing

L. Jorde[1], *C. D. Huff*[2];

[1]Department of Human Genetics, University of Utah School of Medicine, Salt Lake City, UT, United States, [2]Anderson Cancer Research Center, Houston, TX, United States.

Whole-genome sequences of related individuals in large pedigrees provide new opportunities and challenges for disease-gene discovery. They also permit direct estimates of sex-specific human mutation rates. We have analyzed whole-genome sequence data from 21 individuals in a 5-generation pedigree that was ascertained because of autosomal dominant transmission of cardiac septal defects. We used our VAAST software package to identify the disease-causing mutation. VAAST incorporates pedigree information and the observed inheritance pattern with information about genetic variation in a control population and amino acid substitution severity under a unified likelihood analysis framework The variant responsible for septal defects in the family is a known missense mutation in the *GATA4* gene that had been previously identified through traditional linkage analysis. In our whole-genome analysis of the septal defect phenotype, the GATA4 gene was highly significant (Bonferroni corrected p-value = $8.9x10^{-5}$), and no other gene reached statistical significance. To estimate the male-specific intergenerational mutation rate, we identified novel single nucleotide variants (SNVs) that were absent in a father but were present on the paternal chromosomes of one of the father's offspring. We identified 12 de novo mutations in approximately 600 Mb of sequence data, with estimated false-positive and false-negative rates of less than $1x10^{-3}$. We estimated a male-specific, intergenerational mutation rate that is approximately five times greater than the female-specific mutation rate. This result agrees well with estimates based on phylogenetic comparisons. It is also consistent with our mutation rate estimates based on a three-generation kindred in which two members of the third generation have Miller syndrome.

De Novo Mutations in Neurodevelopmental disorders

G. A. Rouleau, *J. Michaud*;

Centre of Excellence in Neurosciences of Université de Montréal, Centre Hospitalier de l'Université de Montréal, Faculty of Medicine, Université of Montréal, Montreal, QC, Canada.

INTRODUCTION: Schizophrenia (SCZ), autism spectrum disorders (ASD) and intellectual deficiency (ID) are common, devastating and poorly treated neurodevelopmental brain disorders. The wide spectrum of symptoms and clinical variability in these disorders suggest a complex genetic etiology, which is consistent with the numerous loci thus far identified by linkage, copy number variation and association studies. Although heritability in all three disorders may be as high as ~80%, the genes responsible for much of this heritability remain to be identified. Based on the observed reduced reproductive fitness, the relatively uniform world wide incidence, the increased risk of disease with increasing paternal age and the phenotypic complexity of each disease, we, and others, hypothesized that a fraction of this missing heritability may be the result of the occurrence of *de novo* mutations affecting any of a large number of genes. In order to test this hypothesis we first sequenced over 400 synaptic genes in 148 subjects with SCZ, 148 subjects with ASD and 96 subjects with ID. Many likely de novo mutations were identified - these plus relevant functional studies will be presented. Next we sequenced the exomes of SCZ, ASD and ID probands, plus their parents, identifying numerous additional *de novo* mutations (DNMs). In addition, 1/4 of identified DNMs are nonsense mutations, which is more than what is expected by chance. Interestingly, some of the identified genes, such as *SHANK3,* show deleterious *de novo* mutations in patients from the three disease cohorts, suggesting close biological overlap in these disorders. Our study supports the notion that DNMs may account for some of the missing heritability SCZ, ASD and ID while providing a list of genes possibly involved in disease pathogenesis.

S11.1
Genetic basis of primary microcephaly

C. G. Woods;
Cambridge, United Kingdom.

Primary Microcephaly can be inherited as a dominant and recessive disorder. Dominant genes are KIF11, and others to be reported. For KIF11 hemizygosity appears to be the mutational mechanism. Recessive genes are MICROCEPHALIN, WDR62, CDK5RAP2, CEP152, ASPM, CPAP, STIL and CEP63, with others to be reported. The mutational mechanism is null mutations - non-sense, splicing and frame-shifting INDELS. The exception being WDR62, where mis-sense mutations are found, but non-sense mutations additionally cause cerebral dysplasia.
All the Primary Microcephaly genes encode proteins involved in mitosis. One is involved in the timing of entry into mitosis, others in the mitotic spindle and the remainder in centrosome and centriole function during mitosis. These processes are ubiquitous, but it remains unexplained why it is only the brain that is affected. Furthermore, no unifying mechanism has yet emerged to explain how these particular mitotic apparatus proteins interact to modulate brain growth.

S12.1
Molecular classification of primary lymphedema

P. Ostergaard;
St. George's University of London, London, United Kingdom.

We have demonstrated that stringent phenotyping can be helpful in gene identification. Building on 12 years of experience in our Primary Lymphoedema Clinic at St George's Hospital, London, an updated classification of this condition has been proposed by Connell *et al* (2012, Clin Genet). This new tool has been useful in our research department and we have had success in identifying genes for Primary Lymphoedema using this rigorous phenotyping combined with linkage analysis, Sanger sequencing and/or Whole Exome Sequencing. In this talk, the classification pathway for Primary Lymphoedema will be presented together with the latest genes we have discovered such as *GJC2*, *GATA2* and *KIF11*.

S14.2
Interrogating the RNA heterogeneity within cellular compartmens

R. Guigo;
Center for Genomic Regulation, Barcelona, Spain.

The unfolding of the instructions encoded in the genome is triggered by the transcription of DNA into RNA, and the subsequent processing of the resulting primary RNA transcripts into functional mature RNAs. RNA is thus the first phenotype of the genome, mediating all other phenotypic changes at the organism level caused by changes in the DNA sequence. While current technology is too primitive to provide accurate measurements of the RNA content of the cell, the recent development of Massively Parallel Sequencing Instruments has dramatically increased the resolution with which we can monitor cellular RNA. Using these instruments, the ENCODE project has surveyed the RNA content of multiple cell lines and subcellular compartments. The results of these surveys underscore pervasive transription, as well as great RNA heterogeneity between and within cells. Comparison of RNA surveys with other genome wide epigenetic surveys_such as those of binding sites for Transcription Factors, or of Histone modifications_reveals a very tightly coupling between the different pathways involved in RNA processing, transcription and splicing in particular.

S15.2

Acromelic dysplasia and TGFbeta signaling

V. Cormier-Daire;
Paris, France.

The acromelic dysplasia group includes four disorders namely Weill-Marchesani Syndrome (WMS), Geleophysic Dysplasia (GD), Acromicric dysplasia (AD) and Myhre syndrome (MS), all characterized by severe short stature, short extremities, restricted joint mobility, thick skin and pseudomuscular build. They are distinct by additional features and their pattern inheritance. WMS is characterized by the presence of dislocation of microspherophakia and has autosomal dominant or recessive mode of inheritance. GD is the more severe one, resembling a storage disorder with a progressive cardiac valvular thickening, tip toe walking, tracheal stenosis, bronchopulmonary insufficiency and often an early death. AD has an autosomal dominant mode of inheritance, distinct facial and skeleton features (a hoarse voice and internal notch of the femoral head). Finally, MS is sporadic, characterized by prognathism, deafness, developmental delay, thickened calvarium, and large vertebrae with short and large pedicles.

We first identified mutations in Fibrillin1(*FBN1*) in the dominant form of WMS and then mutations in A Disintegrin-like And Metalloproteinase domain with ThromboSpondin type 1 repeats 10 (*ADAMTS10*) in the recessive form of WMS. The function of ADAMTS10 is unknown but these findings support a direct interaction between ADAMTS10 and FBN1.

We then identified mutations in *ADAMTSL2* in the recessive form of GD and a hotspot of mutations in *FBN1* in the dominant form of GD and in AD (exon 41-42, encoding TGFβ binding protein-like domain 5 (TB5) of FBN1). The function of ADAMTSL2 is unknown. Using a yeast double hybrid screen, we identified Latent TGFβ Binding Protein 1 as a partner of ADAMTSL2. We found an increased level of active TGFβ in the fibroblast medium from patients with *FBN1* or *ADAMTSL2* mutations and an enhanced phoshorylated SMAD2 level, allowing us to conclude at an enhanced TGFβ signaling in GD and AD. Finally, a direct interaction between ADAMTSL2 and FBN1 was demonstrated suggesting a dysregulation of FBN1/ADAMTSL2/ TGFβ interrelationship as the underlying mechanism of the short stature phenotypes.

To identify the gene responsible for MS, we performed exome sequencing in 2 MS and selected *SMAD4* as a candidate gene. We identified *de novo* missense mutations, all involving Isoleucine residue at position 500, in the MH2 domain of SMAD4 in a total of 20 MS patients. In MS fibroblasts, we found decreased ubiquitination level of SMAD4 and increased level of SMAD4 supporting a stabilization of SMAD4 protein. Functional SMAD4 is required for canonical signal transduction through the oligomerization with phosphorylated SMAD2/3 and SMAD1/5/8. We therefore studied the nuclear localization of mutant SMAD complexes and found that the complexes translocate to the nucleus. We finally observed a decreased expression of downstream TGFβ target genes supporting impaired TGFβ driven transcriptional control in MS.

All together, our findings support a direct link between the short stature phenotypes and the TGFβ signalling. However, the finding of enhanced TGFβ signaling in Marfan phenotypes suggest the existence of yet unknown mechanisms regulating TGFβ action, possibly including tissue specific modulations. Finally, remembering the severity of GD, our ultimate goal is the design of drugs that can selectively inhibit this pathway.

S15.3

Osteogenesis imperfecta

B. Lee;
Baylor College of Medicine and Howard Hughes Medical Institute, Houston, TX, United States.

Over the past several years, a discovery of new genes causing osteogenesis imperfecta (OI) has provided exciting new insights into bone biology and the pathogenesis of brittle bone disease. At the same time, therapeutic studies in the area of osteoporosis have led to study of osteoporosis drugs in osteogenesis imperfecta. Most have focused on the use of anti-resorptive approaches such as intravenous bisphosphonates. More recently studies focused on anabolic therapies such as intermittent parathyroid hormone have been performed in adults with OI. The different clinical and diagnostic endpoints for these studies will be reviewed and potential new therapies informed by pathophysiological discoveries on these new OI genes will be discussed.

S16.1

To Tell or Not to Tell - How should we handle incidental findings obtained in the course of genome sequencing?

C. Netzer;
Universität Köln, Medizinische Fakultät - Uniklinik Köln, Institut für Humangenetik, Köln, Germany.

Next-generation sequencing (NGS) technologies have revolutionized genetic research within a few years and may very soon become part of routine clinical testing. There is a growing debate about the question whether incidental genetic findings about disease susceptibilities should be reported to the patients or research participants in all cases, in special cases, or not at all. The answer to this question is crucial for the informed-consent procedure and for the work-up of NGS data-sets. In this talk, some real-life examples of incidental genetic findings will be presented to illustrate the multiple dimensions of the problem. Possible solutions will be discussed with the audience.

S16.2

Biobanks: should individuals be informed of findings from biobank studies? Can informed consent be realized?

S16.3

Informed consent in non-invasive prenatal diagnosis

H. Strange, *Z. Deans, A. Newson;*
ESRC Centre for Economic and Social Aspects of Genomics (Cesagen), Cardiff, United Kingdom.

Non-invasive prenatal diagnosis (NIPD) offers the opportunity for exciting changes to prenatal screening and diagnosis. It can give definitive results reliably at an early stage of pregnancy and without the miscarriage risk associated with invasive testing. NIPD is already used within the UK for fetal sexing for women at high risk of sex-linked disorders, and in routine screening for fetal RHD in D negative pregnant women. It is also available in the USA and China as advanced screening test for trisomy 21.

While the technology advances quickly, there is a need to examine carefully how the introduction of NIPD into public clinics and the private sphere might affect women and couple's capacity for making informed decisions.

The presentation starts by outlining reasons to safeguard a fully informed decision-making process, as far as is possible. This is followed by highlighting three key areas in which the process of informed decision-making might be affected by the introduction of NIPD. These are: prenatal screening programmes; direct-to-consumer testing; possible expansion to genome-wide sequencing.

Prenatal screening programmes: Against the background concern that prenatal screening and testing programmes have become 'routinised', evidence suggests that, with the apparent ease of NIPD and without any associated risk of miscarriage, healthcare professionals may regard informed decision-making as less important for NIPD.

Direct-to-consumer testing: Any test that is partially carried out at home raises concerns about consent, pressure, and possible coercion by individuals and companies. Direct-to-consumer testing also presents logistical challenges for making sure the results are communicated accurately and are properly understood and interpreted by the recipient.

Possible expansion to genome-wide sequencing: Although not yet clinically available, if NIPD were to be offered for whole genome sequencing, this would present a significant challenge to traditional models of informed consent procedures.

Ichtyosis
***J. Fischer**;*
Institut für Humangenetik, Universitätsklinikum Freiburg, Freiburg, Germany.

The epidermis forms the outermost, protective layer of the skin and functions as the essential barrier of the body against dehydration, mechanical insults, and the intrusion of microbes, toxins, and allergens. Ichthyoses comprise a clinically and genetically heterogeneous group of disorders of keratinization/cornification characterized mainly by abnormal skin scaling over the whole body; some patients present with severe symptoms, including a collodion membrane at birth. The main skin phenotypes are lamellar ichthyosis and congenital ichthyosiform erythroderma. Most ichthyoses are inherited genetic disorders, in which gene defects (mutations) lead to an impaired epidermal permeability barrier. Genetic analyses have elucidated numerous associations between gene mutations and the presence of an ichthyosis phenotype. Here we will present an update on the main genetic forms of ichthyoses.

Using systemic ideas in Genetic Counsellors' group supervision
***T. O'Neill**;*
North Manchester CAMHS, Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom.

The presenter, a Consultant Family Therapist working in child and Adolescent Mental Health, will describe the use of a Reflecting Team format in the supervision of Genetic Counsellors. Reflecting Teams have been used in family therapy since Tom Andersen and his colleagues in Norway introduced them in the 1980's. Giving clients the opportunity to see and hear the therapy team talk about clients' dilemmas remains a widely used practice in contemporary family therapy.

The method has also been applied to other teaching, training and supervision situations because of the potential advantages such as presenting feedback in a non-threatening manner and offering a multiverse of perspectives and new ideas and it is for these reasons that the presenter has applied the approach to supervision with Genetic Counsellors. The presenter will explain some of the background to this approach and the practicalities of its application illustrated by reference to anonymised cases discussed in the supervision.

ES5.2
Next Generation Sequencing and Applications
***I. G. Gut**;*
Centro Nacional de Analisis Genomico, Barcelona, Spain.

Nucleic acid sequencing has been the workhorse of genome research from the very beginning in the late 80's. Classical Sanger sequencing was used for the Human Genome Sequencing project and was successively refined and finally used with automated capillary gel electrophoresis separation. The first sequence of the human genome was generated using exclusively this technology (Lander et al. Nature 2001, Venter et al. Science 2001). In 2005 nucleic acid sequencing saw a paradigm shift with the introduction of the Genome Sequencer from Roche and was shortly followed by other 2nd generation sequencers from Illumina, LifeTechnologies and Helicos. 2nd generation sequencers rely on the preparation of random physically separated arrangements of individual fragments of the input nucleic acid, followed by cyclic base additions to the random array and high resolution imaging. 2nd generation sequencers are combinations of high-resolution imaging instruments and microfluidic devices. 2nd generation sequencers are the main tool used in large-scale projects such as the 1000 Genomes, the International Cancer Genome Consortium (ICGC), the International Human Epigenome Consortium (IHEC) and will play an important role in the International Rare Disorder Research Consortium (IRDiRC).
However, development of sequencing methods has not stopped at 2nd generation. Several instruments have been introduced, that move beyond in their characteristics. Detection systems are shifting from optical detection to electrical detection. I would characterise true 3rd generation as a method that does not rely on a replication method, such as primer extension or oligonucleotide ligation, for sequence determination, and delivers long clonal reads. Methods such as the GridION System from Oxford Nanopore Technologies fall into this category. Even 4th generation sequencing methods are already showing on the horizon with developments of the EU-funded FP7 project READNA (www.cng.fr/READNA). A 4th generation sequencing method would allow the determination of nucleic sequences cell-by-cell within a histological section.

ES6.1
Clinical and genetic heterogeneity of amyotrophic lateral sclerosis
***M. Sabatelli**;*
Department of Neurology, Pol. ‚A. Gemelli', Università Cattolica del Sacro Cuore, Rome, Italy.

Amyotrophic Lateral Sclerosis (ALS) is a fatal neurodegenerative disorder involving upper and lower motor neurons. Within definite ALS, variants are recognized based on the age of onset, site of localization of first signs, rate of progression of the disease, relative mix of upper and lower motor neuron deficits and the presence of fronto tempora dementia (FTD). The question of whether ALS is a single disease with variable expression or different diseases with heterogeneous causes still remains unsolved.
Most ALS cases are sporadic (SALS) while familial ALS (FALS) account for about 5% of total cases. Over the last 20 years the pathogenic role of genes such as SOD1 , TARDBP, FUS, C9ORF72, OPTN, ATXN2 , VCP , ANG and UBQLN-2 has emerged and mutation in these genes have been identified in

about 50-60% of FALS. A large hexanucleotide (GGGGCC) repeat expansion in the first intron of C9ORF72, represent the most common mutation in FALS being respomsible of about 40% of cases. Near 50% of patients harbouring C9ORF72mutation have FTD, compared to 30% of patients with TARDBP mutation and 9% of cases with unknown gene. Patients with FUS and C9ORF mutations have shorter survival with respect to patients with different mutations. .

Discoveries in the genetics of FALS are changing the scenario of sporadic ALS as well, making the distinction between familial and apparently sporadic ALS less clear than previously assumed. In fact mutations in the same genes involved in FALS may be identified also in a considerable proportion of patients with apparent sporadic disease. The same genes may act as either Mendelian genes in FALS or low-penetrance risk alleles in SALS. This challenges the current indication for DNA analysis only in cases with a known family history of ALS.

ES7.1
Next generation sequencing goes diagnostic: First experiences

L. Biesecker;
National Human Genome Research Institute, NIH, Bethesda, MD, United States.

Medicine is being challenged by the DNA sequencing revolution. Next generation (NGS) has led to a precipitous drop in costs, making clinical sequencing of the genome or exome comparable in cost to other diagnostic tests. The question before us is how we can harness this technology to benefit patients. As well, we do not know which medical scenarios are appropriate for NGS, nor how we should work with patients and their families to communicate the results. To address these questions, research is needed to develop an evidence base upon which we can create practice standards. We developed the ClinSeq™ pilot project to explore these questions. The goals of this project are to enroll 1,000 subjects, initially focusing on cardiovascular disease, apply NGS technologies, and pilot approaches to consent, data analysis, and return of results.

The initial analyses of ClinSeq™ have shown that subjects have good abilities to understand the sequencing research through informed consent. They are eager to undergo sequencing and receive results, both for their own benefit as well as to benefit science. They are highly motivated, willing to engage in follow-up research to correlate genotype and phenotype. We began our analyses by screening 572 exomes for highly penetrant mutations for serious medical conditions. These included familial hypercholesterolemia (n=9 identified), cancer susceptibility (n=8), cardiomyopathies (n=4), arrhythmias (n=4), malignant hyperthermia (n=2), and hereditary liability to nerve and pressure palsies (n=3). Most of these have been returned to the subjects with medical and genetic counseling. In total, we have detected and returned genetic test results for 30 patients. Most of these diagnoses were not suspected to be present by the patient or clinician before the sequencing. While this highly educated and affluent cohort of patients is not representative, there is a substantial desire for NGS results. Further analyses of additional categories of genes (e.g., recessive carrier status) will yield many more clinically relevant results. I will give examples of some of the results we have returned to illustrate the range of the disorders and the reactions of the subjects. These data should be useful to others in planning how to deploy MPS in clinical settings.

ES8.2
Myotonic dystrophy: complex repeats in a complex disorder

D. G. Monckton;
University of Glasgow, Glasgow, United Kingdom.

Myotonic dystrophy is an autosomal dominant disorder presenting a wide range of symptoms frequently including cataracts, heart conduction defects, insulin insensitivity and hypersomnia, along with muscular atrophy and myotonia. Disease severity is extremely variable and the disorder displays striking anticipation progressing from the mild late onset form to congenital disease in as little as three generations. The most common form of myotonic dystrophy, type 1, is caused by the expansion of a CTG repeat in the 3'-untranslated region of the DMPK gene. The CTG tract ranges from 5 to ~40 repeats in the general population. Patients inherit from 50 to 1,000+ repeats, with longer alleles associated with earlier age at onset. The expanded repeat is highly unstable and nearly always increases when transmitted from one generation to the next, explaining the anticipation observed. The expanded repeat is also unstable in the soma in a process that is age-dependent, tissue-specific and expansion-biased, with particularly large expansions in the affected tissues. Although the majority of DM1 patients present with a pure expanded CTG repeat array, recent evidence has revealed that a subset of patients carry alleles with variant repeats. These variant repeats stabilise the array and are associated with milder symptoms. Pathogenesis appears to be primarily caused by the gain of function of the DMPK transcript containing a large CUG tract that remains trapped within foci in the nucleus and disturbs the function of two families of RNA splicing factors that leads to genome-wide dysregulation of alternative splicing. In particular, mis-splicing of the CLC1 chloride channel gene appears to be associated directly with myotonia and mis-splicing of the insulin receptor gene with insulin insensitivity. Exciting recent developments suggest that the RNA gain of function defect may be alleviated using antisense oligonucleotides paving the way for new treatments in this devastating disorder.

The 17q21.31 microdeletion syndrome is characterized by intellectual disability (ID), hypotonia, facial dysmorphism, epilepsy, and congenital malformations. The recurrent deletion encompasses five known genes, *CRHR1*, *IMP5*, *MAPT*, *STH,* and *KANSL1*, in addition to four putative genes.

We identified two atypical *de novo* deletions encompassing only part of *MAPT* and *KANSL1* in two children with ID and typical features of 17q21.31 microdeletion syndrome. Next, we selected 16 individuals with core features of the 17q21.31 microdeletion syndrome. Sanger sequencing revealed no pathogenic changes in *MAPT*. However, sequence analysis of *KANSL1* did reveal two heterozygous mutations, a nonsense mutation and a splice site mutation, both predicted to cause loss-of-function.

KANSL1 is a widely expressed gene encoding a member of the highly conserved NSL complex. This complex contains, among others, the H4K16 acetyltransferase KAT8.

To explore the effect of haploinsufficiency of *KANSL1* on gene expression levels, we performed whole transcriptome (mRNA) sequencing using EBV-transformed cell lines of the individual with the *KANSL1* splice site mutation and three individuals with the classical 17q21.31 deletion. Functional annotation clustering of genes that were differentially expressed in all samples compared to controls revealed enrichment of genes involved in neuronal processes. Further evidence that *KANSL1* has a function in neurons is provided by our studies in *Drosophila*. Tissue-specific knockdown of wah (fly ortholog of *KANSL1*) in the mushroom bodies was sufficient to cause a 25% reduction in learning ability ($P<0.05$).

In conclusion, our findings demonstrate that haploinsufficiency of *KANSL1* is sufficient to cause the classical 17q21.31 microdeletion syndrome phenotype.

C01.2

Mutations in the *KIAA1267* gene cause the 17q21.31 deletion syndrome phenotype

M. Zollino, *D. Orteschi, M. Murdolo, S. Lattante, P. Chiurazzi, G. Marangi, G. Neri;*
Catholic University, Rome, Italy.

The chromosome 17q21.31 deletion syndrome is a genomic disorder usually associated to a recurrent chromosome deletion, recently restricted to a 160-274 kb segment on 17q21.31, including only three genes, *MAPT, STH* and *KIAA1267*. A question to be still addressed is whether this condition is a contiguous gene syndrome or a monogenic disorder. *MAPT* has been considered the major candidate gene, however no productive mutations have been identified so far. Starting from the hypothesis that a single gene mutation in undeleted patients could affect either one gene residing within the deletion interval, or another gene participating in a shared molecular pathway, we performed exome sequencing of one undeleted patient and both parents. A *de novo* heterozygous nonsense mutation within exon 6 of the *KIAA1267* gene (OMIM *612452) was identified and validated by Sanger sequencing: c.C1816T, p.R606X. This result prompted us to sequence *KIAA1267* in a second undeleted patient, in which a *de novo* heterozygous frameshift mutation introducing a premature stop codon was detected within exon 13: c.2785_2786 delAG, p.R929G fsX44. Both patients presented with a full chromosome 17q21.31 deletion syndrome phenotype, including intellectual disability, highly distinctive facial features, failure to thrive in infancy, hypotonia, motor delay, and a friendly behavior. We consider that chromosome 17q21.31 deletion syndrome is a single gene disorder, caused by haploinsufficiency of *KIAA1267*. Knowledge of the major causal gene will broaden the diagnostic spectrum of the 17q21.31 deletion syndrome, and will accelerate the understanding of its molecular pathogenesis.

C01.3

Loss of function mutations in *TGFB2* cause Loeys-Dietz syndrome

Loeys-Dietz syndrome (LDS) is an autosomal dominant connective tissue disorder with both features that overlap with and distinguish it from Marfan syndrome (MFS). In its most typical presentation, LDS is characterized by the triad of hypertelorism, bifid uvula/cleft palate and widespread aortic/arterial aneurysms and tortuosity. LDS is most often caused by heterozygous loss-of-function mutations in genes encoding positive effectors of transforming growth factor beta (TGFβ) signaling including either subunit of the TGFβ receptor (TGFβR1/2) and Smad3. Nevertheless, in aneurysmal aortic tissues a signature compatible with increased TGFβ signaling is consequently observed, engendering controversy regarding the mechanism of aortic aneurysmal disease. TGFβs comprise three multipotential cytokines, encoded by three separate genes, that regulate multiple aspects of cellular performance including, proliferation, differentiation, migration and synthetic repertoire. Here, we report heterozygous deletions or loss-of-function mutations of the gene encoding the transforming growth factor beta 2 (TGFβ2) ligand in eight families characterized by a phenotype within the MFS/LDS spectrum and demonstrate upregulation of TGFβ signaling in aortic tissue from affected individuals. Furthermore, haploinsufficient Tgfb2-/+ mice demonstrate aortic root aneurysm by 8 month of age and biochemical evidence of increased canonical and noncanonical TGFβ signaling. Mice that harbor a mutant MFS allele (*Fbn1*$^{C1039G/+}$) in the context of *Tgfb2* haploinsufficiency show a pronounced increase in TGFβ signaling and phenotypic worsening in association with normalization of TGFβ2 expression and excessive expression of TGFβ1. Taken together, these data implicate compensatory autocrine and/or paracrine events and excessive TGFβ signaling in the pathogenesis of TGFβ vasculopathies.

Blue rubber bleb nevus syndrome (BRBN) is a rare sporadic congenital disorder (OMIM # 112200) characterized by multiple venous malformations all over the skin, often on hands and feet. Patients can present with a few to hundreds of cutaneous and pathognomonic gastrointestinal lesions. These are most commonly in the small intestine, documented by endoscopy, colonoscopy, or magnetic resonance imaging (MRI). Although several case reports have been published, the etiopathology of BRBN is still unknown.

Since inherited venous malformations (VMCMs) are caused by germline activating TIE2 mutations and common sporadic venous malformations (VMs)

are due to strongly hyperphosphorylating somatic TIE2 mutations, we hypothesized that BRBN may also be part of the spectrum of TIE2-mediated phenotypes.
To test this, we screened the coding region of TIE2 by direct sequencing of genomic blood DNA and cDNA from the resected lesions of 14 patients. In 16 tissues from 10 patients, we identified mutations leading to amino acid changes, absent in the blood DNA from patients as well as in cDNA from control tissues. These changes occur at highly conserved residues, and are not found in dbSNP. In contrast to VMCMs and VMs, BRBNs predominantly show double (*cis*) mutations, suggesting a phenotype-genotype correlation. They cause ligand-independent receptor hyperphosphorylation *in vitro*. These results unequivocally demonstrate that BRBNs are caused by post-zygotic activating TIE2 mutations.

C01.5

Serin diet relieves symptoms of Hereditary Sensory and Autonomous Neuropathy type 1A caused by a c.992 C>T, p.(Ser331Phe), mutation in SPTLC1

B. W. Rautenstrauss[1,2], *E. Wilichowski*[3], *E. Holinski-Feder*[2], *T. Hornemann*[4];
[1]*Friedrich-Baur-Institute, Munich, Germany,* [2]*Medizinisch Genetisches Zentrum, Munich, Germany,* [3]*Georg-August-University, Göttingen, Germany,* [4]*University Zürich, Zürich, Switzerland.*

Hereditary sensory and autonomic neuropathies (HSAN) are a genetically and clinically heterogeneous group of disorders associated with sensory dysfunction. HSAN1 is a dominantly inherited sensorimotor axonal neuropathy. The patient has 3 healthy siblings and healthy parents. Symptoms: Coinciding with the start of ambulation motor disabilities; generalized hypotrophy; reduced walking distance; unstable gait; multiple falls; no mental retardation; MRI studies of the brain were normal; reduced pain sensitivity: recurrent traumatic and thermal injuries of feet, knees and hands; disturbed wound healing; ulcerated fingertips; unnoticed fracture of a metatarsal bone; at the age of 9 years: bilateral lensectomy due to juvenile cataract; cataract surgery: repetitive ulcerations of the cornea, poor healing tendency; complete retinal detachment (right eye); nerve biopsy: marked wasting of myelinated fibres, axonal damage; axonal motor and sensory neuropathy. Finally a de novo c.992 C>T, p.(Ser331Phe), mutation in the SPTLC1 gene was identified. This mutation turns the sphingolipid synthesis to neurotoxic lipids in this patient as well as in cell cultures. A serin diet (400mg/kg bodyweight) developed in an animal model (SPTLC1 mutation p.(Cys133Trp)) resulted after 3 months in an overall improvement: ameliorated growth of nails and hair; wounds of the skin show faster healing; gain of weight; coughassist could be reduced to only one treatment during the winter period; sweating is reconstituted; ability to an extended period of upright standing. This HSAN patient is an excellent example for effective translational medicine and the first individual in Germany receiving a causal treatment for a Hereditary Sensory and Autonomous Neuropathy.

C01.6

SMA patients show concordant responses to valproic acid from blood to neurons while nonresponsivness is facilitated by CD36

L. Garbes[1], *L. Hessen*[1], *J. Schreml*[1], *I. Hoelker*[1], *T. Bauer*[2], *C. Mueller*[2], *J. Dimos*[3], *M. Peitz*[4], *O. Bruestle*[4], *R. Heller*[1], *B. Wirth*[1];

Proximal spinal muscular atrophy (SMA) is the number one genetic killer during early infancy. SMA is caused by functional absence of SMN1 leading to progressive degeneration of spinal α-motoneurons. Currently, no cure for SMA is available.
Therapeutic approaches are focusing on SMN2, since its copy number mainly modifies disease severity. Previously, we have been able to show that the anti-epileptic drug valproic acid (VPA) increases SMN levels in vitro, ex vivo as well as in VPA-treated SMA patients. A pilot clinical trial with VPA revealed that 1/3 of the patients responded positively to VPA treatment, while for 2/3 either no response or even the opposite effect was detected. To elucidate mechanisms underlying VPA-nonresponsiveness, we collected fibroblasts lines from >30 SMA-patients undergoing VPA-treatment. We demonstrated that response to VPA was concordant in about 65% between blood and fibroblasts. Furthermore, by generating GABAergic neurons from fibroblast-derived iPS cells, we showed that similar response to VPA is retained even in the CNS neurons. This is the first prove that response to a potential SMA drug is concordant between blood, fibroblasts and neurons. Moreover, by transcriptome-wide μ-array we identified increased expression of CD36, a known LCFA-translocase, as the pivotal factor suppressing positive response to VPA.
Our data provide first evidence that monitoring VPA response in fibroblasts is indeed feasible to infer response in CNS neurons. Furthermore, CD36 was identified as the crucial protein suppressing response to VPA. This is of major implication also for other diseases treated with VPA such as epilepsy or migraine.

C02.1

KIAA1797/FOCAD encodes a novel focal adhesion protein with tumor suppressor function in gliomas

A. Brockschmidt[1], *D. Trost*[1], *H. Peterziel*[2], *K. Zimmermann*[3], *M. Ehrler*[1], *H. Grassmann*[1], *P. Pfenning*[4], *A. Waha*[5], *D. Wohlleber*[6], *F. F. Brockschmidt*[1], *M. In a strategy to identify novel genes involved in glioma pathogenesis by molecular characterization of chromosomal translocation breakpoints, we identified the *KIAA1797* gene, encoding a protein with an as yet undefined function, to be disrupted by a 7;9-translocation in a primary glioblastoma culture. Array-based comparative genomic hybridization detected deletions involving *KIAA1797* in around half of glioblastoma cell lines and glioblastomas investigated. Quantification of mRNA levels in human tissues demonstrated highest *KIAA1797* expression in brain, reduced levels in all glioblastoma cell lines and most glioblastomas, and similar levels in glial and neuronal cells by analysis of different hippocampal regions from murine brain. Antibodies against KIAA1797 were generated and showed similar protein levels in cortex and subcortical white matter of human brain, while levels were significantly reduced in glioblastomas with *KIAA1797* deletion. By immunofluorescence of astrocytoma cells, KIAA1797 co-localized with vinculin in focal adhesions. Physical interaction between KIAA1797 and vinculin was demonstrated via co-immunoprecipitation. Functional *in vitro* assays demonstrated a significant decrease in colony formation, migration and invasion capacity of LN18 and U87MG glioma cells carrying a homozygous *KIAA1797* deletion ectopically expressing *KIAA1797* compared to mock-transduced cells. In an *in vivo* orthotopic xenograft mouse model, U87MG tumor lesions expressing *KIAA1797* had a significantly reduced volume compared to tumors not expressing *KIAA1797*. In summary, the frequently deleted *KIAA1797* gene encodes a novel focal adhesion complex protein with tumor suppressor function in gliomas, which we name “focadhesin”. Because *KIAA1797* genetic variation has been implicated in Alzheimer’s disease, our data is also relevant for neurodegeneration.

C02.2

Exome sequencing of late recurrence T-cell acute lymphoblastic leukemia in children confirms second leukemia and exposes predisposition candidate genes

E. Waanders[1], *V. H. J. Van der Velden*[2], *T. Szczepański*[2], *L. E. L. M. Vissers*[1], *J. de Ligt*[1], *C. Gilissen*[1], *A. H. A. van Dijk*[1], *S. V. Van Reijmersdal*[1], *P. M. Hoogerbrugge*[1], *A. Geurts van Kessel*[1], *J. J. M. Van Dongen*[2], ***R. P. Kuiper***[1];
[1]*Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [2]*Erasmus University Medical Center, Rotterdam, Netherlands.*

Second hematologic malignancies in non-syndromic children without family history for cancer may be mistaken for relapses or therapy-related malignancies. Recently, we identified 8 T-cell acute lymphoblastic leukemia (T-ALL) patients with two fully discordant consecutive leukemias based on TCR-rearrangements and DNA copy number aberrations, strongly suggesting predisposition (J.Clin.Oncol.2011). Here, we performed exome sequencing on leukemic and complete remission samples from four of these patients in order to identify predisposing mutations.
Per exome, we found ~25,000 variants. Known, synonymous, and intronic variants as well as variants called in <20% of the reads were excluded. We identified and validated between one and six somatic variants per leukemic sample, the majority of which affected known T-ALL genes, such as *PTEN*, *FBXW7* and *PHF6*. None of these were shared between two consecutive leu-

kemic samples, which confirms that samples are clonally unrelated and thus represent independent second leukemias.

With respect to genetic predisposition, we focused on recurrently affected and known T-ALL associated genes. In three patients we identified highly conserved missense variants in *TYK2, RANBP17,* and *TIAL1*, respectively. *TYK2* belongs to the family of Janus kinases, which play a role in the pathogenesis of several hematologic malignancies. The TYK2 variant G761V is located in a highly conserved region of the pseudokinase-like domain, which is frequently affected in the homologous JAK2 kinase in precursor B-cell leukemias.

In conclusion, we confirmed that consecutive leukemic presentations in patients with late T-ALL recurrences may be fully discordant and, thus, represent independent leukemia occurrences, most likely caused by predisposing germline mutations.

C02.3

Somatic GATA2 zinc finger 1 mutations are exclusively associated with bi-allelic CEBPA mutations in acute myeloid leukemia (AML) and disrupt the capacity of GATA2 to enhance CEBPA-mediated activation of transcription

P. A. Greif[1,2]*, A. Dufour*[1]*, N. Konstandin*[1]*, B. Ksienzyk*[1]*, E. Zellmeier*[1]*, B. Tizazu*[1]*, J. Sturm*[1]*, T. Benthaus*[1]*, M. Yaghmaie*[1,3]*, P. Dörge*[4]*, K. Hopfner*[5]*, A. Cytogenetically normal acute myeloid leukemia (CN-AML) with biallelic CEBPA gene mutations (biCEPBA) represents a distinct disease entity with a favourable clinical outcome. So far, it is not known if other genetic alterations cooperate with biCEBPA mutations during leukemogenesis. To identify additional mutations, we performed whole exome sequencing of five biCEBPA patients and detected somatic GATA2 zinc finger 1 (ZF1) mutations in 2 out of 5 cases. Both GATA2 and CEBPA are transcription factors crucial for hematopoietic development. Inherited or acquired mutations in both genes have been associated with leukemogenesis. Further mutational screening detected novel GATA2 ZF1 mutations in 13 of 33 biCEBPA positive CN-AML patients (13/33: 39.4%). No GATA2 mutations were found in 38 CN-AML patients with a monoallelic CEBPA mutation and in 89 CN-AML patients with wild-type CEBPA status. In Kaplan Meier survival analysis, the presence of GATA2 mutations did not negatively impact on the favourable overall survival and event free survival of biCEBPA patients. In reporter gene assays, all tested GATA2 ZF1 mutants showed reduced capacity to enhance CEBPA-mediated activation of transcription, suggesting that the GATA2 ZF1 mutations may collaborate with biCEPBA mutations to deregulate target genes during malignant transformation. We thus provide evidence for a genetically distinct subgroup of CN-AML. The specific association of mutations affecting two interacting regulators of hematopoiesis suggests a novel concept for leukemogenesis: The simultaneous mutational targeting of two transcription factors that function in the same differentiation pathway in AML.

(P.A.G. and A.D. contributed equally to this work)

C02.4

Integrated genomic and epigenomic profiling of TP53 and non-TP53 Li-Fraumeni syndrome (LFS) tumors reveals multiple and shared hits in the p53 network

R. Krahe*, B. Zhang, X. Hu, J. W. Wong, C. D. Wilson, K. A. Baggerly, N. E. Navin, L. C. Strong, L. L. Bachinski;*

Univ Texas MD Anderson Cancer Center, Houston, TX, United States.

Li-Fraumeni Syndrome (LFS) is a prototypic, clinically and genetically heterogeneous inherited cancer syndrome. Most cases (>70%) are due to dominant, variably penetrant, germline mutations in the tumor suppressor gene *TP53*. In *TP53* and non-*TP53* LFS, there is evidence for risk heterogeneity within and between families. While *TP53* mutations predispose LFS patients, they do not appear to be sufficient and additional genetic and epigenetic "hits" are necessary for tumorigenesis. To identify second somatic hits as downstream drivers of p53-mediated tumorigenesis, we performed genomic and epigenomic profiling of primary soft tissue sarcomas, osteosarcomas and matching constitutive samples of 10 LFS patients (6 with, 4 without *TP53* mutations). We also performed whole genome sequencing of a subset of tumor/normal pairs with an inherited *TP53* mutation. Although we observed chromothripsis in a subset of tumor samples, it was independent of *TP53* mutation status. Integration of the observed genetic genomic and epigenomic alterations into the extended p53 and p16/RB pathways revealed multiple and shared hits (irrespective of *p53* status or tumor type), in numerous p53 transcriptional targets and interacting proteins (e.g., *ATM*, *CDKN1A, CDKN2A, CHK1, PTEN, MDM2/4*). Identification of recurrent somatic alterations in p53-network genes in independent LFS tumors is remarkable. This indicates that p53 defects alone (due to inherited mutations) are not sufficient and that additional hits in genes with p53-associated functions are not redundant but rather are a necessary part of LFS tumorigenesis. Recurrent somatic alterations cooperating with p53 in LFS tumors appear to cluster in a limited number of cellular pathways.

C02.5

Leupaxin mediates cytoskeleton remodeling in prostate cancer cells

S. Dierks*, S. von Hardenberg, T. Schmidt, P. Burfeind, S. Kaulfuß;*

Department of Human Genetics, Göttingen, Germany.

The focal adhesion protein leupaxin (LPXN) is overexpressed in prostate cancer (PCa). Recently, we showed that LPXN is involved in the progression of PCa via deregulation of p120CTN. In the present study we analyzed the LPXN-mediated adhesive and cytoskeletal changes during PCa progression. After downregulation of LPXN expression we could show an unambiguous reduced adhesiveness of PCa cells PC-3 and DU 145. LPXN knockdown resulted in a reduced cell surface area and reduced formation of focal adhesion sites in these cells. Interestingly, we found decreased expression of small GTPase RhoA and increased expression of Rac1. Furthermore, the expression pattern of several integrins was deregulated after LPXN knockdown, specifically β1-integrin expression was downregulated.

To identify a candidate protein that mediates the cytoskeletal changes after LPXN knockdown, we performed a Yeast-two-Hybrid screen. The actin binding protein caldesmon (CaD) was identified as a putative interaction partner of LPXN. Co-immunoprecipitation and a proximity ligation assays confirmed the interaction of LPXN with CaD. Furthermore, we demonstrated that CaD expression is upregulated in PCa cells and that knockdown of CaD by RNA interference leads to an increased migration and invasion, whereas no changes in proliferation were detected. Interestingly, we found that knockdown of LPXN lead to a decrease in phosphorylated, inactive CaD (pCaD) but total CaD levels remained unaffected. Subsequently, low levels of pCaD resulted in reduced migration of PCa cells.

Taken together our present results indicate that LPXN mediates cytoskeletal changes during PCa progression through the regulation CaD phosphorylation.

C02.6

Clinical Application of Next Generation Sequencing Technology for the Detection of Clinically Actionable Mutations

Y. Wen, E. Fang, Y. Li, G. Douglas, C. E. Carmack, ***M. M. Li****;*

Baylor College of Medicine, Houston, TX, United States.

Next-generation sequencing (NGS) technologies have significantly accelerated the identification of cancer-causing mutations. However, the clinical application of NGS technologies to detect cancer gene mutations has been extremely limited. We have assessed the performance of a novel NGS technology that merges multiplex PCR with ion semiconductor sequencing in our clinical diagnostic laboratory. The test interrogates 739 common mutations in 46 cancer genes including many clinically actionable mutations concurrently. First, we studied 12 tumor samples including 4 archived FFPE, 4 blood/bone marrow, and 4 cell line samples with known mutations to evaluate the sensitivity and specificity of the test. We then studied 34 de-identified, archived FFPE tumor samples of unknown genotype to further evaluate the efficacy of the test. Using the technology, we successfully identified all known mutations previously detected by Pyposequencing or Sanger sequencing technologies. Multiple serial dilution studies showed that the test could detect mutations at frequencies as low as 5% with 99% confidence. For the samples of unknown genotype, we detected 29 COSMIC mutations in 22 samples. Analysis of the variant call data showed that a minimum of 100X coverage is required in order to detect mutations at 10% frequency or above; a minimum 300K final library reads are necessary in order to minimize/ eliminate amplicon dropout. Our experience demonstrated that this targeted NGS test can effectively detect hundreds of cancer gene mutations with input DNA as low as ten nanograms, turn around time as short as two days, and significantly lower cost compared to traditional Sanger sequencing.

C03.1

Arm to Leg Transformation in Humans associated with CNVs at the PITX1 locus

M. Spielmann[1,2], *E. Klopocki*[1,2], *F. Brancati*[3,4], *P. Krawitz*[1], *J. Hecht*[1,2,5], *D. Ibrahim*[1,2,5], *K. Dathe*[1], *P. Ferrari*[6], *S. Lohan*[1], *U. Mennen*[7], *S. Mundlos*[1,2];

Here we report three non-related families in which affected individuals show features of an arm-to-leg transformation. On X-ray examination, the distal humerus was broadened and the olecranon was missing thus resembling the shape of the femur. The hands were medially deviated and in the wrist a fusion of the triquetral and pisiform formed a structure similar in shape to the calcaneus of the ankle. Furthermore, attachments of the tendons were abnormal. We mapped the condition to a 5 Mb region on the long arm of chromosome 5 (5q31.1) but were not able to identify a coding mutation. Next we screened the linkage interval for CNVs by custom high-resolution array CGH analysis which detected a microdeletion 400 kb 5' of PITX1. A similar deletion was identified in a second family. A third family did not show the deletion but, suspecting a balanced structural variation, we performed whole genome sequencing in one individual. Using a bioinformatic approach focused on the PITX1 genomic region we identified a translocation with the breakpoint located 3' of the deletions detected in the other cases. PITX1 is a transcription factor known to determine hindlimb identity. Based on previous mouse work, the genomic rearrangements are likely to result in a misexpression of PITX1 in the forelimb thus causing a partial arm-to-leg transformation. The structural variations identified are likely to remove active PITX1 forelimb suppressor or insulator elements and relocate forelimb enhancer elements into the gene desert neighbouring the PITX1 gene.

C03.2

Microduplications Upstream of *MSX2* are Associated with a Phenocopy of Cleidocranial Dysplasia

C. E. Ott[1], *H. Hein*[2,3], *S. Lohan*[1,2], *A. M. Hoogeboom*[4], *N. Foulds*[5], *J. Grünhagen*[1], *S. Stricker*[1,2], *P. Villavicencio-Lorini*[1,2], *E. Klopocki*[1,2], *S. Mundlos*[1,2,3];

Cleidocranial Dysplasia (CCD) is an autosomal dominant skeletal disorder characterized by hypoplastic or absent clavicles, increased head circumference, large fontanels, dental anomalies, and short stature. Although CCD is usually caused by mutations leading to haploinsufficiency of *RUNX2*, the underlying genetic cause remains unresolved in about 25% of cases. Besides RUNX2, MSX2 is another transcription factor known to play important roles during many developmental processes including tissue organogenesis, craniofacial and limb development.

Here we describe two unrelated individuals with microduplications upstream of *MSX2* on chromosome 5q35.2. One of the affected individuals presented with a phenocopy of CCD. In addition to a classical CCD phenotype the other affected individual had a complex synpolydactyly of the hands and postaxial polydactyly of the feet which have so far never been reported in association with CCD or copy number variations (CNVs) on 5q35.2. The microduplications overlap in a ~219 kb region that contains several highly conserved non-coding elements which are likely to be involved in *MSX2* gene regulation. Functional analyses using viral overexpression in chicken cells demonstrated that the inhibitory effect of *Msx2* overexpression on mineralization can not be ameliorated by forced *Runx2* expression.

Our results indicate that CNVs affecting non-coding regions upstream of a gene can cause developmental defects, and that the resulting phenotype can be distinct from those caused by point mutations or CNVs encompassing the corresponding gene. Taken together, our findings reveal an additional mechanism for the pathogenesis of CCD, particularly with regard to the spatiotemporal regulation of *MSX2*.

C03.3

Mutations in distinct domains of BMP1 cause Osteogenesis Imperfecta with variable bone phenotypes

K. Keupp[1,2], *A. Nair*[3], *O. Semler*[4], *Y. Li*[1,2], *H. Thiele*[5], *P. Frommolt*[5], *J. Becker*[1], *C. Netzer*[1], *N. Arkasu*[6], *E. Schoenau*[4], *P. Nürnberg*[5], *M. Hammerschmidt*[7], *T. Carney*[3], *B. Wollnik*[1,2];

Using an innovative exome sequencing strategy, in affected individuals from a consanguineous Turkish family with autosomal recessive Osteogenesis Imperfecta (OI) associated with an increased bone mineralization density, we identified a causative homozygous missense mutation, p.Gly12Arg, in the novel OI gene BMP1. The mutation is located within the signal peptide and we provide evidence for an impaired secretion and alteration in post-translational modification of the mutant protein. To determine the underlying molecular pathogenesis, we show that hypomorphic bmp1 zebrafish mutants present with delayed osteogenesis, defects in bone formation, recurrent fractures in fin rays, and osteopenia in vertebrae, which during larval stages develops into a significant high bone mass phenotype in these mutants. Further screening of patients with OI identified a second homozygous mutation, p.Asp284Val, in BMP1. Interestingly, the index patient of this family presented with a classical severe form of OI with drastically reduced bone density. The mutation is located nearby the proteolytic domain of BMP1 suggesting a different pathogenic mechanism. Ongoing functional studies of both mutations will offer novel insights into the underlying pathogenesis and will show how different functional effects of BMP1 mutations lead to variable bone phenotypes in patients with OI.

Taken together, we present a novel genetic cause for a high mineralization OI phenotype, describe the functional mechanism, and provide evidence for a genotype-phenotype correlation in patients with BMP1 mutations.

C03.4

Increased sensitivity to DNA damage in a recessive form of Weaver syndrome caused by functional loss of an E3 ubiquitin ligase

Weaver syndrome is a rare congenital disorder mainly characterized by pre- and postnatal overgrowth, marked macrocephaly, learning disability and a typical facial appearance. Dominant mutations in EZH2 encoding a histone-lysine N-methyltransferase of the polycomb repressive complex have been recently reported to cause Weaver syndrome. We now present an autosomal recessive form of Weaver-like syndrome in two affected siblings from a consanguineous Turkish family. Using a whole-exome sequencing strategy combined with determination of homozygous stretches of identified variants, we found a homozygous nonsense mutation in a novel gene encoding an E3 ubiquitin ligase. The mutation is located within the N-terminal region of the protein leading to a complete loss of the ubiquitin ligase activity. To determine the underlying molecular pathogenesis, we analyzed patients' fibroblasts and could show that cells lacking this ubiquitin ligase activity have an increased sensitivity to DNA-damage and responded with prolonged activation of checkpoint kinase 1 and increased level of apoptosis. Our data link the molecular pathogenesis of overgrowth syndromes to altered DNA-damage response and increased cancer risk. Additional sequencing of a cohort of patients with Weaver syndrome for mutations identified novel de novo mutations in EZH2 and provided evidence for further genetic heterogeneity in Weaver syndrome. Exome sequencing is currently performed in one large dominant pedigree with Weaver syndrome as well as in unsolved sporadic cases aiming to identify additional genes involved in altered control of growth and DNA-damage response in Weaver syndrome.

Myhre syndrome (OMIM #139210, MS) is a developmental disorder characterized by pre and postnatal short stature, brachydactyly, facial dysmorphism (short palpebral fissures, maxillary hypoplasia, mandibular prognathism, short philtrum), muscular hypertrophy, joint limitation and deafness. Other features include intellelectual disability behavioral disturbance, cardiac defects, and cryptorchidism. Skeletal manifestations include thickened calvarium, cone-shaped epiphyses, shortened tubular bones, hypoplastic iliac wings, broad ribs and large vertebrae with short and large pedicles. All reported MS cases are sporadic supporting de novo dominant mutations. Using exome sequencing in 2 MS cases, we selected mothers against DPP homolog 4 (SMAD4) as a candidate gene based on its pivotal role in BMP and TGFβ signalling. SMAD4 mutations were subsequently found in additional 18 affected individuals. We identified only
3 distinct heterozygous missense SMAD4 mutations all affecting Isoleucine 500 which in located in the Mad Homology 2 (MH2) domain, near the monoubiquitinated site Lys519. We further demonstrated a defect in SMAD4 ubiquitination in patient fibroblasts and increased level of SMAD4 suggesting a stabilization of SMAD4 protein in Myhre syndrome. These results were in contrast of those observed with SMAD4 loss of function mutations, identified juvenile polyposis syndrome and associated with SMAD4 instability. We further study the nuclear localization of mutant SMAD complexes and found that the complexes translocate to the nucleus. We finally observed a decreased expression of downstream TGFβ target genes supporting impaired TGFβ driven transcriptional control in MS.

C03.6

Homozygossity mapping and whole exome sequencing identifies *MAP4* mutations in short stature

C. T. Thiel[1], *D. Zahnleiter*[1], *U. Trautmann*[1], *A. B. Ekici*[1], *A. Reis*[1], *H. Doerr*[2], *A. Rauch*[3];

[1]Institute of Human Genetics, University of Erlangen-Nuremberg, Erlangen, Germany, [2]Department of Pediatrics and Adolescent Medicine, University of Erlangen-Nuremberg, Erlangen, Germany, [3]Institute of Medical Genetics, University of Zurich, Zurich, Switzerland.

Shortness of stature is one of the most common paediatric concerns. 3 % of the general population present with a body height below -2 SD score. However, only in a small number of cases there is a genetic diagnosis. To uncover further underlying genetic mechanism we performed genome wide homozygossity mapping using an Affymetrix SNP 6.0 array in 8 patients with idiopathic short stature of consanguineous families. We identified runs of homozygossity with an average size between 2.7 and 300.1 Mb not reported in European populations. As the gene content averaged 874 genes we carried out whole exome sequencing after Agilent sure select enrichment v3 with 50 Mb. Runs were performed on a Life Tech5500xl platform. After Mapping and SNP calling with LifeScope variants were annotated with ANNOVAR. This identified the homozygous missense mutation p.A391T in the *MAP4* gene not present in 300 controls or the 1000genomes project. MAP4 is a major protein for microtubuli assembly during mitosis. The patient's phenotype showed significant overlap with those reported for Seckel syndrome and Microcephalic Osteodysplastic Dwarfism type Majewski which are also caused by defects in centrosomal proteins. The *MAP4* mutation creates a novel phosphorylation site in the KDM domain of the MAP4 protein which is predicted to destabilise the microtubuli architecture. Immunofluorescence analysis on a fibroblast cell line of the affected patient showed a higher rate of centrosome duplications and confirmed this hypothesis. This result illustrates the feasibility of our approach using exome sequencing to identify recessive genes for short stature.

C04.1

High frequency of indels at the breakpoint junctions of *MECP2* duplication rearrangements strongly support replicative-based mechanisms

C. M. B. Carvalho[1], *M. B. Ramocki*[1,2], *D. Pehlivan*[1], *S. Cheung*[1], *L. M. Franco*[1], *J. W. Belmont*[1], *H. Y. Zoghbi*[1,2], *P. J. Hastings*[1], *J. R. Lupski*[1];

[1]Baylor College of Medicine, Houston, TX, United States, [2]Texas Children's Hospital, Houston, TX, United States.

Copy number gain in Xq28 including *MECP2* is the most commonly identified subtelomeric CNV in patients with developmental delay and associated clinical findings. To date, we have collected a cohort of 65 patients with CNV including *MECP2*. Previous analyses derived from high-resolution comparative genomic hybridization arrays (aCGH) revealed the frequent occurrence of complex rearrangements within our patient cohort in 27% of cases. Here we studied 31 patients carrying duplications including *MECP2* in whom we were able to accomplish DNA sequencing for each of the rearrangement breakpoint junction. Surprisingly, DNA sequencing unveiled the presence of complexities in up to 50% of the rearrangements. All complex alterations have at least one breakpoint within or flanking the low copy repeats (LCRs) supporting our hypothesis that such LCRs stimulate those rearrangements. The most striking observation, however, was the high frequency (42%) of small insertions and deletions (indels) observed at/or flanking the breakpoint junctions, none of which were found present in dbSNP (built 135) suggesting that they were generated concomitant with the rearrangement. This observation strongly supports a role for replication-based mechanisms underlying such rearrangements as break-induced replication (BIR) was recently shown to increase the rate of frameshift mutations in yeast. In addition, SNP genotyping revealed absence of heterozygosity (AOH) within the altered genomic region strongly suggesting that the *MECP2* duplication is mainly an intrachromosomal event. In summary, our results add to a growing body of data documenting a role for a DNA replication mechanism in complex genomic rearrangements associated with genomic disorders.

C04.2

How to deal with genomic imbalances in the imprinted region 11p15.5: Insights in the complex regulation of two imprinting domains

T. Eggermann[1], *M. Begemann*[1], *M. Gogiel*[1], *A. Dufke*[2], *I. Spier*[3], *I. Spier*[3], *S. Spengler*[1];

[1]University Hospital, Aachen, Germany, [2]University Hospital, Tübingen, Germany, [3]University Hospital, Bonn, Germany.

Duplications or deletions affecting the imprinting control regions 1 and/or 2 (ICR1/2) in 11p15.5 have been reported for both growth retardation and overgrowth. However, due to the complexity of the 11p15.5 imprinting regions, the interpretation of copy number variations (CNVs) is difficult. The clinical outcome in 11p15.5 CNV carriers is influenced by the size, the breakpoint positions, their parental origin and the imprinting status of the affected genes. We report on three carriers of different CNVs (two duplications and one deletion) restricted to the telomeric ICR1: two patients were referred with the diagnosis of Silver-Russell syndrome (SRS), in the third case the clinical features were probably not associated with the imbalance. Summarising our results and those from the literature, a central role of the *IGF2* gene and its telomeric enhancer elements for the clinical course of 11p15 disturbance carriers is obvious: whereas duplications or deletions of H19 do apparently not affect the phenotype, imbalances of both IGF2 as well as its enhancer can separately cause abnormal phenotypes depending on the parental origin. As a result, carriers of ICR1 duplication can even show a normal phenotype. A similar pattern can be delineated for the centromeric ICR2: here the type of imbalances affecting the CDKN1C and the KCNQ1OT1 genes and their differentially methylated region influences the clinical outcome. As a result, CNVs in 11p15.5 require an extensive workup to delineate risk figures for 11p15.5 associated syndromes. Additionally they allow profound insights in the complex regulation of the imprinted factors localised in 11p15.5.

C04.3

Nonlinear and nonrandom genome organization of SNRPN, UBE3A, and GABRB3 in the normal human nucleus by three-color 3D-fluorescence in situ hybridization

R. Kawamura[1], *H. Tanabe*[2], *T. Wada*[1,3], *S. Saitoh*[4], *Y. Fukushima*[1], *K. Wakui*[1];
[1]*Department of Medical Genetics, Shinshu University School of Medicine, Matsumoto, Japan,* [2]*The Graduate University for Advanced Studies (Sokendai), Hayama, Japan,* [3]*Kanagawa Children's Medical Center, Yokohama, Japan,* [4]*Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan.*

Higher-order chromatin organization and spatial arrangement of genomic region within the nuclear space seems to play an important role in genome function via epigenetic mechanisms in the human nucleus. The aim of this study was to search for the new evidence related to genomic organization and function. We investigated the spatial positioning of three target regions containing the SNRPN, UBE3A, and GABRB3 genes mapped on chromosome 15q11.2-q12 by three-color 3D-fluorescence in situ hybridization on the interphase nuclei of normal human cells. The three target regions were not arranged linearly in most of the cells analyzed, and GABRB3 was positioned closer to SNRPN than UBE3A at a high proportion differently from genomic map. In addition, the distances from SNRPN to UBE3A (SU) and from UBE3A to GABRB3 (UG) between the alleles in each cell were different in both distances, and the SU ratio (longer/shorter SU distance between alleles) was larger than the UG ratio (longer/shorter UG distance between alleles). Moreover, the distances between the regions were different between the SU and UG regions on each chromosome in each nucleus. Thus, our results indicated that SNRPN, UBE3A, and GABRB3 have a nonlinear and nonrandom curved spatial positioning in principle, but there were some differences between the alleles and between the regions in the nucleus. These observations of structural differences in normal human cells might be reflected the status of gene as the SNRPN gene is known to have paternal-only expression.

C04.4

Age-related somatic structural changes in the nuclear genome of human blood cells

Structural variations are among the most frequent interindividual genetic differences in the human genome. The frequency and distribution of de novo somatic structural variants in normal cells is poorly explored. Using age-stratified cohorts of 318 monozygotic twins (MZ) and 296 single-born subjects, we describe age-related accumulation of copy-number variation in the nuclear genomes in vivo and frequency changes for both megabase- and kilobase-range variants. Megabase-range aberrations were found in 3.4% of subjects ≥60 years old; these subjects included 78 MZ twin pairs and 108 single-born individuals. No such findings were observed in 81 MZ pairs or 180 single-born subjects who were ≤55 years old. Recurrent region- and gene-specific mutations were observed. Longitudinal analyses of 43 subjects whose data were collected 7-19 years apart suggest considerable variation in the rate of accumulation of clones carrying structural changes. Furthermore, the longitudinal analysis of individuals with structural aberrations suggests that there is a natural self-removal of aberrant cell clones from peripheral blood. In three healthy subjects, we detected somatic aberrations characteristic of patients with myelodysplastic syndrome. The recurrent rearrangements uncovered here are candidates for common age-related defects in human blood cells. We anticipate that extension of these results will allow determination of the genetic age of different somatic-cell lineages and estimation of possible individual differences between genetic and chronological age. Our work might also help to explain the cause of an age-related reduction in the number of cell clones in the blood; such a reduction is one of the hallmarks of immunosenescence.

C04.5

Clinically relevant mosaic findings in a total of 8,374 patients and parents in constitutional genome diagnostics using genome wide high resolution SNP array analysis

N. de Leeuw, *J. Y. Hehir-Kwa, B. H. W. Faas, T. K. Rinne, M. J. E. Kempers, S. A. de Munnik, N. F. A. Leijsten, T. C. Machielsen, S. L. J. van Gessel, M. Wunderink, M. J. G. Banning, R. van Beek, M. del Rosario, B. B. A. de Vries, D. F. C. M. Smeets, R. Pfundt;*
Department of Human Genetics, Nijmegen, Netherlands.

We routinely perform genome wide SNP array analysis as the first-line diagnostic test for patients with intellectual disability and/or congenital anomalies and in prenatal diagnosis in case of structural ultrasound anomalies. In addition to *de novo* (6.5%), rare inherited (9.1%) or X-linked (0.8%) copy number variations (CNVs), we observed a significantly increased percentage of homozygosity in patients (6.1%) which subsequently led to the identification of pathogenic mutations in recessive disease genes, uniparental disomies, or low-mosaic aneuploidies in several patients. A mosaic finding was detected in 22 of 6,500 patients and in seven mothers of a total of 1,874 parents. In November 2011, we switched from the Affymetrix 250K SNP array to the CytoScan HD array platform which further enhanced the resolution, improved the detection of mosaic imbalances and also enabled us to detect clinically relevant, mosaic, copy neutral allelic imbalances in an additional three patients. The percentage of mosaicism (CNV, aneuploidy or allelic imbalance) often differed between tissue samples of mesodermal or ectodermal origin from each of these individuals. In two patients such tissue-dependent differences were shown to change over time.

Genome wide SNP array analysis is a suitable and highly effective method to reliably identify mosaic abnormalities that appear to be relatively common in both patients (1 in 300) and parents (1 in 270). Because of the significantly increased recurrence risk, it is crucial to know whether an apparently *de novo* imbalance in an affected child is in fact due to a mosaic aberration in the (unaffected) parent.

C04.6

Modelling neurogenesis impairment in Down syndrome using induced pluripotent stem cells from monozygotic twins discordant for trisomy 21

Y. Hibaoui[1,2], *I. Grad*[1], *M. R. Sailani*[2], *A. Letourneau*[2], *S. Dahoun*[2], *S. Gimelli*[2], *M. F. Pelte*[3], *F. Béna*[2], *S. E. Antonarakis*[2], *A. Feki*[4,1];
[1]*Stem Cell Research Laboratory, Department of Obstetrics and Gynecology, Geneva University Hospitals, Geneva, Switzerland,* [2]*Department of Genetic Medicine and Development, University of Geneva Medical School and Geneva University Hospitals, Geneva, Switzerland,* [3]*Department of Pathology and Immunology, Faculty of Medicine, University of Geneva, Geneva, Switzerland,* [4]*Service de gynécologie obstétrique, HFR Fribourg - Hôpital cantonal, Fribourg, Switzerland.*

Down syndrome (DS), caused by trisomy 21, is the most common chromosomal disorder, with an incidence of 1 in 800 live births. Its phenotypic characteristics include intellectual impairment and several other developmental abnormalities, for the majority of which the pathogenetic mechanisms remain unknown. Here, we report the generation and the characterization of induced pluripotent stem cells (iPSCs) derived from monozygotic twins discordant for trisomy 21: Twin-N-iPSCs for the normal and Twin-DS-iPSCs for the DS-affected iPSCs. We hypothesize that these samples were ideal to study the effect of the supernumerary chromosome 21, since the rest of the genome is identical between the two samples. Karyotype and high-resolution array-based comparative genomic hybridization analysis, confirmed the chromosomal constitution of these iPSCs. Transcriptome analysis by mRNA-Seq showed alterations in the expression of genes that impact on DS features. *In vivo* differentiation of Twin-DS-iPSCs revealed an abnormal teratoma formation in NOD-SCID mice. *In vitro*, Twin-DS-iPSC-derived neurospheres showed a reduced number of neuroprogenitor cells (NPCs). When NPCs were further induced to mature into neurons, we found structural changes in the architecture and density of neural populations together with alterations in the expression of genes involved in lineage specification in neurogenesis and brain development. Furthermore, we provide novel evidence that the increased expression and activity of the dual-specificity tyrosine-(Y)-phosphorylation regulated kinase 1A protein underlie these defects. In conclusion, these findings establish these iPSCs as a unique cellular model to study the detailed mechanisms involved in the pathogenesis of DS and design new therapies.

C05.1

RNAi-based functional profiling of loci from blood lipid genome-wide association studies

H. Runz[1,2], *P. Blattmann*[3,2], *C. Schuberth*[1], *R. Pepperkok*[3,2];
[1]Institute of Human Genetics, Heidelberg, Germany, [2]Molecular Medicine Partnership Unit (MMPU), Heidelberg, Germany, [3]EMBL, Heidelberg, Germany.

Genome-wide association studies (GWAS) are powerful tools to unravel genomic loci associated with common traits and complex human disease. However, GWAS only rarely reveal information on the exact genetic elements and pathogenic events underlying an association. In order to extract functional information from genomic data, strategies for systematic follow-up studies on a phenotypic level are required. Here we address these limitations by applying RNAi to analyze >100 candidate genes within 55 loci identified by GWAS as associated with blood lipid levels, coronary artery disease and/or myocardial infarction for a function in regulating cholesterol levels in cells. The genes were knocked-down with siRNAs and the consequences on cellular free cholesterol (FC) and the efficiency of LDL-internalization into cells were quantified using automated microscopy and multiparametric image analysis. We will show evidence that loss-of-function of a surprisingly high number of the trait-associated genes affected LDL-uptake, FC, or both. For several genes without previously known lipid-regulatory roles the functional effects upon gene knockdown closely correlated with altered LDL-receptor levels. By providing strong evidence for disease-relevant functions of lipid trait-associated genes our study demonstrates that quantitative, cell-based RNAi is a scalable strategy for a systematic, unbiased detection of functional effectors within GWAS loci.

C05.2

Accumulation of common genetic variants influences lipid levels in patients with T2D and improves prediction of hypercholesterolemia

S. M. Willems, A. Hofman, B. A. Oostra, C. M. van Duijn, ***A. Isaacs****;*
Genetic Epidemiology Unit, Department of Epidemiology, Erasmus MC, Rotterdam, Netherlands.

A large proportion of type 2 diabetes (T2D) patients have dyslipidemia, an important cause of micro- and macrovascular complications. A recent GWAS in the general population identified 95 common genetic variants associated with lipid levels. To obtain insight into the genetics underlying diabetic dyslipidemia, genotype scores approximating the additive effects of those variants were calculated for each major lipid class (total cholesterol, TC; high-density lipoprotein cholesterol, HDL; low-density lipoprotein cholesterol, LDL; and triglycerides, TG) in individuals with/without T2D in the Rotterdam Study (n=7735) and Erasmus Rucphen Family Study (n=2313). Adjusted for age, sex and bmi, all four genotype scores were significantly associated with lipid levels in both non-diabetics and diabetics. The genotype scores for HDL, LDL, and TG were also used to predict hypercholesterolemia. The area under the ROC curve (AUC) for the genotype scores was 0.68[0.66-0.69] in non-diabetics and 0.72[0.68-0.76] in diabetics, which was better than the predictive ability of age, sex and BMI ($AUC_{\text{non-diabetics}}$=0.65[0.64-0.66], $AUC_{\text{diabetics}}$=0.69[0.65-0.73]). Combining the genetic scores with the non-genetic risk factors improved the AUC in both non-diabetics and diabetics ($AUC_{\text{non-diabetics}}$=0.69[0.68-0.71], $AUC_{\text{diabetics}}$=0.75[0.71-0.79]). The non-genetic, genetic and combined AUCs for prediction of hypercholesterolemia were all significantly higher in diabetics than in non-diabetics ($P_{\text{nongenetic\_AUC}}=0.038$, $P_{\text{genetic\_AUC}}=0.028$, $P_{\text{combined\_AUC}}=0.006$). In conclusion, genotype scores derived from common lipid variants are associated with lipid levels not only in the general population, but also in patients with T2D and can, especially in diabetics, improve prediction of hypercholesterolemia. These data suggest that the role of common variation may be modified in the context of diabetes.

The exact functions and causative variants remain largely unknown for the 95 genetic loci that are identified to associate with levels of TC, LDL-C, HDL-C or TG. We identified new metabolic or genetic associations (p<5×10-8) for 30 of the 95 lipid loci by further characterizing the loci utilizing extensive serum metabolite profiles, including a broad panel of lipoprotein subclasses and tens of other serum metabolites obtained via NMR spectroscopy, and a dense set of 440,807 directly genotyped and imputed variants around the previously identified lead SNPs in 8330 Finnish individuals.

In the majority of the loci the more detailed metabolite measures appeared to better describe the underlying biology than the conventional lipids. In four loci, including PLTP and LIPC, the directions of associations to small and large HDL particles were the opposite, pinpointing the diversity of HDL subclasses not captured in the routine measurement of HDL-C. Also, 14 loci had associations beyond the individual lipoprotein measures, including the APOA1 locus where a marker known to associate with CAD was associated with serum lactate (p=3.79×10-13). Additionally, in 27 loci we identified SNPs with a stronger association than the previously reported markers, and twelve loci, including APOB and LIPC, had two or more independent associations across the metabolite measures.

Wide metabolite profiling combined with the dense set of SNPs provided insight into the metabolic and genetic architecture underlying the known lipid loci. Further understanding of these processes may open up new possibilities to understand mechanisms involved in atherosclerosis and other metabolic conditions.

C05.4

Estimating the fraction of established metabolic trait loci with discernible pleiotropic effects

L. Marullo[1,2], *B. K. Cornes*[3,4], *J. Dupuis*[5], *J. B. Meigs*[3,4], *A. Morris*[1,6], *I. Prokopenko*[1,6];
[1]Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom, [2]Department of Evolutionary Biology, Genetic Section, University of Ferrara, Ferrara, Italy, [3]General Medicine Division, Massachusetts General Hospital, Boston, MA, United States, [4]Department of Medicine, Harvard Medical School, Boston, MA, United States, [5]Department of Biostatistics, Boston University School of Public Health, Boston, MA, United States, [6]Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, Oxford, United Kingdom.

Genetic variation influences human quantitative trait levels and risk of metabolic disease. The patterns of trait association observed in genome-wide association studies (GWAS) at individual cardio-metabolic risk-loci are highly variable and allelic heterogeneity is often observed for association within and between traits.

The Cross-Consortia Pleiotropy Group was formed to investigate the patterns of multi-trait associations across the genome for cardio-metabolic traits. We aimed to estimate the fraction of established GWAS loci associated with more than one cardio-metabolic trait showing strong (r2>0.8), moderate (r2>0.2) linkage disequilibrium (LD) or evidence of allelic heterogeneity between associated variants.

We evaluated 271 SNPs representing associations from published GWAS meta-analyses (Nov.2010) in Europeans of 20 quantitative and two disease phenotypes from six cardio-metabolic trait consortia. We identified 106 regions associated with multiple traits, defined as sets of adjacent variants located less than 500kb apart. We used LD estimated from 1000 Genomes CEU data.

Across the 106 regions defined by SNPs of interest, we observed 49 (30%) containing the same SNP associated with more than one trait. Of these, 37 contain SNPs associated with highly correlated traits, e.g. lipids and obesity. Of the remaining regions, 38 (23%) contain variants in strong LD and 30 (19%) contain variants in moderate LD, and 46 (28%) regions contain variants in only modest LD (r2<0.2).

Our results highlight that a substantial proportion of metabolic trait loci incorporate complex patterns of multi-trait allelic heterogeneity, suggesting that statistical approaches that model epidemiological correlations between phenotypes may increase power and resolution of gene-mapping efforts.

C05.5

Dysfunctional NO signaling due to a double mutation in GUCY1A3 and CCT7 identified by whole exome sequencing increases risk for myocardial infarction

J. Erdmann[1], *K. Stark*[2], *U. Esslinger*[2], *F. Kaiser*[3], *C. CARDIoGRAM*[1], *H. Schunkert*[1], *C. Hengstenberg*[2];
[1]*Universität zu Lübeck, Lübeck, Germany,* [2]*3 Klinik und Poliklinik für Innere Medizin II, Universitätsklinikum Regensburg,, Regensburg, Germany,* [3]*Universität zu Lübeck, Inst. für Humangenetik, Lübeck, Germany.*

Myocardial infarction is a life-threatening disease, which results from sudden atherothrombotic occlusion of a coronary artery. Most cases of MI occur sporadically but in rare cases the disease accumulates in families. Here we show by using exome sequencing in such family the identification of heterozygous mutations (p.Leu163Phefs*24 and p.Ser525Leu) in two functionally related genes, GUCY1A3 and CCT7, in 7 and 11 out of 15 affected family members, respectively. Single-locus linkage-analysis revealed no significant LOD score, however two-locus linkage-analysis considering both mutations revealed a significant maximum LOD score of 5.68. Moreover, a GWAS of 28K MI or CAD cases and 75K controls identified a signal across the GUCY1A3 locus (P<1.74x10-8 for rs7692387). While GUCY1A3 encodes the alpha1 subunit of soluble guanylyl cyclase (sGC), CCT7 a member of the chaperonin containing TCP1 complex (TRiC/CCT), which, among other functions, stabilizes sGC. This enzyme generates cGMP upon stimulation with nitric oxide (NO) and thereby pacifies platelets among other functions. We subsequently demonstrated that in-vitro sGC activity is severely impaired by the GUCY1A3 and CCT7 mutations. Platelets from double mutation carriers contained less sGC protein and consequently a reduced NO-induced cGMP formation. Moreover, in mice deficient for the alpha1 sGC protein subunit thrombus formation in the microcirculation in-vivo upon local trauma was accelerated. In conjunction, we linked mutations in GUCY1A3 and CCT7; encoding two functionally related proteins, to MI, associated a common variant in one of the genes to the same disease, and propose defective sGC dependent NO signaling as a mechanism leading to MI.

C05.6

Gene expression in an extended pedigree

S. B. Montgomery, *X. Li, K. Karczewski, K. Smith;*
Stanford University School of Medicine, Stanford, CA, United States.

We have used RNA-sequencing to profile the transcriptome of 17 European-descendent individuals in a three generation pedigree. Each individual has a sequenced genome using Complete Genomics technologies. We assess the de novo mutation rate using this extended pedigree. Furthermore, we report patterns of linkage with expressed transcripts to describe the effects of rare and common variants in this cohort. This provides us with an estimate of the functional de novo rate and further allows us to dissect the impact of structural versus single nucleotide polymorphisms. Using techniques we have previously reported (Montgomery, Nature, 2010), we assess allele specific expression (ASE) and now identify variants identical-by-descendent and the subsequent heritability of ASE.

C06.1

The evolution of African great ape subtelomeric heterochromatin and the fusion of human chromosome 2

C. R. Catacchio[1], *M. Ventura*[1], *S. Sajjadian*[2], *L. Vives*[2], *P. H. Sudmant*[2], *T. Marques-Bonet*[3], *T. A. Graves*[4], *R. K. Wilson*[4], *E. E. Eichler*[2];
[1]*University of Bari, Bari, Italy,* [2]*Department of Genome Sciences, University of Washington School of Medicine, Seattle, WA, United States,* [3]*IBE, Institut de Biologia Evolutiva (UPF-CSIC), Universitat Pompeu Fabra, Barcelona, Spain,* [4]*Washington University Genome Sequencing Center, School of Medicine, St. Louis, MO, United States.*

Chimpanzee and gorilla chromosomes differ from human chromosomes by the presence of large blocks of subterminal heterochromatin thought to be composed primarily of arrays of tandem satellite sequence. Due to the high-copy repetitive nature of these sequences, like centromeric and secondary constriction on acrocentric chromosomes, the subtelomeric heterochromatin is not represented in the existing genome assemblies of the chimpanzee and gorilla. We use a combination of molecular cytogenetics, clone-based sequencing, and phylogenetic analysis to explore their sequence composition and organization and show a complex organization composed of specific sets of segmental duplications, which have hyperexpanded in concert with the formation of subterminal satellites. These regions are highly copy number polymorphic between and within species and copy number differences involving hundreds of copies can be accurately estimated by assaying read-depth of next-generation sequencing datasets. Phylogenetic and comparative genomic analyses suggest that the structures have arisen largely independently in the two lineages with the exception of a few seed sequences present in the common ancestor of humans and African apes. We propose a model where an ancestral human-chimpanzee pericentric inversion and the ancestral chromosome 2 fusion both predisposed and protected the chimpanzee and human genomes respectively to the formation of subtelomeric heterochromatin. Our findings highlight the complex interplay between duplicated sequences and chromosomal rearrangements that rapidly alter the cytogenetic landscape in a short period of evolutionary time.

C06.2

Genome-wide search for gender different genetic loci for human anthropometric traits: Methods and results from genome-wide meta-analyses across 270,000 Individuals

T. W. Winkler[1], *J. C. Randall*[2,3], *Z. Kutalik*[4,5], *S. I. Berndt*[6], *R. J. F. Loos*[7,8], *C. M. Lindgren*[9], *K. E. North*[10], *I. M. Heid*[1,11];
[1]*Public Health and Gender Studies, Institute of Epidemiology and Preventive Medicine, Regensburg University Medical Center, Regensburg, Germany,* [2]*Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom,* [3]*Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom,* [4]*Department of Medical Genetics, University of Lausanne, Lausanne, Switzerland,* [5]*Swiss Institute of Bioinformatics, Lausanne, Switzerland,* [6]*Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Department of Health and Human Services, Bethesda, MD, United States,* [7]*MRC Epidemiology Unit, Institute of Metabolic Science, Addenbrooke's Hospital, Cambridge, United Kingdom,* [8]*Charles R. Recently, a sex-specific follow-up of a few genetic variants associated with human anthropometric traits, detected in sex-combined analyses, revealed significant difference between the sexes.

To more systematically detect further sexually dimorphic loci, we conducted sex-specific genome-wide association meta-analyses of 46 studies (60,586 men, 73,137 women) and followed-up the results in 48 independent studies (62,395 men, 74,657 women) within the GIANT consortium. Each study tested for association of 2.8M SNPs and 9 phenotypes: height, weight, body mass index (BMI), waist and hip circumference, waist-hip ratio (WHR), the latter three with and without adjustment for BMI.

Opted to detect signals with association in only one sex, we controlled sex-specific P-Values at 5 % false-discovery-rate (FDR) and as such selected 348 independent signals. A follow-up yielded 7 hits with significant (<5% FDR) replication sex-difference P-values: (a) 6 women-specific loci without any effect in men, including 3 novel (near *MAP3K1, HSD17B4, PPARG*) and 3 previously established (near *GRB14/COBLL1, LYPLAL1/SLC30A10, VEGFA*) loci; and (b) one previously published locus (near *ADAMTS9*) with a less pronounced effect in men. Of particular interest is the *PPARG* region, well-known for its role in type 2 diabetes therapy, which showed a women-specific association with WHR adjusted for BMI. A second approach to search for sex-differences was particularly powered to detect signals with association in both sexes and with opposite effect direction. This method, however, did not yield any signals.

Our results underscore the importance of sex-stratified analyses in order to illustrate a sexually dimorphic genetic underpinning for anthropometric traits.

C06.3

Analysis of structural variation in the Genome of the Netherlands (GoNL) project

V. Guryev[1], *W. Kloosterman*[2], *L. Francioli*[2], *J. Y. Hehir-Kwa*[3], *E. Lameijer*[4], *A. Abdellaoui*[5], *J. de Ligt*[3], *V. Koval*[6], *N. Amin*[6], *F. van Dijk*[7], *L. C. Karssen*[6], *H. Mei*[8], *K. Ye*[4];
[1]*Hubrecht Institute and UMC, Utrecht, Netherlands,* [2]*University Medical Center, Utrecht, Netherlands,* [3]*Radboud University Medical Centre, Nijmegen, Netherlands,* [4]*Leids University Medical Center, Leiden, Netherlands,* [5]*VU University Medical Center, Amsterdam, Netherlands,* [6]*Erasmus Medical Center, Rotterdam, Netherlands,* [7]*University Medical Center, Groningen, Netherlands,* [8]*Netherlands Bioinformatic Centre, Nijmegen, Netherlands.*

on behalf of Genome of the Netherlands consortium

The Genome of the Netherlands (GoNL) is a national collaboration that aims at characterizing genetic variations in the Dutch population of 250 families. Here we report on the pilot results of the structural variation analysis for 18 families. Our analysis employs several methodologies for detection of different types and size ranges of variants.

Using GATK Unified Genotyper, we identified 1,459,968 small indels of which 23% are novel compared to 1000 Genomes phase 1 data, and 86% overlap with Pindel's short indel calls. In silico functional analysis indicates that 819 are causing premature stop codons and frameshifts in 749 genes.

A combination of 4 approaches, read depth (CNVnator, DWAC-Seq), read pair (123SV, BreakDancer and GenomeSTRiP), split-read (Pindel), and *de novo* assembly (SOAPdenovo, CLC) ensures detection of structural variants of different types and size ranges. For example, we identified a 1.8 kb insertion absent in genome reference, but common in Dutch population (allele frequency=42%), while rare (5%) in 1000 Genomes project.

Homozygous DNA segments were identified using PLINK and VCFtools.

We performed hundreds of PCR/Sequencing assays to determine false-positive rate for each tool and to establish de novo mutation rate of indels and structural variants.

The set of wide size range, multi-type, high-quality SVs calls, together with GoNL SNP set (reported separately) describes common genomic variants in the Dutch genomes. This variation catalogue is essential for understanding population history, interpretation of GWAS and analysis of other studies involving West-European samples.

C06.4

Duplications at PAK7 are a significant risk factor for schizophrenia and bipolar disorder

***D. W. Morris**[1], P. Cormican[1], R. D. Pearson[2], B. P. Riley[3], C. C. Spencer[2], E. M. Kenny[1], B. S. Maher[3], B. Wormley[3], G. Donohoe[1], D. Tropea[1], B. P. Coe[4], E. E. Eichler[4], A. McQuillin[5], H. Gurling[5], D. Blackwood[6], F. A. O'Neill[7], S. GENE+ Consortium[8], I. nternational Schizophrenia Consortium[9], W. T. C. C. C[2], W. T. C. C. C2[2], K. S. Kendler[3], M. Gill[1], P. Donnelly[2], A. P. Corvin[1];*

[1]Trinity College Dublin, Dublin, Ireland, [2]University of Oxford, Oxford, United Kingdom, [3]Virginia Commonwealth University, Richmond, VA, United States, [4]University of Washington, Seattle, WA, United States, [5]University College London, London, United Kingdom, [6]University of Edinburgh, Edinburgh, United Kingdom, [7]Queen's University Belfast, Belfast, United Kingdom, [8]deCODE Genetics, Reykjavik, Iceland, [9]Broad Institute, Boston, MA, United States.

To identify novel rare risk copy number variants (CNVs) for schizophrenia we performed a CNV analysis in 1,564 cases and 6,944 controls from Ireland and the UK. Three novel and significant (p<0.01) CNVs from this analysis at chr2cen-q13, chr3p25.1 and chr20p12.2 were confirmed by quantitative real-time PCR and taken forward for replication in a large independent dataset of European ancestry containing 7,123 cases and 62,694 controls. This confirmed association with schizophrenia for rare chr20p12.2 duplications (replication p=0.0008). In the combined sample there are 12 duplications in 8,687 cases and 13 in 69,808 controls (p=4.3x10-6, OR=7.44). All cases had a 132-146.5kb duplication involving the first two exons of the p21 Protein-Activated Kinase 7 (PAK7) gene. Most case carriers of the duplication were severely affected with poor clinical outcome and limited response to conventional antipsychotic therapy. Based on evidence of overlapping genetic etiology we examined 2,686 bipolar disorder cases and identified 4 duplication carriers (p=0.0002). Altogether, these data support PAK7 duplications as a rare but significant risk factor for psychosis (p=2.14x10-7, OR=7.63). PAK7 is one of a family of serine/threonine protein kinases, which are regulated by the Rho family of small G proteins and are involved in multiple intracellular signaling pathways. In mouse cortical neurons, we found that protocols that induce activity-dependent synaptic plasticity also modulated PAK7 expression suggesting that like other p21-activated kinases, PAK7 may play an important role in maintaining synaptic networks. Thus, our novel finding may provide new insight into the pathophysiology of schizophrenia and bipolar disorder.

C06.5

Variation in transcription factor binding among humans

***M. Kasowski**[1], F. Grubert[2], C. Heffelfinger[1], M. Hariharan[2], A. Asabere[1], S. Waszak[3], L. Habegger[1], J. Rozowsky[1], M. Shi[2], A. Urban[2], M. Hong[1], K. Karczewski[2], W. Huber[3], S. Weissman[1], M. Gerstein[1], J. Korbel[3], M. Snyder[2];*

[1]Yale University, New Haven, CT, United States, [2]Stanford University, Stanford, CA, United States, [3]EMBL, Heidelberg, Germany.

Differences in gene expression may play a major role in speciation and phenotypic diversity. Although variations in gene expression among individuals have been documented, the origins of these differences are not clear, and studies that directly measure differences in transcription factor binding sites among humans have not been performed. We have examined genome-wide variation in transcription factor binding in different individuals and a chimpanzee using chromatin immunoprecipitation followed by massively-parallel sequencing (ChIP-Seq). The binding sites of RNA Polymerase II (Pol II) as well as a key regulator of immune responses, NFκB, have been mapped in ten lymphoblastoid cell lines derived from individuals of African, European, and Asian ancestry, including a parent-offspring trio. Using a stringent threshold, approximately 7.5% and 25% of the respective NFκB and Pol II binding regions exhibit differences between any two individuals. To understand the underlying basis of the variations, we examined the effect of SNPs and genomic structural variations (SVs) on binding differences among individuals. We find that many binding differences are associated with SNPs and SVs. Comparison of the binding data with gene expression data generated by RNA-Seq revealed that differences in binding often correlate with gene expression differences. Furthermore, comparison of the Pol II human sites with binding sites identified in the chimpanzee suggests a high level of divergence in binding relative to our closest evolutionary neighbor. Our results indicate that many differences in individuals occur at the level of TF binding and provide insight into the genetic events responsible for these differences.

C06.6

Poly(A) binding protein nuclear 1 (PABPN1) levels affect alternative polyadenylation

***E. de Klerk**[1], A. Venema[1], Y. S. Anvar[1], J. J. Goeman[2], J. T. den Dunnen[1], S. M. van der Maarel[1], V. Raz[1], P. A. C. ,t Hoen[1];*

[1]Leiden University Medical Center, Center for Human and Clinical Genetics, Leiden, Netherlands, [2]Leiden University Medical Center, Department of Medical Statistics and Bioinformatics, Leiden, Netherlands.

The choice for a polyadenylation site (PAS) determines the length of the 3'-untranslated region (3'-UTRs) of an mRNA. Inclusion or exclusion of regulatory sequences in the 3'-UTR may ultimately affect gene expression levels. Poly(A) binding protein nuclear 1 (PABPN1) is involved in polyadenylation of pre-mRNAs. A repeat expansion in PABPN1 causes oculopharyngeal muscular dystrophy (OPMD), a late onset and progressive muscle disorder.

Microarray expression profiling of mice overexpressing expanded-PABPN1 showed alternative PAS usage in 8% of the interrogated genes. We hypothesized that previously observed disturbed gene expression patterns in OPMD muscles may have been the result of an effect of PABPN1 on alternative PAS usage.

To explore PAS usage on a genome-wide level, we developed a single molecule PAS sequencing method. We identified 2,012 transcripts with altered PAS usage. In the far majority, alternative more proximal PAS were used. This resulted in overall shortening of 3'-UTRs and increased expression for most of the transcripts.

We recapitulated these changes in PAS usage in myogenic cells by low overexpression of expanded but not wild-type PABPN1. Since expanded-PABPN1 is known to be trapped in intranuclear inclusions, we investigated the effect of sh-RNA mediated downregulation of PABPN1. We found that reduced Pabpn1 levels also resulted in shortening of 3'-UTRs. Our data suggest that PABPN1 is involved in PAS selection. We propose therefore that reduced availability of functional PABPN1 in OPMD muscles results in use of alternative, proximal PAS, leading to large-scale deregulation of gene expression.

C07.1

Exome sequencing; what are the lessons learned?

***M. Kriek**, E. Aten, G. W. E. Santen, Y. Sun, R. Al Momani, A. van Haeringen, S. A. M. J. Lesnik Oberstein, E. Bakker, M. H. Breuning, G. B. van Ommen, J. T. den Dunnen;*

Center for Human and Clinical Genetics, Leiden, Netherlands.

Today, many scientific laboratories apply whole exome sequencing. Considering the number of published articles and abstracts at different meetings, many groups are successful in identifying causative variants for Mendelian disorders. However, at least as many cases currently remain unsolved and exome sequencing comes with several disadvantages. It is labor intensive, it mostly misses variants outside the targeted regions and it generates sequence data with a large variability in coverage across the regions sequenced. Furthermore, to cope with the sheer number of variants encountered, choices have to be made regarding the variants that deserve follow-up work.

We have attempted to uncover the disease causing genes in 16 different cases using exome sequencing. We were able to solve 9 of them (56%). Important factors to success appear to be (1) phenotyping by expert clinical geneticists, (2) an elaborate 'diagnostic' work-up, such as considering SNP array analysis to perform linkage in extended families, (3) a careful selection of sequencing design and (4) a reproducible and robust protocol for exome sequencing and (5) finally, a proper pipeline for data analysis, both with respect to variant calling and annotation.

We consider factors of failure to be (1) suboptimal work-up or study design, (2) hidden causative variant (e.g. non-conserved missense), (3) genetic heterogeneity of the disorder or a (4) non-genetic cause of the disorder.

We will discuss several examples of cases for which we were (un)successful and what attempts were made to prove the pathogenecity of the variants.

C07.2

Exome sequencing in the clinic: diagnostic-driven analysis of exome sequencing data

__M. Nelen__, C. Gilissen, K. Neveling, R. de Reuver, L. Vissers, N. Wieskamp, W. Buijsman, R. Derks, M. del Rosario, I. Feenstra, H. Ijntema, H. Brunner, H. Scheffer, J. Veltman;
Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.

Exome sequencing has great potential in genetic diagnostics, particularly if used for strong heterogeneous diseases were diagnostic yield is currently low. The analysis and interpretation of exome data in diagnostics has specific challenges with respect to quality control, the possibility of incidental findings, and allowing for easy and flexible interpretation. We now have implemented a routine diagnostic exome sequencing workflow.

Six heterogeneous diseases are interrogated by exome sequencing: Intellectual Disability ('de novo' strategy), Blindness, Deafness, Movement disorders, Oncogenetics, OXPHOS diseases (disease gene package). The patient and/or legal representative need to sign an IC before exome sequencing can be requested by the clinical geneticist. It includes an agreement for sequencing their exome and subsequent reporting of all medically relevant findings, including possible findings not related to the initial enquiry. Sequence variants detected can be analyzed using a diagnostic-oriented GUI that automatically limits genetic findings to the relevant genomic loci for a disease, and allows interpretation using predefined filter schemes.

The results of a cohort of 300 patients (including 100 ID patients) will be presented. QC, cases, and pitfalls will be discussed. Data-analysis shows a median coverage of 67x per exome. With the analysis still ongoing, disease gene package analysis detects on average 378 variants with 2 to 18 private non-synonymous variants per patient. The 'de novo' approach for ID demonstrates its potential with ~25% of the ID-patients having causal mutations identified in known ID-genes.

This represents the first in-use approach to establish a genetic diagnosis of patients by exome sequencing.

C07.3

Next Generation Sequencing in Mainstream Diagnostic Genetic Testing: Two years experience and over 1400 Patient Reports

__D. J. Cockburn__[1], H. Lindsay[1], N. Camm[1], R. Robinson[1], R. Brown[1], L. Mavrogiannis[1], N. Jaggs[1], J. Morgan[2], G. Taylor[2], S. Shepherd[1], T. Lamb[1], C. Watson[2], R. Charlton[1];
[1]Yorkshire Regional Genetics, Leeds, United Kingdom, [2]Translational Genomics Unit, Leeds, United Kingdom.

We have established Next Generation Sequencing (NGS) at the core of diagnostic molecular genetic testing in Leeds.

The first service developed was for breast cancer gene screening, and around 1000 reports have been issued since the first in March 2010. Since then, further NGS services have been developed systematically - some were formerly analysed by Sanger sequencing and transformation has brought considerable benefits including reduced costs and improved turnaround time. Enhanced productivity has provided scope to make continued developments and introduce new diagnostic services, widening benefits to new patient groups. The Leeds repertoire of NGS services so far includes breast cancer (BRCA1&2), HNPCC (3 genes), phaeochromocytoma (9 genes), Marfan syndrome (FBN1), Loeys-Dietz syndrome (TGFBR1&2), hypertrophic cardiomyopathy (4 genes), Li Fraumeni syndrome (TP53), Aicardi-Goutieres syndrome (5 genes), and FAP1 (APC). All current services follow standardised protocols which are conducted in parallel and incorporate long-range PCR to target the genes of interest, robotics and automated library construction. Sequencing is on the Illumina platform and results are processed using NextGENe software. Data handling is facilitated by customised spreadsheets which include quality checks and assist with assessment of variants.

Already, around two thirds of our molecular workload is based on NGS technology (measured by UK workload units). But significant transformations in diagnostic services are anticipated to continue, particularly in the fields of molecular cytogenetics and whole exome analysis.

C07.4

Doubly heterozygous LMNA and TTN Mutations Revealed by Exome Sequencing in a Severe Form of Dilated Cardiomyopathy

__P. N. Robinson__[1], C. Viviani Anselmi[2], P. Krawitz[1], G. Lattanzi[3], Y. von Kodolitsch[4], A. Perrot[1], E. di Pasquale[2], L. Papa[2], P. Portararo[2], M. Columbaro[3], A. Forni[5], G. Faggian[6], G. Condorelli[6], R. Roncarati[7];
[1]Charité Universitätsmedizin Berlin, Berlin, Germany, [2]Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS), Multimedica, Milan, Italy, [3]National Research Council of Italy, Institute of Molecular Genetics, and Laboratory of Musculoskeletal Cell Biology, Rizzoli Orthopedic Institute, Bologna, Italy, [4]Centre of Cardiology and Cardiovascular Surgery, University Hospital Eppendorf, Hamburg, Germany, [5]Department of Cardiac Surgery, University of Verona, Verona, Italy, [6]Department of Medicine, National Research Council of Italy, Milan, Italy, [7]Biomedical and Genetic Research Institute (IRGB), Milan Unit, National Research Council of Italy, Milan, Italy.

Familial dilated cardiomyopathy (DCM) is characterized by cardiac enlargement and heart failure associated with systolic dysfunction and impaired contraction of the left ventricle, and about 30-50% of affected individuals have a familial form of DCM. The genetics of familial DCM are complex, with 31 autosomal and two X-chromosomal disease genes currently known, none of which account for more than about 6-8% of cases. The causes of intrafamilial variability in DCM have remained largely unknown. In this study, whole-exome sequencing (WES) was used to investigate the causes for clinical variability in an extended family with 14 affected subjects, four of whom showed particular severe manifestations of cardiomyopathy requiring heart transplantation in early adulthood. Whole-exome and conventional sequencing identified the mutation p.K219T in the lamin A gene in all 14 affected patients. An additional variant in the gene for titin, p.L4855F, was identified in the severely affected patients. The age to heart transplantation was significantly less for LMNA:p.K219T/TTN:p.L4855F double heterozygotes than for LMNA:p.K219T single heterozygotes by Kaplan-Meier analysis. There was also a clearly different distribution of VO2 and ejection fraction between the two groups. Myocardial specimens of doubly heterozygote individuals showed increased nuclear length and myonuclear clustering compared with samples from single heterozygotes. Our results show how WES can be used to address questions about clinical variability in human genetics. The LMNA and TTN mutational status may be useful in this family for risk stratification in persons at risk for familial DCM.

C07.5

Trio-aware variant calling for accurate genotyping and de novo mutation detection

__L. C. Francioli__[1], K. V. Garimella[2], K. E. Samocha[2,3], F. Van Dijk[4], B. M. Neal[2,3], M. J. Daly[2,3], E. Banks[2], M. Swertz[4], M. A. DePristo[2], P. I. W. de Bakker[1,2,5];
[1]Departments of Medical Genetics and Epidemiology, University Medical Center Utrecht, Utrecht, Netherlands, [2]Broad Institute of Harvard and MIT, Boston, MA, United States, [3]Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston, MA, United States, [4]Department of Genetics, University Medical Center Groningen, Groningen, Netherlands, [5]Division of Genetics, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States.

Background

Detection of *de novo* mutations and accurate genotyping from pedigree NGS data is challenging, especially at low or intermediate depth of coverage. Both require accurate and quantitative calibration of the evidence supporting the individuals' genotypes using all the available information, including their familial relationship and population allele frequency.

Methods

We present here a new GATK module, Phase By Transmission, which uses a probabilistic model to compute the most likely genotype combination within a trio given individual genotype likelihoods and a mutation probability prior. When analyzing multiple samples from the same population, it considers the evidence across all samples in its calculation. This module directly uses variant calls (VCF) as input to easily integrate in NGS processing pipelines for genotyping, and *de novo* mutation detection.

Results

Genotyping accuracy was evaluated using concordance between whole-genome SNP calls from 47 trios sequenced at 12x coverage and Immunochip data (170k loci). More than 35% of the discordant genotypes and more than 99.98% of the Mendelian violations in the SNP calls (when performed without familial relationship) could be corrected.

De novo mutation detection was assessed using whole exome data in a cohort of 104 trios sequenced at 60x depth for which validation data for 94 *de novo* mutations was available as part of an independent study. We reported all 91 validated *de novo* mutations and none of the 3 false positives from the original study, and suggested an additional 32 candidates.

C07.6

The Diagnostic Mutation Database (DMuDB). Collecting, managing and publicising clinical variant data.

__M. Cornell__, A. Devereau;
NGRL Manchester, Manchester, United Kingdom.

DMuDB was established by NGRL Manchester to collect and share genetic variants identified by UK molecular diagnostic laboratories. To date over 41,000 variants from 15,000 patient referrals have been submitted. The database's remit has now expanded to accept members and data from European Molecular Quality Network (EMQN) member diagnostic laboratories worldwide on a subscription basis.

Variant data in DMuDB have been generated as part of a clinical diagnosis rather than research. Therefore, access has been limited to those involved in genetic testing for patient diagnosis. However it is recognised that there may be benefits to the clinical community in allowing wider access. For example, the sharing of BRCA1 and BRCA2 data with the ENIGMA consortium could improve the classification of variants of unknown significance. The need to balance these benefits against the need for confidentiality needs to be recognised though.

We have been investigating the use of the Cafe Variome system to publicise diagnostic variants and allow discovery by interested third parties while controlling access. This has helped highlight issues that will need to be resolved for future sharing of variant data. At the same time, the Human Variome Project (HVP) is developing a worldwide model for sharing variant data collected using country nodes and distributing it to gene/disease specific databases and to central databases, e.g., at NCBI and EBI.

We discuss the issues raised in publicising and sharing data and how the DMuDB/Cafe Variome model relates to the HVP country node model of variant data sharing.

C08.1

The ENCODE effort combining RNA-seq and RT-PCR-seq allows to catalog thousands of novel lncRNAs

C. Howald[1,2], *A. Tanzer*[3], *J. Chrast*[1], *F. Kokocinski*[4], *T. Derrien*[3], *N. Walters*[1], *J. M. Gonzalez*[4], *A. Frankish*[4], *B. L. Aken*[4], *T. Hourlier*[4], *J. Vogel*[4], *S. White*[4], *S. M. Searle*[4], *J. Harrow*[4], *T. Hubbard*[4], *R. Guigo*[3], *A. Reymond*[1];

[1]Center for Integrative Genomics, Genopode building, University of Lausanne, Lausanne, Switzerland, [2]Swiss Institute of Bioinformatics, Lausanne, Switzerland, [3]Centre de Regulacio Genomica, Grup de Recerca en Informatica Biomedica, Barcelona, Spain, [4]Wellcome Trust Sanger Institute, Wellcome Trust Genome Campus, Hinxton, United Kingdom.

Within the ENCODE consortium, GENCODE aimed to accurately annotate all protein-coding genes, pseudogenes and non-coding transcribed loci in the human genome through manual curation and computational methods. Lower confidence transcribed loci were systematically experimentally evaluated by RT-PCR amplification followed by highly multiplexed sequencing readout, a method we coined RT-PCR-seq. 79% of all assessed junctions are confirmed by this evaluation procedure demonstrating the high quality of the annotation reached by the GENCODE gene set. We further took advantage of the deep transcriptome profiling generated by the Illumina "Human Body Map" in 16 human tissues to uncover 5918 novel gene models that do not overlap any loci depicted in GENCODE. They potentially represent new non-coding RNA genes or alternatively unannotated 5' or 3'UTR portions of known genes, as the vast majority of these models was shown to have poor coding potential using comparative genomics and mass spectrometry. We experimentally validated using RT-PCR-seq, 73% of the new HBM models, *de facto* enriching the complexity of the human genome annotation of non-coding RNA genes by more than 4000 novel genes. Our findings demonstrate the effectiveness of unbiased RNA-seq combined with targeted RT-PCR-seq to uncover new genome features. These two technologies were simultaneously similarly paired to unravel expressed pseudogenes by the GENCODE consortium. Our RT-PCR-seq targeted-approach also has the advantage of identifying novel exons of known genes, as we discovered unannotated exons in about 11% of assessed introns. We thus estimate that at least 18% of known loci have yet-unannotated exons.

C08.2

Allele Specific Expression Single cell RNA-Seq Analysis

K. Q. Lao[1], *F. Tang*[2], *R. Tanzi*[3], *C. Barbacioru*[1], *E. Nordman*[1], *S. Bao*[2], *C. Lee*[2], *X. Wang*[1], *B. B. Tuch*[1], *E. Heard*[4], *A. Surani*[2];

[1]Life Technologies, Foster City, CA, United States, [2]Welcome Trust, Cambridge, United Kingdom, [3]Life Technologies, Monza, Italy, [4]Institut Curie, Paris, France.

Dissecting the relationship between genotype and phenotype is one of the central goals in biology. Cell development is driven and controlled by temporal and spatial changes in gene transcription,. Single cell RNA-Seq analysis can be instructive concerning how individual cells respond to signals at critical stages of cell fate determination, or when they acquire aberrant phenotype. Essentially all cells within an individual organism share a virtually identical genotype, but the individual transcriptomes reflect expression of a subset of genes, which is determined by their epigenetic state, including DNA methylation and histone modifications. If these two copies of a gene are expressed at different levels, the quantities of messenger (mRNA) from individual alleles will differ. This is called allele specific gene expression (ASE). ASE is potentially important for development, and during evolution when a new allele emerges from mutation, which might immediately affect development through changes in expression levels in a heterozygous cell. However, the extent of ASE in individual mammalian cells and, has not so far been examined. Here, we took advantage of recent advances concerning single cell RNA-Seq, to analyze allele specific gene expression within individual early mouse blastomeres. We found that around 50% of distinguishable expressed alleles of individual genes showed differential allele specific expression. This shows that ASE is widespread at the earliest stages of mammalian development. ASE is likely to occur as a result of sequence polymorphisms of cis regulatory elements, or this might occur in response to different local chromatin structures mediated by epigenetic modifications.

C08.3

Systematic assessment of the immune system by genetic mapping of its quantitative dimensions

S. Sanna[1], *M. Steri*[1], *G. Sole*[1], *C. Sidore*[2,3], *M. F. Urru*[4], *F. Busonero*[1], *F. Reinier*[5], *M. Dei*[1], *S. Lai*[1], *F. Virdis*[1], *A. Mulas*[1], *M. Marcelli*[4], *R. [1]Istituto di Ricerca Genetica e Biomedica, CNR, Monserrato, Italy, [2]Dipartimento di Scienze Biomediche, Università di Sassari, Sassari, Italy, [3]Center for Statistical Genetics, University of Michigan, Ann Arbor, MI, United States, [4]CRS4, GSP group,, Pula, Italy, [5]CRS4, AGCT group,, Pula, Italy, [6]Laboratory of Genetics, NIA, Baltimore, MD, United States.

Genome-wide association scans (GWAS) have identified hundreds of regions associated with immune diseases, but identification of the specific causal variants and clarification of the underlying functional mechanisms remain a great challenge. Better genetic and phenotypic resolution in GWAS, integrating sequencing data and assessing the immune system's various components, can improve our understanding of such loci and lead to novel discoveries. Here we have used polychromatic flow cytometry to evaluate quantitative variation of 271 immune-related traits, representing levels of the majority of lymphocyte cell populations (T and B cells, Natural Killer cells, regulatory T cells, dendritic cells, and their subsets) as well as T cell maturation, in 1628 volunteers of the SardiNIA project by polychromatic flow cytometry. Heritability estimates showed that the genetic component accounts for >40% of the phenotypic variation for most of the traits. Samples were genotyped with Affymetrix arrays as well as MetaboChip and ImmunoChip, and ~14 Million variants were imputed from a reference panel of 1,656 haplotypes deriving from 828 Sardinian samples sequenced at 3x average coverage. We performed a GWAS for each trait and observed, overall, 101 independent variants at 58 loci (1x10-202<P<5x10-8). Notably, our results include the previously reported association at the Type 1 Diabetes associated IL2RA gene and mean CD25 levels on CD4+ memory T cells (P<10-11). Another five loci have been previously associated with immune and non-immune pathologies, illustrating the relevance of the approach for the identification of immune-related genetic factors in both health and disease.

Psaty*[7], *S. Ripatti*[6,11], *T. Frayling*[5], *A. Teumer*[12], *A. Metspalu*[1], *J. B. J. van Meurs*[3], *L. Franke*[2];

[1]University of Tartu, Tartu, Estonia, [2]University Medical Centre Groningen, Groningen, Netherlands, [3]Erasmus Medical Centre, Rotterdam, Netherlands, [4]Ernst-Moritz-Arndt University Greifswald, Greifswald, Germany, [5]University of Exeter, Exeter, United Kingdom, [6]University of Helsinki, Helsinki, Finland, [7]University of Washington, Seattle, WA, United States, [8]Estonian Genome Center, Estonia, Estonia, [9]University of Groningen, Groningen, Netherlands, [10]Netherlands Genomics Initiative-Sponsored by the Netherlands Consortium for Healthy Aging, Rotterdam, Leiden, Netherlands, [11]Wellcome Trust Sanger Institute, Hinxton, United Kingdom, [12]Ernst-Moritz-Arndt University Greifswald, Greifswald, Netherlands.

Genome-wide association studies (GWAS) have linked many genetic variants in the form of single nucleotide polymorphisms (SNPs) with complex traits. However because of linkage disequilibrium, it is often difficult to identify causal variants. Currently, GWAS are sometimes accompanied by limited eQTL (expression quantitative trait locus) data to prioritize the genes within the associated regions, however, a large reference panel is not yet publicly available.

Here, we report on a comprehensive cis-eQTL (distance between SNP and probe mid-point position < 250kb) meta-analysis of 5,311 samples (full-blood) from seven cohorts using imputed GWAS data. We identified cis-effects for 12,500 unique probes (reflecting 8,600 unique genes) and 12,000 independent SNPs, a number that is twice as large as those currently reported in NHGRI GWAS catalog (of which 38% have a cis-effect in our analyses). Genes for which we did not detect a cis-eQTL were generally very weakly expressed in blood.

Since many of the cis-eQTLs p-values were less than 10-100, we hypothesized that the top eQTLs were enriched in causal variants.. By comparing these extreme eSNPs with small-effect eSNPs, we observed highly significant enrichment of SNPs mapping to splice sites, introns, UTRs, miRNA binding sites and especially transcription factor binding sites. Surprisingly, we found that less than 6% of the top eSNPs were coding while only 3% were non-synonymous, indicating that regulation of gene expression is predominantly determined at non-coding regions. These results imply that a stronger focus on investigating non-coding variants in future GWAS fine-mapping studies is justified.

C08.5

Mapping genetic and epigenetic factors influencing human hippocampal gene expression

L. Priebe[1,2], *C. Wolf*[3], *M. Alexander*[1,2], *N. Karbalai*[3], *K. Pernhorst*[4], *H. Fröhlich*[5], *O. Stegle*[6], *A. Kriegel*[7], *T. Sander*[7], *D. Czamara*[3], *M. Mattheisen*[1,2,8], *B. Several studies have investigated the effects of genetic variation on gene expression (expression quantitative trait loci, eQTLs) in peripheral tissue, cell lines, or post-mortem brain tissue. EQTL studies from pre-mortem, fresh-frozen brain samples would be highly interesting but are hampered by the restricted accessibility of such samples. At the University of Bonn, we have access to a unique sample of pre-mortem human hippocampus samples originating from surgery of treatment-resistant epilepsy patients. To systematically determine eQTLs in a total of 148 hippocampus samples, we generated whole-genome SNP (Illumina Human660W) and gene expression data (Illumina HumanHT-12v3). In addition to the conventional data analysis, we applied a new "hidden factor" analysis that identifies and corrects for unknown confounding factors in the data and thus diminishes the false-positive and false-negative eQTL rate (PEER, https://github.com/PMBio/peer/wiki). Fifteen hidden factors were identified and used as co-variates for expression analysis. We detected 78 trans-regulating (>1Mb between SNP and probe) eQTLs that withstood Bonferroni correction for multiple testing. Moreover, 1,925 cis-regulating (≤1Mb distance) eQTLs remained significant after permutation-based Westfall-Young correction. In an additional step, we extended our analysis to the systematic investigation of the influence of DNA methylation on gene expression. Genome-wide methylation measurement was performed using Illumina's new HumanMethylation450 array which interrogates more than 485,000 methylation sites. To our knowledge, our study is the first to integrate genotype, expression and methylation data from pre-mortem brain tissue and will provide a valuable resource for the functional interpretation of genetic and epigenetic sites, in particular those associated with brain diseases.

C08.6

A gene co-regulation network based on 80,000 samples allows for accurate prediction of gene function

J. Karjalainen, *R. Fehrmann, G. te Meerman, H. Westra, C. Wijmenga, L. Franke;*
University Medical Center Groningen, Groningen, Netherlands.

High-throughput DNA microarray technology now provides us with a detailed view of the human transcriptome under different biological conditions. The increasing amount of publicly available microarray data helps in identifying and predicting genes that contribute to the same biological processes. To create a gene co-regulatory model of the human transcriptome, enabling the prediction of gene function, we analyzed 55,000 human, 17,000 mouse and 6,000 rat Affymetrix microarrays from the Gene Expression Omnibus. We created an integrated three-species gene network with 20,000 unique human genes and developed a principal component based statistical algorithm to predict function for individual genes.

We benchmarked the algorithm against several pathway databases (including Gene Ontology, KEGG, BioCarta and Reactome) and observed that gene function could be generally predicted very well. For over 75% of all 20,000 genes we could predict at least one significant pathway association, function or protein localization. Furthermore, predictions could be made for over 50% of the 5,004 genes that currently lack any known function.

These results indicate that through the integration of many gene expression arrays biological knowledge can be obtained, even for those genes for which currently nothing is known.

C09.1

The Skeletome project: towards a community-driven knowledge curation platform for skeletal dysplasias

T. Groza, H. Ziamatin, R. Paul, J. Hunter, ***A. Zankl****;*
University of Queensland, Brisbane, Australia.

The generation of a comprehensive description of all human diseases and its interconnections in a universal, computer-readable format („the Phenome") is the next frontier in human genetics. Major hurdles include the enormous amount of information to capture and the non-standardised and often ambiguous nature of current clinical terminology. The Skeletome project aims to develop a comprehensive phenotype database for the skeletal dysplasia domain by tapping into the collective knowledge and patient data available around the world and making it accessible in a standardised format. To this aim, we have transformed the current Nosology of Genetic Skeletal Disorders into an ontology. We then created a collaborative editing platform that allows the scientific community to collate their collective knowledge into an online encyclopaedia of skeletal dysplasias. Finally, we have created an online database that allows clinicians worldwide to submit detailed clinical information on patients with skeletal dysplasias and to share this data in anonymised form and in a standardised manner with the scientific community. The systematic use of ontologies and other semantic web technologies ensures a high level of connectivity within the project and with existing biomedical databases, allowing complex querying and computer-assisted reasoning. For example, we have implemented a diagnostic algorithm that suggests diagnoses based on clinical features. The performance of this early prototype already matches the diagnostic accuracy of non-expert clinicians. We hope that the Skeletome platform will become the prototype of phenotypic databases for other rare diseases.

C09.2

Exome sequencing identifies PDE4D mutations as another cause of acrodysostosis

Acrodysostosis [MIM 101800)] is a dominantly inherited condition associating 1) a skeletal dysplasia characterized by facial dysostosis, severe brachydactyly with cone-shaped epiphyses, advanced bone maturation and short stature 2) resistance to mutiple hormones 3) moderate to mild intellectual disability. Differential diagnoses include Albright hereditary osteodystrophy and pseudopseudohypoparathyroidism due to loss of function mutations in GNAS (α-stimulary subunit of the G-protein).

Recently, a recurrent mutation in the PRKAR1A has been identified in 3 individuals with acrodysostosis and resistance to multiple hormones (p.Arg368X). Studying ten unrelated acrodysostosis cases, we identified de novo PRKAR1A mutations in 5/10 (p.Arg368X mutation in 4/10 and p.Tyr373His mutation in 1/10). We then performed exome sequencing in 2/5 remaining cases and selected phosphodiesterase 4D (PDE4D) as a candidate gene. PDE4D encodes a class IV cAMP-specific phosphodiesterase, regulating cAMP concentration. We finally identified heterozygous PDE4D mutations in 4/5 cases. All mutations occurred de novo in all 4 cases. Neither PDE4D nor PRKAR1A mutations were found in one adult patient with characteristic skeletal features but no hormone resistance or facial dysostosis.

Splitting our series based on the disease causing gene revealed interesting genotype-phenotype correlations. Indeed, the four patients carrying PDE4D mutations shared characteristic facial features, namely midface hypoplasia with the canonical nasal hypoplasia and moderate intellectual disability. No hormone resistance was observed in 3/4 patients with PDE4D mutations while hormone resistance was consistently observed in the 5 patients carrying PRKAR1A mutations. Finally, our study further supports the key role of cAMP signaling pathway in skeletogenesis.

C09.3

Primary hypertrophic osteoarthropathy and isolated digital clubbing are caused by mutations in the prostaglandin transporter encoding gene *SLCO2A1*

W. Seifert[1], J. Kühnisch[2,3], B. Tüysüz[4], C. Specker[5], A. Brouwers[6], ***D. Horn**[2];*
[1]Institute of Vegetative Anatomy, Berlin, Germany, [2]Institute of Medical Genetics and Human Genetics, Berlin, Germany, [3]Max-Planck-Institute for Molecular Genetics, Berlin, Germany, [4]Cerrahpasa Medical Faculty, Department of Pediatric Genetics, Istanbul University, Istanbul, Turkey, [5]Dept. of Rheumatology & Clinical Immunology, Centre for Internal Medicine, Kliniken Essen Süd, Essen, Germany, [6]Dept. of Internal Medicine, Gelderse Vallei Hospital, Ede, Netherlands.

Primary hypertrophic osteoarthropathy (PHO) is a rare hereditary condition, which is characterized by digital clubbing, periostosis, arthropathy, pachydermia, and hyperhidrosis. Recently, mutations within the gene *HPGD* encoding the prostaglandin E2 (PGE2) catabolizing enzyme 15-hydroxyprostaglandin dehydrogenase were found to cause PHO. Here, we analyzed PHO patients lacking mutations in *HPGD* for mutations in genes involved in prostaglandin metabolism namely: *PTGS1*, *PTGS2*, *PTGES*, *PTGES2*, *PTGES3*, *PTGER1*, *PTGER2*, *PTGER3*, *PTGER4*, *SLCO2A1*, *SLCO3A1*, *SLCO4A1*, *PTGR1*, and *PTGR2*. In three unrelated families we identified hetero- and homozygous mutations within the solute carrier organic anion transporter family 2A1 (*SLCO2A1*) gene (MIM ID *601460, chromosome 3q21) as underlying genetic cause for isolated digital clubbing and PHO, respectively. Mutations in *SLCO2A1* comprise a homozygous insertion c.830_831insT, resulting in a premature stopcodon at p.Phe276fsX18; a homozygous missense mutation c.1670T>C introducing an amino acid substitution p.Phe557Ser and a heterozygous nonsense mutation c.754C>T resulting in p.Arg252X. *SLCO2A1* encodes the prostaglandin transporter (PGT), which is involved in carrier-mediated re-uptake of PGE2 across the plasma membrane for metabolic clearance of prostaglandins. Consequently, in patients with mutations in *SLCO2A1*, elevated PGE2 levels induce the PHO phenotype as well as isolated digital clubbing. By phenotypic correlation of hitherto identified *SLCO2A1* mutations, we found an incomplete penetrance of isolated digital clubbing in heterozygous carriers, suggesting a threshold effect of impaired PGE2 degradation defining disease progression and severity. In summary, our study establishes mutations in *SLCO2A1* as further molecular determinant of PHO and digital clubbing supporting the importance of PGE2 metabolism for bone, joint and skin physiology.

The term VATER/VACTERL association is used as an acronym for the combination of at least three of the following congenital anomalies: vertebral defects (V), anorectal malformations (A), cardiac defects (C), tracheoesophageal fistula with or without esophageal atresia (TE), renal malformations (R), and limb defects (L). The causes of the VATER/VACTERL association are likely to be heterogeneous, with individual environmental or genetic risk factors still being largely unknown. In the present study we aimed to identify copy number variants (CNVs) that contribute to VATER/VACTERL association. Molecular karyotyping, utilizing 1,134,514 SNPs SNPs (single nucleotide polymorphisms), was performed to screen 47 individuals with VATER/VACTERL association and their parents for causative de novo events. To identify potential CNVs, the SNP fluorescence intensity were analyzed with QuantiSNP using an Objective-Bayes Hidden-Markov model for calling putative CNVs. Genes which were located in regions of rearrangements were prioritized by expression data in mice. Three de novo microduplications were identified involving chromosomal region 1q41, 2q37.3, and 8q24.3. Mice expression data suggest GPR35 and EPPK1 as candidate genes for the VATER/VACTERL association. Currently, both genes are systematically sequenced in the complete sample to identify high-penetrance mutations involving small sequence changes.

C09.5

Comprehensive clinical and molecular analysis of 12 families with type I recessive cutis laxa

***B. L. Callewaert**[1], C. Su[2], T. Van Damme[1], P. Vlummens[1], F. Malfait[1], O. Vanakker[1], B. Schulz[2], M. Mac Neal[2], E. C. Davis[3], J. G. H. Lee[3], A. Salhi[4], S. Unger[5], K. Autosomal recessive cutis laxa type I (ARCL type I) is characterized by generalized cutis laxa with pulmonary emphysema and/or vascular complications. Rarely, mutations can be identified in the *FBLN4* or *FBLN5* genes. Recently, *LTBP4* mutations have been implicated in a similar phenotype. Studying *FBLN4*, *FBLN5* and *LTBP4* in 12 families with ARCL type I, we found bi-allelic *FBLN5* mutations in 2 probands, whereas 9 probands harbored biallelic mutations in *LTBP4*. No mutations were identified in *FBLN4*. *FBLN5* and *LTBP4* mutations cause a very similar phenotype associated with severe pulmonary emphysema, in the absence of vascular tortuosity or aneurysms. Gastro-intestinal and genitourinary tract involvement seems to be more severe in patients with *LTBP4* mutations. Functional studies showed that most premature termination mutations in *LTBP4* result in severely reduced mRNA and protein levels. This correlated with increased transforming growth factor beta (TGFβ) signaling. However, one mutation, c.4127dupC, escaped nonsense-mediated decay. The corresponding mutant protein (p.R1377fsX27) caused altered binding to fibrillin-1 and loss of binding to fibronectin, leading to an abnormal morphology of microfibrils in fibroblast cultures, while retaining normal TGFβ signaling. We conclude that *LTBP4* mutations are more prevalent than *FBLN5* mutations in ARCL type I. *LTBP4* mutations cause disease through both loss of function and gain of function mechanisms.

C09.6

Discriminative features in three cutis laxa syndromes; Geroderma Osteodysplastica, Cutis laxa type IIA, Cutis laxa type IIB

***A. Kariminejad**[1], B. Bozorgmehr[1], M. Kariminejad[1], B. Fischer[2], T. Thatjana Gardeitchik[3], E. Morava[3];*
[1]Kariminejad-Najmabadi Pathology & Genetics Center, Tehran, Islamic Republic of Iran, [2]Max Planck Institute, Berlin, Germany, [3]Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.

Geroderma osteodysplastica (GO), cutis laxa type IIA and IIB are autosomal recessive conditions with cutis laxa as the main clinical feature. It has been difficult to differentiate these conditions solely based on clinical features. In the past few years with the identification of genes responsible for these conditions, it is easier to classify the patients with cutis laxa. Some of the patients initially diagnosed with Geroderma osteodysplastica, or wrinkly skin syndrome turned out to have mutations in *PYCR1*, or *ATP6V0A2* gene.

We present13 patients with genetically confirmed mutations in *GORAB*, *ATP6V0A2* and *PYCR1* genes confirming GO, Cutis laxa type IIA and IIB respectively. We elaborate on clinical features that are similar and different in these three conditions, which can be helpful in differentiating between these syndromes.

These three conditions have cutis laxa of trunk, wrinkling of dorsum of hand and feet, hyperlaxity, pes planus and congenital dislocation of hip and developmental delay in common.

Progeroid features, triangular face, pinched nose, loss of adipose tissue are specific for *PYCR1* mutations. Loose redundant folds in trunk seen in the other two forms of cutis laxa, is not a common feature.

Facial features of *ATP6V0A2* have bossing forehead, downslanting palpebral fissures, midface hypoplasia, anteverted nares, short nose and small mouth. Additional features are late closure of fontanels and myopia.

Droopy, jowly face with a degree of malar hypoplasia and mandibular prognathism is specific for GO. Osteoporosis and bone fracture is a feature of this syndrome not a common finding in the other two.

C10.1

Genomic instability in 25,000 cancer samples: A limited number of copy number aberration configurations

L. Franke, R. Fehrmann, G. te Meerman, J. Karjalainen, H. Westra, C. Wijmenga;
Department of Genetics, University Medical Centre Groningen, 9700 AB, Groningen, Utrecht, Netherlands.

Genomic instability is one of the hallmarks of cancer. However, so far genomic instability has only been systematically investigated in a limited number of individuals.

To overcome this we reanalyzed Affymetrix gene expression data of a heterogeneous set of 25,000 human cancer samples. We observed that the far majority of expression variation among these samples could be attributed to physiological, metabolic and cell-type specific variation. However, by applying principal component analysis we could correct all samples for these differences. After correction we observed that most genes showed very strong dosage-sensitivity to copy number alterations, permitting us to reconstruct aCGH-like copy number aberration profiles for each of the 25,000 cancer samples.

Subsequent analysis of the deletions and duplications revealed that a few combinations of certain deletions and duplications occur very often, irrespective of the particular type of cancer. This indicates the presence of strong selective forces, resulting in the survival of those cancer cells with particular cytogenetic aberrations.

The characteristics of these different cytogenetic aberration configurations are very different: Different classes of genes are affected in different configurations, which suggests that therapeutic intervention might improve by tailoring this to the type of (cyto)genetic aberration configuration that is relevant for each individual cancer sample.

C10.2

Deep intronic APC mutations explain a substantial proportion of patients with familial or early onset adenomatous polyposis

I. Spier[1], S. Horpaopan[1], S. Vogt[1], S. Uhlhaas[1], M. Morak[2,3], D. Stienen[1], M. Draaken[1], M. Ludwig[4], E. Holinski-Feder[2,3], M. M. Nöthen[1], P. Hoffmann[1], S. Aretz[1];
[1]Institute of Human Genetics, University of Bonn, Bonn, Germany, [2]Medizinische Klinik - Campus Innenstadt, Klinikum der LMU, Munich, Germany, [3]MGZ - Center of Medical Genetics, Munich, Germany, [4]Department of Clinical Chemistry and Clinical Pharmacology, University of Bonn, Bonn, Germany.

In up to 50% of patients with colorectal adenomatous polyposis no germline mutation in the currently known genes *APC*, causing Familial Adenomatous Polyposis (FAP) or *MUTYH*, causing *MUTYH*-associated polyposis (MAP), can be identified by routine diagnostics. To uncover aberrant transcripts pointing to pathogenic deep intronic variants, we performed a systematic *APC* mRNA analysis in 125 apparently unrelated mutation negative polyposis patients.

Overall, we identified 11 reproducible aberrant transcripts in 10 patients (8% of whole study cohort; 30% of familial cases; 21% of patients with early onset manifestation). In eight of these patients two different out-of-frame insertions between intact exons (pseudoexons) were found. Sequencing of the aberrant bands revealed a 167 bp insertion from intron 4 in five families with a shared founder haplotype and a 83 bp insertion from intron 10 in three patients, caused by the heterozygous germline mutations c.532-941-G>A, c.1408+731C>T, or c.1408+735A>T, respectively. All mutations are supposed to activate cryptic splice sites. On cDNA level complete skipping of exon 9 was observed in two patients and a complex insertion/deletion rearrangement in another patient.

In conclusion, we identified a few deep intronic hotspots and founder mutations contributing substantially to the *APC* mutation spectrum. cDNA analysis and/or target sequencing of certain intronic regions should be considered as an additional mutation discovery approach in polyposis patients in whom no germline *APC* or *MUTYH* mutation was identified so far, in particular in patients with autosomal dominant pattern of inheritance and/or early onset disease.

C10.3

A common *BIM* deletion polymorphism mediates intrinsic resistance and inferior responses to tyrosine kinase inhibitors in cancer

A. M. Hillmer[1], K. P. Ng[2], C. T. H. Chuah[3], W. C. Juan[2], T. K. Ko[2], N. Takahashi[4], K. Sawada[4], A. S. M. Teo[1], P. N. Ariyaratne[1], Y. Fei[1], X. Y. Woo[1], J. C. Allen Jr[2], A. L. S. Ong[2];
[1]Genome Institute of Singapore, Singapore, Singapore, [2]Duke-NUS Graduate Medical School, Singapore, Singapore, [3]Singapore General Hospital, Singapore, Singapore, [4]Akita University Graduate School of Medicine, Akita, Japan, [5]National University Cancer Institute of Singapore, Singapore, Singapore, [6]National Cancer Centre, Singapore, Singapore, [7]University of Malaya, Kuala Lumpur, Malaysia, [8]National University Hospital Health System, Singapore, Singapore, [9]Jichi Medical University, Tochigi, Japan, [10]Toho University Omori Medical Center, Tokyo, Japan, [11]University of Bonn, Bonn, Germany, [12]Singapore National Eye Centre, Singapore, Singapore, [13]Aichi Cancer Center, Tokyo, Japan.

Tyrosine kinase inhibitors (TKI) elicit high response rates among individuals with kinase-driven malignancies, including chronic myeloid leukemia (CML) and epidermal growth factor receptor-mutated non-small cell lung cancer (EGFR NSCLC). However, the depth and duration of responses are heterogeneous, suggesting the existence of genetic modifiers of response. Using paired-end DNA sequencing, we discovered a common intronic deletion polymorphism in the gene encoding BCL2-like 11 (BIM). BIM is a pro-apoptotic member of the BCL2 family of proteins, and its upregulation is required for TKIs to induce apoptosis in kinase-driven cancers. The polymorphism switched BIM splicing from exon 4 to exon 3, encoding for BIM isoforms lacking the pro-apoptotic BCL2-homology domain 3 (BH3). The polymorphism was sufficient to confer intrinsic TKI resistance in CML and EGFR NSCLC cell lines, a resistance that could be overcome with BH3-mimetic drugs. Importantly, individuals with CML and EGFR NSCLC harboring the polymorphism experienced significantly inferior TKI responses. Our results offer an explanation for the heterogeneity of TKI responses, and suggest the possibility of personalizing therapy with BH3-mimetics to overcome BIM polymorphism-associated resistance.

C10.4

The impact of a cancer family history on ovarian cancer risk in *BRCA1* and *BRCA2* mutation carriers.

J. Oosterwijk, N. Teixeira, M. Mourits, D. van der Kolk, A. van der Hout, L. Jansen, T. de Bock;
UMCG, Groningen, Netherlands.

Purpose: To study the effect of a family history of breast/ovarian cancer on the lifetime risk and age at diagnosis of ovarian cancer in *BRCA1* and *BRCA2* mutation carriers.

Patients and Methods: A prospective single center cohort study including a consecutive series of 1846 women from 367 different *BRCA1/2* families, followed-up between 1996 and 2011. The occurrence and age of diagnosis of breast and ovarian cancer in all available family members was recorded. Cox-regression analysis was applied to assess the correlation between age related penetrance of ovarian cancer and the presence and the age at diagnosis of breast and ovarian cancer within the family.

Results: In total 263 ovarian cancer cases were diagnosed. Among *BRCA2* mutation carriers, the risk of ovarian cancer was significantly higher with relatives with ovarian cancer before age 50: HR=2.34, (95% CI=1.18-4.64, p=0.02) with first-degree affected relatives and HR=2.11 (95% CI=1.12-3.98, p=0.02) with first- or second-degree affected relatives). Family histories with breast cancer reduced ovarian cancer risk, especially in *BRCA2* families: HR=0.47 (95% CI=0.34-0.67) in *BRCA1* and HR=0.29 (95% CI=0.17-0.51) in *BRCA2*, p<0.01).

Conclusion: Our findings indicate that family histories including early age ovarian cancer may double the risk of ovarian cancer in *BRCA2* mutation carriers, while a family history with breast cancer decreases ovarian cancer risk in *BRCA1/2* mutation carriers with more than 50%. These results may be important to apply in cancer risk algorithms used in genetic counselling.

C10.5

Combined whole genomic, exomic and transcriptomic sequencing identifies genes recurrently mutated in Burkitt lymphomas

Germinal center (GC) derived B-cell lymphomas are the most frequent malignant lymphomas with Burkitt lymphoma (BL) being the predominant subtype in children. Within the German BMBF-funded International Cancer Genome Consortium (ICGC) Network Project ICGC MMML-Seq we analyzed four IG-MYC positive BL from children treated within the BFM-NHL trials. Genome, exome, transcriptome, miRNAome and methylome sequencing was performed using Illumina technology.

We detected between 1751 and 3174 somatic mutations. There was a good concordance between exome and whole genome sequencing. We identified between 59 and 105 potentially protein changing somatic mutations, including previously known changes in MYC and TP53. Sanger sequencing validated 20/25 new mutations.

A total of 16 genes were affected at least twice by potentially protein changing mutations, including known lymphoma-associated genes (e.g. FBXO11). Remarkably, two of the genes recurrently mutated, ID3 and SMARCA4, are part of the BL index recently described by us and are strongly expressed in BL (Hummel et al., NEJM, 2006). Analysis of the RNAome sequences confirmed the high expression of both genes in BL and provided evidence for aberrant splicing. As we previously reported recurrent homozygous loss at the ID3 locus (Scholtysik et al., Haematologica, 2010) we sequenced ID3 in an extended series of 100 molecularly pre-characterized IG-MYC positive GC-derived B-cell lymphomas. We identified ID3 mutations in 36/55 IG-MYC positive BL but only 6/45 IG-MYC positive GC-derived other B-cell lymphoma ($p<0.001$). In the BL, ID3 mutation was associated with a BCL6+/BCL2- phenotype, lower genomic complexity (all $p<0.05$) and a trend for a better prognosis.

C10.6

Complex tumor genomes inferred from plasma-DNA and circulating tumor cells of patients with colorectal cancer

***E. Heitzer**[1], M. Auer[1], E. Hoffmann[1], C. Beneken[2], M. Pichler[3], S. Lax[4], P. Ulz[1], J. Waldispuehl-Geigl[1], O. Mauermann[2], C. Lackner[5], G. Höfler[5], F. Eisner[3], H. Sill[6], K. Pantel[2], S. Riethdorf[2], T. Bauernhofer[3], J. B. Geigl[1], M. R. Speicher[1];*
[1]Institute of Human Genetics, Medical University Graz, Graz, Austria, [2]Institute of Tumor Biology, University Medical Center Hamburg Eppendorf, Hamburg, Germany, [3]Division of Oncology, Medical University of Graz, Graz, Austria, [4]Department of Pathology, General Hospital Graz West, Graz, Austria, [5]Institute of Pathology, Medical University Graz, Graz, Austria, [6]Division of Hematology, Medical University of Graz, Graz, Austria.

With the increasing number of available predictive biomarkers the serial accurate monitoring of tumor genotypes, which are prone to changes, becomes more important in the clinical management of human cancer. Here we analyzed peripheral blood of 32 patients with advanced-stage colorectal cancer (CRC) for mutant DNA-fragments in the plasma and circulating tumor cells (CTCs). We demonstrate that a subset of patients had a biphasic size distribution of plasma DNA fragments. This is accompanied by increased numbers of CTCs and elevated plasma-DNA concentrations and has implications for diagnostic tests, because tumor specific copy number changes can be established directly from plasma-DNA. Our CTC analyses included massively parallel sequencing of a panel of 68 CRC associated genes and a comparison with the mutation status in the primary tumors and associated metastases. We demonstrate that CTCs have a tremendous heterogeneity characterized by different copy number changes and mutations in cancer driver genes. Our analyses provide novel insights into tumor evolution and may extend current non-invasive approaches for disease monitoring.

C11.1

High frequency of potentially pathogenic SORL1 mutations in autosomal dominant early-onset Alzheimer disease

***C. Pottier**[1], D. Hannequin[1], S. Coutant[1], A. Rovelet-Lecrux[1], D. Wallon[1], S. Rousseau[1], S. Legallic[1], C. Paquet[2], S. Bombois[3], J. Pariente[4], C. Thomas-Anterion[5], A. Michon[6], B. Croisile[7], F. Etcharry-Bouyx[8], C. Berr[9], J. Dartigues[10], P. Amouyel[11], H. Dauchel[12], C. Boutoleau-Bretonnière[13], C. Thauvin[14], T. Frebourg[1], J. Lambert[11], D. Campion[1];*
[1]Inserm, U1079, Rouen, France, [2]Inserm, U839, Paris, France, [3]EA1046, Lille Nord University Hospital, Lille, France, [4]Inserm, U825, Toulouse, France, [5]University Hospital Nord, Saint Etienne, France, [6]UMR-S975 AP-HP, Paris, France, [7]University Hospital, Groupe Hospitalier Est, Bron, France, [8]Angers University Hospital, Angers, France, [9]Inserm, U888, Montpellier, France, [10]Inserm, U897, Bordeaux, France, [11]Inserm, U744, Lille, France, [12]LITIS, EA 4108, Rouen, France, [13]Nantes University Hospital, Nantes, France, [14]Dijon University Hospital, Dijon, France.

Performing exome sequencing in 14 autosomal dominant early-onset Alzheimer disease (ADEOAD) index cases without mutation on known genes (APP, PSEN1 and PSEN2), we found that in 5 patients the SORL1 gene harbored unknown nonsense ($n=1$) or missense ($n=4$) mutations. These mutations were not retrieved in 1500 controls of same ethnic origin. In a replication sample including 15 ADEOAD cases, two unknown non synonymous mutations (one missense, one nonsense) were retrieved, thus yielding to a total of 7/29 unknown mutations in the combined sample. Using in silico predictions, we conclude that these 7 private mutations are likely to have a pathogenic effect. SORL1 encodes the Sortilin-related receptor LR11/SORLA, a protein involved in the control of Aβ peptide production. Our results suggest that besides the involvement of the APP and PSEN genes, further genetic heterogeneity, involving another gene of the same pathway is present in ADEOAD.

C11.2

Combination of positional cloning and new generation sequencing identifies two novel genes in spastic paraplegia involved in lipid metabolism

***G. Stevanin**[1,2,3], C. Tesson[1,3], M. Nawara[1], M. A. M. Salih[4], R. Rossignol[5], M. Zaki[6], F. Lamari[7], A. Bouhouche[8], F. Santorelli[9], A. Al Drees[4], E. Giraud[5], R. Schule[10], S. Hereditary spastic paraplegias are heterogeneous neurological disorders. Known causative genes account for the majority of dominantly inherited cases, but for less than 40% of the recessive forms. We previously mapped the SPG28 locus in a Moroccan family to chromosome 14. Capture and next generation sequencing of all exons of the SPG28 interval allowed us to identify a homozygous truncating mutation in the *DDHD1* gene, encoding for a phosphatidic acid (PA)-preferring phospholipase A1 that was shown to segregate with the disease in patients. In 2 Saudi-Arabian families, genome wide linkage studies mapped a new disease locus, *SPG49*, to chromosome 4. Classical Sanger sequencing of the 22 assigned genes allowed us to identify a missense mutation in the *CYP2U1* gene, encoding for extra hepatic cytochrome P450 protein. The mutation segregates in patients in the 2 families, while 2 other mutations were identified in the same gene, including a frameshift mutation in a kindred from Egypt. All mutations were absent in large series of healthy unrelated controls.

The SPG28 and SPG49 mutations were associated with a decreased mitochondrial respiratory rate in patient lymphoblasts. Interestingly, these 2 new genes are involved in the same metabolic pathway related to lipid metabolism, paving the way for a better understanding of the mechanisms involved in these diseases. Our study underlies the power of next generation sequencing combined with linkage data in rare and genetically heterogeneous disorders.

C11.3

Exome sequencing reveals causal gene for spinocerebellar ataxia 19

*A. Duarri[1], J. Jezierska[1], M. Fokkens[1], M. Meijers[1], J. Schelhaas[2], G. Hageman[3], B. Kuesters[2], W. den Dunnen[1], C. Verschuuren-Bemelmans[1], B. van de Warrenburg[2], H. Boddeke[1], H. Kremer[1], R. Sinke[1], **D. S. Verbeek**[1];*
[1]UMCG, University of Groningen, Groningen, Netherlands, [2]Radboud University Nijmegen Medical Center, Nijmegen, Netherlands, [3]Medisch Spectrum Twente, Enschede, Netherlands.

Spinocerebellar ataxia type 19 (SCA19) is characterized by a late-onset, slowly progressive, mild cerebellar ataxia, postural head tremor, myoclonic movements, and cognitive impairment. In 2002, we mapped the SCA19 disease gene to chromosome region 1p21-q21 in a Dutch family. This candidate region contained ~500 genes, but prioritized candidate gene sequencing yielded no success.

In a further attempt to identify the disease gene, we performed exome sequencing in two patients of the SCA19 family originally studied. After quality control and other exclusion criteria, we validated 5 missense mutations in potentially interesting candidates. After screening 400 Dutch controls, only one missense mutation remained unique for all SCA19 patients in the family (n=12). In addition, we screened the coding region of this candidate gene in 200 Dutch ataxia cases and identified two more families with missense mutations that had not been reported before. All of these mutations change highly conserved amino acids.

Immunohistochemistry in SCA19 autopsy cerebellum showed a significant loss of Purkinje cells and altered localization of the mutant protein. Analysis of mRNA and protein levels showed increased expression in patient cerebellum compared to controls. The different mutations alter the subcellular localization of the SCA19 protein and lead to reduced protein stability. We were able to rescue the mislocalization of the mutant proteins and increase their protein stability by co-expressing auxiliary subunits. Whether these mutations induce a gain- or loss-of-function is now being investigated.

The identification of new SCA genes remains important as they advance our understanding of the disease etiology.

C11.4

Defective presynaptic choline transport underlies hereditary motor-neuropathy

***K. E. S. Barwick**[1], J. Wright[2], S. Al-Turki[3], M. M. McEntagart[1], A. Nair[1], A. Al-Memar[4], H. Modarres[2], M. Reilly[5], K. Dick[1], A. Ruggiero[2], R. Blakely[2], M. Hurles[3], A. H. Crosby[1];*

The neuromuscular junction (NMJ) is a specialized synapse with a complex molecular architecture that serves to achieve reliable transmission between the nerve terminal and muscle fibre. Using linkage analysis and whole-exome sequencing of DNA samples from subjects with distal hereditary motor neuropathy (dHMN) type VII, we identified a mutation in the presynaptic choline transporter (CHT, SLC5A7), a critical determinant of synaptic acetylcholine (ACh) synthesis and release at the NMJ. This dominantly-segregating, CHT mutation truncates the transporter just beyond the final transmembrane domain, eliminating sequences in the cytosolic C-terminus known to mediate surface transporter trafficking. Our choline transport assays in both transfected cells and patient monocytes revealed significant reductions in hemicholinium-3 (HC-3)-sensitive choline uptake, findings most consistent with a dominant-negative mode of action. The paradigm hereditary disorder of the NMJ is the congenital myasthenic syndrome, a genetically heterogeneous neuromuscular disorder resulting from mutations in genes encoding pre-, post- and synaptic NMJ proteins. The discovery of CHT dysfunction associated with motor neuropathy is an unexpected finding which identifies a new biological basis for this group of conditions and widens the spectrum of disorders that derive from impaired NMJ transmission. Our efforts compel consideration of mutations in CHT or its functional partners in relation to idiopathic forms of the disorder.

C11.5

Mutations in *C8orf37*, encoding a ciliary protein, are associated with autosomal recessive cone-rod dystrophy and retinitis pigmentosa with early macular involvement

***K. Neveling**[1], A. Estrada-Cuzcano[1], S. Kohl[2], E. Banin[3], Y. Rotenstreich[4], D. Sharon[3], T. C. Falik-Zaccai[5,6], S. Hipp[2], R. Roepman[1], B. Wissinger[2], S. J. F. Letteboer[1], D. A. Mans[1], E. A. W. Blokland[1], M. P. Kwint[1], S. J. Gijsen[1], R. A. C. van Huet[1], R. W. J. Collin[1], H. Scheffer[1], J. A. Veltman[1], E. Zrenner[2], A. I. den Hollander[1], B. J. Klevering[1], F. P. M. Cremers[1];*
[1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]University of Tuebingen, Tuebingen, Germany, [3]Hadassah-Hebrew University Medical Center, Jerusalem, Israel, [4]Goldschleger Eye Research Institute, Tel Hashomer, Israel, [5]Western Galilee Hospital, Naharia, Israel, [6]Technion-Israel Institute of Technology, Haifa, Israel.

Cone-rod dystrophy (CRD) and retinitis pigmentosa (RP) are clinically and genetically overlapping heterogeneous retinal dystrophies. By using homozygosity mapping in an individual with autosomal-recessive (ar) RP from a consanguineous family, we identified three sizeable homozygous regions, together encompassing 46 Mb. Next-generation sequencing in these three regions revealed a homozygous nonsense mutation (c.497T>A; p.Leu166*) in *C8orf37*, located on chromosome 8q22.1. This mutation was not present in 150 ethnically matched control individuals, single nucleotide polymorphism databases or the 1000 Genomes database. Immunohistochemical studies revealed C8orf37 localization at the base of the primary cilium of human retinal pigment epithelium cells and at the base of connecting cilia of mouse photoreceptors. *C8orf37* sequence analysis of individuals with retinal dystrophy which carried conspicuously large homozygous regions encompassing *C8orf37* revealed a homozygous splice site mutation (c.156-2A>G) in two siblings of a consanguineous family, and homozygous missense mutations (p.Arg177Trp and p.Gln182Arg) in siblings of two other consanguineous families. The missense mutations affect highly conserved amino acids, and *in silico* analyses predicted that both variants are likely pathogenic. Clinical assessment revealed CRD in four individuals, and RP with early macular involvement in two individuals. The two CRD siblings with the c.156-2A>G mutation also showed unilateral postaxial polydactyly. These results underline the importance of disrupted ciliary processes in the pathogenesis of retinal dystrophies and demonstrate the power of next-generation sequencing combined with homozygosity mapping to identify new disease genes.

C11.6

SUN protein interactions at the nuclear envelope and their role in Emery-Dreifuss muscular dystrophy

***P. Meinke**[1], F. Haque[2], W. Schröder[1], U. Felbor[1], S. Shackleton[2], M. Wehnert[1];*
[1]Institute for Human Genetics Greifswald, University Medicine Greifswald, Greifswald, Germany, [2]University of Leicester, Department of Biochemistry, Leicester, United Kingdom.

Emery-Dreifuss muscular dystrophy (EDMD) is a rare neuromuscular disorder characterized by early contractures, slowly progressive muscular weakness and life-threatening cardiac arrhythmia that can turn to cardiomyopathy. EDMD is genetically heterogeneous, patients can have *LMNA*, *STA*(*EMD*), *FHL1*, *SYNE1* or *SYNE2* mutations. Onset, course and severity of EDMD can vary remarkably, even among patients with mutations in the same gene or carrying the same mutation. Lamin A/C, emerin and nesprins have been shown to interact with SUN1 and SUN2, resulting in a LINC termed complex that connects the nucleoskeleton with the actin cytoskeleton via the nuclear envelope. Thus, the *SUN1* and *SUN2* genes have been considered as functional candidates for EDMD association. We analyzed the *SUN1* and *SUN2* genes in a cohort of 175 unrelated EDMD patients that had previously been excluded from carrying pathogenic mutations in *LMNA*, *STA*, *FHL1*, *SYNE1* and *SYNE2*, and in 70 EDMD patients with defined mutations in these genes. The complete coding region including intron/exon boundaries of both genes was amplified and used for direct Sanger sequencing. As a result, mutations have been found in both patient cohorts. One patient has compound heterozygous mutations in *SUN1*. Additional mutations in *SUN1* or *SUN2* have been found in EDMD patients in combination with *LMNA* or *STA* mutations and are associated with increased disease severity in these individuals. Functional analysis of mutants showed a weakening of binding to other LINC proteins. Our results indicate that *SUN1* and *SUN2* mutations can cause EDMD and worsen the clinical features of the disease.

C12.1

Mutated *GPD1*, encoding Glycerol-3-Phosphate Dehydrogenase 1, causes transient infantile hypertriglyceridemia with fatty liver and hepatic fibrosis

***L. Basel-Vanagaite**[1,2,3], N. Zevit[4,2], A. Har Zahav[2], L. Guo[5], S. Parathath[5], M. Pasmanik-Chor[2], A. McIntyre[6], J. Wang[6], A. Albin-Kaplanski[7], C. Hartman[4,2], D. Marom[4,2], A. Zeharia[4,2], O. Shoerman[4,2], A. Simon[8], G. Rechavi[8,2], M. Shohat[7,2,3], R. Hegele[6], E. Fisher[5], R. Shamir[4,2];*
[1]Schneider Children's Medical Center of Israel and Rabin Medical Center, Petah Tikva, Israel, [2]Tel Aviv University, Tel Aviv, Israel, [3]Felsenstein Medical Research Center, Petah Tikva, Israel, [4]Schneider Children's Medical Center of Israel, Petah Tikva, Israel, [5]New York University School of Medicine, New York, NY, United States, [6]University of Western Ontario, London, ON, Canada, [7]Rabin Medical Center, Petah Tikva, Israel, [8]The Chaim Sheba Medical Center, Tel Hashomer, Israel.

The molecular basis for primary hereditary hypertriglyceridemia has been identified in fewer than 5% of cases. We describe a hitherto unreported autosomal recessive condition manifesting as severe but transient infantile hypertriglyceridemia and fatty liver followed by hepatic fibrosis. We identified the mutated gene responsible for this condition in 10 individuals originating from the same isolated highly inbred population. A single large continuous segment of homozygosity on chromosome 12q13.12 containing 35 OMIM genes was identified in the affected individuals using SNP array-based homozygosity mapping. Candidate gene sequencing revealed a homozygous splicing mutation, c.361-1G>C, in *GPD1*, which encodes glycerol-3-phosphate dehydrogenase 1. This mutation is predicted to result in a truncated protein lacking essential conserved residues including a functional site responsible for initial substrate recognition. Functional consequences of the mutation were evaluated by measuring intracellular concentrations of cholesterol and triglycerides as well as triglyceride secretion in HepG2 (hepatocellular carcinoma) human cells lines overexpressing normal and mutant *GPD1* cDNA. Overexpression of mutant *GPD1* resulted in increased secretion of triglycerides (P = 0.01), supporting the pathogenicity of the identified mutation. *GPD1* mutation may lead to hypertriglyceridemia by limiting the conversion of glycerol-3 phosphate to dihydroxyacetone phosphate, and thus causing an increase in the amount of hepatic glycerol-3 phosphate available for triglyceride synthesis. The transient nature of the hypertriglyceridemia in the individuals described in this study is compatible with the fact that the rates of triglyceride secretion by hepatocytes are higher in neonates than in adults.

C12.2

Familial diarrhea syndrome caused by an activating *GUCY2C* mutation

Boman*[2], *K. H. Biswas*[3], *J. Apold*[2], *N. Hovdenak*[2], *S. S. Visweswariah*[3], *P. M. Knappskog*[2,1];
[1]University of Bergen, Bergen, Norway, [2]Haukeland University Hospital, Bergen, Norway, [3]Indian Institute of Science, Bangalore, India, [4]HudsonAlpha Institute for Biotechnology, Huntsville, AL, United States.

Chronic diarrhea is a frequent health problem, but knowledge about underlying etiological mechanisms is insufficient, and treatment is often ineffective. Rare inherited diarrheas are usually severe recessive diseases. Here we describe the clinical picture and genetic cause of a novel autosomal dominant disease in 32 members of a Norwegian family. Their chronic diarrhea is of early onset, relatively mild, and may in some patients be mistaken for irritable bowel disease. However, the diarrhea is combined with increased susceptibility to inflammatory bowel disease, ileus and oesophagitis. We performed SNP-linkage analysis to identify a candidate region on chromosome 12. This region contained GUCY2C, encoding guanylyl cyclase C, an intestinal receptor for bacterial heat-stable enterotoxins. We identified a heterozygous missense mutation (c.2519G>T) in GUCY2C in all affected family members. Exome sequencing was performed to rule out the possibility of other rare variants in the candidate region. Functional studies of the mutant receptor in HEK293T cells showed markedly increased formation of cellular cGMP in response to endogenous ligands and toxin (ST). This may cause hyperactivation of the cystic fibrosis transmembrane regulator (CFTR) and consequently increased secretion of chloride and water into the intestinal lumen, resulting in chronic diarrhea. In conclusion, increased guanylyl cyclase C signalling disturbs normal bowel function and seems to have a pro-inflammatory effect, either through increased chloride secretion or additional effects of elevated cellular cGMP. The importance of genetic variants in the guanylyl cyclase C/CFTR pathway for conditions like Crohn's disease and irritable bowel syndrome should be further explored.

C12.3

Exome sequencing identifies nonsense mutations in AGK as a cause of Sengers syndrome

Sengers syndrome is a rare autosomal-recessive disorder hallmarked by cardiac and skeletal myopathy combined with congenital cataracts. Lactic acidosis and exercise intolerance are frequently observed while mental development is normal. The clinical course varies from fatal neonatal to more benign forms with survival into the fourth decade of life. Cause of death is invariably heart failure due to a hypertrophic cardiomyopathy.

By exome sequencing of one individual with Sengers syndrome we discovered two nonsense mutations in the gene encoding mitochondrial acylglycerol kinase (AGK). Genetic testing of AGK in additional individuals with congenital cataracts and cardiomyopathy identified numerous loss-of-function mutations in ten families, substantiating the causal nature of AGK deficiency in Sengers syndrome. Western blot experiments confirmed the absence of full-length AGK in muscle from several individuals. Interestingly, absence of AGK causes decreased levels of the adenine nucleotide translocator in the inner mitochondrial membrane in patient's skeletal muscle and a number of patients displayed reduced activities of several respiratory chain complexes. The biochemical phenotype was not expressed in patient's myoblast or fibroblast cell cultures. Our findings suggest a distinct function of AGK in mitochondrial phospholipid metabolism essential for the assembly of inner membrane proteins.

C12.4

Molecular diagnosis in mitochondrial complex I deficiency using next-generation sequencing

Next-generation sequencing has become the core technology for gene discovery in rare inherited disorders. However, the ability to discriminate between pathogenic and benign variants remains a challenge. We used complex I deficiency, one of the most common variants of mitochondrial diseases, as an example to assess the power of exome sequencing in combination with stepwise filtering of gene variants.

Ten unrelated individuals were selected for this study. The first filter criterion was "The presence of known pathogenic variants". This revealed homozygous mutations in NDUFS3 and ACAD9 in two individuals. A second criterion was "The presence of two potentially pathogenic variants in the same structural gene of complex I", which discovered rare variants in NDUFS8 in two unrelated individuals and in NDUFB3, a hitherto unknown disease gene, in a third. Expression of wild-type cDNA in mutant skin fibroblast cell lines rescued complex I activity and assembly, thus providing a function validation of their pathogenicity. Using the third criterion "The presence of two potentially pathogenic variants in the same gene encoding a mitochondrial protein" we discovered in two patients loss-of-function mutations in MTFMT. In three patients the molecular genetic correlate remained unclear and follow-up analysis is ongoing. Appropriate in silico filtering of exome sequencing data, coupled with functional validation of new disease alleles, is effective to rapidly identify disease-causative variants in known and new complex I-associated disease genes.

C12.5

Mitochondrial ribosome assembly defect underlies infantile-onset mitochondrial cardiomyopathy

H. Tyynismaa, *C. J. Carroll*, *P. Isohanni*, *R. Pöyhönen*, *L. Euro*, *U. Richter*, *T. Lahtinen*, *A. Götz*, *A. Paetau*, *H. Pihko*, *B. Battersby*, *A. Suomalainen*;
University of Helsinki, Helsinki, Finland.

Mitochondrial diseases display a progressive course, often manifesting and deteriorating after infection or trauma. Here we investigated the molecular background of cardiomyopathy in siblings with combined deficiency of mitochondrial respiratory chain complexes I and IV. The first patient died at six months of age of cardiomyopathy and cardiac failure manifesting after a respiratory infection. The second patient is a teenager with a clinically stable, currently asymptomatic cardiomyopathy. Using whole-exome sequencing, we found both patients to have a homozygous missense mutation in a novel disease gene, *MRPL44*, which encodes for a protein component of the mitochondrial large ribosome subunit. The mutation affected a conserved amino acid, leading to MRPL44 protein instability and its reduced levels in patient's heart, skeletal muscle and fibroblasts. Only a low level of assembled large ribosome subunit was found in patient fibroblasts, whereas the small subunit was present at normal level. Retroviral expression of wild-type MRPL44 in patient cells rescued all identified defects. The result suggests that MRPL44, which has no homologue in bacteria and has only emerged in the mitochondrial ribosome of eukaryotes, is essential for translation in human mitochondria. Our findings also demonstrate that only a fraction of mitochondrial ribosomes are required to assemble to maintain sufficient respiratory chain function. In conclusion, we have identified a new genetic cause of infantile-onset mitochondrial hypertrophic cardiomyopathy.

C12.6

Different sequencing strategies in the analysis of new ENU-derived mouse models for metabolic bone disease

B. Lorenz-Depiereux[1], *S. Sabrautzki*[2], *S. Diener*[1], *E. Graf*[1], *T. Wieland*[1], *A. Benet-Pagès*[1], *S. Eck*[1], *B. Rathkolb*[2,3], *J. Aguilar-Pimentel*[2,4], *J. Calzada-Wack*[5], *E. Wolf*[3], *M. Ollert*[4], *F. Neff*[5], *M. Hrabé de Angelis*[2,6], *T. M. Strom*[1,7];
[1]Helmholtz Zentrum München, German Research Center for Environmental Health, Institute of Human Genetics, Neuherberg, Germany, [2]Helmholtz Zentrum München, German Research Center for Environmental Health, Institute of Experimental Genetics, Neuherberg, Germany, [3]LMU München, Chair for Molecular Animal Breeding and Biotechnology, Gene Center of the LMU München, München, Germany, [4]Klinikum Rechts der Isar der TU München, Klinik und Poliklinik für Dermatologie und Allergologie am Biederstein, München, Germany, [5]Helmholtz Zentrum München, German Research Center for Environmental Health, Institute of Pathology, Neuherberg, Germany, [6]TU München, Lehrstuhl für Experimentelle Genetik, München, Germany, [7]Klinikum Rechts der Isar der TU München, Institute of Human Genetics, München, Germany.

Animal models are required to understand the molecular mechanisms of metabolic bone disorders in which imbalances of bone metabolism and mineralization lead to a variety of different phenotypes. Within a large-scale genome-wide Munich ENU (N-ethyl-N-nitrosourea) Mutagenesis Project mutant mouse models for metabolic bone disease were identified using three blood parameters (total alkaline phosphatase activity (ALP), total calcium (Ca), and inorganic phosphate (Pi) levels) which were commonly used as biochemical markers in patients with metabolic bone disease. Here, we describe three different sequencing strategies, (1) a candidate gene approach, (2) whole chromosome sequencing, and (3) exome sequencing, to identify novel genes involved in phosphate homeostasis and bone metabolism. In two mutant mouse lines (BAP012, BAP024) we identified novel *Phex* alleles (*Phex* c.148A>T, p. Lys50* and *Phex* c.2197T>C, p.Csy733Arg) by capillary sequencing of the candidate gene and extend the available mouse models for X-linked hypophosphatemia (XLH, OMIM 307800) to the number of 9. In two mutant mouse lines (BAP004, BAP005) the disease causing mutations were identified by linkage analysis, chromosome sorting and whole chromosome sequencing (BAP004: *Jak1* c.1933T>C, p.Ser645Pro and BAP005: *Asgr1* c.815A>G, p.Tyr272Cys). In 20 mutant mouse lines and one C3H wt line we performed exome sequencing using an exome capture kit from Agilent on a HiSeq2000 genome analyzer from Illumina. We identified in each mouse line between 3 and 42 SNVs (single nucleotide variants). We started with the evaluation of the different variants in mouse mutant and control cohorts and will present the data of the SNV evaluation.

C13.1

Mutations in PIGO, a member of the GPI anchor synthesis pathway, cause hyperphosphatasia with mental retardation syndrome

P. M. Krawitz[1], *Y. Murakami*[2], *J. Hecht*[3], *U. Krüger*[1], *S. Holder*[4], *G. Mortier*[5], *B. delle Chiaie*[6], *M. D. Thompson*[7], *T. Roscioli*[8], *S. Kielbasa*[9], *T. Kinoshita*[2], *S. Mundlos*[1], *P. N. Robinson*[10], *D. Horn*[10];
[1]Charite, Berlin, Germany, [2]Osaka University, Osaka, Japan, [3]Berlin Brandenburg Center for Regenerative Therapies, Berlin, Germany, [4]North West Thames Regional Genetics, Harrow, United Kingdom, [5]University Antwerp, Antwerp, Belgium, [6]University Ghent, Ghent, Belgium, [7]University of Toronto, Toronto, ON, Canada, [8]University of Sidney, Sidney, Australia, [9]University Leiden, Leiden, Netherlands, [10]Charité, Berlin, Germany.

More than a hundred cell surface proteins are attached to the plasma membrane by covalent attachment to a glycophosphatidylinositol (GPI) anchor that is assembled in the endoplasmic reticulum (ER) and added to the C-terminus of the proteins. Biosynthesis of GPI anchors involves more than 30 different genes. Genetic defects in various components of the GPI pathway have been identified in a number of phenotypically diverse diseases.

We have recently identified mutations in PIGV in individuals with hyperphosphatasia mental retardation (HPMR) syndrome, an autosomal recessive form of mental retardation with facial dysmorphism, seizures, brachytelephalangy, and persistent elevated serum alkaline phosphatase (hyperphosphatasia). However, not all patients with HPMR syndrome harbor mutations in PIGV. The purpose of the current study was therefore to investigate the molecular etiology of HPMR syndrome in PIGV-negative patients and to establish a next- generation sequencing based screening approach for GPI pathway diseases.

We employed whole-exome sequencing of two siblings with HPMR and identified compound heterozygous PIGO mutations. Screening of further PIGV-negative patients detected compound heterozygous PIGO mutations in another affected individual. The characteristic facial appearance, developmental delay, hypoplastic or even absent terminal phalanges including nails and hyperphosphatasia were present in all affected. In a cell based assay, two of three PIGO mutations had a deleterious effect on PIGO function. Furthermore, by Fluorescense-activated cell sorting analysis we demonstrated that PIGO is essential for GPI anchoring of attached proteins such us CD 59 and uPAR.

Our findings extend the range of reported phenotypes associated with GPI anchor synthesis defects

C13.2

Identification of de novo variants in 51 sporadic patients with unspecific severe intellectual disability and 20 controls by exome sequencing

[1]Institute of Human Genetics, Helmholtz Zentrum München, Neuherberg, Germany, [2]Institute of Human Genetics, Universitätsklinikum Essen, Essen, Germany, [3]Institute of Human Genetics, University of Erlangen-Nuremberg, Erlangen, Germany, [4]Institute of Medical Genetics, University of Zurich, Zurich, Switzerland, [5]Institute of Clinical Genetics, Technische Universität, Dresden, Germany, [6]Institute of Human Genetics, Eberhard Karls Universität, Tübingen, Germany, [7]Institute of Human Genetics, Technische Universität München, Munich, Germany, [8]Institute of Medical Genetics, Charité, University Medicine of Berlin, Berlin, Germany, [9]Institute of Human Genetics, Ruprecht-Karls-University, Heidelberg, Germany, [10]Institute of Human Genetics, Rheinische Friedrich-Wilhelms-University, Bonn, Germany, [11]Institute of Epidemiology II, Helmholtz Zentrum München, Neuherberg, Germany, [12]Research Unit of Molecular Epidemiology, Helmholtz Zentrum München, Neuherberg, Germany, [13]Department of Human Genetics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [14]Institute of Human Genetics, University of Münster, Münster, Germany.

Due to the absence of morphological or positional clues, the etiology of severe intellectual disability (ID) remains elusive in the majority of patients. We analyzed 51 children (32 girls, 19 boys) with severe non-syndromal ID and their healthy parents for de novo SNVs and small indels by exome sequencing. 20 trios with children and/or parents affected by diabetes mellitus type 2 were investigated as controls. Exomes were enriched with SureSelect Human All Exon 50 Mb kits and sequenced to an average read depth of 100. We detected de novo non-synonymous variants in 84% of patients. The number per individual varied between 0 and 4. The average number was higher in the disease (1.4/individual) than in the control group (0.8/individual). Specifically, the disease group showed a considerably higher number of nonsense/splice/indel variants (0.37/individual) than the control group (0.1/individual). 16 patients showed de novo mutations in the known ID genes IQSE2, SATB2, SNC2A, SCN8A, SETBP1, SLC2A1, STXBP1, SYNGAP1, TCF4, and MECP2. We regarded at least 8 variants in 8 novel genes to be disease causing because they fulfilled 4 of the following criteria: mutation type (nonsense/splice/frameshift), location in regions known for de novo microdeletions, haploinsufficiency predictions, brain expression, and functional evidence. In summary, this study clearly demonstrates the power of exome sequencing in identifying a sizable fraction of disease causing mutations in both known and novel genes.

De novo variants

	Cases n=51	Controls n=20
missense	54	14
nonsense	5	0
splice	1	1
frameshift	13	1
synonymous	12	5

C13.3

Dosage imbalance of nonsense-mediated mRNA decay factors is associated with intellectual disability

L. Nguyen[1], *H. Kim*[2], *J. Mokry*[3], *L. Shaffer*[3], *J. Gecz*[1,4];
[1]University of Adelaide, Adelaide, Australia, [2]Havard University, Boston, MA, United States, [3]Signature Genomics Laboratories, Spokane, WA, United States, [4]SA Pathology, Adelaide, Australia.

Nonsense-mediated mRNA decay (NMD) functions to degrade transcripts bearing premature stop codon and is a crucial regulator of gene expression. We implicated NMD and the UPF3B gene as the cause of various forms of intellectual disability (ID) and various other psychiatric traits. In expanding our inquiry, we identified three patients with global developmental delay who carry deletions of the genomic regions encompassing the UPF2 gene, another important member of the NMD pathway. We hypothesized that loss of one allele of UPF2 and likely loss of other NMD factors impair NMD and result in neurological phenotype. Using RNA-SEQ on lymphoblastoid cells from UPF2 del patients we identified 1009 differently expressed genes (DEGs). 38% of these DEGs overlapped with DEGs identified in UPF3B patients. More importantly, 95% of all DEGs in either UPF2 or UPF3B patients share the same trend of de-regulation. This suggested that the transcriptome de-regulation in UPF2 and UPF3B patients is similar. To gauge into the role of other NMD factors we performed a comprehensive search for copy number variations (CNVs) encompassing all known NMD factors in ID patients and controls. Our data indicate that CNVs, especially for UPF2, UPF3A, Y14, SMG6 and EIF4A3 are frequent in patients with neurological disorders and ID in particular. This tells that the changes in copy number of these factors, and as such dosage imbalance of NMD genes, are likely the causes or predisposing factors to ID. Our data strengthen the importance of NMD in normal learning and memory.

C13.4

A truncating mutation of *CEP135* causes primary microcephaly and disturbed centrosomal function

M. S. Hussain[1,2,3], *S. M. Baig*[4], *S. Neumann*[1], *V. S. Peche*[1], *G. Nürnberg*[2,3], *M. Farooq*[4], *I. Ahmad*[2], *T. Alef*[2], *H. C. Hennies*[2,5], *M. Technau*[1], *J. Altmüller*[2], *P. Frommolt*[2,5], *H. Thiele*[2,5], *A. A. Noegel*[1,3,5], *P. Nürnberg*[2,3,5];
[1]Institute of Biochemistry I, University of Cologne, Cologne, Germany, [2]Cologne Center for Genomics (CCG), University of Cologne, Cologne, Germany, [3]Center for Molecular Medicine Cologne (CMMC), University of Cologne, Cologne, Germany, [4]HMG Lab. Health Biotechnology Division, National Institute for Biotechnology and Genetic Engineering (NIBGE), Faisalabad, Pakistan, [5]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), University of Cologne, Cologne, Germany.

Autosomal recessive primary microcephaly (MCPH) is a rare congenital disorder of mental retardation, reduced brain and head size but usually without defects in cerebral cortical architecture and other syndromic abnormalities. MCPH is heterogeneous with 7 known loci: MCPH1-MCPH7. The underlying genes code for centrosomal proteins. We collected 49 MCPH families from Pakistan. Sequencing of *ASPM* and *WDR62*, the two most frequently mutated genes, and exclusion of homozygosity for all known MCPH loci by typing of appropriate microsatellite markers resulted in 14 families with a putatively new disease locus. Out of these, we studied one family with two microcephalic children using homozygosity mapping and found suggestive linkage for regions on chromosomes 2, 4 and 9. We sequenced two positional candidate genes and identified a homozygous frameshift mutation in centrosomal protein135 kDa (*CEP135*), located in the linkage interval on chromosome 4. Post-hoc whole-exome sequencing corroborated this mutation to be the causal variant. Immunostaining of CEP135 showed strong signals in the developing neuroepithelium of the cerebral cortex during embryonic stages E11.5 through E15.5. Fibroblasts obtained from one of the patients showed multiple and fragmented centrosomes, disorganized microtubules, and reduced growth rate. Similar effects were reported after knockdown of CEP135 through RNA interference; we could provoke them also by ectopic overexpression of the mutant protein. Our findings suggest a new locus, MCPH8, at HSA 4q12, further strengthen the role of centrosomes in the cause of MCPH, and place CEP135 among the essential components of this important organelle in particular for a normal neurogenesis.

C13.5

Dysregulation of Rho GTPases in the alphaPix/Arhgef6 mouse model of X-linked intellectual disability is paralleled by impaired structural and synaptic plasticity and cognitive deficits

G. J. A. Ramakers[1], *D. Wolfer*[2], *G. Rosenberger*[3], *K. Kuchenbecker*[3], *H. Kreienkamp*[3], *J. Prange-Kiel*[4], *G. Rune*[4], *K. Richter*[5], *K. Langnaese*[5], *S. Masneuf*[2], *M. R. Bösl*[6], *K. Fischer*[5], *H. J. Krugers*[7], *H. Lipp*[2], *E. van Galen*[1], ***K. Kutsche***[3];
[1]Neurons and Networks, Netherlands Institute for Neuroscience, Amsterdam, Netherlands, [2]Institute of Anatomy and Zurich Center for Integrative Human Physiology (ZIHP), Zurich, Switzerland, [3]Institut für Humangenetik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany, [4]Institute of Anatomy I: Cellular Neurobiology, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany, [5]Institute of Biochemistry and Cell Biology, Otto von Guericke University Magdeburg, Magdeburg, Germany, [6]Center for Molecular Neurobiology, Hamburg, Germany, [7]Swammerdam Institute for Life Sciences, Center for Neuroscience, Amsterdam, Netherlands.

Mutations in the ARHGEF6 gene, encoding the guanine nucleotide exchange factor alphaPIX/Cool-2 for the Rho GTPases Rac1 and Cdc42, cause X-linked intellectual disability (ID) in humans. We show here that alphaPix/Arhgef6 is primarily expressed in neuropil regions of the hippocampus. To study the role of alphaPix/Arhgef6 in neuronal development and plasticity and gain insight into the pathogenic mechanisms underlying ID, we generated alphaPix/Arhgef6-deficient mice. Gross brain structure in these mice appeared to be normal, however, analysis of Golgi-Cox stained pyramidal neurons revealed an increase in both dendritic length and spine density in the hippocampus, accompanied by an overall loss in spine synapses. Early-phase long-term potentiation was reduced and long-term depression was increased in the CA1 hippocampal area of alphaPix/Arhgef6-deficient animals. Knockout animals exhibited impaired spatial and complex learning and less behavioral control in mildly stressful situations, suggesting that this model mimics the human ID phenotype. The structural and electrophysiological alterations in the hippocampus were accompanied by a significant reduction of active Rac1 and Cdc42, but not RhoA. In conclusion, we suggest that imbalance in activity of different Rho GTPases may underlie altered neuronal connectivity and impaired synaptic function and cognition in alphaPix/Arhgef6 knockout mice.

C13.6

The functional spectrum of *SRGAP3* in cognitive development

C. Bacon[1], *V. Endris*[1], *E. Stoeckli*[2], *R. Waltereit*[3], *D. Bartsch*[3], *G. Rappold*[1];
[1]Department of Human Molecular Genetics, University of Heidelberg, Heidelberg, Germany, [2]Institute of Molecular Life Sciences, University of Zürich, Zürich, Switzerland, [3]Department of Molecular Biology, Central Institute of Mental Health, University of Heidelberg, Mannheim, Germany.

Disruption in the *SRGAP3* gene has been associated with abnormal cognitive function. srGAP3 is a member of the Slit-Robo GAP family and is implicated in repulsive axon guidance and neuronal migration through Slit-Robo mediated signal transduction, making it an ideal candidate for orchestrating the formation of functional neural networks during brain development. To uncover the importance of srGAP3 in the underlying neurodevelopmental processes required for normal cognition, a *srGAP3* knockout mouse model was generated (Waltereit et al. submitted). *srGAP3*$^{-/-}$ mice exhibit a complex behavioural phenotype including impaired social interaction along with various neuroanatomical defects. To gain more insight into the molecular processes underlying these defects, we identified novel binding partners of srGAP3. This avenue led us to the discovery that srGAP3 and its novel interacting partner lamellipodin co-localise to the leading edge of cell protrusions and that srGAP3 inhibits protrusion dynamics through lamellipodin. Additionally, *srGAP3*$^{-/-}$ hippocampal neurons exhibit excessive lamellipodia formation. To take the story further, we examined the role of srGAP3 in axon guidance using commissural axon crossing in the spinal cord as a model system. We were able to show that axons were not normally positioned after crossing, implicating srGAP3 in axon repulsion from the floor plate. Taken together, our results have begun to uncover the underlying processes in which *srGAP3* is playing a role during brain development, thus shedding light on the importance of this gene in cognitive processes.

C14.1

ASB10 variants are associated with open-angle glaucoma and silencing impairs ocular outflow

F. Pasutto[1], *K. E. Keller*[2], *N. Weisschuh*[3], *H. Sticht*[4], *J. R. Samples*[2], *Y. Yang*[2], *M. Zenkel*[1], *U. Schlötzer-Schrehardt*[1], *C. Y. Mardin*[1], *P. Frezzotti*[5], *B. Edmunds*[2], *P. L. Kramer*[2], *E. Gramer*[6], *A. Reis*[1], *T. S. Scott*[2], *M. K. Wirtz*[2];
[1]University Hospital of Erlangen-Nuremberg, Erlangen, Germany, [2]Oregon Health & Sciences University, Portland, OR, United States, [3]University Eye Hospital Tübingen, Tübingen, Germany, [4]University of Erlangen-Nuremberg, Erlangen, Germany, [5]University Hospital of Siena, Siena, Italy, [6]University Eye Hospital of Würzburg, Erlangen, Germany.

The molecular events responsible for obstruction of aqueous humor outflow and the loss of retinal ganglion cells in glaucoma, one of the main causes of blindness worldwide, remain poorly understood. We identified a synonymous variant, c.765C>T (Thr255Thr), in ankyrin repeats and suppressor of cytokine signaling box-containing protein 10 (ASB10) in a large family with primary open angle glaucoma (POAG) mapping to the GLC1F locus. This variant affects an exon splice enhancer site and alters mRNA splicing in lymphoblasts of affected family members. Systematic sequence analysis in two POAG patient groups (195 US and 977 German) and their respective controls (85 and 376) lead to the identification of 26 amino acid changes in 70 patients (70 of 1172; 6.0%) compared with 9 in 13 controls (13 of 461; 2.8%; $P = 0.008$). Molecular modeling suggests that these missense variants change ASB10 net charge or destabilize ankyrin repeats. ASB10 mRNA and protein were found to be strongly expressed in trabecular meshwork, retinal ganglion cells and ciliary body. Silencing of ASB10 transcripts in perfused anterior segment organ culture reduced outflow facility by 50% compared with control-infected anterior segments ($P = 0.02$). In conclusion, genetic and molecular analyses provide evidence for ASB10 as a glaucoma-causing gene.

C14.2

Seven New Loci Associated with Age-Related Macular Degeneration

L. G. Fritsche[1], *W. Chen*[2,3], *M. Schu*[4], *B. L. Yaspan*[5], *Y. Yu*[6], *The AMDGene Consortium;*
[1]University of Regensburg, Regensburg, Germany, [2]University of Michigan, Ann Arbor, MI, United States, [3]University of Pittsburgh, Pittsburgh, PA, United States, [4]University School of Medicine, Boston, MA, United States, [5]Vanderbilt University Medical Center, Nashville, TN, United States, [6]Tufts Medical Center, Boston, MA, United States.

Age-related macular degeneration (AMD) is a prevalent disease of complex aetiology and one of the leading causes of vision impairment in industrialized countries. To further our understanding of AMD genetics, 18 groups from 12 countries formed the AMDGene Consortium in 2010.

This endeavor brought together 15 genome-wide association studies comprising 7,650 advanced AMD cases and 51,812 controls of European and Asian ancestry. The meta-analysis revealed SNPs at 32 genomic loci with P < 10-5 that were followed up in 18 additional studies consisting of 9,531 advanced AMD cases and 8,230 controls. In the joint analysis, a total of 19 loci reached genome-wide significance (P < 5x10-8) which included all 12 previously established and the seven novel AMD loci COL8A1/FILIP1L (4x10-13), IER3/DDR1 (2x10-11), SLC16A8 (3x10-11), TGFBR1 (3x10-11), RAD51B (9x10-11), MIR548A2 (5x10-9), and B3GALTL (2x10-8). Pathway analyses of the 19 loci indicated an over-representation of genes involved in complement activity, lipid metabolism and inhibition of angiogenesis thereby falling well into place with known AMD pathomechanisms. While the sensitivity analyses indicated that several loci had differences in disease risk between males and females, or in European and Asian ancestry or disease subgroups, the overall predictive value of these variants displayed similar effectiveness in all samples examined (0.69 < AUC < 0.79).

Our findings can guide future biological and genetic AMD studies, allow better classification of individuals at risk, and might ultimately lead to improved disease treatment and prevention.

Background and aims: Host genetic variation in complement factor H (CFH) show very strong evidence of association with individual susceptibility to meningococcal disease (MD).

Methods: We performed a meta-analysis of two GWAS in Spain (ESIGEM-network) and the UK totaling 894 MD cases and 5,645 controls,with replication in a further 565 MD cases and 2,600 controls of West European descent. The MD cases were genotyped using the Illumina Human-610K Quad Bead Chips for UK and the Illumina Human-660W Quad Bead Chips for Spain. Replication genotyping was done using the Sequenom-MassArray platform.

Results: We note strong evidence of association at the previously reported *CFH* locus on Chromosome 1(rs1065489, *P*=1.18 x 10-8 and rs11582939, *P*=1.95 x 10-8).The second most significant SNP was observed within *ABCA4* (rs544830, *P*=2.93 x 10-6, per-allele OR=1.30).Strong statistical association of this locus with MD was corroborated by two other neighboring SNPs (rs550060, *P*=4.48 x 10-6, per-allele OR=1.29 and rs497511, *P*=4.55 x 10-6, per-allele OR=1.29). These findings within *ABCA4* were further replicated in the Western European collection (*P*=8.72 x 10-5, *P*=1.81 x 10-4, and *P*=6.59 x 10-5 respectively), leading genome-wide significant findings for all three *ABCA4* SNPs (*P*=8.46 x 10-10, *P*=5.28 x 10-9, and P=2.36 x 10-9, respectively) when data from all MD sample collections were jointly analyzed.

Conclusion: As mutations in both *CFH* and *ABCA4* also confer susceptibility to macular degeneration, our observation points to shared mechanisms of pathogenesis between macular degeneration and MD.

C14.4

First genome-wide meta-analyses of nonsyndromic cleft lip with or without cleft palate identify six new risk loci including one subtype-specific locus

Nonsyndromic cleft lip with or without cleft palate (NSCL/P) is one of the most common birth defects in humans. In the last years, the etiology of this phenotypically variable malformation, which involves both environmental and genetic factors, has been elucidated by the discovery of six genetic susceptibility loci in large genome-wide association studies (GWAS). To identify additional loci we conducted the first meta-analyses using the two largest GWAS on NSCL/P that are available to date. Our analyses confirmed all previously identified loci, and identified six new susceptibility regions for the European population (1p36, 2p21, 3p11.1, 8q21.3, 13q31.1, and 15q22). Five of these loci were shown to also play a role in the Asian population. Analyses of the phenotypic subgroups NSCLO (nonsyndromic cleft lip only) and NSCLP (nonsyndromic cleft lip with cleft palate) revealed that a locus on chr. 13q31.1 was a strong susceptibility factor for NSCLP (rs8001641, P_NSCLO = 0.163, P_NSCLP = 6.51x10-11; RRhet_NSCLP = 1.63 (95% CI: 1.28 - 2.07), RRhom_NSCLP = 2.41 (95% CI: 1.84 - 3.16)). The present study is the first to identify a genome-wide significant locus that is specific for NSCL/P subtypes and emphasizes the power of genetic studies when detailed clinical and / or phenotype information is available.

C14.5

Variants in *RUNX3* contribute to susceptibility to psoriatic arthritis exhibiting further common ground with ankylosing spondylitis

U. D. Hüffmeier[1], *S. Uebe*[1], *M. Apel*[1], *A. B. Ekici*[1], *J. Bowes*[2], *E. Giardina*[3], *E. Korendowych*[4], *K. Juneblad*[5], *R. McManus*[6], *P. Ho*[2], *I. N. Bruce*[2], *A. W. Psoriatic arthritis (PsA) is a common inflammatory joint disease distinct from other chronic arthritides and frequently accompanied by psoriasis vulgaris (PsV). In a first genome-wide association study (GWAS), we were able to identify several genetic risk factors. But even combined with previously identified factors, only a fraction of genetic contribution to disease is explained. Therefore we pursued further 16 loci from our GWAS with several SNPs showing association in the range of $5E^{-8}$ (= genome-wide significance level) < p-value < $1E^{-5}$ as well as one functional candidate.

20 of 21 SNPs at 18 loci were successfully genotyped in independent European cohorts of 1,748 PsA cases and 3,926 control probands, furthermore in

a group of 961 German PsV patients. Association to a *RUNX3* variant was replicated and resulted in a combined (GWAS + replication) p-value of $1.52E^{-06}$ in a Cochran-Mantel-Haenszel test and an OR of 1.20 (1.11-1.29). Further analyses based on linkage disequilibrium at *RUNX3* could pinpoint the most significant association to the initial SNP located in the first intron of one isoform. In the smaller patient group of PsV patients and corresponding German control individuals, p-value was $2.5E^{-02}$ and OR 1.22 (0.96-1.56), indicating also a role in skin manifestation of psoriasis.

Our analyses suggest that variants in *RUNX3* contribute to susceptibility to PsA, a genetic factor already described to be associated with another spondylarthritis, ankylosing spondylitis. RUNX3 is a transcription factor involved in CD8 lymphozyte differentiation and therefore a good candidate for PsA and PsV as T-cell mediated diseases.

C14.6

Genome-Wide Association Analysis Identifies the MTHFR-CLCN6-NPPA-NPPB Gene Cluster as an Importance Influence on BNP Levels - Implications for the Use of BNP levels in the Diagnosis and Therapeutic Monitoring of Heart Failure.

P. Surendran[1,2]*, C. Vangjeli*[2]*, N. McCarthy*[2]*, S. Thom*[3]*, P. Sever*[4]*, E. O'Brien*[5]*, N. Poulter*[4]*, J. Mayet*[4]*, A. Hughes*[6]*, D. Shields*[1]*, A. Stanton*[2]*;*
[1]*University College Dublin, Dublin, Ireland,* [2]*Royal College of Surgeons in Ireland, Dublin, Ireland,* [3]*6Department of Cardiology, Imperial College Healthcare NHS Trust, London, United Kingdom,* [4]*Department of Cardiology, Imperial College Healthcare NHS Trust, London, United Kingdom,* [5]*Blood Pressure Unit, Beaumont Hospital, Dublin, Ireland,* [6]*Department of Cardiology, Imperial College Healthcare NHS Trust, London, Ireland.*

Brain Natriuretic Peptide (BNP) levels provide insight into Left Ventricular (LV) filling pressures, and are therefore increasingly used in the diagnosis and management of heart failure.

We conducted a genome wide association analysis to identify genetic variants associated with BNP levels in 737 hypertensive caucasian individuals. 318,000 SNPs were genotyped and an additional 1,972,462 SNPs were imputed from HapMap. Serum BNP levels were measured by immunoassay. LV filling pressures were measured using the echocardiographic derived ratio of early diastolic transmitral flow velocity to mitral annular velocity (E/E'). Linear regression analysis were adjusted for major cardiovascular risk factors.

17 SNPs spanning 150kb of MTHFR-CLCN6-NPPA-NPPB (MCNN) gene cluster were significantly associated with BNP levels. Median BNP levels for AA homozygotes, AG heterozygotes and GG homozygotes for the top-hit SNP (a MTFHR gene SNP), were 25, 32 and 34, respectively ($p=4.9X10^{-9}$). Despite no associations observed between these 17 SNPs and E/E', carriers of gene cluster variants were much more likely to have BNP levels above the cut-off regarded as diagnostic of heart failure (>100 pg/ml). Results showed that individuals who are minor allele homozygotes (GG) had three times elevated BNP levels when compared to major allele homozygotes (AA) (7% *versus* 2%, p=0.01). This is the first study to demonstrate that genetic variants in the MCNN gene cluster influence BNP levels independently of LV filling pressures. Combining MCNN genotyping with BNP measurement is likely to improve the sensitivity and specificity of algorithms that use BNP levels in the diagnosis and management of heart failure.

C15.1

Identification and characterization of genetic disorders with ID in diagnostics and diagnostic related research

M. H. Willemsen[1]*, H. Rensen*[2]*, W. Wissink-Lindhout*[1]*, A. de Brouwer*[1]*, N. de Leeuw*[1]*, R. Pfundt*[1]*, H. G. Yntema*[1]*, L. Vissers*[1,3]*, J. de Ligt*[1,3]*, J. A. Veltman*[1,3]*, H. B. Brunner*[1,3]*, H. van Schrojenstein Lantman-de Valk*[1]*, H. van Bokhoven*[1]*, B. C. J. Hamel*[1]*, T. Kleefstra*[1,3]*;*
[1]*Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [2]*Pluryn, Care provider for people with intellectual disabilities, Oosterbeek, Netherlands,* [3]*Nijmegen Centre for Molecular Life Sciences, Institute for Genetic and Metabolic Disease, Nijmegen, Netherlands.*

The etiology of intellectual disability (ID) is unknown in about 50% of the patients. Knowing the cause enables anticipation on associated health and behaviour problems, and is essential for adequate counseling regarding recurrence risk and prognosis. In recent years, advances in genetic technologies have provided great new opportunities for the identification of genetic defects. We aimed to identify genetic causes of ID in a unique cohort of 254, mainly adult, patients with unexplained ID, selected from a large cohort of individuals from Dutch residential settings. Our studies included a multidisciplinary clinical evaluation, followed by specific genetic diagnostic tests if indicated, and standard genome-wide array analysis and a metabolic screen. In the diagnostic part of the study a genetic diagnosis was established in 17.5%, comprising of 12% chromosomal abnormalities and 5% monogenetic defects, mostly fitting syndromes for which the causative genes were identified recently, such as Pitt-Hopkins and Kleefstra syndrome. In a small minority (<1%) a primary metabolic cause was established. About 60 patients were selected for further research studies, mainly comprising different next generation sequencing approaches. So far, these led to the identification of 14 additional likely molecular diagnoses, including both known and novel genetic defects. Pertinent diagnoses included *de novo* mutations in *PDHA, GRIN2A, DYNC1H1* and *GATAD2B*. This has increased the current diagnostic yield to over 23%. Since several studies are pending, more diagnoses are expected. The majority of selected individuals have an age above 40 years, providing useful information on natural progression and comorbidity of these disorders.

C15.2

High yield of massive parallel exome sequencing in 25 families with autosomal recessive intellectual disability

R. Abou Jamra[1]*, R. Buchert*[1]*, A. B. Ekici*[1]*, S. Uebe*[1]*, S. H. Eck*[2]*, H. Tawamie*[1]*, E. Graf*[2]*, F. F. Brockschmidt*[3,4]*, J. Schumacher*[4]*, M. M. Nöthen*[3,4]*, T. Strom*[2,5]*, A. Reis*[1]*;*
[1]*Institute of Human Genetics, Erlangen, Germany,* [2]*Institute of Human Genetics, Helmholtz Center Munich, Neuherberg, Germany,* [3]*Department of Genomics, Life & Brain Center, University of Bonn, Bonn, Germany,* [4]*Institute of Human Genetics, University of Bonn, Bonn, Germany,* [5]*Institute of Human Genetics, Klinikum rechts der Isar, Technische Universität München, Munich, Germany.*

To elucidate the genetics of autosomal recessive intellectual disability, we undertook systematic autozygosity mapping in 69 large, consanguineous families. We focused on 25 families with small candidate regions of 10 to 45 Mb. After enriching the exomes with the Agilent SureSelect Kit (13 exomes using the 38Mb and 19 using the 50Mb versions, whereas 7 were enriched using both for comparison), we undertook massive parallel sequencing on Solexa or SOLiD. We were able to clarify the causes of intellectual disability in 12 families. We described one new intellectual disability gene, AP4S1, and characterized the AP4 deficiency syndrome. Furthermore, in seven families we identified mutations (two in-frame deletions, two frameshifts, and three missense mutations) in EDC3, ENO2, c9orf4, FAR1, HMG20A, PPFIA1, and SPATA5. In silico analysis predicted pathogenic effects of the mutations, and frequencies in 280 ethnic matched controls were null. The functions of c9orf4 and SPATA5 are unknown, while all other genes are highly expressed in brain and functionally relevant. In addition, we clarified the etiology in four further families by identifying pathogenic mutations in the known genes AIH1, ALDH5A1, GPR56, and HGSNAT. As a consequence of the enriching method, only 67% of the exons were properly covered (i.e. depth >5x at >80% of the nucleotides). To identify the mutations in the rest of the families, ensuring complete and high coverage of all exons in the linkage regions, we designed targeted sequencing enriching sets (Agilent, SureSelect). Sequencing on SOLiD is ongoing.

C15.3

Brain malformation and clinical finding in autosomal recessive primary microcephaly: genotype - phenotype correlation

K. Kahrizi[1]*, N. Hafezi-Nejad*[1]*, A. Tzschach*[2,3]*, M. Garshasbi*[1,4]*, S. Abedini*[1]*, H. Hu*[2]*, H. Ropers*[2]*, H. Najmabadi*[1]*;*
[1]*Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran,* [2]*Max Planck Institute for Molecular Genetics, Berlin, Germany,* [3]*Institut für Humangenetik Universitätsklinikum Tübingen Calwerstr, Tübingen, Germany,* [4]*Department of Medical Genetics, Faculty of Medical Sciences, Tarbiat Modares University, Tehran, Islamic Republic of Iran.*

Background: Autosomal recessive primary microcephaly (MCPH) has underlying genetic defects, of which some are defined to date. However, fewer studies till now have tried to answer the questions regarding the genetic defect in MCPH gene family and the specified brain architecture changes.

Methods: From Iranian cohort of mentally retarded -Intellectual disability (ID) - patients, 51 families with concomitant primary microcephaly in at least two members and modest neurological signs were selected and MRI was performed for the proband of each family. In the previous study, homozygosity mapping, coupled by sanger sequencing or next generation sequencing (NGS) were used to define underlying genetic defects.

Results: Genetic defect was successfully defined in 13 out of 51 families. 4 novel genes were identified using NGS, two of which were responsible for syndromic (TMEM135, TAF2) and two for non-syndromic (CAPN10, ZBTBYO) primary microcephaly. 2 families had defects in recently identified AP-4 complex (AP4M1, AP4E1). Remainings were previously known genes: three WDR62, two CENPJ, one Microcephalin and one PDHX

Moreover, 19 out of 51 families showed different types of brain abnormalities on MRI: Cerebellar hypoplasia in eight, small or hypoplastic corpus callosum in six. Heterotopia, abnormal white matter, enlargement of ventricles and thickening/thinning/agenesis of corpus callosum, each in one.

Conclusion: MCPH can be associated with neurological signs relevant to MRI changes despite spared architecture of the brain, but due to the underlying basis of the disorder. Here we demonstrate new findings of imaging in both recently identified genetic defects and MCPH genes.

C15.4

The utility of exome sequencing in Primary Immunodeficiency Diseases and Immunodysregulative Disorders

__A. Stray-Pedersen__[1,2,3], H. S. Sorte[2], O. K. Rodningen[2], R. Lyle[2], C. G. Gonzaga-Jauregui[3], S. K. Nicholas[4,1], L. Noroski[4,1], C. I. Hanson[4,1], H. C. Erichsen[5], T. G. Abrahamsen[5,6], B. Flatø[7], L. T. Osnes[8], K. R. Heimdal[2], D. E. Undlien[2,6], J. R. Lupski[3], W. T. Shearer[1,4];
[1]Section of Pediatric Allergy and Immunology, Baylor College of Medicine, Houston, TX, United States, [2]Department of Medical Genetics, Oslo University Hospital, Oslo, Norway, [3]Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, United States, [4]Allergy and Immunology, Texas Childrens Hospital, Houston, TX, United States, [5]Department of Pedicatrics, Oslo University Hospital, Oslo, Norway, [6]University of Oslo, Oslo, Norway, [7]Department of Rheumatology, Oslo University Hospital, Oslo, Norway, [8]Department of Immunology, Oslo University Hospital, Oslo, Norway.

Mutations in more than 200 different genes have been reported causing various primary immunodeficiency diseases (PIDs) including immunodysregulative/autoinflammatory disorders. Knowing the exact molecular genetic diagnosis is valuable to direct protocols for immunoreconstitution, immunotherapies, and prophylaxis, and may predict clinical outcomes. For combined T- and B-cell deficiencies and for isolated B-cell deficiencies, phagocyte disorders and defects in innate immunity there are multiple genes known to be causal, and patients with different immunodeficiencies may have overlapping immunological and clinical phenotypes.

We examined the utility of high throughput next generation DNA sequencing with exome capture in the diagnostic workup and research of PIDs, including SCID, severe autoinflammatory disorder, severe congenital neutropenia, hyper IgM syndrome, autosomal recessive agammaglobulinemia and other immunodeficiency diseases with unknown etiology. Based on the clinical and immunophenotypical data, family history and knowledge from similar PID cases, we varied between using candidate gene testing with relevant known PID genes, triotesting (patient + parents) in the assumed *de novo* cases, or focused on genomic regions with unknown candidate genes in the assumed autosomal recessive cases when loss of heterozygozity or copy number variations had been found.

Pathological variants were detected in both well known and less characterized genes. We address the advantages and limitations of this approach i.e. regarding detection of low grade mosaicism. Our project illustrates the capability of targeted exome sequencing to efficiently identify novel variants in a large set of candidate genes, and reinforces the method's clinical utility to identify causal variants of PIDs and other rare immunological disorders.

C15.5

NGS-panel targeting 150 cilia-related disease genes improves diagnostic testing for the broad spectrum of ciliopathies

V. Frank, T. Eisenberger, C. Eitel, C. Decker, H. J. Bolz, __C. Bergmann__;
Bioscientia Center for Human Genetics, Ingelheim, Germany.

Cilia-related disorders (ciliopathies) are characterized by great clinical and genetic heterogeneity. Literally all organs can be affected, frequent cilia-related manifestations are cystic and polycystic kidney disease, retinal degeneration, situs inversus, polydactyly, skeletal features, and defects of the central and peripheral nervous system. These can occur isolated or as part of syndromes, such as Bardet-Biedl, Joubert, Meckel, Jeune, Ellis-van-Crefeld, and Sensenbrenner syndrome. Variable expressivity and overlaps between different entities often make it difficult to give a clear diagnosis. Genotype-phenotype correlations are usually not convincing and mutations in the same gene can cause very different phenotypes. Overall, it is more the rule than the exception that multiple, often dozens of genes are to be considered to be disease-relevant in a patient with suspected ciliopathy. Second-site modifiers are expected to exert an aggravating effect in an epistatic way. In this scenario, altered dosage of disease proteins may disturb cell homeostasis and network integrity contributing to early and more severe disease expression. We designed a "ciliopathy panel" for next-generation sequencing (NGS) that allows the parallel investigation of about 150 cilia-related disease genes in a time- and cost-efficient manner. We present families from a broad spectrum of cilia-related disease phenotypes in which we have used our NGS-panel and identified convincing disease-related mutations in different genes corroborating our hypothesis. This novel genetic testing approach considerably improves genetic diagnostics of ciliopathies and deserves increased attention in genetic counselling and the management of affected families.

C15.6

Next generation sequencing of 105 genes associated with retinal dystrophy: A new era for diagnostic testing

__G. C. Black__, B. Mullaney, J. O'Sullivan, S. Bhaskar, G. Hall, J. Dickerson, S. Ramsden;
Genetic Medicine, Manchester, United Kingdom.

Retinitis Pigmentosa (RP) is a group of highly genetically heterogeneous retinal dystrophies which lead to reduced vision and eventual blindness. RP affects approximately 1:3500 people in the UK. Current diagnostic testing is largely restricted to conventional Sanger sequencing of a small number of genes. As a result of its heterogeneity, RP was an ideal candidate to use a targeted enrichment next generation sequencing approach, technologies not previously utilised in a diagnostic setting, as the basis for a diagnostic service.

We describe our approach to the validation of the entire workflow (assay design, sample preparation, bioinformatic analysis and scientific analysis) of a next generation sequencing targetted enrichment of 105 genes known to cause RP or associated conditions. The process was validated using 50 patients. The validation process included: developing criteria for transcript choice during assay design, documenting laboratory sample processing, defining minimum coverage criteria, assigning quality and coverage thresholds for SNP and indel calling, defining criteria for filtering of benign polymorphisms and assessing SNP concordance between next generation sequencing and Sanger sequencing.

We identified likely pathogenic mutations in 42% (21/50) of patients tested, 64% (9/14) in adRP, 32% (6/20) in sporadic and 37% (6/16) in sporadic patients. We have developed a diagnostic NGS testing strategy that will extend clinical testing to a wider range of RP referral types and improve detection rates across all patients. Furthermore we propose a model on which to base future validation of large scale next generation sequencing target enrichments in a diagnostic laboratory.

C16.1

Non-invasive prenatal detection of fetal autosomal aneuploidies using massively parallel sequencing: a collaborative study in Europe

__W. Hofmann__[1], M. Entezami[2], K. Haug[3], C. Blank[3], M. Wüstemann[4], B. Schulze[5], G. Raabe-Meyer[5], S. Lange-Freitag[6], M. Schelling[7], E. Ostermayer[8], T. Burkhardt[9], R. Zimmermann[9], M. Beck[10], T. Schleicher[10], Y. Kumar[10], D. Schöner[1], S. Grömminger[1], M. Stumm[2];
[1]LifeCodexx AG, Konstanz, Germany, [2]Zentrum für Pränataldiagnostik und Humangenetik, Berlin, Germany, [3]Praenatal-Medizin und Genetik, Düsseldorf, Germany, [4]Zentrum für Pränatalmedizin, Hannover, Germany, [5]Praxis für Humangenetik, Hannover, Germany, [6]Institut of Human Genetics, Technische Universität München, München, Germany, [7]Praxis für Pränatale Diagnostik, München, Germany, [8]Department of Obstetrics and Gynecology, Technische Universität München, München, Germany, [9]Universitätsspital Zürich, Klinik für Geburtshilfe, Zürich, Switzerland, [10]GATC Biotech AG, Konstanz, Germany.

Objectives: Recent advances in non-invasive prenatal diagnosis show that massively parallel sequencing (MPS) of maternal plasma DNA allows an accurate detection of common fetal aneuploidies. Here, we describe a large-scale clinical study, which will be finished in March 2012. The aim of the study is to validate the diagnostic accuracy of our non-invasive prenatal test based on MPS for detecting fetal autosomal aneuploidies.

Method: Maternal blood samples were collected from more than 500 pregnant women prior to invasive prenatal procedures at 7 clinics located in Germany and Switzerland. The extracted maternal plasma DNA was analyzed using Illumina sequencing platform HiSeq2000 in a multiplexed fashion. For data analysis a z-score equation was used to distinguish samples with fetal aneuploidies from samples with a set of normal fetal chromosomes. The results of MPS analysis have been compared with the fetal karyotype obtained from chorionic villi sampling or amniocentesis.

Results: We will present the results of the collaborative, blinded study including sensitivity and specificity of the well-established non-invasive prenatal test for detection of fetal autosomal aneuploidies. Furthermore, advanced algorithms for bioinformatics for detection of these aneuploidies will be discussed.

Conclusions: MPS of maternal plasma DNA is a very promising approach for non-invasive detection of fetal aneuploidies. Their implementation in prenatal care of high risk pregnant women will decrease the use of invasive procedures. However, future clinical studies are required to validate the use of MPS for the detection of broader spectrum of fetal chromosomal abnormalities and fetal genomic imbalances.

C16.2

Further development and larger validation of non-invasive prenatal diagnosis for trisomy 21 using MeDIP real time qPCR

P. C. Patsalis[1], E. Tsaliki[2,3], C. Spyrou[2], G. Koumbaris[2,1], A. Karagrigoriou[4], K. Lamnisou[3], V. Velissariou[5], __E. A. Papageorgiou__[2,1];

[1]*Department of Cytogenetics and Genomics,The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, [2]NIPD Genetics Ltd., Nicosia, Cyprus, [3]University of Athens, Athens, Greece, [4]Department of Mathematics and Statistics, University of Cyprus, Nicosia, Cyprus, [5]Department of Cytogenetics and Molecular Biology, Mitera Hospital, Athens, Greece.*

Nowadays, prenatal diagnosis of Down syndrome is performed using invasive procedures such as amniocentesis or chorionic villi sampling, which are associated with a significant risk of fetal loss (1%). Many attempts have been made in the last two decades towards the development of a non-invasive prenatal diagnostic (NIPD) test. One of the most promising technologies is the application of the Methylated DNA Immunoprecipitation (MeDIP) real-time qPCR-based approach developed by Prof. Philippos Patsalis and his team. The MeDIP methodology was initially combined with high-resolution tiling oligonucleotide array, to identify DNA methylation differences between maternal and fetal DNA across chromosomes 13, 18, 21, X and Y. Thousands of Differentially Methylated Regions (DMRs) were generated and the best were used for the development and validation of the first universal non-invasive prenatal diagnosis for trisomy 21 (NIPD^{21}), using MeDIP real-time qPCR for chromosome 21. The team has recently described an improved version of the diagnostic formula and a much larger validation study (unpublished data). The improved version was created using old and new DMRs and taking into account the genomic position and copy number variation of DMRs. An additional advantage of the new diagnostic formula is that it consists of only seven DMRs, simplifying the diagnostic assay and further reducing the cost. In conclusion, the MeDIP real time qPCR-based approach is an accurate, reliable NIPD test for Down syndrome. It is simple, fast and easy to perform in every genetic diagnostic lab worldwide as it does not require expensive equipment, software or special infrastructure.

C16.3

Analysis of PCR-based monogenic preimplantation genetic diagnosis (PGD) by follow up of untransferred embryos - A multi-center study

*J. Dreesen[1], **A. Destouni**[2], B. Degn[3], M. W. Christensen[3], F. A. G. Carvalho[4], C. Moutou[5], S. Sengupta[6], P. Renwick[7], S. Davies[8], E. Kanavakis[2], G. Harton[9], J. Traeger-Synodinos[2];*
[1]Department of Clinical Genetics, Maastricht University, Maastricht, Netherlands, [2]Medical Genetics, Athens University, Athens, Greece, [3]Centre for Preimplantation Genetic Diagnosis, Aarhus University Hospital, Aarhus, Denmark, [4]Department of Genetics, Faculty of Medicine, University of Porto, Porto, Portugal, [5]Université de Strasbourg FRANCE & HUS - Service de la Biologie de la Reproduction, CMCO, Schiltigheim, France, [6]UCL Centre for PG&D, Institute for Women's Health, London, United Kingdom, [7]Guy's & St. Thomas' Centre for Preimplantation Genetic Diagnosis and Genetics Centre, Guy's & St. Thomas' NHS Foundation Trust, London, United Kingdom, [8]Embryogenesis Assisted Conception Unit, Athens, Greece, [9]Reprogenetics,, Livingston, NJ, United States.

PGD, an established reproductive alternative for couples with high-risk of transmitting a monogenic disorder, currently involves PCR-based methods. PCR protocols must be robust, sensitive and highly accurate, completely precluding misdiagnosis. Misdiagnosis can be adverse (affected pregnancy/baby) or benign. The twelve adverse misdiagnoses reported to the ESHRE PGD-Consortium are likely an underestimate. This study assessed validity, diagnostic value and accuracy of PCR-based PGD, through re-analysis of untransferred embryos from monogenic-PGD cycles. Data from 7 centres included: disease, embryology, assay type (singleplex/multiplex, one- or two-cell biopsy), genotype concordance at PGD and follow-up. Reasons for discordance included ADO, contamination, mosaic embryo, other. Data from 1352 untransferred embryos was analysed for: sensitivity (Se), specificity (Sp), false negative (FN) and positive (FP) rates, Negative (NPV) and Positive predictive value (PPV), diagnostic odds-ratio (OR). Impact of 1- versus 2-cell biopsy, and type of assay (singleplex versus multiplex) on PGD outcome was also assessed. In addition, frequencies of factors leading to discordant results (FP or FN) were estimated.Diagnostic outcomes were better for multiplex assays versus singleplex (OR 2116 versus 154), and for two-cell versus one-cell biopsy (OR 1036 versus 407). However, Sensitivity and NPV of singleplex/multiplex assays compared to one- or two-cell biopsy were not significantly different, indicating that 2-cell biopsy is not essential for more accurate clinical results. Inherent risks of PCR based PGD methods (ADO, contamination) accounted for 40.68% of discordant results, whereas mocaisism (biological risk) accounted for 57.63%. This study demonstrates the validity, robustness and high diagnostic value of PCR-based PGD.

C16.4

Genetic basis of intrauterine fetal demise: the role of cardiac channelopathies

***A. Ghidoni**[1,2], L. Crotti[1,2,3], D. J. Tester[4], R. Insolia[1,2], W. M. White[5], D. C. Bartos[6], M. L. Will[4], E. J. Velasco[6], J. J. Bair[7], A. Besana[8], A. Pfeufer[9], D. L. Background

Intrauterine fetal demise (IUFD) or stillbirth, accounts for 60% of perinatal mortality, and its incidence is 1:200 pregnancies. Despite extensive postmortem investigations, nearly 50% of IUFDs remain unexplained. Since 10-15% of sudden infant death syndrome (SIDS) cases carry functionally relevant long QT syndrome (LQTS)- or Brugada syndrome (BrS)-associated genetic variants, we hypothesized that sudden arrhythmic death may underlie some IUFD as well.

Methods

Ninety-eight IUFD cases with negative diagnostic work-up (gestational age at death >=15 weeks; average 26.3±8.6 w.) were collected. Molecular screening of *KCNQ1* (LQT1), *KCNH2* (LQT2), *SCN5A* (LQT3, BrS1) genes was performed using DHPLC and sequence analysis on genomic DNA extracted from frozen tissue. Each genetic variant identified was evaluated in ethnically-matched controls and reference databases. Novel variants were expressed in mammalian cells and studied using patch clamp technique.

Results

Four missense mutations, absent in >1,000 controls, were identified in 4 IUFD cases (4%). The genetic variants detected in KCNQ1 (-A283T,-R397W) and in the 1b splicing-isoform of KCNH2 (-R25W) were associated with markedly reduced I_{Ks} and I_{Kr} current respectively, consistent with in utero LQTS type 1 and 2. The mutation identified on SCN5A (-T220I), induced a significant reduction in the late I_{Na} current, consistent with a BrS phenotype.

Conclusions

This study represents the largest cohort of stillbirths in which a molecular autopsy was performed. The results of this study highlight that 4% of unexplained fetal demise may be due to life-threatening arrhythmias secondary to underlying cardiac channelopathies, as LQTS or BrS.

C16.5

Metabolic reprogramming of the epigenome by intrauterine exposure to gestational diabetes

***N. El Hajj**[1], G. Pliushch[1], E. Schneider[1], M. Dittrich[2], T. Müller[2], M. Korenkov[3], M. Aretz[4], U. Zechner[5], H. Lehnen[4], T. Haaf[1];*
[1]Institute of Human Genetics, Julius Maximilians University, Wuerzburg, Germany, [2]Department of Bioinformatics, Julius Maximilians University, Wuerzburg, Germany, [3]Teaching Hospital, Klinikum Werra-Meissner, Eschwege, Germany, [4]Städtische Kliniken, Mönchengladbach, Germany, [5]Institute of Human Genetics, University Medical Center, Mainz, Germany.

The offspring of women with gestational diabetes mellitus (GDM) are at greater risk of developing metabolic disorders later in life. Epigenetic processes such as DNA methylation are primary candidates when searching for mechanisms that can stably modulate gene expression and metabolic pathways due to fetal overnutrition. Umbilical cord blood and placenta tissue were obtained from 88 newborns of mothers with dietetically treated GDM, 98 with insulin-dependent GDM and 65 without GDM. Bisulfite pyrosequencing was used to study the methylation levels of seven imprinted genes involved in pre- and postnatal growth, four genes involved in energy metabolism, one anti-inflammatory gene, one tumor suppressor gene and one pluripotency gene. In addition, we examined global DNA methylation of the ALU, LINE1 and alpha-satellite repeat families. The maternally imprinted MEST gene and the non-imprinted glucocorticoid receptor NR3C1 gene as well as ALU repeats showed significantly decreased methylation levels in both GDM groups, compared with controls, in both analyzed tissues. Decreased blood MEST methylation was also observed in adults with severe obesity, compared with normal-weight controls. The fact that two of 14 analyzed genes and ALU repeats showed significant hypomethylation in newborns of GDM mothers suggests that the effects are minor (in the order of several percentage points) but widespread. Epigenetic changes in children exposed to a hypergylcemic intrauterine environment provide a molecular link between GDM and life-long predisposition to metabolic disorders. Overall our results support the idea that adverse early life conditions can have long-term effects on the epigenome and phenotypic consequences.

C16.6

SPOC1 is involved in meiotic sex chromosome inactivation (MSCI)

C. Nelkenbrecher[1], *A. Bördlein*[1], *S. Lukassen*[1], *S. Wolfshöfer*[1], *A. Fitzner*[1], *A. Ekici*[1], *H. Scherthan*[2], *A. Winterpacht*[1];
[1]*Institute of Human Genetics, Friedrich-Alexander-University, Erlangen, Germany,* [2]*Bundeswehr Institute of Radiobiology affiliated to the University of Ulm, Munich, Germany.*

Meiotic sex chromosome inactivation (MSCI) and meiotic silencing of unsynapsed chromatin (MSUC) are two barely understood mechanisms responsible for transcriptional silencing of unsynapsed chromatin during male meiosis. It has been shown that both mechanisms are essential for normal spermatogenesis and fertility. Recently, we identified SPOC1 (PHF13) as a novel gene whose expression is negatively correlated with the survival time in patients with ovarian cancer. SPOC1 associates dynamically with chromatin in cell lines (probably via H3K4me3 binding) and plays a role in chromosome condensation and cell division. We demonstrated that male Spoc1-/- mice show pronounced hypoplasia of the testis with progressive loss of germ cells due to apoptosis in the pachytene stage. Here, we report data of microarray-based gene expression analyses performed with testis tissue from Spoc-/- strains and wild type controls. We identified a chromosome-specific dysregulation of transcripts with a highly significant disproportionate number of X- and Y-linked genes overexpressed in Spoc1-/- tissue. The results were verified using qPCR. Together with the increased apoptosis rate observed during pachytene stage the microarray data strongly suggest an essential function of SPOC1 in meiotic sex chromosome inactivation (MSCI). The formation of the XY-body, the double strand break (DSB) formation/repair, as well as chromosome synapsis seems normal in the knockout testis, which suggests a direct epigenetic effect SPOC1 on X- and Y-linked genes. In conclusion, our data indicate that SPOC1 is a novel factor involved in MSCI, and is essential for the epigenetic control of male germ cell development.

C17.1

The MHC association to celiac disease can be mostly explained by six amino acids in the HLA-DQ heterodimer

J. Gutierrez-Achury[1], *G. Trynka*[1], *K. A. Hunt*[2], *J. Romanos*[1], *C. Wijmenga*[1], *D. van Heel*[2], *P. I. W. de Bakker*[3,4,5];
[1]*Department of Genetics - University Medical Hospital Groningen, Groningen, Netherlands,* [2]*Blizard Institute of Cell and Molecular Science, Barts and The London School of Medicine and Dentistry, London E1 2AT, London, United Kingdom,* [3]*Brigham and Women's Hospital, Boston, MA, United States,* [4]*Broad Institute of Harvard and MIT, Cambridge, MA, United States,* [5]*University Medical Center, Utrecht, Netherlands.*

The major histocompatibility complex (MHC) containing the HLA genes has been associated to immune-related diseases. However, pinpointing the causal variants is challenging due to its characteristic genetic structure. To refine the association signal in HLA in celiac disease we genotyped >10,000 MHC SNPs in 12016 cases and 11920 controls using a custom genotyping array (Immunochip).

We imputed classical HLA-A, B, C, DQA1, DQB1, DRB1, DPA1 and DPB1 alleles and polymorphic amino acids in these genes using a European reference panel. Logistic regression and conditional analysis was used to identify independent associations.

The strongest association was to amino acid 55 in the DQβ1 protomer (x2=9528, df=3, -log(p)=2067), located near the binding groove. Adjusting for the effects of position 55, we found additional associations to positions 57, 203 and 71 in the DQβ1 subunit and to positions 72 and 22 in DQα1. The haplotypes formed by these six positions recapitulate the known risk-conferring effects of the classical DQ2.5 (OR= 10.49), DQ2.2 (OR= 2.02), and DQ8 (OR= 4.4) alleles. After controlling for these HLA-DQ effects, we found 6 other associated variants within HLA-A and HLA-B class I, and in DRB1, DPB1 and DPA1 in class II.

Our results provide a structural basis for the well-known HLA-DQ associations and confirm that six amino acids can explain the bulk of the observed MHC association.

C17.2

Haplotype phasing using next-generation sequencing reads

O. Delaneau[1,2], *J. Zagury*[2], *J. Marchini*[1];
[1]*Department of Statistics, University of Oxford, Oxford, United Kingdom,* [2]*Conservatoire National des Arts et Métiers, Paris, France.*

Next-generation sequencing is now widely used in many studies of human disease and population genetics. Sequencing is still relatively expensive so many studies are collecting low-coverage data that necessitates the use of phasing and imputation methods to call genotypes and haplotypes at polymorphic sites. Sequencing reads carry valuable phase information when spanning two or more heterozygous sites. For example, in the Phase I 1000 Genomes Project data we have found ~33% of the heterozygous sites are covered by phase informative reads. This information is not used by current methods. We have extended SHAPEIT to incorporate the sequencing read information and boost performance. To compare methods and investigate parameters such as coverage, read length and insert size we have carried out an extensive simulation study of sequence read level data using the SFS_code. For example, with 5x paired-end 100bp reads (500bp insert size) using phase-informative reads increases the mean distance between phasing errors from 85.2kb to 94.0kb. The mean switch distance for BEAGLE was much lower at 63.5kb. By adjusting the distributions of read length and insert size performance can be substantially improved. These results indicate the likely benefit of future advances in sequencing technologies. On real data we have achieved similar performance but have found necessary to carefully account for poorly mapped reads and poor calibration of base qualities. Overall our results highlight the gains that can be achieved by using phase-informative reads when estimating haplotypes from next-generation sequence data.

C17.3

Bayesian multivariate phenotype modeling for genome-wide association studies.

V. Iotchkova[1], *J. Marchini*[1], *T. Spector*[2], *C. Gieger*[3], *W. Ouwehand*[4], *N. Soranzo*[4];
[1]*University of Oxford, Oxford, United Kingdom,* [2]*Department of Twin Research & Genetic Epidemiology, King's College, London, United Kingdom,* [3]*Institute of Epidemiology, Helmholtz Zentrum München, Neuherberg, Germany,* [4]*Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom.*

The majority of genome-wide association studies have been carried out using a single binary or single quantitative trait as the phenotype of interest. For many traits several potential phenotypes may be available so it is natural to ask the question of how best to test for association in the presence of multiple phenotypes. We have developed a Bayesian model averaging approach with sparsity inducing priors that allow the set of phenotypes to be partitioned into an associated and un-associated set. In this way we combine both model comparison and model selection. Additional properties are that we allow for correlations between the residuals of both the associated and un-associated phenotypes and allow for multiple cohorts to be analysed together. We have shown using simulated data that these methods lead to an increase in power to detect effects, over and above using single phenotype analysis, and are able to accurately uncover the true set of associated phenotypes. We will present results from a genome-wide association of eight hematological parameters collected on the TwinsUK, KORA and UKBS Common Control collection.

C17.4

Case-control maximum weighted bipartite matching in genome wide association studies

A. Lacour[1], *C. Herold*[1], *D. Drichel*[1], *T. Vaitsiakhovich*[2], *V. Schüller*[2], *T. Becker*[1,2];
[1]*German Center for Neurodegenerative Diseases (DZNE), Bonn, Germany,* [2]*Institute for Medical Biometry, Informatics and Epidemiology, University of Bonn, Bonn, Germany.*

Population stratification in samples of genome wide association studies give rise to large obliterations in the results of statistical tests. In order to correct for stratification effects we have implemented a pairwise case--control matching that is based on the identity-by-state matrix. We obtain a ‚maximum weighted bipartite matching' by making use of an improved Kuhn-Munkres „hungarian" algorithm which solves the assignment problem of weighted bypartite graphs in polynomial time.

A quality control on the matched pairs as well as a rematching of residual sample elements makes sure that we do not loose power due to reducing the sample. In this way, the pairwise matching is extended to tiny clusters with at least one case and one control. Association P-values are obtained by within cluster case-control permutation.

The matching can be performed both genome-wide and window-wise (‚localized matching'). The latter will be applied to the analyses of rare variants, where one would expect that the amount of stratification vary according to

genomic location.
As it turns out from simulation studies the statistical niveau is maintained: local window sizes of a few thousand SNPs are enough to guarantee identification of strata. Thus, our method leads to an increase of power and simultaneously to a reduced false-positive rate in simulations compared to unstratified analyses. As a byproduct, our implementation strongly outperforms common covariate approaches based on multidimensional scaling in runtime, and makes genome-wide application possible. Our method for stratified analyses is implemented in the genome-wide interaction analysis software INTERSNP.

C17.5

Variants in exons and in transcription factors affect gene expression in trans

A. Kreimer[1], *I. Pe'er*[2];
[1]*Department of Biomedical Informatics, Columbia University, New York, NY, United States,* [2]*Department of Computer Science, Columbia University, New York, NY, United States.*

In recent years many genetic variants have been found to be associated with gene expression (eSNPs). However, unraveling the causal variants and the regulatory mechanisms by which they act is still limited. Here we present a computational framework to study *trans*-eSNPs, integrating SNPs that are fully ascertained from sequencing data along with publicly available RNA-seq for 50 Yoruban samples. We focus on pairs of eSNP located within a source gene: anywhere along the span of a Transcription Factor (TF) or within any known exon. We map the source and its *in trans* target onto a Protein-Protein Interaction (PPI) network and study their topological properties.
When considering pairs of exon-source with their corresponding eQTL targets, the more likely their association, the closer they are within the PPI network and the higher the rank of target. These effects are significantly different than chance expectation, as demonstrated by randomly permuted data. These results suggest a mechanism for *trans* regulation by coding variation, thereby pinpointing the causal SNPs.
In addition, the more likely is the association of a TF source eSNP to its target, the higher is its rank. These results pinpoint a causal SNP within a TF and suggest a global property of TF sources as hubs in the PPI, even more so than other TFs. The targets of eSNP TFs are enriched for proteins sorted to intracellular membrane bounded organelles.

C17.6

eQTL mapping in 5,300 blood samples reveals downstream pathways in non-hematological traits

Genome-wide association studies (GWAS) have revealed many SNPs that are associated with complex traits. The next challenge is to identify the functional consequences of these variants. To systematically map these downstream effects, we used expression quantitative trait locus mapping and meta-analysis to identify cis-eQTLs (distance between SNP and mid-probe position < 5Mb) and trans-eQTLs in a cohort of 5,311 peripheral blood samples across seven independent cohorts. When confining our analysis to 4,500 SNPs that are known to be associated with complex traits and diseases, we detected over 1,000 SNPs (24%) with trans-eQTL effects (FDR 0.05) and over 600 SNPs (14%) with both cis and trans-eQTL effects on at least one gene.
Although we studied peripheral blood (?leukocytes) and identified many plausible downstream effects for hematological and immune-related traits, we also detected significant trans-eQTLs for other traits as well. For example, a SNP (rs174550) in FADS1_a gene known to affect lipid and glucose levels_showed significant association in trans with LDLR gene expression levels (p-value: 4.27*10-14), and we furthermore observed a significant correlation between LDLR gene expression and phospholipid levels. When relaxing the FDR to 0.5, we also observed trans effects on two additional genes involved in cholesterol metabolism (INSIG1 and TLE3).
GWAS meta-analyses have revealed a substantial amount of previously unknown biology. Our results indicate that a meta-analysis of eQTL datasets is equally promising, and can reveal downstream effects for genetic variants that are associated with a wide range of complex traits.

Cantú syndrome, also known as hypertrichotic osteochondrodysplasia, is characterized by congenital hypertrichosis, characteristic facial features and cardiac defects. Cantú syndrome is an autosomal dominant disorder with a thus far unknown genetic cause. We used trio-based exome sequencing to detect candidate de novo variants in a selected patient with Cantú syndrome and his healthy parents. We identified a de novo missense mutation in a subunit of a potassium channel. Subsequent sequencing of the candidate gene in additional cases was performed to confirm the initial findings. Sanger sequencing revealed heterozygous missense mutations in the same gene in 13 out of 15 cases. The mutations had occurred de novo in all 7 cases where genetic material from both parents was available. In one male Cantú patient, the mutation was inherited from an affected mother, providing further support for causality of this gene in Cantú syndrome. We built a molecular model to gain insight on the effect of the mutations on protein structure. All mutations affect residues in or close to the transmembrane part of the protein. Using patch clamp experiments we show that the mutations in the potassium channel reduce ATP-mediated inhibition of this channel. Our findings may have direct implications for the treatment of Cantú patients because the channel is a known pharmaceutical target.

C18.2

PNPLA1 mutations cause autosomal recessive congenital ichthyosis in golden retriever dogs and humans

Ichthyoses comprise a heterogeneous group of genodermatoses characterized by abnormal desquamation over the whole body, for which the genetic causes of several human forms remain unknown. We used the spontaneous dog model to perform a genome-wide association study in the golden retriever breed, which is affected by a lamellar ichthyosis resembling human autosomal recessive congenital ichthyoses (ARCI). We identified a new gene, PNPLA1, in which a homozygous indel mutation leads to a premature stop codon in all affected golden retriever dogs. We then found one missense and one nonsense mutation in the catalytic domain of the orthologous human gene in six ARCI patients from two families. Further experiments highlighted the importance of PNPLA1 in the formation of the epidermal lipid barrier. In addition to the identification of a novel gene in human ichthyoses, these results provide insights into the localisation and the function of this yet uncharacterized member of the PNPLA protein family.

C18.3

Mutations in FKBP14 cause a variant of Ehlers-Danlos syndrome with progressive kyphoscoliosis, myopathy and hearing loss

We report on an autosomal recessive variant of Ehlers-Danlos syndrome (EDS) characterized by severe muscle hypotonia at birth, progressive scoliosis, joint hypermobility, hyperelastic skin, myopathy, sensorineural hearing impairment and normal pyridinoline excretion in urine. Clinically the disorder shares many features with the kyphoscoliotic type of EDS (EDS VIA) and Ullrich congenital muscular dystrophy. Linkage analysis in a large Tyrolean kindred identified a homozygous frameshift mutation in FKBP14 in two affected individuals. Based on the cardinal clinical characteristics of the disorder four additional individuals originating from different European countries were identified who carried either homozygous or compound heterozygous mutations in FKBP14. FKBP14 belongs to the family of FK506-binding peptidyl-prolyl cis-trans isomerases (PPIases). ER-resident FKBPs have been suggested to act as folding catalysts by accelerating cis-trans isomerization of peptidyl-prolyl bonds and to act occasionally also as chaperones. We demonstrate that FKBP14 is localized in the endoplasmic reticulum (ER) and that deficiency of FKBP14 leads to enlarged ER cisterns in dermal fibroblasts in vivo. Furthermore, indirect immunofluorescence of FKBP14 deficient fibroblasts indicated an altered assembly of the extracellular matrix in vitro. These findings suggest that a disturbance of protein folding in the ER affecting one or more components of the extracellular matrix might cause the generalized connective tissue involvement in this disorder. FKBP14 mutation analysis should be considered in all individuals with apparent kyphoscoliotic type of EDS and normal urinary pyridinoline excretion, in particular in conjunction with sensorineural hearing impairment.

C18.4

Homozygosity mapping and candidate prioritization identify mutations, missed by whole-exome sequencing, in SMOC2, causing major dental developmental defects

***A. Bloch-Zupan**[1,2,3], X. Jamet[1,2], C. Etard[4], V. Laugel[3], J. Muller[3], V. Geoffroy[3], J. Strauss[5], V. Pelletier[6], V. Marion[7], O. Poch[3], U. Strahle[4], C. Stoetzel[7], H. Dollfus[7,6];*

Inherited dental malformations constitute a clinically and genetically heterogeneous group of disorders. Here, we report on a severe unique dental phenotype that results in dentin dysplasia associated with major microdontia in the primary dentition, oligodontia in the permanent dentition, teeth shape/size abnormalities and thin enamel in a highly consanguineous family. Classical homozygosity mapping (GeneChip Human 250K SNP Affymetrix) revealed a unique zone on 6q27-ter containing 70 genes. The two affected children were found to carry a homozygous mutation at the exon 1 /intron border (c.84+1G>T) in the canonical-splice donor site of intron 1 of SMOC2 gene coding for the SPARC related modular calcium binding 2 matrix protein. The parents of both affected children were heterozygous for this mutation. The SMOC family is well conserved through evolution. Smoc2 gene is indeed expressed throughout mouse odontogenesis. Knockdown of smoc2 in zebrafish showed pharyngeal teeth that had abnormalities reminiscent of the human phenotype. Moreover, smoc2 depletion in zebrafish affected also the expression of three major odontogenesis genes: dlx2, bmp2, and pitx2.
The ultimate proof through whole exome sequencing failed to reveal the mutation because of insufficient coverage of the GC rich region containing the disease causative mutation !

C18.5

Mutations in ROGDI cause epileptic encephalopathy and amelogenesis imperfecta (Kohlschütter-Tönz syndrome)

Kohlschütter-Tönz syndrome (KTS) is an autosomal recessive disease characterized by the combination of epilepsy, psychomotor regression and enamel defects. The molecular basis has not yet been elucidated. Here we report that KTS is caused by mutations in ROGDI. Using a combination of autozygosity mapping and exome sequencing we identified a homozygous frameshift deletion c.229_230del (p.Leu77Alafs*64) in ROGDI in two affected individuals from a consanguineous family. Molecular studies in two additional individuals with KTS from two unrelated Austrian and Swiss families revealed homozygosity for a nonsense-mutation c.286C>T (p.Gln96*), and compound heterozygosity for the splice site mutations c.531+5G>C and c.532-2A>T in ROGDI, respectively. The latter mutation was also found heterozygous in the mother of the Swiss affected individual in whom KTS was reported for the first time in 1974. ROGDI is highly expressed throughout the brain and other organs but its function is largely unknown. Possible interactions with DISC1, a protein involved in diverse cytoskeletal functions, have been suggested. Our finding that ROGDI mutations cause KTS indicates that the protein product of this gene plays an important role in neuronal development as well as amelogenesis.

C18.6

Mutations in GRIP1 cause Fraser syndrome

*M. J. Vogel[1], P. van Zon[1], L. Brueton[2], M. Gijzen[1], M. C. van Tuil[1], D. Schanze[3], A. Kariminejad[4], S. Ghaderi-Sohi[4], E. Blair[5], M. Zenker[3], P. J. Scambler[6], H. Ploos van Amstel[1], **M. M. van Haelst**[1,7];*

[7]*Section of Genomic Medicine, Imperial College London, London, United Kingdom.*

Fraser syndrome (FS) is an autosomal recessive malformation syndrome characterized by cryptophthalmos, syndactyly and urogenital defects. Thus far, mutations in *FRAS1* and *FREM2* have been identified as a cause of FS. Both *FRAS1* and *FREM2* encode extracellular matrix proteins that are essential for the adhesion between epidermal basement membrane and the underlying dermal connective tissues during embryonic development. Mutations in murine *Grip1*, which encodes a scaffolding protein that interacts with Fras1/Frem proteins, result in FS-like defects in mice. We therefore tested *GRIP1* for genetic variants in FS families that did not have mutations in *FRAS1* and *FREM2*. In three unrelated families *GRIP1* mutations were found to segregate with the disease in an autosomal recessive manner (donor splice site mutation NM_021150.3:c.2113+1G>C in two families and a 4-bp deletion, NM_021150.3:c.1181_1184del in the third). RT-PCR analysis of the *GRIP1* mRNA showed that the c.2113+1G>C splice mutation causes skipping of exon 17 leading to a frame shift and a premature stop of translation.

The FS phenotype of the three probands presented here appears to be indistinguishable from the phenotype that results from mutations in *FRAS1* or *FREM2*. This is in line with the assumption that Fras1, Frem2 and Grip1 are indispensable for the integrity of the Fras1/Frem protein complex, and that lack of one of the components leads to a defective complex.

We conclude that mutations in *GRIP1* cause classic FS in humans. Our findings expand the possibilities for diagnostic testing, carrier testing and early prenatal diagnosis for FS patients and their families.

P01. 01. Genetic counseling, including Psychosocial aspects, Genetics education, Genetic services, and Public policy

P01.01

Access to assessment of familial cancer risk by people from minority ethnic communities

A. M. Allford[1], *C. Lewis*[1], *N. Qureshi*[2], *J. Kai*[2];
[1]*Genetic Alliance UK, London, United Kingdom,* [2]*Division of Primary Care, University of Nottingham, Nottingham, United Kingdom.*

Background: Patients from minority ethnic groups diagnosed with, or are at risk of, cancer with a genetic component appear less likely to access screening and other services to assess their higher level of risk than the mainstream population in the UK.

Aim: To explore why people from minority ethnic groups with a significant family history of cancer are under-represented in NHS clinical genetics services to inform interventions and service development to improve quality of care, and review and dissemination of findings at stakeholder and community levels.

Methods: Qualitative study using semi-structured interviews and focus groups with: patients with direct experience of familial cancer risk assessment; and community members from Black Caribbean, South Asian, and White Irish communities with, or at familial risk of breast and ovarian, bowel, and prostate cancer; and clinical genetics and other key NHS staff. Transcripts were analysed using constant comparison of data and processes for validation and feedback with respondents.

Results: Data were generated with a purposeful sample of 58 respondents (15 patients, 20 community members, 23 health and other professionals). Some findings appeared common to all patients, but were amplified for people from minority ethnic communities, for example in relation to the challenges of sharing information and decision-making within families about cancer and genetic risk. Factors further preventing people being empowered to negotiate health services effectively, obtain appropriate referral or further assessment included: language barriers and cultural sensitivities relating to stigma; accessibility of family medical histories; and a non-directive emphasis in genetic counselling.

P01.02

Applying the Estonian Biobank to estimate the potential impact of genomic testing

L. Leitsalu-Moynihan[1], *T. Haller*[1], *K. Fischer*[1], *K. Läll*[2], *P. Ng*[1], *A. Metspalu*[1,3,4];
[1]*Estonian Genome Center, University of Tartu, Tartu, Estonia,* [2]*University of Tartu, Tartu, Estonia,* [3]*Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia,* [4]*Estonian Biocentre, Tartu, Estonia.*

The Estonian Biobank is a population-based biobank of the Estonian Genome Center of the University of Tartu with genotypic, phenotypic, and health information for over 51,000 participants aged 18 years and over. The age, sex, and geographical distribution of the cohort reflects the structure of the Estonian adult population. Besides promoting the development of genetic research, collecting health and genetic information from the Estonian population, the genome center aims to use the collected biobank data and results of associated genetic research to improve public health. The health information has been collected by medical personnel with access to the electronic health records. The health data are expanded periodically through linking to national registries as well as through follow-up.

By having the genotypic and longitudinally collected health data for 5% of the Estonian adult population it is possible to estimate the impact of the genomic information on public health. We attempt to present what portion of the population would benefit from a specific genomic test for an actionable disease by studying the population allele frequencies of the markers associated with the disease and the impact of these markers in the context of the predictive value. This analysis can be done for a large number of diseases. We present it for the type 2 diabetes, hypertension, lactose intolerance, glaucoma, age related macular degeneration to demonstrate how a biobank with a comprehensive database can be applied to estimate the impact of genomic information. This approach is expected to be superior to the simulation studies.

P01.03

Reasons to participate to a biobank study: a systematic review

H. L. Nobile[1,2], *K. Thys*[2], *E. Vermeulen*[3,4], *M. M. Bergmann*[1], *P. Borry*[2];
[1]*German Institute for Human Nutrition, Potsdam-Rehbrücke, Germany,* [2]*K.U.Leuven, Leuven, Belgium,* [3]*VU University Medical Centre, Amsterdam, Netherlands,* [4]*The Netherlands Cancer Institute, Amsterdam, Netherlands.*

The implementation of cohort biobank studies is intrinsically dependent on the successful recruitment of participants. Studies have shown that the decision to enroll is only partly influenced by the information provided during recruitment and mainly relies on individual attitudes and motivations. Cost-benefit analyses (which include the potential benefit of receiving information about one's health) also play a significant role in the decision-making process. Whether the (potential) participant' perception of benefit corresponds to what the researchers communicate in the informed consent procedure is a question that has received increased attention in the last years. Empirical studies addressing individuals' motivations to enroll have been implemented in different biobank settings. For the scope of this review, we focus on the motivations expressed by apparently healthy and legally autonomous participants who actually took part to a biobank study.

To this end, three literature databases (PudMed, Embase and Web of Science) as well as Google Scholar have been searched with standardized keywords. To guarantee its systematic approach, the search had been done twice using the same strings by two different teams of authors. 157 articles considered relevant have then been read independently by four of the authors to decide on their inclusion in the review. The selected articles have been analyzed and their content has been coded and organized by themes independently by two of the authors. The outcome of this work is to provide a comprehensive overview of the reasons to participate to biobank studies as they appear in the literature up to now.

P01.04

Respect of guidelines for breast and ovary surveillance and management in women with a BRCA mutation: a french study

F. Coron[1,2], *A. Damette*[3], *A. Cueff*[2], *C. Populaire*[3], *C. Rambaud*[1], *C. Cassini*[1], *A. Birot*[1], *F. Debomy*[1], *S. Gauthier*[1], *P. Fumoleau*[4], *X. Pivot*[5], *C. Loustalot*[2], *J. Sautière*[6], *M. Collonge-Rame*[3], *L. Faivre*[1,2];
[1]*Centre de génétique, Hopital d'Enfants, Dijon, France,* [2]*Service d'oncogénétique, Centre G.F. Leclerc, Dijon, France,* [3]*Service d'oncogénétique, Besançon, France,* [4]*Service d'oncologie, Centre G.F. Leclerc, Dijon, France,* [5]*Service d'oncologie, Hôpital Minjoz, Besançon, France,* [6]*Service de gynécologie, Besançon, France.*

Pilot follow-up studies in people with a genetic predisposition for cancers, were created in France in 2009. In this context, a specific database was set up for the follow-up of these patients in two French regions. Observance of surveillance recommendations for breast and ovary cancer in patients with a BRCA mutation was studied using the collected data.

The patients were at least thirty years old and had known their genetic status for at least 2 years. Concerning the breast, poor observance was defined as an interval of more than 18 months between breast follow-up examinations. Concerning ovary cancer, poor observance was defined as not having ovariectomy after the age of 50 years. The 2 centers followed 248 women with a BRCA mutation: 232 from 30 to 50 years, and 116 over 50 years.

Prophylactic mastectomy was performed in 11/232 women (5%); nine had already had cancer, and two were asymptomatic. Breast follow-up data were obtained for 101/232 women; 62% of patients followed the guidelines closely and 84% had a follow-up MRI. Ovary follow-up data were available for 73/116 women: only 6/73 of the women over 50 (8%) did not undergo adnexectomy.

In conclusion, the vast majority of women with a BRCA mutation followed the recommendations concerning management of risk of ovarian cancer. 1/3 of patients had insufficiently regular breast surveillance. These results show the importance of setting up pilot studies to improve the management of people with a genetic predisposition for cancer. Data collection is continuing.

P01.05

What do counselees know about (hereditary) breast cancer? - And which role can an Interactive Personal Health Record (IPHR) have in this?

S. J. R. Joosten, *E. van der Looij*, *L. Spruijt*;
Department of Human Genetics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

In order to enhance the realistic expectations and participation during genetic counseling we developed an IPHR.

To study the effects of the IPHR we developed a study which will be conducted in four phases. In the first phase of this study we studied how informed counselees, referred for breast cancer (BC), are prior to their first consult at

the Cancer Genetic Clinic.
A total of 49 counselees completed a questionnaire on topics about knowledge, risk perception (RP), Perceived Personal Control (PPC), and anxiety for BC (Cancer Worry Scale).
The general risk for BC is overestimated by 63% of all counselees (mean 27.8%; SD 21.2), and the chance on having a BRCA1/2 mutation by 84% of the counselees with no mutation in the family (mean 44.2%; SD26.1). The counselees also show a low baseline knowledge level (BKL)(46%). Analysis between different groups of counselees showed that the low educated counselees (LEC)have a poorer RP, and BKL than high educated counselees (HEC). 81% of the LEC overestimated the general risk for BC, and the LEC have a significant lower score on knowledge (38%) than HEC (62%)(p<0.001).
The counselees have no low scores on the PPC-questionnaire (mean score 10.5) and were not anxious (mean score 30).
Counselees, especially the low educated, have a poor RP and BKL prior to their first genetic consult. We expect that the implementation of the IPHR will have a positive effect on RP and BKL, which results in a more active role of the counselee.

P01.06

Group Genetic Counseling for Cardiomyopathy patients is well accepted

E. Otten[1], *E. Birnie*[1], *A. V. Ranchor*[2], *I. M. van Langen*[1];
[1]Clinical Genetics section, Department of Genetics, University Medical Center Groningen, University of Groningen, Groningen, Netherlands, [2]Department of Health Psychology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands.

Background: Group Genetic Counseling (GGC) may have benefits for counselees and counselors (more information, psychosocial support, increased efficiency), although its use has not yet been reported in cardiogenetics. We therefore set up GGC sessions for cardiomyopathy index patients.
Aim: To see whether the quality of care provided by GGC is acceptable to counselees.
Methods: GGC was offered in regional hospitals with few referrals of cardiomyopathy patients to our academic center in the past years. Sessions were led by two counselors: a clinical genetics expert and a group leader. Patients completed questionnaires before and after counseling, measuring sociodemographics, Personal Perceived Control (PPC), State-Trait-Anxiety-Inventory (STAI), Clinical Genetics Satisfaction Indicator, etc.
Results: 53 patients and 36 relatives attended a course of eight GGC sessions. PPC scores (range 0-2) increased in 81% of patients, mean item score (SD): before 0.92 (0.54), after 1.29 (0.38). STAI scores (range 1-4) decreased in 51% of patients, mean item score (SD): before 1.89 (0.58), after 1.68 (0.49). Median score of the Clinical Genetics Satisfaction Indicator (range 1-5) was 4.93.
Conclusion: This is the first report of GGC being used for cardiomyopathy patients. On average, personal perceived control increased and anxiety was lowered. Mean changes in PPC and STAI were comparable to reports for group and individual counseling in oncogenetics. Satisfaction scores were high, patients reported their questions were answered during the sessions and they received no undesired information. Our study indicates GGC is well accepted. We will next investigate whether GGC is more efficient than individual counseling.

P01.07

Progress of the Clinical Utility Gene Card initiative

A. Dierking, *J. Schmidtke*;
Institute of Human Genetics, Hannover Medical School, Hannover, Germany.

As of January 2011, the Clinical Utility Gene Card (CUGC) project receives support by EuroGentest 2 and the European Society of Human Genetics. Based on this support the CUGC initiative can be continued, including the publication, in spring 2012, of the first set of guidelines having undergone updating.
CUGCs are disease-specific guidelines authored by international expert groups. Based on the ACCE framework they are dealing with the risks and benefits of the application of genetic tests in the clinical setting. Each document represents a balanced summary of the analytical and clinical validity, the clinical utility and cost-benefit issues. CUGCs offer quick guidance to all stakeholders, including clinicians, clinical geneticists, referrers, service providers and payers. Each CUGC is peer-reviewed and published by the European Journal of Human Genetics. CUGCs are also freely available on the websites of EuroGentest, the European Society of Human Genetics and Orphanet.
The feedback from the scientific community and the CUGC download rates are promising: the European Journal of Human Genetics counted between 600 and 1,500 downloads, with an average above 1,000, per gene card and year. From 2011 to 2013, 300 new CUGCs are planned to be established. To ensure that all published documents reflect the state-of-the-art, all published CUGCs are annually revised.

P01.08

Developing a genetics-genomics education framework for midwives: a consensus approach using individual/family stories

E. T. Tonkin[1], *M. Kirk*[1], *H. Skirton*[2];
[1]NHS National Genetics Education and Development Centre, University of Glamorgan, Pontypridd, United Kingdom, [2]Plymouth University, Plymouth, United Kingdom.

Competence frameworks in genetics exist for UK health professionals and include a combined framework for nurses, midwives and health-visitors. As part of a review of this framework, the development of a set of competences specifically for the midwifery profession was seen as essential. A national consensus meeting was held involving midwives in practice and management, educators, policy makers and lay representation (n=18). Electronic voting was used to capture opinions anonymously and stimulate discussion.
All but one attendee agreed that “good midwifery care is currently compromised by midwives’ level of genetic competence”. Individual/family and professional stories illustrating a range of experiences and conditions were reviewed and the content mapped to the original framework. Attendees looked for topics missing from the framework and considered whether any of the existing statements should be re-focused. Eight themes [ongoing-care, advocacy, multi-professional team, listening, timeliness, client knowledge, broad knowledge and key indicators (of disease)] were identified and, following discussion, voted on. All themes were to be included within existing statements.
Seven statements now set out the minimum level of competence that should be required of all midwives in the UK at the point of registration. With learning outcomes aligned to the stages of pre-registration training, and practice indicators, this framework will provide guidance to educators, practitioners and managers. The importance of genomics within healthcare is explicit and anticipating that the implementation of new knowledge and technology will impact the midwifery role, the team have endeavoured to ‘future-proof’ the framework.

P01.09

Attitudes of health care professionals towards carrier screening for Cystic Fibrosis. A review of the literature

S. Janssens[1], *A. De Paepe*[1], *P. Borry*[2];
[1]Centre for Medical Genetics, Ghent, Belgium, [2]Center for Biomedical Ethics and Law, Leuven, Belgium.

Recently, commercial companies have started to offer preconceptional carrier tests directly to consumers. This increasing commercial offer creates the background which makes reflection necessary about the desirability to offer population carrier screening in the healthcare system. A positive attitude of potential providers is vital to the success of a screening program.
Therefore, a literature review of the attitudes of healthcare professionals, focused on the attitudes towards carrier screening for Cystic Fibrosis (CF), was performed.
The databases Pubmed, Web of Science, as well as the interface Google Scholar, were searched for the period 1990-2011. Studies were selected if they were published in a peer reviewed journal in English and described the attitudes of potential providers toward carrier screening. Eleven studies were retrieved describing the attitudes toward carrier screening for CF. Studies reported attitudes toward the best time for screening, the best setting to offer screening, the willingness to be involved in a screening program and the concerns about offering screening. Ten papers described a general attitude toward carrier screening.
We can conclude that health care providers are willing to be involved in a carrier screening program, but there is need for appropriate education as well as adequate support. The prospect of an increasing number of genetic disorders for which screening becomes possible and the potential increasing demand for such screening in the future calls the need for further debate on the desirability of carrier screening, and relevant questions such as the conditions screened, the providers involved, the information provision and counseling.

P01.10

The views of CF patient’s parents on genetic testing

V. L. Izhevskaya[1], *L. Y. Ivanova*[2], *E. A. Borzov*[1], *I. V. Zhuravleva*[2], *E. K. Ginter*[1];
[1]Research centre for medical genetics, Moscow, Russian Federation, [2]Institute of Sociology of Russian Academy of Sciences, Moscow, Russian Federation.

Mandatory newborn screening for CF is spent in Russia since 2006. To estimate patient's parents opinion concerning genetic testing we have spent questioning 93 CF patient's parents.Majority of parents (90 %) have learnt about hereditary character of their child disease from the pediatrician, only 64 % of them have been referred to geneticist, and 49 % have been held DNA testing. However 90% respondents have consider, that they have understood the information about repeated genetic risk for CF. However only 51% of them could correctly specify the value of recurrence risk of CF, and only 37 % of them could correctly attribute a risk category. Majority of respondents (82%) have consider that prenatal testing is very useful procedure and 65% of them wanted to use it. Only 1.1 % of respondents have answered that they didn't want to terminate the CF foetus pregnancy. Acceptance of prenatal testing was correlated with the age and educational level of woman, whether or not she was referred for genetic counselling, and whether or not she has received an explanation about repeated risk.

P01.11

Diagnostic and counselling dilemmas in newborn screening for cystic fibrosis

V. Krulišová[1], A. Holubová[1], M. Balaščaková[1], V. Skalická[2], T. Piskáčková[1], J. Bartošová[2], L. Fila[3], V. Vávrová[2], P. Dejmek[4], ***M. Macek Jr.***[1], *F. Votava[4];*
[1]Department of Biology and Medical Genetics, Charles University – 2nd Faculty of Medicine and Faculty Hospital Motol, Prague, Czech Republic, [2]Department of Pediatrics, Charles University – 2nd Faculty of Medicine and Faculty Hospiatl Motol, Prague, Czech Republic, [3]Department of Pulmonology, Charles University – 2nd Faculty of Medicine and Faculty Hospital Motol, Prague, Czech Republic, [4]Department of Pediatrics, Charles University – 3rd Faculty of Medicine and Faculty Hospital Kralovske Vinohrady, Prague, Czech Republic, Prague, Czech Republic.

Introduction: Newborn screening (NBS) for cystic fibrosis (CF) has been implemented as a nationwide immunoreactive trypsinogen (IRT)/DNA/IRT scheme in the Czech Republic since X/2009. DNA testing is associated with inherent drawbacks such as detection of infants with atypical mutations resulting in variable phenotypes.

Objectives: We evaluated a clinical status in individuals (from NBS and non-NBS group) carrying either R117H or D1152H allele in trans with another CF-causing mutation and utilized these data for CF-NBS and genetic counselling.

Methods: The Czech CF registry and an "in house" clinical-genetic database were used.

Results: Of 13 individuals with CF-causing mutations/R117H on a 7T background, 6 symptomatic adults (1 suffering from respiratory symptoms (RS), 1 from pancreatitis, 4 with azoospermia) and 1 child with RS were reported before implementation of CF-NBS. 1 adult with unknown clinical status was identified due to cascade screening. 5 infants were identified in CF-NBS without having CF symptoms. There has been no case with CF-causing mutation/R117H on a 5T background yet.

Of 5 individuals with F508del/D1152H genotype, 2 children and 2 adults suffer from RS and 1 adult from pancreatitis and azoospermia. These cases were reported before implementation of CF-NBS and none from CF-NBS, so far.

Conclusions: Although phenotype in individuals with CF-causing mutation/R117H-7T genotype is usually mild, we follow consensus guidelines and monitor infants on a long-term basis. Albeit limited knowledge exists on phenotypes associated with D1152H, this mutation is considered to be CF-causing mutation and long-term follow up in a CF specialist is essential.

P01.12

Genetics and its Implications for Clinical Dental Practice and Education, Report of Panel 3 of the Macy Study: Are Dental Students Prepared?

R. J. Crout[1]*, G. T. Casto[2];*
[1]West Virginia University School of Dentistry, Morgantown, WV, United States, [2]Indian River State College, Fort Pierce, FL, United States.

Objective: In the Report of Panel 3 of the Macy Study, funded by the NIH and the American Dental Education Association "Knowledge, Skills, and Attitudes Required for Oral Health Professionals to Care for Patients with Genetic Conditions" were outlined. The aim of this study is to investigate the genetic knowledge, skills and attitudes of West Virginia University School of Dentistry's (WVU SOD) students utilizing this report as the source for the specific questions.

Methods: All dental students (195) were invited to participate by answering 16, primarily Likert style questions (1= Strongly Agree to 5 =Strongly Disagree). Questions included Knowledge: of genetic transmission; molecular biology of the human genome; principals of population genetics; Skills: to perform a head/neck exam with special attention to signs of major genetic disorders; to recognize when to refer a patient for genetic screening, testing, and counseling; Attitude: to understand the potential for genetics to contribute to the development of new approaches to prevention, diagnosis and treatment.

Results: 89 (45.6%) filled out questionnaires. When it came to Knowledge of transmission, biology of the human genome, principals of population genetics and Skills to perform a head/neck exam and when to refer, 54.2%, 39.7%, 82.4% and 69.1% disagreed respectively. Attitude, however, revealed that 71.0% agreed they understood the potential for genetics to contribute to new approaches of disease.

Conclusion: Although baseline knowledge and skills of the WVU SOD students were lacking, the students recognized this new technology could potentially contribute to new approaches in prevention, diagnosis and treatment.

P01.13

Direct to consumer testing - a review of the available evidence

L. Goldsmith[1]*, L. Jackson[1], H. Skirton[2];*
[1]Plymouth University, Plymouth, United Kingdom, [2]Plymouth University, Taunton, United Kingdom.

As part of the EuroGentest2 project, we are developing European guidelines on direct to consumer testing for potential consumers and health professionals. We conducted a series of systematic reviews focussed on consumers (17 papers), health professionals (four papers) and current recommendations and position statements (11 documents) to inform this process. Findings indicate a low level of awareness of direct-to-consumer genomic testing in both users and some health professionals. Consumers appeared motivated to purchase tests to obtain information to guide their own health management while some wanted to avoid disclosure of genetic risk to health professionals. Potential users expressed concerns about privacy, reliability of genomic tests and the nature of results. Many consumers preferred to discuss the test with a health professional before and after testing, while health professionals expressed concerns for the consumer such as misinterpretation of results and increased anxiety due to perceived risks. In the review of policies, more potential harms than benefits were cited. An area of concern was the overstatement of the actual predictive power or utility of the results. Strong recommendations were made about the need to involve health professionals and to regulate test quality. We conclude that there is public interest in direct-to-consumer genomic tests. However, while consumer autonomy may dictate freedom of choice in undergoing such tests, health services need to ensure that potential benefits are maximised and harms prevented. Further research into the impact of testing and the views of stakeholders is required to implement appropriate regulation, guidelines and education.

P01.14

"It's our DNA, we deserve the right to test!" A qualitative analysis of a petition for the right to access direct-to-consumer genetic testing without the intermediate of a health care professional

Y. Su[1]*, I. C. Otte[2], P. Borry[3], H. C. Howard[2];*
[1]BGI, Beijing, China, [2]University of Basel, Basel, Switzerland, [3]KULeuven, Leuven, Belgium.

As a relatively new model of genetic test provision, the offer of direct-to-consumer (DTC) genetic testing (GT) has fueled a number of scientific, ethical and policy debates. Proponents of DTC GT claim that the benefits of such services include, among others, increased access for consumers, increased genomics education, and added support for consumer autonomy. A few studies have been published regarding the public's view of these services but none have specifically addressed the public's desire for "unrestricted" access to their genomic information. The goal of this study is to increase our understanding of the public's views of accessing GT without the intermediate of a health care professional. We have conducted an exploratory analysis of comments written by individuals who have signed a public online petition initiated by DIYgenomics.org to support "personal access to genetic information" (http://www.thepetitionsite.com/1/mydna/). Of the 522 individuals who have signed the petition to date, 240 individuals have also written comments; these were the focus of our content analysis. Preliminary results reveal that the main themes raised by the petitioners include: i) the notion that each individual "owns" their DNA and ii) that individuals have the right to access information about their DNA; iii) the notion that regulation of DTC GT falls outside of the realm of the government's control; and iv) the belief that involving health care professionals as intermediates provides no added value for consumers. These results contribute to understanding the public's view of DTC GT services and lay the foundation for further research.

P01.15

Genomics and the prevention of antisocial behavior: A comparative ethical analysis

D. Horstkötter[1,2], *R. Berghmans*[1,2], *G. de Wert*[1,2];
[1]Maastricht University, CAPHRI, Maastricht, Netherlands, [2]Centre for Society and Genomics, Nijmegen, Netherlands.

Current research in the genomics (and neurobiology) of antisocial behavior (ASB) trigger great hopes and expectation concerning the development of new forms of early detection of children at risk and of targeted early prevention. Children as young as preschoolers, toddlers and babies are considered the most important target-group of such efforts. While scientific research progresses continuously, it is of great importance to pro-actively consider the social and ethical implications of potential applications. This presentation reflects on this development from an ethical point of view.

It investigates whether and when it may be justified to expect that early detection and prevention is mainly for the good of those identified and intervened upon, what are relevant caveats and dangers and how both are to be balanced. Issues that will be discussed encompass increased support, empowerment and emancipation as well as dangers of stigmatization and labeling, surveillance and repression, privacy concerns, and possible negative impacts on children's development and (self)perception.

However, unlike much other ELSI research, this presentation wants to avoid any kind of gene-exceptionalism. That is, it will argue that from an ethical point of view it is of secondary interest whether future prevention practices are informed by either new genomical or traditional social/psychological findings. Instead, the ethical evaluation should focus on the characteristics, specificities and conditions of use of any measure applied. To this end, the proposed ethical analysis of early prevention practices will be conducted in a comparative way.

P01.16

Poster for ESHG: Comprehensive embryo screening. Results from two focus group studies

K. Hens, *W. J. Dondorp, G. M. W. R. de Wert;*
Maastricht University, Maastricht, Netherlands.

Genetic testing of embryos is done in two contexts. preimplantation genetic diagnosis (PGD) is done when one or both of the prospective parents are known carriers of a genetic disease, be it a Mendelian condition or a chromosomal translocation. Preimplantation genetic screening (PGS) is the screening of embryos from infertile or subfertile couples undergoing IVF to select the embryo which is most likely to lead to a successful pregnancy. The technique of PGS is not standard offered to couples, because it is still uncertain whether it really leads to improving implantation rates. However, with the introduction of microarray technology, and single cell whole genome sequencing, embryos could also be screened for Mendelian disorders, susceptibility genes and potentially non-medical traits. Hence, the aim of PGS may shift from choosing the best embryo for transfer in order to ensure a successful pregnancy, to choosing the embryo most likely to develop into a healthy child, to even selecting the 'best child'. In order to understand the ethical questions arising from the introduction of comprehensive screening techniques in clinical practice, we have conducted two focus group studies. One study, which was performed in October 2011, explored the opinions of top scientists in the field of embryo testing regarding the technical possibilities and associated ethical questions. The other study, performed in March 2012, was conducted with gynecologists and genetic counselors and explored opinions about possible dilemmas and their solutions in IVF practice. This poster presents the major findings and conclusions of the two studies.

P01.17

Predictive genetic testing for Familial Adenomatous Polyposis (FAP) in young children

A. A. Kattentidt, *M. den Heijer, I. van Kessel, A. Wagner;*
Erasmus Medical Centre, Rotterdam, Netherlands.

Objective. Predictive genetic testing for familial adenomatous polyposis (FAP) is routinely offered to children at-risk from the age of 10 years onwards. Because of absence of medical benefits, potential psychosocial harm and respect to the child's autonomy, predictive testing for FAP at younger age is reluctant. As a result, there is a lack of experience in predictive testing of children at the young age.

Patients and methods. We evaluated 13 children from 8 families, tested for an *APC* mutation at the age younger then 10 years (the male to female ratio was 1.6:1; mean age was 6,4 years (2-9 years); 7 APC-carriers and 6 non-carriers). All parents were re-contacted and structural interviewed.

Results. None of the contacted parents regretted the timing of genetic testing. Ten children were tested at the same moment with an older sibling. The main reasons for testing were 1) testing all children in a family at the same moment (4:13); 2) a possibility to prepare a child for future surveillance (3:13); 3) certainty about the future (3:13). According to the parents none of the children showed changes of mental and physical health after testing.

Conclusion. Genetic testing for FAP at a young age is desired by some parents and is experienced as causing no harm. However, the effects of early genetic testing on children and their own experience should be evaluated in future studies.

a.mouravieva@erasmusmc.nl

P01.18

Factors affecting the utilization of genetic counseling services among Arab Israeli women

R. A. Sharkia[1], *S. Allon-Shalev*[2];
[1]Beit-Berl College, Beit-Berl, Israel, [2]Genetic Institute,Emek Medical Center, Afula, Israel.

High rate of consanguineous marriages, underutilization of prenatal diagnosis services and low rate of pregnancy termination of an affected fetus are the main risk factors leading to high prevalence of infant morbidity and mortality in the Israeli Arab community. The purpose of genetic counseling services is to allow the pregnant couple having informed decisions about their pregnancy, by discussion of various diagnostic tests and preventive measures, expected to decrease congenital morbidity rate. The aim of the study was to identify the factors affecting the utilization of genetic counseling services in the „Triangle region" of North Israel, among Arab pregnant women who were referred by their doctors for genetic counseling. In multivariate analysis, identified factors affecting women's utilization of genetic counseling service were level of income, access to service, abortions in the past, attitudes towards genetic counseling and the level of religiosity. Easier access of genetic counseling services, abortions in the past and woman's positive attitudes toward genetic counseling were proved to be significant predictors to utilizing genetic counseling services. On other hand, low level income and the more religious families were the main factors associated with none utilizing genetic counseling services. We recommend developing and strengthening wide-scale community-based genetic counseling service for the Arab population, preferably operated by professionals who are Arab speakers, with the background support and encouragement of religious leaders.

P01.19

Genetic counseling role in historicist middle east cultures

A. Haghighatfard;
Islamic Azad university-science and reasearch branch, Tehran, Islamic Republic of Iran.

Genetic counseling is a process of communication and education that considering expression and transference of genetic disorders. Achieving to this communication is depended to knowledge about culture and traditions of society and psychological situation of consultant. This article is an inspection about social reactions against genetic counseling as a new branch of medical science in historic and historicist Middle East societies and their own cultures.

Public belief to "paternal big family" and "God willing destiny" are two major challenges of genetic counseling in Middle East. In case of paternal big family Middle East people especially Arab tribes of Persian Gulf region believe that familial marriage especially children of two brothers makes stable and honorable family. For example familial marriage rate in Saudi Arabia and Kuwait are 12 times more than Europe. In the other hand belief to "God willing destiny" that is based on some Quran sentences made kind of religious historicism. In this ideology called "Taghdir", no person can predict about illness or healthy of newborn child because it is part of God desigens and theology.

Now Middle East geneticists are facing with public distrust about genetic counseling; also increasing rate of recessive genetic disorders patients and decreasing the gene pool diversity. In the absence of state programs for public education, "perceived personal control" has a completely different definition from European societies. It seems so that spiritual influence of pioneer Muslim clerics and their fatwa (religious decree) could help to improve people's trust to genetic counseling.

P01.20

A comparison study of the practices of genetic counsellors between France and Canada

C. Cordier[1,2,3], *E. Le Boette*[4,2], *M. Edmont*[2,5], *H. Sobol*[6], *M. Voelckel*[2,7];
[1]Dept of Oncology and Haematology, Hospital of Strasbourg, Strasbourg, France, [2]French Association of Genetic Counsellors, Marseille, France, [3]Centre Paul Strauss, Strasbourg,

France, [4]Dept of medical genetic, Hospital of Strasbourg, Strasbourg, France, [5]Dept of genetic, University hospital, Montreal, QC, Canada, [6]Institut Paoli Calmettes, Marseille, France, [7]Dept of medical genetic, Timone's hospital, Marseille, France.

Genetic counsellors are Health Professionals with specialized training and experience in the areas of clinical genetics and counselling. They did work as members of a multi-disciplinary healthcare team that provides genetic services. In France, the profession of genetic counsellor is relatively recent (2005). This profession has been created due to the increasing number of genetic consultations but also face to the decrease of medical professional in this field. About Canada, the profession has been created, for the same reason, since 1985 by a genetic counsellor graduated in the United-states and by the auspices of geneticists who exercise their profession in Canada. Members of different groups (French and Canadian) have received an electronic survey based on their background, the role and the practice of the profession of genetic counsellors in their own country. The questionnaire was sent to the Association of Genetic Counsellors which transmitted it to all the members. Data were collected during the year 2011. We are looking to see if there are major differences in the practice of exercising the profession, but also in the education and in the collaboration established between genetic counsellors and medical geneticist.

P01.21

Genetic education in Brno, Mendel 190

R. Gaillyová[1,2]*, I. Valášková*[1,2]*, P. Kuglík*[1,3]*, R. Veselská*[3]*, J. Relichová*[3]*, O. Dostál*[4]*, M. Macek jr.*[5]*;*
[1]*University Hospital, Brno, Czech Republic,* [2]*Department of Biology, Faculty of Medicine, Masaryk University, Brno, Czech Republic,* [3]*Department of Experimental Biology, , Faculty of Science, Masaryk University, Brno, Czech Republic,* [4]*Mendel Museum, Masaryk University, Brno, Czech Republic,* [5]*Department of Biology and Medical Genetics, Charles University and 2nd Faculty of Medicine, Prague, Czech Republic.*

The Department of Medical Genetics at the University Hospital Brno (www.fnbrno.cz) has besides its core activities (comprising genetic counseling, molecular diagnostics, pre-graduate teaching of medical genetics at the Masaryk and Mendel Universities in Brno) devoted itself to the popularization of medical genetics to the lay public(http://www.mendelmuseum.muni.cz/cz/lekarska-genetika/).

Since 2009 successful series of public lectures, conducted in association with our partner institutions, on various subjects of medical genetics are held at the premises of the St Augustine‘s Abbey - Mendel Museum, i.e. at the place where in between 1843 -1884 Gregor Johann Mendel spent most of his professional live.

Lecture series „Medical Genetics for the Public“ has been linked to the GenEthics project lectures within the Mendel‘s Refectory that are carried out since 2006 (http://www.mendel-museum.com/eng/7lectures/lectures-ref6.htm). Within these series we have covered various domains of genetic counseling, diagnostic methods in medical genetics, significance of genetic diseases and our collaboration with patient organizations. This year‘s series is dedicated to rare diseases and development of the CZ National Plan ec.europa.eu/health/rare_diseases/national_plans/detailed/index_en.htm. Since 2010, this lecture cycle also takes place under the auspices of the Czech Parliament (MP- J. Husák) and the Olga Havel Foundation (www.vdv.cz; Ms. M. Cerná).

In 2012 the Mendel Museum and the Masaryk University will celebrate the 190th Johann Gregor Mendel´s birthday anniversary (July 20) through an event known as “Mendel 190”, within which planned lecture series will be dedicated to his tribute. Associated events will be organized in Prague and at Mendel´s birthplace (www.vrazne.cz). Supported by CZ.2.16/3.1.00/24022 to MM.

Creating an agenda for effective genetic educational strategies: Needs assessment and prioritization in primary care

E. J. F. Houwink[1,2]*, L. Henneman*[1]*, S. J. van Luijk*[3]*, M. Westerneng*[1]*, C. van der Vleuten*[4]*, G. Dinant*[2]*, M. C. Cornel*[1]*;*
[1]*Department of Clinical Genetics, Section Community Genetics, EMGO Institute for Health and Care Rese, Amsterdam, Netherlands,* [2]*School for Public Health and Primary Care, Department of General Practice, Maastricht University, Maastricht, Netherlands,* [3]*Institute for Medical Education, VU University Medical Center, Amsterdam, Netherlands,* [4]*Department of Educational Development and Research, Maastricht University, Maastricht, Netherlands.*

Purpose

General practitioners (GPs) are increasingly expected to deliver genetics services in daily patient care. Education in primary care genetics is considered suboptimal and in urgent need of revision and innovation.

Aims of our study: exploring the role of genetics in primary care and the need for genetics education and prioritization of GPs' genetics education.

Methods

Three types of focus groups were held (n=44): mono-disciplinary groups of GPs and midwives, respectively and multidisciplinary groups composed of a diverse set of experts. Recurrent themes were identified after verbatim transcription and content analysis.

Consecutively, a Delphi consensus procedure was conducted. A purposively selected heterogeneous panel (n=18) of experts participated. Educational needs regarding genetics in general practice in terms of knowledge, skills and attitudes, were rated and ranked in a Top 10.

Results

Four themes emerged from the focus group study: (1) genetics knowledge, (2) family history, (3) ethical dilemmas and psychosocial effects in relation to genetics and (4) insight into the organisation and role of clinical genetics services. These themes reflected a shift in the role of genetics in primary care with implications for education.

The entire Delphi study panel completed all three rounds. Kendall's coefficient of concordance indicated significant agreement regarding the top ten genetic educational needs ($P<0.001$). “Recognising signals potentially indicative of a hereditary component of a disease” was rated highest.

Conclusion

Results help to develop effective genetics educational strategies (including input for case-based education). Enhancement of primary care providers' competences in genetic patient care could actually become possible.

P01.23

Developing best practice guidelines for provision of clinical genetic service - Examples of testing for monogenic subtypes

T. Rigter[1]*, L. Henneman*[1]*, U. Kristoffersson*[2]*, M. C. Cornel*[1]*;*
[1]*VU University Medical Center, EMGO Institute for Health and Care Research, Community Genetics, Amsterdam, Netherlands,* [2]*Lund University Medical Center, Department of Clinical Genetics, Lund, Sweden.*

Introduction: In 2010 the Council of Europe described that “The development of genetics in health care services has a major impact on the organisation of health care, leading to shifting from curative to preventive services, from in-patients to out-patients treatment, from specialised genetic services to genetics as an integral part of general health services.” The responsibilities of expert geneticists, both in laboratory and clinic, will change. Because of this shifting, new guidance on genetic service provision is urgently needed in many countries.

Methods: In Workpackage 8 within Eurogentest2 an expert meeting, questionnaire and online discussion forum were used to develop recommendations which describe the optimal practice and interaction between different parties involved, including:

- (genetic) patients and their families, the users of the services;
- medical professionals such as primary care workers and other non-genetic specialists;
- genetic professionals from clinical and laboratory background.

Results of this ongoing project include a “Temple of genetic services” depicting interactions between different stakeholders in genetic services. Also experiences with testing for monogenic subtypes have been discussed as best practices in an expert meeting. By describing practices of service provision from oncogenetics, cardiogenetics and MODY we hope to show that different fields ask for different approaches and have their own opportunities and threats when it comes to good genetic service provision.

Implications: The tools that will be developed within this project could help health care stakeholders in different countries to improve genetic services for their citizens.

P01.24

An overview of the genetic testing offer in Europe: trends and forecast

M. Jovanovic-Lassalle[1]*, E. Dequeker*[2]*, B. Belloir*[1]*, A. Mondelaers*[2]*, M. Morris*[2]*, J. Cassiman*[2]*,* ***S. Aymé***[1]*, the Orphanet consortium;*
[1]*Orphanet - INSERM US14, Paris, France,* [2]*Eurogentest, Leuven, Belgium.*

Genetic testing services are now offered internationally, through both the public and private sectors. Physicians prescribing these tests and biologists receiving samples need to know which tests are available, where they are performed and whether identified laboratories meet quality standards. To fulfill this need, www.orpha.net was launched fifteen years ago to set up a database of medical laboratories in the field of rare diseases. Data was collected in 1 country in 1997, 15 in 2003, 26 in 2006 and 36 in 2011, with resources from the EC DG Public Health. In collaboration with the EuroGentest Network of Excellence, information on quality management has been added over the past six years. Information on genetic testing in Orphanet can be searched by disease name or by gene as well as by laboratory or by professional. The website can be freely queried and the complete dataset downloaded from www.orphadata.org. In September 2011, 1,056 laboratories offering tests for 1,811 genes were registered. The test offer differed greatly from one large country to another: from 1,449 genes (Germany) to 541 genes (UK). In medium and small-sized countries, it ranged from 1 to 355 genes. A comparison with the information available at Genetests for the USA highlights the need for a worldwide coordination of cross-border healthcare, as 584 genes are only available for testing in the EU member states and not in the USA. The capacity to access genetic testing on an international scale, however, both increases the availability of testing and raises significant policy issues.

P01.25

Alignment and Assessment Problems in the Undergraduate Genetics Curriculum: A View from the United States

M. Dougherty[1,2], *T. McElhinny*[3], *B. Bowling*[4], *J. Libarkin*[5];
[1]American Society of Human Genetics, Bethesda, MD, United States, [2]Linda Crnic Institute for Down Syndrome, University of Colorado School of Medicine, Denver, CO, United States, [3]Department of Geological Sciences and Department of Zoology, Michigan State University, East Lansing, MI, United States, [4]Department of Biological Sciences, Northern Kentucky University, Highland Heights, KY, United States, [5]Department of Geological Sciences and Center for Integrative Studies in General Science, Michigan State University, East Lansing, MI, United States.

'Backward design' is a model of curriculum development that relies on identifying learning outcomes and defining what constitutes evidence of learning before planning the teaching. Although backward design is widely considered best practice, it is often overlooked by university faculty and may help explain the inconsistency between faculty teaching behavior and the genetics concepts they claim are most important. This paper will review the state of genetics instruction in the United States from the perspective of backward design, with particular attention to the goals and assessments that inform curricular practice. An analysis of syllabi and leading textbooks indicates that genetics instruction focuses most strongly on the structure and function of DNA and Mendelian genetics. At the same time, a survey of faculty indicates that other concepts, such as the application of genetics to society or the environment, are viewed as equally or even more important than certain foundational concepts. This disconnect suggests a need for more explicit goal setting prior to curriculum development. Preliminary analysis of existing assessments, specifically concept inventories developed for higher education, indicates that assessments are poorly aligned with faculty goals for instruction and need to be modified into more valid and reliable measures of student conceptions.

P01.26

Considerations in the review of ethical guidelines pertaining to human genome research in Japan

Z. Yamagata;
University of Yamanashi, Yamanashi, Japan.

Ethical guidelines for human genome research in Japan were formulated in 2001, by three government ministries: the Ministry of Education, Culture, Sports, Science and Technology; the Ministry of Health, Labour and Welfare; and the Ministry of Economy, Trade and Industry.

The present (2012) review has taken into consideration advances in genome research such as the implementation of studies involving large amounts of genomic information, diversification of the study design such as genome cohort studies, and the advent of next-generation sequencing technologies.

The main aspects reviewed are the use of existing samples, method of collection and distribution of resources, the drafting of informed consent so that it will also be applicable to future genome research, and the disclosure of genetic information.

With respect to the use of existing samples, institutions that do not possess a correspondence table can handle samples anonymized in a linkable fashion in the same way that they handle those anonymized in a non-linkable fashion. In terms of collection and sale of samples, requirements and administrative procedures have been revised to enable the more effective use of existing samples and other resources. Regarding the disclosure of genetic information, the revisions adhere to the basic principle of disclosure with respect to the Personal Information Protection Law, but some disclosure-related issues remain unresolved.

New regulations have also been established for safety management measures related to the handling of genetic information, compliance rules for the outsourcing of genetic research, and education and training for researchers and members of ethical review boards.

P01.27

One disorder is not like another - the importance of taking a disorder-centred approach to introducing high-throughput sequencing into the clinic

S. Leonard, *A. Soulier, S. Julia, A. Cambon-Thomsen;*
UMR 1027, Inserm, Université de Toulouse - Université Paul Sabatier -Toulouse III, Epidémiologie et analyses en santé publique : risques, maladies chroniques et handicaps, Toulouse, France.

Now that next generation sequencing has become a reality, it is time to examine how this technology will change the way medicine is practiced in the clinic. A particular concern is that the rapid penetration of systematic technologies into genetic medical departments blurs established frontiers between research and clinics. The benefits and risks of using the technology as part of the diagnostic toolkit for each disorder need to be considered in relation to the characteristics of the patients themselves as well as the societal context in which the tests will be offered. It is vital to consider each patient group in their own right - the different motivations for testing and expectations for the process, and the meaning of results in terms of screening, management, prevention and knowledge. During the course of the European Techgene project, which aimed to develop clinically applicable high throughput sequencing tests, a series of 7 semi-structured interviews was performed with clinicians and researchers dealing with one of four clinical areas: mental retardation, breast cancer, sensory disorders and neurodegenerative disorders. Through these interviews areas of particular and specific concern for each disorder, were highlighted. Proposals were then developed to allow an approach to the introduction of NGS technologies into the clinic in a manner which is tailored to the categories of disorder, to ensure that we are properly prepared to meet the challenges of the new technology and harness its potential for the greatest benefit for patients.

P01.28

A proposal: a family-driven social network model for clinical data sharing and research in intellectual deficiencies and other neurodevelopmental disorders with specific genetic causes

J. Mandel[1,2,3], *J. S. Beckmann*[4,5];
[1]IGBMC, Illkirch, CU Strasbourg, France, [2]Laboratoire de diagnostic génétique CHU Strasbourg, Strasbourg, France, [3]Collège de France, Paris, France, [4]Departement de Genetique Medicale Université de Lausanne, Lausanne, Switzerland, [5]Service de Génétique Médicale CHUV, Lausanne, Switzerland.

CGH-array has led to a rapidly growing number of genetic diagnoses of intellectual deficiency (ID) associated or not to autism. High-throughput sequencing will further accelerate the detection of mutations in ID-related genes. This will be useful for genetic counseling (when penetrance is known to be high). But the extraordinary genetic heterogeneity of ID will render extremely difficult the determination, for each specific cause (recurrent CNV or mutated gene), of genotype-phenotype correlations and natural history, the estimation of penetrance and expressivity variation, and the organization of clinical trials, except for the most frequent causes (see recent work on 16p11.2 del or dup). Symptomatic treatments will be proposed, with little chance to evaluate whether their efficacy depends on the specific genetic cause. It will be difficult to motivate busy MDs to establish and maintain the wide-ranging databases required for such studies. We propose genetic ID databases organized in a social network model, whereby clinical information would be entered mostly by the patient's family. 23andMe or PatientsLikeMe have recently shown that such data can lead to useful research. Contacts between families affected by the same genetic cause could be established in an initially anonymous way as for Relative finder in 23andMe, creating gene- or CNV-specific micro-networks to which interested professionals could be associated, akin to disease-specific patients associations. Anonymized data could be accessible to professionals for specific projects approved by a comity composed of health or research professionals and of family representatives. Concerned families could then decide whether to partipate in such projects.

P01.29

The legal landscape of stratified medicine

A. E. Hall[1], *H. Burton*[1], *A. Pokorska-Bocci*[1], *J. Hitchcock*[1,2];
[1]PHG Foundation, Cambridge, United Kingdom, [2]Lawford Davies Denoon, London, United Kingdom.

This paper examines the extent to which there is a 'lack of fit' between the existing framework of European legislation (and the devolved national legislation which rests thereon), and emerging applications of genomic knowledge in stratified health care. For example, the advent of stratified medicines has enabled the co-development of therapeutic products and 'companion diagnostics' which are used together to prospectively target individuals who through genetic factors, are at risk of disease. This has the potential to increase drug efficacy and safety whilst ensuring greater cost effectiveness. Current legal and regulatory frameworks do not provide a clear route for developing these linked applications and the safeguards, protections and incentives for developing packages of diagnosis, treatment and care sometimes lack coherence.

Other emerging technologies, such as the diagnostic algorithms that support the process of stratification, may not be within the remit of existing legislative frameworks at all, or may be protected by non-patent intellectual property rights, such as copyright. In other respects, the regulatory framework is predicated upon outdated assumptions, such that products and devices can always be easily differentiated, or that the processes in bringing a product, device or test to market will take place entirely within Europe, when increasingly this is a global exercise.

In combination, these factors have the potential to negatively impact upon clinical translation and national healthcare economics. This paper offers an analysis of the existing regulatory gaps and inconsistencies within Europe in the context of stratified medicine, and suggests some proposals for reform.

P01.30

Development of the Hellenic Neuromuscular Disorders (HNDR) Registry

N. Vogiatzakis, *K. Kekou, K. Kosma, E. Kanavakis;*
Dept. of Medical Genetics, University of Athens, Athens, Greece., Athens, Greece.

Over the recent years, a growing number of patient databases are being created to accommodate patient data for various diseases. Registries acting as a hub for information and social awareness, can prove very beneficial to the patients registered and society in general, especially since they help disease organizations with government lobbying. They also provide valuable information to scientists, helping them to perform research on a bigger scale, having access to accumulated medical and genetic data. For neuromuscular disorders in particular, patient registries have played a significant role facilitating clinical trials designed to test for new therapeutic strategies and thus have promoted research regarding those types of diseases. This project aims to create and coordinate the first national neuromuscular disorders registry in Greece. The main concept behind the HNDR is to organize a reliable electronic database, containing clinical and personal data of all patients in order to provide important data for the study and research of neuromuscular disorders in Greece. Ultimately, the goal is to connect the Hellenic registry to the global network of patient registries that is universally being developed ensuring that patients who register in the HNDR can be retrieved if their profile fits to a clinical trial.

P01.31

Incidental findings in genetic testing: current laboratory reporting procedures

L. M. Jackson, *L. Goldsmith, H. Skirton;*
Plymouth University, Plymouth, United Kingdom.

Incidental findings from genetic testing are defined as those that have potential health or reproductive importance and are discovered in the course of testing but beyond the aims of the initial test. Since genetic testing was initiated there has been a potential for incidental findings, but numbers are likely to increase with the emergence of array and sequencing techniques. A genetic incidental finding is unlikely to require immediate treatment; most often it will affect the relative risk of a patient developing a disease. This raises questions as to which genetic incidental findings should be returned to the patient, at what time and by whom. These issues are passionately debated in the ethical literature, however there is a paucity of empirical data on which to base recommendations. The aim of this study was to determine current practice and ascertain the views of many different stakeholders as to future management of incidental findings. In the first phase a systematic review indicated a dearth of empirical evidence on dealing with incidental findings. In Phase 2 we surveyed staff of national health service genetics laboratories in the United Kingdom to determine how incidental findings were reported. Our initial findings indicate a lack of consensus; no universally accepted set of guidelines were used and decisions were made on a case-by-case basis. This individualised approach may interfere with equity of patient care. Findings will be used to shape the qualitative collection phase of the study and generate guidelines concerning the reporting of genetic incidental findings.

P01.32

Ethical implications on disseminating complex genetic information to relatives at risk

M. Nyman[1,2]*;*
[1]*Department of Philosophy and History of Ideas, Aarhus University, Aarhus, Denmark,* [2]*Department of Clinical Genetics, Rigshospitalet, Copenhagen University Hospital, Denmark, Copenhagen, Denmark.*

Background: Genetic counselling focuses on providing patients with qualified professional assistance in understanding and responding to their inherited risk. Genetic information is both individual but at the same time highly familial. Decisions regarding how and by whom relatives at risk for the disorder should be informed are included in the counselling.

Aim: To examine how aspects of respect for autonomy are addressed by genetic counsellors when patients have relatives deemed to be at risk.

Method: Data from empirical observations of genetic counselling, insight in medical charts, and discussion with health care personnel regarding information strategies for relatives was gathered and analysed through a structured, philosophical-theoretical approach.

Results: When relatives are informed by a tested patient, the outcome of their experience and perception of the information is influenced by *how* they are informed.

Counselees are affected by their own diagnosis and may be challenged in disseminating complex genetic information correctly to relatives.

Problems particularly arise when lack of communication in families is present and when relatives are in conflict.

Health care professionals are reluctant to contact relatives at risk directly, to respect their right to not know.

Discussion: Existing procedures for informing relatives at risk may be inadequate. Complexities of genetic information, combined with tested patients' emotional reactions, reduce relatives' access to relevant information, necessary for making autonomous and rational choices about their future.

A more proactive role for health care professionals seem warranted, towards increasing accurate information and knowledge of options, enabling patient and relatives to make informed, autonomous decisions.

P01.33

The challenge of education in birth defects: managementof orofacial clefts

L. A. Magna, *M. C. S. Basso, L. G. Amstalden-Mendes, V. L. Gil-da-Silva-Lopes;*
State University of Campinas, Campinas, Brazil.

Cleft lip and/or palate (CL+/-P) has an incidence of 1/650-1000 live births. It is often accompanied by comorbidities, needing multi professional assessment. It was investigated the knowledge on this matter in a random sample of 292 students attending the last degree of Medicine, Nursery, Speech Therapy and Odontology courses in a Brazilian University. It was used a pre validated auto applicable questionnaire on information of both anatomy and physiology of the motor oral apparatus, either of carriers and non-carriers of CL+/-P, existing feeding resources, indication of particular feeding methods, and skills to give genetics orientations. The questionnaire form applied to the respondents was retrieved immediately it was filled in with his/her answers. The results were treated by descriptive and analytical statistical methods, adopting the 5% significant level. As a whole, there were no significant differences among the students from the different courses. Student's auto evaluation achieved 58.6% of them referring sufficient notion on anatomic alterations of CL+/-P, as well as 51.0% on functional ones. It was observed the lack of systematization on the knowledge of the various topics herein investigated, leading 96.2% of the respondents to not consider them capable, in their particular health field, to deal with affected individuals. Also, 48.3% referred knowledge on CL+/-P etiology, though only 8.6% and 9.9% were able to give genetics orientation for families of carriers of CL+/-P and CP, respectively. A specific multi professional discipline, which fits each particular course, would be an alternative to increase academic capacitation of health professionals.

P01.34

The psychological impact of pancreatic cancer surveillance in high-risk individuals

F. Harinck[1]*, T. Nagtegaal*[2]*, I. Kluijt*[2]*, C. M. Aalfs*[3]*, E. M. Smets*[4]*, J. Poley*[1]*, A. Wagner*[1]*, G. Sidharta*[2]*, J. E. van Hooft*[3]*, H. M. van Dullemen*[5]*, R. Sijmons*[5]*, P. Fockens*[3]*, M. J. Bruno*[1]*, E. M. A. Bleiker*[2]*;*
[1]*University Medical Center Rotterdam - ErasmusMC, Rotterdam, Netherlands,* [2]*The Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands,* [3]*University Medical Center Amsterdam - Academic Medical Center, Amsterdam, Netherlands,* [4]*University Medical Center Amsterdam- Academic Medical Center, Amsterdam, Netherlands,* [5]*University Medical Center Groningen, Groningen, Netherlands.*

Background: The success of pancreatic cancer (PC) surveillance depends to a large extent on the commitment of participants to adhere to the repeated follow-up investigations. We aimed to investigate possible changes in distress in high-risk individuals participating in a PC surveillance program.
Methods: Questionnaires were sent before and after PC-screening tests to high-risk individuals participating in a multicenter nationwide endoscopic ultrasonography (EUS)-MRI-based PC-surveillance study. Distress was assessed with the Cancer Worry Scale, and the Hospital Anxiety and Depression scale.
Results: Forty-seven individuals (87%) completed both pre- and post-surveillance questionnaires (38% male, mean age= 52 yr., range 20-74 yrs.); 44 participated in the PC screening and 3 declined. The expected burden of EUS was significantly higher than the actual experienced burden (p<.001). The number of participants with clinical levels of anxiety and/ or depression was low (n=5) and remained stable over time. The possibility of developing cancer themselves (29% at both time points) and the chance that relatives would develop cancer (19% and 21%, respectively) were the most frequently reported worries. The 3 decliners indicated that they were not fearful of the MRI or EUS, and had low levels of distress.
Conclusion: The results of this prospective study indicate that: (1) the expected burden of EUS is higher than the actual experienced burden; and that (2) mean levels of distress are not significantly influenced by participating in the PC screening program. This finding is of great importance for this high-risk group that might benefit from participation in a life-long repeated PC-surveillance-program.

P01.35

Focusing on patient needs and preferences may improve genetic counseling for colorectal cancer

S. Salemink[1], *N. Dekker*[1,2], *M. Kets*[1], *E. van der Looij*[1], *W. van Zelst-Stams*[1], *N. Hoogerbrugge*[1,3];
[1]*Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [2]*Scientific Institute for Quality of Healthcare, Nijmegen, Netherlands,* [3]*Department of Medical Oncology, Nijmegen, Netherlands.*

During genetic counseling, different items which counselors consider important are discussed. However, little is known about the needs and preferences of counselees. Therefore, counselees with a personal and/or family history of colorectal cancer (CRC), who were referred for genetic counseling regarding CRC, received a slightly adjusted version of the QUOTE-GENE^{ca} questionnaire prior to their first visit at the Hereditary Cancer Clinic. Response rate was 60% (48/80 counselees). Participants rated the importance of 45 items discussed during counseling. Participants considered the items regarding information about their familial CRC risk (100%) and preventive options (98%) important or very important. Fewer participants considered the items of general information on genetics as important. No major differences were seen between participants in relation to individual characteristics. Our data suggest that focusing on familial CRC risk and surveillance options may lead to better satisfaction with genetic counseling.

P01.37

E-learning in Romania - a chance for improving information about rare diseases

M. Gafencu[1], *G. Doros*[1], *M. Puiu*[1], *D. Dan*[2];
[1]*Univ. of Medicine and Pharmacy V. Babes Timisoara, Timisoara, Romania,* [2]*RoNaRD, ANBRARo, Zalau, Romania.*

Introduction - Based on new scientific data up to 6% of total EU population are affected by rare diseases. In Romania, **more than 95% of patients do not have a complete diagnosis or do not receive adequate care and treatment.** All statistics showed that patients are open to use electronic resources in a same way that specialists do. **Aim -** This paper focuse on web solution that helps rare disease patients to learn about their disease and doctors to know how can they get assistance. Material - Our e-university www.edubolirare.ro want to provide information on rare diseases and care of patients suffering from these diseases and for all the interested doctors. The training method used is **blended learning** - a modern concept implemented in the University of Tromso - Norway by the combination of classical face to face with modern Internet-based learning. Results - The project platform offers a wide range of short courses and informations: Legal regulations on patients rights, E-Learning courses, and scientific information about diseases. This virtual platform give quality training programs, presented in an attractive, encouraging continued teaching progress, a lifelong learning, skills needed for diagnosis and management of rare diseases. Conclusions - **Most of rare diseases not currently benefit from specific treatment,** and for other several hundred **there only exist measures** allowing patients to improve quality of life. Access to information about diagnosis and disease management are crucial in rare diseases field and web-based solution can be effective.

P02. Clinical genetics and Dysmorphology

P02.001

Seven items flowchart (7-iF) for the clinical indication to GCK genetic test

M. Pinelli[1], *F. Acquaviva*[1], *N. Tinto*[2,3], *E. Caredda*[4], *D. Pirozzi*[2,3], *S. Cocozza*[1], *L. Sacchetti*[2,3], *F. Prisco*[4], *D. Iafusco*[4];
[1]*DBPCM, Università degli Studi di Napoli, Naples, Italy,* [2]*DBBM, Università degli Studi di Napoli, Naples, Italy,* [3]*CEINGE Advanced Biotechnology, S.c.a.r.l., Naples, Italy,* [4]*Department of Pediatrics, Seconda Università degli Studi di Napoli, Naples, Italy.*

We propose a simple diagnostic flowchart aiming to easily identify, among a diabetic pediatric population, patients with the highest probability to carry a pathological mutation in the GCK gene. Heterozygous individuals for these mutations are affected by a monogenic diabetes, characterized by a moderate increase in fasting glucose and HbA1c levels with, usually, no micro- or macro-vascular complications and no need of pharmacological intervention. The molecular diagnosis provides a perceptible impact on both patient's quality of life (no need of treatment) and health care costs (less frequent follow up visits, no stick for glyceamic controls or drugs to provide).
The proposed 7-item flowchart (7-iF) takes into account the most recent criteria for the etiological diagnosis of diabetes, including the autoimmune pancreatic antibodies, the HbA1c and the familiarity. We validated this approach in one of the largest Italian pediatric diabetes outiclinic cohort.
Of 921 patients, 21 (2.3 %) received positive indication to GCK testing according to the 7-iF. Seventeen underwent to genetic testing and 13 (76 %) carried a pathological mutations 5 were novel mutations. The flowchart had a specificity of 99% and a sensibility of 92%, basing on the estimated frequency of GCK-MODY2 in Italian diabetic patients.
The proposed flowchart successfully identified diabetic patients with high risk to carry a pathological GCK mutation. The flowchart is extremely handily and can be implemented in any clinical setting. The flowchart is implemented in a webtool http://www.geneticamedica.unina.it/diabsun/

P02.002

Mutiple congenital anomalies in a male fetus with a 5.6 MB deletion of 10q25.1-q25.3

H. Jafarieh, *R. Jafarshad, M. Kariminejad, R. Kariminejad, A. Kariminejad;*
Kariminejad-Najmabadi Pathology & Genetics Center, Tehran, Islamic Republic of Iran.

We report on a 34-week-old male fetus with multiple congenital anomalies including hydrocephaly, hypoplastic olfactory bulbs, agenesis of diaphragm, coarctation of aorta, lung hypoplasia, hydronephrosis, hypospadias, short lower limbs, webbing of knees and deep gap between first and second toes. The facial features were dysmorphic with: prominent forehead, hypertelorism, low set and posterior rotated ear, dysplastic ears small mandible and broad based nose. Radiological findings were: markedly thin ribs, flat acetabular roof of pelvic, no talus or calcaneus ossification, hypoplastic pubic ossification, asymmetric femoral size and narrow thorax. Parents are first cousins with history of two spontaneous abortions. Cytogenetic analysis, performed by array-CGH revealed a 5.6 Mb region deletion of chromosome 10q25.1-q25.3. Chromosomal studies of both parents were normal confirming the abnormality to be of de novo origin.
To the best of our knowledge this phenotype with major anomalies which had lead to intrauterine fetal demise (IUFD) has not been reported before with this deletion. The unique presentation of our case notably, agenesis of diaphragm is a very rare finding and not reported previously in 10q deletion cases. It should be taken into consideration that most cases with agenesis of diaphragm had normal chromosomes based on karytoype, and it is possible that minor chromosomal abnormalities were missed with routine cytogenetic techniques.

P02.003

Delineation of a novel, recognizable microdeletion syndrome on 13q12.3 in three unrelated patients with intellectual disability

D. Bartholdi[1,2], *A. Stray-Pedersen*[3], *S. Azzarello-Burri*[1], *M. Kibaek*[4], *M. Kirchhoff*[5], *B. Oneda*[1], *O. Rødningen*[3], *A. Rauch*[1], *S. Kjaergaard*[5];
[1]*Institute of Medical Genetics, University of Zürich, Schwerzenbach, Switzerland,* [2]*University Children's Hospital, UKBB, Basel, Switzerland,* [3]*Department of Medical Genetics, Oslo University Hospital, Oslo, Norway,* [4]*Department of Pediatrics, Odense University Hospital, Odense, Denmark,* [5]*Department of Clinical Genetics, University Hospital of Copenhagen, Rigshospitalet, Copenhagen, Denmark.*

Proximal deletions of the long arm of chromosome 13 have been reported only rarely. Here we present three unrelated patients with intellectual disability carrying novel heterozygous interstitial deletions encompassing 13q12.3. The proximal and distal breakpoints are similar and the deletions span about 1.4 Mb, comprising at least 11 RefSeq genes.

The patients present with moderate intellectual disability, secondary microcephaly and short stature as the leading symptoms. In addition, they experienced pronounced feeding difficulties in early infancy and later on eczema/atopic dermatitis. They display strikingly similar facial features such as fullness of the periorbital region, a flat malar region, a characteristic nose with a bulbous nasal tip and hypoplastic alae nasi, a smooth philtrum and thin upper lip.

Heterozygous deletions of 13q12.3 overlapping about 1 Mb of the distal part of the deletions in our patients have been described in healthy carrier parents of patients with Peters-Plus syndrome (an autosomal recessive disorder caused by inactivation of the *B3GALTL* gene). We therefore propose that the critical region of the 13q12.3 microdeletion syndrome contains only three genes, namely, *KATNAL1*, *LINC00426* and *HMGB1*. So far, little is known about the function of the *KATNAL1* and *LINC00426* genes in humans. HMGB1, however, is an evolutionarily conserved chromatin-associated protein which has been implicated in various disease processes.

In summary, we suggest that microdeletion 13q12.3 represents a clinically recognizable condition characterized by intellectual disability, microcephaly, short stature, a disposition for atopy and characteristic facial features. The critical region encompasses about 300kb with 3 genes assigned to it.

P02.004

Proximal and distal 15q25.2 microdeletions - genotype-phenotype delineation and confirmation of two neurodevelopmental susceptibility loci

S. C. Doelken[1], *K. Seeger*[2], *P. Hundsdörfer*[2], *W. Weber-Ferro*[3], *E. Klopocki*[1,4], *L. Graul-Neumann*[1];

[1]*Institute of Medical and Human Genetics, Charité-Universitätsmedizin Berlin, Berlin, Germany,* [2]*Klinik für Pädiatrie mit Schwerpunkt Onkologie/Hämatologie, Otto-Heubner Centrum für Kinder- und Jugendmedizin, Charité Universitätsmedizin Berlin, Berlin, Germany,* [3]*Department of Pediatrics, Klinikum Neukölln, Berlin, Germany,* [4]*Max-Planck Institute for Molecular Genetics, Berlin, Germany.*

Cooper and coworkers have recently reported distal 15q25.2 microdeletions as a potential novel CNV locus for neurodevelopmental and neuropsychiatric disorders with variable outcome. Previously, more proximal microdeletions of 15q25.2 have been described by Wat et al. as a susceptibility locus for cognitive deficits, congenital diaphragmatic hernia, and Diamond-Blackfan anaemia (DBA).

We present two new 15q25.2 deletion patients and compare them to the 18 patients reported in the literature. Our patient 1 with a deletion overlapping both, the distal and proximal 15q25.2 deletions, presented with mild learning deficits, portal vein thrombosis, iron deficiency anaemia, short stature, and Noonan syndrome aspect. DBA is thought to be caused by reduced copy numbers of RPS17, which is normally present in four copies (two on each allele) in the proximal 15q25.2 region. We demonstrate a 50% reduction in copy number of RPS17 in our patient 1 by quantitative real-time PCR. Loss of two copies of RPS17 might be responsible for at least some of our patients features. As the clinical spectrum of DBA includes individuals without DBA who have other DBA-associated congenital anomalies, patients with proximal 15q25.2 deletions should be monitored for development of anaemia and DBA-associated malignancies.

Patient 2 with the more distal 15q25.2 deletion presented with severe psychomotor retardation, microcephaly and epileptiform signs. He carries two additional microdeletions, the 1q21.1 recurrent microdeletion and a hemizygous deletion on the X-chromosome encompassing OPHN1.

We contribute to the genotype-phenotype delineation for 15q25.2 microdeletions and further expand the characterization of these two novel microdeletion syndromes.

P02.005

Microdeletion in chromosome band 20p13 associated with moderate developmental delay and minimal facial dysmorphism

M. Krajewska-Walasek, *A. Jezela-Stanek, M. Kucharczyk, M. Pelc, A. Gutkowska;*
The Children's Memorial Health Institute, Warsaw, Poland.

The subtelomere screening studies in the patients presenting with mental disability and developmental delay has let to only few reports of cases harboring pure subtelomeric terminal deletions in the 20p13 region. Clinical findings reported for these cases suggest that the phenotypic consequences of this chromosomal imbalance are very variable, in many cases however, the clinical data are rather limited. Hence, to establish the genotype-phenotype correlation of 20pter monosomy is still a challenge.

We report a 9-year-old girl with subtelomeric 20p microdeletion. She was referred to the genetic counseling because of learning difficulties. During the further evaluation: short stature, hypoplastic fingernails, submucous cleft palate with cleft uvula, flat foot, tendency to infections and large fontanelle after birth were noted. No specific facial dysmorphic features were observed. The diagnosis of deletion of 20p13 was established by MLPA, and delineated by arrayCGH, as 46,XX.arr20p13(1-1150000)x1 dn with the size of 1.15 Mb.

Our report is the second, giving the detailed molecular and clinical characteristics of pure, smallest deletion 20p13. In this presentation we have delineated the phenotype of this aberration, providing possible candidate genes and giving data supporting genotype-phenotype correlation.

The study was partially supported by the grant of the Polish Ministry of Science and Higher Education (Contract No 0605/B/P01/2009/37).

P02.006

The clinical overlap between 22q11.2 deletion syndrome and CHARGE syndrome: they are more alike than often anticipated

N. Janssen[1], *L. H. Hoefsloot*[2], *S. C. Saitta*[3,4], *D. M. McDonald-McGinn*[3], *E. H. Zackai*[3,4], *D. A. Driscoll*[3,4], *R. Derks*[5], *W. S. Kerstjens-Frederikse*[1], *B. S. Emanuel*[3,4], *C. M. A. van Ravenswaaij-Arts*[1];

CHARGE syndrome is a highly variable congenital malformation syndrome that shows considerable clinical overlap with other syndromes. The most striking co-occurrence of clinical features is seen with the 22q11.2 deletion syndrome, including congenital heart defects, cleft palate, ear abnormalities, hearing loss, growth deficiency, developmental delay, renal abnormalities, hypocalcaemia and immune deficiency.

We further explored the clinical similarities between the two syndromes by studying patients clinically diagnosed with CHARGE syndrome, but who were shown to carry a 22q11.2 deletion (n=6). Subsequently we analysed the 22q11.2 deletion features in our large patient cohort of *CHD7* mutation carriers (n=834). In 29 patients (3.5%) typical 22q11.2 deletion features, like hypocalcaemia, thymus anomalies and severe immunological problems, were mentioned. This prompted us to study *CHD7* in 20 patients clinically diagnosed as 22q11.2 deletion syndrome but without deletion or mutation of *TBX1*. We found truncating *CHD7* mutations in five of these patients.

Our results demonstrate that the clinical diagnosis of these two highly variable syndromes is challenging. They should therefore be included in a common differential diagnosis and we strongly recommend *CHD7* analysis in patients with a 22q11.2 deletion phenotype without a deletion or mutation of *TBX1*. Conversely, a genome-wide array for 22q11.2 deletions in clinical CHARGE patients without a *CHD7* mutation is recommended. The results also show that there is strong clinical evidence that the molecular pathways of *CHD7* and *TBX1* are linked.

P02.007

The co-occurrence of abnormal movement and 22q11.2 Deletion Syndrome: more than a coincidence?

A. Jacquette[1], *K. NGuyen*[2], *S. Whalen*[1], *T. Lenglet*[3], *B. Degos*[3], *D. Grabli*[3], *A. Eusebio*[4], *J. Azoulay*[4], *N. Philip*[2], *D. Héron*[1], *M. Vidailhet*[3], ***P. Charles***[1];

[1]*Département de génétique, centre de référence des déficiences intellectuelles, Hôpital de la Salpêtrière, Paris, France,* [2]*Département de génétique médicale, Hôpital de La Timone, Marseille, France,* [3]*Département de Neurologie, Hôpital de la Salpêtrière, Paris, France,* [4]*Service de Neurologie et pathologie du mouvement, Hôpital de La Timone, Marseille, France.*

We report five patients who present co-occurrence of abnormal movement and 22q11 Deletion Syndrome (22q11 DS).

Three of them (mean aged 35 years) were addressed to neurologic department for extra pyramidal features leading to diagnosis of early onset Parkinson Disease (PD) with good responsiveness to L-Dopa therapy and dopaminergic denervation on DAT Scan.

The fourth patient presented myoclonic tremor.

Facial appearance and learning difficulties led to diagnosis of 22q11 DS. For the fifth patient, 22q11 Deletion Syndrome was established for several years and myoclonic tremor appeared during evolution.

To date, three cases of extra pyramidal features without relation with neuroleptic therapy, one Tourette syndrome and one myoclonic tremor have been reported in 22q11 DS.

Is it more than a coincidence?

Pathophysiology and signaling pathways involved are unknown. Among the commonly deleted region, which spans over 40 genes, COMT (catechol-O-methyltransferase) polymorphism could represent a good candidate based upon its pharmacological involvement in L-Dopa pathway (sequencing is in progress).

Parkinson disease or other abnormal movement may be occasional features of 22q11 DS.

Geneticists as well as neurologists and physicians caring patients with 22q11 DS should be aware of this possible association.

Genetic testing may be relevant in cases of early onset PD and preexisting learning and behavioral problems and/or facial dysmorphism.

Pathogenesis and etiology remain to be explained.

During the past years interstitial microdeletions of various segments of the short arm of chromosome 2 were recognized as a cause of mental retardation. However, most of these deletions have no recurrent breakpoints which hampers precise genotype phenotype correlation. In this situation thorough clinical characterization of patients with overlapping deletions and comprehensive database search for gene centred information may give insight into the contribution of single genes to the clinical phenotype.

Recently, Wohlleber et al. (2011) described two patients with small interstitial microdeletions 2p14-15 who presented with mild mental retardation and dysmorphisms. We report on a third patient with a de novo 2p14-15 microdeletion. The boy presented at the age of 22 months with muscular hypotonia, developmental delay, absent speech development and facial dysmorphisms (high forehead, sparse eyebrows, short palpebral fissures, hypertelorism, thin vermillion of the upper lip, deep set ears). Measurements (height, length, OFC) were in the lower normal range. He had bilateral deafness with dysplasia of the semicircular canals and was supplied with cochlear implants. Molecular karyotyping (HumanCytoSNP-12 array, Illumina, Ca) revealed a de novo 2.9 Mb microdeletion 2p14-p15 encompassing 12 genes. This deletion overlaps with those previously described, but, in addition, affects the homeobox gene *MEIS1*. The latter has recently been shown to be strongly expressed in the semicircular canals of the developing inner ear in chicken and therefore is a good candidate for dysplasia of the inner ear in our patient. This case contributes to further delineate the 2p14-p15 microdeletion phenotype.

3p deletion syndrome is a rare disorder involving developmental delay and dysmorphic physical features. Most cases are de novo. Here we report a family with 3p-deletion syndrome and a rare 3p-duplication case. Two brothers with intellectual disability (ID) presented fully similar features of 3p-deletion syndrome, including developmental delay, muscular hypotonia, epichantal folds, flat and long philtrum, micrognathia, dolychocephaly, microcephaly, and hypertelorism. From family histories of non-consanguineous parents, a paternal aunt showed ID, delayed speech, and obesity. Karyotype analyses showed the deletion of 3p not only in affected sibs but also in their healthy father. Characterization of the rearrangement extent was performed by InfiniumHD whole-genome genotyping assay (HumanOmniExpress BeadChip arrays). The analysis of brothers showed identical 3p25.3 terminal hemizygous deletion of 10.9 MB. The deletion encompasses 49 RefSeq genes, including proposed 1,5 Mb minimal terminal deletion with causative CRBN and CNTN4 genes, and two others proposed as major candidates for ID: CHL1 mapped at 3p26.3 distally and SRGAP3 mapped at 3p25.3 proximally to minimal terminal region. FISH mapping using whole chromosome paint, MCB and subtelomere probes detected balanced translocation 46,XY,t(3;8)(p25.3;p23.3) in father and a partial 3p25.3 terminal trisomy in the paternal aunt. The duplicated region contains GHRL and PPARG genes which contribute to obesity and behavioral problems presented in the aunt. Despite of controversial results related to candidate regions for 3p-deletion syndrome, this is the biggest deleted region among reported few familial cases, encompassing all candidate genes responsible for ID with apparent clinical consequence of 3p-deletion. Supported by FP7-CHERISH-223692, DFG-LI 820/38-1.

P02.010

A familial case of developmental delay/intellectual disability, variable psychiatric disorders and optic atrophy due to a novel 1.5 Mb deletion on 3q29

E. Biamino[1]*, E. F. Belligni*[1]*, C. Molinatto*[1]*, E. Di Gregorio*[2]*, A. Calcia*[2]*, A. M. Fea*[3]*, P. Cannizzo*[3]*, A. Brusco*[2]*, G. B. Ferrero*[1]*, M. Silengo*[1]*;*

We report on a family segregating a 3q29 deletion centromeric to the classic "Chromosome 3q29 deletion syndrome" (OMIM #609424). The proband, a 4 yr. old girl, presented with severe global developmental delay and autism. Family history was positive for psychiatric/ophthalmologic disorders.

Array-CGH analysis (Agilent, 44K) revealed a 1.5 Mb deletion on chromosome 3q29 (194,529,547-195,888,674 bp, hg18). The deletion, confirmed by a real-time PCR assay, was inherited from the mother, affected by mild depression, and was also present in the maternal uncle (anxiety/depression), two maternal aunts (schizophrenia), the maternal grandmother (microcephaly, depression and visual deficit), and her brother (schizoaffective disorder).

The deletion encompasses 14 genes, including the OPA1 gene, whose haploinsufficiency causes autosomal dominant optic atrophy type 1 (OMIM#165500). Complete ophthalmologic evaluation performed in three deleted subjects of the family (mother, uncle, grandmother) confirmed the presence of a variable degree of optic atrophy. Among the deleted genes, HES1, which encodes for a basic helix-loop-helix transcription factor, is essential for neurogenesis. This gene has been suggested to have a role in the determination of autistic spectrum disorders and could be related with the psychiatric diseases observed in the family.

In conclusion, we detected a novel 3q29 deletion associated with optic atrophy and variable neuropsychiatric manifestations, ranging from mild depression to schizophrenia.

P02.011

EMX2 haploinsufficiency and ambiguous genitalia in a retarded boy

J. Piard[1]*, B. Mignot*[2]*, F. Arbez-Gindre*[3]*, D. Aubert*[4]*, Y. Morel*[5]*, V. Roze*[6]*, P. Jonveaux*[7]*, L. Van Maldergem*[1]*;*
[1]*Centre de Génétique Humaine, Besancon, France,* [2]*Dept of Pediatrics, Besancon, France,* [3]*Dept of Pathology, Besancon, France,* [4]*Dept of Pediatric Surgery, Besancon, France,* [5]*Molecular Endocrinology & Rare Diseases, Lyon, France,* [6]*Dept GBHBDR, Besancon, France,* [7]*Dept of Cytogenetics & Molecular Biology, Nancy, France.*

We report a 28 month-old boy, born to unrelated parents of French ancestry, presenting at birth with 46, XY disorder of sex differentiation (DSD): posterior hypospadias, micropenis (1.2 cm) bifid scrotum, atrophic testes(one undescended), a left hypoplastic ectopic kidney on ultrasound, and no useful mullerian duct residue on genitoendoscopy. Hormonal data supported a diagnosis of testicular dysgenesis: low antimullerian hormone at day 2, undetectable basal testosterone at minipuberty, slightly stimulated by HCG (1,35 nmol/L), and normal gonadotrophins. No significant alteration of *SF1, WT1, Sox9* and *MAMLD1* sequences was found, nor rearrangement of *SRY* or *Dax1*. As the decision was taken to rear him as a male, surgery was limited to Onlay uretroplasty. Testis biopsy showed atrophic testicular tissue with widely spaced seminiferous tubules and rare spermatogoniae. When referred at 28m for developmental delay, no language, bruxism and clumsiness were observed, alongside with a small head (OFC -3SD). Array-CGH (Agilent 180 K) then indicated a 3.85 Mb 10q25.3-q26.12 *de novo* microdeletion encompassing 28 genes, including *EMX2* and *BAG3*. We postulate that *EMX2* haploinsufficiency is responsible for the masculinization defect observed in our patient, similar to what has been described in the mouse by Chung in 1998 and Miller in 2009. There are only a few descriptions of 10q25.3 microdeletion and DSD in medical literature, all but one before the array-CGH era. Our patient represents thus the second case. We recommend considering *EMX2* haploinsufficiency in case of 46, XY DSD with testicular dysgenesis left without a definite molecular diagnosis.

P02.012

5q31 Microdeletions: Definition of a Critical Region and Analysis of *LRRTM2*, a Candidate Gene for Intellectual Disability

*E. Wohlleber[1], A. M. Zink[1], W. Kleffmann[1], J. A. Lee[1,2], J. Senderek[3], E. Mangold[1], U. Moog[4], G. A. Rappold[5], **H. Engels**[1];*
[1]Institute of Human Genetics, Bonn, Germany, [2]Department of Genomics, Life and Brain Center, University of Bonn, Bonn, Germany, [3]Institute of Cell Biology, Eidgenössische Technische Hochschule (ETH) Zürich, Zürich, Switzerland, [4]Institute of Human Genetics, Ruprecht-Karls-University, Heidelberg, Germany, [5]Department of Human Molecular Genetics, Ruprecht-Karls-University, Heidelberg, Germany.

Microdeletions in 5q31 have been reported in only few patients to date. Apart from intellectual disability / developmental delay (ID/DD) of varying degrees, which is common to all reported patients, the clinical spectrum is very wide and includes short stature, failure to thrive, congenital heart defects, encephalopathies and dysmorphic features.

Here, we report a male patient with a 0.9-Mb *de novo* deletion of 5q31.2, the smallest microdeletion of 5q31 reported thus far. His clinical presentation includes mild DD, borderline short stature, postnatal microcephaly and mild dysmorphic signs including microretrognathia. In conjunction with data of seven reported overlapping microdeletions, analysis of our patient enables the tentative delineation of a phenotype map for 5q31 deletions. In contrast to the mild phenotype of small microdeletions affecting 5q31.2 only, carriers of larger microdeletions affecting subbands 5q31.1 and / or 5q31.3 are more severely affected with congenital malformations, growth anomalies and severe encephalopathies.

A 0.24-Mb smallest region of overlap (SRO) in 5q31.2 is delineated which contains only two genes. We propose *LRRTM2* as the most promising candidate gene for ID/DD in this SRO due to its expression pattern, its function as a key regulator of excitatory development and its interaction with Neurexin 1. However, mutational analysis of *LRRTM2* in 330 patients with ID/DD revealed no sequence alterations, excluding intragenic mutations in *LRRTM2* as a frequent cause of ID/DD in patients without microdeletions.

P02.013

A second case of 7p22.1 microduplication: clinical and molecular characterization

***E. Preikšaitienė**[1], J. Kasnauskiene[1], Z. Ciuladaite[1], B. Tumiene[1], P. Patsalis[2], V. Kučinskas[1];*
[1]Dept. Human and Medical Genetics, Vilnius University, Vilnius, Lithuania, [2]Department of Cytogenetics and Genomics, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus.

The use of high-resolution microarray technology for investigation of patients with intellectual disability and/or congenital anomalies provided the possibility to identify new microdeletion/ microduplication syndromes and discover the dosage sensitive genes, which are implicated in the manifestation of various genetic conditions. Microduplication of the 7p22.1 region, 1.7 Mb in size, has very recently been reported, representing the smallest interstitional 7p duplication, associated with specific facial features and speech delay. We report on a new case of even smaller 7p22.1 *de novo* microduplication, 1Mb in size in position 5337072:6316915 (NCBI build 36), detected in a 14.5 years of age patient with mild intellectual disability and similar facial dysmorphism, including macrocephaly, ocular hypertelorism, low set ears and other features. To our knowledge, this is the second report of 7p22.1 microduplication, characterized by array CGH, however more than 60 cases of 7p duplications detected by routine karyotyping and differing in their size and position have been reported to date. Many of them share developmental delay, typical craniofacial and skeletal abnormalities as common clinical features. We suggest that 7p22.1 might be a critical region, representing a novel clinically recognizable microduplication syndrome caused by overexpression of dosage sensitive genes within this chromosomal alteration. There are 15 RefSeq genes included in this duplication. *ACTB* gene is a strong candidate gene for the disturbance of craniofacial development. Further cases with similar duplications will contribute to the delineation of a potential new microduplication syndrome of 7p22.1.

P02.014

Phenotypic Evaluation of 8q11.1-q11.23 Deletion In a Mental Retardation Patient

***E. Gumuslu**[1], N. Cine[1], D. Sunnetci[1], B. Kara[2], R. Akkoyunlu[1], S. Eren[1], H. Savli[1];*
[1]Kocaeli University Medical Genetics Department, Kocaeli, Turkey, [2]Kocaeli University Department of Pediatrics, Kocaeli, Turkey.

We report on a 17 years old male patient with mental retardation, speaking disability and dysmorphic features. He has hyperextansibility, deep set eyes, upslunting palpebral fissures, prominent dysplastic ears, short philtrum, prognatism, narrow and highly arched palate, broad thumb, short and thick hand fingers and macrotestis. Family members of the patient was evaluated genetically, and we found that his mother has 3 spontaneous abortus occured in third trimester. Molecular karyotyping made using array CGH method with CytoSure Syndrome Plus(v2)4x44K microchips and scanned with Agilent Microarray Scanner. Obtained data were analyzed using Cytosure Analysis Software,v.2.0.8. and revealed a heterozygous 7.183 Mb deletion of 8(q11.1-q11.23) region containing PRKDC, RB1CC1, SNAI2 genes. For verification of the array results, FISH analysis was performed with Bluegnome region spesific probes and confirmed the deletion in the region. We concluded that 8q11.1-q11.23 region may contain candidate genes for the related clinical findings.

P02.017

Recognizing adult Aarskog-Scott syndrome carrier females based on craniofacial measurements using interaction variables and a surrogate covariance matrix

***L. Wolf**[1,2], L. Basel-Vanagaite[3,4,5], L. Karlinsky[1], M. Shohat[3,4,5], J. Allanson[6];*
[1]FDNA Ltd., Herzlyia, Israel, [2]The Blavatnik School of Computer Science, Tel Aviv University, Tel Aviv, Israel, [3]Schneider Children's Medical Center of Israel and Rabin Medical Center, Petah Tikva, Israel, [4]Tel Aviv University, Tel Aviv, Israel, [5]Felsenstein Medical Research Center, Petah Tikva, Israel, [6]Dept. Genetics, Children's Hospital Eastern Ontario, Ottawa, ON, Canada.

Aarskog-Scott syndrome is an X-linked recessive syndrome caused by FDG1 mutations and characterized by dysmorphism, shawl scrotum, short stature and brachydactyly. We demonstrate that carrier females are distinguishable based on craniofacial measurements. We evaluated 20 adult females, out of which 16 are obligatory carriers, 1 is a molecularly verified carrier, and 3 are verified non-carriers. First, we compute the likelihood to be sampled from the matched control population for each of 21 craniofacial measurements. The combined likelihood scores demonstrate a moderate recognition rate with Area Under ROC Curve (auc) of 0.74. In order to improve the recognition rate, we consider the interaction variables that correspond to all pairs of measurements. Since the individual measurements of the control population became unavailable once the statistics of each measurement were computed, we cannot directly estimate the distribution of the interaction variables. Instead, we employ a second data set of 21 adult female Navajos, for which five cranio-facial measurements that are common with the ones of the Aarskog-Scott syndrome carrier dataset are available per-person. Employing only these five measurements and correcting for the correlations among the derived interaction variables, we are able to obtain an improved recognition rate (auc of 0.78). This is significantly higher than the recognition rate obtained from these five measurements without considering the interaction variables (auc of 0.65). Therefore, our results highlight the utility of interaction variables in evaluation of facial features and support the usage of surrogate correlation matrices when such data are unavailable.

P02.018

Factors of mortality and morbidity in congenital abdominal defects

***V. L. David**[1], E. Tuluc[2], C. M. Popoiu[3], M. Puiu[3], E. S. Boia[3];*
[1]Emergency Children's Hospital „Louis Turcanu", Timisoara, Romania, [2]Emergency Children's Hospital „Sf. Maria", Iasi, Romania, [3]University of Medicine and Pharmacy „Victor Babes", Timisoara, Romania.

Congenital abdominal wall defects are one of the most common malformations. The purpose of this study is to assess the main factors that may influence the outcomes of the treatment of omphalocelle and laparoschizisul. Between 1999 and 2010, 96 patients (53 boys and 43 girls) were admitted in the Pediatric Surgery Departments of two of the major pediatric hospitals in Romania. There were 62 with laparoschizis and 34 with omphalocelle. Primary closure of the abdominal defect was possible in 49 cases of laparoschizis (79%) and 21 cases of omphalocelle (60%). Complications occurred in 57 patients with infectious one being the most prevalent. Overall mortality rate was 62,5 %, 69% for laparoschizis and 50% for omphalocelle. In table 1 and 2 are summarized the main prognostic factors assessed by us. Conclusions: The main predictors for complications are: low APGAR score, masculine gender, incongruence between abdominal cavity and the herniated bowel, postoperative anemia, thrombocytopenia and renal insufficiency during postoperative course. The main predictors for an unfavorable outcome are: low birth weight, low APGAR score, masculine gender, incongruence between abdominal cavity and the herniated bowel, associated malformations, postoperative anemia, thrombocytopenia, renal insufficiency, pulmonary infections and sepsis during the postoperative course

Aicardi-Goutières syndrome type 1 in a Russian family

G. E. Rudenskaya[1], *E. Y. Zakharova*[1], *E. S. Ilyina*[2];
[1]*Medical Genetics Research Centre, Moscow, Russian Federation,* [2]*Russian State Pediatrics Hospital, Moscow, Russian Federation.*

Aicardi-Goutières syndrome (AGS) is a rare early-onset hereditary encephalopathy with some features of congenital virus infection which often leads to misdiagnosis. AGS is genetically heterogeneous, five genes are known and genotype-phenotype correlations exist. *TREX1* mutations produce AGS type 1, a severe neonatal-onset form making up 25% of AGS cases. Inheritance is autosomal recessive but few cases due to heterozygous *TREX1* mutation *de novo* are known. We diagnosed AGS type 1 in a non-consanguineous family with two affected children, a 1.5-year-old girl (index case) and a 9-year-old boy (whom we did not examine personally). Both children had typical presentation: uncomplicated pregnancy and delivery, normal condition in first weeks of life, unexplainable fever >38ºC, leukocytosis and severe motor and mental delay with variable neurological signs since 1-1.5 months, stabilization and partial improvement with time, multiple petrificates and white matter lesions on CT/MRI. Along with intrafamilial likeness few differences in MRI and clinical signs were seen. There were no characteristic skin chilbains. The boy's previous diagnosis was 'cerebral palsy due to congenital CMV infection', and risk for the second child was mistakenly considered low. AGS was first recognized in the girl. Homozygosity for *TREX1* mutation c.342G>A (p.Arg114His) was detected. The mutation is most common in European populations and is supposed to have common origin due to founder effect [Crow et al, 2006]. Evidently, ours is the first AGS Russian case which shows its underestimation in practice. AGS should be considered in 'CNS congenital infection' with negative virusological tests.

P02.020

A novel heterozygous *ALX4* gene mutation in a familial case presenting parietal foramina and a mild frontonasal dysplasia phenotype

D. R. Bertola[1], *M. G. Rodrigues*[2], *C. R. D. C. Quaio*[1], *C. A. Kim*[1], *M. Passos-Bueno*[2];
[1]*Instituto da Criança - HC/FMUSP, São Paulo, Brazil,* [2]*Instituto de Biociências - Universidade de São Paulo, São Paulo, Brazil.*

ALX4 encodes a transcriptional regulator involved in cell-type differentiation and development during embryogenesis, playing an important role in the processes of cranial development. We will illustrate the clinical heterogeneity of the *ALX4*-related craniofacial malformations by describing the first familial case segregating a heterozygous mutation and with an intermediate phenotype between isolated parietal foramina and the severe *ALX4*-related frontonasal dysplasia with alopecia and genital abnormality phenotype (*ALX4*-related FNDAG).

The proband, the second child of non-consanguineous parents, has had normal cognitive development and his craniofacial features included hypertelorism, telecanthus, epicanthus, broad nasal bridge, notch at the tip of his long nose and fronto-parietal alopecia. These features strongly resembled his mother. He also presented with bilateral cryptorchidism and broad thumbs. Cranial and limbs X-rays disclosed only parietal foramina in both the patient and his mother.

The coding region sequencing of the *ALX4* gene disclosed a novel heterozygous mutation on the proband and his mother: p.Asp326fs (c.1080-1089_delGACCCGGTGCinsCTAAGATCTCAACAGAGATGGCAACT; cDNA reference: NM_021926.3; protein reference: NP_068745.2). This mutation was considered causative of the phenotype based on the facts that it is a frameshift mutation with generation of a stop-codon and it segregates only in the affected individuals within this family.We have, then, expanded the phenotype of the *ALX4*-related craniofacial anomalies by describing a patient harboring a heterozygous loss-of-function mutation in the *ALX4* gene that presents a mild frontonasal dysplasia associated with parietal foramina. This illustrates the broad phenotypic spectrum associated to mutations in *ALX4* gene, ranging from isolated parietal foramina to a severe frontonasal involvement.

P02.021

A homozygous novel WDR72 mutation in two siblings with amelogenesis imperfecta and short stature - coincidence or expansion of the clinical spectrum?

A. Kuechler[1], *E. Prott*[1], *B. Schweiger*[2], *J. Hentschel*[3], *I. Kurth*[3], *A. Schuster*[4], *D. Wieczorek*[1], *H. Luedecke*[1];
[1]*Institut für Humangenetik, Universitätsklinikum Essen, Germany,* [2]*Institut für Diagnostische und Interventionelle Radiologie und Neuroradiologie, Universitätsklinikum Essen, Germany,* [3]*Institut für Humangenetik, Universitätsklinikum Jena, Germany,* [4]*Endokrinologikum Ruhr, Bochum-Wattenscheid, Germany.*

Amelogenesis imperfecta (AI) is a clinically and genetically heterogeneous group of inherited defects of enamel formation. In isolated AI (no additional segregating phenotype), mutations in at least 6 genes are known so far, causing dominant, recessive or X-linked AI and allowing the identification of the molecular etiology in ~40% of affected families. We report on two siblings (11 year-old female and 7 year-old male), born to consanguineous Turkish parents, with mild proportionate short stature, normal OFC, mild developmental delay and amelogenesis imperfecta. Both parents have normal teeth, but mother, maternal grandmother and great-grandfather are/were also of short stature. Affymetrix GenomeWide SNP6.0 Array analysis excluded pathogenic copy number changes but showed that both siblings share large homozygous regions. One of those regions is located on chromosome 15q21.3 and contains the WDR72 gene. Mutations in WDR72 are a very rare cause of autosomal-recessive hypomaturation type of isolated AI. The WDR72 protein is critical for dental enamel formation but its exact function is still unknown. By now, only 6 different truncating mutations have been published. WDR72 sequence analysis in both siblings revealed homozygosity for a novel stop mutation in exon 10 (c.997A>T, p.Lys333X) explaining the AI phenotype. Patient reports with AI and mild short stature due to a brachyolmia were found in the literature. But a spine X-ray performed in the girl excluded brachyolmia. Therefore, it remains unclear whether the short stature in the two siblings is due to the mutant WDR72 or segregates as an independent trait in this family.

Identification of a new mutation in exon 1 of androgen receptor gene in a Turkish patient with complete androgen insensitivity syndrome

V. Topçu[1,2], *H. Ilgın Ruhi*[1], *Z. Şıklar*[3], *H. G. Karabulut*[1], *M. Berberoğlu*[3], *B. Hacıhamdioğlu*[3], *S. Savaş Erdeve*[3], *Z. Aycan*[4], *G. Öçal*[3], *F. A. Tükün*[1];
[1]Ankara University School of Medicine, Department of Medical Genetics, Ankara, Turkey, [2]Zekai Tahir Burak Women's Health Education and Research Hospital, Department of Genetics, Ankara, Turkey, [3]Ankara University School of Medicine, Department of Pediatrics, Division of Pediatric Endocrinology, Ankara, Turkey, [4]Dr. Sami Ulus Obstetrics and Gynecology, Children's Health and Disease Training and Research Hospital, Department of Pediatric Endocrinology, Ankara, Turkey.

We report a 22 months old girl with the diagnosis of complete androgen insensitivity syndrome (CAIS). From her medical history, we learned that she had been operated because of left inguinal hernia. Its pathological examination revealed immature testis without malign transformation. Ultrasonography and MRI had shown testis in right inguinal channel, but no wolffian derivatives. In laboratory, basal testosterone was 57,6 ng/dL, stimulated testosterone was 264 ng/dL, stimulated DHT was 30 ng/dL. Accordingly, stimulated T/DHT ratio was calculated as 8,8. Her basal LH was 2,22 mIU/mL, basal FSH was 0,94 mIU/mL. Direct sequence analysis of the androgen receptor (AR) gene showed c.88G>A mutation in exon 1 causing p.val30met in N-terminal domain of the AR. It may disrupt receptor activity in two ways. Firstly, val30 residue is too close to ^{23}FQNLF^{27}-primary androgen dependent motif which stabilizes hormone-receptor complex via N/C interaction. Although both amino acids are hydrophobic in nature, methionine is a bigger molecule than valine. Hence, it may distort the delicate three dimensional structure of the protein and interfere with receptor activity. Secondly, c.88G>A creates a noncanonical start codon. Translation initiation from this noncanonical start codon removes ^{23}FQNLF^{27} motif and disrupts N/C interaction. There are very few missense mutations in exon 1 shown to cause CAIS, and p.val30met mutation has never been reported before.

P02.023

First report of aortic aneurysm in infancy in a new family with Aneurysms-Osteoarthritis Syndrome due to a *SMAD3* mutation: further delineation of the clinical phenotype

A. Wischmeijer[1,2], *G. Tortora*[1], *L. Van Laer*[3], *N. A. Bolar*[3], *G. Van Camp*[3], *E. Fransen*[3], *D. Pacini*[4], *G. Gargiulo*[5], *M. Bonvicini*[6], *M. Ritelli*[7], *M. Colombi*[7], *L. Garavelli*[2], *M. Seri*[1], *B. Loeys*[3];

Maria Nuova IRCCS, Reggio Emilia, Italy, [3]Department of Medical Genetics, Antwerp University Hospital, University of Antwerp, Antwerp, Belgium, [4]Department of Cardiac Surgery, Policlinico S. Orsola-Malpighi, University of Bologna, Bologna, Italy, [5]Pediatric and Grown-Up Congenital Cardiac Surgery, Policlinico S. Orsola-Malpighi, University of Bologna, Bologna, Italy, [6]Department of Pediatric Cardiology, Policlinico S. Orsola-Malpighi, University of Bologna, Bologna, Italy, [7]Division of Biology and Genetics, Department of Biomedical Sciences and Biotechnology, Medical Faculty, University of Brescia, Brescia, Italy.

Recently, mutations in the *SMAD3* gene were found to cause a new autosomal dominant aneurysm condition similar to Loeys-Dietz Syndrome (LDS), mostly with osteoarthritis, called Aneurysms-Osteoarthritis Syndrome (AOS).

Our proband is a 3-year old boy who underwent correction of an inguinal hernia at 3 months and substitution of the ascending aorta for pathologic dilation at 12 months of age. He also presents LDS-like facial features and elongation and kinking of the thoracic aorta on MRI. Family history reveals aortic dilation in his mother, death due to aortic dissection of an 18-year old maternal aunt, surgical replacement of the ascending aorta because of aneurysm in a maternal uncle at 19 years of age, postpartum death of the maternal grandmother at 24 years and surgical intervention because of thoracic aortic aneurysm in a brother of the proband's grandmother at 54 years. Other clinical findings in affected individuals include pes planus, striae, easy bruising, dural ectasia, degenerative disc disease, hiatus hernia, premature loss of teeth. No radiologic evidence of osteoarthritis was present in the family. Molecular testing of the *TGFBR1* and *TGFBR2* genes, involved in LDS, resulted negative, but analysis of *SMAD3* disclosed the novel heterozygous loss-of-function mutation c.1170_1179del (p.Ser391AlafsX7) in exon 9 in all affected family members, confirming the diagnosis of AOS. *SMAD3* mutations should be considered in patients of all ages with LDS-like phenotypes and negative *TGFBR1/2* molecular tests, especially in the presence of early-onset osteoarthritis. Molecular diagnosis allows early identification of patients and relatives at risk of major cardiovascular complications.

P02.024

Neuroleptic susceptibility in Angelman syndrome

A. Jacquette[1], *A. Afenjar*[2], *D. Héron*[1], *P. Charles*[1];
[1]Département de génétique, centre de référence des déficiences intellectuelles, Hôpital de la Salpêtrière, Paris, France, [2]Service de Neuropédiatrie, Hôpital Trousseau, Paris, France.

We report four patients with Angelman syndrome (Ube3a microdeletion confirmed in 15q11 locus) who present severe extra pyramidal syndrome after neuroleptic medication.

Symptoms resolved with discontinuation of treatment.

Those observations suggest high susceptibility to antipsychotic agents in this population and could be move closer to description of two Angelman patients who develop in adulthood extra pyramidal features consistent with Parkinson Disease with spectacular improvement with L-Dopa therapy (Harbord 2001).

It could be useful to perform DAT-Scan in Angelman patients.

In the same way, in the mouse model (maternal loss of Ube3a), number of neurons in the substantia nigra is significantly reduced and motor deficits could be attributed to the dysfunction of the nigrostriatal pathway (Mulherkar et al, 2010).

Furthermore the dysregulation of CaMKII could be responsible of neurological phenotype and could be improved by Levodopa.

In this population, if neuroleptic medication turns out necessary, we suggest to use atypical neuroleptic with different pharmacokinetic pathway with less affinity to Dopaminergic receptors D2.

Those results could improve our understanding of pathophysiological mechanisms involved in Angelman syndrome and lead to finalize new therapeutic strategies.

P02.025

A case of mosaic paternal uniparental disomy 15 identified by SNP-array analisys.

A. Fabretto[1], *A. Skabar*[2], *M. S. Rocca*[1], *M. D. Perrone*[1], *P. Gasparini*[3], *V. Pecile*[1];
[1]S.C. Medical Genetics - Institute for Maternal and Child Health - IRCCS "Burlo Garofolo"- Trieste, I, Trieste, Italy, [2]S.C. Neuropsychiatry - Institute for Maternal and Child Health - IRCCS "Burlo Garofolo"- Trieste, Italy, Trieste, Italy, [3]Institute for Maternal and Child Health - IRCCS "Burlo Garofolo" – Trieste, University of Trieste, Italy, Trieste, Italy.

Angelman syndrome (MIM 105830) is a complex neurodevelopmental disorder caused by loss of function of the imprinted UBE3A gene in 15q11-q13 region. Approximately 7% of cases are due to paternal uniparental disomy (UPD). Our case is the first child of healthy non consanguineous Italian mating. He was born at term after uneventful pregnancy. At birth no anomalies were referred, birth weight = 3540g (50° centile). Growth curve was normal and at 6 yrs his parameters were: weight = 37Kg (>>97°), height = 125cm (50°-75°) and OFC = 52cm (50°-75°). He had normal motor development (sitting = 6m, walking = 10m). He was evaluated for absence of speech. All audiological investigations were normal. He had friendly personality. No facial dysmorphysms were evidenced and no seizures were referred, although sleeping EEG showed anomalies. Molecular karyotype analysis using "HumanCyto-12 BeadChip" ILLUMINA, revealed a paternal UPD 15 mosaicism. Data analyzed with GenomeStudio 2011.1 (cnv Partition 3.1.6) and PennCNV, showed a 80% percentage of mosaicism, which was calculated from B allele frequencies. Results confirmed by UPD study. Is the first time that we can describe a somatic paternal UPD 15 mosaicism. UPD 15 patients normally have milder phenotype with a better prognosis, and our case is a very mild condition with mainly severe speech delay and truncal obesity. If we compare with other cases due to somatic mosaicisms of the imprinting center, our case could clinically overlap although maybe is still milder. Our work suggests that maybe many cases of AS could have been undiagnosed.

P02.026

Array-based genome-wide genotyping in patients with anorectal malformations and intellectual disability and/or malformations of the brain

G. C. Dworschak[1], *M. Draaken*[1,2], *A. Hilger*[1], *C. Schramm*[1], *E. Bartels*[1], *E. Schmiedeke*[1,3], *S. Grasshoff-Derr*[4], *S. Märzheuser*[5], *S. Hosie*[6], *S. Holland-Cunz*[7], *A. M. Zink*[1], *H. Engels*[1], *D. Schmidt*[1,5], *P. Hoffmann*[1,2], *M. M. Nöthen*[1,2], *M. Ludwig*[8], *H. Reutter*[1,9];
[1]Institute of Human Genetics, University of Bonn, Bonn, Germany, [2]Department of

Genomics - Life & Brain Center, Bonn, Germany, [3]Department of Pediatric Surgery and Urology, Center for Child and Adolescent Health, Hospital Bremen-Mitte, Bremen, Germany, [4]Department of Pediatric Surgery, University Hospital Würzburg, Würzburg, Germany, [5]Department of Pediatric Surgery, Campus Virchow Clinic, Charite University Hospital Berlin, Berlin, Germany, [6]Department of Pediatric Surgery, Klinikum Schwabing, Technische Universität München, München, Germany, [7]Department of Pediatric Surgery, University of Heidelberg, Heidelberg, Germany, [8]Department of Clinical Chemistry and Clinical Pharmacology, University of Bonn, Bonn, Germany, [9]Department of Neonatology, University of Bonn, Bonn, Germany.

Anorectal malformations (ARM) occur in about 1 in 2,500 live births. Similar to most congenital defects, ARM can occur as an isolated malformation or associated with other defects or syndromes. To date, no causative genetic or non-genetic factor has been unequivocally identified in humans. Since intellectual disabilities (ID) are frequently associated with chromosomal aberrations, we suggested that a cooccurrence of ARM and ID will make it more likely to detect causative CNVs (copy number variations).

Molecular karyotyping, utilizing 1,134,514 SNPs (single nucleotide polymorphisms), was performed to screen 30 non-isolated ARM patients with ID and/or malformations of the central nervous system. To identify potential CNVs, the SNP fluorescence intensity was analyzed with QuantiSNP using an Objective-Bayes Hidden-Markov model for calling putative CNVs.

Preliminary results revealed probably causative deletions in five patients encompassing chromosomal regions: 6q14.3-q16.3 (16.5 Mb; 51 RefSeq genes), 13q31.2qter (28.5 Mb; 85 RefSeq genes), 17q12-q21.2 (2.1 Mb; 81 RefSeq genes), and two regions on chromosome 22q11.2 (2.54 Mb; 43 RefSeq genes and 2.52 Mb; 43 RefSeq genes, respectively). In one patient we identified a 7.9 Mb duplication on chromosome 3q26.32-q27.2 harboring 56 RefSeq genes. All findings were confirmed by quantitative PCR. These observations support the previously described association of microdeletion on 22q11.2 and the occurrence of ARM and/or ID suggesting this region to harbor genes, which contribute to both phenotypic features. Studying larger cohorts is likely to detect additional CNVs that might give further information on chromosomal regions and genes involved in the etiology of ARM and/or ID.

P02.027

Specific transglutaminase 1 mutation profiles in bathing suit ichthyosis and self-improving collodion ichthyosis

***B. Hartmann**[1], E. Bourrat[2], C. Blanchet-Bardon[2], C. Derbois[3], S. Cure[4], J. Fischer[1,3];*
[1]Institut für Humangenetik, Freiburg, Germany, [2]Department of Dermatology, Hôpital Saint-Louis, Paris, France, [3]CEA, Institut de Génomique, Centre Nationale de Génotypage (CNG), Evry, France, [4]CEA, Institut de Génomique, Centre Nationale de Séquençage (CNS), Evry, France.

Bathing suit ichthyosis (BSI) and self-improving collodion ichthyosis (SICI) are two minor variants of generalized autosomal recessive congenital ichthyosis (ARCI). BSI is characterized by scaling of the skin in a bathing suit pattern, mainly limited to the trunk, whereas SICI is characterized by complete disappearance of the skin lesions. We report genotypic and phenotypic data from a series of 9 patients born as collodion babies, who developed BSI or SICI due to mutations in the transglutaminase-1 gene (TGM1), including 3 previously unreported missense mutations. All our BSI or SICI patients carried at least one specific missense mutation in TGM1 concerning an arginine at position 307 or 315. In two patients the disease evolved in two phases (BSI to SICI or BSI to ARCI). The other 7 patients exhibited a stable BSI phenotype after shedding of the collodion membrane. This study highlights the possibility of variable evolution of the phenotype of patients with identical mutations in the same gene. Combined with data from the literature, this confirms the hypothesis that only a restricted spectrum of TGM1 mutations is susceptible to lead to a BSI and/or SICI phenotype. This phenotypic variability also depends on other genetic and external factors.

P02.028

Application of high resolution array CGH in newborns with multiple congenital anomalies and isolated cleft lip/palate

***K. Szczaluba**[1], K. Derwinska[1], R. Smigiel[2], A. Kutkowska-Kazmierczak[1], J. Klapecki[1], J. Castaneda[1], Z. Dudkiewicz[1], E. Obersztyn[1], E. Bocian[1];*
[1]Institute of Mother and Child, Warsaw, Poland, [2]Wroclaw Medical University, Wroclaw, Poland.

Molecular karyotyping by array CGH has now been widely used for genetic analysis in the setting of both multiple (MCA) as well as isolated congenital birth defects. The technique has the potential of providing diagnosis in up to 27% of newborns with MCA and accompanying dysmorphism and a significant number of neonates with isolated anomaly [i.e. cleft lip/palate(CL/P), heart defect], where it can also identify new candidate genes.

To assess the frequency of array-detected copy number variations (CNVs) in neonates with congenital birth defects we screened two cohorts of 33 newborns with MCA and 40 newborns with isolated CL/P using whole genome Agilent 180k (hg18) microarray with mean resolution of 16kb.

We have found 19 CNVs, including 17 deletions and 2 duplications ranging in size from 27 kb up to ~16Mb. The prevalence of aberrations in the group with MCA was 25% whereas in the group with isolated CL/P it reached 21%. All CNVs found (except 4 deletions exceeding 5Mb) were unique and did not encompass any known microdeletion/microduplication syndrome regions. Novel candidate genes (T brachyury, SLFN12) were suggested in the group with isolated CL/P, whereas in the MCA group one of the interesting findings was del2q35 (STK36 gene). Our results demonstrate that high resolution array CGH is a powerful diagnostic tool in newborns with MCA and isolated CL/P. It can also help in recognition of genes involved in pathogenesis of congenital anomalies.

The research is funded by the grant of the Polish Ministry of Science and Higher Education NN407459438.

P02.029

1p22 microdeletion represents a novel contiguous gene syndrome associated Diamond-Blackfan anemia

***K. Kurosawa**[1], M. Tominaga[1], N. Furuya[1], K. Enomoto[1], T. Saito[1], J. Nagai[1], M. Masuno[2], S. Hamanoue[1], M. Shiomi[1], H. Kigasawa[1];*
[1]Kanagawa Children's Medical Center, Yokohama, Japan, [2]Kawasaki University of Medical Welfare, Kurashiki, Japan.

Diamond-Blackfan anemia (DBA) is characterized by a profound normochromic and macrocytic anemia with normal leukocytes and platelets, congenital malformations, and growth retardation. The phenotype varies from a mild form to a severe form of fetal anemia resulting in hydrops fetalis. DBA is associated with an increased risk of hematological malignancy and solid tumors including osteogenic sarcoma. Other genetic forms of anemia, such as Fanconi anemia, need to be considered and ruled out as appropriate. The mutations of nine genes encoding ribosomal proteins have been recognized to be responsible for DBA. Most of the mutations are detected by sequence analysis except for the RPS19. We present a patient with mild intellectual disability, chronic normochromic anemia, mild neutropenia, normal platelets, and multiple congenital malformations including characteristic facial appearance, finger-like thumbs, atrial septal defect, growth retardation, and vaginal atresia. The detection of chromosomal aberrations in cells after culture with a DNA interstrand cross-linking agent (MMC) failed to determine the diagnosis as Fanconi anemia. Bone marrow examination revealed hypoplastic, but showed normal balanced hematopoiesis. Microarray CGH analysis revealed 7.9 Mb deletion at 1p22.1-p22.3, involving ribosomal protein L5 (RPL5), and transcriptional repressor protein GFI1. RPL5 is responsible for Diamond-Blackfan anemia, and GFI1 is responsible for autosomal dominant severe congenital neutropenia, where both genes are adjacent to each other. These results indicated that the 1p22 microdeletion represents a novel contiguous gene syndrome associated Diamond-Blackfan anemia, but overlapping with clinical features of Fanconi anemia.

P02.030

Array CGH with normal karyotype. Utility in pediatrics diagnosis.

***M. Perez Sanchez**[1], A. Mora Guijosa[1], S. Roldán[2], J. Barrionuevo Porras[2], A. González Ramírez[3];*
[1]Servicio de Análisis Clínicos. Hospital Virgen de las Nieves., Granada, Spain, [2]Servicio de Pediatría. Hospital Virgen de las Nieves., Granada, Spain, [3]FIBAO. Hospital Clínico San Cecilio., Granada, Spain.

Microarray-based comparative genomic hybridization (array CGH) has provides a relatively quick method to scan the genome for gains and loses of chromosomal material. This new methodologies have led to identification of novel genomic disorder in patients with developmental delay/mental retardation and/or multiple congenital anomalies (DD/MR/MCA), with a significant increase in diagnostic yield .

In this study we present the result of array CGH obtained in 150 children with normal karyotype but DD/MR/MCA. The array CGH 60K from agilent platform was performed.

In 34 patients (22,66%) was detected a chromosomal deletion or duplication on previously described like pathogenic copy number variants (CNVs),. In 15 cases (10%) was necessary the analysis of parental samples, showing that 6 anomalies (40%) had occurred de novo and was classified as pathogenic and in 9 cases (60%) appeared to be inherited from an unaffected parent. In a total of 40 patients (26,66%) was possible to detect a pathogenic CNVs .

Recent studies suggest that when aCGH is performed with an apparently normal karyotype, the diagnostic yield increases by an additional 8-17%. In our study we have obtained a 26,66% of children with pathogenic CNVs that is higher than the results obtained by other authors. This increase at the detection rate probably is due to the array type utilized.

As a conclusion, array CGH can be implemented routinely after a normal chromosome result when a phenotype of DD/MR/MCA is present, but is also appropriate for patients with autism and apparently balanced translocations.

P02.031

Human body asymmetry spectrum - dysmorphic and genetic perspectives for five rare disorders

V. N. Plaiasu[1], D. Ochiana[1], G. Motei[1], D. Stambouli[2], E. Neagu[3], L. Barbarii[3];
[1]IOMC Prof.dr.Alfred Rusescu, Bucharest, Romania, [2]Cytogenomic Medical Laboratory, Bucharest, Romania, [3]National Legal Medicine Institute "Mina Minovici", Bucharest, Romania.

Human body asymmetry is a diagnosis with a large spectrum of features, with a multifactorial aetiology: physiological, osseal, neurological, genetic. There are many aspects to discuss involved in asymmetry: situs anomalies, asymetric cell division, laterality, asymetric embriopathy, hemiasymetries, asymetric vascular syndromes, somatic mosaicism.

Asymmetric entities are classified in non-syndromic and syndromic, congenital or acquired, total or limited. Left-right asymmetry has important implications for human health and development.

We report our clinical experience of some rare entities with body asymmetry:

1) an infant with *Beckwith-Wiedemann syndrome* (MIM: 130650)
2) a newborn with probably *Proteus syndrome* (MIM: 176920)
3) three cases with *Klippel-Trenaunay-Weber syndrome* (MIM: 149000)
4) a girl with short stature, left-right asymmetry and radiologic signs of skeletal dysplasia, with clinical diagnosis of *Conradi-Hünermann syndrome* (MIM: 302960)
5) a six years old female patient with *diploid-tetraploid mixoploidy* (92,XXXX/46,XX), demostrated by cytogenetic studies in blood cultures, with asymmetric overgrowth, abnormal skin pigmentation, mental retardation, the first child of a family with primary subfertility.

Different mechanisms involved in the development of asymmetry in these disorders are discussed: mutations of imprinted genes, mosaicism for a somatic activating mutation, pathogenic gene for vascular and tissue overgrowth, random X-inactivation in affected tissues in heterozygous female, mosaicism versus chimerism.

The diagnostic were given according to the associated clinical features. Clinical delineation of the cases with congenital growth asymmetry remains essential until pathophysiological mechanisms are elucidated. Other laboratory tests like chromosomal analysis, biochemical studies, molecular assay, applied on different tissues, help in the differential diagnosis.

ATP6V0A2-related cutis laxa: Case report and review of the literature

C. Daumer-Haas[1], M. Lindner[1], B. Fischer[2], U. Kornak[3];
[1]Pränatal-Medizin München, Munich, Germany, [2]Institut für Medizinische Genetik und Humangenetik, Charité-Universitätsmedizin Berlin, Germany, Berlin, Germany, [3]Institut für Medizinische Genetik und Humangenetik, Charité-Universitätsmedizin Berlin, Germany, Berlin, Germany.

We report on a 2-3/4 year-old Afghanian male patient diagnosed with ATP6V0A2-related cutis laxa whom we first saw postnatally and who has come for routine follow-up consultations. The parents are double first cousins. The boy initially presented with excessive skin wrinkling, microcephaly with a sloping forehead, large anterior fontanelle, dysmorphic facial features (hypertelorism, downslanting palpebral fissures, broad nasal bridge, long philtrum, micrognathia as well as low-set posteriorly rotated and protruding ears), myopia, atrial septum defect and small penis. At the age of 2 months, an inguinal hernia occured. Meanwhile the furrowing of the skin has markedly improved. Our patient has fortunately not shown any signs of developmental delay which is often present in patients with ATP6V0A2-related cutis laxa. All these findings are consistent with the clinical diagnosis of Wrinkly skin syndrome, the clinically mild phenotype of this disorder. Molecular genetic analysis revealed a homozygous c.1A>T mutation of the ATP6V0A2-gene. This is a yet undescribed pathogenic mutation presumably leading to an impairment of initiation of translation. The 20 exons of the gene encode the a2-subunit of the V-type H+-ATPase complex. Immunolabeling with an antibody against the N-terminal domain of ATP6V0A2 demonstrated loss of the a2-subunit in the patient's fibroblasts.

The ATP6V0A2-related cutis laxa is a rare autosomal recessive disorder first described in 1973 by Dr. Gazit. Up until now approximately 60 cases of ATP6V0A2-related cutis laxa have been reported. (OMIM # 278250).

We compare the phenotype and findings of our case to previously published cases.

P02.033

An autosomal recessive form of atrophoderma vermiculatum: Clinical and genetic characterisation

K. Mäbert[1], T. Naeem Khan[2], M. Jameel[2], S. Mahmood Baig[2], N. Dahl[1], J. Klar[1];
[1]Department of Immunology, Genetics and Pathology, Uppsala, Sweden, [2]Human Molecular Genetics Laboratory, National Institute for Biotechnology and Genetic Engineering (NIBGE), Faisalabad, Pakistan.

Atrophoderma vermiculatum (AV) is a rare, benign skin disorder characterized by the occurrence of pitted atrophic and depressed scars in a reticular pattern. AV usually begins in childhood by symmetric reticular or honeycombed atrophy of the cheek. The genetics behind AV is unclear as most cases appear to be sporadic and the few cases with mendelian inheritance seem to follow an autosomal dominant inheritance pattern.

We have identified a consanguineous Pakistani family segregating autosomal recessive AV. In total, the extended family contains four affected individuals, three affected siblings and their first cousin. Parents to affected individual were healthy. Affected individuals are born with normal skin. Symptoms starts at approximately one year of age by tear shedding provoqued by sunlight, breeze and cool air, followed by the development of characteristic skin changes. The facial skin shows pit like areas of atrophy distributed most prominently over the cheeks, extending to the chin, upper lip, forehead and nasal ridge. The atrophic pits are separated by ridges of normal looking skin.

We have recently initiated homozygosity mapping and exome sequencing to identify the mutation behind autosomal recessive AV. The results from these efforts will be presented.

P02.034

Two cases with different microaberrations of the long arm of chromosome 15 and autism

D. Avdjieva-Tzavella[1], S. Hadjidekova[2], B. Rukova[2], D. Nesheva[2], R. Tincheva[1], D. Toncheva[2];
[1]Department of Clinical Genetics, University Pediatrics Hospital, Medical University, Sofia, Bulgaria, Sofia, Bulgaria, [2]Department of Medical Genetics, Medical Faculty, Medical University, Sofia, Bulgaria.

Autism is a complex neurodevelopmental disorder of the immature brain with unknown origin that manifests in early childhood. The exact aetiology of autism remains speculative, although it is likely to result from a complex combination of multiple non genetic and/or genetic factors. Advances in high-resolution comparative genomic hybridization (CGH) microarray technology have revealed sub-microscopic aberrations that lead to identification of many disease-causing genomic copy number variants (CNVs) in autism. Numerous reports have implicated duplications or deletions of proximal chromosome 15q as significant risk factors for autism and autism-related disorders.

We report two autistic children with 15q11-13 rearrangements. We have used genomic array CytoChip Oligo (BlueGnome, Cambridge, UK), format 2x105K, version 1.1. and BlueFuse Multi software, version 2.2. The 2x105K array detects 35 kbp imbalances on the backbone and has tiling of 20 probes over 137 OMIM disease loci. In the first case a de novo cryptic deletion of 2q36.3 region spanning 1,456 Mb and amplification of (15)(q12q13.1) region spanning 3,473 Mb were found in 12 years old girl with autism, severe mental retardation and dysmorphic features. The second case showed deletion of 15q11.2 region spanning 494, 905 bp in a boy with idiopathic autism. FISH experiments with BAC clone confirm the CytoChip results.

These data strongly support the implication of 15q11-13 rearrangements as a predisposing factor for autism.

P02.035

The clinical and genealogical diagnosis of autosomal dominant spinocerebellar ataxias in Yakutia

M. A. Varlamova, E. E. Gurinova, I. A. Nikolaeva, A. L. Suhomyasova, N. R. Maksimova;
Yakut Scientific Centre of Complex Medical Problems, Siberian Branch of the Russian Academy of Medic, Yakutsk, Russian Federation.

According to genetic-epidemiological investigations of Yakut population in Republic Sakha (Yakutia), the frequency of hereditary diseases in Yakuts are very high. Most common AD disease in Yakuts is a spinocerebellar ataxia. 80% of SCA are SCA 1 type. The high incidence of the SCA1 in Yakutia (38.6 per 100000), compared to 1-2:100000 in the world population.

The aim of study was to establish of the spectrum of genetic form of AD SCA in Yakutia.

A computer database of patients with cerebellar syndrome was established. 83 families with SCA1 and 9 familial and 66 sporadic cases of undifferentiated SCA identified by clinical and genealogical research. Differential diagnosis was performed on the five forms of AD SCA: SCA2, 3, 6, 17 and DRP-

LA. The expansion of CAG-repeats in the genes SCA 2, 3, 6, 17 in the studied sample while was not found.
In four patients from one of the Yakut families the expansion of CAG-repeat in the gene of DRPLA (DRPLA) were discovered. In the proband`s DNA molecular analyses of the DRPLA gene showed two alleles of 23/64 CAG-repeats, in the mother`s DNA - 19/61, in the sibs`s DNA - 19/61 and 19/63 repeats (normal range ≤ 36). This is a first description of family with genetically established DRPLA reported in Yakutia. Most members presented with ataxia and chorea and some of these developed dementia late in the course of the disease. These clinical symptoms of Yakut patients with DRPLA are identical with the cases on another patients with DRPLA.

Jervell and Lange-Nielson Syndrome: Homozygous missense mutation in KCNQ1 in a Turkish family

S. G. Temel[1], *O. Bostan*[1], *H. Cangul*[2], *E. Cil*[1];
[1]*University of Uludag, Faculty of Medicine, Dept. of Pediatric Cardiology, Bursa, Turkey,* [2]*University of Birmingham, Department of Medical and Molecular Genetics, School of Clinical and Experimental Medicine, Birmingham, United Kingdom.*

Long QT syndrome is one of the most common cardiac ion channel disease which its morbidity and mortality rate can be lessened with an early diagnosis and proper treatment. It is a cardiac repolarization abnormality that is characterized by prolonged OT interval and propensity for ventricular tachycardia (VT) of the torsades de pointes type are the charecteristics of the disease. This syndrome represent high risk of presyncope, syncope, cardiac arrest and sudden death. Jervell and Lange-Nielson syndrome (JLNS) is one of the inherited form of long QT syndromes. It is inherited recessively and characterized by profound sensorineural deafness and prolongation of the OT interval, thus representing abnormal ventricular repolarizasiton. JLNS has been shown to occur due to homozygous and copmpound heterozygous mutations in KCNQ1 or KCNE1. There was one clinical report on JLNS in Turkey; however, it was not confirmed by a molecular study. We identified a homozygous mutation in KCNQ1 in a 3.5-yr-old female child with JLNS, who visited the hospital due to recurrent syncope and seizures and had congenital sensorineural deafness. Her electrocardiogram revealed a markedly prolonged QT interval. The sequence analysis of the proband revealed the presence of homozygous missence mutation (c.728G>A, p.R243H). Heterozygous mutation in KCNQ1 was identified on the maternal, paternal and sister side. Even if with a high dose β-blocker therapy the patient has twice VT attacks, because of this reason the implanted cardiac defibrillator (ICD) was planned and implanted. We suggest early genetic diagnosis for proper management of the disease and genetic counseling.

P02.037

Axenfeld-Rieger Syndrome Type 1 - family case report

C. C. Albu[1,2], *D. F. Albu*[1,2], *E. Severin*[1];
[1]*University of Medicine and Pharmacy Carol Davila, Bucharest, Romania,* [2]*Alco San Clinic, Bucharest, Romania.*

INTRODUCTION: The **Axenfeld-Rieger syndrome** is a rare, autosomal dominant disorder, characterized by corneea defects, iris defects and glaucoma. More than 50% of pacients become blind because of glaucoma complications. Other associated developmental defects involve the teeth and facial bones.
MATERIAL AND METHODS: We present a family with **Axenfeld-Rieger syndrome** on four generations. Complete ophthalmic examination (biomicroscopy, gonioscopy, oculo-orbitar ultrasound, corneal topography) and general examination of the patients showed ocular and non-ocular manifestations. The craniofacial and oral examination involved cephalometric radiographs and orthopantomograms. All the patients were screened for mutations in PITX2 and FOXC1 by DNA Analysis.
RESULTS: DNA Analysis of all the patients revealed a mutation of the PITX2 gene.
CONCLUSIONS: We present a family with **Axenfeld-Rieger syndrome** type 1 on four generations, a very rare disorder with clinical and genetic variability.

Muscle hemangiomatosis as a severe presenting feature in a patient with *PTEN* mutation: Expanding the phenotype of vascular malformations in Bannayan-Riley-Ruvalcaba syndrome

Y. Soysal[1], *T. Acun*[2], *C. M. Lourenço*[3], *W. Marques Jr*[4], *C. Yakıcıer*[5];
[1]*Afyon Kocatepe University, Afyonkarahisar, Turkey,* [2]*Zonguldak Karaelmas University Department of Biomedical Engineering, Zonguldak, Turkey,* [3]*University of São Paulo, Faculty of Medicine of Ribeirao Preto,Clinics Hospital of Ribeirao Preto, Neurogenetics Division, São Paulo, Brazil,* [4]*University of São Paulo, Faculty of Medicine of Ribeirao Preto, Clinics Hospital of Ribeirao Preto, Neurogenetics Division, São Paulo, Brazil,* [5]*Acıbadem University, Faculty of Medicine, Department of Medical Biology and Genetics, Istanbul, Turkey.*

Bannayan-Riley-Ruvalcaba Syndrome (BRRS) is a rare autosomal dominantly-inherited hamartoma syndrome with distinct phenotypic features. Mutations in the *PTEN* gene have been identified in PTEN hamartoma tumor syndromes. Our aim was to determine the correlation of phenotype-genotype relationships in a BRRS case. We have evaluated a *PTEN* mutation in a patient with vascular anomalies and the phenotypic findings of BRRS. We described an eight-year-old girl with the clinical features of BRRS, specifically with vascular anomalies. The mutation in the *PTEN* gene was identified by DNA sequencing. In our patient, we defined a de novo non-sense R335X (c.1003C->T) mutation in exon 8, which results in a premature termination codon. Due to vascular anomalies and hemangioma, the patient’s left leg was amputated one year after hemangioma diagnosis. In conclusion, BRRS patients with macrocephaly and vascular anomalies should be considered for *PTEN* mutation analysis and special medical care.

Bardet-Biedl Syndrome with disorder of sex development: A new case report from Tunisia

R. Louati, *T. Rebai*, ***N. B. Abdelmoula***;
Medical University, Sfax, Tunisia.

Bardet-Biedl syndrome (BBS) is a ciliopathy causing multivisceral abnormalities. It is a rare and heterogeneous genetic condition characterized by obesity, mental retardation, dysphormic extremities, retinal dystrophy, hypogonadism and renal anomalies. Prevalence rates are estimated of 1:140000 to 1:160000 in North America and Europe, respectively but in Asian, Australian and African continents, there are only case reports and small serials. To date, mutations in 18 different loci are responsible for BBS phenotype. Here, we report a new case of BBS from Tunisia characterized by sexual ambiguity without renal abnormalities. The patient who is 24 years old was referred to our genetic counselling because of aspermia. Patient history reveals bilateral orchiopexy one year ago. Physical examination showed poor visual acuity, strabismus and gaze nystagmus (with retinal degeneration), obesity, tetramelic postaxial polydactyly, superficial dilatation of veinules, dental problems, short neck, low hairline at the nape of the neck, impaired coordination and ataxia and moderate mental deficiency. At sexual level, the patient had a female voice, small empty scrotums that look like labia majora with a severe microphallus. Cytogenetic evaluation reveals a 46,XY male formula. Tetramelic polydactyly which is described in our patient and in some other members of his family seems to be associated to BBS chromosome 3 locus. Molecular diagnosis will lead to familial genetic counseling as well as to surveillance of the patient who need a multidisciplinary medical care especially to detect renal abnormalities which is the main life-threatening features and the other complications including hypertension and Type 2 diabetes.

Gerardo Hospital MBBM Foundation, Monza, Italy,* [8]*Medical Genetics, Department of Medicine, Surgery and Odontoiatry, Milan, Italy.*

Beckwith-Wiedemann syndrome (BWS) is characterized by cancer predisposition and a variable association of overgrowth, macroglossia, abdominal defects, renal anomalies, *nevus flammeus*, ear malformations, hypoglycemia, hemihyperplasia, and organomegaly. BWS molecular bases are heterogeneous as several mechanisms lead to unbalanced transcription of genes regulated by 11p15 chromosomal region Imprinting Center IC1 and IC2. We searched for epigenotype-phenotype correlations in 265 BWS patients with diagnostic criteria and proven molecular defect. Patients’ characteristics were compared among molecular subclasses: KvDMR1 hypomethylation (IC2, n=153), H19/IGF2 hypermethylation (IC1, n=27), chromosome 11p15 paternal uniparental disomy (UPD, n=65), CDKN1c mutation (n=10), and Multiple Differently Methylated Region Methylation Defect (MDMD, n=9). The table summarizes the differences among groups. Each showed different growth patterns: neonatal macrosomia in IC1 patients, postnatal overgrowth in IC2/CDKN1c/MDMD patients, and hemihyperplasia in UPD patients. Exomphalos was more common in IC2/CDKN1c patients, whereas *diastasis recti* and umbilical hernia were associated with IC1 defects, consistent with organomegaly and polyhydramnios. Renal defects were typical of UPD/IC1 patients, and uretheral malformations of IC1 cases. Ear anomalies and *nevus flammeus* were associated with IC2/CDKN1C/MDMD genotype. Macroglossia, almost always present, was less common in UPD. Wilms' tumor was associated with IC1 defects and never observed in IC2 patients. Hepatoblastoma was typical of UPD and other tumors were randomly scattered among molecular subclasses. In BWS is definable a clear phenotype-epigenotype correlation allowing tailored follow-up and cancer screening procedures.

Beckwith-Wiedemann syndrome - clinical findings in Polish patients with IC2 (KvDMR) hypomethylation in 11p15 region

D. Jurkiewicz, *M. Kugaudo, A. Tańska, E. Ciara, D. Piekutowska-Abramczuk, J. Trubicka, S. Łuczak, M. Borucka-Mankiewicz, P. Kowalski, M. Pelc, A. Jezela-Stanek, K. Chrzanowska, M. Krajewska-Walasek;*
Department of Medical Genetics, The Children's Memorial Health Institute, Warsaw, Poland.

Beckwith-Wiedemann syndrome (BWS) is characterized by overgrowth, macroglossia, abdominal wall defects and a high risk of childhood tumors. BWS is caused by various 11p15 genetic or epigenetic defects leading to defective expression of imprinted genes. The genes in 11p15 region are organized into two imprinted domains controlled by two Imprinting Centers: IC1 (H19DMR) and IC2 (KvDMR). The most common defect in BWS (~50%) is loss of methylation at IC2. Paternal UPD of 11p15, gain of methylation at IC1, mutations in *CDKN1C* gene encoded on 11p15 and chromosomal rearrangements also result in the BWS phenotype. Some specific phenotype-(epi)genotype correlations are observed in BWS. However, there is a marked phenotypic variability within molecular subgroups.
We present fourteen Polish patients with BWS and IC2 hypomethylation. A molecular analysis was performed by methylation sensitive multiplex ligation-dependent probe amplification (MS-MLPA) in a group of thirty five unrelated BWS patients. The analysis demonstrated loss of methylation at IC2 in 40% of investigated patients. All the patients presented clinical features typical for BWS, although in various degree. The study underlines correlation between IC2 hypomethylation and the presence of BWS features such as: macroglossia (14/14 cases), characteristic face (14/14 cases), abdominal wall defects (12/14 cases) and anterior ear lobe creases and/or posterior helical pits (12/14 cases). An interesting finding is a relatively high prevalence of cryptorchidism (5/9 male patients). The further investigations of the genetic background of BWS in Polish population are under way.
The study was financed by National Science Centre, project no. 1149/B/P01/2011/40 (NN407114940).

Ophthalmic status of the patients with Bloch-Sulzberger syndrome

M. O. Mkheidze[1], ***O. K. Janvareva***[2];
[1]*Medical University named after I.I Mechnikov, St.Petersburg, Russian Federation,* [2]*Medical Centre of St.Petersburg University, St.Petersburg, Russian Federation.*

Bloch-Sulzberger syndrome (BSS) or Incontinentia pigmenti (MIM 308300) is an X-linked dominant syndrome with cutaneous, neurologic, ophthalmologic, and dental manifestations. It is caused by mutations in the IKK-gamma gene (IKBKG; MIM 300248, Xq28). A.Garrod reported the first probable case of incontinentia pigmenti in 1906. Subsequently, Bloch and Sulzberger further defined the condition in 1926 and 1928, respectively, as a clinical syndrome with unique features of typical cutaneous manifestations. IKK-gamma is the regulatory subunit of the inhibitor kappa kinase (IKK) complex and is required for the activation of the transcription factor NF-kappaB (NF-kB). NF-kB is central to many immune, inflammatory, and apoptotic pathways. The incidence of BSS is believed to be 1 case per 40,000. Here we reported on 5 female patients with BSS aged from 4 to 20 yr. Proband mothers (3/5) had multiple male miscarriages. All patients had hypopigmented, atrophic patches, conical forms of their teeth and some ophthalmologic findings. Two patients had strabismus and nystagmus due to congenital ectopy of the macula and optic nerve atrophy. Their visual acuity was insufficient and rehabilitation process was difficult without positive prognosis. Three patients had vitreoretinal abnormality as congenital hyperplastic persistent vitreous body complicated with traction retinal detachment. These probands have been observed formerly as the patients suffered from retrolental fibroplasias. Vitrectomy with scleral buckle was performed with successful anatomical results and preservation visual function

Bohring-Opitz symdrome (BOS) is a rare condition comprising distinct facial features including bulging forehead over the metopic suture, frontal nevus flammeus, exophthalmos, retinal abnormalities, hypertelorism, upslanting palpebral fissures, and cleft lip and/or palate, intrauterine growth retardation, severe failure to thrive, flexion deformities of the upper limbs, lower limb deformities, severe developmental delay, and death often early in childhood. Recently, ASXL1 nonsense mutations were identified in 7/13 suspected BOS cases as the cause of the syndrome [Hoischen et al., 2011]. Here we report on 10, clinically undoubtful cases with BOS. All of them fulfilled the diagnostic criteria proposed by Bohring et al. [2006] and all carry a private, previously undescribed heterozygous nonsense/frameshift ASXL1 mutation. As far as parental DNA was available for analysis, the mutations were shown to be de novo. Thus, our data further support ASXL1 as the main cause of BOS and confirm exon 13 (NM_015338) as mutational hotspot in this syndrome. In addition, our data show that in clinically well characterized cases the detected mutation rate may be 100%. Further carefully performed genotype-phenotype studies are necessary to specify the most appropriate key symptoms and to differentiate between BOS and other phenotypically overlapping syndromes or to prove genetic heterogeneity.

Bohring-Opitz Syndrome; BOPS (#605039), also known as C-like syndrome, is a very rare malformation disorder, reported until now in about twenty, unrelated, subjects. The delineation of BOS was made by Bohring, in 1999, on the basis of a complex phenotype characterized by IUGR, feeding problems, severe intellectual ad motor disability, trigonocephaly, frontal nevus flammeus, exophthalmus, cleft palate, flexion of elbows and wrists, hirsutism. More recently (2011) Hoischen , sequencing the exomes of 13 unrelated subjects with BOS, identified mutations of ASXL1 gene, in 7 of them, suggesting the genetic heterogeneity of this disorder. Here we report the follow-up study of three, unrelated, Italian subjects with BOS, and we briefly underline the natural history steps, and the major clinical aspects useful for the diagnosis at different ages. The first two children (a female and a male) are still alive, respectively aged 3 and 7 years; the third patient (a female) passed at age 22. Only the male is able to walk. Absolute lack of language in all patients. Extremely similar, clinical phenotype at birth, with characteristic face, frontal nevus flammeus, severe myopia, BOS "attitude". The face was decidedly less typical in the third patient since the age 15. Severe mental retardation in cases 1 and 3: the male interacts by using cards with images and alphabetical letters.Sequencing analysis of ASXL1 gene in the first and second child, revealed new mutations, respectively c.2407_2411del5 [p.Q803TfsX17] and c.2893C>T[p.R965X]. We are looking for biological samples of the third patient to screen the ASXL1 gene.

P02.045

Unusual presentation of combined saggital-metopic synostosis represents the second case of the Boston-type craniosynostosis syndrome

*A. Janssen[1], M. J. Hosen[2], P. Jeannin[1], P. J. Coucke[2], A. De Paepe[2], **O. M. Vanakker**[2];*
[1]Department of Paediatrics, Jan Palfijn Hospital, Ghent, Belgium, [2]Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium.

Background. Craniosynostosis, caused by early fusion of cranial sutures, can include premature fusion of the saggital (scaphocephaly) or metopic suture (trigonocephaly). Though often occurring as isolated findings, their co-existence in a craniosynostosis syndrome is infrequent and mostly sporadic.

Case description. The male proband presented with premature fusion of the saggital and metopic suture. Imaging revealed also coronal synostosis and multiple endocranial hypoplastic areas. Radiographs demonstrated bilateral agenesis of the middle phalanges in the feet. Family history revealed the father, his sister and half-sister, to have scaphocephaly with 3-4 syndactyly. The paternal grandfather did not have a phenotype, though the great grandfather had bilateral 3-4 syndactyly. Molecular analysis revealed a mutation (p.P148L) in the MSX2 gene, which has been associated with the Boston-type of craniosynostosis in a single family (Warmer et al., 1993). Segregation analysis confirmed non-penetrance in the grandfather.

Conclusion. In this four-generation family with various expression of scaphocephaly and severe trigonocephaly, molecular analysis revealed a missense mutation in MSX2, previously described in the Boston craniosynostosis family. Besides unique features such as incomplete penetrance, limb abnormalities and the cranial sutures involved, our patients share with the original family autosomal dominant inheritance with anticipation and the endocranial hypoplastic areas. Though these findings are diagnostic clues for MSX2-related craniosynostosis, the initial patients in this family presented with isolated scaphocephaly and syndactyly. MSX2 analysis should therefore be considered in patients with scaphocephaly, especially if a positive family history for craniosynostosis or syndactyly is present.

P02.046

Unusual Phenotype of Brachydactyly in a Patient with a GDF5 Splice Mutation

***M. Rieger**[1], S. Mundlos[2], S. Reif[1], F. R. Kreuz[1], J. Plaschke[1], S. Krüger[1], A. Bier[1];*
[1]Gemeinschaftspraxis für Humangenetik, Dresden, Germany, [2]Institut für Medizinische Genetik und Humangenetik der Charité, Berlin, Germany.

Brachydactyly (BD) is characterised by shortening of digits due to abnormal development of phalanges and/or metacarpals. BD has been classified on an anatomic basis into five types (A to E) with several subgroups. This group of inherited hand and foot malformations usually follows an autosomal dominant inheritance.

In recent years, mutations affecting the GDF5, a signal protein of the bone morphogenic protein family, have been shown to result in skeletal malformation syndromes like brachydactyly type A2 (BDA2), brachydactyly type C (BDC), proximal symphalangism, multiple synostoses syndrome 2 and acromesomelic dysplasias of the Hunter-Thompson, Grebe and DuPan types.

Here we report on 21-year-old male with hypoplasia of all middle phalanges, shortening of all metacarpals except of the 2nd metacarpal, normal height, scoliosis, shortening of his arms' length and Madelung deformity. Complete analysis of the growth/differentiation factor 5 (GDF5) gene identified heterozygosity for a novel splice mutation in intron 3 (c.631+2T>G).

Until now, no splice mutations have been described for GDF5. The phenotype of our patient could not be classified as one of the well-known types of BD, since there are overlapping features of several skeletal malformation syndromes. Hence, our findings extend the spectrum of phenotypes caused by mutations in the GDF5 gene.

P02.047

6p24.2 microdeletion involving TFAP2A without classic features of branchio-oculo facial syndrome.

***C. P. Barnett**[1], S. Yu[2];*
[1]Women's and Children's Hospital/SA Pathology, North Adelaide, Australia, [2]SA Pathology at Women's and Children's Hospital, North Adelaide, Australia.

Branchio-oculo-facial syndrome (BOF, MIM 113620) results from haploinsufficiency of TFAP2A on 6p24.2. The cardinal features of BOF are pseudo-cleft of the upper lip, brachial sinus/post auricular linear skin lesion, auricular/lip pits, lacrimal duct obstruction, short stature and intellectual disability. Other features described include coloboma of the iris/retina and preaxial polydactyly. Here we describe a mother and daughter with a deletion at 6p24.2 involving TFAP2A but with a clinical presentation that would not have led to a diagnosis of BOF.

The proband was seen at 3-months of age. She was growth restricted at birth (1985gm at 37 weeks gestation). Examination revealed a non-dysmorphic infant with no evidence of a branchial sinus, linear skin lesion or pseudo-cleft of the lip. A blocked left lacrimal duct was diagnosed in the first few weeks of life. Numerous investigations were performed because of growth restriction and poor feeding. Hearing was normal and renal ultrasound revealed mild pelvicalyceal dilatation. Array CGH revealed a 593 kb deletion at chromosome 6p24.2-p24.3 involving TFAP2A.

The infant's 26-year-old mother was also found to carry the deletion. She has a mild intellectual disability and good general health. She had lacrimal duct obstruction until 11 years of age, requiring surgical intervention. She had normal hearing and normal kidneys and was of normal stature. Close examination of her branchial region and lips/philtrum was normal.

This case adds to the growing list of atypical presentations of "classical" single gene disorders which have only come to light in the array CGH era.

P02.048

BRESEK/BRESHECK syndrome and IFAP syndrome are allelic disorder caused by mutation in MBTPS2

***S. Mizuno**[1], M. Naiki[2], K. Yamada[3], Y. Yamada[3], R. Kimura[3], M. Oshiro[4], N. Okamoto[5], Y. Makita[6], M. Seishima[7], N. Wakamatsu[3];*
[1]Central Hospital, Aichi Human Service Center, Kasugai, Aichi, Japan, [2]Nagoya University Graduate School of Medicine, Nagoya, Japan, [3]Institute for Developmental Research, Aichi Human Service Center, Kasugai, Aichi, Japan, [4]Japanese Red Cross Nagoya Daiichi Hospital, Nagoya, Japan, [5]Osaka Medical Center and Research Institute for Maternal and Child Health, Osaka, Japan, [6]Asahikawa Medical University, Hokkaido, Japan, [7]Gifu University Graduate School of Medicine, Gifu, Japan.

BRESEK/BRESHECK syndrome is a multiple congenital malformation characterized by brain anomalies, retardation, ectodermal dysplasia, skeletal deformities, ear or eye anomalies, and kidney dysplasia/hypoplasia, with or without Hirschsprung disease and cleft palate/cryptorchidism. The syndrome is quite rare, but the combination of ectodermal dysplasia, vertebrae anomaly and Hirschsprung disease is unique to this syndrome.

Here, we report the fourth male patient presenting with brain anomaly, mental and growth retardation, ectodermal dysplasia, vertebral (skeletal) anomaly, Hirschsprung disease, ear anomalies (low-set and large ears), cryptorchidism, and kidney hypoplasia; these manifestations fulfill the clinical diagnostic criteria of BRESHECK syndrome. Since all the patients with BRESEK/BRESHECK syndrome are male, and X-linked syndrome of ichthyosis follicularis with atrichia and photophobia (IFAP) syndrome sometimes associates with some of the features of BRESEK/BRESHECK syndrome, such as mental retardation, vertebral and renal anomalies, and Hirschsprung disease, we analyzed the causal gene of IFAP syndrome, MBTPS2, in our patient and identified an R429H mutation.

This mutation has been reported to cause the most severe type of the IFAP syndrome, including neonatal and infantile death. These results demonstrate that the R429H mutation in MBTPS2 causes BRESEK/BRESHECK syndrome.

Since the original description of IFAP syndrome did not include structural abnormalities, and photophobia, which is one of the triad of IFAP Syndrome, is hardly diagnosed in severely intellectually disabled patients as present case, we propose BRESEK syndrome remains as a clinical entity for diagnosis of congenital anomaly syndrome.

P02.049

Detailed analysis of IGF2 isoforms in patients with imprinting defects

*U. Martiné[1], C. Rudloff[1], D. Langer[1], F. Bohne[1], W. Jessen[1], C. Eider[1], N. Bachmann[2], C. Bergmann[2], T. Eggermann[3], B. U. Zabel[4], T. Enklaar[1], **D. Prawitt**[1];*
[1]Center for Pediatrics and Adolescent Medicine, University Medical Center, Mainz, Germany, [2]Bioscientia Institute for Medical Diagnostics GmbH, Ingelheim, Germany, [3]Institute of Human Genetics RWTH, Aachen, Germany, [4]Center for Pediatrics and Adolescent Medicine, University Medical Center, Freiburg, Germany.

As part of the network „Imprinting Defects“ we aim to understand the regulatory mechanisms of the human organism to achieve monoallelic gene expression and how this is altered in patients with the imprinting defects Beckwith-Wiedemann (BWS) and Silver-Russell syndrome (SRS). They mostly show epigenetic alterations within two clusters of imprinted genes within the chromosomal region 11p15.5. Altered methylation at additional imprinted gene loci can be found in a significant proportion of BWS and SRS patients with unknown molecular cause or pathogenic consequence. One designated effector gene involved in BWS and SRS growth defects is IGF2. It is hyperactivated by loss of imprinting in most BWS patients and silenced in most SRS patients with 11p15.5 epimutations. The IGF2 gene is transcribed from five promoters, each of which drives the transcription of the coding region with an individual first exon. They differ in allele- and tissuespecificity. In addition an alternative splice site lies within the second coding exon present in all promoter isoforms. We analysed the distribution of IGF2 splice-isoforms and promoter usage in selected human fetal tissues and in primary fibroblasts of BWS and SRS patients as well as in patients with multi locus hypomethylation, a patient with an unrelated overgrowth phenotype and normal controls to determine disease associated isoform usage. In addition we established genetically engineered HEK293 cells with isoformspecific IGF2 overexpression and analysed the potential of enhanced IGF2 thresholds in triggering tumorigenesis by critically altered Akt/mTOR and Erk1/2 pathways.

P02.050

Investigation of notch3 in cadasil in 10 patients in Iran

M. Balali[1], *O. Ariani*[1], *S. Saber*[1], *V. Ghodsinejadkalahroudi*[1], *M. Houshmand*[1,2];
[1]*Special Medical Center, Tehran, Islamic Republic of Iran,* [2]*National Institute for Genetic Engineering and Biotechnology, Dep. of Medical Genetics, Tehran, Islamic Republic of Iran.*

Cerebral autosomal dominant arteriopathy with sub cortical infarcts and leukoencephalopathy (CADASIL is an inherited cerebrovascular disease due to mutations of the Notch3 gene at the chromosome locus 19p13. The symptoms of CADASIL are attributed to mutations in this gene. . Allelic variants of Notch3 . In addition to the clinical workup for genetic testing for this mutation can be used in familial or sporadic ischemic disorders of undetermined cause to assist in confirming a diagnosis. our lab‘s CADASIL DNA Sequencing Test will detect approximately 85% of the mutations resulting in the phenotype of the disease. CADASIL experts recommend that people under 65 with the following characteristics should be tested: Depression, memory loss, behavior change, migraine, and/or stroke-like symptoms, such as recurrent stroke at a young age (<29 years old) when associated with prominent white matter disease/diffuse white matter hyperintensities on MRI. • Lack of significant vascular risk factors. It is important to note that because there is no treatment for CADASIL, a similar counseling protocol to Huntington‘s disease should be followed for presymptomatic patients. It is understood that presymptomatic genetic testing for CADASIL can have potential benefit and clinical utility. Often under appreciated, however, are the types of possible adverse outcomes and, the severity and duration of the problems. The American Academy of Neurology has published recommendations and practice guidelines

We have checked eighteen patients since then (referred to our lab or diagnosed by Dr. Aryani). Six of the eighteen cases were affected by CADASIL and the others were normal

P02.051

Eleven patients with Camptodactyly-Arthropathy syndrome in a kindred Turkish family caused by homozygous deletion in PRG4 gene

E. Gül[1], *S. Yılmaz*[2], *K. Bilguvar*[2], *Ö. Kasapçopur*[1], *M. Günel*[2], **B. Tüysüz**[1];
[1]*İstanbul University, Cerrahpasa Medical Faculty, İstanbul, Turkey,* [2]*Yale University, Departments of Neurosurgery and Genetics, New Haven, CT, United States.*

The camptodactyly-arthropathy-coxa vara-pericarditis syndrome (CACP) is an autosomal recessive condition characterized by the association of congenital or early onset camptodactyly and noninflammatory arthropathy with synovial hyperplasia. Progressive coxa vara deformity and/or noninflammatory pericardial or pleural effusions have been observed in some patients. CACP is caused by mutations in Proteoglycan 4 (PRG4) gene, encodes a protein that presents in synovial fluid and at surface of articular cartilage and acts as lubricating glycoprotein in protecting joints. We describe two siblings at age of 2 and 9, and two patients who are their second cousins at ages between 14 and 35. It was noticed that 7 distant relatives of these patients share same findings. Swelling of wrist and elbows were earliest symptoms of the disease, even in first years of life. The age of arthropathy onset was 1 years, and camptodactyly began around 4 years old. Severe hip and vertebral involvement were developed during at the age of 20’s. Patients had mild coxa vara. Although none of the patient had pericarditis, sister of one of the patients with same findings died due to cardiac problems at 34 years old. A novel frameshift mutation including 1 bp homozygous deletion (c.1068delA) in PRG4, predicting early truncation of the protein (p.Thr358fs), was found. This is the first report of PRG4 mutation in Turkish family with CACP and supports the hypothesis that only termination mutations cause phenotype since all previously reported PRG4 mutations are predicted to produce a premature termination.

P02.052

A novel missense mutation (c.1442C>A) in the BRAF gene caused Cardio-facio-cutaneous syndrome: Case report

F. Hazan[1], *E. Karaca*[2], *S. A. Koker*[3], *H. A. Korkmaz*[3], *T. Mese*[4], *H. Onay*[2], *F. Ozkinay*[2];
[1]*Department of Medical Genetics, Dr. Behcet Uz Children‘s Hospital, Izmir, Turkey,* [2]*Department of Medical Genetics, Ege University Faculty of Medicine, Izmir, Turkey,* [3]*Department of Pediatrics, Dr. Behcet Uz Children‘s Hospital, Izmir, Turkey,* [4]*Department of Pediatric Cardiology, Dr. Behçet Uz Children‘s Hospital, Izmir, Turkey.*

Cardio-facio-cutaneous syndrome (CFCS) is a multiple congenital anomaly disorder characterized by craniofacial features, cardiac defects, ectodermal anomalies and neurocognitive delay. CFCS is caused by mutations in BRAF, MEK1, MEK2, KRAS genes encoding proteins of the RAS/ MAPK signaling pathway. In more than 70% of CFCS patients, BRAF gene mutations are detected. BRAF is an oncoprotein and somatic mutations occur in BRAF in approximately 8% of all human cancers. The most common germline BRAF mutations have been identified in 7 out of 18 exons (6, 11-16). In this case report, we present a ten-year-old boy who had characteristic craniofacial features of CFCS, short stature, hypertrophic cardiomyopathy, café au lait spots, developmental delay and severe mental retardation. A novel, de novo missense mutation (c.1442C>A) leading to A481E aminoacid substitution in exon 12 of the BRAF gene was detected by sequence analysis. This mutation was not detected in both parents.

It is considered that the novel mutation defined in the case presented causes CFCS with severe mental retardation and the sequence analysis of exons 6, 11-16 of BRAF gene is recommended in the first step for the molecular diagnosis.

P02.053

Copy number variations shape human brain: The contribution of the array-CGH in the understanding of the genetic bases of congenital brain malformations and cognitive disorders

E. Chabchoub[1,2], *A. Mlika*[3], *A. Attig*[2], *R. Zemni*[2], *R. Ben Mefteh*[2], *M. Kessentini*[4], *H. Kamoun*[4], *R. Mrad*[5], *J. R. Vermeesch*[1], *P. De Cock*[6], *J. P. Fryns*[1];
[1]*Centre for Human Genetics - University Hospitals of Leuven, Leuven, Belgium,* [2]*Department of Genetics and Research Unit 04/UR/08-05 “Molecular Immunogenetics” – Faculty of Medicine, Sousse, Tunisia,* [3]*Department of Paediatrics – Faculty of Medicine, Sousse, Tunisia,* [4]*Department of Genetics – University hospital Hedi Chekir and Faculty of Medicine, Sfax, Tunisia,* [5]*Department of Congenital and Hereditary Diseases - University Hospital Charles Nicolle & Faculty of Medicine, Tunis, Tunisia,* [6]*Department of Paediatric Neurology and Centre for Developmental Disorders – University Hospitals of Leuven, Leuven, Belgium.*

Copy number variants (CNVs) are genomic segments which are duplicated or deleted among different individuals.

Following the recent technological advances leading to the development of molecular cytogenetic techniques and the emergence of the array comparative genomic hybridization (aCGH), CNVs has gained considerable interest as a source of genetic variation likely to play a role in phenotypic diversity and disease.

Several new genomic disorders caused by CNVs of genes whose dosage is critical for the physiological function of the central nervous system (CNS) have been recently identified.

We applied aCGH in a group of patients presenting CNS anomalies to map novel loci involved in brain malformations. Here, we describe some evidence that CNVs are responsible for congenital CNS anomalies ranging from size anomalies to structural brain malformations and neural migration disorders illustrated, respectively, in patients with microcephaly, agenesis of corpus callosum, and pachygyria.

Here, we discuss the mechanisms mediating these rearrangements and suggest candidate genes for the respective disorders within the mapped loci.

P02.054

Report of one case of cerebro-oculo-nasal syndrome

M. Trabelsi, *F. Maazoul, M. Chaabouni, L. Kraoua, I. Ouertani, L. Ben Jemaa, R. Mrad, H. Chaabouni;*
Service des Maladies Congenitales et Hereditaires, Tunis, Tunisia.

Cerebro-Oculo-Nasal syndrome (CONS) is characterized by structural anomalies of the central nervous system, by ocular alterations ranging from anophthalmia/microphthalmia to normal eyes, and by proboscis-like nares. It was first reported by Richieri-Costa and Guion-Almeida in 1993 in two patients with clinical anophthalmia, abnormal nares, central nervous system anomalies, and mental retardation.

In this report, we present an additional sporadic case of this syndrome. A 1-month old boy from non-consanguineous parents with a pregnancy complicated by a gravid diabetes had unilateral anophthalmia, hypertelorism, single nostril orifice and asymmetric mouth. He also had a faun-like ear and three preauricular appendages. Additional findings were umbilical hernia and abnormal dermatoglyphics. CNS malformations will be explored by MRI. Other investigations including cardiac and abdominal ultrasonographies were normal. Karyotype showed a de novo mosaic reciprocal translocation between chromosomes 2 and 3: 46,XY,t(2;3)(p22;p12)[10]/46,XY[46].

Until now about twenty cases of Cerebro-Oculo-Nasal syndrome were reported. Despite marked variability, CONS is so unique that differential diagnosis is extremely limited because of its characteristic nasal configuration. Indeed, our patient presents also proboscis-like nares. Orofacial clefting was variable among reported cases, it was absent in our patient. All cases reported so far have been sporadic suggesting that the syndrome may be due to a new dominant mutation. Characterization of chromosomal breakpoints is planned.

P02.055

Congenital myopathy caused by a novel missense mutation in the *CFL2* gene

C. W. Ockeloen[1]*, J. Gilhuis*[2]*, R. Pfundt*[1]*, E. Kamsteeg*[1]*, P. Agrawal*[3]*, A. Beggs*[3]*, A. Dara Hama-Amin*[4]*, A. Diekstra*[1]*, N. V. A. M. Knoers*[5]*, M. Lammens*[6]*, N. Van Alfen*[7]*;*
[1]*Department of Human Genetics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [2]*Department of Neurology, Reinier de Graaf Group, Delft, Netherlands,* [3]*Program in Genomics and Division of Genetics, The Manton Center for Orphan Disease Research, Children's Hospital Boston, Harvard Medical School, Boston, MA, United States,* [4]*Department of Neurology, Haga Hospital, The Hague, Netherlands,* [5]*Department of Medical Genetics, Utrecht University Medical Centre, Utrecht, Netherlands,* [6]*Department of Pathology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [7]*Department of Neurology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Nemaline myopathy and myofibrillar myopathy are heterogeneous myopathies that both comprise early-onset forms. We present two sisters from a consanguineous Iraqi Kurdish family with predominant axial and limb girdle weakness. Muscle biopsies showed features of both nemaline myopathy and myofibrillar myopathy. We performed homozygosity mapping in both siblings using an Affymetrix 250K Nspl SNP array. One of the overlapping homozygous regions harboured the gene *CFL2.* Because a mutation in *CFL2* was identified in a family with nemaline myopathy, we performed sequence analysis of the gene and a novel homozygous missense mutation in exon 2 (c.19G>A, p.Val7Met) of *CFL2* was identified in both siblings. *CFL2* encodes the protein cofilin-2, which plays an important role in regulation of sarcomeric actin filaments. To our knowledge, this is the second family in which a mutation in *CFL2* causes an autosomal recessive form of congenital myopathy with features of both nemaline and myofibrillar myopathy. Given the clinical variability and the multitude of histological features of congenital myopathies, *CFL2* sequence analysis should be considered in patients presenting with an autosomal recessive form of congenital myopathy.

P02.056

Charcot-Marie-Tooth families analysed with High-Throughput Sequencing

H. Høyer[1,2,3]*, Ø. L. Busk*[1]*, Ø. L. Holla*[1]*, L. Strand*[1]*, C. F. Skjelbred*[1]*, G. J. Braathen*[1,2,3]*, M. B. Russell*[2,3]*;*
[1]*Department of Laboratory Medicine, Section of Medical Genetics, Telemark Hospital, Skien, Norway,* [2]*Head and Neck Research Group, Research Centre, Akershus University Hospital, Lørenskog, Oslo, Norway,* [3]*Campus AHUS, Akershus University Hospital, University of Oslo, Nordbyhagen, Oslo, Norway.*

Background

Charcot-Marie-Tooth (CMT) is the most common inherited neuropathy, affecting 1 per 1,214 persons in the general population. 47 CMT related genes are known to cause CMT by altered gene dosage (20-50 %) or point mutations.

Genetic analysis to discover point mutations have traditionally been performed with Sanger sequencing, a time consuming and expensive analysis. Most genetic laboratories choose to sequence only the most frequently involved genes, meaning that more than 50% of the patients remain genetic undiagnosed.

High-Throughput Sequencing (HTS) opens for the possibility to sequence many genes at the same time, fast and to a low cost compared with traditional methods.

Method

HTS has been used to analyse point mutations in 68 CMT families from a defined epidemiological population. This has been performed by designing a panel containing the known CMT genes, enriching for CMT gene areas. Compared to exome sequencing, sequencing a panel of genes means more samples at shorter time at a lower cost, and fewer problems with unrelated findings.

Results

To our knowledge this is the first report to sequence all the presently known genes related to CMT with HTS for a large population based material. These results will establish the CMT gene frequencies in the Norwegian population which probably might be transferred to other populations.

The results will be presented at the meeting.

P02.057

The clinical presentation of a newborn girl with isodicentric chromosome 22

L. Mämecke*, C. Hoefers, M. Hagemann, K. Hoffmann, D. Wand;*
Institut für Humangenetik, Halle, Germany.

We assessed a ten days-old girl with bilateral praeauricular skin tags, downslating palpebral fissures, micrognathia, deep-seated ears and an anal atresia with vaginal fistula. We suspected cat eye syndrome (CES) which was confirmed by subsequent ophthalmologic evaluation describing coloboma of iris, choroid and retina. Accordingly, cytogenetic analysis identified an extra bisatellited marker chromosome in all metaphases of a lymphocyte culture (47,XX,+idic(22) (pter-q11::q11→pter)). The finding was confirmed by FISH and MLPA analyses. Further clinical studies revealed an open foramen ovale and a ductus arteriosus as well as biliary atresia. Jung Min Ko et al. (2010) reported a patient with the same partial tetrasomy of chromosome 22q11.1, but with milder clinical features.

CES is a complex malformation syndrome with a significant clinical variability ranging from severely affected children to phenotypically unaffected parents carrying the same cytogenetic abnormality. Accordingly, only 40% of the CES-patients present the classical triad of symptoms iris coloboma, anal anomalies, and praeauricular pits or tags. In addition, CES may be associated with cardiac defects, hepatic, renal and skeletal abnormalities and mental retardation.

The cause of this clinical variability remains to be determined. The classical CES is present in most cases and characterized by supernumerary bisatellited and isodicentric marker chromosome containing duplicated material of chromosome 22. The phenotype does not correlate with the size of the marker chromosome. It may be speculated whether mosaic conditions, the genetic background and/or epigenetic factors affect the phenotypic presentation. However, life threatening problems to consider are severe cardiac, renal and/ or biliary defects.

P02.058

Chromosome 9p deletion syndrome and sex reversal: Novel findings and redefinition of the critically deleted regions

R. Onesimo[1]*, D. Orteschi*[2]*, M. Scalzone*[1]*, A. Rossodivita*[1]*, L. Nanni*[1]*, G. Zannoni*[3]*, G. Marrocco*[4]*, D. Battaglia*[1]*, C. Fundarò*[1]*,* ***G. Neri***[2]*;*
[1]*Department of Pediatrics, Catholic University School of Medicine, Rome, Italy,* [2]*Institute of Medical Genetics, Catholic University School of Medicine, Rome, Italy,* [3]*Institute of Pathology, Catholic University School of Medicine, Rome, Italy,* [4]*Department Pediatric Surgery, San Camillo De Lellis, Rome, Italy.*

Deletions of the short arm of chromosome 9 are associated with two distinct clinical entities. Small telomeric 9p24.3 deletions cause genital anomalies in male subjects, ranging from disorder of gonadal sex to genital differentiation anomalies, while large terminal or interstitial deletions result in 9p-malformation syndrome phenotype. The critical region for non syndromic 46,XY sex reversal was assigned to a 1Mb interval of chromosome 9p, extending from the telomere to the *DMRT* genes cluster. The 9p- syndrome was assigned to band 9p22.3p24.1, but a phenotypic map has not been established for this condition, probably because of the lack of detailed molecular and/or phenotypic characterization, as well as frequent involvement of additional chromosome rearrangements. Here we describe a unique patient with a small isolated 9p terminal deletion, characterized by array-CGH and FISH, who shows a complex phenotype with multiple physical anomalies, resembling the 9p- syndrome, disorder of sex development with gonadoblastoma, congenital heart defect and epilepsy. The observed deletion includes the 46, XY sex-reversal critical region, excluding the region so far associated with the 9p- syndrome. Genotype-phenotype correlations are tentatively established comparing our patient to seven other previously reported males with isolated terminal 9p deletions, finely defined at a molecular level. Our observations expand the 9p deletion clinical spectrum, and add significantly to the definition of a 9p- syndrome critical region.

P02.059
Spondyloepiphyseal dysplasia with luxations, CHST3 type (Recessive Larsen syndrome): Further clinical characterization and report of a novel mutation

*P. M. Tamhankar[1], H. Shah[2], **K. M. Girisha**[3];*
[1]Genetics Research Center, IRR, Mumbai, India, [2]Pediatric Orthopedic Service, Department of Orthopedics, Kasturba Medical College, Manipal, India, [3]Genetics Clinic, Department of Pediatrics, Kasturba Medical College, Manipal, India.

Spondyloepiphyseal dysplasia with luxations, CHST3 type (OMIM143095) is an autosomal recessive chondrodysplasia predominantly affecting joints, spine and epiphyses. Mutations in carbohydrate sulfotransferase 3 (*CHST3*) (OMIM603799) have been identified to cause this condition. We describe the clinical features of three patients in a large highly inbred Indian family with a novel homozygous mutation g.G144S (p.431 G>A) in *CHST3*. All of them had thickened mitral valves and short metacarpals. We emphasize thickened mitral valves, short metacarpals, hallux valgus and bifid epiphysis of distal phalanx of thumbs are additional features of this condition that should be looked into while evaluating patients with multiple joint dislocations.

Cohen syndrome is an autosomal recessive disorder characterized by developmental delay, visual impairment, typical facial gestalt (wave-shaped/down-slanting palpebral fissures, short-upturned philtrum, prominent incisors, beak-shaped nose, low-hairline), intellectual deficit (ID) and neutropenia. The conventional mutation screening, performed by DHPLC and/or Sanger sequencing, is time-consuming and has relatively high costs because of the absence of hot-spots and to the high number of exons of the causative COH1 gene. Thus, we designed a Next-Generation Sequencing protocol enabling detection of variants in the whole coding region. We used a method coupling selective amplification to the 454 Roche DNA sequencing platform (Genome-Sequencer-junior). This technology allowed us to identify the second mutation in patients previously analysed by DHPLC and MLPA and to diagnose new patients. Overall the clinical picture of our cohort of 23 patients indicates that the key features of the syndrome are ID, typical facial gestalt, narrow hands/feet with tapering fingers, myopia and/or retinopathy that are present in 100% of cases. Neutropenia, joint hyperlaxity and microcephaly are present in more than 80%. Truncal obesity and social behaviour are present in about 70%. Interestingly, we identified mitral insufficiency in about 20%. In one case aortic and tricuspidal insufficiency was also present. Cardiac anomalies have not been previously reported in patients with documented COH1 mutations. Overall, after the use of a combination of the most sensitive available molecular techniques, the phenotype of Cohen syndrome due to COH1 mutations is quite homogeneous. We thus recommend to request COH1 analysis only for patients with the core phenotype.

P02.061
Monitoring of Congenital Malformations and Hereditary Pathology

***G. Abildinova**, A. Nagimtayeva, R. Nazyrova, M. Utsiyeva;*
National Research Center for Maternal and Child Health, Astana, Kazakhstan.

In order to study the frequency of congenital and hereditary diseases developed a computerized data base „Genetic Registry". The register contains information about 1,500 patients and fetuses with birth defects, genetic disorders, their complex inspection and diagnosis. The structure of the register: birth defects - 759 (51%), chromosomal abnormality - 338 (22.5%), monogenic disorders - 302 (20%), pregnant women at genetic risk - 101 (6.5%).

The 19 registered nosologies that according to the list of the International Registry EUROCAT: anencephaly - 2 (0,2%), spina bifida - 16 (2.1%), encephalocele - 2 (0.2%), hydrocephalus - 43 (5.6%), microtia - 4 (0.5%), cleft palate, cleft lip - 71 (9.3%), congenital heart diseases - 78 (10.2%), atresia of the esophagus - 14 (1.8%), reduction deformities of limbs - 2 (0.2%), polydactyly - 8 (1%), diaphragmatic hernia - 31 (4%), renal agenesis and dysgenesis - 94 (12.3%), herniated umbilical cord - 6 (0.7 %), gastroschisis - 8 (1%), Down's syndrome - 178 (23.4%), multiplex birth defects - 110 (14.5%).

Thus, the register will allow determining the frequency and structure of the congenital malformations and hereditary diseases, to monitor the dynamics of the load of hereditary and congenital disorders in the population of the Republic of Kazakhstan.

P02.062
New TUBB3 gene mutation in a woman with CFEOM3 and brain abnormalities

***A. Drielsma**[1,2], I. Pirson[1], P. Jissendi[3], M. Pandolfo[4], M. Abramowicz[2];*
[1]IRIBHM - Université Libre de Bruxelles, Brussels, Belgium, [2]Department of Medical Genetics, Hôpital Erasme-ULB, Brussels, Belgium, [3]Department of Neuroradiology, Hôpital Erasme-ULB, Brussels, Belgium, [4]Department of Neurology, Hôpital Erasme-ULB, Brussels, Belgium.

Congenital fibrosis of extraocular muscles type 3 (CFEOM3) is a cranial dysinnervation disorder characterized by ophthalmoplegia and ptosis, thought to result from defect in axonal guidance. Isolated CFEOM3 results from mutations in microtubules-associated KIF21A and TUBB3 genes. CFEOM3 caused by TUBB3 gene mutation may also be associated with facial weakness, congenital contractures, intellectual deficiency, progressive polyneuropathy and brain anomalies as dysgenesis of the corpus callosum, anterior commissure, internal capsule, corticospinal tracts and basal ganglia. Other mutations of the same gene are reported in patients without CFEOM who present a wide range of cortical dysplasia including neuronal migration disorders associated with pontocerebellar hypoplasia.

We report on a 26 years old woman who suffered from severe congenital strabismus, ophthalmoplegia, unilateral ptosis and psychomotor retardation. CFEOM3 was diagnosed during strabismus surgery. She also has minimal pyramidal syndrome with conserved muscular strength but fatigability and slowness. Electroencephalogram, somatosensory evoked potentials and intelligence were normal. Magnetic resonance imaging showed dysplastic and hypoplastic vermis, dysmorphic and small corpus callosum, hypoplastic right cerebral hemisphere and peduncle, absent anterior commissure, asymmetric caudate nuclei and dilated ventricles.

Therefore, we sequenced TUBB3 gene in this patient and found a de novo heterozygous missense mutation. This mutation affects a highly conserved amino acid, is predicted to be damaging by Polyphen2 software and was not reported in patients with CFEOM3 (Tischfield, 2010) nor cortical dysplasia (Poirier, 2010) until now. Our finding will help to determine the genotype-phenotype correlation of the TUBB3-related spectrum.

P02.063
Unknown CNVs in cohort of 52 Bulgarian patients with learning disability and congenital malformations

***S. Hadjidekova**[1], D. M. Avdjieva-Tzavella[2], B. B. Rukova[1], D. V. Nesheva[1], T. Radka[2], T. Radka[2], D. Toncheva[1];*
[1]Department of Medical Genetics, Medical University-Sofia, Sofia, Bulgaria, [2]State University Pediatrics Hospital "Queen Evdokia", Medical University-Sofia, Sofia, Bulgaria.

Introduction. The increasing resolution of DNA-microarrays and the techniques optimization allow detection of larger (> Mb) aberrations and a large number of small CNVs, whose clinical significance in some cases is unknown. The interpretation of CNVs with unknown clinical significance remains still a challenge.

Materials and methods. Oligo array-CGH was applied in 52 patients with developmental delay and multiple congenital anomalies in order to unravel the underlying genetic abnormalities. We have used BlueGnome CytoChip oligo 2X105K microarray, v1.1, with 35kbp backbone resolution.

Results. A total of 247 CNVs were detected, of which 15 pathogenic (7 deletions, duplications 8), 124 normal (62 deletions, 62 duplications) and 108 with unknown clinical significance (68 deletions, 40 duplications).

Discussion. Due to insufficient data for the Bulgarian population we made an individual assessment of each variant. In our study 19 variations in chromosomal loci 2q37.3, 10q11.22, Xp22 were found in over 5% patients, which gave us a reason to suppose that they were probably not pathogenic. Twenty-five of the variations occurring in patients with established large pathological aberrations associated with specific phenotype. Therefore, we have assumed that probably they have no pathogenic nature. Thirty-five of the other variants do not contain OMIM genes.

Conclusion. So from total 108 unknown CNVs as potentially pathogenic remain to be seen only 29 variations. Of these, only one aberration in Xq22.1 can be directly related to patient's clinical phenotype. This gave us a reason to accept this deletion as potentially pathogenic.

Congenital myasthenic syndromes (CMS) are clinically and genetically heterogeneous disorders characterized by a neuromuscular transmission defect. Even though CMS are genetic disorders they are highly treatable, and the appropriate drug treatment depends on the underlying genetic defect. This highlights the importance of genetic testing in CMS. In recent years, the molecular basis of CMS has constantly broadened and disease-associated mutations have been identified in 14 genes encoding proteins of the neuromuscular junction. In the dawn of novel sequencing strategies we report on our 14-year experience in traditional Sanger-based mutation screening of a large cohort of 680 independent patients with suspected CMS. In addition to most known CMS-causing genes, we analyzed the functional candidate genes LRP4, VACHT, and CNTN1. In total, we identified disease-causing mutations in 299 patients (44%) of patients in various known CMS genes, confirming the high degree of genetic heterogeneity associated with the disease. Apart from four known founder mutations, and a few additional recurrent mutations, the majority of variants are private, found in single families. Genotype-phenotype correlations reported previously in the literature were extended and refined. Based on these results, we propose an algorithm for genetic testing in CMS.

Management of Pain and Fatigue in The Joint Hypermobility Syndrome (Ehlers-Danlos Syndrome, Hypermobility Type): Principles and Proposal for a Multidisciplinary Approach

M. Castori[1], *S. Morlino*[1], *C. Celletti*[2], *M. Celli*[3], *F. Camerota*[2], *P. Grammatico*[1];

[1]*Medical Genetics, Department of Molecular Medicine, Sapienza University, San Camillo-Forlanini Hospital, Rome, Italy,* [2]*Department of Physical Medicine and Rehabilitation, Sapienza University, Umberto I Hospital, Rome, Italy,* [3]*Department of Pediatrics, Sapienza University, Umberto I Hospital, Rome, Italy.*

Joint hypermobility syndrome (JHS), or Ehlers-Danlos syndrome hypermobility type (EDS-HT), is a underdiagnosed heritable connective tissue disorder characterized by generalized joint hypermobility and a wide range of visceral, pelvic, neurologic and cognitive dysfunctions. Deterioration of quality of life is mainly associated with chronic pain and fatigue. Except for the recognized effectiveness of physiotherapy for some musculoskeletal features, there are no standardized guidelines for the assessment and treatment of pain and fatigue. In this work, a practical classification of pain presentations and factors contributing in generating painful sensations in JHS/EDS-HT is proposed. Pain can be topographically classified in articular limb (acute/subacute and chronic), muscular limb (myofascial and fibromyalgia), neuropathic limb, back/neck, abdominal and pelvic pain, and headache. For selected forms of pain, specific predisposing characteristics are outlined. Fatigue appears as the result of multiple factors, such as muscle weakness, respiratory insufficiency, unrefreshing sleep, dysautonomia, intestinal malabsorption, reactive depression/anxiety and excessive use of analgesics. A set of lifestyle recommendations to instruct patients as well as specific investigations aimed at characterizing pain and fatigue are identified. Available treatment options are discussed in the set of a structured multidisciplinary approach based on reliable outcome tools.

Cornelia de Lange syndrome with mutation in NIPBL and mosaic Turner syndrome in the same individual

M. C. Gil-Rodríguez[1], *J. Wierzba*[2], *A. Polucha*[3], *B. Puisac*[1], *M. Arnedo*[1], *E. Teresa-Rodrigo*[1], *D. Winnicka*[3], *M. Hernández*[1], *A. Vicente-Gabas*[4], *C. Baquero*[4], *J. Limon*[2], ***F. J. Ramos***[1,4], *J. Pié*[1];

[1]*Universidad de Zaragoza, Zaragoza, Spain,* [2]*Medical University of Gdansk, Gdansk, Poland,* [3]*Children´s University Hospital, Lublin, Poland,* [4]*Hospital Clinico Universitario „Lozano Blesa", Zaragoza, Spain.*

Cornelia de Lange syndrome (CdLS) is a dominant inherited disorder characterized by facial dysmorphism, growth and cognitive impairment, limb malformations and multiple organ involvement. Mutations in *NIPBL* gene etiologically account for 60% of CdLS patients. This gene encodes a key regulator of the Cohesin complex, which controls sister chromatid segregation. TS affects about one in 2000 live born females and results from complete or partial absence of one of the X chromosomes, frequently accompanied by cell-line mosaicism.

Here, we report a patient with CdLS due to a mutation in the *NIPBL* gene (c.1445_1448delGAGA) and mosaic TS (mos 45,X/46,XX karyotype). This patient showed the classical and predominant phenotype of CdLS, although without limb reduction. She was also clinically diagnosed with TS because of two typical recognizable features: the peripheral lymphedema and the webbed neck. Molecular characterization showed that the *NIPBL* mutation was present in all the tissues analyzed from different embryonic origins (mesoderm and ectoderm); while FISH analyses revealed that the percentage of cells with monosomy X was low and tissue-specific.

These findings indicate that, ontogenically, the *NIPBL* mutation appeared before the mosaic monosomy X. Moreover, the recent identification of frameshift *NIPBL* mutations in colon cancer cells associated with chromosome aneuploidy suggests that it could affect faithful chromosome segregation.

The coexistence in several patients of both these rare disorders raises the issue of whether there is indeed a cause-effect association. We hypothesize that the NIPBL mutation might be responsible for the loss of one of the X chromosomes in this patient.

P02.067

Costello syndrome - a long way to diagnosis

Y. Mehraein, *M. Pfob*, *M. Eggert*, *S. Müller*, *O. Steinlein*;

Institute of Human Genetics, Munich, Germany.

Costello syndrome is an autosomal dominant disorder associated with postnatal growth retardation, facial dysmorphic features, intellectual deficit as well as skin and cardiac abnormalities. Only a small number of cases with Costello syndrome has been identified so far. The majority of cases is caused by de novo mutations in the ras family oncogene (HRAS - localized in 11p15.5). Here we report a case that took a long time to be diagnosed correctly.

The 26 months old girl presented with respiratory and feeding problems, postnatal growth retardation with relative macrocephaly, typical facial dysmorphism, cardiac arrhythmia, deep creases of hands and feet, loose abundant skin and sparse curly hair. Conventional chromosome analysis revealed a normal female karyotyp 46,XX. Previously performed testing including array-CGH, muscle biopsy, enzyme histochemistry, quantitative Western blot, FAMILION screening for various heart related ion channel mutations and amino acid screening in liquor were without pathological findings.

Due to the patient`s phenotypical characteristics we initiated the molecular analysis of the HRAS gene. After more then two years of diagnostic procedures Costello syndrome could finally be confirmed by a heterozygous mutation c.34G>A, p.G12S, in exon 2 as a de novo mutation. Equal contribution of the first and the second author.

P02.068

Two cases of craniofrontonasal dysplasia

Š. Vejvalková[1], *A. Křepelová*[1], *M. Vlčková*[1], *H. Krásničanová*[2], *M. Havlovicová*[1];

[1]*Institute of Biology and Medical Genetics Charles University, 2nd Faculty of Medicine and Universit, Praha 5 Motol, Czech Republic,* [2]*Pediatric Clinic, Charles University, 2nd Faculty of Medicine and Universit, Praha 5 Motol, Czech Republic.*

Craniofrontonasal dysplasia (CFND) is an X-linked craniofacial disorder with an atenuated manifestation in males, in which affected females show distinct picture of skeletal malformations incuding striking hypertelorism, synostosis of coronal suture, syndactyly and preaxial polydactyly but without intelectual deficit.

We report 2 new cases - the first girl without positive family history shows typical craniofacial features with aditional nonfrequent signs - hypoplasia of corpus callosum, asymetrical mammils, axilar pterygium and slight hypoplasia of pectoral muscle on the left side combined with synpolydactyly of left thumb.

Mutation analysis revealed a new non published mutation c.161>A (change p.Pro>Gln in codon 54) in exon 2 of EFBN1 gen. The father didnot show hy-

pertelorism and later was excluded as a carrier of causal mutation.
Second case - newborn girl expresed craniostenosis of coronal suture with typical hypertelorism, hypoplasia of corpus callosum and suspection from hearing loss (patological TEOAE). First suspection from craniofacial dysmorphism was on prenatal ultrasound screening where picture of cloverleaf skull was seen.
Mutation analysis revealed known causal mutation c.451G>A in exon 3 of EFBN1 gen. The father has significant hypertelorism, MG findings in father and other family members are not available yet.

P02.069
Identification of a novel EFNB1 mutation in a patient with Craniofrontonasal Syndrome and right hallux duplication

A. GEZDIRICI[1], *O. F. Karatas*[1], *H. Ulucan*[1], *E. Yosunkaya*[1], *M. Seven*[1], *A. Yuksel*[2], *M. Ozen*[1];
[1]*Cerrahpasa Medical School Dep. of Medical Genetics, Istanbul, Turkey,* [2]*Bezmialem Vakif University, Istanbul, Turkey.*

Craniofrontonasal syndrome (CFNS) is a rare X-linked dominant disorder characterized by a more severe manifestation in heterozygous females than in hemizygous males. Typical manifestations involve hypertelorism with telecanthus, widow's peak, frontal bossing, craniosynostosis, a bifid or broad nasal tip, wiry hair, and grooved fingernails. Besides, anterior cranium bifidum, axillary pterygia, joint abnormalities, cleft lip and palate, unilateral breast hypoplasia, diaphragmatic hernia, asymmetric lower limb shortness, and agenesis of the corpus callosum are within the rare manifestations of CFNS. Most CNFS patients have mutations in the *EFNB1* located at chromosome Xq13.1. This gene encodes a member of the ephrin family protein, Ephrin B1, which interacts with Eph tyrosine kinase receptors. It functions in the formation of tissue boundaries. Here, we report a 7-month-old female patient who has brachycephaly, frontal bossing, hypertelorism, telecanthus, downslanting palpebral fissures, broad nasal root and bifid nasal tip. She also had large anterior fontanelle and broad right hallux. To confirm CFNS diagnosis, *EFNB1* was sequenced and a novel *de novo* c.402 T>C heterozygous mutation in exon 2 was detected. This change is not reported in the SNP databases. Isoleucine is a highly conserved amino acid and its replacement to threonine in codon 134 may result in a conformational change in the protein. Parents were normal both clinically and genotypically, confirming *de novo* mutation in the patient. This mutation was not previously reported for CFNS.

P02.070
Can *FGFR2* mutations explain craniosynostosis with hydroureteronephrosis?

C. Vanlerberghe[1], *C. Collet*[2], *E. Closset*[3], *S. Petit*[4], *S. Manouvrier*[1,5], *C. Vincent-Delorme*[1];
[1]*Department of Clinical Genetics, Jeanne de Flandre hospital, CHRU, Lille, France,*
[2]*Department of Molecular Genetics, Lariboisière hospital, APHP, Paris, France,*
[3]*Department of Maternal and fetal pathology, Jeanne de Flandre hospital, CHRU, Lille, France,* [4]*Department of Anatomopathology, Centre de Biologie-Pathologie, CHRU, Lille, France,* [5]*Nord de France University, Lille, France.*

Fibroblast growth factor receptor 2 (FGFR2) mutations are well known in syndromic craniosynostosis. We report the first case of *FGFR2* mutation associated with craniosynostosis and bilateral hydroureteronephrosis.

During the second pregnancy of unrelated parents, a megacystis and a megaureter were detected by ultrasound examination at 10 weeks-of-gestation (WG). Subsequently craniosynostosis of the metopic, sagittal and coronal sutures was seen at 26 WG. Chromosomes on amniotic fluid were normal. Termination of pregnancy was performed at 28 WG. Pathology confirmed the renal malformation and a trigonocephaly. Molecular analysis found a *de novo* heterozygous *FGFR2* mutation that had been previously reported in Crouzon, Pfeiffer and Jackson-Weiss syndromes.

Rare renal malformations have been previously clinically reported with syndromic craniosynostosis. *In vitro* studies have shown that FGFRs are expressed in the ureteric bud and in the metanephric mesenchyme of the developing kidney. Exogeneous FGFs affect growth and maturation of both organs in cultured tissues. *In vivo* studies on mice demonstrated that the loss of *fgfr2* often lead to multiple ureteric buds, renal dysplasia and obstructed hydroureter. Therefore the *FGFR2* signaling pathway is critical at early and later stages of kidney development.
Other studies showed *FGFR1* and *FGFR2* overexpression in renal cell carcinoma. A case of bladder papillary carcinoma with Apert syndrome and a germline *FGFR2* mutation has also been previously reported.

Thus, we think that *FGFR2* loss-of-function mutation in this case could explain the whole phenotype. This report highlights the probable relationship between *FGFR2* and renal and vesicoureteral abnormalities in human embryonic development.

P02.071
Ventricular septal defect in crouzon syndrome: case report

N. Unal[1], *F. Hazan*[2], *A. Aykut*[3], *T. Mese*[1], *H. Onay*[3], *F. Ozkinay*[3];
[1]*Department of Pediatric Cardiology, Dr. Behcet Uz Children's Hospital, izmir, Turkey,*
[2]*Department of Medical Genetics, Dr. Behcet Uz Children's Hospital, izmir, Turkey,*
[3]*Department of Medical Genetics, Ege University Faculty of Medicine, izmir, Turkey.*

Crouzon Syndrome (CS) is an autosomal dominant hereditary disease, which is characterized by clinical triad of cranium deformity, facial anomalies and exophthalmia. Crouzon Syndrome is caused by the mutations in the FGFR2 gene. Same gene mutations are observed in Apert, Pfeiffer and Jackson-Weiss syndromes as well. Cardiac anomalies are detected in 10 % of the patients with Apert Syndrome. According to the literature, cardiac anomalies have been reported in only three patients with CS, but there is no report on cardiac anomalies, neither in patients with Pfeiffer nor the ones with Jackson-Weiss syndrome. We describe here a 10 year old CS patient with ventricular septal defect. A heterozygous 868G>C (Trp290Arg) mutation was detected by sequence analysis in the FGFR2 gene. The patient's mother with similar craniofacial features had the same mutation.
Key words: Crouzon Syndrome, FGFR2 gene, ventricular septal defect

P02.072
A CSF1R mutation in a family with hereditary diffuse leukencephalopathy with spheroids

K. Platzer[1], *S. Biskup*[2,3,4], *H. Freitag*[5], *C. Ganos*[6], *G. Gillessen-Kaesbach*[1], *Y. Hellenbroich*[1];
[1]*Institut für Humangenetik, Universität zu Lübeck, Lübeck, Germany,* [2]*CeGaT GmbH, Tübingen, Germany,* [3]*Hertie Institute for Clinical Brain Research, Tübingen, Germany,* [4]*German Center for Neurodegenerative Diseases, Tübingen, Germany,* [5]*Röntgenpraxis im Tesdorpfhaus, Lübeck, Germany,* [6]*Movement Disorders Group, Department of Neurology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Mutations in the colony stimulating factor 1 receptor gene (*CSF1R*) have recently been shown to cause hereditary diffuse leukencephalopathy with spheroids (HDLS), an autosomal-dominant disease leading to progressive cognitive and motor dysfunction. We describe a family from Northern Germany with an apparently autosomal-dominant early onset frontotemporal dementia syndrome. Multiple MRI scans of a 38 year old clinically presymptomatic woman showed slowly progressive bifrontotemporal cortical atrophy and asymmetric hyperintense white matter lesions. Her father and paternal grandfather both suffered of early onset and rapidly progressing dementia and personality change starting in their late 40s, leading to death within a decade. An underlying CADASIL in the family was excluded as molecular analysis of *NOTCH3* showed no pathogenic mutation. Next-generation-sequencing of nine known early-onset dementia genes identified the very likely heterozygous disease causing mutation c.2381T>C (p.I794T) in the *CSF1R*-gene in the female index patient.

P02.073
Danon disease - different phenotypic expression a family with hypertrophic cardiomyopathy

A. V. Popoiu, *G. Doros, C. Popoiu;*
Children's Hospital, Timisoara, Romania.

The rare X-linked dominant lysosomal disorder called Danon disease, is the consequence of the mutation of the lysosome - associated membrane proteine 2 gene (LAMP2), affecting myocytes and skeletal muscles by accumulation of intracytoplasmatic autophagic vacuoles. The characteristic clinical triad of the Danon disease include mental retardation, severe hypertrophic cardiomyopathy, skeletal myopathy.
We describe a case of Danon disease, belonging to a family with known hypertrophic cardiomyopathy with 3 affected generation. The grandmother and mother are known with mild hypertrophic cardiomyopathy. A sister and brother of the affected mother, were both diagnosed with hypertrophic cardiomyopathy and died at 24 years of age, respectively at 36, despite a pacemaker implantation.
The son was diagnosed at the age of 14 years with mild mental retardation, limb-girdle dystrophy, severe hypertrophic obstructive cardiomypathy, WPW syndrome. He presents a massive concentric ventricular hypertrophy of 45 mm, and 2 years later atrial flutter occurred. The parents refused heart transplantation or myomectomy and a defibrilator was implanted. The patient has 2 healthy sisters, were the genetic counseling is of greatest importance.
Conclusion: The LAMP2 mutation was proved as an important cause of massive cardiac hypertrophy with high mortality in the absence of heart

transplantation. The variable phenotypic expression with a usually milder clinical presentation in females is the case in our patients too.

P02.074

Darier Disease - a family case report

D. F. Albu[1,2], C. C. Albu[1,2], E. Severin[1];
[1]University of Medicine and Pharmacy Carol Davila, Bucharest, Romania, [2]Alco San Clinic, Bucharest, Romania.

INTRODUCTION: Keratosis follicularis, also known as Darier disease or Darier-White disease, is an autosomal dominantly inherited genodermatosis characterized by greasy hyperkeratotic papules in seborrheic regions, nail abnormalities, and mucous membrane changes.
The disease was first reported independently by Darier and White in 1889.
MATERIAL AND METHODS: We present a family with Darier Disease on three generations.
Dermatological examination and complete general examination of the patients showed **skin rash,** lesions on the hands and nails and lesions affecting the mucous membranes.
Skin Biopsy, histopatologically examination of the skin and DNA Analysis was necessary to confirm the diagnosis.
RESULTS: A skin biopsy show characteristic degeneration of cells in the epidermis (acantholysis) and abnormally increased keratinisation (hyperkeratinisation).
DNA Analysis of all the patients revealed mutations in the ATП2A2 gene.
CONCLUSIONS: We present a family with Darier Disease on three generations, a rare disorder with variable penetrance, clinical and genetic variability in the same family.

P02.075

Clinical manifestation of congenital bilateral, profound sensorineural hearing loss and adult-onset retinitis pigmentosa is not always Usher syndrome

A. Singer;
Genetic Institute, Ashkelon, Israel.

Usher syndrome is an autosomal recessive condition characterized by a combination of congenital hearing impairment and retinitis pigmentosa (RP). Three types of Usher syndrome are known and differ by the time of onset of the symptoms, severity and progressiveness of deafness and additional vestibular dysfunction. Several genes are known to be associated with the disease. Patients with type II Usher syndrome have congenital bilateral sensorineural hearing loss that is mild to moderate in the low frequencies and severe to profound in the higher frequencies, intact vestibular responses, and bilateral retinitis pigmentosa (RP).
We describe a 30 years old female whose parents are first cousins of Moroccan origin. She has congenital deafness and has been referred by her ophthalmologist because of recently diagnosed RP. A clinical diagnosis of Usher syndrome type II has been suggested. However a molecular workup including testing of the three genes known to cause the disease (*USH2A, GPR98* and *DFNB31)* were all negative.
A founder mutation (c.1355_6delCA, p.Thr452SerfsX3) in the RP gene *FAM161A* has been later described in Moroccan-Jews. Our patient was found to be homozygous to the founder mutation and her parents were heterozygous to this mutation. Information was given to the family during genetic counseling explaining that Usher syndrome was ruled out and a plausible explanation would be that she is expressing two independent diseases. Recently she was tested for mutation in the TMC1 gene associated with autosomal recessive deafness and was found homozygous for the c.1939T > C deleterious mutation.

P02.076

Interstitial 9q34.11-q34.13 deletion in a patient with severe intellectual disability, hydrocephalus and cleft lip/palate

A. Tzschach, U. Grasshoff, K. Schäferhoff, M. Bonin, A. Dufke, M. Wolff, K. Haas-Lude, A. Bevot, O. Riess;
University of Tuebingen, Tuebingen, Germany.

Interstitial deletions of chromosome bands 9q34.11-q34.13 are rare. We report on a 16-year-old female patient with severe intellectual disability, congenital hydrocephalus, cleft lip and palate, talipes equinovarus, epilepsy, kyphoscoliosis, convergent strabismus, severe short stature, dystrophy and facial dysmorphic signs. Array analysis revealed a 3.7 Mb interstitial deletion in 9q34.11-q34.13. The deletion harbors more than 60 genes, including SPTAN1, DYT1/TOR1A, ABL1, ASS1, LAMC3, POMT1, DOLK and GLE1, mutations in which have previously been associated with monogenic disorders. This is the first patient with a deletion of this size and position in 9q34.11-q34.13. Reports of additional patients with aberrations in this region will be needed to establish karyotype-phenotype correlations and to gain information on the contribution of individual genes for the clinical manifestations.

P02.077

Interstitial deletion of 3p22.1p24.1 including haploinsufficiency of the *MLH1* gene in a boy evaluated for developmental delay, short stature and physical anomalies

B. Maas[1], C. Sutter[1], J. Janssen[1], A. Jauch[1], K. Hinderhofer[1], S. Karch[2], **U. Moog**[1];
[1]Institute of Human Genetics, Heidelberg, Germany, [2]University Children's Hospital, Heidelberg, Germany.

Introduction: Molecular karyotyping is a well established method in the evaluation of children with developmental disorders and/or physical anomalies leading to the diagnosis of a relevant chromosomal imbalance in 10-15% of cases. However, unanticipated findings may be a major challenge. We present the case of a boy with developmental delay and multiple physical anomalies in whom array analysis revealed a concomitant diagnosis of a tumor disposition syndrome.
Case Report: A boy of 4 years of age was evaluated for short stature, psychomotor retardation, hypotonia and physical anomalies (e.g. hypospadias, pectus excavatum). Physical examination also showed facial dysmorphism (flat face, down-slanting palpebral fissures), inverted nipples and hyperemia of fingertips and toes. Array analysis (Affymetrix® CytoScan HD) showed a *de novo* 9.5 Mb interstitial deletion on chromosome 3p22.1-p24.1 not detectable by G-banding analysis. The deletion was confirmed by FISH analysis with probes specific for 3p22.3. The deleted region comprised about 60 refseq genes among which *MLH1* (confirmed by MLPA).
Discussion: Overlapping interstitial deletions of 3p22-p24 so far have been rarely reported and most often predate molecular karyotyping. They are associated with global developmental delay, CHD, short stature and mild dysmorphic features. In the present case, based on haploinsufficiency of the mismatch repair gene *MLH1,* a diagnosis of Lynch syndrome (HNPCC) was also established and surveillance guidelines were discussed with the parents.
Conclusion: This case illustrates that any chromosomal imbalance has to be evaluated carefully for alterations potentially affecting cellular key pathways as deletions of tumor suppressor genes with implications for health management.

P02.078

After a long diagnostic journey: Duplication 17q25.1 in a child with multiple disabilities

D. Wahl[1], U. Heinrich[2], M. Gabert[2], G. Buheitel[3], I. Rost[2];
[1]Practice for genetic counselling and psychotherapy, Augsburg, Germany, [2]Centre for Human Genetics and Laboratory Medicine, Martinsried, Germany, [3]II. Children's Hospital of the Central Clinic, Augsburg, Germany.

About 20% of the children with syndromic appearence show submicroscopic duplications and deletions, which are detectable by high resolution Array CGH-diagnostic platforms. We give an account of a meanwhile nearly eight years old disabled girl, who had already been presented to a genetic counsellor as a new born child because of prematurity (34th weeks of gestation), microcephalus, atrial septal defect, stenosis of the left bronchus, sickle feet, muscle weakness, dysmorphic features and feeding problems. A chromosomal analysis was performed and showed a normal female karyotype. In the further course of her development, the girl showed profound psychomotor retardation, speech delay, mental retardation, recurring infections and early behavioural problems. On the occasion of the second presentation at the age of 2 ½ years to the genetic counsellor the first array-CGH was performed using a low-resolution BAC array (resolution 0,44 Mb). The result was interpreted as normal. Because of the persisting impression of a syndromal clinical picture the parents continued presenting her daughter to the genetic counsellor. An Angelman-Syndrome as well as a Rett-Syndrome were excluded. Finally the Array-CGH-examination was repeated using a higher resolution (resolution 25 to 100 kb) and revealed a 830 kb duplication on 17q25.1 that is thought to be causal. The results of the parental analysis will be presented. This case emphazises the benefit of applicating a high resolution array after a normal result with a low resolution array.

P02.079

22q13.3 deletion syndrome - report of three cases

S. Bichev[1], R. V. Vazharova[1], I. Bradinova[1], S. Andonova[1], A. Savov[1], V. Bojinova[2], E. Simeonov[3], I. Kremensky[1];
[1]National Genetic Laboratory, Sofia, Bulgaria, [2]USBALNP „Saint Naum", Sofia, Bulgaria, [3]University Hospital „Alexandrovska", Sofia, Bulgaria.

Phelan-McDermid syndrome (22q13.3 deletion syndrome) is characterized by neonatal hypotonia, global developmental delay, absent to severely delayed speech, and normal to accelerated growth. Most individuals have moderate to profound intellectual disability. Other features include large fleshy hands, dysplastic toenails, and decreased perspiration that results in a tendency to overheat. Behavior characteristics include mouthing or chewing non-food items, decreased perception of pain, and autistic-like affect.

Phelan-McDermid syndrome results from terminal or interstitial deletion of chromosome 22q13.3. On rare occasion an apparently balanced chromosome rearrangement or a mutation disrupts SHANK3. We performed MLPA and whole genome array CGH analysis in 68 patients with mental retardation/congenital anomalies.

In three patients the analysis revealed the presence of interstitial deletion of 22q13.3 chromosome region encompassing SHANK3 gene. In two of them this finding was combined with duplication of 20p chromosome. The severity of the clinical presentation varies among the three patients. All of them have abnormal behavior phenotype (autistic like). The impact of the additional finding of 20p duplications to the clinical features will be discussed.

P02.080

A unique case of familial Diamond-Blackfan anemia

H. S. Sorte[1], *Y. Y. Sheng*[2], *O. K. Rødningen*[1], *R. Lyle*[1], *B. Zeller*[3], *A. Stray-Pedersen*[1];
[1]*Department of Medical Genetics, Oslo University Hospital, Oslo, Norway,* [2]*Department of Medical Genetics, Ullevaal, Oslo University Hospital, Oslo, Norway,* [3]*Department of Pediatrics, Oslo University Hospital, Oslo, Norway.*

Diamond-Blackfan anemia (OMIM #105650) is a rare, autosomal dominant condition characterized by congenital erythroid aplasia with normal leukocytes and platelets. Half of the patients have associated malformations of upper limb and craniofacial region and are growth retarded. DBA cases are mostly sporadic, only 10-25% are familial. DBA is genetically heterogeneous. Causal variants have been identified in nine ribosomal genes, and diagnostic tests are clinical available for only a limited number of them.

We present a 6 year old boy with classical DBA. He was diagnosed in early childhood with severe anemia, is currently transfusion dependent and on steroid treatment. He has short stature and dysmorphic facial features. His paternal grandfather had DBA and died of liver sarcoma, 26 years old, after androgen treatment. The boy's father is asymptomatic.

Exome sequencing (Agilent 38Mb exome capture and 2x100bp Illumina sequencing) detected a novel heterozygous deletion in *RPS26* (c.6_9del). The deletion leads to a framshift, and will most likely cause a premature stop-codon and induce nonsense mediated decay. Sanger sequencing showed that the variant was paternally inherited. Variants in *RPS26* are estimated to cause 2.6% of the DBA cases (DBA10; OMIM #613309). A molecular diagnosis should enable prenatal diagnostic testing, however predicting the diagnostic outcome of an affected fetus is challenging in this family.

This case illustrates the force of targeted exome sequencing to efficiently identify novel variants in a large set of candidate genes, and demonstrates its clinical utility to identify causal variants in rare dominant disorders.

P02.081

Two patients with Diamond-Blackfan anemia: a novel point mutation in RPL5 and a microdeletion encompassing RPL5

R. Floettmann[1], *G. Strauss*[2], *E. Klopocki*[1], *L. M. Graul-Neumann*[1];
[1]*Institute for Medical Genetics and Human Genetics, Charité-Universitätsmedizin Berlin, Berlin, Germany,* [2]*Clinic for Pediatrics, Oncology & Hematology, Charité-Universitätsmedizin Berlin, Berlin, Germany.*

Diamond-Blackfan anemia (DBA; MIM #105650) is a rare congenital red blood cell aplasia with an increased risk of malignancy. DBA exhibits an autosomal dominant pattern of inheritance with incomplete penetrance. Approximately 50% of affected individuals show congenital malformations. DBA has been associated with mutations in nine genes that encode ribosomal proteins, amongst others RPL5. Mutations in RPL5 and RPL11 are more frequently associated with additional congenital malformations compared to the other genes.

We present two patients with DBA: patient 1 carries a missense mutation in RPL5 inherited from the unaffected mother. The mutation c.625C>T (ENST00000370321;p.Arg209Cys) has not been reported in the literature to date but was predicted as disease causing by the prediction tool MutationTaster (www.mutationtaster.org). The girl was hypotrophic at birth, and presented with triphalangeal thumbs as well as unilateral renal agenesis. She did not show any facial dysmorphism or cardiac anomalies.

In patient 2 array CGH analysis detected a de novo 594kb microdeletion on chromosome 1p22.1 encompassing RPL5. The girl was also hypotrophic at birth, and was additionally diagnosed with complex cardiac malformations. All developmental milestones were delayed. At age three years she presented with short stature, brachycephaly, arched eyebrows, left-sided ptosis, short neck, and finger-like thumbs.

We compare the phenotypes of our two patients with distinct mutations affecting the RPL5 gene.

P02.082

Diencephalic-mesencephalic junction dysplasia: A novel recessive brain malformation

M. S. Zaki[1], *S. N. Saleem*[2], *W. B. Dobyns*[3], *J. Barkovich*[4], *H. Bartsch*[5], *A. Dales*[5], *M. Asharti*[6], *A. Grijalvo-Perez*[7], *J. G. Gleeson*[7];
[1]*National Research Centre, Dokki,, Egypt,* [2]*Radiology Department, Cairo University, Cairo, Egypt,* [3]*Department of Pediatrics, Seattle Children's Research Institute, Seattle, WA 98195-6320., Seattle, WA, United States,* [4]*Department of Radiology and Biomedical Imaging, University of California, San Francisco, 94143, USA, San Francisco, CA, United States,* [5]*Multimodal Imaging Laboratory (MMIL), Department of Radiology and Neurosciences, University of California, San Diego, 92093 USA, San Diego, CA, United States,* [6]*Diffusion Tensor Image Analyses and Brain Morphometry Center, Children's Hospital of Philadelphia, Department of Radiology, Children's Hospital of Philadelphia, Philadelphia PA 19104 USA, Philadelphia, PA, United States,* [7]*Neurogenetics Laboratory, Howard Hughes Medical Institute, Department of Neurosciences and Pediatrics, Rady Children's Hospital, University of California, San Diego, 92093 USA, San Diego, CA, United States.*

We describe six patients from three unrelated consanguineous Egyptian families with a novel characteristic brain malformation at the level of the diencephalic-mesencephalic junction (DMJ). Diagnostic testing including high resolution karyotyping and extended metabolic screening were normal. Brain MRI demonstrated a dysplasia of the DMJ with a characteristic "butterfly"-like contour of the midbrain on axial sections. Additional imaging features included variable degrees of supratentorial ventricular dilatation and hypoplasia to complete agenesis of the corpus callosum. Diffusion tensor imaging showed diffuse hypomyelination and lack of an identifiable corticospinal tract. All patients displayed severe cognitive impairment, postnatal progressive microcephaly, axial hypotonia, spastic quadriparesis and seizures. Autistic features were noted in older cases. Talipes equinovarus, non-obstructive cardiomyopathy and persistent hyperplastic primary vitreous were additional findings in two families. One of the patients required shunting for hydrocephalus, however, this yielded no change in ventricular size suggestive of dysplasia rather than obstruction. We propose the term diencephalic-mesencephalic junction dysplasia (DMJD) to characterize this autosomal recessive malformation.

P02.083

De novo duplication 15q22.21-24.1 in patient with mental retardation, congenital heart defect and dysmorphic features

O. Liaugaudienė, *L. Cimbalistienė, Ž. Čiuladaitė, J. Kasnauskienė, E. Preikšaitienė, V. Kučinskas;*
Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania.

We report on a 25 years old female referred for evaluation because of intellectual disability, atrioventricular communication, muscle weakness, neurogenic urinary incontinence and dysmorphic features (long trunk, low forehead with hypertrichosis, strabismus, depressed nasal bridge, full cheeks, retrognathia, high narrow palate, malposition of one central incisor, malocclusion of teeth, brachydactyly of the fingers, small and flat feet). Proband's mother had a congenital heart defect. The propositus was born in a normal delivery but with lower birth-weight (2800 g). In infancy she had poor suck reflex, considerable hypotonia and severely retarded psychomotor development.

Initial karyotype analysis revealed normal female karyotype. Array-CGH (400K) showed and FISH confirmed a *de novo* tandem interstitial 9.0 Mb duplication of 15q22.21-24.1. The duplicated region is gene-rich, encompassing more than 140 genes. At least 11 of duplicated genes are associated with known diseases, including *CLN6, NCH4, KBTBD13, MAP2K1.* The other relevant genes (*MEGF11, ZNF609, TIPIN, PAQR5*) are involved in brain development and functioning. Proband's phenotype is similar to previously reported overlapping duplication (22,23 Mb) in *DECIPHER.*

The abnormal phenotype could be determined by overdose of duplicated genes, the disturbance of genes regulatory sequences, or the excess genetic material which may disorganize chromatin conformation affecting the expression of distance genes. Given its large size, high gene content and de novo origin, the observed duplication is considered as pathogenic and responsible for the clinical phenotype manifesting in our patient.

P02.084

The influence of donor DNA level in blood of simultaneous pancreas kidney allograft recipients as a diagnostic factor for rejection

***A. K. Sarnecka**[1,2], M. Zagozda[1,2], M. Serwanska-Swietek[2], A. Rydzewski[1,2], W. L. Olszewski[1,2], M. Durlik[1,2];*
[1]Mossakowski Medical Research Center, Polish Academy of Sciences, Warsaw, Poland, [2]Central Clinical Hospital, Ministry of Internal Affairs, Warsaw, Poland.

Grafted organ releases into circulation system some cells, DNA and proteins which are partially destroyed by the recipient's phagocytes but they can be detected in spleen dendritic cells. The aim of our research was to study the possible effects of microchimerism in pancreas and kidney rejection. In our previous studies, we looked for the presence of donor-specific STR loci in the recipient blood. In this study we have examined plasma and mononuclear whole blood cells of recipients to assess the amount of SRY gene in sex-mismatched combinations and phospholipase A2-HUMPLA2A1(AAT)n in the same sex recipients after simultaneous pancreas and kidney transplant, in relation to the patients probes before grafting by the use of the Real-time PCR method. Recipient's blood and donors spleen samples were collected before transplantation and at different times after grafting. Genomic DNA was isolated from blood and tissues. The amount of DNA in different samples after tx was calculated by using the comparative Ct method with GAPDH as internal control. We observed increase donor's DNA level in recipient's blood already on day 1 after grafting (STR loci). The quantitative indication of donor DNA in recipient's blood (SRY gene) was possible in 7 day after graft. In case of HUMPLA gene, our results showed that the relative amount of that gene was higher in mononuclear blood cells than in plasma 14 days after transplantation. Donor DNA is present either in passenger cells or recipient's phagocytes. An open question remains whether it may be incorporated into recipient cell genome.

P02.085

Molecular diagnosis of common mutations in COL7a1 Gene among Iranian patients suffering from Epidermolysis Bullosa

***A. KaKavand Hamidi**[1], M. Mahdavi[1], H. Dehganpour[1], N. Hatamnejadian[1], M. Moghaddam[1], B. sedaghati khayat[1], P. Tousi[2], M. Yusefi[2], A. Ebrahimi[1];*
[1]Parseh Medical Genetics Center,Shahid Beheshti uni skin research center, Tehran, Islamic Republic of Iran, [2]Shahid Beheshti university skin research center, Tehran, Islamic Republic of Iran.

Background: The dystrophic forms of Epidermolysis Bullosa (DEB), a group of heritable blistering disorders, show considerable phenotypic variability, and both autosomal dominant and autosomal recessive inheritance can be recognized. DEB is derived from mutations in the type VII collagen gene (COL7A1),

It has been reported that most mutations detected in the recessive disease form are nonsense mutations or small insertions or deletions leading to frame shift and premature translational termination, which tend to produce severe phenotypes. In contrast, missense mutations causing amino acid substitutions, which result in variable phenotypes, predominate in the dominant form of dystrophic Epidermolysis Bullosa.

Methods: DNA specimens (Genomic DNA from the patient) from 50 affected patients, clinically diagnosed, were subjected to mutation analysis by PCR using designed primers for hotspot exons of COL7a1, followed by sequencing of the PCR products.

Result: Studying COL7a1 hotspot exons, 73, 74, 75, showed that 11 out of 50(27%) of probands have mutation. Among these mutations 2 cases were compound heterozygotes, the other 2 cases were deletions and the rest were missense substitutions. A novel mutation has been identified within all mentioned mutations above.

P02.086

Molecular findings in patients with isolated ectopia lentis - results of *FBN1* and *ADAMTSL4* mutation analyses

***A. Laner**[1], E. Mangold[2], T. Martin[3], A. Riess[4], A. Stegerer[1], E. Holinski-Feder[1], T. Neuhann[1];*
[1]Medizinisch Genetisches Zentrum, Munich, Germany, [2]Institut für Humangenetik, Universitätsklinikum Bonn, Bonn, Germany, [3]Gemeinschaftspraxis für Humangenetik, Homburg, Germany, [4]Abteilung Medizinische Genetik, Institut für Humangenetik, Universitätsklinikum Tübingen, Tübingen, Germany.

Ectopia lentis (EL) can occur as an isolated condition or as a feature of syndromal diseases, such as Marfan syndrome (MFS). Isolated ectopia lentis has been associated with mutations in *ADAMTSL4* (autosomal-recessive) and *FBN1* (autosomal-dominant).

We have analyzed 8 patients from 6 families presenting with isolated EL. 4 patients had homozygous mutations in *ADAMTSL4*: 2 unrelated patients (14 and 34 years) carried the common mutation c.767_786del20, p.(Gln256Profs*38); in two siblings (4 and 5 years), the homozygous mutation c.1162dupG; p.(Ala388Glyfs*8), which has not been yet reported, was identified. None of the patients had a history of systemic involvement reported with syndromal EL. We additionally identified 2 heterozygous mutations in *FBN1*. A de novo *FBN1*-mutation c.4043G>A ;p.(Cys1348Tyr), that has not been reported previously, was detected in a 4 year-old child with EL; other features of MFS were not (yet) obvious. The mutation c.2415T>G; p.(Cys805Trp) was identified in a 13-year-old girl with EL not fulfilling MFS diagnostic criteria. She inherited the mutation from a parent who had a history of bilateral lens extraction in childhood and no further clinical signs of MFS. Furthermore, there was a family history of aortic (abdominal) aneurysms. One child with EL neither had a *FBN1* nor *ADAMTSL4* mutation.

These results emphasize the importance of mutation analysis of *FBN1* and *ADAMTSL4* in patients with ectopia lentis, especially in young children since patients with mutations in *ADAMTSL4* do not need the extensive screening exams (especially regarding cardiovascular complications) as patients with a *FBN1* mutation.

P02.087

Translation initiation factor *EIF3A* haploinsufficiency appears to be a neutral variant despite *de novo* occurrence in a patient with developmental delay

***M. Appelbäck**[1,2], O. Bruland[1], M. Mork[3], S. Berland[1], G. Houge[1,2];*
[1]Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, Norway, [2]Department of Clinical Medicine, University of Bergen, Bergen, Norway, [3]Department of Child Neurology, Stavanger University Hospital, Stavanger, Norway.

In a 5 year old boy with idiopathic congenital hypothyroidism detected at birth, mild developmental delay, normal stature (25 centile) and microcephaly (1 cm < 2.5 centile), a 0.1 Mb *de novo* duplication was found seemingly disrupting the *EIF3A* gene of which was later confirmed by molecular investigations and supposed pathogenic. In another patient a routine SNP-array test revealed a 1.4 Mb 10q26.11 deletion affecting 12 protein coding genes, including *EIF3A*. This patient was a 15 year old girl with mild ID, short stature (2.5 centile) and normal head circumference (25-50 centile). The deletion turned out to be maternal, and the mother was completely healthy and could report of average or above-average school performance. Our initial assumption that the *de novo* disruption of the *EIF3A* gene was likely to be pathogenic, given the importance of eIF3A for e.g. normal translation and ERK signal transduction, had to be revised. The dissimilar phenotypes additionally support the hypothesis that *EIF3A* deletions are neutral. This is especially evident in the lack of microcephaly in the girl with the 10q26.11 deletion and the lack of short stature in the boy with the *EIF3A* disruption.

P02.088

An atypical Williams-Beuren deletion encopassing *ELN* and *LIMK1* genes

***B. Demeer**[1], S. Chenichene[2], G. Morin[1], A. Receveur[3], H. Copin[3], A. De Broca[4], O. Godefroy[5], D. Sanlaville[6], P. Saugier-Veber[7], M. Mathieu-Dramard[1];*
[1]Genetics Department, Amiens, France, [2]Cardiology, Pediatrics Department, Amiens, France, [3]Cytogenetics Department, Amiens, France, [4]Neurology, Pediatrics Department, Amiens, France, [5]Neurology Department, Amiens, France, [6]Genetics Department, Lyon, France, [7]Molecular Biology Department, Amiens, France.

Williams-Beuren syndrome is a multisystemic developmental disorder caused by hemizygous deletion of a segment on chromosome 7q11.23, spanning 1.55 Mb or 1.8 Mb, and encoding 28 genes. A few individuals have smaller deletions of the region. with phenotype ranging from supravalvular aortic stenosis syndrome to classic Williams-Beuren Syndrome.

We report a family with dominant supravalvular stenosis. The mother presents supravalvular aortic stenosis, distinctive facies and shows strong anxiety; she also have history of school difficulties and impulsivity and short attention span. Her youngest son have supravalvular aortic stenosis, involvement of the pulmonary branch, and mesenteric, coeliac and renal stenosis; her eldest son have supravalvular pulmonary and aortic stenosis. They both had surgery for bilateral inguinal hernia, normal calcemia, no classical WBS facial dysmorphism when seen at the genetic department, and attention deficit and hyperactivity. The youngest daughter was diagnosed at birth with severe supravalvular aortic and pulmonary stenosis, and facial dysmorphism. Calcemia was normal. Her karyotype and FISH of the 7q11.23 region were negative. QMPSF analysis of the 7q11.23 region found an atypical deletion, confirmed by array-CGH (Agilent 244k), of the entire *ELN* gene and part of the *LIMK1* gene cosegregating with the familial phenotype. Although the loss of an *ELN* allele produces the cardiovascular pathology of WBS, the phenotypic consequences of losing other alleles within the WBS chromosome region are much less clear. Based on study of patients with atypical deletion and mouse models, loss of *LIMK1* gene has a possible putative effect on impaired visuospatial abilities.

P02.089
Emanuel syndrome: breakpoint determination.

***Z. Gencik-Guillier**, A. Lott, H. Gabriel, A. Gencik;*
diagenos, Osnabrück, Germany.

The constitutional translocation between chromosomes 11 and 22 is the most common non- Robertsonian translocation in humans. Clustered breakpoints involving chromosome regions 11q23 and 22q11 have been reported in unrelated families. Balanced translocation carriers are clinically normal. Their offspring have a risk to herit a supernumerary der (22)t(11;22) chromosome, which results in a rather very constant phenotype. This very rare genomic syndrome was named Emanuel Syndrome.

We report a case of a boy with classical features of Emanuel Syndrome: mental retardation, microcephaly, failure to thrive, some organ malformations, ear anomalies, and dysmorphic features with a typical round face, prominent forehead and deep round eyes. After array CGH and caryotyping of patient and his parents and sibs, we also analysed the chromosomal restructuration with a breakpoint - specific PCR to determine its precise localization and to confirm that the breakpoint lies in the region of the recurrent translocations, with a variation of only several nucleotides, if compared to other Emanuel Syndrome patients. The mechanism of the recurrent translocation may be explained by the fact that it lies in a region with a palindromic nucleotid sequence.

P02.090
ECO Syndrome Without ICK Mutation: Genetic Heterogeneity?

***K. Ludwig**[1], R. Salmaso[1], E. Cosmi[2], L. Garavelli[3], B. Campos-Xavier[4], M. Clementi[5], M. Rugge[1], A. Superti-Furga[4];*
[1]Department of Medicine (DIMED), Surgical Pathology & Cytopathology Unit; University of Padova, Padova, Italy, [2]Department of Woman and Child Health, Section of Maternal and Fetal Medicine, University of Padova, Padova, Italy, [3]Clinical Genetics Unit - Department of Obstetrics, Gynecology and Pediatrics - IRCCS Santa Maria Nuova Hospital, Reggio Emilia, Italy, [4]Department of Pediatrics, University of Lausanne (www.skeldys.org), Lausanne, Switzerland, [5]Department of Pediatrics, Clinical Genetics Unit, University of Padova, Padova, Italy.

Endrocrine-cerebro-osteodysplasia (ECO) is a recently described neonatal lethal recessive disorder characterized by multiple congenital anomalies involving the endocrine, central nervous and skeletal system. Six affected individuals from a single consanguineous Old Order Amish family have been reported so far. All affected individuals carried a homozygous missense mutation in the ICK gene. We report a single case, offspring of non-consanguineous parents, with multiple congenital anomalies equalling those of ECO syndrome. Malformations included micromelia, ulnar deviation of hands, brachydactyly, midface hypoplasia, midline cleft-lip and -palate, holoprosencephaly and absence of the adrenal glands. The external phenotype was indistinguishable from that of the published cases of ECO syndrome. Molecular analysis failed, however, to identify mutations in the ICK gene. We therefore think that ECO syndrome might be genetically heterogeneous and not a "private" condition. Consequently the diagnosis of ECO syndrome should be considered in prenatal/neonatal cases of multi-system disorders involving the endocrine glands, the cerebrum and skeletal system.

P02.091
Recurrence risk and (epi)genetic complexity in Silver-Russell and Beckwith-Wiedemann syndrome

***N. Bachmann**[1], A. Bohring[2], K. Mohnike[3], M. Zenker[4], R. Pfäffle[5], H. J. Bolz[1], D. Prawitt[6], C. Bergmann[1];*
[1]Bioscientia, Center for Human Genetics, Ingelheim, Germany, [2]Institute for Human Genetics, University of Münster, Münster, Germany, [3]Department of Pediatrics, University of Magdeburg, Magdeburg, Germany, [4]Institute for Human Genetics, University of Magdeburg, Magdeburg, Germany, [5]Hospital for Children and Adolescents, University of Leipzig, Leipzig, Germany, [6]Center for Pediatrics and Adolescent Medicine, University of Mainz, Mainz, Germany.

Silver-Russell (SRS) and Beckwith-Wiedemann syndrome (BWS) are growth disorders mainly caused by defects in the epigenetically regulated region 11p15.5, containing the imprinting control regions 1 and 2 (ICR1 and ICR2). SRS is characterised by severe intrauterine and postnatal growth retardation, contrary to BWS which presents as an overgrowth disorder associated with embryonal tumors. While the most frequent known aberration in SRS is an ICR1-hypomethylation (>30%), most BWS cases (50-60%) are caused by an ICR2-hypomethylation. In addition, a variety of other genetic and epigenetic alterations in 11p15.5 are known to result in deficient epigenetic regulation.

NLRP2-mutations have recently been identified as a rare heritable cause for methylation defects resulting in BWS in children of unaffected female homozygous mutation carriers. Even though familial cases of BWS and SRS are rare, the identification of heritable factors affecting genomic imprinting in these disorders is crucial to estimate the recurrence risk in affected families.

For illustration of the (epi)genetic complexity, we present several familial and sporadic SRS and BWS cases with rare disturbances in 11p15.5. Furthermore, we refer to Next-Generation Sequencing (NGS) as a suitable testing approach for future detection of genes involved in the regulation of genomic imprinting and further epigenetically regulated regions involved in BWS and SRS.

P02.092
A new case of genome-wide paternal uniparental disomy emphasizing the need of multilocus-testing in imprinting disorders

***M. Begemann**[1], S. Spengler[1], M. Gogiel[1], L. Soellner[1], U. Göretzlehner[2], T. Eggermann[1], G. Strobl-Wildemann[3];*
[1]Institute of Human Genetics, University Hospital Aachen, Aachen, Germany, [2]Frauenklinik Kreiskrankenhaus Ehingen, Ehingen, Germany, [3]MVZ Humangenetik Ulm, Ulm, Germany.

While non-mosaic genome-wide paternal uniparental disomy (UPD) is not consistent with life and leads to hydatidiform mole, UPD of single chromosomes is a well-known cause for a group of congenital diseases usually called imprinting disorders (IDs). Chromosomes associated with IDs are 6, 7, 11, 14, 15 (Transient Neonatal Diabetes Mellitus, Silver-Russell syndrome, Beckwith-Wiedemann syndrome, upd(14)-syndromes, Prader-Willi syndrome, Angelman Syndrome). The clinical outcome of a UPD depends on the transmitting parent. Whereas maternal and/or paternal UPD of the aforementioned chromosomes have clinical consequences, others are not associated with clinical phenotypes (if not carrying a recessive mutation). Therefore it can be argued that UPDs of other chromosomes are underdiagnosed and are detected only by chance. We here present a 19-year old woman carrying a mosaic genome-wide paternal UPD that was coincidentally identified in a multi-locus screening for aberrant methylation. The patient was initially diagnosed as BWS due to a mosaic upd(11p15)pat but presented additional clinical findings including nesidioblastosis, fibroadenomas, hamatomar of the liver, hypoglycemia and ovarian steroid cell tumour. So far, only single cases with similar clinical and molecular findings mainly diagnosed in early childhood have been reported. Based on these data it can be concluded that the mosaic genome-wide paternal UPD (also known as androgenic/biparental mosaicism) in our patient explains the unusual BWS phenotype. These findings emphasize the need for multilocus testing in imprinting disorders to efficiently detect cases with disturbances affecting more than one chromosome.

P02.093
Eight alterations in the genes FOXG1, TCF4 and CDKL5 in a cohort of 70 patients with seizures and intellectual disability

***I. Stefanova**[1], C. Runge[1], S. Purmann[1], G. Uyanik[2], G. Gillessen-Kaesbach[1];*
[1]Institut für Humangenetik, Universität zu Lübeck, Lübeck, Germany, [2]Institut für Humangenetik, Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany.

To date many genes have been identified to be associated with epilepsy, intellectual disability (ID) and other features such as dysmorphism, movement disorders, microcephaly or brain malformations. CDKL5, TCF4, SLC9A6, ARX and FOXG1 are important genes belonging to this group. The conditions caused by mutations in these genes are especially relevant differential diagnoses to Rett and Angelman syndromes. The incidence of these conditions is unknown. In addition, there is only insufficient data available concerning the phenotypic variability, caused by haploinsufficiency of these genes.

In a cohort of 70 patients with seizures or EEG abnormalities and ID, we sequenced the genes CDKL5, TCF4, SLC9A6, ARX and FOXG1. Further we performed MLPA analysis for CDKL5, TCF4, ARX and FOXG1. We found heterozygous pathogenic alterations in eight patients (11,4 %). Four patients showed alterations in FOXG1 (one frameshift, two missense mutations and one deletion) and two in CDKL5 (one splicesite mutation and one deletion). Two patients had the same recurrent missense mutation in the TCF4 gene. We present detailed clinical and molecular data of our patients. We compare the results to the literature and discuss on novel insights into the phenotypes of patients with FOXG1, TCF4 and CDKL5 mutations.

Our study contributes to the delineation of the phenotypes of these rare conditions. Further investigations with new molecular techniques such as next generation sequencing will identify much more patients. The evaluation of the clinical findings in these patients will help to define more precisely the incidence and phenotypic variability in these disorders.

P02.094

Screening of SCN1A and MDR1 polymorphisms in epilepsy

A. Ebrahimi[1]*, M. Houshmand*[2]*, S. Zainali*[3]*, S. Tonekaboni*[4]*, M. Moghaddasi*[5]*, M. Fallah*[3]*, M. Ataei*[2]*, G. Modaber*[2]*, N. Hatamnejadian*[1]*, B. Sedaghaty Khaiat*[1]*, M. Moghaddam*[1]*, S. Sarabi*[1]*, M. Hosseini*[6]*;*

Genetic variability in drug metabolism affects the treatment with Anti Epileptic Drugs (AEDs). Allelic variations in genes include SCN1A and MDR1, encoding AEDs target and drug transport proteins, may affect efficacy and tolerability of antiepileptic drugs. This study designed to evaluate frequency of ABCB1 and SCN1A selected SNPs in genotype and haplotype combination in Iranian population who were affected by Idiopathic Refractory Epilepsy (IRE).About 81 healthy normal samples and 34 probands, clinically diagnosed as one type of IRE, were selected. The genotype of two SNPs in SCN1A (rs2298771, rs7601520) and one in MDR1 (rs1045642) were determined in two groups by ARMS-PCR, PCR- RFLP and confirmed by direct sequencing.

The data analysis shows no statistically significant difference and so the predicted haplotype frequencies including three SNPs did not show significant difference between patients and control group.

P02.095

Whole exome sequencing to identify genes involved in epileptic encephalopathy

C. G. F. de Kovel*, E. Brilstra, R. van ,t Slot, S. van Lieshout, B. P. C. Koeleman;*
UMC Utrecht, Utrecht, Netherlands.

Epileptic encephalopathy is a severe condition occurring often at a very young age. Patients suffer from epileptic seizures, and, presumably as a consequence, show developmental retardation.

When no external cause is prevalent, the condition is assumed to be genetic. In some families, multiple sibs are affected. A few genetic causes for epileptic encephalopathy are known, but many cases cannot be explained. Probably, there is high genetic heterogeneity.

In order to identify more genetic causes for this disorder, we have collected patients with healthy parents. Five families had multiple affected sibs, whereas ten patients had no affected relatives. We performed exon sequencing to look for genetic causes, assuming a recessive model, either homozygous or compound heterozygous in the multiplex families, while in the sporadic cases a de novo mutation is an additional possibility.

So far, we have identified X-linked mutations in CDK16 and GABRE as possible candidates in male patients. Further analysis of the remaining families may identify more candidate mutations. To confirm their pathogenicity, we will combine our results with those of other research groups.

Establishment of Diagnostic Decision Support System (DDSS) in Clinical Diagnosis of Genetic Diseases: The FaceGP DDSS Methodology and Its Applications

K. Kuru[1]*, Y. Tunca*[1]*, M. Niranjan*[2]*;*
[1]*Gulhane Military Medical Academy (GATA), Ankara, Turkey,* [2]*University of Southampton, Southampton, United Kingdom.*

A face develops under the influence of many genes. Thus, facial appearance can be a significant clue in the initial identification of genetic anomalies associated with especially cognitive impairments. It may be possible to diagnose a good number of syndromes correctly by using computer-assisted face analysis. For dysmorphic syndromes -with - known genetic causes, cyto- and/or molecular genetic analysis is the appropriate route of investigation in order to confirm a diagnosis. In this study, in terms of helping non experienced practitioners in diagnosing process as well as supporting experts in their decisions, we established a methodology to ease the process and we refer to our method as FaceGP DDSS. In the methodology, digital facial image processing methods are used to reveal facial features with disorders indicating genotype-phenotype interrelation. A great number of genetic disorders indicating a characteristic pattern of facial anomalies can be typically identified by analyzing specific features with the aid of facial image processing methods such as PCA in order to determine reference values (eigenfaces) and train the system. Distance algorithms such as Euclidean, Mahalanobis are used to construct the correlation of the input image with the trained images in matching. Some image enhancement methods such as histogram equalization and median filter are implemented on detected degraded images to capture better features. This study proposes a novel computer-assisted and cost-effective method by merging several methods in the characterization of the facial dysmorphology, in particular a method relying primary on face image capture and manipulation to diagnose genetic diseases.

A Patient with 3q26.33q27.3 monosomy presenting with intellectual disability, facial dysmorphism and diaphragm evantration

Y. Sahin[1,2]*, P. Şimşek Kiper*[1,3]*, E. Utine*[1,3]*, K. Boduroğlu*[1,3]*;*
[1]*Hacettepe University, Ankara, Turkey,* [2]*Department of Medical Genetics, Ankara, Turkey,* [3]*Clinical Genetics Unit, Ankara, Turkey.*

A Patient with 3q26.33q27.3 monosomy presenting with intellectual disability, facial dysmorphism and diaphragm evantration

We herein describe a 7-year-old female patient who was referred us for facial dysmorphism, intellectual disability and diaphragmatic eventration. The patient was born 2050 grams, to nonconsanguineous parents, as their first liveborn by normal delivery, at term. Prenatal history revealed oligohydramnios and intrauterine growth retardation. Postnatally the patient had irregular respiration and tachypnea. She had a delay in both motor and mental developmental milestones. Fluoroscopy detected eventration of the right diaphragm. Perfusion scintigraphy of the lungs demonstrated segmental perfusion defects bilaterally. Magnetic resonance imaging revealed hypoplasia of corpus callosum and cerebral atrophy. On physical examination body weight was 17.7 kgr (3-10th centile), head circumference was 46 cm (<-2SD), and height was 106 cm (<3rd centile). She had facial dysmorphic features including thin lips, broad base to nose, low set ears, bilateral epicanthi. The patient was clinically suspected to have a chromosomal disorder. The patient had a normal karyotype; however, array-CGH analysis (Agilent 8X60K Array) revealed a 4.3 Mb deletion in 3q26.33q27.3. Previously six cases of microphthalmia or anophthalmia in association with deletions/rearrangements of chromosome 3q involving 3q26.33q27.3 have been reported. The described region was estimated to be 6.7 Mb and was assumed to have an anophthalmia gene at 3q26.33-q28 locus. Our patient did not have any eye malformation. Therefore, the previously descibed region suspected to harbor the anophthalmia gene may be further narrowed down to the 3q27.3-q28 region with the findings of the present patient.

P02.098

Clinical and genetic characteristics of the chest and pleuropericardial manifestations in Armenian children with Familial mediterranean fever

G. G. Amaryan[1]*, H. S. Hayrapetyan*[2]*,* ***T. F. Sarkisian***[2]*;*
[1]*Arabkir Medical Center, Yerevan, Armenia,* [2]*Center of Medical Genetics, Yerevan, Armenia.*

Familial Mediterranean fever (FMF) is an autosomal-recessive disease characterized by febrile aseptic polyserositis. FMF, as ethnic disorder for Mediterranean sea ancestors region, is widespread in Armenians. Chest pain attacks are 2-nd manifestation after febrile abdominal attacks.Objective; to investigate clinical and genetic characteristics of the chest manifestations (pleuritis and pericarditis) in children with FMF. Results: We performed clinical and genetic (MEFV gene mutations) investigations in 715 children (438 boys, 277 girls, mean age 8,64±0,17). Chest pain attacks (pleuritic or/and pericardial in origin), mainly unilateral, short lasting, with dyspnea, superficial, painful inspiration, often developed recurrent pleurisy (81.7%), pericarditis (13.8%). Pleurisy as 1st manifestation was observed in 23.1% of patients. In 1% of cases lung atelectasis and asthma attacks were observed. We detected the most frequent mutations of MEFV gene. Frequency of V726A mutation in Armenians is higher (22.3%) than in other populations with high level of FMF: Jews (3.0%), Turks (2.9%). Risk of leurisy in contrast to other serosities was associated mainly with V726A/M694V compound-heterozygous genotype (81,6%) and was 2.3 time higher than in M694V-homozygotes (71.9%) and M694V-heterozygotes (68,9%) with benign clinical course. Recurrent pericarditis was revealed in 13.8% and associated with M694V-homozygotes in compare to patients without M694V mutation. Conclusions: Taking into consideration our data about more frequent association of V726A mutation with pleurisy, we suppose that the prevalence of V726A compound-heterozygous genotype might be considered as a risk factor for development of the pleurisies. Pericarditis as rare FMF manifestation, was associated with M694V mutation and considered as unfavorable FMF prognosis.

P02.099

Feingold syndrome type II in a family with deletion 13q31q32 comprising the microRNA 17~92 cluster

P. Villavicencio Lorini[1,2]*, E. Klopocki*[1,2]*, M. Trimborn*[1]*, S. Mundlos*[1,2]*, D. Horn*[1]*;*

[1]Institute for Medical Genetics and Human Genetics, Charité-Universitätsmedizin Berlin, Berlin, Germany, [2]Max-Planck-Institute for Molecular Genetics, Berlin, Germany.

Feingold syndrome is characterized by developmental delay/intellectual disability, microcephaly, short stature, characteristic shortening of middle phalanges II/V and various congenital defects of the heart, kidney and gastrointestinal tract. In the majority of patients this syndrome is caused by mutations of N-MYC. Recently, germline deletions of microRNA 17~92 cluster have been identified to be responsible for the Feingold syndrome phenotype in three patients. This variant is called Feingold syndrome type II. Here we report on a family with a 4.5 Mb deletion of the chromosomal region 13q31.3q32.1 comprising the microRNA 17~92 cluster. This deletion was identified by array CGH and confirmed by FISH. The index patient and his mother show the typical phenotypic pattern of Feingold syndrome including developmental delay/intellectual disability in combination with microcephaly, short stature and the digital abnormalities. N-MYC mutations were excluded in the index patient. The 13q31.3q32.1 deletion emerged de novo in the affected mother of the index patient. To clarify whether phenotypic features could be caused by a single copy loss of other involved genes in the deleted chromosomal region we compared the clinical findings of our patients with those of reported patients carrying 13q31q32 deletions. Interestingly, we could not find any further remarkable clinical feature which is not belonging to the phenotypic spectrum of Feingold syndrome in the here reported family. Our findings confirm deletions of the microRNA 17~92 cluster as a further cause of Feingold syndrome.

P02.100

Heterotopic bone formation not related to POH/FOP disease: a new entity.

***E. F. Belligni**[1], E. Biamino[1], E. Di Gregorio[2], A. Calcia[2], C. DeFilippi[1], A. Brusco[2], G. B. Ferrero[1], M. Tartaglia[3], M. Silengo[1];*
[1]Department of Pediatrics, University of Torino, Torino, Italy, [2]Department of Genetics, Biology and Biochemistry, University of Torino, and Medical Genetics Unit, San Giovanni Battista Hospital, Italy, Torino, Italy, [3]Department of Haematology, Oncology and Molecular Medicine Istituto Superiore di Sanità, Rome, Italy.

We present a peculiar case of multiple and massive congenital periarticular calcification in a normally developed female, aged 2 years, the first child of Italian non consanguineous parents. Since her first month, she presented progressive diffuse joints limitation. Skeletal survey and a CT scan at 8 months assessed shoulder, elbow, wrist, hip, knee and ankle joints fixed by periarticular calcifictions. Ectopic bone tissue was present between the occipital skull base and C3 vertebral body. At 10 months, total body MRI showed respiratory and deglutitory muscles calcification, with progressive cranio-caudal involvement. On physical examination at 2 yr., diaphragmatic breathing underlaid gradual respiratory deterioration. Her posture was forced in flexion of elbows, knees and ankles, and movements of the head were completely abolished.

She also had brachydactyly of hands and feet, camptodactyly of the hands, very short fingers of feet. Her eyes are deep-set, the philtrum is short and smooth, but she has no other striking dysmorphisms.

Neurocognitive milestones were properly achieved.

Extensive metabolic workup gave normal results: serum and urine calcium levels were normal, as well as serum and urine phosphorum, sodium, potassium, magnesium, cratinine, PTH, 1-25-OH-Vit D, 25-OH-VitD levels.

Molecular analysis of ACVR1 and GNAS genes ruled out both Fibrodysplasia Ossificans Progressiva (FOP) and Progressive Osseous Heteroplasia (POH), two distinct severely disabling heritable disorders of connective tissue characterized by progressive heterotopic ossification.

Exome sequencing: pending.

Filamin A associated periventricular nodular heterotopia in males

***U. Hehr**[1,2], M. Lange[3], B. S. Kasper[4], N. Di Donato[5], F. Mueller[1], G. Schuierer[6], J. Winkler[7];*
[1]Center for Human Genetics Regensburg, Regensburg, Germany, [2]Department of Human Genetics, University of Regensburg, Regensburg, Germany, [3]Department of Neurosurgery, University Hospital Regensburg, Regensburg, Germany, [4]Epilepsy Center, Department of Neurology, University Hospital Erlangen, Erlangen, Germany, [5]Institute of Clinical Genetics, Technical University of Dresden, Dresden, Germany, [6]Institute of Neuroradiology, University Hospital Regensburg and District Medical Center Regensburg, Regensburg, Germany, [7]Department of Molecular Neurology, University Hospital Erlangen, Erlangen, Germany.

Introduction: Filamin A (FLNA) associated periventricular nodular heterotopia (PVNH; MIM 300049) is an X linked dominant inherited neuronal migration disorder with high perinatal lethality of hemizygous males. Occasional reports of older male patients were associated with hemizygous hypomorphic FLNA alleles or somatic mutations.

Methods: neurological examination, cerebral MR imaging, sequence analysis of the entire FLNA coding region and MLPA.

Results: we here present the neurological findings, selected MR images and results of FLNA mutation analysis for three new male patients. Patient A at the age of 4 years presented with a severe global developmental delay, dolichomicrocephaly, muscular hypotonia, complex cerebral malformations including polymicrogyria and PVNH in MR imaging and was hemizygous for a FLNA missense mutation inherited from his mother. A severe and complex phenotype was also identified in 37 year old patient B with intractable seizures, skeletal features within the OPD spectrum and severe obstructive lung disease, resulting from a mosaic frameshift FLNA mutation. In contrast, a mosaic FLNA splice site mutation was observed in the 63 year old father (patient C) of two daughters with PVNH. MR imaging confirmed for him very subtle PVNH; he has a University degree, under antiepileptic medication is without seizures and otherwise healthy.

Discussion: FLNA mutations in males are rare and should also be considered in patients with more complex phenotypes including PVNH as shown in patients A and B. Furthermore, mosaic Filamin A mutations may be clinically silent, but still be associated with a high recurrence risk as demonstrated in patient C.

P02.102

De novo FMR2 (AFF2) deletion encompassing exons 2 and 3 in a boy with a mild intellectual disability

*A. Behboudi[1,2], T. Zagoras[3], L. Samuelsson[3], C. Jiang[1], E. Kaerrstedt[3], **M. Stefanova**[3,2];*
[1]Systems Biology Research Centre – Tumor biology, School of Life Sciences, University of Skövde, Skövde, Sweden, [2]Department of Medical and Clinical Genetics, Institute of Biomedicine, University of Gothenburg, Gothenburg, Sweden, [3]Department of Clinical Gentics, Sahlgrenska University Hospital, Gothenburg, Sweden.

Alterations of the Fragile Mental Retardation 2 gene (FMR2, synonym AFF2) can result in a mild to moderate intellectual disability (ID), speech delay, hyperactivity, and autistic behaviour. The well-known underlying molecular mechanism of this condition, also referred to as FRAXE, is a (CCG)n trinucleotide repeat expansion which leads to silencing of the FMR2 gene. Additionally, deletions within the FMR2 gene were described in handful number individuals with ID.

Here we report on a de novo 131 kb deletion of FMR2 gene in a 2-years-old boy with a mild developmental delay, behaviour changes, hypotonia, and discrete facial dysmorphism. The deletion, detected by SNP-array analysis (Affymetrix 250 K Nsp I), spans between the base pairs 147454718-147586323 (NCBI36). The aberration and its de novo origin were confirmed by MLPA. RNA analysis on the patient showed a 994 bp deletion of AFF2 transcript, resulting in the complete loss of exons 2 and 3.

In conclusion, this case report further confirms the role of FMR2 gene deletions as a FRAXE phenotype underlying mechanism. RNA analyses demonstrate that the deletion within the FMR2 gene ceases the transcript production.

P02.103

Detection of serum anti-neuronal antibodies in patients with Fragile X syndrome

***M. Lisik**, A. Pyrkosz, E. Gutmajster, A. L. Sieron;*
Department of General, Molecular Biology and Genetics, Katowice, Poland.

Fragile X syndrome (FXS) is the most common form of familial mental retardation and known cause of autism. The mutation responsible for FRAXA is a large expansion of the trinucleotide CGG repeats at 5' end of the *FMR1* gene resulting in the transcriptional silencing of the gene. There are close similarities between autism profiles in idiopathic and comorbid autism (FXS).

Aim: The aim of the study was to investigate the frequency of serum antineural antibodies in a group of 23 Fragile X males.

Material and methods: Serum anti-neuronal antibodies were measured by Western blot technique (Anti-neuronal Antigens EUROLINE-WB EUROIMMUN) in 23 patients with FXS (full mutation in the *FMR1* gene), aged between 10 and 32 years, in comparison to 19 healthy-matched males

Results: We detected the presence of antibodies in the serum of 10 FXS males and in 1 from the reference group. FXS males had significantly higher percent of elevated levels of serum anti-neuronal antibodies (43,48%) than healthy controls (5,26%).

Conclusion: Serum anti-neuronal antibodies were found in a subgroup of FXS patients. Autistic symptoms in FXS may be, in part, caused by autoimmune factors. Further wide-scale studies are necessary to shed light on the role of anti-neuronal antibodies in autistic syndromes

The work was in part financed from Institutional grant KNW-2-021/10 awarded to MZL

P02.104

Offspring of a fully mutated fragile-X male patient: a premutated female baby

L. Van Maldergem[1,2]*, B. Haddad*[3]*, D. Amram*[2]*, C. Touboul*[3]*, E. Flori*[4]*, V. Biancalana*[5]*;*
[1]*Centre de Génétique Humaine, Besançon, France,* [2]*UF Génétique Clinique, Centre Hospitalier Intercommunal, Créteil, France,* [3]*Dept Gyn-Obst, Centre Hospitalier Intercommunal, Créteil, France,* [4]*Dept Cytogenetics, University Regional Hospital, Strasbourg, France,* [5]*Laboratory of Genetic Diagnosis, University Regional Hospital, Strasbourg, France.*

A 28 y-old male originating from eastern Algeria with a diagnosis of Fragile X mental retardation established at the age of 12 y during evaluation of severe learning disabilities married his second-cousin. He required special education in France and is currently working in a shelter. After an arrangement has been decided by his family, his second-cousin who was educated in Algeria was married to him. Although he suffers moderate mental retardation, his wife is of normal intelligence. A pregnancy developed soon thereafter. A male with the full mutation is expected to transmit alleles of premutation size to his daughters, based on an experience of less than ten reported cases. This is why prenatal testing is still recommended for a female fetus of a fully mutated genitor. Fetal DNA was extracted from cultured amniocytes and submitted to Southern blotting and (CGG)n PCR analysis. While the father is mosaic for a methylated full mutation in lymphocytes (around 20% of the cells are not methylated), his wife has two normal alleles. The female fetus harbored a normal allele and a 105 CGG repeats premutation. She was therefore predicted to be unaffected with Fragile X syndrome and the pregnancy was pursued. Repeat ultrasound examination of the fetus was normal. After an uneventful pregnancy, the woman gave birth to a healthy female baby. Reproduction in Fragile X males is exceptional. This case report gives further support to this unusual reverse instability mechanism as a common one.

P02.105

A rare case of Fraser syndrome followed 9 years alive

M. Bembea[1,2]*, C. Jurca*[1,2]*, D. Bembea*[1]*, K. Kozma*[1,2]*, S. Bembea*[1]*, A. Jurca*[1]*;*
[1]*Medicine and Pharmacy Faculty, Oradea, Romania,* [2]*Municipal Clinical Hospital, Oradea, Romania.*

BACKGROUND: Fraser syndrome is a rare autosomal recessive disorder (just over 250 cases reported) characterized by cryptophthalmos, syndactyly and uro-genital anomalies (as major criteria). Survival of affected subjects seems to be up to 25% by 1 year of age and up to 15% at 1-10 years. CASE PRESENTATION: A girl with Fraser syndrome was followed from birth to the time of death (at 9 years of age). Parents were young, healthy, unrelated but originating in the same relatively isolated village. The patient had a healthy brother (4 years older), and a brother with Dandy-Walker malformation (2 years younger). On examination she presented major criteria for Fraser syndrome: bilateral criptophtalmos, syndactyly - both hands and both feet, clitoromegaly, associated with multiple other anomalies. Brain imaging (ultrasound, CT, MRI) revealed no abnormalities. She had clinical progression of multi-sensory impairment, along with learning difficulties and physical disabilities. No cytogenetic anomalies were found and there were no molecular studies conducted. DISCUSSION: Fraser syndrome has a very low frequency. The syndrome can be caused by mutations in two genes, FRAS1 (4q21) and FREM2 (13q13.3). This case posed multiple medical problems determined by multi-sensory involvement and physical and mental retardation. A speculative element of the case presented consists of the familial association of a brother with Dandy-Walker malformation; Fraser syndrome is associated in 20% of cases with Dandy-Walked malformation. CONCLUSION: The case presented could contribute to a better understanding of this rare syndrome, given phenotypical characteristics and survival up to 9 years of age.

P02.106

Frontonasal dysplasia; characterization of a family with an evident pattern of an autosomal dominant inheritance.

J. M. Valdes-Miranda[1]*, M. Martin-DeSaro*[1]*, S. A. Cuevas-Covarrubais*[2]*;*
[1]*Genetica, Hospital General de Mexico, Mexico, D.F., Mexico,* [2]*Genetica, Hospital General de Mexico, Facultad de Medicina, UNAM, Mexico, D.F., Mexico.*

Frontonasal dysplasia is due to disturbance in the development of frontonasal, medial nasal and maxillary prominences, structures derived from the neural cresta. It is a clinically and genetically heterogeneous disease that presents large hypertelorism, broad nasal bridge, bifid hidden skull, nose bifid and cleft lip/palate. By far, most cases show an autosomal recessive pattern. In the present study, we describe a family in three generations with 15 affected members with frontonasal dysplasia and alopecia. The proband was a woman of 22 year old with high forehead, mild alopecia, hypertelorism, broad nasal bridge, nose bifid, hypoplastic midface, sparse eyebrows. She underwent reconstructive surgery of the nose at 19 years. The rest of the family members harbour similar clinical characteristics. There are few reports of frontonasal dysplasia with dominant autosomal inheritance, practically all of them have an autosomal recessive pattern. In the present family we confirm the automosal dominant inheritance in frontonasal dysplasia, linkage analysis is necessary to identify the gene responsible of the disease.

P02.107

Severe FX deficiency caused by a 4-bp deletion compound heterozygous with a large deletion in 13q34

J. Najm[1]*, C. W. Tan*[2]*, M. C. Morel-Kopp*[2]*, J. Teo*[3]*, Q. Chen*[2]*, C. M. Ward*[2]*, U. Felbor*[1]*;*
[1]*Institute of Human Genetics, University Medicine Greifswald and Interfaculty Institute for Genetics and Functional Genomics, Ernst Moritz Arndt University Greifswald, Greifswald, Germany,* [2]*Northern Blood Research Centre, Kolling Institute, University of Sydney and Department of Haematology and Transfusion Medicine, Royal North Shore Hospital, Sydney, Australia,* [3]*Department of Haematology, Westmead Children's Hospital, Sydney, Australia.*

We report the case of a newborn who presented with major bleedings due to severe FX deficiency. The infant was the first child of unrelated caucasian parents. FX levels were markedly reduced (<1%). Both parents had borderline low FX levels. The *FX* gene of the patient and her parents were examined by direct sequencing. The analysis revealed a homozygous 4-bp deletion in exon 2 of the girl. This deletion leads to a frameshift and subsequently to a premature stop codon. The father is a heterozygous carrier of this pathogenic mutation, whereas the mother's sequence for exon 2 was wild type, raising the possibility of a large deletion involving the *FX* gene on one maternal allele, which she could have passed on to the child. Subsequent SNP analysis showed that the patient was homozygous for a variant in intron 2 of the *FX* gene, whereas the father was heterozygous and the mother carried the homozygous wild type allele at this position. As MLPA analysis of the *FX* gene is currently unavailable and deletions involving both *FVII* and *FX* genes have been reported, MLPA analysis was performed for the *FVII* gene, which is located in close proximity to the *FX* gene. This analysis revealed a complete heterozygous deletion of the *FVII* gene which is likely to also involve at least part of the *FX* gene including exon 2, in both the mother and the child. Together, these findings account for severe FX deficiency in the patient.

P02.108

Efficacy and safety of biphosphonates in a Romanian pediatric clinical trial with genetic disorders affecting bone mineralization

V. Dumitrascu[1]*, D. Vlad*[1]*, C. Gug*[2]*, S. Sipos*[1]*, A. Bucur*[3]*, C. Vlad*[4]*, A. Matusz*[5]*;*
[1]*Department of Pharmacology and Biochemistry, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania,* [2]*Department of Genetics, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania,* [3]*Department of Public Health, "Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania,* [4]*Dentissimo Dental Care, Timisoara, Romania,* [5]*European General Practice Research Network Romanian National Representative, Timisoara, Romania.*

Background: Most genetic disorders with increased bone fragility (congenital rickets, osteogenesis imperfecta), include close to normal growth and autosomal dominant inheritance. Previous randomized controlled trials revealed that the majority of children and adolescents with mild and moderate forms of disease have low areal bone mineral density (BMD) at the lumbar spine and that cyclical treatment with biphosphonates has beneficial effects.

Methods: In a two years longitudinal study, we prospectively followed up 35 pediatric patients recruited from a Romanian primary care setting between November 2009 and November 2011. Inclusion criteria: positive family history - presence of at least one fracture or dentinogenesis imperfecta, children > 10 yr of age. Patients were randomized to either risedronate (N=18) or alendronate (N= 17) and study visits occurred every 3 month.

Results: The main efficacy variable was the change in lumbar spine (L_1- L_4) areal BMD Z-score; risedronate increased it by 0.76, whereas patients receiving alendronate therapy experienced an increase of 0.45 ($p > 0.05$). Regarding safety, the incidence of gastrointestinal side effects due to alendronate was higher (47%) when compared with the risedronate group (28%). These results suggest that the skeletal effects of oral alendronate are weaker but still lead to an increase in lumbar spine areal BMD.

Conclusions: In a single dose, pharmacokinetic study, data showed that biphosphonates were well tolerated and reduced fracture rates in a population-based cohort study of children with genetic disorders affecting bone mineralization.

Key words: genetic disorders, bone mineralization, pediatric patients, biphosphonates.

Abbreviations: BMD - bone mineral density

Congenital deafness is one of the most frequent sensory disorders which accounts for about 1 in 1000 newborns, and approximately half of all cases have a genetic etiology. 15-20 cases of congenital/early onset hearing impairment (HI) in 14000 - 15000 live births (~1:900-1:750 newborns) are detected per year in the Sakha Republic (Yakutia) located in Eastern Siberia (Russian Federation). In recent study we registered a large cohort of Yakut patients homozygous for the IVS1+1G>A mutation (70 unrelated deaf subjects in total) [Barashkov et al., 2011].
We collected audiometric data on 40 patients with genotype IVS1+1G>A / IVS1+1G>A. Audiograms from available medical documents were analyzed retrospectively for each ear separately. All 40 patients (80 ears) underwent otoscopic examination, tympanometry, and audiometric testing. Analysis of the audiological characteristics obtained from 40 subjects with genotype IVS1+1G>A / IVS1+1G>A revealed significant association of this genotype with severe to profound HI (85% of severe to profound versus 15% of mild to moderate, $p<0.05$) with mostly symmetrical bilateral hearing loss (29 out of 40 examined patients, $p<0.05$). Moreover, detailed audiological analysis showed a variability in hearing thresholds on different frequency ranges among subjects homozygous for IVS1+1G>A mutation.The study was supported by Russian Foundation for Basic Research ([1]09-04-01123-à, [1]11-04-01221-à), Federal Programs «Scientific and educational staff for innovative Russia» [1]02.740.11.0701 for years 2010-2012, [1]16.740.11.0190 and [1]16.740.11.0346 for years 2009-2013, and the State Scholarship of the Academy of Sciences of the Sakha Republic (Yakutia).

Variability in the level of erythrocyte glucose uptake in two patients with the same SLC2A1 mutation

N. Ishihara[1], *J. Natsume*[1], *K. Yanagihara*[2], *Y. Azuma*[1], *T. Nakata*[1], *T. Negoro*[1], *K. Watanabe*[1,3];
[1]*Department of Pediatrics, Nagoya University Graduate School of Medicine, Nagoya, Japan,* [2]*Department of Developmental Medicine, Osaka Medical Center and Research Institute for Maternal and Child Health, Osaka, Japan,* [3]*Department of Medical Science, Faculty of Health and Medical Sciences, Aichi Shukutoku University, Nagoya, Japan.*

Purpose: Glut1 deficiency syndrome (Glut1-DS) is a treatable epileptic encephalopathy diagnosed by hypoglycorrhachia, impaired erythrocytes glucose uptake, and heterozygous mutations in SLC2A1 gene. Here we report two patients with the same SLC2A1 mutation and different results in the erythrocyte glucose uptake to reveal clinical heterogeneity in Glut1-DS.
Patient 1: A 15-year-old girl, born to healthy non-consanguineous parents. Atypical absence seizures and dystonic posturing were seen since 2 years of age, and astatic episodes after a long walk has seen since 10 years of age. Hypoglycorrhachia and decreased erythrocyte glucose uptake were observed. She was diagnosed with Glut1-DS and started on the ketogenic diet.
Patient 2: A 17-year-old girl, born to healthy non-consanguineous parents. Since 4 years of age, she showed myoclonus, ataxia, and loss of consciousness with drooling. Such events were mostly seen in the late afternoon, and recovered with eating. Hypoglycorrhachia was observed while erythrocyte glucose uptake was normal. She has not started ketogenic diet yet, and her developmental status is severely retarded. Both patients had the same mutation in SLC2A1 (R330X). Discussion and conclusion: This is the first report of a patient with normal erythrocyte glucose uptake caused by the R330X mutation. There is variability in the level of erythrocyte glucose uptake even in patients with the same SLC2A1 mutation. Factors causing the variability remain to be clarified.

P02.111

Gomez-Lopez-Hernandez Syndrome - a further case report

A. L. Burgemeister[1], *A. Seitz*[2], *S. Karch*[3], *D. Choukair*[3], *A. Bockius*[4], *U. Moog*[1];
[1]*Institute of Human Genetics, University of Heidelberg, Heidelberg, Germany,* [2]*Department of Neuroradiology, University of Heidelberg, Heidelberg, Germany,* [3]*Center for Pediatric and Adolescent Medicine, Pediatric Neurology, Heidelberg University Hospital, Heidelberg, Germany,* [4]*Pediatric Practice, Dieburg, Germany.*

Gomez-Lopez-Hernandez syndrome (GLHS), also known as cerebellotrigeminal-dermal dysplasia, is a rare, possibly underdiagnosed neurocutaneous syndrome of unknown origin. GLHS is characterized by the triad of rhombencephalosynapsis, trigeminal anesthesia and partial alopecia of the scalp; however, only rhombencephalosynapsis and partial alopecia have been recognized as consistent features and are obligate diagnostic criteria. Rhombencephalosynapsis is defined as agenesis of the cerebellar vermis and fusion of the cerebellar hemispheres, the superior cerebellar peduncles and the dentate nuclei. Inconsistent features of GLHS include characteristic craniofacial features (brachy-turricephaly, midface hypoplasia, down-slant of palpebral fissures, hypertelorism, lowset posteriorly rotated ears), strabism, short stature, cognitive impairment, ataxia and muscular hypotonia. 27 patients have been published to date, all of them sporadic cases.
We report one further male patient, 6 years of age, to expand awareness of this rare disorder. He presented with short stature, hypospadias, atrial septal defect, mild muscular hypotonia and motor coordination problems, strabism, bilateral parietal alopecia, craniofacial dysmorphic signs, and congenital hypothyroidism also present in his brother. He showed a normal cognitive development. Chromosome analysis, FISH for 22q11 microdeletion and SNP-array analysis yielded no relevant results. A MRI of the brain performed for the evaluation of short stature showed rhombencephalosynapsis and thus led to the diagnosis of GLHS.

P02.112

Gómez-López-Hernández syndrome: description of an additional case with typical phenotypic features and normal cognitive function

S. Munk-Schulenburg[1], *D. Bartholdi*[1], *R. Munk*[2], *K. Schenck-Kaiser*[1], *A. Busche*[1], *J. Fischer*[1];
[1]*Institute of Human Genetics, University Clinic Freiburg, Freiburg, Germany,* [2]*St. Josefskrankenhaus Freiburg, Department of Diagnostic Radiology, Freiburg, Germany.*

Gómez-López-Hernández syndrome (GLHS) also named cerebello-trigeminal-dermal dysplasia is a rare neurocutaneos syndrome with unknown etiology. Based on current data, only 27 patients have been described so far, all sporadic cases. GLHS is characterized by the triad of rhombencephalosynapsis, trigeminal anesthesia and bilateral parietal or parieto-occipital alopecia. Bilateral alopecia is already present in the neonatal period and is highly suggestive of GLHS. Trigeminal anesthesia seems to be very variably in its expression and can be easily missed. Rhombencephalosynapsis is a consistent neuroimaging sign, comprising fusion of the cerebellar hemispheres with agenesis of the cerebellar vermis. Further features described so far include short stature, hypertelorism, down-slanting palpebral fissures, brachy-turricephaly, craniosynostosis, midfacial hypoplasia, mild mental retardation, dyspraxia, ataxia and corneal opacities.
Here we report on an additional patient with typical GLHS. The seven year old girl presented with trigeminal anesthesia with distinctive corneal lesions and visual impairment and mild parietal alopecia. Rhombencephalosynapsis was diagnosed in retrospect. Other phenotypic features were brachy-turricephaly, low set and dorsally rotated ears, strabismus convergens, down-slanting palpebral fissures, hypoplastic end phalanges and interrupted transverse palmar creases. Cognitive function was normal (IQ 104). Based on literature and our additional case we propose that the presence of partial alopecia, trigeminal anesthesia and rhombencephalosynapsis is required for the diagnosis of GLHS. Intellectual impairment is reported in patients but seems not to be a consistent feature of GLHS.

P02.113

Calcaneonavicular coalition in patients with Gorlin syndrome

B. S. Kristiansen[1], *A. Jelsig*[2], *A. Gerdes*[2], *L. B. Ousager*[1];
[1]*Department of Clinical Genetics, Odense University Hospital, Odense, Odense, Denmark,* [2]*Department of Clinical Genetics, Rigshospitalet, Copenhagen, Denmark.*

Basal cell nevus syndrome (BCNS), also known as Gorlin syndrome, is an infrequent autosomal dominant disorder characterized by a predisposition to neoplasm's and other developmental abnormalities.
Key features are jaw keratocysts, calcification of the falx or ectopic calcification, palmar/plantar pits and multiple basal cell carcinomas (BCC). A large proportion of affected patients have a recognizable appearance with macrocephaly, bossing of the forehead, coarse features and facial milia. Gorlin syndrome is caused by mutations in PTCH gene. Complete penetrance and variable expressivity are seen.
Calcaneonavicular coalition is one of the most common types of tarsal coalition and may be a fibrous, cartilaginous or bony union of the two bones.
Calcaneonavicular coalition was seen in three patients from two different families, with known pathogenic PTCH mutations (c.2287dupG and c.1142-1145delATGT).
Family A: An affected father and his two affected daughters all had classical

clinical manifestations of Gorlin syndrome. In addition, they had pain and reduced range of motion in their feet. Unilateral calcaneonavicular coalition was seen in the father and bilateral coalition in one of his daughters.
Family B: A father and son with classical manifestations of Gorlin syndrome. The son was diagnosed with bilateral calcaneonavicular coalition at the age of 38.
One major criteria of Gorlin syndrome is the ectopic calcifications and congenital skeletal malformations. To our knowledge there have not been any reports of tarsal coalition in individuals with Gorlin syndrome in the current literature. Although tarsal coalition is a common condition, this may be manifestation of Gorlin syndrome.

P02.114
Gorlin-Chaudhry-Moss syndrome: a case report

A. Cieślikowska*, M. Kugaudo, M. Krajewska-Walasek, K. Chrzanowska;*
Department of Medical Genetics, The Children's Memorial Health Institute, Warsaw, Poland.

The first description of the Gorlin-Chaudhry-Moss syndrome (GCMS) was published in 1960. Two sisters with craniosynostosis, hypertrichosis, hypoplastic labia majora, dental defects, eye anomalies, and normal intelligence were presented. Two other female unrelated cases have been documented. The inheritance is still not clear, both, autosomal recessive and X-linked dominant inheritance (lethal in males) were proposed. In 2011, Aravea et al. reported two sisters with some similarities to GCMS. However, they had neither craniosynostosis nor hearing loss, but had additional manifestations not previously depicted in GCMS: aplasia cutis, ossification defect of the skull and early mortality.
We report a two-year-old girl born to apparently unrelated parents. She fulfils the clinical criteria of GCMS with the following main clinical features: microsomia, hypertrichosis, midface hypoplasia, brachycephaly, coronal craniosynostosis, low frontal hairline, coarse hair, small ears, short and downslanting palpebral fissures and hypoplastic labia majora. Other features included loose skin, umbilical hernia, high arched palate, microdontia, somewhat hypoplastic and hyperkeratotic toe nails. Radiological evaluation showed hypoplasia of the distal phalanges of the left hand. Karyotype and metabolic screening were normal. Our patient, similarly to the patients described by Aravea et al. has not got hearing loss, the feature observed in the all first three patients with GCMS.
We would like to bring this condition to the attention of clinical geneticists. Future case reports can stimulate detailed clinical and molecular investigations into aetiology of GCMS with all implications for genetic counseling .

P02.115
Mutation-based growth charts for SEDC and other *COL2A1* related dysplasias

P. A. Terhal[1]*, P. van Dommelen*[2]*, G. Mortier*[3]*;*
[1]*Department of Biomedical Genetics, Utrecht, Netherlands,* [2]*Life Style, TNO, Leiden, Netherlands,* [3]*Department of Medical Genetics, University of Antwerp, Edegem, Belgium.*

In a large international collaborative study we have constructed a growth chart for patients with molecular confirmed congenital spondylo-epihyseal dysplasia (SEDC) and other *COL2A1* related dysplasias. The growth chart is based on longitudinal height measurements of 79 patients with glycine substitutions in the triple-helical domain of COL2A1. In addition, measurements of 27 patients with other molecular defects, such as arginine to cysteine substitutions, splice mutations and mutations in the C-terminal propeptide have been plotted on the chart. Height of the patients progressively deviate from that of normal children: compared to normal WHO charts, the mean length/height is -2.6 SD at birth, -4.2 SD at 5 years and -5.8 SD at adult age. The mean adult height (male and female combined) of patients with glycine substitutions in the triple-helical region is 138.2 cm, but there is a large variation. Patients with glycine to cysteine substitutions tend to cluster within the upper part of the chart, while patients with glycine to serine and valine substitutions are situated between +1 SD and -1 SD. Patients with carboxy-terminal glycine substitutions tend to be shorter than patients with amino-terminal substitutions, while patients with splice mutations are relatively tall. However, there are exceptions, and specific mutations can have a strong, or the reverse, a relatively mild negative effect on growth, The observation of significant difference in adult height between affected members of the same family indicates that height remains a multifactorial trait even in the presence of a mutation with a strong dominant effect.

P02.116
Severe growth retardation in an 8.5 year old boy with dup 2p16.2→p22.1

A. Frühmesser[1]*, A. Blassnig-Ezeh*[2]*, B. Simma*[2]*, B. Krabichler*[1]*, C. Fauth*[1]*, J. Zschocke*[1]*, D. Kotzot*[1]*;*
[1]*Division of Human Genetics, Innsbruck Medical University, Innsbruck, Austria,*
[2]*Department of Pediatrics, LKH Feldkirch, Academic Teaching Hospital of Innsbruck Medical University, Feldkirch, Austria.*

So far, interstitial duplications of the short arm of chromosome 2 have been reported rarely and there is no specific phenotype. Here we describe an 8.5-year-old boy with severe growth retardation (110 cm (<< P3)) associated with delayed bone age (age 3 years for wrist and 5 years for forehand at a chronological age of 8 years 3 months), moderate intellectual disability (IQ 79 tested by nonverbal intelligence test), and facial dysmorphisms including relative macrocephaly (54 cm (P75)) with a high, prominent, and broad forehead, and a large anterior fontanel. Hormone values for fT3, fT4, TSH, HGH (basic and stimulated), ACTH, Cortisol, LH and FSH were within normal ranges, whereas IgF1 and IgFBP3 were normal in the lower ranges. Cardiac ultrasound and cerebral imaging were normal. SNP-microarray analysis with the Illumina CytoChip-12v2.1 revealed a duplication of approximately 14.6 Mb carrying 63 genes, with breakpoints between rs2540240 (39,791,569 bp) and rs2540229 (39,797,559 bp) in 2p22.1 and between rs843622 (54,401,986 bp) and rs1682139 (54,410,054 bp) in 2p16.2, respectively, and a formation in maternal meiosis.
Comparison of our patient with cases from the literature and the DECIPHER database allowed the identification a region of around 4 Mb carrying 48 genes, where one or more genes relevant for growth might be located. So far, none of these genes has been associated with growth retardation.

P02.117
MTHFR 677T is a determinant of the degree of hearing loss among Polish males

A. Pollak[1]*, M. Mueller-Malesinska*[1]*, U. Lechowicz*[1]*, A. Skórka*[2]*, L. Korniszewski*[1]*, A. Sobczyk-Kopciol*[3]*, A. Waskiewicz*[4]*, G. Broda*[4]*, K. Iwanicka- Pronicka*[1]*, M. Oldak*[5]*, H. Skarzynski*[1]*, R. Ploski*[6]*;*
[1]*The Institute of Physiology and Pathology of Hearing, Warsaw, Poland,* [2]*Department of Paediatrics, Medical University of Warsaw, Poland, Warsaw, Poland,* [3]*Department of General Biology and Parasitology, Medical University of Warsaw, Poland, Warsaw, Poland,* [4]*Department of Cardiovascular Diseases Epidemiology, Prevention and Health Promotion, Institute of Cardiology, Warsaw, Poland, Warsaw, Poland,* [5]*Department of Histology and Embryology Center of Biostructure Research, Medical University of Warsaw, Poland, Warsaw, Poland,* [6]*Department of Medical Genetics, Medical University in Warsaw, Poland, Warsaw, Poland.*

Hearing impairment (HI) is the most common sensory handicap. Whereas congenital HI has often a genetic basis the etiology of nonsyndromic postlingual HI (npHI) usually remains unidentified. Our purpose was to test whether the *MTHFR* C677T (rs1801133) polymorphism affecting folate metabolism is associated with the occurrence or severity of npHI. We studied rs1801133 genotypes in 647 npHI patients (age < 40, sudden sensorinural loss excluded, HI characterized as mean of better ear hearing thresholds for 0.5-8kHz) and 3273 adult controls from background population. Genotype distribution among patients and controls was similar but among male cases (N=302) we found a dose dependent correlation of *MTHFR* 677T with degree of HI (mean thresholds in dB: 38.8, 44.9 and 53.3, for CC, CT and TT genotypes, respectively; P=0.0013, $P_{cor.}$=0.017). Among male patients rs1801133 TT significantly increased risk for severe/profound HI (OR=4.88, P=0.001). Among controls the known effect of *MTHFR* 677T on homocysteine concentration was more pronounced in men than women (P<0.00004 for genotype-sex interaction) suggesting that in Poland folate deficiency is more prevalent in males. In conclusion, we report a novel effect of *MTHFR* 677T among males with npHI. The functional significance of rs1801133 suggests these patients may benefit from that folate supplementation.

P02.118
Screening for miRNA and common mutations in deaf Brazilian patients

S. M. da Silva-Costa*, F. T. A. Martins, R. M. Alves, A. M. Castilho, E. L. Sartorato;*
UNICAMP, Campinas, Brazil.

Mutations in the genes coding for connexin 26 (*GJB2*) and connexin 30 (*GJB6*) are the main cause of autosomal recessive nonsyndromic sensorineural hearing loss (AR-NSNHL). Lately, mutations in a noncoding microRNA (miRNA) gene, miR96, a member of the miR-183 miRNA cluster that is expressed in the inner ear sensory epithelium, were linked with progressive hearing loss in humans and mice. In the present study, we screened mutations in the *GJB2* gene and two deletions in the *GJB6* gene in 566 unrelated Brazilian patients, with moderate to profound NSNHL. Besides these common mutations we included the investigation of mutations in miR-183 genes family. We have found 13 different mutations in *GJB2*. Thirty-four patients were homozygous for the most frequent mutation, 35delG. Seventeen patients were compound heterozigotes for *GJB2* gene mutations and 33 patients have been identified carrying mutation in only one *GJB2* allele. Deletions in *GJB6* gene have been found in 6 patients, four of them carried mutation in *GJB2* gene in the other allele. Screening microRNA cluster (miR-96/182/183), we have identified nine single-nucleotide polymorphisms and two novel variant sequences located outside the mature miR-96 sequence. Our findings have showed a mutation spectrum of the *GJB2* gene in Brazilian patients with nonsyndromic sensorineural hearing loss and demonstrate the high genetic heterogeneity for the deafness.

P02.119

Identification of two new alpha globin gene mutations in patients suspected of having alpha thalassemia

*M. Hamid[1,2], **G. Shariati**[3,2], A. Saberi[3,2], M. Mohammadi[2], B. Keikhai[4];*
[1]Molecular Medicine Division, Biotechnology Research Center, Pasteur Institute of Iran, Tehran, Islamic Republic of Iran, [2]Narges Medical Genetics & PND Laboratory, No. 18, East Mihan Ave, Kianpars, Ahvaz, Islamic Republic of Iran, [3]Department of Medical Genetic, Faculty of Medicine, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Islamic Republic of Iran, [4]Department of Pediatric Hematology & Oncology, Research Center of Thalassemia & Hemoglobinopathy , Ahvaz Jondishapur University of Medical Sciences Ahvaz, Iran, Ahvaz, Islamic Republic of Iran.

Alpha thalassemia disorder is a hereditary anemias caused by quantitative reduction of the alpha chain of hemoglobin, which the majority is caused by deletion in alpha globin gene cluster and, small group by point mutations. We report two novel point mutations observed in two male from south of Iran with lur ethnic origin, detected during screening for hemoglobinopathies. The patients were initially selected for their hematological indices as belonging to a group suspected for alpha thalssemia. The patients who did not reveal the most common alpha thalassemia deletions (3.7kb, Med, 4.2kb, 20.5kb) by gap-PCR, were subjected for alpha2 and alpha1 globin gene DNA sequencing. Sequence analyses identified Cd 31 A>G and Cd 99 A>T located in alpha 1 globin gene, which the Cd31 was missense and Cd 99 was nonsense mutation. Based on the red cell indices and phenotype, these mutations seem to be associated with a mild alpha-thalassemia (alpha-thal) phenotype.

P02.120

SPG 23: autosomal recessive spastic paraplegia with pigmentation anomalies: further definition in a large Algerian pedigree with pseudodominance.

***M. Hureaux**, M. Irabe, J. Piard, L. Van Maldergem, J. Bresson;*
CHU Besançon, Hôpital St Jacques, Center of Human Genetics, Besançon, France.

Autosomal recessive hereditary spastic paraplegia includes at least fifteen discrete entities differentiated by age at onset of symptoms and presence of distinctive features (pure and complicated forms). Among them, SPG23 has been characterized by presence of skin and/or scalp hypopigmentation. Three autosomal recessive pedigrees have been reported until now, while one is a sporadic case and the other doesn't exclude autosomal dominant inheritance. Hypopigmented macules or scalp hair are present, alongside to spastic paraparesia of variable age at onset. At present, only one pedigree has been subject to a linkage study indicating a locus at 1q24-32 (interval 25cM).

We present a four-generation Algerian family were the index patient, a 34 y-old female with onset of SP at the age of 18y has multiple hypopigmented macules and white forelock. Her maternal grandfather is affected as well in the context of an endogamic population. She married her first cousin and gave birth to a normal baby male with white forelock and hypopigmented macules. Four other remote cousins are affected, all of them born to consanguineous parents.

We suggest that the pedigree is compatible with either pseudo dominance or AD inheritance with incomplete penetrance. In conclusion, we confirm SPG23 as a discrete entity and give further support to an autosomal recessive mode of inheritance.

P02.121

A Microdeletion at the 7q11.23 Locus including HIP1 in a Girl with Developmental Delay, Behavioural Problems, Gait Abnormalities and Facial Dysmorphism

***F. Kießling**[1], K. Hackmann[2], C. Heine[1], S. Syrbe[3], D. Mitter[1];*
[1]Institut für Humangenetik, Universitätsklinikum Leipzig, Leipzig, Germany, [2]Institut für Klinische Genetik, TU Dresden, Dresden, Germany, [3]Klinik und Poliklinik für Gastroenterologie und Rheumatologie, Universitätsklinikum Leipzig, Leipzig, Germany.

Recurrent deletions in the proximal region 7q11.23 are common in patients with Williams-Beuren syndrome (WBS). However, only a few patients with a microdeletion including the HIP1 gene, located in the distal region of 7q11.23, have been reported. These patients show a neurodevelopmental and epilepsy syndrome. HIP1 encodes huntingtin interacting protein-1 which is normally expressed in the brain. HIP1-knockout mice develop a progressive neurologic phenotype with tremor and gait ataxia. Therefore, HIP1 haploinsufficiency has been proposed to lead to cognitive and behavioural dysfunction in these patients. We present a 4 year old girl with motor and speech delay, mild ataxia, and behavioral problems including impulsivity, aggression and mild autistic features. She showed facial dysmorphism, including a short nose with anteverted nares, downturned corners of the mouth, and a full lower lip, reminiscent of patients with WBS. Array-CGH analysis revealed an intragenic 14-23kb deletion in the distal region 7q11.23, which leads to loss of exons 5 to 8 of HIP1. The deletion detected in this patient overlaps with a recurrent distal deletion in 7q11.23 in the patients reported by Ramocki et al. (2010). Those patients had similar clinical features, including intellectual disabilities, neurobehavioral problems and in addition epilepsy. However, no information about facial dysmorphism was reported. Our patient appears to be the first with HIP1 haploinsufficiency. Further, our observation supports HIP1 to be a good candidate gene in patients with developmental delay, behavioral and gait abnormalities and the facial dysmorphism described.

P02.122

Zimmermann-Laband syndrome: a case report

***D. Gün**, N. Koçak, T. Çora, B. Kocabıyık, H. Acar;*
Selçuk University, Selçuklu Medical Faculty,The Department of Medical Genetics, Konya, Turkey.

Zimmermann-Laband syndrome (ZLS) is an extremely rare malformation syndrome. It is characterized by dysplastic or absent nails, hypoplasia of the distal phalanges, scoliosis, hirsutism, gingival fibromatosis and mental retardation. Although the genetic basis of ZLS is unknown, previous studies in cases suggested that the gene responsible for ZLS is located at chromosome 3. ZLS is believed to be inherited as an autosomal dominant inheritance. In contrast, there were evidence of autosomal recessive inheritance for ZLS. In the present report, a 15 year-old female was referred to our department due to intellectual disability. There was no relationship between the patient's parents. We performed cytogenetic analysis by using GTG-banding. The patient's karyotype was 46, XX, and no abnormality was found in any chromosome. Clinical examination show that she had thick eyebrows, bulbous soft nose, large upper lip, large floppy ears, high palate, hypoplastic nails, short distal phalanges, hypertrichosis, pektus excavatum and an operation scar on her back due to scoliosis operation. The patient was evaluated for gingival fibromatosis, were identified as minimal gingival fibromatosis. Other system examinations and laboratory investigations were normal. Patient was diagnosed as a Zimmermann-Laband syndrome. This is the first our experience for this syndrome.

P02.123

Holoprosencephaly overview at the Hospital for Rehabilitation of Craniofacial Anomalies in Bauru, Brazil

***A. L. B. da Rocha**, C. C. Legnaro, R. G. Quiezi, A. Richieri-Costa, L. D. Goes, I. Taíra, C. Bessão, L. A. Ribeiro-Bicudo;*
Hospital de Reabilitação de Anomalias Craniofaciais da Universidade de São Paulo, Bauru, Brazil.

Holoprosencephaly (HPE) is one of the most common congenital malformations in humans and it is characterized by the incomplete separation of the cerebral hemispheres into distinct right and left halves. Structural chromosomal anomalies previously compiled from chromosomal HPE predicted at least 12 different HPE loci. Point mutations in the four major genes, SHH, ZIC2, SIX3, and TGIF, were identified in 20% of our HPE patients. The Hospital for Rehabilitation of Craniofacial Anomalies in Bauru, Brazil has 248 patients registered as HPE. From this total, 137 were classified as classical HPE and 111 were classified as microform of HPE phenotype. We performed mutational analysis in the SHH, SIX3, TGIF, ZIC2, GLI2, PTCH, and GAS1 genes in 149 patients. We found 9 mutations on SHH, 7 on SIX3, 1 on TGIF, 5 on ZIC2, 5 on GLI2, 4 on PTCH, and 5 on GAS1 genes. Two patients presenting a double mutation involving SHH and GAS1 genes, and GLI2 and PTCH genes were identified. Further analysis on 20 new patients for SHH, TGIF and SIX3 genes showed a new mutation on SHH (p.Q46P) which was inherited from the mother. No specific genotype-phenotype correlation according to type or location of the mutations was observed. There were no clinical features unique to individuals with a mutation compared with those without a detected mutation. Identification of new genes related to HPE and the interaction between their products will result in a more rationale understanding of the genetic mechanisms involved. Grants: Fapesp Proc n° 2011/07012-9; 2006/60973-9

P02.124

Validation of "triplet repeat" disease detection and quantitation using micro-fluid technology based platform

***J. Ramic**, N. Lojo-Kadric, K. Radic, K. Bajrovic, L. Kapur-Pojskić;*
Institute for genetic engineering and biotechnology, Sarajevo, Bosnia and Herzegovina.

Classical molecular genetic diagnosis of Huntington disease and similar diseases caused by unstable repetitive sequences relies mainly on the Southern blotting method. Specifically in the case of Huntington disease that we used as a model, which is transmitted in an autosomal-dominant inheritance, increased number of CAG triplet repeat is a genetic cause for the redundant synthesis of the targeted product. In the normal genotype, the numbers of repetitions ranges from 6-26, and with increasing numbers of repetitions also increase the degree of disease. Development of PCR technology has evolved and the possibility of faster and more reliable diagnosis of diseases of this type. Analysis of the PCR product from conventional gel electrophoresis is generally accepted, but it is not always possible to precisely determine the exact number of CAG repetitions that characterize this disease. In the present study we compared the process of PCR-based analysis using micro-fluid technology based platform (Agilent 2100 bioanalyzer, Agilent Technologies, USA) potentially produce more accurate data on qualitative and quantitative aspect of the mutation.

P02.125

Ischemic stroke in a case with moderate hyperhomocysteinemia

***M. Cevei**[1], D. Stoicanescu[2];*
[1]University of Oradea, Faculty of Medicine&Pharmacy, Oradea, Romania, [2]University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania.

Increased concentration of homocysteine is a risk factor for stroke, peripheral vascular disease, myocardial infarction, and venous thromboembolism. It seems that hyperhomocysteinemia affects not only the blood coagulation system, but also the vascular wall structure. MTHFR gene encodes a co-substrate for homocysteine remethylation to methionine, but it is also involved in transsulfuration to cystathionine. We present the case of a 42 years old man hospitalized for treatment and functional rehabilitation in Medical Rehabilitation Clinical Hospital Baile Felix, Romania, after ischemic stroke. The patient with unremarkable anamnesis, negative family history, no known diagnosis of homocystinuria developed an acute cerebrovascular ischemic accident. MRI described an ischemic vascular lesion of the left cerebellar hemisphere with edema, herniation phenomena through foramen magnum and supratentorial and amputation of the fourth ventricle. Ultrasonography of the heart and precerebral arteries revealed normal aspects The most significant laboratory finding was moderate hyperhomocysteinemia. Molecular analysis revealed the presence of a heterozygous MTHFR C677T mutation and the absence of A1298C mutation. After drug therapy, he was admitted in our clinic at about one month after the vascular accident, having only coordination problems. Rehabilitation treatment was complex and involved coordination of several team members, with the following main objectives: coordination and balance in physical activities, through stimulation exercises specific for occupational therapy and kinetotherapy. He showed significant improvement after three weeks of intensive treatment. Prompt response to the rehabilitation programme in this case is another argument for early, individualized treatment, which continues at home, over a long period of time.

P02.126

Phenotype-genotype correlation in patients with mutations in the beta-myosin converter domain

*D. A. Garcia-Giustiniani[1], X. Fernández[1], M. Ortiz-Genga[1], R. Barriales-Villa[1], A. Mazzanti[1], **M. I. Rodríguez-García**[1,2], L. Cazón[1], M. Perez-Barbeito[1], E. Maneiro[1], L. Monserrat-Iglesias[1,2];*
[1]INIBIC, A Coruña, Spain, [2]CHUAC, A Coruña, Spain.

Purpose: Evaluate the genotype-phenotype correlation of mutations located in the beta-myosin converter-domain (aminoacids 709-777). This region is responsible for the elastic distortion of the protein which allows strain to develop within the motor before the cargo is actually moved.
Methods: Identification of mutations in the converter domain of MYH7 was performed in a cohort of more than 800 cases diagnosed either with Hypertrophic (HCM) or Dilated Cardiomyopathy (HCM), followed-up in a single reference unit. We also reviewed the published data about mutations located within this domain.
Results: 6 mutations (G716R, G741R, G768R, I730N [novel mutation], I736T and R719Q) were identified in 11 families (59 relatives-30 carriers). Taking in account our data and data from literature, a total of 21 pathogenic mutations have been identified within this domain. They were distributed in 143 families (470 relatives). 424 relatives were affected or possibly affected (11 with DCM and the rest with HCM) and 382 were mutation carriers. We observed an early onset of disease (27±18 years, 56% males). Thirteen of 21 mutations were associated with a severe adverse event affecting at least one member in 52/143 families: sudden death occurred in 96 patients and at least 56% were younger than 45 years old, heart failure death in 35, cardiac transplantation in 18 and fatal stroke in 6.
Conclusion: Mutations located within the beta-myosin converter domain presented an early onset of disease. A significant proportion of mutations were associated with the occurrence of a serious adverse event and left ventricular dysfunction.

P02.127

Epidemiological and genetic assessment of hypospadias

***D. Stoicanescu**[1], M. Stoian[1], A. Belengeanu[1], M. Cevei[2];*
[1]University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania, [2]University of Oradea, Faculty of Medicine & Pharmacy, Oradea, Romania.

Hypospadias is one of the most common birth defects. In several countries, the incidence appears to be increasing, possibly due to increased reporting of minor degrees of hypospadias, but severe cases were also reported. Some reports have linked its high rate to prematurity and low birth-weight. The etiology is still unknown in many cases, pedigree analyses indicating a heterogeneous pattern of inheritance. A genetic predisposition has been suggested. The aim of this study was to perform an epidemiological study focused on this type of pathology, in newborns from Timisoara, Romania, for a period of three years, between 2008 and 2010 and to highlight the etiological aspects of hypospadias. Methods: data selection, family history, clinical, laboratory, cytogenetic and molecular study. Major and minor congenital defects present in examined patients were recorded. The determined incidence was 0.36% of male newborns. Glanular and distal penile locations prevailed. At birth, mean values were 2982 g weight and 46 cm for height. Frequently associated anomalies were genital, skeletal, nervous system and different minor anomalies. A brotherhood with hypospadias was noted. 8.3% of mothers had previous miscarriages or malformed births. Cytogenetic investigation revealed trisomy 21 in one case. A patient had disorder of sexual development. Environmental exposure to diluents was documented in another case. Identifying patients with a genetic susceptibility and further studies regarding gene and environment interactions will play an important role in preventing the occurrence of the defect.

P02.128

Molecular analysis is essential in the hypotonic infant approach detecting high incidence of Genetic diseases

***G. Queipo**[1], J. Perez[1], L. Gonzalez[1], E. Barragan[2], N. Najera[1], N. Garibay[3];*
[1]Hospital General de México-Facultad de Medicina UNAM, México DF, Mexico, [2]Hospital Infantil de Mexico Federico Gomez, México DF, Mexico, [3]Hospital General de México, México DF, Mexico.

Neonatal central hypotonia is the lack of spontaneous movement, with or without muscular weakness, and generalized hypotonia during the neonatal period. This condition can be caused by a number of different pathological processes in the brain or defects to any structure in the motor unit. Central hypotonia affects the central nervous system, including the spine, and among its most frequent causes is systemic illness. As part of the central approach to the hypotonic baby, it is important to eliminate syndromic and genetic causes. Some reports have been proposed that 40% of the central hypotonic neonates had Prader Willi the most common genetic cause of obesity however, in children under 2 years of age the diagnosis is especially difficult. It is clear that early diagnosis of PWS o any other genetic entity is crucial to avoid complications and decrease morbidity and life expectancy. Nevertheless, other genetic syndromes have central hypotonia as main clinical manifestation during infancy. So, genetic approach is mandatory during the initial clinical intervention. We present the genetic approach in 30 consecutive pediatric patients with central hypotonia as a major symptom, referred by the neuro-pediatrician. According with the clinical genetic evaluation and presumptive clinical diagnosis, molecular analysis was performed detecting that 70% of the cases had a genetic disorder. We conclude that genetic evaluation is crucial in the central hypotonic clinical approach, proposing that all the central idiopathic hypotonic babies should be evaluated by a clinical genetic professional.

P02.129

Incidence of Beckwith-Wiedemann syndrome

C. Molinatto[1], *A. Mussa*[1], *A. De Crescenzo*[2], *N. Chiesa*[1], *G. Baldassarre*[1], *A. Selicorni*[3], *S. Russo*[4], *A. Riccio*[2], *M. Silengo*[1], *G. B. Ferrero*[1];

[1]Department of Pediatrics, University of Turin, Turin, Italy, [2]Genetics and Biophysics Institute, A. Buzzati-Traverso, CNR, Naples, Italy, [3]Pediatric Clinical Genetics, Department of Pediatrics, University of Milano Bicocca, S. Gerardo Hospital MBBM Foundation, Monza, Italy, [4]Laboratory of Cytogenetics and Molecular Genetics, Istituto Auxologico Italiano, Milan, Italy.

Background - Beckwith-Wiedemann syndrome (BWS) is the most common genetic overgrowth disorder, with an incidence ranging 1:13,000-15,000 live births. However, as data on its epidemiology are scanty and estimates show wide variability, there is a feeling that BWS could be more common than previously thought. **Objective -** We assessed its incidence in Piedmont, Italy (4,432,571 population) locating BWS cases born in this region. **Methods -** Patient were searched through local genetic counselling services, BWS Italian Association, malformation registries and rare diseases network. Data from the Italian National Institute for Statistics was used for live births assessment. BWS diagnosis was clinical according to Wecksberg's criteria and molecular testing was performed according to currently employed diagnostic flow-chart. **Results -** 45 clear-cut BWS cases (26 females, 19 males) were born across a 13-year period (1996-2009), providing an incidence of 1:10,569 live birth. Fourty patients accepted molecular testing: 72.5% turned positive showing imprinting center 2 (IC2) hypomethylation (30.0%), paternal chromosome 11p15 uniparental disomy (UPD, 25.0%), IC1 hypermethylation (15.0%), CDKN1c mutation (2.5%), whereas 27.5% turned negative. Mean age at diagnosis was 0.49±1.07 years, with 34 patients diagnosed in the first semester of life, providing a birth prevalence of 1:13,989. Four patients of the cohort developed Wilms' tumor (8.9%) and 2 hepatoblastoma (4.4%) during the observation period, resulting in a 14.2%cancer risk. **Conclusion -** We observed a BWS incidence of 1:10,569 live birth in Piedmont. This estimate results higher than previous figures, and represent the first attempt to correlate epidemiologic and molecular data in BWS.

VATER/VACTERL association refers to the non-random co-occurrence of the following component features: vertebral defects, anal atresia, cardiac malformations, tracheo-esophageal fistula, renal abnormalities, and limb defects. Recent observations suggest that in some patients, the disorder may be inherited. The aim of the present study was to replicate these findings by investigating 116 VATER/VACTERL patients and their relatives. The prevalence of anal atresia (OR 41.7, 95% CI 15.5-112.2) and limb anomalies (OR 6.4, 95% CI 1.6-25.7) was significantly higher among first-degree relatives compared to the general population. This confirms other observations of an increased prevalence of component features among relatives. The fact that the two studies report a higher prevalence for differing specific component features might be explained by the differing malformation spectra of the respective index patients. Conclusion: the present study provides independent support for the hypothesis that some cases of VATER/VACTERL have a genetic basis.

A novel *INPP5E* mutation in a patient with Joubert syndrome

G. Uyanik[1], *M. Güzünler*[2], *F. Sönmez*[3], *D. Yilmaz*[3], *I. Vater*[4], *G. Cömertpay*[1,5], *M. Heise*[1], *S. Cirak*[6], *Y. Hellenbroich*[7];

[1]Institute of Human Genetics, University Medical Center, Hamburg, Germany, [2]Department of Pediatrics, Gördes Hospital, Manisa, Turkey, [3]Division of Pediatric Neprology, Department of Pediatrics, Adnan Menderes University, Aydin, Turkey, [4]Department of Human Genetics, University Hospital Schleswig-Holstein, Campus, Kiel, Germany, [5]Department of Medical Biology and Genetics, Çukurova University, Adana, Turkey, [6]UCL Institute of Child Health, Great Ormond Street Hospital, London, United Kingdom, [7]) Institute of Human Genetics, University Hospital of Schleswig-Holstein, Campus Lübeck / University of Lübeck, Lübeck, Germany.

Joubert syndrome (JS) is an autosomal recessive condition characterized by ataxia, muscular hypotonia, developmental delay, irregular breathing pattern and eye movement abnormalities. The MRI shows cerebellar vermis hypoplasia with accompanying brainstem malformations resulting in the characteristic "molar tooth sign". JS can also be associated with additional features including retinal dystrophy, ocular colobomas, cystic renal disease, nephronophtisis, hepatic fibrosis and polydactyly summerized as JS-related disorders (JRDS).

JS and JSRD are genetically and clinically heterogeneous disorders, so far 16 different causitive genes have been identified in JSRD. Here, we present a 5 years old Turkish girl with JS. The parents were first degree cousins and the patient was on chronic peritoneal dialysis program since the age of 15 months. We decided first to perform a homozygosity mapping by SNP-Array (6.0 Affymetrix) analysis, which showed "loss-of-heterozygosity" for the JBTS1 locus on chromosome 9q34.3. The analysis of the *INPP5E* gene revealed a homozygeous mutation (c.1303C>G; p.R435G) within exon 6, affecting a highly conserved amino acid within the inositol polyphosphate phosphatase catalytic domain of INPP5E. The genetic and clinical data will be presented and compared to the published cases.

Autosomal recessive syndrome characterized by Hypertelorism - Intellectual Disability - Microcephaly - Short stature: clinical delineation and identification of two possible candidate loci

M. Feingold[1], *A. Har Zahav*[2], *K. Neveling*[3], *C. Gilissen*[3], *M. Kwint*[3], *S. Gijsen*[3], *J. Veltman*[3], *H. Brunner*[3], *M. Shohat*[1,4,5], *L. Basel-Vanagaite*[1,4,5];

[1]Pediatric Genetics, Schneider Children's Medical Center of Israel, and Raphael Recanati Genetic Institute, Petah Tikva, Israel, [2]Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, Tel Aviv, Israel, [3]Department of Human Genetics, Nijmegen Center for Molecular Life Sciences and Institute for Genetic and Metabolic Disorders, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands, [4]Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, [5]Felsenstein Medical Research Center, Tel Aviv University, Rabin Medical Center, Beilinson Campus, Petah Tikva, Israel.

Autosomal recessive intellectual disability (ID) is particularly prevalent in consanguineous populations. Numerous genes associated with ID have been identified, and for several genes, mutations can result in both syndromic and non-syndromic ID. We describe a consanguineous family with three boys and one girl affected with a hitherto undescribed autosomal recessive syndromic form of ID characterized by, in addition to ID, hypertelorism, broad nasal bridge with a broad and bifid nasal tip, and microcephaly ranging from -4 SD to -2 SD. One patient has multiple milia and another was diagnosed with keratosis pilaris. Three of the patients have short stature. Neurological examination of all the affected individuals was normal; none of them had seizures. Brain MRI studies showed normal results. We were not able to find any reports of this combination of clinical features in the scientific literature.

Consanguinity increases the coefficient of inbreeding, which in turn increases the likelihood of the presence of pathogenic mutations in a homoallelic state. Homozygosity mapping provides a rapid means of mapping autosomal recessive genes in consanguineous families through identification of „homozygous blocks" suspected of harboring the causative mutated genes. We performed homozygosity mapping using SNP array in four affected family members and identified two candidate loci, one on chromosome 6p12.1-q12.2 and one on chromosome 9p23-p24, possibly containing a homozygous mutation responsible for this family's unique phenotype. None of the genes mapping to these two candidate regions are known to cause a similar syndromic form of ID.

P02.133

A partial de novo deletion of GLRB and GRIA2 in an individual with intellectual disability

K. Hackmann[1], *S. Matko*[1], *E. Gerlach*[1], *M. von der Hagen*[2], *B. Klink*[1], *E. Schrock*[1], *A. Rump*[1], *N. Di Donato*[1];

[1]Institut für Klinische Genetik, Medizinische Fakultät Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany, [2]Abteilung Neuropädiatrie, Klinik und Poliklinik

für Kinder- und Jugendmedizin, Technische Universität Dresden, Dresden, Germany.

Molecular karyotyping revealed a deletion of 102-111 kb in an individual with intellectual disability. This finding was validated as a de novo event by FISH. The aberration partially affects GLRB and GRIA2. Both genes are highly expressed in brain tissues. GLRB encodes the beta subunit of the inhibitory glycine receptor. It has been associated with autosomal re-cessive hyperekplexia. No symptoms of this disorder were found in this case. GRIA2 encodes the GluR2 subunit of a glutamate receptor. Other subunits of glutamate receptors have been associated with intellectual disability. Sequencing did not detect any further mutation in ei-ther of the two genes. Analyses of reversely transcribed RNA from blood revealed the exist-ence of GLRB/GRIA2 fusion transcripts. We were not able to find a fragment that carried an open reading frame across the fusion site. Nonetheless, open reading frames could be restored by different alternative splice events that might occur in neuronal structures. We speculate that either haploinsufficiency of GRIA2 or a GLRB/GRIA2 fusion gene was causing the disorder.

P02.134

Haploinsufficiency of *SOX5*, a member of the SOX (SRY-related HMG-box) family of transcription factors is a cause of intellectual disability

I. Schanze[1], *D. Schanze*[1], *C. A. Bacino*[2], *S. Douzgou*[3], *B. Kerr*[3], *M. Zenker*[1];
[1]Institute of Human Genetics, University Hospital Magdeburg, Magdeburg, Germany, [2]Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, United States, [3]Genetic Medicine, Manchester Academic Health Science Centre, University of Manchester, Manchester, United Kingdom.

Intellectual disability (ID) is a clinically and genetically heterogeneous condition; the cause is unknown in most non-specific and sporadic cases. To establish an etiological basis in those patients represents a difficult challenge. Over the last years it has become apparent, that chromosomal rearrangements below the detection level of conventional karyotyping contribute significantly to the cause of ID.

We present three patients with non-specific intellectual disability who all have a microdeletion in the chromosomal region 12p12.1. In two patients these deletions occurred de novo. All three identified deletions have different breakpoints and range in size from 120 kb to 4.9 Mb. The smallest deletion helps to delineate the critical region to a genomic segment (chr12:23924800-24041698, hg19) encompassing only one gene, *SOX5*. *SOX5* is a member of the SOX (SRY-related HMG-box) family of transcription factors shown to play roles in chondroblast function, oligodendrocyte differentiation and migration as well as ensuring proper development of specific neuronal cell types. Because of these biological functions, mutations in *SOX5* were predicted to cause complex disease syndromes, as is the case for several *SOX* genes, but no such mutations have yet been identified. Our findings indicate that haploinsufficiency of *SOX5* is a cause of intellectual disability. To verify this presumption we are performing mutational analysis in a cohort of patients with non-specific and unexplained ID.

P02.135

Analysis of ring finger proteins RNF133 and RNF148 in Intellectual disability

E. Bonora[1], *A. Wischmeijer*[1,2], *F. Minopoli*[1], *C. Tabarroni*[1], *M. Vidone*[1], *M. Seri*[1], *C. Graziano*[1], *G. Romeo*[1];
[1]Unit of Medical Genetics, University of Bologna, BOLOGNA, Italy, [2]Unit of Clinical Genetics, IRCCS Arcispedale S. Maria Nuova, Reggio Emilia, Italy.

Intellectual disability (ID), also referred to as cognitive impairment or mental retardation, is characterized by a substantial below-average score on tests of mental ability or intelligence, and limitations in functions related to areas of daily life. Intellectual disability can range from mild to profound and can be associated with other clinical findings or can occur as an isolated trait, with an extensive genetic and phenotypic heterogeneity. Taken together, syndromic and non-syndromic forms of intellectual disability affect 1-3% of the population. More than a hundred genes have been associated so far to ID, and they mainly have roles in brain development, synaptic plasticity and function. The ubiquitin proteasome system plays a fundamental role in maintaining the correct balance of protein levels inside cells and any disruption to this system is likely to have severe consequences, as shown for Angelman Syndrome. Several types of ubiquitin ligase have been identified, the largest group being those proteins containing a ‚RING' motif. We analyzed two of these, RNF133 and RNF148, in a cohort of 36 ID patients selected from the CHERISH consortium and negative at the array-CGH analysis. A novel missense change was identified in one patient in RNF148 and was of maternal origin. The unaffected brother does not carry the variant. We therefore performed an expression analysis of the gene and could prove that the mother expresses only the wild type form in blood. Expression analysis in the patient and in different tissues will be reported.Supported by FP7 grant CHERISH (www.cherishproject.eu).

P02.136

Mutations in the intraflagellar transport component IFT144 cause a broad spectrum of ciliopathies extending Jeune and Sensenbrenner syndrome

H. Fehrenbach[1], *V. Frank*[2], *U. Walden*[3], *T. Hampel*[1], *K. Amann*[4], *K. Häffner*[5], *H. J. Bolz*[2], *M. Pohl*[5], *C. Bergmann*[2];
[1]Department of Pediatrics, Children´s Hospital Memmingen, Memmingen, Germany, [2]Bioscientia Center for Human Genetics, Ingelheim, Germany, [3]Department of Pediatrics, Children´s Hospital Augsburg, Augsburg, Germany, [4]Department of Pathology, University of Erlangen-Nürnberg, Erlangen, Germany, [5]Department of Pediatrics and Adolescent Medicine, University Hospital Freiburg, Freiburg, Germany.

Intraflagellar transport (IFT) along the microtubule core organizes the cargo of proteins into and out of the cilium and is needed for its formation, maintenance and function. An emerging number of diseases is related to the dysfunction of cilia, collectively termed ciliopathies. We describe an 8-year-old girl with a complex phenotype that does not fit properly to any known syndrome. Hypotonia, facial dysmorphism and retardation were noted shortly after birth. Other features include short stature, skeletal anomalies, strabism, deafness, subdural hygroma, hepatosplenomegaly, and end-stage renal failure due to focal-segmental glomerulosclerosis. Ten weeks after kidney transplantation, life-threatening acute respiratory distress due to an E. coli sepsis recently made extracorporeal membrane oxygenation necessary. After array-CGH had revealed no pathogenicity, we used our next-generation sequencing (NGS) "ciliopathy panel" which encompassed at that time 131 cilia-related disease and candidate genes targeting 2335 exons and 644 kb of sequence. By this, we identified the homozygous mutation c.1483G>C (p.Gly495Arg) in *WDR19* encoding the intraflagellar transport protein IFT144. This mutation affects an evolutionarily highly conserved residue, is absent from databases, and predicted by different bioinformatic sources to be pathogenic. Our patient emphasizes the usefulness and efficiency of this NGS panel approach and adds to the recent description of three families with *WDR19* mutations and nephronophthisis, Jeune and Sensenbrenner syndrome suggesting that *WDR19* mutations can cause a broad spectrum of ciliopathies.

P02.137

Hematologic anomalies in a rare case of Jacobsen syndrome

C. M. Jurca[1,2], *C. Skrypnyk*[1], *K. Kozma*[1], *A. Jurca*[1], *C. Cladovan*[1,2], *M. Bembea*[1,2];
[1]Faculty of Medicine and Pharmacy, Oradea, Romania, [2]Municipal Clinical Hospital, Oradea, Romania.

BACKGROUND: Jacobsen syndrome is a contiguous gene syndrome caused by partial deletion of the long arm of chromosome 11. It is a rare syndrome, first described in 1973 by Jacobsen, reported so far about 200 cases. The incidence is about 1/100000 newborns. The key features of the syndrome are pre- and post-natal growth failure, mental retardation, facial dysmorphism, thrombocytopenia. CASE PRESENTATION: The patient, now a 19 year-old female, has been followed at the Oradea Genetics Department since the age of 3 months. Phenotypically she shows severe mental retardation, characteristic cranio-facial dysmorphism suggesting Jacobsen syndrome (trigonocephaly, hypertelorism, coloboma, down-slanting palpebral fissures, epicanthic folds, small nose, depressed nasal bridge, small, lowset ears, large mouth). Hematological (pancytopenia) and immunological (IgM deficiency) anomalies were absent in infancy, but become apparent at puberty. Karyotype: 46, XX del (11) (q23.3-qter). DISCUSSION: Authors discuss the hematological and immunological abnormalities of the presented case, in terms of delayed onset of these symptoms and problems raised for differential diagnosis. CONCLUSION: This rare case of Jacobsen syndrome shows hematological and immunological features that can be useful both for practice and for better understanding of genotype-phenotype relationships.

P02.138

A 1 Mb deletion within the Jacobsen-Syndrome critical region causes moderate mental retardation in a boy

I. M. Bader[1], *I. Prassl*[1], *M. Marton*[1], *H. Suess-Burghart*[1], *C. Nevinny-Stickel-Hinzpeter*[2], *M. Cohen*[1], *J. Pricelius*[2], *B. Becker*[2];
[1]Kinderzentrum München, Munich, Germany, [2]synlab, Munich, Germany.

Jacobsen syndrome is a contiguous gene disorder caused by partial deletion of the long arm of chromosome 11. It is characterized by developmental delay /mental retardation, physical growth retardation, facial dysmorphism, visceral malformations and thrombocytopenia. Candidate genes for mental retardation in this region include *SNX19, THYN1, OPCML, NCAPD3* and *NTM*. Here we report a boy with moderate mental retardation, behavioral problems and slightly dysmorphic features but without physical growth retardation, with normal platelet count and no further obvious malformation.

Molecular karyotyping (4x180A, Agilent) was performed on the patient sho-

wing an approximately 1Mb loss of genomic material in 11q25 encompassing only the two genes *NTM* and *OPCML*.
Our findings support the hypothesis that *OPCML* and/or *NTM* are candidate genes for mental retardation.

P02.139
Joubert syndrome: clinical variability in a family

M. Puiu, *S. Dumitriu, C. Haivas, A. Chirita-Emandi;*
University of Medicine &Pharmacy, Timisoara, Romania.

Joubert syndrome is a rare genetic disorder characterized by the underdevelopment or even the absence of vermis cerebelli and a brain malformation (molar sign). Most common manifestations are ataxia, hyperpnea, slep apnea, ocular anomalies, hipotonia.
Presentation: Non-consanguine couple with 6 children of whom 4 with typical manifestations of Joubert syndrome.
Results: Family history reveals one child that died 1 day after birth and one spontaneous abortion at months 2-3 of pregnancy. The affected children have different severity forms of disease in terms of motor coordination, ocular troubles, intellectual impairment, and respiratory problems. Mother presents with retinitis pigmentosa with no other symptoms. Laboratory testing and interdisciplinary consultations are used to staging the disease. MRI done on all brothers reveals the specific form of cerebellum (molar tooth sign). Genetic testing that we had available did not show abnormalities.
Conclusions: The syndrome is managed differently in the four children. Genetic counseling is challenging because of the variable clinical picture as well as the different progression and prognosis of the disease. The children benefited from the adequate and empathic genetic counseling together with psychological counseling of the family who better supported them and differentially addressed their problems.

P02.140
Kabuki syndrome - clinical and genetic study of four new cases

C. Rusu[1], *M. Volosciuc*[2], *E. Braha*[1], *M. Panzaru*[1], *C. Iordache*[1], *R. Russu*[2], *C. Schrander Stumpel*[3];
[1]*University of Medicine and Pharmacy, Iasi, Romania,* [2]*Children's Hospital, Iasi, Romania,* [3]*Academic Hospital Maastricht, Maastricht, Netherlands.*

Kabuki syndrome (KS, Kabuki makeup syndrome, Niikawa-Kuroki syndrome) is an autosomal dominant disorder characterized by distinctive facial features (long palpebral fissures, eversion of the lower lateral eyelid, arched/interrupted eyebrows, depressed nasal tip, abnormal teeth and large/prominent ears), fetal pads, intellectual disability and postnatal growth deficiency. Cardiac, renal and skeletal defects are sometimes associated. Most cases are sporadic, but a few familial cases have been reported, suggesting an autosomal dominant inheritance with variable expressivity.
We present 4 cases with KS in order to show some particularities that could be included in the feature list of the syndrome. Cardiac and renal defects seem more common, whereas skeletal defects have been identified less frequently. Soft skin and moderate/severe intellectual disability seem to be common features. All our cases are males and in 2 of them the mother presented a mild phenotype.
Case 1: postnatal growth retardation, typical face, soft skin, fetal pads, severe vesico-ureteral reflux leading to chronic renal failure, moderate/severe intellectual disability; the mother has typical face and fetal pads;
Case 2: normal growth, typical face, soft skin, fetal pads, heart defect, unilateral renal agenesis, nephrocalcinosis, moderate intellectual disability;
Case 3: normal growth, situs inversus, typical face, fetal pads, cardiac and renal defect, severe intellectual disability with behavioral disturbance;
Case 4: postnatal growth retardation, typical face, soft skin, fetal pads, cardiac and renal defect, gynecomastia, moderate/severe intellectual disability; the mother has typical face and fetal pads.
In conclusion, we present 4 cases with KS to illustrate particular features and to discuss management.

Kabuki syndrome (KS) is a rare syndrome with multiple congenital abnormalities and intellectual disabilities. The most specific feature is a characteristic face. Numerous patients with MLL2 mutations and rare of KDM6A have been reported. Kidney and urologic abnormalities occur in 12 to 43% of KS patients. Kidney function in KS has not been studied. Only 3 cases of terminal renal insufficiency are reported.
Taking advantage of a French cohort including 95 genotyped KS patients, renal ultrasounds and serum creatinine were collected. Renal function was evaluated by estimated glomerular filtration rate. A special attention was given to severe cases and a genotype-phenotype study was conducted for kidney malformation.
Kidney malformations were present in 24% of cases and urinary tract abnormalities in 17%. Renal function was normal except for the two patients with severe renal disease. Patient DIJ002 presented with renal agenesis and controlateral severe hypoplasia. Severe renal insufficiency was diagnosed in the first days of life and progressed to terminal stage at 2 years of age. A MLL2 mutation was found (c.9829C>T, p.Gln3277X). Patient NCK013 presented with tubulointerstitial nephritis during childhood, leading to terminal renal insufficiency at 27 years of age, and no MLL2 or KDM6A mutations or deletions were found.
Kidney malformations were observed in 27% of MLL2 mutation-positive group and 5% of MLL2 mutation-negative group. No correlation was found between renal malformation and the location or type of MLL2 mutation.
Our study emphasizes the need for renal function and ultrasound screening when KS is diagnosed.

P02.142
Investigating KBG Syndrome: Partial deletion of *ANKRD11* results in the KBG phenotype distinct from the 16q24.3 microdeletion syndrome

M. Khalifa, *J. Stein;*
Genetics Department, Akron Children's Hospital, Akron, OH, United States.

KBG syndrome (OMIM 148050) is a very rare genetic disorder characterized by macrodontia, distinctive craniofacial abnormalities, short stature, skeletal and neurologic involvement, and intellectual disability. Approximately 60 cases have been reported since it was first described in 1975. Recently mutations in *ANKRD11* have been documented in patients with KBG syndrome, and it has been proposed that haploinsufficiency of *ANKRD11* is the cause of this syndrome. In addition, copy number variation in the 16q24.3 region that includes *ANKRD11* results in a variable phenotype that overlaps with KBG syndrome that also includes autism spectrum disorders and other dysmorphic facial features. In this report we present a 2 ½ year old African American male with features highly suggestive of KBG syndrome. Genomic microarray identified a 154 kb deletion within *ANKRD11*. The deletion does not involve other nearby genes. This child's mother was mosaic for the same deletion (present in approximately 50% of cells) and exhibited a milder phenotype including macrodontia, short stature and brachydactyly. This family provides additional evidence that *ANKRD11* causes KBG syndrome and the phenotype seems to be dose dependent, differentiating it from the more variable 16q24.3 microdeletion syndrome. This family has additional features that could expand the phenotype of KBG syndrome.

P02.143
Detection of large-scale mtDNA deletions by next-generation-sequencing (NGS) in patients with Kearns-Sayre Syndrome (KSS)

H. Gabriel, *M. Gencik;*
Diagenos, Osnabrück, Germany.

Kearns-Sayre syndrome (KSS) is a severe early-onset multisystemic mitochondrial syndrome. Prominent features include progressive external ophthalmoplegia, retinophathy, encephalopathy, proximal muscle weakness, cardiac arrhythmia and ataxia.

In most affected patients heteroplamic large-scale mtDNA deletions can be found. The percentage of mutated mtDNA varies between patients and from tissue to tissue within the same individual. A high proportion of mtDNA deletions are found consistenly in the most affected tissues (e.g. central nervous system, muscles), whereas very low or undetectable amounts are found in unaffected tissues (e.g. peripheral blood).

Due to the low amount of deleted mtDNA in peripheral blood confirmation of KSS by deletion specific PCR or Southern Blot from blood samples is not possible in most cases. In cases in which a mtDNA deletion is confined to affected tissues (e.g. skeletal muscle), the molecular diagnosis of KSS requires genetic analysis of DNA form muscle biopsy.

To overcome this limitation, we have established a next-generation-sequencing protocol on the Roche 454J platform, which allows the detection of very low amount of deleted mtDNA from peripheral blood samples. With this approach we are able to test for the three most common mtDNA deletions found in approx. 80% of KSS patients.

We could show that this new approach is able to characterize mtDNA deletions in patients with KSS from peripheral blood samples with a very high sensitivity. It allows clincial testing for KSS without muscle biopies.

P02.144

Neurocognitive phenotype and personality profile in men with Klinefelter syndrome and their vulnerability to psychiatric symptoms

A. S. Jensen[1], *A. D. Petersen*[2], *A. Bojesen*[3], *J. Hertz*[4], *M. Wallentin*[5], *J. R. Østergaard*[6], *C. H. Gravholt*[1];
[1]*Department of Endocrinology and Internal Medicine, Aarhus University Hospital,, Aarhus, Denmark,* [2]*Hammel Neurocenter, Aarhus University Hospital, Hammel, Denmark,* [3]*Department of Clinical Genetics, Vejle Hospital, Sygehus Lillebaelt, Vejle, Denmark,* [4]*Department of Clinical Genetics, Odense University Hospital, Odense, Denmark,* [5]*Center of Functionally Integrative Neuroscience, Aarhus University Hospital, Aarhus, Denmark,* [6]*Center for Rare Diseases, Department of Pediatrics, Aarhus University Hospital, Aarhus, Denmark.*

Klinefelter syndrome (KS) is associated with increased risk of psychiatric disease and behavioral problems. The background for these risks is not known.

The aim was to describe the cognitive function, personality traits and the vulnerability to psychiatric symptoms in patients with KS.

41 KS patients and 41 age- and educational-matched control subjects participated in the study. All participants were tested with standardized neuropsychological tests and 4 questionnaires investigating psychological problems.

KS patients scored significantly lower in processing speed, working memory, verbal abilities and showed a selective deficit in executive function compared to control subjects, whereas visual cognitive abilities and cognitive response inhibition was preserved. The KS patients displayed significantly higher levels of cognitive failures, emotional distress and autism traits as reported in questionnaires. Furthermore symptoms of anxiety were also significantly higher among KS patients, whereas there were no difference in depressive symptoms between KS patients and control subjects. On the NEO PI-R personality test KS patients scored high on the neuroticism scale, low on the extraversion scale and low on the conscientiousness scale.

Men with KS have deficits in several cognitive domains and have an altered personality phenotype. Furthermore our results suggest that KS patient may be associated with an increased genetic vulnerability to psychiatric symptoms. In future analyses, we are going to assess the neuroanatomical, neurofunctional, endocrine and genetic basis for the cognitive deficits, altered personality phenotype and increased psychiatric symptoms seen in KS patients. Whether testosterone therapy or other interventions can alleviate these deficits remain to be proven.

P02.145

L1 Syndrome diagnosed in a family with a manifesting female carrier with hydrocephalus and a fetus with agenesis of the corpus callousm.

R. Sukenik-Halevy[1], *A. Reches*[1], *Y. Kaplan*[1], *S. Ben-Shachar*[1], *A. Orr-Ortreger*[1,2], *Y. Yaron*[1,2];
[1]*Genetic Institute, Tel Aviv, Israel,* [2]*Sackler Faculty of Medicine, Tel-Aviv University, Tel Aviv, Israel.*

L1 syndrome is consistent with a variable clinical phenotype, including hydrocephalus, MASA syndrome, hereditary spastic paraplegia, and corpus callosum agenesis. Mutations in the L1CAM gene located on the X chromosome cause the full syndrome in males while females may manifest minor features such as adducted thumbs and/or subnormal intelligence. We present here a family with an unusual presentation of the L1 syndrome.

The couple was referred to genetic consultation after a pregnancy which was terminated due to a diagnosis of agenesis of the corpus callosum in a male fetus. Medical history revealed that the mother was diagnosed with hydrocephalus at 22 years that necessitated a surgical insertion of a shunt. No other family members had symptoms consistent with L1 syndrome**.** Sequencing of the L1CAM gene revealed that the mother was a carrier of a missense mutation: c.791G>A which is known to be causative for L1 syndrome. The mutation was also identified in the fetal DNA and in an asymptomatic maternal sister. The couple chose to proceed with preimplantation genetic diagnosis.

Conclusions: L1 syndrome can be associated with atypical presentations. A high level of clinical suspicion and active work-up is warranted in some cases.

P02.146

Occipital band heterotopia in an infant with partial merosin deficiency due to novel LAMA2 mutations

S. Goobie[1,2], *M. Alturkustani*[1,2], *L. C. Ang*[1,2], *P. Ainsworth*[1,2], *K. Y. Tay*[1,2], *C. Campbell*[1,2];
[1]*London Health Sciences Centre, London, ON, Canada,* [2]*Western University, London, ON, Canada.*

Laminin α2 (merosin) deficiency (MDC1A) is the most common congenital muscular dystrophy in Western countries. Typically patients are hypotonic at birth, with muscle weakness and joint contractures. Many will sit independently, but less than 10% will walk. Lifespan can be shortened due respiratory compromise. Most children with MDC1A will have characteristic cerebral white matter hypodensities detected by MRI after 6 months of age. Neuronal migration defects (cortical dysplasia, polymicrogyria) are rare, occurring in approximately 4% of merosin deficient muscular dystrophies[1].

We report a case of a 1 year old boy with congenital hypotonia and an elevated creatine kinase level. Electromyography was consistent with a myopathic process. MRI of the brain at 14 weeks of age revealed band heterotopia bilaterally in the occipital lobes. There was also the suggestion of polymicrogyria involving the inferior occipital lobes and posterior temporal lobes bilaterally. Sequencing of the LAMA2 gene revealed three novel nucleotide changes of uncertain clinical significance. Two of the mutations were predicted to be probably damaging, and parental mutation analysis confirmed a trans orientation of these two mutations in our patient, which would be consistent with autosomal recessive inheritance. The patient also had one novel splice site mutation in the fukutin gene. Muscle biopsy at 9 months of age showed partial merosin staining and normal alpha dystroglycan staining, which together with the molecular results supports a diagnosis of MDC1A. The finding of band heterotopia in this patient expands the rare cortical dysplasia phenotype seen with this congenital muscular dystrophy.

P02.147

A case of Mandibuloacral Dysplasia type A due to heterozygous LMNA mutation

V. Uliana[1], *M. D'Apice*[2], *M. Balocco*[3], *E. Di Maria*[1,4], *G. Forni*[3], *V. Viassolo*[1], *F. Forzano*[1], *S. M. Lepore*[5], *M. Trabacca*[6], *G. Novelli*[7,8], ***F. Faravelli***[1];
[1]*Division of Medical Genetics, Genova, Italy,* [2]*Genetica Medica, Fondazione Policlinico Tor Vergata, Roma, Italy,* [3]*Centro della Microcitemia e delle Anemie Congenite, Galliera Hospital, Genova, Italy,* [4]*Dept. of Health Sciences, University of Genova, Genova, Italy,* [5]*Biopathology Department, Tor Vergata University, Roma, Italy,* [6]*Department of Internal Medicine, Galliera Hospital, Genova, Italy,* [7]*Genetica Medica, Ospedale San Pietro Fatebenefratelli, Roma, Italy,* [8]*Agenzia di Valutazione del Sistema Universitario e della Ricerca, Roma, Italy.*

Mandibuloacral Dysplasia type A [MADA; OMIM # 248370] is an autosomal recessive disorder, due to mutations in LMNA gene, characterized by peculiar facial dismorphysms, lipodystrophy and progeroid features.

We report a 28-year old Italian female patient with mandibular hypoplasia, scoliosis, lipodystrophy, breast aplasia and metabolic abnormalities. She was found to be heterozygous for a missense mutation c.1045C>T (p.R349W) in exon 6 of the LMNA gene.

She presented a features described in different LMNA-associated entities and a mutation previously described a patient with muscular dystrophy, cardiac involvement and lipodystrophy.

The case underlines the clinical heterogeneity and the unclear genotype-phenotype correlation in laminopathies.

P02.149

Large homozygous interstitial duplication within the LARGE gene in a patient with Walker-Warburg-syndrome

U. Grasshoff[1], *U. Hehr*[2], *M. Bonin*[1], *A. Weichselbaum*[3], *A. Rieß*[1];
[1]*Medical Genetics, Tübingen, Germany,* [2]*Center for and Department of Human Genetics, Regensburg, Germany,* [3]*Childrens Hospital, Tübingen, Germany.*

Mutations in the LARGE gene are a rare condition causing Walker-Warburg-syndrome (WWS). We report on a girl with clinical features of WWS. The 19 months old girl, born to consanguineous parents, shows a very severe global developmental delay and extreme hypotonia. She is not able to turn her head or move any part of her body. Complex brain malformations with ventricular dilatation, absence of the inferior cerebellar vermis, and hypoplastic cerebellum were detected. She has got unilateral microphthalmia and cataract and ureteropelvic junction stenosis with hydronephrosis. Myoclonic seizures started at the age of 6 weeks. CK was highly elevated (>2000 U/l).

The diagnosis of WWS was confirmed by microarray analysis. It revealed an interstitial duplication of a 132 kb segment within the LARGE gene on both alleles (4 copies, 6.0 Affymetrix SNP-Array) in the index patient. The twofold duplication in the index patient was confirmed by MLPA. Both parents have 3 copies analogous to a duplication of one allele. We hypothesize that the partial duplication of the LARGE gene has a loss-of function effect on the duplicated allele with the parents being heterozygote carriers of this autosomal recessive disease, respectively, and the child being homozygous. This is the first case of WWS caused by a large duplication within the LARGE gene emphasizing the need of gene dosis analysis in WWS patients in whom mutations have been ruled out by conventional sequencing analysis. Furthermore it shows that array analysis should be considered even in cases with a presumed autosomal-recessive disease.

P02.150

Distinct and pathogenic substitution of IVS15+5G→A in the SLC26A4 gene in patients with enlarged vestibular aqueduct syndrome or Pendred syndrome in Okinawa islands.

A. Ganaha[1]*, M. Suzuki*[1]*, K. Naritomi*[2]*, T. Kaname*[2]*, K. Yanagi*[2]*, S. Usami*[3]*;*
[1]*Department of Otorhinolaryngology-Head and Neck Surgery, University of the Ryukyus, Nishihara, Okinawa, Japan,* [2]*Department of Medical Genetics, University of the Ryukyus, Nishihara, Okinawa, Japan,* [3]*Department of Otorhinolaryngology-Head and Neck Surgery, Shinshu University, Matsumoto, Japan.*

Background

The SLC26A4 gene, located on chromosome 7q22.3, is responsible for two clinically overlapped syndromes, Pendred syndrome (PS) and enlarged vestibular aqueduct syndrome (EVA). Distinctive SLC26A4 mutations in such patients were described in some ethnic populations. Previous studies revealed that the spectrum of SLC26A4 mutation was different in different ethnic background. For example, a mutation, H723R, was reported as the most common mutation for EVA and PS in Japanese.

We investigated 18 patients from 18 unrelated families with EVA or PS to define the frequency of SLC26A4 mutations and clinical manifestations in Okinawa islands.

Results

Eight patients diagnosed with PS, and 10 patients with NSEVA were examined in the SLC26A gene. Mutations of the SLC26A4 gene were identified in 15 out of 18 patients. Of the 15 patients, four patients were having a homozygous mutation of H723R, six patients were having compound heterozygous mutations of H723R and IVS15+5G>A, four patients were homozygous mutation of IVS15+5G>A, and one patient had heterozygous mutation of IVS15+5G>A.

Among the mutations detected, IVS15+5G→A was most common, accounting for 61.1% (11/18) of the patients. In order to know whether the mutation was pathogenic, we performed a quantitative RT-PCR for SLC26A4 in patients with homozygous mutation of IVS15+5G→A. The result showed that the SLC26A4 gene was not expressed in the patients.

Conclusions

The substitution of IVS15+5G>A in the SLC26A4 gene was most common in PS or EVA patients in Okinawa area. The substitution of IVS15+5G→A caused loss of expression in the gene, which affects PS or EVA.

P02.151

New mutation in PTPN11 gene causing LEOPARD syndrome with prominent cardiac hypertrophy.

V. Rumyantseva*, A. Bukaeva, L. Rizun, E. Zaklyazminskaya;*
Petrovsky Russian Research Centre of Surgery RAMS, Moscow, Russian Federation.

Background: LEOPARD syndrome is a rare autosomal dominant disorder characterized by multiple lentigines and café-au-lait spots, hypertelorism, cardiomyopathy and heart rhythm defects, pulmonary stenosis, abnormalities of genitalia in males, growth retardation, and deafness. Clinical manifestation is highly polymorphic. Mutations in the three genes (PTPN11, RAF1, and BRAF) can be responsible for LEOPARD syndrome. About 85% of all cases are PTPN11-positive.

Clinical case: We did observe 17 y.o. male patient with prominent hypertrophic cardiomyopathy, left outflow tract obstruction, mitral valve insufficiency III-IV, left atrium dilation, ventricular and supra-ventricular extra systoles. The heart rhythm was imposed by pacemaker, implanted in 2005 (at 13 y.o.), the battery was almost discharged. Extra-cardiac symptoms include multiple lentigines, growth retardation, pectus carinatum, and feet deformation. Parents were apparently healthy. Surgery treatment included mitral valve replacement, left ventricular outflow resection, sub-aortic membrane excision, explanation of electrodes, pacemaker and ICD implantation.

Genetic screening results: We did perform Senger sequencing of PTPN11, RAF1 and BRAF genes by direct Sanger sequencing. New genetic variant p.Thr468Met in PTPN11 gene was found in proband's DNA sample but not in a control group. Additionally, several SNPs in RAF1 gene without clear clinical importance were found.

Conclusion: We suspect that new variant p.Thr468Met in PTPN11 gene is a mutation causing LEOPARD syndrome. Clinical phenotype characterized mainly by cardiac and skeletal involvement. It's important for clinicians to make correct and timely differential diagnostics between hypertrophic cardiomyopathy and inherited syndrome accompanied by myocardial hypertrophy.

P02.152

Leri Weill Dyschondrosteosis -The bone microarchitecture in subjects with mutation in the SHOX-gene

M. Frost[1]*, S. J. Hansen*[1]*, C. Fagerberg*[2]*, L. Ousager*[2]*,* ***A. L. Frederiksen***[3]*;*
[1]*Dept. of Endocrinology, Odense University Hospital, Odense, Denmark,* [2]*Dept. of Clinical Genetic, Odense University Hospital, Odense, Denmark,* [3]*Dept. of Clinical Genetic, Vejle Hospital, Vejle, Denmark.*

Background: Leri Weill Dyschondrosteosis (LWD) syndrome is characterized by short stature with mesomelic disproportion of the limbs and Madelung deformity caused by SHOX-haploisufficiency. The morphology of the bones is only partly described.

Aim: To assess volumetric bone mineral density, microarchitecture, and strength in subjects with LWD and controls.

Methods: Controls matched on sex and age. A high-resolution peripheral quantitative CT scanner was used to measure volumetric BMD, bone geometry, and microarchitecture of the non-dominant distal radius and the distal part of tibia. Osteoporosis was defined as a T-score<- 2.5 SD on the basis of a DXA scan.

Subjects: Five families comprising 22 individuals (15 females) aged 38 years [IQR: 21-35] were included and controls. SHOX-mutations: c.440G>T (n=2), c.657delA (n=9), del exon 3-4 (n=2), del SHOX (n=9).

Results: Tibial trabecular thickness was lower in cases (0.067 vs. 0.076, $p<0.05$). In radius the cortical areal was larger in cases (74.4 vs. 56.5, $p<0.001$), cortical thickness was increased (1.16 vs. 0.82, $p<0.001$) and the trabecular number decreased (1.61 vs. 1.90, $p<0.05$). Bone strength was similar in cases and controls. The radial cortex adjacent to ulna was absent in 5 cases. Four subjects were osteoporotic based on a T-score but neither reported a previous fracture.

Conclusion: These results suggest that bone microarchitecture is changed in LWD cases. The increased cortical thickness in radius may be caused by a more proximal measurement of the radius of cases due to the mesomelic forearm. 5 cases had a radial cortical defect.

P02.153

A new inactivating LH receptor mutation causes a disorder of sex development in a 46,XY girl and amenorrhea in her 46,XX sister

U. Groß[1]*, M. Möller-Krull*[1]*, H. Drexler*[1]*, S. Fleischer*[1]*, N. Kandemir*[2]*, H. M. Schulte*[1]*, A. Richter-Unruh*[3]*;*
[1]*Endokrinologikum Hamburg, Center for Hormonal and Metabolic Diseases, Reproductive Endocrinology and Prenatal Medicine, Hamburg, Germany,* [2]*Hacettepe University Faculty of Medicine, Division of Paediatric Endocrinology, Ankara, Turkey,* [3]*Endokrinologikum Ruhr , Center for Hormonal and Metabolic Diseases, Wattenscheid, Germany.*

Leydig cell hypoplasia (LCH) is a rare autosomal recessive condition that interferes with normal development of male external genitalia in 46,XY individuals. In 46,XX women primary and secondary sexual characteristics are developed normally but they are suffering from amenorrhea and infertility. Here we report a family with two affected sisters suspected to have an inactivating mutation in the LH receptor gene (*LHR*).

A 14-year-old girl was referred with lack of the progression in breast development and amenorrhea. In physical examination her height was 165.7cm and weight 81.5 kg. Breast development was Tanner stage I with lipomastia and pubic hair development Tanner stage III. She had female external genitalia with mild posterior labial fusion.

Hormonal evaluation revealed FSH 2.62mIU/ml, LH 10.94 mIU/ml, E2 <10pg/ml,

Testosterone <20ng/dl. Karyotype was 46,XY. Pelvic MRI demonstrated testicular tissue bilaterally in inguinal regions. She had therapeutic gonadectomy.

Her 21-year-old sister was also evaluated when she was 15 years old for amenorrhea. Her secondary sexual characteristics were well developed. Pelvic ultrasonography showed an uterus with atrophic endometrium. In hormonal evaluation, serum LH level was 30.9 mIU/ml, FSH 7.68 mIU/ml, E2 35.44 pg/ml and testosterone 36.8ng/dl.

Sequence analysis of the *LHR* gene showed a new homozygous mutation p.Gly71Ala in both sisters.

This mutation is located in the extracellular ligand-binding domain in exon 2, probably interfering with binding of LH to the LH receptor. *In vitro* experiments with the mutant receptor will follow to get more insights into the binding capacity and activity of this receptor.

P02.154

Splice mutations of the luteinizing hormone receptor gene (*LHR*) as a cause of 46,XY disorders of sex development (DSD)

A. Richter-Unruh[1], *A. Themmen*[2], *M. Verhoef-Post*[2], *S. Fleischer*[3], *M. Möller-Krull*[3], *H. Drexler*[3], *H. M. Schulte*[3], *U. Groß*[3];
[1]*ENDOKRINOLOGIKUM Ruhr, Center for Hormonal and Metabolic Diseases, Wattenscheid, Germany,* [2]*Erasmus University, Internal Medicine, Rotterdam, Netherlands,* [3]*ENDOKRINOLOGIKUM Hamburg, Center for Hormonal and Metabolic Diseases, Reproductive Endocrinology and Prenatal Medicine, Hamburg, Germany.*

Leydig cell hypoplasia (LCH) is a rare autosomal recessive condition that interferes with normal development of male external genitalia in 46,XY individuals. Inactivating mutations of the human luteinizing hormone receptor (LHR) lead to decreased response of Leydig cells to LH and hCG.

Here we report 17 patients in 4 families with 46,XY disorder of sex differentiation caused by homozygous or compound heterozygous mutations in non-coding DNA sequences of the luteinizing hormone receptor gene (*LHR*). 14 patients in 2 different families were homozygous carriers of a mutation at the exon splice donor site in intron 1 (c.161+4A>G) whereas two sisters were heterozygous for a missense mutation (p.Y623S) in combination with a mutation 34 nucelotides downstream of the splice donor site of exon 4 (c.383+34G>A). One patient was homozygous for a splice acceptor site mutation in intron 1 (c.162-3T>G). In vitro minigene expression was employed to examine the effect of the mutations on pre-mRNA splicing, while for one patient testis RNA was available to validate the minigene expression approach. The results of these molecular studies represent a large increase in the spectrum of mutations that cause Leydig cell hypoplasia in 46,XY disorders of sex differentiation patients and to the tools available for its molecular diagnosis.

P02.155

Evaluating the clinical significance of observations of loss of heterozygosity in SNP-arrays

J. Graakjaer, *M. Rasmussen, S. Kolvraa, A. Bojesen;*
Vejle Hospital, Vejle, Denmark.

SNP-based detection of loss of heterozygosity (LOH) is now supported by most major array providers. Many labs are therefore for the first time challenged with the task of interpreting the clinical significance of areas of LOH in the genome. However, until now no formal guidelines for the interpretation of LOH are available. In this study we present our internal workflow for the handling of observations of LOH.

In this workflow we are grouping LOH observations into three groups: LOH interstitially on one chromosome, LOH on one chromosome extending to the telomere and LOH on multiple chromosomes. For each group of LOH observations, we review the possible biological mechanisms, the possible clinical significance and we suggest a procedure for further investigations of the observation. Each workflow takes into consideration resources and time constraints typically present in a clinical genetics laboratory setting.

Hopefully these workflows can aid other laboratories in setting up their own internal workflow for interpreting LOH observations or add to a discussion of this new “challenge” in clinical genetics.

P02.156

The level of hearing loss among patients with the mutation m.A1555G

U. Lechowicz[1], *A. Pollak*[1], *M. Mueller-Malesinska*[1], *L. Korniszewski*[1], *H. Skarzynski*[1], *R. Ploski*[2];
[1]*Institute of Physiology and Pathology of Hearing, Warsaw, Poland,* [2]*Medical University in Warsaw, Warsaw, Poland.*

Many commonly used medications may be in a transient and reversible, or permanent adverse effect on the level of hearing impairment in humans. It is believed that some aminoglycoside antibiotics can damage the sensory epithelium in the inner ear. In case of ototoxic aminoglycosides (eg gentamicin, amikin, streptomycin) causing the damage to the bacterial ribosome, mitochondrial ribosome may be destroyed because of its similarity. Susceptibility to such antibiotics effect is passed in the maternal line, indicating the mitochondrial type of inheritance.

Many mutations in the mitochondrial genes 12S rRNA and tRNASer related to „aminoglycoside“ hearing loss were described. One of them is m.A1555G mutation which occurs in a highly conserved region of 12SrRNA molecule, leading to reduced production of ATP in the cells of the cochlea.

We studied a group of 1933 patients of the Institute of Physiology and Pathology of Hearing for the presence of mutation m.A1555G using RealTime PCR technology. In the studied group 25 patients with this mutation were found.

The aim of this study was to assess the level of hearing loss among patients with the mutation m.A1555G

P02.157

Novel c.1731delC mutation in *RIN2* gene in two Turkish siblings with MACS / RIN2 syndrome

H. Kayserili[1], *A. D. Aslanger*[2], *U. Altunoglu*[1], *E. Aslanger*[3], *B. Satkin*[1], *Z. O. Uyguner*[1];
[1]*Medical Genetics Department, Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey,* [2]*Medical Genetics Unit, Kocaeli Derince Research and Education Hospital, Kocaeli, Turkey,* [3]*Cardiology Unit, Gölcük State Hospital, Gölcük, Kocaeli, Turkey.*

Inherited disorders of connective tissue, such as Ehlers-Danlos(EDS) and the Cutis Laxa syndromes(CLS), are a heterogenous group of disorders which are characterized by hyperextensible skin and joint laxity. Thin/translucent skin with visible veins and easy bruising are also observed in EDS patients. The EDSs involve a genetic defect in synthesis and structure of collagen and collagen fibril assembly while the cutis laxa syndromes(CLs) are characterized by loose/redundant skin and growth retardation and in some types defective biogenesis of elastic fibers have been shown.The mutations in *RIN2* gene were first reported on three patients by Basel-Vanagaite et al.,(2009) in two related families of Israeli-Arab origin who showed macrocephaly, coarse and swollen facial appearance affecting the eyelids, lips, and cheeks, scoliosis, skin hyperlaxity and joint hypermobility. The acronym **MACS**; **M**acrocephaly, **A**lopecia, **C**utis laxa and **S**coliosis; was suggested for this new syndrome related to the cutis laxa group of inherited disorders. Recently novel mutations in *RIN2* gene were identified in three affected patients from Algeria by Syx et al.(2010) who were formerly reported as EDS-like syndrome in 2005 by Verloes et al. The authors discussed that MACS acronym may not be the most appropriate term to sum up the phenotypic spectrum and suggested **‘’RIN2 syndrome’’.**

We here describe the third family with MACS/RIN2 syndrome in two siblings from Turkey also displaying additional findings such as hypogonadism and mediastinal tumor, carrying a novel homozygous c.1731delC mutation resulting in frame shift in *RIN2* gene and causing protein truncation.

P02.158

De Novo triplication of the *MAPT* gene from the recurrent 17q21.31 microdeletion region in a patient with moderate intellectual disability and various minor anomalies

C. Kraus, *A. Gregor, M. Krumbiegel, A. Reis, C. Zweier;*
Institute of Human Genetics, University Erlangen-Nuremberg, Erlangen, Germany.

We report on a 16-year old male patient with moderate intellectual disability, behavioral problems, and further anomalies such as facial dysmorphism, heart defect and urogenital anomalies. By molecular karyotyping we identified the first *de novo* copy number gain to four copies on chromosome 17q21.31 including the *MAPT* gene but not the entire recurrent microdeletion/microduplication region. Recurrent microdeletions of this region including the *MAPT* and the *CHRH1* genes have been shown to be a relatively frequent cause of intellectual disability, while only a few reciprocal duplications in patients with variable cognitive disorders have been published so far.

A common inversion polymorphism in this region has been linked to a distinct H2 haplotype and seems to be associated with an increased risk for microdeletions and -duplications. Our patient and his father were both heterozygous for the H1/H2 haplotype, whereas the mother was homozygous for the H2 haplotype. Interestingly, in our patient the dosage gain apparently occurred on the paternal H1 allele and did not involve the H2 allele as in the previously published cases.

This patient further delineates the genotypic and phenotypic variability associated with copy number variants from the 17q21.31 microdeletion region.

P02.159

Novel mutations causing Marfan syndrome in Czech population and rare case of compound heterozygozity

M. Dvorakova, *P. Cibulkova, E. Augste, A. Boday;*
Laboratory of Molecular Biology, P&R LAB a. s., Novy Jicin, Czech Republic.

Background: Marfan syndrome (MFS) is an autosomal dominant connective tissue disorder mainly involving the cardiovascular, skeletal and ocular systems. The estimated incidence is of about 1:5 000 - 1:10 000 and approximately 25% of cases are associated with *de novo* mutations. MFS is caused by mutations in fibrillin 1 gene (*FBN1*, 15 q15-q21.1.) resulting in defective glycoprotein fibrillin-1. Recently, there are showed that three other genes FBN2 (5q23-q31), TGFBR2 (3p22) and TGFBR1 (9q22) influence MFS.

Aims: In this study we performed SSCP analysis of all 65 exons of FBN1 gene in order to identify novel mutations in 570 unrelated patients with clinical diagnosis of Marfan syndrome.

Materials and Methods: DNA was isolated from whole blood, the molecular analysis includes mlpa (multiplex ligation-dependent probe amplification) and separation of PCR products by SSCP (single-strand conformation polymorphism). Exons with abnormal migrating patterns were sequenced.

Results: We identified 87 *FBN1* mutations, 53 of them have not been previously described. Of the 46 were missense, 15 nonsense, 7 splicing, 17 small deletions or insertions and 2 gross deletions. Than we identified 4 patients with compound heterozygosity at the *FBN1* locus, that is very rare.

Conclusions: We have confirmed 107 cases of Marfan syndrome caused by *FBN1* mutation, which constitutes detection of about 19%. But mutation screening of *FBN1* should yield a result in about 80-85% of MFS patients who meet the Ghent criteria. Our result is much lower due to sensitivity of SSCP and because the patients involved did not meet the Ghent criteria.

P02.160

Interesting case of an atypical Marfan syndrome patient

M. Pfob[1], *M. Eggert*[1], *E. Aichinger*[1], *T. Koeppel*[2], *U. Hoffmann*[3], *O. Steinlein*[1]*;*
[1]*Institute of Human Genetics, Munich, Germany,* [2]*Department of Surgery, Munich, Germany,* [3]*Department of Internal Medicine, Munich, Germany.*

The Marfan syndrome is an autosomal dominantly inherited genetic disorder due to mutations in the fibrillin-1 (FBN1) gene, a gene that encodes a connective tissue protein.

Consequently, mutations in this gene cause skeletal and connective tissue symptoms (pectus carinatum/excavatum, hypermobile joints, arachnodactyly), complications of the cardiovascular system (dilatation/ dissection of ascending aorta, mitral valve prolapse), and the eyes (ectopia lentis, myopia). Patients suffering from Marfan syndrome are at risk of aortic rupture.

Here we report an atypical case of Marfan syndrome.

The 44 year old patient was hospitalized in 2007 with a spontaneous dissection of the arteria carotis interna. Last year, an infrarenal aneurysma of the abdominal aorta was diagnosed. Physical examination showed a patient of below average size (167 cm (mother and father: 160 cm)). The arm span/ body height ratio was 0,98 (<1,05), neither skeletal nor ocular abnormalities were present. Thumb signs and wrist signs were negative. Thus classical characteristics of the syndrome were non-existent. Family history showed that the patient's mother died at the age of 56 due to an arterial rupture.

Molecular analysis of the FBN1 gene revealed a missense mutation c.4727T>C (p.M1576T) in exon 37. This mutation leads to an amino acid exchange in the TGF-beta domain of the FBN1 protein.

In conclusion, the life threatening complications of Marfan syndrome can occur in patients without any of the typical Marfan features.

Duplication of Xq28 including the *MECP2* gene has been described primarily in male patients with severe developmental delay, progressive spasticity, epilepsy, stereotyped hand movements and recurrent infections. The aim of our study was to carry out an epidemiological study in order to determine the number of cases identified in France since the implementation of targeted molecular study (MLPA) and array-CGH, and to estimate the proportion of patients detected by either method. The 15 French cytogenetic and molecular labs were contacted and biological and epidemiological data were gathered in all cases. 71 symptomatic patients with a *MECP2* duplication of less than 4 MB were collected, including 66 boys and 5 females ranging from 0 to 24 years. The *MECP2* duplication was identified in 45 patients (63%) using a targeted analysis, and in 26 patients (37%) using an array-CGH analysis. The majority was inherited from unaffected mothers and the size of the duplication varied between cases. Within the 5 females, the *MECP2* duplication resulted from an unbalanced X-autosome translocation (3 cases), random X inactivation (1 case) or a partial MECP2 duplication (1 case, exon 4 only). Two cases were detected prenatally by array-CGH, in a context of generalized lymphoedema or polymalformations (*MECP2* triplication). From this study, besides the epidemiological data, we conclude that the diagnosis of *MECP2* duplication can be difficult since 1/3 of cases were detected using non targeted analysis. The second step of this study will gather the clinical data from this cohort in order to search for genotype-phenotype correlations.

Dosage changes of MED13L further delineate its role in heart defect and intellectual disability

R. Asadollahi[1], *B. Oneda*[1], *S. Azzarello-Burri*[1], *D. Bartholdi*[1], *A. Baumer*[1], *G. Houge*[2], *A. Rauch*[1]*;*
[1]*University of Zurich, Institute of Medical Genetics, Schwerzenbach-Zurich, Switzerland,* [2]*University of Bergen, Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, and Institute of Clinical Medicine, Bergen, Norway.*

A chromosomal balanced translocation disrupting the MED13L (PROSIT240) gene was previously reported to be associated with transposition of the great arteries (TGA) and intellectual disability (ID) and led to the identification of missense mutations in three patients with isolated TGA. Recently, a homozygous missense mutation in MED13L was found in 2 patients with non-syndromic ID (without cardiac involvement) from a consanguineous family. Next to the clinical findings, studies on *c. elegans* imply a specific role for MED13L in regulating transcription of the Wnt and Shh signaling targets which are crucial for embryonic development. Here, we describe 2 new aberrations of MED13L which were detected by means of molecular karyotyping. The first one is a *de novo* 17 kb out of frame deletion of its exon 2 in a patient with complex congenital heart defect, ID, gross and fine motor coordination problems and dysmorphic features. The second aberration is a 1 Mb *de novo* triplication in 12q24.21 including MED13L, several non protein coding RNA genes and MAP1LC3B2, in a patient with a milder phenotype including learning difficulties and perimembranous VSD (closed spontaneously). These findings suggest that abnormal MED13L dosage affects both, cardiac and neurologic developement. While different missense mutations result in either cardiac or intellectual problems, heterozygous copy number variants can lead to both in a dose dependent manner. Haploinsufficiency of the gene is associated with a more severe phenotype including complex heart defect and ID where as the outcome of increased gene dosage is a milder phenotype in both systems.

Barcelona, Spain.

Background: Medullary cystic kidney disease (MCKD) is a rare autosomal dominant renal disease characterized by medullary cysts, tubulo-intertstitial nephritis, progressive chronic renal failure leading to end-stage renal disease in adult life and, in occasional instances, gout. Two loci have been identified: mutations in the uromodulin gene (*UMOD*, 16p12.3), encoding the Tam-Horsfall glycoprotein expressed in the thick ascending and distal tubules, were found to associate with MCKD type 2 (MCKD2). Clinical symptoms might show inter- and intra-familiar variability, making robust genotype/phenotype correlations hard to establish.

Patients and methods: A 3 generation MCKD2 family was evaluated. Eight members (7 affected, 1 non-affected) were available for molecular and phenotype investigation. Immuno-histochemical analyses of kidney biopsies were performed. Genetic screenings were performed by PCR, direct sequencing and MLPA.

Results: We detected a novel mutation in the *UMOD* gene in 6/7 patients tested with intra-familial variability of the phenotype. In one affected individual we did not find any *UMOD* mutations. However, subsequent screening of the polycystic kidney disease (ADPKD) associated genes *PKD1* and *PKD2* in this patient revealed a novel variant in *PKD1*.

Conclusions: We present the clinical, immuno-histochemical and genetic results of a family demonstrating a unique finding of simultaneous appearance of two different cystic kidney diseases (MCKD2 and ADPKD) and with novel mutations in the *UMOD* and *PKD1* genes. Beside the phenotypic variability of MCKD2, our findings demonstrate the possibility of genetic variety as the cause of cystic kidney disease even within the same family.

Controversy in the mode of inheritance in Familial Mediterranean fever diseases; Molecular Analysis of *MEFV* Gene in Patients

M. S. khaniani, *S. M. Derakhshan, L. mohammadnejad;*
Tabriz university of Medical Science, Tabriz, Islamic Republic of Iran.

Familial Mediterranean fever is an autosomal recessive disorder characterised by episodic fever, abdominal and pleuritic pain, serositis and arthritis. The FMF gene (MEFV) generates a protein found exclusively in granulocytes. In this study, we report our 4-year experience of over 267 Azeri Turkish patients with this disease

in the central region of Algeria

267 Azeri Turkish unrelated subjects clinically diagnosed with FMF from various clinics from north west of Iran were referred by specialists to the Medical Genetic Centre of Tabriz University of Medical Sciences. A clinical diagnosis of FMF was made according to published Criteria. Mutation screening of the MEFV gene was performed for the 2, 3, 5 and 10 exons by using sequencing method.

163 (% 61) of these patients had one or two mutations. Of those with mutations, 83 were compound heterozygous, 46 were homozygous, and 34 had only one identifiable mutation. The most frequent mutations were M694V and E148Q (41% and 23% respectively) of the alleles, followed by V726A (17%), M680I (16%) mutations.

The results show the diversity and the frequency of the FMF mutations in the Iranian Azeri Turkish FMF patients, and indicate that FMF is one of the common inflammatory diseases in the north west of Iran that must be noted in management of cases with episodic fever, abdominal and pleuritic pain have been referred to clinic. Also, the mode of inheritance in almost 30% of FMF patients was Autosomal dominant.

P02.165

Megalencephaly, thick corpus callosum, dysmorphic facial features, and mental retardation in four unrelated patients: a new syndrome?

M. Rio[1], *N. Boddaert*[2], *V. Malan*[1], *J. Amiel*[1], *L. Colleaux*[1], *A. Munnich*[1], *I. Desguerre*[3], *V. Cormier-Daire*[1];
[1]*Department of genetics, Necker Hospital, Paris, France,* [2]*Department of radiology, Necker Hospital, paris, France,* [3]*Department of neurology, Necker Hospital, paris, France.*

Macrocephaly associated with mental retardation is a part of various syndromes including overgrowth conditions, cutis marmorata telangiectatica, Cowden disease, and neuro-metabolic disorders. We report here a new association characterized by progressive macrocephaly, mental retardation, specific facial features and similar magnetic resonance imaging (MRI) findings in four unrelated boys. All patients except one were born from non consanguineous parents. Case 1 walked at 3 years, developed seizures at 5 years. At 15 years, he had limited speech and a large head circumference (59cm, +3SD). Case 2 developed seizures at 3 years, walked at 8. He had limited speech and head circumference was 64 cm (>+4 SD) at 14 years. Case 3 developed seizures at 2 months, walked at 20 months. At 23 years, he had no speech, and head circumference was 62 cm (+4 SD). Case 4 had severe global developmental delay and head circumference curve was above + 2 SD. The four patients had the same dysmorphic features including downslanting palpebral fissures, long and expressionless face, small mouth. Three of them had enamel defect and distal amyotrophy. In all children, brain MRI detected bilateral megalencephaly, a thick corpus callosum, an enlarged white matter and normal ventricles. Whereas CT scans were initially normal, calcifications of basal ganglia were present in case 2 at 15 years, and in case 3 at 23 years. Extensive metabolic and cytogenetic studies were no contributive. We hope that ongoing cytogenetic and molecular studies will further define this new entity distinct from previously known syndromes with megalencephaly.

P02.166

MFRP-related oculopathy in a child and a distinct retinal disease in his mother

A. R. Janecke[1], *M. Ritter*[2], *J. Vodopiutz*[3], *E. Moser*[2];
[1]*Division of Human Genetics, Innsbruck, Austria,* [2]*Department of Ophthalmology, Wien, Austria,* [3]*Department of Pediatrics and Adolescent Medicine, Wien, Austria.*

The combination of nanophthalmos and retinal dystrophy is a rare syndrome recently identified as an inherited autosomal recessive disease caused by mutations in the MFRP gene. A 7-year old boy with high hypermetropia and signs of a progressive retinal dystrophy was referred. His 37-year old myopic mother was known to have a retinal dystrophy since childhood classified as M. Stargardt, consanguinity of the parents was denied. The boy was found to have nanophthalmos with the striking aspect of the fundus with a „macular fold“ and clinical and ERG findings indicating disturbed photopic and scotopic vision. Molecular analysis identified a homozygous truncating mutation in the membrane-type frizzled-related protein (MFRP) gene. Complete sequence analysis of the MFRP gene in the mother showed heterozygosity for the mutation identified in the patient, and no further mutation. The heterozygous mutation of the MFRP gene is not sufficient to cause the phenotype of the mother, and we assume that two phenotypically and genetically distinct retinal dystrophies exist in the family. A comprehensive molecular genetic screening of the mother was initiated.

P02.167

Microcephaly-Capillary Malformation Syndrome (MIC-CAP): a new case

D. J. Morris-Rosendahl[1], *A. Hotz*[1], *H. Gabriel*[2], *T. Polster*[3];
[1]*Institute of Human Genetics, Freiburg, Germany,* [2]*Diagenos, Praxis für Humangenetik, Osnabruck, Germany,* [3]*Epilepsie-Zentrum Bethel, Mara Krankenhaus, Bielefeld, Germany.*

Microcephaly-Capillary Malformation (MIC-CAP) syndrome was first described in 2011 as a disorder combining severe microcephaly with progressive cortical atrophy, intractable seizures, profound developmental delay and multiple small capillary malformations on the skin. An autosomal recessive mode of inheritance was implied in the families of the six described patients. We describe an affected male patient, the first child of non-consanguineous German parents, who was delivered by cesarean section due to pathological CTG at 34 weeks. Oligohydramnios was noted prenatally, a cranial deformity with severe microcephaly was noted after delivery (OFC 29 cm), as well as cutaneous macules. Seizures with tonic or clonic semiology started on the first day of life and have remained pharmacoresistant ever since. His EEG showed multifocal spikes, focal seizure patterns and a sinusoidal alpha activity, often seen in children with severe malformations of cortical development. Brain MRI revealed severely reduced cortical gyration both anteriorly and posteriorly. At the age of 18 months he has no appreciable psychomotor development, no eye contact, no vocalization and spastic quadriparesis with axial hypotonia. He is severely dysmorphic with a disproportionately small cranium and low-sloping forehead, broad nasal bridge, hypertelorism and shallow philtrum. Toes are short and partly overlapping, the big toes have dysplastic nails. The scrotum is hypoplastic with small testes. An international consortium has been established in order to elucidate the molecular genetic cause of the disorder.

P02.168

A de novo 12q13.13 microdeletion in a patient with mild mental retardation, disproportionate habitus, facial dysmorphy and congenital heart defect.

M. Simandlova[1], *M. Hancarova*[1], *J. Drabova*[1], *M. Vlckova*[1], *M. Koudova*[2], *M. Havlovicova*[1], *Z. Sedlacek*[1];
[1]*2nd Medical Faculty, University Hospital Motol, Prague, Czech Republic,* [2]*GHC Genetics, Prague, Czech Republic.*

We report a de novo 12q13.13 deletion in an 4.5-year-old dysmorphic boy with multiple congenital anomalies/mental retardation (MCA/MR) syndro-

me consisting mainly of mild to moderate MR, disproportional habitus with extremely narrow shoulders and long, narrow thorax, facial dysmorphism (long narrow face, hypotelorism, enophtalmus, wide nose), onychodystrophy, fine hair, atypical hand grip between index and middle fingers, ulnar duction of both hands, ventricular septal defect, pulmonary stenosis, and cryptorchism. His behavioural pattern is very remarkable with a sad expression in the face, timidity and balbuties. The deleted region is 0.95 Mb long and encompasses the whole HOXC gene cluster and 19 additional proximally located genes. Although the HOXC cluster was shown to be dispensable in mouse, we speculate that its haploinsufficiency could potentially be responsible for the remarkable disproportionate stature of the proband. Reduced dose of several other genes mapping to the deletion may also influence this specific phenotype, especially RAGR which plays a role in limb bud development and skeletal growth, or SP7 which influences bone formation. MR of the patient could be influenced by neural-expressed genes AAAS and MAP3K12, but the remaining deleted genes could also influence his phenotype. To our knowledge this is the first report of a de novo 12q13.13 microdeletion removing the whole HOXC cluster and several neighbouring genes, which is likely associated with the MCA/MR syndrome in the patient.
Supported by CHERISH and MZ0FNM2012.

P02.169

Microdeletions in 9q33.3-q34.1 are associated with developmental delay, micro-/brachycephaly, and seizures of incomplete penetrance

J. A. Lee[1,2], *J. K. Ehret*[1], *E. Wohlleber*[1], *S. Vogt*[1], *A. M. Zink*[1], *E. Rossier*[3,4], *M. Bonin*[3,5], *U. Grasshoff*[3], *A. Bevot*[6], *M. Mathieu-Dramard*[7], *A. de Broca*[8], *S. Kanafani*[7], *M. Holder-Espinasse*[9], *I. Simonic*[10], *L. Willatt*[10], *J. Andrieux*[11], *H. V. Firth*[10], *A. Dufke*[3], *H. Engels*[1];
[1]Institute of Human Genetics, University of Bonn, Bonn, Germany, [2]Department of Genomics - Life & Brain Center, University of Bonn, Bonn, Germany, Bonn, Germany, [3]Department of Medical Genetics - University of Tübingen, Tübingen, Germany, [4]Genetikum, Neu-Ulm, Germany, [5]Microarray Facility - University of Tübingen, Tübingen, Germany, [6]Children's Hospital - University of Tübingen, Tübingen, Germany, [7]Centre de Génétique, CHU d'Amiens, Amiens, France, [8]Service de Neuropédiatrie, CHU d'Amiens, Amiens, France, [9]Service de Génétique Clinique, Hôpital Jeanne de Flandre, CHRU de Lille, Lille, France, [10]Department of Medical Genetics - Addenbrooke's Hospital NHS Trust, Cambridge, United Kingdom, [11]Laboratoire de Génétique Médicale - Hôpital Jeanne de Flandre, CHRU de Lille, Lille, France.

We report four patients with overlapping microdeletions of chromosome 9q identified by molecular karyotyping using various platforms. Their common clinical features include developmental delay with delayed or absent speech and micro- and/or brachycephaly. *De novo* deletions of 1.76, 1.3, and 2.8 Mb, in 9q33.3-q34.11 were detected in patients 1 through 3, respectively, whereas the 432 kb 9q33.3 deletion in patient 4 was inherited from her mother who is reported to have mild intellectual disability.
The smallest region of overlap (SRO) is defined by the deletion in patient 4 and includes only three RefSeq genes. Interestingly, the three larger deletions have 27 genes in common including *STXBP1*, which plays a role in synaptic transmission. *STXBP1* loss-of-function mutations and deletions have been associated with early infantile epileptic encephalopathy (EIEE, or Ohtahara syndrome), and were identified in patients with intellectual disability and non-syndromic epilepsy. In our cohort, the seizure phenotype appears to be incompletely penetrant. Notably, patient 4 had seizures, although her deletion excludes *STXBP1*. Thus, the involvement of *STXBP1* and/or possibly other genes due to deletion of long-range regulatory elements cannot be ruled out. Sequencing of the three SRO genes in a cohort of unrelated patients with mild to severe idiopathic intellectual disability, as well as gene expression analyses in our patients, is underway to identify the causative gene(s).
We suggest that microdeletions of this region on chromosome 9q may cause a clinical spectrum including developmental delay especially concerning speech, micro- and / or brachycephaly, mild dysmorphisms and seizures of incomplete penetrance.

P02.170

Description of 2 patients with overlapping duplication of chromosome 20q11.2 with abnormal shape head and intellectual deficiency

M. Avila[1,2], *P. Callier*[3], *H. Dahlgaard Hove*[4], *M. Kirchhoff*[4], *C. Thauvin-Robinet*[1,5], *N. Marle*[3], *A. Mosca-Boidron*[3], *A. Masurel-Paulet*[1], *F. Huet*[2], *F. Mugneret*[3], *S. Kjaergaard*[4], *L. Faivre*[1,5];
[1]Centre de Génétique, Centre de Référence Maladies Rares- Anomalies du Développement et Syndromes Malformatifs de l'Intégration Est - Hôpital d'enfants- CHU de Dijon, Dijon, France, [2]Service de Pédiatrie 1, Hôpital d'Enfants - CHU de Dijon, Dijon, France, [3]Laboratoire de Cytogénétique, Plateau Technique de Biologie -CHU de Dijon, Dijon, France, [4]Departement of Clinical Genetics, Unit for Rare Diseases, University of Copenhagen, Copenhagen, Denmark, [5]Equipe émergente GAD, IFR Santé STIC, Université de Bourgogne, Dijon, France.

The current use of microarray-based comparative genomic hybridization allowed the identification of novel cytogenetic abnormalities. Partial trisomies of the long arm of chromosome 20 are rare. Here we report de novo 20q11.2 confirmed in CGH-Array in two boys with intellectual deficiency, speech delay, and distinctive dysmorphic features with abnormal shape head and short hands. The breakpoints and sizes of the duplications are different but included the *ASLX1* gene (MIM612990). *ASLX1* is a human homolog of the Drosophila *asx* gene which is an homeotic gene. Recently, de novo heterozygous nonsense or truncating mutations in the *ASLX1* gene have been reported in 7 of 13 unrelated patients with Borhing-Opitz syndrome (MIM605039), a severe developmental and malformation disorder. The finding of two other patients in the literature with overlapping 20q11 microduplication and clinical features allowed us to reduce the minimal critical region to 7,4MB encompassing 173 genes including *ASLX1* gene. Interestingly, patients display clinical features in common with Borhing-Opitz syndrome, and in particular abnormal shape head. We hypothesize that the duplication of *ASLX1* is responsible of a milder phenotype resembling Borhing-Opitz syndrome. These observations give data in favour of a novel microduplication syndrome and suggest a contribution of *ASLX1* to the phenotype. Reporting of additional patients with molecular characterization will allow more detailed genotype-phenotype correlations.

P02.171

CGH Array in Miller-Dieker syndrome

B. Bozorgmehr[1], *F. Afroozan*[1], *S. Tonekaboni*[2], *R. Kariminejad*[1], *A. Kariminejad*[1];
[1]Kariminejad-Najmabadi Genetic centere, tehran, Islamic Republic of Iran, [2]Mofid Children Hospital, tehran, Islamic Republic of Iran.

Miller-Dieker syndrome is one of the reason of profound neurodevelopmental delay with lissencephaly.A contiguous gene deletion in 17p13.3 is documented.It is characterized by microcephaly,bitemporal narrowing ,small nose,anteverted nostils,prominent upper lip,micrognathia,low set ears,vertical ridging and forrowing in central forehead,hypotonia,seizure,brain malformation like incomplete development of brain often with smooth surface (lissencephaly), hypoplasia of corpus callosom, and profound mental ratardation. we are reporting , two patients aged 1 and 2 years with microcephaly ,profound mental retardation,bitemporal narrowing,low set ears,and lissencephaly.In CGH Array ,we found the deletion in 17p13.3 which documented the disease.in this article we want to emphasize on CGH Array in lissencephaly spectrum.

Constitutional mismatch repair deficiency (CMMR-D) syndrome is a rare inherited childhood cancer predisposition caused by biallelic germline mutations in one of the four MMR-genes, *MLH1*, *MSH2*, *MSH6* or *PMS2.* Due to a wide tumor spectrum, the lack of specific clinical features and the overlap with other cancer predisposing syndromes, diagnosis of CMMR-D is often delayed in pediatric cancer patients. We report of three new CMMR-D patients each of whom developed more than one malignancy. The common finding in these three patients is agenesis of the corpus callosum (ACC) and gray matter heterotopia present in two patients. Fifty-seven CMMR-D patients with brain tumors (therefore all likely had cerebral imaging) have previously been reported, one of whom had cerebral malformations. Taken together with our patients, the prevalence of cerebral malformations is at least 4/60 (6.6%). This number is well above the population birth prevalence of 1 to 4/4,000 live births with these cerebral malformations, suggesting that ACC and heterotopia are features of CMMR-D. The presence of cerebral malformations in pediatric cancer patients should alert to the possible diagnosis of CMMR-D. ACC and gray matter heterotopia are the first congenital malformations described to occur at higher frequency in CMMR-D patients than in the general population. Further systematic evaluations of CMMR-D patients are needed to identify possible other malformations associated with this syndrome.

P02.173
Array detection of apparent mosaic monosomy 7 - a marker for underlying disorders of genome maintenance?

S. A. McKee[1], *D. LaGrave*[2], *J. Wales*[3], *S. McNerlan*[1], *J. Achermann*[4], *M. Humphreys*[1];
[1]Northern Ireland Regional Genetics Service, Belfast, United Kingdom, [2]Cytogenetics & Molecular Cytogenetics, ARUP Laboratories, Salt Lake City, UT, United States, [3]Academic Unit of Child Health, Sheffield Children's Hospital, Sheffield, United Kingdom, [4]Institute of Child Health, UCL, London, United Kingdom.

The increasing availability and precision of array-based comparative genomic hybridisation (aCGH) techniques allow detection of subtle abnormalities that may have previously eluded traditional analyses. We present a male baby (Case 1), born at 36+4/40 gestation, with dysmorphic facies, severe micrognathia, cleft palate, choanal stenosis, small extremities, hypoplastic terminal phalanges and normal genitalia. He had a ventricular septal defect and a patent ductus arteriosus. aCGH analysis on blood DNA revealed mosaic monosomy for chromosome 7 (estimated 6% of cells). Mosaicism was not detected in fibroblasts, and there was no overt evidence of a blood dyscrasia on a blood smear. He died at age 4 months.

Monosomy 7 is a common feature in several myeloproliferative disorders and is very rare as a constitutional abnormality. We previously identified three male patients (Cases 2-4) with features reminiscent of IMAGe syndrome (Intrauterine growth retardation, Metaphyseal dysplasia, Adrenal insufficiency and Genital abnormalities), who were found to have monosomy 7 mosaicism in blood or bone marrow. This was associated with a confirmed myelodysplastic process in at least one child, who underwent bone marrow transplantation in the first year, remaining stable at age 7 years. The other two died in early infancy. Case 1 above, however, had normal adrenal function and normal genitalia, possibly suggesting a different underlying disorder.

We hypothesise that these children display defective genome maintenance contributing to their phenotype, with monosomy 7 as a secondary event. Exome sequencing is in progress in two of our cases.

P02.174
Syndromic Moyamoya disease and hemophilia A caused by Xq28 deletion in Czech patient

R. Pourová, *J. Drábová, S. Kaloušková, V. Komrska, A. Tomek, Z. Zmítková, D. Novotná, M. Havlovicová;*
Charles University in Prague, Second Medical Faculty, Prague, Czech Republic.

There are 5 types of Moaymoya disease (MYMY) with genetical alignment, of which type 4 is syndromic. MYMY4 described patients suffer from MYMY, growth retardation, hypergonadotropic hypogonadism (HH), azoospermia and stigmatization. Cardiomyopathy, cataract and stroke may also occur.

We present a 19-years old Czech patient with normal intellect, who has dysmophic features, growth retardation since 10 years of age, HH with regress of puberty in 15 years and azoospermia, but shows neither neurologic nor cardiologic symptoms. Unlike any of described patients he suffers from severe hemophilia A with level of factor VIII under 1% and low level of inhibitor (antibodies against exogenous FVIII).

The patient has normal karyotype 46,XY and there has been found no mutation in F8 gene. Array CGH investigation was later performed in this patient and cryptic deletion within Xq28 was detected. The deletion removed approximately 100 kb and the deleted region harboured promotor of F8 gene as well as genes MTCP1/MTCP1NT and BRCC3, which might play an important role in syndromic MYMY development.

After obtaining the array CGH result, we immediately performed MRI, MRA and TCCS (transcranial colour coded sonography) with perfectly normal results.

Phenotype - genotype correlation will be further discussed.

Supported by CZ.2.16/3.1.00/24022, MZ0FNM2005 and IGA-NS-9913-4.

P02.175
The NSEuroNet Database: an online resource for mutation spectrum and phenotype correlations in RASopathies

C. Lissewski[1], *J. Allanson*[2], *H. Cavé*[3], *B. Kerr*[4], *M. Tartaglia*[5], *M. Zenker*[1];
[1]Institute of Human Genetics, University Hospital Magdeburg, Magdeburg, Germany, [2]Children's Hospital of Eastern Ontario, Ottawa, ON, Canada, [3]Department of Genetics, Hôpital Robert Debré AP-HP, Paris, France, [4]Genetic Medicine, St. Mary's Hospital, Manchester Academic Health Sciences Centre, School of Biomedicine, University of Manchester, Manchester, United Kingdom, [5]Dipartimento di Ematologia, Oncologia e Medicina Molecolare, Istituto Superiore di Sanità, Rome, Italy.

Mutations in proteins involved in the RAS/MAPK pathway cause Noonan syndrome, Costello syndrome, cardio-facio-cutaneous syndrome, Noonan syndrome with multiple lentigines/LEOPARD syndrome, Noonan syndrome with loose anagen hair/Mazzanti syndrome, CBL mutation-associated syndrome, neurofibromatosis type 1 and related phenotypes, collectively called RASopathies. While the number of mutations and sequence variants identified in RASopathy genes is still increasing, the probability for novel mutations to be reported to the public has become quite low and the significance of rare variants may even remain unclear. Moreover, phenotypic data of published cohorts is hardly comparable due to the lack of standardization, and individual study cohorts do not reach the statistical power for reliable genotype-phenotype correlations.

To overcome these limitations, the NSEuroNet Consortium has established a database that contains all published germline mutations in the known RASopathy genes (excluding NF1), unpublished mutations observed by the consortium partners and collaborators, as well as polymorphisms and unclassified variants. In addition, standardized clinical datasets on a steadily increasing number of patients with a molecularly proven RASopathy are collected in order to establish genotype-phenotype correlations. Data can be submitted by registered users via an online questionnaire, are reviewed and then added to the database.

The database will be freely accessible. It can be browsed for genes, mutations or phenotypes through a user-friendly graphical surface. We introduce this novel resource which will be of great value for scientists as well as for clinical geneticists involved in counselling of patients with these disorders and their families.

P02.176
Genotype-phenotype correlation in cohort of patients with myotonic syndromes.

S. A. Kurbatov[1], *V. P. Fedotov*[1], *E. A. Ivanova*[2], *N. M. Galeeva*[2], *A. V. Polyakov*[2];
[1]Genetic counseling, Regional Clinical Hospital, Voronezh, Russian Federation, [2]Russian Research Center for Medical Genetics, Moscow, Russian Federation.

Myotonic syndromes (MS) - a heterogeneous group chloride and sodium channels diseases with marked clinical polymorphism and often overlapping phenotypes. Attempts are being made to optimize the algorithm of finding causative mutations in the genes for the diagnosis of MS.

We have conducted a molecular genetics study in 94 patients from 65 unrelated families with MS. In 44 patients with myotonia congenita (MC) were revealed 26 different mutations in the *CLCN1* gene, in 39 patients with myotonic dystrophy type 1 (DM1) were detected increased number of CTG-repeats (n>50) in the *DMPK* gene and in 8 patients with clinical hyperkalemic periodic paralysis (HYPP) with myotonia - mutations in the *SCN4A* gene.

In the three formed groups, we performed a study of the decrement of compound muscle action potential (CMAP) (50 Hz 200 repetitions): 34 cases of MC, 25 cases of DM1 and 7 cases of HYPP. Decrement of CMAP was observed in all patients with MC and was 68±21%, no significant statistical differences in the values of the decrement between the patients with Thomsen (7cases) and Becker (27cases) myotonias: 74±8% and 67±22% accordingly. In patients with DM1 decrement of CMAP was detected in 15 of 25 patients and was 33±14%. In patients with HYPP decrement was found in one of seven patients and was 34%.

The largest decrement of CMAP allows statistically to distinguish between groups of patients with MC from the DM1 and HYPP (p>0,001).

Statistically significant difference between decrement of CMAP in patients with DM1 and HYPP wasn't established.

P02.177
LMX1B mutations in Nail-Patella Syndrome (NPS)

L. Rocha[1,2], *S. Fernandes*[1], *J. P. Oliveira*[1,2];
[1]Genetics Department, Porto, Portugal, [2]CHSJ, Porto, Portugal.

Introduction: Nail-Patella syndrome (NPS; MIM 161200) is a rare (1/50000 births) autosomal dominant disorder characterized by dysplastic nails, absent or hypoplastic patellae, elbow dysplasia, iliac horns, glomerulopathy, and glaucoma. NPS is caused by mutations in the LMX1B gene (LIM homeobox transcription factor 1-beta), mapped at chromosome 9q34. The main pathogenic mechanism underlying NPS, particularly of the skeletal defects, is the haploinsufficiency of LMX1B.

Material and Methods: Genomic DNA was extracted from 4 patients with the clinical diagnosis of NPS and an unequivocal autosomal dominant pattern of inheritance. The 8 exons of LMX1B were amplified by PCR and sequenced in an ABI Prism 3500 genetic analyzer. MLPA technique (SALSA P289-A1 LMX1B) was used for detection of deletions and/or duplications.

Results: Four different mutations were detected: two nonsense mutations - p.Q60X, on exon 2, and p.C142X, on exon 3; one missense mutation - p.R223Q, on exon 4; and a duplication of exon 3 (dup Ex.3). Mutations p.C142X and dup Ex.3 are novel.
Conclusions: The genetic diagnosis of NPS was confirmed by the identification of a pathogenic LMX1B mutation in all four patients. Three of those mutations are located in the LIM domains (exons 2_4) and remainder in the homeodomain of LMX1B (exons 4_6), the former causing a decrease in transcriptional activity and the latter leading to loss of DNA binding activity.

P02.178

A review of breast cancer risk and female patients with neurofibromatosis type 1 in the West of Scotland.

C. M. Watt[1], *E. McGuire*[2], *N. Bradshaw*[1], *S. Gibson*[1], *M. Longmuir*[1], *D. Meechan*[3], *V. Murday*[1], *L. Snadden*[1], *E. Tobias*[1], *M. Whiteford*[1], *R. Davidson*[1];
[1]*West of Scotland Regional Genetics Service, Glasgow, United Kingdom,* [2]*University of Glasgow, Glasgow, United Kingdom,* [3]*Molecular Genetics Laboratory, Ninewells Hospital, Dundee, United Kingdom.*

Background: The West of Scotland (WoS) Clinical Genetics service received a referral from a general practitioner asking us to meet with a 46 year old woman with neurofibromatosis type 1 (NF1) to discuss her risk of breast cancer and screening requirements.
Anecdotal evidence and case reports have indicated an associated increased risk of breast cancer and NF 1. A 2006 study showed an increased risk of breast cancer in women under 50 years but failed to show significance overall. In 2007 a population based study showed with significance that women with NF 1 below the age of 50 years had a five fold increased risk of breast cancer in the population studied.
It was decided to review a cohort of female patients with NF 1 from the WoS and compare the observed cases of breast cancer in this cohort with expected figures in the expected population.
Methods: The pedigrees of families affected by NF 1 were reviewed, inclusion and exclusion criteria were applied producing a cohort of female patients with know NF 1 and who were 20 years or older. 4 women were excluded due to incomplete information and 26 were under 20 years of age the final cohort included 119 patients. Statistical significance of the results was shown using the Poisson distribution.
Results: The results from this study showed a 4.13 fold risk of breast cancer over all ages and, a 20.8 fold risk less than 50 years of age. These results could prove challenging in genetic counselling.

P02.179

A 19-year-old man with intellectual disability, neurofibromatosis, multiple exostoses, and a paracentric inversion (inv(9)(q12q22.3))

J. Wickert[1], *S. Fuchs*[1], *R. Nguyen*[2], *G. Uyanik*[1], *V. Mautner*[2];
[1]*Institute of Human Genetics, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,* [2]*Department of Neurology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Here, we present a man with neurofibromatosis type 1 (NF1) and multiple hereditary exostoses (HME). The patient is affected by multiple exostoses like benign enchondromata of the tubular bones, multiple cutaneous neurofibromas, axillary and inguinal freckling and café au lait spots. In addition, the patient has a global developmental delay with intellectual disability, a disproportionate short stature associated with macrocephaly, facial dysmorphisms, and shortened extremities with brachydactyly and proximal placement of thumb. A paracentric inv(9)(q12q22.3) was identified by conventional karyotyping and fluorescence in situ hybridization in the index patient. The array-CGH (180K) showed no evidence of a clinically significant deletion or duplication. His 22-year-old sister and the 50-year-old father are also affected by NF1. The heterozygous mutation c.4299insTT in exon 25 of NF1 gene could be detected. Only the index patient and his sister are affected of HME and a disproportionate short stature. The molecular genetic analysis of the EXT1 gene revealed the heterozygous mutation c.1723-1G>T in intron 8. The inversion inv (9)(q12q22.3) was not detected in the lymphocytes of the sister
We report this unusual case of a patient with neurofibromatosis type 1, exostoses, disproportionate stature and profound intellectual disability. NF1 and HME are sufficiently explained by the identification of the heterozygous familial mutations in NF1 and EXT1 genes. However, the profound intellectual disability and facial dysmorphisms are found only in the index patient. Whether the inversion inv(9)(q12q22.3) contributes as another piece of puzzle to the complex phenotype of the index patient is not defined yet.

P02.180

Molecular characterization of two similarly emerging NF1 microdeletions with Oligo-Array-CGH: differentiation of a 66,84-84,42 kb intragenic and a 160,69-178,14 kb contiguous gene deletion in two NF1 patients with different clinical characteristics

U. Heinrich[1], *D. Wahl*[2], *J. Höfele*[1], *H. Klein*[1], *K. Mayer*[1];
[1]*Centre for Human Genetics and Laboratory Medicine, Martinsried, Germany,* [2]*Practice for Genetic Counselling and Psychotherapy, Augsburg, Germany.*

Neurofibromatosis type 1 (NF1) results from microdeletions encompassing the entire NF1 gene and a variable number of flanking genes in 5-10% of patients. Three recurrent microdeletion types have been described: 1.4 Mb type-1, 1.2 Mb type-2, and 1.0 Mb type-3 microdeletions. Usually, a more severe phenotype has been reported in patients carrying genomic microdeletions involving the entire NF1 gene compared to patients with intragenic NF1 mutations.
We demonstrate the results of the molecular genetic analysis in two 2 and 4 year old NF1 patients mainly presenting with multiple café-au-lait-spots and a positive family history in one case. MLPA analysis using Salsa-Kit P081/P082 detected an indistinguishable deletion in both cases of at least 48 kb starting in intron 27b and comprising the 3' terminal half of the NF1 gene including the last but one exon 48. Efforts to specify the deletions applying Salsa P122 NF1-area probemix confined the deletion sizes to a maximum of 579 kb in both cases that remained still indistinguishable. Finally, oligo-array-CGH with the microarray kit 244A resolved a 66,84-84,42 kb intragenic NF1 deletion and a 160,69-178,14 kb gene deletion involving two distally adjacent genes, respectively. Atypical microdeletions less than 1 Mb encompassing the NF1 gene and distally adjacent genes are very rare. We want to highlight the clinical manifestations in our patients with regard to both deletion types identified. This study confirms that array-CGH is a sensitive approach for accurate characterization of NF1 microdeletions to differentiate between the types of microdeletions with respect to patients' follow-up care.

P02.181

Nonfracture Osteogenesis imperfecta (or another collagenopathy ?) in a 2 year old Russian boy with a mutation in the COL1A2 gene

L. M. Graul-Neumann[1], *C. Ehlers*[2], *G. C. Schwabe*[3];
[1]*Institute of Medical and Human Genetics, Berlin, Germany,* [2]*IMitteldeutscher Praxisverbund, Humangenetik, Dresden, Germany,* [3]*Children's Hospital, Pediatric Hematology & Oncology, HELIOS Klinikum Berlin-Buch, Berlin, Germany.*

Case Report:
Our patient is the second child of healthy parents.
He had congenital clubfeet, a unilateral hernia inguinalis, a large frontal fontanel, frontotemporal alopecia, blue sclerae, normal teeth.
Clubfeet were present at birth, but so far no osseous fractures have been reported.
At the age of 2 years, height and weight were at P3, OFC at P97 and hypermobility of the hip joints was evident. Serum levels of calcium, phosphate and alkaline phosphatase were normal.
Radiographs showed wormian bones, normal skeletal mineralisation.
As some of the clinical features were suspicious of OI we initiated a molecular analysis. In exon 23 of the *COL1A2* gene a *de novo* not yet described heterozygous missense mutation c.1316G>A (p.Gly439Asp) was identified.
Comment:
The mutation described here is characteristic for osteogenesis imperfecta as Glycin substitutions are typical for OI. Comparable mutations have only been twice recorded in Ehlers-Danlos syndrome - but the published mutations were all located in exon 8 and not in exon 23 as in our case (LOVD; submitted by S. Symoens, Ghent University, Belgium). Collagen structural defects, which are usually glycine substitutions or exon skipping defects, act in a dominant negative fashion. They usually result in a phenotype that ranges from lethal to moderately severe depending on the collagene chain affected, its location within the chain, and the specific amino acid substituted.
In summary, the patient presented here exhibits particular phenotype with only mild osseus involvement, some features reminiscent of a connective tissue disease, alopecia and a novel *COL1A2* mutation.

P02.182

Visual Function and Ocular Manifestations in Noonan Syndrome

R. Radhakrishnan[1], *K. Rauen*[2], *D. Orel-Bixler*[3], *S. P. Shankar*[4];
[1]*Cornell University, Ithaca, NY, United States,* [2]*University of California,, San Francisco, CA, United States,* [3]*Berkeley Optometry, University of California,, Berkeley, CA, United States,* [4]*Emory University School of Medicine, The Department of Human Genetics, Atlanta, GA, United States.*

Purpose of study: To determine visual function and characterize ophthalmic manifestations in Noonan syndrome.

Introduction: Noonan syndrome is a developmental syndrome caused by heterozygous mutations in the genes PTPN11, SOS1, RAF1, NRAS, CBL, or KRAS. It is inherited in an autosomal dominant manner. Clinical features in this syndrome include congenital heart defects, short stature, developmental delay of variable degree and ocular involvement.

Methods: Thirty individuals were studied in the Berkeley and Chicago RAS/MAPK symposium by visual function assessment, slit lamp exam and dilated fundus exam.

Results: The Ocular findings in 30 Noonan syndrome patients have been tabulated below. We noted the following parameters.

Conclusion: Ophthalmic manifestations are commonly noted features in Noonan syndrome. Most individuals have good visual function with majority having stereopsis. Annual eye exams are recommended and necessary to correct refractive errors, prevent amblyopia and in monitoring for intracranial complications such as hydrocephalus or rarely intracranial tumors.

Results of Ocular Findings in Noonan Syndrome

Number	Parameters	Results	n=30

Atrioventricular canal defect in patients with RASopathies

F. R. Lepri[1]*, M. Digilio*[1]*, M. Dentici*[1]*, A. Henderson*[2]*, A. Baban*[1]*, M. Roberti*[1]*, R. Capolino*[1]*, P. Versacci*[3]*, C. Surace*[1]*, A. Angioni*[1]*, M. Tartaglia*[4]*, B. Marino*[3]*, B. Dallapiccola*[1]*;*
[1]*Medical Genetics, Cytogenetics, Pediatric Cardiology, Bambino Gesù Pediatric Hospital, IRCCS, ROME, Italy,* [2]*2Northern Genetics Service, Newcastle upon Tyne Hospitals, Newcastle, United Kingdom,* [3]*Pediatric Cardiology, Department of Pediatrics, Sapienza University, ROME, Italy,* [4]*Department of Hematology, Oncology and Molecular Medicine, Istituto Superiore di Sanità, ROME, Italy.*

Congenital heart defect (CHD) affects 60-85% of patients with RASopathies. Pulmonary valve stenosis (PVS) and hypertrophic cardiomyopathy (HCM) are the most frequent anomalies, although the spectrum of cardiac defects is wider. We analysed the clinical and molecular characteristics of atrioventricular canal defect (AVCD) in patients with mutations affecting genes in the RAS/MAPK pathway. Between 2002 and 2011, 101 patients with cardiac defect and a molecularly confirmed RASopathy were collected. Complete or partial (including cleft mitral valve) AVCD was diagnosed in 8/101 (8%) patients, including 7/8 with *PTPN11* gene mutations, 1/8 with a *RAF1* gene mutation. The only recurrent mutation was *PTPN11* c.124A>G (Thr42Ala). AVCD was partial in 6 cases, complete in one; in 4 was associated with other cardiac defects, including subvalvular aortic stenosis, mitral valve anomaly, PVS, and HCM. The associated cardiac defects were mutation-specific. Maternal segregation was observed in two families with *PTPN11* mutations and in one with *RAF1* mutation. CHDs in the affected relatives were discordant in families with *PTPN11* mutations, and concordant in the mother-sib pair with *RAF1* mutation. This study recommend to check Noonan syndrome features in syndromic patients with AVCD. Although mutations are heterogeneous, partial AVCD, and its association with left-sided obstructions, PVS and HCM must be considered clinical markers of RASopathies, often displaying genotype-phenotype correlation. Familial segregation of AVCD should be considered in the genetic counselling of families with RASopathies.

P02.185
Mutations in *PTPN11*, *SOS1* and *RAF1* genes and clinical characteristics of Noonan syndrome patients.

M. Gos[1]*, J. Klapecki*[1]*, R. Frazao*[2]*, J. Majewski*[2]*, A. Abramowicz*[1]*, A. Kutkowska-Kazmierczak*[1]*, K. Szczałuba*[1]*, P. Lepage*[2]*, E. Obersztyn*[1]*, J. Bal*[1]*, E. Bocian*[1]*;*
[1]*Institute of Mother and Child, Warsaw, Poland,* [2]*McGill University and Genome Quebec Innovation Centre, Montreal, QC, Canada.*

Short stature, congenital heart defects, craniofacial dysmorphia and skeletal defects (thorax deformation) are the main clinical features typical for Noonan syndrome (NS). The disease is caused by mutations in genes encoding proteins of RAS/MAPK pathway, mainly in *PTPN11*, *SOS1* and *RAF1* genes. Together, 171 patients with clinical suspicion of NS were examined by an experienced clinical geneticist and the molecular analysis of *PTPN11*, *SOS1* and *RAF1* genes was performed. The pathogenic mutations in *PTPN11*, *SOS1* and *RAF1* genes were found in 65 (38.0%), 14 (8.2%) and 13 (7.6%) patients, respectively.

The clinical analysis of NS patients revealed that there is significant variation in disease phenotypic expression depending on the mutation presence in specific gene. The short stature was statistically more frequent in patients with mutations in *RAF1* and *PTPN11* (76.9% and 69.2%) than in *SOS1* (42.9%; $p<0.05$). Pulmonary valve stenosis was present in 30 (46.2%) patients with mutation in *PTPN11*, 7 (50.0%) in *SOS1* and 5 (38.5%) in *RAF1*, although the observed differences were not statistically significant. The hypertrophic cardiomyopathy and strabismus were more common in patients with mutated *RAF1* (46.2% and 38,5% vs. 2.7% and 12.3% for *PTPN11* and *SOS1* together, $p<0.05$). The delayed psychomotor development, speech delay and cryptorchidism were more frequently observed in patients with *PTPN11* and *SOS1* mutations (45.2%, 21.9% and 65.1% vs. 15.4%, 0% and 16.7% for *RAF1*, $p<0.05$). Our results confirm a significant correlation between the NS-causing mutation in specific gene and clinical symptoms of the disease.

Supported from NCN research project no. DEC-2011/01/D/NZ5/01347.

P02.186
Phenotype-genotype associations and significant differences between *PTPN11* and *SOS1* mutated patients with Noonan syndrome

***E. Ciara**, M. Kugaudo, S. Łuczak, M. Pelc, A. Tańska, D. Jurkiewicz, D. Piekutowska-Abramczuk, P. Kowalski, M. Borucka-Mankiewicz, J. Trubicka, A. Jezela-Stanek, M. Jędrzejowska, A. Cieślikowska, D. Gieruszczak-Białek, A. Skórka, K. Chrzanowska, M. Krajewska-Walasek;*
The Children's Memorial Health Institute, Warsaw, Poland.

Noonan syndrome (NS) is an autosomal dominant disorder caused by heterozygous gain of function mutations in various genes (mainly *PTPN11*, *SOS1*, *RAF1* and *KRAS*) encoding proteins of the Ras-MAPK signaling pathway. Here we report genotype-phenotype correlation in a well-characterized cohort of 63 Polish patients affected by NS. We identified pathogenic mutations in *PTPN11* for 32 (51%), *SOS1* for 12 (19%), *RAF1* for 2 (3%) and *KRAS* for 1 (2%) unrelated patients. Our total mutation detection rate was 75%. All patients presented phenotype typical for NS, however we observed differences in the prevalence of some features depending on the mutated gene. Ptosis, macrocephaly, hypotonia, hyperkeratosis, sparse eyebrows, mitral valve anomalies and renal defects were significantly more prevalent among individuals with *SOS1* mutations. Whereas short stature, pulmonic stenosis, atrial septal defect, sparse hair and skin pigmentation were significantly more frequently associated with presence of *PTPN11* mutations Two characteristic NS features, such as mental retardation and hypertrophic cardiomyopathy were rarely associated with *PTPN11* or *SOS1* mutations, while were observed in our *RAF1* cases. Additionally, we revealed that 10 affected mothers and one affected father manifested a milder phenotype than their sick children.

The study was supported by National Science Centre Project no. PB0056/B/P01/2008/35 and by Children's Memorial Health Institute Project no. 190/08.

P02.187
Extreme clinical variability in Noonan-like syndrome with loose anagen hair due to the Ser2Gly SHOC2 mutation

G. Baldassarre[1]*, C. Rossi*[2]*, M. Tartaglia*[3]*, M. Silengo*[1]*, G. B. Ferrero*[1]*;*
[1]*Department of Pediatrics, Torino, Italy,* [2]*Department of Medical Genetics, Bologna, Italy,* [3]*Department of Hematology, Oncology and Molecular Medicine, Roma, Italy.*

Noonan syndrome (NS) belongs to a group of developmental disorders due to deregulation of the RAS/MAPK pathway named RASopathies, including Cardiofaciocutaneous (CFCS), Costello (CS), LEOPARD (LS), Neurofibromatosis type I (NF1) and Legius syndrome. Some of these conditions, as CS, NF1 and Legius syndrome, are gene specific being caused by mutations in HRAS, NF1 and SPREAD1 genes respectively; the others syndromes are characterized by a considerable molecular overlapping. Two additional NS-like conditions have been recently described, caused by mutations in CBL and SHOC2 genes. In particular, a specific SHOC2 gene mutation (4 A>G predicting the Ser2Gly aminoacid substitution), is responsible for a distinctive condition "Noonan-like syndrome with loose anagen hair (NS-LAH)", characterized by a specific ectodermal phenotype. Here we report two cases of NS-LAH SHOC2 mutated patients revealing the extreme clinical variability of this condition. The first patient presented common NS features at birth with typical facial dysmorphisms and hypertrophic cardiomyopathy. However, he had a dramatic clinical evolution in the first months of life rather resembling that typical of CS. Central nervous system (CNS) involvement with drug-resistant epilepsy and severe developmental delay occurred associated with significant growth delay and dystrophyc appearance. The second patient presented a distinctive NS-LAH phenotype at birth, without CNS anomalies or cardiac defects documented in the 18 months clinical follow-up. These two cases represent the mild and the severe end of the same phenotypic spectrum, demonstrating that SHOC2 genotype-phenotype correlation is more complex than previously thought, and preventing the possibility of a genotype-based prognosis.

P02.188

Boy with Noonan syndrome with multiple giant cell lesions (NS/MGCL) and review of the literature

O. Bartsch[1]*, W. Coerdt*[2]*, W. Wagner*[3]*, J. Karbach*[1]*;*
[1]*Institut für Humangenetik, Universitätsmedizin der Johannes Gutenberg-Universität Mainz, Mainz, Germany,* [2]*Institut für Pathologie, Universitätsmedizin der Johannes Gutenberg-Universität Mainz, Mainz, Germany,* [3]*Klinik für Mund-, Kiefer- und Gesichtschirurgie, Universitätsmedizin der Johannes Gutenberg-Universität Mainz, Mainz, Germany.*

Noonan syndrome with multiple giant cell lesions (NS/MGCL) was recently shown to be part of the phenotypic spectrum of the syndromes of the RAS/MAPK pathway. We report on a 13-year-old boy with a typical phenotype of Noonan syndrome including atrial septal defect, pulmonic stenosis, short stature, pectus excavatum, and multiple giant cell lesions of both jaws, and a *de novo* mutation in exon 3 of *PTPN11*, c.236A>G (predicting Q79R). *PTPN11* mutations are the most frequent cause of Noonan syndrome and Q79R is a well-described recurrent mutation. Including this patient, 24 subjects with molecularly confirmed NS, LEOPARD or CFC/MGCL syndrome have been reported to date. Of these, 21 subjects (87.5%) had *PTPN11*, *SOS1* or *RAF1* mutations and three (12.5%) had *BRAF* or *MAP2K1* mutations, confirming that MGCL is a rare complication of the deregulated RAS/MAPK pathway. The lesions of the mandible and to a lesser extent of the maxilla were first noted between ages 2 and 19 years (median 11 years) and were combined with facial asymmetry in 5/24 patients (21%). With one exception (mutation not reported), all 24 subjects demonstrated known mutations in the *PTPN11, SOS1, RAF1, BRAF,* and *MAP2K1* genes that were previously reported with RASopathies without MGCL.

P02.189

Widening the phenotypic spectrum of 5q35.3 microduplication encompassing *NSD1*: description of two more patients with the reversed Sotos syndrome phenotype

H. Gaspar*, B. Maas, A. Jauch, K. Hinderhofer, J. W. G. Janssen, U. Moog;*
Institute of Human Genetics, Heidelberg, Germany.

Background: Loss-of-function mutations in *NSD1* and 5q35 microdeletions encompassing *NSD1* are a major cause of Sotos syndrome which is characterized by overgrowth, macrocephaly, characteristic facies and other features. Among several patients with partial trisomy 5q, five patients with confirmed microduplication of the 5q35.3 region including *NSD1* have been described. They show a 'reversed phenotype' of Sotos syndrome with microcephaly, short stature and mental retardation. We here report on two siblings with interstitial duplication 5q35, widening the phenotypic spectrum.

Patients: Both siblings had microcephaly, behavioral problems with agitation and lack of social distance, and a distinctive facial phenotype with thin upper lip, flat philtrum, short palpebral fissures and epicanthic folds. The 13-year-old girl showed mild to moderate mental retardation, short stature and cataracts. Her 15-year-old brother had learning problems with an IQ of 78. His length was within the lower normal range. The biological parents were neither available for clinical examination nor for testing.

Methods: Besides chromosomal analysis (with a resolution of about 550 bands) we performed SNP-array analysis (Affymetrix® Cytogenetics Whole-Genome 2.7M) and FISH (using a specific probe for NSD1).

Results: Chromosomal analysis was normal in both siblings. Molecular karyotyping in the sister revealed a 1.6 Mb interstitial duplication of 5q35.2-q35.3 containing 40 RefSeq genes including *NSD1* and the duplication could be confirmed in both siblings by FISH analysis. The siblings illustrate intrafamilial variability of the reversed Sotos syndrome phenotype.

Center for Human Genetics, CHU Sart-Tilman, University of Liège, Liège, Belgium.

Bladder extrophy (BE) is a complex congenital anomaly,part of the clinical spectrum of the bladder extrophy-epispadias complex (BEEC).The BEEC represents a spectrum of urological abnormalities in which part of all the distal urinary tradt fails to close and is exposed to the outer abdominal wall.Previously,nine cases of classical extrophy of the bladder with underlying microduplication 22q11.2 have been reported (Lundin et al.2010;Draaken et al.,2010;Ludwig et al.,2011).A 10-year-old boy was referred for genetic evaluation for psychomotor retardation.He had a bladder extrophy at birth.He was adopted.He showed short stature,scar of repair of bladder extrophy,micropenis.Multiple ligation-dependent probe amplification(MLPA) analysis performed using the SALSA MLPA KIT P250 DiGeorge (MRC-Holland,Amsterdam,Netherlands)detected a micro-duplication 22q11.2.The duplication was confirmed in FISH and array-CGH.The array-CGH (Affymetrix Cytogenetics Whole-Genome,2,7 M Array) identified a duplication of 2419 kb in the 22q11.2 regionIn conclusion,this report extends the phenotypic spectrum of bladder extrophy in microduplication 22q11.2 and may point to possible gene(e) located in 22q11.2 playing a putative role in urogenital development.It provides further evidence of genotype-phenotype correlation

P02.191

Two years experience of Fibular Aplasia, Tibial Campomelia, and Oligosyndactyly

O. Sezer[1]*, I. Gebesoglu*[2]*, E. Gokce*[3]*, S. Gunes*[4]*;*
[1]*Department of Medical Genetics, Samsun Maternity and Children Diseases Hospital, Samsun, Turkey,* [2]*Department of Pediatrics, Samsun Maternity and Children Diseases Hospital, Samsun, Turkey,* [3]*Department of Radiology, Samsun Maternity and Children Diseases Hospital, Samsun, Turkey,* [4]*Department of Medical Biology, Faculty of Medicine, Ondokuz Mayis University, Samsun, Turkey.*

Fibular Aplasia, Tibial Campomelia, and Oligosyndactyly (FATCO) syndrome (MIM#246570) is an extremely rare syndrome related with shortening and anterior bowing of the lower limb at the distal third of the tibia overlying soft tissue dimpling, oligodactyly of the foot, and oligosyndactyly of the hand, is associated with autosomal dominant inheritance/sporadic. So far no disease gene/genes were identified. According to our knowledge this is the 11th case of FATCO described in literature and 3rd case in Turkey. We presented two years of experiences of FATCO syndrome.

The patient was born at term with uneventful pregnancy and delivery. He was the first child of healthy parents, 17 years old mother and 25 years old father. They were non-consanguineous, both born in same small town.

The pregnancy was follow-up regularly. During follow-up pregnancy of mother triple screening test risk was low. Fetal ultrasonography showed echogenicity of the tibial osseous and shortening of both tibias during 21st, 25th and 27th weeks, respectively. The right upper extremity had evaluated in normal range and the left upper extremity could not be evaluated due to fetal position. His birth weight and head circumference was normal but length was short, 46 cm (<3 percentile). Our case demonstrated major common findings of FATCO syndrome.

We will discuss the perinatal and postnatal futures of the propositus during gestation, newborn and two years old period with previous patients in the literature.

P02.192

Ohdo syndrome Maat-Kievit-Brunner type is caused by mutations in *MED12*

A. T. Vulto-van Silfhout[1]*, A. Hoischen*[1]*, B. W. M. van Bon*[1]*, C. Gilissen*[1]*, F. Gao*[2]*, J. M. Spaeth*[2]*, B. C. Hamel*[1]*, T. Kleefstra*[1]*, W. M. Nillesen*[1]*, H. G. Yntema*[1]*, H. van Bokhoven*[1]*, B. B. A. de Vries*[1]*, H. G. Brunner*[1]*, T. G. Boyer*[2]*, A. P. M. de Brouwer*[1]*;*
[1]*Department of Human Genetics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [2]*Department of Molecular Medicine/Institute of Biotechnology, University of Texas Health Science Center, San Antonio, TX, United States.*

Ohdo syndrome [MIM 249620] is characterized by intellectual disability and the typical facial features including blepharophimosis. Clinically the blepharophimosis-intellectual disability syndromes have been classified in five distinct subgroups: del(3)(pter) type, Ohdo type, Say-Barber-Biesecker-Young-Simpson (SBBYS) type, Verloes type, and Maat-Kievit-Brunner (MKB) type. Here, we performed exome sequencing in two families with two affected males with Ohdo syndrome MKB type. Two novel missense mutations were identified in Mediator of RNA polymerase II transcription subunit 12 (*MED12*; NM_005120.2), p.(Arg1148His) and p.(Ser1165Pro), that segregated with the disease phenotype. Upon subsequent analysis of an additional cohort of seven single male patients with the broad definition of Ohdo syndrome, we detected one additional *de novo* missense change in *MED12*: p.(His1729Asn) in a patient with the MKB type. The occurrence of three different hemizygous missense mutations in three unrelated families with Ohdo syndrome MKB type, suggests that *MED12* is the causative gene for this Ohdo syndrome subtype.

Previously, three other specific missense mutations in *MED12* have been described in patients with FG syndrome and Lujan-Fryns syndrome. Our patients clearly differ from these two syndromes as they have the classical Ohdo features ptosis and blepharophimosis, while the high palate and high, prominent forehead as seen in Lujan-Fryns and FG syndrome and the typical ears in FG syndrome are less apparent. However, in adulthood the facial appearance of Ohdo patients type MKB becomes more coarse, and the distinction from FG syndrome becomes less apparent. Further studies are necessary to determine the exact genotype-phenotype correlations in *MED12* mutations.

P02.193

Two novel GJA1 missense mutations in patients presenting with oculodentodigital dysplasia

A. Jamsheer[1,2], *A. Sowinska*[1,2], *A. Latos-Bielenska*[1,2];
[1]*Department of Medical Genetics, University o Medical Sciences, Poznan, Poland,* [2]*Center for Medical Genetics GENSIS, Poznan, Poland.*

Oculodentodigital dysplasia (ODDD) also known as oculodentoosseus syndrome (OMIM #164200) is a rare congenital, predominantly autosomal dominant disorder that comprises craniofacial, ocular, dental, and digital abnormalities. The syndrome is caused by GJA1 mutations. The clinical phenotype of ODDD involves characteristic facial dysmorphic features, ocular findings (microphthalmia, microcornea, glaucoma), syndactyly type III of the hands (fusion between fingers 4 and 5), phalangeal abnormalities, diffuse skeletal dysplasia, enamel dysplasia, and hypotrichosis. In two unrelated patients presenting with the typical clinical symptoms of ODDD, we demonstrated two different novel missense mutations of the GJA1 gene: c. 257C>A (p.S86Y) and c.317T>G (p. L106R). Our report expands the known mutational spectrum of the GJA1 gene and provides evidence on the importance of this highly conserved amino acid residues for the native functioning of the corresponding protein.

P02.194

Familial Osteofibrous Dysplasia with Pectus Excavatum: A Phenotypic Evaluation

M. J. Gray[1], *S. Manners*[2], *H. Crawford*[2], *L. McEntee*[2], *D. Markie*[3], *S. P. Robertson*[1];
[1]*Department of Paediatrics and Child Health, University of Otago, Dunedin, New Zealand,* [2]*Department of Orthopaedic Surgery, Starship Children's Hospital, Auckland, New Zealand,* [3]*Department of Pathology, University of Otago, Dunedin, New Zealand.*

Four generations of a New Zealand family have autosomal dominant inheritance of bilateral congenital bowing of the tibia, hypoplastic fibula and pectus excavatum. The first three generations (reported in 1978) had several incidences of radiolucent lesions and pseudoathrosis of the tibia following fracture that required surgical intervention. The two affected members of the fourth generation have not sustained either fractures of the tibia or radiolucent lesions, but anterolateral bowing of the tibia was a persistent feature. One of these two individuals presented with thoracic scoliosis in addition to the tibial and pectus malformation. Congenital bowing of the tibia with the presence of radiolucent lesions or pseudoathrosis in this family is reminiscent of osteofibrous dysplasia (OFD). OFD can occasionally exhibit familial aggregation as in this family but is usually a unilateral, sporadic condition. Sporadic OFD presents with the same phenotype of anterolateral bowing, radiolucent lesions, pseudoathrosis upon fracture and apparent healing of bowing and/or lesions as skeletal maturity proceeds. The additional phenotypic features are suggestive of a mild anomaly in skeletal development that is especially apparent in the tibia. This family may inform the genetic basis of OFD and allied bone neoplasms such as adamantinoma and non-NF1 tibial pseudoarthosis.

P02.195

A novel C-terminal stop mutation in *COL1A2* in a family with moderate osteogenesis imperfecta

M. Reuter[1], *C. Marschall*[2], *C. Thiel*[1], *A. Reis*[1];
[1]*Institute of Human Genetics, Erlangen, Germany,* [2]*Zentrum für Humangenetik und Laboratoriumsmedizin, Martinsried, Germany.*

Osteogenesis imperfecta is a connective tissue disorder, the vast majority caused by mutations in *COL1A1* or *COL1A2*-genes. These genes encode for collagen 1, which consists of two α1- and one α2-chains forming a triple-helical structure. The spectrum of clinical severity is wide, ranging from mild predisposition to fractures to perinatal lethality. We describe a 24-year-old female patient with postnatal femur fracture, blue sclerae, and approximately 30 fractures until her 16th year of life. Her father had blue sclerae and about 25 fractures between his 8th and 20th year of life. Molecular analysis revealed a heterozygous nonsense mutation c.4060C>T (p.Gln1354X) within the last exon of the *COL1A2*-gene in both patients. Such mutations are rare and the clinical phenotype has so far not been characterized. Nonsense or frameshift mutations in *COL1A1* typically lead to mRNA-decay and haploinsufficiency of the affected protein, resulting in mild forms of the disease. Nonsense mutations in *COL1A2* which lead to mRNA decay do not cause osteogenesis imperfecta. Missense mutations in *COL1A1* or *COL1A2* that affect triple helix formation lead to severe forms of the disease, attributed to a dominant negative effect of the dysfunctional protein. Nonsense mutations in the last exon, as it is found in our patients, are predicted not to result in mRNA decay but in the generation of a truncated protein. The respective domain is considered to be important for the assembly of the three chains. A dominant negative effect affecting a domain beyond the triple helix could account for the moderate clinical phenotype.

P02.196

Recurrence of osteogenesis imperfecta: a case report

A. Kondo, *J. Nishikata, K. Mitsuzuka, S. Sato, H. Yokoyama, M. Mizoguchi, H. Ishimoto, S. Izumi;*
Tokai University, Isehara, Japan.

Perinatal lethal osteogenesis imperfect (OI) is the result of heterozygous mutations of the COL1A1 and COL1A2 genes. Point mutations resulting in the substitution of Gly residues in Gly-X-Y amino acid triplets of the triple helical domain of the alpha 1(I) or alpha 2(I) chains are the most frequent mutations. They interrupt the repetitive Gly-X-Y structure that is mandatory for the formation of a stable triple helix. Most babies have their own private de novo mutation. However, the recurrence rate is about 7% owing to germline mosaicism in one parent.

29y/o lady had recurrence of OI. Her first fetus was diagnosed as OI at 21 weeks gestation and she declined. She referred to us for her second pregnancy because of ultrasound findings. Short long bones with fractures, small chests and soft skulls were significant and the fetus was also suspected OI at 19 weeks gestation. Type II OI was suspected with these findings.

Her previous doctor explained her it would not recur because most cases of OI type II represent autosomal recessive traits. However, there is another possibility with germline mosaicism and this case could be in this group. In addition, similar extremely severe types of OI, Types VII and VIII, can be caused by recessive mutations to other genes.

It is very important to make an accurate diagnosis to plan future pregnancy. Hence genetic test for OI patients is recommended even if it is difficult to perform genetic test for every patients with OI in Japan.

P02.197

A new overgrowth syndrome with cranio-facial dysmorphisms, complex cardiac abnormalities, progressive scoliosis and mild cognitive impairment

M. Dentici[1], *M. Tartaglia*[2], *B. Dallapiccola*[1];
[1]*Bambino Gesú Pediatric Hospital, IRCCS, Rome, Italy,* [2]*Dipartimento di Ematologia, Oncologia e Medicina Molecolare, Istituto Superiore di Sanità, Rome, Italy.*

We report on two sisters of 14y6m and 11y old, born from healthy non consanguineous parents, presenting strictly overlapping clinical features. All auxological parameters were above 97th centile in both siblings. Facial dysmorphisms included flat face, palpebral fissures slant down, hypertelorism, deep set eyes, thick eyebrows, flat nasal bridge, prominent naso-labial folds, long philtrum, low set ears, open mouth appearance and multiple oral frenula. Cardiac evaluation showed DIA II with left-right shunt in both sisters while the younger also presents restrictive interventricular septal defect, right branch block, left ventricular hypertrophy and at 9 years of age she was diagnosed with mixoma which was surgically removed. Skeletal abnormalities included short neck, progressive severe scoliosis that requires the use of corset, brachymetacarpia of digit 5 and hallux valgus. Brain MRI displayed abnormality of white matter and asymmetry of the lateral ventricles. Psychomotor development was mildly delay. High-resolution array- comparative genomic hybridization (CGH) analyses was performed on the older sibling and did not disclose any disease-causing genomic rearrangement. According to our knowledge the siblings don't fit into any known disorder. The clinical history of the siblings was uploaded to the the web-based Dysmorphology Diagnostic System (DDS) developed by DYSCERNE, a European network of Centres of Expertise in dysmorphology (DG Sanco- Project:

2006122). The DDS experts' panel discussed over differential diagnosis and we concluded that the present siblings are likely affected by a previously undescribed autosomal recessive disorder. Exome sequencing and filtering the results based on a hypothesis-driven strategy is currently undergoing.

P02.198

Papillon-Lefevre syndrome and *GJB2* associated hearing loss in two sibs

B. F. Stadheim[1], *A. S. Rossow*[2], *J. C. Sitek*[1], *T. E. Prescott*[1];
[1]*Oslo University Hospital, Oslo, Norway,* [2]*TAKO centre, Lovisenberg Diakonale Hospital, Oslo, Norway.*

Papillon-Lefevre syndrome (PLS, OMIM #245000) is an extremely rare autosomal recessive disorder associated with mutations in *CTSC* (chromosome 11q14.2). Palmo-plantar hyperkeratosis beginning in early childhood is the hallmark of severe disease. The disorder is most often diagnosed by dentists, however, because of severe painful progressive periodontal disease with premature loss of teeth which affects both primary and secondary dentition. Pyogenic liver abscesses, presumably a consequence of neutrophil dysfunction, have been reported. Systemic retinoids, especially acitretin, can be very effective in treating the skin lesions and may have some effect on the periodontal manifestations. Dental implants may be an option.

Mutations in *GJB2* (chromosome 13q12.11) are a cause of autosomal recessive non-syndromic mild to profound sensorineural hearing impairment which is usually congenital (OMIM #220290). Estimated prevalence in the general population is 14:100,000.

We present a brother and sister who both have molecularly confirmed PLS as well as *GJB2* associated hearing loss. Seven of nine surviving sibs have neither disorder. Three sibs died of unknown cause in infancy. The parents, originally from Somalia, are not consanguineous by history. Both teenagers presented with severe periodontal disease and palmo-plantar hyperkeratosis interfering with mobility and sleep. The boy is deaf; the girl has minimal residual hearing

This case reminds us that treatment and follow-up can be significantly influenced by making the correct diagnosis of a rare disorder and that two monogenetic conditions occasionally co-occur

P02.199

CYP2C9 and VKORC1 polymorphisms influence the warfarin dose adjustment during initial anticoagulation and follow-up of 360 days

P. C. J. L. Santos[1], *C. L. Dinardo*[1], *I. T. Schettert*[1], *R. A. G. Soares*[1], *L. Kawabata-Yoshihara*[2], *I. M. Bensenor*[2], *P. A. Lotufo*[2], *J. E. Krieger*[1], *A. C. Pereira*[1];
[1]*Laboratory of Genetics and Molecular Cardiology, Heart Institute (InCor), University of Sao Paulo, Sao Paulo, Brazil,* [2]*University Hospital of the University of Sao Paulo, Internal Medicine Division, Sao Paulo, Brazil.*

Background: Warfarin is an anticoagulant that has been the standard to prevent and treat thromboembolism and, genotypic variations in the CYP2C9 and VKORC1 have been reported to predict dosing. Objectives:As an initial step towards clinical pharmacogenetic implementation, the main aim of this study was to determine whether CYP2C9 and VKORC1 polymorphisms influence the warfarin dose adjustment during initial anticoagulation and follow-up of 360 days. Methods: Two hundred six patients who were beginning warfarin therapy were selected. They were assessed with general and clinical characteristics, response to therapy followed on days 7-10, 30, 60, 180, 360, and adverse events. Results: During 360 days, the total dose variation was associated with predicted metabolic phenotypes according to CYP2C9*2 and CYP2C9*3 (extensive metabolizer (EM): +1.7±1.5 mg/week and intermediate or poor metabolizers (IM+PM): -5.5±2.5 mg/week; p= 0.03, adjusted for covariates). Dose variation during first month was also associated. Patients carrying VKORC1 and CYP2C9 variants presented lower required dose compared to patients carrying wild-type genotypes (p= 0.04 and p= 0.03, respectively). Conclusions: This genetic information is important in the initial anticoagulation dosing and during treatment maintenance. In this scenario, the present study could help to design programs towards individualization of warfarin therapy in the Brazilian population.

P02.200

Dosage-sensitive network in polycystic kidney and liver disease: Multiple mutations cause severe hepatic and neurological complications

J. Kleffmann[1], *V. Frank*[2], *C. Roth*[1], *H. J. Bolz*[2], *A. Ferbert*[3], *C. Bergmann*[2];
[1]*Department of Neurosurgery, Klinikum Kassel, Kassel, Germany,* [2]*Bioscientia Center for Human Genetics, Ingelheim, Germany,* [3]*Department of Neurology, Klinikum Kassel, Kassel, Germany.*

Autosomal dominant polycystic kidney disease (ADPKD) is one of the most common genetic disorders. Most elderly patients also show liver cysts. Polycystic liver disease (ADPLD) can also occur isolated, but may also encompass kidney cysts. Variable disease expression even in the same family is incompletely understood. ADPKD and ADPLD overlap not only clinically, but also genetically and functionally. Both genes known for ADPLD, *PRKCSH* and *SEC63,* encode proteins that are involved in posttranslational translocation and quality control of proteins (such as the ADPKD proteins). We describe a family with liver and kidney cysts in which the much more severely affected index patient harbours a total of four mutant alleles in genes for ADPKD and ADPLD with massive hepatic and neurovascular complications leading to stroke at the age of 38. All other affected family members displayed a mild phenotype with practically no disease burden and a few liver and kidney cysts to varying degrees. In line with recent functional data, we postulate a dosage-sensitive, tissue-dependent network for polycystic liver and kidney disease in which additional mutational hits exert an aggravating effect and contribute to earlier and more severe disease expression. This concept may describe a general principle for the modification of disease expression and demonstrates how trafficking and quality control of proteins matter in human disease.

P02.201

Polycystic kidney disease (ARPKD/ADPKD) gets complex: Genetic network and mutations in multiple cilia-related genes

V. Frank[1], *M. Kuhn*[1], *T. Eisenberger*[1], *H. Fehrenbach*[2], *L. Pape*[3], *K. Häffner*[4], *S. Weber*[5], *J. Gellermann*[6], *M. Schröder*[7], *K. Latta*[7], *S. Berland*[8], *T. Fiskerstrand*[8], *K. Zerres*[9], *H. J. Bolz*[1], *C. Bergmann*[1,9];
[1]*Bioscientia Center for Human Genetics, Ingelheim, Germany,* [2]*Department of Pediatrics, Children´s Hospital Memmingen, Memmingen, Germany,* [3]*Department of Pediatric Nephrology, Hepatology and Metabolic Diseases, Hannover Medical School, Hannover, Germany,* [4]*Department of Pediatrics and Adolescent Medicine, University Hospital Freiburg, Freiburg, Germany,* [5]*Department of Pediatric Nephrology, University Hospital Essen, Essen, Germany,* [6]*Department of Pediatric Nephrology, Charité Berlin, Berlin, Germany,* [7]*Department of Pediatrics, Clementine Children´s Hospital, Frankfurt, Germany,* [8]*Department of Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, Norway,* [9]*Department of Human Genetics, RWTH Aachen University, Aachen, Germany.*

Polycystic kidneys paved the way for elucidation of cilia-related disorders and notably most ciliopathies have a renal cystogenic component. Autosomal dominant polycystic kidney disease (ADPKD) is one of the most common Mendelian disorders with a prevalence of 1:500-1000 and typically a late-onset disease caused by mutations in *PKD1* or *PKD2*. About 2% of ADPKD patients show an early and severe phenotype with considerable perinatal morbidity and mortality that can be clinically indistinguishable from the recessive form of polycystic kidney disease (ARPKD) caused by *PKHD1* mutations. We demonstrate severely affected PKD patients who carry, in addition to their expected familial germline defect, further mutations that are likely to aggravate the phenotype. We also show that polycystic kidney disease may also be mimicked by mutations in *HNF1ß* and genes typically causing other ciliopathies, such as Nephronophthisis and Meckel syndrome. Due to these aspects, we established a novel genetic testing approach based on Next-Generation Sequencing (NGS) that allows simultaneous investigation of all PKD and other ciliopathy genes.

P02.202

Pre and post-axial polydactyly caused by a novel dominant GLI3 mutation in a large kindred

M. Volodarsky, *O. Birk*;
Ben-Gurion University of the Negev, Beer-Sheva, Israel.

A large Jewish Moroccan kindred presented with 12 cases of isolated polydactyly. Affected individuals had either pre-axial, post-axial or combined polydactyly. Most had also syndactyly. Using polymorphic markers adjacent to candidate genes, linkage to SHH, GJA1, HOXD13, LMBR1, FBLN1 was ruled out. Analysis using markers D7S691 and D7S1526 near GLI3 followed by sequencing of the coding sequence of the gene, demonstrated that the phenotype in this family was due to a novel c.A1802G (p.H601A) mutation in exon 12 of GLI3 abrogating one of the C2H2 type zinc fingers of the encoded protein.

The study demonstrates the significant phenotypic variability of GLI3 mutations, with the same mutation leading to pre or post-axial polydactyly.

P02.203

Candidate genes and CNVs in patients with polymicrogyria.

N. Di Donato[1], *U. Hehr*[2], *G. Schuierer*[3], *J. Lemke*[4], *G. Hahn*[5], *J. Schallner*[6], *A. Rump*[1], *E. Schrock*[1], *K. Hackmann*[1];
[1]*Institut für Klinische Genetik, Dresden, Germany,* [2]*Zentrum für Humangenetik, Regensburg, Germany,* [3]*Institut für Neuroradiologie, Regensburg, Germany,*

[4]*Universitätsklinik für Kinderheilkunde, Inselspital Bern, Bern, Switzerland,* [5]*Institut und Poliklinik für Radiologische Diagnostik am Universitätsklinikum Dresden, Dresden, Germany,* [6]*Sozialpädiatrisches Zentrum am Universitätsklinikum Dresden, Dresden, Germany.*

Polymicrogyria (PMG) represents a common cortical malformation and is characterized by an excessive number of small gyri as a result of the abnormal neuronal migration. Up to date mutations in 35 genes are related with various neuronal migration disorders. 13 chromosomal loci were associated with PMG.

Here we present the results of high resolution array CGH analysis (Agilent 2x400k) in 21 patients with PMG.

In one patient we identified de novo deletion 15q26.3 (24 Mb). Although known from the literature in association with developmental delay/multiple malformations this locus was not previously associated with PMG.

11 patients showed copy number variations (CNVs) neither listed as benign nor previously described in the literature. 7 patients had a single aberration (4 losses and 3 gains). In 3 patients a combination of 2 CNVs and in one patient 4 CNVs (gains) were seen. The size of the copy number losses and gains varied from 25 kb to 250 kb and from 36 kb to 250 kb, respectively. In six patients a segregation analysis was possible. A de novo event could be confirmed in one patient (loss). Four patients showed maternal inheritance (one mother partially affected) of the CNVs and one patient had two CNVs, one inherited from either parent. Two discovered CNVs reside within the known PMG loci 4q22.1 and 13q22.1.

In 9/21 patients only CNVs listed in Database of Genomic Variance were found.

The phenotype, candidate genes, possible causative role of the rare CNVs and further studies using NGS will be discussed.

P02.204

Polymicrogyria, schizencephaly, and eye anomalies in a girl with *COL4A1* mutation

T. M. Neuhann[1], *F. Baumeister*[2], *J. Kohlhase*[3], *S. Balg*[1], *E. Holinski-Feder*[1], *A. Abicht*[1], *B. Ertl-Wagner*[4];
[1]*Medizinisch Genetisches Zentrum, Munich, Germany,* [2]*RoMed Klinikum Rosenheim, Rosenheim, Germany,* [3]*Praxis für Humangenetik, Freiburg, Germany,* [4]*Institute of Clinical Radiology, University of Munich – Grosshadern Campus, Munich, Germany.*

Mutations in *COL4A1* are associated with autosomal-dominant type 1 porencephaly; brain small-vessel disease; and hereditary angiopathy with nephropathy, aneurysms, and muscle cramps (HANAC) syndrome. Recently, mutations in *COL4A1* have also been identified in patients with presumed Walker-Warburg syndrome. Schizencephaly and abnormal gyration (such as polymicrogyria) have not been described as primary features.

We describe a girl with a novel mutation in *COL4A1* (c.2716+2T>C, IVS33+2T>C, het.). She was presented at the age of 4 months with complex brain (schizencephaly, polymicrogyria, hypoplastic corpus callosum, and ventriculomegaly) and eye (congenital cataract, microphthalmia) abnormalities. Her development was markedly delayed. In the further course, she developed West syndrome.

Prenatally she was diagnosed with bilateral cataracts and transient ventriculomegaly. Within the first month of life, the girl suffered from bilateral fulminant orbital phlegmona; consecutively, both orbits became markedly microphtalmic. When reassessing the consecutive MRI and CT scans that had been performed since birth, multifocal bleeding episodes at different stages of development and organization as well as porencephalic changes were detected in the early brain imaging studies. Polymicrogyria and schizencephaly most likely developed secondary to the vascular changes and bleeding episodes caused by the mutation during early stages of fetal development. Her parents and the dizygotic twin sister are healthy and do not carry the mutation.

This case highlights, that the brain phenotype may change over time in patients with *COL4A1* mutations and may mask the primary defects expected in these patients.

P02.205

New insights into Potocki-Lupski syndrome by characterisation of the duplicated region 17p11.2 with self-designed two-colour FISH probes

B. Katmer[1], *E. Rossier*[1], *G. Tariverdian*[1], *M. Viellieber*[2], *P. Ruef*[3], *H. Büttel*[3], *K. Mehnert*[1], *I. Dietze-Armana*[1];
[1]*genetikum, Neu-Ulm, Germany,* [2]*St. Annastiftskrankenhaus, Ludwigshafen, Germany,* [3]*SLK-Kliniken Heilbronn GmbH, Heilbronn, Germany.*

The Potocki-Lupski syndrome (PTLS, MIM 610883) is a microduplication syndrome caused by a common duplication of about 3,7Mb in 17p11.2. The PTLS-associated duplication is reciprocal to the common 17p11.2 deletion syndrome (Smith-Magenis syndrome). Both, deletion and duplication rearrangements are caused by nonallelic homologous recombination between flanking repeat gene clusters (Zhang et al. 2010). Clinical features of PTLS include infantile hypotonia, failure to thrive, mental retardation, autism, behavioural abnormalities and speech delay.

Here we report about two patients with PTLS who were ascertained by karyotyping and array-CGH analyses. Patient 1, a 5 year old boy, showed an uncommon duplication of 4,7Mb. He demonstrated classical features like hypotonia, failure to thrive, mental retardation, speech delay, auto aggressive behaviour and facial dysmorphisms, but no congenital malformations. Patient 2, a 2 month old boy, presented the common duplication of 3,7Mb with hypotonia and additional club feet.

Our study was established to design new self-designed two-colour FISH probes for investigation the duplication region more precisely. Therefore, we amplified two genes from proximal and distal part of the duplication by Long Range PCR with a size in total of 30kb. After fluorescent labelling with different colours we hybridised the FISH probes on patients metaphase spreads. Both revealed an inverted duplication due to specific signal pattern.

Using our self-generated protocol to establish PTLS specific FISH probes it is possible to detect how the duplicated region is arranged. Furthermore, we demonstrate patients from the literature with similar duplication segments in comparison of their phenotype for phenotype-genotype correlation.

P02.206

The frequency and exact karyotypes of complex chromosomal aberrations in Prader-Willi syndrome

N. Murakami, *K. Obata, S. Sakazume, Y. Kido, Y. Oto, T. Nagai;*
Dokkyo Medical University Koshigaya Hospital, Koshigaya, Japan.

The pathogenesis of Prader-Willi syndrome (PWS) includes deletion chromosome 15q11-13, maternal uniparental disomy (matUPD), and imprinting center abnormality. Some complex chromosomal aberrations are also known to cause PWS. But the frequency and exact karyotypes of chromosomal aberrations have not been reported. All 217 patients followed by us were diagnosed either by G-banding analysis, FISH, or methylation test. Six of them (2.7%) showed complex chromosomal aberrations (shown below). Four (case 1-4) had an extrachromosome originating from chromosome 15, one Robertsonian translocation between chromosome 14q and 15q (case 5), and one translocation between chromosome 15q12 and 16q24 (case 6). All of the 4 patients with extrachromosome had matUPD. On the extrachromosome, 3 of these 4 (case 1, 3, 4) showed no SNRPN. The other one (case 2) had SNRPN on the paternally-originated extrachromosome. The patient with Robertsonian translocation (case 5) had matUPD and his mother had the same karyotype with normal phenotype. One with translocation (case 6) showed no SNRPN on translocated chromosome 15.

In summary the frequency of complex chromosomal aberration was around 2.7% and many of them had matUPD with extrachromosome 15.

Karyotypes of cases

Oro-dental abnormalities in a group of patients with Prader-Willi syndrome

D. Belengeanu, *D. Stoicanescu, C. Bratu, A. Podariu;*
University of Medicine and Pharmacy, Timisoara, Romania.

Prader-Willi syndrome is characterized by obesity, short stature, facial dysmorphism and behavior problems. The main features in the oral area include enamel hypoplasia, delayed tooth eruption, tooth decay and poor oral hygiene. Other reports mention micrognathia, xerostomia, hypodontia, supernumerary teeth, teeth fusions and dental erosion. The aim of this study is to evaluate oro-dental phenotype in Prader-Willi patients and recommending strategies for the dental management of cases with this syndrome. Due to very low incidence of the disease in general population, the study group included 12 patients, aged between 4 and 25 years. Evaluation of dental caries was carried out according to WHO criteria. Orthopantomographies were performed. Based on the radiological appearance of 7 teeth in the left hemimandibula, a dental maturity score was calculated, which was used to determine dental age. Enamel hypoplasia was revealed in 9 cases (75%). Cavities were recorded in all cases, causing massive crown destructions in adults, with early loss of a variable number of teeth, between 4 and 7, after the age of 20. Xerostomia was noticed in all, anodontia of one canine, microdontia and supernumerary tooth-odontom type occured each in one case, poor oral hygiene in 5 cases. An interesting feature was the finding of premature eruption of permanent teeth, 3 patients had early second molar eruption. Accelerated dental age was recorded in patients who were treated with growth hormone. Regular dental examination in Prader-Willi patients is necessary for correct management and justifies its inclusion in the panel of their mandatory investigations.

P02.208

Primordial Dwarfism: A case report of two South African patients

S. Moosa[1], *L. Bhengu*[1], *A. Jackson*[2];
[1]*Division of Human Genetics, National Health Laboratory Service, Johannesburg, South Africa,* [2]*Medical Research Council, Human Genetics Unit, Edinburgh, United Kingdom.*

Primordial dwarfism (PD) is the term used for a group of genetic disorders, which result in severe short stature and growth failure. „Primordial" has been defined as belonging to or being characteristic of the earliest stages of development. Thus, PD is a class of disorders where growth delay occurs at the earliest stages of embryonic development. Unlike some of the other forms of dwarfism where neonates may have normal growth parameters, children with PD are born small. Here we report on two South African girls with PD, aged four and six years. Short stature was evident at birth. Currently their growth parameters fall below the -8SD and -10SD curves, respectively. Both girls have clinical features suggestive of a diagnosis of Majewski Osteodysplastic Primordial Dwarfism Type II (MOPD II), and molecular testing has confirmed that the four year old is homozygous for a mutation in the causative gene, pericentrin (*PCNT*). Apart from severe intrauterine and postnatal growth failure, patients with MOPD II have microcephaly, skeletal dysplasia and a distinctive facial appearance. Individuals with MOPD II are at increased risk for several significant complications, which include insulin resistance, diabetes mellitus and central nervous system vascular malformations. As adults, their average height approaches 100cm, making them among the smallest of human beings. We compare the physical features and radiological findings of these two patients, followed by a brief discussion on the associated co-morbidities and current research on the genetic basis and natural history of PD.

P02.209

Primrose syndrome with testicular cancer: case report and review of the literature

D. Liebrecht[1], *C. Daumer-Haas*[1], *T. Braun*[2], *C. Hann von Weyhern*[3];
[1]*Praenatal-Medizin München, Munich, Germany,* [2]*Klinik und Poliklinik für Hals-Nasen-Ohrenheilkunde Ludwig-Maximilians-Universität München, Munich, Germany,* [3]*Medizet Pathologie Standort Harlaching, Munich, Germany.*

We report on a male patient with the rare finding of enlarged calcified external ear auricles combined with macrocephaly, mental retardation, dysmorphic facial features, bilateral cataracts, hearing impairment, sparse body hair, progredient muscle wasting, severe kyphoscoliosis and behavioural problems. All findings are consistent with the clinical diagnosis of Primrose syndrome. At the age of 28 years the patient developed a germ cell tumor and a seminome of his testicles, which was effectively treated by orchiectomy and chemotherapy. The patient died at the age of 31 years because of pneumonia. Array-CGH analysis performed by us on asservated DNA from testicular tissue, revealed no microdeletion or microduplication.

Primrose syndrome is an extremely rare neurodegenerative disorder of unknown cause. The first patient diagnosed with Primrose syndrome was described in 1982 by Dr. D. A. Primrose. Between 1982 and 2011 there have been published about seven cases of Primrose syndrome (OMIM #259050). To our knowledge our case is the second reported case of Primrose syndrome with testicular cancer; the first case was reported by Mathijssen et al., 2006. This new case of testicular cancer confirms an increased risk to malignancies, especially testicular tumors, as a part of Primrose syndrome.

We compare the phenotype and findings of our case to previously published cases of Primrose syndrome in order to expand the phenotypic spectrum. Up to now all cases of Primrose syndrome are mentioned to be sporadic without familial occurrence or consanguinity and probably related to a novel autosomal dominant mutation of a yet unknown gene.

P02.210

Identification of mosaic AKT1 mutations in two patients affected with Proteus syndrome but not in three patients affected with an asymmetric and disproportionate overgrowth not fulfilling the Proteus syndrome criteria

D. Emmerich[1], *M. Kolanczyk*[1,2], *S. Mundlos*[1,2], *S. Tinschert*[3];
[1]*Charité - Universitätsmedizin Berlin, Institut für Medizinische Genetik und Humangenetik, Berlin, Germany,* [2]*Max Planck Institute for Molecular Genetics, Research Group Mundlos, Berlin, Germany,* [3]*Technische Universität Dresden, Institut für Klinische Genetik, Dresden, Germany.*

Proteus syndrome (PS) [OMIM#176920] is a highly variable disorder characterized by asymmetric and disproportionate overgrowth of body parts, including bone overgrowth. The concept of a dominant lethal gene defect surviving by mosaicism was proposed by Happle over twenty years ago to explain the mosaic distribution of lesions and the sporadic occurrence. Recently, an activating missense mutation in the *AKT1* gene has been found by Lindhurst *et al.* (2011) to be associated with the PS. The AKT1 serine-threonine protein kinase is a central mediator of PI3-Kinase signaling which influence cell proliferation and apoptosis (Lee *et al.* 2011). Here, we screened affected tissues from two patients with classical PS and three patients with an asymmetric and disproportionate overgrowth not fulfilling the PS criteria; one of the latter with unilateral lower extremity overgrowth and two with cranial bone overgrowth. We used restriction-enzyme assay described by Lindhurst *et al.*. To test our method we created mutated PCR fragments and showed a sensitivity up to ~5% mutated PCR-fragments. We detected the *AKT1* mutation in the affected bone, fat and cartilage but not in the blood sample of two Proteus syndrome affected patients. The mutated allele frequency ranged between 4 and 20 percent. We did not detect *AKT1* mutation in affected tissues of the patients with cranial bone overgrowth and unilateral extremity overgrowth. This data suggest a different molecular mechanism accounts for the overgrowth in these distinct from PS cases.

P02.211

Causal mutations of *PRSS1* gene and association with hereditary chronic pancreatitis

L. Vavrova[1], *M. Milly*[1], *I. Mlkva*[2], *D. Ilencikova*[1], *M. Konecny*[1];
[1]*Department of Clinical Genetics, St. Elizabeth Cancer Institute, Bratislava, Slovakia,*
[2]*Centre of Clinical Genetics, University Hospital, Bratislava, Slovakia.*

Hereditary chronic pancreatitis (HCP) belongs into the group of rare diseases. HCP follows an autosomal dominant inheritance pattern with a penetrance of approximately 80%. The incidence is expected to be 3,5-10 cases/100 000 inhabitants in Europe and USA. It was shown that in approximately 50% of families affected with HCP, mutation of *PRSS1* gene was present.

PRSS1 gene encodes cationic trypsinogen and some mutations described in this gene lead to higher stability of prematurely activated trypsin in pancreas or higher autocatalytic activation of inactive trypsinogen to trypsin. Another gene associated with HCP is *SPINK1*. This gene encodes serin protease inhibitor Kazal type I, which is markedly upregulated in the pancreas during active inflammation. Variants present in this gene may interrupt the specific inhibition of active trypsin in pancreas.

Recently we have started the analysis of mutations in *PRSS1* and *SPINK1* genes in Slovak HCP families. Although, we have so far tested only few families, several mutation carriers were already identified. One unreported variant, the p.Ile141Asn that we detected, presumably has a negative effect on the protein function. This novel variant may be specific for our population and will be analyzed further.The genetic testing resulting in discovery of the mutations in mentioned genes associated with HCP may help to enroll the patients into special preventive programs. Here we discuss the importance of genetic testing of *PRSS1* and *SPINK1* in patient with pancreatitis as the risk of pancreatic cancer is elevated in patients with diagnosed HCP to more than 50% .

P02.212

A large deletion in the GNAS gene in a patient with pseudohypoparathyroidism type 1a (PHP-1a)

E. Tønne[1], *M. A. Kulseth*[1], *A. G. Myhre*[2], *T. Prescott*[1];
[1]*Department of Medical Genetics, Oslo, Norway,* [2]*Department of Pediatrics, Oslo, Norway.*

Albright hereditary osteodystrophy (AHO) is a rare autosomal dominantly inherited condition associated with short stature, obesity, subcutaneous ossifications and shortening of the long bones of the hands and feet. Some degree of development delay, generally mild, is common. The underlying molecular cause is reduced activity of the alpha subunit of the stimulatory guanine nucleotide-binding protein (Gsalpha). Gsalpha is encoded by GNAS and heterozygous mutations including missense, nonsense, small insertions and deletions in GNAS exons 1-13 have been reported to cause AHO. Submicroscopic deletion detected by array CGH, involving the whole GNAS locus, has also been reported. GNAS is subjected to maternal imprinting in some human tissues, including the thyroid gland, and hormone resistance (particularly for parathyroid hormone and thyroid-stimulating hormone) is associated with AHO, only when the genetic defect is maternally inherited.

AHO with hormone resistance (pseudohypoparathyroidism type 1a (PHP-1a)) was diagnosed clinically in an adopted boy with subcutaneous ossification on the left leg, short stature (2.5 percentile), brachydactyly, obesity (weight for height 97.5 percentile), a round face with a short neck and mild development delay. He had PTH resistance with hypocalcemia and mild TSH resistance.

MLPA analysis revealed heterozygosity for a deletion of exon 7-13 in GNAS. The clinical feature of PTH resistance indicates that the deletion was located at the maternal allele. This case underscores the usefulness of MLPA in the diagnosis of AHO. To the best of our knowledge, a similar partial GNAS deletion has not been described previously.

P02.213
Genetic study of PTEN mutations among individuals with ASDs / MR and macrocephaly

***M. Havlovicova**, P. Vasovcak, A. Krepelova, M. Simandlova, T. Marikova, A. Holubova, Z. Sedlacek;*
Department of Biology and Medical Genetics, Charles University 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic.

Autism spectrum disorders (ASDs) are a group of severe neurodevelopmental conditions among which pervasive developmental disorder (not otherwise specified) and autistic disorder are the most common. The prevalence of ASDs is currently estimated at 60 and 13 per 10,000 for ASDs and autism, respectively. Autistic disorder is often associated with macrocephaly; 24% of patients have head circumference (HC) at >98th centile. Mutations in the PTEN gene have been reported in patients with ASDs and significant macrocephaly (HC ranging from +2.5 SD to +8 SD). Germline PTEN mutations also cause a variety of inherited cancer predispositions like the Cowden, Bannayan-Riley-Ruvalcalba, Proteus and Proteus-like syndromes. These conditions may also have neurobehavioural features resembling autism as well as overgrowth and macrocephaly. On the contrary, most macrocephalic autistic patients with confirmed PTEN mutations were lacking the typical signs of these syndromes, at least at the time of testing. We have selected 53 autistic individuals with HC ranging from +2 SD to +4.8 SD (including their relatives) for PTEN mutation analysis. Three novel (p.Asp331Thrfs*11, p.Thr321Glnfs*23, p.Glu242*) and two known germline mutations (p.Pro246Leu, p.Arg130*) have been found in 8 of the 53 probands (15%). We discuss possible genotype/phenotype correlation in our group of patients. Our data support former findings that PTEN mutations are frequent in patients with ASDs and macrocephaly. Therefore PTEN testing should be considered in such patients. The findings may impact the assessment of the recurrence risk and medical management of the families including early cancer prevention. Supported by CZ.2.16/3.1.00/24022 and MZ0FNM2012.

P02.214
Ptosis, arched eyebrows, hypernasal speech, obesity & mild learning disability- a clinical & mapping study

***S. A. Lynch**[1], M. Akram[2], N. Goggin[2], M. Earley[3], S. Ennis[4], J. Conroy[4];*
[1]National Centre for Medical Genetics, Dublin, Ireland, [2]Department of paediatrics, Ardkeen Hospital, Waterford, Ireland, [3]Dept of Surgery, Temple Street Children's Hospital, Dublin, Ireland, [4]School of Medicine & Health Science, University college Dublin, Dublin, Ireland.

We report 15 members of a three generation pedigree with ptosis, velopharyngeal incompetence, dysmorphism and a learning disability. The index case presented with nasal regurgitation, ptosis, obesity and developmental delay. His mother has similar features. She has 6 children, 4 of whom are affected. The maternal grandfather had ptosis & cannot read or write. He had 8 children, 5 affected & 3 unaffected. Two aunts of the index case have ptosis, obesity & learning difficulties. One has a son with ptosis. Mapping analysis was performed on an Illumina Human-1M array on 15 samples including 8 affected & 7 unaffected individuals. Three regions of interest on Chromosome 2, 10 & 18 were identified. A number of genes within these regions are of interest including: NRXN1, NLGN1, PIK3CA, FXR1. However, one gene, FOXI2, stands out. Many of the forkhead genes have important biological functions in multiple species. Mutations in FOXL2 cause Blepharophimosis-ptosis-epicanthic inversus, a dominant disorder with ptosis as a prominent feature. Mutations in FOXC2 cause Lymphoedema-Distiachiasis, a dominant disorder also causing ptosis & cleft palate. FoxO proteins play a critical role in cellular differentiation, proliferation, apoptosis and stress resistance. Therefore there is evidence that mutations in forkhead proteins can result in many of the clinical findings seen in our patients (ptosis, velopharyngeal insufficiency, speech & language difficulties & obesity). We are currently performing exomic sequencing on 5 members of the family (4 affected & 1 unaffected) & will perform Sanger sequencing on any variant of interest in the other family members.

P02.215
Hemodynamic and genetic analysis in children with idiopathic/heritable and congenital heart disease associated pulmonary arterial hypertension

***N. Pfarr**[1,2], J. Szamalek-Hoegel[1], C. Fischer[1], N. Ehlken[2], T. Becker-Grünig[2], O. Miera[3], M. Gorenflo[4], A. Hager[5], K. Hinderhofer[1], C. Nagel[2], D. Schranz[6], E. Grünig[2];*
[1]University Hospital of Heidelberg, Institute of Human Genetics, Heidelberg, Germany, [2]Centre for pulmonary hypertension/Department of Pneumology, Thoraxclinic, Heidelberg, Germany, [3]German Heart Center Berlin, Berlin, Germany, [4]University Hospital of Heidelberg, Department of Paediatric Cardiology, Heidelberg, Germany, [5]Clinic of Pediatric Cardiology and Congenital Heart Defects, Munich, Germany, [6]University of Giessen, Department of Paediatric Cardiology, Giessen, Germany.

Background: Idiopathic (I) pulmonary arterial hypertension (PAH) is rare in childhood and can be heritable (HPAH) caused by defects of genes participating in the TGFß signaling pathway. The genetic background of PAH associated with congenital heart defects (CHD-APAH) is less clear. The aim of this study was to compare hemodynamic and genetic findings in children with I/HPAH and APAH-CHD.

Methods: Prospectively included were consecutive children with invasively confirmed diagnosis of I/HPAH or CHD-APAH. Assessment of family members, pedigree analysis and systematic screening for mutations in the genes BMPR2, ACVRL1, ENG, SMAD1, SMAD5 and SMAD9 was performed.

Results: 19 children with I/HPAH (6.3±4.7 years) and 11 with CHD-APAH (7.2±4.5 years) were included. Four mutations (BMPR2 n=2; ACVRL1 n=2), and 3 not yet described unclassified sequence variants (ACVRL1 n=1; SMAD9 n=2) were found in I/HPAH children. One ACVRL1 mutation has not been described before. In CHD-APAH patients 1 BMPR2 mutation and 2 unclassified sequence variants (ENG n=1, BMPR2 n=1) were identified.

Conclusion: Mutations and unclassified variants with functional impact in different TGFß signalling genes occurred in 21% of I/HPAH patients and 27.3 of patients with CHD-APAH and may influence the clinical status of the disease. Therefore, genetic analysis in children with various forms of PAH is important, may be of clinical and prognostic relevance, and shows the complexity of the genetic background.

P02.216
Associated malformations in patients with radial ray deficiency

***C. Stoll**, B. Dott, Y. Alembik, M. Roth;*
Genetique Medicale, Strasbourg, France.

Infants with radial ray deficiency (RRD) often have other associated congenital malformations. The purpose of this investigation was to assess the prevalence and the types of associated malformations in a defined population. Each affected child was examined by a geneticist, all elective terminations were ascertained, and the surveillance for malformations was continued until 1 year of age. The associated malformations in infants with RRD were collected in all livebirths, stillbirths and terminations of pregnancy during 26 years in 346,831 consecutive births in the area covered by our population based registry of congenital malformations. Of the 67 infants with RRD born during this period (prevalence at birth of 1.93 per 10,000), 60 (89.6 %) had associated malformations. There were 18 (26.9%) patients with chromosomal abnormalities including 15 trisomies 18, and 32 (47.8%) nonchromosomal recognized dysmorphic conditions. There were no predominant recognised dysmorphic conditions, but VA(C)TER(L) association. However, other recognised dysmorphic conditions were registered including, Fanconi, thrombocytopenia absent radius, and Holt-Oram. Thirty two (47.8 %) of the patients were multiply, non syndromic, non chromosomal malformed infants (MCA). Malformations in the cardiovascular system, the urogenital system, the central nervous system, and the digestive system were the most common other malformations. Prenatal diagnosis was performed in 47.8 % of dysmorphic syndromes with RRD. The overall prevalence of associated malformations, which was more than one in two infants, emphasizes the need for a thorough investigation of infants with RRD. A routine screening for other malformations may be considered in infants and in fetuses with RRD.

P02.217
'Noonan Spectrum Test' - comprehensive screening for RASopathies

***S. Borras**[1], D. Bromley[1], P. Scully[1], J. M. Coxhead[1], S. Spiden[2], J. Short[2], J. Robinson[1], D. Huntley[1], A. Curtis[1], R. Taylor[2];*
[1]NewGene Ltd., Newcastle upon Tyne, United Kingdom, [2]SW Thames Molecular Genetics Diagnostic Laboratory, St George's Healthcare NHS Trust, London, United Kingdom.

The Ras/MAPK signal transduction pathway is critical for the regulation of proliferation and differentiation of multiple cell types. Deregulation of the pathway results in a number of disorders with overlapping physical manifestations. These include postnatal growth reduction; skeletal, ectodermic and haematologic anomalies; congenital heart defects and hypertrophic cardiomyopathy, and variable cognitive deficit. With an incidence of 1:100-2500 in all live births, Noonan syndrome (NS) is the most common RASopathy. To date, pathogenic mutations in twelve genes (*PTPN11, SOS1, RAF1, SHOC2, BRAF, MAP2K1, MAP2K2, SPRED1, CBL, KRAS, NRAS* and *HRAS*) have been shown to underlie NS and other Ras/MAPK-related conditions that include Cardio-facial-cutaneous (CFC), Costello, LEOPARD and Legius syndromes, enabling a molecular diagnosis in up to 75% of affected patients.

In a joint collaboration between SW Thames Molecular Genetics Diagnostic Laboratory and NewGene, we have developed a single diagnostic test to screen for all the Noonan spectrum disorders, based on next generation sequencing (NGS) technology. The NGS assay, using the Roche amplicon approach with multiplex PCR, has been validated using samples from patients referred for Noonan related syndromes that were previously tested by a 3-stage approach at St George's. We compare the cost and turn-around-times of this 'Noonan Spectrum Test' with similar assays currently available in the EU and the US and outline a new service strategy for molecular diagnosis of RASopathies. We include some case studies to demonstrate the benefits of this approach to testing.

P02.219

De novo mosaic ring chromosome 18 in a child with a Fallot type double outlet right ventricle, developmental delay, growth retardation, and polysplenia with right isomerism

***I. Sudholt**, B. Oneda, A. Rauch;*
Institute of Medical Genetics, University of Zurich, Zurich-Schwerzenbach, Switzerland.

We report on a 9 months old child with Fallot type double outlet right ventricle, developmental delay, growth retardation, microcephaly, polysplenia with right isomerism, latent hypothyroidism, absent 12th rib, strabismus and dysmorphic features. Karyotyping and FISH studies revealed two cell lines, one with monosomy 18 (13 %) and one with r(18) (87 %). Ring chromosome 18 is a rare chromosome disorder with highly variable phenotype, which probably depends on the extent of the terminal 18q and 18p deletions. A clear genotype-phenotype correlation though, was hampered by the lack of exact breakpoint mapping in previously published cases. The majority of reported patients showed mild features of the 18q- syndrome. Only a minority of patients with ring chromosome 18 presented with clinical features of 18p- syndrome or a combination of these two syndromes.The phenotype of the 18q- syndrome is characterized by characteristic face, mental retardation, short stature, microcephaly, abnormal male genitalia, congenital heart defect, congenital aural atresia/stonosis, hypotonia, foot deformity, and white matter abnormalities. Common features in 18p- syndrome patients are dysmorphic features, growth and mental retardation, immunological problems, skeletal abnormalities, cardiac defects, brain malformations, alopecia and dystonia. High-resolution SNP-array molecular karyotyping in our patient revealed a 14.7 Mb deletion and an adjacent 277 kb duplication at chromosome 18p and a 3,8 Mb deletion at 18q. This finding explains the clinical overlap with 18p- syndrome in our patient. We just identified a second patient who is currently under further investigation.

P02.220

Is Roferon-A (Interferon alpha-2a) Teratogenic Risk Factor-X?

***M. A. Soylemez**, A. Tafazzoli, H. Kazan, P. Gültepe, G. Koc, G. Girgin, T. Avcılar, S. Ergunsu, M. Avsar, C. Erzik, M. Gülçebi, I. Guney;*
Marmara University Medical School, Istanbul, Turkey.

BACKGROUND Roferon-A (Interferon alpha-2a) is a pregnancy risk category C drug, which has been shown to demonstrate a statistically significant increase in abortifacient activity in rhesus monkeys when given at approximately 20 to 500 times the human dose. A particular birth defect may have its origins through multiple mechanisms and possible exposures, including medications. A specific pathogenic process may result in different outcomes depending upon factors such as embryonic age at which a drug is administered, duration, dose of exposure and genetic susceptibility. This case report discusses the teratogenic effect of Roferon A.

CASE An infant was exposed to 1x1 1000000IU /day of Roferon-A from the beginning of pregnancy until the 28th gestational week. Preterm newborn (28th week) showed the following abnormalities: Cliteromegaly, hydranencephaly, microcephaly, hypotelorism, frontal bossing, asymmetry of head , big right ear, cleft plate, absence of nasal bridge and single alae nasi. Chromosomal analysis of proband revealed 46,XX karyotype.

CONCLUSIONS Identifying teratogenic mechanisms may not only be relevant for etiologic and post-marketing research, but may also have implications for drug development and prescribing approach for women of reproductive age. Six teratogenic mechanisms are associated with medication use. Many medications classified as class X are associated with at least one of these teratogenic mechanisms. Our patient may be the first case which is possible to be related with one of these mechanisms of Roferon-A. Moreover, in the present case, teratogenic effects were observed even though the dose was lower than in the previously reported Roferon-A embryopathy cases.

P02.221

Rubinstein-Taybi-like syndrome: clinical and molecular genetics delineation

*E. Chabchoub[1,2], **I. Chabchoub**[3], B. Dimitrov[4], N. Ardeshirdavani[1], J. R. Vermeesch[1], A. Landolsi[3], A. Zakhama[5], S. Ben Ahmed[3], J. P. Fryns[1];*
[1]Centre for Human Genetics – University Hospitals of Leuven, Leuven, Belgium, [2]Department of Genetics and Immunology, Research Unit 04UR0805 - Faculty of Medicine - University of Sousse, Sousse, Tunisia, [3]Department of oncology – University Hospital Farhat Hached, Sousse, Tunisia, [4]Department of Clinical Genetics - Guy's and St Thomas' Hospital – NHS Foundation Trust, London, United Kingdom, [5]Department of Pathology - University Hospital Fattouma Bourguiba, Monastir, Tunisia.

In 1963, Rubinstein and Taybi reported a syndrome (RTS) characterized by mental retardation, broad thumbs and toes, and recognizable facial abnormalities with a high propensity to neoplasms. RTS is caused by submicroscopic 16p13.3 deletions in approximately 10% of patients. Mutations in the *CREBBP* gene (16p13.3) explain about 30% of the cases. Recently, mutations in the *EP300* gene (22q13) were reported in 5 patients. *EP300* gene can be considered as a rare cause of RTS.

We report here, three patients presenting clinically with a RTS. These are two Belgian patients, a male and a female, aged respectively 29 and 11 years, followed in the genetics and paediatric neurology clinics in Leuven and a Tunisian patient followed in the oncology clinics of Sousse (Tunisia). The conventional karyotype was normal. We found no deletion on 16p13 by FISH. By aCGH we detected in the first patient a terminal deletion on chromosome 6q and a terminal duplication on 7q. We confirmed by FISH that these submicroscopic chromosomal abnormalities were the product of an unbalanced reciprocal translocation (6;7). The second patient has a *de novo* microduplication of 500 kb on chromosome 5q11.2. We found no abnormality in the third patient by aCGH at a resolution of 1 Mb.

In this report, we will discuss the pathogenic relevance of these abnormalities and their possible contribution to the clinical phenotype. In conclusion, we show that aCGH is a powerful tool for investigating the genetic aetiologies of Rubinstein-Taybi-like syndrome.

P02.222

Midline defect with single central incisor masks facial phenotype of Rubinstein-Taybi syndrome

***B. Albrecht**[1], O. Bartsch[2], D. Wieczorek[1];*
[1]Institut fuer Humangenetik, Essen, Germany, [2]Institut fuer Humangenetik, Mainz, Germany.

We report on a patient followed from one to 11 years of age. She presented with intellectual disability and facial dysmorphism. She was born to healthy unrelated German parents and has a healthy elder sister. Pregnancy was complicated by polyhydramnios. Caesarean section was performed at 38th week of gestation. Birth measurements were normal, but the patient needed ventilation and showed brachycardia. A naevus of the glabella, choanal atresia, a fleshy nose, a high arched palate and ovarian cysts were diagnosed after birth. At the age of one year a single central incisor and right sided aortic arch and left sided vena cava superior were observed. MRI scan showed a thin corpus callosum and mild frontal brain atrophy. The patient walked and talked at the age of 3 years. She is short and obese and has normal head circumference. She has myopia and had mucotympanon during childhood. Endocrine follow up showed elevated oestriol levels and premature thelarche. She has a single central incisor of her permanent teeth, but molecular analyses in *SHH* and *SIX3* genes gave normal results, as did numerous other investigations. At the age of 10 years broad thumbs and toes became more obvious and talon cusps were observed, leading to the tentative diagnosis of Rubinstein-Taybi syndrome (RTS). Detection of a deletion of exons 24 to 31 of the *CREBBP* gene confirmed RTS. Although holoprosencephaly is described in RTS the alteration of the facial gestalt by the midline defect postponed the final diagnosis for 10 years.

P02.223

Defect initiation of proteoglycan synthesis in patients with joint dislocations,bicuspid aortic valve and other heart defects

Bicuspid aortic valve (BAV) is the most frequent inborn heart defect. It is associated with insufficiency and/or stenosis of the heart and results in the pathologic changes in left-ventricular structure and function as well as a dilatation of the ascending aorta. BAV increases the risk of cardiac death. We studied a family with inherited joint dislocations and a congenital heart disease with multiple defects (BAV with aortic root dilatation, mitral valve prolaps, VSD, ASD). We mapped the disease to chromosome 11 and subsequently identified hypomorphic mutations in glucuronyltransferase-I (GlcAT-I), the enzyme catalyzing the synthesis of the last step in the linker region tetrasaccharide formation, which connects glycosaminoglycans and the core protein of a proteoglycan. We showed that the mutations reduce enzymatic activity and decrease the levels of all three lines of O-glycanated proteoglycans, namely dermatan sulfate, chondroitin sulfate and heparan sulfate proteoglycans. Real-time PCR showed that GlcAT-I is expressed in heart, aorta, bone, and osteoblasts - tissues affected in the patients. Further, GlcAT-I protein was present in the medial tissue of the human aorta, indicating that altered GlcAT-I function may be involved in developmental or degenerative aortic root dilation and aortic aneurysm. Our results point to the proteoglycan synthesis as a candidate gene pathway for several cardiovascular malformations as well as for congenital joint dislocations.

Deletion of a long-range cis-regulatory element for the TWIST1 gene in a family with mental retardation and mild craniofacial dysmorphism

***W. Heinritz**[1], K. Kölzsch[2], G. Rettenberger[3];*
[1]Private Practice for Human Genetics, Cottbus, Germany, [2]Social pediatric center at the Carl-Thiem Hospital Cottbus, Cottbus, Germany, [3]genetikum, Neu-Ulm, Germany.

Disruption of the normal *cis*-regulatory architecture of disease gene loci has been described as a special cause of different genetic disorders. The *TWIST1* gene locus might be one of those. Mutations within the coding region of *TWIST1* are associated with the Saethre-Chotzen syndrome. Large deletions encompassing *TWIST1* and its neighbouring genes also contribute to this disorder, but some patients have additional significant learning difficulties, which led to the suggestion of a novel microdeletion syndrome 7p21.1. Here we describe a three generation family, in which several members have a slight to moderate mental retardation and mild craniofacial dysmorphism. On array-CGH analysis variable constellations of two different copy-number changes flanking the *TWIST1* gene at 7p21.1 could be detected in the affected and non-affected probands. One is a duplication of ~800 kb nearly 270 kb upstream of *TWIST1*, which contains 3 genes of so far unknown function (*TWISTNB*, *MIR3146*, *TMEM1*). The other, a small deletion of ~150 kb, is located approximately 2.9 Mb downstream of *TWIST1* and encloses the gene LOC729920. Both changes are not yet known as pathogenic or benign CNVs. Based on the clinical and molecular findings in our family and considering the current knowledge about '*cis*-ruption disorders' we suggest - in particular for the smaller deletion - disease causing effects on the function of *TWIST1* and/or other genes nearby.

P02.225

A syndromic condition with scalp defects, developmental delay and dysmorphic features maps to chromosome 20.

***M. Sukalo**[1], L. Al-Gazali[2], C. Rusu[3], A. Ekici[4], M. Zenker[1];*
[1]Institute of Human Genetics, University Hospital of Magdeburg, Magdeburg, Germany, [2]Department of Paediatrics, Faculty of Medicine & Health Sciences, Al Ain, United Arab Emirates, [3]Human Genetics, University of Medicine and Pharmacy, Iasi, Romania, [4]Institute of Human Genetics, University Hospital of Erlangen, Erlangen, Germany.

In 2007, Al-Gazali et al. reported on an apparently new autosomal recessive condition comprising hypotonia, developmental delay, cutis aplasia of the vertex and dysmorphic features in an inbred Arab family. It was proposed that this could represent a severe recessive form of scalp-ear-nipple syndrome (Clin Dysmorphol 2007).

We performed homozygosity mapping in this family and found clear evidence of linkage to a single large region on chromosome 20 encompassing an interval of approximately 35 Mb (15,200,000 - 51,300,000). The locus was confirmed but not further refined by another affected child born to this family more recently. In a sporadic patient with scalp defects, mild-to-moderate cognitive impairment and facial dysmorphism, we discovered a significant stretch of homozygosity overlapping with the above mentioned region. This girl was born to healthy parents originating from a remote area in Romania but who denied consanguinity.

We hypothesize that the affected individuals in these two families share the same very rare autosomal recessive condition, the hallmarks of which are congenital scalp defects and intellectual disability. The gene for this condition is probably located on chromosome 20. Further investigations are on the way to identify the causative gene for this syndrome.

P02.226

A *de novo* mutation in the *SETBP1* leading to Schinzel-Giedion syndrome and juvenile myelomocytic leukemia

***E. Mihci**[1,2], A. Hoischen[3], B. W. Van Bon[4], G. Tezel[5], B. G. Nur[1], N. E. İlhan[6], A. Yesilipek[6];*
[1]Akdeniz University School of Medicine Department of Pediatric Genetics, Antalya, Turkey, [2]Akdeniz University School of Medicine Department of Medical Genetics, Antalya, Turkey, [3]Radboud University Medical Centre Department of Human Genetics, Nijmegen, Netherlands, [4]Radboud University Medical Centre, Department of Human Genetics, Nijmegen, Netherlands, [5]Akdeniz University School of Medicine Department of Neonatalogy, Antalya, Turkey, [6]Akdeniz University School of Medicine Department of Pediatric Hematology and Oncology, Antalya, Turkey.

Schinzel-Giedion syndrome (SGS; MIM #269150) is a rare multiple congenital malformation syndrome. A clinical diagnosis of SGS may be made by identifying the dysmorphic features, including prominent forehead, midface retraction, and short, upturned nose plus typical skeletal anomalies or hydronephrosis. Typical skeletal anomalies of SGS include a sclerotic skull base, wide supraoccipital-exoccipital synchondrosis, inreased cortical density or thickness and broad ribs. In addition, there is an increased prevalence of neoplasia in SGS.

We present a 3-month-old girl patient with both SGS and juvenile myelomonocytic leukemia. She had craniofacial abnormalities, hypertrichosis over forehead, bilateral grade 3 degree hydronephrosis, secundum atrial septal defect, skeletal abnormalities, hydrocephaly and severely hypotonia. She was the first child of the parent and her family history was unremarkable. Her karyotype was 46, XX. In her follow-up, she had high white blood cells (WBC: 55.040/mm^3) and high level liver enzymes activity. Her bone marrow biopsy consisted with juvenile myelomonocytic leukemia. She died at the age of 10 month since untreatable bronchopneumonia. Mutation analysis for the mutation hotspot in the *SETBP1* gene showed a *de novo* mutation (p.Asp868Asn (c.2602G>A)). In the literature, overexpression of *SETBP1* had been related with growth advantage in hematopoietic progenitor cells. Our case had both juvenile myelomonocytic leukemia and SGS. To our knowledge, leukemia in SGS was not described previously. This *de novo* mutation may be associated with leukemia in SGS.

Sertoli cell tumor and gonadoblastoma in an untreated 29-year-old 46,XY phenotypic male with Frasier syndrome carrying a *WT1 IVS9+4C>T* mutation

***S. Kitsiou-Tzeli**[1], M. Deligiorgi[2], S. Malaktari-Skarantavou[2], C. Vlachopoulos[3], S. Megremis[1], I. Fylaktou[1], J. Traeger-Synodinos[1], C. Kanaka-Gantenbein[4], C. Stefanadis[3], E. Kanavakis[1];*
[1]Department of Medical Genetics, Medical School, University of Athens, Aghia Sophia Children's Hospital, Athens, Greece, Athens, Greece, [2]Department of Endocrinology and Metabolism, Hippokration General Hospital of Athens, Greece, Athens, Greece, [3]1st Department of Cardiology , Medical School, University of Athens, Hippokration Hospital, Athens, Greece, Athens, Greece, [4]Division of Endocrinology, Diabetes and Metabolism, First Department of Pediatrics, Medical School, University of Athens, Aghia Sophia Children's Hospital, Athens, Greece, Athens, Greece.

Objective: Frasier Syndrome (FS) phenotype in 46,XY patients usually consists of female external genitalia, gonadal dysgenesis, high risk of gonadoblastoma, and development of end stage renal failure usually in the second decade of life. FS is caused by heterozygous de novo intronic splice site mutations of the Wilm's tumor suppressor gene 1 (*WT1*), although few cases with typical exonic *WT1* Denys-Drash mutations that resemble an FS phenotype have been described. The aim of this study was to present further data on the spectrum of FS phenotypes, through the evaluation of a 29-year-old patient with a predominantly male phenotype and coexistence of Sertoli cell tumor and gonadoblastoma.

Results Genetic analysis using standard methods for DNA sequencing confirmed FS due to a *WT1* gene mutation, IVS9+4C>T.

Conclusions This very rare case illustrates the natural course of FS over many years, due to neglect by the patient to address his need for follow-up and adds further data on the spectrum of FS phenotypes associated with IVS9+4 C>T mutations. The coexistence of the rare Sertoli cell tumor and gonadoblastoma, emphasizes that the early clinical recognition and molecular identification supports appropriate patient management, especially with respect to the high risk of gonadal malignancy.

P02.228

Lobar holoprosencephaly and eye anomalies in a patient with a deletion in the *SHH* regulatory region

*R. G. Quiezi[1], K. A. Williamson[2], D. R. FitzPatrick[2], M. Ansari[2], S. MacKay[2], A. Richieri-Costa[1], **L. A. Ribeiro-Bicudo**[1];*
[1]Hospital de Reabilitacao de Anomalias Craniofaciais, Bauru, Brazil, [2]MRC Human Genetics Unit, Edinburgh, United Kingdom.

HPE is one of the most common congenital malformations in humans and it is characterized by the incomplete separation of the cerebral hemispheres into distinct right and left halves. Clinical expression is extremely variable ranging from minor facial signs to complexes craniofacial anomalies such as ciclopia. Main genes involved include *SHH, GLI2, PTCH1, TGIF, ZIC2, TDGF1, SIX3, GAS1, ZIC3.* We report a Brazilian patient presenting a mild form of lobar HPE associated with eye anomalies who presented a deletion in the SHH. Brain CT Scan showed hypotelorism, hypoplastic nasal structures, the premaxilla is highly placed with a single central maxillary incisor, midline clefting extending from the premaxilla to hard palate, lateral ventricles are hypoplasic and fused at the midline. Array-CGH analysis showed a loss at the chromosome 7q36.3 - 155,452,499-155,992,499bp; (size 540 kb) in the *SHH* regulatory region. In mice, the *Shh* gene has six enhancers that regulate *Shh* transcription in the embryonic forebrain. The *Shh* floor-plate enhancers (SFPE2) and *Shh* brain enhancer (SBE1) are localized approximated 200 kb downstream from *Shh* promoter, the other enhancers, SFPE1, SBE4, SBE2 and SBE3 are approximated 400 kb upstream from *Shh* promoter, and three of these enhancers are highly conserved in human. The microdeletion found in our study affected at least three of these enhancer elements (SBE2, SBE3 and SBE4) and suggests that the HPE phenotype is probably casual for loss of *SHH* enhancers.

P02.229

Deletion causing SHH disruption in a family with severe hydrocephalus

***L. K. McGregor**[1], H. Salvemini[1], S. Kerin[2], J. Nicholl[2];*
[1]South Australian Clinical Genetics Service, Adelaide, Australia, [2]Molecular Pathology, Adelaide, Australia.

A couple presented to the SACGS with a history of two previous TOP for severe hydrocephalus. The gender of the first fetus was uncertain, and the second was male. Given the likelihood of X-linked recessive inheritance, the L1CAM gene was tested in fetus 2 and returned a normal result. An array CGH test was also performed. This showed a 7q36 terminal duplication in fetus 2, no DNA was available from fetus 1. Parents were tested and the duplication was identified in the father who was phenotypically normal. An MRI scan was then arranged in the father which showed a small tectal hamartoma not causing obstruction.

The 7q36 duplication in this case was 562kb in length, with one breakpoint disrupting the SHH (sonic hedgehog) gene. Heterozygous deletions of the SHH gene are known to cause holoprosencephaly and the maldevelopment of midline brain structures. Duplication of 7q36, has been reported to cause hydrocephalus, hypotonia and cleft palate, with variable severity. It has previously been postulated that overexpression of SHH could contribute to this phenotype.

It was explained to the parents that the SHH gene disruption was a likely but uncertain cause of the hydrocephalus. They embarked on a third pregnancy. CVS and FISH showed that the fetus did not carry the duplication. A normal male was subsequently born.

P02.230

Case report of Shwachman-Bodian-Diamond syndrome (SBDS) with a combined point mutation and large deletion

***G. Rettenberger**[1], S. Dahlum[1], F. Austrup[2], D. Wüller[3], P. Lohse[4], E. Gödde[2], K. Mehnert[1];*
[1]genetikum, Neu-Ulm, Germany, [2]LADR MVZ Ihr Labor vor Ort, Humangenetik, Recklinghausen, Germany, [3]Christophorus-Kliniken GmbH, St.-Vincenz-Hospital, Coesfeld, Germany, [4]Institut für Laboratoriumsmedizin und Humangenetik, Singen, Germany.

Shwachman-Bodian-Diamond syndrome is a rare autosomal recessive disorder characterized by exocrine pancreatic insufficiency, hematologic defects, short stature and skeletal malformations. Here we describe one patient with features of a skeletal dysplasia. Initial analysis with 180k oligo-aCGH detected a 220 kb deletion harbouring the complete SBDS gene and part of the neighboring gene TYW1 indicating a possible cause for clinical sign of a skeletal dysplasia. Array-CGH in both parents demonstrated the same deletion in the healthy father. Sequencing of the SBDS gene in the patient detected an already published donor splice site mutation in intron 2 of the SBDS gene demonstrating the second mutation on the patients non deleted allele.

Additional sequence analysis of the respective mutation in both parents detected the heterozygous mutation in the healthy mother giving the couple a 25% recurrence risk for following new pregnancies.

This is to our knowledge the first case with a combination of a classical small point mutation combined with a large deletion in SBDS. Initial detection started from aCGH and thus demonstrates the usefulness of initial screening by aCGH, because small proportions of already known monogenic disorders should be due to large deletions not detectable by conventional sequencing. Up to date 25% of SBDS-patients described in the literature lack mutations in the SBDS-gene. Due to the detected mutations prenatal testing could be offered for the new pregnancy.

Molecular investigations of Estonian patients with Silver-Russell and Beckwith-Wiedemann syndrome

***T. Kahre**[1,2], P. Mee[3], M. Vals[1,2], K. Muru[1,2], K. Joost[1,4], R. Teek[1,2], K. Õunap[1,2];*
[1]Department of Genetics, United Laboratories, Tartu University Hospital, Tartu, Estonia, [2]Department of Pediatrics, University of Tartu, Tartu, Estonia, [3]United Laboratories, Tartu University Hospital, Tartu, Estonia, [4]Department of Biochemistry, University of Tartu, Tartu, Estonia.

Silver-Russell (SRS) and Beckwith-Wiedemann (BWS) syndromes are both clinically heterogeneous disorders. Due to variable presentation molecular confirmation of these diseases is necessary. SRS is mainly characterized by severe pre-and postnatal growth restriction and typical triangular face. BWS is an overgrowth syndrome involving predisposition of tumor development. Defective expression of imprinted genes (IGF2, H19, CDNK1C, KCNQ1, KCNQ1OT1) at 11p15 is implicated in etiology of both syndromes. IRC1 hypomethylation is the major cause of SRS and IRC2 hypomethylation mostly found in BWS. Both disorders occur sporadically, but familial inheritance is also described.

Altogether 28 patients were enrolled in BWS and 20 patients in SRS group. All patients` clinical symptoms were re-evaluated by one investigator. In BWS patient's group 19/28 and in SRS patients 14/20 fulfilled the minimal diagnostic criteria. Molecular analysis was performed by methylation-specific MLPA (MRC-Holland).

In SRS group hypomethylation in IRC1 region was found in 4 SRS patients including 2 siblings. One SRS patient had maternal duplication in 11p15 involving both IRC1 and IRC2 regions. She has inherited 11p15 region duplication from her mother who shows overgrowth since the birth and clinical features of BWS. Patients´ mother has inherited duplication from father. Therefore 38.5% (5/13) of SRS patients exhibited an epimutation at the 11p15 region, which is consistent with other investigations. Interestingly, two familial SRS cases were found in the group.

BWS was confirmed in one patient with hypomethylation in IRC2. In almost 95% of BWS patients we could not confirm the clinical diagnosis, therefore molecular investigations should continue.

P02.232

Monozygotic male twins with ICR1 and ICR2 hypomethylation on chromosome 11p15

***A. Tańska**[1], E. Ciara[1], A. Marczak-Hałupka[2], M. Kalina[3], M. Kugaudo[1], D. Jurkiewicz[1], D. Piekutowska-Abramczuk[1], M. Borucka-Mankiewicz[1], P. Kowalski[1], S. Łuczak[1], M. Pelc[1], J. Trubicka[1], E. Arasimowicz[1], M. Krajewska-Walasek[1], K. H. Chrzanowska[1];*
[1]Department of Medical Genetics, The Children's Memorial Health Institute, Warsaw, Poland, [2]Department of Neonatal Pathology and Infants, Paediatric Centre, Sosnowiec, Poland, [3]Department of Pediatrics, Endocrinology and Diabetes, Medical University of Silesia, Katowice, Poland.

Silver-Russell syndrome (SRS) is a congenital imprinting disorder mainly characterized by intrauterine as well as postnatal growth restriction, body asymmetry, relative macrocephaly and a typical triangular face. SRS is mostly caused by dysregulation of imprinted genes controlled by ICR1 and ICR2 located on chromosome 11p15.5 or maternal uniparental disomy of chromosome 7.

Here we report on a pair of male monozygotic twins discordant for SRS. They were delivered by caesarean section at 34 weeks of gestation. Birth weight of the twin A (2400 g; 25th-50th centile), as well as other auxologic parameters were appropriate for gestational age. Birth weight of the twin B was 1150g (<5th centile) and the difference between head and chest circumference amounted to 9 cm. He experienced severe failure to thrive requiring feeding by gastrostomy. At the age of 4.5 years, the brothers presented height and weight diversity of 13 cm and 6.1 kg, respectively.

Genomic DNA extracted from peripheral blood of both twins was analysed at the differentially methylated regions of *H19* and *KCNQ1OT1* genes. Methylation specific MLPA analysis revealed ICR1 and ICR2 hypomethylation in both brothers. Second analysis performed on DNA isolated from buccal swabs also indicated decreased level of methylation in both ICRs.

So far, in SRS, one concordant and four discordant monozygotic pairs carrying the ICR1 epimutation have been observed. This is the first report on monozygotic twins discordant for SRS with both ICR1 and ICR2 hypomethylation.

The study was supported by the Polish National Science Centre (grant No NN 407 285339).

P02.233

Silver-Russell Syndrome - correlations between the phenotype and (epi)genetic alterations

K. H. Chrzanowska[1], *A. Tańska*[1], *A. Marczak-Hałupka*[2], *E. Ciara*[1], *M. Kalina*[3], *M. Kugaudo*[1], *E. Arasimowicz*[1], *H. Kołodziejczyk*[1], *A. Świąder*[1], *M. Ginalska-Malinowska*[1], *M. Szarras-Czapnik*[1], *M. Syczewska*[1], *D. Jurkiewicz*[1], *M. Krajewska-Walasek*[1];

[1]The Children's Memorial Health Institute, Warsaw, Poland, [2]Paediatric Centre, Sosnowiec, Poland, [3]Medical University of Silesia, Katowice, Poland.

Silver-Russell syndrome (SRS) is a well known congenital imprinting disorder with hypomethylation of ICR1 on chromosome 11p15.5 or maternal uniparental disomy of chromosome 7 (mUPD7) identified in about 60% and 10% of patients, respectively. The disease is characterized mainly by severe pre- and postnatal growth retardation, relative macrocephaly and a small triangular face. Several scoring systems have been proposed but making diagnosis may be still challenging due to wide spectrum of clinical features. Thus studies of patients with confirmed diagnosis of SRS may provide additional valuable information. We performed retrospective and prospective study of a group of 55 SRS patients diagnosed and followed at a single centre (CMHI). Among them there were 45 with ICR1 hypomethylation and 10 with mUPD7. Maternal hetero-, isodisomy and a mixture of hetero- and isodisomy were demonstrated. Growth parameters, phenotype characteristics and developmental anomalies were analyzed and scored. Mean birth weight was lower (-3.1±0.156 SD vs. -2.8±0.306 SD) and head circumference was significantly larger (-0.638±0.174 SD vs. -2.042±0.421 SD; p=0.002) in ICR1 hypomethylation than in UPD7 patients. Asymmetry (face/body/limb) and major congenital anomalies were also more frequent in patients with ICR1 hypomethylation; three individuals manifested gonadal dysgenesia and ambiguous genitalia, 2 males and 1 phenotypically female with male karyotype (46,XY CGD). Cesarean sections were exceptionally frequent in both groups (~50% in ICR1 hypomethylation and in 70% mUPD7). Follow-up of somatic development in both SRS groups enabled analysis of the phenotype depending on epigenetic modulations.

The study was supported by NSC_PL (grant NN 407 285339).

Submicroscopic chromosomal imbalances significantly contribute to the phenotype of SRS and SRS-like patients

S. Spengler[1], *M. Begemann*[1], *N. Ortiz Brüchle*[1], *M. Baudis*[2], *B. Denecke*[3], *P. Kroisl*[4], *B. Oehl-Jaschkowitz*[5], *B. Schulze*[6], *G. Raabe-Meyer*[6], *C. Spaich*[7], *P. Blümel*[8], *A. Jauch*[9], *U. Moog*[9], *K. Zerres*[1], *T. Eggermann*[1];

[1]Institute of Human Genetics, University Hospital Aachen, Aachen, Germany, [2]Institute of Molecular Biology, University of Zürich, Zürich, Switzerland, [3]IZKF, University Hospital Aachen, Aachen, Germany, [4]Institute of Human Genetics, Graz, Austria, [5]Gemeinschaftspraxis für Humangenetik, Homburg, Germany, [6]Praxis für Humangenetik, Hannover, Germany, [7]Institute for Clinical Genetics, Stuttgart, Germany, [8]G v Preyer Kinderspital, Wien, Austria, [9]Institute of Human Genetics, Heidelberg, Germany.

Application of microarray-based molecular karyotyping has lead to a more than two-fold increase in the detection rate in comparison to conventional cytogenetics in patients with mental retardation (MR) and further congenital anomalies. However, it is not routinely implemented in molecular diagnosis for syndromes not typically associated with MR, including Silver-Russell syndrome (SRS). SRS is a clinically and genetically heterogeneous disorder characterized by growth retardation, relative macrocephaly, a triangular face and asymmetry. The clinical spectrum is broad and the diagnosis is rather subjective. Up to now, in nearly half of the SRS patients (epi)genetic alterations on chromosomes 7 and 11 can be detected while ~50% remain without molecular diagnosis. Recently, submicroscopic imbalances have been reported in single cases but systematic studies are missing.

To determine the contribution of submicroscopic imbalances to the aetiology of SRS, we performed molecular karyotyping in 41 patients referred as SRS without (epi)genetic alterations on chromosomes 7 and 11 using the Affymetrix SNP Array 6.0.

Thereby we identified pathogenic de-novo copy number variations with sizes ranging from 672 kb to 9.158 Mb in eight patients. Some of them were associated with known microdeletion syndromes with overlapping features with SRS. In 5 further patients imbalances with so far unknown clinical significance were detected.

In conclusion, as pathogenic submicroscopic imbalances were detectable in a significant proportion of our patients molecular karyotyping should generally be implemented in routine diagnostics for growth retarded patients with even slight dysmorphisms suggestive of SRS.

The mutation in KRT5 gene in Iranian EB patients

H. Dehganpour[1], *M. Moghaddam*[1], *N. Hatamnejadian*[1], *M. Mahdavi*[1], *A. Kakavand*[1], *B. Sedaghaty khayyat*[1], *M. Yousefi*[2], *P. Tousi*[2], *A. Ebrahimi*[1,2];

[1]Parseh Medical Genetic Counseling Center, Tehran, Islamic Republic of Iran, [2]Shahid Beheshty University Skin Research Center, Tehran, Islamic Republic of Iran.

INTRODUCTON: Epidermolysis Bullosa (EB) is a group of inherited disorders in which skin blisters develop in response to minor injury. There are four main types of EB Including: SIMPLEX, JUNCTIONAL, HEMIDESMOSAL and DYSTROPHIC. Because of many overlapping clinical manifestations, identifying the exact type of EB is complicated. The most severe and common form of EB is SIMPLEX that caused by a mutation in either of the keratin genes, KRT5 or KRT14.The purpose of this study is to investigate of KRT5 gene common mutation in Iranian affected patients.

MATERIALS and METHODS: Eighty clinically diagnosed patients as EB evaluated and their DNA extracted from blood sample.PCR reaction fallowed by direct sequencing were done using designed primers for hotspot exons of KRT5 gene including exon 1, 4, 5 and 7.

RESULTS: A novel mutation was detected in codon 308 and about 18 % of patients illustrated a kind of mutation in selected regions. The most hotspots were exon 4 and 5. Interestingly the most of mutations were diagnosed in compound heterozygous form.

Identification of a novel deletion in the *DHCR7* gene in a patient with SLOS

K. Hinderhofer[1], *B. Maas*[1], *M. Witsch-Baumgartner*[2], *H. Gaspar*[1], *D. Haas*[3], *C. R. Bartram*[1];

[1]Institute of Human Genetics, Heidelberg University, Heidelberg, Germany, [2]Division for Human Genetics, Innsbruck Medical University, Innsbruck, Austria, [3]Division of Inborn Metabolic Diseases, University Children's Hospital, Heidelberg, Germany.

Smith-Lemli-Opitz syndrome (SLOS) is an autosomal recessive defect of cholesterol biosynthesis with characteristic dysmorphism, mental and growth retardation, and multiple congenital malformations. Mutations in the human Δ7-sterol reductase (*DHCR7*) gene are the genetic cause of this syndrome. In most of the analyzed patients with distinct phenotypic features and/or biochemical findings two mutations can be identified by sequencing of coding exons 3 to 9 and adjacent intron boundaries of the *DHCR7* gene (detection rate approx. 96%). In a small number of clinically and/or biochemically positive patients, only a single heterozygous mutation can be identified. We analyzed 9 of these patients by self-made multiplex ligation-dependent probe amplification (MLPA) of exons 3 to 8 of the *DHCR7* gene. In one patient, we could identify a heterozygous deletion of exons 3 to 6, in addition to the heterozygous common mutation p.Arg352Trp (c.1054C>T) in exon 9 of the *DHCR7* gene. The deletion leads to an almost complete loss of the gene which is presumably disease causing. At birth the patient was small for gestational age, had short proximal limbs, syndactyly of toes 2 and 3, an atrial septal defect, horseshoe kidney, and typical facial features. During the first year psychomotor retardation, muscular hypotonia, and feeding difficulties evolved. Plasma sterol analysis showed elevated 7- and 8-dehydrocholesterol and decreased cholesterol. Exon deletions in the *DHCR7* gene have only been reported once in a SLOS patient with holoprosencephaly. Therefore, we recommend MLPA analysis in patients suspected of SLOS harbouring only one mutation identified by exon sequencing.

In frame deletion and missense mutations of the C-terminal helicase domain of SMARCA2 in three patients with Nicolaides-Baraitser syndrome

C. Zweier[1], *D. Wolff*[1], *S. Endele*[1], *S. Azzarello-Burri*[2], *J. Hoyer*[1], *M. Zweier*[1], *I. Schanze*[1], *B. Schmitt*[3], *A. Rauch*[2], *A. Reis*[1];

[1]Institute of Human Genetics, University Erlangen-Nuremberg, Erlangen, Germany,
[2]Institute of Medical Genetics, University of Zurich, Zurich-Schwerzenbach, Switzerland,
[3]Department of Pediatric Neurology, University Children's Hospital, Zurich, Switzerland.

Using high resolution molecular karyotyping with SNP arrays to identify candidate genes for etiologically unexplained intellectual disability, we identified a 32 kb *de novo* in frame deletion of the C-terminal helicase domain of the *SMARCA2* gene in a patient with severe intellectual disability, epilepsy, sparse hair, prominent joints and distinct facial anomalies. Sequencing of the gene in patients with a similar phenotype revealed *de novo* missense mutations in this domain in two further patients, pointing to a crucial role of the SMARCA2 C-terminal helicase domain. The clinical features observed in all three patients are typical of Nicolaides-Baraitser syndrome, an only rarely reported syndrome with mainly moderate to severe intellectual disability and other typical aspects like a recognizable facial gestalt, sparse hair, epilepsy, wrinkling of the skin, prominent interphalangeal joints and broad distal phalanges. Notably, one of our patients with a p.Gly1132Asp mutation showed typical morphological features but an exceptional good development with borderline overall IQ and learning difficulties, thus expanding the phenotypic spectrum of Nicolaides-Baraitser syndrome.

P02.238

Co-occurrence of the SMMCI syndrome and a 5q21 deletion in a young girl patient

A. Uwineza, *G. Pierquin, A. C. Hellin, M. Jamar, J. H. Caberg, K. Segers, V. Diderberg, V. Bours;*
Center for Human Genetics, CHU Sart-Tilman, University of Liège, Belgium., Liège, Belgium.

Solitary median maxillary central incisor (SMMCI) or single central incisor is a rare dental anomaly. It is estimated to occur in 1:50,000 live births. SMMCI syndrome is a complex, autosomal dominant developmental disorder in which an SMMCI is seen in association with midline nasal cavity defects (choanal atresia, mid-nasal stenosis, nasal pyriform aperture stenosis) and variably holoprosencephaly.

We report a 21month-old girl, who was the second child of unrelated parents. She was referred to our genetic counseling service for evaluation of dysmorphic features suggesting the SMMCI syndrome and psychomotor development delay. On physical examination, she presented a single central incisor, choanal atresia, nasal pyriform aperture stenosis, ocular hypotelorism, short stature and microcephaly. No brain anomalies were identified by cerebral CT-scan.

A de novo heterozygote missense mutation 494C>T was identified within SHH gene, leading to the replacement of Alanine at amino acid position 165 with Valine. Affymetrix Whole-Genome 2.7M Array Chip revealed a deletion of 695kb of the 5q21.1-q21.2 region.

In conclusion, it difficult to establish genotype-phenotype correlations of the 5q21 deletion because of the simultaneous presence of the SMMCI syndrome.

P02.239

Two Portuguese families with recurrent episodes of pain and different SCN9A mutations - Primary Erythermalgia or Paroxysmal Extreme Pain Disorder?

M. I. G. Rodrigues;
Department of Medical Genetics, Hospital Dona Estefânia, Centro Hospitalar de Lisboa Central, EPE, Lisbon, Portugal.

Background: Mutations in *SCN9A* gene can cause three very different pain phenotypes: Primary Erythermalgia (PE), Paroxysmal Extreme Pain Disorder (PEPD) and Channelopathy-associated Insensitivity to Pain (CIP). The first two disorders result from gain-of-function mutations and are characterized by recurrent episodes of pain, but the accompanying manifestations are usually distinct.

Objectives: The authors aim to present two Portuguese families with recurrent episodes of pain, in which the diagnosis between PE and PEPD was difficult to establish due to overlapping clinical manifestations. The first family is one large kindred with 26 affected subjects and the second family has 3 affected members.

Methods: After characterizing the clinical manifestations, we performed mutation analysis of *SCN9A* gene in 17 of the 26 affected and in 2 non affected members of family 1, as well as in all the affected subjects of family 2.

Results: In all the affected individuals of family 1, except for one female subject, a heterozygous missense mutation c.4835T>C (p.Leu1612Pro) was identified. In family 2 complete sequencing of *SCN9A* gene revealed a heterozygous unclassified mutation c.4880T>G (p.Met1627Arg), which is most likely pathogenic and is present in all the affected family members.

Conclusion: We believe that these two families are the first Portuguese families reported to have mutations in *SCN9A* gene, in which the molecular diagnosis was determining to correctly classify the clinical phenotype. This stresses the importance of performing mutation analysis in affected individuals to confirm the clinical diagnosis and to support pharmacological treatment, which can reduce the frequency of pain episodes.

P02.240

Clinical variability of Sotos syndrome patients with no NSD1 deletion identified

I. M. Furquim[1], *C. E. F. Andrade*[1], *M. R. Passos-Bueno*[2];
[1]*Hospital Santa Marcelina, São Paulo, Brazil,* [2]*Centro de Estudos do Genoma Humano, São Paulo, Brazil.*

Sotos syndrome is an overgrowth syndrome characterized by increased birth length and weight, excessive growth during the first years of life, advanced bone age, learning disability, and distinctive facial features (including macrocephaly, ocular hypertelorism and prominent mandible). Other findings associated with Sotos syndrome are: behavioral problems, cardiac anomalies, cranial MRI/CT abnormalities, scoliosis and seizures. Sotos syndrome is estimated to occur in 1:14,000 live births, and most cases are sporadic. Even though *NSD1* is the only gene associated with the Sotos syndrome, in nearly 20% of the cases no genic abnormality can be found. In 5 affected unrelated patients who are currently being treated at Hospital Santa Marcelina, in Sao Paulo, Brazil, no *NSD1* deletion or duplication was identified by the MLPA method. The purpose of this report is to describe the phenotypic spectrum of these patients. Molecular genetic testing is important not only to confirm the diagnosis, but it also may help determining genotype-phenotype correlations and monitoring the affected patients in order to identify medical complications that may arise from their condition.

P02.241

Partial deletion of SOX6 in a boy with mental retardation, extrapyramidal motor disorder and skeletal anomalies

B. Maas[1], *K. Hinderhofer*[1], *A. Jauch*[1], *J. W. G. Janssen*[1], *C. R. Bartram*[1], *B. Assmann*[2], *H. Runz*[1];
[1]*Institute of Human Genetics, Heidelberg University, Heidelberg, Germany,* [2]*University Children´s Hospital, Heidelberg University, Heidelberg, Germany.*

We report on a 17-year old boy who was referred to us with a seemingly progressive neuropsychiatric disorder of unclear aetiology. He presented with mild mental retardation, developmental delay, skeletal malformations with sternum abnormalities and L-DOPA responsive extrapyramidal motor disorder including ataxia, dysarthria, apraxia, tremor and mimic tics. Array CGH analysis (Affymterix 2.7M array) revealed a monoallelic de novo 84 kb deletion on chromosome 11p15.2 encompassing exon 14 to 16 of the SOX6 gene. The deletion was confirmed by MLPA (multiplex ligation dependent probe amplification). SOX6 belongs to the family of Sry-related HMG box transcription factors with regulatory functions during embryonic development. It plays important roles during early chondrogenesis, muscle development, erythropoiesis and development of the central nervous system. While Sox6 knockout mice show an early lethality, conditional Sox6-knockouts (Sox6fl-) revealed skeletal anomalies with short sternum, including fusion of the fourth and fifth sternebrae (Dumitriu et al., 2006). Due to the fundamental role of SOX6 in a variety of developmental processes and the skeletal similarities between the patient and the mouse model we suggest the partial deletion of SOX6 as apparently disease causing in this patient.

P02.242

Molecular Genetic Confirmation of the Diagnosis Spastic Paraplegia 31 in a Teenage Boy

F. Stock[1], *U. Hehr*[2], *A. Merkenschlager*[3];
[1]*Institut für Humangenetik, Universitätsklinikum Leipzig, Leipzig, Germany,* [2]*Zentrum und Institut für Humangenetik, Universität Regensburg, Regensburg, Germany,* [3]*Klinik und Poliklinik für Kinder und Jugendliche, Universitätsklinikum Leipzig, Leipzig, Germany.*

Spastic paraplegia (SPG) 31 (MIM #610250) is an autosomal dominant neurodegenerative disease. Typical signs are proximal weakness of the lower extremities and progressive spasticity with gait abnormalities, the upper extremities and the sensory system are usually not affected. The age of onset is during the first or second decade in 70 % of affected individuals, in the remainder after the age of 30 years. The genetic cause of SPG31 are mutations in the *REEP1* gene (MIM *609139) on chromosome 2p11.2, which were described for the first time in 2006 in six unrelated families. Variable expressivity and incomplete penetrance have been noted. Recent studies indicate that *REEP1* mutations are the third most frequent cause of hereditary spastic paraplegia, being responsible for 6-8% of cases.

We present a 14-year-old boy from an otherwise neurologically unremarkable family showing abnormal statomotoric and language development. At first muscular dystrophy was suspected until he showed signs of spastic paraplegia at the age of 7 years. Muscle biopsy and neuroradiologic imaging were normal. The boy is receiving regular treatment by physiotherapy, surgery (elongation of Achilles tendons) and medication (botox injections, baclofen). Now at age 14 years he is in a stable condition, being able to ambulate using several auxiliary devices, and an excellent swimmer. Various genetic investigations (genes *SPG3*, *SPG4*, *SPG7*, *SPG20*, karyotyping) did not disclose a cause for his disease. After seven years of diagnostic attempts we found a novel heterozygous truncating mutation in the *REEP1* gene, c.550C>T (p.Gln184X), which confirmed the diagnosis in this patient.

P02.243

Hereditary Spastic Paraplegia Type 8 (SPG8): A novel mutation in a German family

***F. R. Kreuz**, J. Fiedler, A. Bier, S. Reif, S. Krüger, J. Plaschke;*
Gemeinschaftspraxis für Humangenetik, Dresden, Germany.

Hereditary Spastic Paraplegia (HSP) is caused by progressive upper motor neuron axons degeneration. Central-motor-system deficits lead to lower limb paraparesis. HSP can be classified in pure HSP with lower limb spasticity only and complicated HSP with other neurological and non-neurological symptoms. SPG8 is one of the more aggressive subtypes of autosomal dominant pure HSP. The age of onset varies from the twenties to the sixties and there is relatively little interfamilial variability. The *KIAA0196* gene, consisting of 29 exons coding for the strumpellin protein with 1150 amino acids, has been identified as the SPG8 locus mapped to chromosome 8q24.12. There have been only three mutations reported in six families until now.

Here we report on a male patient, aged 27 years, and his mother, aged 50 years. Both suffer from spastic-atactic gait disorder, pes cavus, muscle atrophy at lower limbs ("stork-legs"), muscle hypertonia, brisk reflexes, wide reflex zones, and cloni.

DNA analysis of *KIAA0196* gene revealed the novel missense mutation c.1859T>C; p.Val620Ala in both patients. We did not find this mutation in 598 control chromosomes of German origin. It affects the same α-helix motife (amino acids 619-628) like two mutations in five of the six reported families and resides within the 75 amino acid domain well conserved among mammals.

The novel heterozygous missense mutation in exon 15 of the *KIAA0196* gene co-segregates with SPG8 in this family and was not detected in the mother's elder healthy son, her healthy brother and her mother.

P02.244

Subtelomeric 10q deletion: A new case with vertebral anomalies

***J. Pilch**[1], R. Śmigiel[2], I. Łaczmańska[2], J. Kozłowska[2], E. Gutmajster[3], A. L. Sieroń[3];*
[1]Department of Child Neurology, Medical University of Silesia, Katowice, Poland, [2]Genetics Department, Wroclaw Medical University, Wrocław, Poland, [3]Department of General, Molecular Biology and Genetics, Medical University of Silesia, Katowice, Poland.

10q terminal deletion is characterised by psychomotor and growth retardation, congenital heart defect, genital and urinary tract anomalies, microcephaly and facial dysmorphic features consisting of hypertelorism, strabismus, broad prominent nasal bridge and low-set malformed ears. Some authors observed behavioral disorders. We report on a boy with psychomotor and growth retardation. He was born from second bigeminal pregnancy with unilateral cryptorchidism. Twin brother healthy. Clinical evaluation revealed microcephaly, widow's peak, palpebral fissures slanted up, epicanthic folds, strabismus, hypermetropia, malformed ears, thin upper lip, low posterior hairline, webbed and short neck, asymmetric thorax, scoliosis, clinodactyly. Radiogram of cervical spine showed abnormal lordosis, fusion of vertebre, C5-C7 spina bifida. A standard karyotype was normal. Some of dysmorphic features, especially webbed and short neck with chest deformity, suggested Noonan syndrome. Molecular analyses of PTPN11 and SOS1 genes did not confirm this diagnosis. Further clinical evaluation showed behavioural problems consisting of hyperactivity, hyperkinesis with destructive tendency. Some behavioural anomalies are frequently observed in chromosomal microaberrations. MLPA studies with a set of subtelomeric probes identified subtelomeric deletion of chromosome 10q. Subsequent FISH analysis with specific 10q probes confirmed this deletion. Parent's studies to asses the presence of cryptic translocation are in progress.

P02.245

Evaluation after sudden unexplained death in young patients

***B. M. Beckmann**[1], I. Sinicina[2], G. Niedobitek[3], C. Marschall[4], I. Rost[5], A. Kleinmann[6], S. Greil[6], M. Graw[2], H. Netz[6], S. Kääb[7];*
[1]Medizinische Klinik und Poliklinik I, Ludwig-Maximilians-Universität, München, Germany, [2]Institut für Rechtsmedizin, Ludwig-Maximilians-Universität, München, Germany, [3]Institut für Pathologie, Unfallkrankenhaus Berlin and Sana Klinikum Lichtenberg, Berlin, Germany, [4]Labor Dr. Klein und Dr. Rost, Ludwig-Maximilians-Universität, München, Germany, [5]Labor Dr. Klein und Dr. Rost, München, Germany, [6]Abteilung Kinderkardiologie, Ludwig-Maximilians-Universität, München, Germany, [7]Medizinische Klinik und Poliklinik I, Ludwig Maximilians Universität, München, Germany.

Introduction: Hereditary arrhythmia syndromes are found in more than half of initially unexplained cases of sudden cardiac death (SUD) in young persons. Additionally to autopsy findings, examination of relatives and molecular testing if appropriate enables establishing the diagnosis.

Methods: Family members of 29 SUD patients consulted our clinic. Mean age of death was 24±15 years. Pedigree analysis and clinical examination in relatives was performed, followed by phenotype guided genetic testing in the deceased, if appropriate. In case of no clinical suspicion in relatives but death related to specific triggers (e.g. swimming) sequencing of the RYR2-gene resp. the 3 mostly affected LQTS genes was performed. If a mutation was found cosegregation within the family was verified before establishing the diagnosis.

Results: In n=16 cases (55%) a hereditary arrhythmia syndrome could be found. In n=12 (75%) of these cases clinical examination of relatives led to the diagnosis. In 3 families two arrhythmia syndromes (LQTS and CPVT, resp. HCM) were present.

Conclusion: In case of SUD in a significant percentage of cases a postmortem diagnosis can be performed. When there are only unspecific findings clinical screening of relatives leads to a proper diagnosis in a large proportion. Genetic evaluation should follow clinical family examination because: 1. therapy should be started without waiting for the genetic result if indicated. 2. in 3 families (18%) two hereditary disorders were present and 3. in 2 families the phenotype of the deceased was untypical so that the proper diagnosis would not have been made without family screening.

P02.246

Male with mosaicism for a supernumerary derivative X chromosome lacking the *XIST* gene and phenotypic features of craniofrontonasal syndrome

***J. Morgenthaler**, C. Evers, J. W. G. Janssen, A. Jauch, U. Moog;*
Institute of Human Genetics, Heidelberg University, Heidelberg, Germany.

Background: Craniofrontonasal syndrome (CFNS, OMIM 304110) is an X-linked disorder with typical craniofacial dysmorphism (brachycephaly, facial asymmetry, coronal craniosynostosis, hypertelorism, broad nasal root, bifid nasal tip), syndactyly, broad halluces, and hypoplastic corpus callosum. Mutations in the gene for ephrin-B1 (EFNB1) located at Xq13.1 have been identified as the primary cause of CFNS which paradoxically shows a more severe phenotype in heterozygous females than in hemizygous males. In rare cases, CFNS can be caused by X-chromosome anomalies.

Case report: We describe a five month old boy with severe dysmorphic features including a broad face, hypertelorism, broad nasal root, bifid nasal tip and multiple congenital anomalies (agenesis of the corpus callosum, patent ductus arteriosus, VSD and hypospadias).

Cytogenetics including FISH analysis revealed mosaicism for a supernumerary derivative X chromosome (mos 47,XY,+der(X)del(X)(p11.1)del(X)(q13) [7]/46,XY[23] lacking XIST. Parental cytogenetic studies were normal.

Discussion: The severe phenotype of CFNS in females with a heterozygous EFNB1 mutation is hypothesized to result from inequalities in gene dosage for EFNB1 due to X inactivation. A patchy ephrin-B1 defect leads to disturbed closure of cranial sutures by a process termed cellular interference. Mosaicism for a derivative chromosome expressing EFNB1 in one cell line due to a lack of XIST may explain similar phenotypic features in the present male patient and one other previously published case.

P02.247

Cryptic deletion in chromosome 1q43 associated with syndactylies detected by arrayCGH - a different critical region for syndactylies?

***E. E. Fiedler**, B. C. Gläser, H. Heilbronner, S. Biskup;*
Institut für Klinische Genetik, Stuttgart, Germany.

We report a case of a woman with a known familial history of syndactylies probably associated with a cytogenetically balanced translocation t (1;9)(q43;q32). At the age of 19 years she came for genetic counseling while being pregnant. She herself was analyzed by cytogenetic karyotyping where a translocation was detected which she inherited from her father. As her father, her brother and her half-brother from father's side also had syndactylies of hands and feet as well as a skeletal dysplasia and were carriers of this specific translocation, we performed arrayCGH analysis on all of them. ArrayCGH analysis revealed a microdeletion in 1q43 which spans over 528 kb of size in all three members of this family who bear the translocation. The deletion includes partly the CHRM3 (cholinergic receptor, muscarinic 3) and the FMN2 (formin-2) gene, two genes which are hardly described in literature until now. Formin-1 is the founding member of a family that share specific domains of homology and are classified together as the formin homology proteins. Deficiency mutations in formin-1 lead to profound developmental defects in limb and kidney formation. To date variations in formin-2, a gene which seems to have a high degree of similarity to formin-1, are rarely detected and understood.

In order to elucidate this specific region, we intend to perform next generation sequencing (NGS) to correlate the clinical phenotype to this deleted region.

P02.248

CGH-array detection of a "de novo" chromosome 19p13.3 deletion: case report.

***F. Blanco-Kelly**, M. Trujillo-Tiebas, I. Lorda, C. Ayuso;*
Servicio de Genética, ISS-Fundación Jiménez Díaz, Madrid, Spain.

Introduction: the development of high-resolution array-CGH has allowed the identification of genomic alterations not previously detectable with routine techniques. We present a patient with a "de novo" genomic imbalance of 19p13.3, not detected by routine techniques (high resolution G-banded chromosome analysis and MLPA).

Patients and Methods: five members of the same Spanish family: the index patient, a 23 year old male who presented athonic epileptic crisis, mild mental retardation and dysmorphic phenotype, the unaffected parents and two unaffected sisters.

Oligonucleotide comparative genome hybridisation-based microarray analysis (array-CGH; 105A or 180K, Agilent Technologies) was performed on each DNA sample of each family member.

Results: the proband showed three deletions not previously described in the general population, two of them potentially pathogenic, deletion in 19p13.3 and 22q21.3. He also presented eighteen copy number variations (CNVs) previously described in the general population,

The deletion in 22q21.3 was also present in the sisters and in the mother.

The 19p13.3 monosomy covers 821kb (from position 982,017 to position1,803,579) which includes 33 genes, four of them pathological (STK11, NDUFS7, GAMT and TCF3).

Conclusions:

The "de novo" 19p13.3 monosomy seems to be responsible for the pathology of the proband.

This is the first case of 19p13.3 monosomy described in Spanish population (two cases have been previously reported among other populations, Siggberg, 2010 and Smith, 2010).

CGH-arrays allows for the genetic diagnosis of new syndromes, but further studies are needed to establish genotype-phenotype correlation.

P02.249

A rare combination of Syntelencephaly, Wormian bone and Split Metopic suture

***A. KOPARIR**[1], H. Aydın[1], E. Koparır[1], H. Ulucan[1], E. Yosunkaya[1], M. Seven[1], A. Yüksel[2], M. Ozen[1];*
[1]Istanbul university cerrahpasa medical school, Istanbul, Turkey, [2]Bezmialem Vakif University, Istanbul, Turkey.

Syntelencephaly is a rare anomaly characterized by fusion of the hemispheres in the posterior frontal and parietal regions and is considered a new variant of holoprosencephaly.Wormian bones are accessory bones that occur within cranial suture and fontanelles, most commonly within the posterior sutures. They occur more frequently in disorders that have reduced cranial ossification, hypotonia or decreased movement, thereby resulting in deformational brachycephaly.Here, we report a one-week- old male who presented with abnormal head shape and concern for craniosynostosis. He had rachycephaly, alopecia, right hemiparesis and closed anterior fontanelle. Three dimentional CT scan revealed absence of the anterior fontanelle, sagittal wormian bone and split metopic suture. Alopecia was noted in the skin overlying the wormian bone. MRI scanning showed

deficient formation of the interhemispheric fissure with fusion of parietal lobes and agenesis of corpus callosum. We used a custom array with a 44K whole genome and extra 14,217 additional probes for all known 226 genes of skeletal dysplasia. We detected no significant copy number changes in our patient. To our knowledge, this is the first reported case with syntelencephaly, wormian bone and split metopic suture.

P02.250

Identification of TAZ mutation in a family with X-linked dilated cardiomyopathy by Next Generation Sequencing

***B. Chung**, E. Man, T. C. Yung, K. S. Lun, K. T. Chau;*
Department of Paediatrics, The University of Hong Kong, Hong Kong, Hong Kong.

Familial dilated cardiomyopathy (DCM) is defined as DCM of unknown cause in 2 or more closely related family members. We reported a family with 2 male siblings both presented with heart failure in infancy and subsequently confirmed to have DCM without conduction abnormalities. Endo-myocardial biopsy (in the elder sibling), extensive metabolic workup, viral studies and NimbleGen CGX-12 array were all normal. Oligonucleotide-based target capture (Sureselect, Agilent) followed by next generation sequencing (Illumina HiSeq2000) was used to capture variants of 46 genes implicated in the causation of cardiomyopathy (Partners Healthcare Center for Personalized Genetic Medicine). Clinically significant /novel variants are confirmed by independent Sanger sequencing. A hemizygous variant c.718G>C (p.Gly240Arg) in exon 10 of TAZ gene is identified. This variant is likely pathogenic as it has been reported in 5 individuals with X-linked infantile DCM and was described in a family with endocardial fibroelastosis. So far, the 2 siblings did not show evidence of skeletal myopathy, stunted growth, neutropenia or abnormal urine organic acid analysis. Next generation sequencing (NGS) allows efficient screening of a panel of genes in complex disorders like DCM, in which there is substantial overlap among phenotypes, multiple causative genes, and some mutations associated with > 1 phenotype. The identification of TAZ mutation has major impact in the medical surveillance of our patients as they need to be monitored for symptoms of Barth syndrome in addition to DCM. (Funding support from Children's Heart Foundation, Hong Kong)

P02.251

Novel insertion in exon 5 of the *TCOF1* gene in Twin Sisters with Treacher Collins syndrome

***B. A. Marszalek-Kruk**[1], P. Wojcicki[2], R. Smigiel[3], W. H. Trzeciak[4];*
[1]Department of Genetics, Wroclaw University of Environmental and Life Sciences, Wroclaw, Poland, [2]Department of Plastic Surgery, Wroclaw Medical University, Wroclaw, Poland, [3]Department of Genetics, Wroclaw Medical University, Wroclaw, Poland, [4]Faculty of Public Health, WSPiA, Poznan, Poland.

Treacher Collins Syndrome (TCS) is an autosomal dominant disorder, associated with an abnormal differentiation of the first and the second pharyngeal arches during fetal development. It cause craniofacial deformities with typical clinical symptoms: downward slanting of the eyelids, hypoplasia of the zygomatic bone, mandibular hypoplasia. The estimated incidence is 1/50000 live births, with 60% of the cases resulting from a *de novo* mutations. The syndrome is mostly caused by mutations in the *TCOF1* gene, which encodes the serine/alanine-rich protein named Treacle. TCS can be also caused by mutations in the *POLR1C* and *POLR1D* genes encoding subunits of RNA polymerases I and III. Over hundred mutations of the *TCOF1* gene responsible for TCS have been described, which about 70% are deletions.

Investigated DNA fragments were amplified by PCR and were subsequently subjected to multitemperature single-stranded conformation polymorphism analysis. Fragment of the allele, which exhibited an abnormal MSSCP pattern were eluted from the gel and used as template for reamplification of single band by PCR method. The PCR products were purified followed by direct sequencing.

In the patients - two monozygotic twin sisters a novel, heterozygotic insertion c.483_484ins185 was detected. It is the longest discovered in *TCOF1*. This mutation was absent in the patients' father, brother and uncle, which probably indicates a *de novo* origin. The c.483_484ins185 insertion causes a reading-frame shift and premature termination of translation at 167aa.

We believe that these findings facilitated a precise diagnosis of both patients and extended our knowledge on the pathogenesis of TCS.

P02.252

Beta-globin deletion in a transfusion dependent child with parents showing no elevated HbF

***N. Bayat**, M. Ashki, S. Farrashi, N. Faramarzi Garous, S. Vakili, M. Montajabi Niat, A. Azarkeivan, H. Imanian, H. Najmabadi;*
Kariminejad-Najmabadi Pathology & Genetics Center, 14665/154, Tehran, Iran, Tehran, Islamic Republic of Iran.

The molecular investigation of beta-globin gene cluster deletions is usually performed in the presence of fetal hemoglobin (HbF). In this study, a family showing no elevated HbF (0.6% and 0%), the mean corpuscular value (MCV: 59.9 fL and 64.7 fL), and HbA2 (3% and 2.9%) for the maternal and paternal sides respectively has referred to our laboratory having a 3 months old child with severe anemia undergoing blood transfusion every 15 days.

Firstly, the most common alpha thalassemia deletions were investigated by gap-PCR and the paternal side revealed homozygote alpha gene deletion -α3.7and consequently the child has inherited the -α3.7in heterozygous form. The maternal side did not show any alpha gene mutation even by alpha-globin DNA sequencing. Direct sequencing for beta- globin gene was also performed and no mutation was detected for the family. Finally, multiplex ligation probe amplification (MLPA) was subjected to detect alpha- and beta- globin large deletions in the affected child and the results indicate a huge homozygote deletion in beta-globin gene cluster with the same pattern as Indian GγAγ (δβ)° or Belgian (50 Kb) deletions. The deletion was confirmed in both paternal and maternal sides in heterozygous form.

This study shows that MLPA can effectively identify different and unknown types of beta-globin gene deletions, to allow characterizing previously unsolved thalassemia intermedia genotypes, and remarks the probability of presence of beta deletions in cases that do not show significant elevations of HbF.

P02.253

Mutations in WNT10A are present in more than half of isolated hypodontia cases

M. H. van den Boogaard[1]*, M. Creton*[2]*, Y. Bronkhorst*[1]*, A. H. van der Hout*[3]*, F. A. M. Hennekam*[1]*, D. Lindhout*[1]*, M. Cune*[4,5]*, J. K. Ploos van Amstel*[1]*;*
[1]*Department of Medical Genetics, University Medical Center Utrecht, The Netherlands;, Utrecht, Netherlands,* [2]*Department of Oral and Maxillofacial Surgery, Prosthodontics and Special Dental Care, University Medical Center Utrecht, The Netherlands;, Utrecht, Netherlands,* [3]*Department of Genetics, University Medical Center Groningen, The University of Groningen, Groningen, Netherlands,* [4]*Department of Fixed and Removable Prosthodontics, Academic Centre for Dentistry and Oral Health, University Medical Center Groningen, The University of Groningen, The Netherlands, Groningen, Netherlands,* [5]*Department of Oral and Maxillofacial Surgery, Prosthodontics and Special Dental Care, St. Antonius Hospital Nieuwegein, The Netherlands., Nieuwegein, Netherlands.*

Hypodontia or the congenital absence of one or more permanent teeth is the most common congenital anomaly in man. The disorder is highly heritable and occurs as an isolated anomaly or as a symptom of a large variety of syndromes, including Ectodermal Dysplasia (ED). The recent finding of hypodontia in carriers of the autosomal recessive disorder odonto-oncychodermal dysplasia due to mutations in *WNT10A* (OMIM 257980; OODD) made *WNT10A* an interesting candidate gene for dental agenesis. This motivated us to study the contribution of *WNT10A* mutations in comparison with mutations in other genes that are associated with hypodontia in isolated hypodontia patients. We tested a panel of 34 probands that show variable severity of isolated tooth agenesis for mutations in the candidate gene *WNT10A* and the genes *MSX1*, *PAX9*, *IRF6* and *AXIN2*. The probands all had agenesis with a range of 6 - 28 teeth. Nineteen cases with non-syndromic probands (56%) showed alterations in the WNT10A gene: 8 probands were homozygous, 4 probands were compound heterozygous and 7 probands were heterozygous for a single WNT10A mutation. In individuals, tested as heterozygote for a WNT10A mutation, tooth agenesis was comparable in males (6/9; 67%) and females (7/12; 58%). In conclusion, we identified *WNT10A* as a major gene in the aetiology of isolated hypodontia. By including this gene, the yield of molecular diagnostics in isolated tooth agenesis has increased significantly from 15% to 71%. This approach will be of help in a more optimal counselling of patients with hypodontia and their family members.

P02.254

Live-born Child with Trisomy 22

T. Heinrich[1]*, I. Nanda*[1]*, M. Rehn*[2]*, U. Zollner*[2]*, E. Frieauff*[3]*, J. Wirbelauer*[3]*, T. Grimm*[1]*, M. Schmid*[1]*;*
[1]*Department of Human Genetics, Würzburg, Germany,* [2]*Departments of Gynecology and Obstetrics, University Hospital, Würzburg, Germany,* [3]*University Children's Hospital, University of Würzburg, Würzburg, Germany.*

Chromosomal abnormalities represent a major cause of spontaneous abortions (SABs). Trisomy 22 has been identified as the third most common trisomy in SABs, representing 16% of cases. Due to severe organ malformations associated with trisomy 22 a live-born child is a very rare event. Here, we report on a male infant with complete, non-mosaic trisomy 22 in peripheral blood lymphocytes (PBLs) and skin fibroblasts.

The patient was born at 35+5 weeks by caesarean section as the second child of a 44-year-old female and a 40-year-old male. The parents are healthy and unrelated. Prenatal sonographic examinations had revealed IUGR, dolichocephalus, SUA, absent right kidney, and hypospadia. Due to the parents' beliefs they did not opt for additional prenatal diagnostic procedures and chose to continue the pregnancy.

Birth weight and length were below the 3rd percentile; APGAR 5/6*/8* (*CPAP). GTG-banded chromosomes from PBLs and fibroblasts showed an additional chromosome 22 in all metaphases analyzed (47,XY,+22). SNP array and aCGH demonstrated a complete trisomy 22. Clinical features included dolichocephalus, hypertelorism, flattened nasal bridge, dysplastic ears with preauricular sinuses and tags, medial cleft palate, anal atresia, and coronary hypospadia with scrotum bipartitum. Echocardiography showed persistent foramen ovale and ductus Botalli. Essential therapy was implemented in close coordination with the parents. The child died 29 days after birth due to respiratory insufficiency and deterioration of renal function; an autopsy was not performed. This patient's history complements other reports illustrating that children with complete trisomy 22 can survive until birth and even some time beyond.

P02.255

Recurrent hypoglycemia due to growth hormone deficiency and resistance in a preterm with Turner syndrome

N. Salem[1]*, W. Bonfig*[2]*, K. Heiliger*[1]*, M. Hempel*[1]*, G. Lederer*[1]*, M. Bornkamm*[2]*, K. Wieland*[2]*, P. Lohse*[3]*, S. Burdach*[2]*,* ***K. Oexle***[1]*;*
[1]*Humangenetik, TUM, München, Germany,* [2]*Kinderklinik, TUM, München, Germany,* [3]*Clinical Chemisty, LMU, München, Germany.*

Objectives: i) To report a case of infantile hypoglycemia in Turner syndrome (TS) patient with growth hormone (GH) deficiency and resistance, and ii) to compare conventional cytogenetics and array CGH in the diagnosis of a complex TS karyotype. *Case report:* In a preterm (32 weeks) with prolonged and cholestatic jaundice, recurrent hypoglycemia occurred at the age of 1.5 months and related to GH deficiency. There were no other endocrine or syndromic features. GH therapy was started at a usual dose of 25-30 µg/kg/d but hypoglycemia recurred. Hepatopathy and hypogammaglobulinemia suggested X-recessive GH deficiency type 3 with non-random X-inactivation but resolved spontaneously. Nonetheless, a TS karyotype 45,X[75]/46,X,i(Xq)[21]/47,X,i(Xq)x2[4] was diagnosed with an apparent isochromosome fusion at the centromere. Upon this diagnosis, GH dose was doubled (50 µg/kg/d) and blood glucose normalized consistently. In array CGH, the signal of Xp deviated more strongly than that of Xq but the relation of the signals differed substantially from what the karyotype predicted. The isochromosome fusion point was relocated to Xp11.22, distal to a block of mental retardation genes that escape X-inactivation. *Conclusions:* i) TS with GH deficiency or resistance is a differential diagnosis of hypoglycaemia in infants. ii) Array CGH is useful in precisely delineating isochromosome structure but may be erroneous in quantification of TS mocaicism.

P02.256

Maternal isodisomy for chromosome 9 in a patient with IgA nephropathy, short stature and intellectual disability

S. Azzarello-Burri*, B. Oneda, A. Baumer, S. Pajarola, D. Niedrist, A. Rauch;*
Institute of Medical Genetics, University of Zurich, Switzerland.

Descriptions of patients with maternal isodisomy 9 are rare in the literature (10 cases of maternal UPD 9 and 2 cases of paternal UPD 9). The possibility of hidden mosaicism or homozygosity of mutations in autosomal recessively inherited diseases hampers the delineation of a clear UPD 9 phenotype.

Here we report a 34 years-old man with maternal isodisomy for chromosome 9 detected by genome-wide combined copy number and genotype profiling using a high-resolution CN/SNP array. The major problems in this patient were renal failure because of IgA nephropathy, hypothyroidism, short stature with overweight, hypercholesterinemia, hypertriglyceridemia and hyperuricemia. Other features were dislocation of the patella, atopic eczema, eye problems (strabism, nystagmus, myopic astigmatism), inguinal hernias and umbilical hernia as an infant. Since infancy a disproportional large distended abdomen was noted with unidentified cause. At the age of about 15 years some hearing problems on the left side were noted.

The young man was able to live alone and was working 50% at a protected workplace.

No evidence of trisomy 9 mosaicism could be detected in blood and buccal smears.

P02.257

Can we prevent ELST related hearing loss through early audiological ELST diagnosis? - A case of deafness due to microscopic ELST and an international collaborative study

M. M. Poulsen[1]*, S. Gimsing*[2]*, C. Thomsen*[3]*,* ***M. Bisgaard***[1]*;*
[1]*Department of Cellular and Molecular Medicine, Copenhagen N, Denmark,* [2]*Department of Audiology, Vejle Hospital, Vejle, Denmark,* [3]*Department of Diagnostic Radiology, Rigshospitalet, Copenhagen, Denmark.*

Background

Endolymphatic sac tumours (ELSTs) occur in up to 16% of von Hippel-

Lindau (vHL) patients. Timely diagnosis and surgical excision of tumors is essential to prevent severe audio-vestibular morbidity as even microscopic ELSTs can cause irreversible hearing loss. We present a case in which deafness caused by a microscopic ELST possibly could have been prevented by early pre-symptomatic audiometric diagnosis.

Methods

Full medical records of the patient's subjective audio-vestibular symptoms, audiological examinations, and Magnetic Resonance Imagings (MRIs) of the inner ear from 1995-2011 were collected and evaluated.

Results

A 42-year-old male *VHL* mutation carrier with initial normal hearing was followed for twenty years with audiometry and MRI of the brain and inner ear as part of a surveillance program. He reported occasional bilateral tinnitus, but no subjective hearing-loss until 2009 when in his right ear hearing began to deteriorate and progress to total deafness.

Despite annual MRIs, a right-sided ELST was not visible until 4 months after onset of deafness in 2010, when it appeared as 4 x 3 mm tumor mass. Although his hearing was objectively within normal limits until 2009, a distinct audiometric pattern of low-frequency hearing loss could retrospectively be seen from first audiometry.

Conclusions

Previous reports suggest that certain audiometric patterns as seen in our patient may indicate early ELST development. Accordingly, audiometry may be an important diagnostic tool to detect non-symptomatic ELSTs. To investigate the use of audiometry for this purpose we have initiated an international collaborative study and hope to attract new collaborators: http://icmm.ku.dk/english/icmm-staff/marie_luise_bisgaard/vhl_collaborative_research/

P02.258

A 725 kb deletion within the 22q13.1 chromosomal region detected by array CGH associated with Waardenburg syndrome

E. Siomou[1], *E. Manolakos*[2], *M. Petersen*[2], *L. Thomaidis*[3], *Y. Gyftodimou*[4], *I. Papoulidis*[1];
[1]*Eurogenetica, Thessaloniki, Greece,* [2]*Eurogenetica, Athens, Greece,* [3]*Department of Pediatrics, University of Athens, Aglaia Kyriakou Children's Hospital, Athens, Greece,* [4]*Department of Genetics, Institute of Child Health, Athens, Greece.*

Waardenburg syndrome (WS) is a rare (1/40,000) autosomal dominant disorder resulting from melanocyte defects, with varying combinations of sensorineural hearing loss and abnormal pigmentation of the hair, skin, and inner ear. Due to the variety of additional clinical symptoms and genetic heterogeneity, WS is classified into four clinical subtypes (WS1-S4). Mutations in six genes have been identified to be associated with the different subtypes of WS, among which *SOX10* (SRY bOX10 transcription factor) gene, which is localized within the region 22q13.1. Whole gene *SOX10* deletions have been described by Bondurand et al. [2007] suggesting that haploinsufficiency due to *SOX10* gene deletions should be encountered when testing for WS. *SOX10* is a member of the *SOX* family transcription factors and is a key transcription factor of neural crest development. In this study we report a case of a 13 year old male with a unique de novo 725 kb deletion within the 22q13.1 chromosomal region, encompassing *SOX10* and another 13 OMIM listed genes and presenting clinical features of a neurologic variant of WS. **Very few patients have been documented with whole gene deletions of *SOX10* and also very few data is known regarding deletions within 22q13.1 and of neurologic defect candidate genes such as** *PLA2G6*, *KCNJ4* and *PICK1*, **which are localised within the deleted region.** In this study **we compare the clinical features of our patient to other reported cases with analogous 22q13.1 deletions and look into** genotype-phenotype correlations**.**

P02.259

WAGRO syndrome caused by deletion 11p14.2p11.2

M. Hejtmankova, *M. Trkova, E. Svobodova, V. Becvarova, L. Hnykova, D. Stejskal;*
GENNET, Prague, Czech Republic.

WAGR is a contiguous gene deletion syndrome caused by loss of distal portion of chromosome 11p13 band. Its subphenotype WAGRO including obesity is associated with additional haploinsufficiency of BDNF gene with locus 11p14.1.

We present a case where diagnosis of the WAGRO was delayed because of the absence of predictable tumor in a mentally retarded female with aniridia and severe obesity with onset at 10 years of age. She had craniofacial dysmorphism, nasal cleft, and large anterior fontanelle. Diagnosis of aniridia and cataracts was confirmed early after birth. Multiple renal cysts spontaneously disappeared in later life. Menarche started at the age of eleven, but secondary amenorrhea ensued early. Enuresis nocturna and epilepsy have been a constant problem. Neither gonadoblastoma nor Wilms tumor were diagnosed. She was referred to geneticist to specify the diagnosis at the age of 24.

We have used effective genetic diagnosis work-up: a routine G- banded karyotyping and SNP array (Illumina HumanCytoSNP-12v2.1) analysis. The deletion has been detected by classical karyotype and further updated by SNP array. The 18 Mb haploinsufficiency of 11p11.2 -14.2 has been confirmed containing over 70 genes including PAX6 and WT1 associated with WAGR. Haploinsufficiency of BDNF in this deleted region can explain the WAGRO phenotypic features.

The observed disease phenotype depends on gene dosage and specific sequences involved in hemizygous deletion. It is necessary to determine the extent of each 11p deletion. The early diagnosis may provide a possibility of more specific health supervision which could be essential for the patient's prognosis.

P02.260

The mitochondrial ND1 m.3337G>A mutation associated to multiple mitochondrial DNA deletions in a patient with Wolfram syndrome and cardiomyopathy

N. Mezghani[1], *M. Mnif*[2], *E. Mkaouar-Rebai*[1], *N. Kallel*[2], *I. Haj Salem*[1], *N. Charfi*[2], *M. Abid*[2], *F. Fakhfakh*[1];
[1]*genetic laboratory, sfax, Tunisia,* [2]*Service d'endocrinologie C.H.U. Habib Bourguiba, sfax, Tunisia.*

Wolfram syndrome (WFS) is a rare hereditary disorder also known as DIDMOAD (diabetes insipidus, diabetes mellitus, optic atrophy, and deafness). It is a heterogeneous disease and full characterization of all clinical and biological features of this disorder is difficult. The wide spectrum of clinical expression, affecting several organs and tissues, and the similarity in phenotype between patients with Wolfram syndrome and those with certain types of respiratory chain diseases suggests mitochondrial DNA (mtDNA) involvement in Wolfram syndrome patients. We report a Tunisian patient with clinical features of moderate Wolfram syndrome including diabetes, dilated cardiomyopathy and neurological complications.

The results showed the presence of the mitochondrial ND1 m.3337G>A mutation in almost homoplasmic form in 3 tested tissues of the proband (blood leukocytes, buccal mucosa and skeletal muscle). In addition, the long-range PCR amplifications revealed the presence of multiple deletions of the mitochondrial DNA extracted from the patient's skeletal muscle removing several tRNA and protein-coding genes.

Our study reported a Tunisian patient with clinical features of moderate Wolfram syndrome associated with cardiomyopathy, in whom we detected the ND1 m.3337G>A mutation with mitochondrial multiple deletions.

P02.261

Array-CGH detection of cryptic genomic rearrangements in children with X-Linked Intellectual Disability

K. Giannikou[1,2], *S. Sofia Kitsiou-Tzeli*[1], *H. Frysira*[1], *V. Oikonomakis*[1], *K. Kosma*[1], *A. Syrmou*[1], *A. Xaidara*[1], *E. Kanavakis*[1,3], *M. Tzetis*[1];
[1]*Department of Medical Genetics, Medical School, University of Athens, Greece, Athens, Greece,* [2]*Alexander S. Onassis Public Benefit Foundation, Athens, Greece,* [3]*Research Institute for the Study of Genetic and Malignant Disorders in Childhood, "Aghia Sophia, Children's Hospital", Athens, Greece.*

Clinical and genetic observations have shown that X-Linked Intellectual Disability (XLID) is a very heterogeneous entity, involving syndromic and non-syndromic indistinguishable forms with more than 100 causative genes implicated and an estimated prevalence of ~10% in males. Underlying X chromosome defects are not always visible with conventional cytogenetic techniques as a first-line approach, making the genetic evaluation and diagnosis difficult. Array Comparative Genomic Hybridization (Array-CGH) has proven a high throughput method, allowing genome wide XLID gene screening in the diagnostic workup. Overall 198 male patients with a large spectrum of phenotypic variability (developmental delay, seizures, dysmorphic feautures, congenital anomalies), normal previous conventional karyotype and negative genetic tests (FRAX, RETT, FISH tests or metabolic screens) were analyzed with Agilent platform 4x180K and 1x244K oligoarrays(>170.000 probes and >236.000 probes respectively with a high resolution of 8.9 Kb). 14 X-chromosome cryptic rearrangements containing clinically relevant genes were detected in 21 patients, explaining partially or completely the pathological phenotype (Table below).The remarkable percentage of positive patients is probably due to the strict criteria of patient selection. Array-CGH offers a higher diagnostic yield for the identification of previously unreported X-linked aberrations of unclear significance, elucidating novel non-syndromic/syndromic forms and permitting better dinstiction and correct reclassification of specific XLID cases.

P02.262
Interstitial Xq duplication in a male patient - clinical, cytogenetic and arrayCGH characterization of a new case

B. Goryluk-Kozakiewicz, *M. Jędrzejowska, M. Kucharczyk, M. Pelc, A. Jezela-Stanek, A. Cieślikowska, A. Gutkowska, M. Krajewska-Walasek;*
The Children's Memorial Health Institute, Warsaw, Poland.

Prevalence of isolated Xq duplications is presently unknown. At least 30 male patients with this aberration have been reported, with the majority localized within Xq12-q24. Large, cytogentically visible Xq duplication are rare. However, application of microarray-based technique gives the chance for detection of smaller aberrations, as well as defined genes influencing the causative phenotype.

Clinical manifestations in described cases vary depending on the gender of the patient and on the size of duplication, hence gene content of the duplicated segment. Consequences of over-expression of X-linked genes are not well known. In most male cases the consistent phenotype includes profound muscle hypotonia accompanied by severe psychomotor and growth failure, hypoplastic genitalia, seizures and craniofacial dysmorphism. Such phenotype seems to be quite specific, however, due to rarity of this disease, it is difficult to suspect it based on clinical symptoms.

In our presentation we report the clinical and laboratory data of 3-year-old boy with profound generalized hypotonia, growth failure resulting from Xq duplication identified cytogenetically as 46, XY,dup(X)(q21q22?)mat. Further delineation of the duplicated region by arrayCGH refined the breakpoints to Xq13.1-q22.11 and showed the duplication size of 32 Mb. This is only the second case with similar aberration characterized molecularly.

By comparison of our patient's phenotype with the previously reported male with overlapping duplicated region, we hope that presented detailed results give insight into the genotype-phenotype correlation of Xq-linked genes duplication.

The study was partially supported by the grant of the Polish Ministry of Science and Higher Education (Contract No 0605/B/P01/2009/37).

P02.263
A 91kbp interstitial deletion of Xq24 encopassing the UBE2A gene, in a boy presenting with intellectual disability, impaired speech, microcephaly, growth retardation VSD and hirsutism.

C. Vinkler[1,2], *A. Frumkin*[3], *M. Michelson*[1,2], *B. Tziperman*[2], *T. Lerman-Sagie*[2], *D. Lev*[1,2];
[1]*Institute of Clinical GeneticsWolfson Medical Center, Holon, Israel,* [2]*Metabolic Neurogenetics Service, Wolfson Medical Center, Holon, Israel,* [3]*The Department of Genetic and Metabolic Diseases, Hadassah, Hebrew University Medical Center, Jerusalem, Israel.*

Interstitial deletions of chromosome Xq24 are rare with only five reported cases so far. In all of these cases the deletions included the *UBE2A* gene and the size of the deletion was almost identical, ranging from 275kb to 371kb and encompassing between 5 and 6 genes in addition to the *UBE2A* gene.

We describe a 2y and 3m old boy with a 91 kb deletion in the Xq24 region detected by array comparative genomic hybridization (array CGH). His phenotype includes: severe intellectual disability with absent speech, hypotonia, feeding problems, mild conductive hearing loss, recurrent aspiration pneumonia and prolonged neonatal hypoglycemia. He has microcephaly (-4.5 SD) and growth retardation (his weight is -4.5 SD and height -5 SD). His dysmorphic features include: large open fontanel, hypertelorism, up-slanted palpebral fissures, synophrys, depressed nasal bridge, marked general hirsutism a ventricular septal defect and normal genitalia. The mother carries the same deletion. The deleted X chromosome in her blood lymphocytes is completely inactivated (0:100).

This is the smallest deletion encompassing the *UBE2A* gene reported so far. Only three genes are located in the deleted Xq24 region found in this boy: *NKRF*, *UBE2A* and *CXorf56*. *UBE2A* deficiency syndrome that is caused by point mutations in the *UBE2A* gene, has been shown to cause syndromic X-linked intellectual disability (XLID) with dysmorphic features, severely impaired speech, small penis and hirsutism. Our case further supports previous suggestion that deletion of *UBE2A* is sufficient to cause the *UBE2A* deficiency syndrome.

P02.264
Interstitial duplication in the case of Yunis Varon Syndrome

A. M. Tarko[1], *A. M. Pyrkosz*[2], *E. Kortyczko*[1], *E. Musialik-Świetlińska*[1], *I. Maruniak-Chudek*[1], *M. Nycz-Bochenek*[2];
[1]*Dept. of Neonatal Intensive Care, Upper Silesian Centre of Child's Health, Katowice, Poland,* [2]*Dept. of General and Molecular Biology and Genetics, Medical University of Silesia, Katowice, Poland.*

Brief Introduction: The aim was to evaluate the relationship between abnormality in the region of 5p15.31-5p15.2 represented on the microarray analysis, classified as an interstitial duplication and the subsequent clinical presentation of Yunis Varon Syndrome.**Materials and Methods**: Neonate with dysmorphic, typical phenotypic and radiologic features of Yunis Varon Syndrome, born as 37 weeker, 2300g, Apgar score 1/2/3/3, a first child to a healthy couple. Prenatal ultrasound scans, fetal biometry and fetal MRI were performed showing malformations in central nervous system, hypertelorism, micrognathia, abnormal views of extremities. Chromosomal caryotyping from amniotic fluid cells cultures was done - 46, XX.Postnatally the baby was growth restricted, hypotonic and dysmorphic. Microcephaly, hypertelorism, microtia, narrow high-arched palate, wide fontanelles, bilaterally absent thumbs and great toes were observed. Radiologically - aplasia of both clavicles. ASD II in echocardiogram. No abnormalities in abdominal ultrasound scans. Chromosomal karyotyping from peripheral blood lymphocytes was correct female karotype.Autopsy showed agenesis of corpus callosum with atrophic subcortical nuclei and hydrocephalus, middle and external ear anomalies, bilateral dysplasia of eye bulbs, hyperaemia of kidneys and lungs and focal liver necrosis.Microarray analysis was performed using NimbleGen CGX-12, revealing abnormality in the region of 5p15.31-5-p15.2, covering ADCY2, MTRR, SEMA5A, TAS2R1, CCT5, CMBL genes, which is classified an interstitial duplication.**Conclusions**: Microarray analysis using NimbleGen 135k CGX-12 enables to identify submicroscopic changes, localized in genome regions bigger than 30-100 kb and therefore, abnormality in the region of 5p15.31-5p15.2 classified as an interstitial duplication can highly be a pathogenic one.

Expanding the clinical phenotype of patients with *ZDHHC9* mutation

A. Masurel-Paulet[1], *F. Levy*[2], *C. Thauvin- Robinet*[1], *J. Thevenon*[1], *S. Chancenotte*[2], *M. Ruffier-Bourdet*[2], *M. Bonnet*[2], *S. El Chehadeh*[1], *V. Desportes*[3], *J. Chelly*[4], *L. Faivre*[1];
[1]*Centre de génétique et Centre de Référence Anomalies du développement et Syndromes malformatifs, CHU, Dijon, France,* [2]*Centre Référent des Troubles du Langage et des Apprentissages, CHU, Dijon, France,* [3]*Service de neurologie pédiatrique, Hôpital Femme Mère Enfant, CHU, Lyon, France,* [4]*Service de génétique moléculaire, Hôpital Cochin, Paris, France.*

In 2007, four families with a mutation in the *ZDHHC9* gene have been described, out of the screening of 250 families with X-linked intellectual deficiency (ID). ID was either isolated or associated with a marfanoid habitus. ZDHHC9 encodes for a palmitoyl transferase that catalyses the posttranslational modification of NRAS and HRAS. Since this first description, no additional patient has been described. A new family has been identified in France from the systematic screening of X-linked ID genes in 95 families, carrying the unreported *p.R298X* variant leading to a stop codon, cosegregating with the disease. A 18-year-old patient and his 40-year-old maternal uncle have been evaluated. Clinical examination revealed normal growth parameters, lingual fasciculations, a limited extension of the elbows and metacarpophalangian joints, and acrocyanosis. There was no facial dysmorphism or marfanoid habitus. Brain MRI revealed dysplastic corpus callosum. Neuropsychological testing demonstrated a mild to moderate mental retardation. The younger suffers of significant impairment of behaviour requiring attention or treatment, and the older a generalised anxiety disorder (ICD 10). Speech evaluation revealed a satisfactory oral language since both were able to provide information and to understand conversations of everyday life. Occupational therapy examination revealed impaired visuospatial and visuomotor performance with poor drawing/graphic skills. These manifestations appear not enough specific to permit to define specific criteria justifying *ZDHHC9* screening in patient with ID, and emphasized the value of next generation sequencing for genetic counselling in families with X-linked ID.

A clinical study of patients with pericentromeric deletion and duplication within 16p11.2-p12.2

N. Okamoto[1], *K. Saito*[2], *T. Matsui*[2], *N. Harada*[2], *N. Miyake*[3], *N. Matsumoto*[3];
[1]*Department of Medical Genetics, Osaka Medical Center & Research Institute for Maternal and Child Health, Osaka, Japan,* [2]*Department of Molecular Genetics, Advanced Medical Science Research Center, Mitsubishi Chemical Medience Corporation, Tokyo, Japan,* [3]*Department of Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Japan.*

The pericentromeric region on 16p is susceptible to chromosomal rearrangements. There are many reports that deletions of 16p11.2 are observed about 1% among patients with autism. The 16p11.2-p12.2 deletion syndrome is characterized by developmental disabilities and dysmorphic features. We have identified pericetromeric deletion and duplication, within 16p11.2-p12.2 in three patients by Cytogenetics 2.7M array. Patient 1 was a 10-year-old girl with autism and obesity. She had a heterozygous 593kb deletion in 16p11.2. Her mother with the same deletion was not autistic, but was obese. Patient 2 was a 2-year-old boy with VSD, hypotonia, developmental delay and frequent ear infections. He had.dysmorphic features including flat face, down slanting palpebral fissures, low-set posteriorly rotated ears and thin upper lip. Autistic features were not seen. Microarray analysis revealed a 7.7Mb deletion at 16p11.2-p12.2. He showed common clinical features to the 16p11.2-p12.2 deletion syndrome. Patient 3 was an 8-year-old girl with developmental delay, autism and dysmophic features including hypertrichosis, wide mouth and macrocephaly. She showed poor communication skills and ritualized patterns of interests and behavior. Microarray analysis revealed a 6.7Mb duplication at 16p11.2-p12.2. The duplicated region of patient 3 was very similar with the deleted region of the patient 2. We suggest that 16p11.2-p12.2 duplication may be a new syndrome with autism.

P03.004

17q21.31 microdeletion syndrome in monozygotic twins

M. Vlckova[1], *M. Hancarova*[1], *J. Drabova*[1], *Z. Zmitkova*[1], *M. Koudova*[1,2], *R. Alanova*[1,3], *K. Mannik*[4], *A. Kurg*[4], *Z. Sedlacek*[1];
[1]*Department of Biology and Medical Genetics, Charles University 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic,* [2]*GHC Genetics, ltd. - Private Medical Facility, Prague, Czech Republic,* [3]*Institute for the Care of Mother and Child, Pregue, Czech Republic,* [4]*Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia.*

Chromosome 17q21.31 microdeletion syndrome is a genomic disorder caused by recurrent ~600 kb deletion of the region containing the common 900 kb inversion. The inversion is associated with the H2 haplotype present in ~20% of Europeans. H2 carries additional low-copy repeats susceptible to NAHR which can lead to the deletion. The syndrome is characterised by intellectual disability, hypotonia, long face, tubular or pear-shaped nose, bulbous nasal tip and friendly behaviour.

We present monozygotic twin sisters carrying the microdeletion and showing only slightly different phenotypes. Both had disproportionate short stature, short upper and lower limbs, thoracic hyperkyphosis, low-pitched voice and similar long, thin and coarse face, coarse hair, thick eyebrows, pear-shaped nose, smooth broad philtrum, thick lips, mandibular prognathism, and hirsutism. Twin A had high palate and Twin B had wide-spaced teeth, diastema, more severe intellectual disability, more coarse facial features, strabismus, and horizontal nystagmus.

The microdeletion was identified in Twin A using BAC array CGH and confirmed in both twins but not in the parents using FISH. Potential genomic differences were subsequently searched using Illumina Human CytoSNP-12 SNP arrays (~300K) and Nimblegen 2.1M whole-genome CGH array. These analyses identified no differences potentially responsible for the phenotypic differences, which could possibly be related to a more severe perinatal history of Twin B or the variable expressivity of the disorder. The father and mother were homozygous for H1 and H2, respectively, and the maternal 17q21.31 allele was missing in the twins.

Supported by CHERISH 223692, SF0180027s10, CZ.2.16/3.1.00/24022 and MZ0FNM2012.

P03.005

De novo ring chromosome 21 with a complex 21q interstitial and terminal deletion with array-CGH, in patient with several congenital anomalies, mental retardation and thrombocytopenia

A. Barcia Ramírez[1,2], *G. Cruz Guerrero*[1], *L. Alcaraz Mas*[3], *A. Moro Ortiz*[1], *M. Viloria*[1], *M. Miranda Díaz*[1];
[1]*Hospital Universitario Nuestra Sra. de Valme, Sevilla, Spain,* [2]*Instituto Hispalense de Pediatría, Sevilla, Spain,* [3]*Bioarrays, Alicante, Spain.*

We present a 20 months old infant with a de novo ring chromosome 21, detected in prenatal kariotype, with breaking point in p11.1 and q22.3, in which postnatal array-CGH demonstrated an almost complete loss of the q arm in the affected chromosome, with little microduplication fragments within four deleted fragments (1.2 Mb to 23 Mb) between 21q11.2-q21.1 and the chromosome end. Phenotypically, the infant presents moderate to severe growth and developmental delay, structural cardiac defects, bilateral hip dysplasia, microcephaly with cerebral atrophy, mild thrombocytopenia and facial dysmorphism, with similar features that those described in patients with partial or complete 21 monosomy. There are multiple affected genes, one of them, RUNX1, has been reported to pedisponse, when in haploinsufficiency, to thrombocytopenia and acute myelogenus leukemia. In this case, the array-CGH has contributed to a more accurate diagnosis of the chromosome disorder, which with at first seemd just a terminal 21q deletion instead of an almost complete 21 monosomy.

P03.006

Homozygous 2p21 deletion syndrome due to maternal uniparental disomy 2

U. Siebers-Renelt, *B. Dworniczak, P. Wieacker, A. Röpke;*
Institut für Humangenetik, Muenster, Germany.

The 2p21 deletion syndrome (MIM 606407) is a contiguous gene syndrome caused by homozygous deletions on chromosome 2p21. Depending on the size of the deletion different clinical symptoms have been described. Deletions of the SLC3A1 and PREPL genes are responsible for the hypotonia-cystinuria syndrome. Homozygous mutations in the SLC3A1 gene were found in patients with isolated cystinuria (MIM 220100). We report on a girl born preterm to non consanguineous healthy parents. At delivery, the mother was 44 years old. After birth, meconium ileus and a persistent Ductus arteriosus Botalli had to be corrected surgically. Profound muscular hypotonia was present and psychomotor development was delayed. Failure to thrive was so severe that at 2 years age tube feeding was still necessary. Karyotype on conventional cytogenetic analysis was apparently normal (46,XX). Array-CGH analysis uncovered a small homozygous deletion of approximately 28.6 kb that disrupts the PREPL and the CAMKMT genes but not the SLC3A1 gene. Quantitative PCR analysis of both parents demonstrated a heterozygous deletion of the same size in the maternal blood only. We hypothesized that a maternal uniparental disomy could be responsible for the homozygosity of the deletion in the daughter. A microsatellite analysis showed maternal isodisomy 2 in the critical region 2p21. Possibly meiotic non-disjunction followed by trisomy rescue led to homozygosity for the small maternal deletion. This case illustrates a complex multistep process leading to a disease causing genomic imbalance. Moreover, it underlines the necessity of investigations in the parents for a correct interpretation of array-CGH results.

P03.007

De novo chromosome (2)(q24.2q24.3) deletion in a 17-months old developmentally delayed girl

M. Stoian[1], *V. Belengeanu*[1], *N. Andreescu*[1], *S. Farcas*[1], *D. Misceo*[2], *T. H. Gamage*[2], *E. Frengen*[2];
[1]*University of Medicine and Pharmacy, Timisoara, Romania,* [2]*Department of Medical Genetics, Olso University Hospital and University of Oslo, Oslo, Norway.*

We present a 17 months old female patient, first examined at the age of 11 months for developmental delay. The girl is the second child of a healthy and non-consanguineous couple. The family history was unremarkable. She was delivered by caesarian section at 38 weeks of gestation with a birth weight of 2900 g (pc=25th), length of 50 cm (pc=50th) and cranial circumference of 32.5 cm (pc=10th). Clinical evaluation revealed: hypotonia, microcephaly, high forehead, hypertelorism, palpebral ptosis, strabismus, arched mouth, low set ears, pectus excavatum, coxofemoral dysplasia. Development milestones were delayed, she held her head at 6 months, sat at 11 months and started to walk sustained at 17 months. For lack of eye contact and repetitive hand movements we performed FISH analysis using Abbott probes for Angelman syndrome, but result was negative. Cerebral MRI evaluation was normal. Upon last evaluation at age of 17 months, the patient had length of 80 cm (pc=50th), head circumference 44 cm (<pc3rd), weight of 8400 g (<pc3rd). 180k Agilent aCGH detected a deletion on chr2: 162261555-164571028 bp hg19, chromosome(2)(q24.2q24.3). The deletion was confirmed using qPCR. Parents were checked and deletion occurred de novo. Nine genes are located in the deleted region including TBR1, SLC4A10, KCNH7 and FIGN, which may be good candidates in generating the phenotype TBR1 is involved in cortical development SLC4A10 has been previously associated to epilepsy. KCNH7, is involved in the regulation of NMDA receptor level in cortical neurons. FIGN are molecular chaperones with a role in embrionic development.

P03.008

Same genotype, different phenotype in a mother and son with genomic imbalance

S. Custódio, *S. Serafim, A. Sousa, R. Silveira-Santos, M. Ávila, P. Dias, A. Medeira, I. Cordeiro;*
Hospital de Santa Maria - Centro Hospitalar Lisboa Norte, Lisboa, Portugal.

With the broad application of molecular techniques like aCGH, findings of inherited chromosomal imbalances from unaffected or mildly affected parents have become more frequent. The phenotypical variability in these cases is often attributed to genetic, epigenetic and environmental modifiers.

Here we report a 33 years-old male with cognitive impairment, speech delay, epilepsy and hearing deficiency but no dysmorphic features. Subtelomeric FISH studies detected a 5p monosomy and a 18p trisomy consistent with the presence of a derivative chromosome from a (5;18) translocation. The same rearrangement was found on the unaffected mother. Subsequent aCGH analysis further delineated the rearrangement as a 1,7 Mb terminal deletion of 5p and a 2,1 Mb terminal duplication of 18p.

The patient's phenotype is consistent with other reported 5p distal deletions upstream from cri-du-chat syndrome critical region. The 18p duplication doesn't seem to contribute to the phenotype, as reported patients with larger duplications, in some cases encompassing the whole short arm, were clinically normal.

Absence of clinical phenotype in the mother may be due to a second hit on the patient, for example, a recessive mutation within the hemizygotic region, or a mutation in its vicinity that alters expression pattern of contained genes.

P03.009

First case of 5q13.2 duplication revealed by array comparative genomic hybridization

O. S. Kurinnaia[1,2,3], *S. G. Vorsanova*[1,2,3], *Y. B. Yurov*[2,1,3], *I. Y. Iourov*[2,1];
[1]*Institute of Paediatrics and Paediatric Surgery, Ministry of Health, Moscow, Russian Federation,* [2]*Mental Health Research Center, RAMS, Moscow, Russian Federation,* [3]*Moscow City University of Psychology and Education, Moscow, Russian Federation.*

We report on a case of 5q13.2 duplication uncovered by array comparative genome hybridization (array CGH). The proposita (age 9 months) presented with brain malformations (cerebellar hypoplasia and atrophy of frontal and temporal lobes), congenital heart and eye abnormalities, muscle weakness/atrophy, brachycephaly, broad nasal bridge, short nose, high palate, low-set and deformed ears, short neck, distal digital and nail hypoplasia. Array CGH revealed an interstitial duplication of 5q13.2 (approximately 3.8 Mb) spanning chromosome 5 region from 68.9 to 72.7 Mb according to NCBI Build 37.3. The region contains 74 genes, from which 14 are indexed in OMIM. Among notable disease-associated genes of this region are SMN1(*600354), SMN2(*601627), NAIP(*600355), GTF2H2(*601748), MCCC2(*609014). In addition, a deletion of 2q37.3 (subtelomeric 2q) encompassing 3 genes, two of which are also indexed in OMIM, was detected. Although 2q37.3 deletion represents a CNV, its impact on clinical manifestations in the index case cannot be excluded. It is to note that mapping of spinal muscular atrophy (SMA) genes (i.e. SMN1 and SMN2) to 5q13 have suggested these loci to be susceptible to genetic instabilities and DNA duplications. However, no cases of large constitutional duplications within 5q13.2 have ever been reported. One can hypothesize that genomic organization of SMA region predisposes both to small intragenic and large constitutional chromosomal duplications. Our case report supports current trends in molecular cytogenetics, which postulates molecular karyotyping (array CGH) as the most effective way to reveal previously unreported cases of constitutional chromosomal and genomic rearrangements.

P03.010

Morbid obesity, hypogonadism, minor facial dysmorphism and mild mental retardation in a patient with a 2.7 Mb duplication on chromosome (6)(q14.1) detected by arrayCGH

N. Andreescu[1], *V. Belengeanu*[1], *D. Misceo*[2], *M. Stoian*[1], *A. Belengeanu*[1], *S. Farcas*[1], *T. H. Gamage*[2], *E. Frengen*[2];
[1]*University of Medicine and Pharmacy „Victor Babes", Timisoara, Romania,* [2]*Department of Medical Genetics, Olso University Hospital and University of Oslo, Oslo, Norway.*

The association of obesity and developmental delay as presenting clinical features was the subject of many reports. Several gene mutations and genomic imbalances of specific loci scattered on different chromosomes have been reported to be involved in the pathogenesis of human obesity. Here we present a 29 years-old male, with hypogonadism, morbid obesity, minor facial dysmorphism and mild mental retardation evaluated for a suspected diagnosis of Prader-Willi syndrome. His weight was 180 kg (>95th percentile), height was 172 cm (25th percentile) and BMI was 60.84 kg/m2. His deceased father and paternal grandparents presented morbid obesity. As PWS was suspected, FISH analysis using specific probes was performed and didn't reveal the microdeletion. Next we performed a 180k aCGH which detected a duplication on the chromosome (6)(q14.1) (chr6: 76096298-78763228 bp hg19). Imbalances of the long arm of chromosome 6 were reported in several patients with Prader-Willi-like phenotype and SIM1 has often been considered the possible causes of nonsyndromic and PWS-like monogenic obesity. However SIM1 is not involved in the duplication detected in the patient. A recent study found 2 patients with comparable clinical features to our patient, having interstitial deletions at 6q14.1q15, partially overlapping our patient's duplicated region. Thus it is possible that alteration of dosage-sensitive genes in the 6q14.1q15 region may represent the cause of a novel clinically recognizable syndrome. The identification of the specific mechanisms of genetic predispositions for morbid obesity is important for the adequate management of individuals with morbid obesity and may improve the outcome of these patients.

P03.011

Gene regulatory variation in Cynomolgus monkeys

A. Gschwind[1,2], *E. Migliavacca*[1,2], *T. Heckel*[3], *U. Certa*[3], *A. Reymond*[1];
[1]*Center for Integrative Genomics, University of Lausanne, Lausanne, Switzerland,* [2]*Swiss Institute of Bioinformatics, Lausanne, Switzerland,* [3]*F. Hoffmann-La Roche AG, Basel, Switzerland.*

Macaque monkeys are a key model species for various fields of biomedical research such as simian immunodeficiency virus pathogenesis, transplantation biology, drug development and safety testing. Cynomolgus monkeys (*Macaca fascicularis*) are the most widely used non-human primate species for drug safety testing in pharmaceutical companies and experimental results might be influenced by variation in biological processes among the individuals sampled. Knowledge of genetic factors contributing to variability with respect to biological drug responses could help to design better experimental approaches, which in turn would help to reduce, refine or even replace animal experiments. We attempted to investigate the importance and implications of genetic variation on cellular processes using genome-wide information on copy number variation (CNV) and gene expression from Cynomolgus monkeys originating from three different populations used in pharmaceutical research (Mauritius, China and the Philippines). Using aCGH data and a CNV calling pipeline combining different methods for CNV calling, we quantified copy number variation among our cohorts, which we then correlated with tissue specific gene expression data from five different tissues (heart, kidney, liver, lung, spleen). We identified several loci where copy number variation is associated with changes in gene expression levels of several genes in a tissue specific manner. Of interest is, that many of these changes occur in the kidney, which is also involved in drug metabolism. Using further downstream analyses, we will attempt to get information on the cellular processes possibly affected by these gene regulatory changes and make statements on potential implications for drug safety testing.

P03.012

Clinical utility of molecular karyotyping using high resolution array comparative genomic hybridization (aCGH)

M. Tzetis[1], *S. Kitsiou-Tzeli*[1], *H. Frysira*[1], *K. Giannikou*[1,2], *V. Oikonomakis*[1], *K. Kosma*[1], *A. Syrmou*[1], *A. Xaidara*[1], *E. Kanavakis*[1,3];
[1]*Dept of Medical Genetics, Athens, Greece,* [2]*Alexander S. Onassis, Public Benefit Foundation, Athens, Greece,* [3]*Research Institute for the Study of Genetic and Malignant Disorders in Childhood, "Aghia Sophia, Children's Hospital", Athens, Greece, Athens, Greece.*

Array comparative genomic hybridization (aCGH) is used to detect small copy number variants (CNVs) within the genome that are not visible by conventional karyotyping. The clinical application of aCGH has helped the genetic diagnosis of patients with unexplained developmental delay (DD)/ intellectual disability (ID), autism spectrum disorders (ASD), with or without multiple congenital anomalies (MCA) and/ or nonspecific features. We have implemented aCGH (244K & 4x180K Agilent aCGH platform, theoretical resolution <50Kb), since 2008 on 334 patients with various degrees of DD/ID, seizures, ASD, MCA and normal previous conventional karyotype. The patients had also received other genetic tests (FRAX, RETT, single FISH tests or metabolic screens), which were normal. Clinically significant submicroscopic imbalances were detected in 84 (~25.15%) patients. From the total of 103 pathological CNVs detected, 38 were *de novo,* 5 were maternally inherited (one mosaic) while 4 were paternally inherited. In 66 patients 1 pathological CNV was detected, 51 were deletions (range: 0.03-18.4Mb) and 15 were duplications (range: 0.071-34.2Mb). More specifically 30 had one of the previously well known microdeletion/ microduplication syndromes, while six others had an additional smaller aberration modifying the final phenotype. The remaining had recently recognized syndromes or novel pathogenic imbalances some of them overlapping with reported cases in DECIPHER and ISCA databases. 18 patients had more than 1 pathological aberration, six had a combination of 2 deletions, 10 a combination of a deletion/duplication, one 3 deletions, and finally one had a combination of 2 duplications and 1 deletion with sizes ranging from 0.025-19.8Mb.

P03.013

Back to the karyotype: a case of mosaic marker chromosome 11 detected by aCGH

R. Silveira-Santos, *A. C. Sousa, M. Avila, S. Serafim, S. Custódio, A. B. Sousa, I. Cordeiro;*
Serviço de Genética Médica, Hospital Santa Maria, Lisboa, Portugal.

Array comparative genomic hybridization (aCGH) is currently being used in many cytogenetic laboratories as a first-line approach to detect chromosome imbalances associated with development delay, mental retardation and congenital anomalies. However some abnormalities are better elucidated by conventional techniques such as standard karyotyping, namely when the presence of a marker chromosome or chromosomal mosaicism is suspected.

Here we report the clinical and cytogenetic findings of a 4-year old girl with intellectually disability, mild dysmorphism and macrocephaly with a 5,9 Mb gain in chromosome 11 detected by aCGH and a previous normal prenatal karyotype.

The size and pattern of the aCGH showing a three and four copies profile suggested a complex rearrangement involving the 11q11-q12.2 region, compatible with a supernumerary marker chromosome (SMC). The case was then reevaluated by karyotyping revealing a de novo mosaic SMC in approximately 70% of the cells analyzed.

Although aCGH accurately identified the chromosome and gene content of the SMC in the patient presented here, karyotype was necessary to determine the presence and structure of the marker and to established the associated abnormal cell line.

We compare our patient with other reported cases of SMC(11), to determine the respective contributions of this rearrangement to the phenotype.

Genomic instability in the Alzheimer's disease brain: cancer-like cellular behavior mediates neurodegeneration via non-malignant aneuploidization

I. Y. Iourov[1,2], *S. G. Vorsanova*[1,2,3], *T. Liehr*[4], *A. D. Kolotii*[2], *I. A. Demidova*[1,2,3], *A. K. Beresheva*[1,2,3], *I. V. Soloviev*[1], *Y. B. Yurov*[1,2,3];
[1]*Mental Health Research Center, RAMS, Moscow, Russian Federation,* [2]*Institute of Paediatrics and Paediatric Surgery, Ministry of Health, Moscow, Russian Federation,* [3]*Moscow City University of Psychology and Education, Moscow, Russian Federation,* [4]*Institute of Human Genetics and Anthropology, Jena, Germany.*

Uncovering relationship between genomic instability and neuronal cell cycle and death is required for identification of the Alzheimer's disease (AD) neurodegeneration pathway. A hypothesis considering structural and functional alterations to genome landscape was proposed to link ectopic cell cycle events and aneuploidy. Previous experimental evidences suggest that genomic landscape in the AD brain is featured by of genomic or chromosomal instability manifesting as tetraploidy and aneuploidy. Aberrant DNA replication, leading to intracellular replication stress in the AD brain is likely to produce the accumulation of genomic instabilities in vulnerable neuronal cells and to promote neurodegeneration. Here, we report on molecular cytogenetic analysis of aneuploidy, tetraploidy, and DNA replication events in the AD hippocampus to define the role of neuronal genome instability in AD pathogenesis. Increased aneuploidy rates (4-21%) (monosomy and trisomy) affecting chromosome 21 and chromosome X was observed in the AD brain in contrast to 1.2-3.6% rates in the unaffected brain. However, increased rates of tetraploidy and DNA replication activity in AD were not observed. We were able to demonstrate that the incidence of aneuploid neuronal cells affected by aneuploidy was significantly higher in degenerating brain areas (hippocampus, prefrontal cortex) as to less affected areas (cerebellum). This suggests that cancer-like cellular behavior in the AD brain mediates neurodegeneration via non-malignant aneuploidization and represents the leading genetic factor contributing to AD pathogenesis. Thus, neurocytogenomics provides for a new molecular/cellular mechanism underlying somatic neural genome diversity in brain diseases. Supported by DLR/BMBF (BLR 11/002).

Assessment of genotoxic risks in Tunisian health care workers occupationally exposed to antineoplastic drugs

G. Ben Salah[1], *K. Jmel-Hammami*[2], *F. Kallabi*[1], *S. Maatoug*[1], *M. Larbi-Masmoudi*[2], *F. Fakhfakh*[1], *H. Ayadi*[3], *H. Kamoun*[1];
[1]*Laboratory of Human Molecular Genetics, Faculty of Medicine, Sfax, Tunisia,*
[2]*Occupational Medicine, Hedi Chaker Hospital, Sfax, Tunisia,* [3]*Centre of Biotechnology, Sfax, Tunisia.*

Antineoplastic drugs (AND) constitute a heterogeneous group of chemicals known for their mutagenic, carcinogenic and teratogenic effects. They include alkylating agents, mitotic spindle inhibitors, free radical generators. Hospital personnel handling AND are potentially exposed to health risk; however, investigations on their genotoxicity are inconsistent, and little information in Tunisian medical staff was available. Hence, our aim was to evaluate cellular DNA damage of medical staff occupationally exposed to AND under routine working conditions. The level of cellular DNA damage was determined in lymphocytes with chromosomal aberration (CA) and sister chromatid exchange (SCE) assays of 26 exposed subjects and 30 controls, matched for age and sex. An individual DNA repair capacity was determined by a mutagen sensitivity assay with Bleomycin (BLM) treatment in the late S-G2 phase of the cell cycle. Statistical analysis was performed using Mann-Whitney U test and Chi-square test. The results showed a significant increase in CA frequency ($p<0.01$) and SCE frequency ($p<0.05$) in exposed subjects compared with controls. The mutagen sensitivity assay showed a significant increase breaks/cell (b/c) frequency in exposed subjects ($p<0.05$). Our study has shown that increased genetic damage was evident in medical staff due to AND occupational exposure. We suggest that cytogenetic follow up studies should be included in regular health examination for this population, at least in cases of accidental exposure.

P03.016

Are apparently balanced chromosome rearrangements associated to a higher risk of congenital anomalies due to cryptic genomic imbalances?

B. Hernández-Charro, *M. Moreno-Igoa, A. Bengoa, A. Pérez-Juana, M. Artigas, M. A. Ramos-Arroyo;*
Genetics Department. Complejo Hospitalario de Navarra, Pamplona, Spain.

Genomic imbalances detectable by array-CGH have been postulated as the underlying cause of developmental delay and/or congenital abnormalities (DD/MCA) in 10-15% of patients with normal karyotype. Similarly, over 40% of apparently balanced chromosome rearrangement (ABCR) carriers with abnormal phenotype present copy number variants (CNVs), both at the breakpoints and elsewhere in the genome, implying a potential higher risk for DD/MCA.

We present the preliminary results of an on-going genome-wide arrayCGH analysis (Agilent 180K) in three populations: G-1) Individuals DD/MCA and normal karyotype (n=5), G-2) ABCR carriers with DD/MCA (n=9), G-3) ABCR carriers with normal phenotype (n=6).

A similar total number of CNVs per individual was present in all three groups (Table 1). However, potentially pathogenic imbalances were significantly more frequent among DD/MCA patients, independently of their karyotype (10,3% and 14,4%, in G-1 and G-2 groups, respectively), than in phenotypically normal ABCR carriers (1,5%). All imbalances among ABCR carriers were located outside of the breakpoint regions. Pathogenic imbalances were present in 80%-G1 and 77.8%-G2 of DD/MCA patients and in 16,7% in phenotypically normal group.

Genomic imbalances have an important role in the pathogenesis of phenotypic abnormalities. However, simple ABCR do not seem to confer a significantly higher risk for DD/MCA associated to the presence of cryptic genomic imbalances. Further systematic and comparative studies will be needed to provide adequate prenatal genetic counselling in pregnancy with ABCR.

CASK gene heterozygous deletion in a female patient with microcephaly and cerebellar hypoplasia

J. B. Melo[1], *S. I. Ferreira*[1], *A. Mascarenhas*[1], *A. Jardim*[1], *L. Ramos*[2], *J. Saraiva*[2], *I. M. Carreira*[1];
[1]*Cytogenetics and Genomics Laboratory, Faculty of Medicine, University of Coimbra, Coimbra, Portugal,* [2]*Genetics Department, Pediatric Hospital, CHUC, Coimbra, Portugal.*

CASK gene (OMIM 300172) has an important function during neural development, having a crucial role during synaptogenesis and cerebellar and forebrain development. It encodes a member of the membrane-associated guanylate kinase (MAGUK) protein family, highly expressed in the nervous system of both adult and fetuses. *CASK* gene deletions, duplications and mutations have been recently reported to be associated with mental retardation and microcephaly with pontine and cerebellar hypoplasia (MICPCH - OMIM 300749). Deletions have only been reported in female patients, while mutations have been reported in both males and females. Missense mutations can cause a milder phenotypic spectrum while inactivating mutations and deletions can be associated with reduced male viability or even *in utero* lethality.

We report a female patient with mental retardation, ataxia, microcephaly, cerebellar hypoplasia, ventricular septal defect and scoliosis that was analyzed with a 4x180K Agilent oligonucleotide array-CGH. Array analysis revealed a 900 Kb *de novo* deletion at Xp11.4 between positions 41,342,834-42,241,039 involving *CASK* gene. This report, together with published data, reinforces the hypothesis that haploinsufficiency of *CASK* gene is responsible for mental retardation associated with MICPCH. In the presence of a clinical phenotype with these characteristics, *CASK* gene mutations but also genomic copy number changes should be considered.

P03.018

ArrayCGH analysis of constitutional cryptic deletions of 1q43-q44 and 3p26.3 in a boy with microcephaly and developmental delay

R. V. Vazharova[1], *I. Bradinova*[1], *S. Andonova*[1], *S. Bichev*[1], *A. Savov*[1], *V. Bojinova*[2], *I. Kremensky*[1];
[1]*National Genetic Laboratory, Sofia, Bulgaria,* [2]*USBALNP Saint Naum, Sofia, Bulgaria.*

Mental retardation is a distressing disorder affecting approximately 3% of the population. Among these, cytogenetic anomalies explain about 30% of patients with more severe mental retardation. Using conventional methods, detection of subtle structural aberrations is limited to 6-10Mb. We observed a boy in which developmental delay and mild dysmorphic phenotype in spite of a normal karyotype remained highly suggestive for a chromosomal aberration. The most impressive features were microcephaly, absent speach and epilepsy. MLPA analysis for deletions / duplications of subtelomeric chromosome regions using commercial kits P070 and P036 (MRC, Holland) detected a deletion of 3p. Array CGH analysis was performed using custom designed whole-genome oligonucleotide arrays (OGT, UK), covering the human genome at a median density of 2.5 kb. Except the deletion of 3p26.3 encompassing 1.054 Mb arrayCGH revealed a constitutional interstitial deletion of 2.64 Mb at 1q43-q44. Possible impact of both cryptic chromosomal aberrations on the patient's phenotype is discussed.

P03.019

Outcome of Array-CGH analysis in 197 Spanish patients with idiopathic mental retardation, dysmorphic features and/or congenital anomalies.

V. López-González[1], *J. A. Piñero-Fernández*[1], *M. J. Ballesta-Martínez*[1], *L. Villacieros-Hernández*[1], *L. Armengol-Dulcet*[2], *E. Guillén-Navarro*[1];
[1]*Unidad de Genética Médica. Servicio de Pediatría. Hospital Universitario Virgen de la Arrixaca, Murcia, Spain,* [2]*Quantitative Genomic Medicine Laboratories, S.L., Barcelona, Spain.*

INTRODUCTION: Array genomic hybridization (aCGH) is being used clinically to detect pathogenic copy number variants (CNVs) in individuals with intellectual disability (ID), dysmorphic features (DF) and/or congenital anomalies (CA). It is now widely adopted as a first-tier clinical diagnostic test. Our aim is to review the diagnostic yield in our unit.
MATERIAL AND METHODS: We performed a retrospective review of aCGH data (180-400k) of 197 patients with ID, DF and/or CA, with normal karyotype and subtelomeric MLPA, between july 2009 and july 2011.
RESULTS: We found pathogenic genomic imbalance in 28 (14.2%) of these 197 patients. Within this group, 4 patients (14.28%) had previous balanced rearrangement in karyotype. The size of the pathogenic structural aberrations found varied from 17 Kb to 14.1 Mb. In 90 patients (45.68%) polymorphic CNVs were detected, non-clinically significant CNVs in 39 (19.8%) and variants of uncertain clinical significance (VOUS) in 40 (20.3%). Parental complementary aCGH analysis was done in 39 patients.
CONCLUSION: 1) The diagnostic yield of our study (14.2%) was consistent with prior reports (11-20%). 2) aCGH is a valuable tool in patients with mental retardation, dysmorphic features and/or congenital anomalies of unknown etiology. 3) Further investigations are needed in order to clarify the role of VOUS in the pathogenesis since they account for a significant proportion of our results. 4) Effective clinical interpretation of these studies requires considerable skill and experience.

Autism spectrum disorders (ASD) are a group of highly heritable complex neurodevelopmental disorders and identifying its genetic bases has been challenging. The susceptibility genes so far identified seem to be involved in the proper establishment of the synaptic cleft, the secretion of surface proteins, the excitation/inhibition balance, or the overall cellular translation processes, suggesting that impacting translation-dependent processes like synaptic plasticity or cell-to-cell connectivity may lead to an ASD phenotype. Chromosomal imbalances identified by conventional or molecular cytogenetic techniques account for 10-15% of patients with autism. Here, we report a third case of pure *de novo* 20q13.33 deletion in a boy presenting with autism. Metabolic evaluation and standard karyotype were reported as normal, as was *FMR1* molecular analysis. The Human Genome Microarray CGH 180K from Agilent® used for array-CGH analyses revealed an interstitial deletion of at least 556 kb in the 20q13.33 region (arr20q13.33(61,229,038-61,785,825)x1, hg18). This deletion encompassed 21 genes including *CHRNA4* and *KCNQ2*. These genes are interesting candidate genes in the autistic phenotype since they have been reported in association with entities with exclusive neurological manifestations such as epilepsy. The frequent association between epileptic and autistic phenotypes suggests that these diseases may share common predisposing genes. Interestingly, a *de novo* 20q13.33 duplication encompassing *CHRNA4* and *KCNQ2* in a girl with autism has also been reported. This study underlines that copy number variations of the 20q13.33 region can cause autism and emphasizes the importance of array-CGH in the genetic work-up of patients with autism.

P03.021
A de novo balanced translocation that affects chromosomal bands Xp21.2 and 11q13.1 is associated with an autism spectrum disorder.

P. M. Kroisel[1], *K. M. Roetzer*[1], *M. Mach*[1], *M. R. Speicher*[1], *A. Kortschak*[2], *W. Kaschnitz*[2], *M. Auer*[1], *J. B. Geigl*[1], *K. Wagner*[1];
[1]*Institute of Human Genetics, Medical University of Graz, Graz, Austria,* [2]*Department of Paediatrics, Medical University of Graz, Graz, Austria.*

An autism spectrum disorder was diagnosed in a 3 1/2 year old boy and consecutive cytogenetic analysis revealed a balanced translocation involving the X chromosome and chromosome 11 leading to the following karyotype: 46,Y,t(X;11)(p21.2;q13.1).ish t(X;11)(wcpX+,wcp11+;wcpX+,wcp11+) dn. No additional obvious phenotype anomalies or dysmorphic features could be recognized. A cryptic genomic unbalance up the achieved resolution was be ruled out by application of a 60k Agilent array CGH analysis which showed normal results. Balanced chromosomal aberrations in patients with a particular phenotype represent a valuable resource to identify causative genes involved in such cytogenetic rearrangements. Besides conventional but tedious approaches like FISH analysis using tiling path clones to finally identify chromosome breakpoint spanning clones and the gene(s) affected, recently more straightforward methods were demonstrated to be successful. These techniques include so called array painting procedures as well as breakpoint analysis of balanced chromosome rearrangements by next-generation paired-end sequencing. The particular chromosomal breakpoints involved in this specific case are close to or nearly identical to chromosomal bands in similar rearrangements reported in a very few patients with autistic traits. However the number of potential candidate genes at these loci is still to high for a classical Sanger sequencing strategy to characterize the involved gene. Since our group has already successfully applied the array painting methodology in comparable settings we have now also started to evaluate the next-generation paired-end sequencing approach to compare the efficiacy of these quite different techniques in the described patient as well as similar cases.

P03.022
Brain-specific X chromosome aneuploidy is likely to contribute to the pathogenesis of autism and can explain the unsolved paradox of male susceptibility

Y. B. Yurov[1,2,3], *S. G. Vorsanova*[2,1,3], *A. D. Kolotii*[2], *T. Liehr*[4], *I. Y. Iourov*[1,2];
[1]*Mental Health Research Center, RAMS, Moscow, Russian Federation,* [2]*Institute of Paediatrics and Paediatric Surgery, Ministry of Health, Moscow, Russian Federation,* [3]*Moscow City University of Psychology and Education, Moscow, Russian Federation,* [4]*Institute of Human Genetics and Anthropology, Jena, Germany.*

Autism is a common childhood psychiatric disorder characterized by impaired social interaction and communication, repetitive/stereotypic behavior. Numerous studies indicate that chromosomal and genomic imbalances play a role in the etiology and pathogenesis of autism. However, the incidence and role of genomic imbalances in the autistic brain - the prime target of the disease - have not been addressed. Here, we report on the first evaluation of mosaic aneuplody in the autistic brain. Postmortem brain tissue samples (cerebral cortex and cerebellum) of 12 autistic patients and 12 age-/sex-matched controls were provided by the Brain and Tissue Bank for Developmental disorders, University of Maryland. In the male autistic brain, we observed statistically significant increase of chromosome X aneuploidy rates in the cerebral cortex and cerebellum (p=0.0166) as compared to control samples. Autistic spectrum disorders currently affect four times as many males as females. Mosaic chromosome X aneuploidy in the brain may help to explain the preponderance of autism among males in addition to specific alterations of the X chromosome genes. We conclude that intercellular genomic variation manifesting as brain-specific low-level mosaic aneuploidy is one of the possible genetic factors likely contributing to autism neuropathology. Our findings support the hypothesis that somatic genome instability could affect as homeostasis of aneuploid neurons as functioning of the neuronal network in the whole autistic brain, playing, therefore, an important role in the pathogenesis. Supported by BMBF/DLR (RUS 09/006).

P03.023
Evaluation of genomic imbalances in apparently balanced rearrangements

T. I. Mancini[1], *M. M. Oliveira*[1], *A. B. Perez*[1], *C. A. Kim*[2], *D. Bertola*[2], *R. S. Guilherme*[1], *S. Bragagnolo*[1], *V. A. Meloni*[1], *A. R. Dutra*[1], *M. C. Cernach*[1], *A. Garcia*[1], *S. S. Takeno*[1], ***M. I. Melaragno***[1];
[1]*UNIFESP, Sao Paulo, Brazil,* [2]*USP, Sao Paulo, Brazil.*

Apparently balanced rearrangements are generally associated with a normal phenotype. In some cases, however, phenotype alterations are observed, which have been attributed to different pathogenic mechanisms including intragenic rupture, deletions, duplications, position effect, or may even be a chance association. We investigated 11 patients with altered phenotype and apparently balanced rearrangements: eight *de novo* translocations, two inherited inversions and one complex *de novo* rearrangement. Cytogenetic and molecular techniques, including SNP-array and fluorescent *in situ* hybridization (FISH) detected genomic imbalances in two patients. Using 200 kb filter in array analysis, one female patient with an apparently balanced translocation between chromosomes 6 and 14 was found to have a 1.1 Mb deletion in 6p. In another female patient, who presented a complex rearrangement involving chromosomes 2, 10, 13 and 21, two deletions of 10q were detected, one of them next to the breakpoint measuring 1 Mb, and the other one, more distal, approximately 7 Mb in size, probably related to the phenotype. Two of the patients had genomic imbalances smaller than 200 kb, involving genes which might be related to their phenotype. We concluded that molecular techniques such as arrays, associated to cytogenetic methods can help in detecting genomic imbalances which are invisible under the microscope and unveiling the role of genes involved in the phenotype variability of patients with apparently balanced rearrangements. Furthermore, the molecular characterization of the alterations found provides information for the follow-up of the patients and genetic counseling of their families (Financial support: FAPESP, Brazil).

P03.024
Two balanced chromosomal modifications transmitted from parents to their offspring

D. Mierla, *L. Neagu*, *S. Grigore*, *V. Radoi*;
Life Memorial Hospital, Bucharest, Romania.

A 33 years old pregnant woman was investigated by amniocentesis.

Prenatal karyotype from cultured amniocytes was performed due to increased risk for trisomy 21 at serological test without ultrasonographic abnormalities.

Fetus' karyotype established by GTG banding was: 46,XX,t(3;6)(q28;q13);inv(5)(p14q11.2). We performed chromosome analysis in the parents for checking if chromosome modifications in fetus are „de novo" or are inherited from parents. Mother's karyotype revealed the inversion on chromosome 5 [46,XX,inv(5)(p14q11.2)] and father's karyotype showed the other modification, the translocation t(3;6)(q28;q13).

We informed the family about results and we found out that the mother's brother has the same modification as her and this man was cytogenetic investigated because his infertility.

Conclusion: Kariotypes of fetus and his parents were performed for correct genetic advices.

P03.025
Cytogenetic effect in vivo and in vitro of the antihypertensive drugs ARBs on human lymphocytes

I. Huerta[1], *M. Barasoain*[1], *M. Télez*[1], *P. Gurtubay*[2], *B. Criado*[3], *A. Domínguez de Bidaurreta*[4], *E. Ortiz-Lastra*[5], *J. González*[5], *G. Barrenetxea*[5], *I. Arrieta*[1];
[1]*Department of Genetic, Physical Anthropology and Animal Physiology. Faculty of Science and Technology. University of the Basque Country, Bilbao, Spain,* [2]*Unit of Reproductive Medicine. School of Nursing., Cruces, Spain,* [3]*Department of Genetics. Cooperativa de Ensino Superior Politecnico e Universitario, Porto, Portugal,* [4]*Primary Care Unit. Interior Comarca, Bilbao, Spain,* [5]*Department of Medical-surgical Specialities. Faculty of Medicine. University of the Basque Country, Bilbao, Spain.*

Hypertension is the most prevalent, treatable risk factor for diseases of the heart, brain and kidneys. The majority of hypertensive patients need long-term administration of antihypertensive agents and that is why the duration of the pharmacological treatment requires documentation of long-term safety and efficacy, including sensitive indices of genotoxic damage.

Angiotensin II receptor blockers (ARBs) are a widely used class of drugs that are growing in popularity due to the excellent blood pressure control and tolerability. However, recent concerns have surfaced about possible links between ARBs and increased cancer risk.

Chromosomal aberrations (CAs) represent the most extensively used and validated biomarker in populations exposed to genotoxic agents and it is also associated with a higher cancer risk. This study aimed to evaluate the genotoxic potential of five kinds of ARBs (candesartan, valsartan, eprosartan, telmisartan and olmesartan), assessed *in vivo* and *in vitro* for their capacity of inducing CAs on lymphocytes of 55 patients and 10 controls.

Results revealed that total number of CAs as well as the mean frequency of CA/cel and % of aberrant cell were increased for the patients and at the therapeutic doses tested *in vitro* compared to the controls. Chromatid type aberrations were the predominant CA. Most of the chromosomal breakpoints locations coincided with specific *loci* known as fragile sites, which are preferential targets for mutagens and carcinogens.

The results are consistent with our previous studies of beta-blockers genotoxicity and provide evidence for an association between antihypertensive therapy and DNA damage in human lymphocytes.

P03.026

Step by Step, Formation of Complex Chromosomal Rearrangements

B. Satkin, *B. Karaman, K. Yilmaz, U. Altunoglu, S. Basaran;*
Medical Genetics Department of Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey.

Complex Chromosome Rearrangements (CCR) are defined for the aberrations involving three or more breakpoints on two or more chromosomes. The occurrence is extremely rare. There is no available classification according to the formation mechanism.

We report here a new familial case of CCR involving chromosomes 3, 6 and 10 with 4 breakpoints

Proband, 33 years old male, was referred to our cytogenetic laboratory for chromosome analysis due to the history of repeated miscarriages.

Chromosome analysis revealed a balanced CCR in the proband (Karyotype: 46,XY,t(3;6;10) (3pter->3q12::6q24->6qter;6pter->6q14.2::10p11.2->10pter;3qter->3q12::6q24->6q14.2::10p11.2>10qter). The mother with a history of two alive sibs and four miscarriages, was the carrier of the same CCR. Surprisingly the brother of the proband was a carrier of a simple reciprocal translocation, (46,XY,t(6;10)(q14;p12)).

CCR was confirmed with FISH study by using Chromoprobe Multiprobe System (Cytocell) and centromeric probes of 3, 6, and 10.

We suggest that the CCR in the family most likely have arisen in two consecutive steps; the first step was the translocation t(6;10)(q14;p12) and the second step was the new translocation occurred between the chromosomes 3 and derivative 10.

We concluded that the mother was hidden mosaic for both of the cell lines, simple translocation and complex rearrangement. This family was interesting to understand the formation mechanisms of CCR.

P03.027

3D position of constitutive heterochromatin regions within the nucleus of chorionic villi and embryonic tissues.

I. Trofimova[1,2], *K. Solovyov*[3], *E. Fedorova*[3], *V. Vasilyev*[3], *T. Kuznetzova*[2];
[1]*Saint-Petersburg State University, Saint-Petersburg, Russian Federation,* [2]*Ott's Institute of obstetrics & gynecology RAMS, Saint-Petersburg, Russian Federation,* [3]*Institute of Experimental Medicine of the North-West Branch of the Russian Academy of Medical Sciences, Saint-Petersburg, Russian Federation.*

Nuclear architecture and chromatin organisation during interphase are known to play crucial roles in the regulation of gene expression. Constitutive heterochromatin regions (CHR) in chromosomes of embryonic tissues are characterized by tight condensation, late replication and methylation. Meanwhile decondensation, hypomethylation, early replication and DNAse 1 hypersensitivity CHR in human trophoblast cells were registered. These data could be indicated CHR in chromosomes of chorionic villi has unusual functional state.

The aim of study was analysis of 3D position of CHR of chromosome 1 (1q12) in human trophoblast and embryonic cells. It is known that CHRs are associated with nuclear periphery and form chromocenter. Our 3D-FISH results showed a significant repositioning of 1q12 towards the centre of the nucleus and near of chromocenter in chorionic villi sample from early pregnancy (4-5 week). We found no change in the position of 1q12 in human embryonic tissues and chorionic villi from 5-6 week to 36 week pregnancy. Almost all of FISH-signals (correspond to 1q12) were closer to the nuclear periphery and in chromocenter.

In conclusion, today little is known about the nuclear organization in extraembryonic and embryonic tissues. Data of 3-D FISH analysis of this work have indicated in possible functional role of CHR in embryogenesis of human.

P03.030

Frequency of chromosomal aberrations among general human population

I. Aganovic, M. Mackic, ***S. Ibrulj****;*
Center for genetics, Sarajevo, Bosnia and Herzegovina.

Genetic monitoring is used for surveillance of professionally exposed people to ionizing radiation, chemicals and medical treatments and rarely to investigate the state of general population exposed to environmental mutagens that include all mentioned and life-style factors and habits. We have performed cytogentic analyzes of chromosomal aberrations (CA) in blood lymphocytes among healthy population, including the data of their age, gender and smoking habits (none of them was professionally exposed to ionizing radiation).

Analyzes were done for 200 examinees, 200 cells were counted for each of them for CA. Laboratory used standard method of 48h cultivation of peripheral blood lymphocytes.

We concluded that there is no significant difference in CA frequency among gender ($p > 0,05$); that there is highly significant difference in frequency of acentric fragments among age groups (20-29y; 30-39y; 40-49y; 50-59y and 60-70y)($p<0,001$); and that there is no significant difference in frequency of acentric fragments and ring chromosomes depending of smoking habits ($p>0,05$) but there is significant difference in frequency of minute fragments depending of smoking habits($p<0,05$). These suggest that smoking can cause genetic instability in humans and potential micro mutations that eventually may play a role in cancerogenesis.

P03.032

Submicroscopical duplication of the Wolf-Hirschhorn critical region. Case report.

R. Zordania[1], *K. Kuuse*[1], *A. Tiidema*[1], *O. Zilina*[1], *E. Kurvinen*[1], *K. Õunap*[1,2];
[1]*Department of Genetics United Laboratory Tartu University Hospital, Tartu, Estonia,*
[2]*Department of Pediatrics, University of Tartu, Tartu, Estonia.*

Chromosomal rearrangements in the short arm of chromosome 4 can result in two different clinical entities: deletion causes Wolf-Hirschhorn syndrom (WHS) - characterized by severe growth delay, mental retardation, facial dysmorphism and congenital anomalies. Genotype-phenotype correlations of patients with WHS point to a critical locus (4p16.3) to be responsible for the main characteristics of this disorder. In addition it was shown that not only deletions but also duplications of the WHS critical region cause mental retardation and anomalies. The duplication phenotype overlaps partially with the deletion phenotype, but facial dysmorphism is different.

We report clinical and laboratory data of one month old patient. He was born to young unrelated healthy parents, 1G/1P, pedigree unremarkable. Patient was macrosomic, head circumference compared to body was microcephalic, he had dysmorphism- periorbital fullness, large hands and feet, macroglossia, umbilical hernia, developmental delay, but no congenital anomalies. Cytogenetic investigation using Giemsa banding revealed karyotype 46,X,add(Y)(q12)dn. Using HumanCytoSNP-12 array (Illumina Inc) a 6,8 Mb duplication was found in the region 4p16.3-16.1. The result was confirmed with FISH-analysis using WHS Region Probe (Cytocell, UK).

The patient had pathological unbalanced translocation and his final karyotype was 46,X,der(Y)t(Y;4)(q12;p16)dn.ish der(Y)t(Y;4)(Yqter-,WHSCR+).arr 4q16.3q16.1(1-6,806,837)x3.

Conclusion: using different laboratory cytogenetic methods allowed to get a correct diagnosis, the family got appropriate genetic consultation and prenatal invasive diagnostics during following pregnancy.

P03.033

Impact of different chromosomal inversions on infertility

A. Mohseni Meybodi, *H. Gourabi, S. Zari Moradi, H. Karimi, M. Tahsili, K. Anissi Hemaseh, S. Asia, Z. Saffari, T. Tavakol zadeh, Z. Beheshti, P. Fahimi, P. Pirasteh, N. Shahrokhshahi;*
Department of Genetics, Reproductive Biomedicine Research Center, Royan Institute for reproductive Biomedicine,ACECR., Tehran, Islamic Republic of Iran.

Objective: One of the frequent occurrences in chromosome rearrangements is inversion of different Chromosomes. An inversion does not usually have phenotypic effect in the majority of inversion heterozygote carriers, when it is a balanced rearrangement. However, infertility, miscarriages and/or chromosomally unbalanced offspring can be observed in carriers of either type of inversions especially per centric inversions.

Material and Methods: We investigated the karyotypes of 13017 infertile individuals being referred to Genetic laboratory of Royan infertility institute between 2005 and 2011, using standard GTG banding. We attend to report the variety of heterozygous par centric and per centric inversions. C- Banding for par centric inversions of the long arm of Y chromosome used for

more precise detection.
Results: A total of 252 cases (1.93%) showed these chromosomal alterations. Twenty one (0.16%) were inv(Y)(p11.2q11.2), fifteen (0.11%) inv(Y)(q11.2q12), one hundred thirty nine (1.06%) inv(9)(p11q12), forty four (0.34%) inv(3)(p11q11.2), nine (0.07%) inv(2)(p11.2q13), and twenty four (0.18%) inversions of other chromosomes.
Conclusion: Human inversion mutations occur at a low but detectable frequency. Although the number of inversions has been considered normal variants such as inv (9)(p11q12), we are trying to discuss the importance of this chromosomal rearrangement and its role on infertility or spontaneously abortions. Carriers of such inversions are at risk of producing abnormal gametes during meiosis that may lead to unbalanced offspring. Our data suggests that it's better for all couples with the same symptoms to have karyotype analysis on a parallel with their routine tests.

P03.034

Mosaic trisomy 1q and Fryns-like phenotype

A. Rajaee, *A. Kariminejad, R. Kariminejad, K. Najafi, S. Ghaderi-Sohi, M. Kariminejad;*
Kariminejad-Najmabadi Path. & Genetics Center, Tehran, Islamic Republic of Iran.

Fryns Syndrome is a lethal condition characterized by diaphragmatic hernia, coarse facial features, lung hypoplasia, cardiac defects, and the characteristic distal limb defects. Autosomal recessive inheritance has been suggested on the basis of occurrence in both sexes and recurrence in siblings with healthy parents. Cases with chromosomal abnormality have been reported with clinical findings very similar to Fryns syndrome. Duplication and or deletion of long arm of chromosome 1, and anomalies of chromosomes 15, 6 and 22 have been reported in cases with Fryns-like syndrome.
Herein, we reported a case of midtrimester fetus with multiple congenital anomalies. Prenatal ultra-sound at 21 weeks of gestation demonstrated congenital hernia of diaphragm and hydrocephaly. Pregnancy was terminated and fetus was sent for autopsy, karyotyping and aCGH. Autopsy examination showed microphthalmia of left eye, hydrocephaly, hypoplasia of corpus callosum, left optic nerve hypoplasia, congenital hernia of diaphragm, micrognathia, dysplastic ears, lung hypoplasia (left lung), malformed uterus and right club foot. Chromosomal study showed mosaic 46,XX/47,XX+1(q21-q41). Array comparative genomic hybridization (a-CGH) confirmed mosaic duplication of long arm of chromosome 1q21 to 1q41. Our fetus has many of the clinical features of Fryns syndrome. Our case gives further evidence that 1q duplications are associated with a Fryns-like phenotype including congenital hernia of diaphragm, pulmonary hypoplasia, micrognathia, long philtrum and joint contractures.

P03.035

Mosaic interstitial duplication of the long arm of chromosome 20 associated with vertebral malformations as the only major phenotypic manifestation

B. Pabst[1], *K. Miller*[1], *B. Bohnhorst*[2], *J. Weidemann*[3], *J. Schmidtke*[1], *M. Arslan-Kirchner*[1];
[1]*Institute of Human Genetics, Hannover Medical School, Hannover, Germany,*
[2]*Department of Paediatric Pulmonology, Allergology and Neonatology, Hannover Medical School, Hannover, Germany,* [3]*Institute of Diagnostic and Interventional Radiology, Hannover Medical School, Hannover, Germany.*

Duplication of the long arm of chromosome 20 as the only chromosomal aberration is rarely described. Better known are reports on patients with a mosaic trisomy 20 or a rearranged chromosome 20 with additional imbalances.
We report on a girl born in the 35th week of gestation to a 31 year old mother. The patient is the second child of healthy parents. Birth weight, length and head circumference were within the normal range according to the gestational week. The girl presented with some mild dysmorphic features, e.g. low set and dysplastic ears, short nose with depressed nasal root, simple philtrum and thin lips. Ultrasounds of heart, abdomen and kidneys were normal while the corpus callosum was shortened and thicker than usually. Multiple vertebrae anomalies, e.g. hemi as well as cleft vertebrae and rip fusion were identified by radiography. Cytogenetic and molecular cytogenetic analysis revealed a mosaic female karyotype with a duplication of part of the long arm of chromosome 20 in 8% of blood cells. The karyotype is described as 46,XX,dup(20)(q11.2q13.3)/46,XX. ish dup(20)(D20S1157+,20QTEL14+,wcp20+). The parents have normal karyotypes.
Hemi and cleft vertebrae as well as rip fusion have been described in cases with duplication 20 associated with other chromosomal imbalances. The present case helps to further establish the correlation of these malformations with duplication of a part of the long arm of chromosome 20.

P03.036

Chromosome kissing in association with the ATR-X syndrome

H. Tanabe[1], *T. Wada*[2];
[1]*The Graduate University for Advanced Studies (Sokendai), Kanagawa, Japan,*
[2]*Kanagawa Children's Medical Center, Kanagawa, Japan.*

ATR-X (X-linked α-thalassemia / mental retardation) syndrome is one of the syndromes associated with abnormal epigenetic gene regulation, which appears males with X-linked mental retardation, HbH disease, skeletal abnormalities, and autistic behavior. ATR-X syndrome is caused by a mutation in the ATRX gene localized on the X chromosome (Xq21.1), which encodes ATRX protein, one of the chromatin-remodeling proteins. However, the details of molecular mechanism with symptoms of this syndrome are still unknown. Here to learn more about the relationships between nuclear architecture and failure of epigenetic regulation in the ATR-X syndrome, we examined characteristics of spatial positioning of following three chromosome arm specific regions by 3D-FISH technique; 1) Xq (ATRX gene has mapped on), 2) 16p (HBA has mapped on), and 3) 11p (HBB has mapped on). After image acquisition by confocal laser scaning microscope, analysis of relative spatial positioning of three painted regions was performed. The results showed that neighborhood association of particular two chromosome territory regions called as chromosome kissing was observed with high frequency between Xq and 16p and between 11p and 16p in cell nuclei from the ATR-X syndrome patients, respectively. The frequency of the same combination from the normal individual is approximately halves of them, respectively. Thus we considered that the spatial arrangement of nuclear architecture has been affected after one has been attacked with the ATR-X syndrome.

P03.037

Use of customised array CGH to investigate the sequence composition around the breakpoints of *de novo* CNVs according to their parental origin

S. Thomas, *S. Laird, S. Huang, J. Crolla, P. Jacobs;*
Wessex Regional Genetics Laboratory, Salisbury, United Kingdom.

Among a large series of *de novo* CNVs identified by array CGH, we found the proportion of LCR-mediated imbalances (formed by non-allelic homologous recombination) to be significantly higher among maternally- compared to paternally-derived CNVs. To investigate the contribution of repetitive sequences other than LCRs to the formation of CNVs, we refined the breakpoint intervals (BPIs) of 37 patients with *de novo* non-LCR mediated CNVs (18 maternal and 19 paternal) using an Oxford Gene Technology customised oligonucleotide array and screened the BPIs for the presence of homologous and/or repetitive sequences. Twelve BPIs (in 10 patients) could not be refined further due to the high repetitive sequence content. For the remaining BPI the average size was reduced from 113kb (range 14 - 391kb) to 2.6kb (121bp - 34kb). At least 17/36 maternal and 18/38 paternal breakpoints occurred within the intron of a gene. The majority (76%) of BPI contained at least one repetitive sequence element and for 8/18 maternal CNVs and 5/19 paternal CNVs, the same or similar repetitive sequence element was present at both BPI. However, for those CNVs where both breakpoints were mapped to intervals below 1kb, only 1/9 showed significant homology between the BPI. Therefore, although we have demonstrated the utility of large scale breakpoint mapping using customised array CGH, further work to try and determine the exact breakpoint site by junction fragment cloning will be required to assess the contribution of repetitive sequences other than LCRs to the formation of CNVs.

P03.038

A case of *de novo* complex chromosomal abnormality involving a t(8;10) and an interstitial deletion 5q(q33.1→q34) characterized by GTG banding, FISH and cCGH

N. Oliva-Teles[1], *S. Pires*[1], *J. Aguiar*[1], *M. Mota-Freitas*[1], *B. Marques*[2], *H. Correia*[2], *J. Sales-Marques*[3], *A. Fortuna*[1];
[1]*INSA-Centro de Genética Médica Jacinto Magalhães, Porto, Portugal,* [2]*INSA, Lisbon, Portugal,* [3]*Centro Hospitalar Vila Nova de Gaia – Espinho, Espinho, Portugal.*

Interstitial deletions of the long arm of chromosome 5 involving the region 5q33.1→q34 are rare occurrences. The clinical features of patients carrying similar deletions include dysmorphic facial features, such as epicanthus, retrognatia, protruding left ear and asymmetric mouth, high-arched palate, four finger lines and clinodactyly of digits II and V on both hands.
We report on a female child aged 13 presenting with development delay, agenesis of the corpus callosum, hallux diverted into, clinodactyly of 3rd, 4th and 5th fingers, obesity, hepatic steatosis, vesicular lithyasis and bilateral macular changes. Classical karyotyping using high resolution GTG banding revealed a *de novo* complex rearrangement including three abnormal chromosomes: 5, 8 and 10; apparently there was an inversion in the long arm

of chromosome 5 and a t(8;10). FISH whole chromosome painting probes confirmed an apparently balanced t(8;10), a deleted chromosome 5 and confirmed the inexistence of any other chromosomal involvement.
To define the deletion breakpoints and the extent of the deletion, cCGH techniques were performed and revealed an interstitial deletion 5(q33.1→q34). The final karyotype was: 46,XX,der(5)inv(5)(q21q33.1)del(5)(q33.1q34) t(8;10)(q13;q21.2)dn. ish cgh del(5)(q33.1q34).
The authors enhance the importance of using high resolution banding combined with molecular cytogenetic techniques for more precise definition of complex chromosomal rearrangements in patients with uncharacteristic phenotypic features and compare the present case findings with previously published data.

P03.039

A de novo complex chromosomal rearrangement involving four chromosomes in an infertile male with oligospermia: Case report

A. Mohseni Meybodi, *M. Tahsili, H. Gourabi, H. Vaziri Nasab, P. Pirasteh, T. Tavakol zadeh, M. Totonchi, S. Asia;*
Department of Genetics, Reproductive Biomedicine Research Center, Royan Institute for reproductive Biomedicine,ACECR., Tehran, Islamic Republic of Iran.

Purpose: Complex chromosomal rearrangements (CCR) are rare events involving more than two chromosomes and more than two breakpoints. They are usually associated with infertility or sub fertility in male carriers. We examined a 29 year oligosperm man with a history of Varicocelectomy, normal testes size and normal endocrinology profile,who referred for chromosome analysis to genetic laboratory of Royan infertility institute.
Method: Chromosomal analysis was performed from peripheral blood lymphocyte cultures and analyzed by GTG banding. Additional tests such as C-banding and multicolor fluorescence in situ hybridization (FISH) procedure for each of the involved chromosomes were performed to determine the patterns of the segregations. Y chromosome micro deletions in the azoospermia factor (AZF) region were analyzed with multiplex polymerase chain reaction. To identify the history and origin of this CCR, all the family members were analyzed.
Result: The case was a complex chromosomal translocation; 46,XY,t(13;16;14;18) (q31.2;p13.2;q24.2;q21.2). No micro deletion in Y chromosome was detected. Just his monozygous twin brother has the same de novo reciprocal exchanges. The other siblings and parents were normal.
Conclusion: CCR are associated with male infertility as a result of the disruption of spermatogenesis due to complex meiotic configurations and the production of chromosomally abnormal sperm. In other words, it is likely that these chromosomal rearrangements might have influence in decreasing the number of sperms. To have a chance of healthy offspring**,** preimplantation genetic diagnosis (PGD) method is suggested.

P03.040

Complex translocation involving 13, 15 and 16 chromosomes: a case report

L. Letica, *R. Lasan Trcic, K. Crkvenac Gornik, I. Tonkovic Djurisevic, M. Miklos, S. Huljev Frkovic, D. Begovic;*
Division of Genetics, Department of Pediatrics, University Hospital Centre, Zagreb, Croatia.

Complex chromosomal rearrangements (CCR) occurring in phenotypically normal persons are rare. CCR are usually considered to include severe reproductive impairment by disturbing the meiotic process and producing unbalanced gametes responsible for high reproductive risk. Most of CCR are reported to be de novo.
We report a case of a complex translocation in a 38 years old female with menopause praecox and sterility. Conventional chromosomal analysis revealed an apparently balanced translocation involving 13, 15 and 16 chromosomes. This balanced complex translocation (BCT) involves three chromosomes and three different breakpoints. Molecular cytogenetic analysis with whole chromosome probes , centromeric and locus specific FISH probes showed breaks at 13q21.2, 15q26 and 16q23. Carriers of balanced complex translocation have a high risk of having spontaneous abortions or a child with an unbalanced karyotype. Our patient was informed by genetic counsellor.

P03.041

High frequency of copy number abnormalities in adult patients with mental disabilities and psychiatric disorders

M. Viñas[1,2], ***N. Baena***[1]*, E. Gabau[3], C. Mata[1], S. Esteba[4], N. Ribas[4], R. Novell[4], M. Guitart[1];*
[1]Genetic Laboratory. UDIAT-CD. Corporació Sanitària Parc Taulí, Sabadell, Spain, [2]Cellular Biology, Immunology and Physiology Department. Universitat Autònoma de Barcelona, Cerdanyola, Spain, [3]Pediatric Service. Corporació Sanitària Parc Taulí, Sabadell, Spain, [4]Specialized Service in Health Mental and Intellectual Disability. Parc Hospitalari Martí i Julià, Girona, Spain.

Background: Copy number variants (CNV) are associated with a significance increased risk of diseases for the individual and/or their family members. They are contributing to the development of congenital anomalies, intellectual disabilities, spectrum autism disorder and other psychiatric disorders. It is known that the prevalence of psychiatric disorders among adults with intellectual disability is higher than in control population.
Methods: We analyzed a cohort of 100 adult patients affected by mild/moderate intellectual disability associated with psychiatric disorders and minor dysmorphic features. Genetic analysis included array comparative genomic hybridization (aCGH) (Agilent 400K), performed in 45 cases at present.
Results: We detected 89 rare and potentially pathogenic CNVs in 37 cases, with an average of 2,4 CNV/case (1-8). These CNVs include 184 genes (2,07 genes/CNV). At present, we can correlate known CNVs with intellectual disability and/or psychiatric disorders in 13 patients (31,1%). Deletions and duplications found in these cases are: del2p12, del2p16.3, dup3q29, del12p12.1, dup15q11q13, del15q13.1q13.3, dup15q25.2, del15q26.2, dup15qter, dup17q24.1q24.2, del22qter, and dupXq22.1. Genes responsible of psychiatric disorders and some of them also with intellectual disability are: *CTNNA2, NRXN1, PAK2, SOX5, GABRB3, CHRNA7, ADAMTSL3, MCTP2, APOH* and *SHANK3.* Del2p16.3 is present in three patients and is the only recurrent CNV associated with psychiatric disorders. *NRXN1* gene is related with susceptibility to autism, schizophrenia and mental retardation.
Conclusion: We most emphasise the high frequency of rare CNVs associated specially with psychiatric disorder in patients with mild/moderate intellectual disability.
This work was supported by a grant of FIS (PI080778).

P03.042

Detection of cryptic chromosome rearrangements by BAC Genome Array-CGH in five patients, with normal and/or abnormal karyotypes, associated with Mental Retardation, Autism and/or Epilepsy: new insights for genotype/phenotype correlation

V. Cabras[1], A. Milia[2], C. Montaldo[3], ***A. Nucaro***[4]*;*
[1]Experimental Medical Pathology Departement, Cagliari, Italy., Cagliari, Italy, [2]Experimental Biology Department, Cagliari, Italy., Cagliari, Italy, [3]Surgical Sciences Department, University, Cagliari, Italy., Cagliari, Italy, [4]Genetic and Biomedical Research Institute-CNR, Cittadella Universitaria. Monserrato,Cagliari, Italy., Monserrato(Cagliari), Italy.

We re-examined ten patients with normal and/or abnormal karyotypes and dysmorphic features, associated with Mental Retardation, Autism and/or Epilepsy. We applied a fast BAC Genome Array- CGH platform (Cytochips Blue-gnome, Techno-genetics - Bouty). Cyto-Chips are high quality BAC microarrays (4898 BAC Clones spotted in quadruplicate 0.6 Mb). This approach led us to discover further cryptic chromosomal rearrangements, previously undetected by conventional cytogenetic procedures. We identified two genes: **SLC8A3** (human gene for member 3 of solute carrier family 8), a sodium-calcium exchanger electively expressed in the brain, and a possible candidate gene for Epilepsy (Nucaro et al 2010) and the **CSMD1** gene (Cub and sushi multiple domains 1) a candidate gene for Autism associated with Mental Retardation (MR) and Epilepsy (Nucaro et al 2011). This approach allows us to better delineate the genotype/phenotype correlation in our patients. Our experience shows the validity of the BAC platform as a reliable method for genome-wide screening of chromosomal aberrations, as well as oligonucleotide-based Array CGH, in patients with idiopathic Mental Retardation and/or in association with Autism and Epilepsy.

P03.043

A de novo interstitial deletion at 1p36.11 in a patient presenting with severe psychomotor delay, sensoneural hearing loss, congenital heart defect and dysmorphic features

Ž. Čiuladaitė, *A. Utkus, J. Kasnauskienė, E. Preikšaitienė, A. Pečiulytė, V. Kučinskas;*
Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania.

We report on a patient with severe psychomotor delay, sensoneural hearing loss, absent speech, hydrocephaly, congenital heart defect, broad thumbs, dysmorphic features (flat nasal bridge, pointed chin, low-set, abnormal ears) and *de novo* interstitial deletion at 1p36.11 detected by arrayCGH (400K). The deleted segment at 1p36.11 is 1 Mb in size and involves 20 protein coding genes. Based on the clinical and molecular data analysis we suspect *PIGV* gene as one of the strongest candidate genes responsible for severe psychomotor delay, deafness and limb anomalies in our patient. Horn et al. (2011) reported two cases with homozygous and compound heterozygous missense mutations of *PIGV* and intelectual disability, hearing loss, muscular hypotonia and dysmorphic features, which are observed in our patient either. Besides, the main clinical features of our patient are also common for 1p36 monosomy syndrome. The critical region for 1p36 monosomy syndrome is located at 1p36.33 and is 25 Mb proximally from the interstitial deletion at 1p36.11 detected in our patient. We predict that the overlapping phenotype of nonoverlapping deletions within 1p36 region could be caused both by haploinsufficiency of one or more genes because of their deletion and because of the disturbance of their expression by disruption of an essential regulatory element or position effect as the juxtaposition of a euchromatic gene with a region of heterochromatin. The expression studies of candidate genes, especially *PIGV* gene in cases of 1p36 deletions are indicated.

P03.044

A 3.8 Mb deletion in 10q11.21-q11.22 in a 7-year-old Iranian boy with mild dysmorphic features and developmental delay

***A. Rajaee**, A. Kariminejad, F. Afroozan, M. Mirzazadeh, R. Kariminejad, M. H. Kariminejad;*
Kariminejad-Najmabadi Pathology & Genetics Center, Tehran, Islamic Republic of Iran.

Here we report on a 7-year-old Iranian boy with mild dysmorphic features including high nasal bridge, low-set prominent ears. The patient also had developmental delay, mild intellectual disability, increased deep tendon reflex, spasticity and ataxia. Brain MRI performed at ages 5 and 6 showed fluid collections in temporal lobe beside of sylvian fissure compatible with arachnoid cyst. Whole genome BAC Array CGH was performed using CYTOCHIP genomic BAC array and showed a 3.8 Mb interstitial deletion on long arm of chromosome 10 encompassing bands 10q11.21-q11.22. Thirteen OMIM genes are situated in this region. To date, ten patients with deletion of 10q11.2 documented with routine karyotyping, and an additional 19 patients with deletion of 10q11, overlapping 10q11.21-q11.22 region, confirmed by array comparative genomic hybridization (aCHG) have been reported. Intellectual disability and developmental delay were the only clinical features common to all cases. Ataxia and increased deep tendon reflex, additional findings in our patient, were reported in only a few of the aCGH confirmed patients. Our case is of interest in that it is the first case of pure deletion of 10q11.21-q11.22 region.

P03.045

Difficulties in the molecular diagnosis of a patient with features of 1p36 deletion

***A. Jezela-Stanek**, M. Kucharczyk, A. Gutkowska, M. Pelc, K. H. Chrzanowska, M. Krajewska-Walasek;*
Department of Medical Genetics, The Children's Memorial Health Institute, Warsaw, Poland.

Deletion 1p36 is one of the most common subtelomeric aberration with an estimated incidence of 1 in 5 000 to 1 in 10 000 live births. It is characterized by severe developmental delay, microcephaly with distinct facial phenotype which is often accompanied by internal organs malformations and seizures.

We present a case of 8-year-old boy with multiple congenital anomalies/ mental retardation in whom neither classical G-binding karyotype nor FISH for 1p36 deletion and subtelomeric MLPA test revealed any aberration. He presents with aggressive behavior, craniofacial features consisting of microbrachycephaly, straight eyebrows, deep-set eyes, epicanthal folds, midface hypoplasia, broad and flat nasal bridge, long philtrum, pointed chin, low-set, abnormal ears. Besides, absence of the septum pellucidum, Ebstein anomaly and club foot were noted.

Despite the normal results of FISH and MLPA subtelomeric screening and because of either facial dysmorphism predictive for deletion 1p36 (midfacial hypoplasia and horizontal eyebrows) or heart defect (Ebstein anomaly) further molecular analysis - arrayCGH - was performed. This only allowed confirm the clinical diagnosis and let to recognition of deletion. Interestingly, the Agilent SurePrint G3 Human CGH and SNP Microarray 4x180K revealed 2 aberrations: within 1p36.22-p36.32 (including 8.43 Mb, 101 genes) and 1p36.12 (of 0.44 Mb, 12 genes).

In this presentation we like to underline the importance of detailed analysis of clinical features which may lead to the diagnosis, even with the correct result of screening studies.

The study was partially supported by the grant of the Polish Ministry of Science and Higher Education (Contract No 0605/B/P01/2009/37).

P03.046

Pure 1q43q44 deletion characterized by array CGH - a case report

***S. Papuc**[1], M. Budisteanu[2,1], A. Tutulan-Cunita[1], I. Borcan[1], M. Cristea[1], A. Arghir[1];*
[1]"Victor Babes" National Institute of Pathology, Bucharest, Romania, [2]"Prof. Dr. Alex. Obregia" Clinical Hospital of Psychiatry", Bucharest, Romania.

Deletions involving chromosome 1q43q44 generate a recognizable phenotype, including psychomotor retardation, characteristic dysmorphic features, microcephaly, hypoplasia or agenesis of the corpus callosum and various other anomalies.

We present the clinical and molecular findings of a 3 year-old girl, referred for genetic investigations due to phenotypic features suggestive of 1q43q44 deletion.

Classical and molecular cytogenetic investigations were performed on peripheral blood lymphocytes by GTG-banded karyotyping, FISH and array CGH. Karyotype analysis was performed for both parents.

Cytogenetic analysis showed a de novo terminal deletion of chromosome 1, 46,XX,del(1)(1q43q44). Array CGH (105K, Agilent) was performed for accurate characterization of 1q deletion and for exclusion of other imbalances at 1q or in other genomic regions. A 10,98 Mb deletion of chromosome 1, spanning from 238,224,320-249,212,668 (hg19), was the only aberration detected. The results were confirmed by FISH.

Our case add data to the current body of knowledge regarding the pure deletion of 1q43q44; detailed molecular characterization allows for better genotype-phenotype correlations and contributes to the further delineation of the phenotypic spectrum in this syndrome.

Acknowledgments: Financial support: Research National Projects: PN 09.33.02.03, PNII 42-130/2008.

P03.047

A de novo interstitial deletion of 20q11.21q11.23 in a boy with prenatal diagnosed megacystis and cystic renal dysplasia, analatresia, ventricular septal defect (VSD), dysmorphic features and abnormal feet

***D. Mueller**[1], H. Duba[1], S. Deutschbauer[2], G. Webersinke[2];*
[1]Human Genetics Departement, General Women and Children Hospital, Linz, Austria,
[2]Laboratory for Molecular Biology and Tumorcytogenetics, Department of Internal Medicine, Hospital Barmherzige Schwestern, Linz, Austria.

Background: Interstitial deletions involving 20q11 are very rare. Only 3 cases with similar clinical features have been reported (Hiraki Y et al, Am J Med Genet 2011,155A(2):409-14).

Case report: We describe a boy with de novo 20q11.21q11.23 deletion. Molecular characterization of del(20)(q11.21q11.23) by high-resolution SNP microarray showed an approximately 5,7 Mbp deletion. A megacystis was diagnosed in early pregnancy which led to hydronephrosis IV and oligo/anhydramnios. Postnatal the boy showed multiple congenital anomalies such as analatresia, a ventricular septal defect, hypoplastic aortic arch, hyospadia, deformity of the thorax, hipluxation on both sides, talipes calcaneus and flatfeet as well as dysmorphic facial features including microcephalia, retro-/micrognathia, deep set ears, broad nasal bridge. Furthermore feeding difficultiers were reported. Due to the renal disorder the boy died because of renal failure a few weeks after birth.

Discussion: Compared to the other three cases with deletion 20q11-q12 there is a similarity between our patient and the patient described by Hiraki Y et al. Because of our patient´s early death we will not know if there would have been a mental retardation or behavior abnormality. The 5,7 Mbp deleted segment identified in our patient encompasses at least 81 genes and 9 miRNAs.

Our case adds new information to characterize the phenotype of patients with rare proximal microdeletion (20q).

P03.048

A 25 Mb Deletion of Chromosome 4q13.2 -q22.3 in a Male Fetus with severe skeletal abnormalities

***M. Mirzazadeh**, A. Kariminejad, A. Rajaee, K. Najafi, R. Kariminejad, S. Ghaderi-sohi, M. H. Kariminejad;*
Kariminejad-Najmabadi Pathology & Genetics Center, Tehran, Islamic Republic of Iran.

We report on a 20-week-male fetus with interstitial deletion of the long arm of chromosome 4q13.2-q22.3. Ultra-sound examination at 19 weeks revealed multiple congenital anomalies and therapeutic abortion was performed at 20 gestational weeks. Fetus was sent for autopsy examination and aCGH study. Autopsy examination revealed micromelia of upper and lower limbs, long philtrum, micrognathia, small low-set ears, hypertelorism, abnormal segmentation of right lung, adrenal agenesis. Radiology showed triangular shaped hypoplastic ossification representing the humerus. There was absent ossification of the radius and ulna with marked micromelia of all those 3 bones. In the lower extremities, a thin single ossification of the femur with absence of a severely hypoplastic tibial anlage was seen. The pelvis was tiny, high, narrow ileum and only ischial ossification was present. The skull showed a posterior ossification defect. The thorax showed elongated clavicles and 12 ribs. Array comparative genomic hybridization was performed, revealing a 25 Mb deletion of chromosome 4q13.2-q22.3. Even though skeletal abnormality and limb shortening has been previously reported in 4q deletion cases, none of them have such severe skeletal anomalies as seen in our case.

P03.049

Clinical consequences of 8pter deletion - new case of a girl with subtle facial dysmorfism and moderate mental retardation

***A. Gutkowska**, M. Kucharczyk, M. Pelc, M. Kugaudo, M. Jędrzejowska, M. Krajewska-Walasek;*
The Chidren's Memorial Health Institute, Warsaw, Poland.

Microscopically visible 8pter deletions are associated with growth and mental impairment, minor facial anomalies, congenital heart defect and behavioral problems. Submicroscopic subtelomeric 8p deletion is fairly uncommon. The patients either with microcephaly, normal facial appearance, mild mental retardation or clinical phenotypes of autism were described. One could speculate that there is strong correlation between the clinical phenotypes and the size of 8pter deletion.

We present a case of pure 8pter deletion found in a 17-year-old girl with microcephaly, minor dysmorphic features, developmental delay, moderate mental retardation, dyslalia and the features of depression, born as 5th child of healthy parents. In her family history there were no cases of neither miscarriages nor mental retardation. Cytogenetic classic study revealed no visible aberrations, but no high resolution analysis was performed. The diagnosis of deletion of 8pter region was establish by MLPA, confirmed by FISH and delineated by array-CGH. Our patient has the terminal deletion of the 8p with the proximal breakpoint at 10075000 bp in band p23.1. The deleted region has the size of ~ 10,1 Mb and contains 154 genes possibly involved in the phenotype of our patient. Examination of the mother did not show this deletion, the father was unavailable for this study. Our report shows that the clinical phenotype of 8p deletion is determined not only by the size and location of the deleted region but also by other factors.

The study was partially supported by the grant of the Polish Ministry of Science and Higher Education (Contract No 0605/B/P01/2009/37).

P03.050

Multiple Genomic Rearrangements in a consanguineous family

***R. F. Oliveira**[1], A. Beleza-Meireles[1], F. Rodrigues[1], A. Matos[1], S. Maia[1], M. Venâncio[1], L. Ramos[1], E. Matoso[2], I. Carreira[2], J. Saraiva[1];*
[1]Carmona da Mota's Pediatric Hospital - CHUC, Coimbra, Portugal, [2]Cytogenetics Laboratory-Faculty of Medicine, University of Coimbra, Coimbra, Portugal.

Introduction

The birth prevalence of congenital disorders in children of first-cousin parents is about double of the general population (4-5%). Some cases can be explained by the cumulative inheritance of susceptibility genetic variation, including unbalanced genomic rearrangements.

Clinical Report

The proband, a 2 year-old boy, born to consanguineous parents (r=1/8), was referred to the medical genetics clinic due to global psychomotor development delay, unspecific facial dysmorphisms, oesophageal atresia and failure to thrive. Since there was a family history of learning difficulties, the parents and the siblings were also studied. The etiologic investigation revealed a heterozygotic 19q13deletion on subtelomeric MLPA analysis in the proband, in both affected parents and in the two healthy sisters, and a 19q13nullisomy in the older brother. As this was the more severely affected member an arrayCGH was performed which revealed a 1p33tetrasomy and a 3p21.31duplication. The parents' arrayCGH identified a 1p33duplication in both parents and a 3p21.31duplication in the mother.

Proper cognitive assessments were performed to all members and array-CGH analysis is being carried out to the proband and his sisters.

Discussion/Conclusion

Co-inheritance of genomic abnormalities may explain the developmental disorders and cognitive deficits in this family. The affected genomic regions include putative relevant genes, such as *CHMP2A,* which participates in cell cycle progression regulation, *NSUN4*, which interferes with DNA methylation and *TREX1* that interferes in cell apoptosis. It is likely that the cumulative effect of aberrations contributes to more pronounced clinical phenotypes. Genotype-phenotype relation is under investigation and will be discussed in the presentation.

P03.051

ArrayCGH characterization of a deletion on 2q13 associated with developmental delay and facial dysmorphism (case report)

***I. Slamova**[1,2], E. Zrnova-Hladilkova[1,2], T. Barøy[3], V. Vranova[1,2], S. Prasilova[2], R. Gaillyova[2], E. Frengen[3], P. Kuglik[1,2];*
[1]Department of Genetics and Molecular Biology, Institute of Experimental Biology, Faculty of Science,, Brno, Czech Republic, [2]Department of Medical Genetics, University Hospital, Brno, Czech Republic, [3]Department of Medical Genetics, Oslo University Hospital, Ullevål, Norway, Oslo, Norway.

Genomic imbalances play a major role in the pathogenesis of many human genetic diseases. The modern genome-wide analysis tools (such as array-CGH) have led to the discovery of novel copy-number variations (CNVs); many of them are known to be associated with diseases. Recently, CNVs at 2q13 have been described in literature and the DECIPHER database as increasing risk for developmental delay and cranial facial dysmorphism.

We present a 5-year-old girl, who was born with microcephaly, navel cord hernia, and mild dysmorphic features (deep-set short nose, small chin, low hairline, and low-set ears). A neuropsychological examination revealed mild psychomotor retardation and speech delay. The proband suffers from frequent febrile convulsion, dental caries and frequent respiration infections.

G-banded karyotyping at 550 bands resolution defined the karyotype of the proband as normal.

An approximately 1.79 Mb deletion in chromosome band 2q13 (chr2:111415137-113194067 bp, hg19) was identified by arrayCGH and verified by real-time quantitative PCR (qPCR). The patient's karyotype was therefore revised as 46,XX.arr 2q13(111,415,137-113,194,067)x1 mat. The deletion on 2q13 was also detected in the maternal grandmother using a specially designed FISH probe.

Inherited chromosomal aberrations from parents in whom the variant was insufficient to cause such disease might be still causative for a pathological phenotype in the next generation. The mother and the grandmother had normal phenotype (except a mother's speech delay in childhood). Distinguishing pathogenic and benign CNVs is still challenging in the clinical practice.

P03.052

Trisomy 8p11.23 as a result of a dicentric chromosome 8

***S. Midyan**[1], A. Hovhannisyan[1], A. Gasparyan[1], E. Klein[2], T. Liehr[2], H. Mkrtchyan[1,2];*
[1]Center of Medical Genetics and Primary Health Care, Yerevan, Armenia, [2]Jena University Hospital, Institute of Human Genetics, Jena, Germany.

Here we present on a case with de novo dic(8;8)(p11.2;q11). An eight years old boy was referred for genetic studies. He had microcephaly, autism, developmental delay, mental retardation, a dysmorphic face, joint problems and chest deformation. GTG banding analyses of the index patient and his parents were done according to standard protocols. The parents karyotypes were normal. To characterise the aberrant chromosome 8 found in the patient fluorescence in situ hybridization (FISH) was performed using centromeric probe for chromosome 8 and subcentromeric probes set (partial chromosome paint probes for 8p and 8q, BAC probes RP11-503A24 located on 8p11.21, RP13-116A4 located on 8q11.21 and centromeric probe). The dicentric chromosome 8 with duplication of a small region 8p11.23 was discovered: dic(8)(pter->q11::p11.23->qter).

Partial trisomy 8p is a relatively frequent anomaly as this can be result of an inversion-duplication or be found in the offspring of balanced translocation carriers; different breakpoints related to 8p have been reported, even though genes from the olfactory receptor gene family are involved more frequently. Still, there are controversial information about clinical features of these patient. In the sSMC database (http://www.fish.uniklinikum-jena.de/sSMC.html) cases with duplication of the same region with and without clinical findings are described. Our report provides one more case with features which shares some common clinical descriptions of partial trisomy 8p syndrome. Supported in parts be DFG (LI 820/38-1) and the Else Kröner-Fresenius-Stiftung (2011_A42).

P03.053

Atypical chromosomal rearrangements in Down syndrome - clinical and cytogenetic study

***S. Popa**[1], C. Rusu[1,2], M. Gramescu[1], C. Bujoran[1], R. Popescu[1], E. Graur[1], V. Vasilica[1], E. V. Gorduza[1,3];*
[1]University of Medicine and Pharmacy "Grigore T. Popa", Iasi, Romania, [2]"Sf Maria" Children's Hospital, Iasi, Romania, [3]"Cuza Voda" Obstetrical Hospital, Iasi, Romania.

Down syndrome (DS) is one of the most common genetic disorder, and is caused by complete or partial 21 chromosome trisomy. The incidence of DS has a wide geographic variation, and is related directly to prenatal medical care assistance (country economic status). A variety of chromosomal abnormalities can be associated with this disorder.

In the last 10 years in the Cytogenetic laboratory of University of Medicine and Pharmacy „Grigore T. Popa" Iasi were performed 2491 constitutional karyotypes with G banding and were confirmed cytogenetically 571 cases with DS. From the number of diagnosed patients we discriminate: (i) 510 cases (89.00%) with homogenous trisomy of chromosome 21 (from these five cases also present chromosome 9 inversion); (ii) 31 cases (5.41%) with chromosome 21 trisomy in mosaic without translocations; (iii) 25 cases (4.36%) with unbalanced Robertsonian translocations between the following groups of chromosomes: 14 and 21 (14 cases), 21 and 21 (6 cases), 13 and 21 (3 cases), 15 and 21 (one case), 22 and 21 (one case); (iv) 5 cases (0.87%) with different abnormalities other than chromosomal 21 trisomy: one case of chromosome 21 inverted duplication, one case of chromosome 21 dicentricity, one case of chromosome 21 insertion into chromosome 18, and two cases involving one or more translocations of chromosomes other than chromosome 21.

We focus our study on the latter 5 cases that present atypical cytogenetic DS, in order to illustrate some rare variants of chromosomal abnormalities and cytogenetic particularities. Each individual case is compared to literature data.

P03.054

Mosaic interstitial duplication 14q

K. Hansson[1], *C. Ruivenkamp*[1], *A. Gijsbers*[1], *L. Rövekamp-Abels*[2], *L. Smit*[2], *M. Laurense-Bik*[1], *K. Heijboer*[1], *M. Kriek*[1], *M. Koopmans*[1], *L. M. E. Smit*[3];
[1]*Leiden University Medical Center, Leiden, Netherlands,* [2]*Juliana Children's Hospital, The Hague, Netherlands,* [3]*Juliana Childrens's Hospital, The Hague, Netherlands.*

Interstitial duplications in the long arm of chromosome 14 are rarely encountered. We report a male patient who was born with multiple congenital anomalies. The patient had microcephaly with structural brain abnormalities on MRI, polycystic kidneys, a VSD and an ASD. Newborn hearing screening showed mild-moderate hearing loss. He had low-set, posteriorly rotated dysplastic ears and a cleft of the soft palate. Furthermore a sacral dimple was present, a small penis and overlapping toes of the left foot with of proximal placement of the 5th toe.

Conventional karyotyping demonstrated a mosaic (95%) interstitial duplication in the long arm of chromosome 14. SNP array analysis was performed to characterize the duplication in more detail. Both parents had a normal karyotype. Detailed molecular characterizations and reports of chromosomal imbalances in combination with clinical phenotypes are important for accurate genotype-phenotype correlations in genetic counseling.

P03.055

A new case with de novo proximal duplication of 10q11.2q21.3

H. Mkrtchyan[1,2], *S. Midyan*[1], *A. Gasparyan*[1], *T. Liehr*[2], *A. Hovhannisyan*[1];
[1]*Centre of Medical Genetics and Primary Health Care, Yerevan, Armenia,* [2]*Jena University Hospital, Institute of Human Genetics, Jena, Germany.*

Here we report on a case with de novo duplication of proximal 10q11.2 to 10q21.3. An eleven months old boy with developmental delay was referred for genetic studies. The patient was the first child of a healthy, non-consanguineous parent. He presented with microcephaly, deep set eyes, arched palate, hypotelorism, strabismus, down slanted corners of the mouth, hypotrophy and motor development delay. Cardiac problems included coarctation of aorta and open arterial duct. His right hand showed an absence of the middle metacarpal bones.

The patient karyotype was 46,XY,dup(10)?(q24.3-qter)dn. To characterize the der(10) fluorescence in situ hybridization (FISH) was applied using whole chromosome painting, multicolor banding (MCB) and subcentromere specific probe sets for chromosome 10. Finally, the aberration was described as dup(10)(q11.2q21.3)dn. To the best of our knowledge only seventeen cases with proximal duplication 10q11-q22 were reported, yet. All of them had common dysmorphic features, cardiac or renal defects. Our patient shares some of these features but others as kidney defects, muscle hypo- or hypertonia, feedings difficulties are absent. In conclusion, only molecular cytogenetics allows us to precisely describe aberrant chromosomes; here we report a new case with proximal duplication 10q11 to q21.3 without involving chromosomal band q22 as in other previously found cases. Supported in parts be DFG (LI 820/38-1).

P03.056

Severe phenotype in a child with inverted duplication 10q24.1>q26.3: array-based evidence for the inverted low copy repeat model

O. Rittinger, *S. Kalb, G. Kronberger, I. Vlasak, G. Sander;*
Universitätsklinik fü rKinder- und Jugendheilkunde, Salzburg, Austria.

Background. Duplication of the distal long arm of chromosome 10 causes a clinically recognizable dysmorphic syndrome. Most patients are severely mentally retarded. Congenital malformations including microphthalmia and heart defects are suggested to occur only in larger duplications including q24. Generally the aneuploidy is caused by a translocation inherited in an unbalanced fashion. Here we report on microarray analysis of a large de novo inverted 10q duplication & subtelomer deletion.

Case report. The female patient was term-born, small for gestational age, referred because of growth and psychomotor delay, microcephaly, severely handicapped vision due to right-sided microphthalmia, coloboma of the iris and choroidea, small palpebral fissures and bilateral ptosis, ventricular and atrial septum defect.

Lab results. GTG studies with a lymphocyte culture showed an extended long arm of chromosome 10. FISH using wcp 10 and subtelomeric probe 10q revealed the extra material to be exclusively derived from chromosome 10 and lack of the subtelomeric region 10q, respectively. Microarray investigation affirmed the 10q24.1>q26.3 duplication and adjacent subtelomeric deletion including a 6kb single copy stretch within the duplicated segment.

Conclusion. The clinical severity of chromosome 10q duplication seems to depend particularily on the involvement of 10q24 suggesting a dosis effect in the respective genes. The subtelomeric deletion most likely does not influence the phenotype. This report adds to the still few patients with 10q duplication delineated by array methods and the increasing understanding of genotype-phenotype correlations. Also, our results provide molecular evidence for the inverted low copy repeat model postulated by Bonaglia (2000).

A de novo interstitial duplication 14q32.11-q32.32

A. Hovhanissyan[1], *S. Midyan*[1], *A. Gasparyan*[1], *T. Liehr*[2], *H. Mkrtchyan*[1,2];
[1]*Centre of Medical Genetics and Primary Health Care, Yerevan, Armenia,* [2]*Jena University Hospital, Institute of Human Genetics, Jena, Germany.*

The 2- year- old patient presented with minor clinical features, as epicanthus, microcephaly, full lips and developmental delay. The child was born at 39 weeks of gestation with a birth weight of 3200g and length 50cm after the pregnancy with polyhydramnios.

Additional material in the distal part of chromosome 14q was identified by GTG-banding. The parents karyotypes were normal. Standard fluorescence in situ hybridization (FISH) was performed using whole chromosome painting, multicolour banding (MCB), subtelomeric and different bacterial artificial chromosome (BAC) probes for chromosome 14. FISH analysis showed duplication of distal part of chromosome 14. Subtelomeric probe 14q and BAC probes in 14q24.3 (73.0-73.2Mb) , 14q32.33 (105.7-105.8 Mb), 14q32.33 (106.0-106.1 Mb), and 14q32.33 (106.1-106.2 Mb) showed no duplication, while the probes RP11-1A3 (14q32.11; 89.4-89.5 Mb) and RP11-65M20 (14q32.11, 91.8-92.0 Mb) demonstrated two signals, each on the der(14). Finally, based on GTG-banding and FISH results the derivative was described as dup(14)(q32.11q32.32)dn. Only few cases with "pure" duplication of this distal region of chromosome 14q were described (Decipher). In most of them mental retardation, developmental delay, microcephaly were described. Here we report on a new case with de novo duplication of 14q32.11q32.32 (located possibly between 89.4-92.0 Mb). Supported in parts be DFG (LI 820/38-1).

P03.058

De novo 2p21-p16.3 duplication in a patient with severe growth retardation and significant delayed bone age.

C. Bandelier[1], *M. Ravoet*[1], *A. I. Diplas*[1], *Y. Gillerot*[1], *V. Beauloye*[2], *N. Revencu*[1];
[1]*Centre for Human Genetics, Cliniques universitaires Saint-Luc, Université catholique de Louvain, Brussels, Belgium,* [2]*Paediatric Endocrinology Unit, Cliniques universitaires Saint-Luc, Université catholique de Louvain, Brussels, Belgium.*

Herein, we report on the phenotype of a 12-year-old girl with partial trisomy 2p. She is the second child of healthy non-consanguineous parents of Belgian origin. She was born at term after a pregnancy complicated by intrauterine growth restriction and oligohydramnios. The growth retardation persisted postnatally. In addition, she presented diaphragmatic hernia, moderate psychomotor development, feeding difficulties, and recurrent respiratory infections. She had prominent forehead, relative macrocephaly, marked hypertelorism, thin upper lip and delayed closure of the anterior fontanelle. The veins were visible on trunk and extremities. She had lumbar hyperlordosis. At the age of 12, her growth parameters were: height 114.0cm (-5.6 SD), weight 18.5kg (-5.8 SD), and OFC 49.4cm (-2.2 SD) (father's height: 156.5cm (-3.6 SD), mother's height: 154cm (-2.1 SD)). According to Greulich and Pyle, bone age was 6 years and 10 months at the age of 10 years and 6 months. The IGF-1 levels were relatively low (64 ng/ml; normal: 78-405 ng/ml) and she had been treated by growth hormone therapy for 19 months without any clear benefits on growth.

Genetic workup identified a *de novo* tandem dup(2)(p21~22p16) by high-resolution conventional karyotyping, followed by FISH. SNP-array revealed a 9.6 Mb interstitial duplication, arr 2p21p16.3(42,295,716-51,981,249)x3, encompassing 45 genes.

To our knowledge, this is the first case of 2p21-p16.3 duplication. Pure 2p trisomy, encompassing this region, is very rare, and was mostly identified by standard karyotyping. Molecular characterization of additional patients will allow a better determination of the breakpoints and the genes involved in the phenotype.

P03.059

A de Novo 5 Mb duplication of Xp11.23-p11.3 with non-random X inactivation: Clinical report of female twins and molecular cytogenetic characterization

C. Evers[1], *J. W. G. Janssen*[1], *A. Jauch*[1], *K. Hinderhofer*[1], *B. Maas*[1], *U. Haug*[2], *U. Moog*[1];
[1]*Institute of Human Genetics, Heidelberg University, Heidelberg, Germany,* [2]*Center for Child Neurology and Social Pediatrics Maulbronn, Maulbronn, Germany.*

Introduction:

Partial duplications of the short arm of the X chromosome (Xp) in males result in intellectual disability, facial dysmorphism and variable malformations. In females, a normal phenotype should be expected if the abnormal X chromosome is preferentially inactivated. Recently, duplications of Xp encompassing band p11.2 were found in females with developmental delay and other anomalies. Unexpectedly, most of them showed preferential activation of the duplicated X chromosome.

Clinical Report and Genetic Findings:

We describe female twins of twentyfive months of age with developmental delay, seizures, EEG and MRT abnormalities, and facial dysmorphism. Both children were sociable and smiled frequently. The first child had a small atrial septum defect, the second had a patent foramen ovale and a dilated renal pelvis. SNP-Array analysis in one child and both parents showed a *de novo* ~5 Mb duplication of Xp11.23-p11.3 in the child. Subsequent FISH analysis confirmed this duplication in both children. The twins showed selective inactivation of the normal X chromosome in more than 80% of blood cells.

Discussion:

The described twins have phenotypic features in common with other males and females carrying a partially overlapping Xp duplication. These individuals have developmental delay, seizures, EEG abnormalies, similar behavioral phenotypes and facial dysmorphism. The described twins as well as almost all reported affected females show selective inactivation of the normal X chromosome, suggesting that increased expression of a gene within the common duplicated region leads to skewed X-inactivation. Functional disomy for genes within the duplication results in the described phenotype.

The discovery of complex structural variations that exist within individual genomes has prompted a need to visualize chromosomes at a higher resolution than previously possible. In response to the need for such high resolution visualization, we have developed a new generation of fluorescent *in situ* hybridization probes targeting specific regions of the genome. These new probes, Agilent SureFISH probes, are designed using an *in silico* design strategy that specifically avoids placing oligonucleotides in repetitive regions of the genome, allowing for highly specific detection of the region of interest. Each SureFISH probe is designed to a specific region of the genome and is generated from complex libraries containing hundreds to thousands of unique high quality long oligonucleotides. The resulting probes provide high specificity and enable users to detect aberrations in targeted regions of the genome as well as aberrations near highly repetitive elements. Because Agilent SureFISH probes are designed for specific, non-repetitive, regions of the genome, they provide superior resolution as compared to other available technologies.

P03.061

How to narrow down chromosomal breakpoints in small and large derivative chromosomes - a new probe set

M. Voigt;
Jena University Hospital, Institute of Human Genetics, Jena, Germany.

Here a new fluorescence in situ hybridization (FISH-) based probe set is presented and its possible applications are highlighted in thirty-four exemplary clinical cases. The so-called pericentric-ladder-FISH (PCL-FISH) probe set enables a characterization of chromosomal breakpoints especially in small supernumerary marker chromosomes (sSMC), but can also be applied in large inborn or acquired derivative chromosomes. PCL-FISH was established as 24 different chromosome-specific probe sets and can be used in two- up multicolor-FISH approaches. PCL-FISH enables the determination of a chromosomal breakpoint with a resolution between 1 and ~10 megabasepairs and is based on locus-specific bacterial artificial chromosome (BAC) probes. Thus, PCL-FISH leads to a better resolution than most FISH-banding approaches. To approve the result eight of the in 29 sSMC cases were studied by array-CGH; the used sSMC-specific DNA was obtained by glass-needle based microdissection and DOP-PCR-amplification. Results obtained on 29 sSMC cases and 5 larger derivative chromosomes are presented and discussed. Finally, application perspectives of the probe set in tumor as well as in evolutionary cytogenetic studies are given. Supported in parts by Else Kröner-Fresenius-Stiftung (2011_A42), the Deutscher Akademischer Austauschdienst (DAAD), the Monika-Kutzner-Stiftung and the Stefan-Morsch-Stiftung.

Patients with deletions of 1q24q25 share common features of growth deficiency, microcephaly, small hands and feet, dysmorphic face and severe cognitive deficits. We report fifteen patients with 1q24q25 deletions, who show distinctive features of a clinically recognizable 1q24q25 microdeletion syndrome: prenatal and postnatal growth deficiency, microcephaly, mental retardation, small hands and feet with distinctive brachydactyly and fifth finger clinodactyly, single transverse palmar flexion creases and a distinctive dysmorphy (hypertelorism, small and low set ears, short nose with bulbous nasal tip and micrognathia). Radiographs demonstrate disharmonic osseous maturation with markedly delayed bone age. Occasional features include cleft lip and/or palate, genital, cardiac and renal abnormalities.

Using array comparative genomic hybridization, we defined the critical deletion region as 717kb at 1q25.1 (chr1 :173,710,633-174,427,602, hg19 coordinates), containing 7 genes and including CENPL (Centromere protein L).

CENPL encodes centromeric protein L, a protein essential for proper kinetochore function and mitotic progression. The growth deficiency in this syndrome is similar to what is seen in other types of primordial short stature with microcephaly, such as Majewski osteodysplastic primordial dwarfism, type II (MOPD2) and Seckel syndrome, which result from loss-of-function mutations in genes coding for centrosomal proteins. Therefore, CENPL is a candidate for microcephaly and for growth deficiency in 1q24q25 microdeletion syndrome.

P03.063

A new multicolor-fluorescence in situ hybridization probe set directed against human heterochromatin: HCM-FISH

H. Nelle[1], *M. Buksch*[1], *M. Ziegler*[1], *N. Kosyakova*[1], *S. Morlot*[2], *W. Fischer*[2], *B. Belitz*[3], *V. Trifonov*[4], *A. Weise*[1], *A. Hamid*[1], *T. Liehr*[1];
[1]*University Hospital, Jena, Jena, Germany,* [2]*Partnerschaft Georgstraße, Hannover, Germany,* [3]*Praxis für Humangenetik, Berlin, Germany,* [4]*Molecular and Cellular Biology Department, Institute of Chemical Biology and Fundamental Medicine, Novosibirsk, Russian Federation.*

Here a new multicolor fluorescence in situ hybridization (mFISH-) probe set is presented and its possible applications are highlighted in fifteen clinical cases. The so-called heterochromatin-M-FISH (HCM-FISH) probe set enables a one-step characterization of the large heterochromatic regions within the human genome. HCM-FISH closes a gap in the up to now available mFISH probe sets as those do normally not cover the acrocentric short arms, the large pericentric regions of chromosomes 1, 9 and 16, as well as, the band Yq12. Still, these regions can be involved in different kinds of chromosomal rearrangements like translocations, insertions, inversions, amplifications and marker chromosome formation. Here examples are given for all these kinds of chromosomal aberrations, detected as constitutional rearrangements in clinical cases. Application perspectives of the probe set in tumor as well as in evolutionary cytogenetic studies are given. Supported in parts by BMBF/DLR (BLR 08/004 and BRA 09/020), DFG (LI 820/19-1, LI 820/32-1), Else Kröner-Fresenius-Stiftung (2011_A42) and Dr. Robert Pfleger Stiftung.

P03.064

Hyperspectral Imaging of Chromosomes: a New Approach for Label Free Karyotyping

***S. Luckow**, A. Lorenz, K. Rebner, R. W. Kessler;*
Reutlingen Research Institute, Process Analysis and Technology, Reutlingen University, Reutlingen, Germany.

Staining techniques are routinely used to identify metaphase chromosomes based on their unique banding pattern. Advanced molecular cytogenetic techniques like Fluorescence-In-Situ-Hybridization (FISH) provide a more sensitive tool for complex and small structural aberrations. In both cases a broad expert knowledge is necessary to understand and diagnose diseases.
We have developed a new technique for fast and label free karyotyping using a Hyperspectral Imaging System (HSI) which can easily be integrated into a standard light microscope. With this system we measure the stray light interference pattern of an unstained chromosome or substructures of the chromosome with a diode array spectrometer. The complex spectra can be interpreted as spectra of "nanostructured particle arrays" of different size and refractive indexes. The signature of each spectrum is due to the superposition of the interference pattern of the different layer thicknesses, the spectral interference of the band pattern and changes in refractive indexes along the chromosome axis. The hyperspectral data can be analyzed using multivariate data analysis and the chromosomes can be classified by their individual spectral features.
The results are confirmed with model particle array measurements. These measurements show strong correlation with calculated Mie interference spectra. Furthermore, FDTD (Finite Difference Time Domain) simulations of model chromosomes confirm the photon diffusion pattern as well. Substructures of chromosomes can also be analyzed by Near Field Spectroscopy (imaging beyond diffraction limit) measuring the stray light pattern of sub structures of chromosomes as small as 50 nanometers.

P03.065

Origin of genomic imbalances detected by array-CGH in children with intellectual disability.

***M. Drozniewska**[1], O. Zuffardi[2], O. Haus[1,3,4];*
[1]Department of Clinical Genetics, CM UMK in Bydgoszcz, Bydgoszcz, Poland, [2]General Biology and Medical Genetics, Pavia University, Pavia, Italy, [3]Genetic Counseling Center, Medical University, Wroclaw, Poland, [4]Department of Hematology, Medical University, Wroclaw, Poland.

We present the data from the genetic screening of 14 children with intellectual disability (ID), dysmorphic features and congenital malformations. 28 parents were also included to this study. The diagnostic algorithm included classical cytogenetic analysis (CC), performed according to the standard procedures, array-CGH performed with Agilent SurePrint 3G Human CGH Microarray Kit (4x180K platform) and subtelomeric FISH experiments performed with Vysis ToTel subtelomeric probes.
All children presented normal karyotype. Subtelomeric FISH showed normal hybridization pattern in all children. In 14 children 16 different imbalances were found, of which 8 were duplications and 8 deletions. All parents were analysed with CC and a-CGH, which helped to establish the origin of aberrations found in children. 8 aberrations were de novo, 3 of maternal and 3 of paternal origin. In one patient presence of 2 aberrations was the result of paternal balanced translocation.
The use of array-CGH technique helped in direct genotype-phenotype correlation in our patients. In only 4 de novo cases the size and gene content of aberration strongly correlated with patients phenotype. In 3 de novo cases the conclusion of pathogenic influence of the imbalance still need more evidence. In familial cases it was not possible to exclude the potential pathogenic role of inherited changes - further molecular analysis is required.

P03.066

Molecular cytogenetic analysis of a new case of inv dup chromosome 15 syndrome .

***I. Ben Abdallah Bouhjar**, H. Hannachi, H. Ben Khelifa, N. Soyah, H. Elghezal, A. Saad, S. Mougou Zerelli;*
Laboratory of cytogenetic and biology of reproduction, Sousse, Tunisia.

The chromosome region 15q11q13 is known for its instability, and many rearrangements may occur in this imprinted segment. Supernumerary marker chromosomes formed by the inverted duplication of proximal chromosome 15q region was identified as one of the must frequent human marker chromosomes. We report here, the clinic finding and cytogenetic analysis of a girl with mental retardation. The child has a clinic who should suspect a chromosomic aberration because she has a developmental delay, hypotonia and dysmorphic features. Standard cytogenetic techniques and FISH analysis using painting and locus specific probes were performed to identify and characterize the chromosome anomaly. A supernumerary marker chromosomes formed by the inverted duplication of proximal chromosome 15 was identified. FISH using chromosome 15 specific centromeric probes (Spectrum Green,CEP 15q11.2,D15Z1) and SNRPN, UBE3A and PML genes confirm the duplication of 15q11-13 region in the dicentric marker chromosome. The critical region involved in duplications is a gene-rich region that comprises the three γ-amino butyric acid (GABA)-A receptor subunit genes (GABRB3, GABRA5, and GABRG3). These subunit genes may contribute to the clinical picture. In fact, even if it is still unclear how the GABAergic neuromodulators influence the developing brain, alterations of this system may cause both epilepsy and behavior problems to occur. Therefore, unexpected prenatal diagnosis, for maternal age or serum screening, of such a chromosomal abnormality would certainly lead to difficulties in genetic counselling and prognosis.

P03.067

Low level mosaicism of chromosomal aneuploidies in intellectual disability

***B. Oneda**[1], R. Riera-Baldinger[1], D. Bartholdi[1], S. Azzarello-Burri[1], D. Niedrist[1], M. Kraft[2], A. Rauch[1];*
[1]Institute of Medical Genetics, University of Zurich, Schwerzenbach, Switzerland, Zurich, Switzerland, [2]Institute of Human Genetics, Friedrich-Alexander University of Erlangen-Nuremberg, Erlangen, Germany, Erlangen, Germany.

It has been shown that oligonucleotide array comparative genomic hybridization (array-CGH) allows the identification of mosaic aberrations. The detection sensitivity was reported to correlate with aberration size. We used a high resolution array to molecular karyotype 73 patients with intellectual disability. In 4/73 (5.5%) patients, mosaicism was found. The first one for chromosome 18 of 21 Mb, with a copy number variant of 1.7, indicating a deletion mosaicism. The second and the third one for chromosomes X and 3, of 18 Mb and 19 Mb, respectively. The copy number level was for both 2.3, pointing to a trisomy mosaicism. In the last case, a trisomy 14 in mosaic form was detected, with a copy number level of 2.4. Importantly, this finding matched, perfectly the phenotype, which reflected the mosaicism on the skin. Despite the size of this aneuplody, it had gone unrecognized with classical karyotyping due to the low mosaic rate and possibly due to selection that might occur during culturing the lymphocytes. For the first three cases, we performed a fluorescence-in-situ-hybridization (FISH) and we confirm the mosaic aneuploidy. The abnormality was detected in 4/26 (15%), 1/31 (3%) and 6/41(15%) metaphases, respectively.
Our findings demonstrate the power of molecular karyotyping using high resolution arrays to detect low level mosaicism, which would go undetected using classical karyotyping. Moreover, they raise the question whether low level mosaicism of certain chromosomal regions are indeed the cause of some cases of intellectual disability and warrant further investigation.

P03.068

Evaluation of the SNP 6.0 Array for molecular karyotyping in patients with intellectual disability

***M. Zweier**[1], J. Hoyer[1], S. Uebe[1], A. B. Ekici[1], A. Reis[1], A. Rauch[2];*
[1]Institute of Human Genetics, University Erlangen-Nuremberg, Erlangen, Germany,
[2]Institute of Medical Genetics, University of Zurich, Schwerzenbach-Zurich, Switzerland.

In the last years molecular karyotyping has evolved into a common technique for diagnostic testing in patients with intellectual disability (ID). It has been shown that high resolution array systems uncover apparently pathogenic copy number variations (CNVs) in up to 15 % of patients with ID and normal conventional karyotype.
In this study we analyzed 79 patients with intellectual disability with the Affymetrix 6.0 SNP array and scored CNVs with a minimum size of 100 kb and 5 markers. We detected a total of 855 aberrations with a mean of 10.82 CNVs per patient. A group of 820 molecularly karyotyped controls and the Database of Genomic Variants were used to rule out common genomic variants and artefacts, resulting in 56 remaining rare individual CNVs in 40 patients with sizes from 114 kb to 11.350 Mb. The first 23 of these CNVs, including the smallest one, were systematically validated by an independent method (QPCR, MLPA, FISH) and could all be confirmed. Segregation analy-

sis of 54 CNVs in 38 patients was performed in the respective families (13 de novo, 20 maternal, 21 paternal). In case of parental inherited CNVs the phenotype of the parents and the affected region/gene content were re-evaluated. In summary, 20 CNVs in 18 affected individuals were assumed to be potentially pathogenic, varying from large de novo aberrations and frequent recurrent microaberration syndromes to single gene defects (NRXN1, CDKL5). In conclusion, we identified potentially disease causing CNVs in 22.8 % of affected individuals, exceeding the prognosticated rate.

P03.069

A 7 Mb microdeletion in chromosome 2 band p13.3p15 associated with devolopmental delay, heart abnormalities and facial dysmorphisms

__D. Bondavalli__[1], V. Uliana[1], M. Malacarne[2], F. Forzano[1], E. Di Maria[1,3], C. Marciano[1], A. Cocchella[1], V. Viassolo[1], C. Viaggi[2], D. Coviello[2], M. Pierluigi[2], F. Faravelli[1];

[1]Division of Medical Genetics, Galliera Hospital, Genova, Italy, [2]Laboratory of Genetics, Galliera Hospital, Genova, Italy, [3]Dept. of Health Sciences, University of Genova, Genova, Italy.

We report on a patient with a de novo 7 Mb deletion in the short arm of chromosome 2, from band 13.3 to 15. The proband, a girl, presented congenital heart defects (atrial septal defect and muscular ventricular septal defect), facial dysmorphisms, poor growth, intellectual disability, interstitial lung disease and severe gastroesophageal reflux.

The rearrangement encompassed 47 genes, 2 of which are known disease gene (C2ORF86 and ANTXR1).

Three cases with partially overlapping deletions were reported in literature and database. Wohlleber and co-workers (2011) described two patients with a de novo 2p14p15 deletions. One patient with a de novo 2p14 deletion was reported in ECARUCA database.

Our patient presented more severe clinical features and a deletion larger in size than patients reported to date.

We suggest that the complex phenotype of our patient is caused by the haploinsufficiency of several genes in the region or by different molecular mechanisms described in chromosomal rearrangements, such as impaired expression patterns.

P03.070

A new intersticial deletion of the long arm of chromosome 4 (q13.2:q13.3) in a girl with growth hormone deficiency

__C. Baquero__[1], I. Bueno[1], M. Artigas[1], G. Bueno[1], A. Miralles[1], B. Puisac[2], J. Pié[2], F. J. Ramos[1];

[1]Servicio de Pediatría-Hospital Clinico Universitario „Lozano Blesa“, Zaragoza, Spain, [2]Dpto. Fisiología, Facultad de Medicina-Universidad de Zaragoza, Zaragoza, Spain.

Intersticial deletions of chromosome 4 long arm are relatively rare, with less than 70 cases reported. The majority of cases are terminal 4q deletions with loss of the bands q31-q33, resulting in a characteristic phenotype. In contrast, deletions within the proximal long arm of chromosome 4 have rarely been reported. There is a wide clinical presentation among patients who share similar breakpoints. We report one patient with proximal intersticial deletion of chromosome 4q, defined at the molecular level by array-CGH. The proband had a 7.7 Mb deletion, spanning from band q13.2 to q13.3.

The patient, a 11 year-old female was found to have craniofacial dysmorphic features, hiperextensible joints, severe short stature with growth hormone deficiency , developmental delay and seizures. No signs of puberty were observed.

Pure intersticial deletions of 4q have been rarely reported in the literature and none of them was accurately mapped by last generation molecular techniques. Intersticial deletions of 4q are associated with a variable phenotype, including growth retardation, dysmorphic features, upper and lower limbs malformations, developmental delay (speech delay is usually more severe than motor delay) and seizures. The deleted region in our patient contains several genes (*MUC7, ENAM, SLC4A, GC)*, including the *GNRHR (Gonadotropin-Releasing Hormone Receptor)* gene*,* associated with hypogonadotropic hypogonadism.

This is the first report of a patient with a 4q13.2- q13.3 deletion and growth hormone deficiency.

P03.071

How common are the cryptic inverted duplication deletion rearrangements among cytogenetically visible terminal deletions?

__L. Brown__[1], B. Lomax[1], T. Gillan[1], G. Horvath[2], P. Eydoux[1], K. Schlade-Bartusiak[1,3];

[1]Department of Pathology and Laboratory Medicine, Vancouver, Canada, Vancouver, BC, Canada, [2]Department of Biochemical Diseases, Vancouver, Canada, Vancouver, BC, Canada, [3]Child and Family Research Institute, Vancouver, BC, Canada.

Inverted duplication deletions (inv dup dels) are rare chromosomal rearrangements characterized by the presence of terminal deletions with contiguous interstitial duplications. They originate through asymmetrical breakage of a dicentric intermediate, formed after the repair of a double strand break. Some, like the inv dup 8p, are recurrent and mediated by either parental paracentric inversions or low copy repeats. Non-recurrent inv dup dels have been described for many chromosome arms, usually with the cytogenetically visible duplicated region longer than the deleted one. Inv dup dels associated with large deletions and small duplications can be misdiagnosed cytogenetically for pure terminal deletions, with consequences for genotype - phenotype correlations and patient management.

We used microarray (Affymetrix) to define 12 cases of cytogenetically diagnosed terminal deletions (with breakpoints at 3p25.3, 5p15.3, 5p15, 6q25.3, 7q34, 9p23, 10p13, 10q26.3, 10q26.12, 15q26.1, 18p11.2, Xp22.31). Pure terminal deletions were confirmed in 9 cases. Inv dup del was diagnosed in one patient, with a terminal deletion of 13.4 Mb at 9p23-p24.3 accompanied by a contiguous, 822 kb duplication at 9p22.3-p23. FISH analysis confirmed the inverted nature of this duplication. Two other patients showed discordant results on the array: one with mosaicism for cell lines with two different 5p terminal deletions and the other with an interstitial deletion of 15q25.3-q26.2.

Our study of terminal deletions revealed a discordant array result in 3/12 (25%) of cases. One inv dup del was observed (8% of the group), which suggests that inv dup del rearrangements are not infrequent among the cytogenetic terminal deletions.

P03.072

Paracentric Inversion of Chromosome 5 detected in Prenatal Diagnosis

__P. Botelho__[1], M. Souto[1], A. Costa[2], M. Martins[3], O. Moutinho[3,4], R. Pinto Leite[1];

[1]Laboratório de Citogenética, Serviço de Genética, Centro Hospitalar Trás-os-Montes e Alto Douro, Vila Real, Portugal, [2]Universidade de Trás-os-Montes e Alto Douro, Vila Real, Portugal, [3]Serviço de Genética, Centro Hospitalar Trás-os-Montes e Alto Douro, Vila Real, Portugal, [4]Serviço de Ginecologia/Obstetrícia, Centro Hospitalar Trás-os-Montes e Alto Douro, Vila Real, Portugal.

Inversions are a fairly uncommonly detected chromosome rearrangement, not considering the variant forms, with a estimated frequency range 0.12‰ to 0,7‰ (pericentric) and 0,1‰ to 0,5‰ (paracentric). Usually they are balanced with no clinical significance unless the breakpoint occurs within a gene. Between 85-90% of inversions are inherited and the risk of having a phenotypic consequences depends of the type (para- or pericentric) and size of the inversion.

The authors report a case of a paracentric chromosome 5 inversion detected on prenatal diagnosis. Amniotic fluid and blood samples (parent's) cultures were performed; high resolution GTL-banded metaphases were analyzed according laboratory routine protocols. Fluorescence *in situ* Hybridization (FISH) was done with painting, subtelomeric and unique sequence for Cri-du-Chat probes to confirm the cytogenetic analysis. A small paracentric inversion, between the bands p13.1 and p15, was detected and it was inherited from the mother. Since the region involved was very small (band p13.1 and p15), this inversion was difficult to detect, and only with high resolution chromosomes it was possible to visualize it.

Inversions involving the chromosome 5 are rare and is important that the new cases detected should be reported for determining the genotype-phenotype correlation to be used for genetic counseling and risk evaluation.

P03.073

A case with isochromosome18p

__I. M. Bradinova__[1], R. Vazharova[1], S. Bichev[1], S. Andonova[1], V. Bojinova[2], A. Savov[1], I. Kremensky[1];

[1]National genetic laboratory, Sofia, Bulgaria, [2]USBALNP „Saint Naum“, Sofia, Bulgaria.

Isochromosome 18p (i(18p)), is a rare chromosomal disorder that occurs once in about every 140.000 live births, affects males and females equally and results in tetrasomy 18p. Most of the cases are due to a de novo formation but in the literature familial cases were reported. The phenotype of tetrasomy 18p has been primarily delineated by published case series and reports. Findings reported in more than 25% of these cases include neonatal feeding

problems, growth retardation, microcephaly, strabismus, muscle tone abnormalities, scoliosis/kyphosis, and variants on brain MRI. Developmental delays and cognitive impairment are universally present.

Marker chromosomes are seen in the 0.06% of the population and are small chromosomes that are additional to the normal chromosome count, the origin of which cannot be determined by standard chromosome analysis. Molecular cytogenetic testing as M-FISH and CGH array techniques can be used to determine the origin of the marker chromosome and help reaching exact diagnosis in such patients.

Here, we report a young female with dysmorphic features as microcephaly, dolichocephaly, high arched palate, low-set ears, open mouth appearance, high palate and long philtrum, clinodactily, presenting a small metacentric chromosome at the routine chromosomal analysis. Besides the dysmorphic features she also has muscle hypotonia, spasticity, strabismus growth and intellectual retardation.

The performed CGH array revealed the presence of chromosome 18p tetrasomy in this patient. The diagnosis of tetrasomic 18p syndrome is consistent with the complex clinical features in our patient.

P03.074

High resolution array CGH study in newborns with isolated cleft/lip palate

K. W. Derwinska[1], *K. Szczałuba*[1], *E. Obersztyn*[1], *J. Castañeda*[1], *R. Śmigiel*[2], *E. Bocian*[1];
[1]*Institute of Mother and Child, Warsaw, Poland,* [2]*Department of Genetics, Wroclaw, Poland.*

Clefting is a common condition, found in 1/700-1/1000 births, with a complex etiology. Although most cases are isolated, a subset is associated with other anomalies and linked to already known syndromes involving cleft lip or palate (CL/P), such as van der Woude syndrome. Until now, a number of genes have been suggested to be involved in clefting events, but they account for small proportion of the recognized etiology. With the implementation of array CGH for diagnostics purposes, among the mechanisms leading to clefting, microdeletions have been hypothesized to play a significant role.

Herein we present a study of 33 patients with isolated CL/P with the use of whole genome Agilent 180k microarray with mean resolution of 16kb. We have found 10 copy number variations (CNV) overall (9 deletions and 1 duplication), ranging in size from 27 kb up to ~8Mb. Microaberrations found in the study are not covering any known microdeletion/microduplication syndrome regions. The summary of all cases and genotype-phenotype correlation will be presented. The most interesting ones will be presented in details, i.e del 17q12 where only *SLFN12* is deleted.

Our results demonstrate that a high resolution array CGH is an efficient tool in diagnostics of patients with patients with isolated cleft lip/palate. Furthermore characterization of the novel pathogenic CNVs identified in our study can help in understanding the role of defined genes in clefting.

The research is founded by the grant of the Polish Ministry of Science and Higher Education NN407459438.

Chromosomal aberrations and Micronuclei frequency in patients treated with J-^{131} for therapeutic causes

M. Mackic-Djurovic[1], *I. Aganovic*[1], *S. Begovic- Hadzimuratovic*[2], *E. Kucukalic*[2], *S. Ibrulj*[1];
[1]*Center for Genetics, Sarajevo, Bosnia and Herzegovina,* [2]*Department for nuclear medicine, Sarajevo, Bosnia and Herzegovina.*

Patients with thyroid diseases have been treated with different doses of J-^{131} in therapeutic causes. Using standard method (cultivation 48 hours of peripheral blood lymphocytes) 12 patients have been cytogenetically analyzed two times. First culture was set before treatment with J-^{131}, and another was set 7 days after application of J-^{131}. Chromosomal aberrations (CA) were analyzed - 200 cells per patient and micronuclei frequency (MN) 1000 cells per patient. Micronuclei appear during cell division as result of acentric fragment or whole chromosomes condensation left in anaphases (it is considered as marker of structural or/and numerical chromosomal aberrations existence).

Applied doses of J-^{131} were 10mCi; 15 mCi and 20 mCi for 4 patients per each dose. At first set of analyzes as initial no significant CA or MN‘s were found. At second set of analyzes for patients who received doses of 10 mCi and 15 mCi it is apparent slow increase of CA and MN frequency (small aberrations); while for those who received dose of 20 mCi there is apparent increase of CA (even bicentric chromosomes) as well as increase of MN‘s frequency alone or with 2 micronuclei per cell.

This is initial phase of research that is going to be further investigated on large number of patients.

P03.076

Comparative array-CGH platform analysis in a clinical setting for diagnosing individuals with intellectual disability and developmental delay

E. Vallespin[1], *L. Rodríguez-Revenga*[2], *I. Madrigal*[2], *M. Palomares*[1], *A. Mur*[3], *F. Santos*[1], *P. Lapunzina*[1], *M. Milá*[2], *J. Nevado*[1];
[1]*INGEMM-IDIPAZ-HULP, Madrid, Spain,* [2]*Biochemistry and Molecular Genetics Department. Hospital Clínic, Barcelona, Spain,* [3]*Paediatrics Service. Hospital del Mar. Barcelona, Spain - Paediatrics and Obstetrics Deparment, Universidad de Barcelona. Barcelona, Spain, Barcelona, Spain.*

We investigate the practical performance of three different microarray platforms for their implementation in our diagnostic setting in two hundred cases of Spanish DD/ID in 2 hospital centers.The total cohort consisted of 200 patients, 100 of who were analyzed with KaryoArray®v3.0, 32 on the Agilent Human Genome CGH 244K and for the remaining 68 patients, on the Agilent Human Genome CGH 44K.As we expected targeted array revealed less common CNVs than did the whole-genome arrays, which has a clear advantage in clinical use. Nowadays it is straighter forward to recognize alterations against background of CNVs.These data support that higher yields mainly depend on patient inclusion clinical criteria and the microarray design. When non-strict criteria are followed, higher yields are also found using Karryoarray. The frequency of VOUS was similar in all three platforms (around 5% of cases). Although more studies are required in order to asses the real significance of these CNVs with unclear clinical relevance, we speculate that some of them are likely to be pathogenic.The classification and interpretation of all the CNVs detected in both groups showed that CMA is a clinical useful tool for genetic diagnosis of ID/DD, with an overall diagnostic yield of around 15%.However and considering the resolution of each of the array platforms, all pathogenic imbalances, except one case, would have been identified despite the platform used.

	Agilent 4x44K	Agilent 244K	KaryoArray®v3.0
Pathogenic	3%	18.75%	25%
VOUS	4.4%	6.25%	5%
Benign	75%	75%	42%
None CNV detected	17.6%	0%	31%

P03.077

A rare variant of Klinefelter syndrome patient with a mosaic 48,XXXY/47,XXY/46,XX/45,X/46,XY karyotype studied by GTG-banding and fluorescence in situ hybridization.

A. Mohseni Meybodi, N. Shahrokhshahi, H. Gourabi, S. Zari Moradi, S. Gilabadi, H. Vaziri Nasab, K. Anissi Hemaseh, T. Tavakol zadeh, Z. Beheshti, ***H. Karimi****;*
Department of Genetics, Reproductive Biomedicine Research Center, Royan Institute for reproductive Biomedicine,ACECR., Tehran, Islamic Republic of Iran.

Klinefelter syndrome is the first human sex chromosomal abnormality to be reported. The majority of Klinefelter syndrome patients have the XXY karyotype. Approximately 15% of Klinefelter patients, however, are mosaics with variable phenotypes.

A 39-year-old male was investigated for primary infertility. Clinical examination showed an intelligent man with normal facial appearance and small firm testes. Testicular histopathology revealed marked atrophy of the testes with no spermatogenesis and absence of germ cells. Hormonal profile showed elevated levels of FSH, LH and low levels of testosterone. Chromosome analysis from whole blood culture showed cells with 48,XXXY/47,XXY/46,XX/45,X/46,XY mosaicism. The predominant cell line was 47,XXY (86.66%). This was confirmed by fluorescence in situ hybridization (FISH) using a dual-color X/Y probe. In our case, FISH also detected the presence of a small population of cells with the 48,XXXY and 45,X karyotypes not previously detected in the initial 30-cell GTG-banding analysis. 46,XY/47,XXY mosaicism is not uncommon. However, mosaicism of multiple sex chromosome aneuploidy is rarely observed. Thus, this case illustrates the utility of FISH as an adjunct to conventional cytogenetics in assessing the chromosome copy number in each cell line of a mosaic. Because most infertile individuals with Klinefelter syndrome may wish to reproduce with the aid of modern reproductive technology, it is important that accurate estimation of the frequency of abnormal cells be obtained for accurate risk estimation and genetic counseling.

P03.078

Genomic imbalances in infertile men detected by array analysis

R. Mikelsaar[1], *M. Nelis*[2], *A. Kurg*[2], *O. Žilina*[2], *O. Bartsch*[3], *M. Punab*[4], *P. Korrovitš*[4], *R. Rätsep*[5];
[1]*Institute of General and Molecular Pathology, University of Tartu, Tartu, Estonia,* [2]*Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia,* [3]*Institute of Human Genetics, Mainz University School of Medicine, Mainz, Germany,* [4]*Centre of Andrology, Tartu University Hospital, Tartu, Estonia,* [5]*Institute of Physiology, University of Tartu, Tartu, Estonia.*

Array analysis frequently reveals the cases of multiple independent structural abnormalities with more complex phenotypes than expected. We present results of two infertile men. They were studied cytogenetically using GTG banding and FISH methods, and whole-genome array analysis (Illumina).

Case 1: 46,XY,t(10;15)(p11.1;q11.1) in an infertile man with glaucoma. FISH (Oncor) and array analysis showed that translocation was reciprocal (recT) and apparently balanced. Array analysis revealed two uncommon novel deletions in 2q22.1 and 18q22.1, which contribute to the genomic instability. Infertility might be caused by several factors including both genomic instability and a high frequency of sperm aneuploidies reported in a male carriers of a recT. Glaucoma was probably caused by the mutation(s) of *LRP1B* gene, located in the breakpoint region 2q22.1.

Case 2: 46,XY,t(5;13)(q33;q12.1) in an infertile man with allergy. It was recT confirmed by FISH (Cytocell). Array analysis showed that it was balanced, but also revealed a novel 681-kb microduplication at 9q31.1 (arr 9q31.1(102,352,111-103,033,172)x3). Infertility might be caused by the haploinsufficiency of tubulin (*TUBA3C*) gene located at breakpoint region 13q12.1 but also by arised genomic instability. He also had allergy, unlike his non-allergic parents with normal karyotypes but with microduplication in the same region, where allergy-related quantitative trait locus (QTL) 12 is localized. In our patient, probably both QTL 12 and balanced translocation gave rise of genetic over threshold, and disorder.

These findings show that one aberration can often predispose to the formation of others with phenotypic consequences.

Supported by target financings SF0180096s08 and SF0180027s10.

Molecular-cytogenetic analysis of marker chromosomes - clinical importance and diagnostic possibilities

P. Tesner[1], *R. Mihalová*[2], *V. Zimanová*[1], *J. Drábová*[1], *D. Novotná*[1], *E. Kočárek*[1];
[1]*Department of Biology and Medical Genetics, Charles University - 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic,* [2]*Institute of Biology and Department of Medical Genetics, 1st Faculty of Medicine, Charles University and General Teaching Hospital, Prague, Czech Republic.*

Supernumerary marker chromosomes (SMCs) are structurally abnormal chromosomes unidentifiable by classical cytogenetic methods. Their general incidence is about 1:2,000 (regardless of gender, ethnicity, etc.). SMCs represent a highly heterogeneous group of chromosomal aberrations associated with different clinical consequences: The majority of SMC-carriers have no clinical symptoms, but some SMC could be related to fertility problems (particularly in males), to mental retardation or to congenital defects. To determine the clinical importance, it is essential to identify an original chromosome, from which the SMC was derived and determine as accurately as possible the genetic material that is present in the SMC.

We demonstrate four cases of predominantly mosaic non-acrocentric SMCs and diagnostic procedures which enabled their determination. These patients represent all groups with higher SMC frequency mentioned above. All cases were examined postnatally, but one of them is closely related to ongoing pregnancy (previous pregnancy of this female with primary finding of SMC was terminated due to multiple foetal defects). Our report discusses diagnostic possibilities, reliability, and limitation of some common molecular cytogenetic techniques, especially standard fluorescence in situ hybridisation (FISH) using satellite probes, whole chromosome painting probes and/or locus-specific probes, and multicolour FISH (painting and centromeric one). Some SMC samples were submitted for further examination by array-CGH, but this analysis failed in cases with low frequency mosaics.

Our work is supported by Grant Agency of Charles University (No. 264811) and Technology Agency of the Czech Republic (No. TA01010931).

P03.080

SNP array evaluation of a mosaic supernummery marker chromosome in a girl with developmental delay

M. Rasmussen[1], *J. Graakjaer*[1], *A. Skytte*[1], *U. Dunkhase-Heinl*[2], *A. Bojesen*[1];
[1]*Department of Clinical Genetics, Vejle Hospital, Sygehus Lillebælt, Vejle, Denmark,*
[2]*Department of Pediatrics, Kolding Hospital, Sygehus Lillebælt, Kolding, Denmark.*

Clinical report

The propositus is a 7-year-old female, who is the second child of non-consanguineous parents. Pregnancy was uneventful with an uncomplicated delivery at term. Births weight 2.7 kilos and birth length 50 centimeters. In infancy she had problems feeding and showed delayed motor milestones and speech development. She has no malformations or dysmorphic features.

Materials and methods

G-band chromosome analysis was performed on PHA-stimulated peripheral blood lymphocytes; 20 metaphases were analyzed revealing 5 metaphases with a small supernumerary marker chromosome and 15 metaphases with a normal karyotype. The identity of the marker was investigated by FISH analysis using a chromosome 15 and a chromosome 14/22 centromere probe. None of these FISH analysis revealed the chromosomal origin of the marker chromosome.

SNP-array detected a mosaic gain of chromosome 1 material. The genotype data clearly showed the presence of a third allele but the intensity data were only slightly differed from normal.

FISH using a chromosome 1 centromeric probe subsequently confirmed the chromosome 1 origin of the marker chromosome. In order to estimate the mosaic level, 300 metaphases were scanned detecting 44 metaphases with the marker chromosome.

Both parents had a normal SNP-array.

Discussion

SNP array provides a high-resolution method to detect mosaic gains and loses and can be used as a first choice to characterize a marker chromosome. This strategy is both cost and time efficient.

Marker chromosomes of chromosomal 1 origin without phenotypic consequences have been described. We believe that this marker chromosome explains the phenotype of the patient.

P03.081

Rare case of three small supernumerary marker chromosomes originated from chromosomes 1, 12 and 18 in a girl with congenital abnormalities

M. Gogiel[1], *J. Hagh*[2], *H. Schüler*[1], *I. Rad*[3], *M. Omrani*[4], *K. Eggermann*[1], *S. Spengler*[1], *U. Gamerdinger*[5], *G. Schwanitz*[6];
[1]*Department of Human Genetics, University Hospital, RWTH, Aachen, Germany,*
[2]*Praxisgemeinschaft für Medizinische Genetik, Düsseldorf, Germany,* [3]*Department of Medical Genetics, University Motahhari Hospital, Urmia, Islamic Republic of Iran,*
[4]*Department of Medical Genetics, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [5]*Department of Pathology, University Hospital, Gießen, Germany,* [6]*Department of Human Genetics, University Hospital, Bonn, Germany.*

The genetic relevance of small supernumerary marker chromosomes depends on their amount and type of additional euchromatin. If they are present as mosaics the phenotype of the carrier depends on the amount of pathologic cells and their equal or unequal distribution in the patient. Three different SMCs are therefore an extreme rare finding.

We present the case of a patient showing 3 different autosomal markers as a mosaic combined with a normal cell line.

Two of the markers were identified as derivates of chromosome 12 and 18 which are classified as frequent aberrations, the third was originated from chromosome 1. The extra chromosomes were analysed by a combination of SNP array and FISH (cen and wcp probes). The size and the frequency were striking different. Besides, we observed an unequal combination of the 3 derivates.

We report on a four years old girl. She revealed a mosaic karyotype in her lymphocytes:

mos48,XX,+mar1,+mar2[18]/47,XX,+mar1[8]/49,XX,+mar1,+mar2,+mar3[2]/46,XX[2].ish der(1)(wcp1+,D1Z1+), der(12)(wcp12+,D12Z1+), der(18)(wcp18+,D18Z1+). By SNP array investigation (Affymetrix 6.0 SNP array) we identified gains of 1p12→p11.2, 12p13.1→q13.11, 18p11.21. Patenal origin could be delineated for der(1) and der(18).

Clinical evaluation revealed severe mental retardation, absent speech, prominent forehead, epicanthus folds, hypertelorism, large ears, depressed broad nasal bridge, long smooth philtrum and a wide mouth with thin upper lip. She still walks on the tips of her toes.

A karyotype-phenotype correlation was set up and the clinical findings of our patient were compared with the patients features of patients with isolated duplications of the three regions mentioned above.

P03.082

Genomic imbalances in a cohort of Iranian patients affected by multiple congenital anomalies (MCA)

A. Rashidi-Nezhad[1,2], *S. M. Akrami*[1], *E. Amini*[3], *F. Farzanfar*[4], *C. Azimi*[4], *A. Reymond*[2];
[1]*Department of Medical Genetics, Tehran, Islamic Republic of Iran,* [2]*Center for Integrative Genomics, Lausanne, Switzerland,* [3]*Maternal, Fetal and Neonatal Research Center, Tehran, Islamic Republic of Iran,* [4]*Department of Genetics, Cancer Research Center, Cancer Institute of Iran, Tehran, Islamic Republic of Iran.*

Congenital anomalies (CA) affect 2-3 % of live births and are seen in 25% of deaths in perinatal period and the first year of life. Cryptic genomic imbalances might be an important cause of CA. New high resolution oligo array platforms have been shown increased detection rate as well as potential to discover new regions involved in CA. In this study genomic imbalances were studied in a cohort of MCA patients using conventional and newer molecular cytogenetic techniques and compared their cost effectiveness in routine clinical perspective.

Eighty five Iranian patients affected by MCA were studied for chromosomal aberrations using G-banding. Three MLPA kits were used to screen for genomic imbalances in subtelomeric and 21 microdeletion syndromes. Nimblegen Human CGH 3x720K Whole-Genome Tiling v3.1 Array was used to interrogate genomic imbalances through the genome.

In G-banding 8 patients showed aneuploidies. Two patients diagnosed with marker chromosomes and 1 patient with an additional segment on 4q. The last three patients and other patients with normal results in karyotype were further analyzed with MLPA and array CGH. MLPA detected 8 and array CGH detected additional 4 clinically significant genomic imbalances. The overall detection rate was 28.2%.

In conclusion, array CGH detects all genomic imbalances detected by karyotype and MLPA. Array CGH recommended as the first line test in MCA patients and karyotyping just if be necessary. The exception is for those who are suspected to aneuploidies according to their phenotypes that karyotype is suggested first then array CGH if karyotype be normal.

P03.083

Mental retardation, speech delay, attention-deficiency/hyperactivity disorder, and delicate microangiopathy in a boy with 11p13 deletion

A. Kashevarova[1], *E. Tolmacheva*[1], *O. Salyukova*[1], *P. Magini*[2], *C. Graziano*[2], *G. Romeo*[2], *J. Kasnauskiene*[3], *V. Kučinskas*[3], *I. Lebedev*[1];

[1]*Institute of Medical Genetics, Tomsk, Russian Federation,* [2]*University of Bologna, Bologna, Italy,* [3]*Vilnius University, Department of Human and Medical Genetics, Vilnius, Lithuania.*

Deletions of the 11p14-p12 region has been previously described in WAGR and Potocki-Shaffer syndrome both accompanied by mental retardation (MR). *SLC1A2, PRRG4,* and *BDNF* were hypothesized to contribute to the abnormal mental development in patients with 11p deletion. Here we report on a 5.9-year-old boy with MR, speech delay, attention-deficiency/hyperactivity disorder, delicate microangiopathy, and 11p13 deletion. Parental DNA was not available for analysis. A 1.155 Mb deletion was detected by array CGH and confirmed by real-time PCR. Deleted region includes *CD44, SLC1A2, PAMR1, FJX1, TRIM44, LDLRAD3, MIR3973, COMMD9,* and *PRR5L*. Some of these genes are expressed in brain. In particular, SLC1A2 protein is responsible for glutamate transport. Accumulation of extracellular glutamate causes calcium homeostasis dysfunction, increased production of NO, free radicals, and cytotoxic transcription factors, proteases activation, and, as a consequence, neuronal damage leading to neurodegenerative disease, inflammation or ischemic events. Yet although the function of *FJX1* in human remains unknown, in rodent it regulates dendrite extension. TRIM44 may play a role in neuronal differentiation and maturation. LDLRAD3 participates in amyloid precursor protein proteolysis leading to beta amyloid formation which fibrillar form is the primary component of amyloid plaques found in the brain of patients with Alzheimer disease. COMMD9 presumably regulates the ubiquitin pathway and homeostasis. Based on the brain specific functions reported for these genes, the detected 11p13 deletion can be considered to be pathogenic. This study was supported by European Community's Seventh Framework Programme, CHERISH project no. 223692.

P03.084

Submicroscopic chromosomal rearrangements in Ukrainian families with severe syndromic mental retardation

N. V. Hryshchenko[1], *O. O. Soloviov*[1], *L. V. Tavokina*[2], *A. O. Brovko*[2], *G. M. Bychkova*[3], *C. Graziano*[4], *J. A. Hettinger*[5], *L. A. Livshits*[1];

[1]*Institute of Molecular Biology and Genetics NAS of Ukraine, Kyiv, Ukraine,* [2]*Clinic ISIDA-IVF, Kyiv, Ukraine,* [3]*Research Centre for Radiation Medicine, NAMS of Ukraine, Kyiv, Ukraine,* [4]*U.O. Genetica Medica, University of Bologna, Bologna, Italy,* [5]*Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus.*

Upon the identification of de novo genomic/chromosomal rearrangements, the recurrence risk is considered very low.

We report on two Ukrainian mental retardation (MR) families with paternal origin unbalanced translocation grown out of balanced ones in their healthy fathers.

The first proband is a 16 years old girl with severe MR, trigonocephaly, dystrophic features. The proband's aunt has the same MR phenotype. The karyotyping results are: father - 46,XY,t(2;10)(q35;q26),9ph and proband - 46,XX,der(10)t(2;10)(q35;q26)pat. 44K array-CGH of proband showed del10q26.3-qter (2257 kb) together with dup2q35-qter (24378 kb). The CNVs are pathogenic with many MR candidate genes involved in. The same rearrangements have been confirmed in the aunt on 400K array-CGH. Thus proband has derivative chr10 of paternal origin generated by translocation, involving the chr2 long arm. This unbalanced translocation in the aunt and balanced one in proband's father had the same origin from one of their parents.

The second proband is a 20 years old woman with severe MR, hypertelorism, generalized hirsutism, dystrophic features. Two pathogenic CNVs have been identified by 400K CGH-analysis: del5p15.2 (10 Mb) and dup10q25.3-26.3 (18 Mb). Karyotype analysis showed: mother - 46, XX, father - 46,XY,t(5;10)(p15.2;q25.3) and proband - 46,XX,der(5)t(5;10)(p15.2;q25.3)pat. Proband has paternal origin unbalanced translocation involving the short arm of chr5 and the chr10 long arm.

These data demonstrate that the identification of such pathogenic CNV by CGH accompanied by FISH is important not only for diagnosis but also for recurrence risk to family members' estimation.

This research is a part of CHERISH project (n° 223692).

P03.085

Identification of recurrent chromosomal syndromes in patients with mental retardation using 44K array-CGH: report of two cases.

H. Ben Khelifa[1], *S. Mougou*[2], *N. Soyah*[3], *I. Ben Abdallah*[2], *H. Hannechi*[4], *S. Bouraoui*[2], *A. Saad*[2];

[1]*laboratory of Cytogenetics,Molecular Genetics and Reproductive Biology - Farhat Hached hospital, Sousse, Tunisia,* [2]*Laboratory of Cytogenetics, Molecular Genetics and Reproductive Biology - Farhat Hached Hospital, Sousse, Tunisia,* [3]*Department of Pedriatics, Sousse, Tunisia,* [4]*Laboratory of Cytogenetics,Molecular Genetics and Reproductive Biology - Farhat Hached Hospital, Sousse, Tunisia.*

Mental retardation (MR) is a condition of incomplete development of the brain with the onset occurring before 18 years and is estimated to affect 1-3% of the population. The etiology of MR is very heterogeneous and in about half of cases the cause still elusive. Chromosome imbalances are one of the most important causes. The advance of cytogenetic technologies has improved the diagnostic rate of small chromosome abnormalities such as microarray-based comparative genomic hybridization. The complementarity of cytogenetic tools (Karyotype, Fluorescent in Situ Hybridization and array-CGH) is still needed to characterize the cryptic chromosomal imbalances.

In this study, genomic DNA's from 13 patients with unexplained MR were analyzed by genome wide high-resolution 44K Agilent® oligonucleotides arrays. Pathogenic microdeletions have been detected in two patients presenting MR and congenital malformations, encompassing regions of Xp22.3 and 8p23.1 containing dosage sensitive genes critical for normal development. These results were in accordance with those observed in previous studies: the detection rate of our pathogenic CNV's was 15,4 % (14,4% in other studies). The causality of these rearrangements were determined as well as their parental origin.

It is true that whole genome arrays have significantly succeeded in revealing recurrent chromosomal syndromes but in other way, these high sensitive technologies have complicated the clinical interpretation of many copy number variants of unclear significance. This emphasizes the need of conventional and molecular cytogenetic combination to better clarify the phenotype-genotype correlation in patients with unexplained MR.

P03.088

Microcephaly and Blepharophimosis in a girl with 46,XX,ins(6;3)(q23;q27q21)

G. Yesil[1], *C. Sayar*[2], *G. Toksoy*[3];

[1]*Bezmialem Vakif University of Medicine, Istanbul, Turkey,* [2]*Zeynep Kamil Pediatric Gynecology & Obstetrics Training and Research Hospital, Istanbul, Turkey,* [3]*Istanbul University Faculty of Medicine, Istanbul, Turkey.*

This clinical report describes a one year old girl with severe microcephaly, moderate developmental delay and blepharofimosis. She had no internal organ malformations and structural brain abnormalities. Frequent upper respiratory infections were noted. The chromosome analysis revealed 46,XX,ins(6;3)(q23;q27q21) de novo. 44k array was also performed and showed no abnormalities.

The Blepharophimosis phenotype is known to be associated with the FOXL2 gene which is located at 3q22.3. The ATR gene that is responsible for the Seckel Syndrome phenotype is located at 3q23. We are awaiting targeted array analysis results, which will show us the etiology of overlapping microcephaly and blepharophimosis phenotypes.

P03.089

A patient with moderate intellectual disability and a deletion of 2p14-p15 overlapping with deletions of previously published cases

A. Vazna[1], *M. Hancarova*[1], *S. Vejvalkova*[1], *J. Drabova*[1], *M. Trkova*[2], *Z. Sedlacek*[1];

[1]*Department of Biology and Medical Genetics, Prague, Czech Republic,* [2]*Gennet, Prague, Czech Republic.*

Microdeletions spanning 2p14-p15 have been described in two patients with developmental and speech delay and intellectual disability (ID) but no congenital malformations or severe dysmorphy. One additional patient with a similar deletion has been identified in the ISCA study of developmental delay. We report a prematurely born boy with a de novo deletion encompassing the deletion overlap of these three cases. He had clinical features partly consistent with the first two cases from whom detailed description is available including absent speech, severe microcephaly, long face, bulbous nasal tip and thin upper lip. He had thin short stature and moderate ID, and his overall clinical picture was more severe compared to the first two cases. His karyotype was normal but Illumina HumanCytoSNP-12 BeadChip analysis revealed a 3.7 Mb long deletion of 2p14-p15 between (and including) the COMMD1 and SPRED2 genes. FISH confirmed the deletion in the patient but not in the parents. The deletion affected 17 protein-coding RefSeq genes and 3 non-coding RNA genes. The shortest region of overlap of the four deletions contained 10 genes. Some of them including SLC1A4 and CEP68 could be candidates for ID. The Decipher database and two recent studies of large ID cohorts (ISCA and WashU/Signature) list additional patients with deletions extending proximally into the region of the 2p15-p16.1 microdeletion syndrome. Multiple genes from this region may thus be associated with ID, and some patients may show composite phenotypes. Analysis of additional cases is needed to clarify this complexity. Supported by CHERISH, CZ.2.16/3.1.00/24022 and MZ0FNM2012.

We report on a *de novo* interstitial del/dup aberration consisting of a 13.3 Mb deletion of 5q15-5q21.3 (92.1-105.4 Mb, hg19) in tandem with a 23.6 Mb direct duplication of 5q21.3-5q23.3 (106.1-129.7 Mb, hg19). Although the aberration covered a total of 60.6 Mb, it was cryptic, i.e., not detectable by karyotyping at a resolution level of 500 bands. Array CGH indicated a diploid region of 0.6 Mb between deletion and duplication. The aberration affected a 14-month-old boy conceived after intracytoplasmic sperm injection who presented with developmental delay, muscular hypotonia, partial agenesis of the corpus callosum, prominent forehead, low set ears, hypertelorism, wide-bridged nose, retrognathia, high palate, and cryptorchidism. The duplicated segment comprised the *LMNB1* gene, thus predicting adult-onset autosomal-dominant leukodystrophy and revealing a temporal dimension of the phenotype. Counselling problems implicated by this prediction include "the right not to know" that the patient might want to use when coming of age.

P03.091

Microdeletion and Microduplication Syndromes

K. Mrasek[1], *E. Klein*[1], *D. Hardekopf*[2], *S. Pekova*[2], *S. Bhatt*[1], *N. Kosyakova*[1], *T. Liehr*[1], *A. Weise*[1];
[1]*Jena University Hospital, Friedrich Schiller University. Institute of Human Genetics, Jena, Germany,* [2]*Chambon Laboratory for Molecular diagnostics, Prag, Czech Republic.*

The widespread use of whole genome analysis based on array comparative genomic hybridization (aCGH) in diagnostics and research has led to a continuously growing number of microdeletion and/or microduplication syndromes (MMSs) connected to certain phenotypes. These MMSs also include increasing instances in which the critical region can be reciprocally deleted or duplicated. This review catalogues the currently known MMSs and the corresponding critical regions including phenotypic consequences. Besides the pathogenic pathways leading to such rearrangements, the different detection methods and their limitations are discussed. Finally, the databases available to for distinguishing between reported benign or pathogenic copy number alterations are highlighted. Overall, a review of MMSs that previously were also denoted 'genomic disorders' or 'contiguous gene syndromes' (CGS) is given.

A further case of microdeletion 15q26.1 encompassing CHD2 and RGMA: clinical description and review of the literature

C. Courage, J. Lemke, N. Aliu, S. Gallati, ***C. Rieubland****;*
Division of Human Genetics, Department of Pediatrics, Inselspital, University of Bern, 3010 Bern, Switzerland.

Chromosomal abnormalities including microdeletions and microduplications are known to cause severe developmental disorders, mental retardation, dysmorphism and seizures. We report a further case of microdeletion 15q26.1 in a 25 year old man, presenting with mental retardation (IQ 48), generalized seizures with onset at 2 years of age, severe kyphoscoliosis, truncal obesity, growth retardation (height on the 3rd centile), psychiatric disorder with anxious and aggressive behavior, astigmatism, delayed puberty, normal head circumference and dysmorphism (upslanting palpebral fissures, long eyelashes, hypoplastic alae nasi, short philtrum, narrow hands and feet, tapering fingers). He was the first child born to non-consanguineous Swiss parents, family history was unremarkable. Array-CGH revealed a 415kb microdeletion at 15q26.1 encompassing only two genes: CHD2 and RGMA. The deletion was confirmed by qPCR and found to be *de novo*. To our knowledge this is the third case reported with microdeletion 15q26.1 encompassing only these two genes. So far CHD2 haploinsufficiency has been associated with lordokyphosis, reduced body fat and growth retardation in mouse model. RGMA seems to perform several functions in the developing and adult nervous system and could be a candidate gene for mental deficiency and seizure disorder. We review the clinical features of the reported cases and discuss the role of CHD2 and RGMA as critical genes in microdeletion syndrome 15q26.1.

P03.093

3q26.33-3q27.2 microdeletion: a new microdeletion syndrome?

F. Forzano[1], *F. Faravelli*[1], *G. Mandrile*[1], *V. Uliana*[1], *E. Di Maria*[1,2], *M. Malacarne*[3], *D. Coviello*[3], *M. Dubois*[4], *S. Zwolinski*[4], *A. Dubois*[4];
[1]*Medical Genetics Unit, Galliera Hospital, Genova, Italy,* [2]*Department of Health Sciences, University of Genova, Genova, Italy,* [3]*Laboratory of Genetics, Galliera Hospital, Genova, Italy,* [4]*Institute of Genetic Medicine, Newcastle upon Tyne, United Kingdom.*

We describe two unrelated patients carrying the same 3q26.33-3q27.2 microdeletion.

Patient 1, 6 years old, was initially seen at age 2 years. Parents reported IUGR since the first month. Cesarean section was performed at 32 gw due to growth arrest; BW 1380 g, L 39.5 cm, OFC 29.5 cm. Array-CGH: de-novo 4 Mb deletion.

Patient 2, 17 years old, was initially seen at 5 months. Pregnancy was unremarkable; emergency Caesarean section was performed at 37 wg because of maternal hypertension. BW 1500 g, OFC 29.5cm; he required resuscitation. Tonic seizures developed at three hours of age. Array-CGH: 4.28 Mb deletion.

Both presented with neonatal hypotonia, muscular hypotrophy, severe feeding problems (gavage feeding), recurrent upper airways infections, developmental delay (both sat at 18 months, Pt1: at 6 years has no language, nor sphincter control, and does not walk independently; Pt2: walked at 4 years and has language delay), severe growth impairment (all measures below 3rd centile).

Both patients share common dysmorphic features: thin skin, flat facial profile, medially sparse eyebrows, epicanthal folds, flat nasal bridge and tip, short philtrum, downturned corners of mouth.

Patient 1 had also oral aversion, gastroesophageal reflux, bladder diverticula and vesicoureteral reflux, retractable lift right testicle, markedly delayed teeth eruption. Patient 2 had also micropenis, which required testosterone replacement, and mirror movements.

P03.094

A comparative cytogenetic analysis of miscarriages following natural conception and assisted reproductive technologies

A. V. Tikhonov[1,2], *A. A. Pendina*[2], *O. G. Chiryaeva*[2], *L. I. Petrova*[2], *V. S. Dudkina*[2], *N. A. Sadik*[2], *O. A. Efimova*[2], *I. A. Galembo*[1], *J. G. Lezhnina*[2], *T. V. Kuznetzova*[2], *V. S. Baranov*[2];
[1]*Saint-Petersburg State University, Saint-Petersburg, Russian Federation,* [2]*D.O.Ott's Institute of Obstetrics and Gynecology, Saint-Petersburg, Russian Federation.*

Chromosomal abnormalities are the most common cause of spontaneous miscarriage during the first trimester. We performed a comparative study of abnormal karyotype frequency and type in miscarriages following natural conception (group I, n=558) and assisted reproductive technologies (ART) (group II, n=121). Standard karyotyping was made on QFH/AcD banded metaphase chromosomes, obtained from chorionic villi samples. The rate of abnormal karyotypes was 66,5% in group I vs. 50,4% in group II. The difference is explained by the lower percentage of abnormal karyotypes in miscarriages from patients under 35 in group II compared to group I (36,5% vs. 63,1%). In miscarriages from patients over 35 the frequency of abnormal karyotypes was higher compared to normal in both groups: 76,7% vs. 23,3% in group I and 65,5% vs. 34,5% in group II). This tendency was registered when the terms of miscarriages were analyzed: in miscarriages under 7 weeks of gestation from group II the frequency of chromosomal pathology was lower, than in their counterparts from group I (45,6% vs. 66,2%). In miscarriages over 7 weeks from group II the frequency of abnormal karyotypes increased up to 57,7%. These results demonstrate a leading role of non-genetic factors in early pregnancy loss for ART clinic patients under 35. A wide spectrum of aberrations, including trisomies, monosomy X, polyploidy and structural chromosomal rearrangements, detected in miscarriages did not differ between groups, indicating no increased risk of chromosomal pathology, associated with ART.

P03.095

Microduplication 22q11 in two patients with learning disabilities

C. C. Legnaro[1], *R. M. C. S. Sandri*[1], *B. F. Gamba*[2], *L. A. Ribeiro-Bicudo*[1];
[1]*Hospital de Reabilitação de Anomalias Craniofaciais - HRAC - USP, Bauru, Brazil,*
[2]*Universidade Estadual Paulista - Unesp/Brazil, Botucatu, Brazil.*

Susceptibility of the chromosome 22q11 region rearrangements has been recognized in clinical disorders as DiGeorge/Velocardiofacial syndrome. The 22q11.2 microdeletion syndrome is the most common of these conditions, representing a spectrum of clinical anomalies affecting multiple organ systems. 22q11.2 duplication syndrome has also been recently characterized as a different clinical entity with features overlapping 22q11.2 deletion syndrome. Evidence has implicated low-copy repeats (LCRs) on 22q as mediator of nonallelic homologous recombination that result in rearrangements of 22q. We performed Multiplex ligation-dependent probe amplification (MLPA) using SALSA MLPA kit P250 DiGeorge in two patients presented with learning disabilities and detected variable microduplication of 22q11 region. Patient 1 showed a microduplication including the region between LRC22-F and LCR22-H involving the SMARCB1 and SNRPD3 genes. Patient 2 showed microduplication at LCR22-D, involving the TOP3B gene. Chromosomal rearrangements in distal 22q11 region, as well as microduplications, are less common than rearrangements in the proximal region. One possible explanation is that LCR22E-H is smaller than the proximal LCRs are thus less susceptible to rearrangements. Our preliminary results do no support a correlation between the size of the duplication and the severity of the phenotypic presentation.

P03.096

MLPA as screening method in detection of submicroscopic rearrangemets detected in patients with developmental delay/intellectual disability

L. Morozin Pohovski, *I. Barisic;*
Children's University Hospital Zagreb, Clinical Hospital Centre Sisters of Mercy, Zagreb, Croatia.

Chromosomal rearrangements represent a significant cause of developmental delay/intellectual disability (DD/ID). The implementation of Multiplex Ligation-Dependent Probe Amplification (MLPA) has enabled the analysis of chromosomal aberrations beyond the range of routine karyotyping. In this study we prospectively screened 150 patients with DD/ID with or without dismorphic features or additional congenital abnormalities using SALSA MLPA P036, SALSA MLPA P070 and SALSA MLPA P245 kits, which are specifically designed to detect subtelomeric chromosome imbalances and 21 microdeletion syndromes respectively. The aim of the study was to determine the ability to detect chromosomal abnormalities in patients with DD/ID using a combination of MLPA kits and to analyze the feasibility of the use of additional MLPA specific telomere and microdeletion probe mix as an additional confirmatory test. The MLPA screening revealed chromosome aberrations in 21 (14%) cases: 11 subtelomeric rearrangements (3 deletions: del4p, del15q and del22q, 4 duplications: dup 9p, dupX/Yp, 3 deletions and duplications: dup3p/del8q, dup8p/del18q, del 12p/dup22q and one del/dup19p) and 10 microdeletions (5 DiGeorge syndrome, two 17q21.31 microdeletions, one 15q24 microdeletion and one Prader-Willi/Angelman syndrome). The use of two subtelomeric kits per patient has reduced the rate of false positive and negative results and improved diagnostic yield. MLPA specific telomere and microdeletion probe mix have proven to be suitable for confirmation and better characterization of selected aberrations. Conclusion: MLPA is a fast, sensitive and cost-effective technique for screening DD/ID patients. Use of combination of appropriate kits improves diagnostics and is now used in our routine work.

P03.097

NRXN1 deletions identified by array comparative genome hybridisation in a clinical case series - further understanding of the functional relevance to neurodevelopmental disorders.

C. Ogilvie[1], *J. Ahn*[1], *H. Grayton*[2], *D. A. Collier*[2], *S. Curran*[2];
[1]*Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom,* [2]*Institute of Psychiatry, King's College, London, United Kingdom.*

Microdeletions in the NRXN1 gene have been associated with a range of neurodevelopmental disorders, including autism spectrum disorders, schizophrenia, intellectual disability, speech and language delay, epilepsy and hypotonia. We carried out array CGH analysis on 10,397 individuals referred for diagnostic cytogenetic testing, using a custom oligonucleotide array, which included 215 NRXN1 probes (median spacing 4.9kb). We found 34 NRXN1 deletions (0.33% of referrals) ranging from 9 to 942kb in size, of which 18 were exonic (0.17%), and predominantly affected the alpha isoform of NRXN1. No NRXN1 duplications were found. Several patients had exonic deletions in both NRXN1 and other loci implicated in neurodevelopmental disorders (CNTNAP2, CSMD3 and the Williams-Beuren syndrome locus) and two patients had duplications of the 22q11.2 locus. Patients with NRXN1 deletions had a range of phenotypes including developmental delay, learning difficulties, ADHD, autism, speech delay, social communication difficulties, epilepsy, behaviour problems and microcephaly. The targeting of dense oligonucleotide probes to the NRXN1 locus on array comparative hybridisation platforms provides detailed characterisation of deletions in this gene, and is likely to add to understanding of the function and mechanism of action of NRXN1 in neural development.

P03.098

Clinical phenotypes and genotype-phenotype analysis of intragenic *NRXN1* deletions

F. O. Bartel, *Y. A. Zarate, J. S. Geer, M. J. Lyons, R. C. Rogers, S. A. Skinner, B. R. DuPont, A. Dwivedi;*
Greenwood Genetic Center, Greenwood, SC, United States.

Neurexin1 (*NRXN1*) is a presynaptic neural cell adhesion molecule and receptor which functions in the stabilization of the synapse by interaction with postsynaptic neuroligin proteins. The *NRXN1* gene is 1.1MB in size and codes for two protein isoforms *NRXN1a* and *NRXN1b*, each of which has multiple promoters and collectively may code for thousands of different transcripts. Previous reports have demonstrated a significant association of copy number variation within this gene to both autism spectrum disorder and schizophrenia, as well as addiction, intellectual disability and vertebral anomalies. We have identified 11 patients with *NRXN1* intragenic deletions by chromosomal microarray. Deletions ranged in size from 8kb to 352 kb. Family study was conducted for six cases and identified three as *de novo* changes and three as maternally transmitted. Cognitive or behavioral reasons for referral were given for 10 of the 11 patients (90%) ranging from profound intellectual disability and encephalopathy to developmental delay. Five of 11 patients had a diagnosis of autism or autism spectrum disorder (45%). The characterization of these patients will expand the clinical phenotype associated with *NRXN1* deletions, and aid in the genotype phenotype correlation of deletions within this structurally complex gene.

P03.099

Structural chromosomal aberrations diagnosed by FISH

T. Zolotukhina, *N. Shilova, J. Kozlova, M. Minzhenkova, J. Markova;*
Federal State Budgetary Institution "Research Centre for Medical Genetics" of RAMS, Moscow, Russian Federation.

GTG-banded karyotyping provides gold standard in clinical cytogenetics which is widely used in medical-genetic consultations, despite of development and adoption of up-to-date molecular methods. However, GTG-method often is limited in sensitivity. Accuracy of cytogenetic diagnostics of chromosomal rearrangements increases with using FISH, which is an excellent approach to this aim. We used FISH-method with different DNA-probes and have developed the algorithm of investigations. We analyzed the karyotypes of 31 patients with dysmorphic features and congenital malformations. When the analysis of GTG-karyotypes at level 550 bands revealed presence of chromosomal structural rearrangements (deletions or duplications), we investigated parents' karyotypes to establish the origin of aberrations. In 27 cases these aberrations arised de novo, and in other cases were non-balanced variants of parents' translocations. For identification of chromosomal rearrangements we used FISH with different DNA-probes: WCP, PCP, CEP, subtelomeric probes, LSI, and also multicolor technologies - mFISH, mBAND, m-cenFISH. In cases of deletions we used appropriate chromosome-specific subtelomeric probes. In cases of additional material of unknown origin we used mFISH, subtelomeric probes then mBAND. When derivate chromosomes were revealed chromosome-specific CEP and then mFISH was used. In cases sex chromosome abnormalities we used PCP X long and shot and LSI SRY. In cases supernumerary chromosomal rearrangements - m-cenFISH, WCP, then subtelomeric probes. In result of the application of listed FISH-probes the patients' karyotypes were verified and breakpoints were estimated. The FISH-tests developed algorithm utilization allows to determine the origin of rearrangements and to reduce research time and costs.

P03.100

The cytokinesis-blocked micronucleus (CBMN) assay in workers at stone-crushing units

***G. Kaur**, G. Gandhi;*
Department of Human Genetics,Guru Nanak Dev University, Amritsar, India.

The stone-crushing industry is a labour -intensive sector where most of the operations are performed in a highly dust-polluted area often violating the pollution control board guidelines. Since the cytokinesis-blocked micronucleus assay (CBMN) assay provides a deeper insight into the mechanisms contributing to genome damage events that could increase risk of developmental and degenerative diseases, in the present study chromosomal damage was assessed by CBMN in peripheral lymphocytes of 23 stone-crushing unit workers(32.69±1.42 y) employed for more than six years(7.74±0.25y) with a daily work schedule of 8-12h/day, in comparison with 09(33.00±0.50 y) controls matched for gender, age, and socio-economic status and smoking habits with no past/present history of any exposures. The study was cleared by the Institutional Ethics Committee. Voluntary written informed consent was obtained from all study participants and a face- to -face interview was conducted using a pre-designed questionnaire. The results of the assay reveal a statistically significant ($p \leq 0.000$) two fold elevated percent frequency of MNd cells in the workers (0.55±0.02) compared to the control group (0.26±0.03). As these workers are continuously being exposed to workplace genotoxicants (causing structural alterations to chromosomes which can lead to altered gene dosage and expression), the evaluation of chromosomal damage in these occupationally- exposed workers can be an important pathogenetic and prognostic predictor of future disease-related changes.

P03.101

Cytogenetic abnormalities in peripheral blood lymphocytes of patients with malignant salivary gland tumors during neutron therapy

***A. Melnikov**[1], S. Vasilyev[2], E. Smolnikova[3], L. Urazova[1], L. Musabaeva[1], V. Velikaya[1], O. Gribova[1], I. Lebedev[2], E. Choynzonov[1];*
[1]Research Institute of Oncology, Tomsk, Russian Federation, [2]Research Institute of Medical Genetics, Tomsk, Russian Federation, [3]The Siberian State Medical University, Tomsk, Russian Federation.

Neutron therapy is used in more than 25 leading radiology centers in the world, however, cytogenetic monitoring of cancer patients during this type of therapy have not been performed. The frequency and spectrum of cytogenetic damages in peripheral blood lymphocytes were investigated in 9 patients with malignant neoplasms of the parotid salivary glands during the treatment by fast neutrons in the cyclotron U-120. There were three time points: before treatment, 24 h after the first fraction and at the end of the neutron therapy. Mode of exposure included: single focal dose - 1.6-2.4 Gy, 3-4 sessions, and the total tumor dose - 5.5-8.4 Gy (equivalent to 23-44 Gy of photon radiation). Chromosomal aberration analysis was performed according to standard protocol in the first mitosis of PHA-stimulated lymphocytes. Cytokinesis-blocked micronucleus test was performed in combination with FISH using a pancentromeric DNA probe. It was shown that chromosome-type aberrations were prevalent among all cytogenetic abnormalities both before and after neutron therapy. The frequencies of chromosome-type aberrations and all micronuclei increased significantly after both the first fraction and the whole therapy comparing with the levels before the therapy ($p<0.05$). The predominant chromosome-type aberrations were paired (acentric) fragments (57 % of all chromosome-type aberrations). The observed mutagenic effect could be considered to optimize the neutron therapy in patients with tumors of the salivary glands. This research is supported by the target Federal Program of „Research and development on priority directions of scientific-technological complex of Russia for 2007-2013 years" No. 16.512.11.2063.

P03.102

Clinical and molecular characterization of a patient with de novo 0.45 Mb deletion of 2p16.1

***M. Hančárová**[1], M. Simandlová[1], J. Drábová[1], K. Männik[2], A. Kurg[2], Z. Sedláček[1];*
[1]Department Of Biology And Medical Genetics, Prague, Czech Republic, [2]Institute of Molecular and Cell Biology, Tartu, Estonia.

The widespread use of microarray methods has contributed to the identification of several new rare microdeletion syndromes including that associated with deletions of 2p15-p16.1. The 2p15-p16.1 microdeletion syndrome is characterized by developmental delay, intellectual disability, autism, microcephaly, growth retardation, facial abnormalities, disturbed vision and other symptoms. We report here an 11-year-old autistic girl showing clinical features consistent with the syndrome. Conventional cytogenetic analysis of the patient showed a normal female karyotype. Illumina HumanCytoSNP-12 BeadChip analysis revealed a 0.45 Mb long deletion of the paternal allele of 2p16.1. FISH analysis confirmed the deletion in the patient but not in any of her parents. The deleted region contains only 3 protein-coding RefSeq genes, BCLA11, PAPOLG and REL, and 1 long non-coding RNA gene FLJ16341. Based on high phenotype similarity of our patient with 6 reported patients showing the typical phenotype of the 2p15-p16.1 microdeletion syndrome we propose that the critical region of the syndrome can be narrowed down and that these brain expressed genes can be considered candidates for the clinical symptoms. However, multiple deletions of variable length within the interval between 2p14 and 2p16.1 have been described in patients with intellectual disability but not necessarily the other typical symptoms of the syndrome and some of these deletions do not overlap. This observation indicates that also other genes located in this broader unstable region are associated with cognitive functioning. Supported by CHERISH 223692, SF0180027s10, CZ.2.16/3.1.00/24022 and MZ0FNM2012.

P03.103

A *de novo* 3.8 Mb duplication of chromosome 14q22.3q23.1, including *OTX2* and *ARID4A*, in a developmentally delayed boy

***K. Bjørgo**, T. Barøy, E. Ormerod, O. Rødningen, E. Frengen, D. Misceo, M. Fannemel;*
Dept. of Medical Genetics, Oslo University Hospital and Oslo University, Oslo, Norway.

We present a three year old developmentally delayed boy with a vocabulary of less than twenty words, who started walking two years of age. He has thin, fine hair and a preauricular tag, but otherwise no dysmorphic features. Magnetic resonance imaging (MRI) of the brain revealed a subarachnoidal cyst. A *de novo* 3.8 Mb duplication involving chromosome 14q22.3q23.1 was detected by aCGH analysis (chr14:55331483-59107556 bp, hg19). There are no previous reports of patients carrying a duplication of similar size in this region, which in addition to the relatively high number of genes involved make genotype-phenotype correlations challenging. Among the 32 RefSeq genes affected by the duplication, genes of potential interest are *OTX2*, *ARID4A, GCH1* and *DACT*. *OTX2,* orthodonticle homeobox 2, is a homeodomain-containing transcription factor expressed in brain, whose haploinsufficiency is linked to ocular developmental anomalies and developmental delay. *ARID4A,* AT rich interactive domain 4A, is a gene involved in chromatin remodeling, therefore likely to have pleiotropic effect. *GCH1*, GTP cyclohydrolase 1, partially duplicated at the proximal border of the imbalance, causes dopa responsive dystonia and malignant hyperphenylalaninemia with autosomal recessive inheritance, although the patient's phenotype is not consistent with this syndrome. *DACT,* dapper, antagonist of beta-catenin, homolog 1, partially duplicated at the distal border, is involved in the Wnt- mediated developmental processes.

We suggest that increased dosage of *OTX2* and ARID4A might have a relevant role in the emergency of the clinical phenotype in our patient.

P03.104

Complex X-chromosome rearrangement. How could it happen?

***A. T. Hoejland**, J. Graakjaer, S. Koelvraa, A. Bojesen;*
Department of Clinical Genetics, Vejle Hospital, Vejle, Denmark.

We report the SNP-array finding of a complex X-chromosome rearrangement in a now 4 year old girl with delayed psychomotor development and failure to thrive.

We found on the short arm of the X-chromosomes neighbouring regions with different aberrations, namely a duplication (Xp22.2), a loss of heterozygosity (LOH) segment (Xp22.11-Xp22.2) with normal allele frequency and a deletion (Xp21.1-Xp22.11). There were no other findings on SNP-array to suggest different reasons for the girl's symptoms. SNP-arrays on both parents were also performed. The mother had a duplication (Xp22.11-Xp22.2) matching the duplication and LOH segment in the girl. The father had no deletions or duplications. G-band karyotypes from the girl showed visible aberrations in both X-chromosomes; one with a duplication in Xp and one with a deletion in Xp (46,XX,dup(X)(p22.1p22.2)mat,del(X)(p21p22.2)dn)

Results of additional FISH analyses, using probes corresponding to the duplicated segment Xp22.2, the segment containing LOH (Xp22.11-Xp22.2) and the deleted segment (Xp21.1-Xp22.11), showed that the paternally derived X-chromosome did not harbour any of these three segments, suggesting that the unbalanced complex duplication/LOH was a result of inheritance of two derivative X-chromosomes. A maternal derivative X-chromosome with a duplication segment corresponding to the LOH region combined with insertion of the paternal duplication segment and a derivative paternal X-chromosome with a deleted segment encompassing all three regions.

We speculate that the reason for this complex rearrangement could be a post zygotic mitotic recombination, perhaps caused by an inverted duplication on the maternal X-chromosome, although this could not be verified.

P03.105

Chromosome evolution 180 degrees backwards - a case report

S. Müller, *M. Neusser, M. Pfob, Y. Mehraein, O. Steinlein;*
Institute of Human Genetics, University Hospital, Ludwig-Maximilians-University, Munich, Germany.

We present molecular cytogenetic evidence that the carrier of a paracentric inversion inv(7)(q11.23q22.1) has reversed the evolutionary inversion that distinguishes the chromosome 7 homologs of human and gorilla. The inversion was observed in a 41 years old patient with inconspicuous phenotype after routine cytogenetic analysis because of recurrent abortions in the partner of the patient. FISH experiments with a panel of BAC probes localized the inversion breakpoints at 76,5-76,9 Mb and 102,2-102,4 Mb (GRCh37.p5, Feb 2009), respectively. The proximal breakpoint maps approximately two Mb distal of the Williams-Beuren Syndrome critical region. Importantly, both breakpoints reside in large clusters of primate specific segmental duplications, which by non-homologous allelic recombination (NAHR) may have facilitated both the evolutionary inversion in the human/chimpanzee common ancestor and the inversion in the case presented here, and possibly also in several other cases described in the literature as inv(7)(q11q22). In summary, this example adds to the mounting body of evidence that some structural chromosomal aberrations in humans can be caused by inherent instability of genomic regions that were already prone to break during evolution, thus demonstrating that evolutionary genomic changes and human chromosome pathology may be two sides of the same coin.

P03.106

A novel report of partial trisomy of distal 7q and partial monosomy of distal 13q in a child with mental retardation,dysmorphism and ambiguous genitalia

A. Shojaei[1], *J. Tavakkoly-Bazzaz*[1], *R. kariminejad*[2], *M. Razzaghy-Azar*[1], *I. Bahman*[3], *F. Behjati*[3]*;*
[1]*Department of Medical Genetics, School of Medicine, Tehran University of Medical Sciences, Tehran, Tehran, Islamic Republic of Iran,* [2]*2- Kariminejad & Najmabadi Pathology and Genetics Center, Tehran, Iran, Tehran, Islamic Republic of Iran,* [3]*3-Genetics Research Center, University of Social Wefare and Rehabilitation Sciences, Tehran, Iran, Tehran, Islamic Republic of Iran.*

A four year old boy was hospitalized with neurodevelopment delay, growth delay, mental retardation, brachycephaly, neuromuscular abnormality, several dysmorphic features and ambiguous genitalia. Cytogenetics investigation using high resolution GTG banding technique showed an abnormal chromosome 13 described as 46, der(13)t(7;13)(q32;q32)mat. The mother had a balanced reciprocal translocation between chromosomes 7 and 13. FISH technique using subtelomeric probes for 7q and 13q confirmed the translocation and the der13 in the child. For Further characterization of the breakpoints aCGH was used.whole genome oligoarray was performed using CYTOCHIP ISCA 4X44K version1.1.In the involved chromosomes using array CGH showed a 7.7 Mb deletion at 13q33.3 to qter and a 22Mb gain at 7q33 to q36.3. The breakpoints using conventional Cytogenetics technique were furtherer refined with array CGH from 7q22 to 7q33 and from 13q32 to 13q33.The concomitant occurrence of partial monosomy 13q with other chromosomal abnormalities is uncommon. The patient's intellectual disability seems to be in accordance with 13q deletion syndrome and his ambiguous genitalia is more likely to be due to 7q partial trisomy. Specific neurological and neuromuscular problems like seizure and hypo/hypertonia have been described in most 7q partial trisomy patients but not in 13q partial monosomy. Dysmorphic features like low set ears, frontal bossing and positional abnormalities in teeth,epicantic fold and hypertelorisum, Low hair line and Retro/micrognathia , present in our patient, have been described in other cases of partial trisomy 7q and 13q deletion.

Partial Trisomy 1q associated to Partial Monosomy 11q: Cytogenomic and Clinical findings

L. D. Kulikowski[1], *V. F. A. Meloni*[2], *S. S. Takeno*[2], *A. L. P. Luce*[2], *C. B. Mello*[3], *M. I. Melaragno*[2]*;*
[1]*Department of Pathology, Cytogenomics Laboratory, LIM 03, Universidade de São Paulo, Brazil, São Paulo, Brazil,* [2]*Department of Morphology and Genetics, Universidade Federal de São Paulo, Brazil, São Paulo, Brazil,* [3]*Núcleo de Atendimento Neuropsicológico Infantil Interdisciplinar , AFIP, Universidade Federal de São Paulo, Brazil, São Paulo, Brazil.*

Citogenomics methods have provided significant improvement in the diagnosis of rare diseases in individuals with developmental delay, multiple congenital anomalies and autism spectrum disorders. We describe a patient with partial trisomy 1q and partial monosomy 11q and a 46,XY,der(11)t(1;11)(q41;q24)pat karyotype. Further investigations using FISH-BACs and SNP-array (6.0 Affymetrix) disclosed a ~37 Mb duplication of 1q32.3q44 associated to a ~2 Mb deletion of 11q25. The patient, a 13 year-old boy, has short stature, facial and corporal dysmorphisms. Cardiac evaluation showed atrial septal defect corrected by surgical treatment. He presents intellectual disability, aggressive and hyperactive behavior, limited verbal language repertoire and dysarthria. To the best of our knowledge, this is the first report of a partial trisomy 1q32 associated to a partial monosomy 11q25 in the literature. Thus, the patient revise karyotype is 46,XY.ish der(11)t(1;11)(q32.3;q25)pat (RP11-663C5-,RP11-262H5+;RP11-15J5+,RP11-265F9-).arr 1q32.3q44(212,508,954-249,224,376)×3,11q25(132,927,027-134,944,770)×1. Among the duplicated genes at 1q region, DISC1 and TRAX are crucial in neural development and TBCE and RAB3GAP are associated with neurodevelopmental disorders and mental retardation. Also the genes RYR2, VTSIP, ARVD2, ARVC2 are associated to cardiac abnormalities. Comparing the molecular karyotype and the phenotype of our patient to few similar cases, the clinical features of our patient are more likely due to partial trisomy 1q than to partial monosomy 11q. Although one of the critical regions for conotruncal heart defects, that include JAM3 gene, is within 129.0-130.6 Mb at 11q25. Cytogenomic methods extended the scope of molecular diagnosis thus making possible a more comprehensive approach to identify pathogenic genomic imbalances.

P03.108

A girl with partial trisomy 2p and monosomy 9p syndromes and sex reversal

L. L. Roese, *K. T. Abe, M. Schneider, M. D. V. Oliveira, M. F. Pereira, A. L. V. Coelho, D. R. Carvalho, C. E. Speck-Martins;*
SARAH Network of Rehabilitation Hospitals, Brasilia, Brazil.

Partial trisomy 2p is associated with multiple distinctive findings including psychomotor delay and dysmorfic facial features. The deletion 9p syndrome is characterized by mental retardation, trigonocephaly, midface hypoplasia and a long philtrum. Distal 9p deletions have also been reported in patients XY and sex reversal, with or without 9p deletion syndrome. Our patient presented low birth-weight, developmental delay, generalized hypotonia and seizures. Facial dysmorphisms included high forehead, wide nasal root, anteverted nares, short neck, and normal external female genitalia. Conventional cytogenetic analysis was performed. Array-CGH was carried out using the Constitutional Chip 4.0 BAC Array platform. The karyotype was 46,XY,der(9)t(2;9)(p21;p24).arr 2p25.3p21(366,137-42,681,415)x3,9p24.3p24.2(97,018-2,299,539)x1mat. She inherited the chromosome 9 derivative from her mother who had the karyotype 46,XX,t(2;9)(p21;p24). Our patient did not present with trigonocephaly, but presented with other features characteristic for 9p deletion phenotype. Considering the extent of the 9p deletion in this patient (~2 Mb from the telomere), our results support the observations made by some authors, suggesting a more distal critical region for 9p deletion syndrome phenotypes. Our patient had also a 2p duplicated segment an average of 42 Mb. This segment was larger than those described by some authors (in general, 2p23→2pter), but presented many features in common with those described for them. The differences could be explained due the different breakpoints and genes involved in each patient. The present study could contribute to the description of unusual chromosomal aberrations affecting chromosomes 2 and 9 with sex reversal.

P03.109

A boy with partial trisomy 3p and monosomy 10q due to an unbalanced 3p:10q translocation

M. S. YILDIRIM, *A. G. ZAMANI, E. TUNCEZ;*
Department of Medical Genetics, Meram Medical Faculty, Konya University, Konya, Turkey.

Trisomy 3p syndrome is a rare syndrome characterized by psychomotor and mental retardation, decreased muscle tone, seizures, short neck, hypertelorism/telecanthus, dysmorphic ears and congenital heart defects. Partial deletion of the long arm of chromosome 10 is a relatively frequent cytogenetic abnormality and exists considerable heterogeneity in the clinical presentation even among family members who share the same deletion boundaries. Common facial appearance, cardiac and urogenital anomalies, and a high incidence of neurodevelopmental deficits are relatively consistent features for deletion 10q syndrome.

We report a 6 years old boy presented with dysmorphic features such as microcephaly, hypertelorism, narrow palpebral fissures, epicanthal folds, flat nasal bridge, deep philtrum, prognatism, malocclusion of teeth, large-protruding ears, uplifted earlobes, short neck, neck webbing, wide spaced nipples, umblical hernia, camptodactyly of third fingers, clinodactyly of fifth fingers, sandal gap, overriding toes, clinodactyly of fourth toes, cryptorchidism, micropenis. The patient also had seizures, growth retardation and mental motor retardation. Abdominal USG showed hydronephrosis and a cranial MR examination revealed enlarged posterior fossa. After conventional cytogenetic screening the karyotype of the proband was described as 46,XY,der(10)t(3;10)(p24;q26). This karyotype confirmed by microarray analysis. This analysis showed a 9,45 Mb gain in chromosome 3 and 5,07 Mb loss in chromosome 10. His father is a carrier of a balanced translocation between chromosomes 3 and 10 [46,XY,t(3;10)(p24;q26)]. So our patient has a partial duplication of 3p and partial deletion of 10q.

This case presented to contribute the literature owing to rarity of the trisomy 3p and distal monosomy 10q syndrome.

P03.110

Partial trisomy of 7q34 with loss of the heterochromatic region of Y chromosome

***D. Begovic**, R. Lasan Trcic, S. Huljev Frkovic, L. Letica, I. Tonkovic Djurisevic, K. Crkvenac Gornik, M. Salamon;*
Medical School University of Zagreb, Department of Pediatrics, Zagreb, Croatia.

We present a male infant with partial trisomy of the long arm of chromosome 7. The patient is the first child of healthy and unrelated parents, born on term, birth weight 3750 g (50 to 75 centile), length 58 cm (+4 SD). Because of dismorphia, cardiac defect and delayed psychomotor development the cytogenetic study was performed at the age of 20 months.

The karyotype 46,X,der(Y)t(Y;7)(q12;q34)dn revealed de novo partial trisomy 7q34 and loss of heterochromatic region of chromosome Y. High resolution GTG banding revealed de novo derivate Y chromosome from translocation (Y;7)(q12;q34) in all methapases and normal karyotype in the patient's father. FISH with wcp from chromosome 7 showed two normal signals, and an extra signal in the long arm of chromosome Y. Chromosome Y showed presence of SRY, centromere and loss of heterochromatic region.

Cases with a 7q34 pure partial trisomies are uncommon. Patient shares most of the common findings with previously described patients such as post natal growth retardation, hypertelorism, epicanthus, low-set ears, micrognathia, short neck, hypotonia, skeletal anomalies, cardiac defect and developmental retardation with IQ 47. He is also characterized by hyperflexible fingers, Sydney line on and right testicular retention, a feature that has previously not been described.

Cases like these are useful, given clinical manifestation are only due to pure 7q trisomy: however, further molecular studies are needed to determine genes located in this region of the long arm of chromosome 7, and to elucidate the phenotypic correlation of the regions of this chromosome partial trisomy.

P03.111

Two distinct phenotypes in 11 individuals, demonatrating alternate unbalanced recombinants derived from a cryptic paternal balanced translocation between chromosomes 10 and 14

***A. Mory**[1], L. Linde[2], E. Dagan[1,3], N. Hawash-Moustafa[1], H. Mandel[1,4], R. Gershoni-Baru[1,4];*
[1]Rambam Medical Center, Institute of Human Genetics, Haifa, Israel, [2]BioRap Technologies Ltd. at the Rappaport Institute, Haifa, Israel, [3]Department of Nursing, University of Haifa, Haifa, Israel, [4]The Ruth and Bruce Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel.

Background: Two syndromes, each characterized by a distinct cluster of clinical features, segregated in 11 individuals from one kindred. All affected children were the products of non-consanguineous matings. However, all affected individuals shared a common progenitor. The diagnosis of unbalanced chromosomal abnormalities was sought. Yet, cytogenetic studies were reported to be normal. Molecular cytogenetics tools were undertaken to further investigate this prototype of abnormalities.

Methods: Following signed informed consent (parental), blood samples were drawn, for DNA extraction, from all available patients (n=10) and parents (n=6), pertaining to three nuclear families, from one kindred. Clinical, neurological and developmental assessments were undertaken in selected patients and two distinct phenotypes, A and B were deliniated, marked by mental retadation, either moderate or severe, respectively, and salient dysmorphic features associated with early scenescence (phenotype B). Whole genome SNP array analysis using the „HumanCytoSNP-12v2.1 DNA Analysis BeadChip Kit (Illumina)" was undertaken on two affected individuals demonstrating distinct phenotypes.

Results: Whole genome SNP array analysis identified an unbalanced cryptic translocation involving a terminal 5 Mb deletion (100273988-106353482) of 14q32.2-14Q32.3 and a terminal 5 Mb duplication (125708-5329074) of 10p15.3 -10P15.1 in patient with phenotype A. An alternate unbalanced recombinant, namely terminal 5 Mb deletion (125708-5329074) of 10p15.3 -10p15 and terminal 5 Mb duplication (100273988-106353482) of 14q32.2-14q32.3, was shown in patient with phenotype B. **Conclusions**: Investigations of apparently balanced chromosomal rearrangements in patients with abnormal phenotype by molecular cytogenetics tools, especially by array CGH, has become the gold standard for deciphering cryptic chromosomal abnormalities.

P03.112

Application of array-CGH in prenatal diagnosis and aborted fetuses

***P. C. Evangelidou**, C. Sismani, M. Ioannides, A. Alexandrou, M. Moutafi, P. Patsalis;*
Department of Cytogenetics and Genomics, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus.

Array -CGH, in postnatal diagnosis for intellectual disability is currently being used as a first-tier diagnostic test. However, in prenatal diagnosis, chromosomal analysis remains the method of choice. Its introduction in routine prenatal diagnosis is still in its infancy and further studies are needed prior to its implementation. Here we present our results from application of array-CGH in selected amniotic fluid and CVS samples as well as in first and second trimester samples from aborted fetuses (POC-Products Of Conception or skin biopsies). Fifty-one prenatal cases were referred for array-CGH for ultrasound abnormalities (N=37) or for further investigation of chromosomal abnormalities (N=14). The 105K Cytochip array, (BlueGnome Ltd.) was applied and two *de novo* and one inherited, from an affected mother, deletions (6%) ranging from 2.5-14Mb, were detected. In addition the origin of two marker chromosomes was identified. One of the abnormalities detected, would have been missed with conventional cytogenetics highlighting the importance of array-CGH in prenatal diagnosis. In addition the characterization of chromosomal abnormalities with array-CGH offers valuable information for the pregnancy outcome. Forty-six samples from aborted fetuses which failed to grow in vitro were analyzed using the Cytochip BAC array and six (13%) autosomal full trisomies were detected. No cases were detected with submicroscopic copy number changes that could have been missed with conventional cytogenetics. However since BAC arrays were used further studies are necessary with higher resolution arrays in order to evaluate the importance and the value of array-CGH in miscarriages.

P03.113

Prenatal diagnosis of common chromosome disorders by QF-PCR.

***V. S. Baranov**, T. E. Ivashchenko, Y. A. Nasykhova, O. A. Tarasenko, L. I. Talantova, Y. S. Nikolaeva, A. L. Koroteev, O. G. Chiryaeva, L. I. Petrova, N. A. Sadik, V. S. Dudkina, T. V. Kuznetzova;*
D.O.Ott Research Institute of Obstetrics and Gynecology, Saint-Petersburg, Russian Federation.

The quantitative fluorescent PCR assay, implemented during the last few years, opens the way for common chromosome disorders prenatal diagnoses within a few hours after sampling. Study summarizes 3 years prenatal diagnosis for chromosome abnormalities by QF-PCR experience. 17 STR markers (D21S11, D21S1437 D21S1411, D21S226, D13S628, D13S634, D13S742, D18S380, D18S386, D18S391, D18S535, AMXY, DXS981, DXS6854, X22, P39, XHPRT) were used throughout the study. Altogether 53 aneuploidies (34 trisomy 21 cases, 11- trisomy 18, 3 47 XXY, 2 45X and 2 69 XXY) out of total 1105 fetuses were picked up. Submicroscopic polymorphic microsatellites duplications were observed in 12 cases as clear trisomic triallelic or diallelic patterns for one chromosome-specific STRs. Duplications were detected in two sample for one STR on chromosome 21 (D21S1437), in six cases for one of the markers selected on chromosome 13 (4 cases for D13S634 and 2 for D13S742), in three sample for STRs on sex chromosome (2 cases for X22 and 1 for P39) and in the remaining case with D18S51 marker. The maternal duplication origin have been demonstrated in 5 cases by QF-PCR analysis of the same marker in both parents, in one sample polymorphism was found as inherited from the father. In three cases *de novo* origin of duplication was proved.

The submicroscopic duplications in microsatellites should be treated with caution as it needs further discrimination for both partial trisomy or full autosomal trisomy detected with single informative STR. The analysis of both parents with the same marker enables rare inherited polymorphism identification.

P03.114

De novo pure subtelomeric microduplications as a cause of dysmorphic syndromes of unexplained etiology

***M. Kucharczyk**, D. Sielska-Rotblum, A. Gutkowska, M. Kugaudo, A. Jezela-Stanek, A. Marczak, M. Białecka, K. Chrzanowska, M. Krajewska-Walasek;*
Department of Medical Genetics, The Children's Memorial Health Institute, Warsaw, Poland.

Unbalanced chromosomal rearrangements in gene-rich subtelomeric regions lead to mental retardation (MR), dysmorphy, multiple congenital anomalies (MCA) and/or abnormal growth or behavior. The number of reported deletions is much higher than the number of duplications, which likely reflects both ascertainment bias and limitations of available diagnostic methods. Duplications may result in milder phenotypes, or certain characteristic features that are different to those of the corresponding deletions, and consequently, patients may not present for clinical evaluation. New molecular techniques (MLPA or array-CGH) allow easier identification of subtelomeric microduplications, but their frequency and clinical significance are still largely unknown. Previous studies gave a frequency of subtelomeric duplications of 0-2%; most have been described in sporadic cases with their genomic sizes poorly determined.

We estimated the frequency of pure subtelomeric microduplications in a group of 491 patients with MR, dysmorphy and/or MCA and normal karyotype using MLPA and delineated the identified microduplications using array-CGH. In 3 patients (prevalence of ~0,61%), MLPA revealed a subtelomeric duplication without a concurrent deletion: duplication of 4p15.2pter (24.91 Mb), 9p13.1pter (38.55 Mb) and 17p13.2pter (5.77 Mb); all had occurred de novo.

Based on our findings and literature data, pure subtelomeric microduplications are an infrequent cause of dysmorphic syndromes. However, further studies are needed to clinically and molecularly define novel duplication syndromes, what is particularly important for dysmorphology and genetic counseling.

The study was partially supported by the grant of the Polish Ministry of Science and Higher Education (Contract No 0605/B/P01/2009/37).

P03.115
Submicroscopic Xq28 deletions are frequent in "MECP2-mutation-negative" Rett syndrome girls

***S. G. Vorsanova**[1,2,3], Y. B. Yurov[2,1,3], O. S. Kurinnaia[1,2,3], V. Y. Voinova[1,3], M. A. Zelenova[2,3], A. P. Silvanovich[2], I. Y. Iourov[2,1];*
[1]Institute of Paediatrics and Paediatric Surgery, Ministry of Health, Moscow, Russian Federation, [2]Mental Health Research Center, RAMS, Moscow, Russian Federation, [3]Moscow City University of Psychology and Education, Moscow, Russian Federation.

MECP2 mutations are a well-recognized cause of Rett syndrome (RTT). From 60 to 90% cases of RTT usually demonstrate point or frameshift mutations of MECP2. In the remainder, the cause of the disease is usually unidentified. Occasionally reported cases of Xq28 deletions encompassing MECP2 suggest that at least a small proportion of MECP2-mutation-negative RTT cases might result from submicroscopic subtelomeric Xq losses. Using array comparative genome hybridization (array CGH) with a higher coverage of chromosome X, we have tested whether submicroscopic Xq28 deletions (encompassing MECP2) contribute to the etiology of RTT in "MECP2-mutation-negative" cases. We have found that 4 girls among 28 RTT females without MECP2 mutations (addressed by direct sequencing) exhibited submicroscopic Xq28 deletions. The size of the deletions was estimated to be approximately 603kb. It is noteworthy that all the deletion cases demonstrated almost exactly the same breakpoints located at 153.25 and 153.86 Mb of chromosome X according to NCBI Build 37.3. Clinical manifestations in these cases resembled to classical RTT with additional clinical manifestations such as atypical facial dysmorphisms, congenital heart malformation, intrauterine growth retardation, congenital eye malformations probably due to losses of other genes located at Xq28. Two deletion cases were associated with late-onset regression (at 24 and 38 months). Our data indicate that about 14% of MECP2-mutation-negative RTT cases can arise from submicroscopic Xq28 deletions. This suggests that array CGH (chromosomal microarray) analysis is warranted in MECP2-mutation-negative RTT cases, regardless of monogenic nature of the disease.

P03.116
The ring 14 syndrome: phenotypic map

***M. Zollino**[1], E. Ponzi[1], G. Gobbi[2], G. Neri[1];*
[1]Catholic University, Rome, Italy, [2]Neuropsichiatria Infantile,IRCCS Istituto delle Scienze Neurologiche, Bologna, Italy.

The ring 14 syndrome is a rare condition, whose precise clinical and genetic characterization is still limited. Pathogenic mechanisms are unknown, with particular regard to the severe seizure disorder. We analyzed 27 patients with ring 14 syndrome and 9 patients with linear 14q deletions, affecting the proximal (n=3) or the distal (n=6) segment. Clinically, the ring14 syndrome was characterized by a recognizable phenotype of shortness of stature, distinctive facial appearance, microcephaly, scoliosis, and ocular abnormalities, consisting mainly of abnormal retinal pigmentation, but also retinitis pigmentosa, strabismus, glaucoma, and abnormal macula. Nearly all patients presented with severe intellectually disability, and some had aggressive and hyperactive behavior. Drug-resistant epilepsy was another consistent finding. Genetically, the ring was complete in 6/27 cases, while it showed a small terminal deletion, varying in size from 0.3 to 5 Mb, in the other 21. In two of these a cryptic 14q duplication of 2.5 and 9.7 Mb, respectively, proximal to the deleted segment, was also identified. Deleted rings were 75% paternal and 25% maternal in origin. UPD (14) was excluded in all cases. Our observations, along with literature review of additional 39 ring 14 cases and 42 linear deletions, led us to map retinal abnormalities and epilepsy to the proximal 14q11.2- q12 region, and behavior disorders, susceptibility to infections and typical facial characteristics to the 14q32 region. We consider that haploinsufficiency is the most likely underlying mechanism for facial dysmorphisms, susceptibility to infections and behavior disorder, and gene silencing for seizures and retinal abnormalities.

P03.117
ArrayCGH characterisation of ring chromosome 9 formation due to inverted duplication and terminal deletion in a patient with sex-reversal

***I. Barisic**[1], L. Morozin Pohovski[1], K. Dumic[1], I. Petkovic[1], M. Riegel[2], A. Schinzel[2];*
[1]Childrens University Hospital Zagreb, Clinical Hospital Centre Sisters of Mercy, Zagreb, Croatia, [2]Institut für Medizinische Genetik, Medizinische Fakultät Universität Zürich, Zürich, Switzerland.

We present the molecular characterisation of the case of ring (9) chromosome arisen as a healing mechanism in a patient with inverted duplication and terminal deletion. Ring chromosome 9 was initially diagnosed by high resolution karyotyping and shown to have an additional duplication of band p23. Fluorescent in situ hybridisation (FISH), multiplex ligation-dependent probe amplification (MLPA) and quantitative fluorescent-polymerase chain reaction (QF-PCR) maker analysis were used to characterise additionally the aberration and to establish parental origin. The final karyotype was designated as 46,XY,r(9)(p24.3;q34.3) inv dup(9)(p24.3p22.3)mat. Array-CGH was performed to further map the aberration. The result revealed a complex rearrangement involving deletion of 841,839 bp the at band 9p24.3, followed by an intact segment approximately 926,106 bp in size, and a large duplication of 12.73 Mb extending from band p24.3 through p22.3. The patient presented overlapping clinical features of the terminal deletion and associated duplication. The deletion involved sex reversal critical region which resulted in ambiguous external genitalia and bilateral ovotestes. In addition, she presented with growth retardation, dysmorphic features, cerebellar hypoplasia, a small atrial septal defect and low-normal intellectual development. There is only one report of a patient with ring chromosome 9 containing an inverted 9p22.3-p24.3 duplication, but without terminal deletion. Phenotypic characteristics are similar to our patient, confirming the hypothesis of a separate dup9p22.3-p24.3 phenotype, distinct from the well described 9 p duplication syndrome, thus confining its critical region to 9p22.1-p22.2.

P03.118
Clinical consequences resulting of the ring chromosome 13 configuration

***R. S. Guilherme**[1], C. A. Kim[2], S. Bragagnolo[1], M. A. Ramos[1], N. B. Spinner[3], L. K. Conlin[3], R. Daber[3], L. D. Kulikowski[2], M. I. Melaragno[1];*
[1]University Federal of São Paulo, São Paulo, Brazil, [2]University of São Paulo, São Paulo, Brazil, [3]Children's Hospital of Philadelphia, Philadelphia, PA, United States.

Ring chromosomes usually result from two terminal breaks in both chromosome arms followed by fusion but can also be formed by different mechanisms. We studied three patients with r(13) karyotyping with G-banding, array (platform Illumina Quad610) and FISH with bacterial artificial chromosome probes, as follows. **Patient I.** Three year-old boy, preterm, IUGR, microcephaly, narrow and oblique forehead, upslanting palpebral fissures, ocular hypertelorism, prominent nasal bridge, high palate, prominent incisors, large and dysmorphic ears, peno-scrotal inversion, scrotal hypoplasia, prominent and large halluces, renal ectopia, hypotonia and severe neuro-psychomotor delay. Cytomolecular results: 46,XY,r(13)(p13q33.1).arr 13q33.1(101,543,509-103, 001,462)x3,13q33.1q34(103,003,268-114,142,980)x1 **Patient II.** One year-old boy, IUGR, microsomia, microcephaly, micrognathism, bilateral epicanthic folds, long eyelashes, small nose, prominent nasal bridge, long philtrum, broad helices, low set dysmorphic ears, high palate, thin upper lip, thoraco-lombar scoliosis, right feet pos-axial polydactyly, hypotonia and neuro-psychomotor development delay: 46,XY,r(13)(p13q34). arr 13q21.33q34(70,141,036-113, 656,958)x3,13q34(113,759,040-114,123,122)x1. **Patient III. 5** year-old boy, preterm, IGRU, microcephaly, ocular hypertelorism, proeminent nasal bridge, long nose, spaced nipples, otitis, leucopenia, speech delay, hypotonia and neuro-psychomotor development delay: 46,XY,r(13)(p13q34).arr 13q34(110,304,519-114,123,122)x1. The patients I and II present a duplicated segment associated with the terminal deletion that was inverted in patient II, while the patient III showed simple terminal deletion. We can observe the three patients present clinical features usually found in del(13q), partial duplication 13q and r(13) considering their phenotypes are influenced by many factors such as the size of the deletion, presence or not of interstitial duplication, ring instability and epigenetic factors, showing the difficulty in defining a specific phenotype r(13) patients. (FAPESP)

P03.119

Robertsonian translocation and consanguinity

T. Cora, *N. Kocak, A. Kalaycı, H. Acar;*
Selcuk University, Selcuklu Medical Faculty, KONYA, Turkey.

Robertsonian translocation, which occur with a prevalence of ~1 in 1000 in the general population, result from the rearrangement of two acrocentric chromosomes. The most common Robertsonian translocation is between chromosomes 13 and 14. This translocation can occur de novo or be transmitted by one of the parents. The rearrangement form trivalents at meiosis may result in unbalanced gametes. Zygotes carrying monosomy are not compatible with life and most translocation trisomy conceptuses are expected to result in the First trimester loss. However, some of them survive beyond the second trimester and to term. There may be infertility problems and miscarriage in couples carrying these translocations. In the present report, a couple was referred to our clinic due to an 8 years history of infertility. There was a first cousin marriage between couple. Their families also present numerous consanguineous marriage. Cytogenetic analyses were done in the couple and their families. Both couples have a 45,XX,t(13;14)(q10;q10) and 45,XY,t(13;14)(q10;q10) karyotypes. Cytogenetic analyses were also extended to their parents. Female proband's mother and male proband's father were found to be 44,XX,t(13;14),t(13;14) and 44,XY,t(13;14),t(13;14), respectively, indicating double Robertsonian translocation while their couples have normal karyotypes. All other possible carriers of Robertsonian translocation in the family were analysed. Each couple in this family was given genetic counselling who has been seeking pregnancy and healthy child. Thus, they were taken under preimplantation genetic diagnosis programme.

P03.120

De novo and inherited copy number variants are a common cause of short stature

D. Zahnleiter[1], *U. Trautmann[1], A. B. Ekici[1], D. Wieczorek[2], E. Kunstmann[3], H. Doerr[4], A. Rauch[5], C. T. Thiel[1];*
[1]Institute of Human Genetics, University of Erlangen-Nuremberg, Erlangen, Germany, [2]Institute of Human Genetics, University of Essen, Essen, Germany, [3]Private clinic, Wurzburg, Germany, [4]Department of Pediatrics and Adolescent Medicine, University Erlangen-Nuremberg, Erlangen, Germany, [5]Institute of Medical Genetics, University of Zurich, Zurich, Switzerland.

Shortness of stature is one of the most common paediatric concerns. 3 % of the general population present with a body height below -2 SD score. In the majority of cases the underlying cause remains unknown. Recent GWAS found significant evidence for both single nucleotide and copy number polymorphisms associated with height variation in the general population. These associations explain only a small fraction of the overall variability of human height. To identify novel genetic causes of growth retardation under a "rare variant - frequent disease" hypothesis we performed molecular karyotyping in 121 families with idiopathic short stature using Affymetrix SNP 6.0 array and scored copy number variants (CNVs) with a minimum size of 10 kb and 5 markers. A total of 4,432 aberrations with an average of 36 copy number changes per individual were identified. After exclusion of common polymorphisms using 820 healthy control individuals and comparison with known pathogenic CNVs, we carried out a gene-centric analysis by investigating known gene functions, tissue expression and murine knock-out phenotypes. We found 14 potentially pathogenic CNVs (11.6 %) in 14 patients, including 6 duplications and 8 deletions. All aberrations were larger than 100 kb. 6 were de novo with 1 overlapping the 22q11.1 microdeletion region, and 8 inherited from the affected parent, including the 1q21 region in 2 cases and 3q29 in 1 case. In conclusion, our data indicate that CNVs are one of the main causes of growth retardation in a frequency comparable to other conditions as e.g. intellectual disability.

SHOX (short stature homeobox-containing gene) is a member of the highly conserved paired homeobox (HOX) family and is known to control important aspects of growth and development. This gene, located in the PAR1 regions of chromosomes X and Y, is the first gene shown to be involved in the development of characteristic features of Turner syndrome.

We present the case of a female patient, the first child of a Caucasian unrelated family with mild dysmorphic features, microcephaly, growth and mental retardation. MLPA analysis of the telomeres revealed an Xpter duplication, later confirmed with FISH analysis using commercially available SHOX probes. Also, the blood karyotype investigation showed a deletion on the long arm of chromosome 13, region q12q14, which includes CDX2, HMGB1, BRCA2, KL and TNFSF11 genes.

The implications of SHOX duplication and interstitial deletion of 13q for the patient's phenotype individually and in combination are discussed, along with a short review of the literature.

P03.122

High resolution oligo array-CGH analysis of single cells

P. Costa, ***A. De Witte****, S. Fulmer-Smentek;*
Agilent Technologies, Santa Clara, CA, United States.

Genomic imbalances are a major cause of constitutional and acquired disorders. The ability to characterize single cells isolated from solid tumors or pre-implantation samples represents an important advancement. FISH and PCR-based methods have been used to analyze chromosomes of a single cell. However, these approaches can only analyze a limited number of genetic loci simultaneously. By contrast, analysis of genome-wide copy number changes at the single-cell level can be performed by comparative genomic hybridization (CGH). Bacterial artificial chromosome (BAC) arrays have been used for this purpose. However, typically BAC arrays only contain a few thousand probes and are prone to batch-to-batch variation in performance.

Here we describe a method for researchers that combines single-cell whole genome amplification (WGA) with copy number analysis employing high-resolution *in situ* synthesized Agilent SurePrint G3 8x60K oligo CGH microarrays. As a proof-of-principle experiment, we assayed the copy number difference between a reference sample and a test sample with a known aberration, each using amplified DNA that was diluted to single cell levels. We visualized the expected aberrations in Agilent CytoGenomics software. We then assayed the genomic aberrations in single cells biopsied from embryos, in which not only we detected whole chromosome losses or gains, but also found smaller aberrations of portions of chromosome arms.

The ability to detect abnormalities involving any of the 24 chromosomes represents a major advantage over FISH and PCR-based methods. The high reproducibility of high-resolution oligo CGH microarrays offers new possibilities for research on genetic analysis of single cells.

P03.123

SNParray-detected seemingly neutral familial CNVs as causative pathogenic events

M. Trková[1], *V. Bečvářová[1], L. Hnyková[1], J. Horáček[1], V. Krutílková[1], E. Hlavová[1], D. Rašková[1], M. Hejtmánková[1], E. Zemánková[2], A. Baxová[3], G. Křečková[4], D. Čutka[5], D. Stejskal[1];*
[1]Gennet, Prague, Czech Republic, [2]E-med, Benešov, Czech Republic, [3]UK 1.LF a VFN, Prague, Czech Republic, [4]Gennet, Liberec, Czech Republic, [5]CLG, České Budějovice, Czech Republic.

SNP array represents a unique technique for the identification of cytogenetically undetectable submicroscopic alterations (microdeletions, microduplications) and copy number neutral events (LOH, UPD). Routine usage of the whole genome genotyping by the Illumina HumanCytoSNP-12v2.1 generates both types of results; the definite pathogenic/benign CNVs and CNVs or LOH regions of uncertain clinical significance.

In 686 analysed samples during 2 year period (10/11) the total of 2699 CNVs was detected; 913 CNVs in fetuses with abnormal ultrasound findings and 1756 CNVs in children with psychomotoric retardation and/or genetic stigmatisation: 4.4% (41/913) and 6.6% (116/1756) of clinically relevant pathogenic CNVs in prenatal and postnatal samples, respectively; 3.9% (36/913) and 4.1% (72/1756) CNVs of uncertain clinical significance in prenatal and postnatal samples, respectively.

85 parent samples were analysed to clarify the CNV relevance and 18 of CNVs were confirmed as de novo and likely pathogenic microdeletion/ microduplications. Out of the total of 49 maternally or paternally inherited CNVs, 26 were assessed as the genomic variants. Interestingly, 23 of the parental CNVs are likely pathogenic as different mechanisms of the variable expressivity or incomplete penetrance of each of the familial alterations were documented: mosaics, X-linked CNV, discreet parental phenotype, second hit model, different aberration size and copy number and uncovered

mutation on the second chromosome. Therefore, we conclude that the proof of inheritance of seemingly neutral genetic aberration does not exclude its pathogenic role.

P03.124

Characterization of a postnatal "de novo" sSMC derived from chromosome 20

M. García[1], *M. Guzmán*[2], *M. Sánchez*[1], *E. Abarca*[1], *L. Rodríguez*[1];
[1]*Laboratorio AbaCid-Genética., Madrid, Spain,* [2]*Servicio de Pediatría. Grupo Hospital de Madrid, Madrid, Spain.*

A genetic imbalance induced by the presence of a sSMC (S*mall Supernumerary Marker Chromosomes)* is the major reason for clinical symptoms in sSMC carriers, although the 44% of prenatally ascertained cases with sSMC are familial cases without clinical effect. Nevertheless, the risk of an abnormal phenotype associated with a *de novo* sSMC is 7%-28%.

sSMCs cannot be easily characterized by conventional cytogenetic banding techniques generating a lot of diagnostic problems, nevertheless, the recent application of new molecular techniques have resolved the limitations of those techniques and therefore increased the right prognosis for all patients.

Here we report a 2 months old girl who showed at birth a weight of 2050 gr p(<3), an OFC of 32cm p(<3), and a length of 43,5 cm p(<3), together with hypotonia. She was the second child of a healthy couple with a previous healthy child and 3 previous miscarriages. Her evolution at home was with no gain weight and after 2 months, an intrathoracic stomach with duodenal bulb infradiaphragmatic, a light colpocephaly and corpus callosum hypoplasia were diagnosed. After surgery she is having good evolution, getting oral alimentation and at 4 months old she weights 4110 gr. She had a normal prenatally karyotype: 46,XX but a postnatal karyotype showed a "de novo" small marker in all cells: 46, XX + mar. The application of an Array-CGH showed a **gain in the gene dosage [min(20)(:p11.1→q11.21:)] which was confirmed by FISH to be present in th sSMC.**

Array-CGH and FISH are essential for diagnosis of sSMC.

P03.125

Structural abnormalities of the sex chromosomes in gonadal dysgenesis

L. Caba[1], *M. Covic*[1], *C. Rusu*[1], *M. Volosciuc*[2], *L. Butnariu*[1], *E. Braha*[1], *M. Panzaru*[1], *R. Popescu*[1], *C. Bujoran*[2], *V. Martiniuc*[3], *M. Gramescu*[1], *I. Ivanov*[1], *A. Sireteanu*[1], *M. Macovei*[1], *E. Gorduza*[1];
[1]*University of Medicine and Pharmacy „Grigore T. Popa", Iasi, Romania,* [2]*Children Hospital „Sfanta Maria", Iasi, Romania,* [3]*"Cuza-Vodă" Obstetrics and Gynecology Hospital, Iasi, Romania.*

Introduction: Gonadal dysgenesis are characterized by absence or underdevelopment of the gonads which produce sterility (infertility) and sexual characteristics remain underdeveloped. They are caused by numerical and structural abnormalities of the sex chromosomes.

Material and methods: Our group is formed by 23 patients with structural abnormalities of the sex chromosomes diagnosed in Medical Genetics Center Iasi, Romania, between January 2001-December 2010 from a number of 2362 karyotypes. Chromosomal analysis was done using cultures of lymphocytes and GTG bands. In selected cases we used fluorescence in situ hybridization (FISH) postnatal and in one case antenatal FISH discover the abnormality.

Results: There were 20 cases with X chromosome structural abnormalities and just 3 of the Y chromosome, in all cells or in mosaic form. For X chromosome, the abnormalities were: isochromosome (12 cases of q arm isochromosome), ring (5 cases) and deletions (2 for p arm and 1 for q arm). For Y chromosome there were three abnormalities: dicentric, ring and marker chromosome.

Conclusions: Structural abnormalities of X and Y chromosome are less common than aneuploidy in gonadal dysgenesis and the most frequent clinical picture for female gonadal dysgenesis is Turner syndrome. The karyotype and FISH are useful for cytogenetic characterization of these abnormalities.

P03.126

Subtelomere deletion and additional chromosomal segments in mental retardation

A. M. Mohamed[1,2], *A. K. Kamel*[1], *M. O. El-Ruby*[1], *I. H. Mazen*[1], *H. A. Hussein*[1];
[1]*National Research centre, Cairo, Egypt,* [2]*National Research Centre, Cairo, Egypt.*

The prevalence of mental retardation is estimated to be 1 to 3% of the general population. Mental retardation has many etiologies which can be broadly classified into genetic and environmental causes. The condition is common and the cause of MR is still largely unknown in 30-50% of cases. We reported on three female cases with mental retardation and multiple congenital anomalies and have additional (add) chromosomal segments. The parents of the three cases have normal karyotype. Karyotype in the 1st case was 46,X,add(X)(q), the second 46,XX,dd(2)(q), the third case 46,XX,add(21)(q). Using the total subtelomere (Vysis), case 1 has an additional segmene of chromosome 7(q31-36) and deletion of chromosome Xq subtelomere. Case 2 has additional segment of chromosome 15(q25-26) and del of chromosome 2q subtelomere. Case 3 has additional segment of chromosome 17q(22-25) and deletion of 21 subtelomere. Deletion of the subtelomere may be the underlying mechanism of these abnormalities. The FISH technique can identify to a certain limits the sites and extent of deletion and duplication. We recommend array CGH to detect the exact copy number of deletion and duplication and this can explain the relation of genotype/phenotype.

P03.127

Molecular screening for subtelomeric aberrations in Thai patients with idiopathic mental retardation and autism by multiplex ligation-dependent probe amplification (MLPA)

S. Rujirabanjerd, *O. Plong-on, T. Sripo, P. Limprasert;*
Faculty of Medicine, Prince of Songkla University, Hat Yai, Songkhla, Thailand.

Chromosomal rearrangements involving telomeres have been identified to account for approximately 5-10% causes of mental retardation (MR). This finding leads to the suggestion that all cases of undiagnosed MR should be screened for subtelomeric aberration. Nevertheless, resolution of standard karyotyping using G-banding is limited and cannot detect this anomaly. Therefore, in this study, multiplex ligation-dependent probe amplification (MLPA) technique, was used to screen 129 patients with idiopathic MR. Twelve of them were also diagnosed with autistic disorder. We identified 5 patients (3.87%) with subtelomeric aberration. All have MR with normal karyotypes. One patient has a submicroscopic deletion at 1p36.33 which was confirmed by real-time PCR. There are two patients with subtelomeric duplication at 15q11.2 and 11p15.5 subsequently. Two patients have the same duplication at Xp22.33. Results were confirmed by using additional MLPA probes. Parental samples were also examined when available. Interestingly the deletion at 1p36.33 and duplication at Xp22.33 fall into the regions where copy number variation (CNV) have been reported. However the pathologic effect of these aberrations is still inconclusive. Further characterization of these aberration boundaries and screening in normal population should be performed. Nonetheless this study shows that MLPA technique is able to detect subtelomeric aberration in patients with idiopathic MR and may increase diagnostic yield especially where array facility is unavailable.

P03.128

De novo supernumerary dicentric marker chromosome 15 with contained Prader-Willi Angelman Critical Regions in a girl with a subtle phenotype

A. K. Eek[1], *L. Strand*[1], *M. Svendsen*[1], *K. O. Clausen*[1], *G. J. Braathen*[1,2,3];
[1]*Department of Laboratory Medicine, Section of Medical Genetics, Telemark Hospital, Skien, Norway,* [2]*Head and Neck Research Group, Research Centre, Akershus University Hospital, Lørenskog, Norway,* [3]*Campus AHUS, Akershus University Hospital, University of Oslo, Nordbyhagen, Norway.*

Background: Supernumerary marker chromosomes (SMC) are structurally abnormal chromosomes that most often are derived from the acrocentric chromosomes and especially chromosome 15.

Large SMC (15) which include the Prader-Willi Angelman Critical Region (PWACR) are nearly always sporadic and maternally derived when parental origin have been established.

Most cases with large SMC(15) have a severe phenotype typically including hypotonia, motor and speech delay, seizures, moderate to severe learning disability and autism while dysmorphic features are absent or subtle and growth is usually normal. Hence chromosome analysis may not be thought of. Cases are most easily ascertained through chromosome and fluorescence in situ hybridisation (FISH) studies.

Method: A three year old girl from a bilingual family was investigated. She had hypotonia, a modest speech delay and unsteady gait due to a foot deformity. Different genetic methods such as chromosomal analysis, FISH, Multiplex Ligation-dependent Probe Amplification (MLPA), array comparative genomic hybridization (ACGH) and single nucleotide polymorphism array (SNP array) were used to elucidate her phenotype.

Results: The results will be presented at the meeting.

P03.129

Deletion of the 3q26 region including the *Evi1 and MDS1-gene* in a neonate with congenital thrombocytopenia and subsequent aplastic anemia

***M. Nielsen**, C. L. Vermont, E. Aten, G. Santen, C. A. Ruivenkamp, M. H. Breuning;*
Centre of Human and Clinical Genetics, Leiden, Netherlands.

Gene-targeting studies in mice showed a key role of EVI-1 protein in maintaining hematopoiesis and argue for gene dosage requirement of EVI-1 in the regulation of hematopoietic stem cells. Furthermore, a fusion transcript of *Mds1* and *Evi1* was shown to play a critical role in maintaining long-term hematopoietic stem cell function. Inappropriate activation, usually due to a translocation, of EVI1 is a well known andunfavorable change in several myeloid malignancies. We report for the first time a constitutional deletion encompassing the *Evi1 and Mds1* in a human, and argue that this is causative for the congenital bone marrow failure in this patient.

P03.130

A phenotypically normal male carrying an unbalanced translocation 47,XY,+der(22)t(X;22)(q13;q11.2)

***T. D. Jensen**, A. L. Frederiksen, M. Rasmussen, A. A. Rasmussen, A. Bojesen;*
Department of Clinical Genetics, Vejle Hospital, Vejle, Denmark.

Background We have carried out genetic counselling of a pregnant couple expecting their first child. The mother was nine weeks pregnant at first contact. A known translocation, t(X;22)(q13;q11), runs in the father's family. The father has been told, based on chromosome analysis on a CVS from his mother, that he carries an unbalanced translocation, which may result in a Klinefelter syndrome phenotype. He is phenotypically normal, also as regards stigmata consistent with Klinefelter syndrome, but has never been karyotyped postnatally. **Methods** In light of this, we performed chromosome analysis of the father using standard karyotyping, whole-chromosome painting (WCP) with chromosome X and 22 centromeric probes and finally SNP-array analysis. CVS taken from the mother was analysed using routine rapid qPCR, MLPA subtelomere analysis and standard karyotyping. **Results** The results showed that the father carries two normal chromosomes 22, a normal X chromosome and an additional chromosome consisting of X and 22 material. His karyotype is 47,XY,+der(22)t(X;22)(q13;q11.2). The derivative chromosome harbours the X-inactivation center (XIC) at Xq13, which undoubtedly explains its lack of severe phenotypic impact. The results of the CVS analyses were normal, showing that the parents were expecting a child with a normal 46,XY karyotype.

P03.131

Triploidy masaicism in a six -year-old dysmorphic girl with mild mental retardation

***F. Behjati**[1,2], S. Ebrahimian Motlagh[2], N. Zarbati[2], E. Bagherizadeh[2], Z. Hadipour[2], N. Mohammadkhani[2], M. Asami[2], F. Hadipour[2], R. Pazhoomand[1], Y. Shafeghati[2];*
[1]Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran, [2]Sarem Cell Research Center & Department of Medical Genetics, Sarem Hospital,, Tehran, Islamic Republic of Iran.

A 6 year-old dysmorphic girl with mild mental retardation and dysmorphism is described. Clinical features of the child included patchy hyper pigmented skin, high nasal bridge, short philtrum , microgonathia , simple ear, simian crease, brachydactyly and syndactyly in all foot fingers.

Chromosomal study was performed using GTG banding technique on peripheral blood sample and skin biopsy to rule out chromosomal mosaicism. Interphase FISH investigation on Peripheral blood and skin biopsy, using X and Y chromosome centromeric probes, was carried out.

The child's peripheral blood karyotype was triploid with 69, XXX chromosome complements. Metaphase spreads obtained from skin biopsy revealed two cell lines: the majority of cells (42 cells, 84%) were 69,XXX and 8 cells(16%) were 46,XX. FISH result was as follows: interphase cells of cultured peripheral blood revealed 3 signals indicating X chromosomes and none for Y signal, in all studied cells and skin biopsy culture showed 34% of cells with 2 X chromosome signals and 66% with 3 signals confirming mosaicism for triploidy. Parent's karyotypes were normal.

Triploidy is usually an unviable situation unless a normal diploid cell line is present. The peripheral blood karyotype was pure triploidy while the skin cells demonstrated a mosaic pattern. The interphase FISH showed a higher percentage of normal karyotype. This study reiterates the use of cytogenetic studies on skin biopsy and interphase FISH for the evaluation of mosaicism. To our knowledge, this is one of the rare reported cases of triploidy in a patient surviving to the age of 6 year.

P03.132

A boy with partial trisomy 10q due to an unbalanced 10q:22p translocation

***E. TUNCEZ**, A. G. ZAMANİ, M. S. YILDIRIM, A. ACAR;*
Department of Medical Genetics,Meram Medical Faculty, Konya University, Konya, Turkey.

Distal trisomy 10q syndrome is a rare syndrome characterized by microcephaly, facial dysmorphism, hypotonia, joint laxitiy, scoliosis, short neck, growth retardation, mental motor retardation, cardiac, ocular and renal abnormalities. Most of the cases are diagnosed in infancy or in childhood and rarely include prenatal findings.

We report a 15 years old boy presented with dysmorphic features such as microcephaly, round face, facial hirsutism, frontal upsweep, low frontal hairline, hypertelorism, epicanthal folds, blepharophimosis, thick eyebrows, long curved eyelashes, flat nasal bridge, hypoplastic alae nasi, macrostomia, bow-shaped mouth, malocclusion of teeth, prominent incisors, high palate, gum hypertrophy, micrognathia, simple ear, short neck, kyphosis, scoliosis, hypogonadism, fusiform digits, bilateral hallux valgus, short third toes on right foot, syndactyly 2-3 of toes on left foot. The patient also had hypotonisity, growth retardation and mental motor retardation. Echocardiography showed pulmonary stenosis and a cranial MR examination revealed thin corpus callosum, small arachnoid cyst on anterior temporal lobe but hearing test was normal. After conventional cytogenetic screening the karyotype of the proband was described as 46,XY,der(22)t(10;22)(q24;p11). His mother is a carrier of a balanced translocation between chromosomes 10 and 22 [46,XX,t(10;22)(q24;p11)]. So our patient has a partial duplication of 10q and partial deletion of 22p. Rearrangement of 22p11->pter does not have clinical implications. So clinical features of the proband suggested as a result of trisomy 10q24->qter.

This case presented to contribute the literature owing to rarity of the partial trisomy 10q syndrome.

P03.133

Increased risk of trisomy 21 (T21) in offspring of carriers of balanced non-contributing autosomal rearrangement (Rea) is not accounted for by interchromosomal effect (ICE). A post fertilization effect of paternal Rea on segregation of maternal chromosomes is suspected

***N. V. Kovaleva**;*
St. Petersburg State Pediatric Medical Academy, St. Petersburg, Russian Federation.

Recent studies showed that chromosomal rearrangement could affect the behavior at meiosis of other chromosomes (interchromosomal effect). If ICE makes any appreciable contribution to etiology of aneuploidy, one may expect an incidence of balanced Rea in parents of aneuploid offspring is increased over population figure.

Objectives: Meta analysis of own and published data on incidence of autosomal balanced Rea in patients with T21, in parents of offspring with T21, and in newborn controls. Meta analysis of own and published data on parental and cell origin of T21 in offspring of carriers of autosomal balanced Rea.

Results: An increase in incidence of reciprocal translocations and inversions (but not of robertsonian translocations) in parents of offspring with T21 (7.1‰ and 2.7‰) compared to controls (1.5‰ and 0.4 ‰), $p<0.001$ and $p<0.01$, correspondingly. Absence of typical female predominance among carrier parents (12 females/13 males) and a predominance of paternally derived Rea in patients with T21 (5 maternal/9 paternal). Similar proportion of T21 of maternal origin in the affected progeny of both maternal and paternal Rea carriers. However when the Rea was maternal, a typical prevalence of errors in the 1st meiotic division of oogenesis was observed while in cases where the Rea was paternal, the profile of errors in oogenesis was different, with a high proportion of errors in 2nd meiotic division.

Conclusion: We did not find evidence of paternal ICE. Instead, the data obtained allow us speculating about a post fertilization effect of paternal Rea on segregation of maternal chromosomes.

P03.134

A prenatal diagnosis case with trisomy 4 confined to placenta

***M. Souto**[1], P. Correia[2], P. Botelho[1], R. Nogueira[3], M. Martins[4], O. Moutinho[4,2], R. Pinto Leite[1];*
[1]Laboratório de Citogenética, Serviço de Genética, Centro Hospitalar Trás-os-Montes e Alto Douro, Vila Real, Portugal, [2]Serviço de Ginecologia/Obstetrícia, Centro Hospitalar Trás-os-Montes e Alto Douro, Vila Real, Portugal, [3]Serviço de Anatomia Patológica, CGC, Centro de Genética Clínica, Porto, Portugal, [4]Serviço de Genética, Centro Hospitalar Trás-os-Montes e Alto Douro, Vila Real, Portugal.

Confined placental mosaicism (CPM) is diagnosed when some trisomic cells are detected on chorionic villus sampling (CVS) and only normal cells are found on a prenatal test, such as amniocentesis. CPM is detected in approximately 1-2% of ongoing pregnancies that are studied by CVS at 10 to 12 weeks of pregnancy.

Most pregnancies that are diagnosed with CPM continue to term with no complications and the children develop normally. However, some pregnancies with CPM have complications, due to placental dysfunction, uniparental disomy of the fetus and undetected mosaic trisomy of the fetus. The risks for these settings depend of the origin of error, level of mosaicism and chromosome involved.

The study of CVS in normal karyotype fetus with ultrasound abnormalities may be considered, since in some cases, can help in the diagnosis.

Case report:

A 31 years-old primigravida was referred to amniocentesis at 25 weeks of gestation after the detection of ultrasound abnormalities and intrauterine fetal death (IUFD). The karyotype was 46, XY. The post mortem examination showed early fetal death with a maturity corresponding to 24 weeks, IUGR and short femur, coexisting micrognathia, nuchal edema (2.1mm), mild hydrocephalus, cerebellar vermis hypoplasia, bilateral pyelectasis and pulmonary hypoplasia. Cytogenetic analysis of placenta sampling showed a karyotype of 47, XY, +4 in all cells examined.

Mosaicism of trisomy 4 is a rare condition, with 8 cases reported in the literature, and usually associated with anomalies. The authors compare the cytogenetic and the fetus's clinical findings with those described in the literature.

P03.135

Study of Turner Syndrome and presentation of unique cases within the Jordanian population

***H. Daggag**, W. Srour, M. El-Khateeb, K. Ajlouni;*
National Center for Diabetes, Endocrinology and Genetics, Amman, Jordan.

Chromosomal number and structure determine the normal gender phenotype in humans. Carrying a copy of the X and Y chromosome determines the male phenotype and carrying two copies of the X chromosome determines the female phenotype. However, in some cases abnormalities in number and/or structure of the chromosomes are associated with a wide range of syndromes, including Turner syndrome. Turner syndrome affects approximately 1 in 2,500 liveborn females, with the most common karyotype in the affected individuals being 46, XO. The reminder of the patients, however, carry mosaic cell lines containing a second sex chromosome (either X or Y chromosome). In about 6% of the female Turner syndrome patients, the second cell line would contain a structurally abnormal Y chromosome. In the current study, we have reviewed 136 positive Turner syndrome cases that have been referred to the National Center for Diabetes, Endocrinology and Genetics, Amman, Jordan. We summarize the data obtained, with a special focus on 2 cases with unique karyotypes and 16 cases which present with structural abnormalities of the Y chromosome. Experimental approaches utilized include standard karyotyping, probe-specific FISH and *SRY* gene sequencing.

P03.136

Turner syndrome with a ring X chromosome and atypical manifestation

***E. Braha**[1], M. Gramescu[1], C. Bujoran[2], M. Panzaru[1], R. Popescu[1], M. Volosciuc[2], C. Rusu[1], E. Gorduza[1];*
[1]University of Medicine and Pharmacy „Grigore T.Popa", Iasi, Romania, [2]Pediatric Hospital „Sfanta Maria", Iasi, Romania.

Turner syndrome is a disease characterized by ovarian dysgenesia determinated by partial or complete absence of one X chromosome. Approximately 6% of patients have ring X chromosome. Clinical features are heterogeneous and typical physical anomalies are often mild or absent.

The 3 years 10 months old girl was reffered to the genetic department due to myelomeningocele and severe developmental delay. The patient had short stature, a broad forehead, dysmorphic face Kabuki-like, myelomeningocele, bilateral hydronephrosis, possible cardiac anomalies (heart murmur 2/6 degree on left sternal border) and mental retardation. The karyotype showes mosaicism 45,X [51.06%]/ 46,X,r(X) [48.94%] . FISH test for XIST locus is in study.

Patients with r(X) are reported to have a higher incidence of a more severe phenotype and usually present mental retardation. Some studies have shown a correlation between the phenotype severity and the presence or absence of a functional XIST. Our patient showed a atypical clinical features with reminescent features of Kabuki syndrome. The prognosis of the patient is poor, is largely based on the severity of clinical condition.

P03.137

The power of SNP array: incidental diagnosis of paternal uniparental disomy of chromosome 15 in a child with a large chromosomal deletion of 11q21q22.3

***K. Schlade-Bartusiak**[1,2], T. Tucker[1], T. Oh[3], T. Nelson[1], P. Eydoux[1], M. Van Allen[3,2], M. Steinraths[3];*
[1]Department of Pathology and Laboratory Medicine, University of British Columbia, Vancouver, BC, Canada, [2]Child and Family Research Institute, Vancouver, BC, Canada, [3]Department of Medical Genetics, University of British Columbia, Vancouver, BC, Canada.

Array analysis is a first line diagnostic test used to search for copy number changes in children with developmental delay and/or congenital anomalies. SNP-based arrays provide additional information about copy number neutral large contiguous regions of homozygosity (LCSH), which can reflect parental relatedness or uniparental disomy (UPD). A proportion of Prader-Willi and Angelman syndromes are caused by maternal and paternal UPD of chromosome 15, respectively. Both syndromes have distinct phenotypes and are usually suspected clinically and confirmed with molecular studies.

Here we report a patient with prenatal onset of growth impairment, developmental delay, bilateral iris colobomas and dysmorphic features. SNP array (Affymetrix) analysis showed a 12.9 Mb deletion of chromosome 11q21q22.3, as well as a 25 Mb LCSH on chromosome 15q11.2q21.1. As a single LCSH detected on SNP array is suggestive of UPD, molecular analysis of the methylation pattern and parental inheritance was performed and confirmed the presence of paternal UPD of chromosome 15. On reevaluation at 20 months of age, the patient showed global developmental delay but overall good health including no seizures. In general, she was felt clinically to be doing better than expected for a child with both Angelman syndrome and additional large chromosomal imbalance.

This is a first report of a patient with a UPD syndrome and additional, apparently unrelated, chromosomal rearrangement. The diagnosis of Angelman syndrome was not suspected clinically in our patient and represents a fortuitous finding. This case highlights the power of SNP based arrays in providing relevant clinical diagnosis.

P03.138

Maternal segmental uniparental disomy 14 in an adult patient with typical upd(14)mat phenotyp

***D. Niedrist**, B. Oneda, A. Baumer, A. Rauch;*
Institute of Medical Genetics, University of Zurich, Schwerzenbach-Zurich, Switzerland.

We report on a 26 year old graduate student with short stature (161cm), low birth weight (2010g at term), feeding difficulties in the first 3 years of life followed by abiding hunger, truncal obesity, muscular hypotonia, small hands and feet, precocious puberty and hyperlipidemia. Chromosomal examination revealed a normal male karyotype 46,XY and methylation/deletion testing on 15q11-q13 gave no clue for Prader-Willi-Syndrome. In the following marker testing for upd 14 only 2 out of 4 markers were informative and the 2 informative markers showed biparental inheritance. Molecular karyotyping was performed (Affymetrix Cytogenetics 2.7M Array) and no known chromosomal aberration was found. However on chromosome 14 a very long homozygosity was suspicious. We repeated marker testing on chromosome 14 with 7 markers and could verify **segmental maternal uniparental disomie 14q24.2-qter**. The phenotype of our patient fits well for maternal uniparental disomy 14. We conclude upd in the region 14q24.2-qter being responsible for the full phenotype of upd (14) mat and emphazise the importance of testing several informative markers in this region in patients with suspected upd 14. Our results are confirmed by different reports in the literature about patients with epimutations at 14q32.2.

P03.139

Simultaneous occurrence of a duplication encompassing the Wolf-Hirschhorn-Syndrome critical region 2 and a terminal deletion of chromosome 4p in a patient with multiple congenital malformations and developmental delay.

***S. Leubner**, S. Anders, S. Demuth, S. Riedel, C. Ramel, A. Junge;*
Mitteldeutscher Praxisverbund Humangenetik, Dresden, Germany.

We report on a female patient with multiple congenital malformations (e.g. anal atresia, tetralogy of Fallot, club foot and cervical spine abnormalities), delayed motor skills and language impairment that shows a small duplication in the short arm of chromosome 4 and a terminal deletion of 4p.

Conventional cytogenetic analysis (GTG- banding), Fluorescence- in situ hybridization (FISH), multiplex ligation- dependent probe amplification analyses (MLPA) and array- based comparative genomic hybridization (aCGH) were performed.

We used an oligonucleotide- based array with an average probe distance of 100 kb (CytoChip Oligo 2x105k v.1.1, BlueGnome). The aCGH analysis re-

vealed a 0.5 Mb duplication, encompassing the Wolf- Hirschhorn- Syndrome critical region 2 (WHSCR-2), and a terminal deletion on 4p16.3 spanning 1.6 Mb.
According to our current knowledge there are only two cases given in the literature with simultaneous occurrence of a duplication of the WHSCR-2 and a terminal deletion 4p (reviewed by Roselló et al. 2009).
The data of our patient help to improve characterization of the phenotype caused by a duplication of the WHSCR-2 in combination with a terminal deletion of chromosome 4p.

P03.140

Wolf-Hirschhorn syndrome phenotype due to der(4)t(4;8)(p16.1;p23.1) caracterized by aCGH

K. T. Abe[1], *L. M. Formigli*[1], *M. Leyser*[2], *B. L. S. Dias*[2], *L. L. Roese*[3], *M. Schneider*[1], *M. V. Oliveira*[1], *C. E. Speck-Martins*[1];
[1]*SARAH Network of Rehabilitation Hospitals, Brasília - DF, Brazil., Brasilia - DF, Brazil,* [2]*SARAH Network of Rehabilitation Hospitals Rio de Janeiro – RJ – Brazil, Rio de Janeiro, Brazil,* [3]*SARAH Network of Rehabilitation Hospitals, Brasília – DF, Brazil., Brasilia - DF, Brazil.*

A partial 4p deletion causes a Wolf-Hirschhorn syndrome (WHS) phenotype. On the other hand, 8p23.1->pter duplication was reported without phenotypic effect. We report on 5-year-old female with deletion of 4p and duplication of 8p presenting WHS phenotype. GTW-banding, FISH and array-CGH were performed and the karyotype was 46,XX,der(4)t(4;8)(p16.1;p23.1)dn.arr 4p16.1(130,000-8,202,790)x1,8p23.1(304,160-6,396,578)x3. She had developmental delay, seizures and dysmorphisms as long eyelashes, synophrys, malrotated helices of ears, micrognatia, a posterior cleft palate, feeding difficulty, cardiac disease and hiper-rotated kidneys. At five years, she has no verbal comunication, and does not walk. The patient phenotype is likely due to 4p deletion and the small 8p duplication seen has no phenotypic effect as reported in the literature. A report of the same band region 8p23.1 is refered to interrupt on *GATA4* gene related to congenital heart defects, however our patient has a 8p duplication started at 5Mb from that gene, thus we thought that her cardiac disease could not related to *GATA4* gene. Furthermore, the breakpoint in 8p is related as recurred in the same region on patients presenting t(4;8) with about 8 Mb trisomic 8p segment. Differently, our patient has an average 6.09 Mb duplication 8p, and lead to smaller size duplication than refered in the related reports. Although the basic genomic defect and the phenotype in WHS is heterogeneous, most of the morphological traits of the hybrid phenotype in the child with der(4)t(4;8)(p16.1;q23.1) can be attributed to deletion of 4p16.1, since terminal duplication of 8p likely have no phenotypic effect.

P03.141

Delineation of syndromic Wolff-Parkinson-White due to a 20p12.3 microdeletion of the *BMP2* region in a boy, his sister and their mosaic mother

M. Nystad[1], *A. Jørgensen*[1], *Ø. Nilssen*[1,2], *V. Marton*[1,2];
[1]*Department of Medical Genetics, Division of Child and Adolescent Health, University Hospital North Norway, NO9038 TROMSOE, Norway,* [2]*Department of Clinical Medicine – Medical Genetics, Faculty of Health Sciences, University of Tromsø, NO9037 Tromsø, Norway.*

OBJECTIVE:
We report on the clinical and genetic findings in a family with variable phenotypic expression of a 20p12.3 microdeletion. The proband was a young man with re-entrant tachycardia due to Wolff-Parkinson-White syndrome (WPW), dysmorphic features, skeletal findings and cognitive deficits.
METHODS:
DNA from the patients, the father and an older, healthy sister of the proband was analysed using a 105 k (G4425B-014698) Human Genome CGH Oligo Microarrays (Agilent Technologies, CA). An additional Affymetrix 2.7 SNP array analysis was performed on DNA from the mother to check for mosaicism. FISH-analysis of metaphase chromosomes (>50 metaphases) and interphase nuclei (>100 nuclei) were done using BAC FISH probes (RP11-184L8 (*BMP2*-gene) and a control probe RP11-977N11 (20q13.2)) were obtained from Empire Genomics (http://www.empiregenomics.com).
RESULTS:
Agilent 105k aCGH analysis revealed a 970 kb deletion, including the *BMP2*-gene, with genome position g.(6265313_6333051)_(7158672_7235395), at 20p12.3, in the proband, and in the mother. FISH-analysis of the proband and his younger sister detected a microdeletion of the *BMP2*-gene in all cells analyzed. Fifty seven percent of the mother´s blood cells manifested the deletion, revealing a mosaic state. aCGH and SNP array analysis provided no calls for mosaicism.
CONCLUSIONS:
We have reported three patients with 20p12.3 microdeletion, without complete penetrance for WPW syndrome and cognitive impairment. Mosaicism might escape detection by array-based karyotyping techniques. This underscores the importance of employing FISH analysis whenever mosaicism is suspected.

P03.142

Chromosome Xp deletions- Variable phenotypes within several families

A. Reches[1], *R. Sukenik-Halevy*[1], *A. Orr-Ortreger*[1,2], *Y. Yaron*[1,2], *S. Ben-Shachar*[1];
[1]*Genetic Institute, Tel Aviv, Israel,* [2]*Sackler Faculty of Medicine, Tel Aviv, Israel.*

Background: The clinical expression of Xp deletions varies according to gender, deletion size and genomic content, X inactivation pattern and other factors. We describe our experience with female carriers of Xp deletions.
Method: Families of female Xp deletion carriers were assessed. Family history was obtained and clinical evaluation of family members was preformed. Karyotype was analyzed for available family members, as well as in the setting of prenatal diagnosis. Assessment of the X inactivation pattern was evaluated when possible
Results: Three families were assessed. Family 1 consisted of multiple female carriers of an Xp22.1 deletion. All had short stature and some had additional problems such as delayed motor & speech development, emotional oversensitivity, excessive weight gain and attention deficit disorder. Prenatal diagnosis was declined. CMA analysis is pending Family 2 was ascertained during pregnancy with a complex fetal heart malformation. The female fetus had a terminal deletion at Xp22. The pregnancy was terminated. Both mother and maternal grandmother, who had short stature, had the same deletion, as well as 2 female fetuses in subsequent pregnancies. All had a skewed X inactivation pattern. Family 3 presented in pregnancy with fetal short femurs at 22 weeks. Fetal karyotype showed a maternally inherited terminal deletion at Xp21.3. Pregnancy was terminated. The couple is in the midst of PGD, so far with low ovarian response
Conclusions: Xp deletions are associated with variable inter and intra-familial phenotypes. This difficulty in predicting clinical outcome is a challenging issue, especially in prenatal counseling.

P03.143

The breakpoint sequence of a 10,5Mb Xp22 duplication causing a developmental disorder in a male patient.

T. Bettecken[1], *B. Nehls*[1], *E. Schellenberger*[2], *W. Kress*[3];
[1]*Center for Applied Genotyping - CAGT, MPI for psychiatry, München, Germany,* [2]*Kinderklinik am Mönchberg, Würzburg, Germany,* [3]*Institute of Human Genetics, Würzburg, Germany.*

Microscopically visible segmental duplications of the short arm of the X chromosome are relatively rare findings and only a few reports exist. All male patients reported show mental retardation combined with various additional dysmorphic features. Most cases are inherited from a heterozygous but otherwise asymptomatic mother. Here, we report on the breakpoint sequence of an Xp22 duplication found in a now 17 year old severely retarded patient. The duplication was initially seen by classical cytogenetic analysis and confirmed later by molecular karyotyping on Illumina SNP chips. The limits of the duplication could be determined this way to within a few kilobases. The duplicated region comprises of about 10.5 Mb on Xp22 and is containing more than 200 genes. The breakpoints of the duplication were determined by sequencing the 5.5 kb amplicon containing the breakpoints and found to lie in a region of Alu elements of about 300 bp and of very high homology.

P03.144

A report of a new case with Xq chromosome duplication

L. I. Butnariu, *C. Rusu*, *L. Caba*, *M. Panzaru*, *E. Braha*, *M. Macovei*, *M. Gramescu*, *E. Gorduza*;
University of Medicine and Pharmacy "Grigore T. Popa", Department of Medical Genetics, Iasi, Romania.

Rare duplications can occur on the long arm of the X chromosome and may be familial or de novo. They may lead to different phenotypes, depending on the X chromosome region affected. Most dup (Xq) females appear phenotypically normal, or may manifest short stature, facial dysmorphy and gonadal dysgenesis.We present the phenotypic findings of one patient with Xq duplication: C.I, female, 1 year old who was reffered to our hospital for proportional dwarfism. Clinical evaluation also revealed craniofacial dysmorphy: down-slanted palpebral fissures, epichantus, broad nose and lowset ears. Other features were mild pectus excavatum, right hand with clinodactyly of the fifth finger and mild psychomotor retardation. Paraclinical evaluation:

growth hormone and thyroid hormone levels were normal.

The karyotype was abnormal and revelead a Xq duplication: 46,X,dup(X)(q13q22), who included “critical region” (Xq13-q21) involved in premature ovarian failure. The proximal region of Xq contains genes that normally escape to X chromosome inactivation. In this context we appreciate that the patient may have fertility problems such as primary or secondary amenorrhea.

We could not do the karyotypes of the parents, necessary to establish the origin of the chromosomal abnormality, because the child was placed in a institutional care setting.

P03.145

Familial interstitial direct duplication of chromosome (X)(q23q25) detected by aCGH associated with phenotypic variability

V. Belengeanu[1], *D. Misceo*[2], *M. Stoian*[1], *N. Andreescu*[1], *S. Farcas*[1], *D. Belengeanu*[1], *T. H. Gamage*[2], *T. Barøy*[2], *E. Frengen*[2];
[1]*University of Medicine and Pharmacy, Timisoara, Romania,* [2]*Department of Medical Genetics, Olso University Hospital and University of Oslo, Oslo, Norway.*

Chromosomal rearrangements occur frequently in patients with mental retardation associated or not with other anomalies. Two brothers and their mother were investigated for mental retardation. Initially, a 32 years-old man was evaluated due to short stature, facial dysmorphism with prognathism, obesity, hypoplastic genitalia, developmental delay and behaviour problems, especially with regard to eating. His brother presented with mild facial dysmorphism, mental retardation and misbehaviour. The mother had milder phenotypic features and mild mental retardation. For this family the IQ varies from 40 for propositus, to 50 for his brother, and 60 for their mother.

Standard cytogenetic analysis for propositus was normal. Because the clinical signs were suggestive for Prader-Willi syndrome, FISH analysis was performed, but no deletion on 15q11q13 was found. Addional testing with MS-MLPA for Prader-Willi syndrome was also negative. Array CGH analysis (180k Agilent) on patient revealed a chromosome X duplication, chrX:115568872-126991548 bp, hg19. By quantitative Real-Time PCR the duplication was verified in the proband and also detected in his brother and mother. BAC FISH established that the duplication is in situ and has a direct orientation. Result of the X inactivation study in the mother showed 100% skewing in leukocytes.

In our case the duplicated region Xq23q25 seems be associated with phenotypic variability. Because the phenotypic variability of the two brothers couldn’t been explained we suspected a possible influence of other genes on the expression of the genes within Xq23q25 region, as well as epigenetic factors influence.

P04.02

Partial deletion of *DMRT1* causes 46,XY ovotesticular disorder of sexual development (DSD)

S. Ledig[1], *O. Hiort*[2], *L. Wünsch*[2], *P. Wieacker*[1];
[1]*Westfälische Wilhelms Universität Münster, Münster, Germany,* [2]*University of Lübeck, Lübeck, Germany.*

Ovotesticular disorder of sexual development (DSD) is an unusual form of DSD, characterized by the presence of testicular and ovarian tissue in the same individual. In a subset of patients ovotesticular DSD is caused by 46,XX/46,XY chimerism or mosaicism. To date only few monogenetic causes are known to be associated with XX and XY ovotesticular DSD like mutations in *RSPO1*, *SRY* and *SOX9*.

We performed high-resolution array-CGH (comparative genomic hybridization) in a female patient with 46,XY ovotesticular DSD with testicular tissue at the one side and an ovary harbouring germ cells on the other. We identified in the patient a small deletion affecting exons 3 and 4 of the *DMRT1* gene. Results obtained by array-CGH were confirmed by RT-qPCR (quantative PCR).

To this point of time, deletions and missense mutations of *DMRT1* are associated only with XY gonadal dysgenesis. But according our present findings we conclude that haploinsufficiency of *DMRT1* can cause both, XY gonadal dysgenesis and XY ovotesticular DSD. Furthermore, to the best of our knowledge, this is the smallest deletion affecting *DMRT1* in a patient with DSD presented to this point of time

P04.03

High throughput copy number counting in single cells - a method for the detection of meiotic and mitotic errors

A. Daser[1], *E. Day*[2], *B. Konfortov*[2], *A. Immesberger*[3], *H. Turley*[3], *T. Hahn*[1,3], *U. Zechner*[4], *T. Haaf*[5], *P. H. Dear*[2], *M. Schorsch*[1,3];
[1]*SH-Gen Research, Wiesbaden, Germany,* [2]*MRC-Laboratory of Molecular Biology, Cambridge, United Kingdom,* [3]*Kinderwunschzentrum, Wiesbaden, Germany,* [4]*Institut für Humangenetik, Mainz, Germany,* [5]*Institut für Humangenetik, Würzburg, Germany.*

Clinical background are the low pregnancy and baby take home rates after in vitro fertilisation techniques (IVF). Major reason is the high frequency of chromosomally abnormal (i.e. aneuploid) oocytes. Selection of euploid oocytes is thus an attractive strategy to increase the number of live births following IVF.

The ploidy status of oocytes can be indirectly investigated by analysing the chromosome content in polar bodies (PB) I and II which are results of the first and second meiotic division before and after fertilisation; errors in meiotic divisions are due to chromosome non-disjunction and early sister chromatid separation. Therefore investigation of the chromosome content of PB I and II requires techniques which allow investigation of all chromosomes at the resolution of chromatids.

In contrast to microarray formats we count chromatids directly - molecular copy number counting (MCC) applied to a single cell, i.e. polar body. MCC is based on limiting dilution of the DNA to a concentration of less than one molecule per PCR reaction and digital PCR. The number of chromatids per chromosome is analysed by counting the numbers of positive PCR reactions representing target sequences on all chromosomes. To investigate all chromosomes with several markers we run a multiplex PCR followed by single marker PCRs with the BioMark system from Fluidigm.

This method is simple and applicable to monitor not only meiotic but also mitotic cell divisions, copy number changes in general and to establish haplotypes for regions of interest in any given single cell.

P04.04

M2/ANXA5 is a risk factor for recurrent pregnancy loss (RPL) in a population undergoing in vitro fertilisation (IVF)

F. Tüttelmann[1], *R. Pavlik*[2], *S. Hecht*[2], *N. Bogdanova*[1], *M. Nothnagel*[3], *T. Balschun*[3], *M. Krawczak*[4], *C. Thaler*[2], *A. Markoff*[5];
[1]*Institute of Human Genetics, Münster, Germany,* [2]*Hormone and Fertility Center LMU, Obstetrics and Gynecology, Munich, Germany,* [3]*Institute of Clinical Molecular Biology, UKSH, Kiel, Germany,* [4]*Institute for Medical Informatics and Statistics, UKSH, Kiel, Germany,* [5]*Institute of Medical Biochemsitry, ZMBE and IZKF, Münster, Germany.*

Carriage of the M2 promoter haplotype of ANXA5 was verified as risk factor for RPL in various patient cohorts. M2/ANXA5 results in reduced expression levels of the protein in placenta leading to various thrombophilia related placental pathologies and ultimately RPL. We performed a risk stratification study in women undergoing IVF.

The IVF cohort of 695 women from the Hormone and Fertility Center, Munich, 500 fertile female controls from the Institute of Human Genetics, Münster and 533 population controls from the PopGen biobank, Kiel were genotyped via sequencing. Equal genetic backgrounds were confirmed through genome-wide SNP analysis.

Carriers of M2 faced a higher relative risk of 1.2 to belong to the IVF group compared to population controls and of 1.4 in comparison with fertile women. This overall elevated risk was contributed by a subgroup of women with previous pregnancy losses, where the appropriate relative risks amounted to 2.3 and 3.8 accordingly. Carriage of M1 or M2 was not associated with biochemical pregnancy loss, implantation rates, ovary reserve, hormone status, number and quality of egg cells and general embryonal development. Interestingly, successful pregnancy outcomes tended to be more frequent for M1 carriers with comparable losses rate. This would signify a possible protective function for M1 in pregnancy, as previoulsy suggested.

In conclusion, the effect of M2/ANXA5 on pregnancy losses was reconfirmed. This excludes biochemical pregnancy losses and implantation failures. There is a possible protective effect of M1 carriage on pregnancy outcomes that needs further evaluation in other patient cohorts.

P04.05

Y chromosome AZF deletions/duplications and spontaneous pregnancy loss

S. Madjunkova[1], *A. Kumnova*[2], *K. Stankova*[3], *P. Gerasimova*[4], *M. Madjunkov*[5], *D. Plaseska-Karanfilska*[1];
[1]*Macedonian Academy of Sciences and Arts, Skopje, The Former Yugoslav Republic of Macedonia,* [2]*Private health organization „Aida“, Gjakovica, Kosovo, Republic of,* [3]*Private health organization „INA“, Skopje, The Former Yugoslav Republic of Macedonia,* [4]*Private health organization „Dr. Pavlina Gerasimova“, Skopje, The Former Yugoslav Republic of Macedonia,* [5]*Clinic for gynecology and obstetrics, Medical faculty, Skopje, The Former*

Yugoslav Republic of Macedonia.

Spontaneous abortion (SA) is the most common pathology in obstetrics with incidence of 10-15% among clinically recognized pregnancies. The occurrence in three or more consecutive pregnancies is defined as recurrent SA with incidence of 0.5-3% in women trying to conceive. The etiology is diverse and multifactorial (uterine abnormalities, autoimmune, infectious, endocrine, and genetic factors) but still the major part of it (50-60%) remains idiopathic. The male factor has been poorly evaluated in SA. The aim of this study was to determine the association of Y chromosome AZF deletions/duplications with spontaneous pregnancy loss. One hundred and seven men from couples experiencing two or more SA, and 116 fertile men were enrolled in this study. DNA extracted from whole blood was tested for presence of sex chromosome aneuploidies, AZF deletions, partial AZFc deletions and duplications using 13-plex quantitative fluorescent PCR and subsequent capillary electrophoresis on ABI 3130 Genetyc Analyzer. In total, three partial AZFc deletions (1 gr/gr and 2 b2/b3) and 21 AZFc duplications (12 b2/b4 and 9 b2/b3) were detected. Partial AZFc deletions were slightly more frequent among men with SA (1.87%) in comparison to controls (0.86%), while the AZFc partial duplications were more frequent among controls (12.07%) than in men with SA (6.54%). None of the men with SA and controls had any sex chromosome aneuploidy or complete AZF deletions. In conclusion, our study suggests that partial AZFc deletions might represent a male risk factor for SA, while partial AZFc duplications might have a protective role.

Introduction. Infertility is a worldwide reproductive health problem that affects approximately 15% of married couples. Defects in the CYP21A2 gene cause steroid 21-hydroxylase deficiency, which is the most frequent cause of congenital adrenal hyperplasia (CAH). CAH is a genetic condition that can affect both men and women. In this study we have analyzed mutations of the CYP21A2 gene in couples with unexplained fertility problems and healthy controls.

Methods. DNA was extracted from peripheral blood samples. Allele specific PCR was performed for the detection of mutations IVS2-12 A/C>G and I172N. Gene deletion/conversion was detected with competitive PCR and capillary electrophoresis.

RESULTS. 160 couples with unexplained fertility problems and 200 healthy controls were included in the study. All three mutations were detected as presented in the table.

Cconclusions. The present finding indicates that no significant difference in the prevalence of CYP21A2 mutations can be found in probands with fertility problems when compared with controls without an infertility history. The results also imply that the presence of the most common mutations in the CYP21A2 gene by heterozygote carriers has no influence on their fertility.

Results of CYP21A2 mutation analysis

Mutations	Couples with unexplained fertility problems (n = 320)	Healthy controls (n = 200)
IVS2-12 A/C>G	4	3
Exon 4/I172N	1	0
deletion/conversion	3	3
Total CYP21A2 mutations	8	6
Chi square (all samples vs. Controls) 0.11, p = 0,739 (df = 1)		

P04.08

Spectrum of chromosomal heteromorphism variants of infertile patients undergoing for Assisted Reproductive Technology (ART)

S. Zoukovskaya[1], *N. Rumiantsava*[2], *L. Savenko*[2], *H. Abramchik*[1], *L. Shamgina*[1];
[1]*Center of Reproductive Medicine, Minsk, Belarus,* [2]*Republican Medical Centre "Mother and Child", Minsk, Belarus.*

Cytogenetic studies of infertility patients, couples with recurrent pregnancy loss are important part of ART service. Variation in length of heterochromatin regions, stalks, satellites are described as phenomena without phenotypic effects, but relationships between chromosome polymorphism and reproduction are under investigation.

We present the data of chromosome heteromorphism variants (ChrHV) detected in couples, referred to ART.

Among 2148 patients, examined by standard karyotyping during 2010-2011 years, ChrHV were revealed in 460 cases (22%, sex ratio 1:1). The spectrum of involved chromosomes included: 1 (2.4%), 9 (6.1%), 13 (23.5%), 14 (26.3%), 15 (23.5%), 16 (2.2%), 21 (17.7%), 22 (11.5%), Y (3.7%). Heteromorphism of single chromosome was detected in 82.8%, two chromosomes in 14.6%, three chromosomes in 2.6% cases. Total number of ChrHV was 68. Single variant (ps+, pss, pstk+, ph, phqh, qh) was revealed in 80.4% patients. Association of 2 variants in the same (13pstk+ps+; 14pstk+ps+; 15pstk+ps+, etc.) or different chromosomes (1qh+,Yqh+; 13ps+,22ps+; 14pstk+, 15pstk+; 21pstk+,Yqh-, etc.) was found in 16.1% cases. 3% persons displayed 3 variants: 9ph,13pstk+,21pstk+; 9qh-,14pstk+,15pss; 13pstk+,14pstk+,15pstk+; 13pstk+,21pstk+,22pstk+; 14pstk+,15pstk+ps+; 14pstk+,15pstk+,15pstk+; 15pstk+,21pstk+,22pstk+; 21pstk+,22pstk+ps+,etc. One patient showed 4 variants: 46,XX,14pstk+,21pstk+,21pstk+ps+. The common ChHV were: 14pstk+ (17,4%), 15pstk+ (13%), 13pstk+ (12,2%), 21pstk+ (9,3%). Polymorphism of heterochromatic segments of chromosomes 1, 9, 16, Y identified in 13% cases. Variants 9phqh, 15pss, var15(q11.2q13) registered rarely.

Results demonstrate a wide spectrum of ChHV in infertile couples. For best understanding of relationships "ChHV-reproductive failure-outcome prognosis", especially in rare sporadic variants, the balance of karyotype is to be confirmed with suitable methods, including molecular cytogenetic analysis.

P04.09

Chromosomal outcome of 110 children born after Assisted Reproductive Technology (ART)

S. Zari Moradi, *H. Gourabi, A. Mohseni Meybodi, N. Masoudi, K. Anissi Hemaseh;*
Department of Genetics, Reproductive Biomedicine Research Center, Royan Institute for reproductive Biomedicine ,ACECR., Tehran, Islamic Republic of Iran.

There is a large population of children conceived via Assisted Reproductive Technology (ART), which continues to increase worldwide, without a clear understanding of associated long-term outcomes. There is growing evidence that ART children seems to be different from naturally conceived children. For routing through

these differences, we evaluated cytogenetic results occurring in children born after ART, using their cord blood lymphocytes.We investigated the karyotypes of 110 samples From January 2010 till January 2012, using standard GTG banding. 5 (4.5%) chromosomal alterations were detected among these children. 3(2.72%) of these

aberrations were diagnosed in one of the parents, and 2(1.81%) were de novo changes. In comparison with the frequency of these abnormalities in newborns of general population (0.5%-1%), our results shows a slightly higher incidence of chromosomal changes among children born after ART. There is no much higher risk

of chromosomal abnormalities due to ART. Therefore, these alterations could be correlated with the underlying parental

risk of abnormalities and not with the ART procedure itself. Although ART is now accepted as the treatment of choice for severe infertilities, concerns about its safety and the potential risks for the offspring remain.

P04.10

SEMA7A and *SEMA3A* in congenital hypogonadotropic hypogonadism

J. Känsäkoski[1], *E. Laitinen*[2], *R. Fagerholm*[1], *T. Raivio*[1,2], ***J. Tommiska***[1,2];
[1]*University of Helsinki, Institute of Biomedicine/Physiology, Helsinki, Finland,* [2]*Children's Hospital, Helsinki University Central Hospital (HUCH), Helsinki, Finland.*

Congenital hypogonadotropic hypogonadism (HH) is characterized by incomplete or absent puberty caused by the lack or deficient number of hypothalamic gonadotropin-releasing hormone (GnRH) neurons, disturbed secretion or action of GnRH, or both. Several genes are connected with the disorder, but in ~70% of the cases the genetic cause remains unresolved. *Sema3a* and *Sema7a* mutant mice have a reduced number of GnRH neurons in their brains, *Sema3a* being essential for the patterning of vomeronasal axons while in *Sema7a* mutants the olfactory system remains unaffected. Thus, *SEMA3A* is a good candidate gene for Kallmann syndrome (HH and hyposmia/anosmia) and *SEMA7A* for normosmic HH (nHH). Whole-exome sequencing of a patient with nHH revealed a heterozygous mutation, R148W, in *SEMA7A*. It was predicted probably damaging by PolyPhen2, and absent in 200 controls. Sanger-sequencing of *SEMA3A* and *SEMA7A* in 40 other patients revealed no other rare variants. However, the patient with the *SE-*

MA7A mutation also had a heterozygous mutation, C389X, in *KISS1R*, a gene implicated in autosomal recessive nHH and encoding kisspeptin receptor with an important role in regulating GnRH secretion. No other *KISS1R* mutation was found in the patient when genomic DNA and cDNA was sequenced. We hypothesize that the nHH of this patient could result from a combination of a reduced number of GnRH neurons and a reduced number of functional kisspeptin receptors in them. Our findings provide support for the role of *SEMA7A* mutations in the pathogenesis of HH in human, and for the proposed digenic or oligogenic inheritance in this disorder.

P04.11

Evidence for expression of *Cyp19A1* (cytochrome P450, family 19, subfamily A, polypeptide1) in human embryonal carcinoma cell line

K. Fallah-Zadeh[1,2], *R. Favaedi*[1], *M. Khosravifar*[1], *P. Afsharian*[1], *M. Nabioni*[2], *M. Shahhoseini*[1];
[1]*Department of Genetics, Reproductive Biomedicine Center, Royan Institute for Reproductive Biomedic, Tehran, Islamic Republic of Iran,* [2]*Department of Animal Biology, Faculty of Biological Science, Kharazmi University (TMU), Tehran, Islamic Republic of Iran.*

Introduction
Cyp19A1 is a single copy gene located on chromosome 15q21.2 in human genome which encodes aromatase, the key enzyme for estrogen biosynthesis. In the final step of mentioned process, this integral membrane enzyme catalyzes the removal of 19-methyl group of the A-ring of androgens in an irreversible manner, resulting in conversion of androgen to estrogen which named aromatization. In human, aromatase gene is expressed in a tissue specific manner, in the way that expression of *Cyp19A1* has been reported in organs such as gonads, brain, skin, placenta and adipose.
Embryonal carcinoma (EC) cells derived from testicular tumors are valuable tools for investigating embryogenesis and developmental biology processes. Since EC cells are malignant but their terminally differentiated derivatives are not, understanding the expression profile of these embryonal cells maybe be of value for diagnostic and maybe therapeutic purposes in embryology.
Material and methods
In the current work, the mRNA expression level of *Cyp19A1* gene was evaluated in a human EC cell line named NT2/NTERA2, using quantitative real-time PCR technique.
Result and discussion
Our results clearly showed the expression of *Cyp19A1* in NT2 cell line. Our finding implies a dynamic role of *Cyp19A1* aromatase gene in developmental processes and maybe in cancer.

P04.12

Performance Evaluation of the Celera Cystic Fibrosis Genotyping Assay with the 3500xL Genetic Analyzer (RUO*) and Three Nucleic Acid Isolation Technologies

K. C. Young, *P. P. Wadia, D. A. Bost;*
Celera, Alameda, CA, United States.

Cystic Fibrosis is a recessive inherited genetic disorder, resulting from an unregulated cystic fibrosis transmembrane conductance regulator (CFTR) gene. Detection of this disorder is crucial in deciding timely treatment, leading to a better quality of life. The Celera Cystic Fibrosis Genotyping Assay is a qualitative *in vitro* diagnostic device used to genotype a panel of 32 mutations (plus poly-T and exon 10 polymorphisms) in the CFTR gene from genomic DNA isolated from human whole blood. The assay provides information intended for use in the carrier screening of adults of reproductive age, as an aid in newborn screening, and in the confirmatory diagnostic testing of newborns and children.
Due to differences in sample preparation technologies, three different methods were used to assess the isolation of genomic DNA from EDTA human whole blood. Two operators independently processed 22 samples on two days using the MagNA Pure Compact Nucleic Acid Isolation Kit (Roche), the QIAamp DNA Blood Kit (Qiagen), and the Puregene Blood Core Kit (Qiagen). The extracted DNAs were characterized for concentration, purity, and performance in the detection of wild-type and mutant alleles using the Celera Cystic Fibrosis Genotyping Assay with the 3500xL genetic analyzer (Life Technologies; RUO*).
The results demonstrated that DNA isolated by these sample preparation methods were of sufficient concentration and purity to allow accurate genotyping by the Celera Cystic Fibrosis Genotyping Assay with the 3500xL genetic analyzer.

The former annotated pseudogene DHFRL1 is expressed and functional

G. McEntee, *S. Minguzzi, K. O'Brien, N. Ben Larbi, C. Loscher, C. Ó Fágáin, A. Parle-McDermott;*
Dublin City University, Dublin 9, Ireland.

Dihydrofolate reductase (DHFR) is a folate enzyme which reduces dihydrofolate into tetrahydrofolate in the presence of NADPH. DHFR was previously thought to be the only enzyme capable of this reaction however we show that humans have a second dihydrofolate reductase enzyme encoded by the former pseudogene DHFRL1 (dihydrofolate reductase like - 1), located on chromosome 3.We demonstrate that the DHFRL1 gene is expressed and shares some commonalities with DHFR. Recombinant DHFRL1 can complement a DHFR negative phenotype in both bacterial and mammalian cells. Enzyme kinetics shows that the Km for NADPH is similar for both enzymes but DHFRL1 has a higher Km for dihydrofolate when compared to DHFR, indicating a lower affinity for the substrate. Localization of DHFRL1, visualized using confocal microscopy, shows that DHFRL1 has a strong presence in the mitochondria, where it is proposed by Anderson et al (2011) to participate in de novo thymidylate synthesis to support mitochondrial DNA replication. We also found that DHFRL1 has the ability to bind its own mRNA in the same translational auto-regulation method as DHFR; with both enzymes capable of replacing each other. Methotrexate (MTX), a potent inhibitor of DHFR, is known to disrupt this regulation mechanism. We demonstrate that DHFRL1, which has a lower binding affinity for MTX, requires a higher concentration of the drug to disrupt the protein: RNA binding complex. The identification of a second dihydrofolate reductase enzyme encoded by a previously unrecognised retrogene will have a major impact on previous research surrounding DHFR.

P04.14

Maternal stress factors associated with Down syndrome birth

S. K. Dey, *S. Ghosh;*
West Bengal University of Technology, Kolkata, India.

Down syndrome due to trisomy 21 is the most common human chromosomal abnormality. In order to gain insight into maternal stress factors responsible for nondisjunction, we genotyped 12 microsatellite markers spanning along 21q from centromere to telomere in 138 individuals with free trisomy 21 and in their parents and analyzed the association among reduced recombination, maternal age and nondisjunction. The approach was informative for 119 families in determining parental origin with 89.91% being maternal and 10.09% is paternal. The distribution of nondisjunction in maternal meiotic I and meiotic II stages were 81.19% and 19.81% respectively. The mean maternal age of nondisjunction in our Indian population is 27.58±6.4 years which is significantly lower than that of Caucasians. We created a genetic map of long arm (21q) in maternal meiosis I nondisjoined chromosome 21. The distribution of chiasma shows a difference throughout the length of 21q with more recombination towards telomeric end in comparison to control data. The telomeric exchange is found to be a significant risk factor for meiotic I nondisjunction, irrespective of the age of the mother. An increase in both zero- and one exchange events in younger mother (< 29) suggests reduction of recombination. The linkage map of 21q (39.58cM) was significantly shorter than the control female linkage map, indicating an overall reduction of recombination. Telomere length estimation indicates that telomere length attrition may be associated in some way with meiosis I and meiosis II nondisjunctions of chromosome 21.Reduced recombination & telomeric exchange are important maternal stress factors .

FMR1Genotype Repeat Size Analysis as a Genetic Test Necessary Prior Fertility Treatments.

R. ESPEJO[1], *A. ZUÑIGA*[2], *L. PEDROLA*[2], *Y. ROMERO*[2];
[1]*Hospital de la Ribera, Alzira (Valencia), Spain,* [2]*HOSPITAL DE LA RIBERA, ALZIRA (VALENCIA), Spain.*

Premature ovarian failure [POF (MIM 311360)] is an early ovarian dysfunction characterized by cessation of menstruation before the age of 40 years. The aetiology of this disorder is complex and the underlying genetic defects are largely unknown. It has been estimated that ~21% of POF cases are associated with expanded alleles of the *Fragile X mental retardation* [*FMR1,* FXS (MIM 309550)] gene. Intermediate and pre-mutated *FMR1* alleles may become unstable generating a full mutation with further expansion in the following generations, when passed from a female to her offspring. Such females, also called Fragile X intermediate or pre-mutation carriers, are phenotypically normal although with an increased risk of POF. We report a case of a healthy, 34-year-old woman who had premature ovarian failure (POF), (FSH measurement = 102,00 mIU/ml, LH measurement = 18,00 mIU/ml). Her condition was considered idiopathic because she did not show any of the known POF-related conditions such as ovarian surgery, previous chemotherapy or radiotherapy, or autoimmune disease. Laboratory tests prior to initiating a stimulation cycle were normal including karyotype. GnRH and follicle stimulating hormone treatment was recommended but the first treatment cycle was unsuccessful in inducing ovulation. Before the second cycle, analysis of FMR1 genotype repeat size was performed and result showed a permutated FMR1 allele (90 Cogs repeats). Patient was derived to a Preimplantational Genetic Diagnosis Program. The association between premature ovarian failure (POF) and the *FMR1* repeat number has been widely investigated and must be taken in account in Reproductive and Infertility Programs.

Genetic polymorphisms of Glutathione S-transferase M1, T1 and P1 in Tunisian infertile men

M. Cherif[1], *S. Baklouti*[1], *M. Ghorbel*[1], *N. Zribi*[2], *S. Daoud*[2], *A. Sellami*[2], *N. Chakroun*[2], *F. Fakhfakh*[1], *L. Ammar-Keskes*[1];
[1]*Laboratory of Human Molecular Genetics, Sfax, Tunisia,* [2]*Laboratory of Histology, Sfax, Tunisia.*

Introduction: Genetic causes are responsible of 60% of cases of idiopathic male infertility. Polymorphisms of genes that encode Glutathione S-transferases (GSTs), a group of phase II enzymes that detoxify endogenous and exogenous electrophiles, can affect the biotransformation of toxic compounds to which the male productive system is exposed. Some reports attested the association of GSTs gene polymorphisms with male infertility. In order to investigate whether there is an impact of genetic variations of GSTs on semen quality and male fertility, we studied three genetic polymorphisms in GSTT1, GSTM1 and GSTP1 in infertile men and controls from Tunisia.
Methods: Participant's were 159 men with idiopathic infertility and 102 fertile men. Basic semen analysis was performed including total sperm count and concentration, motility and morphology. Genotyping of GSTM1 and GSTT1 polymorphisms were performed using the multiplex PCR. The GSTP1 Ile 105 Val polymorphism was determined using PCR-RFLP.
Results: GSTM1 null genotype (GSTM1 0/0) was significantly associated with reduced sperm count in infertile men semen (oligozoospermia) (P=.001) and GSTT1 null genotype (GSTT1 0/0) was significantly associated with low sperm motility (P=.001). However, infertile men had a higher prevalence of the wide type of GSTP1 allele (GSTP1 Ile 105) than the fertile group (80.5% and 72.54%, respectively; P=.034) and the presence of the homozygote mutant genotype (GSTP1 Val/Val) was less common in infertile men than in fertile group.
Conclusion. Our results suggest that both GSTM1 and GSTT1 gene polymorphisms have a negative impact on semen quality and are associated with male infertility in Tunisia.

P04.18

An association between the IGF2 ApaI polymorphism and spontaneous abortion

B. Tretyak, *H. Makukh, D. Zastavna, M. Tyrkus;*
State institution "Institute of Hereditary Pathology of Academy of Medical Science of Ukraine", Lviv, Ukraine.

The imprinted IGF2 gene encodes insulin-like growth factor II, displays loss of imprinting (LOI) or aberrant imprinting in human diseases is important for human placental development. Accordingly to GWAS, IGF2 is associated with human longevity and an association between the IGF2 ApaI polymorphism and body mass index was confirmed.
The PCR- RFLP analysis has been performed and the distribution of ApaI IGF2 genotypes was determined in 146 patients with muscle weakness and elevated creatine kinase, in 107 miscarriages' chorionic villi samples (MCV) and control samples. RNA from 41 MCV samples was reverse-transcribed and subjected to IGF2 loss of imprinting (LOI) analysis.
The differences of AG and GG ApaI IGF2 genotypes frequencies between experimental and control groups were significant. The AG ApaI IGF2 genotype was detected in 69.2% of MCV versus to 22.5% in control and 40.4% in patients with muscle weakness and significantly increases the risk of spontaneous abortion (OR=7.72; CI: 3.30-18.03). MCV samples with confirmed heterozygous AG genotype undergo to LOI analysis and expression from both alleles was detected in 37 (90.2%) samples. The revealed deviation from Hardy-Weinberg equilibrium in the control group can be explained by the possibility that embryos with the AG ApaI IGF2 genotype are more often eliminated compared with other genotypes that could be realized by the loss of imprinting mechanisms.

P04.19

The role of thrombophilia in implantation failure and recurrent spontaneous abortion

E. Kurvinen[1], *T. Kahre*[1,2], *Ü. Murumets*[1], *R. Zordania*[1];
[1]*Department of Genetics, United Laboratories, Tartu University Hospital, Tartu, Estonia,* [2]*Department of Pediatrics, University of Tartu, Tartu, Estonia.*

It`s accepted, that trombophilia is one of the possible etiological factors of *in vitro* fertilization (IVF) failure and recurrent pregnancy loss (RPL). We conducted this study to determine the role of thrombophilic inherited and acquired factors in the etiology of infertility in 150 families. We analysed clinical, laboratory and genealogical data of families in two groups: in the first group we enrolled women who had had at least two IVF failure (n=75), but no deliveries. Second group consisted of women (n=75) who had conceived spontaneously and had uneventful pregnancies (at least two pregnancy loss previously). All the women underwent a complete screening for congenital (factor V Leiden-FVL, factor II c.20210G>A, antithrombin, proteiin C, proteiin S deficiency, MTHFR c.677C>T and c.1298A>C) and acquired (APC resistancy) thrombophilia risk factors. Conventional cytogenetical analysis was performed in all women and their partners. Inherited thrombophilia mutations were revealed in 82.4% of in the first group versus 64.8% in RPL group. APC resistancy was diagnosed in 3% among IVF failure patients and 30% in RPL patients. About half of the cases in both groups it was caused by F V Leiden mutation. No differences was found between groups concerning MTHFR mutations. Combined thrombophilia (the presence of two genetic factors of thrombophilia) was present in 5% of first and 12% among second group of patients. Our data suggest that factor V Leiden mutation alone or combined with acquired factors can have a role in recurrent fetal loss in families without conceiving problems.

P04.20

Application of a Scoring System in PGD for late onset diseases and cancer predispositions.

V. Gold[1], *S. Peleg*[1], *V. Lisiansky*[1], *N. Mey-Raz*[1], *I. Wagman*[1], *D. Ben Yosef*[1], *A. Amit*[1], *Y. Yaron*[1,2,3], *M. Malcov*[1];
[1]*Racine IVF Unit, Lis Maternity Hospital. Sourasky Medical Center, Tel Aviv, Israel,*
[2]*Prenatal Diagnosis Unit, Genetic Institute, Sourasky Medical Center, Tel Aviv, Israel,*
[3]*Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel.*

Introduction: PGD is widely used for cancer predisposition mutations with variable penetrance and additional late onset diseases. The number of families affected by these conditions that opt for PGD increases continuously as molecular techniques are advancing. Nonetheless, the indication for PGD in these cases keeps raising ethical issues.
Aim: to summarize our experience in PGD for couples affected with late onset diseases following the evaluation of each case by a quantitative Scoring System (SS).
Methods: PGD was performed by embryo biopsy, followed by single cell multiplex nested PCR for the familial predisposition mutation and for 4-8 flanking polymorphic markers. The devised SS considers disease characteristics (onset, severity, penetrance, inheritance pattern) and patient clinical variables (carrier status, infertility, objection to terminate pregnancy, additional genetic syndrome) resulting in an absolute numeric value for every patient.
Results: the evaluation of 31 couples by the SS showed that some conditions such as FAP or Huntington definitely justify PGD while others like BRCA or HNPCC require the contribution of patient variables in order to justify inclusion into PGD program. Seven healthy pregnancies were achieved.
Conclusion: the employment of a SS that takes into account the disease characteristics as well as the patients' clinical variables allows for the objective determination wherein PGD is justified. We envision that the continuous discovery of cancer predisposition and late onset mutations will highlight PGD as the most appropriate reproductive option for preventing the perpetuation of severe inherited predisposition in families with several affected or deceased members.

P04.21

Interleukin 6 polymorphism in recurrent pregnancy loss

V. Radoi[1,2], *C. Bara*[2], *L. Bohiltea*[2];
[1]*Life Memorial Hospital, Bucharest, Romania, Bucharest, Romania,* [2]*UMF Carol Davila, Bucharest, Romania.*

Introduction
About 15 - 20% of clinically recognized pregnancies end in miscarriage among Caucasians. The etiology of recurrent pregnancy loss remains unclear and the possible immunological etiologies of pregnancy failure have been intensively investigated.
The maternal immune system confronts the embryo/ fetus with a host

defense reaction, based on the recognition of paternally derived antigens. Cytokines have been described to play a major role in the pathogenesis of recurrent miscarriage.

Objective

We purpose to investigate the relationships between recurrent pregnancy loss and single nucleotide polymorphism - 174 G / C in the promoter region of the interleukin 6 gene in Romanian population.

Material and methods

The diagnosis of RPL was based on a documented history of at least two spontaneous consecutive miscarriages. Each woman underwent a diagnostic work - up to rule out a verifiable cause for the recurrent miscarriage.

We studied 37 women with recurrent spontaneous abortions (>2) and 40 women experiencing at least one live birth and no abortions referred to Life Memorial Hospital. DNA extraction and PCR were employed to genotype women for the presence of a polymorphism in the promoter region of interleukin 6 gene.

Results

There was a not significant difference in the - 174 C/G genotype frequency (GG vs. GC/CC) between the women with RPL and controls (p value = 0,47). We did not detect any homozygote for C allele in 77 subjects.

Conclusion

The interleukin 6 polymorphism investigated was not associated with recurrent pregnancy loss in Romanian population.

P04.22

Iron deficiency and targeted deletion of iron regulatory protein 2 affect sperm motility and male fertility

*B. Marohn[1], P. Grzmil[2], E. G. Meyron-Holtz[3], J. Schmidtke[1], **S. Schubert**[1];*
[1]Institute for Human Genetics, Hannover Medical School, Hannover, Germany, [2]Institute for Human Genetics, Georg August University, Göttingen, Germany, [3]Laboratory for Molecular Nutrition, Faculty of Biotechnology and Food Engineering, Technion - Israel Institute of Technology, Haifa, Israel.

The iron metabolism is regulated both, at the systemic and cellular level, amongst others, by the iron regulatory proteins (IRP) 1 and 2. IRP2 regulates proteins involved in iron transport and storage such as transferrin receptor 1 (TfR1), ferroportin and ferritin. *Irp2* knock out mice exhibit misregulated expression levels of these proteins and develop anemia and a late onset progressive neurodegeneration.

Infertility of *Irp1*$^{+/-}$/*Irp2*$^{-/-}$ breeding pairs and the abundant expression of IRP2 in the testis of wild-type mice indicate an important role of IRP2 in the regulation of testicular iron homeostasis. This project focused on how testicular iron metabolism, spermatogenesis and spermiogenesis are affected by IRP2 deficiency. Spermatogenesis and fertility of *Irp2*$^{-/-}$-mice are not affected. However, sperm motility of IRP2-deficient males is significantly enhanced in comparison to age-matched C57BL/6J wild-type controls.

We kept *Irp2*$^{-/-}$-mice and age-matched controls on a low iron diet in order to analyze if the increased sperm velocity is a result of iron deficiency and if lack of iron could affect spermatogenesis and male fertility in general. While sperm of wild-type mice on a low iron diet mimic the behaviour of *Irp2*-deficient mice under normal conditions, sperm motility and fertility of homozygous *Irp2* knock out mice on a low iron diet are significantly reduced. Whether this effect is mediated by structural abnormalities of the sperm flagellum and/or due to a lower ATP production in IRP2-deficient sperm is currently under investigation.

P04.24

Array-CGH analysis in male infertility

***W. Lissens**[1], D. Vandermaelen[1], S. Seneca[1], B. Menten[2], G. Vandyck[1], H. Tournaye[3], K. Stouffs[1];*
[1]Center for Medical Genetics, UZ Brussel and Vrije Universiteit Brussel, Brussels, Belgium, [2]Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium, [3]Center for Reproductive Medicine, UZ Brussel and Vrije Universiteit Brussel, Brussels, Belgium.

In order to identify genetic causes of male infertility, many individual genes have been studied for the presence of mutations in infertile patients. However, these studies were rather disappointing. Therefore, we looked for the presence of copy number variations (CNVs) in 9 infertile men with a maturation arrest of spermatogenesis and in 20 control males with normal sperm parameters. After several elimination steps, 7 regions remained. These regions, including four deletions and three duplications, were further investigated by qPCR in patients and in a large number of controls. The 4 deletions were present in heterozygous form and contained the SLC25A24, FAM82A1, C17ORF51 and SIRT4 genes. By sequencing no mutations were detected in the non-deleted copies of these genes. The three duplications involved the genes THRAP3+C1ORF113, SYT6 and PLSCR2. Due to their known function the genes SYT6, PLSCR2 and SIRT4 have a potential role in male infertility but are presumably not involved in maturation arrest at the spermatocyte stage. SLC25A24 has two transcript variants of which only variant 2 is testis-specific. Besides multiple heterozygous deletions of the start codon region, we detected one patient with a maturation arrest of spermatogenesis (not tested by array CGH) who was having a homozygous deletion of this region. More patients and controls are being investigated. In addition, immunohistochemistry is performed to determine the localization of the SLC25A24 proteins in testicular tissues. The role of the genes FAM82A1 and C17ORF51 is under investigation. These studies will clarify whether these genes are linked to male infertility.

P04.25

A methylation-sensitive SNP in PIWIL2 is associated with male infertility

***C. Friemel**[1], S. Bens[1], A. Caliebe[1], J. Gutwein[1], J. Richter[1], A. Schmutzler[2], R. Siebert[1], O. Ammerpohl[1];*
[1]Institute of Human Genetics, Christian-Albrechts-University Kiel, Kiel, Germany, [2]Center for Reproductive Medicine, Christian-Albrechts-University Kiel, Kiel, Germany.

Epigenetic mechanisms have recently emerged as playing a crucial role in the pathogenesis of various common diseases. We hypothesized that aberrant DNA methylation patterns also contribute to the causes of male infertility. The aim of this study was to identify CpG loci differentially methylated in infertile men as compared to fertile male controls.

Using the HumanMethylation450k BeadChip DNA from peripheral blood cells obtained from 33 infertile men, as well as 10 fertile male controls was analyzed. A total of 596 differentially methylated CpG loci were revealed by this approach (p<0.001). These genes were enriched for PIWIL family members (Enrichtment=39.32). As PIWILs are involved in the regulation of spermatogenesis, we further focused on this group of genes.

Notably, one differently methylated CpG site, which was located in the S-shore region of PIWIL2 showed a significantly lower methylation level in patients as compared to controls (p<0.01). Remarkably, DNA methylation at this site showed a bimodal distribution with very low levels in a subgroup of 8 patients (mean methylation = 37.8% vs. 83.7% in controls). Further evaluation revealed that this site contains a rare single nucleotide polymorphism (SNP) and that lower methylation levels in the affected patient subgroup were reflected by heterozygosity for this SNP. Based on our findings we propose that heterozygosity for a methylation-sensitive SNP in PIWIL2 is associated with male infertility.

P04.27

Y chromosome haplogroups do not confer susceptibility to partial AZFc deletions in Tunisan infertile men

***M. Ghorbel**[1], S. Baklouti Gargouri[1], N. Zribi[1], F. Ben Abdallah[1], M. Cherif[1], R. Keskes[1], N. Chakroun[2], A. Sellami[2], K. McElrevaey[3], F. Fakhfakh[1], L. Ammar-Keskes[1];*
[1]Laboratory of Human Molecular Genetics, Faculty of Medicine, Sfax, Tunisia, [2]Laboratory of Histology & Embryology, Faculty of Medicine, Sfax, Tunisia, [3]Human Developmental Genetics, Institut Pasteur, Paris, France.

Introduction: Partial AZFc deletions related to testis-specific gene families are common mutations of the Y chromosome, but their contribution to spermatogenic impairment is still unresolved, and the risk factors related to the onset of microdeletions remain unknown. With this in mind, we investigated the possible association between Y chromosome haplogroups and predisposition to partial AZFc deletions a Tunisian population. Materiel et methodes : The study involved 216 infertile patients (68 azoospermic, 63 oligospermic and 85 normospermic). Identification of haplogroups was made by PCR using a set of binary markers. We also screened partial microdeletions of Y chromosome AZFc region by polymerase chain reaction (PCR) according to established protocols. Redultats : Eleven haplogroups were identified (E3b2, J1J*, E1, E3b*, F, G, K, P/Q, R*, R1and R1a1), with a high frequency of E3b2 (35.18%) and J1J* (30.9%), knowing that E3b2 is the most frequent haplogroup in the north African populations. Only 30 patient carried a partial AZFc microdeletion (13.88%). Gr/gr was found in 80% of patients (24/30) with seven different haplogroups (E1, E3b*, E3b2, F, J1J*, R1a1* and R1). E3b2 was the most frequent (54.16%). However, the frequency of J1J* was only 16.66%. Conclusion : This study suggests lack of significant evidence of increased of AZFc partial microdélétion in a specific haplogroupe of Y chromosome in Tunisian infertile men.

P04.28

Application of mFISH in identification of supernumerary marker chromosome in a female with infertility

***T. E. Zerova**, M. I. Kononenko, A. S. Dariy, S. V. Denisenko;*
The Human Reproduction Problems Clinic, Kyiv, Ukraine.

Supernumerary marker chromosome (SMC) belongs to a heterogeneous group of structurally rearranged chromosomes, it is difficult to be identified due to small size. The occurrence of SMCs is 0,1-0,72/1000 in phenotypically normal individuals (Blennow et al., 1994).
After introduction of multiplex fluorescrence in situ hybridization (mFISH) it has become possible to investigate origin of SMCs.
In our case a phenotypically normal 27-year-old female with infertility (3 years) was analysed after two unsuccessful ICSI courses. The cytogenetic analysis identified mosaicism of cells with SMC. The female patient's karyotype was 47,XX,+mar[15]/46,XX[20]. The karyotype of her husband was normal.
The following banding methods for studing SMC were used: GTG, QFQ, CBG,DA/DAPI. The SMC appeared to be of a small size, metacentric, bisatellited,DA/DAPI positive at both centromeres. mFISH was performed using Spectra Vysion Assay (Abbott Inc, USA) and the Applied Imaging Spectra Vysion Imaging System.
SMC was identified as an inverted duplication of chromosome 15.
This is the most widespread group of SMCs - approximately 50% of healthy SMCs carriers have SMC derived from chromosome 15(Liehr et al., 2004). A review of studies involving this type of SMCs suggested that they can be divided into several groups. Our case belongs to the group with those SMCs that are inv dup (15) with breakpoints in 15q11 and contain very little or no euchromatic material and exert no phenotypic effect.
It should be taken into account that when the next ICSI procedure is successful, prenatal diagnosis should be subsequently performed.

P04.29

Non-disjunction of the bivalent is not the predominant mechanism leading to aneu-ploidy in humans

K. R. Held[1], *V. Baukloh*[2], *S. Arps*[3], *S. Wittmann*[1], *S. Knebel*[1];
[1]*Reprogenetics Germany, Hamburg, Germany,* [2]*Fertility Center Hamburg, Hamburg, Germany,* [3]*MVZ Genteq, Hamburg, Germany.*

Results obtained by array comparative genomic hybridization (aCGH) of first polar bodies (PB1) suggested that non-disjunction of the bivalent is not the predominant mechanism leading to aneuploidy in humans (Gabriel et al., 2011) and that a greater number of chromosome segregation errors taking place at second meiotic division (MII) compared with first meiotic division (MI) (Fragouli et al., 2011). The aim of our study was to confirm both observations by analyzing the segregation errors of chromosomes X, 13, 15, 16, 17, 18, 21 and 22 in PB1 and PB2 in a large cohort of patients (3307 cycles) aged 24 to 48 years.
PBs were analyzed by FISH with 5-chromosome probes (15 846 oocytes from 2958 cycles) or with 8-chromosome probes adding chromosomes X, 15 and 17 (1970 oocytes from 394 cycles). The data were allocated to the age groups ≤ 35 years, 36 to 40 years and > 40 years.
Our data confirm the observations by Gabriel et al., 2011, that premature chromatid seperation is the predominant mechanism leading to aneuploidy in humans (Angell's hypothesis). In oocytes of reproductively older women there is an excess of chromosome errors originating from MII compared with MI. The data suggest that the decrease in fertility of older women is due to a significant increase in segregation errors both in MI and to a larger extent in MII. These data were supported by preliminary data from 36 cycles analyzing all chromosomes in PB1 and PB2 from 202 oocytes by aCGH.

P04.30

Functional assessment of mismatch repair

P. Tulay[1], *S. Jaroudi*[2], *S. B. SenGupta*[1];
[1]*University College London, London, United Kingdom,* [2]*University of Oxford, Oxford, United Kingdom.*

Introduction: Mismatch repair (MMR) plays an important role in repairing mismatched bases and insertion/deletion of loops. MMR genes were shown to be expressed in the early stages of mammalian development. However, the gene expression profile alone cannot determine the activity/functionality of the repair pathways. Investigating the repair capacity of MMR proteins in preimplantation embryos is important since the rates of cell proliferation and DNA replication are high in the early embryo. This study aims to develop a functional assay to assess the efficiency of MMR in preimplantation embryos.
Methods: Complementary synthetic oligonucleotides were used to form a heteroduplex DNA fragment of 180 base pairs in length. The constructs were exposed to nuclear/whole cell extracts. Semi-quantitative analysis of the mismatched base was performed by minisequencing. Control studies were carried out in the absence of any nuclear/whole cell extracts. MMR efficiency was also studied in four mouse blastocysts. MMR efficiency was assessed as described for the nuclear/whole cell extracts.
Results: Heteroduplexes were repaired in nuclear and whole cell extracts. Control studies in the absence of nuclear and whole cell extracts showed no repair. Repair was observed in the mouse blastocysts though the efficiency was not as high as the nuclear/whole cell extracts.
Conclusion: MMR efficiency in designed mismatched heteroduplexes was successfully analysed in the presence of nuclear/whole cell extracts and in mouse blastocysts. This assay can easily be modified to detect different/multiple mismatches with different lengths in addition to modifying the construct into assessing insertion/deletion loops with different sizes.

P04.31

Cytogenetic analysis of 102 missed and spontaneous abortions in the western regions of Ukraine

I. Tkach, *N. Huleyuk, H. Beskorovajna, I. Sedneva, O. Lototska-Savchak;*
Institute of Hereditary Pathology, NAMS of Ukraine, Lviv, Ukraine.

Background: Approximately 15% to 20% of pregnancies result in spontaneous miscarriages and missed abortions and most often occur in the first trimester. In 60-80% of cases they are caused by chromosomal changes in the embryo/fetus. The present study displays frequency and spectrum of chromosomal abnormalities in embryos derived from missed and spontaneous abortions in the western regions of Ukraine.
Methods: The study population consisted of 102 embryo tissues from women with the final diagnosis of missed (99 cases) or spontaneous (3) abortions. Cytogenetic analysis was performed in the uncultured chorionic villi samples, using standard G-banding.
Results: Karyotype results were obtained in 50 of 102 cases (49%), one of them from spontaneous abortion. Among the abortions the gonosomal constitution of XY prevailed (n = 36), followed by XX (n=14). Chromosomal abnormalities were found in 25 cases (50%): autosomal trisomies in 9 cases (36%), gonosomal trisomies 47,XXY in 2 cases (8%) and triploidy in 14 cases (56%) (9 XXY : 5 XXX). Autosomal trisomies involved chromosome 2 (one case), 16 (tree cases), 19 (one case), 20 (one case, spontaneous abortion) and 22 (tree cases). One case of triploid abortion showed mosaicism with chromosome 20 - 70,XXX,+20/69,XXX.
Conclusions: Conventional methods of cytogenetic investigation of material from missed abortions produce results in half of the cases. Presence of Y chromosome in 72% of incidents shows prevalence of male gender in affected pregnancies. Triploidy was predominant followed by autosomal and gonosomal trisomy. Among autosomal trisomies, chromosomes 16 (12%) and 22 (12%) were prevalent.

P04.32

Identification of differentiallymethylated genes in the extraembryonic tissues of human embryos with mosaictrisomy 16

E. N. Tolmacheva, *A. A. Kashevarova, N. A. Skryabin, I. N. Lebedev;*
Research Institute of Medical Genetics, Tomsk, Russian Federation.

Chromosomal mosaicism results from mitotic non-disjunction in aneuploid or primarily euploid cell. However, the inducing factors of mitotic instability are poorly investigated. Earlier we showed
the high frequency of epimutations of two cell cycle control genes (*RB1* and *P14ARF*) in the extraembryonic tissues of miscarriages with mosaic trisomies involved different chromosomes. So, we can not exclude that the increase of a certain chromosome dose may lead to abnormal epigenetic status of genes. The present work was aimed to identify a spectrum of differentially methylated genes in the cytotrophoblast (CT) and in the extraembryonic mesoderm (EM) of 13 miscarriages with trisomy 16, and 7 first trimester induced abortions using HumanMethylation27 BeadChip (Illumina). The level of aneuploid cells was 4-93% in the CT and 65-98% in the EM. There were no differentially methylated CpG-sites in the CT with pure trisomy (≥90% of trisomic cells) and in the EM, whereas there were 20 hypermethylated CpG-sites in 20 genes in the CT with mosaic trisomy (<90% of trisomic cells). These 20 differentially methylated genes belong to the following functional groups: transport (*ABCC3, P2RY6, PDZD3, PKDREJ, SEC31B, SLC17A4, SLC22A18, TRPV6*), signal transduction (*ADRB3, P2RY6, PDZD3, PKDREJ*), cell proliferation (*THBS4*), cell death (*NOL3*), response to stress (*ADRB3, NOL3, TIMP3, TP53TG1*), cell adhesion (*TECTA, THBS4*), etc. Thus, hypermethylation of these genes is most likely associated with trisomy rescue events and mosaicism origin but not to the increase of chromosome 16 dose. This study was supported by Federal Program P1161.

Polymorphism of folate cycle and integrins genes and pregnancy loss

E. Mashkina[1], *K. Kovalenko*[1], *N. Fomina*[2], *T. Shkurat*[1];
[1]*Research Institute of Biology, Southern Federal University, Rostov-on-Don, Russian*

Federation, [2]Southern Federal University, Rostov-on-Don, Russian Federation.

The causes of pregnancy loss are diverse. Polymorphism of candidate genes may influence on the early stages of embryogenesis. The role of gene polymorphisms of folate cycle, and coagulation factors in pregnancy loss is discussed. We analyzed the frequency of gene polymorphism MTHFR (C677T), MTRR (A66G), MTR (A2756G), ITGB3 (T1565C), ITGA2 (C807T), FGB (-455G-A), PAI 1 (-675 5G/4G) among 124 women with pregnancy loss in the first trimester. The control group included 114 women with normal pregnancy. The frequency of the investigated genotypes among two groups of women is not different. The exception was the gene methionine synthase. The frequence of 2756GG genotype was three times higher in the group of women with pregnancy loss than control (OR = 3.71). The frequency of allele 2756G MTR gene was 0.26, which exceeds the controls (P = 0.028). The number of homozygotes-455AA FGB was 2.6% in the control group and 6.5% in the comparison group (OR = 2.79).The combination of gene polymorphisms of folate cycle and integrins increase risk of pregnancy loss in the first trimester. The frequence of integrins polymorphisms did not differ in women with pregnancy loss and control group. However the combination of polymorphisms of three genes (MTRR, MTR ITGB3) increases the risk of pregnancy loss is 5 times.

P04.36

Birth of healthy twin after implanting a singleton male embryo, a hemophilia PGD case

S. Zeinali[1]*, P. Fouladi*[2]*, H. Bagherian*[2]*, S. Kianfar*[2]*, S. Sarhadi*[2]*, F. Zandieh*[3]*, F. Ramezanzadeh*[3]*, S. Amanpour*[3]*, S. Amanpour*[3]*;*

A family with one hemophiliac child who had come for prenatal diagnosis (PND), requested to have a healthy child via preimplantation genetic diagnosis (PGD). The affected boy's mutation had been characterized in the previous PND and the mother was an obligate carrier. For performing PGD we tested several STR markers on the affected boy and his mother's DNA to determine the informative ones. Reprogrammed induction of super-ovulation was performed by HCG injection and 34 to 36 hours later oocyte were picked up using ultrasound guide. Three days after insemination, embryo biopsy was performed using SATURN laser. The biopsy pipette was inserted through the hole, and the selected blastomere was removed gently by aspiration. In total eight cells were removed from eight embryos. Each cell was analyzed by two rounds of multiplex nested PCR for STRs and direct DNA sequencing. Only one healthy male and two none carrier female embryos were identified. The mother insisted on the transfer of only the male embryo. Pregnancy progressed well and sonography in week 8 indicated twin pregnancy. The mother was disappointed in having twin boys and decided to terminate pregnancy. Intensive counseling was provided and she was persuaded to continue the pregnancy. Both fetuses were checked for hemophilia during 11th weeks of gestation using CVS. Chromosomal abnormalities were checked by means of QF PCR and karyotyping. The children were delivered with no complication and later coagulation analysis revealed no complication. The mother is now happy in deciding to continue the pregnancy to term.

Translocation and aneuploidy analyses of polar bodies and trophectoderm cells using 24sure: First results in a clinical setting

M. Stumm[1]*, R. Wegner*[1]*, C. König*[2]*, M. Schlawinsky*[2]*, M. Klein*[2]*, J. Gerike*[3]*, S. Marr*[3]*, M. Bloechle*[3]*;*
[1]*BG Berlin-Genetics GmbH, Berlin, Germany,* [2]*ImaGenes / Source BioScience LifeSciences, Berlin, Germany,* [3]*Kinderwunschzentrum an der Gedaechtniskirche, Berlin, Germany.*

Objective: Recent studies have shown that biopsy of polar bodies (PB) from oocytes and trophectoderm cells (TE) from blastocysts followed by array comparative genomic hybridisation (aCGH) might be a good strategy for the detection of genomic imbalances in human embryos. The combined detection of aneuploidies for all chromosomes and of unbalanced aberrations in just one experiment makes aCGH-analyses very helpful, especially in gametes and embryonic cells from translocation carriers. Here, we report our first experiences and data from aCGH analyses in a real clinical setting.

Methods: Polar bodies of more than 20 cycles and trophectoderm cells of more than 10 cycles (including different translocation carriers) were biopsied. The samples were amplified by whole genome amplification (WGA) using the SurePlex Kit [BlueGnome] and their genomes examined by aCGH using 24sure and 24sure+ Cytochips [BlueGnome].

Results: aCGH results of more than 150 PB- and more than 50 TE-samples are presented. Technical problems and methodical limitations are discussed. Different strategies are shown for practicable and cost effective analyses of polar bodies and trophectoderm cells in a clinical setting using 24sure and 24sure+ Cytochips.

Conclusion: Molecular karyotyping by aCGH allows a combined detection of aneuploidies and structural aberrations and therefore, may help to identify euploid embryos with higher implantation potential.

P04.38

Detection of PRDM9 variations in patients with meiotic disorders

A. Alemany-Schmidt*, D. Heine-Suñer, M. Navarro-Palou, A. Voltes-Cobo, E. Piñero-Martos, J. Rosell, J. Burgués Gasión, M. Oliver-Bonet;*
Hospital Universitari Son Espases, Palma, Spain.

In the last seven years genetics and molecular biology have begun to uncover the role of PRDM9 in mammalian meiosis as a major determinant of meiotic recombination hotspots. PRDM9 contains an N-terminal KRAB domain, a central SET domain and a C-terminal tandem-repeat zinc-finger array. It is known that the zinc-finger array serves for binding to the DNA and marking the hotspots and that the H3K4 trimethylase activity of the SET domain could be responsible for activating these hotspots by chromatin remodeling. The zinc-finger array is coded by a variable microsatellite (differences in nucleotides and number of microsatellites).

Due to its role in homologous recombination, mutations/variations in PRDM9 might be associated with different pathologies of meiotic origin. Mutations in any of its domains could be the cause of some cases of infertility. Moreover, according to several authors, variation within the PRDM9 zinc-finger domain might be involved in the mechanisms responsible for de novo genomic disorders that result from unequal meiotic exchanges at minisatellites.

Therefore, the PRDM9 gene has been sequenced in 3 distinct groups (controls=83, infertile=14, transmitting parents of de novo rearrangements=20) in order to analyze the presence of mutations/variations associated with infertility and the origin of de novo genomic disorders. Preliminary results show the presence of SNPs and uncommon variants of the zinc-finger array in all groups. However, this presence has not been associated with any statistical significance.

Further studies including a bigger number of analyzed samples will contribute to determine the role of PRDM9 in pathologies of meiotic origin.

P04.39

Investigation of Angiotensin II Type 2 Receptor Gene A1675G Polymorphism and Distribution of Genotypes in Preeclampsia and Normal Pregnancies

L. Özpak[1]*, A. Pazarbaşı*[1]*, M. Kasap*[1]*, D. Alptekin*[1]*, F. T. Özgünen*[1]*, C. Bereketoğlu*[2]*, M. B. Yılmaz*[1]*, S. K. Sel*[1]*, T. Tufan*[1]*, G. Cömertpay*[1]*, & N. Uslu*[1]*;*
[1]*Çukurova University, Adana, Turkey,* [2]*Marmara University, Istanbul, Turkey.*

Angiotensin II type 2 receptor (AT2R) gene polymorphism in the development of preeclampsia in pregnant woman might be thougt to play an active role. Therefore, we assessed whether AT2R gene A1675G polymorphism increase the risk of preeclampsia.The study cohort was a group of 95 woman with preeclampsia and 78 healthy pregnant woman subjects from the general turkish population. We were studied, by RFLP analysis, to validate the role that the AT2R gene A1675G polymorphism plays in preeclampsia. Among controls, the AT2R Hyp188III genotypes of G/G, A/G, and A/A were observed in 10%, 49%, and 41% , respectively, whereas the G/G, A/G, and A/A genotypes were observed in 24%, 45%, and 31% of case patients, respectively. The G/G genotype of the Hyp188III site in the AT2R gene were associated significantly with the risk of developing preeclampsia.Polymorphisms of AT2R gene in the renin angiotensin system pathway were associated significantly with preeclampsia risk.

P04.40

A genome-wide expression profile of decidual tissue in preeclampsia

E. Trifonova[1]*, N. Ershov*[2]*, T. Gabidulina*[3]*, V. Stepanov*[1]*;*
[1]*Institute for Medical Genetics, Siberian Branch of Russian Academy of Medical Sciences, Tomsk, Russian Federation,* [2]*The Institute of Cytology and Genetics, The Siberian Branch of the Russian Academy of Sciences, Novosibirsk, Russian Federation,* [3]*IInstitute for Obstetrics and Gynecology, Siberian Branch of Russian Academy of Medical Sciences, Tomsk, Russian Federation.*

Preeclampsia is a common pregnancy-specific disorder with unknown etiology diagnosed in 5-17% of pregnancies. It is the leading cause of maternal and perinatal morbidity and mortality. Candidate genes associated with preeclampsia have not been fully described. To investigate how the expression of maternal genes contributes to the mechanisms underlying the progression of the disease, we investigate global placental gene expression in preeclampsia using microarray technology. Genome-wide transcriptional profiling was performed on decidua basalis tissue from preeclamptic (n=10) and normal (n=11) pregnancies. Among the 26000 genes that were screened, 79 were found to be differentially expressed between normal and pre-eclamptic tissues. Among these candidates, 59 were up-regulated and 20 were down-regulated. The up-regulated genes included *LEP, BHLHB2, SIGLEC6, RDH13, BCL6, SYDE1,* which are well-known differentially expressed genes for pre-eclampsia, as well as *CORO2A, CEBPA, HK2* which was recently proved to be linked with the etiology of this disease. Gene ontology analysis further revealed several biological processes that could be associated with the development of pre-eclampsia, including response to stress, immune system process, regulation of cell communication, intracellular signaling cascade etc. Furthermore, when our patients were classified as cases of mild or severe pre-eclampsia, the expression of 10 genes could be correlated with the severity of this disorder. This finding may provide insight into the pathophysiology of the disorder and lead to new therapeutic possibilities for this disease. This work was supported by the Russian Foundation for Basic Research.

P04.41

Polymorphisms in the ANXA5 gene promoter in Japanese women with pre-eclampsia

H. Kurahashi[1], *H. Miyamura*[1,2], *H. Nishizawa*[2], *S. Ota*[1], *M. Suzuki*[1], *A. Inagaki*[1,2], *H. Egusa*[1,2], *S. Nishiyama*[1,2], *Y. Udagawa*[2];
[1]*Division of Molecular Genetics, Institute for Comprehensive Medical Science, Fujita Health University, Toyoake, Aichi, Japan,* [2]*Department of Obstetrics and Gynecology, Fujita Health University School of Medicine, Toyoake, Aichi, Japan.*

Annexin A5 (ANXA5) forms an antithrombotic shield on the apical surface of syncytiotrophoblasts in the placental villi. A common haplotype called M2 consisting of minor alleles of four SNPs in the promoter region of the ANXA5 gene is more frequent in women with recurrent pregnancy loss. In this study, association between the M2 and pre-eclampsia (PE) was examined. Placental DNAs from 47 Japanese PE patients and 50 normotensive controls were genotyped. The M2 was recorded in 12 out of 47 PE placentas (25.5%) but 5 out of 50 controls (10%), and the difference was statistically significant (P=0.04). However, when maternal blood samples were genotyped, the M2 was observed only in 7 out of 34 PE patients (17.5%) and 5 out of 22 controls (13.2%) (P=0.66). In case of placentas carrying the M2, mothers were also found to carry the M2 in 2 out of 4 (50%) in the control group, and the frequency was not high in PE group (4 out of 6, 67%). Placental expression of ANXA5 was examined by qRT-PCR, but not different between PE and controls (P=0.71). However, the expression levels were lower in M2 carriers than in non-carriers in each group (P=0.076, P=0.004). Our data might indicate that hypomorphic alleles in the ANXA5 promoter in placenta, not in maternal blood, are essential to the onset of PE, and that the reduced expression of ANXA5 in placental villi carrying the M2 might be associated with local hypercoagulable state possibly leading to the onset of PE.

P04.42

Preimplantation genetic diagnosis (PGD) after trophectoderm biopsy - results from 2010 to 2012

U. Koehler[1], *U. Schön*[1], *V. Mayer*[1], *A. Stegerer*[1], *K. Sendelbach*[1], *M. Locher*[1], *B. Paulmann*[2], *D. Shakeshaft*[3], *R. Suttner*[3], *B. Seifert*[2], *W. Würfel*[3], *E. Holinski-Feder*[1];
[1]*MGZ - Medizinisch Genetisches Zentrum, Munich, Germany,* [2]*KITZ - Kinderwunsch Therapie im Zentrum, Regensburg, Germany,* [3]*Kinderwunsch Centrum München, Munich, Germany.*

The German Supreme Court (BGH) stated in July 2010 that preimplantation genetic diagnosis, PGD (or PID) is in accordance with the Embryo Protection Act (ESchG) and can be offered couples at risk for monogenic diseases and chromosomal aberrations. Here we present the results of PGD for monogenic diseases as well as for reciprocal and Robertsonian translocations employing trophectoderm (TE) cells from day 5 blastocysts. Protocols for mutation analysis for a number of genes involved in severe monogenic inherited disorders were established and optimized to fit into the short time span of 24 hours between biopsy and embryo transfer. PCR strategies for mutation detection involved either indirect methods (linkage analysis with polymorphic markers), or direct mutation detection by sequence or fragment length analyses. For couples, who are carrier of a reciprocal or Robertsonian translocation, array CGH (24sure technology) was performed. Here, only a minority of TE samples (approx. 33%) revealed an euploid, balanced result, whereas the majority of samples (approx. 66%) were aneuploid showing an unbalanced karyotype due to the balanced translocation in the parents, or due to aneuploidies of other chromosomes than expected from the parents´ karyotype. In the majority of cases, at least one embryo was unaffected, which led to a transfer of one or two embryos in each cycle. Our results of >100 samples clearly demonstrates the reliability of trophectoderm biopsy for PGD. Even more, the pregnancy rate strikingly increased to a rate above 60% per embryo transfer.

P04.43

First pregnancy after preimplantation genetic screening (PGS) in a balanced translocation carrier with 46,XX,t(4;14)(q25;q32.1) karyotype

U. Noss[1], *S. Bug*[2], *J. Pricelius*[2], *B. Groß*[1], *M. Stecher*[2], *B. Becker*[2], *C. Nevinny-Stickel-Hinzpeter*[2];
[1]*Center for Reproductive Medicine, München, Germany,* [2]*synlab Medizinisches Versorgungszentrum Humane Genetik, München, Germany.*

We report on the outcome of assisted reproductive treatment comprising PGS of a couple with a healthy daughter and the desire for a second child. The 33 year old consulter was diagnosed as balanced translocation carrier of a t(4;14)(q25;q32.1), her non-consanguineous partner showed a normal karyotype. They reported a history of seven pregnancy losses. Cytogenetic diagnostic on the most recent product of conception revealed a genetic cause demonstrating in the karyotype of 46,XX,der(14)t(4;14)(q25;q32.1)mat. The couple agreed to array based PGS, which was performed by trophectoderm analyses of five day 5-blastocysts. While embryos were vitrified, laser dissected biopsies of two to six cells each were subjected to whole genome amplification and then hybridized to 24sure+ microarrays utilizing the SurePlex DNA amplification system and the 24sure protocol (BlueGnome, Cambridge, United Kingdom).

Although presenting with normal morphology, four of the blastocysts were assigned a minimal potential for nidation and normal development due to the presence of multiple aneuploidies. As suspected, three of them displayed partial and whole chromosome imbalances of chromosomes 4 and 14 originating from maternal derivatives. Interestingly, two of them harboured a plethora of imbalances affecting additional chromosomes, another one a trisomy 9 as sole abnormality. One biopsy appeared euploid and the respective embryo was transferred. Ongoing pregnancy was confirmed biochemically and by ultrasound. This case illustrates the benefit of PGS for translocation carriers with chromosomal breakpoints leading to a low risk for the birth of a child with imbalanced karyotype but elevated risk for still births or early pregnancy losses.

P04.44

Cytokine gene expression in women with embryo loss

K. Kovalenko, *E. Mashkina, I. Pokudina, T. Shkurat;*
Research Institute of Biology, Southern Federal University, Rostov-on-Don, Russian Federation.

Recurrent miscarriage is often defined as three or more consecutive miscarriages. While it has a number of causes, the more important ones relate to chromosomal and genetic abnormalities and autoimmunity. An aberrant maternal immune response, whereby the requisite adaptations to support conceptus development fail, is one likely mechanism contributing to unexplained recurrent miscarriage. In this study, we examined expression of IL-1β, IL-6, IL-10, and TNF-α in human chorion and endometrium tissues from women with normal and miscarriage pregnancies using quantitative RT-PCR assays. We found that IL-1β mRNA expression is higher in endometrium than in the chorion both in miscarriage and normal pregnancy. In miscarriage expression level is higher than in normal pregnancy (in the chorion and endometrium). IL-6 mRNA expression lower than half the samples in the endometrium than in the chorion and in miscarriage expression level lower than in normal pregnancy. IL-10 and TNF-α mRNA expression in two compared groups did not differ. Inadequate expression of IL-6 and IL-1β mRNAs in chorion and endometrial tissues may predispose to recurrent miscarriage through a perturbed maternal immune response, effects on decidual tissue remodeling and angiogenesis, or dysregulated trophoblast differentiation and invasion.

P04.45

Gene mutations of EG-VEGF and its receptor genes in patients of recurrent pregnancy loss

M. Su[1], *L. Wu*[2], *P. Kuo*[1];
[1]*Department of Obstetrics and Gynecology, National Cheng-Kung University Hospital, Tainan, Taiwan,* [2]*Institute of Molecular Medicine, College of Medicine, National Cheng Kung University, Tainan, Taiwan.*

Recurrent pregnancy loss (RPL) is a multi-factorial disorder and up to 50% of cases remain undetermined causes after detailed clinical examination. Angiogenesis plays a critical role in early gestation and endocrine gland-derived VEGF (EG-VEGF) is a newly found angiogenesis-associated gene. The role of EG-VEGF and its two receptor genes (PKR1, PKR2) in human early pregnancy was believed to have a direct effect on both endothelial and trophoblastic cells and are likely to play important roles in placentation. We previously found gene polymorphisms of PKR1, PKR2 were significantly associated with human RPL using tag SNP analysis. We now direct sequenced these genes in 100 RPL patients and 100 normal controls, trying to fine map the variation sites that interfere with early pregnancy and further functional validate in vitro studies. We found allele and genotype frequencies of PKR1(I379V) and PKR2(V331M) were significantly higher in the normal controls and may play protective roles in RPL (p<0.05). Both variants induced nonsynonymous change of amino acids and located in the intracellular C-terminal domains of G protein-coupled receptors. We further demonstrated PKR1(I379V)- and PKR2(V331M)-overexpressed cell had altered intracellular calcium influx and significantly higher ability of cell invasiveness in both HEK293 and JAR (trophoblast) cell lines. We therefore concluded that PKR1(I379V) and PKR2(V331M) may play protective roles in preventing RPL by altering intracellular calcium signaling and enhancing trophoblast cell invasion ability.

P04.46

The distribution of HLA-G 14 bp insertion/deletion polymorphism and IL-10 SNP -1082G/A,- 592C/A, -819C/T in the case of recurrent pregnancy loss (RPL)

K. Sosnina, *D. Zastavna, O. Terpylyak, M. Tyrkus;*
Institute of Hereditary Pathology, NAMS of Ukraine, Lviv, Ukraine.

Pregnancy prolongation considerably depends on non-classical HLA-G antigen and is associated with HLA-G 14bp (+)insertion/(-)deletion polymorphism. HLA-G gene transcription in trophoblast cells is under control of cytokines secreted by placenta. The interregulation of HLA-G and IL-10 genes expression is discussed. The aim of our research is to analyze the distribution of HLA-G 14bp insertion/deletion polymorphism and IL-10 SNP-1082G/A, -592C/A, -819C/T among the families with RPL. Methods: DNA extraction from peripheral blood cells and chorionic villi, PCR, agarose gel electrophoresis. Results: 140 women with RPL, 86 spontaneously aborted embryos and 100 reproductively healthy women have been observed. Significantly higher HLA-G gene genotype +14bp/+14bp frequency has been shown in the group of women with RPL (P<0.05) and in the group of spontaneously aborted embryos (P<0.05) in comparison with the control group. The presence of this genotype in women, or embryos is associated with 3-fold increased risk of RPL (OR = 3.41, CI: 0.98-11.85 and OR = 2.75 CI: 1.10-6.90). The analysis of distribution of IL-10 SNP-1082G/A, -592C/A, -819C/T genotype has shown the significantly higher 1082GG-genotype (P<0.01) and 592CC, 819 CC-genotypes (P<0.05) frequency in the group of women with RPL in comparison with the control group. The increasing of risk of RPL up to 4 times with 1082GG-genotype (OR=3.43; CI: 1.72-6.84) and 592CC, 819 CC-genotypes, (OR=3.87; CI: 1.23-12.20) has been established. Conclusions: HLA gene mutations and changes in the genes which interact with HLA-system can cause the reproductive dysfunction among women and lead to early fetal loss.

P04.47

Problems with Robertsonian translocations between chromosomes 13 and 14 may also cause problems for men.

A. Klímová*;*
Department of Medical Genetics, Ústí nad Labem, Czech Republic.

Robertsonian translocation is the most common type of chromosome rearrangement with a prevalence of 1 in 1000 in the general population. The most common subtype of Robertsonian translocation is seen between chromosomes 13 and 14. According to available literature, the der(13;14) women have a 1% chance of having a baby with trisomy 13, whereas the males with any Robertsonian combination have a slim chance - below 1%, of their children being affected.

We present three cases of unbalanced form of Robertsonian translocations detected by fluorescent in situ hybridisation, quantitative fluorescent polymerase chain reaction and spectral karyotyping.*The first case* is represented by a fetus in whom trisomy 13 syndrome 46,XY,+13,der(13;14)(q10;10) was revealed during prenatal screening. Consequently, oligohydramnion and cheilognathopalatoschis was observed in the fetus and the pregnancy was terminated. Translocation 45,XX,der(13;14) was found in the mother. Her medical history was significant for eight spontaneous abortions. The *second case* features a fetus with trisomy 13 syndrome 46,XX,+13,der(13;14)(q10;q10). The pregnancy was terminated because of multiple malformations. Balanced translocation 45,XY,der(13;14) was found in the father. In most cases couples carrying Robertsonian translocation may request preimplantation genetic diagnosis in order to select embryos with no genetic imbalance and hence increase their chances of a successful pregnancy. But our *third case* describes a couple evaluated for primary sterility - translocation 45,XY,der(13;14) was found in men. The couple had a history of three unsuccessful attempts on in vitro fertilisation with PGD. Their first spontaneous pregnancy ended in miscarriage. It was found karyotype 46,XX,+13,der(13;14)(q10;q10) from the sample.

P04.48

Role of TNF-α, IFN-γ, IL-6, TGF-β1 and IL-10 in Pathogenesis of Recurrent Pregnancy loss

E. Ozturk[1], *S. Pehlivan*[2], *S. Oguzkan-Balci*[2], *M. G. Ugur*[1], *Y. Ozkan*[1], *O. Balat*[1]*;*
[1]*University of Gaziantep, Faculty of Medicine, Department of Obstetric and Gynaecology, Gaziantep, Turkey,* [2]*University of Gaziantep, Faculty of Medicine, Department of Medical Biology and Genetics, Gaziantep, Turkey.*

Aim : According to previous investigations, certain cytokines may play a role in recurrent pregnancy loss (RPL) and also some cytokine gene polymorphisms may affect the level of cytokine production. The aim of our study was to investigate the potential associations between IL-6 (-174), IL-10 (-1082, -819), IFN-γ (+874), TGF-β1 (codon 10/25) and TNF-α (-308) gene polymorphisms and RPL.

Method: A case control study was carried out in 49 RPL patients and 39 healthy control women. Cytokine genotyping was performed by PCR-SSP.

Results: RPL patients had significantly higher frequencies of TNF-α polymorphism in both GA genotype (high expression) (p=0.020) and A allele (p=0.026). No statistically significant differences were observed between groups in genotype and allele frequencies of IL-6 and IFN-γ genes. The haplotypes of TGF-β1 and IL-10 were compared in terms of their expressions and it was shown that the CC/GC, CC/CC, TT/CC, TC/CC haplotypes (low expression) of TGF-β1 had significantly decreased in the patients (p=0.049), whereas there were no statisticaly significant differences in the haplotypes of IL10 (p>0.05).

Conclusion: Our results showed that the high expression of TNF-α gene was associated with susceptibility PRL. The low expression of TGF-β1 gene may be a risk factor for the development of PRL. This would further help in efficient management of immunologically mediated recurrent miscarriages at the sample/individual level. This study which is **the first** to search eight polymorphisms of five cytokine genes at the same time in RFLP patients.

P04.49

DNA fragmentation status in patient's with necrozoospermia

S. Jallad, *S. Braham, S. Ibala, A. Saad, M. Ajina, M. Mehdi;*
Laboratory of Cytogenetic Molecular Biology and Human Biology of Reproduction, Soussa, Tunisia.

Introduction : Necrospermia is still a poorly documented cause of male infertility, Several hypothesis have been made forward to explain the relationship between necrospermia and DNA fragmentation. Our aim was to determine if a relationship exists between the levels of sperm DNA fragmentation and necrospermia in infertile men.

Patients and methods: Semen samples obtained from 70 infertile men were analysed according to world health organization guidelines .The eosin-nigrosin viability test was performed and the percentage of viable and non viable sperm were assessed by counting a minimum of 100 spermatozoa. Patients were subdivided in three groups: normozoospermia, moderate necrozoospermia and severe necrozoospermia. DNA fragmentation was detected by TUNEL assay, approximately 500 cells were counted, and DNA fragmented index (DFI) was calculated. Results: The DFI was 9.28 ± 2.98 % in patients with normal level of dead spermatozoa, 20.25 ± 3.21 % in patients with moderate necrozoospermia, and 35.31 ± 5.25 % in patients with severe necrozoospermia. Sperm DNA fragmentation was significantly higher in patients with necrozoospermia. A strong correlation was found between the degree of necrozoospermia and sperm DNA fragmentation; In addition statistically significant correlations were found between the DFI level and sperm motility, abnormal sperm morphology. However no evident correlation was found between the DFI and sperm count or paternal age.

Conclusion: our study showed a high DFI in necrozoospermic men, particularly when necrozoospermia exceeding the proportion of 80 %. So severe necrozoospermia is a predictive factor for an increased risk of sperm DNA damage.

P04.50
Association study of single nucleotide polymorphisms in SLC6A14 gene with male infertility

*Z. Moneva[1], **D. Plasheska-Karanfilska**[1], P. Noveski[1], T. Plasheski[2];*
[1]Macedonian Academy of Sciences and Arts, Research Center for Genetic Engineering and Biotechnology “, Skopje, The Former Yugoslav Republic of Macedonia, [2]of Endocrinology and Metabolic Disorders, Faculty of Medicine, Skopje, The Former Yugoslav Republic of Macedonia.

The gene SLC6A14, encoding for amino acid transporter related to appetite control has been found to be in association with X-linked obesity. The results of several studies point to an increased likelihood of abnormal semen parameters among overweight men. Possible association of three single nucleotide polymorphisms (SNPs) in the SLC6A14 gene and male infertility was the subject of our study. We have analyzed 123 infertile males of different ethnic origin (83 Macedonian, 30 Albanian, 10 of other origin) which have previously been diagnosed either with idiopathic azoospermia (50) or oligozoospermia (73) in comparison to 127 fertile men (98 Macedonians and 29 Albanians) as controls. The methodology included multiplex PCR followed by single nucleotide extension reaction and capillary electrophoresis on ABI 3130 Genetic Analyzer for detection of SLC6A14 303 A/T (SNP1), 20649 C/T (SNP2) and 22510 C/G (SNP3). The allele frequencies showed a significant difference between the infertile patients and fertile controls (p=0,044) only for the 22510 C/G SNP located in the 3’ untranslated region of the SLC6A14 gene (0,463 in infertile men versus 0,339 in fertile controls for the minor C allele). The distribution of haplotypes including the three SNPs, as well as only SNPs 2 and 3 that lie less than 2kB apart was also analyzed. The ACG and CG haplotypes were more frequent among fertile control men than among infertile patients (0,520 vs. 0,366; p=0, 014 and 0,661 vs. 0,537; p=0, 044 respectively). In conclusion, this is the first report that links the SLC6A14 polymorphisms with male infertility.

P04.51
PRM1 and PRM2 gene polymorphism in Czech and German men with idiopathic oligozoospermia

***P. Křenková**[1], F. Tüttelmann[2], S. Kliesch[3], P. Paulasová[1], J. Diblík[1], M. Macek jr.[1], M. Macek sr.[1];*
[1]Department of Biology and Medical Genetics, Prague, Czech Republic, [2]Institute of Human Genetics, University of Münster, Münster, Germany, [3]Department of Clinical Andrology, Centre of Reproductive Medicine and Andrology, University of Münster, Münster, Germany.

The aim of our study was to verify the impact of the most frequent ACC haplotype formed by PRM1 230A>C and PRM2 298G>C/373C>A variants on spermatogenesis in Czech and German males with idiopathic oligozoospermia.

PRM1 and PRM2 sequencing was performed on 3130xl Genetic Analyzer in 52 men with idiopathic oligozoospermia, in 52 normozoospermic and in 75 Czech males with proven fertility. The three SNPs were also analysed by Taqman assays in 108 German males with less and 160 with more than 20 million sperm per millilitre.

In PRM1 we detected the common variant (230A>C) with an overall minor allele frequency (MAF) of 28.5% and three rare variants (c.54G>A, c.102G>T and c.166C>T) with overall frequencies of 0.56%, 0.28% and 0.28%, respectively. In PRM2 we detected the two common polymorphisms (298G>C and 373C>A) with overall MAFs of 49.1% and 29.3%, respectively, and two rare variants (c.201C>T, c.377C>T), both with overall frequencies of 0.28%.

Despite the ethnical difference the allele prevalences of the most frequent PRM1 and PRM2 polymorphisms are identical in Czech normozoospermic and Czech fertile as well as German normozoospermic males, except the four rare PRM1 and PRM2 SNPs were present only in Czech males. The prevalence of all detected variants and the ACC haplotype was not significantly different between men with idiopathic oligozoospermia and controls in Czech and German males. In conclusions, we could not confirm the impact of PRM1 and PRM2 gene variants on sperm counts

Supported by MZ0FNM2005 and CZ.2.16/3.1.00/24022.

P04.52
Investigation of mutations in the Synaptonemal Complex Protein 3 (SYCP3) gene among azoospermic infertile male patients in the Turkish population

***H. Gurkan**[1], F. Aydın[2], A. Kadıoglu[3], S. Palanduz[4];*
[1]Trakya University, Medical Faculty, Department of Medical Genetics, Edirne, Turkey, [2]Istanbul University, Istanbul Medical Faculty, Department of Medical Biology, Istanbul, Turkey, [3]Istanbul University, Istanbul Medical Faculty, Department of Andrology, Istanbul, Turkey, [4]Istanbul University, Istanbul Medical Faculty, Department of Medical Genetic, Istanbul, Turkey.

Objective: To investigate possible mutations and/or single nucleotide polymorphisms in the synaptonemal complex protein 3 (SYCP3) gene among non-obstructive azoospermic infertile males in a Turkish population.

Design: Nine exon deep intronic primers belonging to the SYCP3 gene were designed and amplified by PCR, and the nucleotide sequences were identified by automated DNA sequence analysis.

Patients: Seventy-five non-obstructive azoospermic infertile male patients were included in the study. These patients were unrelated to each other and had 46,XY chromosome structure without Y microdeletion. In addition, 75 individuals whose fertility was proven by reproduction were enrolled in the study as controls.

Main Outcome Measure(s): PCR and automated DNA sequence analysis to detect mutations and/or single nucleotide polymorphisms in the SYCP3 gene.

Results: No mutations were detected in the 9 exons of SYCP3. A total of 11 variations, however, were detected: 7 have been identified in the NCBI SNP database, whereas 4 have not.

Conclusions: Based on the results, we agree with the idea that SYCP3 mutations are not associated with the genetic susceptibility for meiotic arrest in infertile male patients with non-obstructive azoospermia in the Turkish population and that further studies investigating the other components of the synaptonemal complex protein (SYCP1, SYCP2) should be conducted.

P04.53
Factor II G20210A and factor V G1691A mutations and methylenetetrahydrofolate reductase C677T polymorphism in 155 women with repeated pregnancy loss

***S. Seyedhassani**[1,2], M. Houshmand[2], M. Neshan[1,3], F. Saeb[1], S. Salari[1], M. Saffar[4], S. Kalantar[4];*
[1]Dr. seyedhassani genetic center, Yazd, Islamic Republic of Iran, [2]National Institute of Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran, [3]Yazd welfare organization, Yazd, Islamic Republic of Iran, [4]Yazd medical science university, Yazd, Islamic Republic of Iran.

Introduction: pregnancy is the process from the fertilized ovum to the fetus with capability of extra uterine survival. Pregnancy loss is the most common complication of pregnancies. About 1 in 300 couples and 0.5-2% of women are involved in repeated pregnancy loss (RPL). Various etiological factors involve in RPL and the main part of them remains unknown. Among them the thrombophilic factors are important.

Material and methods: Genetic counseling program was done for 158 couples suffering from RPL. Three molecular genetic variations were investigated in main thrombophilic agents: G20210A in factor II, G1691A in factor V and C677T in MTHFR gene. The method was PCR-RFLP.

Results: No G20210A mutation was found in Factor II gene. Heterozygote G1691 mutation in factor V gene was found in 3 women (1.94%). But, C677T polymorphism in MTHFR gene was found in 33 women (21.3%). Among them, 4 cases (12.12%) were homozygote and 29 cases (87.88%) were heterozygote.

Discussion: Assessment of variations in thrombophilic related genes can be useful in etiologic evaluation and planning of effective treatment in RPL women. Genetic counseling, clinical aspect of abortions and genotype-phenotype correlation should be considered for request of molecular thrombophilic tests in RPL.

P04.54
DNA fragmentation in chromosomal translocation carriers

***E. Shilnikova**[1,2], I. Fedorova[2], A. Gzgzyan[2];*
[1]Saint-Petersburg State University, Saint-Petersburg, Russian Federation, [2]Ott’s Institution of Obstetrics and Gynecology, Saint-Petersburg, Russian Federation.

Carriers of a chromosomal structural abnormality, as reciprocal or robertsonian, have a normal phenotype but often have fertility problems. Infertility of men with chromosomal translocations could therefore be partly explained by high DNA fragmentation in sperm. The aim of this study was to analyze the sperm DNA fragmentation in translocation carriers.

One robertosonian translocation carrier 46,XY,der(13;14)(q10;q10), 3 reciprocal translocations carriers: 46,XY,t(6;19)(p22;q12); 46,XY,t(2;3)(q33;q29); 46,XY,t(1;5)(p22;q32),t(6;12)(q15;q21) and 5 fertile donors were recruited. Semen analysis was evaluated according to WHO guidelines (2010). The method used to assess sperm DNA fragmentation was the terminal deoxynucleotidyl transferase-mediated dUTP nick-end labeling (TUNEL) assay.

DNA fragmentation frequency in sperm from donors was 0,26±0,09%, whereas that from translocation carriers was 0,91±0,53%. Significantly increased rate was seen among oligoasthenoteratoozoospermia patients: 46,XY,der(13;14)(q10;q10) and 46,XY,t(2;3)(q33;q29) (1,4% and 1,35%, respectively). Sperm DNA fragmentation rate in 46,XY,t(6;19)(p22;q12) and 46,XY,t(1;5)(p22;q32),t(6;12)(q15;q21) teratozoospermic patients in both cases was 0,45%. In the present study, the DNA fragmentation rates were significantly different between the carriers of a chromosomal structural abnormality with abnormal and normal spermogram (p=0,0007). Therefore, the present results suggest that the DNA fragmentation rate may depend not only of the presence of a structural abnormality but also on the spermogram parameters.

In conclusion, the infertility of men carrying a chromosomal structural abnormality could be explained by the poor-quality semen, and/or the elevated rate of DNA fragmentation.

P04.55

TSPY1 copy number variation and male infertility

P. Noveski[1], L. Chakalova[1], T. Plaseski[2], D. Plaseska-Karanfilska[1];
[1]Macedonian Academy of Sciences and Arts, Skopje, The Former Yugoslav Republic of Macedonia, [2]Clinic of Endocrinology and Metabolic Disorders, Faculty of Medicine, Skopje, The Former Yugoslav Republic of Macedonia.

Testis-specific protein, Y-linked 1 (TSPY1) gene is located on the short arm of Y chromosome (Yp11.2) and is present as an array of approximately 18-76 gene copies. It encodes a testis-specific protein that is thought to have a role in sperm differentiation and proliferation. It has recently been suggested that TSPY1 copy numbers may influence spermatogenic efficiency. In this study, we compared the relative TSPY1 copy number between men with spermatogenic failure and fertile controls. The study group included 60 azoospermic men, 66 men with oligozoospermia and 119 fertile controls of similar ethnic origin. Relative TSPY1 copy number was determined by quantitative PCR compared to a single copy HPRT1 gene. Y chromosome haplogroups were determined by analysis of 28 single nucleotide polymorphisms (SNPs) by multiplex SNaPshot. Infertile patients showed higher mean dCt values in comparison with the fertile control men with a borderline statistical significance (p= 0,0785). Oligozoospermic men showed statistically higher mean dCt value when compared with the fertile controls (p=0,0170). This difference was even higher when Macedonians with oligozoospermia were compared with the Macedonian fertile controls (p=0,0098). The dCt differed between different Y chromosome haplogroups (p=0,0027), but no difference was observed between infertile and fertile men with the most common Y chromosome haplogroups. In conclusion, the initial results of the study investigating relative TSPY1 copy number in infertile men showed an association of TSPY1 gene copy number with oligozoospermia. Our results also showed that the TSPY1 gene copy number differs between different Y chromosome lineages.

P04.56

Association between ubiquitin-specific protease 26 (USP26) gene variations and male infertility in Iranian men.

H. Gourabi[1], M. Totonchi[1], U. Asadpoor[1], S. Zari Moradi[1], M. Sabbaghian[2], M. Sadighi Gilani[2], K. Anissi Hemaseh[1], H. Hosseinifar[1], **A. Mohseni Meybodi**[1];
[1]Department of Genetics, Reproductive Biomedicine Research Center, Royan Institute for reproductive Biomedicine,ACECR., Tehran, Islamic Republic of Iran, [2]Department of Andrology, Reproductive Biomedicine Research Center, Royan Institute for reproductive Biomedicine,ACECR., Tehran, Islamic Republic of Iran.

The human X chromosome is enriched with testis-specific genes that may be crucial for male fertility. Recently, mutations in ubiquitin specific protease 26(*USP26*) gene have been proposed to be associated with male infertility. This gene locates on $X_{q26.2}$. Some mutations and haplotypes on this gene have been proposed to be associated with male infertility. In this study, five different mutations on USP26 were investigated: 1737G>A,1090C>T, 370-371ins ACA,494T>C and 1423C>T. The study included 120 infertile men with non-obstructive azoospermia and 60 fertile men. Besides family history of reproduction, hormonal evaluation and semen analysis were performed. DNA was extracted from blood samples. PCR-SSCP, PCR-RFLP and PCR Product Cloning methods were used and resumed by sequencing to insuring about the mutations. Moreover, USP26 gene expression was studied by Real-Time PCR after RNA extraction followed by cDNA synthesis from testis biopsy in obstructive and non obstructive azoospermia patients. Surprisingly the mutation frequency was the same in both groups (6.67%). The results indicate that there is a haplotype between three observed mutations in Iranian population include:370-371insACA, 1423C>T and 494T>C,as reported before in some other populations.This haplotype was seen in the control group as well. Serum testosterone concentrations and testicular volume did not differ in the mutation positive group compared with the non-mutation group. About the USP26 gene expression, there was no significant difference among these two groups. These results indicate that these alterations might not be involved in male infertility in Iranian population and their role in infertility is still controversial.

P04.57

Molecular characterisation and analysis of spermatozoa in an infertile man with oligozoospermia and mosaicism of an unbalanced Y;autosome translocation

A. Röpke[1], D. Dossow-Scheele[1], Y. Stratis[1], S. Kliesch[2], P. Wieacker[1], F. Tüttelmann[1];
[1]Institut für Humangenetik, Münster, Germany, [2]Centrums für Reproduktionsmedizin und Andrologie, Münster, Germany.

We report on an infertile male patient with an unremarkable general medical history and clinical examination including genital exam. He had severe oligozoospermia in two semen samples with slightly elevated FSH levels of 7.6 U/l and otherwise normal hormone values.

Conventional cytogenetic analysis on peripheral lymphocytes revealed a mosaicism of cells with an unbalanced Y;autosome translocation found in 10 metaphases and in 20 metaphases an apparently normal karyotype summarised as 45,X,der(Y)t(Y;21)(q12;q21),-21[10]/46,XY[20]. FISH analysis demonstrated the presence of the subtelomeric probe DXYS224 on the derivative Y chromosome indicating a breakpoint closely to the telomere region of Yqter. CGH analysis using the 400k array set from Agilent revealed loss of 9.2Mb spanning the chromosomal region 21q11.2-q21.2 with loss of 13 genes. Loss of Y chromosomal material was not observed. Both, FISH and CGH also indicated mosaicism with aberrant and normal cells.

Furthermore, we analysed spermatozoa by FISH using BAC probes for region 21q11.2 (inside the deleted region) and 21q22.3 (as control probe) and centromeric probes for the X and Y chromosomes. The FISH results demonstrated a normal signal pattern with one normal chromosome 21 and one X or one normal Y chromosome in most spermatozoa (73%). On the other hand, 10% of the analysed spermatozoa showed only one normal chromosome 21 without any specific gonosomal signal. These spermatozoa would lead to fertilised eggs with only one X chromosome. Other signal constellations were only found in few spermatozoa each.

P04.58

Screening for Microdeletions in the AZF Region of the Y Chromosome in Patients with Disorders of Sex Development due to 45,X/46,XY Chromosome Abnormalities

M. Y. Nishi, P. T. L. Santos, E. M. F. Costa, B. B. Mendonca, S. Domenice;
Laboratorio de Hormonios e Genetica Molecular LIM42, Hospital das Clinicas da Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil.

The etiology of the disorders of sex development (DSD) in patients with 45,X/46,XY karyotype is not yet completely understood. Deletions of AZF region (AZFa, AZFb and AZFc sub-regions), which might predispose to Y loss, have been identified in Klinefelter syndrome (KS) and in 45,X/46,XY subjects. **Objective**: to screen Yq microdeletions in Brazilian patients with DSD due to 45,X/46,XY chromosomal abnormalities. Twenty-six 45,X/46,XY or 45,X/46,X,idic(Y) subjects were selected: 16 with mixed gonadal dysgenesis (MGD) and 11 with Turner syndrome (TS). Eight Y *loci* were screened using PCR: DYZ3 (centromere); DYS280, *UTY* (AZFa); DYS216, DYS231, DYS224 (AZFb); *DAZ*, *PPP1R12BP1* (AZFc). **Results**: Yq microdeletions were detected in 6 (22%) patients (3 MGD; 3 TS). Regarding MGD patients, the 3 deletions span at least 6, 4.5 and 3 Mb. In the 3 TS patients the deletion spans at least 3 Mb. **Discussion**: Yq deletions identified in these patients involved the AZFb and AZFc regions. The longest deletions of Yq were identified in 2 MGD patients with male phenotype. The AZFc region was deleted in all 6 patients. Likely, the AZFc deletions are the most common identified in patients with idiopathic infertility due to oligozoospermia or complete absence of germ cells as in KS. In 45,X/46,XY patients, there are a few reports identifying deletions in AZFb/AZFc regions. Extensive studies are needed to establish the exactly association between Yq microdeletions and the various degrees of gonadal dysgenesis in these patients and to confirm the role of this mechanism for the formation of 45,X cell line.

Changes in age of pregnant women who undergo amniocentesis

I. Tonkovic Djurisevic, M. Miklos, K. Crkvenac Gornik, L. Letica, R. Lasan, S. Huljev Frkovic, D. Begovic;
Division of Genetics, Department of Pediatrics, University Hospital Centre Zagreb, Zagreb, Croatia.

Karyotyping of fetal cells obtained by amniocentesis reveals the number and structure of chromosomes. Amniocentesis is offered to all women of advanced maternal age, in Croatia 35 years of age and older. Serum screening and ultrasonography are noninvasive techniques and can assist all women, regardless of their age, in a decision concerning invasive testing. There has

been an increasing trend among women to delay childbearing, a characteristic in the most countries, including Croatia. The reason is associated with the increasing number of women wanting to receive higher education and to achieve financial independence.
During the last two decades the average age of mothers at birth of their child in Croatia increased by 3.3 years. Our results show that the average age of pregnant women who undergo amniocentesis follows the increasing trend of maternal age by four years, from 33 to 37 years of age. At the same time, the percentage of pregnant women with the single indication for the amniocentesis of advanced maternal age (AMA) is slightly decreased, while those with pathological ultrasound and/or biochemical screening increased. Although the majority of pregnant women who performed amniocentesis were aged 35 years or older, during the 15-year period, the proportion of women under 35 increased from 17.5% to 23%.
These results are evidence of an increased access to prenatal diagnosis of younger women in Croatia at increased risk for fetal chromosomal aberration. Decision about accepting or declining the prenatal testing should be made by pregnant women with their partners after genetic counseling.

P05.03

DNA diagnostics of human chromosomes numerical abnormalities using fluorescent quantitative PCR analysis in Belarus

T. Asadchuk, *K. Mosse;*
Scientific-Practical Center "Mother and Child", Minsk, Belarus.

Numerical abnormalities of human chromosomes are the most frequent cause of congenital human pathology. The frequency of chromosome 21 trisomy (Down syndrome) constitutes 1:780 in Belarus.
One of the most effective strategies for molecular diagnostics of aneuploidies and triploidies is based on quantitative PCR analysis. We selected and tested the most informative DNA-markers of chromosomes 13, 18, 21 and X. For sex determination and Klinefelter syndrome identification we tested the microsatellite markers of chromosome Y.
On the basis of current molecular genetic technologies there has been developed a method of DNA diagnostics of the most frequent aneuploidies using multiplex PCR and automated capillary electrophoresis based on the simultaneous testing of 15 microsatellite markers of chromosomes 13, 18, 21, X, Y in a single analysis. The method was tested on samples with chromosomal pathologies established by karyotype. According to the results of testing DNA samples from fetuses with Down, Edwards, Patau, Turner and Klinefelter syndromes, changing of quantitative characteristics of the alleles of respective chromosomes was detected in all the samples, indicating a high informative capacity of the developed protocol. Then with this particular test we analyzed 70 DNA samples from fetuses having the risk of chromosomal pathology. DNA was extracted from the amniotic fluid cells. Numerical abnormalities of human chromosomes were detected in 5 cases.
DNA diagnostics of human chromosomes numerical abnormalities using fluorescent quantitative PCR analysis has high throughput and low costs, and DNA analysis results can be obtained in less than 6 hours.

P05.04

Moving from chromosome analysis of cultured amniocytes: implementation of SOGC guidelines for amniotic fluids in a Canadian setting

J. McGowan-Jordan[1,2], *E. McCready*[1,2], *E. Sinclair-Bourque*[1]*;*
[1]*CHEO, Ottawa, ON, Canada,* [2]*University of Ottawa, Ottawa, ON, Canada.*

Chromosome analysis has been gold standard for prenatal detection of aneuploidies for decades. To supplement this procedure many diagnostic labs have introduced QF-PCR as a rapid aneuploidy screen for chromosomes 13, 18, 21, X or Y. There is also an increasing use of microarray testing for more complex prenatal cases with ultrasound abnormalities. In Sept 2011, the Society of Obstetricians and Gynaecologists of Canada (SOGC) and the Canadian College of Medical Geneticists (CCMG) published a joint clinical practice guideline that supports replacement of conventional karyotyping with QF-PCR whenever prenatal testing is performed solely because of an increased risk of aneuploidy for chromosomes 13, 18, 21, X or Y. Implementing this major change in analysis criteria at the same time as increased availability of prenatal microarray brings its own set of challenges: it is highly desirable to maintain a DNA source for all pregnancies with normal QF-PCR results to enable possible downstream molecular testing. Retention of a DNA source also facilitates testing should anomalies be detected later in the pregnancy, necessitating microarray. We have developed an algorithm for prenatal testing of pregnancies at risk for trisomy vs those at risk for other genetic imbalances which allows for the maintenance of a DNA source without extensive culturing. Our approach reduces chromosome analysis of cultured amniocytes by 75% while maintaining clinically appropriate testing. This approach and its implementation are discussed.

P05.05

Chromosome microarray analysis in routine prenatal diagnosis practice: a prospective study on 2800 clinical cases

F. Fiorentino[1], *F. Caiazzo*[1], *S. Napoletano*[1], *L. Spizzichino*[1], ***S. Bono***[1], *S. Michiorri*[1], *A. Nuccitelli*[1], *A. Gordon*[2], *G. Rizzo*[1], *M. Sessa*[1], *M. Baldi*[1]*;*
[1]*"GENOMA"- Molecular Genetics Laboratory, ROME, Italy,* [2]*Bluegnome Ltd, Cambridge, United Kingdom.*

Objectives: Although several studies have demonstrated the usefulness of chromosome microarray analysis (CMA) in clinical prenatal diagnosis practice, only limited conclusions could be drawn due to the small size of the cohorts analysed. To assess the feasibility of offering CMA for prenatal diagnosis as a first-line diagnostic test, a large-scale prospective study was performed on a cohort of 2800 consecutive prenatal samples, with parallel processing for both CMA and conventional cytogenetic analysis.
Methods: Women undergoing amniocentesis or chorionic villus sampling (CVS) for standard karyotype were offered CMA. A total of 2800 prenatal samples were processed in parallel using both CMA and G-banding for standard karyotyping.
Results: Clinically significant copy number variations (CNVs) were identified in 94(3.4%) samples, 70(74.5%) of which were also detected by conventional karyotyping. In 24 cases (0.9%), CMA identified pathogenic CNVs that would have remained undiagnosed if only a conventional karyotype had been performed, 16 of which were concerning well-established syndromes. The selection of an array platform specifically developed for prenatal applications, allowed us to detect a single occurrence of variation of unclear significance. CMA was also able to detect chromosomal mosaicisms as lower as 3.3% level.
Conclusions: The results of this study demonstrate that CMA improves the detection of fetal chromosome aberrations than conventional karyotyping, without missing potential pathogenic chromosomal abnormalities, with no appreciable increase in results of unclear clinical relevance. These findings provide substantial evidence for the feasibility of introducing CMA into routine prenatal diagnosis practice as a first-line diagnostic test.

P05.06

ArrayCGH as diagnostic tool for genetic analysis of spontaneous abortions

A. Lott, *H. Gabriel, M. Gencik;*
diagenos, Osnabrueck, Germany.

Spontaneous abortions are common, with 10-15% of all clinically recognized pregnancies ending in early pregnancy loss. In 40-50% of these cases, fetal chromosomal abnormalities are responsible. Identification of these abnormalities helps to estimate recurrence risks in future pregnancies.
For the last decades chromosome analysis has been the golden standard to detect genomic imbalances in spontaneous abortions. However, due to culture failure or maternal contamination often no fetal karyotype can be obtained. Since DNA-based technologies do not require dividing cells , array comparative genomic hybridization can overcome some of these limitations.
To evaluate the efficiency of arrayCGH as an alternative method for identification of chromosome anomalies in abortion material, we present the results of a study on more than 50 cases referred to our laboratory for cytogenetic analysis. So far, about 40 percent of our cases show genomic imbalances. We present two cases with an interesting correlation of clinical observation and genomic imbalance.

P05.07

Array-CGH results in fetuses with central nervous system

S. Ergin[1], *B. Karaman*[1], *B. Satkin*[1], *I. H. Kalelioglu*[2], *H. Kayserili*[1], *A. Yuksel*[2], *S. Basaran*[1]*;*
[1]*Medical Genetics Department of Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey,* [2]*Obstetrics and Gynecology Department of Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey.*

The central nervous system (CNS) anomalies are seen in 1:1000 ratios in new born population. 5-50 % is identified to have chromosome anomalies referred during antenatal ultrasonography (USG) due to any CNS abnormalities. CNS malformations are related to specific chromosome anomalies, such as ventriculomegaly with trisomy 13, 18, 21, and microduplication of 16p; holoprosencephaly with trisomy 13, 18, microdeletions of 7q, 2p, 13q, 18p, 21q, and microduplication of 3p; hydrocephaly with trisomy 13, 18, 9, microdeletion of 4p, microduplications of 1q, 3q, 5p, 9p and mosaicism of trisomy 8; corpus callosum agenesis (CCA) with trisomy 8, 18, 13, microdeletions of 2q, 6q, 15q, 13q, 1q, 3p, 3q, microduplicatios of 8p, 11q, and triploidy; choroid plexus cyst (CPC) with trisomy 18, 21, and 13; Dandy Walker malformation with trisomy 13, 18, microdeletions of 3q, 6q, 13q, 11q and microduplication of 5p, 8p, 8q and triploidy.

Array-CGH technique specifically designed for molecular karyotyping, which is the finest detection method of chromosomal abnormalities enable us to detect the imbalances as low as 5 Mb.

We aimed to investigate 35 fetuses, with various CNS anomalies, for possible submicroscopic imbalances, with Array-CGH (CGX-720K, NimbleGen-Roche), previously known to have normal karyotypes. Patient collective includes cases with ventriculomegaly (n:16), holoprosencephaly (n:6), hydrocephaly (n:5), CCA (n:3), CPC (n:3), Dandy-Walker malformation (n:2). Two chromosomal imbalances were revealed in the collection. One was 11.57 Mb deletion in 7q35qter in a case with holoprosencephaly and the other was 137.507 Kb deletion in 3p26.1p25 with CCA.

Final results will be presented.

P05.09

Optimization and validation of RHD and KELL genotyping for non-invasive prenatal diagnostics

J. Böhmova, *R. Vodicka, M. Lubusky, R. Kratochvilova, R. Vrtel, M. Studnickova, M. Kvapilova;*
University Hospital and Palacky University Olomouc, Olomouc, Czech Republic.

Introduction: There are two reasons for establishing a methodology for non-invasive determination of RHD and KELL genotypes in early pregnancy.

1) To identify fetuses which are at risk of hemolytic disease of fetus and newborn by alloimmunized pregnant women.

2) To prevent alloimmunization during pregnancy.

There is no method validation on a representative number of samples in the Czech Republic, which would allow to introduce methodology into clinical practice. Project is supported by IGA MZ CR: NT12225.

Aim: Evaluate two different cell free fetal (cff) DNA separation procedures based on adsorption on the surface of silica gel and on the separation on magnetic particles. Optimize and evaluate RHD and KELL genotyping.

Material and methods: We tested both isolation procedures in 76 cffDNA samples.

Together 200 control samples were used for genotype assessment. Optimization and calibration of RHD and KELL genotyping was done using Real-Time PCR and by capillary electrophoresiss minisequencing .

Results: There were found significant differences in the yield of cell free fetal DNA between the tested cffDNA isolation methods. Silicagel membrane based method for isolation of cffDNA shorter molecules is more suitable than the magnetic particle one.

To determine the sensitivity threshold there were performed RHD and KELL calibrations by Real time PCR and capillary electrophoresis with a dilution series RHD and KELL genotypes. Both methods are able to clearly recognize the fetal genotype.

The optimization was further examined to detect RHD and KELL genotypes simultaneously and together with multiplex SNP assay as an internal cffDNA control.

P05.10

Clinical application of array-CGH in prenatal diagnosis: case reports of pregnancies with abnormal ultrasound findings and apparently normal karyotype

D. Grochova[1], *Z. Dobsakova*[1], *I. Grochova*[1], *D. Leznarova*[1], *E. Popelinska*[1], *P. Vlasin*[1,2];
[1]*Cytogenetics laboratory Brno, Brno, Czech Republic,* [2]*Center of prenatal disgnosis, Brno, Czech Republic.*

Conventional G-banding karyotyping is a standard method used in prenatal diagnosis to detect chromosomal abnormalities larger than 5 Mb. However, many genetic syndromes are often associated with sub-microscopic deletions or duplications. Array-CGH is a modern method, which allows detection of small variations in the genome. Its application is mainly in postnatal diagnosis, where it helps to clarify diagnosis, prevention and prognosis. In prenatal diagnosis it has limited use. This is mainly because a number of aberrations detected by array-CGH have not been described and their clinical significance is unknown. Due to this fact we use a BAC-based array (BlueGnome), which is focused on areas in the genome having demonstrable connection with 110 microdeletion syndromes described in the OMIM database.

We used array-CGH to detect sub-microscopic aberrations in carefully selected 67 prenatal cases, which were primarily indicated for conventional cytogenetics based on serious ultrasound findings. Case reports, in which array-CGH enabled detection of changes that conventional cytogenetics did not reveal and cases, where array-CGH clarified the origin of a genetic extra-material (i.e. marker chromosomes) will be presented. In total, array-CGH detected clinically relevant chromosomal abnormalities in 13,5 % cases (9/67).

From our four-year experience we can say, that array-CGH is an appropriate tool with high resolution to detect small changes in the genome and provides important diagnostic information for prenatal genetic counselling. It can be applied in cases where amniocytes failed to grow for conventional karyotyping, in cases of clonal selection or for detection of sub-microscopic changes caused by inversion/translocation.

P05.11

Limitations of prenatal detection by FISH method - a case report with a complex chromosomal mosaic with 6 cell lines

E. Gorduza[1], *V. Martiniuc*[2], *M. Holicov*[2], *A. Bivoleanu*[2], *M. Volosciuc*[3], *M. Gramescu*[1], *C. Bujoran*[3], *E. Braha*[1], *C. Rusu*[1], *L. Caba*[1], *R. Popescu*[1], *M. Macovei*[1], *C. Avatajitei*[1], *M. Onofriescu*[1], *M. Stamatin*[1];
[1]*University of Medicine and Pharmacy, Iasi, Romania,* [2]*Maternity „Cuza-Voda", Iasi, Romania,* [3]*"St. Mary" Children Hospital, Iasi, Romania.*

In the period 2004-2011 in Prenatal Diagnosis Laboratory of „Cuza-Voda" Maternity Iasi were made 1425 prenatal cytogenetic analysis by FISH method, using Aneuvision probes for chromosomes 13, 18, 21, X and Y. Unfortunately, conventional chromosomal analysis based on amniocytes culture could not be applied and thus the results were formulated only by FISH. We present a case showing one of the limitations of FISH technique in prenatal diagnosis. Pregnant women, aged 26 years, were investigated in our laboratory at 16 weeks of pregnancy because of a risk of 1/200 for trisomy 21 at triple test. Analysis on the UV emission microscope revealed two chromosomal fluorescent signals for chromosomes 13, 18, 21 and X, and one signal for chromosome Y. Because the XXY trisomy is not a reason for therapeutic abortion, pregnancy continued and resulted in the birth of a male child with 2750 g weighth and 47 cm length. Neonatal clinical examination showed scaphocephaly, hypertelorism, epicantus, antevertate nostrils, prominent upper lip, micrognathia, bilateral cryptorchidism and hypotonia. In order to elucidate the causes of facial dysmorphia was made a constitutional chromosomal analysis, which revealed a mosaic with 6 cell lines and chromosomal formula: 48,XY,+mar,+mar[29]/47,XY,+mar[14]/48,XY,r(X),+mar[10]/49,XY,r(X),+mar,+mar[3]/46,XY[3]/50,XY,r(X),r(X),+mar,+mar[3]. By FISH technique with probes for centromere of chromosome X the X ring chromosomes was confirmed, while the origin of marker chromosomes has not been established. Our paper shows the failure of characterization of prenatal chromosomal mosaics by FISH technique and the need for other methods to confirm the diagnostic.

P05.12

The use of chromosome microarray analysis as a first-line test in pregnancies with *a priori* low risk for detection of submicroscopic chromosomal abnormalities

F. Fiorentino[1], *S. Napoletano*[1], *F. Caiazzo*[1], *M. Sessa*[1], *S. Bono*[1], *L. Spizzichino*[1], *S. Michiorri*[1], *A. Gordon*[2], *A. Nuccitelli*[1], *G. Rizzo*[1], *M. Baldi*[1];
[1]*"GENOMA"- Molecular Genetics Laboratory, ROME, Italy,* [2]*Bluegnome Ltd, Cambridge, United Kingdom.*

Objectives: In this study we aimed to explore the usefulness of chromosome microarray analysis (CMA) in groups of pregnancies with *a priori* low risk for detection of submicroscopic chromosome abnormalities, usually not considered an indication for testing, in order the assess if CMA improves the prenatal detection rate of chromosomal aberrations.

Methods: A total of 2800 prenatal samples were processed. The indications included: advanced maternal age (AMA), abnormal results of maternal serum screening tests (MSS), abnormal ultrasound findings (AUS), known abnormal fetal karyotype (AFK), parental anxiety (PA), family history of a genetic condition (FIS), cell culture failure (CCF).

Results: the use of CMA resulted in an increased detection rate regardless of the indication for analysis. This was evident in high-risk groups AUS-AFK (7/114, 6.1%), and also in low-risk groups, such as AMA (7/1033, 0.7%) and PA (10/1569, 0.6%). A total of 24(0.9%) fetal conditions would have otherwise been overlooked if only a standard karyotype had been performed, 17(0.6%) of which if offering CMA to high-risk pregnancies only.

Conclusions: The results of this study demonstrate that more widespread testing by CMA in fetuses would result in a higher detection of chromosome abnormalities prenatally, also in low risk pregnancies. Our findings provide substantial evidence for the utility of using CMA as a first-line diagnostic test to all pregnant women undergoing invasive prenatal testing, regardless of risk factors.

Indication	No. Samples analysed (%)	No. Samples with chr. Abn. (%)	No. Samples w/ chr. abn. not det. by conv. karyotyping	aCGH detection rate

Optimization of isolation of cell-free fetal DNA from plasma of pregnant women

G. Repiska[1], T. Sedlackova[1], G. Minarik[1,2];
[1]Comenius University in Bratislava, Faculty of Medicine, Bratislava, Slovakia, [2]Geneton Ltd., Bratislava, Slovakia.

Cell-free DNA released from fetal cells (cffDNA) represents important alternative source of material for non-invasive prenatal diagnostics. Because of the low quantity and increased fragmentation of cffDNA in maternal plasma, the DNA extraction method is crucial step for further analyses of cffDNA.

The aim of this study was to directly compare the yield of extracted DNA after using three commercial kits widely used for isolation of nucleic acids.

For cffDNA extraction from plasma of pregnant women carrying male fetuses three commercial kits and corresponding original protocols were used (QIAamp DNA Blood Mini Kit, QIAamp DSP Virus Kit, QIAamp Circulating Nucleic Acid Kit). Extracted DNA was used for amplification by qPCR. Marker - gene DYS14 located on the Y chromosome was used for comparison of circulating fetal DNA recovery. Gene for androgen receptor located on the X chromosome was used as a marker for detection of total circulating DNA. Ct values from qPCR were used for determining the relative quantity. Variability between categories was estimated by Repeated measures ANOVA and Tukey´s test.

Statistically significant difference was proved after Ct values comparison (F=48.43, p<0.0001). The yield of isolated DNA was significantly higher using Virus Kit than Blood Mini Kit (p<0.0001) and CNA Kit than Blood Mini Kit (p<0.0001). Virus Kit and CNA Kit did not significantly differ in the amount of isolated cffDNA.

According to our finding CNA Kit and Virus Kit are equally suitable for extraction of fragmented circulating DNA derived from fetal cells, when yield of isolation is important.

P05.14
Do uniparental isodisomies or microimbalances lead to early losses of pregnancy?

S. Bug[1], B. Solfrank[1], J. Pricelius[1], C. Andrew[2], M. Botcherby[2], M. Stecher[1], S. Bingemann[1], B. Becker[1], C. Nevinny-Stickel-Hinzpeter[1];
[1]synlab Medizinisches Versorgungszentrum Humane Genetik, München, Germany, [2]BlueGnome Ltd., Cambridge, United Kingdom.

Aneuploidy is known to be a common cause of spontaneous abortion. We designed a combined platform utilizing array based comparative genomic hybridization (aCGH) and single nucleotide polymorphisms (SNPs) to further elucidate genetic causes underlying pregnancy losses displaying 46,XX- or 46,XY-karyotypes. Simultaneous determination of imbalances at high resolution and genome-wide heterozygosity state was performed on a targeted CGH+SNP 8x60K microarray (BlueGnome, Cambridge, UK). Results were juxtaposed to those of a second panel displaying aneuploidies. Copy number imbalance and loss of heterozygosity (LOH) findings were compared to cases reported in the literature to determine their clinical relevance.

There was no difference in the type or frequency of microimbalances between the group of samples with aneuploidies and the group of samples with normal karyotypes. Most small imbalances could be identified as copy number variations, only few unknown variants remained and were equally distributed to cases with and without aneuploidy. No aberration associated with any common microdeletion or microduplication syndrome was detected in cases with normal karyotype. A complete hydatidiform mole was identified showing genome wide uniparental isodisomy. Segmental stretches of copy number neutral LOH occured at comparable frequency in both groups of samples. They varied from 8,9-14,2 Mb in size and mapped to various chromosomes with very little overlap. A thorough investigation was done to differentiate pathogenic changes from statistically unusual though benign features of the genome.

Overall, even in this relatively small number of cases, aCGH+SNP analysis picked up aberrations of putative pathological relevance, which were missed following standard diagnostic procedure.

P05.15
Prenatal array CGH identifies genomic imbalances associated with congenital diaphragmatic hernia (CDH)

P. D. Brady, E. Mattheeuws, P. DeKoninck, J. P. Fryns, J. A. Deprest, K. Devriendt, J. R. Vermeesch;
K.U. Leuven, Leuven, Belgium.

Congenital Diaphragmatic Hernia (CDH) is caused by a defect in the formation or closure of the diaphragm, with incidence of 1.7 - 5.7 per 10,000 live-births. Genetic factors have long been considered to play an important role in the pathogenesis of both syndromic as well as isolated CDH. We have previously published our findings from a retrospective study using a targeted custom design array. Here, we present our findings from both the retrospective and on-going prospective study into the use of a high-resolution genome-wide oligonucleotide array for prenatal diagnosis. In this study we have now screened over 60 cases of CDH by array CGH and identify 6 genomic imbalances responsible for the diaphragm defect. Interestingly, the array results highlight duplications of EFNB1 as a cause, and redefine the minimal deleted CDH region at 15q26 to a single gene NR2F2. This study provides more insight into the genetic etiology of CDH.

P05.16
Analysis of CYP21A2 gene in Congenital Adrenal Hyperplasia patients from Bashkortostan Republic of Russia

A. Rakhimkulova[1], V. Akhmetova[1], I. Gilyazova[1], O. Malievsky[2], E. Khusnutdinova[1];
[1]Institute of Biochemistry and Genetics, Ufa Scientific Centre of RAS, Ufa, Russian Federation, [2]Bashkir State Medical University, Ufa, Russian Federation.

Congenital adrenal hyperplasia (CAH) describes a group of autosomal recessive disorders caused by complete or partial defects in one of several steroidogenic enzymes. More than 95% of all CAH cases are caused by 21-hydroxylase deficiency.

We analyzed CYP21A2 gene in 101 unrelated CAH patients from Bashkortostan Republic. The large gene deletions or large gene conversions (delA2/LGC) were found in 28.5% of 202 unrelated CAH alleles. The most frequent point mutations were R356W (14.1%), I2splice (13.9%), I172N (6.2%) and Q318X (4%). Other mutations (V281L, P30L and P453S) met rarely with frequency from 2.7% to 0.5%. The clusters of mutations of CYP21A2 gene in one chromosome: Q318X+R356W (5%), I172N+Q318X (1%), delA2orLGC+V281L (1%), were found in 7 CAH patients.

Furthermore, we identified two additional mutations of CYP21A2 gene in CAH patients. In one patient with salt wasting form (SW) of CAH we found previously described missense mutation R426C in exon 10. The other allele carried the I2splice mutation. In another patient with SW we found previously unreported deletion of 3 nucleotides in exon 9 of CYP21A2 gene that led to the deletion of isoleucine in 384 amino acid sequence. The novel mutation delIle384 was identified in heterozygous state with delA2/LGC of CYP21A2 gene.

In conclusion, previously described diagnostically significant CYP21A2 gene mutations were present in about 72.3% of unrelated CAH alleles. The new mutation corresponds to 0.5% of mutant alleles in our cohort of 101 patients. The discovery of the novel mutation increases our knowledge of CAH caused by 21-hydroxylase deficiency.

P05.17
A cytogenetic study from chorionic villus of 110 spontaneous abortions

C. Gug[1,2], R. Mihaescu[1], V. Dumitrascu[1], C. Muresan[1], B. Muresan[3], D. Stoian[1], M. Militaru[4], A. Trifa[4], O. Marginean[1];
[1]University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania, [2]Genetics Laboratory Dr. Cristina Gug, Timisoara, Romania, [3]Dept. Fetal Medicine, Privat Hospital "President", Timisoara, Romania, [4]University of Medicine and Pharmacy "Iuliu Hațieganu", Cluj-Napoca, Romania.

A total of 110 cases of first trimester spontaneous abortions were analyzed cytogeneti-cally. A long term culture was used for the chorionic villi. The maternal age ranged from 21-42 years and the gestational age from 6-12 weeks. In 7 cases, it was not possible to perform the karyotype (in vitro culture failed). Abnormal karyotypes were found in 52 cases (47,3%). The sex ratio (male/female) in chromosomally abnormal abortions was 0,42 and in normal abortions, it was 0,20 which is different from 1,2 found in earlier studies. The most frequent chromosome abnormalities found were trisomies (61,5%), followed by polyploidy (17,3%), structural anomalies (9,61%) abnormality of gonosomal chromosome (9,61%), double trisomy (1,9%) and monosomy (1,9%). Among the trisomies, the prevalent ones were of chromosome 21 (8 cases), followed by chromosome 16 (4 cases), chromosome 14,19,20 (3 cases each), the chromosome 1,8,13,10,15,17 (6 cases). In one case, there was a double trisomy (48,XY,+13,+15). Although polyploidy is a rare abnormality we detected tetrapoidy in 5 cases, all with 92,XXYY and triploidy in 5 cases, with 69,XXX (2 cases) and 69,XXY(2 cases). The abnormality of the gonosomal chromosomes were found in 3 cases of X monosomy, followed by 2 cases of XXY. Structural anomalies were represented by Marker chromosomes (2 cases), unbalanced translocations (2 cases) and Robertsonian translocations trob(13;14) with trisomy 13 (1 case). Cytogenetic investigations of spontaneous abortions provide valid information as to the cause of abortion. This information may be helpful for genetic counseling and could contribute to prenatal diagnosis in subsequent pregnancies.

Prenatal expression of dehydrated hereditary stomatocytosis

G. Morin[1,2], *S. Blesson*[3], *V. Picard*[4], *B. Demeer*[1,2], *A. Suc*[5], *S. Lanta*[2], *J. Potin*[6], *P. Naepels*[2], *H. Sevestre*[7], *J. Gondry*[2], *A. Toutain*[3], *M. Mathieu*[1,2];
[1]*Clinical Genetic Unit, Amiens, France,* [2]*Prenatal Diagnosis Unit, Amiens, France,* [3]*Clinical Genetic, Tours, France,* [4]*Laboratory of hematology, Le Kremlin Bicêtre, France,* [5]*Neonatology, Tours, France,* [6]*Fetal Medecine Unit, Tours, France,* [7]*Pathology, Amiens, France.*

Dehydrated hereditary stomatocytosis belongs to the group of autosomal dominant haemolytic anemias. No causative gene is known but a linkage was found with the 16q23-q24 chromosomal region. In addition to chronic haemolysis, dehydrated stomatocytosis can be responsible of pseudohyperkalemia, hyperferrinemia and perinatal edema.

From 1996, 5 families have been reported with prenatal / perinatal ascitis or hydrops. The reason of these effusions is not elucidated but the anemia is probably not the unique mechanism.

We present 2 novel families with prenatal ascitis. In the first family, due to the severity of the ascitis, a pregnancy was medically stopped at 28 weeks of amenorrhea. The disease was inherited from the father, presenting with moderate haemolytic anemia, splenomegaly, hyperkaliemia and hyperferritinemia. In the second family, the prenatal and neonatal ascitis of the 2 affected children was spontaneously regressive. The affection was inherited from the asymptomatic mother who only presented macrocythemia and hyperferritinemia.

In case of unexplained prenatal / perinatal ascitis, the diagnosis of dehydrated hereditary stomatocytosis must be considered and the parents investigated.

P05.19

Double trisomy in pregnancy

M. Miklos, *I. Tonkovic Djurisevic, K. Crkvenac Gornik, L. Letica, R. Lasan, S. Huljev Frkovic, D. Begovic;*
Division of Genetics, Department of Pediatrics, University Hospital Centre Zagreb, Zagreb, Croatia.

Double trisomy is extremely rare in liveborns, but it is a relatively common event in pregnancies ending in early abortions and usually involves at least one nonviable trisomy. Prevalence of double trisomy is higher within first trimester spontaneous abortions (~2%) than within the second trimester pregnancy (~0.01%). Double trisomy is associated with advanced maternal age and mean gestational age has been described to be significantly lower for double trisomy cases than that reported for single trisomy ones.

Our results of only two double trisomy cases from samples of amniocentesis, using routine cytogenetic analysis of cultured amniotic fluid cells with GTG-banding confirm the fact that double trisomy in second trimester of pregnancy, also in liveborns, usually involves the sex chromosomes in combination with potentially viable autosomal trisomies such as 21, 18 and 13. Both of them were in mosaic form (48,XXX,+21/46,XX and 48,XXY,+21/47,XY,+21).

Double trisomies within first trimester of spontaneous abortions, in regular and mosaic form, were present in 1.86% of cases. These cases were lethal in first trimester of pregnancy due to the presence of nonviable autosomes in double trisomies or combination of autosomal and gonosomal trisomies.

Our cases emphasize the importance of genetic counseling to assess the recurrent risk of double trisomy.

P05.20

Investigation of *MTHFR* and *MTHFD* polymorphisms as maternal risk factors for Down syndrome

L. C. Bohiltea, *R. Cretu, D. Neagos;*
Genetic Department, UMF Carol Davila, Bucharest, Romania.

Members of the family of B9 vitamins are commonly known as folates. A number of studies have associated polymorphisms found in genes involved in folate metabolism to an elevated maternal risk for Down syndrome (DS). Central role in this process is played by

MTHFR, *MTR*, *RFC1* and *MTHFD* genes. In this study, we evaluated the role of three common polymorphisms in folate

metabolizing genes as possible risk factors for having a child with DS. The prevalence of these variant genotypes in mothers of DS children (case mothers) (n=26) was compared with controls (n=46). Investigated polymorphisms include methylenetetrahydrofolate reductase (*MTHFR*) 677C>T and 1298A>C and methylenetetrahydrofolate dehydrogenase (*MTHFD*) 1958 G>A. Present results indicate that none of the, *MTHFD* 1958G>A, *MTHFR* 677C>T, and *MTHFR* 1298A>C polymorphisms is an independent risk factor for a DS offspring at a young maternal age. The combined *MTHFR* 1298CC/*MTHFD* 1958GG, *MTHFR* 1298(AC or CC)/*MTHFD* 1958GG, *MTHFR* 1298AA/MTHFD 1958GA, *MTHFR* 1298CC/*MTHFD* 1958GA and *MTHFR* 1298CC/*MTHFD* 1958AA genotypes compared with the *MTHFR* 1298AA/*MTHFD* 1958GG genotype was associated with increased DS risk (with related P values: 0.019, 0.038, 0.046, 0.05 and respectively 0.019). These results show that maternal polymorphisms of folate metabolism could be implied in pathogenesis of Down syndrome.

P05.21

Prenataldiagnosis of a *de novo* euchromatic variant 16p11.2

V. Lima[1], *C. Reis*[1,2], *V. Maloney*[3], *A. Neto*[1], *M. Cunha*[4], *P. Maciel*[5,6], *F. Carvalho*[1], *A. Barros*[1], *J. Oliveira*[1], ***S. Dória***[1];
[1]*Dept. of Genetics, Faculty of Medicine, University of Porto, Porto, Portugal,* [2]*2Department of Medical Genetics, Centro Hospitalar de Coimbra, Coimbra, Portugal,* [3]*Wessex Regional Genetic Laboratory, Salisbury NHS Foundation Trust, Salisbury, United Kingdom,* [4]*4Department of Gynecology and Obstetrics, Centro Hospitalar de São João, Porto, Portugal,* [5]*5Life and Health Sciences Research Institute (ICVS), School of Health Sciences, University of Minho, Braga, Portugal,* [6]*6ICVS/3B's - PT Government Associate Laboratory, Braga/Guimarães, Portugal.*

Introduction: Chromosome euchromatic variants most commonly result from copy number variation (CNV) of gene and pseudogene containing polymorphic genomic segments that became visible at the cytogenetic level. Intrachromosomal rearrangements of the proximal short arm of chromosome 16, leading to 16p+ morphology can raise interpretation problems because both euchromatic variants (16p11.2v) and unbalanced duplications have been described in this region.Case report: An amniocentesis performed at 16 weeks gestation, due to maternal age, revealed a *de novo* 16p+ chromosome by GTL banding. C banding and N/DAPI staining were negative. WCP labeled all 16p+ chromosome. MLPA analysis with eleven probes for 16p11 (kit P343) was normal, while, array CGH pointed to a 1.9 MB duplication in 16p11.2. Fetal ultrasound did not show any morphological defects. Postnatal FISH study with a panel of RP11 BACs confirmed the presence of a duplication involving the CNVs regions of proximal 16p11.2 (euchromatic variant) and no evidence of a duplication in the autism or development delay region 16p11.2. Discussion: The occurrence of *de novo* structural euchromatic chromosome abnormalities presents a genetic counseling dilemma, particularly when ascertained in the prenatal setting, as the prognosis can be more reliably discussed when the chromosome abnormality is transmitted by a phenotypically unaffected parent. Fetal ultrasound, postnatal clinical reports, molecular cytogenetic analyses may all contribute with critical data to the genetic counseling. Professionals involved in prenatal diagnosis and genetic counseling should be aware of the euchromatic variant 16p11.2v in order to establish the differential diagnosis and provide parents with proper information.

Indications for Fetal Karyotyping and Ultrasonographic Findings in Common Trisomies; Alterations in over 2 Decades

S. Basaran[1], *B. Karaman*[1], *M. Kirgiz*[2], *G. Toksoy*[1], *I. H. Kalelioglu*[3], *R. Has*[3], *K. Aydinli*[3], *H. Ermis*[3], *H. Kayserili*[1], *T. Dehgan*[2], *B. Satkin*[1], *A. Yuksel*[3];
[1]*Medical Genetics Department of Istanbul Medical Faculty,Istanbul University, Istanbul, Turkey,* [2]*PREMED Center for Genetic Diagnosis, Istanbul, Turkey,* [3]*Obstetrics and Gynecology Department of Istanbul Medical Faculty,Istanbul University, Istanbul, Turkey.*

Advanced Maternal Age (AMA) was the first screening parameter of trisomies at the beginning of prenatal diagnosis era. The developing of the new screening techniques using biochemical parameters in maternal serum (MS) and ultrasonographic (USG) markers allowed us to get higher detection rates for common trisomies in all pregnancies.

We retrospectively evaluated the results of 25808 prenatal cases obtained in 2 periods (from 1989 to 1999 and 2000 to 2011), under the aspect of the presence of AMA, MS- biochemical screening and USG findings prior to the cytogenetic diagnosis. This series covered 23427 amniotic fluid and 2381 chorionic villi samples in which 462 trisomy 21, 127 trisomy 18 and 51 trisomy 13 cases were diagnosed.

We determined to reveal the alterations of the indications of the fetal karyotyping over time, and further more to identify the most frequent USG findings detected in trisomies.

AMA, which was the most common parameter in the 1st period, decreased, while MS- biochemical and USG screening tests became more effective over time.

The most common observed USG findings was nuchal translucency in all trisomies. Cystic hygroma, ascites in trisomy 21 and 18; cardiac anomalies in trisomy 18 and 13; urogenital anomalies in trisomy 13; omphalocele in trisomy 18 were more frequently identified USG findings.

Widely usage and increased experience in screening tests led to detect more cases with common aneuploidies with reduced number of prenatal invasive procedures in high risk pregnancies. Further more, younger women gained a chance for prenatal diagnosis for chromosome anomalies.

P05.23

Non- invasive fetal sex determination using a converntional nested PCR analysis of fetal DNA inmaternal plasma

M. Hashmi[1], *A. Nazemi*[2], *M. Entezari*[3];
[1]*Scientific Society of Cellular and Molecular, Centeral Commission of Scientific, Literary and Artistic .Science and Research branch, Islamic Azad University, Tehran, Islamic Republic of Iran,* [2]*Tonekabon branch, Islamic Azad University, Tonekabon, Islamic Republic of Iran,* [3]*Tehran medical branch, Islamic Azad University, Tehran, Islamic Republic of Iran.*

Prenatal diagnosis is usually performed by collecting fetal samples through amniocentesis or chorionic villus sampling. However, these invasive procedures are associated with some degree of risk to the fetus and/or mother. Therefore, in recent years, considerable effort has been made to develop non-invasive prenatal diagnostic procedures. One potential non-invasive approach involves analysis of cell-free fetal DNA in maternal plasma or serum. The objective of our study was to investigate the feasibility of using fetal DNA in maternal plasma for prenatal diagnosis.

For this experimental study, to develop a nested PCR technique for fetal SRY gene identification using cell-free fetal DNA in maternal plasma. Peripheral blood samples were obtained from 32 pregnant women at the gestational period from 8 to 13 weeks and cell-free DNA was extracted by the phenol/chloroform method from plasma. The nested PCR was carried out to amplify the fragment of SRY gene by two sets of PCR primer pairs. Analysis was then performed on the PCR product.

Specifically, the presence of Y-chromosome sequences in maternal blood plasma indicates that the fetus is male, whereas lack of a signal will indicate that the fetus is female.

Among the 32 pregnant women bearing male fetuses, SRY sequences were detected in 16 plasma samples after nested PCR amplification, while the 18 women bearing female fetuses had the positive results. The sensitivity were 87.5% (28/32). The nested PCR amplification of SRY sequence is a convenient and low-cost approach for the noninvasive early prenatal diagnosis of sex-linked inheritant.

P05.24

Qualitative analysis of the results from the first trimester screening

B. M. Muresan[1], *C. M. Muresan*[2], *C. Gug*[2];
[1]*Fetal Medicine Centre, President Clinic, Timisoara, Romania,* [2]*University of Medicine and Pharmacy Victor Babes, Timisoara, Romania.*

Introduction

The first trimester screening is based on the following criteria - maternal age; double test (PAPP-A; free ß-HCG), FHR, nuchal translucency, facial angle, tricuspid flow, ductus venosus flow, nasal bone.

Objectives

The aim is to estimate a qualitative analysis of the first trimester screening based on the rate of detection and on the false positive rate - FPR.

Material and method

During the aug.2010-dec.2011 we performed the first trimester screening at 671 patients; 37 patients had multiple pregnancies. The ultrasound screening was performed on GEVoluson730Expert, at a fetal CRL of 44-85 mm. The PAPP-A; free ß-HCG was carried out on BRAHMS or Delphia.The calculation of risk was evaluated with the FMFsoftware and all the ultrasound criteria (NT, FA, NB, TR, DV) were analyzed in 538 cases. Based on the results of the screening we performed 31 invasive procedures: 28 CVS and 3 amniocentesis (the amniocentesis cases refused CVS).

Results

Our results are the detection of a number of 7 chromosomal abnormalities :T21 - 4, T18 - 1, T13 - 1 and 1 case of triploidy. At a cut-off level at 1: 150 we obtained a FPR of 3.5% and if we set the cut-off level at 1: 100 - the FPR is 2.38%. All the cases with chromosomal abnormalities belong to the group of risk > 1: 100.

ConclusionThe setting of the cut-off level at 1: 100 and at 1: 150 doesn't modifies the rate of detection of chromosomal abnormalities, only the FPR increases from 2.38% to 3.5%

Investigation of HbQ-Iran in couples referred to Pasteur Institute of Iran

S. Ahmadi, *M. Taghavi basmanj, F. Bayat, A. Valaei, N. Sabokbar, M. Mortezazadeh, Z. Kainimoghadam, A. Amirian, A. Kordafshari, A. Sanjari, M. Choobini, F. Navab moghadam, M. Karimipour, S. Zeinali;*
Pasteur Institue of Iran, Tehran, Islamic Republic of Iran.

Introduction :

Alpha thalassemia is the most common inherited disorder of hemoglobin synthesis in the world . Single nucleotide mutation in α1 or α2 genes produce abnormal α-chain hemoglobin . Hb Q disorders are regard as rare Hb variants . Several Hb Q have been reported sofar including Hb Q-iran , Hb Q-thailand , Hb Q-india .

Materials & Methods :

In this study one couple refered from primary health care (PHC) centers to Pasteur institute of iran with MCV>80 , MCH>28 , HbA2=2 and Hb variant=14 . Genomic DNA was extracted by salting out method. DNA sequencing using Big Dye from ABI was used .

Result :

A total of 1000 individuals with microcytic hypocromic anemia were screened for the most common type of α-thalassemia . We investigated molecular basis of Hb variant in the couple using multiplex gap PCR , MLPA &direct DNA sequencing . No deletion was found . DNA sequencing revealed codon 75 G>C , Asp>His in α2 gene mutation in both couple .

Discussion:

Heterozygous individuals for Hb Q -Thailand generally present with moderate red cell microcytosis due to the association of the mutation with deletion -α4.2 Kb , but those carrying Hb Q-Iran or Hb Q-India are hematologically normal and no association with α-thalassemic phenotype has been reported . Since Hb Q-Iran is usually associated with normal CBC , it may not be detected through routine National Screening Program , therefore it's true ferequency can not easily be determined.

P05.29

Chromosomal Imbalances in Holoprosencephaly Sequence; Results of 87 Cases Diagnosed Prenatally

B. Karaman[1], *B. Satkin*[1], *I. H. Kalelioglu*[2], *R. Has*[2], *S. Ergin*[1], *H. Kayserili*[1], *H. Ermis*[2], *A. Yuksel*[2], *S. Basaran*[1];
[1]*Medical Genetics Department of Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey,* [2]*Obstetrics and Gynecology Department of Istanbul Medical Faculty,Istanbul University, Istanbul, Turkey.*

Holoprosencephaly sequence (HPE, # MIM 2361000), is the most common developmental defect of midline cleavage in human embryonic forebrain, with a variable phenotypic expression. Several mechanisms play a role in the etiopathogenesis; genetic, environmental, multi-factorial, and unknown.

The rate of chromosome abnormalities is ~ 40 % in patients with HPE. The most common chromosomal abnormality involved is trisomy 13, followed by trisomy 18, triploidy and deletion 7q36.3. In approximately 18%-25% of cases monogenic syndromes are diagnosed. To date, 12 genes are known to be associated with HPE. Human Sonic Hedgehog gene (SHH*)* located on chromosome 7q36 is the best known gene related.

This study comprises the results of cytogenetic, molecular cytogenetic and molecular karyotyping studies obtained in tissue samples (51 fetal blood,19 chorionic villus and 17 amniotic fluid) of 87 fetuses diagnosed ultrasonographically as having HPE.

Karyotype analysis was performed in all cases. Molecular cytogenetic technique using subtelomeric probe7q36.3 was applied in 12 cases. Six cases with normal karyotype were investigated by oligonuclotide Array-CGH (Roche-NimbleGen).

Chromosomal abnormalities were detected in 51.7 % of cases (45/87). The predominant chromosomal abnormality was trisomy 13 (n:24), which was followed by trisomy 18 (n:5), and triploidy (n:5). Terminal 7q deletion being the most frequent structural anomaly observed (n:9), was *de novo* in 6 cases and unbalanced product of maternal translocations in 3. Furthermore, deletion of 18p and paternally inherited balanced inversion of chromosome 11 was observed in single cases.

The clinical and laboratory findings will be discussed in view of the literature.

P05.30

Prenatal screening for aneuploidies in Iranian families using QF-PCR

P. Rostami, *S. Valizadegan, R. Najafi, M. Mahdizadeh, M. Ghalandari, H. Imanian, S. Almadani, F. Afroozan, S. Keyvani, R. Heydari, A. Kariminejad, R. Kariminejad, H. Najmabadi;*
Kariminejad-Najmabadi Pathology & Genetics Center, tehran, Islamic Republic of Iran.

Quantitative fluorescence polymerase chain reaction (QF-PCR) has been introduced in a number of genetic laboratories as an inexpensive, rapid and reliable method for prenatal recognition of aneuploidy in chromosomes 13, 18, 21, X and Y. The aim of this study was to investigate the efficacy of QF-PCR for the prenatal recognition of common aneuploidies and compared our findings with cytogenetic results in Iran.

A multiplex-PCR involving 15 short tandem repeat (STR) sequences was established for aneuploidy screening and chromosomal study was performed for all samples and the results werecompared.

Total of 654 prenatal samples were analyzed including 616 amniotic fluid and 38 chorionic villous samples (CVS). The following abnormalities were detected in 21 (3.2%) individuals: 11 (1.7%) with Down syndrome, 4 samples (0.6%) with Edward syndrome, 2(0.3%) samples with Patau syndrome, 1 (0.15%)sample with Turner syndrome, and 1 (0.15%) 47,XYY. All of the CVS samples were normal. In addition, 2 cases (0.3%)showed triploidies. All aneuploidies detected by QF-PCR, were confirmed by cytogenetics results. Elevensamples (1.7%) shown maternal cell contamination in whichthree of their results were failed. Additional chromosomal aberrations; inversion 9, t(9;14) and XX/XY mosaicism, were detected in 3 cases by karyotyping. In conclusion,usingQF-PCR with cytogenetic study simultaneously for all prenatal cases provide a rapid andreliable method in families at risk for aneuploidies. We also recommend all families that are seeking prenatal diagnosis of single gene disorders a QF-PCR to be added to their work up.

P05.31

Prenatal diagnosis of a complex de novo translocation without ultrasound abnormalities

R. Wimmer[1]*, R. Chaoui*[2]*, F. Wagner*[3]*, K. R. Heidtke*[3]*, D. Liebe*[1]*, G. Thiel*[1]*;*
[1]*Praxis für Humangenetik, Berlin, Germany,* [2]*Praxis für Pränataldiagnostik, Berlin, Germany,* [3]*ATLAS Biolabs GmbH, Berlin, Germany.*

Apparently balanced de novo aberrations without any abnormalities in the ultrasound at prenatal diagnosis are a challenging setting for genetic counselling, especially if multiple breaks have occurred.

Here, we report on an amniocentesis performed because of advanced maternal age that revealed a complex de novo translocation involving chromosome 2, 7 and 18, and showing multiple breakpoints on each of the implicated chromosomes. The risk for mental retardation in balanced de novo aberrations increases by the number of chromosomal breaks. As we could find at least eight breaks by chromosomal analysis, a high risk for mental retardation was assumed even without ultrasound findings. A prenatal microarray analysis was recommended. Four major abnormalities were found, on chromosome 2 two deletions (328kb in 2q22.1 and 2415kb in 2q22.1-q22.3) and one duplication (777kb in 2q14.3), a further deletion in 18q12.2 (1935kb), as well as additional minor changes on chromosome 7. The genetic content of the rather large aberrations on chromosome 2 was not helpful with regard to the postnatal prognosis. Nevertheless, the deletion in 18q12.2 including the gene KIAA1328 was found to be described in association with mental retardation and only mild dysmorphic features. Finally, the parents decided to terminate the pregnancy.

P05.32

Prenatal diagnosis of multiple small supernumerary marker chromosomes (sSMCs) of different centromeric origin

M. Volleth[1]*, T. Liehr*[2]*, D. Schanze*[1]*, M. Zenker*[1]*, P. Muschke*[1]*, I. Schanze*[1]*;*
[1]*Dept. of Human Genetics, Magdeburg, Germany,* [2]*Institute of Human Genetics, Friedrich Schiller University, Jena, Germany.*

Small supernumerary marker chromosomes (sSMCs) are structurally abnormal chromosomes that cannot be identified or characterized unambiguously by conventional banding techniques alone (Liehr et al. 2004). Fluorescence in-situ hybridization (FISH) with centromeric and subcentromeric probes enables the rapid identification of sSMCs originating from pericentromeric regions.

We report on a fetus with up to 5 markers of different origin in one cell. Amniocentesis was undertaken for the reason of advanced maternal age. Chromosome analysis revealed the occurrence of one to six sSMCs (mean 2.6 per cell) in both independent cultures. Molecular karyotyping using an SNP-Array (Affymetrix) revealed amplification of 6.7 Mb from 4p12-q12 (arr 4p12q12(46.567.172-53.241.307)x3). FISH using a centromeric probe confirmed the homology to chromosome 4 of one of the sSMCs. The largest marker amongst the other sSMCs, probably a ring chromosome, originates from chromosome 9 and includes mainly the heterochromatic band of the long arm: min(9)(:p12→q12:). The remaining markers are very small and contain centromeric material from chromosomes 6, 14 and 22 only. Due to the fact that phenotypic abnormalities have been described in patients with duplications of the 4p12 region, the couple decided to terminate the pregnancy. The aborted fetus could not be investigated. Chromosome analyses of the parents´ lymphocytes were inconspicuous.

The maternal origin of markers from the amplified 4p segment and the different centromeric origin of the sSMCs, point to the possibility that the degrading second polar body had been incorporated into the zygote. We compare the present case with previously published cases.

Supported by Else Kröner-Fresenius-Stiftung (2011_A42).

P05.33

Array-CGH identification of de novo mosaic supernumerary marker chromosome 19 in prenatal diagnosis

A. Zagorac, *K. Ogrizek Pelkic, N. Kokalj Vokac;*
University Medical Centre Maribor, Maribor, Slovenia.

Small supernumerary marker chromosomes (sSMC) are relatively rare in the general population, found in approximately in 0,1-1/1000 live births. They are defined as additional structurally abnormal chromosomes which cannot be identified with conventional cytogenetic techniques. The frequency of supernumerary markers found in prenatal diagnosis is about 0,076%. The clinical significance of sSMC varies widely, and the phenotype associated with presence of a de novo sSMC may differ from normal to severely abnormal.

We describe a finding of a „de novo“ mosaic supernumerary marker chromosome 19 , its genomic characterisation and its possible impact on the phenotype.

Amniocentesis was performed on a 33 year old primigravida because of an increased risk finding at maternal serum and nuchal translucency screening.

The cytogenetic analysis detected a supernumerary marker chromosome: 47,XY,+mar(56)/46,XY(47), in three independent cultures, confirmed using FISH as chromosome 19. To define the exact duplicated region array-CGH was performed. The aCGH finding indicated three copies of 19q12q13.11, 5,05 Mb in range. The final cytogenetic result was: 47,XY,mar.ish der(19)(wcp19+).arr 19q12q13.11(32545077-37601048)x3 dn.

According to involved genes in the duplicated region on 19q carrier could have a phenotipic consequences, especially developmental delay. Although the ultrasound scan was normal, the parents decided to terminate the pregnancy.

In order to offer appropriate genetic counselling an accurate identification of marker chromosomes „de novo“ found in prenatal diagnosis is fundamental. We emphasize the importance of array-CGH in prenatally detected „de novo“ sSMC and determination of genotype-phenotype correlation for better risk evaluation.

P05.34

Whole genome microarray in clinical practice: Investigation of 2,024 miscarriage, stillbirth and fetal malformation referrals

M. D. Pertile, *R. Oertel, L. Hills, A. Boys, F. Norris, I. Burns, D. L. Bruno, H. R. Slater;*
Murdoch Childrens Research Institute, Melbourne, Australia.

We have used whole genome microarray as a replacement for conventional chromosome analysis to investigate genomic abnormalities in approximately 2,000 miscarriage, stillbirth and fetal malformation referrals. NimbleGen 135K CGH array was employed in the early phase of the program (1,248 referrals) prior to using Illumina Cyto-SNP12 array (776 referrals). Greater than 98% of samples yielded informative results, a substantial improvement over conventional chromosome analysis which typically has a success rate of 60-95% depending on referral type. Male to female sex ratio was 1.2 in keeping with strict tissue selection protocols.

Whole chromosome aneuploidy predominated, accounting for 578 abnormal results. However, 82 (4.1%) CNVs of unknown, uncertain or pathogenic significance were also identified. Clearly pathogenic genomic disorders were significantly enriched in this series. These included 7q11.23 (Williams) deletion (2 cases), 7q11.23 duplication (1 case), 5q35.2q35.3 (Sotos) deletion (1 case), 15q11.2q13 (Angelman) deletion (1 case) and 22q11.21 (Di George) deletion (2 cases), accounting for approximately 1 in 285 (0.35%) referrals. We found little evidence for submicroscopic, unbalanced rearrangements being transmitted by balanced carrier parents. Such rearrangements do not contribute significantly to the burden of miscarriage or stillbirth. Large (>6 Mb) genomic imbalances were identified in 31 cases. Uniparental disomy (UPD) was rare. One case of paternal isodisomy 14 was identified in 762 informative results obtained by SNP array. Chimerism was identified in 4 pregnancies; complete mole in 12 cases. Our data demonstrate that whole genome microarray is a powerful tool for investigating genomic abnormalities that contribute to miscarriage, stillbirth and fetal abnormality.

P05.35

Prenatal diagnosis of microdeletion 17q12 in a fetus with cystic kidney disease

V. Schneider, *K. Hoertnagel, C. Daumer-Haas, K. Gloning, S. Minderer, T. Schramm;*
Praenatal-Medizin Muenchen, Munich, Germany.

Genomic rearrangements such as deletions, duplications and insertions result in copy number variation (CNV) that may cause phenotypes by affecting dosage-sensitive genes, disrupting genes, creating fusion genes, and other mechanisms. Until now, numerous microdeletion and microduplication syndromes with characteristic phenotypes have been described.

We report a case of a 32-year-old pregnant woman. Sonographic examination in the 22nd week of gestation showed bilateral cystic kidney disease and oligohydramnios. Amniotic fluid sampling was performed for molecular genetic testing and karyotyping. The cytogenetic karyotype was normal (46, XY). HNF1B analysis by sequencing showed no mutation but MLPA revealed a heterozygous deletion of the complete gene. For precise characterization of the extent of the deletion Array CGH analysis was done showing a deletion of at least 1,3 Mb corresponding to the cytogenetic region 17q12 (arr17q12(34437534x2, 34817422-36168104x1, 36473175x2). This contiguous gene deletion syndrome comprises 11 OMIM genes, including HNF1B.

Involvement of the HNF1B gene causes cystic renal disease and maturity onset diabetes of the young (Renal cysts and diabetes syndrome, RCAD, OMIM 137920). According to data of the literature and DECIPHER database, patients with microdeletion 17q12 may exhibit cognitive impairment, speech delay, seizures, autism and psychiatric disorders, possibly due to haploinsufficiency of the LHX1 gene. Dysmorphic features are reported to be only mild.

The pregnant woman decided to continue pregnancy. Delivery date is in March 2012. The pregnancy outcome will be reported.

This case report underlines the importance of Array CGH analysis in the diagnostic work up of prenatally detected fetal anomalies.

P05.36

The Efficiency Of Multiplex Ligation-Dependent Probe Amplification Technique In The Diagnosis Of Fetal Chromosomal Abnormalities

G. Toksoy[1], *B. Karaman*[1], *Z. Uyguner*[1], *K. Yılmaz*[1], *R. Has*[2], *H. Kayserili*[1], *S. Basaran*[1];
[1]*Department of Medical Genetics, Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey,* [2]*Department of Obstetrics and Gynecology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey.*

With standard karyotyping techniques chromosomal abnormalities are detected in only about 20% of patients with multiple congenital abnormalities/mental retardation (MCA/MR). At the 500-600 band level the resolution for detection is about 5 Mb. Fluorescence in situ hybridization (FISH) technique can unveil submicroscopic aberrations (<5Mb), which increases the detection rate an additional 4-8% in the etiology of MCA/MR. Molecular techniques can identify abnormalities <5 Mb.

The clinical findings of MCA/MR cases can guide the clinician toward syndrome-specific FISH probes. However, this is usually limited for prenatal cases. Multiple Ligation-dependent Probe Amplification (MLPA) extends the boundaries of the diagnosis of chromosomal anomalies that are undetectable by classical methods.

In this study, we aimed to search for subtelomeric aberrations and syndrome-related microdeletions/duplications by using SALSA P070 and P245 probe-sets of MLPA in 66 samples of fetuses with major ultrasonographic abnormalities carrying normal karyotypes with conventional methods.

Two microdeletions (18p11.3->pter and 7q11.23) and one microduplication (18q23) were identified (4.5 % - 3/66) by MLPA. Deletions were confirmed by FISH and duplication was confirmed by microarray.

The advantage of MLPA is the ability of searching multiple loci in one test run, which could be very helpful in prenatal diagnosis of cases with abnormal ultrasound findings where the karyotypes were normal.

P05.37

Possibility of MLPA prenatal detection of the most clinically important chromosomal abnormalities

L. Dvořáková, ***J. Paděrová****, D. Chudoba, D. Novotná, H. Kuželová, P. Křenková, J. Drábová, Z. Zmítková, M. Macek jr., M. Macek sr.;*
Department of Biology and Medical Genetics, Prague, Czech Republic.

The aim of this study is the verification of the possibility to extend of the diagnostic spectrum of MLPA by simultaneous implementation of aneuploidy, centromeric and subtelomeric kits to detect aneuploidies of all chromosomes.

The 65 samples of fetal cell cultures derived for prenatal diagnosis with normal karyotypes (20) and different chromosomal abnormalities (45) were reexamined by MLPA MRC Holland kits. The combination of kits for the examination of aneuploidies of chromosomes 13, 18, 21, X and Y (PO95-A2), centromeres (P181-A2/182-B1) and subtelomeres (P036-E1 and P070-B2) was used.

MLPA results were identical with karyotypes in all euploid samples as in cultures with trisomies 2, 4, 5, 6, 9, 13, 14, 15, 16, 18, 21, double trisomy 15 and 18, syndromes XXX, XYY and XXY, except triploidy 69,XXX. Abnormal clone in mosaics was disclosed in 3/4 cases except 45,X/46,XX. All four balanced Robertsonian and reciprocal as well as unbalanced Robertsonian (13;14, 14;15, 14;21) and 4 reciprocal translocations (3;4, 3;6, 4;21, 9;15) were confirmed. The origin of 4 extra marker chromosomes derived from chromosomes X, Y, 15 and 21 was revealed. The 5 cases with the deletions of chromosomes Y, 9p and 18p and 1 case of duplication 3p were disclosed. Only ins(3;4)(p21;q26) and Y chromosome inversion were missed, because the breaks were not in the detectable regions of used kits.

This pilot study suggests that the MLPA kits combination might allow rapid, reliable prenatal detection of clinically significant abnormalities of all chromosomes, except 69,XXX and inversions/insertions.

Supported by MZ0FNM2005 and CZ.2.16/3.1.00/24022.

P05.38

Discrepancies between QF-PCR and karyotype results in a rare prenatal case of mosaic trisomy 18 and supernumerary marker chromosome 18

A. Pavel[1], *L. Dimos*[1], *F. Nedelea*[1,2], *I. Gussi*[3,4], *R. Simion*[1], *D. Stambouli*[1];
[1]*Cytogenomic Medical Laboratory, Bucharest, Romania,* [2]*Filantropia Hospital, Bucharest, Romania,* [3]*University of Medicine and Pharmacy, Bucharest, Romania,* [4]*Cantacuzino Hospital, Bucharest, Romania.*

Chromosomal aneuploidy is a common cause of human genetic disorders and cytogenetic analysis remain the standard method of diagnosis. Quantitative Fluorescence PCR (QF-PCR) is a rapid assay used to identify most common aneuploidies of chromosomes 13, 18, 21, X, Y. This method uses highly DNA polymorphic markers (STRs) specific for each chromosome, to determine the number of alleles of the analyzed chromosomes. In this rare case a sample of amniotic fluid was referred for prenatal diagnosis with a high risk indication 1:2 for Edwards Syndrome after combined first trimester screening, in the absence of any detectable fetal malformation. QF-PCR was followed by cytogenetic analysis of cultured cells. The results of QF-PCR revealed an abnormal pattern of allele ratio suggesting mosaic of three full copies of chromosome 18, whereas cytogenetic analysis revealed a 50% mosaic of a supernumerary centromeric marker 18. Due to the discrepancy of these results, genetic counseling advised to continue the investigation with a second sample either fetal blood or amniotic fluid. Also, array-CGH was recommended to clarify these unusual results. The results of the second amniotic fluid sample confirmed the presence of extra marker 18. After counseling about the associated risk of abnormal outcome, parents decided to continue the pregnancy. Postnatal blood karyotype revealed a third cell line of full trisomy 18 in 5% of peripheral cells, confirming the QF-PCR findings. QF-PCR technique is a trustworthy method for detecting aneuploidies and even mosaics in a low percentage. The results should always be considered in any circumstances.

P05.39

Prenatal diagnosis of a case with mosaic 22q11 microdeletion syndrome

S. Farcas, *V. Belengeanu, M. Stoian, N. Andreescu, A. Ratiu, D. C. Crisan, D. Iacob;*
University of Medicine and Pharmacy, Timisoara, Romania.

Mosaic microdeletion syndromes are rarely reported and the prenatal diagnosis of those cases might be difficult because low levels of mosaicism can be easily missdiagnosed. We present a case of a pregnant women who at the 20 weeks of gestation, after a routine ultrasonography screening found polyhidramnios, intrauterin developmental delay, tetralogy of Fallot, timus hypoplasia for the fetus. Amniocentesis was performed and FISH analysis was done. Besides common aneuploidies probes, also LSI TUPLE1 probe (Abbott) for DiGeorge syndrome was used for diagnosis confirmation. A total number of 100 cells were evaluated for each probe. Results were normal for common aneuploidies. In 13 cells a 22q11.2 microdeletion was found and the finding was conclusive for mosaic 22q11.2 microdeletion (13%). Genetic counselling was offered to parents who decided to terminate the pregnancy and requested to be informed about the risk for the following pregnancy. The indemn parents were screened for the same deletion by using FISH analysis which revealed that the father also presents a very low level of mosaic for microdeletion of chromosome 22q11.2 in his peripheral lymphocytes.

This case sustains the importance of widening the FISH studies spectrum when ultrasonography shows cardiac malformations in association with other defects which can be a hallmark of a specific chromosomal deffect allowing an ethiologic diagnosis. The prenatal diagnosis of an affected fetus facilitated in this case the identification in a parent with normal phenotype of a very low level of 22q11.2 microdeletion and allowed an adequate genetic counselling.

P05.41

Next generation sequencing application for a heterogenous disorder: a pilot study on inherited peripheral neuropathies

C. Buxton[1], *P. Lunt*[2], *F. Sansbury*[3], *P. Turnpenny*[3], *M. Williams*[1], *T. Antoniadi*[1];
[1]Bristol Genetics Laboratory, Southmead Hospital, Bristol, United Kingdom, [2]Dept of Clinical Genetics, St Michaels Hospital, Bristol, United Kingdom, [3]Dept of Clinical Genetics, Royal Devon and Exeter Hospital, Exeter, United Kingdom.

Inherited peripheral neuropathies (IPN) are a heterogeneous group of disorders with an overall prevalence of 1 in 2,500 and more than 50 genes implicated. Bristol Genetics Laboratory currently provides a specialist UKGTN Sanger sequencing service for 12 neuropathy genes.

The aim of this project is to evaluate the application of targeted capture NGS technology to the diagnosis of IPN using a pilot cohort of ten recruited/consented patients; three unrelated individuals with a known mutation/SNP profile including quantitative changes and seven with an uncharacterized genetic aetiology. A solution-based oligonucleotide capture array was designed using Agilent eArray (SureSelect) to capture a 450KB target encompassing coding exons and 5‘ and 3‘ UTRs of 65 neuropathy genes. DNA libraries were run on Illumina GAII and MiSeq sequencers for comparison and to aid in evaluating bioinformatics approaches to variant calling and dosage enumeration. Data analysis will be performed using open source tools (Galaxy).

We aim to assess the quality of genetic data, the extent of genetic variation in patients with IPN, the utility of current bioinformatics packages and databases in assigning variant status, the ability to detect quantitative changes, and potential new genotype-phenotype correlations.

The experience gained through validating a new technology in a clinical context and the workup of various approaches to downstream analysis together with clinically relevant variant findings will be presented.

This work will further the knowledge of the genetics of IPN and contribute to improved genetic testing for patients with these diseases.

P05.42

The non-invasive prenatal tests available in Romania

A. M. Stan[1], *C. Dragomir*[1], *E. Severin*[2], *L. Savu*[1];
[1]Genetic Lab S.R.L., Bucharest, Romania, [2]UniverMed, Bucharest, Romania.

The detection of cell-free fetal DNA in maternal circulation opened a new, noninvasive approach for prenatal diagnosis (NIPD). The NIPD approach has been studied for more than a decade. It started with the fetal RHD genotyping and gender determination, allowing at the moment the noninvasive detection of specific mutations causing diseases and selected chromosomal aneuploidies.

We performed the noninvasive detection of fetal RHD genotype in Romania since 2010 and we considered this approach an improvement in the management of mother-fetus RhD incompatibility in our country.

This short study aim was to improve the protocol for non-invasive fetal RHD genotyping in our laboratory since we notice a nonspecific amplification band in some RHD negative samples.

A three-step method was used for noninvasive fetal RHD genotyping. For the ccftDNA extraction we proceed from 1ml maternal plasma using the QIAamp® DSP Virus kit. The fetal RHD genotyping was determined using specific primers for two sequences in the exon 5 and exon 7 of the RHD gene; we also included the GAPDH, β-globin, DYS14 and SRY sequences detection as internal controls. To overcome our issue, five different PCR reactions were performed. The PCR products were automated analyzed by high-resolution capillary electrophoresis.

We tested 93 plasma samples using both protocols and the results were confirmed by the invasive method.

We conclude that our protocol for RHD genotyping is rapid and feasible. Also, the fetal gender determination is currently performed as a useful tool for screening the pregnancies at risk for inheriting an X-linked recessive disorder.

P05.43

Clinical application of non invasive RHD genotyping using cell free fetal DNA in maternal plasma

M. Grande[1], ***E. Ordoñez***[2], *A. Payaró*[3], *N. Dominguez*[4], *I. Teixidó*[1], *V. Cirigliano*[2], *A. Borrell*[1];
[1]Department of Maternal-Fetal Medicine, Institute Gynecology, Obstetrics and Neonatology, Hospital Clínic Barcelona, Barcelona, Spain, [2]Department of Molecular Genetics, General Lab, Barcelona, Spain, [3]ASSIR Manso. Institut Català de la Salut., Barcelona, Spain, [4]ASSIR Numància. Institut Català de la Salut., Barcelona, Spain.

To assess the accuracy of non invasive fetal RHD genotyping in the second trimester of pregnancy using cell free fetal DNA in maternal plasma and the practicality of avoiding the use of prophylactic antenatal anti-D gammaglobulin in RhD negative fetuses.

Fetal RHD genotyping was offered to RhD negative pregnant women attending the West Barcelona Health district. A total of 284 cases were collected at 24-26 weeks of gestation and tested for fetal RhD status using multiplex rt-PCR amplification of exons 5, 7 and 10 of the RHD gene. Women carrying RhD negative fetuses were counseled about the possibility of avoiding prophylactic anti-D immunoglobulin. Diagnostic accuracy and feasibility of routine application of non invasive RHD genotyping were compared with established postnatal RhD typing in umbilcal cord blood.

A total of 183 fetuses were genotyped as RhD positive (64 %) and 96 RhD negative (34%). Two samples were not informative as RhD sequences were detected in amount compatible with a maternal positive genotype. Three RHD variants were identified (1%), all results were confirmed in the newborns. No false positive or negative results were observed in sigleton pregnancies. One false positive result was observed in a twin pregnancy, follow up allowed determining a paternal RHD variant as its cause. Antenatal anti-D immunoglobuline was only requested in 5 cases of RhD negative fetuses.

Non invasive fetal RHD genotyping in the second trimester of pregnancy proved to be efficient and reliable. This approach allowed avoiding unnecessary use of antenatal immunoglobulin in our population.

P05.44

Preimplantation genetic diagnosis of metabolic diseases in Gennet

I. Soldatova, *M. Putzová, I. Borgulova, V. Krutilkova, J. Mika, R. Křen, D. Stejskal;*
GENNET, Prague, Czech Republic.

In 2007 we completed the first in vitro fertilization cycle (IVF) followed by preimplantation genetic diagnosis(PGD). Since than , we have performed over 170 cycles with scheduled PGD for 53 different monogenic disorders. One third of those were metabolic diseases with X-linked and autosomal recessive types of indications.

PGD in our centre is based on principle of haplotyping analysis for determination of disease-associated haplotype derived from family members. During the IVF cycle haplotyping technique by multiplex PCR is used on products of multiple displacement amplification (MDA) from one blastomere biopsied from the cleavage-stage embryo on the day 3 (In rare cases of ambiguous result from the blastomere , analysis may be repeated from trophectoderm and embryo is still managed to be transferred on the day 5).

PGD is available for a large number of monogenic disorders. Presented group of metabolic disease forms the most frequent group of examinated disorders in our centre. We have completed 15 IVF cycles - in 11 cases the embryo was transferred. The success rate of PGD procedures of metabolic diseases is approximately 40% (gravidity confirmed by the fetal heart beat).

PGD is a reproductive option for couples at substantial risk of conceiving a pregnancy affected with known genetic metabolic diseases who wish to avoid the emotional burden associated with an affected child or termination of pregnancy.

P05.45

Preimplantation genetic diagnosis and polar body diagnosis for Fragile X syndrome

A. J. Hehr[1], *B. Paulmann*[2], *Z. Kowalzyk*[1], *C. Gassner*[2], *B. Seifert*[2], *U. Hehr*[1,3];
[1]Center for Human Genetics Regensburg, Regensburg, Germany, [2]KITZ Regensburg, Regensburg, Germany, [3]Department of Human Genetics, University of Regensburg, Regensburg, Germany.

Introduction: Fragile X (FRAXA) syndrome is one of the more frequent indications for preimplantation genetic diagnosis (PGD). However, FRAXA premutation carriers are at increased risk for premature ovarian failure and have to cope with significantly lower pregnancy rates per oocyte retrieval (ESHRE data collection X: 17,5%) when compared to PGD for other single gene disorders (ESHRE 22,1%).

Methods: 13 oocyte retrieval cycles (ORC) for polar body diagnosis in 8 families at risk for FRAXA and 26 ORC for 15 families at risk for Cystic Fibrosis (CF) as control group.

Results: For the FRAXA group less metaphase II oocytes could be retrieved (mean 8.31/cycle; CF: 12.15/cycle). With identical embryo transfer rates of 77% per ORC a significantly lower rate of clinical pregnancies (2/10=20%; CF: 9/20=45%) and life births (2; CF: 8 + 1 ongoing pregnancy) was obtained in the FRAXA group per embryo transfer cycle when compared to the CF group.

Discussion: PBD allows the earliest view on oocyte maturation in heterozygous FRAXA carrier females in a diagnostic setting. Our data indicate that PBD results for FRAXA are at least comparable to PGD on day 3 embryos. However, in concordance with the ESHRE PGD data we also observed a reduced number of metaphase II oocytes, lower impregnation and pregnancy rates for Fragile X syndrome when compared to PBD for Cystic Fibrosis, which should be emphasized early during genetic counseling.

P05.47
Virus detection from amniotic fluid and peripheral blood in pregnant women

L. Lazar[1], M. Csire[2], B. Pályi[2], E. Barcsay[2], M. Takács[2], A. Beke[2], C. Papp[1], B. Nagy[1], J. Rigó Jr[1], G. Berencsi[2];
[1]Semmelweis University, Budapest, Hungary, [2]National Epidemiological Center, Budapest, Hungary.

Background: Transplacental viral infections was widely investigated in last decades. Embryo-fetal infections have been reported to cause recurrent spontaneous abortions, and fetal malformations. The possible mechanisms include production of toxic metabolic byproducts, fetal or placental infection, chronic endometrial infection, and chorio-amnionitis. The aim of our study was to detect EBV, CMV, HHV-6, HHV-7, HHV-8,HPV and Torque teno virus DNA from amniotic fluid samples.

Materials and methods: Amniotic fluid (during artifitial membrane rupture) and periferal blood samples were collected at delivery, from 106 pregnant women. DNA was isolated with silica adsorption method. Viral DNA was determined with real time PCR method. IgG and IgM was also determined form peripheral blood samples.

Results: Viral DNA was detected in 27 of 106 amniotic flud samples. We detected CMV DNA in nine, HHV-7 DNA in eight, HHV-8 DNA in five, EBV DNA in four amniotic fluid samples. CMV, HHV-7 and EBV positivity was two-twofour fold higher in amniotic flud samples than in peripheral blood samples. 69,81% of maternal blood samples was positive for HHV6 IgG.

Conclusions: Our results suggest that viral infections occure more often in pregnancy, than previously where supposed. In case of abnormal prenatal/ ultrasound findings, and amniotic fluid sampeling rises the possibility of PCR viral detection from aniotic fluid.

P05.48
Deletion 18q21.2q21.31 encompassing *TCF4* diagnosed by CGH-Array in a fetus presenting with hypoplastic corpus callosum

N. Marle[1], P. Callier[1], A. Mosca-Boidron[1], C. Thauvin-Robinet[2], N. Laurent[3], M. Gérard[4], A. Masurel-Paulet[2], T. Rousseau[5], M. Payet[1], C. Ragon[1], F. Mugneret[1], L. Olivier-Faivre[2];
[1]Laboratoire de Cytogénétique, CHU Le Bocage, Dijon, France, [2]Département de Génétique, Hôpital d'Enfants, Dijon, France, [3]Laboratoire d'Anatomie-Pathologie, CHU Le Bocage, Dijon, France, [4]UF de Génétique Clinique, CHU Robert Debré, Paris, France, [5]Maternité du Bocage, Dijon, France.

We report on a fetus with subtotal corpus callosum agenesis and bilateral ventriculomegaly diagnosed by ultrasonography at 25 weeks of gestation. After MRI confirmation, pregnancy was terminated. Conventional cytogenetic analysis on amniotic fluid cell cultures revealed a normal karyotype (46,XY). Fetal autopsy showed hypoplastic corpus callosum with fragmented fibers and bilateral ventriculomegaly. Array-CGH analysis (Agilent®, 4x44K) was performed on DNA extracted from frozen fetal tissue samples and showed a 3 Mb interstitial 18q deletion: arr 18q21.2q21.31(49190680-52188365)x1. FISH on metaphase spreads from amniotic fluid cultures with RP11-344A12 BAC probe confirmed the deletion. This deletion which occurred *de novo*, encompasses 10 genes including *TCF4*.

Haploinsufficiency of *TCF4* was identified as the underlying cause of Pitt-Hopkins syndrome. Pitt-Hopkins syndrome (PTHS, OMIM 610954) is characterized by severe intellectual disability, typical facial gestalt and daily episodes of hyperventilation followed by apnea. Other common findings are epilepsy and brain abnormalities such as hypoplastic corpus callosum. About sixty cases of PTHS confirmed by molecular studies have been reported in the literature. Most of them result from mutations or intragenic deletions or insertions. In 30 % of cases, PTHS results from submicroscopic deletion including *TCF4* and detected by Array-CGH analysis. Clinical reevaluation found facial features suggestive of PTHS.

This is the first report of a submicroscopic deletion including *TCF4* found after prenatal diagnosis of a corpus callosum abnormality. These results allow reassuring genetic counseling for later pregnancies and give the opportunity to discuss the usefulness of Array-CGH in isolated hypoplasia/agenesis of the corpus callosum.

P05.49
Study of the methylenetetrahydrofolate reductase and the reduced-folate carrier-1 gene polymorphism in healthy and severe pre-eclamptic patients

G. Szabo, L. Lazar, J. Rigo Jr., B. Nagy;
Semmelweis University, Budapest, Hungary.

One-carbon cycle is involved in the synthesis of purins and pyrimidines required for DNA synthesis and repair. These one-carbon groups are served by the tetrahydrofolate and the S-adenosylmethionine. Deficiencies of the folate, and methionine pathway leads to elevated homocysteine levels. These disorders have been implicated in placental diseases. Studies have shown that homocysteine levels are elevated by patients with severe pre-eclampsia than by healthy pregnant normotensive women. Methylenetetrahydrofolate reductase (MTHFR) gene C677T missense mutation is connected with elevated serum homocysteine levels. The mutation G80A of the reduced-folate carrier (RFC-1) gene leads to higher plasma folate levels. We identified polymorphisms of these genes by severe pre-eclamptic patients and healthy controls.

Blood samples were collected from healthy pregnant normotensive women (n=82) and women with pre-eclampsia (n=75). DNA was isolated and quantitative real-time PCR method combined with melting curve analysis was performed for the detection of the two polymorphisms.

The frequency of A allele in the RFC-1 gene was 46,57% by controls and 41% by pre-eclamptic patients. Overall distribution of genotypes was not significantly different between the two groups (p=0.58). In the study groups by the MTHFR gene the frequency of T allele was 32% in pre-eclamptics, 35.92% in controls. The distribution of genotypes was not significantly different between the two study groups (p=0.15).In pre-eclampsia the one-carbon cycle is disturbed. We studied single nucleotid mutations in the genes of two enzymes involved in the cycle and found no significant differences. Examinations of other genetical compounds help understanding elevated homocysteine levels in pre-eclampsia.

P05.50
Preimplantation diagnosis of hearing impairment

D. Raskova[1], P. Seeman[1], D. Stejskal[1], I. Borgulova[1], V. Krutilkova[1], M. Brandejska[1], J. Mika[1], M. Malikova[2], M. Putzova[1];
[1]Centre for Medical Genetics and Reproductive Medicine GENNET, Prague 7, Czech Republic, [2]Institute of Biology and Medical Genetics,2nd Medical Faculty, Charles University, Prague 5, Czech Republic.

In our centre we have been providing preimplantation genetic diagnosis (PGD) since 2007. Up to now we have accomplished 173 IVF cycles followed by PGD in about 50 genetic diseases. We used genetic haplotyping technique by multiplex PCR on products of MDA (multiple displacement amplification) from 1 blastomere biopsied from embryo. On average 5-6 embryos were biopsied in one IVF cycle. The success rate of the procedure (calculated on the fetal heart beat pregnancy) is approximately 30%.

We present four families in which both parents are heterozygous for 35delG mutation in GJB2 gene (Connexin 26) and have one deaf child, homozygote of the same mutation.

One family with Waardenburg syndrome, autosomal dominant inherided, where the mutation p.Phe45Leu in PAX3 gene was confirmed and the haplotypic analysis for PGD is prepared.

Six IVF cycles was realized in these families undergone PGD, recommended due to the high risk of recurrence of hearing impairment in offspring. One cycle was not followed by embryotransfer. Three pregnancies was confirmed. One of them was finished by missed abortion in 9th week. Three hearing children were born - one girl and twins, boy and girl.

One woman patient conceived spontaneously before repeated IVF cycle and gave birth to one healthy hearing son.

P05.51

A generic, fast and flexible protocol for preimplantation HLA-typing alone or in combination with a monogenic disease

G. Kakourou[1], *J. Traeger-Synodinos*[1], *C. Vrettou*[1], *A. Destouni*[1,2], *S. Davies*[3], *G. Kokkali*[4], *M. Mastrominas*[3], *K. Pantos*[4], *A. Kattamis*[5], *P. Delaporta*[5], *C. Sofokleous*[1], *E. Kanavakis*[1,2];
[1]University of Athens, Department of Medical Genetics, "Aghia Sophia" Children's Hospital, Athens, Greece, [2]Research Institute for the Study of Genetic and Malignant Disorders in Childhood, „Aghia Sophia" Children's Hospital, Athens, Greece, [3]Embryogenesis, Assisted Conception Unit, Athens, Greece, [4]Genesis Athens Clinic, Center for Human Reproduction, Athens, Greece, [5]Thalassaemia Unit, University of Athens, „Aghia Sophia" Children's Hospital, First Department of Paediatrics, Athens, Greece.

HLA-typing of *in-vitro* fertilization (IVF) embryos aims to establish a pregnancy that is HLA-compatible with an affected sibling who requires haematopoietic stem-cell transplantation. The procedure can be performed with or without preimplantation genetic diagnosis (PGD) for exclusion of a single-gene disorder (SGD). HLA-PGD is, however, a multistep, technically challenging procedure at every stage. To address the aspect of genetic analysis through simplifying patient work-up and PGD application, we developed a fast, reliable, accurate HLA-PGD protocol, to allow minimal work-up time and high flexibility for combination with any SGD.

Recent HLA-PGD requests included 11 families to treat β-thalassaemia and 1 family each for Diamond-Blackfan anaemia, Chronic Granulomatous disease, Sideroblastic anaemia and preimplantation-HLA-typing only.

For HLA-haplotyping we selected 22 short tandem repeats distributed across the entire HLA-locus (4Mb) following published guidelines. PCR primers were designed with properties allowing multiplex analysis in any combination. The resulting one-step, single-tube, multiplex fluorescent touchdown-PCR, was minimally modified to incorporate multiplex protocols for direct and indirect genotyping of the SGDs, supporting concurrent SGD exclusion and HLA-typing. Amplification efficiency and allele-dropout, from single lymphocyte testing, ranged from 97.6-100% and 0-6.2%, respectively. Five clinical cycles were performed with a diagnosis achieved for 92.8% of amplified biopsied blastomeres. Embryo transfer took place in three cycles and one pregnancy was established.

Our protocol enables HLA-typing in a single-PCR, reducing risk of contamination and cost and providing faster results. For different SGDs, it requires minimum optimization before clinical application, decreasing the waiting time from referral to treatment for all HLA-PGD cases.

P05.52

Prenatal BoBs complements excellently karyotyping in routine prenatal diagnostics

N. J. Horelli-Kuitunen, *A. M. Slunga-Tallberg*, *K. J. Kiiski*;
Medix Laboratories Ltd, Espoo, Finland.

The new bead-based multiplex assay Prenatal BACs-on-Beads (PN_BoBs™) was validated and utilized for routine use in prenatal diagnostics. PN_BoBs assay detects aneuploidies (13,18,21,X,Y) along with nine of the most common microdeletion syndromes. The validation contained 57 different fetal samples with a success rate of 98.2%. The diagnostic cases included fresh amniotic fluid (AF), chorion villus (CV) samples (group A) and tissue samples (skin or placenta) from cases with unexplained fetal loss (group B). We have now studied 118 samples (group A 55 and group B 63 cases) the success rate being 96.6 %. In group A PN_BoBs revealed two microdeletions (monosomy 22q11), one monosomy X, trisomy 18, and trisomy 21. No false positive results were detected, but one false negative result (69,XXX) was reported, and one sample with maternal cell contamination (MCC) was detected. In group B three cases of trisomy 21 and one trisomy 13 were detected. The overall abnormality detection rate was 1/12 and the additional detection rate of PN_BoBs over karyotyping was 1/59, revealing two microdeletions. The advantage of PN_BoBs is the simultaneous detection of both trisomies and microdeletions in addition to reliability and quickness. Furthermore PN_BoBs is unsensitive for MCC and it detects even 30% mosaicism. 6/118 had minor interpretation difficulties but in case of abnormalities no interpretation difficulties have arised. The reason for failures (3,4%) were due to low level of DNA. In conclusion PN_BoBs has additional informational value over QF-PCR as it also detects common microdeletions and therefore it better complements karyotyping.

P05.53

24 chromosomes in 24 hours: Validation study of a new assay for rapid detection of aneuploidies and terminal imbalances of all chromosomes in chorionic villous samples

S. Zahn, *S. Kerber*, *R. Achmann*, *L. Argyriou*, *C. Kähler*, *B. Auber*, *K. Held*;
MVZ genteQ GmbH, Hamburg, Germany.

Conventional karyotyping after cell culture still represents the gold standard in prenatal diagnosis. In general, results are available 10-12 days after sample reception. To bridge this gap, rapid testing for common aneuploidies using QF-PCR or FISH is performed. In chorionic villous samples (CVS), direct or short-term incubation preparations are recommended to obtain an early complete chromosome analysis. However, the labour input is substantial and the results are often of poor quality. As the likelihood for chromosomal aberrations other than trisomies 21, 18 and 13 in CVS is higher as compared to amniocytes, we evaluated the KaryoLite™BACs on Beads™ technology (Perkin Elmer, Turku, Finland) as an alternative testing method for aneuploidies and terminal imbalances of all chromosomes within 24 hours. Endpoints of the study were analytic sensitivity and ease of use.

This molecular karyotyping assay consists of 91 BAC coupled beads providing information about the dosage of proximal and terminal regions of each chromosome arm using comparative hybridisation.

In this validation study, we investigated 102 CVSs with known aneuploidies (n=93, autosomal=69, gonosomal=24), polyploidies (n=3) and terminal imbalances (n=6) previously analysed by QF-PCR and karyotyping.

From our data we conclude that Karyolite™ BoBs™ provides correct and rapid results on all aneuploidies and - if covered by the assay - terminal imbalances, based on minute (<50ng) amounts of DNA in a single assay. As expected, due to methodological restrictions, female triploidies could not be diagnosed. The test has an acceptable workload and is easy to use.

P05.54

Undetected sex chromosome aneuploidy by chromosomal microarray - practical implications

K. Markus-Bustani[1], *Y. Yaron*[1,2], *M. Goldstein*[1], *A. Orr-Urtreger*[1,2], *S. Ben-Shachar*[1];
[1]The Genetic Institute, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [2]Sackler Faculty of Medicine, Tel-Aviv University, Tel Aviv, Israel, Israel.

We report on a case of a female fetus found to be mosaic for Turner syndrome (45,X) and trisomy X (47,XXX) by karyotype, with 3:1 ratio between the two cell lines respectively. However, chromosomal microarray analysis (CMA) failed to detect the aneuploidy due to a normal average dosage of the X chromosome in the direct amniotic fluid sample. This case represents an unusual instance in which CMA may not detect chromosomal aberrations. Such a possibility should be taken into consideration in similar cases where CMA is used in a clinical setting, and especially in cases suspected for sex chromosome aberrations, in which mosaic states are common.

P05.55

Chromosomal mosaicism in invasive prenatal investigations in 1998-2010 in a fetal medicine department.

V. Curtisova, *P. Čapková*, *I. Dhaifalah*;
Department of Human Genetics and Fetal Medicine, Fakultní nemocnice Olomouc, Olomouc, Czech Republic.

Counselling after a diagnosis of chromosomal mosaicism in a prenatal invasive sample is difficult, as the impact of the finding on the fetus is difficult to predict. We review all cases of level II and III mosaicism in our prenatal invasive samples between 1998 and 2010 and present the results. 4803 amniocentesis (Amnio) were performed with 26 (0,5%) cases of mosaicism, and 643 CVS with 23 (3,6%) cases of mosaicism. Of 23 ascertained outcomes of Amnio pregnancies 4 were terminated, 1 miscarried, 16 resulted in birth of a normal baby and 2 babies had abnormalities, which were probably unrelated to the cytogenetic finding. Of 22 ascertained outcomes of CVS pregnancies 5 were terminated, 2 miscarried, 14 resulted in a birth of a normal baby and 1 baby had abnormalities, which were unrelated to the cytogenetic finding. Negative outcomes were found in mosiacist variants of chromosomal aneuploidies which are in a pure form connected with known syndromes (trisomy 21, monosomy X and so on).

P05.56

Fetal RHD genotyping in maternal plasma: 2 years of experience

E. Guinchard, *S. Monnier*, *C. Marthinet*, *E. Monier*;
EFS Rhône-Alpes site de Lyon-GHE, Bron, France.

backround

Fetal RHD genotyping in maternal plasma is carried out for almost 2 years in the laboratory.

Aims: The analysis performed from 10 weeks of pregnancy involves three of the 10 exons of this gene: exons 4, 5 and 10 by real-time PCR. Two genes controls are used: SRY and CCR5 gene.

The criteria for technical and biological validation have been defined. Any negative or abnormal results (absence of amplification of the three exons or amplification of one or two of the three exons) must be controlled on a new sample taken 15 days later.

The reporting of results is standardized with well-defined biological comments. The report is accompanied by a tracking sheet of pregnancy. The feedback at birth in the laboratory by the motherhood, (indicating RH1 phenotype at birth and sex of the child) can be difficult and allows tracking of results, and is an quality indicator, the target being the absence of false negatives.

Results: Since 2010, 64 analyzes were performed: 38 results were positive, 14 negative and 12 undetermined usually corresponding to a maternal RHD gene variant. In several cases, variant RHD genes were found in the newborn.

Conclusion: the experience of almost two years shows that this technique guided by procedures and very precise and rigorous criteria of validation is reliable. Situations of maternal variants are the most difficult situations that should lead to careful interpretation of the results.

The laboratory is also part of a quality initiative, by participating and developing an inter-laboratory quality control.

P05.57

Evaluation of Prenatal BoBs® for the detection of mosaicism in prenatal diagnosis

Y. K. Kwok[1], *Y. K. Y. Cheng*[1], *C. Wong*[1], *H. K. Wong*[1], *K. O. Leung*[1], *A. C. S. Chan*[1], *S. Dallaire*[2], *T. Y. Leung*[1,3], *M. Schermer*[2], *K. W. Choy*[1,3,4];
[1]Department of Obstetrics and Gynaecology, Hong Kong, Hong Kong, [2]PerkinElmer, Waltham, MA, United States, [3]CUHK-BGI Innovation Institute of Trans-omics, Hong Kong, Hong Kong, [4]CUHK-Shenzhen Research Institute, Hong Kong, Hong Kong.

Objective: To evaluate the effectiveness of a new prenatal diagnostic platform - prenatal bacterial artificial chromosomes-on-Beads® (Prenatal BoBs®) in detecting mosaicism and comparing it's performance with quantitative fluorescence polymerase chain reaction (QF-PCR)

Methods: A validation study of Prenatal BoBs® was firstly performed using artificially constructing mosaic samples involving various aneuploidies and microdeletion conditions. Furthermore, we compared the accuracy between Prenatal BoBs® and QF-PCR in 16 archived real clinical mosaic cases according to the conventional karyotype results.

Results: In the validation study, Prenatal BoBs® allowed the detection of mosaicism at a level of 20 to 40%. Among 16 real clinical mosaic cases, 4 (25%)cases could be identified by both Prenatal BoBs® and QF-PCR but 8 (50.3%) cases were missed by both tests. Three cases (18.8%) were detected by Prenatal BoBs® but missed by QF-PCR, while QF-PCR detected 1 case which was missed by Prenatal BoBs® due to the mosaic region did not having probe covered. The overall sensitivity of Prenatal BoBs® in detecting mosaicism is 43.8% (7/16) which is slightly higher than 31.3% (5/16) of QF-PCR.

Conclusion: Prenatal BoBs® has a sensitivity of 44% in the detection of real clinical mosaic cases. The threshold mosaic level to be detectable by Prenatal BoBs® is 20% according to the validation study. This assay is likely superior in detecting mosaicism.

P05.58

Clinical use of array-CGH in foetuses with ultrasound anomalies and normal karyotype

L. Gwanmesia[1], *S. Gimelli*[1], *K. Aliferis*[1], *M. Billieux*[2], *I. Eperon*[2], *V. Mirlesse*[2], *J. Pellegrinelli*[2], *R. Robyr*[3], *P. Extermann*[4], *E. Antonelli*[5], *E. Ranza*[1], *S. Dahoun*[1], *F. Sloan-Béna*[1], *S. Fokstuen*[1];
[1]Genetic Medicine, University Hospitals of Geneva, Geneva, Switzerland, [2]Department of Gynecology and Obstetrics, University Hospitals of Geneva, Geneva, Switzerland, [3]Echofemme, Centre for Prenatal Diagnosis and Echography, Geneva, Switzerland, [4]Dianecho, Centre for Obstetrical and Gynecological Echography, Geneva, Switzerland, [5]Gynecology and Obstetrics, Private Practice, Geneva, Switzerland.

Prospective application of array-CGH in pregnancies with ultrasound anomalies and to a lesser extent in pregnancies referred for other reasons has recently become a common investigation in clinical practice. We summarize our experience on prenatal array-CGH analysis performed on 40 pregnancies with foetuses presenting isolated or multiple malformations, and/or intrauterine growth retardation detected by ultrasound and with a normal karyotype on chorionic villi or amniotic fluid samples. All parents received genetic counselling and gave their informed consent. We used the 44k Agilent-based oligonucleotides array and performed 3 hybridisation experiments per case: the DNA samples of the foetus and both parents were independently co-hybridized with a reference commercialised DNA. Eight out of 40 samples (20%) carried copy number variations (CNVs). The rate of clinically significant de novo alterations was 1/40 (2.5%) as was the rate of de novo findings with uncertain clinical significance. We found a single inherited CNV in two foetuses while 3 other foetuses each carried 2 inherited variants . Our results support the ability of array CGH to identify cryptic chromosomal abnormalities which cannot be detected by standard karyotyping. Thus, the percentage of prenatal genetic diagnosis increases, which has a strong impact on genetic counselling. We encourage the use of CGH-array for clinical practice in foetuses with ultrasound anomalies and normal karyotype.

P05.59

‚I do not want my baby to endure as I did'. Prenatal and Preimplentation Genetic Diagnosis for BRCA1/2 Mutations

E. Dagan[1,2], *A. Mory*[1], *Y. Goldberg*[3], *R. Gershoni-Baruch*[1,4];
[1]Rambam Medical Center, Institute of Human Genetics, Haifa, Israel, [2]Department of Nursing, University of Haifa, Haifa, Israel, [3]Obstetrics and Gynecological Ultrasound Unit, Carmel Medical Center, Haifa, Israel, [4]Ruth and Bruce Rappoport Faculty of Medicine, Technion Institute of Technology, Haifa, Israel.

Prenatal and preimplantation genetic diagnosis (PND/PGD) can be employed to prevent transmission of BRCA1/2 mutations, thereby, obviating adverse clinical-psychological associations. It remains debated whether PND/PGD should be offered for low penetrance, late onset syndromes. A case history and issues related to PND/PGD for breast-ovarian cancer syndrome in Israel and across countries is presented.

Sarah, 34 years old, 9-10 weeks spontaneously pregnant seeks PND for BRCA1 mutation. She was diagnosed with bilateral breast cancer at 29 and 32 years of age, respectively, followed by mastectomy, reconstruction, and chemotherapy. Her mother had breast cancer at age 46; no other case of cancer in the family was reported.

This case history stimulates several questions. How personal and family history of cancer should be regarded in the context of PGD/PND; does the gender of the fetus, or the carrier status (whether due to a BRCA1 or BRCA2 mutation) should be considered; is it ethical to allow PGD or PND for late onset diseases with incomplete penetrance.

PGD/PND for hereditary breast-ovarian and bowel cancer was considered in 2006, in UK. Israel and Germany advocate and ban, respectively, PGD/PND for cancer susceptibilities, whilst other Western countries are somewhere in between. The criteria that each country adopts in favor or against PGD/PND, for late onset diseases may reflect the complex social and family ethical values regarding the technology of assistance reproduction. Comprehensively, with genetic diagnosis at hand these days, PND/PGD for BRCA1/2 mutation carriers is at the front door and becomes relevant within the clinical setting.

P05.60

Unexpected findings in prenatal diagnosis of fetal ultrasound abnormalities using SNP array

J. Knijnenburg, *M. I. Srebniak, G. Oudesluijs, R. H. Galjaard, D. Van Opstal;*
Erasmus Medical Center, Rotterdam, Netherlands.

Objective: To get insight into the frequency and nature of the so-called "unexpected findings" when using SNP array in prenatal diagnosis. This is important for setting-up a good pre-test counseling.

Methods: We performed HumanCytoSNP-12 array (Illumina) analysis of uncultured amniotic fluid cells and LTC-villi in 344 cases of fetal anomalies after exclusion of the common aneuploidies and triploidy. For correct interpretation, simultaneous analysis of both parents was performed in most cases. According to our policy, only clinically relevant copy number variants (CNVs) were reported to the clinical geneticist who counselled the parents.

Results: On a total of 344 arrays, 36 (10,5 %) CNVs were found that were interpreted as clinically relevant based on current knowledge. 24 (7 %) were most probably causative explaining the ultrasound abnormalities and 12 (3,5 %) were so-called "unexpected findings" that are most likely not directly associated with the fetal anomalies. In the latter cases the involved CNVs were risk factors for mental disability, autism spectrum disorder, schizophrenia etc. CNVs involving genes like DMD or BRCA2 were not found so far.

Conclusions: These findings stress the importance of a pre-test counseling with special attention for this type of risk factors, taking into account that risk figures are based upon postnatal studies and that the prenatal manifestation of such factors is not yet studied. In our opinion, the pregnant woman should get the opportunity to decide whether she wants to be informed about these CNVs, which may potentially complicate decision-making on continuation or termination of the pregnancy.

P05.61

The results of the Pilot Project for prenatal diagnostics of fetal malformations in Tomsk region

L. P. Nazarenko, *A. A. Rudko, K. V. Puzyrev, S. L. Vovk, V. P. Puzyrev;*
State Research Institute of Medical Genetics, Tomsk, Russian Federation.

In 2010, the Russian Government has appointed Tomsk region as the participant in the Pilot Project for prenatal diagnostics of child malformation on the basis of integrated (ultrasonic and biochemical) screening in the first trimester of pregnancy. The sonographic marker of chromosomal anomalies (CA) in this Program was the measure of nuchal translucency by 3D ultrasonic apparatus accompanied by the maternal serum markers of free beta-HCG and PAPP-A. On the basis of these parameters we calculate the cumulative risk of CA and form the group of expectant mothers with high risk for birth of a child with defects. These women are recommended to pass the invasive diagnostics.

During the first year of realization of this Project in Tomsk Region we examined 9.575 expectant mothers (93.5% out of women registered in first trimester or 73.4% out of all pregnant women).

As a result of prenatal screening, 124 women were selected to high-risk group of CA (1.4 % of all examined). We carried out 119 invasive manipulations for karyotyping of fetal cells. In 34 cases (28.6%) CA was diagnosed by cytogenetic methods, including FISH. Down syndrome was the most common among the detected fetal CA (17 cases). Edwards syndrome was detected in 5 cases; Patau syndrome was found in 3 cases; Klinefelter syndrome was observed in 4 cases; Turner syndrome was detected in 2 cases. Other chromosomal anomalies were detected in 2 fetus.

Thus the “Prenatal Diagnostics” program allows effectively diagnosing the fetal malformations and preventing the birth of children with CA.

Quantitative Fluorescent PCR analysis (QF-PCR) is now widely used for prenatal detection of the most common autosome aneuploidies - trisomy 21, trisomy 18, trisomy 13 and some of the sex chromosomes aneuploidies. It provides rapid and accurate results. Aneuploidies involving sex chromosomes detected by QF-PCR could reflect different types of underlying chromosomal rearrangements including mosaics and structural abnormalities.

We report two prenatal cases of XX disomy in male fetuses (SRY positive) detected by QF-PCR on uncultivated amniocytes. Both patients were referred for amniocentesis because of positive maternal serum screening.

DNA was extracted from uncultivated amniocytes, amplified with commercial QF-PCR kit Aneufast (Molgentix SL, Barcelona, Spain) and analyzed on ABI 3110 XL Karyotyping was performed on cultured amniocytes using standard protocol.

QF-PCR showed results consistent with sex chromosomes aneuploidy, SRY was present. Pseudoautosomal markers AMEL, X22, DXYS218 were in diallelic trisomic pattern in case 1. Markers AMEL, DXYS218, DXYS267 were in diallelic trisomic pattern in case 2. Markers on chromosome X were in hemizygous pattern in both cases. Cytogenetic analysis revealed 45, X/46, XY - [75%]/ [25%] karyotype in case 1 and 45, X in case 2.

The wide range of clinical manifestations of 45, X/46, XY mosaics is a genetic counseling challenge during pregnancy.

Pathological QF-PCR results involving the sex chromosomes require additional cytogenetic analysis in order to clarify the underlying chromosomal rearrangement.

P05.63

Study of the reduced folate carrier-1 (RFC-1) *A90G* polymorphism in Down syndrome

B. Nagy*, J. Schönléber, G. Szabó, L. Lázár, J. Rigó Jr;*
Semmelweis University, Budapest, Hungary.

RFC-1 gene encodes the reduced folate carrier 1 protein which plays role in the folic acid adsorption by transporting 5-methylenetetrahydrofolate to cells. Polymorphisms in folate metabolic genes have been associated with the development of Down syndrome. We determined the *RFC-1 A*80*G* polymorphism in Down syndrome.

Materials and methods: DNA was isolated from amniotic fluid of 92 Down syndrome and 76 heathy cases by silica adsorption method (High Pure PCR Template Preparation Kit, Roche, Germany). PCR was performed with LightSnip mixture of *RFC-1* (TibMolbiol, Germany) with LightCycler DNA Master HybProbe kit (Roche). Following melting curve analysis aleles were assigned and statistical analysis was performed to compare the allele and genotype frequencies.

Results: The melting point of the PCR product was 55 ºC for the *G*, and 65 ºC for the *A* allele. We observed significant difference in the frequency of the *G* allele in Down syndrome group (69.1% vs. 30.9%), higher what we expect having three alleles from chromosome 21. Accordingly it was similar with the genotypes. We found 31.8% *GGG*, 40.6% *AGG, 17,6% AAG* and 9.8% *AAA* genotypes in Down group and 28.4% *GG*, 51.4% *GA* and 20.2% *AA* in control group. **Discussion**: Polymorphism in the folate metabolism enzymes could increase the risk of chromosomal segregation and the risk of development Down syndrome. We detected high frequency of G alleles in Down syndrome cases.

Lack of association between plasminogen activator inhibitor-1 4G/5G polymorphism and retinopathy of prematurity in premature neonates

I. Akalin[1,2]*, D. Armangil*[3]*, Y. Aslan*[4]*, B. Saygin*[4]*, H. Erdöl*[5]*, M. Yurdakök*[6]*;*
[1]*Trabzon Women‘s and Children‘s Hospital, Genetic Diseases Diagnosis Center, Trabzon, Turkey,* [2]*Istanbul Medeniyet University, Medical Genetics, Istanbul, Turkey,* [3]*Trabzon Women‘s and Children‘s Hospital, Neonatology Unit, Trabzon, Turkey,* [4]*Karadeniz Technical University, Faculty of Medicine, Neonatology Unit, Trabzon, Turkey,* [5]*Karadeniz Technical University, Faculty of Medicine, Ophthalmology Unit, Trabzon, Turkey,* [6]*Hacettepe University Faculty of Medicine, Neonatology Unit, Ankara, Turkey.*

INTRODUCTION: Retinopathy of prematurity (ROP) is a proliferative vascular disorder in premature neonates. Due to differences in individual responses to the treatment, various genetic factors have been investigated in the etiology of ROP. We investigated the gene polymorphism of plasminogen activator inhibitor (PAI-1) 4G/5 as a risk factor of ROP development.

METHODS: 73 neonates with ROP and 101 controls were enrolled to study. The mean gestational ages were 29.4±0.8 weeks and 30±1.4 weeks, respectively. The mean birth weight was 1322±431 g and 1414±313 g, respectively. Genotyping was analyzed using real time polymerase chain reaction methods.

RESULTS: We found no significant differences in allele frequency of the PAI-1 genes between control group and neonates with ROP (*p*=0.540 and p=0.527, respectively). The proportion of 4G/4G, 4G/5G and 5G/5G genotypes did not differ statistically between the ROP and control groups (p>0.05). Having PAI-1 4G/4G genotype polymorphism seems to developed the risk of ROP (OR =0,702; 95% CI: 0.300-1.639) less than PAI-1 4G/5G polymorphisms (OR =1.064; 95% CI: 0.469-2.410). 4G/4G genotype frequency was decreasing as the stages of ROP were increasing though there was no statistically significant difference between proportion of genotypes and ROP stages.

CONCLUSION: This study showed that PAI-1 4G/5G genotype which is known as a risk factor for angiogenesis is not a predisposing factor for ROP development. Our study is the first report to investigate the association of PAI-1 gene polymorphisms on retinal angiogenesis and given clues of decreased risk for ROP development within the 4G homozygous neonates.

The reliability of maternal serum triple screening for the prenatal diagnosis of fetal chromosomal abnormalities in Turkish women

A. Pazarbasi[1]*, O. Demirhan*[1]*, M. Kasap*[1]*, D. Alptekin*[1]*, U. Luleyap*[1]*, B. Yilmaz*[1]*, A. I. Guzel*[2]*, S. K. Sel*[1]*, E. Tunc*[1]*, L. Özpak*[1]*, F. T. Özgunen*[3]*, H. Kasap*[1]*;*
[1]*Faculty of Medicine, Department of Medical Biology and Genetics, Adana, Turkey,* [2]*Faculty of Medicine, Department of Medical Biology and Genetics, Rize, Turkey,* [3]*Faculty of Medicine, Department of Obstetrics and Gynecology, Adana, Turkey.*

The purpose of this study was to evaluate the reliability of maternal serum triple marker screening of alpha-fetoprotein, human chorionic gonadotropin, and unconjugated estriol for the prenatal diagnosis of fetal chromosomal abnormalities in Turkish pregnant women. Medical records were used to analyze indications of amniocentesis and quantitative fluorescent-polymerase chain reaction. A total of 1725 pregnancies with chromosomal abnormality risk according to triple test screening were accepted for fetal chromosome analysis and quantitative fluorescent-polymerase chain reaction. Weeks of pregnancy of the subjects ranged between 13 and 22. Chromosomal aberrations were observed in 56 (3.2%) cases. About 44.6% of the abnormalities detected were numerical aberrations; however, 55.3% of the abnormalities were structural aberrations. Abnormalities detected were inversion of chromosome 9 in 20 cases, trisomy 21 in 14 cases, 46,XX/47,XX, + 21 in 1 case, trisomy 18 in 2 cases, trisomy 13 in 1 case, 47,XXY, in 1 case, 45,X, in 1 case, structural abnormalities in 12 cases, and mosaic or tetraploidy in 6 cases.

Second trimester triple test is an effective screening tool for detecting fetal Down syndrome in Turkish women.

The relationship between haplotype & IVSII-745 mutation in β-thalassemia

A. Amirian[1], *M. Taghavi*[1], *F. Bayat*[1], *A. Valaei*[1], *F. Navvabmoghaddam*[1], *S. Ahmadi*[1], *M. Mortezazadeh*[1], *Z. Kaeinimoghaddam*[1], *A. Kordafshari*[1], *F. Maryami*[1], *M. Karimipour*[1], *S. I. R. O. Zeinali*[2];

[1]*Pasteur Institute of Iran, Tehran, Islamic Republic of Iran,* [2]*Pasteur Institute of Iran & Kawsar Human Genetics Research Center, Tehran, Islamic Republic of Iran.*

The relationship between haplotype & IVSII-745

The hemoglobin disorders are a group of autosomal recessive disorders causes anemia with different severities.

β-thalassemia is one of the commonest genetic disorders characterized by either absence or reduced β-globin chains synthesis. One of the mutations causing β-thalassemia especially in south and north of Iran is IVSII-745. There are numerous polymorphic base substitutions within the β -glibin-gene cluster, that are in linkage disequilibrium with β -globin-gene mutations.

The aim of this study was to analyze the relationship between β-globin cluster haplotype and IVSII-745 mutation.

Materials and Methods:

After obtaining informal consent, DNA was extracted from 5 ml of peripheral blood of β-thalassemia carriers referred from primary health care centers(PHC). ARMS- PCR was performed for detecting the common mutations. Haplotype analysis was done by using PCR-RFLP in three different sites. Polymorphisms included: GγHindIII, 3ψβHincII, AvaII/β. Polymorphisms were done by digesting PCR products by aproprate restriction enzyme.

Results and Discussion:

In this study, 35 β- thalassemia carriers and their parents with IVSII-745 mutation were studied. Total of 35 cases with IVSII-745(C>G) , 30% had the pattern type I and type V (- - +). In the remaining cases that have informative pattern (70%) had haplotype VII (- - -). Rest of the cases didn't have informative pattern.

Our study showed that based on haplotype analysis, it became apparent that non-random association of polymorphic restriction sites in the β-gene cluster occurs within the mutations in β-globin gene like IVSII-745.

Prenatal diagnosis by array CGH of a fetus with Thrombocytopenia-Absent Radius (TAR) syndrome in the first trimester

E. Manolakos[1], *M. B. Petersen*[1], *S. Orru*[2], *V. Bacoulas*[3], *I. Papoulidis*[4];

[1]*Eurogenetica, Athens, Greece,* [2]*Department of Medical Genetics, University of Cagliari, Cagliari, Italy,* [3]*Fetal Medicine Centre, Athens, Greece,* [4]*Eurogenetica, Thessaloniki, Greece.*

Thrombocytopenia-Absent Radius (TAR) syndrome (MIM 274000) is a very rare condition (0.5:100,000) characterized by absence of the radii with the presence of both thumbs and thrombocytopenia. However, other congenital anomalies can occur, and affect the skeletal, cardiac, gastrointestinal, and genitourinary systems. The mode of inheritance of TAR syndrome is unknown. Presence of a minimally deleted 200-kb region at chromosome band 1q21.1 is necessary but not sufficient to cause the phenotype. One or more as-yet-unknown modifiers are thought to be necessary for the expression of the TAR syndrome phenotype. Whereas TAR syndrome has been described in numerous patients, a very limited number of prenatally diagnosed cases have been reported and only five cases have been genetically tested and verified the microdeletion in the 1q21.1 region. We report clinical, molecular and cytogenetic studies of a prenatally diagnosed fetus with TAR syndrome with a small (334 kb) deletion characterized by the array-CGH technique and emphasize that array-CGH remains a useful tool in the precise description of TAR syndrome as well as other haploinsufficiency syndromes.

Triploidies identified at prenatal diagnosis

V. Cejnova[1], *M. Wilimska*[1], *V. Harmas*[1], *J. Mareckova*[2], *A. Klimova*[1], *M. Soukupova*[1], *M. Stara*[1], *J. Lastuvkova*[1];

[1]*Regional Health Corporation, Masaryk Hospital in Usti nad Labem, Department of Medical Genetics, Usti nad Labem, Czech Republic,* [2]*Regional Health Corporation, Masaryk Hospital in Usti nad Labem, Department of Pathology, Usti nad Labem, Czech Republic.*

Triploidy, the presence of an extra haploid set of chromosomes, is one of the most frequent chromosomal abnormalities affecting human gestation. Its prevalence among all pregnancies has been estimated to be approximately 1% to 3%. Triploidy may be the result of either digyny (extra haploid set from mother) or diandry (extra haploid set from father).

Two distinct phenotypes observed in triploid fetuses have been shown to be associated with parental origin of the triploidy (McFadden and Kalousek 1991). The diandric phenotype is characterised by a normally sized or mildly symmetrically growth retarded fetus with normal adrenal glands, and is associated with an abnormally large, cystic placenta with histological features known as partial hydatidiform mole (Type I). The digynic phenotype is characterised by marked asymmetric intrauterine growth restriction (IUGR), marked adrenal hypoplasia, and a very small, non-molar placenta (Type II).

We present chromosomal, fetal ultrasound and pathological findings in two cases of triploidy diagnosed prenatally. The parental origin of the additional haploid chromosome set was determined based on a range of highly polymorphic microsatellite markers. In the first case, the fetal karyotype was 69,XXY and the histological investigation showed bilateral cystic renal dysplasia. There were external and internal fetal anomalies, and marked IUGR in the second case of triploidy (69,XXX). The parental origin of the triploidies was found to be maternal and both triploidies were screen positive for trisomy 18.

It has been published that digynic triploidy predominates in fetuses, and diandry accounts for about 50-60% of early triploid spontaneous abortions.

Screening for prenatal diagnosis of chromosomal abnormalities

C. M. Muresan[1], *B. M. Muresan*[2], *C. Gug*[1];

[1]*University of Medicine and Pharmacy V. Babes , Timisoara, Timisoara, Romania,* [2]*Fetal Medicine Centre, President Clinic, Timisoara, Romania.*

Introduction: Invasive procedures for prenatal diagnosis can be performed on different reasons: at demand of the patient, usually advanced maternal age; determined by the results of biochemical test; combined screening, which includes specialized ultrasonography (visualization of fetal anomalies or soft markers).

Objectives: The aim is to establish the qualitative analysis from the indications of invasive testing for prenatal diagnosis (detection rate of chromosomal abnormalities and the false positive rate - FPR).

Material and method: During ian.2010-dec.2011 we examined a number of 947 pregnant patients. We performed a number of 86 invasive procedures in order to determine fetal karyotype: 15 - advanced maternal age; 20 - biochemical risk + maternal age; 51 - ultrasound criteria + maternal age ± biochemistry.

The calculated risk was estimated by introduction of data in the software Astraia. The cut-off level for the 1st trimester screening was set at 1: 150 and for the 2nd trimester - at 1:250.

Results: Prenatal diagnosis revealed 10 chromosomal abnormalities (T21 - 4, T18 - 3, T13 - 2 and 1 case of triploidy). All this cases belong to the group with ultrasound exam. For the same rate of detection, the FPR is 8% for all invasive procedures. If we exclude the invasive diagnosis on demand, the FPR is 6.44% and if we analyze only the cases (51 pregnancies) with ultrasound screening - the FPR is 4.3%.

Conclusion: We observe that if we analyze pregnancies including ultrasound screening, the FPR drops almost to the half value (from 8% to 4.3%).

P05.70

Paternal uniparental diploidy mosaicism in a fetus with multiple abnormalities including findings of Beckwith-Wiedemann Syndrome

F. Stellmer[1], *K. Schoner*[2], *R. Bald*[3], *W. Schmitt*[4], *S. Kerber*[1], *B. Auber*[1], *K. Held*[1], *R. Achmann*[1];

[1]*MVZ genteQ GmbH, Hamburg, Germany,* [2]*Universitätsklinikum Giessen und Marburg, Marburg, Germany,* [3]*Klinikum Leverkusen, Leverkusen, Germany,* [4]*Zentrum für Reproduktionsmedizin, Medizinische Genetik, Pränataldiagnostik, Würzburg, Germany.*

We describe a fetus with multiple abnormalities in prenatal ultrasound, especially hydrops, hepatomegaly and a retroperitoneal tumour. After fetal karyotyping following amniocentesis showed a normal female karyotype, uniparental disomy was suspected and analysis of microsatellites for chromosomes 13, 18 and 21 was performed, comparing fetus and parents. Results were suspicious for a mosaic paternal uniparental diploidy with a normal biparental cell line. The rate of uniparental cells was about 80%. Uniparental diploidy was also found in fetal blood and after induced abortion in fetal tissue with variant frequencies. Autopsy revealed macroglossy, hemihypertrophy and viszeromegaly of liver, pancreas, adrenal glands, ovaries and skelettal musculature. Furthermore the fetus showed multiple tumours concerning heterotopic tissue of the adrenal glands, nodular nephroblastomatosis of the kidneys and haemangioma of the heart. All features resembling Beckwith-Wiedemann Syndrome. There are few reports on fetuses with mosaic uniparental diploidy. Analysis for genome-wide uniparental disomy should be considered in fetuses with an atypical phenotype.

Frequency of the DPYD * 2A allele in the Czech population

M. Koudová[1], *M. Bittóová*[1], *R. Vlčková*[1], *R. Alánová*[1,2], *I. Slepičková*[1], *E. Lavická*[1], *M. Hlaváčová*[1], *V. Indráková*[1], *M. Hrabíková*[1], *L. Pavlíčková*[1];
[1]GHC Genetics, ltd. - Private Medical Facility, Prague, Czech Republic, [2]Institute for the Care of Mother and Child, Prague, Czech Republic.

5-fluorouracil (5-FU) is used for chemotherapy of many tumors. Enzyme DPD (dihydropyrimidine dehydrogenase) has a key function for 5-FU metabolism and is encoded by *DPYD* gene. Mutant allele DPYD * 2A is caused by inherited mutation IVS14 +1 G> A *DPYD* gene and produce non-functional enzyme, so the 5-FU treatment leads to toxic reactions.

212 males and 210 females (age 18-69 years) of the Czech population were tested. DNA was isolated from oral mucosa or blood by using QIAmp DNA Minikit / DNA QuickGene 810. DPYD * 2 allele was tested by using certificated method strip assay (PGX-5FU) and by new created metod High-Resolution Melting. Were compared to results of both methods with each other and assessed allele frequency in the Czech population.

DPYD * 2A allele was demonstrated in a heterozygous state in 3/422 (0.7%), in the homozygous state was not found. Czech frequency of DPYP * 2A allele 0.36% is 2.5 times lower than the reported frequency 0.91% in the European population. The results of both methods were completely identical.

New cheaper method for detection DPYD * 2A was introduced and validated. Low frequency of DPYD * 2A allele in the Czech population assume the presence of other mutations in the *DPYD* gene and in other genes affecting the metabolism of 5-FU (eg . *TYMS, MTHFR*). Genetic test is recommended prior to cancer treatment by 5-FU, because are suitable the lower doses in the heterozygotes and choose other chemotherapy for the homozygotes with risk of toxic reaction.

P06.002

Concordant change of the 5-hydroxymethylcytosine status and mRNA expression at the LZTS1 loci in breast cancer

W. Liou, ***M. Wielscher***, *W. Pulverer*, *A. Weinhäusel*;
Austrian Institute of Technology, Vienna, Austria.

Analysis of 5-methylcytosine (5-mC) patterns in DNA for the identification of epigenetic dysregulation in cancer is well established whereas elucidation of the role of 5-hydroxymethylcytosine has yet to be unravelled. TET-proteins convert 5-mC, usually found in CpG context, to 5-hmC, which is assumed to be involved in gene expression regulation and might prove to be intriguing for cancer diagnostics. DNA samples from breast cancer tissue (n=6) and blood samples from healthy patients (n=6) were glucosylated with 5-hydroxymethylcytosineglucosyltransferase and digested with the restriction endonuclease MspI. As control reaction each sample was treated with MspI without prior glucosylation. Thus, the selective glycosylation of 5-hmC to glucosyl-5-hydroxymethylcytosine (glu-5-hmC) enabled us to distinguish between 5-hmC and methylated or unmodified cytosine. After digestion, the samples were analysed for 5-hmC in 325 loci by a targeted microarray. Through this approach the detection of one potential gene loci with a significant difference (P<0.05) was achieved. The marker LZTS1was validated with qPCR on breast cancer samples (n=32) and normal tissue (n=6), showing a higher level of 5-hmC in normal breast tissue. As next step the mRNA expression of LZTS1 was monitored in the validation set, which enabled us to detect a significant decrease of mRNA expression of the tumor suppressor gene LZTS1 in cancerous tissue. Our detection of 5-hmC DNA changes might contribute to understand possible functions of 5-hmC as an epigenetic regulator, because to our best knowledge we are the first that show a direct connection between 5-hmC alterations and a changed mRNA-expression on experimental basis.

P06.003

Analysis of FLT3 mutations in infant acute leukemia

F. Zaker[1], *M. Hashemi*[2], *M. Sheikhi*[3];
[1]Tehran Medical University,, Tehran, Islamic Republic of Iran, [2]Islamic Azad University,Tehran medical Branch, Tehran, Islamic Republic of Iran, [3]Islamic Azad University,Science and Research Branch, Tehran, Islamic Republic of Iran.

FLT3-gene mutations cause leukemic cells to proliferate uncontrollabely and leads to a poor prognosis.The aim of this study is to explore appropriate at diagnostic molecular tests and to screen mutations that occur in patients with acute leukemia.

91 infant Acute Myeloid Leukemia and Acute Lymphoid Leukemiaof patients investigate for FLT3- gene mutations in acute leukemia and ITD mutation (Internal Tandem Duplication) that codes juxamembrane region in FLT3 receptor and also the point mutation that is coded by exon 17 in that is FLT3 receptor kinase region .ITD mutation in FLT3 receptor was analyzed by PCR in 11,12 exons and 11 intron , using designed primers. For analysis of point mutation of Exon 17 in FLT3 receptor gene ,the genomic DNA of patient was amplified using the PCR. Resulted PCR products were studied by ECOR V enzyme and RFLP In cases of positive ITD, the Sequencing Method was applied.

ITD mutation was observed in 7 cases of 91 studied acute leukemia patients. Under investigation the sequence of PCR products in the mutation samples showed that different insertions of ‚s' are seen in JM region.

Also, 2 of 91 patients, studied had point mutation of in which their (D835) distributions in were not identical in FAB subtypes.Studying history of these patients, it was cleared that there was not significant relation between chromosome variations and induction of mutation and it can be decided about the treatment by molecular diagnosis of this mutaions independent of FAB classification and before the treatment get started.

B-cell activating factor: variability of selected exonic regions and association with acute lymphoblastic leukemia in paediatric patients

D. Kalina[1], *V. Nordheim*[1], *Z. Splichal*[1], *J. A. Bienertova Vasku*[1], *J. Tomandl*[2], *M. Jurajda*[1], *P. Bienert*[1], *Z. Krenova*[3], *J. Sterba*[3], *A. Vasku*[1];
[1]Department of Pathological Physiology, Faculty of Medicine, Masaryk University, Brno, Czech Republic, [2]Department of Biochemistry, Faculty of Medicine, Masaryk University, Brno, Czech Republic, [3]Department of Paediatric Oncology, University affiliated Hospital, Masaryk university, Brno, Czech Republic.

Introduction: There is emerging evidence that B-lineage neoplasms have aberrant expression of B-cell activating factor (BAFF, TNFSF13B) that enables the B cells to escape apoptosis. The aim of our study was to investigate circulating levels of BAFF in paediatric malignancies related to B-cell growth, i.e. B-cell acute lymphoblastic leukaemia (B-ALL) and B-lineage lymphomas.

Materials and methods: This cross-sectional study included the total of 18 children with B-lineage neoplasms (11 children with B-cell lymphoma, mean age at onset ± SD: 11.4 ± 4.8 y) and 7 children with B-cell precursor ALL, mean age at onset ± SD: 6.1 ± 6.1 y) whose serum levels of BAFF before the start of the treatment were examined using the ELISA-based methodology. Exons 1, 4 and 5 of BAFF gene were investigated using the direct sequencing in all patients.

Results: We observed significant differences in circulating levels of BAFF between the B-ALL patients and B-cell lymphoma patients (Bcp-ALL: 7764 ± 6329 pg/ml, B-cell lymphoma: 2675 ± 1544 pg/ml; p = 0.0268), the circulating levels of BAFF being substantially higher in B-ALL cases than in B-cell lymphoma cases. However, no genetic variability was observed in any of examined exonic regions of BAFF gene.

Discussion: This is the first study to report elevated BAFF levels in acute lymphoblastic leukemia in children. Although highly limited in number of cases, our study provides a potential basis for further evaluation of BAFF as a diagnostic and/or prognostic marker in B-ALL.

P06.005

SNP rs4132601 as a possible risk allele of acute lymphoblastic leukaemia development in children

M. Kreile[1,2], *L. Piekuse*[1], *B. Lace*[3], *Z. Kovalova*[2], *G. Medne*[2], *E. Cebura*[2], *M. Grutupa*[2], *A. Krumina*[3];
[1]Riga Stradins University, Riga, Latvia, [2]Children's Clinical University Hospital, Riga, Latvia, [3]Latvian Biomedical Research and Study Centre, Riga, Latvia.

Background. Acute lymphoblastic leukaemia (ALL) is the most common cancer among children, with an annual incidence rate of approximately 3.9 per 100 000 children. Recent case control genome wide association studies confirmed single nucleotide polymorphism (SNP) rs4132601T>G of *IKZF1* gene, which is located on chromosome 7, to increase significantly risk of developing childhood ALL. There are no available data about rs4132601. G allele is a risk allele from familial studies evaluating allelic transmission distortion.

Aim. To confirm role of *IKZF1* gene rs4132601G allele in relationship to childhood ALL development.

Material and methods. Eighteen pre-B ALL patient' case-parent trios were recruited at Children's Clinical University Hospital. The presence of polymorphism was analyzed using PCR with subsequent restriction enzyme *MboI* digestion and visualized in polyacrylamide gel. Transmission distortion test was performed as implemented in PLINK 1.07.

Results. SNP rs4132601 G allele frequency in patients was 0,472. Four out of

18 patients were homozygous for the risk allele. There was not found significant association between analyzed SNP in ALL familial studies (p=0.449, OR=0.75, CI95% 0.35-1.58).
Conclusions. In present study, we could not confirm any significant evidence about rs4132601 G allele as a risk allele. However HapMap project in European samples observed allele frequency was 0.301, thus justifying further studies in a larger sample of ALL patients' parents' trios.

P06.006
Detection of DNMT3A Mutation in Iranian patients with acute myeloid leukemia

L. Kokabee[1], *A. Ahmadzadeh*[2], *M. Kokabee*[2], *M. Karimipoor*[1];
[1]*Pasteur Institute of Iran, Tehran, Islamic Republic of Iran,* [2]*Shariati Hospital, Tehran, Islamic Republic of Iran.*

Acute myeloid leukemia (AML) is a disease with marked heterogeneity in both response to therapy and survival. The advent of molecular diagnostics has heralded an explosion in new prognostic factors, including mutations in DNMT3A gene that encodes DNA methyltransferase.
In this study, mutation in exon 20 of DNMT3A gene of 25 untreated cytogenetic normal AML patients (The mean age of patients was 39 year) were analyzed. For this purpose, genomic DNA was extracted from peripheral blood (referred to Shariati hospital, Tehran, Iran) by standard methods. PCR amplification and DNA Sequencing was performed for exon 20 of the DNMT3A gene.
DNA sequencing at two patients showed 2 different missense mutations in exon 20 of DNMT3A gene. These missense mutations were predicted to affect amino acid R882 (Polyphen 2). A patient had the R882H (CGC to CAC) variant and another one had R882P (CGC to CCC). These two patients had a normal cytogenetic profile and their white-cell counts were significantly higher than other patients.
In any case, DNMT3A mutations are associated with poor overall survival, suggesting that they have an important common effect on the potential of AML cells to cause lethal disease. Recent study showed that older AML patients with R882-DNMT3A mutation has shorter disease free survival (DFS), while in younger patients (<60 years) non R882-DNMT3A mutation have shorter DFS.

P06.007
The simultaneous usage of BAC based high throughput FISH analysis and the Real-Time PCR technology at the diagnosis of the adult myeloid leukemia cases

D. Yavuz, *N. Uzulmez, D. Sunnetci, N. Cine, H. Savli;*
Medical Genetics Department, Medicine Faculty of Kocaeli University, Kocaeli, Turkey.

Introduction**:** Leukemia occurs as a result of limitless and uncontrollable production of the blood cells. Among Myeloid Leukemias, CML and AML take place. In our study, Real-Time PCR and BAC Based High Throughput FISH Analysis methods are utilized simultaneously at the diagnosis of the adult myeloid leukemia cases and it is aimed to determine the aberrations that occur in the genome level.
Materials and Methods: Without a gender consideration, peripheral blood samples taken from 47 AML or CML diagnosed individuals between ages 18-80 are examined with the Real-Time PCR method in the RNA level and with the BAC Based High Throughput FISH Analysis method in the DNA level and scanned to see where most of the genetic damages take place.
Results: As a result of the Real-Time PCR studies; translocation in 10 patients (21,3%) and as a result of the FISH Analysis; aberrations with several sizes in various of the genome in 13 patients (27,7%) were encountered. In 27 patients (54,4%) no existence of genetic damages were seen with either methods. The most frequent aberration is the trisomy 8 and loss of Y chromosome which was stated in 3 (6,4%) AML cases.
Conclusion: The simultaneous usage of these two methods for the diagnosis of the leukemia cases provides a new approach to hematology in terms of supporting the diagnosis and determine the prognosis.

P06.008
Pharmacogenetic study in Argentinean children with Acute lymphoblastic Leukemia (ALL)

H. V. Aráoz[1], *M. E. Foncuberta*[1], *K. D´Aloi*[2], *C. Alonso*[2], *M. S. Felice*[2], ***L. P. Chertkoff***[1];
[1]*Hospital de Pediatría „Prof. Dr. Juan P. Garrahan". Servicio de Genética, Buenos Aires, Argentina,* [2]*Hospital de Pediatría „Prof Dr. Juan P Garrahan". Servicio de Hemato-oncología, Buenos Aires, Argentina.*

The aim of this study was to evaluate the influence of the most common genetic variants in the genes methylenetetrahydrofolate reductase (MTHFR), thiopurine methyltransferase (TPMT), and glutathione-S-transferases P1, T1 and M1 (GSTP1, GSTT1, GSTM1) on the outcome of ALL treatment.
Patients and Methods
Samples from 310 ALL patients treated with 2 consecutive BFM-based protocols were analyzed. Genetic variants in TPMT, MTHFR, GSTP1, GSTM1 y GSTT1 were identified by PCR-RFLP or allele-specific PCR. Toxicity was evaluated in 165 patients during consolidation phase according to WHO criteria. Children received 2 or 5 g/m^2/day of methotrexate (MTX) according to risk group, inmunophenotype and protocol, together with 25 mg/m^2/day of 6-Mercaptopurine. Patients allocated in High Risk Group also received the so-called High-risk blocks. The association between toxicity and genotypes was assessed by Fisher-exact Test. The pEFS was estimated by Kaplan-Meier and differences were assessed by log-rank test.
Results
Children who received 2 g/m^2/day of MTX and carried at least one 677T allele variant in MTHFR showed an increased risk of developing severe leukopenia (p=0.004) and neutropenia (p=0.003) during the consolidation phase. MTHFR polymorphisms did not seem to modulate MTX toxicity at 5g/m^2/day. None of the variants evaluated influenced treatment efficacy significantly. Nevertheless, in the intermediate group risk the pEFS for patients with heterozygous genotype for TPMT was higher than that for the wild type group (87% vs. 71%).
Conclusions
Further studies would be necessary to validate these results in order to better define MTX and 6-Mercaptopurine doses in ALL treatment.

P06.009
Anti-mutagenic and Pro-apoptotic Effects of Apigenin on Human Chronic Lymphocytic Leukemia

M. Nouri Long, *M. Hashemi, M. Entezari;*
Islamic Azad University,Tehran Medical Branch, Tehran, Islamic Republic of Iran.

Diet can play a vital role in cancer prevention. Nowadays the scientists are looking for food materials which can potentially prevent the cancer occurrence. The purpose of this research is to examine antimutagenic and apoptotic effects of apigenin in human lymphoma cells. In present study human chronic lymphocytic leukemia (Eheb cell line) were cultured in RPMI 1640 (Sigma), supplemented with 10% fetal calf serum, penicillin-streptomycin, L-glutamine and incubated at 37 ºC for 2 days. In addition cancer cell line was treated by and apigenin and cellular vital capacity was determined by MTT assay.
Then effect of apigenin in human lymphoma B cells was examined by flow cytometry techniques. The apigenin was subsequently evaluated in terms of anti-mutagenic properties by a standard reverse mutation assay (Ames test).This was performed with histidine auxotroph strain of Salmonella typhimurium (TA100). Thus, it requires histidine from a foreign supply to ensure its growth. The aforementioned strain gives rise to reverted colonies when expose to sodium azide as a carcinogen substance. During MTT assay, human chronic lymphocytic leukemia revealed to have a meaningful cell death when compared with controls (P<0.01) Apoptosis was induced suitably after 48 hours by flow cytometry assay. In Ames test apigenin prevented the reverted mutations and the hindrance percent of apigenin was 98.17%.These results have revealed apigenin induced apoptosis in human lymphoma B cells in vitro.

The APC gene polymorphisms and implication in colorectal cancer susceptibility

M. L. TOMA[1], *M. Stavarachi*[1], *P. Apostol*[1], *S. Spandole*[1], *T. Burcos*[2], *L. Belusica*[3], *I. Radu*[1], *D. Cimponeriu*[1];
[1]*Department of genetics Bucharest, Bucharest, Romania,* [2]*Coltea Hospital, Bucharest, Romania,* [3]*"Prof. Dr. Dimitrie Gerota" Hospital, Bucharest, Romania.*

Colorectal cancer (CRC) is a complex genetic disease, which results from interactions between multiple genes and environmental factors without any single factor having strong independent effects. The goal of the analysis was to determine if exist an associations between four polymorphism of APC gene (rs41116, rs465899, rs2229992 and rs2019720) and colorectal cancer patients. Blood samples were obtained, after informed consent, from individuals with CRC (M:F=95:85) and healthy persons (M:F=27:33). Genomic DNA was extracted from peripheral blood leucocytes using commercial kits and the APC gene polymorphisms were assessed by PCR-RFLP. Among the analyzed polymorphisms, we observed significant differences between patients and control group for polymorphism rs2019720 in terms of the distribution of genotypes and alleles. For this polymorphism from the promoter region of the APC gene we obtained an association with disease. Thus, the CC genotype (OR 2.307) and allele C (OR 1.843) are associated with increased risk, while the AA genotype (OR 0.453) and allele (OR 0.543) are associated with decreased risk for CRC. In this study, APC polymorphism rs2019720 may contribute to CRC susceptibility in Romanian patients. Thus, this potential link must be evaluated between in much powerful studies. This study was supported by Grant CNCSIS TD 224/2008.

A novel pathogenic germline mutation in the adenomatous polyposis coli gene in a tunisian family with FAP

I. M. Abdennadher[1], *R. A. Dammak*[1], *A. Amouri*[2], *L. Ayadi*[3], *S. Ellouze*[3], *R. Gargouri*[1];
[1]*Centre de biotechnologie de Sfax, Sfax, Tunisia,* [2]*Hopital Hédi chaker, Sfax, Tunisia,* [3]*Hopital Habib Bourguiba, Sfax, Tunisia.*

Familial adenomatous polyposis (FAP) is an autosomal dominant disorder which typically presents with colorectal cancer in early adult life, secondary to extensive adenomatous polyps of the colon. In addition to the colonic manifestations, the syndrome presents several extracolonic features including, congenital hypertrophy of the retinal pigment, osteoma and desmoid tumors. In this study, we aimed to investigate the clinical and genetic features in a Tunisian family with FAP. Sequence of the APC gene (Adenomatous Polyposis Coli) revealed a novel mutation (c.2016-2017 del TA) in exon 15,present in all affected individuals in an heterozygous state. The frameshift mutation generates a premature stop codon at amino acid 677 of the APC protein (p. H672Qfs X5). The unaffected family members did not harbor this mutation, however, a first degree relative of the patient aged of 32 year-old was phenotypically normal but carries the c.2016-2017 del TA mutation. This discrepancy can be explained by the effect of modifier gene which can affect the expressivity of the disease. Moreover an other first degree relative who is the patient's daughter, aged 8 year-old carries the mutation in an heterozygous state and should benefit of a colonoscopical follow-up knowing the phenotypic variability in her family.

Background and Aim: Gastroesophageal Reflux disease is a risk factor for esophageal adenocarcinoma but the studies that investigate the relationship between erosive esophagitis and esophageal adenocarcinoma usually focus on symptom-related evidence or on polymorphism but there are not any epigenetic gene expression studies on this topic. In this study we aimed to evaluate the relationship of erosive esophagitis and esophageal adenocarcinomas if there is a genetic tendency for EAC.

Methods:*The Human Epigenetic Chromatin Modification Enzymes RT2 Profiler*^{TM} *PCR Array* was used to detect the expression of 84 key genes encoding enzymes. It was used in 60 patients prospectively (20 patients with control group, 20 patients with erosive esophagitis and 20 patients with esophageal adenocarcinoma).

Results: AURKA, AURKB, NEK6 were expressed at significantly higher levels in the esophageal adenocarcinoma than the control group. MBD2, were expressed significantly lower in esophageal adenocarcinoma than the control group. AURKA, AURKC, HDAC9, NEK6, were expressed at significantly higher levels in erosive esophagitis than control group. There was no upregulated gene difference between erosive esophagitis and esophageal adenocarcinoma. MBD2 was significantly downregulated in esophageal adenocarcinoma than erosive esophagitis. The NEK6 and AURKA were significantly upregulated genes in esophageal adenocarcinomas and erosive esophagitis than control groups.

Conclusion: This is the first and pioneering study about the genetic tendency of erosive esophagitis and esophageal adenocarcinoma. AURKA and NEK6 are two promising genetic markers for erosive esophagitis and esophageal adenocarcinoma.

ASCL1 activation as a consequence of a t(12;14)(q23.2;q32) in B-cell chronic lymphocytic leukemia

T. Malli[1], *H. Bösmüller*[2], *R. Marschon*[1], *W. Kranewitter*[1], *M. Erdel*[1], *S. Deutschbauer*[1], *M. Rammer*[1], *H. Rumpold*[3], *G. Webersinke*[1];
[1]*Laboratory for Molecular Biology and Tumorcytogenetics, Department of Internal Medicine, Hospital Barmherzige Schwestern, Linz, Austria,* [2]*Department of Pathology, Hospital Barmherzige Schwestern, Linz, Austria,* [3]*Department of Internal Medicine I, Hospital Barmherzige Schwestern, Linz, Austria.*

B-cell chronic lymphocytic leukemia (B-CLL) is frequently accompanied by characteristic cytogenetic abnormalities. Nevertheless, the molecular mechanisms underlying the disease remain largely unknown.

We investigated a translocation between chromosomes 12 and 14 in a patient with B-CLL. FISH confirmed the involvement of the immunoglobulin heavy chain (IgH) locus on chromosome 14 in the translocation. The breakpoint region on derivative chromosome 12 was amplified using long distance inverse PCR and sequenced. Chromosome 12 was disrupted in the region between the *C12orf42* and *ASCL1* (Achaete-scute complex homolog 1) genes. The breakpoint on chromosome 14 was located in the switch region upstream of the IgH Cμ sequence. As a consequence of the rearrangement the *ASCL1* gene was brought into proximity of the enhancer downstream of the IgH joining region and was highly expressed in the bone marrow of the patient in comparison to normal bone marrow and that of other B-CLL patients.

ASCL1 codes for a basic helix-loop-helix transcription factor involved in neural development. The gene is overexpressed in neuroendocrine cancers like small cell lung cancer and medullary thyroid cancer. *ASCL1* plays a role in cell proliferation and differentiation and interacts directly or through its targets with members of the NOTCH, the WNT and the SHH pathways.

Though *ASCL1* activation in B-CLL seems to be a rare event, deregulation of some of its downstream targets or interaction partners, due to different molecular mechanisms, could play a role in the genesis of B-CLL.

Gene expression profiling of B-CLL in Ukrainian patients exposed to low doses of ionizing radiation in post-Chernobyl period

H. Savli[1], *D. Sunnetci*[1], *N. Cine*[1], *D. Gluzman*[2], *M. Zavelevich*[2], *L. Sklyarenko*[2], *V. Nadgornaya*[2], *S. Koval*[2];
[1]*Medical Genetics Department, Medicine Faculty of Kocaeli University, KOCAELİ, Turkey,* [2]*RE Kavetsky Institute of Experimental Pathology Oncology and Radiobiology, Kyiv, Ukraine.*

Introduction: After Chernobyl accident, B-cell Chronic Lymphocytic Leukemia (B-CLL) became a predominant form of hematopoietic malignanices in clean-up workers. We have analyzed gene expression patterns in B-CLL patients exposed to low doses of ionizing radiation in post-Chernobyl period with the aims to identify genes associated with disease progression in order to shed light on the biology of progression.

Materials and methods: The samples of the peripheral blood and bone marrow of 44 Ukrainian B-CLL patients were analyzed morphologically and immunocytochemically according to new WHO classification. Total RNA was isolated, gene expression levels were determined by microarray method comparing with 17 healthy donors.

Results: We investigated interactions using the Ingenuity Pathway Analysis (IPA) software and found 1191 network eligible up-regulated genes and 3398 Functions/Pathways eligible up-regulated genes, 1225 network eligible down-regulated genes and 2657 Functions/Pathways eligible down-regulated genes. Gene networks identified around MYC, HNF1A, and HNF4A, YWHAG, NF-κB1 and SP1 as up-regulated; CEBPA, YWHAG, SATB1 and RB1 as down-regulated. G protein coupled receptor signaling, Arachidonic Acid and Linoleic Acid metabolsims, calcium signaling, metabolsim of Xenobiotics by cytochrome P450 are significant up-regulated pathways. Eif2 and Cdc42 signaling, regulation of eIF4 and p70S6k signaling, protein ubiquitination pathway and oxidative phosphorylation are the most significant down-regulated pathways obtained in our study.

Conclusion: Our study represents one of the rare genomic studies concerning relationship between ionizing radiation and B-CLL. NF-κB gene network was conspicuous in terms of being determined also in our previous studies about the gene expression on prostate cancer and acute myeloid leukemia.

Frequencies of BCR-ABL1 fusion transcripts among Iranian patients with leukemia

M. Hamid[1], *M. Akbari*[2];
[1]*Molecular Medicine Division, Biotechnology Research Center, Pasteur Institute of Iran, Tehran, Islamic Republic of Iran,* [2]*Department of Medical Genetics, Faculty of Medical Sciences, Tarbiat Modares University, Tehran, Islamic Republic of Iran.*

In this study, we report the frequencies of BCR-ABL fusion transcript variants studied in leukemia patients from Iran. The leukemia patients including 348 chronic myloid leukemia (CML), 72 acute lymphoblastic leukemia (ALL), 34 acute myeloid leukemia (AML), 25 myelodysplastic syndromes (MDS), and 7 chronic lymphoid leukemia (CLL) were enrolled in this study. Peripheral blood samples were analyzed by multiplex RT-PCR from 486 leukemia patients to detect different types of BCR-ABL transcripts.The BCR-ABL transcript frequencies for CML, ALL, AML, CLL and MDS patients were 92.0% , 12.5%, 26.4%, 14.2% and 4% respectively for all transcripts. The majority of CML patients with positive BCR-ABL expressed one of the p210BCR-ABL transcripts (86.6%) while the remaining showed other transcripts (p190BCR-ABL 25 (7.8%)) and p230BCR-ABL 2 (0.6%)). The rate of co-expression of the p190/p210 transcripts were 16(5%). In other types of leukemia patients the rates of expression of those transcripts were different. we didn‘t observe a significant correlation between BCR-ABL1 variants, sex type, age and WBC count of studied leukemia patients.

AHR, AHRR, ARNT gene polymorphisms role in bladder cancer development

L. Akhmadishina[1]*, M. Urmantsev*[2]*, A. Izmailov*[2]*, S. Izmailova*[2]*, G. Korytina*[1]*, O. Kochetova*[1]*, V. Pavlov*[2]*, T. Viktorova*[1,2]*;*
[1]*Institute of Biochemistry and Genetics, Ufa Scientific Center, Ufa, Russian Federation,* [2]*Bashkir State Medical University, Ufa, Russian Federation.*

To assess c.1661 G>A AHR, c.565C>G AHRR, c.522G>C ARNT gene polymorphisms contribution in the development and severity of bladder cancer we carried out a study 220 DNA bladder cancer patients samples and 216 healthy individuals DNA samples. No association with disease was observed for AHR polymorphism. It has been established that with increasing c.565C>G AHRR G allele dose, increased its protective effect (additive model, OR=0.61, [p=0.02). It has been shown ARNT GC genotype is a resistance factor to disease development (OR=0.56, 95%CI (0.38-0.85), p=0.005). Thus we can assume AHRR and ARNT polymorphisms make a definite contribution to the development and severity of bladder cancer However, the results should be confirmed in replication.

P06.018

Expression profile of bladder cancer cell lines after treatment with potential new drug- Helix lucorum hemocyanin (HlH)

O. S. Boyanova[1]*, P. Dolashka*[2]*, L. Velkova*[2]*, B. Rukova*[1]*, I. Dimova*[1]*, S. Hadjidekova*[1]*, D. Toncheva*[1]*;*
[1]*Department of Medical Genetics, Medical University- Sofia, Sofia, Bulgaria,* [2]*Institute of Organic Chemistry with Centre of Phitochemistry, BAS, Sofia, Bulgaria.*

Urinary bladder cancer is socially significant healthcare problem- negative environmental factor, infections and aging of the world population are responsible for its growing incidence. This requires elaboration of new drug development. Such a potential new drug is Helix lucorum haemocyanin (HlH) - a highly immunogenic glycoprotein with xenogenic nature and a lot of mannose residues.

The anti-tumor effect of HlH was investigated on CAL-29 and T-24 bladder tumor cell line and results suggest 35%-50% inhibition of cancer cell viability in a dose 500ug/ml of HlH after 72h of incubation.

Gene expression profiling of the tumor cells before and after HlH treatment using the panel for 84 genes for Human Inflammatory cytokines and receptors was performed.

Results presume more than 10 times upregulation of genes for inflammatory response activation, cell mediated immunity and proinflommatory cytokines: C4A, CCR4, CARD-18, IL36A, IL37, CXCR1, IL9, LTA, MIF and TNF in CAL-29 cell line treated with HlH (G1). In the same group more than 4 time overexpression of TOLLIP gene was achieved.

In T-24 cell line treated with HlH (G2): IFNA2, IL37, CXCR1, IL36B, IL5 and AIMP1 genes were significantly overexpressed. In the both group CXCR1 gene (for IL8 receptor) had the highest expression.

Gene for CXCL1 was notably downregulated compare to ABCF1, BCL6, IL1A, IL1B in both groups.

Our results suggest that HlH can perform both: growth inhibiting effect (on cell line level) and immune response activation (according gene expression profile) in bladder cancer.

Association of Gene Variants of IL-12 & IL-18 and Serum IL-18 with Bladder Cancer Risk in North Indian Cohort

P. K. Jaiswal*, V. Singh, P. Srivastava, R. Kapoor, R. D. Mittal;*
Sanjay Gandhi Postgradute Institute of Medical Sciences Lucknow India, Lucknow, India.

Background and Objective: Bladder cancer (BC) is multifactorial disorder and genetic changes may be a crucial etiologic factor. Interleukin-18 and Interleukin-12 plays an important role as immunomodulatory factors in cancer pathogenesis that augment IFN-γ secretion. To test this hypothesis, we investigated association of IL-18 gene promoter polymorphisms at *-137G/C*, *-607C/A* and *IL12(-16974)A/C* with the risk of BC in a North Indian cohort.

Material and Methods: Genetic polymorphisms were analyzed in 200 BC patients and 200 age, ethnicity and sex-matched controls, using Restriction Fragment Length Polymorphism and Amplification refractory mutation specific-polymerase chain reaction. The concentrations of IL-18 in serum were determined by ELISA.

Results: Significant association was observed with *IL18(-137)G/C* heterozygous genotype having 1.96 folds risk of BC as well as C allele carrier and variant allele having 2 fold and 1.6 fold risk for BC respectively. *IL18(-607) C/A*, CA genotype also showed a high risk (OR=1.59) for BC. While *IL12(-16974) A/C* heterozygote genotype and C allele carrier showed reduced risk for BC. Hetero genotype of *IL18(-137)G/C* was associated with risk of recurrence (HR= 2.35) in BC patients receiving BCG treatment showing least survival. Serum IL-18 levels were significantly higher in BC patients than in the healthy subjects (p=0.025).

Conclusion: Our results suggest functional IL-18 polymorphism contributes to the bladder cancer susceptibility. A relation between IL-18 gene polymorphism and serum content with cancer progression has been registered in present study. Further confirmation in large population based studies is needed.

Analysis of mitochondrial DNA and p53 gene mutations in bladder tumors

T. Avcilar[1]*, D. Kirac*[2]*, D. Ergec*[1]*, G. Koc*[1]*, K. Ulucan*[1]*, Z. Kaya Atabey*[3]*, E. C. Kaspar*[4]*, L. Turkeri*[5]*, A. I. Guney*[1]*;*
[1]*Marmara University, Faculty of Medicine, Department of Medical Genetics, Istanbul, Turkey,* [2]*Yeditepe University, Faculty of Medicine, Department of Medical Biology, Istanbul, Turkey,* [3]*Marmara University, Faculty of Medicine, Department of Medical Biology, Istanbul, Turkey,* [4]*Yeditepe University, Faculty of Medicine, Department of Biostatistics, Istanbul, Turkey,* [5]*Marmara University, Faculty of Medicine, Department of Urology, Istanbul, Turkey.*

Introduction: The effect of mitochondrial DNA (mtDNA) mutations and p53 gene mutations have been investigated separately in various tumors; however, both of these factors were not investigated in bladder tumors. Therefore, to understand the significance of mtDNA and p53 gene mutations in bladder cancer development, these mutations were investigated in bladder cancer patients.

Methods: Bladder cancer tissues were obtained by radical cystectomy or transurethral resection from 30 patients and 27 controls. After the isolation of DNA from peripheral blood, exon 5,6,7 and 8 of p53 gene as well as ATPase6, Cytb, ND1, and D310 regions of mtDNA were amplified by PCR. Mutations were detected with direct sequencing. Results were evaluated statistically.

Results: In patient group, 33 mtDNA gene mutations were found in which six of them are novel and 14 of them cause amino acid changes. Also G8697A, G14905A, C15452A and A15607G mutations were found statistically significant in patients when compared to controls. Additionally, in patient group three, p53 gene mutations were detected in which two of them are novel. In novel mutations, adenine insertion at 12570 was found statistically significant in patients when compared to controls (66%).

Conclusion: Especially high incidence of the novel mutation at position 12570 in p53 gene may be an important marker for the detection of bladder tumors. Therefore it should be investigated with further studies. Also high incidence of other mtDNA mutations and p53 gene mutations in patients suggests that mitochondria and p53 gene could play an important role in carcinogenesis.

P06.021

Distribution of mutations in breast/ovarian cancer susceptibility genes in the north-east of Spain.

M. Infante Sanz[1]*, E. M. Esteban Cardeñosa*[1]*, E. A. Velasco Sampedro*[1]*, E. Lastra Aras*[2]*, G. Marcos García*[3]*, L. Hernández Sanz*[1]*, N. Martínez Martín*[1]*, M. Durán Domínguez*[1]*, C. Miner Pino*[1]*;*
[1]*IBGM, Valladolid, Spain,* [2]*Servicio de Oncología, Complejo Hospitalario de Burgos, Burgos, Spain,* [3]*Servicio de Oncología, Hospital Río Hortega, Valladolid, Spain.*

Mutations in susceptibility breast/ovarian cancer (BOC) genes show different spectra according to geographic origin. To date, few *BRCA1* and *BRCA2* mutations are described as founder in Spanish population, intriguingly linked to geographic distribution. Other susceptibility genes that share key roles in Fanconi Anemia pathway are now being scanned for mutations.

A total of 1275 unrelated families have been tested for BRCA mutations in the IBGM. Samples and written informed consent of BOC cases and relatives were collected at the Genetic Counselling Units of East CyL. DNA was scrutinized for BRCA mutations by HA-CAE and subsequently sequence analysis of abnormal patterns. Additionally, MLPA was performed in high-risk patients with familial history of BOC without point mutations. Moreover, other genes as *PALB2* or *RAD51C* were tested in families with specific cancer features.

Seventy-four different deleterious DNA changes in BRCA genes have been identified in our laboratory in 186 unrelated families (69 BRCA1+ and 117 BRCA2+ families). Spanish founder mutations were predominant in our samples: 330A>G, 5242C>A and 5272-1G>A in *BRCA1* and 3036_3039delACAA, 5374_5377delTATG and 9254_9258delATCAT in *BRCA2*. Remarkably, 187_188delAG-*BRCA1* mutation was absent in our region. Five different large rearrangements in seven ovarian unrelated patients have been detected during MLPA analysis. No pathological mutations were identified in either *RAD51C* or *PALB2*.

Our target population shows a particular *BRCA1* and *BRCA2* mutation spectra where Spanish founder mutations are leading. Although mutations in other susceptibility BOC genes do not yield results so far, comprehensive studies with larger number of samples would be performed.

P06.022

Identification of mutations in patients with bone marrow failure syndromes associated with the development and progression of MDS and acute leukemia

D. Steinemann[1], *M. Stanulla*[2], *J. Skokowa*[3], *K. Welte*[3], *B. Schlegelberger*[1];
[1]*Institute of Cell and Molecular Pathology, Hannover, Germany,* [2]*Department of General Pediatrics, University Hospital Schleswig-Holstein, Kiel, Germany,* [3]*Institute of Molecular Haematopoesis, Hannover, Germany.*

Most bone marrow failure syndromes (bmfs) are associated with a marked propensity to transform into myelodysplastic syndrome (MDS) or acute leukemia, with a cumulative rate of transformation that may exceed 20% (e.g., in the case of severe congenital neutropenia). The genetic (and epigenetic) changes that contribute to malignant transformation in bmfs patients are largely unknown.

To elucidate the underlying molecular mechanisms of cancer susceptibility and progression in secondary MDS or acute leukemia in bmfs patients we conducted a comprehensive genome-wide characterization of genetic aberrations in the malignant cells at high-resolution level. We used high density DNA microarray (Agilent 400k/180 k) and direct sequencing of putative cancer genes to analyze a series of 30 CN patients at different time points during the progression into MDS and AML (50 samples in total). Large genomic alterations, namely monosomy 7/-7q, +21q or +3q were associated with leukemic progression. Beside common copy number variants like *UGT2B*, *GSTT1*, *HEATR4*, no microdeletions or microduplications were detected in the primary or secondary diseases. However, we found recurrent somatic missense and frameshift mutations in the transcription factor *RUNX1/AML1* in 10% of the patients.

Notably, *RUNX1/AML1* mutations have recently been described in Fanconi anemia during leukemic progression. *RUNX1/AML1* may have a more general role in the malignant transformation of patients with bone marrow failure syndromes like congenital neutropenia.

P06.023

Detection by HRM and COLD-PCR-HRM BRAF mutational status in paraffin blocks of melanoma patients

E. Esteban Cardeñosa[1], *M. Durán Domínguez*[1], *M. Infante Sanz*[1], *G. Martínez García*[2], *C. Miner Pino*[1];
[1]*Instituto Biología y Genética Molecular IBGM-CSIC-UVA), Valladolid, Spain,* [2]*Hospital Clínico Universitario, Valladolid, Spain.*

Over 50% of melanoma tumors have BRAF oncogene mutation. In 2011 we have obtained the first results of clinical trials of targeted therapy with molecules that act on BRAF signaling pathway (Ras / Raf / MEK / ERK). Vemurafenib and GSK2118436 showed an increase in overall survival and disease-free in p.V600E BRAF carriers patients. In the coming months, these molecules will be approved for clinical use in Europe.

The application of analytical methods of high sensitivity in determining the mutational status of BRAF will be crucial to the imminent clinical application of new drugs, as the results will select patients eligible for or untreated.

We have studied the 11 and 15 exons of BRAF by HRM-sequencing, and COLD-PCR-HRM-sequencing in 20 paraffin blocks of melanoma, previously studied by Sanger sequencing.

Mutation was detected p.V600E of exon 15 in 9 of them for HRM, and 11 by COLD-HRM, compared to 8 previously detected by sequencing.

The sensitivity of such methods as HRM and COLD-PCR-HRM is greater than sequencing. These results should be compared with those obtained by the proposed clinical diagnostic tests (eg cobas 4800 BRAF V600 Mutation Test Roche©).

Our previous results show the necessary standardization of the methods of detection of somatic mutations, especially in cases where the determined result to apply the therapy to the patient.

P06.024

Comprehensive BRCA1 and BRCA2 mutational profile in Lithuania

R. Janavicius[1], *V. Rudaitis*[2], *L. Griskevicius*[3];
[1]*Vilnius university hospital Santariskiu clinics, Hematology, oncology and transfusion medicine center, Vilnius, Lithuania, Vilnius, Lithuania,* [2]*Vilnius university hostpital Santariskiu Clinics Centre of Women Health and Disease, Vilnius, Lithuania,* [3]*Vilnius university hospital Santariskiu clinics, Hematology, oncology and transfusion medicine center, Vilnius, Lithuania.*

The germline mutations in BRCA1/2 genes are the most significant and well characterized genetic risk factors for breast and/or ovarian cancer. Detection of mutations in these genes is an effective method of cancer prevention and early detection. Different ethnic and geographical regions may have different BRCA1 and BRCA2 mutation spectrum and prevalence due to founder effect. The population of Lithuania has over several centuries undergone limited mixing with surrounding populations and is mostly of indigenous Baltic origin, which is different from Slavs. The aim of our study was to asses full BRCA1/2 mutational profile in Lithuanian population.

We performed comprehensive mutation analysis of BRCA1/2 genes in 567 unrelated breast and/or ovarian cancer patients (with/without family history) and predictive unaffected patients using high resolution melting (HRM) screening followed by direct sequencing and MLPA for large genomic rearrangements (LGRs). RESULTS. Overall, we have identified 23 different mutations (14 in BRCA1 and 9 in BRCA2 genes). Seven frequent pathogenic mutations in BRCA1 gene comprised 51%, 27%, 9%, 3%, 2%, 1,5% and 1,5% respectively of all BRCA1 mutations; a single BRCA2 mutation (c.658delGT) comprised 42% of all mutations in this gene. Four novel BRCA1 and 4 novel BRCA2 genes mutations; 2 different LGRs were found in BRCA1. The most common c.4035delA (47% of all BRCA1/2 mutations) appears to be true Lithuanian (Baltic) founder mutation. Characterization of BRCA1/2 mutational profile in Lithuania enabled to develop screening protocol using HRM for 7 common BRCA1/2 point mutations, which comprise 89% of all mutations detected in our country.

Analysis of breast cancer predisposition genes by direct sequencing and multiplex ligation-dependent probe amplification technique

f. keshavarzi;
sanandaj branch, Islamic Azad University , Iran andGenetics Laboratory of Dr.Zeinali, Kawsar Human Genetics, sanandaj, Islamic Republic of Iran.

Objective: In hereditary breast and ovarian cancer (HBOC) families, a large percentage of cases are attributable to hereditary factors compatibles with autosomal transmission of a major tumor suppressor gene with incomplete penetrance. Screening for BRCA1 mutations is now standard practice for HBOC cases in world, and permits medical follow-up. Estimates in different countries range from 5 to 15% the BRCA1 related cases of hereditary breast cancer due to copy number changes of one or more exons of this gene. Exon deletions and amplifications will usually not be detected by sequence analysis of the complete BRCA1 gene, therefore MLPA screening is needed.

Materials and methods: Hundred probands were fully screened for small mutations, and cases for which no causative abnormality were found (n=34) were screened by MLPA.

Results: A total of 5 pathogenic rearrangements in the BRCA1/2 gene were found, accounting for 7% of all mutations and the families with the disease-causing mutations were 16 percent of all families to review allocated. In addition, more than 80 percent of reassortments are related to the BRCA1 gene and less than 20 percent due to mutations in the BRCA2 gene.

Conclusion: These data demonstrate that dosage analysis is an essential component of genetic screening for cancer predisposition genes.

BRCA,MLPA, HBOC

BRCA diagnostics on formalin-fixed, paraffin-embedded (FFPE) tissue

A. Gehrig, *C. R. Müller*;
Department of Human Genetics, Würzburg, Germany.

Introduction:

In about 25% cases, hereditary breast and ovarian cancer (HBOC) is caused by a mutation in the *BRCA1* or *BRCA2* gene. Therefore, analysis of carrier status in a family should begin with an individual that has been diagnosed with HBOC to maximize the chances of identifying the familial mutation. In many HBOC families, all affected individuals are deceased and the only material available for genetic analysis is archived pathological specimens. Sanger sequencing of DNA extracted from FFPE tissue is time-consuming and expensive due to the comparatively small amounts and high degree of DNA fragmentation.

Methods:

Genomic DNA from tumor-free and tumor FFPE tissues from different individuals was isolated using the QIAamp DNA FFPE Tissue Kit (Qiagen) according to the manufacturer´s instructions. All coding regions of *BRCA1* and *BRCA2* were amplified with the multiplex PCR Kit BRCA-MASTR v2.1 (Multiplicom). Next generation sequencing was performed using the 454 sequencing kit on a GS Junior (Roche). Data were analysed by NEXTGENe software (Softgenetics).

Results:

In all samples, data analysis showed an even coverage over both genes of at least 15-fold. In the tumor-free sample, no pathogenic mutation was detected. Analysis of the tumor sample revealed a "homozygous" variation in *BRCA2* that could be verified as heterozygous germline variation in DNA isolated from the individual's lymphocytes.

Conclusions:

NGS is a powerful tool for the determination of germline variations in fragmented DNA from FFPE tissue.

Meiotic drive at the BRCAs loci in Spanish families with breast/ovarian hereditary cancer.

A. Lasa[1], *J. Salazar*[1], *T. Ramón y Cajal*[2], *L. González*[1], *L. Alías*[1], *M. Cornet*[1], *A. Iturbe*[1], *M. Baiget*[1];

[1]Genetics Department,CIBERER U-705. Hospital Sant Pau, Barcelona, Spain, [2]Oncology Departement. Hospital Sant Pau, Barcelona, Spain.

Objective: To analyse the sex and *BRCA* segregation ratios in families with breast and/or ovarian cancer in whom pathogenic mutations were identified.

Methods: From the breast and/or ovarian cancer families referred to our hospital, we selected couples that were proven carriers of a *BRCA* mutation. We compared the sex and *BRCA* allele transmission ratios from 305 descendents assuming an equal (1:1) distribution.

Results: We found a 2.2 fold excess of female births (101 females *vs* 49 males for *BRCA1* and 110 females vs 45 males for *BRCA2*) in our pedigrees. We observed that the mutated *BRCA1* allele segregated more often than the wild type allele (ratio 3:1) in the female offspring and that the number of carriers was higher than expected (74% carriers *vs* 24% non-carriers). Interestingly, in the male offspring the wild type *BRCA1* allele segregated more often than the mutated allele (37% carriers *vs* 63% non-carriers). For the *BRCA2* gene, the mutated allele segregated more often than the wild type allele in the female offspring (carriers 68% vs non-carriers 32%) whereas in the male offspring we did not observe TRD.

Conclusions: The results observed in the female offspring of BRCA1/2 carriers suggest a clear tendency to transmit the mutated allele (ratio 3:1). The finding of a high proportion of female carriers may have important implications for the genetic counselling of these families. Prezygote events, meiotic drive, survival of gametes or preferential fertilisation are possible explanations for the observed TRD.

Genomic capture and massively parallel sequencing identifies accurately inherited mutations in several genes in BRCA1 & 2 negative families with strong breast/ovarian cancer history

F. Fostira[1], *T. Walsh*[2], *A. Stavropoulou*[1], *M. Tsitlaidou*[1], *S. Casadei*[1], *S. Glentis*[1], *G. Fountzilas*[3], *I. Konstantopoulou*[1], *M. King*[2], *D. Yannoukakos*[1];

[1]NSCR Demokritos, Athens, Greece, Greece, [2]University of Washington, Seattle, WA, United States, [3]Aristotle University of Thessaloniki, Thessaloniki, Greece, Greece.

Inherited germline mutations in known and yet to be discovered genes predispose for breast and/or ovarian cancer. Mutations within BRCA1 and BRCA2 are the most common, but within the last years more than twenty different genes have been linked to breast and/or ovarian cancer susceptibility. Using BROCA to capture and sequence 21 known breast cancer genes in one test, we screened genomic DNA from 42 Greek patients with breast cancer diagnosed before the age of 40 and with a family history of breast or ovarian cancer. Patients had been previously screened for BRCA1 and BRCA2 by Sanger sequencing. Truncating mutations or missenses previously established as damaging were identified in 8 patients, in BRCA1, BRCA2, CHEK2, PALB2, and MSH2. All mutations were different. All were confirmed by Sanger sequencing with diagnostic primers from patients' genomic DNA. Of the 8 mutations, 3 were genomic deletions detected by read depth from BROCA data. In addition to the 8 patients with confirmed damaging mutations, 5 other patients harbored mutations at splice sites, in ATM, BRCA2, and RAD51C. These splice variants have been confirmed in genomic DNA; their effects on transcripts are being evaluated. We conclude that among Greek patients with familial breast cancer, the mutational spectrum is highly heterogeneous with respect to both loci and alleles. These patients are well served by an approach that detects all classes of mutations in all known breast cancer genes.

P06.029

BRCA1 mutation screening in brazilian hereditary breast cancer and ovary syndrome using High Resolution Melting

N. M. Cury[1,2], *V. E. F. Ferraz*[1], *M. R. Luizon*[1], *C. A. Ferreira*[2], *A. A. Marques*[2], *W. A. Silva Jr*[1,2];

[1]Medical School of Ribeirão Preto, University of São Paulo, Brazil, Ribeirão Preto, Brazil, [2]National Institute of Science and Technology in Stem Cell and Cell Therapy (INCTC), Regional Blood Center of Ribeirão Preto, Ribeirão Preto, Brazil.

About 10% of cases of breast and/or ovary cancer are characterized as hereditary, where the presence of germline mutations in BRCA1 gene increases the risk of developing these cancers during woman's lifetime. The present study aims to characterize BRCA1 gene mutations associated with Hereditary Breast/Ovary Cancer Syndrome (HBOC). The twenty two coding exons of BRCA1 were analyzed using High Resolution Melting method, followed by DNA sequencing. MLPA technique was also used to detect gross deletions. We investigated 41 patients from the Cancer Genetic Counseling Service of the HCFMRP-USP that fulfilled the criteria for genetic testing according to NCCN Clinical Practice Guidelines in Oncology v.1.2010. A total of 21 mutations were identified, two of which are pathogenic: deletion of exons 17-18 and deletion of exon 19. Both of them are located in the BRCT domain of BRCA1 gene, impairing the binding of essential phosphoproteins critical for the activation of DNA repair complex. Because four missense mutations (Pro871Leu, Glu1038Gly, Lis1183Arg, Ser1613Gly) occurred simultaneously in half of patients, we analyzed the presence of the possible haplotypes also in 82 healthy controls and verified that the haplotype Leu-Gly-Arg-Gly, composed of all the mutated residues, showed significant difference ($p < 0.05$) between the groups suggesting a possible association with increased risk for HBOC. This study suggests that haplotypes consisting of non-synonymous mutations can confer increased risk for HBOC due to the cumulative effect of these mutations on the BRCA1 protein structure. Financial Support: Capes, FUNDHERP, INCTC/CNPq.

Germline BRCA1 and BRCA2 mutations in Croatian families with breast/ovarian cancer predisposition: Identification of three novel mutations

V. Musani[1], *M. Levačić Cvok*[2], *I. Sušac*[3], *M. Sabol*[1], *P. Ozretić*[1], *D. Car*[1], *D. Eljuga*[4], *S. Levanat*[1];

[1]Rudjer Boskovic Institute, Zagreb, Croatia, [2]Rudjer Medikol Diagnostics ltd, Zagreb, Croatia, [3]Eljuga Polyclinic, Zagreb, Croatia, [4]Clinic of Gynecology and Obstetrics, University Hospital Center, Zagreb, Croatia.

Breast cancer is the most common cancer in women after non-melanoma skin cancer, and it is the leading cause of cancer deaths in Croatia. Ovarian cancer is in the fifth place, both in incidence and mortality. About 5-10% of all breast and/or ovarian cancer cases are hereditary, and germline mutations in BRCA1 and BRCA2 account for the majority of hereditary breast and ovarian cancers. The contribution of BRCA1 and BRCA2 mutations to hereditary breast and ovarian cancer in Croatia is unknown. The purpose of this study was to estimate the incidence and spectrum of pathogenic mutations in BRCA1/2 genes in high risk women in Croatia. BRCA1/2 genes from 167 candidates (145 families) were scanned for mutations using High-resolution melting analysis (HRMA), direct sequencing and Quantitative multiplex PCR of short fluorescent fragments (QMPSF). We identified 14 pathogenic point mutations in 17 candidates, 9 in BRCA1 and 5 in BRCA2. Of those, 11 have been previously described and three were novel (c.5335C>T in BRCA1, and c.4139_4140dupTT and c.8175G>A in BRCA2). No large deletions or duplications involving BRCA1 and BRCA2 genes were identified. Two common BRCA1 sequence variants: c.2077G>A and c.4956G>A, were found more frequently in mutation carriers compared to healthy controls. In silico analyses identified one BRCA1 sequence variant (c.4039A>G) and two BRCA2 variants (c.5986G>A and c.6884G>C) as harmful with high probability and inconclusive results were obtained for one novel BRCA2 variant: c.3864_3866delTAA. Combination of QMPSF and HRMA methods provides high detection rate and complete coverage of BRCA1/2 genes.

P06.031

Identification of *BRCA1/2* mutations in an unselected breast cancer population and referral to the Clinical Genetic Center

A. J. van den Broek[1], *K. de Ruiter*[1], *L. J. van 't Veer*[2], *R. A. E. M. Tollenaar*[3], *F. E. van Leeuwen*[1], *S. Verhoef*[4], *M. K. Schmidt*[1,2];
[1]*Psychosocial Research and Epidemiology, Netherlands Cancer Institute, Amsterdam, Netherlands,* [2]*Molecuar Pathology, Netherlands Cancer Institute, Amsterdam, Netherlands,* [3]*Surgery, Leiden University Medical Center, Leiden, Netherlands,* [4]*Family Cancer Clinics, Netherlands Cancer Institute, Amsterdam, Netherlands.*

BRCA1/2-screening guidelines are aiming to select women who have a high prior probability to be a mutation carrier. We screened *BRCA1/2* mutations in research setting and evaluated Dutch diagnostic *BRCA1/2*-screening criteria in a consecutive, hospital-based series of breast cancer patients <50 years.

We collected clinico-pathological data of 5433 invasive breast cancer patients, diagnosed <50 years in ten hospitals between 1970 and 2003. Germline DNA isolated from FFPE-tissue was tested for the most prevalent pathogenic *BRCA1/2* mutations. For 1539 cases from 5 hospitals complete family history and hormone receptor status (ER, PR, HER2) data was available. For patients from one hospital (NKI-AVL; n=1588) we identified those referred to the CGC for diagnostic *BRCA1/2*-screening.

Results shown are preliminary, final results will be available at ESHG 2012. We identified 4.9% *BRCA1/2* carriers in this unselected breast cancer cohort. Following current Dutch screening criteria, 60% of these carriers could have been identified (sensitivity 58.7%; specificity 78%). Selection of not only patients diagnosed with a triple-negative tumor at age <40 years, but also those with a triple-negative tumor diagnosed at age 40-50 years increased sensitivity to 73.3% (specificity 71.4%). Of 83 *BRCA1/2* mutation carriers from the NKI-AVL, 46% had been referred to the CGC (data linkage ongoing); of those not referred, the 8 carriers diagnosed after 1994 (discovery of the *BRCA* genes) were less likely to meet the criteria for referral.

A more optimal sensitivity and specificity for *BRCA1/2*-screening of breast cancer patients may be achieved based on age and tumor criteria.

P06.032

Validation of three BRCA1/2 mutation-carrier probability models Myriad, BRCAPRO and BOADICEA in a population-based series of 183 German families

M. Shoukier[1], *S. Schneegans*[1], *A. Rosenberger*[2], *U. Engel*[1], *M. Sander*[3], *G. Emons*[3];
[1]*Institute of Human Genetics, University Medical Center, Georg August University, Göttingen, Germany,* [2]*Department of Genetic Epidemiology, University Medical Center, Georg August University, Göttingen, Germany,* [3]*Department of Gynecology and Obstetrics, University Medical Center, Georg August University Göttingen, Göttingen, Germany.*

Many studies have evaluated the performance of risk assessment models for BRCA1/2 mutation carrier probabilities in different populations, but to our knowledge very few studies have been conducted in the German population so far. In the recent study, we validated the performance of three risk calculation models by names BRCAPRO, Myriad and BOADICEA in 183 German families who had undergone molecular testing of mutations in BRCA1 and BRCA2 with an indication based on clinical criteria regarding their family history of cancer. The sensitivity and specificity at the conventional threshold of 10% as well as for a threshold of 20% were evaluated. The ability to discriminate between carriers and non-carriers was judged by the area under the receiver operating characteristics curve. We further focused on the performance characteristic of these models in patients carrying large genomic rearrangements as a subtype of mutations which is currently gaining increasing importance. BRCAPRO and BOADICEA performed almost equally well in our patient population, but we found a lack of agreement to Myriad. The results obtained from this study were consistent with previously published results from other population and racial/ethnic groups. We suggest using model specific decision thresholds instead of the recommended universal value of 10%. We further suggest integrating the CaGene5 software package, which includes BRCAPRO and Myriad, in the genetic counselling of German families with suspected inherited breast and ovarian cancer because of the good performance of BRCAPRO and the substantial ease of use of this software.

P06.033

MASTR assays on the Ion PGM Sequencer, streamlining the diagnostic workflow

D. Goossens[1], *H. P. J. Buermans*[2], *A. Buffone*[3], *J. T. den Dunnen*[4], *R. H. Vossen*[2], *G. Giannini*[3], ***J. Del-Favero***[1];
[1]*Multiplicom N.V., Niel, Belgium,* [2]*LGTC, Leiden University Medical Center, Leiden, Netherlands,* [3]*Department of Molecular Medicine, Sapienza University, Rome, Italy,* [4]*LGTC, Leiden University Medical Center and Center for human and Clinical Genetics, Leiden, Netherlands.*

Multiplicom's MASTR assays allow multiplexed PCR amplification of numerous target sequences and therefore substantially reduce processing cost and front-end workload in combination with massive parallel sequencing (MPS) platforms. This is demonstrated by the fast uptake of the BRCA MASTR assay in European clinical diagnostic laboratories resulting from the facts that (i) only 5 robust PCR reactions are required to amplify all coding exons of BRCA1/2 and (ii) multiple DNA samples can be processed simultaneously. Additionally, processing cost is reduced by a factor 2-5, compared to Sanger based sequencing resulting from the combination of highly specific amplification (> 96% on target specificity) and a narrow spread factor (i.e. average number of all reads divided by the read number of the lowermost amplicon) of 2,5.

To increase the accessibility of MPS in clinical diagnostics, we worked out and performed a protocol to sequence the BRCA MASTR assay amplicons on an Ion PGM Sequencer. Hereto, amplicons from each of 14 DNA samples were enzymatically sheared followed by ligation of individual PGM adapters. After mixing the adapter ligated samples, an OneTouch based 100 bp ePCR was performed. The resulting ePCR library was sequenced using the 100 bp sequencing kit in combination with a single "Ion316 chip". The obtained sequencing data showed excellent characteristics and in depth analysis was performed for coverage uniformity on the one hand and base calling accuracy on the other. We will present detailed conclusions related to the performance characteristics and points for future improvements.

Study of several hormone receptor gene polymorphisms in breast cancer patients

A. Belengeanu, *D. Stoicanescu, M. Stoian, N. Andreescu, A. Anghel;*
University of Medicine and Pharmacy, Timisoara, Romania.

Androgen receptor gene polymorphisms and PROGINS have been related to a lower risk of breast cancer. The aim of the present study was identifying polymorphisms in the structure of the genes that code for progesterone and androgen receptors, variations that with or without those of estrogen receptors, could be correlated with breast cancer. 60 tumor samples from breast cancer cases were analyzed in order to find out several polymorphisms in the structure of the genes coding for progesterone and androgen receptors and compared to results obtained from the blood analysis of healthy subjects. The number of CAG repeats in the androgen receptor gene ranged from 8 to 27 repeats. The majority of cases had a range between 17 and 24, the size of the PCR products being around 230 bp. 15 alleles (12.5%) had less than 16 CAG repeats and 9 alleles (7.5%) had 25 or 27 CAG repeats. Considering the lower number of CAG tandem repeats, all cases with 11/8 repeats were in stage III and from the 2 cases with 11/9 repeats, 1 was in stage II and the other one in stage IV. The size of the PCR products of PROGINS receptor gene was 175 bp for the majority of the cases, only 6 (5%) longer alleles with 481 bp were detected. One of the detected cases was in stage IV of malignancy, the others were in stage III and all had ductal carcinoma. The obtained data are important for developing early detection and treatment strategies.

P06.035

Bcl-2 gene expression level in tumor and non tumor breast tissues

I. Rostamizadeh[1], *E. Sakhinia*[2], *S. Hosseini*[3], *M. Sakhinia*[4];
[1]*Department of Medical Genetic,Tabriz science medical university, Tabriz, Islamic Republic of Iran,* [2]*Department of Medical Genetic, Faculty of Medicine, Tabriz, Islamic Republic of Iran,* [3]*Research assistant, Genetics & Genomics Department, UAB, USA, Florida, FL, United States,* [4]*Faculty of Medicine, University of Liverpool, United Kingdom, Liverpool, United Kingdom.*

Breast cancer is the most common non-skin cancer and the second most frequent cause of death due to cancer among women. There has been much interest in the development and use of molecular-based research aimed at identifying biologic markers for the diagnosis of the disease, whilst the treatment of breast cancer has progressively improved. This development is underpinned by the knowledge of the genetic molecular alterations in the patient tissues. Several genes responsible for expression have been identified by cDNA microarray study in breast cancer, with the Bcl-2 gene indicated as a likely candidate. In this study, we studied bcl-2 gene expression level in parallel tumor and non tumor breast tissues. Forty samples including 19 tumor, 18 non tumor (marginal) and 3 benign breast tissues which were all pathologically diagnosed, were subjected to RNA extraction and polyA RT-PCR with the expression level of bcl-2 quantified using real-time PCR. By comparing tumor with non tumor tissues we found bcl-2 over-expression in all of the timorous tissues. Our data suggests that dysregulated bcl-2 gene expression is potentially involved in the pathogenesis of breast cancer. In conclusion, using gene expression analysis may significantly improve our ability for screening cancer patients and will prove a powerful tool in diagnosis, prognostic and cooperative group trials in the bcl-2based therapy project.

P06.036
Search for novel hereditary breast cancer (BC) genes suggests a causative role of heterozygous BLM mutation

E. N. Suspitsin[1,2], *A. P. Sokolenko*[1,2], *A. G. Iyevleva*[1,2], *N. V. Mityushkina*[1], *S. N. Abysheva*[1], *D. E. Matsko*[1], *E. N. Imyanitov*[1,2];
[1]N.N. Petrov Institute of Oncology, St.-Petersburg, Russian Federation, [2]St.-Petersburg State Pediatric Medical Academy, St.-Petersburg, Russian Federation.

Sequencing analysis of candidate genes involved in the maintenance of genome integrity (CHEK1, PARP1, PARP2, BRIP1, BLM, DDB, RNF8, FANCG, BARD1, RAD51C) in 95 hereditary BRCA1/BRCA2/NBS1/PALB2/TP53 mutation-negative BC cases has revealed 2 women with clearly inactivating genetic event. Both cases were heterozygous for c.1642 C>T (Q548X) mutation in the Bloom Syndrome gene, BLM. The subsequent extended study has confirmed frequent occurrence and BC-predisposing role of the above allele (17/1498 (1.1%) BC patients vs. 2/1093 (0.2%) healthy females, p = 0.004). As expected for hereditary BC gene, the BLM heterozygotes tended to be overrepresented in patients with family history of the disease, younger age at onset, or BC bilaterality. Unlike BRCA1-related hereditary tumors, BLM-associated BC were frequently hormone receptor positive (13/18, 72%). While virtually all BC arising in BRCA1/2 carriers contain somatic deletion of the remaining wild-type allele, none of BLM-driven cancers demonstrated loss of heterozygosity at BLM locus. 5 patients carrying BLM mutation were treated by neoadjuvant therapy and therefore were available for immediate evaluation of tumor chemosensitivity: 3 showed nearly complete pathological response, and 2 experienced partial clinical response. Elevated frequency of BLM Q548X mutations in Russian (Slavic) subjects allows to expect noticeable occurrence of Bloom Syndrome in Russia and neighboring countries; absence of appropriate clinical records in major Russian genetic centers suggests that at least some of these patients remain undiagnosed and/or have relatively mild presentation of this disease.

P06.037
Whole genome expression, canonical pathway and gene network analysis in breast cancer

D. Sunnetci[1], *N. Canturk*[2], *N. Cine*[1], *C. Ercin*[3], *T. Simsek*[2], *H. Savli*[1];
[1]Medical Genetics Department, Medicine Faculty of Kocaeli University, KOCAELİ, Turkey, [2]Department of General Surgery, Medicine Faculty of Kocaeli University, KOCAELİ, Turkey, [3]Pathology Department, Medicine Faculty of Kocaeli University, KOCAELİ, Turkey.

Introduction: Breast cancer is the most common cancer in women and constitutes 23% of all female cancers. Despite advances in treatment options, such as surgery and chemotherapy, breast cancer still remains being the most deadly second malignancy in women. Therefore, requirement of new prognostic markers is increasing. For this purpose, we studied gene expression profiles of breast cancer.
Materials and Methods: RNA samples were obtained from healthy and cancerous tissues taken from twenty patients diagnosed as breast cancer. These RNA samples were hybridized with microarray chips (Agilent Human 4 X 44K Oligo Microarrays). Gene expression, canonical pathway and network analysis were performed using GeneSpring GX 11.0 software.
Results: In our study, we found 585 downregulated and 413 upregulated genes. The canonical pathways significantly regulated were process of the immune system, T cell differentiation, T cell activation, lymphocyte activation, leukocyte activation, lymphocyte differentiation, leukocyte differentiation, immune system development, cell activation, hematopoietic or lymphoid organ development, hematopoiesis, signal transduction, immune response, signal transmission, the signal process, part of the plasma membrane, T cell receptor complex.
Conclusion: In this study, FOXM1, IFNG and MMP9 pathways has been identified among the data sets. These candidate pathways are important for the development of new biomarker panels to use for breast cancer prognosis in clinical practice.

P06.038
Contribution of truncating *PALB2* mutations to breast and ovarian cancer

N. Bogdanova[1,2], *D. Prokofyeva*[3,1], *T. Dörk*[1];
[1]Gynaecology Research Unit, Hannover Medical School, Hannover, Germany, [2]Clinics of Radiation Oncology, Hannover Medical School, Hannover, Germany, [3]Institute of Biochemistry and Genetics Ufa Science Center, Ufa, Russian Federation.

Familial breast and ovarian cancer is associated with mutations in *BRCA1* and *BRCA2* but these genes explain only a minority of cases. Germ-line mutations in *PALB2*, encoding the partner and localizer of BRCA2, have also been identified as breast cancer susceptibility alleles, and the geographical spread and risks associated with *PALB2* mutations are subject of intense investigation. We have scanned the whole coding region of *PALB2* using high-resolution melting analysis and direct sequencing of genomic DNA samples to investigate the prevalence of *PALB2* mutations in a series of 158 German patients with bilateral breast cancer and in a second series of 253 unselected patients with epithelial ovarian cancer from Bashkortostan. 17 sequence alterations were identified. Truncating *PALB2* mutations were identified in 2/158 (1.3%) bilateral breast cancer patients and in 1/253 (0.4%) ovarian cancer patients. One nonsense mutation, p.E545X was new, whereas the two other mutations, c.509_510delGA and c.172_175delTTGT had been previously described. The c.172_175delTTGT deletion, found in one Russian ovarian cancer/ melanoma patient, was subsequently screened in 365 breast cancer cases from Bashkortostan, and two further carriers were detected among patients of Russian descent (0.5%). Our results indicate that *PALB2* germ-line mutations account for a small but not negligible fraction of breast cancer, though they make a minor contribution to ovarian cancer. The observation that two of the three identified truncating mutations have been described in different studies, may provide a rationale for mutation-specific screening approaches in extended series of Eastern and Central European cancer patients.

P06.040
Associations Between HER2/neu ,TOP2A ,Chromosome 17 Copy Numbers and RASSF1A , APC Gene Promotor Hypermethylations of Patients with Breast Cancer

A. Nursal, ***O. Cilingir***, *M. Ozdemir, S. Artan, B. Durak Aras, E. Ciftci*;
Eskişehir Osmangazi University, Eskişehir, Turkey.

Associations Between HER2/neu ,TOP2A ,Chromosome 17 Copy Numbers and RASSF1A , APC Gene Promotor Hypermethylations of Patients with Breast Cancer
Backround: Breast cancer is an important public health problem worldwide. The HER2 /neu protooncogene is amplified and overexpressed in approximately 25-30% of invasive breast carcinomas. DNA topoisomerase 2-alpha enzyme controls and alters the topologic states of DNA during transcription. RASSF1A and APC gene are putative tumor-suppressor genes that are frequently inactivated epigenetically in breast cancer.
Method: In this study we analysed retrospective HER2, TOP2A gene and CEP17 copy number alterations by fluorescence in situ hybridization (FISH) in primary tumor core biopsies from 60 high-risk primary breast cancer patients (tumors ≥2 cm and/or lenfatic metastase and/or distant metastases and/or under 40 years) . The methylation levels of the RASSF1A, APC gene promoters were assessed Methylation Sensitive High Resolution Melting Analysis (MS-HRM).
Results: In our study, HER2/neu amplifications were identified in 25% and TOP2A coamplications in 53.4% and deletions in 13.3% of patients. HER2/neu gen amplification is found to be associated with high grade, ER negativity and PR negativity. Polysomy17 was present in 23.3% of patients. RASSF1A and APC methylation frequencies were 96.6% and 43.3%. HER2/neu gene amplification was found to be high RASSF1A promotor methylation levels.
Conclusions:. Our study is important as being the first study that analyzes association between HER2/neu, TOP2A gene copy numbers and RASSF1A, APC gene promotor methylation status in Turkish population.
Key words: Breast cancer, HER2/neu gene, TOP2A gene, FISH, RASSF1A gene, APC gene, Methylation, MS-HRM Analysis

P06.041
Necessity of HPV genome screening in women due to its role in breast cancer

K. Haratian[1], *A. Mohseni Meybodi*[2];
[1]Department of Pathobiology,Alborz University of Medical Sciences, Tehran, Islamic Republic of Iran, [2]Department of Genetics,Reproductive Biomedicine Research Center,Royan Institute for Reproduction Biomedicine, ACECR., Tehran, Islamic Republic of Iran.

It seems, there is an increment document that high-risk human papilloma virus (HPV) is involved in tumors in over just cervical cancer. For instances, it is already almost accepted that some HPVs have a major role in a significant proportion of head and neck tumors.It also has long been hypothesized that some tumorigenic viruses, such as HPV, may have etiological or even helping role in some human breast cancers. A number of reports have indicated HPV DNA in breast cancer tissue specimens and some normal or pre-cancerous breast tissues. Many of them rely on standard polymerase chain reaction (PCR), which is criticized for its tendency for contamination. We examined the presence, genotype, viral load, and physical status of HPV in a number of Iranian patients with breast carcinoma utilizing Real-time PCR setting (with sequencing), and immunohistochemistry based on HER2/neu overexpression. In this presentation, we attempt to summaries our achievements in using mentioned technologies to explore how HPVs may help to cause or progress malignancies especially in those that are affected by some other tumorigenic factors. Finally, the exigency of women screening for HPV and its potential importance in developing breast cancer, will be discussed.

P06.042

Multiplex single-nucleotide primer extension assay for detection of low-penetrance breast cancer susceptibility polymorphisms

I. Maleva[1]*, G. Bozhinovski*[1]*, E. Smickova*[2]*, G. Kondov*[3]*, Z. Spirovski*[3]*, D. Plaseska-Karanfilska*[1]*;*

Breast cancer is one of the most common cancers among women in developed countries. Approximately 10% of sufferers have a genetic predisposition and 25% of patients with familial breast cancer carry mutations in BRCA1 or BRCA2 high-penetrance genes. Recently, genome-wide association studies have identified several SNPs as low-penetrance breast cancer susceptibility polymorphisms. The aim of this study was to develop an easy, rapid and cost-effective method for genotyping of low-penetrance breast cancer susceptibility polymorphisms within six genes and gene-free genomic regions. We have designed a multiplex single-nucleotide primer extension assay to genotype rs2981582 (FGFR2), rs3817198 (LSP1), rs889312 (MAP3K1), rs3803662 (TNRC9/LOC643714), rs1328615 (8q) and rs1045485 (CASP8) in a single reaction. Using this method, we analyzed 92 breast cancer patients, of which 26 with familial breast cancer and 86 controls from the general population. Our results showed that SNP rs1045485 in CASP8 is significantly associated with decreased breast cancer risk [p=0.0081; OR (95%CI)=2.37 (1.24-4.56)], while rs889312 in MAP3K1 showed a significant association with increased breast cancer risk [p=0.0151; OR (95%CI)=2.31 (1.16-4.61)] only among patients with positive family history of breast cancer. In conclusion, we present an effective new genotyping method that can be applied in medium-scale association studies.

Evaluation of cisplatin and cisplatin nanoparticles on the MCF-7 cell line

M. J. Mokhtari[1]*, A. Akbarzadeh*[2]*, M. Hashemi*[3]*, R. Mahdian*[4]*, G. Javadi*[3]*, Z. Hoseineian*[3]*, H. Mohammadi*[5]*;*
[1]*Department of Biology, Zarghan Branch, Islamic Azad University, Zarghan, Islamic Republic of Iran,* [2]*Pilot Biotechnology Department, Pasteur Institute of Iran, Tehran, Islamic Republic of Iran,* [3]*Department of Biology, Science and Research Branch, Islamic Azad University, Tehran, Islamic Republic of Iran,* [4]*Department of Molecular Medicine, Biotechnology Research Center, Pasteur Institute of Iran, Tehran, Islamic Republic of Iran,* [5]*Young Researchers Club, Kermanshah Branch, Islamic Azad University, Kermanshah, Islamic Republic of Iran.*

Introduction: Breast cancer is one of leading causes of mortality worldwide. Cisplatin is a traditional cancer drug commonly used in chemotherapy for killing breast cancer cells. Modulation at the mRNA levels of apoptotic related genes often correlate with the sensitivity of various types of cancer cells to chemotherapeutic agents. Nanoparticulate drug delivery systems are being developed to deliver smaller doses of chemotherapeutic agents in an effective from and control drug distribution with in the body.
Material and methods: In the present study, we synthesized the magnetic nanoparticles. Then nanoparticles were loaded by cisplatin. Then, cell toxicity was evaluated by the MTT assay. Finally, we compared the effect of cisplatin and cisplatin nanoparticles on the mRNA expression levels *BCL2*-gene in MCF-7 breast cancer cell line.
Result: Our initial results indicate that nanoparticles are effective anticancer agents. We also found that cisplatin nanoparticles induce apoptosis in human breast cancer cell line.
Discussion: In the present study, we have shown that the strongly increased *in vitro* cytotoxicity of cisplatin nanoparticles compared with the free drug in MCF-7 cell line. In summary, our results indicate that cisplatin nanoparticles are effective anticancer agents and justify study of these agents *in vivo*.

Association of polymorphisms in low-penetrance genes with breast cancer risk in Bulgarian cohort of familial cases and controls

R. Dodova[1,2]*, D. Kachakova*[1,2]*, A. Vlahova*[3]*, T. Dikov*[3]*, S. Christova*[3]*, S. Valev*[4]*, M. Taushanova*[4]*, C. Timcheva*[4]*, V. Mitev*[1,2]*, R. Kaneva*[1,2]*, A. Mitkova*[1,2]*;*
[1]*Molecular Medicine Center, Sofia, Bulgaria,* [2]*Department of Medical Chemistry and Biochemistry, Medical University, Sofia, Bulgaria,* [3]*Clinic of General and Clinical Pathology University Hospital "Aleksandrovska", Medical University, Sofia, Bulgaria,* [4]*Medical Oncology Clinic National Oncology Hospital, Sofia, Bulgaria.*

Background: Although the germ-line mutations in *BRCA1/2* and other breast cancer susceptible genes account for up to 10% of the familial cases, the majority of patients with this diagnosis do not harbour mutations in the main disease associated loci. This observation has led to the proposal that the susceptibility to breast cancer is determined by a large number of loci, each with a small effect on the breast cancer risk.
Materials and methods: We have performed a case-control study of eight SNPs, previously associated with breast cancer in extensive GWASs. The studied group consisted of 191 Bulgarian patients with family history of breast cancer and 151 healthy controls. The genotyping was performed by TaqMan technology and the results analysed using Plink and VassarStat Statistical Calculator.
Results and discussion: Three of the studied polymorphisms: rs2981579 and rs2981582 in *FGFR2* gene and rs3757318 in C6orf9, demonstrated significant association with breast cancer risk. The genotype A/A of both rs2981579 (OR=1.668; p=0.007) and rs2981582 (OR=1.782; p=0.005) appeared to increase the risk of breast cancer. The homozygosity for the G allele in rs3757318 (OR=1.678; p=0.03) was also associated with increased risk, while the genotype A/G appeared to have protective effect (OR=0.472; p=0.003). The other studied SNPs did not show any statistically significant association with breast cancer in the investigated sample.
Conclusions: Our results demonstrated significant association of rs2981579 and rs2981582 in *FGFR2*, and rs3757318 in C6orf9 with increased breast cancer risk which is in concordance with previous GWASs.

P06.045

Oestrogen Receptor-α Gene Polymorphism (T392C) in Iranian Women with Breast Cancer

S. Abbasi*;*
Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.

Background: Receptor-mediated oestrogen activation plays a part in the development and progression of breast cancer. Evidence suggests that alterations in oestrogen signalling pathways, including oestrogen receptor-α (ESR1) occur during breast cancer development.
progression of breast cancer.
Methods: The ESR1 gene was analysed in 150 Iranian patients who were newly diagnosed with invasive breast tumours and in 147 healthy individuals. Single-strand conformation polymorphism PCR and direct sequencing were done.
Findings: Silent single nucleotide polymorphisms (SNPs), as reported in previous studies, were found but at significantly different frequencies. The frequency of allele C/C in codon 10 rs2077647 (T/C, S392S) of exon 1 was significantly higher in patients with breast cancer (45.7%) than in the controls (39.8%; p=0.148). We found that allele C/C in codon 10 was significantly more common in patients with breast cancer who had a family history of breast cancer (78.9%) than in those without such a history (40.8%; p=0.001). The allele 1 in codon 10 showed an association with the occurrence of lymph node metastasis (58.7% and 43.3% with and without lymph node metastases, respectively). Therefore, this SNP marker further increased predictive accuracy in the Iranian population.
Interpretation: Our data suggest that ESR1 polymorphisms correlated with various aspects of breast cancer in Iranian women, as determined during pre-surgical assessment, might represent a surrogate marker for predicting breast cancer.

P06.046

Prognostic significance of the urokinase-type plasminogen activator (uPA) and its inhibitors (PAI-1 and PAI-2) mRNA expression in Iranian breast cancer

L. Kokabee[1]*, R. Esmaeili*[2]*, K. Majidzadeh-A*[2]*, R. Mahdian*[1]*,* ***M. Karimipoor***[1]*;*
[1]*Pasteur Institute of Iran, Tehran, Islamic Republic of Iran,* [2]*Iranian Center for Breast Cancer (ICBC), Tehran, Islamic Republic of Iran.*

One of the most thoroughly studied systems in relation to prognostic relevance in breast cancer is the plasminogen activation system. The system comprises of the urokinase Plasminogen Activator (uPA) and its inhibitors, the Plasminogen Activator Inhibitor-1 (PAI-1) and Plasminogen Activator

Inhibitor-2 (PAI-2). In this study, we are investigating the prognostic value of the expression level of uPA and PAI-1 and PAI-2 in 30 sporadic breast cancer patients.

The mRNA expression level of uPA, PAI-1 and PAI-2 was analyzed in tumor tissues and its adjacent normal tissues from 30 patients by quantitative PCR. Gene fragments were amplified in a ABI 7300 real-time PCR system using gene-specific primers and Taq Man probe. The results were normalized to TFRC and ACTB mRNA. The data of real-time RT-PCR will be compared with clinical course of the disease (three years follow up).

Quantitative real-time RT-PCR is a highly sensitive, reproducible, and fast method for measuring gene expression of uPA, PAI-1 and PAI-2 in breast cancer. Some studies have shown the relationship between high expression of UPA system and aggressive course of breast cancer. In addition *in vitro* studies of high expression of UPA have been shown the modulation of angiogenesis.

P06.047

Real-Time Analysis of the expression of isoforms angionegnicaanti- and pro-angiogenic in breast cancer.

R. CASTRO[1], *P. M. Biselli-Chicote*[1], *V. R. Regiani*[1], *D. S. Neto*[1,2], *V. R. Regiani*[1], *N. A. B. Junior*[1,3], *J. L. E. Francisco*[1,3], *É. C. Pavarino*[1], *D. A. P. C. Zuccari*[1,4], *E. M. Goloni-Bertollo*[1];
[1]Faculty of Medicine of Sao Jose do Rio Preto, SÃO JOSÉ DO RIO PRETO, Brazil, [2]Pathology Service, Hospital de Base, São josé do rio preto, Brazil, [3]Department of Gynecology and Obstetrics, Hospital de Base, São josé do rio preto, Brazil, [4]Center for Studies and Research on Cancer Faculty of Medicine, São josé do rio preto, Brazil.

Breast cancer is the most frenquently diagnosed cancer and the leading cause of cancer death in females. About half breast cancer cases and 60% of the deaths are estimated to occur in economically developing countries. Angiogenesis plays a critical role in local growth of solid tumors and subsequently in the process of distant spread. Numerous studies have demonstrated the importance of angiogenesis in cancer. Nevertheless, 3' alternative splice site selection in exon 8 of VEGF gene results in a sister family of isoforms, VEGFxxxb, which are anti-angiogenic and downregulated in tumor tissues. We quantitatively analyzed the expression of pro-angiogenic and anti-angiogenic VEGF isoforms in breast carcinoma and adjacent normal tissue samples. For that purpose, total RNA from 16 tumor samples and their respective margins were obtained and synthesized cDNA from. We designed and synthesized primers and specific probes for each isoform, which were used for the analyses of expression by real time PCR. So far, were observed different expression between the anti- and pro- angiogenic isoforms in the tumor samples compared to normal tissue. These results evidence that the selection of different splicing sites may actually interfere in tumor angiogenesis and consequent tumor progression and metastasis. A bigger sample size might help in more advanced studies and collaborate to better development of researches on tumor angiogenesis involving VEGF gene. Studies approaching control of VEGF splicing in order to promote the selection of the distal splicing site (anti-angiogenic) instead of proximal site (pro-angiogenic) might promote an efficient therapy for breast cancer.

P06.048

A novel missense mutation in IDH2 gene of a glioma patient

G. Stancheva[1,2], *T. Goranova*[2], *M. Laleva*[3], *M. Kamenova*[4], *A. Mitkova*[1,2], *N. Velinov*[3], *R. Kaneva*[1,2], *G. Poptodorov*[3], *V. Mitev*[1,2], *N. Gabrovsky*[3];
[1]Department of Medical Chemistry and Biochemistry, Medical University, Sofia, Bulgaria, [2]Molecular Medicine Center, Medical University, Sofia, Bulgaria, [3]Department of Neurosurgery, University Multiprofile Hospital for Active Treatment and Emergency Medicine "N.I.Pirogov", Sofia, Bulgaria, [4]Department of Pathology, University Multiprofile Hospital for Active Treatment and Emergency Medicine "N.I.Pirogov", Sofia, Bulgaria.

IDH2 gene encodes mitochondrial NADP-dependent isocitrate dehydrogenase - an enzyme that catalyzes the oxidative decarboxilation of isocitrate to α-ketoglutarate. Mutations in IDH2 and its cytosolic isoform - IDH1, were found in brain tumours and acute myeloid leukemia (AML). While the data about survival benefit of AML patients with mutations are controversial, IDH1 and IDH2 aberrations in gliomas are associated with better prognosis.

A recent analysis by direct sequencing of exon 4 of IDH2 gene in brain tumour tissues, including astrocytomas and oligodendrogliomas, revealed a new mutation in IDH2 gene that was not described to date. It was a homozygous one-nucleotide A-to-G substitution at position 386 which caused amino acid change lysine to arginine (c.386A>G, K129R). The aberration was in a highly conserved region of the protein which suggested that it might be associated with the development of the brain tumour. The mutation was detected in one patient with glioblastoma (grade IV) who had overall survival of 30.3 months. This was similar to median survival time in our group of patients with already known IDH2 or IDH1 mutations - about 32 months vs. 5 months in non-mutated cases. The effect of the newly found aberration on protein structure and function should be studied further.

P06.049

Investigation of the telomerase expression level in colon cancer patients and its relation with multi drug resistance.

s. shabani, *f. mahjoubi*;
national institute of genetic engineering and biotechnology, tehran, Islamic Republic of Iran.

One of the most common causes of mortality in the world is cancer. In spite of recent advances in the treatments of cancer, the clinical outcome is far away from expectation yet. Drug resistant remains a major obstacle to the effective cure of almost all cancers. We aimed to investigate the possible association between telomerase expression level and multidrug resistance in colon cancer patients.

In this regards tumor and adjacent normal tissues of 80 colon cancer patients were assessed for the expression level of telomerase by Real Time RT-PCR.

Here we are presenting our data regarding to the correlation between telomerase level and failure to chemotherapy in this group of Iranian colon cancer patients. To our best knowledge, this is the first data derived from an in vivo study. Our data will be compared with other published reports which had the focus on only in vitro (cell lines) system.

P06.050

Impact of cancer-testis antigens crosstalk with self-renewal cell signaling pathways in esophageal squamous cell carcinoma

M. R. Abbaszadegan, *M. M. Forghanifard*;
Human Genetics Division, Immunology Research Center, Avicenna Research Institute, Mashhad University of Medical Sciences (MUMS), Mashhad, Islamic Republic of Iran.

Aberrant expression of cancer-testis antigens (CTAs) is reported in variety of tumor cell types, but their functions and related pathways in tumorigenesis are poorly understood. Several CTAs are expressed in human cancers as well as human mesenchymal stem cells. CTAs play a role at earlier stages of embryonic development, stem cell self-renewal and tumorigenicity. Role of CTAs was examined in tumorigenesis of esophageal squamous cell carcinoma (ESCC) with respect to cell signaling pathways. Gene expression analysis of MAGE-A4, LAGE1 and NY-ESO1, EGFR, TWIST1, PYGO2 and MAML1 were performed using comparative real-time RT-PCR in 44 ESCC patients. Overexpression of all genes was detected in 90.2%, 39%, 41.5%, 43.9%, 41.5%, 36.6% and 43.9% of samples, respectively. There are significant correlations among gene transcripts expression as it was shown in the table below. MAGE-A4, TWIST1 and MAML-1 expression were significantly correlated with lymph node metastasis, MAGE-A4 was significantly correlated with tumor staging and TWIST1 expression was significantly correlated with tumor invasion ($p<0.05$). Hierarchical gene clustering data revealed that TWIST1 is related to CTA genes. Correlated overexpression of CTAs and key factors of cell signaling pathways imply a strong cross talk between them through tumorigenesis in ESCC. Interactions of CTAs with Twist1 could trigger epithelial-to-mesenchymal transition and favor metastasis of tumor cells. This provides a support for role of CTAs in the self-renewal and differentiation of tumor cells.

Gene expression correlations between CTAs and Self-Renewal Genes

	LAGE1	MAGEA4	NY-ESO1	EGFR	MAML1	PYGO2	TWIST1
LAGE1		0.008		0.011			
MAGEA4	0.008		0.018				0.016
NY-ESO1		0.018					0.043
EGFR	0.011					0.001	
MAML1						0.006	0.0041
PYGO2				0.001	0.006

P06.051

SDHB germline mutation in a patient with Carney-Stratakis syndrome

M. Thalhammer[1], *E. Heitzer*[2], *B. Liegl-Atzwanger*[3], *M. Auer*[2], *M. R. Speicher*[2], ***J. B. Geigl***[2];
[1]Division of General Surgery, Medical University Graz, Graz, Austria, [2]Institute of Human Genetics, Medical University Graz, Graz, Austria, [3]Institute of Pathology, Medical University Graz, Graz, Austria.

Carney-Stratakis syndrome is a recently described, very rare familial syndrome characterized by gastrointestinal stromal tumors (GIST) and paragangliomas. The majority of cases are caused by germline mutations of the succinate dehydrogenase (SDH) subunit genes *SDHB, SDHC* and *SDHD*. Tumor predisposition is inherited in an autosomal dominant manner with incomplete penetrance.

Here, we present a 47-year old patient with a gastrointestinal stromal tumor (GIST) diagnosed at the age of 17 years. Because of severe anemia, total gastrectomy was performed at the age of 45 years, exhaustive clinical screening revealed a non-functioning, abdominal, extra-adrenal paraganglioma.

As a consequence, the patient was referred to our genetic service and molecular genetic diagnosis was initiated. Family history did not reveal the presence of any paragangliomas, gastric stromal sarcomas or further tumor entities. Molecular genetic analysis by direct DNA sequencing showed a putative splice mutation c.287-2A>G in the *SDHB*-gene. This mutation has been reported previously in patients with inherited paraganglioma but never in the context of Carney-Stratakis syndrome. The damaging effect of the mutation in mRNA splicing could be confirmed on the basis of cDNA analysis. By array-CGH we identified the most frequently reported genetic alteration in paraganglioma, i.e. loss of chromosome 1q. In addition, we observed a loss of chromosome 11.

As a consequence, especially in young patients with GIST and/or paragangliomas molecular diagnostics should be offered to identify germline mutations in SDH genes. This is of high relevance as mutated tumours in most cases do not respond to treatment with tyrosine kinase inhibitors.

P06.052
Evaluation of Caspase-8 -652 6N ins/del polymorphism in breast cancer

M. Hashemi, E. Eskandari Nasab, M. Taheri, H. Rezaei, M. Mashhadi, F. arbabi, S. Hashemi, M. Jahantigh;
Zahedan University of Medical Sciences, Zahedan, Islamic Republic of Iran.

In the present study, we examined the impact of CASP8 -652 6N ins/del (rs3834129) and the risk of breast cancer in a sample of Iranian population. This case control study was done on 236 breast cancer patients and 203 cancer free healthy female. Bi-directional PCR allele-specific amplification (Bi-PASA) was used for detection of CASP8 -652 6N ins/del polymorphism. Our findings indicated that the CASP8 -652 6N del/dl genotype was inversely associated with breast cancer risk (OR=0.33, 95% CI=0.17-0.65, p=0.001). The frequency of del allele in cases and controls were 29.1% and 38.6%, respectively. An inverse association between CASP8 6N del variant and the risk of breast cancer (OR=0.66, 95% CI=0.66-0.87, p=0.002) was found.

In conclusion, the finding suggests that the CASP8 -652 6N del polymorphism plays a protective role in susceptibility to breast cancer in our population.

P06.053
Evaluating of CBX8 Gene Expression in Gastric cancer

M. Ghalandari, M. Behmanesh, M. Sadeghizadeh;
tarbiat modares university, tehran, Islamic Republic of Iran.

Cbx8 is a member of polycomb group proteins which their functions in development and progression of cancer has been investigated a lot. CBX8 regulates proliferation of diploid human and mouse fibroblasts and its ectopic expression leads to repression of the Ink4a-Arf locus and cellular immortalization. Regarding to the function of this gene in regulation of Senescence we studied the expression of CBX8 in gastric tumors one of the most cause of cancer death worldwide. Using real-time quantitative reverse transcription-PCR assay based on SYBER green we evaluated the expression of CBX8 gene in thirty gastric cancer specimens in comparison with their normal marginal tissues . Despite the differences in the expression of this genes found on each pair samples between tumor and marginal tissues, statistical analysis didn't show significant differences in the mean expression of CBX8 between tumor and marginal in total . But it was possible to divide the data into two group; group1 in which the gene was overexpressed in tumor and group 2 in which the gene was downregulated in tumor samples. On each group the difference in CBX8 gene expression was significant between tumor and marginal tissues. Our data suggest that this variation in the gene expression pattern may be due to different origin of gastric cancer.

P06.054
Detection of genomic imbalances in cervical lesions positive for HPV by microarray comparative genomic hybridization

P. Grozdanov[1], A. S. Galabov[1], V. Zlatkov[2], G. Ganchev[3], I. Dimova[4], S. Hadjidekova[4], D. Toncheva[4];
[1]*Department of Virology, Institute of Microbiology "Stephan Angeloff", Sofia, Bulgaria,* [2]*G&O "Majchin Dom" Hospital, Sofia, Bulgaria,* [3]*National Institute of Oncology and Hematology, Sofia, Bulgaria,* [4]*Department of Medical genetics, Medical University, Sofia, Bulgaria.*

Widely known as a sexually transmitted agent, genital human papillomavirus (HPV) is considered to be major factor in the development of cervical intraepithelial neoplasia and cervical carcinoma. HPV can be associated with benign warts (HPV types 6 and 11) and related to anogenital tumors (HPV types 16, 18, 31, 33, 35, 45). Practically 100% of cervical cancer - the second most common tumor in women worldwide, contain DNA sequences of high-risk oncogenic genital papillomavirus. Effective diagnosis of these infections today is almost entirely related to the use of molecular techniques for detection of viral DNA and identification of viral genotypes.

The objective of our study was to investigate the incidence and type of genomic imbalances in cervical lesions with different HPV status. We have applied array Comparative Genomic Hybridization (array CGH) in selected groups. In HPV16 positive cervical cancer samples we discovered pathologic deletions in 11q22.1, 1p36.23 and 3q deletion, as well as some benign polymorphisms. In the group of cervical cancer, positive for low risk HPV, we found only polymorphic copy number variations. In samples with cervical dysplasia, positive for HPV16, pathologic imbalances were detected such as deletions in 4p16.2, 17p13.3 and 22q13.33.

This report summarizes and complements the current information on the prevalence of human papillomaviruses in the Bulgarian population and presents the results of our research on benign, precancerous and cancerous changes using array CGH analysis.

P06.055
Importance of SULT1E1 in the cervical carcinogenesis

C. Backsch, K. Grabert, A. Schneider, L. Jansen, I. B. Runnebaum, M. Dürst;
Klinik für Frauenheilkunde und Geburtshilfe, Universitätsklinikum Jena, Jena, Germany.

Background:

Persistent infection with a high-risk human papillomavirus type is a prerequisite for the development of cervical cancer (CxCa). However, additional genetic alterations, including the reactivation of telomerase activity, are required. Our previous studies (microcell-mediated chromosome transfer, microarray-analysis, loss of heterozygosity analysis) revealed a role of the chromosomal region 4q13 in the regulation of telomerase.

Objectives:

The aim of the present study was to validate the differential expression of one of our candidate genes, SULT1E1, located within 4q13 in biopsy material. Furthermore the ability of SULT1E1 to suppress telomerase activity and to induce senescence in different functional assays is investigated.

Methods:

Gene expression of SULT1E1 and hTERT was validated by real-time PCR in normal cervical tissues, high-grade lesions (CIN2/3) and CxCa. SULT1E1 was expressed stably in various cell lines in order to analyze its effects on telomerase activity, telomere length and senescence using telomerase PCR ELISA kit, telomere length kit and ß-galactosidase staining, respectively.

Results and Conclusions:

The mRNA expression level of SULT1E1 was significantly (p<0,05) lower in CxCa as compared to CIN2/3 or normal tissue. Only low levels of SULT1E1 were detected in the cervical carcinoma cell lines SiHa, ME180 and SW756. Reconstitution of SULT1E1 via lentiviral-mediated gene transfer in these cell lines resulted in a slightly decreased telomerase activity in SiHa and ME180 cells. Telomere length assays and senescence tests are still ongoing.

Our first results thus far suggest that SULT1E1 maybe a putative telomerase suppressor gene and loss of its function may contribute to the transformation process.

P06.056
A new combined approach at the diagnosis of childhood Acute Lymphoblastic Leukemia patients: Real Time PCR and BAC based high throughput FISH analysis

Z. Ilkay, N. Cine, D. Sunnetci, N. Uzulmez, D. Yavuz, H. Savli;
Medical Genetics Department, Medicine Faculty of Kocaeli University, KOCAELİ, Turkey.

Introduction: Acute lymphoblastic leukemia (ALL) is a disease characterized by the accumulation and leukemic transformation of immature lymphoid cells in the blood and bone marrow. Aim of this study was to determine genomic level aberrations for the diagnosis of childhood ALL patients using quantitative real time PCR (Q-RT-PCR) and high throughput BAC based molecular FISH analysis simultaneously.

Materials and Methods: In this study, Q-RT-PCR was performed on RNA samples and high throughput BAC based molecular FISH analysis was performed on DNA samples obtained from peripherial blood and bone marrow of 29 pre-diagnosed ALL patients between the ages of 0-18 regardless of gender.

Results: As a result of high throughput BAC based molecular FISH analysis, aberrations with various sizes were detected in various regions of the genome in 17 (58,6%) patients. The presence of MLL-AF4 fusion gene was identified in a patient (3,4%) among 17 patients using Q-RT-PCR method in addition to the found aberrations. The presence of MLL-AF4 and BCR-ABL fusion genes were found using Q-RT-PCR as an only result in 2 (6,9%) patients. Using both methods no aberrations were found in 10 (34,5%) patients. Gain of chromosomes X and 21 in a frequency of 20,7%, loss of chromosomes 9p and 6q in a frequency of 10,3% were the most common chromosomal aberrations detected in our study.

Conclusion: We think that rapid diagnosis and increased sensitivity is the significance of the simultaneous use of these two methods in hematological malignancies.

P06.057

Dysregulation of FAS and FASL in Chordoma: Study of their Role in Zebrafish Notochord Development and Regression

L. Ferrari[1], *A. Pistocchi*[2], *N. Boari*[3], *P. Mortini*[3], *F. Cotelli*[2], *P. Riva*[1];
[1]Dipartimento di Biologia e Genetica per le Scienze Mediche, Università degli Studi di Milano, Milan, Italy, [2]Dipartimento di Biologia Sezione di Citologia e Istologia, Università degli Studi di Milano, Milan, Italy, [3]Dipartimento di Neurochirurgia, San Raffaele Scientific Institute - Vita-Salute University, Milan, Italy.

Chordoma is a rare malignant bone tumor arising from notochord remnants, characterized by local invasiveness and variable tendency for recurrence. As the apoptotic pathway mediated by FAS-FASL was found to be involved in notochordal cells regression, we studied their expression in 34 chordomas and observed that most of them express FAS, but not FASL. To verify a possible implication of FAS/FASL pathway dysfunction during development leading to tumorigenesis, we started in vivo studies on zebrafish, firstly investigating fas-fasl horthologue genes expression by RT-PCR in whole embryos and larvae. While fas was maternally and zigotycally expressed, fasl showed a stage-specific expression. Following microinjection of a GFP-construct activated by the twhh promoter, we specifically sorted by FACS the GFP-positive notochordal cells at different developmental stages in which we studied fas-fasl expression by means of RT-PCR. We observed that fas was expressed at all the analyzed stages, while fasl is modulated during development. Immunohistochemical experiments showed notochord fasl expression at 48 hpf, 3 and 5 days post fertilization (dpf) and at 9 mm. fasl expression seems to decrease when notochordal cells disappear during chord regression, suggesting the activity of apoptotic mechanisms fas-fasl-mediated. Studies on fas and fasl silencing, by means of morpholino oligos injections, allowed us to observe notochord anomalies such as packed notochordal cells, curved body and bent tail. Further analysis will be performed to verify whether the reactivation of fas-fasl pathway might rescue the normal phenotype, allowing to unravel the role of this mechanism in chordoma development.

P06.058

The role of microRNAs in resistance to imatinib in chronic myeloid leukemia patients

I. R. Minniakhmetov[1], *D. Islamgulov*[1], *N. Ryabchikova*[2], *A. Karunas*[1], *E. Khusnutdinova*[1];
[1]Institute of Biochemistry and Genetics, Ufa, Russian Federation, [2]Bashkir State Medical University, Ufa, Russian Federation.

Chronic myeloid leukemia (CML) is a myeloproliferative disorder characterized by the expression of the BCR-ABL oncoprotein, which is essential for the pathogenesis of the disease. Imatinib, an ATP-competitive selective inhibitor of BCR-ABL, has unprecedented efficacy for the treatment of CML. Nevertheless resistance to imatinib is observed in over 30% cases of CML. Several cellular and genetic mechanisms of imatinib resistance have been proposed, including overexpression of the BCR-ABL gene, the tyrosine kinase domain mutations, pharmacokinetic and pharmacodynamic factors.

The purpose of this study was to investigate the mechanisms of resistance to imatinib in CML patients. We have analyzed mRNA level of BCR-ABL gene by quantitative real time RT-PCR in 114 patients and have studied BCR-ABL mutations in patients with high level of expression of fusion gene. Mutation status was studied by direct sequencing of BCR-ABL cDNA samples. BCR-ABL mutations were founded in 16 (32%) patients with resistance to imatinib treatment. The mutation spectrum included four missense mutation: M351T (7 cases), T315I (4), T315I+M351T (2), M244V (1) and H396R (1). Next we conducted a search for microRNAs specifically targeting 3'UTR of BCR-ABL, using the miRBASE program to scan human genome (http://microrna.sanger.ac.uk/) and analyzed microRNAs expression profile. The down-regulation of miR-203-b (25-fold), mir-323 (4-fold) and miR-196-b (2-fold) in the group of patients with resistance was discovered. In conclusion, our data showed that mutations in the BCR-ABL kinase domain may cause, or contribute to, resistance to tyrosine kinase inhibitors in CML patients, but resistance mechanisms might also be regulated by microRNAs.

P06.059

Chronic myeloid leukemia: molecular monitoring of residual disease by genomic DNA compared to conventional cytogenetic and mRNA analysis in follow-ups up to 8 years.

I. S. Pagani[1], *O. Spinelli*[2], *C. Pirrone*[1], *A. Bussini*[2], *T. Intermesoli*[2], *F. Pasquali*[1], *F. Lo Curto*[1], *A. Lanfranchi*[3], *F. Porta*[3], *A. Rambaldi*[2], *G. Porta*[1];
[1]University of Insubria, Varese, Italy, [2]USC Hematology, Ospedali Riuniti di Bergamo, Bergamo, Italy, [3]Spedali Civili di Brescia, Brescia, Italy.

Chronic myeloid leukemia (CML) is a clonal myeloproliferative disorder resulting from a balanced reciprocal translocation, producing the BCR-ABL1 fusion gene in the Philadelphia (Ph) chromosome. The first line therapy of CML is Imatinib mesylate, which targets Bcr-Abl protein. The gold standard for diagnosing CML is cytogenetic analysis, a direct not-sensitive method to detect Ph-positive cells. The real-time reverse transcriptase PCR (qRT-PCR) is a sensitive quantitative manner to monitor residual leukemia, evaluating levels of BCR-ABL1 transcripts. Undetectable levels of mRNA, however, can reflect either an effective elimination of leukemia cells, or the presence of quiescent leukemia stem cells transcriptionally silent.

We developed a novel highly sensitive method to identify quiescent leukemic cells through quantitative real-time PCR (Q-PCR) based on the DNA.

We monitored eight CML patients in the early chronic phase and in follow-ups up to 8 years under Imatinib treatment. We carried out patient specific Q-PCR assays to monitor minimal residual disease, testing the same samples in parallel by cytogenetic analysis and by standard qRT-PCR. In all positive samples for chimeric transcript we measured positive levels of corresponding genomic DNA. In 13% of samples, with undetectable levels of mRNA, we showed the persistence of quiescent leukemic cells with Q-PCR. Finally we showed a patient with undetectable levels of both mRNA and correspondent DNA in three several consecutive follow-ups during the last year.

In conclusion the DNA genomic Q-PCR is a sensitive and direct technique to identify quiescent leukemic cells and possible candidates to stop imatinib therapy.

Measurement of concentration of differentially fragmented DNA with commonly used methods

T. Sedlackova[1], *G. Repiska*[1], *G. Minarik*[1,2];
[1]Comenius University in Bratislava Faculty of Medicine, Bratislava, Slovakia, [2]Geneton, Ltd., Bratislava, Slovakia.

Introduction: Circulating nucleic acids are curently studied as potential diagnostic markers of oncological diseases as well as in relation to preeclampsia pathogenesis. Fragmentation and concentration are limiting characteristic features of circulating nucleic acids. Aim of our study was to determine possible impact of DNA fragmentation on measurement of DNA concentration.

Methods: DNA originated from blood of 10 volunteers was isolated using QIAamp® DNA Blood Mini Kit according to the manufacturers protocol. The DNA samples were fragmented by ultrasound with use of Covaris S220 to obtain DNA fragments with various length (150 - 1500 bp). DNA concentration was quantified with three methods: absorbance measurement at 260 nm, fluorescence measurement with PicoGreen® and qPCR with Alu based assay. DNA fragmentation was checked on agarose gel.

Results: DNA quantification with PicoGreen® was affected by degree of fragmentation. DNA concentration significantly decreased as the level of DNA degradation increased (p< 0,0001; F= 65,34). The A_{260}-based quantification was not influenced by the fragment length (p= ns). Regarding the qPCR measurement, DNA concentration of fragments with length above 500 bp was not affected by the fragmentation degree. However, concentration in samples with 150 bp fragments was significantly decreased (p< 0,0001; F= 55,61).

Conclusion: Our study showed, that accuracy of DNA quantification by fluorescence and qPCR depends on the level of DNA fragmentation, while the spectrophotometric measurement of DNA concentration is not affected by DNA fragmentation. Therefore, non-fragmented DNA should be quantified, especially when short fragments are crucial for downstream applications (for example next generation sequencing).

Classic Hodgkin lymphoma (cHL) is a lymphoid malignancy characterized by the presence of Reed-Sternberg cells. Approximately 40-60% of cHL have been associated with Epstein-Barr virus (EBV) infection. Transcription factors of the B lineage are not expressed in RS cells but these may express other markers of hematopoietic cell lines. In an effort to identify the participation of Pax5, NOTCH1 and the latent state genes of EBV involved in the cHL oncogenic process, 58 lymph node samples of Mexican pediatric patients were analyzed. Detection and genotyping of EBV was performed by PCR and in situ hybridation. Expression of NOTCH1, Pax5 and LMP1B was identified by immunohistochemistry and immunofluorescence. NOTCH1 expression was detected in 85.3% of cHL cases. 80% of cases of cHL were positive for EBV, B subtype had the highest presentation. With these results we concluded that RS cells have an aberrant immunophenotype in comparison to their cells of origin (B lymphocytes), due to molecular mechanisms involved in the loss of expression of transcription factors of B lineage (Pax5). The expression of LMP1 and LMP2 that constitutively activate Notch1 signaling pathway, induces changes in the identity of B cells, a mechanism suggested in animal models and cell lines. The presence of B subtype in the majority of the cases may suggest a poor prognosis, as it enhances proliferation and immortalization of RS cells. We identified 4 cases with A and B subtypes in the same sample, which is very interesting since this has only been reported in HIV patients.

P06.062

Role of VHL gene mutations and loss of heterozygosity in human renal cell carcinoma development in patients from Bashkortostan Republic of Russia

***I. Gilyazova**[1], L. Kutlyeva[1], R. Khusainova[1,2], A. Zagidullin[2], A. Khaliullin[2], E. Klimentova[3], A. Shafigina[3], V. Pavlov[2], E. Khusnutdinova[1];*

[1]Institute of Biochemistry and Genetics,Ufa Science Centre, RAS, Ufa, Russian Federation, [2]Bashkir State Medical University, Ufa, Russian Federation, [3]Bashkir State University, Ufa, Russian Federation.

Von Hippel-Lindau (VHL) tumour suppressor gene inactivation is associated with clear cell renal cell carcinoma (ccRCC)development. The aim of the study was to provide the analysis of *VHL* inactivation in ccRCC tumors and to evaluate relationships between *VHL* inactivation and tumor hystopathological characteristics. *VHL* genetic inactivation was examined among 92 sporadic ccRCC cases from Bashkortostan Republic using SSCP-analysis followed by Sanger sequencing of *VHL* gene. Besides, loss of heterozygosity (LOH) studies were performed using microsatellite markers (*VHL - D3S1038* and *D3S1317*, *RASSF1 - D3S966* and *D3S1568*, *FHIT - D3S1234* and *D3S1300*) of region 3p12-p26 on paired normal-tumor tissues. Analysis of microsatellite markers of *VHL* gene revealed deletions in 32,5% of ccRCC, *RASSF1* - 30,4%, *FHIT* - 22,6%. *VHL* and *RASSF1* gene deletions frequency was almost equal in groups with stages I, II and III,IV. *FHIT* gene deletions frequency was higher in patients with stages I and II (P=0,008). *VHL* mutations were revealed in 20 tumor tissues. Not a single normal tissue had *VHL* mutations. The majority of mutations were deletions reported previously and touching HIF binding β-domain. We have also detected *VHL* deletions in the 1st and 2nd exons haven't been described previously: c.185_195del(p.Val62_Ser65del), c.216_228del (p.Gln73_Phe76del), c.402_407del (p.Leu135_Phe136del). It is known that exon 2-encoded residues are involved in two functions: substrate protein recognition and transcription-dependent nuclear/cytoplasmic trafficking. We also found 6 undescribed deletions in the third *VHL* exon; their roles are to be determined. It is supposed that different domain mutations inactivate *VHL* function differently that may reflect clinical outcome.

P06.063

Identification of germline alterations in the cancer predisposing gene *CDH1* in patients with orofacial clefts

***I. Vogelaar**[1], J. Figueiredo[2], I. van Rooij[1], S. Melo[2], C. Carels[1], R. van der Post[1], J. Simoes-Correia[3], R. Seruca[2], M. Ligtenberg[1], N. Hoogerbrugge[1];*

[1]Radboud University Nijmegen Medical Center, Nijmegen, Netherlands, [2]Institute of Molecular Pathology and Immunology of the University of Porto, Porto, Portugal, [3]Institute for Biomedical Research in Light and Image, Faculty of Medicine, University of Coimbra, Coimbra, Portugal.

CDH1 mutation carriers have a lifetime risk of hereditary diffuse gastric cancer (HDGC) up to 80% and in addition females have a lifetime risk of lobular breast cancer up to 60%. Furthermore, an association between *CDH1* mutations and orofacial clefts (OFC) has been observed, suggesting that E-cadherin, the protein encoded by *CDH1*, is involved in lip and palate development. *CDH1* is a reasonable candidate gene for OFC because E-cadherin plays an important role in cell adhesion and the protein is expressed in the lip and palate region during the critical stages of embryonic development.

To determine whether *CDH1* is a susceptibility gene for OFC and to assess whether *CDH1* mutation screening in OFC patients allows identification of families at risk for HDGC, direct sequencing of the full coding sequence of *CDH1* was performed in a cohort of 56 children with different types of non-syndromic OFC. Two putative pathogenic variants, c.1108G>T (p.(Asp370Tyr)) and c.2413G>A (p.(Asp805Asn)) were detected in two patients. Functional assays on these variants are currently ongoing.

In conclusion, two putative pathogenic germline variants of the *CDH1* gene have been found in a cohort of 56 OFC patients. *CDH1* mutation screening in patients with OFC might increase the chance to identify individuals at risk for hereditary gastric and breast cancer whom could benefit from intensive clinical surveillance.

P06.064

TNIP1 is a novel fusion partner gene to PDGFRB in chronic myelomonocytic leukemia associated with eosinophilia

***S. Moshir**[1], T. von Kanel[1], N. Cantoni[2], A. Huber[1], B. Röthlisberger[1];*

[1]Center of laboratory medicine, division of medical genetics, Aarau, Switzerland, [2]Center of oncology/haematology, cantonal hospital Aarau, Aarau, Switzerland.

Gene fusions involving the catalytic domain of Tyrosine Kinases (TKs) are found in a variety of haematological malignancies. A significant minority of patients with Clonal Eosinophilia carry abnormal gene fusions linking *PDGFRA*, *PDGFRβ*, and *FGFR1*. Rearrangements of Platelet Derived Growth Factor Receptor beta (*PDGFRβ*), a Transmembrane Tyrosine Kinase receptor, are rare but recurrent in patients with Eosinophilia-associated Atypical Myeloproliferative Neoplasie (Eos-MPNs). Using fluorescence in situ hybridization (FISH) we found a cryptic deletion of *PDGFR*β (5q33-34) in a MPN patient with abnormal Eosinophilia. Array CGH in bone marrow tissue confirmed the deletion and led to identification of *tumour necrosis factor α-induced protein 3-interacting protein 1 (TNIP1)* as fusion partner. In a next step, we characterized the genomic breakpoints by gap-PCR and sequencing, revealing that the fusion gene comprises *TNIP1* exons 1 to 12 and *PDGFR*β exons 12 to 23. If accurately spliced, this fusion gene does not contain premature stop codons, and the catalytic domain of *PDGFR*β is fully maintained. Reverse transcription PCR and quantitative PCR finally revealed that the fusion gene is expressed both in the bone marrow and in the blood sample of the patient.

To our knowledge, this is the first report of a *TNIP1-PDGFR*β fusion gene. Patients with *PDGFR*β fusions genes are excellent candidates for treatment with Tyrosin Kinases inhibitors (TKI). The patient is currently treated with Imatinib (400 mg/day).

P06.065

Frequency of germ line MUTYH mutations in patients diagnosed with colorectal cancer in Castilla y León (Spain).

*M. Tascón[1], L. Pérez-Cabornero[1], M. Infante[1], E. Velasco[1], E. Lastra[2], G. Marcos[3], E. Esteban-Cardeñosa[1], C. Miner[1], **M. Durán**[1];*

[1]IBGM, Valladolid, Spain, [2]Oncología Médica, Hospital General Yagüe, Burgos, Spain, [3]Oncología Médica, Hospital Rio Hortega, Valladolid, Spain.

MUTYH-associated polyposis (MAP) is an autosomal recessive cancer predisposition syndrome associated with the development of colorectal tumors and colonic polyps at an early age. MAP syndrome is associated to germline biallelic mutations in the MUTYH gene which lead to deficient DNA repair through the base-excision repair system and accumulation of G:C→T:A transversions. Occurrence of such mutations in oncogenes and tumor suppressor genes drives colorectal carcinogenesis and is associated with the development of colonic polyps. The aim of this study was to assess the frequency of germline MUTYH mutations in patients with MAP and other hereditary colorectal cancer (CRC) phenotypes. A total of 30 patients were included. Samples were screened for the MUTYH germline mutations by capillary array electrophoresis (HA_CAE) method. In all mutation-positive cases, results were confirmed by sequencing. Biallelic germline MUTYH mutations were identified in 2 of 30 (6.6%) patients with a phenotype of hereditary colorectal cancer. Besides, four monoallelic variants were detected in different samples that are described in LOVD database (MUTYH_00078, MUTYH_00005, MUTYH_00063, MUTYH_00086). A genotype-phenotype correlation has found in these patientns. Germline MUTYH mutation screening should be considered in the differential diagnosis of hereditary colorectal syndromes, we are considering the validity and applicability of MUTYH mutation screening in our population.

P06.066

Pharmacogenetic Markers Associated with Adverse Events in Colorectal Cancer patients treated with 5-FU prodrugs

K. Toome[1], A. Mägi[2], H. Roomere[1], J. Jaal[2];
[1]Asper Biotech, Tartu, Estonia, [2]Tartu University Hospital, Tartu, Estonia.

Intravenous fluorouracil (5-FU) has been used for the treatment of colorectal cancer over 40 years. Lately, oral 5-FU prodrugs have been additionally developed. However, only a fraction of the administred capecitabine reaches its target cells and is transformed into active metabolites which cause permanent inhibition of the enzyme thymidylate synthase (TYMS) and further DNA synthesis. Polymorphisms in TYMS and MTHFR genes presumably affect the clinical response of 5-FU.

Retrospective pharmacogenetic study was performed to investigate germline polymorphisms of the two genes involved in fluorouracil pathway and their potential association with toxicities in patients treated with capecitabine.

The germline DNA of 36 patients treated with capecitabine was genotyped for two variants (677C>T; 1298A>C) in MTHFR gene and one variant in TYMS (28-bp tandem-repeat) gene. The 28-bp tandem-repeat was genotyped by PCR amplification to discriminate between 2R and 3R alleles, PCR fragments were separated by eletrophoresis on 2.5% agarose gels. MTHFR polymorphisms were genotyped using APEX based microarray.

Adverse events were more frequent in patients heterozygoys for TYMS 2R/3R. Patients carrying the 1298C/C genotype had a low risk of developing side effects compared to patients with the A/C or A/A genotype when treated with capecitabine. Similarly, diplotype (CA-CA) showed a negative effect on the incidence of adverse events. In contrast, MTHFR haplotype (677C-1298C) showed a protective effect.

In conclusion, in colorectal cancer patients, the incidence of side-effects induced by capecitabine might be genetically predicted. However, these preliminary findings must be confirmed in larger and prospective clinical studies.

P06.067

Genetic Screening of Colorectal Cancer Patients to Detect Hereditary Colorectal Cancer Syndromes in Estonian Population

M. Kask[1], K. Toome[2], J. Jaal[3], J. Soplepmann[3], V. Afanasjev[3], P. Laidre[3], T. Erm[3], K. Raime[2], K. Vaidla[2], H. Roomere[2];
[1]The University of Tartu, Tartu, Estonia, [2]Asper Biotech, Tartu, Estonia, [3]Tartu University Hospital, Tartu, Estonia.

About 700 new colorectal cancer cases are diagnosed in Estonia annually, which places the incidence of colorectal cancer to the third place of all cancer cases.

Aim of the study was to detect hereditary syndromes in patients diagnosed with colorectal cancer to improve screening strategy in Estonia and provide genetic testing and counceling to family members of the patients.

The study involved a systematic analysis of 180 patients diagnosed with colorectal cancer. MSI testing, BRAF V600E mutation detection, immunohistochemistry and mutation analysis of MLH1, MSH2, MSH6, PMS2, APC and MUTYH genes were performed. MSI and BRAF analyses were performed on tumors from all the patients. Based on revised Bethesda guidelines and the results of MSI and BRAF analyses, samples were chosen for IHC analysis and DNA sequencing of MLH1, MSH2, MSH6 and PMS2. Patients subjected to the sequencing of APC and MUTYH genes were chosen based on family history and histologically described polyposis. The analysis of family history and previous diseases revealed six patients with an indication for hereditary breast and ovarian cancer testing.

MSI-H and BRAF mutation were observed in 30 and 28 out of all cases, respectively. Several polymorphisms in MLH1 (13); MSH2 (11); MSH6 (10) and PMS2 (15) genes, and a few previously not described variants of unknown significance were found. Deleterious germline mutation was found in APC gene. One polymorphism was found in BRCA1, BRCA2, RAD51 and also in CHEK2 gene using Hereditary Breast and Ovarian Cancer Assay. Significance of these findings will be further evaluated.

P06.068

Association between 18q LOH and metastatic potential of colorectal cancer

M. Hiljadnikova Bajro[1], T. Josifovski[2,3], M. Panovski[2], A. J. Dimovski[1];
[1]Faculty of Pharmacy, University SS Cyril and Methodius, Skopje, The Former Yugoslav Republic of Macedonia, [2]University Clinic for Digestive Surgery, Medical Faculty, Ss. Cyril and Methodius University, Skopje, The Former Yugoslav Republic of Macedonia, [3]Clinical Hospital Sistina, Skopje, The Former Yugoslav Republic of Macedonia.

Background: Identification of genetic markers to complement clinicopathological evaluation in cancer diagnosis and selection of appropriate treatment is a major challenge for molecular oncology today. Loss of heterozigosity (LOH) at several chromosomal regions harboring tumor suppressor genes or oncogenes, is one of the most promising molecular markers with prognostic significance for colorectal cancer (CRC).

Aim: To evaluate the involvement of 18q LOH in colorectal carcinogenesis and its value as a prognostic molecular marker.

Materials and Methods: A total of 314 randomly selected patients undergoing colon and/or rectum resection for pathohistologically confirmed CRC were included in the study. LOH analysis was performed using fluorescence multiplex PCR with 4 microsatelite markers: D18S46, D18S58, D18S61 and D18S535, and subsequent capillary gel electrophoresis on AbiPrism310.

Results: LOH at 18q defined as loss at any of the evaluated markers is detected in 57% of tumor samples. Most efficient molecular marker is D18S46, conferring LOH status to 65% of cancers with this type of chromosomal instability. Cancers with 18q LOH are prone to development of distal metastases (OR=6.35, 95%CI=1.183-34.042, p=0.02), which is considered a pathohystological criterion for poor outcome. LOH at this chromosomal region is also associated with tumor size, though without statistical significance (p=0.25).

Conclusion: Our results identifying association between 18qLOH and development of metastases indirectly support the hypothesis that 18qLOH is a molecular marker of poor outcome in CRC. Further studies investigating the 5-year survival in our patients will be performed to confirm these findings and provide additional details for the observed association.

P06.069

Study of expression of cancer/testis Antigens PAGE4, SPANX, and SCP-1 as putative biomarkers to predict liver metastasis in colorectal cancer (CRC) in Iranian CRC patients

R. Molania[1,2], F. Mahjoubi[1], S. Khatami[2], B. Mahjoubi[3];
[1]National Institute of Genetic Engineering and Biotechnology,Medical Biotechnology Division., Tehran, Islamic Republic of Iran, [2]Molecular Genetics Department, School of Science, Chamran University., Ahvaz, Islamic Republic of Iran, [3]Surgery Department, Rasoul Hospital., Tehran, Islamic Republic of Iran.

Cancer testis antigens (CTAs) are a large family of tumor-associated antigens that mainly express in testis and placenta and in some human cancers with different histological origin. CTAs are considered promising target molecules for early diagnosis, prognostic and immunotherapy.

In this study we aimed to employ conventional RT-PCR and Quantitative real-time RT-PCR to examined whether or not PAGE4, SPANX, SCP-1 antigens are express in colorectal tumors. In this regards, 70 tumor samples and adjacent normal tissues of patients with colorectal cancer were evaluated.

In this presentation we will discuss our data in regards to use of these CTAs as putative prognostic marker for liver metastasis in CRC patients.

P06.070

Identification and confirmation of DNA methylation markers for colorectal cancer testing

M. Hofner[1], W. Pulverer[1], M. Sonntagbauer[1], C. Noehammer[1], T. Bachleitner-Hofmann[2], G. Egger[2], A. Weinhaeusel[1];
[1]AIT - Austrian Institute of Technology GmbH, Vienna, Austria, [2]Medical University Vienna, Vienna, Austria.

Early diagnosis of colorectal cancer (CRC) is of high importance because prognosis for patients with CRC depends on stage at time of diagnosis. Thus there is great need to identify novel biomarkers for diagnostic improvements of CRC. Patients at risk for CRC are identified by screening programs using the FOBT (fecal occult blood test) which provides 61-96% sensitivity and 91-98% specificity. However recall rate due to many false positives are leading to unnecessary colonoscopy and anxiety. This causes also a high workload for confirmatory initial diagnosis by colonoscopy. There remains a need for a minimally invasive, cost-effective procedure that could be used alongside FOBT screening and eventually prior colonoscopy to improve screening sensitivity. To improve CRC initial diagnosis we have elucidated a panel of candidate DNA methylation biomarkers from tissue DNA testing (tumors: n=18; normal tissue: n=18) using a targeted DNA methylation microarray. The top 24 candidates were then subjected to qPCR based confirmation of microarray data. DNA from blood (n=8) was also included in qPCR analyses; based on these data the minimal set of markers for perfect classification could be reduced to a single gene enabling 100% correct classification (AUC=1). Further we designed qMSP for bisulfite based confirmation of findings. By qMSP 96-100% of all different samples were classified correctly. Thus we have elucidated candidate markers which should be validated on different sample cohorts and might be good targets for minimal invasive CRC testing using cell free DNA from serum. Collaborations for validation of markers are envisioned.

P06.071
Intermediate- and low-methylation epigenotypes do not correspond to CpG island methylator phenotype (low and -zero) in colorectal cancer

*P. Karpinski[1], M. Walter[2], E. Szmida[1], D. Ramsey[3], B. Misiak[1], J. Kozlowska[1], M. Bebenek[4], Z. Grzebieniak[1], N. Blin[1], **M. M. Sasiadek**[1];*
[1]Wroclaw Medical University, Wroclaw, Poland, [2]University of Tuebingen, Tuebingen, Germany, [3]University of Limerick, Limerick, Ireland, [4]Lower Silesian Oncology Center, Wroclaw, Poland.

Most recent genome-wide studies on the CpG island methylation in colorectal cancer (CRC) have led to the discovery of at least three distinct methylation clusters. However, there remains an uncertainty whether the CRC clusters identified in these studies represent compatible phenotypes.

We performed comprehensive genome-scale DNA methylation profiling by Illumina Infinium HumanMethylation27 of 21 DNA pools that represent 84 CRC samples divided according to their high-, intermediate-, and low-methylation epigenotypes (HME, IME, and LME, respectively) and 70 normal-adjacent colonic tissues. We have also examined the relationship between three epigenotypes and chromosomal gains and deletions (assessed by Comparative Genomic Hybridization) in a group of 100 CRC samples.

HME subgroup showed features associated with CpG island methylator phenotype - high (CIMP-high) including methylation of specific CpG sites (CpGs) as well as significantly lower mean number of chromosomal imbalances when compared to other epigenotypes. IME subgroup displayed lowest number of methylated CpGs (717 versus 2399 and 2679 in HME and LME, respectively) and highest mean number of chromosomal imbalances when compared to HME ($p = 0.001$) and LME ($p = 0.004$). A comparison between the methylation profiles of three epigenotypes revealed more similarities between the HME and LME (1669 methylated CpGs overlapped) than HME and IME (673 methylated CpGs overlapped).

Our results provide evidence that IME and LME CRCs show opposite features to those that have been previously attributed to CIMP-low and CIMP-0 CRCs. These discrepancies should be considered when interpreting the data from a particular epigenotyping method.

P06.072
Tumor-specific age-dependent DNA methylation of RUNX3, CDKN2A and CACNA1G genes in colorectal cancer

***E. Hernández-Illán**[1], A. Castillejo[1], A. Martínez-Cantó[1], M. I. Castillejo[1], E. Irles[1], V. M. Barberá[1], R. Lázaro[2], E. Ochoa[3], J. L. Soto[1];*
[1]Hospital Universitario Elche, Elche, Spain, [2]Hospital La Plana Castellón, Villarreal, Spain, [3]Hospital Provincial Castellón, Castellón, Spain.

Promoter methylation of tumor suppressor genes has a crucial role in tumorigenesis. It is widely assumed that epigenetic alterations that accumulate during aging might be involved in aging-related pathologies. However, little is known about the cross-talk between aging and cancer in terms of DNA methylation.

We aimed to explore the association between the methylation status of marker genes in normal and tumor tissues with age in colorectal cancer (CRC) patients.

A cohort of 197 unselected CRC patients was studied (median age=71; range 30-94 years). Tumor (n=197) and normal (n=20) colon tissues were analyzed for the panel of eight markers used to assess the CpG Island Methylator Phenotype (CIMP): *RUNX3, CACNA1G, IGF2, MLH1, NEUROG1, CRABP1, SOCS1,* and *CDKN2A.* This study was approached by Methylation Sensitive MLPA. Microsatellite instability (MSI) and *BRAF* V600E mutation were also analyzed.

We found 22.84% (45/197) of tumors with CIMP+ (cutoff: five positive markers); 5.08% (10/197) with *BRAF* mutation and 9.64% (19/197) with MSI. None of the 20 matched normal tissues analyzed from patients with CIMP+ tumors showed significant methylation (10 patients older and 10 younger than the median age). CIMP+ tumors were associated to older patients (OR=2.23; p=0.022); proximal location (p=0.002); *BRAF* mutation (p<0.001) and MSI (p<0.001). Tumor methylation age-dependent was given by *RUNX3* (OR=3.53; p<0.001); *CDKN2A* (OR=2.26; p=0.007) and *CACNA1G* (OR=2.46; p=0.018).

Our results suggest that methylation at *RUNX3*, *CDKN2A* and *CACNA1G* genes is tumor specific and age dependent in CRC patients. The epigenetic landscape of CRC might be different depending on patient age.

P06.073
A DNA methylation survey of 117 tumor samples and corresponding normal controls revealed more than 640 genes aberrantly methylated in colorectal cancer

***J. Kolarova**[1], J. Gutwein[1], O. von Kampen[2], C. Schafmayer[3], H. Kalthoff[4], J. Hampe[2], R. Siebert[1], O. Ammerpohl[1];*
[1]Institute of Human Genetics, Christian-Albrechts-University Kiel, Kiel, Germany, [2]Institute of Internal Medicine I, Christian-Albrechts-University Kiel, Kiel, Germany, [3]Department of General and Thoracic Surgery, Christian-Albrechts-University Kiel, Kiel, Germany, [4]Institute for Experimental Oncology, Christian-Albrechts-University Kiel, Kiel, Germany.

Colorectal carcinoma (CRC) is still a leading cause for cancer related death in the western world [1]. At molecular level colorectal carcinoma is characterized by both, genetic aberrations and extensive alterations in the gene expression pattern.

Epigenetic mechanisms and particularly DNA methylation are well known to contribute to the stability of the genome and to the establishment of tissue specific gene expression patterns [2]. Consequently, alterations in the methylome are a typical hallmark of cancer, contributing the malignant phenotype, e.g. in CRC [3].

In this study we included genomic DNA isolated from 117 CRC tissue samples and the corresponding control tissue from the same patients. Detailed clinical, histological as well as molecular data (e.g. age at diagnosis, treatment regimen, MSI status) were available from all patients.

Within the BMBF funded NGFN-Network „Integrated genomic investigation of colorectal carcinoma" we used Illumina's HumanMethylation450k BeadChip to identify genes aberrantly methylated in CRC as compared to normal colon tissue. This array is designed to assay the methylation status of 485,577 CpG loci in parallel.

By this approach we have identified more than 1,380 CpG loci corresponding to more than 640 genes aberrantly methylated in CRC. Furthermore, hierarchical cluster analysis based on these loci separated the samples into two different CRC subentities and the controls. The putative use for diagnostic, prognostic or therapeutic purposes is currently under investigation.

Dual blockade of IGF-IR and EGFR sensitizes colorectal cancer cells to 5-FU-based radiochemotherapy

***S. Kaulfuß**[1], H. Seemann[1], R. Oberthür[1], J. Scharf[2], P. Burfeind[1];*
[1]Institute of Human Genetics, Göttingen, Germany, [2]Department of Internal Medicine, HELIOS-Klinikum, Erfurt, Germany.

Receptor tyrosine kinases (RTKs) are known to be key players in the development of colorectal cancer (CRC). Recently, we could show that inhibition of the RTKs insulin-like growth factor-I receptor (IGF-IR) and epidermal growth factor receptor (EGFR) in CRC cells by siRNA approach or by small molecule inhibitors NVP-AEW541 and erlotinib, respectively, results in decreased proliferation and induction of apoptosis, with having additive effects when both receptors were blocked simultaneously. In the present study we analysed the effect of RTK inhibition in the context of 5-Fluorouracil-based radiochemotherapy (RCT). Inhibition of IGF-IR and EGFR using NVP-AEW541 and erlotinib results in a sensitization of CRC cells (DLD-1, SW837 and Caco-2) to RCT and a poor survival in therapy treatments. In addition, dual blockade of both receptors in CRC cells enhanced the therapy success. To identify the molecular mechanisms underlying this sensitization of CRC cells we analysed the DNA repair mechanisms. Phospho-H2AX staining as marker for double strand breaks revealed impairment of DNA repair in single inhibitor treatments 24h after RCT and even more pronounced effects were observed when both receptors were inhibited simultaneously. Furthermore, we could show using proximity ligation and co-immuoprecipitation assays that IGF-IR and EGFR form heterodimers in CRC cells in a ligand-dependent manner. Taken together, these results indicate that the RTKs EGFR and IGF-IR play important roles in the resistance of CRC patients to neoadjuvant RCT and that simultaneous treatment of RCT resistant patients with a combination of RTK inhibitors can circumvent these problems.

KRAS mutation genotypes and prometer methylation of tumor suppressor genes in cancer tissue and peripheral blood in colorectal cancer patients

***F. Ozen**[1], N. Kocak[2], C. Ulasoglu[3], &. Sezgin[4], A. Colak[5], O. Ozdemir[6];*
[1]Medeniyet University Göztepe Training and Research Hospital, Medical Genetics, Istanbul, Turkey, [2]Konya Selçuk University Medical Faculty, Konya, Turkey, [3]Medeniyet University Göztepe Training and Research Hospital, Gastroenterology, Istanbul, Turkey, [4]Sivas Cumhuriyet University, Medical Faculty, Medical Genetics, Sivas, Turkey, [5]Sivas Cumhuriyet University , Medical Genetics, Sivas, Turkey, [6]18 Mart University Medical Tıp Faculty, Medical Genetics, Canakkale, Turkey.

Objective: The aim was to evaluate the value of testing KRAS mutation genotypes and methylation of tumor suppressor genes(TSG) in peripheral blood samples besides colorectal cancer tumor tissue.

Materials and Methods: The promoter methylation status of TSG in tumor tissue and peripheral blood samples in 89 colorectal cancer patients (32F/57M) were evaluated by sodium bisulfite conversion and DNA amplification with methylation specific multiplex PCR technique.Also, KRAS in codons 12 and 13 were analyzed for possible genotypic mutations.

Results:TSG was inactivated in 6 samples in 32 females and 11 of 57 males in peripheral blood ($p>0.05$).Testing of tumor tissue revealed a positivity of TSG inactivation in 17 females and 29 males ($p>0.05$).KRAS mutation was present in 7 females and 22 males in blood samples ($p>0.05$) and 20 vs 36 for females and males,respectively in biopsy specimen. Overall KRAS mutation or TSG inactivation was 8/32 vs 27/57 for females and males ($p<0.02$). Total alterations were 82% vs 41.5% for tissue and blood,respectively ($p<0.001$). Total mutant KRAS ratio in tissue was 63%.

Conclusion: Genes exhibit tumor suppressor activities in tissue and peripheral blood samples. The treatment choice depending on these results should be further evaluated.Screening KRAS and inactivated TSG from tumoral and blood samples may give clinical clues. Mutation or inactivation over 80% and significant gender difference need to be verified by large series.

Interlaboratory comparison of the *K-ras* mutation testing techniques

F. A. Amosenko[1,2], *I. V. Karpov*[3], *V. A. Shamanin*[3], *S. P. Kovalenko*[3], *L. N. Lyubchenko*[2], *A. V. Polyakov*[1];
[1]*Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation,* [2]*N.N. Blokhin Cancer Research Center, Russian Academy of Medical Sciences, Moscow, Russian Federation,* [3]*Laboratory of Gene Diagnostics Ltd, Novosibirsk, Russian Federation.*

Treatment of metastatic colon cancer with the anti-EGFR antibodies, cetuximab and panitumumab, is reported to be ineffective in carcinomas with *K-ras* point mutations in codons 12 or 13. We compared four the most frequently used methods for *K-ras* testing: ACRS, SSCP, allele-specific RT PCR and Sanger sequencing in clinical practice. Samples from 62 colorectal cancer patients (frozen tissues after manual dissection) were tested in different laboratories.

The results, received with ACRS, SSCP and allele-specific RT PCR have coincided for 59 carcinomas (95.2 %). To investigate the apparent discrepant results between these methods for three samples we used commercial TheraScreen KRAS Kit (DxS Ltd, Manchester, England). Specificity and sensitivity of allele-specific RT PCR were 100 % (34/34) and 96.4 % (27/28) respectively and with the use of ACRS or SSCP- 94.1 % (32/34) and 100 % (28/28) respectively. Falsely positive findings were absent with allele-specific RT PCR, but were discovered in two cases with ACRS or SSCP analysis (5.9 %). The single falsely negative result was received with allele-specific RT PCR (3.6 %). Sensitivity of direct sequencing was significantly lower than with the use of ACRS, SSCP or allele-specific RT PCR: 78.6 % (22/28).

Allele-specific RT PCR, ACRS and SSCP showed high and similar diagnostic sensitivity and specificity (from 94 to100 %) for the studied series of samples. These techniques are able to detect somatic *K-ras* mutations in DNA samples when the mutant DNA represents at least 5 % of total DNA.

P06.077

miR-21 expression in tumor tissue progressively increases during the development of colorectal cancer

N. Matevska[1], *A. Eftimov*[1], *T. Josifovski*[2], *N. Jankulovski*[3], *M. Panovski*[2], *A. J. Dimovski*[1];
[1]*Center for Biomolecular Pharmaceutical Analyses, Faculty od Pharmacy, Skopje, The Former Yugoslav Republic of Macedonia,* [2]*University Clinic for Abdominal Surgery, Faculty of Medicine, Skopje, The Former Yugoslav Republic of Macedonia,* [3]*Universtiy Clinic for Abdominal Surgery, Faculty of Medicine, Skopje, The Former Yugoslav Republic of Macedonia.*

MicroRNAs (miRNAs) are endogenously expressed noncoding RNAs with important posttranscriptional regulatory functions. Recent data suggest that miRNAs may play significant roles in carcinogenesis.The aim of this study was to identify the differential miRNA expression patterns associated with colorectal cancer (CRC) in Republic of Macedonia and to evaluate their diagnostic and/or prognostic potential. We assessed the expression levels of eleven miRNAs (miR-17-3p,miR-18a,miR-20a,miR-21,miR-92a,miR-106a,miR-125b,miR-137,miR-143,miR-145 and miR-200c) in 89 CRC and 40 normal colon tissues. We observed statistically significant up-regulation of miR-18a, miR-20a, miR-21 and miR-200c and down-regulation of miR-145 in CRC compared to normal mucosa ($p<0.001$). Multivariate analysis showed that miR-20, miR-21 and miR-145 are independent variables for discrimination between normal and tumor tissues ($p<0.001$). Combination of the later three miRNAs as biomarkers for diagnosis increases the power of the test and enables higher accuracy for overall correct classification (95.35%) compared with their separate use (86.05%, 89.92% and 67.44% respectively). Furthermore, we found higher miR-21 expression levels in microsatellite and chromosomal stable tumors ($p=0.039$) which suggests the possibility for distinct mechanism in CRC etiopathogenesis mediated by dysregulation of proto-oncogene miRNAs that predominantly occurs in MSI-/CIN-/CIMP-tumors. In addition, our results indicate correlation between the miR-21 expression levels and CRC clinical stage ($p<0.001$). The expression of miR-21 progressively increases with average fold-change of 1.79, 5.65, 11.59 and 33.85 (stage I,II,II and IV respectively) compared to the control group. This illustrates the potential use of miR-21 expression levels in providing higher accuracy of staging on initial biopsies and identifying candidates for more aggressive initial therapies.

Mismatch repair-deficient colorectal cancers (CRC) display widespread instability at DNA microsatellite sequences (MSI). Although MSI has been reported to commonly occur at coding repeats, leading to alterations in the function of a number of genes encoding cancer-related proteins, nothing is known about the impact such a process could have on microRNAs. In miRbase V15, we identified few human microRNA genes with mono- or di-nucleotide repeats (n=27). Out of the 24 microRNA genes successfully studied, 15 were found unstable in a large series of MSI CRC cell lines and primary tumors. Frequencies of instability ranged from 2.5% to 100%. Following a maximum likelihood statistical method, microRNA genes were separated into two groups that differed significantly in their mutation frequencies and in their tendency to represent mutations that may be or not under selective pressures during MSI tumoral progression. The first group included 21 genes that displayed no or few mutations in CRC. The second group contained 3 genes with frequent (≥80%) and sometimes bi-allelic mutations in MSI tumors. For *hsa-mir-1303*, the only miR expressed in colonic tissues, no direct link was found between the presence or not of mono or bi-allelic alterations and the levels of mature miR expression in MSI cell lines. Any impact MSI might have on the reliable processing of *hsa-miR-1303*, and potentially the production of mutant miRs is still to be determined. Overall, our results provide evidence that DNA repeats contained in human miRNA genes are relatively rare and preserved from MSI mutations in MMR-deficient cancer cells.

Introduction

The success of a treatment with monoclonal antibodies (mAB) or „small molecules" (e.g. tyrosine kinase inhibitor, TKI) depends on the mutational status of tumor-relevant genes in solid tumors (tab.1).

Materials and Methods

NGS is applied for mutational screening (tab.1) in 40 CRC, 34 NSCLC, 2 Melanoma, 2 GIST. DNA was isolated from FFPE-tumor tissue, amplicons (300bp) were prepared and multiplex identifiers (MID) were added manually. After purification, the pooled library was sequenced using the GS junior (454 Life Sciences, Branford, CT, USA) with an aimed coverage of 1000-fold.

Results

17/40 CRC showed a *KRAS*-mutation, 5/40 CRC a *BRAF*-mutation. Both GISTs had a *c-KIT*-mutation. In 9/34 NSCLC an *EGFR*-mutation could be detected and another three had a *KRAS*-mutation. One melanoma showed a *KRAS*-mutation. Some of these mutations only could be detected due to the high coverage.

Conclusion

Our data show that NGS is a feasible method in routine molecular pathology to examine mutational status of tumor-relevant genes in a cost effective and comprehensive manner. In contrast, conventional capillary sequencing techniques often lack the sensitivity and cost effectiveness to detect tumor mutations occurring at less than 20% frequency. With 454-sequencing, mutations can be detected against a wildtype-background of 95% (Coverage 1000x), which is very important in solid tumors. With NGS, we were able to improve our mutation detection rate, an important step towards personalized medicine.

[1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [2]Technische Universitat Dresden, Dresden, Germany.

Childhood colorectal cancer (CCRC) is a rare condition, mainly characterized by non-polyposis, microsatellite-stable tumors with a higher frequency of signet ring cell histology than in adults, suggesting a different biology. In many patients the genetic cause remains unknown.

We performed whole exome sequencing on germline DNA of four children with CRC, diagnosed between age 13 and 15. Per patient, we validated an average of 45 candidate pathogenic variants by Sanger sequencing , and tested parental DNA to reveal the modes of inheritance.

In one child a paternal *BRCA2* mutation and a maternal change in *PARP1* were identified. The co-occurrence of these two mutations appears relevant, since both proteins are involved in DNA repair. The second patient, a child of distantly related parents, carried a homozygous *SEC31B* variant. In yeast, Sec31p is involved in cell cycle progression and therefore might play a role in cancer development. *De novo* mutations were identified in two patients, affecting highly conserved protein-coding positions in *CCDC13*, a gene with unknown function and in the RAS pathway gene *SOS2,* respectively. In the latter patient, *in vitro* expression of this mutant in HEK293 cells revealed an increase of RAS activity, suggesting a gain-of-function effect.

Our data indicate that exome sequencing is a powerful tool for unraveling genetic predisposition in CCRC, which turns out to be a heterogeneous condition with different models of inheritance. Elucidating the genetic cause of CCRC will facilitate decisions on surveillance of patients and relatives and might reveal new treatment targets.

TGFBR1 Intralocus Epistatic Interaction as a Risk Factor for Colorectal Cancer

A. Martínez-Cantó[1], *A. Castillejo*[1], *T. Mata-Balaguer*[1], *M. I. Castillejo*[1], *E. Hernández-Illán*[1], *E. Irles*[1], *V. M. Barberá*[1], *C. M. Egoavil*[1], *C. Guarinos*[2], *C. Alenda*[3], *E. Ochoa*[4], *R. Lázaro*[5], *S. Fajardo*[1], *J. Lacueva*[6], *R. Calpena*[6], ***J. L. Soto***[1];
[1]Molecular Oncology Group. Elche University Hospital, Elche, Spain, [2]Research Unit. Alicante University Hospital, Alicante, Spain, [3]Pathology Department. Elche University Hospital, Elche, Spain, [4]Molecular Biopathology Unit. Castellon Provincial Hospital, Castellon, Spain, [5]Pathology Department. La Plana Hospital, Villareal, Spain, [6]Surgery Department. Elche University Hospital, Elche, Spain.

In colorectal cancer (CRC), an inherited susceptibility risk affects about 35% of patients, whereas high-penetrance germline mutations account for < 6% of cases. A considerable proportion of sporadic tumors could be explained by the coinheritance of multiple common low-penetrance variants. We assessed the susceptibility to CRC conferred by 14 polymorphisms and the allele-specific expression (ASE) of *TGFBR1* in a case-control designed study (504 controls and 521 patients with sporadic CRC). Polymorphisms were genotyped with the iPLEX Gold (MassARRAY-Sequenom) technology. Descriptive analyses of the polymorphisms and association studies were performed with the SNPator workpackage. No relevant associations were detected between individual polymorphisms or haplotypes and the risk of CRC. The *TGFBR1**9A/6A polymorphism was used for the ASE analysis by fragment analysis using cDNA from normal tissue. The relative level of allelic expression was extrapolated from a standard curve. ASE was found in 25.4% of patients and 16.4% of controls. No significant differences between the ASE values of patients and controls were identified. Interestingly, a combined analysis of the polymorphisms and ASE for the association with CRC occurrence revealed that ASE-positive individuals carrying one of the most common haplotypes (H2: 20.7%) showed remarkable susceptibility to CRC (RR: 5.25; 95% CI: 2.547-5.250; p < 0.001) with a synergy factor of 3.7. In our study, 54.1% of sporadic CRC cases were attributable to the coinheritance of the H2 haplotype and *TGFBR1* ASE. These results support the hypothesis that the allelic architecture of cancer genes, rather than individual polymorphisms, more accurately defines the CRC risk.

P06.083

Constitutional mismatch repair-deficiency syndrome and high-grade brain tumors in siblings with biallelic MSH6 mutations

D. Ilencikova[1], *D. Sejnova*[2], *L. Kovacs*[1], *P. Babal*[3];
[1]II. Pediatric Department of Children University Hospital, Comenius University, Bratislava, Slovakia, [2]Department of Pediatric Oncology, Faculty of Medicine, Comenius University – Medical School and University Children´s Hospital, Bratislava, Slovakia, [3]Department of Pathology, Faculty of Medicine, Comenius University, Bratislava, Slovakia.

Constitutional mismatch repair-deficiency syndrome (CMMR-D) is a rare autosomal recessive disease, first reported in 1999. It is characterized by hematological malignancies, brain tumors and tumors of the large intestine with an early formation. Skin maculae with diffuse margins and irregular pigmentation are similar to *café au lait* present in neurofibromatosis 1, and they may occur together with hypopigmented areas. Development of this syndrome is caused by biallelic mutations in genes that are associated with Lynch syndrome (hereditary non-polyposis colorectal cancer - HNPCC). *MLH1, MSH2, MSH6* and *PMS2* genes belong to the mismatch repair system and play a basic role in the genome integrity. In the heterozygous state, the mutation of one of these genes causes HNPCC. Biallelic mutations of the aforementioned genes are characterized by occurrence of the first malignancies (brain tumors, leukemias) at the age of 2 and occurrence of other types of tumors with increasing age. *Wimmer* and *Kratz* summarized data from 52 reports covering 92 CMMR-D patients and performed genotype-phenotype correlation output from the last 12 years. We present a case with CMMR-D caused by novel homozygous *MSH6* mutations leading to gliomatosis cerebri and T-ALL in an 11-year-old female and glioblastoma multiforme in her 10-year-old brother, both with rapid progression of the diseases. A literature review on brain tumors in CMMR-D families shows that they are treatment-resistant and lead to early death. Identification of patients with CMMR-D is critical, and specific cancer screening programs with early surgery are recommended.

P06.084

Lack of association between ERCC2 K751Q polymorphism and thyroid cancer risk

J. Hoppe-Gołębiewska[1], *S. Hryhorowicz*[2], *M. Kaczmarek-Ryś*[1], *L. Jakubowska-Burek*[3], *K. Ziemnicka*[4], *J. Sowiński*[4], *R. Słomski*[1,5];
[1]Institut of Human Genetics, Polish Academy of Sciences, Poznań, Poland, [2]The Nanobiomedical Center, Poznań, Poland, [3]Department of Gastroenterology, Human Nutrition and Internal Diseases, University School of Medical Sciences, Poznań, Poland, [4]Department of Endocrinology and Internal Diseases, University School of Medical Sciences, Poznań, Poland, [5]Department of Biochemistry and Biotechnology, University of Life Sciences, Poznań, Poland.

Thyroid carcinomas belong to tumors with well prognosis, slow progress and low benignity but with tendency to recurrences and regional or remote metastasis. Papillary and follicular thyroid cancer are the most frequent in endocrine system with unidentified genetic background.

In this focus searching for molecular markers of disease course, good or poor prognosis and response on medical treatment is fundamental. It is expected that SNP polymorphisms research in genes demonstrating association with neoplastic diseases will be helpful in understanding of molecular mechanisms of thyroid gland tumors development and allow to better diagnosing.

The published data on the association ERCC2 K751Q polymorphism with cancer remained controversial.

We analyzed polymorphism K751Q in ERCC2 gene (c.2251A>C, rs13181) in group of 451 Polish patients with differentiated thyroid cancer and 560 individuals from Polish population. Sequence variants were determined by pyrosequencing.

We didn't observed significant differences in allele frequencies in patient with thyroid cancer and population group (p=0,64). In DTC patient group allele A was present with frequency 0,61 and allele C with frequency 0,39. In population frequency for allele A was 0,59 and for allele C 0,41.

Spontaneous and dioxidine-induced DNA damage in cultured human multipotent mesenchymal stromal cells and peripheral blood lymphocytes

A. Chausheva*, V. Nikitina, E. Voronina, S. Smirnikhina, A. Zhanataev;*
Federal State Budgetary Institution "Research Centre for Medical Genetics" of the Russian Academy of, Moscow, Russian Federation.

Numerous studies have shown the possibility of genetic transformation of multipotent mesenchymal stromal cells (MSC). The DNA damage can lead to chromosomal abnormalities and gene mutations associated with risk of malignization. To determine the genetic stability and sensitivity of MSCs to the ROS-mediated DNA-damage, we have studied spontaneous and dioxidine-induced DNA damage in cultured human MSCs from adipose tissue and compared it with cultured peripheral blood lymphocytes.

Dioxidine is a mutagen with prooxidative type of genotoxic action. The peripheral blood lymphocytes from 5 healthy donors and MSCs from adipose tissue of 8 healthy donors were exposed during 24 h to dioxidine in concentrations 0.01mg/ml and 0.1mg/ml. The levels of DNA damage have determined as %tail DNA in alkaline comet assay.

The mean value of spontaneous DNA damage in cultured lymphocytes was higher than that in cultured MSCs (7.7±0.5% vs. 4.8±0.5 %DNA in tail, p≤0.05). The mean values of dioxidine-induced DNA damage in concentration of 0.01 mg/ml were 10.9±0.70 % DNA in tail in the lymphocytes and 13.0±0.9 %DNA in tail in MSCs. After the exposure to dioxidine in concentration of 0.1 mg/ml, 17.1±1.9 %DNA in tail in the lymphocytes and 16.7±2.0 %DNA in tail in MSCs were observed. So, although end-point values of genotoxic effect of dioxidine was similar for both type of cells (p>0.05), MSCs showed greater sensitivity, particularly when agent in lower concentration was used.

In conclusion, spontaneous level of DNA damage in the MSCs was lower compared with lymphocytes, but MSCs indicated higher response to ROS-mediated DNA-damage.

Dioxidine influence on whole-genome methylation status in peripheral blood lymphocytes in vitro

S. A. Smirnikhina[1]*, E. S. Voronina*[2]*, L. D. Katosova*[2]*, V. I. Platonova*[2]*, A. V. Lavrov*[2]*;*
[1]*Federal State Budgetary Institution ï¿½Research Centre for Medical Geneticsï¿½ of the Russian Academy of, Moscow, Russian Federation,* [2]*Federal State Budgetary Institution "Research Centre for Medical Genetics" of the Russian Academy of, Moscow, Russian Federation.*

Introduction. Chemical mutagens can lead to genes mutations and chromosomal aberrations as well as to epigenetic changes. Toxins and other exogenous agents can cause nonspecific (whole-genome DNA hypomethylation and histone deacetylation) and specific (hypo- and hypermethylation of several genes) modifications of genome. Dioxidine is well-studied agent with proved mutagenic activity. Frequency of chromosomal aberrations in peripheral blood lymphocytes increases from spontaneous level of 2.25±0.17% to 8.06±0.37% and 17.00±0.86% after dioxidine exposure in concentrations of 0.01 and 0.1 mg/ml respectively. The aim of this study was to estimate dioxidine influence on whole-genome methylation status in human peripheral blood lymphocytes. Materials and Methods. Samples of peripheral blood were obtained from 14 healthy donors. DNA methylation was analyzed using methyl-sensitive Comet assay with additional step of restriction by *Hpa*II and *Msp*I enzymes. DNA methylation in lymphocytes was estimated before cultivation, after 25-hours cultivation without dioxidine and with dioxidine addition in final concentrations of 0.01 and 0.1 mg/ml after 24-hours cultivation of whole blood. DNA methylation level was defined as the ratio of mean of DNA value in comet's tails after *Hpa*II restriction to that after *Msp*I restriction. Results. DNA methylation levels in lymphocytes before and after cultivation didn't differ (45.28% and 44.80% respectively p>0.4). Lymphocytes after the cultivation with low dioxidine concentration have shown the increased DNA methylation level up to 46.14% (p<0.001) however high dioxidine concentration causes DNA hypomethylation down to 42.31% (p<0.001). Conclusion. Nonspecific hypomethylation caused by dioxidine exposure can result in genome instability and diseases including cancer.

Background: There is a lack of suitable markers for the early and reliable detection of malignant tumors, including non-small cell lung cancer (NSCLC). We've performed a genome-wide analysis in early NSCLC to find DNA methylation-based biomarker candidates.

Methods: We've analysed samples from 48 patients with stage I NSCLC and 18 matching cancer-free lung samples using microarrays that cover the promoter regions of more than 14,500 genes. DNA methylation changes were correlated with gene expression levels. In addition, survival analysis was performed. The gene expression and DNA methylation changes were validated with real-time qPCR analysis and bisulfite sequencing with HiSeq 2000 instrument (Illumina).

Results: We observed hypermethylation of 496 CpGs in 379 genes and hypomethylation of 373 CpGs in 335 genes in NSCLC. 378 of 869 (43.5%) CpGs discriminating the NSCLC and control samples showed the expected inverse correlation between CpG methylation and gene expression levels. As a result of a survival analysis, we found 10 CpGs in 10 genes, in which the methylation level differs in different survival groups.

Conclusions: We have identified a set of genes with altered methylation in NSCLC. We also found a set of genes that associated with the survival of the patients. These marker candidates of NSCLC will need a further analysis in order to determine their clinical utility.

P06.088

XPD Lys751Gln polymorphism in Romanian patients with myelodisplastic syndrome

C. Duicu[1]*, C. Banescu*[2]*, I. Macarie*[1]*, M. Dobreanu*[1]*;*
[1]*University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania,* [2]*Genetic Department, University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania.*

Polymorphisms in DNA repair genes have been associated to repair DNA damages, and might contribute to the individual susceptibility to develop different types of malignant hemopathias. One of the most studied DNA repair system in humans is nucleotide excision repair pathway. The *XPD* gene (xeroderma pigmentosum group D) is involved in nucleotide excision repair system. An *XPD* variant in exon 23 leading to a Lys751G1n aminoacid substitution has been associated with reduced DNA repair capacity.

To investigate the possible association between the *XPD*
Lys751G1n and the risk of myelodisplastic syndrome in a Romanian population, we analyzed DNA samples from a case-control study of 26 MDS cases and 50 healthy subjects as a control group.

The *XPD* codon 751 genotypes were determined using a PCR-RFLP technique. No statistically significant difference was found for the genotypic and allelic distributions of the polymorphisms in the *XPD* gene between the patients and the control subjects. In conclusion polymorphism in *XPD* codon 751 is not associated with the development of MDS.

DNA repair *XRCC3* polymorphism and acute myeloid leukemia

C. Banescu[1]*, C. Duicu*[2]*, I. Benedek*[2]*, I. Pascanu*[2]*, K. Csep*[2]*, A. Todoran*[2]*, M. Dobreanu*[2]*;*
[1]*Genetic Department, University of Medicine and Pharmacy, Tg. Mures, Romania,*
[2]*University of Medicine and Pharmacy, Tg. Mures, Romania.*

The X-ray repair cross-complementing group 3 (*XRCC3*), has an important role in homologous recombination (HR), one of the main pathways for the repair of DNA double strand breaks and maintenance of genomic integrity. Acute myeloid leukemia (AML) is characterized by genetic instability. We hypothesized that polymorphisms in the *XRCC3* repair gene may lead to genetic instability and subsequent AML. The aim of this study was to determine the frequency of the *XRCC3* Thr241Met polymorphisms among AML patients. Therefore we performed a case-control study including 50 de novo AML patients and 50 healthy subjects as a control group.

Genotyping was performed by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP), with the digestion of restriction endonuclease NlaIII. The restricted products were analyzed on 2% agarose gel stained with ethidium bromide and analyzed under UV light. We found a significantly higher frequency of the polymorphic variants *XRCC3* Thr241-Met genes in AML cases, when compared with controls (P = 0.04; odds ratio =2.54). *XRCC3* 241Met allele is associated with an increased risk for AML. In conclusion, we consider that polymorphism *XRCC3* Thr241Met polymorphism may be a risk factor for the development of AML.

DNMT3B C46359T and *SHMT1* C1420T polymorphisms in carcinogenesis of head and neck

T. B. Castro, *M. Succi, A. L. S. Galbiatti, L. M. R. B. Silva, J. N. G. Silva, J. V. Maniglia, É. C. Pavarino, E. M. Goloni-Bertollo;*
São José do Rio Preto Medical School, São José do Rio Preto, Brazil.

Introduction: Folate is an essential nutrient for the synthesis, repair, and methylation of DNA. Polymorphisms in genes involved in folate metabolism may alter these processes and, consequently, modulate the cancer development. **Objectives:** Investigate *DNMT3B* C46359T (rs2424913) and *SHMT1* C1420T (rs1979277) polymorphisms related to folate pathway in head and neck cancer risk and the association between these polymorphisms with gender, risk factors and clinical histopathological parameters. **Methods:** A case-control study was conducted in 725 individuals in a Brazilian population (237 patients with head and neck cancer and 488 control individuals without cancer history). The Real-Time PCR technique was performed for genotyping the polymorphisms. Chi-square test and multiple logistic regression test were used in the statistical analysis. **Results:** No significant difference in genotypes distribution was observed between groups in both polymorphisms evaluated. Male gender and tobacco consumption were associated with increased risk for head and neck cancer ($P<0.05$). There were no significant associations between the polymorphisms and risk of disease, however, the tobacco and alcohol habits analyzed together showed association with *SHMT1* C1420T polymorphism ($P<0.05$). For clinical histopathological parameters, *SHMT1* C1420T polymorphism was less frequent in patients that had larynx as primary site ($P<0.05$). **Conclusion:** The male gender and tobacco habit may be predictors of the head and neck cancer and the polymorphisms investigated have no association with head and neck cancer risk. However, further studies involving genes related to folate metabolism may contribute to the understanding of this cancer type development.

Developmental pluripotency associated-2 (DPPA2) gene may be a metastatic marker for colorectal cancer

R. Raeisossadati[1], M. M. Forghanifard[1], ***S. Sardari***[1]*, A. Tavassoli[2], M. Moghbeli[1], M. R. Abbaszadegan[3];*
[1]Department of Biology, Mashhad Branch, Islamic Azad University, Mashhad, Islamic Republic of Iran, [2]Endoscopic and Minimally Invasive Research Center, Qaem Hospital, Mashhad, Islamic Republic of Iran, [3]Division of Human Genetics, Immunology Research Center, Avicenna Research Institute, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran.

Colorectal cancer (CRC) is the third most frequent malignancy in the world. Cancer cells have countless behaviors of pluripotent embryonic and germ line cells, such as unlimited proliferation and the capacity of self-renewal as well as migration. Active embryonic genes in tumor cells may be associated with invasiveness and indefinite growth of such cells. Developmental pluripotency associated-2 (DPPA2) is implicated in regulatory pathways maintaining the pluripotency of embryonic stem cells. DPPA2 expression in human germ line and early stage embryo is also being extended to a significant subset of malignant tumors. However, its expression in CRC remains to be clarified. In this study, the expression level of DPPA2 in 38 CRC samples was compared with related normal tissues by real-time PCR assay. Expressional analysis represented the overexpression of DPPA2 in 31.5% of tumor specimens. In the advanced stages (III/IV) of tumor development, the overexpression of DPPA2 was significantly correlated with the lymph node metastasis of tumor cells ($p<0.05$). These results not only emphasize on the probable role of DPPA2 gene overexpression in the development of CRC tumors through advanced stages but also draw attention to the possible function of this gene in epithelial mesenchymal transition (EMT) of colorectal tumor cells. In summary, having revealed the clinical relevance of DPPA2 expression in CRC, we extrapolate the potential of this gene as a promising marker to evaluate the risk of lymph node metastasis and a possible therapeutic target to prevent functional metastasis.

Expression of Selected Drug Resistance Genes in Breast and Colon Cancer Patients

J. Markus*, E. Weismanova, J. Palaj, K. Rauova, V. Lehoczka, S. Spanik;*
St. Elizabeth Cancer Institute, Bratislava, Slovakia.

The ABC transporters have been studied extensively for over two decades. Their structure and function is well described as well as their involvement in the resistance of cancers to therapy. Despite being one of the best studied protein families with important effect on the cancer therapy, the ABC transporters are not routinely diagnosed in clinical practice. This has many reasons, one of them being lack of relevant clinical data or their inconclusiveness. The main aim of this study was to collect more information about the relevance of the relationship between the drug-resistance genes and therapy response. We have analyzed expression of selected ABC transporter genes in the tissues of breast and colon cancer patients. Analysis was performed in over 200 patient samples, with diagnoses ranging from benign lesions to invasive cancers. Our real-time PCR-based analysis revealed frequent overexpression of certain ABC genes in all types of cancers. Most frequently overexpressed genes included ABCC1, ABCC2, ABCC5 and ABCC11. The expression status of ABC genes was subsequently correlated to the clinical data of the patient. The effects of the ABC genes expression on the therapy outcome will be discussed.

Comprehensive genomic study in ductal breast cancer

I. Dimova[1]*, R. Panov[2], G. Antov[3], D. Nesheva[1], S. Maslyankov[4], D. Toncheva[1];*
[1]Medical University - Sofia, Sofia, Bulgaria, [2]Tokuda Hospital Sofia, Sofia, Bulgaria, [3]Institute of Genetics, Sofia, Bulgaria, [4]Specialized Hospital of Oncology, Veliko Tarnovo, Bulgaria.

Despite of the large number of molecular studies in breast cancer, the data are still insufficient for understanding its molecular pathogenesis. In this study we have performed whole genome analysis by DNA microarrays for determining the type, incidence and fine mapping of unbalanced genomic aberrations in ten ductal breast cancers. Trisomies of whole chromosomes or chromosome arms with the highest frequency were observed for chromosomes 20 (80%) and 7 (40%), the most common monosomies were discovered for chromosomes 8 and 15 (60%), followed by 4, 18 and 21 (50%). Significant micro-aberrations were determined by selection of aberrant clones with more than 40% frequency and detection of alterations of high amplitude in more than 30% of tumors. Doing this, we detected significant aberrations for known tumor-driving genes such as MUC1 in 1q21, LASP1 (in 17q11-q21.3) and HER-2 (17q21.1), ZNF217 and AURKA (STK6) in 20q13.2-q13.3. In addition, we suggest as new potential oncogenes TNS1 (2q35), SH3BP5 (3p25), HSPB1 (7q11), and ZNF503 (10q22). The genes, located in the most significant deleted small overlapping regions, were: EPS15 (1p32), ARL15 (5q11), CD2AP (6p12), IKBKB (8p11), KIF11 (10q23), ATM (11q22), CYP27B1 (12q13), EFTUD1 (15q26), and CHAF1B (21q22). Our results showed at a high resolution the unbalanced genomic aberrations for whole genome along all chromosomal regions and complement with additional data the genomic characteristics of ductal breast cancer.

Absence of epidermal growth factor receptor gene mutations in patients with first diagnosis of prostate cancer

B. Zagradisnik*, K. Zerjavic, T. Hajdinjak, G. Hlebic, D. Bratus, N. Kokalj Vokac;*
University Medical Centre Maribor, Maribor, Slovenia.

BACKGROUND: Mutations in the tyrosine kinase domain of the epidermal growth factor receptor (EGFR) gene are known for a variety of human cancers. In prostate cancer they represent a rare event although the increased tyrosine phosphorylation is an important feature of advanced prostate cancer. In this study we investigated the presence of most common somatic mutations in the EGFR gene in patients with first diagnosis of prostate cancer. The aim was to evaluate the utility of EGFR mutation analysis for early identification of prostate cancers with aggressive growth potential.
METHODS: First voided urine was collected from patients after digital rectal examination. RNA was extracted from urine sediment and used for cDNA synthesis. Exon 19 deletions were detected with polymerase chain reaction and capillary electrophoresis. The L858R mutation was detected with PCR followed by MscI digestion and agarose electrophoresis.
RESULTS: Study sample included 65 patients. All had confirmed diagnosis of prostate cancer with positive biopsy and samples were collected before planed surgery. Gleason score 6 was determined for all cases. No frame shift mutations in exon 19 of the EGFR gene were detected and the L858R mutation was also absent,
CONCLUSIONS: Our results show that EGFR mutations did not occur in these

patients suggesting these mutations may be very rare events in early phase of prostate cancer. Consequently the analysis of EGFR mutations appears not to be informative for evaluation of growth potential of prostate cancer and for disease prognosis.

Prolonged HPV infection can produce chronic inflammation and link to ESCC in Iran

*F. Biramijamal[1], **A. Hossein-Nezhad**[2], M. Soltani[1], G. Irvanloo[3];*
[1]NIGEB, Tehran, Islamic Republic of Iran, [2]Endocrinology and Metabolism Research Institute, Tehran, Islamic Republic of Iran, [3]Cancer Institute, Tehran, Islamic Republic of Iran.

Prolonged inflammation, or chronic inflammation, can lead to cancer. This process can be occurred in present of prolonged infections or irritants. Now, it is clear that tumor microenvironment is accompanied by inflammatory cells which their production including cytokines can promote tumor progression.

In previous study, we showed that chronic inflammation is involved in developing of esophageal cancer, esophageal squamous cell carcinoma (ESCC), in Iran. The incidence of ESCC is high in northern Iran. Environmental exposure to polycyclic aromatic hydrocarbons (PAHs) has been suggested to provoke inflammation. They are easily distributed throughout the human body and produce PAH-DNA adducts which are risk factors for ESCC. Also, it is shown that human papillomavirus (HPV) genome integrate into the host cell chromosome and lead to malignant cell transformation. This infection can be contributed to carcinogenesis by inactivating the p53 protein in oral cancers through *p53* gene mutation.

We assessed the HPV infections in ESCC tissues. The samples (tumor and control tissues) were collected from Tehran and the HPV infections were determined by in situ hybridization analysis.

Our data showed that the presence of type of 16 or 18 HPV in esophageal cancerous tissues. Based on above results, it can be concluded that prolonged HPV infection accompanied by presence of PAHs may produce chronic inflammation and link to ESCC in Iran.

Mutation screening in Adenomatous Polyposis Coli (APC) gene in patients clinically diagnosed as Familial Adenomatous Polyposis (FAP)

***O. C. Vincenzi**[1,2], G. A. Molfetta[1,2], C. A. Ferreira[1,3], W. A. Silva Jr[1,2];*
[1]University of São Paulo, Ribeirão Preto, Brazil, [2]National Institute of Science and Technology in Stem Cell and Cell Therapy, Regional Blood Center of Ribeirão Preto, Ribeirão Preto, Brazil, [3]National Institute of Science and Technology in Stem Cell and Cell Therapy, Regional Blood Center of Ribeirão Preto, Ribeirão Preto, Brazil, Ribeirão Preto, Brazil.

Colorectal cancer is an important malignant neoplasm. Its development involves storage of mutations in oncogenes and in tumoral supressor genes, as well as epigenetic changes. One of these abnormal genes is the Adenomatous Polyposis Coli (APC), a tumor suppressor that presents mutations which may be associated to colorectal adenomas that develop into adenocarcinomas. Defects in this gene cause Familial Adenomatous Polyposis (FAP), an autosomal dominant pre-malignant disease that usually progress to malignancy. Its main characteristic is the large development of pre-cancerous colonic polyps in the intestines, which invariably evolve for the installment of cancer. The goals of this project are the screening for mutations in the APC gene (GenBank M74088) using High Resolution Melting technique and DNA sequencing, and the search for deletions using MLPA. The research includes 16 patients with clinical suspicion of FAP which were attended at the University Hospital and have signed for the consented forms. Of the 15 exons, 14 were screened so far and a nonsense mutation was found (Arg302Stop), producing an inactive protein of reduced size. This mutation was transmitted from mother to both children. We also found a deletion detected by MLPA in another family; the proband showed deletions of the entire exon 1 and 12 of the APC gene, besides a deletion of the exon 1 of MUTYH gene. All exons of APC and MUTYH will be screened and genetic counseling will be offered to the families carrying mutations. Financial support: FAPESP (2011/11456-0), INCTC.

Does FIP1L1-PDGFRA fusion play role in pathogenesis of nasal polyposis?

*G. Yalçıner[1], K. Bozdemir[2], **N. Y. Kutlay**[3], A. S. Bilgen[2], B. Tarlak[2], A. Tükün[3], A. Kutluhan[2];*
[1]Ankara Atatürk Training and Research Hospital, ENT Clinic,, Ankara, Turkey, [2]Ankara Atatürk Training and Research Hospital, ENT Clinic, Ankara, Turkey, [3]Ankara University, Faculty of Medicine, Ankara, Turkey.

Top of Form

Background: Nasal polyposis (NP) is a common chronic inflammatory disease of the nasal mucosa. Although NP occurs 4% of population, the exact mechanisms leading its development are still unknown. On histopatological examination, tissue eosinophilia is a hallmark of NP. Recent studies examining eosinophyl biology have focused on delineating the molecular basis of FIP1L1-PDGFRA fusion gene Considering the eosinophils are the most important cells in NP and the role of FIP1L1-PDGFRA fusion gene in the ethiology of hyper eosinophilic syndrome, it was aimed to investigate FIP1L1-PDGFRA fusion gene at the NP.

Methods: We enrolled the NP patients to this translational study approved by the institutional ethical comittee of Ankara Atatürk Hospital. All individuals provided informed consent, The nasal polyp tissue and normal nasal mucosa biopsy materials were obtained from 20 patients who had undergone a NP operation in the Hospital ENT Clinic. Fluorescent in-situ hybridisation (FISH) was performed using LSI 4q12 Tri-Color Rearrangement probe (Vysis, 05N52-020) on touch-samples slides prepared from fresh biopsies FISH was also performed on nasal mucosa biopsy samples of 20 patients who were operated for nasal septal deviation as control group. Laboratory studies were carried out as blinded.

Results: The FIP1L1-PDGFRA fusion was not found .The nasal polyp tissue and normal nasal mucosa biopsy materials were obtained from 20 patients. The control specimens were all normal.

Conclusions: Further prospective, longitudinal studies are required to establish whether FIP1L1-PDGFRA fusion and the other eosinophilia related biomarkers play role in the pathogenesis of NP.

Longitudinal study of t(14;18) positive Follicular Lymphomas identifies different patterns of genetic and epigentic evolution

***A. Haake**[1], M. Kreuz[2], H. Trautmann[3], L. Theil[1], M. Szczepanowski[4], K. Koch[4], D. Herrmann[3,1], R. Küppers[5], R. Scholtysik[5], W. Klapper[4], C. Arnold[6], D. Hasenclever[2], M. Löffler[2], C. Pott[3], R. Siebert[1];*
[1]Institute of Human Genetics, University Hospital Schleswig-Holstein Campus Kiel/Christian Albrecht University Kiel, Kiel, Germany, [2]Institute of Medical Informatics, Statistics and Epidemiology (IMISE), University Leipzig, Leipzig, Germany, [3]Medical Clinic II/Clinic and Policlinic, University of Schleswig-Holstein Kiel, Kiel, Germany, [4]Institute of Pathology, University Hospital Schleswig-Holstein Campus Kiel/Christian Albrecht University Kiel, Kiel, Germany, [5]Institute of Cell Biology (Cancer Research), Universtity Duisburg-Essen, Essen, Germany, [6]Bioinformatics Group, Department of Computer Science, and Interdisciplinary Center for Bioinformatics, University of Leipzig, Leipzig, Germany.

Follicular Lymphomas (FLs) are germinal center-derived B-cell lymphomas which in the vast majority of cases carry a t(14;18)(q32;q21). This translocation juxtaposes the enhancers of the immunoglobulin heavy chain (IGH) locus at 14q32 to the BCL2 gene at 18q21. Although crucial in the initiation of the malignant process, the t(14;18) translocation alone is not sufficient to drive lymphomagenesis. As a prerequisite to model the pathogenesis of FL from initiation to disease progression we here investigated the clonal evolution in t(14;18) positive FLs. To this end, we performed morphologic, immunohistochemic, interphase cytogenetic, mutational and epigenetic studies in pairs of initial and relapsed FL tumor biopsies within the framework of the BMBF-funded HaematoSys Systems Biology Network. We studied genomic copy number changes using SNP 6.0-Chips, chromosomal translocations with fluorescent in situ hybridization (FISH), mutations of immunoglobulin (IG)- and non-IG genes via cloning and sequencing and additionally next generation sequencing as well as DNA-methylation by 27K BeadArrays. Integrated analysis of the first 16 tumor pairs obtained after an interval of between 12 and 101 months provide evidence for different modes of lymphoma progression. In particular, phylogenetic trees derived from mutational and cytogenetic studies showed different ways of branching which correlated with patterns of differential DNA methylation. Our findings suggest that genetic and epigenetic changes might interact in the pathogenesis and evolution of t(14;18)-positive FLs.

P06.099

Abnormal methylation of tumor-related genes in gastric carcinomas and their adjacent nontumor areas.

***N. Chekunova**, I. Bykov, T. Kchorobrich, M. Nemtsova;*
I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation.

Gastric cancer (GC) is the second leading cause of cancer death and the fourth most common malignant tumor in the world. GC develops through the accumulation of genetic and epigenetic alterations. Epigenetic silencing of tumor-related genes, due to hypermethylation of the CpG sites in the promoter regions, has emerged as one of the main genetic alterations in cancer development.

We examined 106 frozen gastric carcinoma tissues and their adjacent nontumor areas for CpG-island hypermethylation in 5 tumor-related genes (*CDH1, RASSF1A, MLH1, N33, DAPK*) by methyl-sensitive PCR. Samples for detecting hypermethylation in the nontumor tissues were located no farther than 4 cm from tumor.

Hypermethylation of *E-cadherin*, *N33* and *DAPK* (61%, 66% and 48%) was detected more frequently than that of *RASSF1A* and *hMLH1* (25% and 20%) in carcinoma tissues. Genes *CDH1, N33, DAPK* were methylated both in tumor tissues and in the adjacent nontumor areas. Hypermethylation of *RASSF1A, MLH1* were detected in gastric carcinomas only.

The current study shows that hypermethylation of multiple tumor-related genes is detected frequently in gastric carcinoma as well as in adjacent normal tissues. Our findings suggest that a mechanism leading to CpG-island methylation is likely to be involved in the early gastric carcinogenesis process, by establishing field cancerization in gastric mucosa.

P06.100

CpG-island hypermethylation in 5 tumor-related genes (CDH1, RASSF1A, MLH1, N33, DAPK) as diagnostic and prognostic biomarkers for gastric cancer.

***A. Udilova**, I. Bykov, T. Kchorobrich, M. Nemtsova;*
I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation.

Promoter hypermethylation of tumor suppression genes is a central mechanism for epigenetic inactivation and silencing of these genes in cancer cells. Analyses of the promoter hypermethylation patterns in different genes have identified specific alterations that may serve as useful diagnostic and prognostic biomarkers.We investigated the clinical and prognostic importance of CpG-island hypermethylation in 5 tumor-related genes (CDH1, RASSF1A, MLH1, N33, DAPK) for gastric cancer patients. We examined abnormal methylation and methylation index (MI) in 106 gastric cancer patients. Methylation index (MI) was defined as the ratio between the numbers of methylated genes to total number of examined genes in each sample. Statistical significance was evaluated using the Mann Whitney U-test.

There was a significant difference in the frequency of hypermethylation of these genes among different clinical groups of patients. Abnormal methylation of *CDH1* and *N33* genes is related to the progress of gastric cancer and metastasis to lymph nodes ($p < 0.05$). Abnormal methylation of *CDH1* is specifically associated with diffuse-type GC ($p< 0,05$). Abnormal methylation of *DAPK* gene, in contrast, is a marker of favorable prognosis, being more frequently methylated in non-metastatic gastric carcinomas ($p< 0,05$). There was no significant difference between groups of patients with IM> 0,5 and IM< 0,5.

The use of molecular genetic markers, such as promoter hypermethylation of tumor suppression genes, may be an additional factor of the diagnosis and prognosis for gastric cancer.

P06.101

Genomic rearrangements in Slovak BRCA1/2 families: rare deletion of complete BRCA1 gene represents a potential founder mutation

***M. Konecny**[1], V. Vranova[2], K. Zavodna[1], Z. Bartosova[1];*
[1]Department of Clinical Genetics, St. Elizabeth Cancer Institute, Bratislava, Slovakia, [2]Laboratory of Molecular Cytogenetics, Institute of Experimental Biology, Faculty of Science, Masaryk University, Brno, Czech Republic.

Germline mutations in BRCA1 and BRCA2 genes account for a major proportion of hereditary breast and ovarian cancer cases. Most of these mutations consist of point mutations: deletions, insertions, nonsense or missense mutations, and splice variants, however an increasing number of large genomic rearrangements have been identified. In Slovak HBOC families large genomic rearrangements are responsible for approximately 10% of BRCA1/2 positive families.

Genomic BRCA1, BRCA2 and CHEK2 rearrangements were analysed by MLPA (Multiplex Ligation-Dependent Probe Amplification) and in some cases approved by Plexamp (DNA Quantitative Multiplex Amplification System by Prestagen). The complete deletion of BRCA1 gene was closer characterized by special BRCA1 region MLPA kit and oligonucleotide array based comparative genomic hybridization (aCGH).

Large genomic rearrangements were identified altogether in 5 families, while no LGR was indentified in BRCA2 gene, one deletion of exons 9 and 10 was identified in CHEK2 gene and two different deletions were detected in BRCA1 gene. Deletion of exons 21 and 22 of BRCA1 was previously described in Czech HBOC population and was detected in one family. Complete deletion of BRCA1 gene was previously reported in two Spanish and one German HBOC family and was identified in 3 Slovak families. This deletion was further characterized; however exact breakpoints have not been detected yet.

We report the spectrum and frequency of detected genomic rearrangements of BRCA1, BRCA2 and CHEK2 gene and also the potential founder origin of rare complete BRCA1 deletion in Slovak HBOC families.

Mutation analysis of cKit and PDGFRα genes in GIST patients from Slovakia

***G. Minarik**[1,2], Z. Lasabova[3], T. Szemes[4,2], T. Burjanivova[3], P. Szepe[3], V. Buzalkova[3], D. Porubsky[4], J. Sufliarsky[5], L. Plank[3];*
[1]Comenius University in Bratislava Faculty of Medicine, Bratislava, Slovakia, [2]Geneton, Ltd., Bratislava, Slovakia, [3]Comenius University in Bratislava Jessenius Faculty of Medicine, Martin, Slovakia, [4]Comenius University in Bratislava Faculty of Natural Sciences, Bratislava, Slovakia, [5]National Cancer Institute, Bratislava, Slovakia.

Gastrointestinal stromal tumors (GIST) represent most common mesenchymal neoplasms. In 1998 activating mutations in gene coding cKit tyrosine kinase (KIT) were identified to be present in most of GIST tumors. Later on mutations in other tyrosine kinase - PDGFRα (PDGFRA), were identified as causative in GISTs. Mutation analysis of KIT and PDGFRA could be used in GIST therapy decision and in clinical prognosis of GISTs, therefore KIT and PDGFRA mutation analysis is currently a predictivelly important step in diagnostic protocol with its both prognostic and predictive consequences.

In our study KIT and PDGFRA mutation status was analyzed during differential diagnosis protocol applied to GIST bioptic material in Slovakia. We have performed mutation analysis of most commonly mutated exons in KIT (9, 11, 13, 17) and PDGFRA (12, 14, 18) genes in patients and combined the data with most important clinical parameters.

Totally 278 GIST suspect patients have been screened for mutations in analyzed exons of KIT and PDGFRA. According to information from other publications as well as in silico analysis with PolyPhen-2 predictor 233 patients have been identified with GIST causal mutation. Of those most prevalent mutations were deletions present in KIT exon 11 with proportion of 41.20%. The most frequent single mutation was KIT exon 9 p. 503-504_dup2 with proportion 9.44%. Genotype-phenotype correlation analysis reveal the statistically significant association between intestinal localization of tumors and presence of KIT exon 9 p. 503-504_dup2 mutation ($p<0.001$) and gastric localization of tumors and presence of PDGFRA exon 18 p. D842V mutation ($p=0,021$).

P06.103

Expression analysis of KIT gene splice variants Kit+ and KitA+ in gastrointestinal stromal tumors.

***A. V. Gaponova**[1,2], T. Kekeeva[1], L. Zavalishina[1], Y. Andreeva[1], G. Frank[1];*
[1]Herzen Moscow Oncological Research Institute, Moscow, Russian Federation, [2]Russian State Medical University, Moscow, Russian Federation.

Gastrointestinal stromal tumors are the most common mesenchymal tumors of the gastrointestinal tract. 5% of GISTs are caused by oncogenic mutations in PDGFRA gene, 60-89% by mutations in KIT gene. Exon 10 KIT pre-mRNA contains splice site. Alternative splicing results in the presence of two mRNAs KIT isoforms: KitA+ and Kit+, containing an in-frame GNNK deletion.

We investigated mutational status of KIT and PDGFRA genes and Kit+/KitA+ mRNA isoforms expression from 25 GIST patients. Analysis of mutations in KIT exons 9, 11 and PDGFRA exon 18 was conducted by PCR following by sequencing. cDNA from normal testicle tissue was used as control. Isoform expression analysis was perfomed by RT-PCR.

We observed mutations in 21/25 (84%) tumors (KIT exon 9 - 8%, KIT exon 11 - 52%, PDGFRA exon 18 - 20 %). Kit+ expression is dominate over KitA+ expression in 21 samples, 2 samples demonstrate equal expression of both isoforms, only Kit+ expression was detected in 2 samples. It’s interesting that equal expression of both isoforms or only Kit+ expression are detected in specimens with KIT exon 9 and PDGFRA exon 18 mutations only. It is known that these mutations are connected with unfavourable prognosis and low response to Gleevec. No correlation was observed between expression level of isoforms and intensity of IHC staining of c-kit.

Our data suggests the possible correlation between the isoforms expression and the mutational status of GISTs. Further investigation may be helpful for the isoform role in GIST development and tumor response to target therapy.

Cancer cell apoptosis can be induced by Cis-diamminedichloroplatinum II (cisplatin), an efficient anticancer agent. bcl-2 and bax are members of the bcl-2 family that play key roles in the regulation of apoptosis. The ratio between bax and bcl2 often determines whether a cell will live or die. In this study, U87MG and A172 cells were treated with various concentrations of cisplatin for different times (24, 48 and 72 h). Then, cell viability was assessed using MTT assay and IC50 was determined. The two glioma cell lines were treated with IC50 dose of cisplatin at 48 h for different times(24, 48 and 72 h), RNA was extracted and cDNA was synthesized. Quantity of bcl-2 and bax genes expression compare to tbp gene were analyzed using very sensitive quantitative Real-time PCR. bcl-2 gene expression was decreased and bax gene was increased in a time-dependent manner by cisplatin, that was statistically significant ($P<0.05$). The results showed that cisplatin exerted a time-dependent inhibitory effect on the viability, via up regulation of bax and down regulation of bcl-2 gene, in U87MG and A172 cells.

P06.105

Molecular alterations of EGFR and PTEN genes in primary glioblastoma: associations with prognostic

I. Rodríguez-Hernández[1], *I. Matos-García*[2], *R. García-Valiente*[1], *J. Gonzalez-Valero*[3], *Á. Santos-Briz*[4], *J. Gómez-Moreta*[5], *J. García*[3], *R. González-Sarmiento*[1];

[1]*Molecular Medicine Unit, Department of Medicine, University of Salamanca, Salamanca, Spain,* [2]*Department of Oncology, University Hospital of Salamanca, Salamanca, Spain,* [3]*IBMCC, Center for Cancer Research (USAL-CSIC), Salamanca, Spain,* [4]*Department of Anatomopathology, University Hospital of Salamanca, Salamanca, Spain,* [5]*Department of Neurosurgery, University Hospital of Salamanca, Salamanca, Spain.*

EGFR is frequently amplified, overexpressed or mutated in glioblastoma, the most common and devastating malignant brain tumor. Commonly lost in these tumors is also PTEN, an inhibitor of the PI3K signaling pathway activated by EGFR.

In this study, we aimed to characterize the molecular alterations of EGFR and PTEN in 60 patients diagnosed with primary glioblastoma. We analyzed mutational status of PTEN and EGFR tyrosine kinase domain; we evaluated EGFR amplification and PTEN deletion by FISH and we determined EGFRvIII expression by RT-PCR.

20.8% patients showed pathogenic mutations in PTEN and 68.2% tumors presented PTEN locus deletion. 20% patients with PTEN deletion showed additionally PTEN mutation. Regards to EFGR, no mutations were detected in the tyrosine kinase domain, whereas 32.7% glioblastomas showed EGFR amplification and 31.7% expressed EGFRvIII truncated variant. 46.1% patients with EGFRvIII expression showed EGFR amplification, resulting in the overexpression of constitutively active EGFR lacking I and II extracellular domains. Furthermore, we have found 5 novel EGFR non canonical splice variants in the extracellular domain. Four were truncated proteins and only one generated an in-frame protein lacking aminoacids 20-251 in a tumor with EGFR amplification. In summary, 73.3% of glioblastomas analyzed presented any alteration in PTEN and/or EGFR.

Finally, we investigated the prognostic impact of these alterations in patient outcome. EGFRvIII expression was a significant prognostic factor ($HR = 2.56$, 95% C.I. 1.17-5.57, $p = 0.018$). Patients with EGFRvIII variant expression had a higher median survival than those without it (16.7 months vs. 10.1 months)(Supported by FIS PI10/00219).

P06.106

MGMT methylation and serum albumin in survival for glioblastoma patients

V. Asmoniene[1], *D. Skiriute*[1], *A. Tamasauskas*[1], *A. Sinkus*[2];

[1]*Laboratory of Neurooncology and Genetics, Neuroscience Institute, Kaunas, Lithuania,* [2]*Lithuanian University of Health Sciences, Kaunas, Lithuania.*

Glioblastoma is the most malignant astrocytic brain tumor (astrocytoma WHO grade IV) with very poor prognosis of a median survival of 14-15 months after diagnosis, despite applied treatment (surgery, chemotherapy, radiotherapy). Till now, only MGMT (O(6)-methylguanine-DNA methyltransferase) promoter methylation is confirmed molecular prognostic factor and helpful marker for chemotherapy of glioblastoma. Serum albumin level were investigated only in some glioblastoma patients studies.

Where, hypoalbuminaemia was associated with significantly reduced median survival. The aim of this study was to investigate MGMT promoter methylation status in histologically confirmed glioblastoma samples and pre-operative serum albumin level of 70 glioblastoma patients.

MGMT promoter methylation status were determined by MS PCR. Survival was determinated by using the Kaplan-Meier method and a multivariate Cox regression model (SPSS).

This study shows that MGMT promoter methylation and serum albumin are significant predictors of survival in glioblastoma patients.

New insights into glioblastoma development by integrative genetic analysis of multifocal glioblastoma multiforme

K. Becker[1], *D. Krex*[2], *E. Gerlach*[1], *K. Hackmann*[1], *A. Rump*[1], *G. Schackert*[2], *L. Kaderali*[3], *E. Schrock*[1], *B. Klink*[1];

[1]*Institut für Klinische Genetik, Medizinische Fakultät Carl Gustav Carus, TU Dresden, Dresden, Germany,* [2]*Klinik und Poliklinik für Neurochirurgie, Universitätsklinikum Carl Gustav Carus, TU Dresden, Dresden, Germany,* [3]*Institut für Medizinische Informatik und Biometrie, Medizinische Fakultät Carl Gustav Carus, TU Dresden, Dresden, Germany.*

Glioblastoma multiforme (GBM) is the most common and malignant type of brain tumor in adults with an average survival time of less than 12 months and targeted therapies are not yet available. Therefore, we investigated different foci in multifocal GBM by an integrative approach in order to identify markers of tumor initiation and progression as well as potential therapeutic targets. We combined high resolution array CGH and expression arrays on fresh frozen tissue from 11 tumor foci from 6 patients with spectral karyotyping (SKY) on corresponding primary cell cultures. Moreover, *PTEN* Sanger sequencing was performed. Array CGH-analysis detected multiple aberrations in the tumors investigated. Additionally, SKY-analysis revealed multiple translocations including complex rearrangements. We found that different tumor foci derived from the same patients shared the majority of aberrations detected, indicating that these aberrations had probably emerged early in tumorigenesis. Interestingly however, some of the aberrations differed between the tumor foci from the same patient and thus must have occurred later in tumor development. These observations support the hypothesis that different tumor foci in multifocal GBM are of monoclonal origin and then develop independently of each other by clonal evolution. In accordance with this hypothesis, some of the tumor foci from the same patient shared the same *PTEN* mutation whereas others displayed different *PTEN* mutations. We are currently analyzing the expression data which will also be presented. Taken together, multifocal GBM provide an excellent model for investigating tumor progression and might help distinguishing between driver and passenger alterations in GBM.

P06.108

High Frequency of Mutations in the PIK3CA Gene Helical and Kinase Coding Regions in a Group of Iranian Patients with High Grade Glioblastomas: Five Novel Mutations

P. Derakhshandeh-Peykar[1,2], *J. Alivi*[2], *A. Hosseinnejad*[3], *B. Rautenstrauss*[1], *R. Ebrahimzadeh Vesal*[2], *A. Doriani*[2];

[1]*Medizinisch Genetischen Zentrum (MGZ), München, Germany,* [2]*Tehran University of Medical Sciences (TUMS), Tehran, Islamic Republic of Iran,* [3]*Shariati hospital, Tehran University of Medical Sciences (TUMS), Tehran, Islamic Republic of Iran.*

Glioblastoma multiform (GBM; WHO grade IV) and Anaplastic Astrocytomas (AA; WHO grade III) are highly aggressive and lethal astrocytic brain tumors. To detect cancer specific somatic mutations in two hot-spot regions of PIK3CA gene, the helical and kinase domains (encoded by exons 9 and 20, respectively) in GBM and AA, we examined the respective sequences 31 paraffin-embedded samples (23 GBM and 8 AA). The samples were obtained from a group of Iranian patients affected with high grade glioblastoma (HGG). The overall prevalence of PIK3CA mutations was 23% (7/31) for both tumor types (22% in GBM, and 25% in AA). Five mutations were detected in exon 20, p.Arg992Gln (c.2976G>A), p.Met1005Val (c.3014A>G), p.Ile1019>Val (c.3056A>G), p.Ser1008Cys (c.3024C>G), p. Asn1044Asp (c.3130A>G), and one mutation in exon 9, p.Glu545Ala (c.1634A>C). Additionally exons 4-8 of *P53* gene in four unrelated young patients, who showed no mutations in *PIK3CA* exons 9 and 20, were analyzed. Three mutations were identified: p.Pro72Ala (c.214C>G), g.11608G>T (homozygote splice mutation), and p.Thr170Thr (c.510G>A silent mutation). In conclusion mutation detection in *PIK3CA* in patients with a high degree of malignancy and early age at diagnosis should be included in molecular diagnostic protocols, also with regard to possible upcoming therapies.

Genetic Analysis of Long-Term Survivors with High-Grade Gliomas

***L. Roque**[1], C. Martins[1], I. Francisco[1], C. Albuquerque[1], S. Esteves[2], A. Azevedo[3], D. Salgado[3], I. Costa[3], T. Pimentel[3], J. Nunes[3], J. M. Bravo-Marques[3], V. Moura-Nunes[1], C. Faria[4], M. Santos[4], J. Lobo Antunes[4], J. Pimentel[5], P. Castanho[6], M. Mafra[7];*

[1]UIPM-Portuguese Cancer Institute, Lisbon, Portugal, [2]Clinical Cancer Research-Portuguese Cancer Institute, Lisbon, Portugal, [3]Neurology Department-Portuguese Cancer Institute, Lisbon, Portugal, [4]Neurosurgery Department - Hospital de Santa Maria, Lisbon, Portugal, [5]Neuropathology Department - Hospital de Santa Maria, Lisbon, Portugal, [6]Neurosurgery Department - Hospital de S.José, Lisbon, Portugal, [7]Neuropathology Department - Hospital de S.José, Lisbon, Portugal.

Background: High-grade gliomas have poor prognosis. Only 3-5% survive more than five years being referred as long-term survivors. Factors determining this outcome are largely unknown.
Aim: Identify specific genetic parameters that might be associated to long-term survival.
Methods: Evaluation of genomic imbalances by chromosomal CGH and of MGMT and MMR genes methylation levels (%) by MLPA analysis in 3 groups of patients. Group 1: 13 long-term survivors; Group 2: 17 patients with an overall survival (OS)< 5 years and $\text{MGMT}_{av} \geq 25\%$; Group 3: 29 patients with OS<5years and $\text{MGMT}_{av}<25\%$. Statistical analysis was performed using Mann-Whitney and Fisher's Exact tests with p-value adjustment for multiple tests (Bonferroni).
Results: Multiple chromosomal imbalances were observed in all groups being gains at 7p/q regions the most frequent alteration. None of the long-term survivors had 7p12 (EGFR) amplifications and loss of 10q23 (PTEN) region were significantly less frequent: 23,1% in group 1 *v.s.* 88,7% and 86,2% in groups 2 and 3. MS-MLPA analysis revealed that MGMT and 4 of the MMR genes were significantly more methylated in the long-term survivor group than in the others. Accordingly for groups 1, 2 and 3 mean methylation levels were respectively for MGMT (70,6%; 54,1%; 8,6%), MSH2 (6,8%; 0,8%; 0,8%), MSH6 (25,3%; 22,4%; 4,7%); PMS2 (24,7%; 5,5%; 2,2%) and MLH3 (56,5%; 11,2%; 3,1%)
Conclusions: Our data underlies that long-term survival is associated to an absence of 7p12 (EGFR) amplification, infrequent 10q23 (PTEN) loss and higher levels of MGMT; MSH2, MSH6, PMS2 and MLH3 methylation.

Association of different ovarian tumor types in a patient with Gorlin Syndrome

***G. Tortora**[1], P. De Iaco[2], M. Procaccini[2], A. Pellegrini[2], M. Rossi[2], I. Neri[3], D. Santini[4], L. Pastorino[5], G. Bianchi-Scarrà[5], M. Lima[6], D. Turchetti[1];*

[1]U.O. Genetica Medica, Policlinico S.Orsola-Malpighi, Bologna, Italy, [2]SSD Oncologia Ginecologica, Policlinico Sant'Orsola-Malpighi, Bologna, Italy, [3]U.O. Dermatologia, Policlinico Sant'Orsola-Malpighi, Bologna, Italy, [4]U.O. Anatomia e Istologia Patologica, Policlinico Sant'Orsola-Malpighi, Bologna, Italy, [5]U.O. Laboratorio di Genetica dei Tumori Ereditari, Istituto Nazionale per la Ricerca sul Cancro, Genova, Italy, [6]U.O. Chirurgia Pediatrica, Policlinico Sant'Orsola-Malpighi, Bologna, Italy.

A 29 years old woman came to our attention with the suspicion of Gorlin Syndrome (GS). At age 15 she had undergone unilateral oophorectomy for a large mass of the right ovary and excision of several masses of the left ovary, diagnosed as fibromas; at age 18 she had multiple fibromas of the left ovary removed and two years later she underwent surgery for an uterine septum. Recently, she has undergone left oophorectomy for a large cystic mass: pathological examination revealed a granulosa cell tumor with theca-cell areas.
Maternal family history was unremarkable, whereas paternal family history was largely unknown, except for hysterectomy in her grandmother. The proband has two healthy younger brothers (27 and 18 years old); her mother had three spontaneous miscarriages. Physical examination showed coarse face with hypertelorism and three skin lesions, of recent onset, which were removed and diagnosed as basal cell carcinomas. To confirm the suspicion of GS, the search for germline mutations in PTCH1 gene was carried out, which detected the heterozygous mutation c.1067_1067+3>TT, already reported in GS patients. Although ovarian cysts and ovarian fibromas, often bilateral, are reported in 25-50% of GS female patients, to our knowledge, this is the first case of a granulosa cell tumor associated to multiple ovarian fibromas in a GS patient, whose clinical manifestations were mainly and heavily affecting ovaries.
Other investigations (X-rays of the skull and ortopantogram) are ongoing, as well as molecular analysis in parents and sibs.

A conditional mouse model for granulosa cell tumour driven by WT1

***C. Steinwender**[1], S. Fees[1], C. Spangenberg[1], D. Prawitt[2], E. Bockkamp[3], R. Keppler[1], K. Reicherter[1], B. Zabel[1], E. Lausch[1];*

[1]University of Freiburg, Centre for Pediatrics and Adolescent Medicine, Freiburg, Germany, [2]Medical Centre of the Johannes Gutenberg-University Mainz, Centre for Pediatrics and Adolescent Medicine, Mainz, Germany, [3]Medical Centre of the Johannes Gutenberg University Mainz, III. Department of Internal Medicine, Mainz, Germany.

The Wilms tumour protein 1 (WT1) is essential for male sex determination. Not much is known about it's expression and function in the embryonic and adult female genital tract and if WT1 can trigger ovarian tumorgenesis.
To this end, we generated two different conditional mouse models, both based on an inducible Wt1 tTA knockin effector line carrying a tetracycline-dependant activator (tTA) in place of the first exon of the endogenous murine Wt1 locus. In the first model, tripel transgenic animals bearing a tetracycline-responsive transgene for Cre-recombinase, and the Cre reporter line ROSA26 lacZ, the fate of WT1-positive cells was followed in vivo by tetracycline administration using beta-galactosidase to identify cells and tissues derived from WT1-positive precursors. In tripel transgenic animals of the second model, the Wt1 tTA knockin effector line and the tetracycline-responsive Cre-recombinase should excise the third exon of Ctnnb1 (βCat-Flox-Ex3), which may in that case trigger ovarian tumorgenesis.
Histochemical staining of embryos demonstrated earliest Wt1 expression in the urogenital ridge at day 10.5 post coitum (d.p.c.). When the fate of Wt1-positive cells was analysed in the ovaries of adult mice, beta-galactosidase activity could be detected in oocytes, stromal and granulosa cells. Tripel transgenic mice of the second model developed huge ovarian carcinoma. Molecular and histological analysis suggested that this is due to Ctnnb1 overexpression and that the carcinoma were granulosa cell tumours.
Our results show that WT1 has an essential function in the female genital tract and present a new mouse model for granulosa cell tumours.

P06.112

Evaluation of methylation status in glutation S-transferase P1(GSTP1) gene promoter in human breast cancer and it's relation to tumor grade and stage

***S. A. S. Shargh**[1], H. Yazdi[2];*

[1]Azad Islamic University of Chalous, Chalous, Islamic Republic of Iran, [2]Consultor of academic research, Tehran, Islamic Republic of Iran.

Glutation S-transferase P1 (GSTP1) gene methylation in promoter CpG islands has been described as a specific biomarker for many types of cancer including breast cancer as a tumor suppressor gene . At presents study we found the GSTP1 gene promoter to be methylated in breast cancer tissues. To study the difference of sequence in hypermethylated GSTP1 promoter in cancer tissues and non methylated status in normal tissues, we analyzed the cytosine methylation status as epigenetic changes in 50 tumors from patient's with breast cancer and 50 normal breast tissues that obtained from the same breast tumor in adjacent region. In order to study the promoter methylation status for GSTP1 gene in breast cancer, 40 CpG sites [nucleotide(nt) 197,190,187,185,183,182,176,162,155,152,148,145,141,132,127,124,112,109,101,99,81,77,74,71,54,53,48,47,43,42,40,38,23,22,15,14,13,11,8,4] were screened. The GSTP1 methylation was detected in %.41.3 of breast tumors which was associated with higher tumor grade (p=0.467) and tumor stage(p=0.048) .

Histone deacetylases activate the HGF/c-Met pathway via repression of microRNA-449 in human hepatocellular carcinoma

*R. Buurman[1], E. Gürlevik[2], V. Schäffer[1], M. Eilers[1], M. Sandbothe[1], H. Kreipe[3], L. Wilkens[1,3], B. Schlegelberger[1], F. Kühnel[2], **B. Skawran**[1];*

[1]Institute of Cell and Molecular Pathology, Hannover, Germany, [2]Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany, [3]Institute of Pathology, Hannover, Germany.

BACKGROUND & AIMS: Histone deacetylation represents an important epigenetic modification in cancer development and is responsible for chromatin remodeling. In this study, we aimed to identify microRNAs affected by histone deacetylation and to understand functional consequences. METHODS: HCC cell lines and immortalized liver cell lines were treated with the histone deacetylase inhibitor TSA. Differentially expressed mRNAs and miRNAs were identified using mRNA and miRNA expression profiling. Findings were validated by siRNA mediated silencing of HDAC1-3, transfection of miR-449 into a HCC cell line, Western blotting and by luciferase reporter assays. RESULTS: Here we show that HDAC1-3 are consistently up-regulated in primary HCC. MiRNA profiling identified hsa-miR-449a to be significantly up-regulated after HDAC inhibition. c-MET encoding the receptor tyrosine kinase for hepatocyte growth factor (HGF) is a putative target gene of miR-449. Indeed, HDAC inhibition and miR-449 transfection resulted in reduced expression of c-MET. Increased apoptosis and decreased proliferation after histone deacetylation and miR-449 upregulation confirmed the miR-449 tumor suppressive role. MiR-449 was found to bind directly to c-MET. Importantly, primary human HCC showed reduced expression of miR-449 and increased expression of c-MET. CONCLUSIONS: This work opens up new avenues for targeted therapies of HCC, either via treatment with histone deacetylase inhibitors or, possibly by direct transfer of specific miRNA-449.

Detection of EGFR expression levels in tissues of head and neck cancer patients and cell lines

A. Kalayci[1], *T. Cora*[1], *H. Acar*[1], *B. Keles*[2], *K. Ozturk*[2];
[1]*University of Selcuk, Selcuklu Medical Faculty, Department of Medical Genetics, Konya, Turkey,* [2]*University of Selcuk, Selcuklu Medical Faculty, Department of Otolaryngology, Konya, Turkey.*

Head and neck squamous cell carcinoma (HNSCC) is the sixth most common cancer worldwide and includes epithelial malignancies of the oral cavity, pharynx and larynx. Epidermal growth factor receptor (EGFR) is involved in tumor development and is highly expressed in head and neck squamous cell carcinomas. EGFR is a 170-kDa transmembrane glycoprotein with an extracellular ligand-binding and a cytoplasmic domain with intrinsic tyrosine kinase activity. EGFR overexpression has been observed in both premalignant lesions and malignant head and neck tumors. Eventhough there are several studies which are analysing the expression of EGFR in malignant tumors, we have very limited information about their expression and activation in adjacent normal tissue from head and neck cancer patients. Therefore, we have investigated the differential expression of EGFR a) in tumor tissue b) in adjacent normal tissue c) blood tissue in head and neck cancer patients and d) SCCL-MT1 and USC-HN2 cell lines by using RT-PCR. At tumor and adjacent normal tissues, the amount of EGFR mRNA wasn't different than eachother. Also, there weren't any EGFR mRNA levels in blood tissues. This findings are shown that expressions of the other variations of EGFR also can be effective on head and neck cancers.

Polymorphism of GSTT1, GSM1 and GSTP1 genes investigated in patients with head and neck squamous cell carcinoma

A. Russo, *P. R. Francelin, M. A. Palmejani, A. L. S. Galbiatti, L. S. Raposo, G. D. Ferreira, É. C. Pavarino, E. M. Goloni-Bertollo;*
São José do Rio Preto Medical School, São José do Rio Preto, Brazil.

Variations of activation and detoxification of chemical compounds in the xenobiotics metabolism are involved in head and neck tumorigenesis, even as polymorphisms in genes of the glutathione S-transferase superfamily, which act in phase II of this metabolic pathway. Aim: To investigate the A313G and C341T GSTP1 polymorphisms, GSTT1 and GSTM1 null genotype in patients with head and neck cancer and compare with subjects with no history of cancer to evaluate the association between these polymorphisms and the risk factors (smoking and drinking) and the histopathologic characters of the tumor. Methods: Were included 775 individuals, 261 patients and 514 controls. Molecular analysis was performed by PCR-RFLP. For statistical analysis we used the chi-square and multiple logistic regression. Results: The significant results with $p< 0.05$ showed that age ≥48 years, smoking and drinking and the presence of A313G GSTP1 polymorphisms were predictors for the development of cancer of the head and neck. In individuals with the GSTM1 null genotype and age <48 years; the A313G GSTP1 polymorphism and age ≥48 years, smoking and drinking; the GSTT1 null genotype and primary anatomical sites pharynx and larynx present increased chances for the development of head and neck cancer. Conclusion: In conclusion, the presence of GSTP1 A313G variant is associated with decreased risk for head and neck cancer and age ≥ 48 years, male gender and smoking and drinking; GSTM1 null genotype and age <48 years; GSTT1 null genotype and primary anatomical sites pharynx and larynx are associated with increased chances for developing this disease.

Chronic infection by Hepatitis B Virus (HBV) is one of the most aetiologically associated risk factor for the development of hepatocellular carcinoma (HCC). However, the role of HBV in HCC remains unclear due to technological limitation. Here, we employ novel enrichment and pooling strategy coupled with the next generation state-of-the-art FLX deep sequencing to comprehensively characterize HBV in 48 HCC patients. Our data suggest preferential integration of HBV into genic regions and many are predicted to alter gene regulation. Notably, integration of HBV into tumor tissues is less random than integration into the adjacent non-tumorous tissues. In tumor tissues, there is preferential integration of HBV into selected chromosomes. Within the HBV genome, the preferred region involved in integration is at the 3'end of the HBX gene and the 5' of the precore/core protein. The 3'end of the HBx is often deleted upon integration. The most common type of chimeric transcript observed is the HBx-human transcripts which can be expressed. This study represents a comprehensive characterization of HBV in HCC patients at the genetic level which may facilitate our understanding of the potential role of HBV in HCC development.

Functional analysis of 30 putative *BRCA1* splicing mutations in German families with hereditary breast and ovarian cancer

J. Hauke[1,2], *A. A. Becker*[1,3], *S. Engert*[4], *J. Köhler*[1,3], *N. Arnold*[5], *E. Hahnen*[1,3], *A. Meindl*[4], *R. K. Schmutzler*[1,3], *B. Wappenschmidt*[1,3];
[1]*Department of Gynaecology and Obstetrics, University Hospital of Cologne, Cologne, Germany,* [2]*Center for Molecular Medicine Cologne (CMMC), University of Cologne, Cologne, Cologne, Germany,* [3]*Center for Molecular Medicine Cologne (CMMC), University of Cologne, Cologne, Germany,* [4]*Department of Gynaecology and Obstetrics, Klinikum rechts der Isar at the Technical University, Munich, Germany,* [5]*Department of Gynaecology and Obstetrics, University Hospital Schleswig-Holstein, Christian-Albrechts-Universität Kiel, Kiel, Germany.*

Since 1997, more than 4500 families fulfilling the criteria for hereditary breast and/or ovarian cancer were screened for *BRCA1* and *BRCA2* mutations at the German consortium of hereditary breast and ovarian cancer (GC-HBOC) centres Cologne, Munich and Kiel. More than 1200 different *BRCA1* mutations have been described as disease-causing. Variants disrupting invariant splice sites are generally considered as clinically significant. However, numerous intronic and exonic variants outside invariant splice sites with uncertain affect on *BRCA1* pre-mRNA processing have been detected. We characterized 30 distinct *BRCA1* variants, which have not been sufficiently described before on transcript level, by quantitative PCR and sequencing using mRNA extracted from blood lymphocytes. 13 variants disrupt invariant splice sites, resulting in exon skipping and/or activation of cryptic splice sites. Experimental analysis of more distant intronic or exonic variants is mandatory and can be supported by *in silico* analyses. Ten intronic mutations were tested using the *Human Splicing Finder* prediction algorithm and analyzed for aberrant splicing. Four mutations caused splicing defects while the remaining ones were neutral, which was in-line with *in silico* predictions. Interestingly, we identified 5 out of 7 exonic variants analyzed affecting *BRCA1* pre-mRNA processing (silent: c.710C>T; missense: c.787A>G, c.4794G>A, c.5193G>C, c.5527G>C). Those variants were located close (≤ 3bp) to the respective intron/exon borders, highlighting the importance of splicing analysis even for silent mutations. In conclusion, our results contribute to the recent knowledge of deleterious *BRCA1* splicing mutations. The clinical consequence of mutations with only minor effects on alternative splicing remains to be explored.

Mutation screening of *RAD51D* in non-*BRCA* breast/ovarian cancer families from Spain.

O. Diez[1,2], *M. de la Hoya*[3], *G. Ruiz de Garibay*[3], *J. Balmaña*[4], *A. Tenés*[2], *G. Montalbán*[1], *M. Masas*[2], *R. Moreno*[1], *N. Gadea*[4], *N. Bosch*[4], *S. Bonache*[5], *T. Caldés*[3], *P. Pérez-Segura*[6], *S. Gutiérrez-Enríquez*[2];
[1]*University Hospital Vall d'Hebron, Barcelona, Spain,* [2]*Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain,* [3]*Laboratorio de Oncología Molecular. Hospital Clínico San Carlos. Instituto de Investigación Sanitaria del Hospital San Carlos (IdISSC), Madrid, Spain,* [4]*Medical Oncology Department, University Hospital Vall d'Hebron, Barcelona, Spain,* [5]*Vall d'Hebron Institute of Research (VHIR), Barcelona, Spain,* [6]*Servicio de Oncología Médica. Hospital Clínico San Carlos. Instituto de Investigación Sanitaria del Hospital San Carlos (IdISSC), Madrid, Spain.*

Introduction: Mutations in the *BRCA1* and *BRCA2* genes are involved in approximately 25% of hereditary breast/ovarian cancer families and predisposition to the syndrome may be attributed to mutations in genes of moderate risk. Recently, germ line mutations in *RAD51D* were identified in families with breast and ovarian cancer cases.

Objectives: We aimed to determine the prevalence of germ line *RAD51* mutations in Spanish breast/ovarian cancer families previously found to be negative for *BRCA1BRCA/2* mutations.

Methods: We performed mutational analysis in 289 index patients: 144 from breast cancer families and 123 from families with breast and ovarían cancer cases. Mutation detection was performed with High resolution melting curve analysis (HRM) or Sanger sequencing, and MLPA for large rear-

rangements.
Results: We found one nonsense mutation (c.674C>T; p.Arg232X) in a patient with ovarian cancer diagnosed at 44 years of age and no family history. We also detected some common polymorphisms and missense variants. The clinical significance of all detected variants is currently under evaluation.
Conclusions: Our preliminary data suggest a very low frequency of deleterious mutations in *RAD51D* in our study population. The results support the association of mutations in this gene with the presence of ovarian cancer.

P06.119

HIWI as a prognostic marker for early stages of colorectal cancer

M. Moghbeli[1]*, M. M. Forghanifard*[1]*, R. Raeisossadati*[1]*, S. Boroumand*[2]*, M. R. Abbaszadegan*[3]*;*
[1]*Department of Biology, Mashhad Branch, Islamic Azad University, Mashhad, Islamic Republic of Iran,* [2]*Department of Pathology, Omid Hospital, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran,* [3]*Division of Human Genetics, Immunology Research Center, Avicenna Research Institute, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran.*

Dysregulation of self-renewal pathways is likely a requirement for cancer development. HIWI proteins and their interaction with piRNAs have indicated their key function in stem cell development. Although Hiwi overexpression has been observed in several cancers, the relationship between Hiwi and colorectal cancer (CRC) is unclear. In this study, we assessed the Hiwi mRNA expression in 38 CRC patients (20Male/18Female, Mean age 56) by comparative real-time PCR. Overexpression of Hiwi mRNA transcripts observed in 35% (13/38) of patients. There was not any significant correlation between mRNA expression and patients' survival, tumor size and location. However, it was observed that the stage of tumor has a significant correlation with hiwi expression, in which the hiwi overexpression prohibits the tumor extension toward the higher stages (P=0.034). Furthermore, significant correlations were observed between overexpression of either Hiwi and self-renewal marker SALL4 (p=0.002) or HIWI and cancer testis antigen DPPA2 (p=0.019). Few target molecules have been identified that enable the prognosis of colorectal cancer with a high sensitivity and specificity, especially in the early clinical stages of cancer. This report emphasizes the importance of HIWI as a proper candidate for use in the proggnosis of colorectal cancer in the early stages, and represents a complex network between Hiwi and other self renewal markers such as Dppa2 and Sall4 in colorectal cancer.

P06.120

Alterations of the human β defensin-1 gene in Acute Myeloid Leukemia: association with FLT3 gene

H. Kim*, N. Yu;*
laboratory medicine, Seoul, Korea, Republic of.

INTRODUCTION: Defensins are a family of antimicrobial peptides produced by WBCs and epithelial cells that functions in the host innate defense. Both HBD1 and HBD2 have been shown to induce the migration of immature dendrite cells (DC) and memory T cells. *Fms*-like tyrosine kinase-3 (FLT3) provides an important stimulus for resident DC production in vivo and indicating its important in migratory DC generation. We then analyzed the frequency distribution of promoter polymorphisms and determined the effect of these base changes on transcriptional activity of the HBD1 promoter and the prevalence of FLT3 mutation in patients with various AML.
METHODS: Genomic DNA was isolated from a BM slide or BM aspiration with various 47 AML patients and 43 controls using QIAamp DNA kit (Qiagen, Hilden, Germany). The PCR products of hBD-1 gene were then digested by the restriction enzymes *Nla*IV, *Hga*I, and *ScrF*I, respectively.
RESULTS: AML patients had significantly different mutation frequency of at position -44 and -20 in the 5'-UTR (, p=0.000, p=0.05, respectively). Of the 47 patients with AML, alterations in FLT3 gene were detected in 13 (27.6%) patients. These mutations included FLT3/ITD in 9 (19.1%) and FLT3/TKD mutation in 4 (8.5%) patients. Statistically significant differences for -44 allele frequencies were found between patients with AML with the mutation of FLT3/ITD and the wild types of FLT3/ITD.
CONCLUSIONS: These data suggest that HBD-1 is a potential tumor suppressor gene for AML. Promoter point mutations may be responsible for AML-specific loss of HBD-1 expression.

Human Papilloma Virus infection and KRAS mutations in lung squamous cell carcinoma patients from Iran

L. Emrahi Govar[1]*, E. Sakhinia*[2]*, R. Ahangari*[3]*, A. Ebrahimi*[4]*,* ***K. Nejati-Koshki***[1]*, R. Gharehmohammadlou*[5]*, A. Fakhrjou*[6]*;*
[1]*Department of Genetic,Faculty of Medicine, Tabriz University of Medical Science, Tabriz, Islamic Republic of Iran,* [2]*Department of Genetic,Faculty of Medicine, Tabriz University of Medical Science,, Tabriz, Islamic Republic of Iran,* [3]*Tabriz Molecular Diagnosis Center,Tabriz University of Medical Science,, Tabriz, Islamic Republic of Iran,* [4]*Tabriz Molecular Diagnosis Center,Tabriz University of Medical Science, Tabriz, Islamic Republic of Iran,* [5]*Tuberculosis and Lung Diseases Research Center,Tabriz University of Medical Science, Tabriz, Islamic Republic of Iran,* [6]*Department of Pathology,Faculty of Medicine, Tabriz University of Medical Science, Tabriz, Islamic Republic of Iran.*

Lung cancer is the leading cause of cancer death for both women and men. Non-small cell lung cancer (NSCLC) represents more than 80% of lung cancers and is sub grouped in squamous cell carcinoma (SCC), adenocarcinomas (ADC) and large cell carcinoma(LCC). SCC accounts for about 30% of all cases of patients with NSCLC. Mutations in ras oncogens appear to play a significant role in the development of NSCLC. The role of HPV infection in the development of carcinomas was also demonstrated. The aim of this study was to determine the association between HPV infection and K-ras mutations in patients with SCC. DNA was isolated from Fifty patients with histologically confirmed SCC. HPV typing was done by Nested-PCR and direct sequencing. High risk HPV was detected in 9 (18 %) patients. HPV-18 was the most frequent type in the cases. To investigate gene- virus interactions, DNA from the 9 HPV positive and 9 HPV negative patients, as controls, were subjected to mutation analysis in exons 2 and 3 of the K-ras gene using direct sequencing. Among the two K-ras exons tested, no mutation was found in two groups. Our overall findings demonstrate that the HPV infection has a significant impact on NSCLC. However, due to the small number of patients, our finding could not demonstrate a positive association between HPV-infection and K-ras mutation in patients with lung SCC. Our results are preliminary and larger cohorts are needed for better understanding the contribution of genetic alternations and HPV infection in lung SCC.

Comparison of Methylation-Specific qPCR (MS-qPCR) and pyrosequencing for the analysis of *p16/INK4a* in lymph node samples

L. De Chiara[1]*, V. Leiro-Fernández*[2]*, M. Botana-Rial*[2]*, C. Represas-Represas*[2]*, A. Fernández-Villar*[2]*, D. Valverde*[1]*;*
[1]*Universidad de Vigo. Departamento de Bioquímica, Genética e Inmunología, Vigo, Spain,* [2]*Complejo Hospitalario Universitario de Vigo. Servicio de Neumología, Vigo, Spain.*

Introduction: Promoter hypermethylation of tumor suppressor gene p16/INK4a has been found in a wide variety of neoplasia, suggesting in some cases its utility as diagnostic or prognostic tool. The aim of this study was to compare two methods (MS-qPCR and pyrosequencing) for the quantitative methylation analysis of this gene.
Methods: 62 patients with confirmed diagnosis of non-small cell lung cancer were included (56.9% with ganglionar metastasis). DNA from lymph nodes was extracted and sodium bisulfite modification, required for both techniques, was accomplished. The same portion of CpG island containing 11 CpG sites was independently analyzed using both techniques. For the MS-qPCR, pre-amplification with universal primers followed by TaqMan-based qPCR with methylation-specific primers and probe was used. The relative methylation percent was estimated based on a standard curve build with variable proportions of fully-methylated/unmethylated control and using MYOD1 to normalize the DNA input. On the other hand, templates for pyrosequencing were obtained amplifying bisulfite-treated DNA with biotinylated primers. Methylation percent was calculated by averaging across all CpG sites interrogated.
Results: Differences in the methylation percent were found between the two techniques, resulting in different cut-offs for MS-qPCR and pyrosequencing (2.25 and 9.95 methylation percent, respectively). According to MS-qPCR, p16/INK4a promoter was considered hypermethylated in 33.33% of the cases with metastasis, and in 24.24% for pyrosequencing.
Conclusion: Pyrosequencing and MS-qPCR show good linearity for known methylation percents. In this cohort positive predictive value was 100% for MS-qPCR and pyrosequencing.

Inflammatory Response Evaluation in EGFR Mutation Negative Lung Adenocarcinomas

M. C. Stoicea*, A. G. M. Grigore, F. L. Cionca, G. Cardos;*
„Victor Babes" National Institute of Pathology, Bucharest, Romania.

Activation of the epidermal growth factor receptor (EGFR) constitutes a major molecular pathway involved in the carcinogenesis of nonsmall cell lung carcinomas. In EGFR mutation negative cases, K-ras activation represents an alternative molecular pathway responsible for primary resistance to tyrosine kinase inhibitors. We investigated a number of 34 randomly selected cases of advanced lung adenocarcinomas from patients with a long history of active smoking. The DNA samples extracted from formalin fixed, paraffin embedded tumoral material were initially tested for EGFR mutations by PCR and sequencing of exons 18, 19 and 21. Since the studied cases showed no mutations on any of the EGFR exons, they were subsequently tested for K-ras mutations in codons 12 and 13 using the PCR-RFLP method. K-ras codon 12 mutation was identified in 12 lung adenocarcinomas (35.29%). Considering the worse prognosis in K-ras positive cases, we further assessed the tumoral associated inflammatory response compared to EGFR-negative, K-ras negative patients. The inflammatory infiltrate was significantly increased in K-ras negative tumors, opposed to K-ras positive cases where inflammatory cells showed reduced counts. Our findings indicate a medium negative correlation (r = -0.35) between K-ras mutational status and the inflammatory response in EGFR-negative advanced lung adenocarcinomas, which was statistically relevant (p = 0.001). These findings indicate a possible impact of K-ras mutation on tumoral biology in diminishing the level of inflammation elicited by the tumor, favouring cancer progression and lowering prognosis.

P06.124

Identification of candidate genes involved in maintaining Interstitial Cajal Cells and Interstitial Cajal-like Cells in mutant mice

G. Cardos[1]*, A. M. Niculescu*[2]*;*
[1]*„Victor Babes" National Institute of Pathology, Bucharest, Romania,* [2]*SC Agilrom Scientific SRL, Bucharest, Romania.*

Interstitial Cajal Cells (ICC) are involved in gastro-digestive tract motility and neurotransmission, but also in gastro-intestinal tumors (GIST) pathogenesis. Other extra-digestive organs (gallbladder, heart, uterus, etc) have been shown to contain Interstitial Cajal-like Cells (ICLC), whose function is yet unknown. Both cell types express the Kit protein, a tyrosine-kinase receptor with essential role in maintaining these phenotypes.

Our study was focused on comparative investigation of gene expression in normal and mutant mice by DNA microarray, in order to contribute in understanding the physiology of ICC and ICLC.

Total RNA was extracted by RNeasy Mini Kit (Qiagen) from heart and gallbladder tissues sampled from control and Kit mutant mice (WBB6F1/J-KitW/KitW-v/J strain) and analyzed by Bioanalyzer (Agilent Technologies). DNA microarrays from Whole Mouse Genome Microarray Kit (Agilent Technologies) hybridized and scanned by Agilent DNA Microarray Scanner were analyzed by Feature Extraction5.1.1. and GeneSpring GX10 Software (Agilent Technologies).

In the myocardium, three genes demonstrated differential expression by >2 fold (p<0,05) in mutant versus control mice and may be involved in maintaining ICC and ICLC phenotypes: the Timp4 and Dnaja1 genes down-regulated and the Serpinb2 gene up-regulated.

Of the 22 genes different expressed in the gallbladder, only one was found down-regulated in mutant mice (the PYCARD gene, involved in apoptosis); some of the 21 over-expressed genes are involved in different metabolic processes: signal transduction, cell adhesion, proteolysis (NOS1AP, ITGB3, Ctsj genes), etc.

Some of these genes may become candidate biomarkers for studying ICC, ICLC and associated pathology in humans.

Detection of the JAK2V617F mutation in polycythemia vera and other myeloproliferative disorders in Iranian patients

S. Vlizadegan*, R. Najafi, S. Khalili, G. Esmailnia, M. Ghalandari, P. Rostami, H. Imanian, H. Najmabadi;*
Kariminejad – Najmabadi Pathology & Genetics Center, tehran, Islamic Republic of Iran.

A somatic mutation in the JH2 autoinhibitory domain of the Janus kinase 2 (JAK2) tyrosine kinase have been implicated in polycythemia vera (PV), essential thrombocythemia (ET), myelofibrosis as well as other myeloproliferative disorders. This mutation, (V617F) a change of valine to phenylalanine at the 617 position, appears to render hematopoietic cells more sensitive to growth factors such as erythropoietin and thrombopoietin.

The aim of this study was identification of JAK2 mutations among patients with PV , ET and idiopathic myelofibrosis who were refered to our center since 2008. We have analyzed leukemic patients by ARMS-PCR method for screening of patients for a single point mutation.

The JAK2 (V617F) mutation was studied in 236 patients, of whom 33 (34%) out of 97 patients with PV were identified, 64 (49.2%) out of 130 patients with ET and 1 (11.1%) of 9 patients with idiopathic myelofibrosis were detected. In PV patients 14.5% were homozygous and 19.5% were heterozygous, these values were 9.2% and 40% among ET patients and all of the mutant alleles detected for myelofibrosis patients were in heterozygous form. In previous studies, the JAK2 mutation was identified in 60-70% patients with PV, 30-40% of ET patients and 11-14% of patients with idiopathic myelofibrosis and the range of heterozygosity and homozygosity in patients with PV were 48% and 25%, respectively. The difference between our results and the other studies could be due to the misdiagnosis of the patients by the physicians who referred the patients for molecular diagnosis in Iran.

Ion AmpliSeq™ Cancer Panel - Accurate and Sensitive Detection of Over 700 Somatic Mutations in a Single Day

M. Andersen[1]*,* ***R. Wicki***[2]*, J. Rothberg*[1]*;*
[1]*Life Technologies, Carlsbad, CA, United States,* [2]*Life Technologies, Darmstadt, Germany.*

Selective enrichment of the coding regions from genomic DNA has proven beneficial in the detection of genetic disorders without the cost, labor, and time associated with sequencing the entire genome. Widespread diagnostic utilization of whole exome sequencing has been has been limited by the extensive time required for typical hybridization-based exon capture strategies, which can take several days. We have developed a quick, easy-to-use, multiplex PCR based, enrichment method for next-generation sequencing. The process combines the speed and specificity of PCR reactions with the efficiency of unprecedented levels of plexy. The Ion AmpliSeq™ Cancer Panel consists of 190 amplicons and surveys 739 known cosmic mutations in approximately 20 kb of sequence from 46 genes including EGFR, KRAS and BRAF. This kit is ideally suited for both fresh and archival (FFPE) samples, requiring only 10ng of DNA per reaction. When the libraries are processed and sequenced with the Ion OneTouch™ and PGM™ Sequencer, mutations at only 5% frequency can be quantified from DNA to results in less than 12 hours.

The Ion AmpliSeq™ Cancer panel was tested using FFPE preserved, KRAS mutation containing cells lines mixed together at various concentrations. Several known mutations were verified and quantified down to 5% frequency. The results were further confirmed by CAST PCR.

Ion AmpliSeq™ Primer Panels are available in custom assay sets and scalable to over 1,000 amplicons per tube. With barcode compatibility, and multiple chip capacities, this technology enables rapid and efficient focused sequencing in a variety of settings.

Combined point mutations in codon 12 and 13 of KRAS oncogene in prostate carcinomas with high gleason score

F. Silan[1]*, S. Atik*[1]*, Y. Gultekin*[2]*, D. Kılınc*[2]*, C. Alan*[3]*, A. Uludag*[1]*,* ***A. Colak***[4]*, O. Ozdemir*[1]*;*
[1]*Department of Medical Genetics, Faculty of Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey,* [2]*Department of Urology,Faculty of Medicine, Cumhuriyet University, Sivas, Turkey,* [3]*Department of Urology, Faculty of Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey,* [4]*Department of Medical Biology and Genetics,Faculty of Medicine, Cumhuriyet University, Sivas, Turkey.*

The G to T transversions in codon 12 and C to T transitions in codon 13 of KRAS proto-oncogene are predominant point mutations that occur in about 20% of different cancers in human. It was aimed to investigate the prevalence and predictive significance of KRAS mutations in patients with prostate carcinomas. In a total of 30 fresh tumoural tissue specimens were investigated in patinet with prostate carcinomas of different scores(GS). All tumoural specimens were histo-pathologically diagnosed and genotyped for codon 12, 13 KRAS point mutations by reverse hybridisation and direct sequencing methods. KRAS mutations were found in 12 (40%) samples with 29 samples deriving from adenocarcinomas and 1 sample was small cell prostate carcinoma. In 1 (3.44%) sample codon 12 was found to be mutated and in 2 (6.8%) samples codon 13 and in 9 (31%) samples combined codon 12 and 13 were found to be mutated particularly in higher grade of tumoural tissues. Current preliminary results indicate that combined point mutations in codons 12 and 13 KRAS gene play crucial role in prostate carcinomas with high GS.

Study of HER-1 497K polymorphism in EGFR gene in patients with laryngeal cancer

J. Fernández Mateos[1]*, E. Sánchez Tapia*[1]*, J. Gómez González*[2]*, E. del Barco Morillo*[3]*, J. Cruz Hernández*[3]*, R. González Sarmiento*[4]*;*
[1]*Centro de Investigación del Cáncer, Salamanca, Spain,* [2]*Servicio de Otorrinolaringología. Hospital Clínico de Salamanca, Salamanca, Spain,* [3]*Servicio de oncología. Hospital Clínico de Salamanca, Salamanca, Spain,* [4]*Unidad de Medicina Molecular-Departamento de Medicina. Universidad de Salamanca., Salamanca, Spain.*

Introduction and aim

Head and neck squamous-cell carcinoma is the sixth most frequent neoplasia worldwide and the most malignant tumour in the superior aero-digestive tract. The highest rates in the whole world of laryngeal cancer are encountered in Spain, especially in men, although the number of women is rapidly increasing. 95% of laryngeal cancer is developed in men between 45 and 70 years old, with a maximum of incidence in the sixth decade. It has been described that EGFR is over expressed in the epidermoid carcinoma of the larynx, and the HER-1 497K polymorphism has been associated with a higher risk of mortality in these tumours.

In this study we have analysed the possible association between this polymorphism and the developing of laryngeal cancer.

Methods

Genomic DNA was extracted from peripheral blood leukocytes by standard techniques. We selected 65 patients from Salamanca (Spain) with cancer of the larynx and 385 healthy subjects as controls. Clinical characteristics have also been studied. The HER-1 497K polymorphism in the EGFR gene was realised by DHPLC (Denaturing High Performance Liquid Chromatography).

Statistical analysis was performed comparing the different distribution of the polymorphism in the EGFR gene in subgroups of patients and controls.

Results and conclusion

No statistical differences have been shown in the distribution of the HER-1 497K polymorphism comparing cases and controls (p<0.05).

Our results do not support the hypothesis that the HER-1 497K polymorphism is associated with increased susceptibility to suffer laryngeal cancer.

In vitro sensitivity profile of Laryngeal cell carcinoma

A. L. S. Galbiatti[1,2], *H. C. Caldas*[1,2], *J. A. Padovani Junior*[1,2], *É. C. Pavarino*[1,2], *E. M. Goloni-Bertollo*[1,2];
[1]*Faculdade de Medicina de São José do Rio Preto, São José do Rio Preto, Brazil,* [2]*FAMERP, São José do Rio Preto - SP, Brazil.*

Introduction: The research of chemosensitivity is important to screen new therapeutic agents, identify patterns of chemosensitivity for different tumor types and to identify chemotherapy regimens to patients because antineoplastic agents increase acute toxicity and side effects and tumors may exhibit resistance to chemotherapeutic. Objectives: To evaluate the sensitivity of *Hep-2* cells line (Laryngeal carcinoma) to MTX chemotherapeutic *in vitro* in three different concentrations. Methods: Cells were plated in six-well culture plates at a density of 1 × 10^5/well and incubated with three different concentrations 0.25 μM, 25 μM, and 75 μM of the Metrotexate for 24 hours at 37 °C. Cell Apoptosis was evaluated by double staining with fluorescein isothiocyanate (FITC) label Bcl-2 (100: sc-509) by Flow Cytometry Technique. Statistical analysis was performed by Chi square test (X2) to compare the cell viability. Correlation coefficient of Pearson (R2) between the concentrations also was measured. Results: For the treatment with 0.25 uM, 25.0 uM and 75.0 uM MTX concentration, the viable cells were 85,43%, 22.46% and 8.42%, respectively. There was positive association between the 0.25 mM (X2=55.001; p<0.0001), 25 mM (X2=2991.3; p<0.0001) and 75 mM (X2=5091.7; p<0.0001) MTX concentrations. There was a good correlation between cell viability and the different doses of the chemotherapy (R2 = 0.9276). Conclusions: According to the dose was increasing, the cells became more sensitive and lower resistant to the MTX chemotherapeutic. Moreover, there are a positive correlation between cell viability and the three different doses of the MTX chemotherapeutic. Financial support: Fapesp, CNPq, Capes FAMERP/FUNFARME.

The Expression of RLIP76 in Leukemia Cell Lines

A. TOYLU[1], *O. Altiok Clark*[1], *A. Irfanoglu Timuragaoglu*[2];
[1]*Akdeniz University School of Medicine Department of Medical Genetics, Antalya, Turkey,* [2]*Akdeniz University School of Medicine Department of Haematology, Antalya, Turkey.*

RLIP76 is a membrane-located protein mediating the transport of multiple molecules, including both glutathione-conjugated or lipid-oxidized metabolites and drugs.

Besides this transport function, RLIP76 acts as an anti-apoptotic protein, interacting with Ras/Ral and EGF-R signaling. Studies have shown that there is an increased expression of RLIP76 in several types of cancer cells and that it plays a prominent role in drug resistance. The expression of RLIP76 in leukemia cells has also been reported, but the cell type and differentiation-related alterations are not yet known.

The aim of this study was to investigate RLIP76 expression in leukemia cells. The analysis of RLIP76 expression was performed at the mRNA level on several leukemia cell lines by using quantitative PCR.

Our results suggest that the expression of RLIP76 may exhibit a differential pattern in several types of leukemia cells.

P06.131

Prognostic impact of del(17p) and del(22q) as assessed by interphase FISH in sporadic colorectal carcinomas

M. Gonzalez-Gonzalez[1], *L. Muñoz-Bellvis*[2], *C. Mackintosh*[1], *C. Fontanillo*[1], *M. Gutierrez*[1], *M. Abad*[2], *O. Bengoechea*[2], *O. Blanco*[2], *E. Fonseca*[2], *M. Fuentes*[1], *J. De las Rivas*[1], *A. Orfao*[1], ***J. Sayagues***[1,2];
[1]*Centro de Investigación del Cáncer (IBMCC-CSIC/USAL), Universidad de Salamanca, Salamanca, Spain,* [2]*Hospital Universitario de Salamanca, Salamanca, Spain.*

Purpose: Most sporadic colorectal cancer (sCRC) deaths are caused by metastatic dissemination of the primary tumor. New advances in genetic profiling of sCRC suggest that the primary tumor may comprehend a cell population with metastatic potential. Here we compare the cytogenetic profile of primary tumors from metastatic versus non-metastatic sCRC.

Patients and Methods: We prospectively analyzed the frequency of numerical/structural abnormalities of chromosomes 1,7, 8, 13, 14, 17, 18, 20, and 22 in 58 sCRC patients (31 non-metastatic vs. 27 metastatic) through FISH analysis.

Results: From a total of 18 probes, significant differences emerged only for 17p11.2 and 22q11.2. Patients with metastatic sCRC showed an increased frequency of del(17p11.2) (10% vs. 67%;p<.001) and del(22q11.2) (0% vs. 22%;p=.02) as compared to non-metastatic cases. Multivariate analysis of prognostic factors for overall survival (OS) showed that the only clinical and cytogenetic alterations that had an independent impact on patient outcome were the presence vs. absence of del(17p) with a 17p11.2 breakpoint and del(22q11.2). Based on these two cytogenetic variables patients were classified into three groups: low- (no adverse features), intermediate- (one adverse features) and high-risk (two adverse features)- with significantly different OS rates at 5-years (p<.001): 92%, 53% and 0%, respectively.

Conclusion: Our results unravel the potential implication of del(17p11.2) and del(22q11.2) chromosomal abnormalities in the sCRC pathogenesis, as these are intrinsically related to an increased metastatic potential and extremely poor outcome. Additional prospective studies in larger series of patients are necessary to confirm the clinical utility of the new prognostic markers identified.

The Relationship of Metalloproteinase Gene Polymorphisms with Disease and Prognosis in Non-Small Cell Lung Cancer Patients Undergoing Resection

M. Sanli[1], *E. Akar*[1], *S. Pehlivan*[2], *K. Bakir*[3], *B. Tuncozgur*[1], *A. F. Isik*[1], *L. Elbeyli*[1], *M. Pehlivan*[4];
[1]*University of Gaziantep, Faculty of Medicine, Department of Thoracic Surgery, GAZIANTEP, Turkey,* [2]*University of Gaziantep,Faculty of Medicine, Department of Medical Biology and Genetics, GAZIANTEP, Turkey,* [3]*University of Gaziantep, Faculty of Medicine, Department of Pathology, GAZIANTEP, Turkey,* [4]*University of Gaziantep, Division of Hematology, Faculty of Medicine,, GAZIANTEP, Turkey.*

In this study, we searched the relationship of matrix metalloproteinase (MMP) 2, 7, 13 gene expressions and polymorphisms with susceptibility and prognosis in patients operated for NSCLCs. The study group consisted of 132 patients who had undergone radical surgery in our clinic from 1997 to 2008. In the pathology arm of the study, sections were obtained from paraffin embedded blocks and then were analyzed immunohistochemically after treatment with MMP 2, 7 and 13 antibodies by using streptavidin-biotin method. In the genetic arm of the study, DNA samples were isolated from pathology blocks for NSCLC and from blood samples for the control group. MMP gene polymorphisms were analysed by PCR-RFLP method. The obtained results were compared with those of the control group to evaluate disease susceptibility, correlation with other clinical parameters and with survival and prognosis by using appropriate statistical methods. When MMP polymorphisms are compared in healthy and NSCLC DNA, a decrease was seen in MMP2(-735) GG genotype and increases were seen in MMP13(A77G) AG and GG genotypes (p=0.008, p=0.047, p=0.047 respectively). Median overall survival time was found as 29.5 months in MMP13 AA/AG genotypes and 9.3 months in GG genotype. MMP2, 7, and 13 expressions were not found to have a statistically significant influence on the prognosis of the patients. Decreases in MMP2(-735) GG genotype and increases in MMP13(A77G) polymorphism AG and GG genotypes increase the risk for NSCLC. Furthermore, the presence of MMP13(A77G)GG genotype is an unfavorable prognostic factor.

Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran, [3]Tabriz Molecular Diagnosis Center and Tuberculosis and Lung Diseases Research Center, Tabriz University of Medical Science, Tabriz, Islamic Republic of Iran, [4]Pathology Department, Faculty of Medicine, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran, [5]Intenal Disease Department, Faculty of Medicine, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran, [6]Tabriz Molecular Diagnosis Center, Tabriz University of Medical Science, Tabriz, Islamic Republic of Iran.

Lung cancer is the leading cause of cancer-related deaths across the world. Prevalent inconsistencies in the association of the high-risk Human Papilloma Virus (HPV) infection with lung cancer were found amongst recent studies.We evaluated the frequency of HPV positivity in NSCLC in an open case control study.50 recently diagnosed patients with squamous cell carcinoma of the lung were selected for HPV DNA extraction from paraffin-embedded blocks HPV DNA was the detected by nested-PCR. DNA amplification was initially performed using MY09/MY11 as the outer and GP5+/GP6+ as the inner primers. DNA was then sequenced for the determination of high-risk HPV types.Saliva samples of 94 control cancer-free subjects were collected for DNA analysis. High risk HPV was detected in 9 (18 %) patients and 6 (5.3%) control subjects, which was proven to be statistically significant. HPV-18 was the most frequent type both in the cases and controls. HPV-6 DNA was detected in one patient from each of the case group and the controls. In conclusion, HPV infection has a significant impact on NSCLC. Despite HPV-16 having a stronger impact, HPV-18 is more likely to cause malignant degeneration in such cancers amongst some communities. It is vital to introduce and conduct immunization schedules in health care systems to protect communities to some extent.

P06.134

Human papillomavirus DNA and abnormal p53 Tumor Suppressor Gene in lung carcinoma

*H. Jafari[1], **E. Sakhinia**[1,2,3], A. Fakhrjou[4], R. Gharemohammadlou[5,3], A. Ebrahimi[2], K. Nejati[2];*
[1]Human Genetics Department, Medicine School, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran, [2]Tabriz Molecular Diagnosis Center, Tabriz University of Medical Science, Tabriz, Islamic Republic of Iran, [3]Lung Diseases Research Center, Tabriz University of Medical Science, Tabriz, Islamic Republic of Iran, [4]Pathology Department, Faculty of Medicine, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran, [5]Intenal Disease Department, Faculty of Medicine , Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran.

A powerful relationship has been established between high-risk human papillomaviruses (HPV) and lung cancer. Inactivation of P53 is the most common genetic abnormality in lung cancer. We evaluate the frequency of HPV types and TP53 mutations in squamous cell carcinoma (SCC) of lung, among patients from the north-west of Iran. 50 Paraffin embedded blocks of lung SCC were selected for detection of HPV DNA by Nested PCR with the MY09/11 and GP5+/6+ primer sets, Then DNA sequenced for HPV typing. Equal numbers of positive and negative samples for the HPV DNA were examined for the presence of mutations in exons 5-7 of the TP53 gene by PCR and direct sequencing. 9 (18%) out of 50 samples presented the HPV DNA: eight were HPV-18 and one was HPV-6. TP53 mutations were found in 5 samples (27.7%). Of these, 4 cases showed mutations in exon 5 and one case contained a mutation in exon 7. One of HPV negative samples had a mutation in exon 5. Three of the HPV positive cases demonstrated a mutation in exon 5 and one in exon 7. The frequent mutation in exon 5 was the C to G transversion (c.409C>G), and the T to A tansversion (c.770T>A) in exon 7. Both anomalies were missense mutations, L137V and L257Q respectively. Our study showed that HPV-18 is more likely to result in the development of lung cancer in some communities. Genetic alterations, alongside environmental factors, thus play a significant role in the pathogenesis of lung SCC.

P06.135

Cervical cancer as a part of Lynch Syndrome?

***K. Rønlund**[1], A. Skytte[1], D. G. Crüger[1], I. Bernstein[2], M. Waldstrøm[3];*
[1]Department of Clinical Genetics, Vejle Hospital, Vejle, Denmark, [2]The Danish HNPCC Register, Department of Surgical Gastroenterology, Hvidrove Hospital, Hvidovre, Denmark, [3]Department of Pathology, Vejle Hospital, Denmark., Vejle, Denmark.

Background: Pedigrees from Lynch families often include cases of cervical cancer. Cervical cancer is however not defined as an extra colonic cancer in Lynch syndrome. Therefore we set out to investigate if cervical cancer could be a part of the Lynch syndrome.
Materials and method: We used data from the Danish HNPCC register on women from Lynch families with in situ carcinoma in cervical tissue (CIN III) or cervical cancers. We obtained tissue samples from 20 out of 29 patients. We conducted immunohistochemical staining for MMR genes (MLH1, PMS2, MSH2 and MSH6). We used a HPV (*human papilloma virus*) genotyping analysis to identify infection.
Results: Among the cervical cancers 5 were adenocarcinoma and 2 were squamous cell carcinoma. There were full correlation between the mutation in the family and the loss of either MLH1 or MSH2 expression. Loss of expression of MMR genes was found in 5 of 7 (71%) cases of cervical carcinoma but in only one of the carcinoma in situ (p=0.007). All samples positive of HPV were detected in squamous cell carcinoma in situ. Conclusions: The results indicate a relation between the MMR mutation found in families and loss of MMR genes in cervical tumors. Our data also suggest that women with Lynch syndrome are at higher risk of developing adenocarcinomas than the background population. Loss of MMR gene expression seems to be a late event in the carcinogenesis of cervical cancer. Further research is needed to determine the precise relationship between Lynch syndrome and cervical cancer.

ALC1 as a candidate oncogene in human malignant glioma

***V. Riehmer**[1,2], R. Wagener[2,3], A. Heimbach[2], E. Littmann[2], V. H. Hans[4], A. Brockschmidt[2], R. G. Weber[1,2];*
[1]Department of Human Genetics, Hannover Medical School, Hannover, Germany, [2]Institute of Human Genetics, University of Bonn, Bonn, Germany, [3]Institute of Human Genetics, University of Kiel, Kiel, Germany, [4]Department of Neuropathology, Evangelisches Krankenhaus Bielefeld, Bielefeld, Germany.

Copy number gain of chromosomal arm 1q is quite a frequent aberration in malignant glioma. Therefore, we aimed to identify novel glioma-relevant oncogenes located on 1q. We screened glioblastoma cell lines by array-based comparative genomic hybridization (array-CGH) and detected an amplification in 1q21.1 encompassing the *ALC1* (amplified in liver cancer 1) gene in LN308 cells. *ALC1* (syn.: *CHD1L*) encodes the chromodomain helicase DNA-binding protein 1-like protein, a chromatin-remodeling enzyme implicated as an oncogene with a major impact in hepatocellular carcinoma development. To explore whether *ALC1* is of relevance for the tumorigenesis of malignant glioma, we analyzed *ALC1* copy number, mRNA and protein expression in 28 glioblastomas and 11 glioblastoma cell lines, and functional effects of *ALC1* overexpression. Array-CGH detected a copy number gain of 1q21.1 including *ALC1* and increased *ALC1* mRNA levels compared to astrocytes in around 20% of glioblastomas, and protein expression was significantly increased in glioblastoma cell lines compared to astrocytes. While *ALC1* overexpression showed a significant increase in viability of glioblastoma cells, which was reversible by RNAi, no significant influence on proliferation was detected by determination of growth curve and cell cycle analysis, and colony formation and migration capacity were decreased in some glioblastoma cell lines. No regulatory effects of *ALC1* overexpression were observed on epithelial (E-cadherin, α-E-catenin and β-catenin) or mesenchymal (N-cadherin, vimentin, fibronektin, α-SMA, snail and slug) marker expression. While *ALC1* showed copy number gain and increased mRNA and protein expression in a fraction of glioblastomas, no important functional effects of *ALC1* overexpression were detected.

Increased gene copy number of *MET* in the bronchial mucosa of patients with malignant pleural mesothelioma

***A. G. Zamani**[1], A. Zamani[2], T. F. Eroglu[1], S. Yildirim[1], G. Durakbasi-Dursun[3];*
[1]Department of Medical Genetics, Meram Medical Faculty,Konya University, Konya, Turkey, [2]Department of Pulmonary Medicine, Meram Medical Faculty,Konya University, Konya, Turkey, [3]Department of Medical Biology, Meram Medical Faculty,Konya University, Konya, Turkey.

Background: c-Met has been shown to be overexpressed in malignant pleural mesothelioma (MPM) tumor tissues as compared with normal pleura. However, the amplification of this proto-oncogene in the airways of patients with MPM has not been reported.
Objectives: To investigate the amplification of c-Met in bronchial mucosa of patients with MPM.
Method: Bronchial mucosa biopsy specimens obtained bronchoscopically from three patients with histologically proven MPM, were subjected to interphase fluorescence in situ hybridization (FISH) analysis. The cell touch preparations were obtained by lightly pressing fresh tissue onto slides. FISH was performed according to standard procedures using a c-Met probe in combination with a chromosome 7-specific centromere probe (CEP-7). Specimens were considered to be amplified if the gene copy number was ≥3 times the pooled mean for corresponding normal tissue.
Results: Increased c-Met copy number was identified in all patients.
Conclusion: Our findings demonstrate that amplification of c-Met is not restricted to the MPM tumor tissue, but is also amplified in the bronchial mucosa.

P06.138

MC1R gene variants and Malignant Melanoma susceptibility in the Canary Islands population

E. Córdoba-Lanús[1]*, J. Hernández-Jiménez*[1]*, C. Medina-Coello*[1]*, A. Espinoza-Jiménez*[1]*, A. González-Hernández*[1]*, M. C. Rodríguez-Pérez*[1]*, G. Carretero*[2]*, A. Perera-Molinero*[3]*, J. Suárez-Hernández*[4]*, R. Fernández-de-Misa*[1,4]*;*
[1]*Research Unit, Hospital Universitario N/S de Candelaria, Santa Cruz de Tenerife, Spain,* [2]*Dermatology Department, Hospital Universitario Dr. Negrin, Las Palmas de Gran Canaria, Spain,* [3]*Anatomy Pathology, Hospital Universitario N/S de Candelaria, Santa Cruz de Tenerife, Spain,* [4]*Dermatology Department, Hospital Universitario N/S de Candelaria, Santa Cruz de Tenerife, Spain.*

Several *MC1R* variants are associated with increased risk of malignant melanoma (MM) in a variety of populations. The high diversity within the *MC1R* gene observed in populations living in higher latitudes is explained by either relaxation of selective pressure or by selection for lighter pigmentation in countries with reduced ultraviolet radiation. We aim to examine the influence of the *MC1R* variants (red-hair colour, RHC: D84E, R151C, R160W and Non-RHC: V60L, R163Q, T314T) on the MM risk in Caucasians and then restrict the analysis to a well defined population (Canary Islands), adjusting for the main phenotypic pigmentation features.

Methods: 938 Caucasian individuals were genotyped for *MC1R* variants by SNaPshot® and direct sequencing. 447 were MM patients (350 with three generation of Canarian ancestors) and 491 were healthy control subjects (296 Canarians) from general population. The analysis was adjusted for age, sex, hair colour, eye colour, skin phototype and ancestry.

Results: Carriers of the R151C and R163Q variants were at an increased risk of melanoma (OR=2.78 (1.58-4.90) and OR=5.45 (2.44-12.18), respectively) in the overall cohort. We observed similar results In the Canarian sample for carriers of the R151C variant but the R163Q variant showed even a higher risk for MM (OR=7.15; 2.38-21.52). The risk of carrying RHC variants was 3.12 (1.92-5.05) in the Caucasian population and 2.27 (1.31-3.91) in the Canarian individuals.

Conclusion: R151C and R163Q variants confer an increased risk of MM in the analysed population. Our results highlight the importance of the sample population selection in this kind of studies.

P06.139

Heading for a more effective and individualized patient care in multiple endocrine neoplasia type 1 (MEN 1)

L. Schaaf[1]*, S. Noe*[1,2]*, M. E. N. 1 Study Group*[1]*;*
[1]*Max-PLanck-Institute of Psychiatry , Endocrinology, Munich / München, Germany,* [2]*Klinikum Rechts der Isar, munich/ München, Germany.*

MEN1 is an autosomal-dominant inherited disorder characterized by the combined occurrence of primary hyperparathyroidism (pHPT), gastroenteropancreatic neuroendocrine tumors (GEP), adenomas of the pituitary (APA), adrenal cortical tumors (ADR) and other tumors. As the tumors appear in an unpredictable schedule, uncertainty about screening programs and genotype-phenotype correlation is persisting. In the German database a total of 683 tumors occurred consisting of 273 pHPT, 138 APA, 166 GEP, 57 ADR, 24 thymic - and bronchial-carcinoids as well as 25 neoplasms of other tissues.

The age-related penetrance was determined as 10 % , 35%, 67 % , 81 % and 100 % at 20, 30, 40, 50 and 65 years respectively. Although pHPT being the most frequent first manifestation (41 %), also GEP (22 %) or APA (21 %) were found to be the first presentation.To initiate a supranational data base, statutes have been elaborated to ensure a consistent data collection to define the influences of epigenetic factors in manifestation and progression of the syndrome.As a first step a summary file of 10 major items was developed. Every interested center is invited to an active collaboration. The aims are 1.) a multidisciplinary approach comprising clinicians of different specialities as well as basic scientists involved in the field 2.) providing diagnostic certificates and folders to all known European MEN 1 patients and 3.) the implementation of a supranational MEN1 patient association and a data base.

P06.140

Identification of a new frameshift mutation in the MEN I gene

M. Hedayati*;*
RIES, Tehran, Islamic Republic of Iran.

Multiple endocrine neoplasia type 1 (MEN1) is an uncommon autosomal dominant cancer syndrome. The classical form of MEN1 is characterized by tumors of the parathyroid, pituitary, and pancreas. MEN1 is a tumor suppressor gene whose germline mutations have been reported in MEN1 syndrome. Although hyperparathyroidism in MEN1 syndrome is the most common manifestation, parathyroid carcinoma is rare. This study aimed to identify mutations in an Iranian pedigree with MEN1. In this report, we presented a male patient who was diagnosed at 44-year-old with a primary hyperparathyroidism (PHPT), parathyroid tumor, recurrent renal stones, maxilla giant cell granuloma, thymic tumor, diabetes mellitus, and developed Cushing syndrome secondary to hypersecretion from neuroendocrine tumor. Genetic analysis revealed a novel germline frame shift mutation in exon 10 of the MEN1 gene, c.1642-1648dup. This heterozygote mutation is a duplication of seven nucleotides (GGTCCAG) which results in a premature termination codon at 558 (p.Val550fs). Three generation of his family members were also evaluated for *MEN1* gene, and the same mutation was detected in one of his sons. Menin truncated protein due to the premature stop codon in MEN1 gene seems to prevent interaction with various cellular proteins, inhibiting tumor suppress activity of menin protein and increasing the potential for tumorgenesis. Finding the same mutation in a younger member of this patient's family allows for prophylactic thymectomy and hopefully the avoidance of the malignant course seen in this patient. We suggest that in patients with ACTH-producing thymic NETS, the possibility of MEN1 should be considered.

P06.141

New epigenetic markers of breast cancer identified by unbiased screening of differential methylation of the genomes

V. V. Rudenko[1]*, A. S. Tanas*[1]*, E. B. Kuznetsova*[1]*, T. V. Kekeeva*[1,2]*, D. V. Zaletayev*[1]*, V. V. Strelnikov*[1]*;*
[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*Moscow Hertzen Research Oncological Institute, Moscow, Russian Federation.*

We have performed screening of 100 breast cancer (BC) samples and adjacent tissues by use of a method for unbiased screening of differential methylation that integrates amplification of intermethylated sites, capillary electrophoresis and computational biology and is designated AFLOAT (Amplified Fragment Length Oriented Analysis Technique). This has allowed us to identify abnormal methylation of CpG islands belonging to different regions of the *LAMB1, RAI1, KCNH8, DOCK6, GPC2, SH3KBP1, PPP2R5C, PHF1, ATMIN, C2CD2, TAF4, KIAA1324L, IQSEC2, AX746725/AK127124, TMEM176A/TMEM176B, FOXM1/HKMT1188* genes and intergenic CpG islands located on 1p33, 5p15.33, 12q13.13, 13q32.1.

SH3KBP1 and *PHF15* genes demonstrate significantly more frequent methylation in BC neoplastic grade 2 (G2) compared to G3. At the same time, *GPC2* reveals differences within G2, which is in agreement with the anxiety of other researchers regarding the subjectivity and insufficient reproducibility of the grading. Possibly, molecular markers might supplement morphological characteristics in defining neoplastic grade.

Methylation markers panel incorporating all of the 20 genes demonstrates 83,7% sensitivity and 93,9% specificity in discriminating BC against adjacent tissues. Exclusion of the least informative markers has led to the development of two systems that are optimized by the number of markers. The first includes 13 markers and is characterized by a sensitivity of 93.9% and a specificity of 93.9%, the second consists of seven markers, with a sensitivity of 89.8% and a specificity of 100%.

Evaluation of methylation pattern in promoter region of E-cadherin in Iranian Patients with Squamous Cell Carcinoma of Esophagus (SCCE)

S. Mohammad Ganji[1], *E. Samei*[2], *F. Rastgar-Jazii*[3], *A. Sahebghadam-Lotfi*[4], *F. Fereidooni*[5], *S. Irani*[6];

[1]Department of Microbiology, Faculty of sciences, Azad Islamic University, Ghom unit, Ghom, Islamic Republic of Iran, [2]Department of Genetics, , Science and Research branch, Islamic Azad University, Tehran, Islamic Republic of Iran, [3]Department of tissue engineering and cell culture, National Institute for Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran, [4]Department of tissue engineering and cell culture, National Institute for Genetic Engineering and Biotechnology,, Tehran, Islamic Republic of Iran, [5]3- Department of Pathology. Cancer Institute, Imam Khomeini Hospitals Complex, Tehran University, Tehran, Islamic Republic of Iran, [6]2- Department of Genetics, Science and Research branch, Islamic Azad University, Tehran, Islamic Republic of Iran.

It has proven that E-cadherin to be widely down-regulated and tightly associated with tumor invasion and metastasis in multiple human cancer types. Recent researches have shown that aberrant methylation around gene promoter region attributes to E-cadherin silencing. However, the detailed information about this epigenetic inactivation in squamous cell carcinoma of esophagus (SCCE) is rare. For this reason, we studied for methylation at the E-cadherin gene promoters on 44 fresh tumor tissues and 19 non-tumor adjacent normal tissues, obtained from 44 patients affected by squamous cell carcinoma of esophagus in Iran. Up to now, we have done DNA extraction with phenol- chloroform method on tissue samples and the bisulfate treatment on DNAs for carrying up methylation-specific polymerase chain reaction assay (MS-PCR). MS-PCR has done with two set of specific primers for methylated and unmethylated status of E-cadherin gene promoter. Moreover, we have examined the expression of this gene by RT-PCR with two set of specific primers for and β- actin. For this step, we tried to synthesis the cDNA on RNAs Extracted from above tissues. Though, we have finished these experiments on most of samples, the results showed the 40%Methylation at the E-cadherin gene promoter in the tumor samples, while none of the non-tumor tissues exhibited the aberrant methylation. Also, RT-PCR experiments confirmed the expression of E-cadherin in all of non-tumor samples and unmethylated tissues. These data suggest that epigenetic silencing via aberrant methylation of the E-cadherin promoter is a common cause of inactivation of this gene in SCCE.

P06.143

Hypermethylation of TWIST1 and NID2 in tumor tissues and voided urine in urinary bladder cancer patients

Z. Yegin, ***S. Gunes***, *R. Buyukalpelli*;

Ondokuz Mayis University, Samsun, Turkey.

Purpose: We aimed to investigate the methylation patterns of TWIST1 and NID2 genes in bladder cancer and assess the use of these epigenetic changes in urine for sensitive/spesific detection of bladder cancer.

Method: The methylation status of 2 genes (TWIST1 and NID2) was analyzed by methylation-spesific PCR (MSP) in 56 cases of urinary bladder cell carcinoma samples. 24 cases had paired voided urine samples for analysis. In addition, 15 normal voided urine samples from sex- and age-matched (±5) controls were included.

Results: Methylation of TWIST1 was detected in %98.2 (55/56) of the cases and methylation of NID2 was detected in %96.4 (54/56) of the cases in urinary bladder tumor tissues. Furthermore, methylation of TWIST1 and NID2 could be detected in %87.5 (21/24) and %95.8 (23/24) of the voided urine samples of bladder cancer patients, respectively. In 15 normal urine controls, no aberrant methylation was detected except for TWIST1 methylation in only 1 normal urine sample (%6.6). The comparison of methylation analysis with urine cytology for cancer detection is one of the issues that will be explained at the presentation of the study.

Conclusion: This two-gene biomarker panel seems as a promising candidate for non-invasive detection of bladder cancer.

P06.144

MGMT promoter hypermethylation is a frequent event in glioma patients but has no prognostic value

S. Pierini[1], *T. Goranova*[1], *G. Stancheva*[1,2], *M. Laleva*[3], *M. Kamenova*[4], *A. Mitkova*[1,2], *N. Velinov*[3], *R. Kaneva*[1,2], *G. Poptodorov*[3], *V. Mitev*[1,2], *N. Gabrovsky*[3];

[1]Molecular Medicine Center, Medical University of Sofia, Sofia, Bulgaria, [2]Dept. Medical Chemistry and Biochemistry, MU - Sofia, Sofia, Bulgaria, [3]Dept. Neurosurgery, University Hospital N.I.Pirogov, Sofia, Bulgaria, [4]Dept. Patholgy, University Hospital N.I.Pirogov, Sofia, Bulgaria.

O-6-methylguanine-DNA methyltransferase (MGMT) gene encodes a DNA-repair protein that removes alkyl groups from the O6 position of guanine. Epigenetic modifications, such as hypermethylation along the promoter region, are a cause of gene inactivation and they are associated with better prognosis and benefit from alkylating agents. Assessing promoter hypermethylation of MGMT is therefore of great interest because it might have prognostic value, or be a predictive marker for therapy responses.

We examined the promoter methylation status of 103 glioma patients by Methylation-Sensitive High Resolution Melting (MS-HRM). After DNA extraction from paraffin-embedded tumour tissues, genomic DNA was bisulfite modified. Initially a PCR was run using primers specific for modified DNA but with no effective CpG nucleotides, then the HRM was performed. Finally, the data were statistically analyzed.

MS-HRM demonstrated positive methylation of MGMT in 80 patients (77.7 %) and no methylation in 23 patients (22.3%). In the group of long-term survivors MGMT methylation frequency was even higher (14 out of 15 patients, 93.3%). However, no statistical significance was reached comparing the methylated and unmethylated groups according to the overall survival - the median survival was 10.5 and 8.2 months for the methylated and the unmethylated group, respectively (p>0.05). Also, no significant survival benefit was found in the methylated group of patients treated with chemotherapy or radiotherapy.

Our results agree with the high MGMT methylation frequency shown in analogue reports but contrary to them the methylated group in our study did not show any survival benefit.

P06.145

Deletions of the MGMT gene region on chromosome 10q26.3 in gliomas

E. Alekseeva[1,2], *O. Babenko*[1,2], *V. Zemlyakova*[1,2], *E. Kuznetsova*[1,2], *A. Smolin*[3], *E. Prozorenko*[4], *D. Zaletayev*[1,2], *V. Strelnikov*[1,2];

[1]Research Centre for Medical Genetics, Moscow, Russian Federation, [2]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation, [3]Academician N.N. Burdenko Main Military Clinical Hospital, Moscow, Russian Federation, [4]N.N. Blockin Russian Research Center for Oncology, Moscow, Russian Federation.

Sensitivity of gliomas to alkylating agents is determined to a great extent by the activity of the DNA repair protein O^6-methylguanine-DNA-methyltransferase (MGMT) in the tumor cells: high activity of this protein forms the resistant phenotype of the tumor. The *MGMT* gene located on chromosome 10q26.3 is a classic tumor suppressor gene. It is known that methylation of the *MGMT* promoter leads to both inactivation of the gene and increase of the tumor's sensitivity towards alkylating drugs. Methylation of the *MGMT* gene promoter is currently considered to be the main marker of the tumour's sensitivity to the alkylating agent temozolomide. Deletion of 10q26.3 locus containing the *MGMT* gene can be an alternative mechanism of its inactivation. We have been the first to conduct a targeted analysis of loss of heterozygosity (LOH) at the *MGMT* gene region on chromosome 10q26.3 in gliomas. A panel of microsatellite markers to detect LOH in the area under study, which includes four intragenic and five flanking microsatellite polymorphisms, has been developed and characterized. Frequency of LOH evaluated by this assay in gliomas equals 51% (18/35). In all cases the deletion size exceeded that of the *MGMT* gene. Thus, the deletion of the *MGMT* gene happens more frequently than the methylation of the gene's promotor. Substantial frequency of the *MGMT* gene's deletions calls for more detailed research as a potential marker of the gliomas sensitivity to alkylating drugs.

P06.146

miRNA expression in two colon cancer cell lines treated with an histone deacetylase inhibitor

C. Jimenez Criado, *A. Pascual Rodriguez*, *R. Gonzalez Sarmiento*;

Centro de Investigacion del Cancer, Salamanca, Spain.

Introduction: the presence of HDAC is necessary for the normal regulation of gene expression. Multiple studies have already revealed that inhibition of these proteins may lead to deregulation of gene expression and increase in cell proliferation. We have analyzed the effect of a histone deacetylase inhibitor (HDACI) in colon cancer cells, measuring miRNA expression in cell cultures after treatment.

Experimental design: we performed an array expression analysis of miRNA. Previously, we quantified the amount of miRNA using a comercial Small RNA kit (Agilent Technologies) allowing miRNA quantified in total RNA.

Results: array expression analysis using bioinformatic programmes showed that after treatment with the histone deacetylase inhibitor, the miRNA were grouped in 7 different expression clusters. These clusters group the miRNA with a similar expression throughout the treatment.

Conclusion: Analysis of expression of these clusters will allow to check if important pathways are modified for cell viability after treatment with these inhibitors.

Matrix Metalloproteinase-9 as Prognostic Marker of Cancer

***D. Schveigert**, J. Didziapetriene;*
Institute of Oncology, Vilnius University, Vilnius, Lithuania.

MMPs are being studied in a variety of tumor systems to ascertain their role in tumor progression. MMPs contribute in multiple ways to all stages of malignant progression, including tumor invasion, metastases and angiogenesis. The aim of this study was to investigate MMP-9 gene expression and to identify MMP-9 (-1562 C/T) gene promoter variations in breast, non-small cell lung cancer (NSCLC) patients' blood and tumor samples, and in prostate cancer patients blood. **Materials and methods:** A total of 188 patients with histopathologically diagnosed breast, NSCLC or prostate cancer tumors were enrolled to the study. MMP-9 gene expression was assessed by reverse transcription-PCR method. The MMP-9 (-1562 C/T) polymorphism variants were determined by the polymerase chain reaction-based restriction fragment length polymorphism method. **Results:** MMP-9 expression in breast cancer patients' blood correlated with disease stage (p=0.041) and tumor differentiation grade (p=0.037). Also a significant association (p=0.018) between clinical stage and MMP-9 polymorphism was found. MMP-9 expression and all polymorphism variants (CC, CT, TT) were detected in all NSCLC patients' samples, but without statistical correlations. For prostate cancer patients with identified CC or CT MMP-9 polymorphism variant survival time was longer compared with those patients with TT variant (p<0,001). There were no statistical correlations with Gleason score or PSA. **Conclusions:** MMP-9 expression and identification of polymorphisms variants could serve as prognostic marker for breast and prostate cancer. Additional studies with larger population are warranted for NSCLC.

P06.149

Expression of MRP1 and LRP in breast cancer patients: Correlation with response to chemotherapy treatment

*M. Taheri[1,2], **F. Mahjoubi**[1], R. Omranipour[3];*
[1]Department of Clinical Genetic, National Institute of Genetic Engineering and Biotechnology (NIGEB), Tehran, Islamic Republic of Iran, [2]2Department of Genetics, School of Medicine, Zahedan University of Medical Sciences, Zahedan, Islamic Republic of Iran, [3]Institute of Cancer, Imam Khomeini Hospital, Tehran, Islamic Republic of Iran.

Background: Drug resistance is still a great obstacle to the success treatment of breast cancer. In this study we attempted to investigate the possible correlation between MRP1 and LRP and clinical response in women with breast cancer.

Materials and Methods: Tumor and adjacent normal tissues from 54 breast cancer patients were assessed for the expression level of MRP1 and LRP by Real Time RT-PCR.

Results: A statistically significant increase in MRP1 and LRP expression level was observed when tumor tissues were compared with normal breast tissues. Furthermore, MRP1 and LRP expression levels were significantly different in patients responding to chemotherapy compared to noresponding patients.

Conclusion: Our results suggest that MRP1 and LRP in human breast cancer cells may affect the clinical response to treatment and determination of MRP1 and LRP (either alone or in combination) may be valuable for the prediction of the chemotherapy outcome in breast cancer patients which remains to be cleared.

P06.150

The Frequency of mtDNA Alterations of G13397A, 12308G and G10398A in Involvement of Metastasis on IRANIAN Breast Cancer Patients

***M. Ghaffarpour**[1,2,3], F. Fereidooni[4], N. Moazami[2], M. Houshmand[1,3];*
[1]Medical genetics department, National Institute of Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran, [2]Iranian Research Organization for Science and Technology(IROST), Tehran, Islamic Republic of Iran, [3]Special Medical Center, Tehran, Islamic Republic of Iran, [4]The cancer Institute of Iran ,Imam Khomeini Hospital Complex, Tehran University of Medical Science, Tehran, Islamic Republic of Iran.

Background and aim: The role of mtDNA alteration is recognized as being in carcinogenesis. mtDNA alteration G13397A and alteration of 12308 in tRNA Leu gene have been reported in involvement in metastasis but to date there was not shown on clinical breast cancer samples as a prognosis factors. It has been also shown that mtDNA alteration G10398A in breast cancer patients correlated with increased breast cancer risks and metastasis. The aim of this study was to address the question if the mtDNA alterations of G13397A, 12308G&G10398A can play a role in promoting of tumor and leading to metastasis.**Patients and tissue specimens**; 69 paired Fresh tumor and adjacent normal samples were obtained from patients with BC (31of 69 metastasis and 38 of 69 non metastasis) who underwent surgery for mama mastroctomy between October 2007 and Nov 2009. No patients had received any preoperative chemotherapy and or radiotherapy. Follow-up was continued until Jan 2012.We searched for mtDNA alterations of G13397A, 12308G and G10398A were analyzed by means of PCR sequencing.**Result and conclusion:** The G13397A mutation was not seen for all patient including metastasis and non-metastasis.It has not been found any role for G13397A mutation in involvement in metastasis on IRANIAN breast cancer patients. The frequency of 12308 G alteration was 28 %(8 0f 31) for metastasis patients. The rate of mtDNA alteration G10398A was 50 %(17 of 34) for BC patients including 9 of 15 (60.3%) for metastasis subjects and 8 of 19 (42.1%) for non-metastasis subjects.

P06.151

MTHFR gene C677T polymorphism is associated with the increased risk of cervical cancer in Russians

***N. A. Nigmatullina**, A. A. Arkhipova, B. G. Begiev, I. I. Ahmetov;*
Kazan State Medical University, Kazan, Russian Federation.

Methylenetetrahydrofolate reductase (MTHFR) catalyzes the synthesis of 5-methyltetrahydrofolate, which is involved in the methylation of homocysteine to methionine. A common variant of this enzyme, resulting from a 677C>T (Ala>Val) substitution in the gene, has been shown to have reduced activity and is associated with hyperhomocysteinemia. Altered homocysteine levels, a functional marker of folate inadequacy, might contribute to the carcinogenic process. There is a growing body of epidemiological evidence suggesting that the MTHFR 677T allele and reduced dietary folate may increase the risk of cervical cancer. The aim of the study was to examine the association of the MTHFR genotype with the odds ratio (OR) for cervical cancer among women. MTHFR gene variants were determined in 127 women with cervical cancer and 175 healthy controls (all Caucasians and citizens of Russia). The MTHFR 677T allele frequency was significantly higher in women with the cervical cancer compared to controls (36.2 vs 22.0%; P = 0.0002). Those women with TT genotype were at six times the risk for cervical cancer [OR, 5.948; 95% CI, 2.406-14.704] compared to women with the homozygous MTHFR CC genotype. In conclusion, the MTHFR 677T allele and TT genotype are associated with the increased risk of cervical cancer in Russian women.

P06.152

What about the relatives who have MTHFR C677T polymorphism?

***A. Uudag**[1], F. Silan[2], A. Uludag[2], C. Silan[3], S. Atik[2], E. M. Sahin[1], O. Ozdemir[2];*
[1]Department of Family Medicine, Faculty of Medicine,Canakkale Onsekiz Mart University, Canakkale, Turkey, [2]Department of Medical Genetics, Faculty of Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey, [3]Department of Pharmacology, Faculty of Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey.

Methylenetetrahydrofolate reductase (MTHFR) which affects both DNA synthesis/repair and methylation, plays a crucial role in regulating folate metabolism. MTHR C677T polymorphism has a role about cardiovasculer diasease, stroke, early pregnacy loss and in puplished datas show that MTHFR C677T polymorphism can be responsable some of malignancies such as lung and breast cancer.

We examined if the patients whose MTHFR C677T polymorphism had been studied have any malignancy stories in their family. We called 18 female and 7 male who have homozygote mutant genotype, 31 female and 25 male who have heterozygote genotype and 32 female and 24 male homozygote wild genotype for MTHR C677T polymorphism.

In homozygote mutant group(n:25) ; there are 14 relatives have malignancy stories, 7 relatives had lung cancer and 3 relatives have breast cancer. 56%, OR 3,8, p:0,007 (Compared to wild group)

In heterozygote group(n: 56); there are 17 relatives have malignancy stories, 3 relatives had lung cancer, 3 relatives had meningioma, 2 relatives had prostate cancer and 2 relatives had leukemia. 30 %, OR 1,308 p: 0,526 (Compared to wild group)

In wild group(n:56); there are 14 relatives have malignancy stories, 5 relatives had lung cancer and 5 relatives had breast cancer. 25 %

Published data on the association between the MTHFR C677T gene polymorphism and malignancy stories in their family who have MTHFR gene polymorphisms are inconclusive. We need further studies lead us understanding of the role of the MTHFR polymorphism and the mechanism of cancer development.

P06.154

Lynch-Syndrome or not? MUTYH associated polyposis in patients with MSI-H tumors and immunohistochemical loss of MMR proteins

M. Locher[1,2], *M. Morak*[2,1], *B. Heidenreich*[2], *G. Keller*[3], *A. Laner*[1], *E. Holinski-Feder*[1,2];
[1]*MGZ – Medizinisch Genetisches Zentrum, Munich, Germany,* [2]*Medizinische Klinik - Campus Innenstadt, Klinikum der LMU München, Munich, Germany,* [3]*Institute of Pathology, Technical University of Munich, Munich, Germany.*

Lynch-syndrome is caused by germline mutations in DNA mismatch repair (MMR) genes predisposing for early-onset colorectal cancer/associated tumors with microsatellite instability, negative immunohistochemical staining and dominant inheritance, but in ~10-15% without germline mutation detection.

The recessively inherited MUTYH associated polyposis (MAP) shows a variable phenotype which can overlap with Lynch-syndrome. We analysed the two common MUTYH mutations p.Tyr197Cys and p.Gly396Asp in 83 MMR-gene mutation-negative patients with MSI-H tumours showing loss of MMR protein staining.

We detected the pathogenic MUTYH mutation p.Tyr197Cys homozygously in one patient with clinical presentation of two adenocarcinomas and rectal adenomas (56 years), urinary bladder carcinoma, sebaceous gland carcinoma (revealing loss of MSH2 and MSH6 proteins and MSI-H) (66 years) and positive family history. Tumor sequencing of the sebaceous gland carcinoma showed two somatic pathogenic transversion mutations in MSH2, other tumors had transversions in KRAS.

In three patients with MLH1-deficient tumors a heterozygous, monoallelic mutation in MUTYH was identified, but no second mutation or deletion in MUTYH, OGG1 and MTH1.

The incidence of 1,2% for biallelic MUTYH mutations in unsolved patients shows that two somatic mutations in MMR genes due to a base excision repair deficiency is rare, but can mimick Lynch-Syndrome.

P06.155

Promoter hypermethylation of tumor suppressor genes in serum as potential biomarker for the early diagnosis of nasopharyngeal carcinoma

F. Tian, *S. P. Yip, W. C. Wu;*
The Hong Kong Polytechnic University, Kowloon, Hong Kong.

Nasopharyngeal carcinoma (NPC) is a common head and neck cancer in Southern China. Studies have shown that promoter hypermethylation of tumor suppressor genes may serve as a promising epigenetic biomarker for early diagnosis of NPC, which is of great significance in improving patient's survival rate. Resulting from DNA leakage due to tumor necrosis or apoptosis, cell-free circulating DNA in blood has been proven sharing a similar hypermethylation status as the primary tumor. Therefore, cancer-derived DNA in serum may be used for promoter hypermethylation status screening of tumor suppressor genes.

In this study, cell-free circulating DNA is extracted from 40 NPC patients before treatment and 40 age- and sex-matched healthy subjects. Promoter hypermethylation status of five tumor suppressor genes (*RASSF1A*, *CDKN2A*, *DLEC1*, *DAPK* and *UCHL1*) was assessed by methylation-specific polymerase chain reaction assay (MSP) after sodium bisulfite conversion. Differences of methylation status of five tumour suppressor genes and clinicopathological parameters (staging, age) between NPC patients and healthy subject would be compared.

To date, promoter hypermethylation status of four genes has been analyzed in 19 NPC samples. *RASSF1A*, *CDKN2A*, *DLEC1* and *DAPK* were found to be methylated in 5.3%, 0%, 5.3% and 5.3% patients, respectively. Hypermethylation of at least one gene was observed in 15% of the patients. Preliminary data suggest that the sensitivity of promoter hypermethylation detection of these fours genes in serum samples was low. A more definite conclusion has yet to be testified by future study.

P06.156

Differential DNA damage response in breast cancer cells with genetic deficiencies in *BRCA1* or *NBN*

B. Schröder-Heurich[1], *N. Bogdanova*[1,2], *B. Wieland*[1], *T. Dörk*[1];
[1]*Gynaecology Research Unit, Hannover Medical School, Hannover, Germany,* [2]*Clinics or Radiation Oncology, Hannover Medical School, Hannover, Germany.*

Genetic predisposition towards breast cancer includes *BRCA1* and *BRCA2* mutations but also mutations in genes encoding the MRE11-RAD50-NBN (MRN) complex which plays a major role in radiation-induced DNA damage response (DDR). Double-strand breaks initiate localization of DDR proteins such as gammaH2AX, 53BP1 and MDC1 forming nuclear foci which provide a platform for subsequent assembly of signalling proteins and disappear after successful double-strand break repair. Here we comparatively analysed the DNA damage response in two different breast cancer epithelial cell lines from patients with germ-line mutations in *BRCA1* or *NBN*, respectively.

We performed immuncytochemical assays to monitor the cellular response after irradiation with different doses (1.5Gy, 6Gy) and after different time-points (0.5hrs, 24 hrs, 48hrs). There was a dramatically reduced level of gammaH2AX and MDC1 foci formation in *NBN*-deficient breast cancer cells at 30 min after irradiation in comparison to wild-type, while 53BP1 foci were two-fold reduced but clearly detected. *BRCA1*-deficient breast cancer cells, in comparison with wild-type and *NBN*-deficient cells, showed a heightened response to irradiation with an up to two-fold increase of gammaH2AX, 53BP1 and MDC1 foci formation 0.5 hrs after treatment (1.5Gy, 6Gy). In addition, these cells showed a prominent delay in repair kinetics after irradiation.

In summary, the present results indicate a defective DNA damage response in two breast cancer cell lines with genetic mutations in double-strand break repair pathway genes. However, these deficiencies manifest at differential stages and time-points, suggesting that breast cancer can be functionally dissected according to the underlying germ-line mutations.

P06.157

Analysis of the nucleotide sequence diversity within the SUZ12 gene and its pseudogene SUZ12P to investigate the signature of nonallelic homologous gene conversion

T. Mußotter[1], *J. Vogt*[1], *K. Bengesser*[1], *D. N. Cooper*[2], *H. Kehrer-Sawatzki*[1];
[1]*Institute of Human Genetics, Ulm, Germany,* [2]*Institute of Medical Genetics, Cardiff, United Kingdom.*

Nonallelic homologous recombination (NAHR) and nonallelic homologous gene conversion (NAHGC) are alternative processes depending upon whether the respective recombination intermediates are resolved with or without crossover. Since NAHR events give rise to genomic rearrangements, it is likely that recombination intermediates are more frequently resolved by the non-crossover pathways associated with NAHGC. Low-copy repeats exhibiting meiotic NAHR activity have been shown to be involved in frequent NAHGC-mediated sequence exchange. In addition, the LCRs located within the NF1 gene region (termed NF1-REPs), which mediate meiotic NAHR causing type-1 NF1 microdeletions, manifest an increased SNP frequency suggestive of frequent NAHGC. In this study, we have investigated whether NAHGC might also operate between the SUZ12 gene and its pseudogene (SUZ12P), duplicated sequences that flank the NF1-REPs and undergo mitotic NAHR giving rise to type-2 NF1 microdeletions. To this end, we determined the pattern of variation (SNP density and occurrence of shared SNPs between SUZ12 and SUZ12P) within the NAHR breakpoint cluster regions observed in patients with type-2 NF1 microdeletions. We did not however identify a significant increase in SNP frequency within the analysed NAHR breakpoint clusters of 20 healthy individuals of European descent above the genomic average SNP frequency of 1 SNP/kb. Furthermore, no evidence was noted of greater homology between SUZ12 and SUZ12P within the NAHR breakpoint clusters that would have been indicative of concerted evolution. We conclude that, in contrast to the flanking NF1-REPs, the SUZ12 gene and its pseudogene SUZ12P are not involved in frequent sequence transfer by NAHGC.

P06.158

Investigation of the gene conversion patterns associated with mitotic NAHR in the neurofibromatosis type-1 (NF1) gene region causing NF1 microdeletions

K. Bengesser[1], *J. Vogt*[1], *T. Mußotter*[1], *K. Claes*[2], *K. Wimmer*[3], *L. Messiaen*[4], *V. Mautner*[5], *L. Kluwe*[5,6], *D. Cooper*[7], *H. Kehrer-Sawatzki*[1];
[1]*Institute of Human Genetics, University of Ulm, Ulm, Germany,* [2]*Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium,* [3]*Division of Human Genetics, Medical University Innsbruck, Innsbruck, Austria,* [4]*Medical Genomics Laboratory, Department of Genetics, University of Alabama at Birmingham, Birmingham, AL, United States,* [5]*Department of Neurology, University Hospital Hamburg Eppendorf, Hamburg, Germany,* [6]*Department of Maxillofacial Surgery, University Medical Centre, Hamburg-Eppendorf, Germany,* [7]*Institute of Medical Genetics, School of Medicine, Cardiff University, Cardiff, United Kingdom.*

Nonallelic homologous recombination (NAHR) is an important mutational mechanism underlying polymorphic and pathogenic copy number variation in the human genome. It is generally assumed that NAHR is mechanistically similar to allelic homologous recombination (AHR) between homologous chromosomes during meiosis. AHR-associated crossovers are processed by Holliday junction intermediates. Where interacting homologous DNA sequences exhibit nucleotide differences, mismatches in the recombining heteroduplex DNAs are to be expected. Recombination-associated mismatch repair is typically biased, with the unbroken DNA-strand being used as a mismatch repair template. This results in regions of marker loss in the broken DNA-strand, which are termed conversion tracts. Since mismatch repair frequently proceeds via an excision-based mechanism, AHR-associated conversion tracts are usually continuous. However, the breakpoint regions of several meiotic NAHR-mediated rearrangements have been shown to exhibit a pattern of discontinuous or 'patchy' conversions. In order to investigate whether patchy gene conversion is also a feature of mitotic NAHR events, we investigated the sequence characteristics of the breakpoint regions of 25 type-2 NF1 microdeletions mediated by postzygotic (mitotic) NAHR between the SUZ12 gene and its pseudogene, SUZ12P. However, instead of patchy gene conversion, we observed precise transitions between sequences derived from SUZ12P and SUZ12, respectively, as evidenced by the analysis of paralogous sequence variants and SNPs. Further, we did not observe distinct types of breakpoint-spanning fragments which would have been indicative of uncorrected mismatches resulting from the recombination. We conclude that recombination-associated gene conversion events resulting from heteroduplex-associated mismatch-repair are likely to be differently processed during meiotic versus mitotic NAHR.

P06.159

Mechanisms underlying non-recurrent microdeletions causing neurofibromatosis type-1 (NF1)

J. Vogt[1], *K. Bengesser*[1], *K. Claes*[2], *K. Wimmer*[3], *L. Messiaen*[4], *L. Kluwe*[5,6], *V. Mautner*[5], *H. Kehrer-Sawatzki*[1];
[1]*Institute of Human Genetics, University of Ulm, Ulm, Germany,* [2]*Center for Medical Genetics, Ghent University Hospital, Gent, Belgium,* [3]*Division of Human Genetics, Medical University Innsbruck, Innsbruck, Austria,* [4]*Medical Genomics Laboratory, Department of Genetics, University of Alabama at Birmingham, Birmingham, AL, United States,* [5]*Department of Neurology, University Hospital Hamburg Eppendorf, Hamburg, Germany,* [6]*Department of Maxillofacial Surgery, University Medical Center, Hamburg-Eppendorf, Germany.*

NF1 microdeletions encompassing the NF1 gene region at 17q11.2 are present in 5-10% of patients with NF1. In particular recurrent NF1 microdeletions have been investigated in detail. However, the mechanism underlying non-recurrent (atypical) NF1 microdeletions are not well delineated. NF1 microdeletions with non-recurrent breakpoints are heterogeneous in terms of their size, breakpoint position and number of deleted genes. Furthermore, extended sequence homology is not observed in the respective breakpoint regions. In this study, we have analysed 12 atypical NF1 deletions using high resolution custom made array CGH. We could assign the breakpoints to regions of 1.2-6 kb. In six of these 12 atypical NF1 deletions, we identified the breakpoints at basepair level. Four of these six deletions were mediated by non-homologous end joining (NHEJ) as concluded by the absence of or only minor (1-2bp) homology at the breakpoints. Two of these six NF1 deletions exhibited microhomologies of 24 and 33 bp at the breakpoint sites indicative of microhomology-mediated end joining (MMEJ) as underlying mechanism. We conclude that NHEJ or MMEJ are the prevailing mechanisms underlying non-recurrent NF1 deletions that lack any complexity at the deletion breakpoint sites. However, three of the 12 NF1 deletions investigated by us represent complex rearrangements most likely caused by replication associated erroneous template switches. Our study indicates for the first time, that also non-recurrent NF1 microdeletions are mediated by a variety of mutagenic processes including mechanisms of double strand repair such as NHEJ and replication based mechanisms such as Fork stalling and template switches (FoSTeS).

P06.160

Improved detection of type-2 NF1 microdeletions and identification of breakpoint clusters

H. Kehrer-Sawatzki[1], *J. Vogt*[1], *T. Mußotter*[1], *K. Bengesser*[1], *C. Fu*[2], *K. Claes*[3], *D. N. Cooper*[4], *L. Messiaen*[2];
[1]*Institute of Human Genetics, University of Ulm, Ulm, Germany,* [2]*Medical Genomics Laboratory, Department of Genetics, University of Alabama at Birmingham, Birmingham, AL, United States,* [3]*Center for Medical Genetics, Ghent University Hospital, Gent, Belgium,* [4]*Institute of Medical Genetics, School of Medicine, Cardiff University, Cardiff, United Kingdom.*

Neurofibromatosis type-1 (NF1) is an autosomal dominant inherited disease that occurs with a frequency of 1:3000. Whereas 95% of all NF1 patients harbour mutations within the NF1-gene, 5% of NF1 patients exhibit large deletions of the NF1-gene and its flanking regions (termed NF1 microdeletions). Four types of NF1 microdeletions have been identified (type-1, type-2, type-3 and atypical) that differ with respect to breakpoint localization and the underlying causative mechanism. Multiplex-ligation-dependent probe-amplification (MLPA) has frequently been employed to identify NF1 microdeletions. However, the unambiguous typing of NF1 deletions is impossible in many instances due to the spacing of the probes included in the currently available MLPA-kit (P122-C1, MRC-Holland). Indeed, distinguishing between type-2 and certain atypical NF1 deletions is impossible using this MLPA-kit. In this study, we have developed an improved set of MLPA-probes that allows the unambiguous identification of type-2 NF1 deletions and potentiates breakpoint-mapping by PCR. Using a combination of this improved MLPA-technique and breakpoint-spanning PCR, we analysed 29 NF1 microdeletions initially considered to be type-2 deletions according to results obtained with the MLPA-kit P122-C1. We determined that 23 of the 29 deletions were indeed classical type-2 microdeletions, with breakpoints located in the SUZ12 gene and its pseudogene SUZ12P. However, 6 deletions turned out to be atypical exhibiting only one of both breakpoints within the SUZ12 sequences. Taken together with 16 previously identified type-2 deletions whose breakpoints have been localized, the analysis of a total of 37 type-2 NF1 deletions revealed a significant clustering of breakpoints within the SUZ12 sequences.

Marqués de Valdecilla, Santander, Spain,* [6]*Hospital Reina Sofía, Córdoba, Spain,* [7]*Hospital de Jerez de la Frontera, Cádiz, Spain,* [8]*-, Jaén, Spain,* [9]*CGCGenetics/CircaGen, Madrid, Spain.*

BRCA1 and BRCA2 are the most important breast cancer susceptibility genes. The conventional BRCA1 and BRCA2 mutation screening, performed by heteroduplex analysis and/or Sanger sequencing, is time consuming and has relatively high costs due to the absence of hot spots and to the high number of exons per gene. Usually, several months are necessary to complete the diagnosis. To overcome these limitations and to reduce the time needed for diagnosis, we designed a next generation sequencing protocol enabling simultaneous detection of variants in the two genes.

For resequencing BRCA1 and BRCA2, we used Multiplex Amplification (MASTR by Multiplicom) and the 454 GS Junior DNA sequencing instrument (Roche Diagnostics), which is based on pyrosequencing. Bioinformatic analysis was performed by two complementary approaches: Our pipeline (which comprises mapping and comparing reads against the reference sequence, aligning reads, classifying and identifying of SNPs and mutations), and by the Amplicon Variant Analyzer (AVA) software from Roche. We successfully validated this technology with a set of 6 cases carrying known mutations previously detected by Sanger Sequencing, and a reference HapMap sample (NA12144).

The application of this technology in 51 cases with suspected hereditary breast cancer, allowed the identification of 11 pathogenic mutations (3 missense, 1 novel nonsense, 6 frameshift and 1 splice variant), 6 unclassified variants and a high number of polymorphisms.Massive parallel resequencing of the BRCA1/BRCA2 genes is effective as a high throughput, rapid and cost-effective methodology for routine diagnosis of hereditary breast and ovarian cancer.

P06.162

Participation of miRNAs in conditioning of the colon polyposis

P. Borun[1], *T. Banasiewicz*[2], *J. Paszkowski*[2], *R. Slomski*[1], *A. Plawski*[1];
[1]*Institute of Human Genetics, Poznan, Poland,* [2]*University of Medical Sciences, Poznan, Poland.*

Two types of miRNA: miR135a and miR-135b, encoded by three genes, are involved in the regulation of APC gene expression. The miRNA genes are located respectively, on chromosomes 3, 12 and 1. The miR135a and miR-135b interact with the 3' UTR sequences of the APC mRNA on the basis of partial complementarity and lead to its degradation. It was assumed that changes in the sequences encoding miR135a and miR-135b can affect their affinity to the 3 ,UTR of APC gene mRNA and, by increasing its degradation, cause a decrease in amount of functional APC protein, which can cause similar to haploinsufficiency effects. In addition, changes in the 3 ,UTR sequences may influence the affinity to the sites recognized by miRNA or induce the formation of new sites complementary to the miRNA sequences leading to faster degradation of mRNA. The study group consisted of 300 patients with FAP without detected mutation in APC gene and 300 healthy controls. The sequence of genes encoding miR135a and miR-135b, and 3 ,end sequence of the APC gene were tested. We analyzed occurrence of mutations in the studied fragments and compared frequencies of polymorphisms in the studied groups. The research was funded by Polish Ministry of Science and Higher Education, project number N401 331936.

P06.163
Effect of the PARP-inhibitor PJ34 on *NIS* expression and epigenetics modifications in human thyroid tumour cells

E. Lavarone[1], *N. Passon*[2], *C. Puppin*[1], *G. Damante*[1,2];
[1]Dipartimento di Scienze Mediche e Biologiche, Università di Udine, Udine, Italy, [2]Istituto di Genetica, Azienda Ospedialiero-Universitaria di Udine, Udine, Italy.

Sodium iodide symporter (NIS) expression is crucial for the management of thyroid patologies, cancer in particular. Unfortunately NIS expression is often reduced in thyroid cancer; in many cases also his functionality is damaged. Since PARP-1 is supposed to be part of a multimeric repressor involved in cancer NIS uderexpression, in this study various human thyroid tumour cell lines (TPC1, BCPAP, FRO, WRO) were treated with the PARP-inhibitor PJ34, and the effects on the expression of NIS and several thyroid-specific transcription factors, together with the activity of NIS promoter, were evaluated. PJ34 treatment didn't affect thyroid-specific transcription factors expression, whereas we observed a strong increase in NIS mRNA levels in all the cell lines. Accordingly, in transfection experiments performed in TPC1 cells, treatment with PJ34 increased NIS promoter activity. It is well known that post-translational histone modifications are involved in the control of gene transcription. Thus, we have also investigated the epigenetic status of NIS promoter after PJ34 treatment in TPC1 cell line. In addition to an increase of activatory histone modifications (H3K9K14ac, H3K4me3) surprisingly we observed also an increase of H3K27me3, a classical repressive mark.

We concluded that PJ34 action, that implies mechanisms acting on epigenetic marks, is specific on NIS expression, suggesting it as a potential strategy to induce radioiodine sensitivity in human thyroid tumours.

Whole genome microarray analysis in non-small cell lung cancer

M. Alzeyadi, *I. Dimova, V. Ranchich, B. Rukova, D. Nesheva, Z. Hamude, S. Georgiev, D. Petrov, D. Toncheva;*
Medical University Sofia, Sofia, Bulgaria.

Lung cancer is a serious health problem, since it is the leading cause for death world widely. Molecular-cytogenetic studies could provide with reliable data about genetic alterations which could be related to disease pathogenesis and used for better prognosis and treatment strategies. We have performed whole genome oligonucleotide microarrays-based comparative genomic hybridization in ten samples of non-small cell lung cancer. Trisomies were discovered for chromosomes 1, 13, 18 and 20. Affected by genetic gain were chromosome arms 5p, 7p, 11q, 20q and Xq**,** and by genetic losses - 1p, 5q, 10q and 15q. Microstructural (<5 Mbp) genomic aberrations were revealed in regions 7p (containing EGFR) and 12p (containing KRAS) for gains and in 3p26 and 4q34 for losses. Based on high amplitude of alterations and small overlapping regions, new potential oncogenes have been suggested - *NBPF4* (1p13.3); *ETV1*, *AGR3* and *TSPAN13* (7p21.3 -7p21.1); *SOX5* and *FGFR1OP2* (12p12.1-12p11.22); *GPC6* (13q32.1). Significant genetic losses were assumed as containing potential tumor-suppressor genes: *DPYD* (1p21.3); *CLDN22*, *CLDN24*, *ING2*, *CASP3*, *SORBS2* (4q34.2-q35.1); *DEFB* (8p23.1)**.** Our results complement the picture of genomic characterization of non-small cell lung cancer.

Molecular genetic testing in patients with Non-Small Cell Lung Carcinoma

D. Konvalinka[1], *J. Šimová*[1,2], *B. Kubová*[1], *I. Urbanovská*[1], *M. Jalůvková*[1], *J. Žmolíková*[1], *I. Žebráková*[1], *R. Skalíková*[1], *M. Uvírová*[1], *J. Dvořáčková*[2];
[1]CGB laboratory Inc., Ostrava, Czech Republic, [2]Faculty of Medicine, University of Ostrava, Ostrava, Czech Republic.

Introduction: Non-Small Cell Lung Carcinoma (NSCLC) is one of the most serious cancers. For targeted biological treatment, sensitive and specific identification of genetic changes is necessary. Identification of genetic changes (mutations) within EGFR, KRAS and ALK oncogenes, associated with NSCLC, allows choosing the patients, which benefit from biological therapy.

Material and Methods: DNA is isolated from biopsy and cytology specimens with verified histological diagnosis. Mutation detection is performed by real-time PCR, fragment analysis, primer-extension analysis and mutant-enriched PCR. Wt-EGFR patients (e.g. with no mutation detected) are tested for ALK gene rearrangement, causing the EML4-ALK fusion gene formation. Analyses are performed on histological slides using the FISH method.

Results: Since 10/2010 till 12/2011, 199 DNA samples were analyzed. Out of these, 12 patients (6 %) were found to be positive for activating mutations within EGFR gene. Since 07/2011 till 12/2011, 54 patients were analyzed for ALK gene rearrangement. This change has been proven in 2 cases.

Discussion: Activating mutations of the EGFR gene correlate with therapeutic response to tyrosin kinase inhibitors. Frequency of mutations within the EGFR gene is 5 - 20 %. ALK gene rearrangement can predict therapeutic response for ALK inhibitors. These rearrangements are found approximately in 5 % of NSCLC patients. Our results correlate with abovementioned findings**.** Occurrence of certain mutations, e.g. T790M, as well as KRAS gene mutations and ALK gene rearrangements predicts resistance to TKIs therapy.

Conclusions: Determination of tumor mutational status can provide powerful tool for setting up strategy and therapeutic protocols in NSCLC patients.

Introduction Noonan syndrome (NS) is a genetic disorder caused by a germline mutation in the PTPN11 gene in about 40% of cases. These patients are predisposed to develop a myeloproliferative-myelodysplastic syndrome (MPD), the juvenile myelo-monocytic leukemia (JMML). To date, few data concerning its incidence and prognosis are available.

Methods 562 patients carrying a germline mutation of PTPN11 have been studied. JMML was diagnosed in 21 of them (NS-JMML). In 11 other patients, hematologic anomalies suggestive of a MPD have been noted. Cytologic, genetic and clinical features of these 2 groups of patients have been compared with 24 patients presenting a PTPN11-associated sporadic JMML.

Results Hematological anomalies are found in 32/562 (5.7%) of NS patients and encompass a broad phenotypic spectrum ranging from transient MPD to JMML. Hematologic presentation of NS-MPD and NS-JMML is not different from sporadic JMML but the overall survival is considerably altered in NS-JMML patients and boys. The mutation D61H of PTPN11, never reported in NS, is found in 2 patients with a particularly severe neonatal course. More generally, the spectrum of PTPN11 mutations is narrower in NS-MPD and NS-JMML patients than in the whole cohort of NS patients, with an increased incidence of mutations of the 61, 139 and 506 codons. We were not able to identify additional recurrent genetic alteration with the SNP array analysis of 12 NS-JMML patients.

Conclusion Some PTPN11 mutations are associated with an increased risk of JMML. Additional cooperating factors may explain the genotype-phenotype correlation in the other cases.

P06.167
Platform comparison of expression data and identification of novel mutations in *CIC* in oligodendrogliomas

S. Schauer[1], *K. Szafranski*[2], *J. A. Campos Valenzuela*[3], *A. Rump*[1], *K. Hackmann*[1], *D. Krex*[4], *E. M. Gerlach*[1], *G. Schackert*[4], *L. Kaderali*[3], *M. Platzer*[2], *E. Schrock*[1], *B. Klink*[1];
[1]Institut für Klinische Genetik, Medizinische Fakultät Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany, [2]Leibniz Institute for Age Research – Fritz Lipmann Institute (FLI), Jena, Germany, [3]Institut für Medizinische Informatik und Biometrie, Medizinische Fakultät Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany, [4]Klinik und Poliklinik für Neurochirurgie, Universitätsklinikum Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany.

Various studies indicate that the success of treatment and thus the overall survival time of patients suffering from gliomas depend on molecular features of the tumor.

We analyzed 17 oligodendroglial tumors by high resolution array CGH (Agilent 400K) and for the first time by systematic comparison of platforms for gene expression analysis. We performed transcriptome next generation sequencing (RNA-Seq) using a 2x100nt paired-end approach on the Illumina-HiSeq2000-platform, miRNA array, 8x60k expression array and Exon array analyses (Agilent). Additionally, Sanger sequencing of candidate genes *(IDH1*, *IDH2*, *CIC*, *FUBP1)* was carried out.

Array CGH revealed structural changes including the previously described 1p/19q-codeletion in 11/17 tumors (69%). We identified seven novel mutations in the *CIC* gene on 19q (altogether 9/17), including one exon-spanning deletion. In the latter, RNA-Seq revealed a notably decreased gene expression. The *IDH1* c.395A>G mutation was the most frequent alteration found in 14/17 tumors (82%). Sequencing of *FUBP1* on 1p uncovered mutations in three cases.

This let us observe a strong association between the presence of *CIC* and *IDH1* mutation and the 1p/19q-codeletion, since all tumors showing mutations in *CIC* also contained the *IDH1* mutation as well as the 1p/19q-codeletion except for one case (*CIC* and *IDH1* mutation only). These results emphasize the critical role of *CIC* for the development of oligodendroglioma.

RNA-Seq data will help to identify aberrant mRNAs and new fusion-genes. In the long run, these studies aim to contribute to the understanding of the complex tumorigenesis of oligodendrogliomas and the finding of molecular targets for directed therapy.

P06.168

Genotype-fenotype correlation in optic nerve gliomas in Slovak NF1 patients

A. Rybarova[1], *M. Nemethova*[2], *A. Zatkova*[3], *A. Hlavata*[1], *L. Kovacs*[1], *L. Kadasi*[2], *D. Ilencikova*[1];

[1]*2nd Department of Pediatrics, Comenius University, Medical School and University Children's Hospital, Bratislava, Slovakia,* [2]*Department of Molecular Biology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia,* [3]*Laboratory of Genetics, Institute of Molecular Physiology and Genetics, Bratislava, Slovakia.*

Introduction: Neurofibromatosis type 1 (NF1; OMIM 162200) is in 15% of cases complicated by optic nerve gliomas (ONG). Genotype-fenotype correlations in patients with NF1 and ONG help to determine the risk group for developing a severe form of NF1.

Materials and methods: We evaluated 51 Slovak patients with NF1 and divided then into two groups 1) with ONG (21 patients), 2) without ONG (30 patients). All of them underwent a clinical examination and molecular diagnostics of *NF1 gene* using protocol based on RNA.

Results: In the group with ONG patients, there was a significantly higher incidence of freckling (95%), brain hamartomas (71%) and neurofibromas (70%), compared to group without ONG. A half of mutations in the ONG group were located in the first 5'tertile (first 16 exons) of the *NF1 gene*. There were 15 novel mutations identified.

Discussion: Our results confirm the clustering of mutations in the 5' tertile of *NF1 gene* in patients with optic nerve glioma and sugguest the incidence of a more severe form of NF1. This may contribute to prognosis prediction.

P06.169

The contribution of MLPA and aCGH to establish the genetic profile of Oral cancer

I. M. Carreira[1], *I. P. Ribeiro*[1], *F. Marques*[2], *I. P. Baptista*[2], *J. Ferrão*[1], *J. B. Melo*[1];

[1]*Cytogenetics and Genomics Laboratory, Faculty of Medicine, University of Coimbra, Coimbra, Portugal,* [2]*Department of Dentistry, Faculty of Medicine, University of Coimbra, Coimbra, Portugal.*

Oral squamous cell carcinoma (OSCC) is one of the most common malignant lesions of head and neck. Besides technologic advances, the genetic mechanisms involved in the pathogenesis and progression of this disease are still not clear; thus the improvement in the diagnosis and treatment is limited, which means scarce benefit to the patients. The main goal of this study was to characterize the genetic profile of the OSCC by Multiplex Ligation-dependent Probe Amplification (MLPA). We also applied array-CGH, not only to corroborate the MLPA results but also to identify putative key regions associated to OSCC. To achieve these purposes, biopsies of tumor and biopsies from resection margin of the same patient, were acquired from 23 patients with diagnosis of OSCC. Tissue from healthy donors was used as control. The array-CGH from tumor biopsies was performed using a 4x180K oligonucleotide microarray. With the MLPA we detected frequently losses in chromosomes regions of 3p, 4q, 5q, 8p, 9p, 11q and gains in chromosomes regions of 3q, 6p, 8q, 11q, 16p, 16q, 19q and 20q. The analysis of the tissue from resection margin identified alterations spread over several chromosomes, namely in 6p, 9p, 16p, 17p, and 19q. With array-CGH we detected imbalances in all chromosomes. In conclusion, this kind of studies improves the understanding of these devastating tumors through identification of key chromosomal regions involved in tumor biology, which may be very useful to the follow-up of these patients and also allows the development of novel therapeutic targets.

P06.170

Vitamin D receptor gene polymorphism as prognostic indicator for oral cancer

K. Zeljic[1,2], *G. Supic*[2], *M. Stamenkovic Radak*[1], *Z. Magic*[2];

[1]*Faculty of Biology, University of Belgrade, Belgrade, Serbia,* [2]*Institute for Medical Research, Military Medical Academy, Belgrade, Serbia.*

It has been reported that genetic polymorphisms in the vitamin D receptor gene (VDR) could influence the risk of oral cancer. Among numerous identified polymorphisms in the VDR gene, FokI (rs2228570) is considered as functional polymorphism and results in synthesis of 427 amino acids long protein, while mutated form results in synthesis of protein shorter for three amino acids. It could be assumed that this functional polymorphism has influence on survival and may be used as oral cancer prognostic indicator. The goal of this study was to investigate the association of VDR FokI polymorphism with oral cancer survival. The study was performed in 110 patients with diagnosed oral cancer. Genotypes were determined by the PCR-RFLP method. All data were statistically analyzed using the SPSS software. The VDR FokI polymorphism was associated with a decreased overall survival (p=0.042, log-rank test). Patients with *wild type* ff genotype had significantly worse survival (p=0.012, log-rank test) compared to the heterozygous and mutated variants together. Stratified analysis by the lymph node involvement and tumor stage revealed that *wild type* ff genotype was associated with the poor survival in groups with and without lymph node involvement (p=0.025, p=0.040, respectively) and in stage III tumors (p=0.026). Multivariate Cox's regression analysis revealed that VDR FokI could be considered as independent prognostic factor (HR=0.600, 95% confidence interval= 0.377-0.954, p=0.031).

Our data suggest that VDR FokI polymorphism is associated with the survival and could be considered as independent prognostic indicator for oral cancer.

P06.171

Ovarian carcinoma - profiling of the gene expression and candidates for targeted therapy

D. N. Nikolova[1], *N. Doganov*[2], *R. Dimitrov*[2], *K. Angelov*[3], *S. Low*[4], *I. Dimova*[1], *D. Toncheva*[1], *Y. Nakamura*[4], *H. Zembutsu*[4];

[1]*Medical University Sofia, Sofia, Bulgaria,* [2]*University Hospital of Obstetrics and Gynecology, Sofia, Bulgaria,* [3]*National Hospital of Oncology, Sofia, Bulgaria,* [4]*Human Genome Center, Institute of Medical Science, Tokyo University, Tokyo, Japan.*

Ovarian cancer is the second most common gynecologic malignancy and the fifth leading cause of cancer deaths in women. The genome-wide microarray consisting of approximately 38,500 transcripts enabled us to obtain comprehensive gene expression profiles related to phenotypic and biological information in cancer cells. We have identified multiple targets that may be applicable for development of novel anti-cancer drugs and/or diagnostic biomarkers. Through gene-expression profile analysis of 22 epithelial ovarian cancers coupled with purification of cancer cell population by laser microbeam microdissection (LMM) on a microarray, we identified a number of transcripts that were over-expressed in ovarian cancers. Altogether, we identified 273 transcripts that were commonly up-regulated and 387 transcripts that were down-regulated in ovarian carcinomas. Among these 273 transcripts identified, only 87 (31.9%) transcripts were reported as up-regulated genes in previous microarray studies, in which bulk cancer tissues and normal ovarian tissues were used for the analysis. We further propose a number of genes probable to be good candidates for a target therapy of ovarian cancer. Among them we focus on *CHMP4C* (chromatin-modifying protein 4C) that was over-expressed very commonly in ovarian carcinoma, but were not expressed in the normal human tissues examined. Our data should be helpful for a better understanding of the tumorigenesis of ovarian cancer and should contribute to the development of diagnostic tumor markers and molecular-targeting therapy for patients with ovarian cancer.

P06.172

Clinical trials for p53 marker validation

B. Wolf[1], *S. Kappel*[1], *D. Kandioler*[2];

[1]*Medical University of Vienna, Department of Surgery, Research Laboratories, Vienna, Austria,* [2]*Medical University of Vienna, Department of Surgery, Vienna, Austria.*

The moderate efficacy of cancer therapy is still the major challenge in surgical oncology.

The use of genetic markers has been suggested to improve treatment efficacy. However, a clear algorithm for the clinical evaluation of a potential marker is currently lacking.

Based on the well-established phase I-III clinical trials we present an algorithm, which we propose for reliable clinical evaluation of genetic markers like p53.

Phase I marker studies aim to demonstrate the robustness, specificity and prevalence of the potential new marker and the formulation of a marker hypothesis. Phase II marker studies focus on the marker test; concerning reproducibility, sensitivity and specificity of the test, and the result interpretation. Phase I and phase II marker studies may be performed retrospectively using adequately collected samples. Phase III marker trials aim to confirm the clinical relevance of the marker providing a high level of evidence (level I). The latter trials have to be prospective, randomised, controlled investigations taking the qualified trial design into particular consideration. The clinical utility of a marker depends on its ability to guide three therapeutic decisions: "Who to treat", "How to treat" and "How much to treat". These questions have to be answered by different marker types -prognostic, predictive and pharmacodynamic- implicating that the projected phase III trial endpoints have to be different. As a marker, p53 has passed phase I and II. Currently phase III trials evaluating p53 are missing probably because it is not clear whether p53 should be evaluated as prognostic or predictive marker.

P06.173

Phase II clinical trial for optimising radiotherapy for rectal cancer using genetic markers

S. Kappel[1], *B. Wolf*[1], *C. Brostjan*[1], *I. Kührer*[2], *B. Teleky*[2], *R. Schmid*[3], *M. Mittlböck*[4], *C. Kulinna-Cosentini*[5], *F. Wrba*[6], *D. Kandioler*[2];
[1]*Medical University of Vienna, Department of Surgery/ Surgical Research, Vienna, Austria,* [2]*Medical University of Vienna, Department of Surgery, Vienna, Austria,* [3]*Medical University of Vienna, Department of Radiotherapy, Vienna, Austria,* [4]*Medical University of Vienna, Center for Medical Statistics, Informatics and Intelligent Systems, Vienna, Austria,* [5]*Medical University of Vienna, Department of Radiology, Vienna, Austria,* [6]*Medical University of Vienna, Department of Clinical Pathology, Vienna, Austria.*

In rectal cancer preoperative radiation plus surgery has proven superiority to surgery alone and is widely accepted as standard therapy. However, a significant reduction in local recurrence has been achieved by a questionable risk/benefit ratio.

Radiation therapy is suggested to depend on sufficient tumour oxygenation and to act via induction of apoptosis. TP53 gene mutations represent a crucial defect in the apoptosis pathway, are involved in regulation of tumour vascularisation and are present in 60% of rectal cancers.

The study aims to correlate pathological tumour-response to radiation therapy with three parameters: the genetic status of the marker TP53, differences in perfusion MRI results eight weeks after radiation treatment and differences in the concentration of circulating angiogenesis factors in blood.

Eligible patients in our study receive standard preoperative short-term radiation for 5 days followed by surgery after a delay of eight weeks. The sample size calculation is based on an estimated 40% difference in response rates comparing patients with TP53 normal and mutant tumours. The required patient number to reach the study endpoint is 60.

The TP53 status is analysed in tumour tissue from diagnostic biopsies. Tumour stage is assessed by MRI at time of diagnosis and immediately before surgery. MRI staging will be compared to pathohistological staging. Concentrations of circulating angiogenesis factors are assessed at several time points.

The trial prepares the way for interventional trials and offers potential restriction of preoperative radiation for rectal cancer to those patients who will benefit, saving patients from negative side effects.

P06.174

Novel p53 gene mutations at codons 65 and 100 among Iranian esophageal cancer patients: it may modify MDM2-p53 interaction

F. Biramijamal[1], *M. Soltani*[1,2], *G. Irvanloo*[3];
[1]*NIGEB, Tehran, Islamic Republic of Iran,* [2]*Azad University, Karaj, Islamic Republic of Iran,* [3]*Caner Institute, Tehran, Islamic Republic of Iran.*

The incidence pattern of esophageal cancer is different among Iranian population and up to 171/100000 in Northern Iran. In previous study, we showed that p53 gene mutations occurred in esophageal squamous cell carcinoma (ESCC) from Iran frequently. The p53 protein has an important role in tumorgenesis in various types of cancer. This protein is a transcription factor and it can induce apoptosis to prevent the development of cancer or tumor growth. Also, Several studies were described the p53 genetic polymorphism in exon 4, at codon 72, and susceptibility to several types of cancer and diseases. We studied association of the p53 genotypes at codon 72 with esophageal cancer risk in Iran.

To investigate the p53 Pro72Arg genotype among healthy controls and ESCC patients, we collected samples from blood and tumor tissues. The p53 genotypes were determined by direct DNA sequencing and PCR-RFLP analysis. During this study, we found novel p53 gene mutations at codon 65 (AGA→AAA) and codon 100 (CAG→ CAA) among patients.

Additionally, we assessed protein expression of p53 and MDM2 in esophageal tumor tissues by immunohistochemistry method. We found that abnormal accumulation of the p53 protein was not associated with MDM2 protein expression.

The p53 and MDM2 proteins are related to cancer. The p53 protein prevents tumor growth, but, MDM2 promotes proliferation of tumor cells. It is described that MDM2 protein can bind to prolin-rich region in p53 protein (residues 61-94). So, p53 point mutation at codon 65 may modify MDM2-p53 interaction.

P06.175

Whole genome expression, canonical pathway and gene network analysis in the cases of papillary thyroid cancer

N. Cine[1], *I. Tarkun*[2], *N. Canturk*[3], *Y. Gurbuz*[4], *D. Sunnetci*[1], *H. Savli*[1];
[1]*Medical Genetics Department, Medicine Faculty of Kocaeli University, Kocaeli, Turkey,* [2]*Department of Internal Medicine, Medicine Faculty of Kocaeli University, Kocaeli, Turkey,* [3]*Department of General Surgery, Medicine Faculty of Kocaeli University, Kocaeli, Turkey,* [4]*Pathology Department, Medicine Faculty of Kocaeli University, Kocaeli, Turkey.*

Introduction: Papillary carcinoma is the most frequent thyroid cancer and constitutes % 75-80 of thyroid cancers. Finding of scientific markers for papillary thyroid cancer and its variants can make easier to confirm the results taken from Fine Needle Aspiration cytology. The objective of this study consists in elucidating the role of genetic factors in the mechanisms of the development of papillary thyroid cancer and to screen patterns of whole genome expressions in patients with papillary thyroid cancer.

Materials and Methods: RNA samples were obtained from healthy and cancerous tissues taken from cancer detected nodule from eight patients diagnosed as papillary thyroid cancer. These RNA samples were hybridized with microarray chips (Agilent Human 4 X 44K Oligo Microarrays). Gene expression, canonical pathway and network analyisis were performed using GeneSpring GX 11.0 software.

Results: 40 downregulated and 124 upregulated genes were detected in our study. The canonical pathways significantly regulated were extracellular region, collagen, multicellular organismal process, cell adhesion, biological adhesion and multicellular organismal development.

Conclusion: Upregulation of HMGA2 gene which was reported before as a novel molecular marker in development of thyroid carcinoma is noteworthy in our study. This gene is upregulated in malignant forms of thyroid cancers has been reported. It's suggested that HMGA2 might be used as a molecular marker for classification of thyroid tumors in terms of being malignant or benign forms.

P06.176

Characterization of PMS2 rearrangements in Lynch syndrome patients uncovers the first deleterious PMS2-PMS2CL hybrid allele

A. Wernstedt[1], *E. Valtorta*[2], *F. Armelao*[3], *R. Togni*[4], *S. Girlando*[4], *M. Baudis*[5], *K. Heinimann*[6], *L. Messiaen*[7], *N. Staehli*[2], *J. Zschocke*[1], *G. Marra*[2], *K. Wimmer*[1];
[1]*Division of Human Genetics, Medical University Innsbruck, Austria, Innsbruck, Austria,* [2]*Institute of Molecular Cancer Research, University of Zurich, Switzerland, Zurich, Switzerland,* [3]*Department of Gastroenterology, Ospedale S. Chiara, Azienda Provinciale per I Servizi Sanitari, Trento, Italy, Trento, Italy,* [4]*Department of Pathology, Ospedale S. Chiara, Azienda Provinciale per I Servizi Sanitari, Trento, Italy, Trento, Italy,* [5]*Institute of Molecular Life Sciences, University of Zurich, Switzerland, Zurich, Switzerland,* [6]*Research Group Human Genetics, Department of Biomedicine, University of Basel, Switzerland, Basel, Switzerland,* [7]*Medical Genomics Laboratory, Department of Genetics, University of Alabama at Birmingham, USA, Birmingham, AL, United States.*

Heterozygous *PMS2* germline mutations are associated with Lynch syndrome. Up to one third of *PMS2* mutations are genomic deletions. Their detection is complicated by a pseudogene (*PMS2CL*), which-owing to extensive interparalog sequence exchange-closely resembles *PMS2* downstream to exon 12. A recently re-designed multiplex ligation-dependent probe amplification (MLPA) assay identifies *PMS2* copy number alterations with improved reliability when used with appropriate reference DNAs. We used this assay to study 13 patients with PMS2-defective colorectal tumors. Three presented deleterious alterations: (i) An *Alu*-mediated deletion strengthening the view that the high frequency of *PMS2* deletions is related to a high density of *Alu* elements within the genomic sequence of the gene. (ii) A 125-kb deletion encompassing at least two further genes with tumor suppressing functions in a young colorectal cancer patient. This raises the possibility that *PMS2* mutations of this type may confer a higher penetrance of tumor susceptibility. (iii) The first *deleterious* hybrid *PMS2* allele produced by recombination with crossover between *PMS2* and *PMS2CL*, with the breakpoint in intron 10 (the most 5‘ breakpoint of its kind reported thus far). We discuss mechanisms that might generate this allele in different chromosomal configurations (and their diagnostic implications) and describe an allele-specific PCR assay that facilitates its detection. Our data indicate that, for gDNA-based *PMS2* mutation analysis, the re-designed *PMS2* MLPA assay is a valid first-line option that can identify roughly a quarter of all *PMS2* mutations.

P06.177

Mutation of the PPP2R1A gene as part of the sporadic endometrial serous carcinoma genetic profile

V. Streinu[1], *C. Cieza-Borrella*[1,2], *M. Nuñez-Lozano*[1], *M. Sancho-de-Salas*[3,2], *R. Lozano-Mejorada*[4,2], *A. Garcia-Iglesias*[5,2], *J. J. Cruz-Hernandez*[4,2,6], *R. Gonzalez-Sarmiento*[1,2,6];
[1]Molecular Medicine Unit, Department of Medicine, University of Salamanca, Salamanca, Spain, [2]IBSAL, Salamanca, Spain, [3]Anatomo-Pathology Service, University Hospital of Salamanca, Salamanca, Spain, [4]Oncology Service, University Hospital of Salamanca, Salamanca, Spain, [5]Gynecology Service, University Hospital of Salamanca, Salamanca, Spain, [6]Institute of Cellular and Molecular Biology of Cancer (USAL-CSIC), Salamanca, Spain.

Introduction and Aim: Endometrial serous carcinoma (ESC) is the most aggressive subtype of endometrial carcinoma. Some of its mainly mutated genes are p53, p16, E-Cadherin, accompanied sometimes by mutations in PTEN, PIK3CA, KRAS, BRAF. Recent studies show the involvement of PPP2R1A in the pathogenesis of ESC. PPP2R1A encodes a constant regulatory subunit of Ser/Thr phosphatase 2 implicated in the negative control of cell growth and division. Although its role in carcinogenesis remains still unveiled, molecular studies indicate that its mutation may be a factor to take into consideration when doing a genetic mapping, thus influencing the treatment of the disease.

Our aim was the study of the PPP2R1A gene in order to determine the frequency of mutations in the sporadic ESC in Spanish patients.

Patients and Methods: A set of 12 patients with sporadic endometrial carcinoma with serous component was studied through analysis of the tumoural DNA by PCR, CSGE, cloning and automatic sequencing of the full coding region and the exon-intron boundaries.

Results: The results are annexed in the table. We found 4 previously reported PPP2R1A pathogenic mutations (33.33%), two of the patients carry additional gene mutations.

Conclusions: The study indicates that PPP2R1A gene mutations play an important role in the carcinogenesis of sporadic ESC in Spanish patients and as such should be included in its molecular profile.

First steps towards an individualized immunotherapy for primary liver cancers.

C. Schroeder[1], *M. Sturm*[1], *S. Junker*[1], *M. Löffler*[2], *M. Walzer*[2], *M. Günder*[2], *S. Stevanovic*[2], *H. Rammensee*[2], *P. Horvath*[3], *D. Zieker*[3], *S. Nadalin*[3], *A. Königsrainer*[3], *F. Fend*[4], *O. Riess*[1], *P. Bauer*[1];
[1]Deptartment. of Medical Genetics, Tuebingen, Germany, [2]Department of Immunology, Tuebingen, Germany, [3]Department of General Visceral and Transplant Surgery, Tuebingen, Germany, [4]Department of Pathology, Tuebingen, Germany.

Primary liver cancer is within the top ten most common cancers worldwide. Over 500‘000 patients are diagnosed with hepatocellular carcinoma each year. The prevalence in Europe and the USA has been rising constantly over the last decades. Yet, therapeutic options are limited. The BMBF supported project ‘IndividuaLIVER’ aims at establishing an individualized immunotherapy for primary liver cancers.

This approach is based on the detection of somatic mutations in tumor tissue. Hence, we sequenced a pair of tumor tissue and blood sample in one patient suitable for vaccination. Both samples were conditioned and sequenced using a targeted whole-exome resequencing approach. The on-target ratio was 0.79 / 0.77 (tumor / blood), overall coverage at a depth of 10x was 91.6 % / 90.44 %. With stringent filter criteria, we were able to detect a total of 23 somatic sequence changes suitable for vaccination. The laboratory turnaround time is estimated to be 6-7 weeks. Validation was carried out using a second bioinformatic analysis method and a deep-sequencing approach with customized targets (av. depth: 728x). We were able to confirm 12 somatic variants. All sequence changes were further prioritized by an HLA-allele-specific SYFPEITHI-score. Taken together a total of 3 sequence changes were rated suitable for HLA and mutation specific vaccination.

Using this approach, we are able to detect somatic sequence changes within tumor tissue that might lead to successful individualized immunotherapy within a reasonable time frame. The next steps will be design and administration of an individualized multi-peptide anti-cancer vaccine.

P06.179

S-adenosylmethionine alters the transcription profile in prostate cancer cells

T. Schmidt, *P. Burfeind, W. Engel;*
Department of Human Genetics, Göttingen, Germany.

Epigenetic alterations are critical steps in cancerogenesis. DNA hypomethylation in cancer cells is probably as frequent as DNA hypermethylation and might activate oncogene transcription. Recent studies point to a role for S-adenosylmethionine (SAMe), a major methyl donor in biological transmethylation events, as a demethylation inhibitor. In prostate cancer cells, treatment with SAMe leads to increased methylation levels of promoters from several genes like the urokinase plasminogen activator and thus causes the downregulation of the respective genes. To gain a more general overview concerning the effects of SAMe treatment on cancer cells, we performed whole transcriptome shotgun sequencing on prostate cancer cells treated with SAMe. We found altered transcription levels of 160 genes, 90 of which were downregulated. Most of these genes are associated with biological processes critical in cancerogenesis e.g. epithelial-mesenchymal-transition, invasion, migration and proliferation of cells. The expression levels of some genes (e.g. KLF8, BDNF, S100P etc.) were confirmed by realtime PCR and methylation specific PCR was carried out. Treatment of prostate cancer cells with SAMe was found to result in an increased global methylation status of the DNA suggesting that reversing DNA hypomethylation might be one major mechanism of SAMe action. Next, we performed functional studies with SAMe-treated cancer cells as well as human fibroblasts and discovered a decreased potential for proliferation, migration and invasion of cancer cells but not of fibroblasts. Taken together, we provide a more comprehensive overview of effects caused by SAMe and present novel target genes for therapeutic options in prostate cancer.

P06.180

Can mycoplasma-mediated oncogenesis be responsible for formation of prostate cancer?

S. Erturhan[1], *H. Ozgul*[1], *S. Pehlivan*[2], *O. Bayrak*[1], *I. Seckiner*[1], *T. Sever*[2], *M. Karakok*[3];
[1]University of Gaziantep, Faculty of Medicine, Department of Urology, GAZIANTEP, Turkey, [2]University of Gaziantep, Faculty of Medicine, Department of Medical Biology and Genetics, GAZIANTEP, Turkey, [3]University of Gaziantep, Faculty of Medicine, Department of Pathology, GAZIANTEP, Turkey.

Aim : The origin of chronic inflammation preceding the development of prostate cancer (PCa) remains unknown and chronic inflammation associated with infections has been defined as an important cancer-promoting condition. In our study, to investigate relationship between mycoplasma sp. infection and PCa were aimed.

Method: Benign prostate hyperplasia and tumor tissue samples from 31 patients with PCa and healthy control groups (benign prostate hyperplasia) were studied. Moleculer DNA analyses was done after nested-PCR performed in two steps with seven primers (four auter and three iner) that can recognize at least 15 different Mycoplasma using two different PCR methods.

Results: Mycoplasma sp. DNA was detected in benign prostate hyperplasia, prostate tumor tissue samples at ratio 12.9% (4/31) and 35.9% (11/31), respectively. No mycoplasma DNA was determined in tissues of 31 healthy control group.

Conclusion: The relationship between mycoplasma sp. infection and Prostate cancer has been investigated for the second time in literature, and a significantly high existence of Mycoplasma sp. In conclusion, our data suggest that mycoplasma infections could be play a role in the etiology (mycoplasma-mediated multistage carcinogenesis) of prostate cancer. Further experimental and clinical studies are needed for development of a tool for early diagnosis and treatment of prostate cancer.

P06.181

Search for prognostic biomarkers in prostate cancer patients after radical prostatectomy

S. Wyder[1], F. Huber[2], M. Schindler[1], R. Jaggi[1], G. Kristiansen[2,3];
[1]University of Bern, Bern, Switzerland, [2]University Hospital Zurich, Zurich, Switzerland, [3]University Hospital Bonn, Bonn, Germany.

New biomarkers are needed to better predict the clinical outcome of patients with clinically localized prostate cancer. The available clinical and histopathological variables currently used lack accuracy to predict the course of the disease often leading to over- or under-treatment. Molecular scores have the potential to improve risk-stratification with respect to timing and intensity of treatment. We have developed an mRNA-based expression signature in a cohort of more than 150 patients who underwent radical prostatectomy between 1993 and 2006.

We measured the expression of approx. 200 genes in RNA derived of formalin-fixed, paraffin-embedded (FFPE) tumour samples. We used the Nanostring nCounter gene expression system, a digital, enzyme-free technology which features excellent reproducibility and high sensitivity on partially degraded RNA extracted from archival FFPE tumour samples. We identified several genes that significantly predicted biochemical relapse in univariate analysis. A multi-gene molecular score was developed which predicts biochemical relapse in univariate and multivariate analyses when controlling for clinical and pathologic variables. The prognostic value of the score is currently being retrospectively assessed in an independent cohort.

P06.182

Expression of the SHB gene in prostate cancer

J. Mares[1], M. Schmidt[1], J. Mudrunka[1], J. Soukup[1], S. Vesely[1], M. Klabanova[2], L. Jarolim[1];
[1]Charles University, Prague 5, Czech Republic, [2]Diana Lucina, Prague 4, Czech Republic.

SHB (Src homology 2 domain-containing adapter protein B) is involved in receptor tyrosine kinase signaling, angiogenesis, apoptosis and cell regulation regulation. A detailed analysis of expression of the SHB gene has not been conducted in prostate cancer so far. We aimed to compare the SHB expression in prostate cancer and benign prostatic hyperplasia with clinicopathological data and evaluate its diagnostic and prognostic potential.

Isolation of mRNA from prostate cancer in 56 patients has been performed in period 2008 - 2011. As a control group, 26 patients with benign prostate hyperplasia were used.

Statistically significant lower relative expression of SHB in prostate cancer tissue was detected (p< 0.001). In comparison of patients distributed to localized (T2) and locally advanced (T3, T4) groups, decreased expression in locally advanced disease with statistical significance (p< 0.0236). In comparison of groups divided by Gleason score (GS <7 and GS ≥ 7), age and PSA, no differences have been detected. According to our results the level of SHB expression analysed by using RT-PCR in patients with prostate cancer can give additional prognostic information.

The project was supported by Diana Lucina and by grants MSM 0021620808 and GAUK 200090.

P06.183

Analysis of V89L polymorphism of the testosterone 5-alpha-reductase II gene in prostate cancer patients from Bashkortostan Republic of Russia

R. Zubairov[1], I. Gilyazova[1], A. Mustafin[2], A. Papoyan[2], I. Sultanov[2], D. Zapevalova[3], V. Pavlov[2], E. Khusnutdinova[1];
[1]Institute of Biochemistry and Genetics, Ufa Science Center, RAS, Ufa, Russian Federation, [2]Bashkir State Medical University, Ufa, Russian Federation, [3]Bashkir State University, Ufa, Russian Federation.

Prostate cancer (PC) is one of the most common visceral malignancies in human. In recent years, its incidence has increased in Russia. The study was performed to investigate the role of various genotypes involved in steroid metabolism and synthesis in the causation of prostate cancer. We investigated the *SRD5A2* gene Ala49Thr (rs9282858), Val89Leu (rs523349) polymorphisms and variation of TA)n repeats in a cohort of 91 PC patients and 100 controls, matched for sex, age and area of residence. The enzyme 5α-reductase, which converts testosterone to dihydrotestosterone (DHT), performs key functions in the androgen receptor signaling pathway. There were no significant correlations of A49T polymorphism and (TA)n repeats with the disease. The analysis of the V89L polymorphism showed significant differences in the distribution of allele and genotype frequencies between PC patients and healthy individuals. The frequency of genotype *SRD5A2*V/V* in patients was significantly higher (54.1%) than in controls (36.5%, χ2=4,27, p=0,04, OR=2,05, CI95% =1,03-4,09). The frequency of genotype *SRD5A2* L/ L* in control group was higher (18.9%) compared with patients (8.23%), but differences were not statistically significant (P>0.05).

The V89L variant was not associated with the grade or stage of prostate cancer, or with patient age.

Thus, the genotype of *SRD5A2*V/V* and allele and *SRD5A2*V* are showed to be markers of the increased risk for prostate cancer development in Bashkortostan Republic. Further large-sample studies will be required to confirm the association and to assess any interactions with environmental factors.

P06.184

The TMPRSS2/ERG fusion gene expression in tumor epithelium and tumor-associated stromal cells in prostate cancer.

T. V. Kekeeva[1,2], L. Zavalishina[1], Y. Andreeva[1], G. Frank[1], D. Zaletaev[2];
[1]Moscow Herzen Oncological Research Institute, Moscow, Russian Federation, [2]Sechenov Medical Academy, Moscow, Russian Federation.

Due to intensive investigations for the last ten years it has become increasingly clear that tumor microenvironment plays a critical role in prostate carcinogenesis. Tumor microenvironment undergoes significant modification such as protein expression alterations and various genetic changes of stromal cells. Accumulation of multiplicity genetic alterations is typical not for only cancer epithelial cells but tumor-associated fibroblasts and endothelial cells as well. Further more these stromal cell alterations are not tumor epithelium specific.

We investigated *TMPRSS2/ERG* fusion gene expression in prostate cancer and tumor microenvironment. Tumor epithelia and tumor-associated stroma 34 prostatectomy specimens from patients with pT1-T4 stage prostate cancer were isolated using laser capture microdissection. mRNA expression of *TMPRSS2* and *TMPRSS2/ERG* significant in prostate carcinogenesis were investigated using RT-PCR following by sequencing.

We found *TMPRSS2/ERG* expression only in 65% (22/34) tumor epithelium samples and neither of adjacent tumor stroma. Also we detected *TMPRSS2* expression in all tumor epithelium samples and 5/34 stroma specimens. The possible explanation of *TMPRSS2* expression in the microenvironment is the presence of single tumor cells, which we observed by cytokeratine IHC staining. Nevertheless the fusion gene expression is not characteristic for the tumor-associated stroma.

The finding of frequent genetic alterations in tumor-associated stroma suggests a more important role for stromal fibroblasts in prostate cancerogenesis than was previously appreciated. Some molecular alterations are common for prostate cancer and tumor microenvironment but *TMPRSS2/ERG* fusion gene is the tumor feature only.

P06.185

Genome-wide increase in differential DNA methylations in TMPRSS:ERG fusiongene negative prostate tumours

Prostate cancer is the second most common cancer among men worldwide. Despite intensive scientific efforts basic molecular reasons mostly remained obscure. Lately, it became evident that alterations in the DNA methylation pattern can be one of the leading causes for tumour formation. Therefore, we initiated the first high throughput sequencing study investigating genome-wide DNA methylation patterns in a large cohort of 104 human prostate tissues including normal controls using MeDIP-Seq. Comparative analyses identified more than 147,000 cancer-associated epigenetic alterations, affecting more than 75% of homeobox genes and 50% of the known cancer associated genes in their promoter region.

We could show that the increased expression of EZH2, originating in about 50% of prostate tumours in an ERG involving fusiongene (TMPRSS2:ERG), might explain the remarkable differences in DNA methylation between tumour and normal tissues. The methylation patterns, however, are strikingly more dissimilar in TMPRSS2:ERG fusiongene negative samples to normal prostate tissues than those in fusiongene positive tissues. We identified a mechanism of hypermethylation of miRNA-26a as an alternative pathway of ERG independent EZH2 activation which in turn can explain the observed increase in differential methylation in fusiongene negative tumours.

P06.186

Interaction of the RAD51 paralogs in the mammalian 2/3 hybrid system

***D. Endt**, A. Niklaus, D. Schindler;*
Department of Human Genetics, Wuerzburg, Germany.

The five RAD51 paralogs, RAD51B, RAD51C, RAD51D, XRCC2 and XRCC3, play an important role in homologous recombination, a process crucial for the error-free removal of DNA double-strand lesions. These proteins share 20-30% homology and interact with each other and the RAD51 recombinase, an ortholog of E. coli RecA. Previous investigations in the yeast two-hybrid system, co-immunoprecipitations from human cell extracts and co-expression in the baculovirus system have shown that the paralogs form two complexes, RAD51C/XRCC3 and RAD51B/RAD51C/RAD51D/XRCC2. RAD51B has been reported to stabilize the interaction of RAD51D and XRCC2. Here we aimed at extending these findings in a human cellular environment. For that purpose we used the mammalian two- and three-hybrid system (M2/3H). We cloned full-length cDNA of each of the five RAD51 paralogs into the pM and pVP16 vectors. In M3H studies, the additional expression vector pCMV-Tag3b was used. Firefly luciferase (pGl4.31) served as reporter gene for the assay. As control for transfection efficiency we co-transfected renilla luciferase (pRL-null). As internal standard and positive control we employed the reported interaction of FANCA and FANCG. In M2H studies the previously reported interactions were confirmed, except that of RAD51C and RAD51D. This weak interaction required the presence of RAD51B for activation or stabilization, whereas XRCC2 did not boost it. Likewise, some of the other interactions were be influenced by a third paralog in M3H studies. Additional RAD51 protein seemed not to effect interactions of RAD51C/RAD51D and RAD51D/XRCC2 but those of RAD51C/XRCC3 and RAD51C/RAD51B. Bidirectional testing showed slight differences in interaction strength.

P06.187

Detection of micro-metastases of renal cell carcinoma by CA9 marker using Real-time PCR

***B. Bajelan**[1], M. Hashemi[2], H. Ghaffari[3];*
[1]Islamic Azad University,Science and Research Branch, Tehran, Islamic Republic of Iran, [2]Islamic Azad University,Tehran Medical Branch, Tehran, Islamic Republic of Iran, [3]Oncology and Stem Cell Research Center of Shariati Hospital, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.

The global prognosis of renal cell carcinoma (RCC (remains poor, about 40% of patients will develop metastasis after nephrectomy. There is a strong need to identify the early metastasis with conventional and molecular risk factor. The analysis of molecular markers provides a new tool for prediction of prognosis for early metastasis. The present study aimed to test if analysis of the CA9 gene in peripheral blood can provide useful information to predict Micro metastasis.

In this experimental study, patients (n=30) with a renal cell carcinoma were evaluated for peripheral blood CA9 expression none randomly. Data of tumor grade were received from pathologists. Total RNA extraction and cDNA synthesis was performed and CA9 gene expression level were compared between patients and normal group (n=16) by Real-time PCR.

Six of patients show high CA9 expression (3 in grade I, 2 in grade II and 1 in grade III) but no significant difference was found between CA9 expression level and tumor grade. After one year follow up 4 patients were found to have a metastasis, but no significant difference was found between CA9 expression level and metastatic patients. (p>0/05)

Ca9 is a tumor-specific marker for RCC with a high degree of expression in the conventional renal cell carcinoma. On the basis of the results of this study, the detection of Ca9 gene expression in the peripheral blood of patients with RCC may prediction factor for increasing risk of micro metastasis.

P06.188

Identification of new diagnostic markers for renal cell carcinoma

***S. Schmidt**[1,2], S. Erb[2], S. Burghoff[1], S. Leisz[2], K. Hoffmann[1], B. Seliger[2];*
[1]Institute for Human Genetics, Martin-Luther University Halle-Wittenberg, Halle/Saale, Germany, [2]Institute for Medical Immunology, Martin-Luther University Halle-Wittenberg, Halle/Saale, Germany.

The renal cell carcinoma (RCC) is one of the most frequent malignant tumours and is often associated with the loss of function of the von-Hippel-Lindau gene (VHL). The ubiquitin ligase VHL triggers the degradation of the hypoxia-inducible factor α (HIFα) under normoxic conditions. HIF is the major transcription factor reacting to hypoxia. As in the majority of cases this tumour is resistant to chemotherapy. Therefore, the aim of the study was to identify possible new diagnostic and therapeutic target genes, like VHL, in the HIF pathway in 24 RCC cell lines derived from patient tumour tissue. The cell lines were characterized with respect to mutations in VHL, the expression profile of HIF associated genes (HAF, FIH, VEGF, CMET, MITF, EGFR, TGFβR) at RNA and protein level, proliferation, anchorage independent growth and activation of signalling pathways. The cell lines show a high variability concerning generation time in general and with respect to serum reduction and anchorage independent growing. The identified expression profile of HIF associated genes reveals possible target candidates for diagnostics. VHL sequencing identified both known and unknown mutations. Most of the VHL mutations were found in exon 1. 11 of 18 analysed cell lines had no VHL mutations in exon 2 and 3. First results gained by linking immune blots and expression profiling suggest a correlation of FIH protein expression with HIF target gene vascular endothelial growth factor (VEGF) expression. New possible targets associated with HIF for example FIH were identified to diagnose RCC and could be therapeutically relevant.

P06.189

Vitamin D receptor polymorphisms and renal cancer risk in Bashkortostan Republic of Russia

***L. Kutlyeva**[1], I. Gilyazova[1], R. Khusainova[1], A. Zagidullin[2], A. Khaliullin[2], E. Klimentova[3], A. Shafigina[3], V. Pavlov[2], E. Khusnutdinova[1];*
[1]Institute of Biochemistry and Genetics, Ufa Science Centre, RAS, Ufa, Russian Federation, [2]Bashkir State Medical University, Ufa, Russian Federation, [3]Bashkir State University, Ufa, Russian Federation.

Renal cell carcinoma (RCC) is the most common neoplasm affecting the adult kidney. One of the most important events in RCC is metabolism of vitamin D, which exerts its activity through binding to the nuclear vitamin D receptor (VDR).

The aim of investigation was to analyze risk of RCC in patients from Bashkortostan Republic depending on *VDR* polymorphisms. A case-control association study included 176 RCC patients and 165 controls, matched for age, sex and area of residence. We used PCR-RFLP genotyping of *VDR* gene polymorphisms at tree localizations rs731236 (TagI), rs7975232 (ApaI), rs1544410 (BsmI), rs2228570 (FokI).

Statistically significant differences were observed in the TagI genotype t/t between RCC patients and controls (p=0.024, OR=2.93 (95%CI 1.13-7.87)). Analysis of other gene polymorphisms didn‘t show significant differences between patients and controls (p>0.05) in general cohort and taking into consideration sex, pathological stage and histological grade of RCC.

The polymorphisms *BsmI, ApaI, TaqI* of *VDR* gene demonstrated strong linkage disequilibrium (D‘>30%). The FokI wasn't in linkage disequilibrium with any of the other examined *VDR* polymorphisms (D‘<30%).

Haplotype analysis showed that haplotypes tAB (p=0.0030), tAb (p=0.0125), TAB (p=0.0393), TaB (p=$1.9606e^{-5}$) were significantly prevalent in RCC patients. The most patients with lower stage of RCC had haplotype tAb (p=0.002), whereas patients with higher stage had haplotype tAB (p=0.02). We revealed haplotype tAb (p=0.002) of *VDR* gene to be a risk factor for RCC development in males.

The analysis of genetic variation in *VDR* gene may provide insight into the role of vitamin D in RCC development.

P06.190

Amplicon-Based Ultra-Deep Next-Generation Sequencing and its application to characterize mutated transcripts of RB1 gene in peripheral blood cells of childern patients with germinal retinoblastoma

***I. Valášková**[1,2], J. Kadlecová[1,2], S. Dudová[1,2], M. Vaňásková[1], J. Zrůstová[1], T. Kepák[3], R. Gaillyová[1,2];*
[1]University Hospital Brno, Medical Genetics Dpt., Brno, Czech Republic, [2]Masaryk University, Faculty of Medicine, Brno, Czech Republic, [3]University Hospital Brno, Clinic of Pediatric Oncology, Brno, Czech Republic.

Introduction: RB1 (gene controlling cell division) mutations constitute a disease-defining molecular aberration in Retinoblastoma, the most common primary ocular malignancy (retina cancer) of childhood. In germinal retinoblastoma (40% of all retinoblastomas) a germline RB1 cancer-predisposing mutation is present in all of the body‘s cells. Therefore molecular diagnostics of germinal retinoblastoma is performed by PCR assays targeting the RB1 gene with genomic DNA, obtained from peripheral blood. Mutational analysis of RB1 transcripts obtained from peripheral blood using current sequencing standard - Sanger capillary sequencing (which sensitivity is about 15%) is complicated by the nonsense-mediated mRNA decay (NMD), an mRNA surveillance pathway that ensures the rapid degradation of mRNAs containing premature translation termination codons. The Next-Generation Sequencing (NGS) - technology Roche 454 is based on pyrosequencing. It means that each sequenced fragment is clonally copied. This allows increasing of sensitivity under 1%

Method: In amplicon covering transcript of RB1 gene we applied the 454 Titanium chemistry assay (454 Life Sciences) to perform ultra-deep sequencing of specific cDNA PCR products using the GS Junior System sequencer from Roche's 454 Life Sciences. In median, 5 446 reads per amplicon were generated, thereby allowing a highly sensitive assessment of mutational burden in RB1transcripts of retinoblastoma patients. To assess sequencing error rates, we included a control amplicon from the normal transcript.

Conclusion: We here demonstrate that amplicon-based ultra-deep NGS is a suitable method to accurately detect and quantify the variety of transcript aberrations with high sensitivity and enables an individualized monitoring of disease.

P06.191

Renal tumour after maternal transmission in a SDHD-linked pedigree

E. Beristain[1], *M. Vicente*[1], *I. Guerra*[1], *B. Gutierrez*[1], *B. Catón*[2], *J. de Diego*[2], *G. Pérez de Nanclares*[1];
[1]*Hospital Txagorritxu, Vitoria-Gasteiz, Spain,* [2]*Hospital Santiago Apóstol, Vitoria-Gasteiz, Spain.*

The succinate dehydrogenase complex-subunit D (SDHD) gene, located on chromosome 11q23, encodes an anchoring subunit of the mitochondrial respiratory chain complex II. It functions as a tumour suppressor gene and causes hereditary paraganglioma type 1 when mutated. Renal tumours have also been associated to SDHD mutations.

Mutations in SDHD exhibit a clear parent-of-origin effect, with autosomal dominant paraganglioma occurring only with paternal transmission, though maternal transmission has been rarely described. Since the maternal allele of SDHD is not methylated, a number of hypothetical mechanisms have been suggested to explain the observed transmission pattern: 1) an unidentified tumour suppressor gene is inactivated in the imprinted region on chromosome 11p15; 2) the maternally derived SDHD is partially inactivated; 3) tissue-specific quantitative imprinting of SDHD confers subtle allele-specific expression differences.

Our aim was to characterise the inheritance pattern of SDHD-Trp5Stop mutation in a 4-generation family, mainly affected with paraganglioma.

Twelve microsatellite markers on 11p15 and 11q13-q23 were genotyped in germline DNA from 15 mutation carriers, as well as in tumoral DNA from the 6 patients (4 paraganglioma, 1 pheocromocytoma, 1 renal tumour). All the tumours, except the renal one had paternal inheritance of the mutation and showed LOH of the twelve microsatellites. The mutation was inherited from the mother in the patient with a renal tumour, who also had prostate cancer. In the latter, LOH of the twelve microsatellites was found in the renal but not in the prostate tumour, which confirms that maternal inheritance of SDHD mutations can cause this disorder.

P06.192

shRNA Mediated RHOXF1 Knock Down in Breast Cancer Cell Lines

S. Ghafouri-Fard, *D. Zare Abdollahi, M. Omrani;*
Department of Medical Genetics, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran.

Background: RHOXF1 has been shown to be expressed in embryonic stem cells, adult germline stem cells and some cancer lines. It has been proposed as a candidate gene to encode transcription factors regulating downstream genes in the human testis with an antiapoptotic effect. Its expression in cancer cell lines has implied a similar role for it in the process of tumorigenesis.

Method: The human breast cancer cell lines MDA-MB-231 and MCF-7 were cultured in DMEM medium supplemented with 10% fetal bovine serum,100 U/ml penicillin, and 100 μg/ml streptomycin. Cells were transfected with pGFP-V-RS plasmid having RHOX1 specific shRNA cassette and plasmid with scrambled sequence cassette as the negative control. Transfection efficiency was monitored by the expression of green fluorescent protein (GFP) 24 hours post transfection. RNA was extracted from cells 48 hours after transfection and cDNA was synthesized. Quantitative real-time RT-PCR was performed for RHOXF1, CASP8, BCL2 and HPRT genes.

Results: Decreased RHOXF1 expression was confirmed in cells after transfection. shRNA mediated knock down of RHOXF1 resulted in significant decrease in BCL2 expression in both cell lines but no change in CASP8 expression.

Discussion: RHOXF1 can mediate transcriptional activation of the BCL2 in cancers, so render tumor cells resistant to apoptotic cell death induced by anticancer therapies. shRNA targeting RHOXF1was shown to specifically mediate the RHOXF1 gene silencing. shRNA mediated knock down of RHOXF1 can be effective in induction of apoptotic pathway in cancer cells via BCL2 downregulation, so it can have potential therapeutic usefulness in human breast cancer.

P06.193

Evaluation of silibinin on CD82 gene in prostate cancer PC-3 cells using quantitative Real-time PCR

M. Mokhtari[1], *M. Hashemi*[2], *M. Shokrgozar*[3], *N. Motamed*[4];
[1]*Islamic Azad University,Zargan Branch, Tehran, Islamic Republic of Iran,* [2]*Islamic Azad University,Tehran medical Branch, Tehran, Islamic Republic of Iran,* [3]*3Pasteur Institute of Iran, Tehran, Islamic Republic of Iran,* [4]*University College of Science, University of Tehran, Tehran, Islamic Republic of Iran.*

Prostate cancer is one of the most common cancer in developed countries. Most of cancer deaths are due to the development of metastasis. Hence, the prevention of metastasis process is critical. Silibinin is a flavonoid component that inhibits cell proliferation and causes cell death of human prostate cancer. In this study, the expression of CD82 gene in PC-3 cells treated with escalating concentrations of silibinin was evaluated that can result in new view for prostate cancer therapy.

In this study, PC-3 cells were treated with different concentrations of silibinin at 24h. The IC50 was determined. RNA was extracted by trizol. Then cDNA was synthesized. Precise primers were designed for CD82 and GAPDH genes by specific software. Quantity of CD82 gene expression compare to GAPDH gene in different concentrations of silibilin was analyzed using very sensitive quantitative Realtime PCR. CD82 gene expression in PC-3 cells treated by 100, 150 and 200μg/ml of silibinin at 24h were increased as 1.97±0.26 (P<0.05), 3.00±0.26 and 3.43±0.43 (P<0.01), respectively.

The results of quantitative Real-time PCR indicated that silibinin can probably decrease metastasis, by up-expression of CD82 metastasis suppressor gene in PC-3 cells.

[1]*3rd Dept Intern Med, Semmelweis University, Budapest, Hungary,* [2]*Dept Pulmonology, Semmelweis University, Budapest, Hungary,* [3]*Department of Family Medicine, Semmelweis University, Budapest, Hungary,* [4]*5Medical and Health Science Centre, Debrecen, Hungary,* [5]*4Department of Radiology and Oncotherapy, Semmelweis University, Budapest, Hungary,* [6]*6Department of Pulmonology, Erzsébet Teaching Hospital,, Sopron, Hungary,* [7]*Department of Oncology, Korányi National Institute of TB and Pulmonology, Budapest, Hungary,* [8]*Pulmonology Hospital, Törökbálint, Hungary, Budapest, Hungary.*

AH8.1 is a haplotype which extends through the whole MHC region in the short arm of chromosome 6. It is the most frequent, very conservative haplotype in the Caucasian population. Previously we have reported on a strong association of AH8.1 and colorectal cancer with an odds ratio of 2.51 which was higher in subjects of <65 years (4.07) or among women (3.77). It is far higher than any risk reported for SNPs in the GWAS or candidate gene studies. Literature data indicate that AH8.1 is a strong risk factor for ovarian cancer and for non-Hodgkin lymphoma as well. Here we have determined the carrier state of AH8.1 in 105 patients with small cell lung cancer (SCLC) (61.6±7.8 years), 91 patients with non- SCLC (58.7±9.0 years) and 252 age-matched control subjects (66.7±7.3 years). Subjects carrying all the four marker alleles of AH8.1 (C allele of AGER 429T>C, G allele of HSP70-2 1267A>G, A allele of TNFalpha -308G>A as well as G allele of LTA 252A>G polymorphisms) were considered as AH8.1 carriers. 23/105 (22%) SCLC patients, 13/91 (14%) non-SCLC patients and 32/252 (13%) healthy controls carried the AH8.1 haplotype. Odds ratio of the AH8.1 carriers for SCLC was 1.93 (1.07-3.49), p=0.036) (for men: 3.15 (1.23-8.07) p=0.025), while for non-SCLC it was not significant. These findings indicate that carriers of the AH8.1 haplotype are at increased risk for SCLC similarly to colorectal and other types of cancer. This high risk is most probably due to the altered immune system of the AH8.1 carriers.

P06.196

Splicing functional assays of a single minigene with eight exons of the BRCA2 gene

A. Acedo, B. Díez-Gómez, Á. Curiel, C. Hernández-Moro, M. Infante, C. Miner, M. Durán, ***E. A. Velasco****;*
Instituto de Biología y Genética Molecular (CSIC-UVa), Valladolid, Spain.

Splicing disruptions is one key pathogenic mechanism in inherited diseases. We are currently investigating the contribution of aberrant splicing of BRCA1/2 genes to hereditary breast/ovarian cancer. A powerful approach to study the splicing outcomes of DNA variants is a splicing reporter minigene especially when patient RNA is not available. We constructed a single minigene of 8 BRCA2 exons (19 to 26) in a pSPL3-derived plasmid in 5 cloning steps, which is, as far as we know, the largest BRCA2 minigene ever reported. The genomic fragment from exons 19 to 26 is more than 27 kb in length that was reduced to a final insert of 4.7 kb with internal deletions of introns 20, 21, 24 and 25.This construction was transfected in HeLa cells and we observed a main RNA isoform of the expected size of 1.5 Kb that contained the vector constitutive exons and BRCA2 exons 19 to 26. Several splicing variants of each exon were generated in the wild type minigene by PCR mutagenesis and assayed to demonstrate the usefulness and reliability of this large construction. Splicing reporter minigenes are straightforward and robust tools to distinguish between pathogenic mutations and innocuous variants. The use of minigenes with several exons facilitates the analysis of putative splicing variants in a single minigene and emulates the physiological genomic context where the splicing reactions take place.

Application of High Resolution Melting Technique for detection of Germ Line single Nucleotide Polymorphisms in STK11 Gene among Patients with Various Gastrointestinal Cancers

S. Hosseini[1]*, A. Nazemi*[1]*, M. Hashemi*[2]*;*
[1]*Islamic Azad University,Tonekabon Branch, Tonekabon, Islamic Republic of Iran,*
[2]*Islamic Azad University,Tehran Medical Branch, Tehran, Islamic Republic of Iran.*

High Resolution Melting is a method that analyzes genetic variations such as Single Nucleotide Polymorphisms in PCR amplicons. Since HRM characterizes nucleic acid samples based on their disassociation (melting) behavior, the nucleotide sequence of amplicon is an important factors affecting the melting curve.The STK11 gene encodes a member of the serine/threonine kinase and regulates cell polarity and function as a tumor suppressor gene. The germ-line mutations in this gene are associated with Peutz-Jeghers syndrome. The patients with this syndrome are prone to some types of neoplasm.

Genomic DNA was extracted from the whole blood samples of 56 patients with various gastrointestinal cancers. The nucleotide changes in the entire STK11 gene were analyzed by Real-time PCR and HRM technique.

The nucleotide screening by HRM technique showed two types of SNPs in introns 6 and 7 of STK11 gene in 10 patients. Four patients had C / T substitution [cluster id/dsSNP/rs9282860] with homozygous genotype in intron 6, and six patients showed a C/G substitution [cluster id/dsSNP/rs2075607] with heterozygous genotype in intron 7. The direct sequencing of the fragments confirmed that the results obtained by HRM were 100% reliable.

In this study we found no SNP in exons of STK11 gene. However, two SNPs were found in the introns of this gene. Our results show that the primary screening of the STK11gene by the HRM technique is easily applicable to detect the unknown germ line and somatic mutations in patients with neoplasia at a relatively low cost.

Synovial sarcoma (SS) is an aggressive type of tumor, comprising approximately 10% of soft tissue sarcomas. Over 90% of SS cases are characterized by the t(X;18)(p11.2;q11.2) translocation, which results mainly in the formation of oncogenic SS18-SSX1 or SS18-SSX2 fusions. In a typical SS18-SSX fusion transcript, exon 10 of SS18 is fused to exon 6 of SSX1/2. However, several variant fusion transcripts have been already described. In the present study, we examined the fusion transcript type in a series of 40 primary untreated SS tumor specimens using reverse transcription polymerase chain reaction (RT-PCR). We detected SS18-SSX1 transcript in 22 (55%) patients and SS18-SSX2 transcript in 17 (42,5%) patients, while in one patient none of SS18-SSX1/2 fusion transcripts were identified. Among the cases under study, two tumors carried novel SS18-SSX1 and SS18-SSX2 variant translocations that were allegedly created by an alternative splicing and in additional case an unusual translocation variant previously described by other group was found. Our data suggest that alternative splicing may play an important role in novel fusion transcript formation and additionally we show that it may be a recurrent event in SS. Furthermore, we describe the first case of a complex rearrangement possibly linking SS to REPS2 gene.

Genomic and epigenomic characterization of T-cell prolymphocytic leukemia (T-PLL)

A. K. Bergmann[1,2]*, O. Ammerpohl*[1]*, J. Dürig*[3]*, I. Ringshausen*[4]*, M. Seifert*[5]*, A. Teske*[6]*, U. Dührsen*[3]*, R. Küppers*[5]*, R. Siebert*[1]*;*
[1]*University Hospital Schleswig-Holstein, Institute of Human Genetics, Kiel, Germany,* [2]*Department of General Pediatrics, Kiel, Germany,* [3]*University Hospital Essen, Department of Hematology, University of Duisburg-Essen, Essen, Germany,* [4]*Technical University Munich, Department of Hematology and Oncology, Munich, Germany,* [5]*Institute of Cell Biology (Cancer Research), University of Duisburg-Essen, Medical School, Essen, Germany,* [6]*Complete Genomics Inc., Mountain View, CA, United States.*

T-PLL is an aggressive postthymic T-cell malignancy with distinctive clinical, morphologic, cytogenetic and molecular features (*Dürig et al., Leukemia, 2007*). We have initiated a comprehensive genetic and epigenetic profiling of T-PLL. First, we investigated the presence of the hallmark changes inv(14)(q11q32)/t(14;14)(q11;q32) and t(X;14)(q28;q11) by interphase FISH using probes for the TCRAD locus in 14q11 and its both partners involved in the named changes, i.e. TCL1 in 14q32 and MTCP1 in Xq28. In 43 cases with features of T-PLL acquired over the last 25 years we identified TCRAD breaks in 93%, TCL1 breaks in 74% and MTCP1 breaks in 14%. TCL1 and MTCP1 breaks were mutually exclusive. Two cases contained a TCRAD break with a partner other than TCL1 and MTCP1 and 3 cases did not show breaks in any of these three loci. To determine the pattern of secondary genetic changes on a base pair level we have performed custom full genome sequencing of flow-sorted T-PLL cells and corresponding non-T-cells of the same patients using Complete Genomics* technology. Initial analyses of the first three patients suggest the genomic landscape of T-PLL to be highly complex with a mean number of 150 protein-changing somatic single nucleotide mutations and in-dels. Validation of these findings and extension into the full cohort is ongoing and supplemented by DNA-methylation profiling using Illumina 450K Methylation BeadArrays. We are confident that the combined genomic and epigenomic profiling of T-PLL will identify potentially druggable pathways in this still poor-prognosis disease.

Genetic replication study of susceptibility loci for testicular germ cell cancer in the Croatian population

D. Lessel[1]*, M. Gamulin*[2]*, T. Kulis*[2]*, M. R. Toliat*[3]*, M. Grgic*[2]*, Z. Kastelan*[2]*, P. Nürnberg*[3]*, C. Kubisch*[1]*;*
[1]*Institute of Human Genetics, University of Ulm, Ulm, Germany,* [2]*Clinical Hospital Centre Zagreb, Zagreb, Croatia,* [3]*Cologne Center for Genomics, University of Cologne, Cologne, Germany.*

Testicular germ cell tumour (TGCT) is the most common cancer in young men showing a pronounced degree of heritability. Recent genome-wide association analyses in British and US samples have identified six susceptibility loci of genome-wide significance. The goal of our study was to perform a genetic replication analysis of these loci in an independent European population. We therefore analyzed six single nucleotide polymorphisms [rs2900333 (ATF7IP), rs210138 (BAK1), rs755383 (DMRT1), rs995030 (KITLG), rs4624820 (SPRY4), and rs4635969 (TERT/ CLPTM1L)], each representing one of the published susceptibility loci, in a Croatian case-control sample consisting of 331 tumour-free male controls (> 50 years of age) and 325 cases. Indeed, five of these SNPs were found to be associated in the Croatian population: rs995030 (OR 2.94, p=1.835e-10), rs755383 (OR 1.53, p=0.00023), rs210138 (OR 1.68, p=0.00031), rs4624820 (OR 1.50, p=0.00041) and rs4635969 (OR 1.35, p=0.01739), a finding which is still significant after conservative correction for multiple testing. Similar to previous studies, the association was comparable for different histological subtypes. Moreover, we evaluated if any SNP was associated with aggressiveness of TGCT measured by different staging categories. Interestingly, while rs2900333 near ATF7IP just showed borderline association with all-TGCT [OR 1.26, p=0.062], it showed significant association with the more aggressive forms of the tumour [OR 1.55, p=0.0067]. In summary, our data provide further evidence that the previously identified loci are involved in the susceptibility for TGCT and suggest a possible role of ATF7IP in regulating the progression of TGCT, although it has to be confirmed in independent samples.

P06.201

Comprehensive mutation screening of miRNA loci in testicular germ cell tumours

S. de Boer[1]*, A. Notini*[1]*, R. Hersmus*[2]*, Y. van der Zwan*[2]*, L. Looijenga*[2]*, S. White*[1]*;*
[1]*Monash Institute for Medical Research, Melbourne, Australia,* [2]*Erasmus MC, Rotterdam, Netherlands.*

MicroRNAs (miRNAs) are endogenous small non-protein coding RNAs which regulate basic cellular processes. There is considerable evidence that expression of miRNA genes is deregulated in human cancer, and specific over- or underexpression has been shown to correlate with particular cancer types.

Testicular germ cell tumours (TGCTs) are the most common malignancy affecting males between the ages of 15 and 45 years, and are associated with significant morbidity including infertility. These cancers are most commonly formed from undifferentiated fetal germ cells contained within the testis. There are several methods for identifying variants in DNA. High-resolution melting curve (HRM) analysis and multiplex ligation-dependent probe amplification (MLPA) are two sensitive, cost effective and high throughput techniques for rapidly screening a large number of DNA samples. To identify point mutations we performed HRM analysis on eight miRNA loci implicated in either testis cancer and/or pluripotency. To identify deletions and duplications we developed an MLPA mix containing probes that recognize 50 miRNA sequences that have been identified as being deleted or duplicated in tumours.

We have carried out a pilot study using these two approaches on 48 TGCT samples. To date we have identified a number of potential variants that we are currently confirming with independent techniques. Given the success of this initial screen we plan to study an additional 100 DNA samples. Our findings will give a better understanding of the genetic basis of testis cancer, and may lead to improved diagnostic or therapeutic protocols.

P06.202

Whole exome analysis of testicular germ cell tumours

S. White[1]*, S. de Boer*[1]*, A. Notini*[1]*, R. Hersmus*[2]*, Y. van der Zwan*[2]*, D. Belluoccio*[3]*, L. Looijenga*[2]*, P. Western*[1]*;*
[1]*Monash Institute of Medical Research, Melbourne, Australia,* [2]*Erasmus Medical Center, Rotterdam, Netherlands,* [3]*Agilent Technologies, Melbourne, Australia.*

Testicular germ cell tumours (TGCTs) are the most common cancer in adolescents and young men, with a median age of diagnosis of approximately 30 years. Although the majority of cases can be successfully treated with radical surgery and/or chemotherapy, these treatments have significant undesirable side effects including renal, vascular, neural toxicity and negative effects on fertility. There is also compelling evidence for long term increased risks of secondary malignancies, cardiovascular disease and metabolic syndrome.

Despite the frequency with which TGCTs occur, little is known about the genetics underlying TGCT initiation and progression. In order to obtain a better understanding of this condition we have performed whole exome analysis on DNA from two TGCT samples, plus matched non-tumour material. Exome capture was carried out with the SureSelect Human All Exon kit from Agilent, which targets 44 Mb of exonic regions, and sequencing was performed on an Illumina HiSeq 2000 instrument.

Data analysis identified several potentially de novo variants that we are currently validating, and we are planning to screen a larger cohort of TGCT samples for specific genes. This study will improve our understanding of the genetic basis of TGCT, with implications for diagnosis and therapy.

P06.203

Nuclear localization of human homeodomain TGIFLX gene and its mRNA expression in stable cancer cell lines

A. Ghaffari Novin[1]*, M. Noori-Dalooii*[1]*, M. Famil- Tokhmehchi*[2]*, R. Raoofian*[1]*, M. Heidari*[1]*;*
[1]*Department of Medical Genetic, Faculty of Medicine, Tehran University of Medical Sciences, Tehran, I, Tehran, Islamic Republic of Iran,* [2]*Eye Research Center, Rassul Akram Hospital, Faculty of Medicine, Tehran University of Medical Sciences, Tehran, I, Tehran, Islamic Republic of Iran.*

Background and Aim: Homeodomain transcription factors play a central role in expression of genomic information in all organisms. TGIFX homeobox gene was originally discovered in the human adult testis. Our previous study suggested that TGIFLX could be involved in prostate cancer and azoospermia. The main aim of our study is to analyze the function of TGIFLX protein. One way to analyze transcription factors in eukaryotic cells is to study their nuclear localization, as reported for various organisms such as human and land plants using pEGFP-N1 vector, a eukaryotic expression vector encoding EGFP.

Methods: We cloned entire coding sequence of *TGIFLX* gene into above plasmid and subsequently, SW48 and Caco2 colorectal cancer cell lines was transfected with the recombinant vector harboring *TGIFLX* cDNA. Gene expression analysis of TGIFLX verified using RT-PCR and western blot techniques.

Results: The TGIFLX expression was confirmed by microscopic analysis and RT-PCR technique. Following molecular cloning and characterization of *TGIFLX* transcription factor in stable cell lines , we then for first time studied the nuclear localization and expression of TGIFLX in colorectal cancer cell lines (SW48, Caco2) by means of imaging and tracking of GFP molecules. Interestingly, we found aberrant expression of *TGIFLX* mRNA in SW48 but not in the Caco2 cell line.

Conclusion: This is the first report to perform visualization of nuclear localization of TGIFLX transcription factor by establishing new colorectal cancer cell lines with this gene and potential involvement of *TGIFLX* gene dysregulation in human colorectal cancer cancers.

Department of Biochemistry and Biotechnology, University of Life Sciences, Poznań, Poland.*

Differentiated thyroid cancer (DTC) originate from thyroid follicular C cells and belong to group of slowly progressing benign tumors with good prognosis. Very serious problems are recurrences and regional or remote metastasis. Numerous cases of osteolytic, cerebral and pulmonary metastasis were observed. Progression from well differentiated thyroid cancer to malignant anaplastic carcinoma is possible.

Very important seems to be searching for molecular markers of disease course, good or poor prognosis and response on medical treatment. SNP polymorphisms research in genes associated with neoplastic diseases will be helpful in understanding of molecular mechanisms of thyroid gland tumors development and allow to better diagnosing.

Mutations in CHK2 gene are thought to predispose to sarcomas, breast cancer, and brain tumors. Protein product of this gene is a cell cycle checkpoint regulator and tumor suppressor and is a member of the CDS1 subfamily of serine/threonine protein kinases.

We examined two sequence variants in CHK2 gene in group of 516 Polish patients with differentiated thyroid cancer and 500 individuals from population group. I157T and R145W variants were analyzed by pyrosequencing. There were differences in allele and genotype frequencies in analysis of I157T variation. Allele C was present with frequency 0,05 and allele T - 0,95 in patient with thyroid cancer, compared with 0,03 and 0,097 in control individuals respectively. The differences in allele frequencies were statistically significant (p=0,0072).We didn't observed any variability in R145 position neither in DTC patients nor population group. Project supported by Polish National Science Center grant NN402287436.

P06.205

Evaluation of CYP2C9, CYP2C19 and CYP2D6 gene polymorphisms in thyroid cancer

A. Uludag[1]*, S. Ozdemir*[2]*, C. Silan*[3]*, A. Uludag*[4]*, S. Atik*[1]*, F. Silan*[1]*, O. Ozdemir*[1]*;*
[1]*Department of Medical Genetics, Faculty of Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey,* [2]*Department of Nuclear Medicine, Faculty of Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey,* [3]*Department of Pharmacology, Faculty of Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey,* [4]*Department of Family Medicine, Faculty of Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey.*

Thyroid cancer incidence has increased worldwide during the previous years. Incidence of thyroid cancer is 33599 in European Union countries. It is 1,4 % of all cancers. Mortality of tyhroid cancer is 0,3%.

CYP2C9, CYP2C19 and CYP2D6 genes have been reported to be coding the enzymes responsible for the metabolism of many drugs, including warfarin and other drugs with a narrow therapeutic index. Realising the importance of inter-individual differences in the genetic profile in determining the outcome of a drug therapy. This study was conducted to explore the types and frequencies of CYP2C9, CYP2C19 and CYP2D6 alleles in healthy controls and thyroid cancer patients.

Total genomic DNA was isolated from peripheral blood samples with EDTA and spin column method. A total of 103 subjects including 49 healty control and 53 thyroid cancer patients were recruited into the study. CYP2C9 allele *1, *2, *3, CYP2C19 allele *1, *2, *3 and CYP2D6 allele *1, *2, *3, *4,*5 have been studied by real time PCR method for both two groups.

In thyroid cancer group allel frequency of CYP2C9 *2 was 4,62%, *3 was 19,44%. CYP2C19 *2 and *3 allel frequencies were 17,59% and 0% respectively. Those ratios were 9,18%, 6,12%, 11,22% and 5,10% respectively.

According to our study, genes have roles in drug methoblism like CYP genes may act an important role in cancer ethiopathogenesis and further studies including larger control and patient groups are needed.

P06.206

The possible role of the xenobiotic transporter P-glycoprotein polymorphism that encoded by the MDR1 3435 C>T gene in the susceptibility of differentiated thyroid cancer

S. Ozdemir[1], *A. Uludag*[2], *F. Silan*[2], *S. Atik*[2], *B. Turgut*[3], *O. Ozdemir*[2,4];
[1]*Department of Nuclear Medicine,Faculty of Medicine, Canakkale, Turkey,* [2]*Department of Medical Genetics, Faculty of Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey,* [3]*Department of Nuclear Medicine,Faculty of Medicine,Cumhuriyet University, Sivas, Turkey,* [4]*Department of Medical Genetics, Faculty of Medicine, Cumhuriyet University, Sivas, Turkey.*

P-glycoprotein (Pgp), encoded by the multidrug resistance 1 (MDR1) gene is an efflux transporter and plays an important role in pharmacokinetics. The current preliminary study was designed to determine association between germ-line polymorphism in MDR1 gene with differentiated thyroid carcinoma (DTC). In the current case-control study of 60 thyroid carcinomas (TC); 45 papillary TC (PTC), 9 follicular TC(FTC) and 6 differentiated TC(DTC) of well-differentiated TC of uncertain malignant potential were examined. Genomic DNA was extracted from peripheral blood with EDTA, target gene was genotyped by multiplex Real-time PCR and PCR-based reverse-hybridization StripAssay method. Carriers of the variant allele of MDR1 exon 26 polymorphism were at 2.8-fold higher risk of DTC than the control group(odds ratio [OR]: 0.3805, 95% confidence interval [Cl]: 0.1597-0.9065.There was an association between DTC and MDR1 C3435T polymorphism in the presented results(p> 0.046). Presented results showed that the homozygous MDR1 3435TT genotype increases the risk factor to develop differentiated thyroid cancer and large-scale studies are needed to validate this association.

P06.207

Exploring the methylome of thyroid cancer at single C resolution: From screening to clinical diagnostics

W. Pulverer[1], *K. Vierlinger*[1], *O. Koperek*[2], *K. Kaserer*[2], *A. Weinhäusel*[1];
[1]*Austrian Institute of Technology, Vienna, Austria,* [2]*Medical University Vienna, Vienna, Austria.*

Thyroid nodules are endemic in iodine deficient areas, like Europe's alpine regions, where they have a prevalence of 10-20 %. Since 5% of these nodules are malignant, all thyroid nodules have to be clinically evaluated to discern benign from malignant cases. The current method of choice for diagnosis is based on fine needle aspiration (FNA) followed by cytological evaluation. Despite many advances in the diagnosis and treatment of thyroid nodules this method has a high rate of suspicious or indeterminate (e.g. follicular neoplasia) diagnosis. Patients with such a suspicious diagnosis will undergo surgery. The consequence is an extensive overtreatment of patients, as only approximately 20% of the indeterminate cases will be identified as malignant at surgery.

In the present study we address the call for minimally invasive diagnostics based on state of the art molecular techniques to clearly discriminate between the different benign and malignant thyroid entities. Therefore we employed 48 thyroid nodules, consisting of follicular thyroid adenomas/carcinomas (FTA/FTC), papillary thyroid carcinomas (PTC) and struma nodosa (SN) to a whole genome methylation screening using Illuminas Infinium 450k BeadArrays. The data gave first insights in the methylome of thyroid nodules at single C resolution at a whole genome scale. We could clearly differentiate between the different histological groups based on their methylation patterns. We present a bioinformatics analysis and assessment of the discriminatory power for the differentially methylated genomic regions.

P06.208

miR-106b is down-regulated in follicular carcinomas and may modulate the expression of C1orf24 in thyroid carcinoma cell lines

G. Carvalheira, *B. Nozima, J. M. Cerutti;*
UNIFESP, São Paulo, Brazil.

We have previously showed that C1orf24 (alias NIBAN) is highly expressed in thyroid carcinomas compared to benign lesions. However, the molecular mechanism underlying its expression remains unclear. One of the post-transcriptional mechanisms of gene regulation is the action of the microRNA. microRNA expression varies according tissue, development stage and cancer types. Therefore, we used miRBase Sequence database to identify microRNAs that potentially regulate C1orf24 expression. miR106b was selected for further validation by quantitative PCR in 64 thyroid nodules (09 CVPTC, 18 FVPTC, 11 FTC, 11 HCA and 15 FTA). The data obtained by qPCR showed that the expression of miR106b was down-regulated in malignant lesions compared to benign lesions (p value 0.0060), while C1orf24 expression presented high levels in malignant ones (p value 0.0018). Therefore, to investigate whether miR106b modulates the C1orf24 expression, miR106b was transiently transfected into a follicular thyroid carcinoma cell line (WRO), which we have previously show to have high levels of C1orf24 expression. The results showed that the ectopic expression (30nM at 72hr) of miR106b decreases both C1orf24 mRNAs (p value < 0.05) and proteins levels when compared to negative control. These finds suggest that miR106b may modulate C1orf24 gene expression and may play an important role in thyroid tumorigenesis. Additionally, it may help understand the molecular mechanisms underlying its activation in other tumor subtypes where it was found highly expressed.

P06.209

Comparison of genetic changes in schistosome-related transitional and squamous bladder cancers using fluorescence in situ hybridization.

M. S. Aly[1,2], *A. A. Mahmoud*[2];
[1]*Faculty of Science, Beni Suef University, Cairo, Egypt,* [2]*Faculty of Science, Jazan University, Jazan, Saudi Arabia.*

In western countries, more than 90% of primary bladder carcinomas are transitional cell carcinoma (TCC), whereas squamous cell carcinoma (SCC) comprises less that 10%. Carcinoma of the urinary bladder is the most common malignancy in many tropical and subtropical countries due to endemic infection by *Schistosoma hematooium*. Compared with non-schistosome bladder cancer, schistosome-related bladder cancer has different clinical and pathological features.

In this study, dual-color FISH cytogenetic analysis was performed using two oncogenes (HER-2/neu and MCY) and a tumor suppressor gene (p53) in relation to chromosomes 8 and 17 centromeres in a group of patients presenting with schistosomal associated squamous and transitional cell carcinoma.

To the best of our knowledge, this is the first report to compare genetic alterations in both transitional and squamous subgroups of schistosomal bladder cancers in Egyptian patients using the FISH technique.

Thirty-sex percent of SCC cases showed gene amplification for **Her2/neu**. On the other hand, for the gene p**53**, 68% had gene deletion. Whereas 29% of the cases show gene amplification for c-myc gene. In TCC cases, 8 cases (23.5%) had gene amplification for Her2/neu gene. On the other hand, 50% of cases had two copies of the gene **P53**, and the other (50%) had gene **P53** deleted. While for the gene **C-myc**, 9 cases (26.4%) show gene amplification.

Our data showed that different histologic subgroups of bladder tumors are characterized by distinct patterns of genetic alterations. The genetic changes found in the transitional cell group are differing from tumors exhibiting squamous differentiation.

P06.210

TSPY and TSPX gene copy number assessment in patients with gonadal tumours, prostatic cell lines and control groups

M. Kvapilova, ***R. Vodicka****, R. Vrtel, K. Krizova, J. Böhmova, H. Filipova, J. Santavy;*
Faculty of Medicine Palacky University Olomouc, Olomouc, Czech Republic.

Background: TSPY gene is localized on Y chromosome and have a homologue TSPX on X chromosome. TSPY is specific expressed in testes. TSPX is normally expressed in ovaries and testis. Over expression of TSPY was discovered in tumour tissues. Product of TSPY accelerates a pass trough G2/M phase via cycline D2 and positively affects the cell proliferation. Over-

expression of TSPX or SET leads to cell retaining in G2/M.
Aim: Quantification of TSPX/X gene copy number and study of potential changes in the TSPY/X copies and their mutual ratios.
Method: There were assessed 10 women and 8 men patients with gonadal tumours, 5 prostatic cell lines (DU-145, LAPC-4, PC-3, RWPE-I, LNCeP), 80 woman and 80 man controls in the study. The study was supported by IGA UPOL LF_2011_004.
Relative copy number of TSPY/X genes was quantified by capillary electrophoresis in comparison to one-copy genes AMELY/X.
Results: We observed more TSPY gene copies in patients with seminomas compare to TSPX gene than in control group. Number of TSPX gene copies in men control group is higher than in patients with seminomas. More variability in TSPX gene copies was indicated in women with ovary carcinoma compare to controls. The women control group has more TSPX gene copies than patients with tumours in average. In prostatic cell lines DU-145, LAPC-4 and LNCeP was significantly increased amount of TSPY copies compare to control group.
Conclusion: Obtained data could contribute to understanding of TSPY/X gene role in tumor-genesis process in gametogenetic tissues.

P06.211

Evidences of the association between *UCP2* gene expression with Obesity, Family history of cancer and Metabolism

K. Mirzaei[1,2], *A. Hossein-nezhad*[1], *H. Ansar*[1], *S. Emamgholipour*[1], *s. Keshavarz*[2];
[1]*Endocrinology and Metabolism Research Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Islamic Republic of Iran,* [2]*Department of Nutrition and Biochemistry, school of Public Health and institute of public health research, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Islamic Republic of Iran.*

Increased risk of cancer is one of the consequences of obesity. UCP2 has been implicated in free radical scavenging relevant to pathological processes, including obesity and has a unique role in energy balance and their responses to inflammatory stimuli. UCP2 expression was changed in human cancer and may correlate with the degree of oxidative stress. The aim of study was measurement of *UCP2* and *PGC1α* gene expressions *in vitro* in samples of PBMCs derived from all participants in a cellular model and to investigate their potential correlation with family history of cancer.
A total of 220 obese subjects were included in study. The PBMCs were separated, total cellular RNA was extracted and the cDNA was synthesized. Real-time PCR using specific primer pairs was performed. We analyzed our findings according to categorized group: group with a family history of cancer and Individuals without a family history of any cancer.
Of the 220 participants, 20 (9.09 %) had a family history of cancer and 200 (90.91%) hadn't family history of any cancer. The mean of age and BMI were 36.99±9.02years and 34.99±4.13kg/m^2 respectively. We found significantly lower relative *UCP2* gene expression in group with a family history of cancer. The estimated family history of cancer relative risk attributable to UCP2 gene expression was 1.46%. We found significantly lower *PGC1α* gene expressions in low *UCP2 gene expression* group.
It seems that the relative expression of involved genes in energy balance may have important role in cancer risk in obese subjects.

P06.212

Detection of *GNAQ* and *GNA11* mutations in plasma of metastasized uveal melanoma patients by deep amplicon sequencing

M. Zeschnigk[1], *C. H. D. Metz*[2], *N. Bornfeld*[2], *D. R. Lohmann*[1];
[1]*Institute of Human Genetics, University of Duisburg-Essen, Essen, Germany,*
[2]*Department of Ophthalmology, University of Duisburg-Essen, Essen, Germany.*

Elevated levels of DNA are frequently found in the cell free plasma of cancer patients. Activating mutations in *GNAQ* and *GNA11* are highly specific for uveal melanoma. To establish a reliable assay which might allow for early detection and monitoring of metastatic disease we determined the proportion of *GNAQ* or *GNA11* mutant reads in DNA from cell free plasma of uveal melanoma patients by ultra-deep sequencing. We isolated cell-free DNA from 23 blood samples from patients with metastasized uveal melanoma. *GNAQ* and *GNA11* regions of interest were amplified on 6 ng DNA. To detect even low proportion of mutant sequence reads ultra deep sequencing of amplicons was performed (Roche GS Junior).Levels of DNA ranged from 20 to 1550 ng per ml of plasma. On average about 2600 sequence reads were obtained for each amplicon (range: 281 to 6191). We detected either GNAQ Q209 or GNA11 Q209 mutations in the plasma from 9 out of 23 patients. The proportion of mutant reads ranged from 2 to 38 %. However, the background noise (0.5% at any given nucleotide position) limited the sensitivity of detection. We found no correlation between amount of cell-free DNA in plasma and the proportion of mutant reads. This suggests that at least in some patients elevated DNA levels in the plasma do not originate from tumor cells. Ultra-deep amplicon sequencing can be used to detect low proportion of tumor DNA in plasma. This biomarker might thus be helpful to measure tumour burden and to monitor anti-metastatic treatment.

P06.213

Valproic acid achieves its anticancer activity by re-expression of cyclin D2

D. Witt[1], *P. Burfeind*[1], *S. von Hardenberg*[1], *L. Opitz*[2], *G. Salinas-Riester*[2], *S. Schweyer*[3], *P. Thelen*[4], *S. Kaulfuß*[1];
[1]*Institute of Human Genetics, Göttingen, Germany,* [2]*Department of Developmental Biochemistry, Göttingen, Germany,* [3]*Department of Pathology, Göttingen, Germany,* [4]*Department of Urology, Göttingen, Germany.*

Histone deacetylase inhibitors (HDACi) are widely known as remedies against epilepsy. But in the last years, HDACi research in the field of cancer expanded. In this study we demonstrated that the treatment of primary murine prostate cancer (PCa) cells derived from the well-established TRAMP (transgenic adenocarcinoma of mouse prostate) model with the HDACi valproic acid (VPA) has an anti-proliferative, anti-migrative and anti-invasive effect on the cells.
To our knowledge this is the first study that identified that treatment of PCa cells with VPA leads to the re-expression of cyclin D2, which is known to be frequently inactive in patients with PCa. Additionally, we could demonstrate that VPA specifically induces re-expression of cyclin D2 in human colorectal and mammary gland adenocarcinoma cell lines, whereas VPA treatment has no effect in NIH/3T3 fibroblasts. Moreover, the intensity of re-expression is dependent on the inhibition of proliferation, because for NIH/3T3 cells no inhibition of proliferation after VPA treatment was observed.
The re-expression of cyclin D2 can also be achieved by other HDACis. The conclusion that cyclin D2 re-expression observed in cancer cells after the treatment with VPA is activated by an increase of histone acetylation was shown by chromatin immunoprecipitation studies for the promoter region of the cyclin D2 gene. However, the re-expression seems not to be due to changes in the methylation status of the cyclin D2 promoter region. In summary, our results propose VPA as an anticancer therapeutic option in tumors with epigenetically repressed cyclin D2 expression.

P06.214

Current variant of uncertain significance rates in *BRCA1/2* and Lynch Syndrome testing (*MLH1, MSH2, MSH6, PMS2*)

J. M. Eggington[1], *L. Burbidge*[1], ***K. Copeland***[2], *B. B. Roa*[1], *D. Pruss*[2], *K. Bowles*[1], *E. Rosenthal*[1], *L. Esterling*[1], *R. J. Wenstrup*[1];
[1]*Myriad Genetic Laboratories, Inc., Salt Lake City, UT, United States,* [2]*Myriad Genetics, Inc., Salt Lake City, UT, United States.*

Laboratories that provide full gene sequencing frequently detect Genetic Variants of Uncertain Significance (VUSs). VUSs present a challenge to the clinician in how to appropriately guide the medical care of their patient in the context of an inconclusive test result. While the majority of VUSs are eventually discovered to be non-disease causing, some are pathogenic. Myriad Genetic Laboratories, Inc. has pursued protocols to collect sufficient data to appropriately reclassify VUSs. Statistical techniques that lead to VUS reclassification have been developed on a large *BRCA1/2* dataset. While the basis of these statistical techniques has been published, they have been further refined such that they are now applicable to not only *BRCA1/2*, but also Lynch Syndrome genes as well as *APC*. We report the current VUS rate in *BRCA1/2* as 3.0%, *MLH1+MSH2+MSH6* as 7.3% and *PMS2* as 4.4%. The continual drop in VUS rate through time reflects the success of these VUS reclassification techniques and Variant Classification Programs. In recent years the application of these techniques has also led to significant drops in VUS rates in non-European ethnic groups, with the most prominent change being in *BRCA1/2*. Characterizing VUSs gives the clinician the required information to appropriately manage their patient.

P06.215

Investigation of the VDR gene polymorphisms and expression association with Family history of cancer in obesity

A. Hossein-nezhad[1], *K. Mirzaei*[1,2], *H. Ansar*[1], *S. Emamgholipour*[1], *s. Keshavarz*[2];
[1]*Endocrinology and Metabolism Research Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Islamic Republic of Iran,* [2]*Department of Nutrition and Biochemistry, school of Public Health and institute of public health research, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Islamic Republic of Iran.*

Population-based study demonstrated that VDR gene variation, especially *FokI* SNPs owing to its functional significance, may influence risk of some cancer. The aim of this study is to measure *VDR* expression *in vitro* in samples of PBMCs derived from all participants in a cellular model and to investigate their potential correlation with family history of cancer. We analyzed

VDR FolkI polymorphism (*rs* 10735810) and its correlation with VDR gene expressions in obese subjects with and without a family history of cancer separately.
A total of 190 obese subjects were included in study. *FOKI* was genotyped and the PBMCs were separated by Ficoll-hypaque technique. Total cellular RNA was extracted and Real-time PCR performed. We analyzed our findings according to categorized group: group with a family history of cancer and Individuals without a family history of any cancer.
23 (12.1 %) had a family history of cancer and 167 (87.89%) hadn't family history of any cancer. The mean of age and BMI were 35.32±8.31years and 33.32±3.24kg/m^2 respectively. The frequency of ff genotype was significantly higher in subjects with family history of cancer. We found significantly lower relative *VDR* gene expression in group with a family history of cancer ($p<0.05$). However *VDR* expressions were low in ff genotype in group without a family history of cancer, but its expression were low in every three genotypes in group with a family history of cancer.
It seems that the having ff genotype and lower expression of *VDR* could be associated with risk of cancer.

P06.216
Overexpression of VEGF isoforms generated by alternative splicing in head and neck cancer

P. M. Biselli-Chicote[1], *G. H. Marucci*[1], *R. Castro*[1], *B. R. Cunha*[2], *J. Maniglia*[3], *D. S. Neto*[4], *E. H. Tajara*[5], *É. C. Pavarino*[6], *E. M. Goloni-Bertollo*[6];
[1]*Genetics and Molecular Biology Research Unit – UPGEM, Sao Jose do Rio Preto Medical School - FAMERP, São José do Rio Preto, Brazil,* [2]*Sao Jose do Rio Preto Medical School - FAMERP, São José do Rio Preto, Brazil,* [3]*Department of Othorrinolaringology and Head and Neck Surgery, Sao Jose do Rio Preto Medical School - FAMERP, São José do Rio Preto, Brazil,* [4]*Patology Service, Hospital de Base, Sao Jose do Rio Preto – FAMERP, Sao Paulo, Brazil, São José do Rio Preto, Brazil,* [5]*Department of Molecular Biology, Sao Jose do Rio Preto Medical School – FAMERP, Sao Jose do Rio Preto Medical School - FAMERP, São José do Rio Preto, Brazil,* [6]*Genetics and Molecular Biology Research Unit – UPGEM, Department of Molecular Biology, Sao Jose do Rio Preto Medical School - FAMERP, São José do Rio Preto, Brazil.*

Vascular endothelial growth factor (VEGF) is a potent mitogen for endothelial cells and its overexpression is associated with tumor growth and metastasis. However, the selection of a alternative splicing site at the end of the exon 8 of *VEGF* gene results in a sister-family of isoforms, VEGFxxxb, that seems to have anti-angiogenic proprieties. The aim of this work was to quantitatively analyze the expressions of *VEGF* gene isoforms generated by alternative splicing in samples of head and neck squamous cells carcinoma and adjacent normal tissues, and to determine the effect of regulatory proteins (SRp55, SRp40, ASF/SF2 and SRPK1) in the control of *VEGF* gene splicing. The overexpression of both VEGF isoforms was observed in head and neck squamous cells carcinoma related to normal tissue samples. Positive correlation between VEGFxxx and VEGFxxxb expression was observed in head and neck tumors. SF/SF2 presented higher expression in tumors when compared to normal tissues. Pharynx tumors presented overexpression of VEGFxxx. VEGFxxxb was underexpressed in oral cavity tumors. Overexpression of both VEGF isoforms was observed in aggressive tumors. There was a positive correlation among ASF/SF2, SRp55 and SRp40 proteins and both VEGF isoforms, and among SRPK1 protein and ASF/SF2, SRp55 and SRp40 in tumor tissues. The results suggest that both VEGF isoforms play a role in angiogenesis promotion in head and neck tumors. VEGF isoforms present differential expression related to the anatomic sites of tumor and tumor aggressiveness. ASF/SF2, SRp55 and SRp40 proteins are involved in the regulation of the VEGF gene splicing mechanism.

P06.217
The additional effect of VHL and PTEN mutations in tumour development

R. Keppler, *C. Steinwender, K. Reicherter, B. Zabel, E. Lausch;*
Centre for Paediatrics and Adolescent Medicine, University of Freiburg, Freiburg, Germany.

The von Hippel-Lindau (VHL) protein is well described as an ubiquitin E3 ligase for HIFalpha subunits but plays also a role in microtubule stability, ECM formation and cilia assembly. Due to germline mutations in the VHL gene patients develop retinal and CNS haemangioblastomas (HBs), pheochromocytomas (PCCs) and clear cell renal carcinomas (ccRCCs). Interestingly, cystic lesions of VHL patients possess an increased activation of phosphoinositide-3 kinase (PI3K) pathway and downstream mTOR signaling. The PI3K pathway is negatively regulated by PTEN which is one of the most frequently inactivated tumour suppressor genes. Partial deletion of Pten in mice results in tumour formation in a tissue specific manner. As PCCs are also part of the PTEN associated tumour spectrum, we hypothesized that VHL and PTEN may interact functionally in tumour suppression.
Here, we present two Vhl knockin mouse models with endogenous tumour formation. The effect of Vhl type IIB (V2B) and type IIC (V2C) germline mutations was analyzed over several generations. Additionally, Vhl knockin mutations were also combined with hemizygous inactivation of Pten, and the impact on tumour spectrum, incidence and tumour progression was investigated in over 300 mice of the distinct genotypes at the ages of 3 to 12 months. Pten knockout mice developed various tumours at 9 to 12 months independent of the Vhl genotype. Furthermore, V2B mice displayed a clear Vhl genotype dependent effect on the development of renal cysts. Additionally, we observed a significantly increase in incidence and tumour mass of PCCs in V2B and V2C compound hemizygous mice.

P06.218
Variability in von Hippel-Lindau disease-Manifestation rate throughout life

M. M. Poulsen, *E. Budtz-Jørgensen, M. Bisgaard;*
Department of Cellular and Molecular Medicine, University of Copenhagen, Copenhagen N, Denmark.

Background
Clinical management and counseling of von Hippel-Lindau (vHL) families is complicated by variable phenotypic expression. Natural history of disease progression is not fully understood, and better knowledge of specific factors' influence would greatly benefit vHL management. We aim to describe the variability in vHL-manifestation development throughout life and to assess association to gender and genotype.
Methods
Full medical records were collected from 52 *VHL* mutation carriers, 26 female and 26 male. Patients were followed from birth, and age-dependent manifestation rates were analyzed using Poisson regression. Relative rates between age groups were compared using robust standard errors which allowed for heterogeneity between patients. Effects on manifestation rates of gender and genotype (truncating mutation versus missense mutation) were determined.
Results
Overall, 381 manifestations were diagnosed in 42 subjects, while 10 were asymptomatic mutation carriers. Maximum manifestation rate was reached in the 30-34 year age-group with 0.880 manifestations per year ((95% CI: 0.57-1.36). Compared to the 30-34 year group, the relative rates of especially the younger, but also of older groups were lower. We found a trend of a higher relative manifestation rate among patients with truncating *VHL* mutations compared to those with missense mutations ($p= 0.060$) and less when comparing men and women ($p= 0.58$).
Conclusions
Rate of manifestation development is associated to age, increasing from birth to the 30'ies. Also, truncating *VHL* mutation carriers seem to have a higher rate of tumor development. Better knowledge of factors influencing phenotypic variability will facilitate surveillance targeting and counseling of affected families.

CIZ Gene Rearrangements in Pediatric CD10-Negative Acute Lymphoblastic Leukemia

M. Shago[1], *G. Maire*[2], *O. Abla*[1], *J. Hitzler*[1], *S. Weitzman*[1], *M. Abdelhaleem*[1];
[1]*The Hospital for Sick Children, Toronto, ON, Canada,* [2]*Mount Sinai Hospital, Toronto, ON, Canada.*

The *CIZ (ZNF384)* gene, located distal to the *TEL (ETV6)* gene at 12p13.31, is a putative zinc finger transcription factor which is recurrently rearranged in acute leukemia. Rearrangements of the *CIZ* gene result in attachment of various 5' partner gene sequences to form *CIZ* fusion genes. The *CIZ* gene has three known partners: *TAF15* at 17q12 (16 cases), *EWSR1* at 22q12 (4 cases), and *E2A* at 19p13 (3 cases). We present seven new pediatric pre-B ALL patients with *CIZ* gene rearrangement. Our patients had lymphoblasts with a CD10-negative immunophenotype, similar to the antigenic profile seen in *MLL* gene-rearranged ALLs. Followup on the patients ranges from 3 to 5 years, and none of the patients have relapsed. Identification of the rearrangements was facilitated using dual-colour breakapart probes for the *E2A*, *CIZ*, and *EWSR1* loci. Four of the patients had *E2A-CIZ* gene rearrangement and one had *EWSR1-CIZ* gene rearrangement. Two patients had *CIZ* gene rearrangement involving regions on chromosomes 6 and 22, suggestive of additional *CIZ* partner genes. Copy number and expression microarray analyses have been performed, and results comparing the genomic and gene expression changes in *CIZ* rearrangement ALL to that of other ALL subtypes will be presented. Our data suggests that *CIZ* gene rearrangement may have an incidence of ~3% in pediatric ALL, with an incidence of at least 18% in CD10-negative pre-B ALL. *CIZ* gene rearrangement may be associated with a more favorable prognosis than *MLL* gene rearrangement, and *CIZ* FISH analysis is recommended in patients with CD10-low/negative ALL.

P07.02

Chromosome 11 as a target of breakpoint mapping in acute myeloid leukemia

I. Sarova[1]*, J. Brezinova*[1]*, D. Bystricka*[2]*, Z. Zemanova*[2]*, Z. Krejcik*[1]*, J. Cermak*[1]*, J. Vydra*[3]*, A. Jonasova*[4]*, K. Michalova*[2,1]*;*
[1]*Institute of Hematology and Blood Transfusion, Prague 2, Czech Republic,* [2]*Center of Oncocytogenetics, Prague 2, Czech Republic,* [3]*Faculty Hospital Kralovske Vinohrady, Prague, Czech Republic,* [4]*1st Department of Internal Medicine of General University Hospital and 1st Faculty of Medicine, Prague, Czech Republic.*

In acute myeloid leukemia (AML), chromosome 11 breakpoints are typically localized at chromosomal band 11q23.3 where a proto-oncogene *MLL* (myeloid/lymphoid leukemia) is frequently altered. However, recurrent aberrations of other regions of chromosome 11 without identification of altered gene have been described. The aim of this study was characterization of chromosome 11 aberrations in bone marrow and peripheral blood cells of AML patients and mapping of recurrent breakpoints using conventional and molecular cytogenetic methods (FISH with BAC probes, mFISH, mBAND and aCGH).
During years 2006-2011, chromosome 11 aberrations were proved in 55 (17%) out of 318 newly diagnosed AML patients. We identified approximately 30 different chromosome 11 breakpoints, 13 as recurrent (in chromosomal bands 11p15, 11p13, 11p12-p11.2, 11q13.2, 11q14.2, 11q21, 11q22.3, 11q23.3) and two altered genes: *MLL* (11q23.3) and *NUP98* (11p15).
In conclusion, chromosome 11 aberrations are the most frequent cytogenetic abnormalities in AML with many repeated as well as sporadic breakpoints on both short and long arm. The *MLL* gene is famous for the great number of partner fusion genes. We identified two new *MLL* gene translocations. The breakpoint localization in chromosomal regions without known gene associated with leukemogenesis predicts their involvement in malignant process. However, the reason for breakage and role of genes localized at the breakpoint for cancer origin and progression is still under discussion. Therefore, the significance of new chromosomal breakpoints could be revealed by further studies only.

P07.03

Do vessel-forming endothelial cells in B-cell lymphomas carry the hallmark chromosomal translocation and belong to the tumor cell clon?

K. Korte[1]*, W. Klapper*[2]*, R. Zühlke-Jenisch*[1]*, R. Siebert*[1]*;*
[1]*Institute of Human Genetics, University Hospital Schleswig-Holstein Campus Kiel/ Christian Albrecht U, Kiel, Germany,* [2]*Institute of Pathology, University Hospital Schleswig-Holstein Campus Kiel/ Christian Albrecht University Kiel, Germany, Kiel, Germany.*

Angiogenesis is one of the hallmark features of cancer. Recently it has been suggested that vessel-forming endothelial cells in B-cell lymphomas could be derived from clonal tumor-cells (Streubel et al., 2004). This hypothesis was based among others on the observation that the hallmark chromosomal translocations in these lymphomas, i.e. t(14;18) in follicular lymphoma, t(8;14) in Burkitt lymphoma and t(11;14) in mantle cell lymphoma, were detectable in microvascular endothelial cells of various B-cell lymphomas. To independently corroborate these findings we here investigated vessel nuclei by means of interphase FISH for the presence of t(8;14)(q24;32), t(14;18)(q32;q21) or t(11;14)(q13;q32) in 28 B-cell lymphomas known to carry these characteristic translocations. Simultaneous immunofluorescence staining of endothelial cells using a vWF-antibody and of B-lymphocytes using a PAX5-antibody was performed to accurately distinguish these cell populations from each other. All investigated samples carried the hallmark translocations in a significant number of B-lymphocytes. Additionally, we observed FISH patterns suggesting presence of these translocations in cells surrounding blood vessels as well as in some vascular intraluminal and intramural nuclei. Nevertheless, we failed to unambiguously distinguish nuclei from endothelial cells from lymphocyte nuclei. Thus, we investigated whether clonal B-lymphocytes invading blood vessel carrying the entity typical hallmark translocation could be mistaken for endothelial cells. Indeed, immunofluorescence staining showed intramural and intraluminal PAX5-positive cells in vessels and vessel walls. In summary, we failed to unambiguously assign clonal cells carrying the lymphoma-specific translocations to endothelial cells. Instead, nuclei with lymphoma-specific translocations in vessels could exist due to vessel-invading neoplastic lymphocytic cells.

Determination Of Genotoxic Effects Of Boric Acid In Cervical Carcinoma Cell Lines

E. Kahraman[1]*, M. Korkmaz*[1]*, I. Deliloglu Gurhan*[2]*;*
[1]*Celal Bayar University, Manisa, Turkey,* [2]*Aegean University, Izmir, Turkey.*

Aim: It has been shown that boron could be anti-carcinogenic effects in limited number of epidemiological and in vitro studies. In this context, particularly its preventive and therapeutic potential for prostate and cervical cancer gaining power by the day. In this study that planned, investigated the cytogenetic effects of boron in cervical carcinoma cell lines.
Methods And Materials: In our study, HTB-32 (from ATCC) and CCL-62 (HeLa contaminant, from ATCC) that cervical carcinoma cell lines were used. On this cell lines were treated 250 µM, 500 µM, 1000 µM doses of Boric acid. For estimate of genotoxicity while chromosome abnormalities in shape (CAs) were evaluated in terms of frequency, also Micronucleus (MN) frequency were calculated. Number of MN calculated for each boron doses in 1000 pieces binucleotid cells. For chromosome analysis, numbers of break and gap were evaluated for each dose in 50 pieces metaphase. The data that obtained, compared with the control group by applying the chi-square in SPSS 16.0 program.
Results And Discussion: In conclusion, statisticaly we didn't find significant genotoxic effects of boric acid when compaired with control group in human servical carcinoma cell lines ($p>0.05$). Our data suggested that boric acid no effects that increase or decrease on incidence of MN and CAs in human cervical carcinoma cell lines.

A functional assay for the identification of DNA double strand break (DNA-DSB) repair deficiency in heterozygous carriers of *BRCA2* and *RAD51C* mutations

A. A. Becker[1,2]*, J. Weimer*[3]*, M. K. Graeser*[1]*, C. Landwehr*[4]*, T. Hilger*[5]*, R. G. Weber*[6]*, B. Wappenschmidt*[1,2]*, A. Meindl*[7]*, N. Arnold*[3]*, R. K. Schmutzler*[1,2]*;*
[1]*Division of Molecular Gynaeco-Oncology, Department of Gynaecology and Obstetrics, University Hospital Cologne, Cologne, Germany,* [2]*Center for Molecular Medicine Cologne (CMMC), University of Cologne, Cologne, Germany,* [3]*Department of Gynaecology and Obstetrics, University Hospital Schleswig-Holstein, Christian-Albrechts-Universität Kiel, Kiel, Germany,* [4]*Institute for Medical Diagnostics, Berlin-Steglitz, Germany, Berlin, Germany,* [5]*Department of Radiation Therapy, University Hospital Cologne, Cologne, Germany,* [6]*Department of Human Genetics, Hannover Medical School, Hannover, Germany,* [7]*Department of Gynaecology and Obstetrics, Klinikum rechts der Isar at the Technical University, Munich, Germany.*

Mutations in breast cancer gene 1 and 2 (BRCA1/2) account for 50% of the familial aggregation of breast and ovarian cancer. Numerous allelic variants are of unknown clinical relevance (unclassified variants, UCV). We recently identified RAD51C as a third high penetrance gene. Like BRCA1/2, RAD51C is also involved in homologous recombination repair (HRR) in response to DNA-DSB. Patient lymphocytes carrying a pathogenic BRCA1/2 variant exhibit an increased level of chromosomal damage after irradiation. We aimed at developing a reliable functional test system which allows the evaluation of HRR deficiency in heterozygous patient lymphocytes. Carriers of pathogenic BRCA2 mutations, pathogenic RAD51C mutations, healthy controls as well as BRCA2 UCV carriers were γ-irradiated in G2 phase to introduce DNA-DSB. Repair capacity was subsequently assessed on metaphase chromosomes stained by multicolour fluorescence in situ hybridisation. Chromosomal translocations and breakages were counted per mitosis and referred to total chromosomal number. Lymphocytes from carriers of pathogenic BRCA2 and RAD51C mutations revealed a significantly higher mean aberration frequency than from controls ($p<0.001$, student's t-test). Patients carrying an UCV in BRCA2 could be allocated to either the pathogenic or the control group. In summary, our assay may enable the identification of HRR deficiency irrespective of the underlying gene defect and may also serve as a biomarker for sensitivity to PARP inhibition.

Chromosomal aberration in cervical cancer: FISH or chips?

V. Vranova[1,2]*, L. Moukova*[3]*, I. Slamova*[1]*, H. Filkova*[2]*, P. Kuglik*[1,2]*;*
[1]*Institute of Experimental Biology, Faculty of Science, Masaryk University, Brno, Czech Republic,* [2]*Department of Medical Genetics, University Hospital, Brno, Czech Republic,* [3]*Department of Gynaecological Oncology, Masaryk Memorial Cancer Institute, Brno, Czech Republic.*

Cervical tumorigenesis is linked with numerous chromosomal aberrations. Different studies investigated alterations in this cancer mainly by fluorescence *in situ* hybridization (FISH) or metaphase comparative genomic hybridization (mCGH). Currently, high throughput methods such as array-comparative genomic hybridization (array-CGH) together with single nucleotide polymorphism (SNP) arrays are available to study genome-wide aberrations.

We identified highly complex large-scale alterations of 13 cervical tumors (spinocellular carcinoma stage IA-IIIB) using genome-wide microarrays (Agilent). The most common regions of copy number gain were 3q22qter (6/13), 20q11q13.3 (5/13) and 8q21.3qter (4/13) and of copy number loss 13q11q21.2 (4/13), 3q and 4q (3/13). Patients with lymph nodes positive for metastases had often duplications in regions 2p, 5p and 19p and deletion at 3p compared to patients with lymph nodes negative for metastases.

However, array-CGH was not able to detect gains at 3q26 and 8q21 in four patients as compared to results obtained by Cervical FISH Probe Kit (Abbott). This kit allows simultaneous identification of HPV-infected cells and copy number aberration of the *hTERC* (3q26) and *MYCC* genes (8q21). Failure of array-CGH in detecting these aberrations can be probably explained by their presence in HPV-infected cells only whose abundance was very low in the four patients.

Array-CGH represents a perspective method for whole-genome screening and identification of potential biomarkers, which may enable a better risk stratification of HPV-positive women.

Nevertheless, reliable determination of DNA copy number aberrations requires either tissue sections from representative regions of tumor or FISH analyses of selected genes.

P07.07

Mapping of the minimal deleted region in 13q in chronic lymphocytic leukaemia with concomitant translocation-deletion of 13q14 by mBAND technique

***L. L. P. Siu**, K. F. Wong;*
Queen Elizabeth Hospital, Kowloon, Hong Kong.

Background: We have previously demonstrated by interphase fluorescence *in situ* hybridization (I-FISH) submicroscopic 13q deletion in chronic lymphocytic leukaemia (CLL) with 13q14 translocation. In this study, we employed multi-colour banding technique (mBAND) to further elucidate the translocation breakpoint and map the minimal deleted region in chromosome 13.

Methods and Result: 6 cases of CLL with 13q14 translocation diagnosed during 1997-2011 were available for study (Table 1). mBAND hybridization with direct fluorochrome-labeled region-specific partial chromosome paints on chromosome 13 (mB13) was performed on fixed cytogenetic preparations. Metaphases were captured on Carl Zeiss Z2 microscope using Isis/mFISH imaging software (MetaSystems, Altlussheim, Germany) after overnight hybridization. Analysis was based on fluorescent banded profile along the length of individual chromosome. Metaphases showing 13q translocation provided positive identification of the tumour clone. Deleted 13q was shown in 5 cases with the deleted 13q breakpoints unambiguously identified. The minimal deleted region was mapped to 13q14.3q21.1.

Conclusion: mBAND is a high-resolution tool for genetic study at single-cell single-metaphase level with a high sensitivity and specificity. It can refine the breakpoints for a more definitive karyotype. Our study has helped confirm the frequent occurrence of deleted 13q in CLL with 13q translocation, and map the minimal deleted region to 13q14.3q21.1.

Table 1: CLL with 13q14 translocation

Case	G-band karyotype	I-FISH for 13q14	mBAND for chromosome 13

P07.08

Independent coexistence of clones with 13q14 deletion at reciprocal translocation breakpoint and 13q14 interstitial deletion in chronic lymphocytic leukemia

***M. Hruba**, P. Dvorak, L. Weberova, I. Subrt;*
Institute of Medical Genetics, Faculty of Medicine and University Hospital in Pilsen, Pilsen, Czech Republic.

13q14 deletion is the most frequent chromosomal aberration in chronic lymphocytic leukemia (CLL), occurring in more than 50% of CLL cases. It is found predominantly as an interstitial deletion, less frequently in a form of reciprocal translocation with deletion at 13q14 breakpoint. The parallel presence of two clones with the different forms of 13q14 deletion has been noticed only once so far. By detailed metaphase analysis (G-banding, FISH) on IL2 and DSP30 stimulated CLL cells, we revealed the translocation form of 13q14 deletion in 13 of 135 patients with 13q14 deletion (13/135; 10%). The coexistence of a clone with the deletion at reciprocal translocation breakpoint and another clone with the interstitial deletion was found in 5 of the translocation cases (5/13; 38%). In one of them a subsequent clonal analysis proved an independent origin of the both coexisting clones, giving the evidence of their purely coincidental presence. We showed the coexistence of clones with the translocation form of 13q14 deletion and clones with the interstitial deletion not to be rare. As a mark of clonal evolution it could signify an increased risk of disease progression. Based on our presented results we assume that 13q14 reciprocal translocation with deletion at the breakpoint could be formed independently from formation of more common interstitial deletion also in other translocation cases.

P07.09

Detection of chromosomal abnormalities in chronic lymphocytic leukemia (CLL): FISH or MLPA?

***A. Busch**, A. Glaser;*
Institute of Human Genetics, Jena, Germany.

Chronic lymphoid leukaemia (CLL) is a genetically heterogeneous disease with recurrent chromosomal aberrations of prognostic significance. Current strategies for detecting chronic lymphocytic leukemia (CLL) include Fluorescence In Situ Hybridisation (FISH) and cytogenetics. Multiplex Ligation-dependent Probe Amplification (MLPA) is a multiplex PCR method detecting abnormal copy numbers in genomic DNA.

We studied a cohort of bone marrow samples from suspected leukemia patients and compared the results of FISH with cytogenetics and MLPA. We used a panel of 7 FISH hybridisation probes known to be of diagnostic relevance in CLL. Concordance between MLPA and FISH was excellent, when the abnormal clone was present more than 50% of the cell population. The use of MLPA allowed the identification of small alterations undetected by FISH, but e.g. translocations remain undetected. MLPA additional with cytogenetics represents a useful technique for the characterization of genomic changes in CLL. It is easy to use, faster and less cost intensive than FISH.

P07.10

Correlation between interphase FISH and real-time quantitative PCR for the therapeutic monitoring of chronic myeloid leukaemia

***W. S. Wong**, L. L. P. Siu, H. F. Wong, K. F. Wong;*
Haematology Laboratory, Queen Elizabeth Hospital, Kowloon, Hong Kong.

Background

Both interphase FISH (I-FISH) and real-time quantitative PCR (RQPCR) have been used for the monitoring of patients with chronic myeloid leukaemia (CML) on tyrosine kinase inhibitor (TKI) therapy. We compared the international standardized ratio (ISR) from the RQPCR test with I-FISH on patients with standard 9;22 reciprocal translocation and variant 9;22.

Methods and Result

104 samples from 54 patients with CML on TKI were studied during 2008 - 2011. 14 patients have ≥ 3 serial samples. ISR was derived from ratio of [*BCR-ABL1*]/*ABL1* transcript. I-FISH was performed with dual-fusion *BCR-ABL1* probes. ISR and I-FISH results were analyzed according to the cytogenetics response (Table 1). ISR showed wide inter-individual variation for the same tumor load as shown by I-FISH. The time to reach major molecular response (ISR $\leq 0.1\%$) ranged from 152 - 744 days after complete cytogenetic remission as shown by I-FISH. The falling trend of I-FISH correlated with ISR except in 2 patients, with one of them having a variant 9;22 translocation.

Conclusion

I-FISH is a better indicator of the tumour load especially in patients with variant 9;22 translocation while RQPCR is sensitive to detect *BCR-ABL1* fusion. Further study is required to determine the relationship between ISR values and cytogenetic responses as previous studies were mostly based on the latter.

Table 1. Correlation of ISR and I-FISH in classical and variant 9;22 translocation.

Group	N =	I-FISH, %	ISR
CCgR, FISH: 0%	36		
CCgR, classical 9;22	31	0	0 - 1.481, median = 0.141 (1/31, ISR = 10.243)
CCgR, variant 9;22	5	0	0.006 - 1.962, median = 0.126
PCgR, FISH: <35%	31		
PCgR, classical 9;22	25	1 - 33.5	0.303 - 18.669, median = 2.02
PCgR, variant 9;22	6	2.5 - 29.5	1.431 - 10.337, median = 3.548
No CgR, FISH >= 35%	37		
No CCgR, classical 9;22	22	49 - 100	3.58 - 63.583, median = 26.497
No CCgR, variant 9;22	15	41.5 - 99.5	10.823 - 56.845, median = 18.962

P07.11

Intermittent Dosing of Imatinib Mesylate in the Treatment of Childhood Chronic Myeloid Leukemia: a Case Report.

M. Adamaki[1], *A. Athanasiadou*[1], *Y. P. Ktena*[1], *A. Divane*[2], *M. Moschovi*[1];
[1]*Hematology-Oncology Unit, First Department of Pediatrics, National University of Athens, Aghia Sofia Children's Hospital, Athens, Greece,* [2]*"Life Code", Genetic Centre for Research and Diagnosis, Athens, Greece.*

Introduction: Chronic myeloid leukemia (CML) is rare in childhood (less than 5% of all childhood leukemias). The main characteristic is the Philadelphia chromosome and the tyrosine kinase inhibitor imatinib mesylate is the treatment of choice.
Purpose: To investigate whether intermittent dosing of imatinib is also an effective treatment in minimizing the adverse effect.
Material-Method: A 6-year-old girl presented with abdominal pain, leukocytosis ($27.8x10^9$/L) and thrombocytosis ($1.072x10^9$/L). Bone marrow studies suggested the diagnosis of CML. Cytogenetic studies revealed 46,XX,t(9;22)(q34;q11). The translocation was confirmed by FISH and RT-PCR. Treatment with imatinib was initiated at 400mg/m^2/day, followed 200mg/m2/day when minimal residual disease (MRD) was undetectable. MRD reappeared positive, so the dose was adjusted to 400mg/m^2/day but the patient experienced dry skin and significant hair loss. To avoid toxicity, the drug was given on alternate months (one on/one off).
Results: MRD is undetectable and the patient is in stable remission three years following the end of the treatment.
Conclusions: No guidelines exist regarding dosage and duration of treatment with imatinib, especially for childhood CML. In this report, intermittent administration of imatinib proved efficient, both in achieving complete stable remission and in minimizing toxicity.

Clonal Evolution in Chronic Lymphocytic Leukaemia

C. Lopez[1,2], *D. Costa*[1,2], *J. Delgado*[3,2], *C. Gómez*[1,2], *A. Arias*[1,2], *C. Muñoz*[1,2], *M. Rozman*[1,2], *D. Colomer*[1,2], *N. Villamor*[1,2], *E. Campo*[1,2], *A. Carrió*[1,2];
[1]*Hematopathology Unit. Hospital Clinic, Barcelona, Spain,* [2]*Institut d'Investigacions Biomédiques Agustí Pi i Sunyer (IDIBAPS), Barcelona, Spain,* [3]*Hematology Department. Hospital Clinic, Barcelona, Spain.*

INTRODUCTION: Chronic lymphocytic leukaemia is characterized by variable clinical course. The most frequent chromosomal abnormalities are trisomy 12, deletion of 13q14.3, 11q22.3 and 17p13; all of these are a relevant prognostic factor. Clonal evolution (CE) is defined as acquired aberration during the disease course.
The goal of this study is to determine the frequency of CE in CLL patients using conventional and molecular cytogenetics and its relationship with prognostic markers such as CD38 and ZAP70.
MATERIAL AND METHODS: Seventy-three patients with CLL were analysed by conventional and molecular cytogenetics (FISH) at diagnosis and during follow-up. Median time of observation after first analysis was 32 months (range 5-116). The second study was undertaken at follow-up (n=34), at clinical progression before treatment (n=24), and at relapse after treatment (n=15).
RESULTS: CE was observed in 38/73 (52%) of the patients using both techniques. The 70% (14/20) of patients with CE by conventional cytogenetics had normal karyotype at diagnosis. On the other hand, the 63% (19/30) of patients with CE by molecular cytogenetics had FISH abnormalities at diagnosis.
CE was detected during follow-up (14/34); at progression before treatment (12/24); and relapse after treatment (12/15) which was correlated with CE (p=0.042). In relation to ZAP-70, it was differentially expressed in patients with CE (p=0.039).
CONCLUSION: Clonal evolution is a significant event in CLL patients. Conventional and molecular cytogenetics were necessary to detect clonal evolution. We believe that CE could be a new prognostic factor and an indicator of change in clinical course of the disease.

P07.13

Cytogenetic studies on a chronic myeloid leukemia case developing into acute myeloid leukemia after treatment with imatinib.

W. G. Kroes[1], *E. den Ouden*[1], *E. Kok*[1], *J. Kerkhoffs*[2];
[1]*Leiden University Medical Center, Leiden, Netherlands,* [2]*HAGA Hospital, The Hague, Netherlands.*

A 34-year-old male was diagnosed with CML in April 2006. At the time of diagnosis all metaphases in the bone marrow showed t(9;22)(q34;q11.2). After one year of daily treatment with 400 mg imatinib no Philadelphia-chromosome positive metaphases were found in the bone marrow. FISH showed 2.5% of the 200 interphase nuclei positive for BCR/ABL1. Surprisingly, a monosomy 7 was detected in 15 out of 20 metaphases, whereas at this time no clinical signs of MDS or AML were present. Three months later, cytogenetic studies of bone marrow demonstrated 3 clones: 46,XY,t(9;22)(q34;q11.2)[2]/45,XY,-7[13]46,XY[5]. There were still no morphological signs of MDS or AML. After three more years, monosomy 7 was detected in all metaphases and by FISH in 90% of 200 interphase nuclei. Again FISH for BCR/ABL1 was negative. This time bone marrow cytology showed AML. The patient received one cycle of induction therapy with cytarabine and daunorubicine till now.
Transformation of a Ph-negative clone with monosomy 7 and no clinical signs of MDS into overt AML is a rare but recurrent phenomenon. Therefore patients showing monosomy 7 during imatinib treatment should be closely monitored both cytogenetically and clinically for signs of MDS or AML.

P07.14

Effect of new tubulin inhibitors drugs in colon cancer cells

A. Pascual-Rodriguez[1], *C. Jimenez Criado*[1], *R. Álvarez Lozano*[2], *E. Caballero Salvador*[2], *R. González Sarmiento*[1];
[1]*Centro de Investigación del Cáncer, Salamanca, Spain,* [2]*Departamento de Química Farmaceútica. Universidad de Salamanca, Salamanca, Spain.*

Introduction: Cell cytoskeleton is composed of microtubules formed by polymerization of tubulin. Antitumor drugs that perform on the microtubules are divided in three groups according to the zone of interaction: Vinca, Colchicine and Taxan-binding domain. First and second one prevent tubulin polymerization. Paclitaxel is a microtubule stabilizing agent. We have studied the effect of three new molecules that bind on the colchicine domain in two cell lines of colon cancer.
Experimental design: Cell lines were treated with drugs A, B and C, derived from the isocombretastatin and Paclitaxel with a concentration of 50 nm. The cells were collected at times 24, 48 and 72h after incubation with the drug, using as negative control untreated cells (0h). Protein were removed from each culture and we prepared cultures for immunofluorescence analysis. Expression studies of tubulin was performed by Western Blot. We performed a study of cell death by flow cytometry. Finally, we made a study of immunolocalization and stability of microtubules by immunofluorescence.
Results: Our results show that none of the new drugs reduce or increase the amount of tubulin. The viability study showed that Drug A and B not induce apoptosis, however, Paclitaxel and Drug C significantly increased apoptosis after 24 hours of exposure. Drug A does not induce changes in the microtubules at 72h, Drug C and Drug B produce a destabilization of microtubules and inhibit tubulin polymerization.
Conclusion: None of these drugs improve the effect of paclitaxel.

P07.15

Detection of donor cells with a clonal abnormality 20 years after transplantation: Is this evidence of Donor Cell Leukemia (DCL)?

G. V. N. Velagaleti, *V. Ortega*, *D. Means*;
University of Texas Health Science Center, San Antonio, TX, United States.

DCL is a rare complication following BMT with unknown etiology. We report a patient who showed no cytogenetic evidence of engraftment for 20 years following which donor cells were detected with a clonal abnormality. A 59-year-old female diagnosed with CML in 1986 underwent an allogenic BMT from her brother in 1987. Subsequently, she developed graft-versus-host disease in 1990, suggesting possible rejection of donor cells. Afte rrelapse in 2000 her chromosome analysis demonstrated the karyotype 46,X,-X, t(1;7)(p10;p10), add(4)(p16),t(9;22) (q34;q11.2),-15,+3mar[16]/46,XX,der(9)add(9)(p24)t(9;22)(q34;q11), add(18)(p11.3),-19,der(22)t(9;22)[4]. Since Gleevec treatment was unsuccessful due to intolerance, follow-up studies in 2006 revealed persistence of known Ph+ clones and an additional Ph+ clone. Upon treatment with dasatinib she achieved partial remission and chromosome studies in 2007 showed, for the first time, donor cells with trisomy 8 (T8) and recipient cells with the Ph+ clone; 46,XX,t(9;19)(p24;p13.1),t(9;22)(q34;q11.2),t(14;18)(q24;11.2)[2]

//47,XY,+8[3]/46,XY[20]. Subsequent studies demonstrated donor cells with T8 in 15-35% of metaphases. Constitutional T8 was ruled out as the donor's blood karyotype was normal. T8 is an additional anomaly in 10% of CML cases emerging at the time of acute transformation and after imatinib treatment. Although engraftment is an immediate response, the cytogenetic evidence of donor cells did not become apparent due to the proliferative dominance of Ph+ clones. Dasatinib treatment in our patient effectively removed the dominant Ph+ clones, facilitating the detection of donor cells with T8. Since the etiology of DCL and the significance of the T8 in donor cells in our patient are unclear, the patient is monitored closely for secondary MDS /AML.

P07.16

Variant chromosomal translocation in Ewings Sacoma

S. K. Kousar Jahan[1,2];
[1]Al Jawhara Center for Molecular Medicine Bahrain, Manama, Bahrain, [2]Kidwai Memorial Iinstitute of Oncology, Bangalore, India.

This study reports the cytogenetic findings on a fine needle aspiration (FNA) specimen from ten patients with Ewing's Sarcoma (ES) using G-banding technique. Out of ten ES cases t(11;22)(q24;q12) was observed in 6 cases(60%), only del(22)(q12) in one case(10%) and variant translocation t(1;11;22)(q31;q24;q12), t(11;12;22)(q24;p13;q12) & t(4;22)(q35;q12) in 3 cases (30%). In third variant case only chromosome 22q12 was involved in translocation and del (22) (q12) (EVS gene) in another suggests that the rearrangement of 22q12 is the cytogenetic hallmark of ES. Specific chromosomal abnormalities often correlate with particular morphologic or phenotypic subtypes of tumor and play an important role in prognosis.

P07.17

Gain of the short arm of chromosome 2 in Chronic Lymphocytic Leukaemia

M. Stoklasova[1], *T. Sablaturova*[1], *A. Strnkova*[1], *L. Dostalova*[1], *M. Brejcha*[2], *Y. Brychtova*[3], *J. Malcikova*[3], *D. Adamova*[4], *V. Heinzova*[4], *M. Urbankova*[5], *J. Zivna*[6], *I. Zygulova*[4], *N. Rytikova*[7], *M. Matuska*[8];
[1]P+R LAB a.s., Novy Jicin, Czech Republic, [2]Hospital Novy Jicin a.s, Novy Jicin, Czech Republic, [3]University Hospital Brno and Faculty of Medicine Masaryk University, Department of Internal Medicine – Hematology and Oncology, Brno, Czech Republic, [4]Silesian Hospital in Opava, Opava, Czech Republic, [5]Hospital Sumperk a.s., Sumperk, Czech Republic, [6]Hospital Hranice a.s, Hranice na Morave, Czech Republic, [7]Hospital Krnov, Krnov, Czech Republic, [8]Faculty Hospital Ostrava, Ostrava, Czech Republic.

Background: Chromosomal abnormalities are important prognostic factors in chronic lymphocytic leukaemia (CLL). Interphase FISH (I-FISH) is standard method for detection of important aberrations in CLL. However, progress in cultivation technique such as application of CpG-oligonucleotides and IL-2 as B-cell mitogens allows to reveal another chromosomal aberrations. Recently, gain of the short arm of chromosome 2 (2p) was found as one of recurrent aberrations.

Aims: Metaphase cytogenetic and molecular-cytogenetic analyses were performed in 477 CLL-patients from 2008 to 2011 to find out gain of 2p.

Methods: Conventional cytogenetics was performed on peripheral blood or bone marrow samples cultured in medium with stimulants. I-FISH was performed on unstimulated cells for detection of trisomy 12, del(11q), del(13q), del(17p). Gain of 2p was confirmed by multicolor FISH, the range of the gain was determined by multicolor banding.

Results: Gain of 2p was detected in 20/477 (4,2 %) cases. In 17/20 cases, the partial trisomy of 2p was identified as a result of unbalanced translocation with other chromosomes and direct duplication of 2p was presented in 3/20 cases. Four of all these cases had jumping translocation of 2p (in one case together with direct duplication of 2p). I-FISH revealed aberrations in 19/20 cases. The most frequent abnormalities were del(13q) and del(11q).

Conclusion: Mitotic stimulation using CpG-oligonucleotides and IL-2 is an efficient method that can improve quality of cytogenetic analysis. Detection of another aberrations i.e. gain of 2p provide new prognostic information in CLL. These findings can significantly modify prognosis of patients evaluated by FISH.

P07.18

A pediatric chronic myeloid leukemia case progressing to blast crisis characterized by the deletion of Ikaros.

A. Athanasiadou[1], *M. Adamaki*[1], *G. Lambrou*[1], *Y. P. Ktena*[1], *V. Papasavva*[2], *K. Dioikitopoulou*[2], *A. Divane*[2], *M. Moschovi*[1];
[1]Hematology-Oncology Unit, First Department of Pediatrics, National University of Athens, Aghia Sofia Children's Hospital, Athens, Greece, [2]"Life Code", Genetic Centre for Research and Diagnosis, Athens, Greece.

Introduction: Rearrangements in the gene IKZF1 (Ikaros) are considered as an additional adverse risk factor, among other prognostic markers, in leukemia.

Purpose: To present the case of a pediatric patient with BCR/ABL1 positive CML who was treated with imatinib and achieved remission, but transformed to lymphoid blast crisis (BC) with detected deletion of Ikaros within 205 days following diagnosis.

Material-Method: A 12,5-year-old girl presented with leukocytosis and bone marrow (BM) studies suggested the diagnosis of chronic phase (CP) CML. Cytogenetic analysis demonstrated 46,XX,t(9;22)(q34;q11). The patient was treated with imatinib (400mg/m^2/day) and achieved remission.

Results: On the 205th day, the blood test revealed a 73% blast count and BM studies suggested a diagnosis of B-cell ALL. Cytogenetic findings revealed 46,XX,der(3)t(1;3)(q12;p26),t(9;22)(q34;q11). FISH analyses were negative for translocations, but three copies of PBX1 were detected. MLPA analysis revealed a deletion in Ikaros, including exons 4-8, and in the EBF1 gene, in exon 1. No copy number variation was found in the BM sample from the CML diagnosis. The patient received chemotherapy according to the ALL IC-BFM 2009 protocol plus imatinib (400mg/m^2/day), but failed to achieve complete remission and the duration of survival from the onset of BC was 75 days.

Conclusions: Abnormalities of Ikaros are associated with a very poor outcome and a high rate of relapse in childhood leukemia. Deletion of Ikaros was not detected in CP-CML, but was identified as an acquired lesion in the BC-CML sample. This finding suggests that alterations in Ikaros contribute to the pathogenesis of BCR/ABL1 ALL.

Prognostic Genetic Markers in Glial Tumors

C. Karakurt[1], ***M. Ozdemir***[1], *A. Arslantas*[2], *E. Ciftci*[3], *B. Durak Aras*[1], *O. Cilingir*[1], *A. I. Gurler*[1], *S. Artan*[1];
[1]Eskisehir Osmangazi University, Medical Faculty, Department of Medical Genetics, Eskisehir, Turkey, [2]Eskisehir Osmangazi University, Medical Faculty, Department of Neurosurgery, Eskisehir, Turkey, [3]Eskisehir Osmangazi University, Medical Faculty, Department of Pathology, Eskisehir, Turkey.

Glioblastoma is the most common primary brain tumor in adults and the most malignant types of human cancers with median survival time of <1 year detected in a population-based study. Although histopathological diagnosis of GBM is known as a gold standard, the primary and secondary subtypes that have at least two distinct pathways contributing to the tumorigenesis of GBM, are histologically indistinguishable and molecular markers are necessary for prognostic predictions of the GBM cases. Frequent mutations of the genes involved in G1-S cell cycle transition control have been previously reported in both subtypes of the GBM. This study was planned to determine prognostic values of growth-control molecules including MDM2, CDK4 protooncogenes and RB1tumor suppressor gene in primary GBMs. Of 40 cases, 26 were male and 14 were females and the mean age was 55.45+/- 2.25. Since no brain tumor history, the GBM subtype of all was primary GBM. The genomic copy aberrations of the genes were determined by the FISH assay in tumor sections of the cases. Of 40 cases, no gene copy number aberrations was seen in four cases whereas the MDM2, CDK4 gene amplifications and RB1 gene deletion were detected in 62,5%, 60.0% and 47.5% of the cases, respectively. The copy number alterations for all analysed genes were seen in seven cases. However, no significant differences between the worse survival and genetic markers was highlighted. Further detailed study related with genetic and epigenetic markers in larger population is necessary for clinical outcome of patients with primary GBM.

Genotoxicity of hepatitis B virus

H. G. Durakbasi-Dursun[1], *A. G. Zamani*[2], *O. Ural*[3], *D. Fındık*[4], *M. N. Somuncu*[5];
[1]Department of Medical Biology Meram Medical Faculty, Konya University, Konya, Turkey, [2]Department of Medical Genetics, Meram Medical Faculty, Konya University, Konya, Turkey, [3]Department of Infectious Diseases Selcuklu Medical Faculty, Selcuk University, Konya, Turkey, [4]Department of Microbiology, Selcuklu Medical Faculty, Selcuk University, Konya, Turkey, [5]Department of Medical Genetics Meram Medical Faculty, Konya University, Konya, Turkey.

Background: Chronic hepatitis B is one of the major causes of cirrhosis and hepatocellular carcinoma worldwide. An estimated more than 350 million people are chronically infected with hepatitis B virus (HBV), characterized with various clinical states. Although HBV shows mainly pathologic effect on liver, it can also infect peripheral mononuclear cells. Since HBV has the capability of integrating in the human genome and causing chromosomal rearrangements, it might act as a clastogenic factor and exert a direct genotoxic effect on lymphocytes.

Aim: In this study, potential genotoxic effect of HBV was investigated on peripheral lymphocytes in chronic HBV patients ,HBV carriers and normal

controls by the micronucleus (MN) technique, is used as an index of chromosomal damage.
Method: The MN assay was performed on peripheral blood lymphocyte cultures from chronic HBV patients, HBV carriers and controls. The cells with 1-4 nuclei and micronucleated cells were scored. Then frequency of micronuclei and cytokinesis- blocked proliferation index (CBPI) were calculated. The obtained data were compaired between HBV patients, HBV carriers and controls.
Results: There were no differences among HBV patients, HBV carriers and controls in terms of MN frequency and CBPI.
Conclusion: Our findings suggest that HBV does not show genotoxic effect at least as MN formation and CBPI.

P07.22

The detection rate of chromosomal abnormalities in mature lymphocytic neoplasms is increased by adding CpG oligonucleotide DSP30 and IL-2 to the culture medium

***H. Devos**, A. De Backer, S. Scheers, J. Wauters, G. Mortier, E. Van Assche;*
Center of Medical Genetics, Edegem, Belgium.

It has been shown that the addition of the CpG-oligodeoxynucleotides DSP30 and IL-2 to the culture medium increases the mitotic activity of chronic lymphatic leukemia cells and consequently the detection rate of chromosomal abnormalities in this malignant haematological disorder. With this study we aimed to investigate the effect of this addition in the diagnosis of a broader group of mature lymphoid malignancies. From January till December 2010, bone marrow samples for staging of lymphoid malignancies were cultured in either a conventional medium or in a medium with DSP30 and IL-2. Between 5 and 20 G-banded metaphases were analysed in each sample.
Classification of the chromosomes and definition of a clone were made according to ISCN (2009). In total, 233 samples were included in the study. In 99% of the samples a successful stimulation for metaphase generation was obtained. In 34/233 samples an abnormal karyotype was observed, suggestive for invasion of lymphoid malignant cells into the bone marrow. In 15 of those 34 abnormal samples, the aberration was only found in the cultures with added DSP30 and IL2. However, in one sample the chromosomal abnormality was only observed in cultures with the conventional medium and not in those with DSP30 and IL2. For this patient, the final diagnosis was not a lymphoid neoplasm but acute myeloid leukemia.
Our findings confirm that stimulation of cultures with DSP30 and IL-2 in case of mature lymphoid malignancies results in an increased detection rate of clonal abnormalities.

P07.23

A new type of karyotype evolution?

***K. Shirneshan**, J. Schanz, C. Ganster, F. Braulke, D. Haase;*
Department of Hematology and Oncology, Goettingen, Germany.

Cytogenetic findings play an important role in the diagnosis and assessment of prognosis of myelodysplastic syndromes (MDS) and are emerging as an important factor in treatment allocation and in selection and monitoring response to therapy. Abnormalities involving chromosome 7 are frequent in MDS and suggest an intermediate to poor prognosis. In 2% of MDS patients we observed a coexistence of monosomy 7 and 7q-deletions at the same time by FISH analysis of CD34+ peripheral blood cells. Two patients showed an increase of -7 clone size parallel to a decrease of 7q- clone size during progress. Now we report a case of a 72-year old man with suspected MDS. Analysis of bone marrow revealed MDS RA. Banding analysis of bone marrow cells showed three clones with different chromosome 7 abnormalities: del 7q in 22%, ring chromosome 7 in 22% and monosomy 7 in 11% of the metaphases.
We hypothesize that chromosome 7 is subject to karyotype evolution during MDS progression. Due to the existence of the third clone with r(7) we assume that r(7) is a transitional stage of karyotype evolution between 7q- and -7 which is resulting of loss of telomere ends in 7q- cells. FISH analysis confirmed deletion of telomeres in r(7). Follow up analyses of this patient will allow further examination of karyotype evolution involving chromosome 7 abnormalities.

P07.24

The molecular background of the medulloblastoma - identification of the most common chromosomal aberrations in Polish patients.

***J. Trubicka**[1], A. Tańska[1], M. Perek-Polnik[2], D. Abramczuk-Piekutowska[1], E. Ciara[1], D. Jurkiewicz[1], S. Łuczak[1], M. Pelc[1], M. Borucka-Mankiewicz[1], P. Kowalski[1], K. Chrzanowska[1], M. Krajewska-Walasek[1];*
[1]Children's Memorial Health Institute, Department of Medical Genetics, Warsaw, Poland, [2]Children's Memorial Health Institute, Department of Oncology, Warsaw, Poland.

Medulloblastoma (MB) is a highly malignant primary brain tumor that originates in the cerebellum or posterior fossa and the most common malignant brain tumor in childhood. The exact pathogenesis of MB remains unclear. Up to date multiple molecular dysfunctions are known to be responsible for medulloblastoma formation, including aberrant activation of the Sonic Hedgehog or Wingless signaling pathways as well as mutational inactivation of DNA repair genes results in genome instability. The most common genetic alterations identified in medulloblastoma is isochromosome 17 (currently reported in 30-50% of patients). Others less common chromosomal changes observed in MB include chromosome 6, 8, 9q, 16, 18 and X.
In our project on medulloblastoma's genetic background we determined the frequency of the most common chromosomal aberrations in Polish patients with MB. We screened a total of 21 patients, using a multiplex ligation-dependent probe amplification analysis (MLPA) and identified 11 carriers (52,3%) of chromosome 17 aberrations (including 8 patients with isochromosome - 38%) and 5 carriers (29,4%) with abnormalities within chromosome 6. All the identified changes were somatic mutations. These findings suggest that the identified common chromosomal aberrations are the consequence of another molecular mechanism involved in the pathogenesis of medulloblastoma. The analysis on the genetic background of MB in the Polish population will be continued.
The study was financed by the National Science Centre, project no. 6917/B/P01/2011/40.

P07.25

Comprehensive high-resolution genomic profiling and cytogenetics of two pediatric and one adult medulloblastoma

***L. Xu**[1,2], H. Holland[1], P. Ahnert[1,3,4], H. Kirsten[1,3,4], R. Koschny[5], M. Bauer[6], R. Schober[6], J. Meixensberger[2], W. Krupp[2];*
[1]Translational Centre for Regenerative Medicine (TRM), University of Leipzig, Leipzig, Germany, [2]Department of Neurosurgery, University of Leipzig, Leipzig, Germany, [3]Institute for Medical Informatics, Statistics and Epidemiology, University of Leipzig, Leipzig, Germany, [4]LIFE Center (Leipzig Interdisciplinary Research Cluster of Genetic Factors, Phenotypes and Environment), University of Leipzig, Leipzig, Germany, [5]Department of Internal Medicine, University of Heidelberg, Heidelberg, Germany, [6]Division of Neuropathology, University of Leipzig, Leipzig, Germany.

Medulloblastoma (WHO grade IV) is a rare malignant, invasive embryonal tumor which mainly occurs in children and represents less than 1% of all adult brain tumors. Systematical comprehensive cytogenetic and molecular biological analyses on medulloblastomas are very limited but necessary to provide more detailed information.
Therefore, we performed comprehensive cytogenetic analyses (blood and tissue) of two pediatric and one adult medulloblastoma, WHO grade IV, using trypsin-Giemsa staining (GTG-banding), spectral karyotyping (SKY, only tissues), and molecular karyotyping using genome wide 6.0 SNP-arrays.
We confirmed frequently detected chromosomal aberrations in medulloblastoma, such as +7q, -8p/q, -9q, -11q, -12q, +17q, and identified novel genetic events. Applying SNP array, we identified constitutional de novo losses 5q21.1, 15q11.2, 17q21.31, 19p12, (pediatric medulloblastoma), 9p21.1. 19p12, 19q13.3, 21q11.2 (adult medulloblstoma) and gains 16p11.1-16-p11.2, 18p11.32, Yq11.223-Yq11.23 (pediatric medulloblastoma), Xp22.31 (adult medulloblastoma), possibly representing inherited causal events for medulloblastoma formation. We show evidence for somatic segmental uniparental disomy in regions 1p36, 6q16.3, 6q24.1, 14q21.2, 17p13.3 and 17q22, not previously described for primary medulloblastoma.
Analyses of tumors and matched normal tissues (blood) with a combination of SNP arrays and complementary techniques will help to further elucidate potentially causal genetic events for tumorigenesis of pediatric and adult medulloblastoma.

Analysis of chromosomal abnormalities in phenotypically normal plasma cells detected by I-FISH in monoclonal gammopathy of undetermined significance

***A. Mikulasova**[1,2,3], P. Kuglik[1,2], J. Smetana[1,2], H. Greslikova[1,2], R. Kupska[1], P. Nemec[1,2], L. Rihova[1,3], M. Klincova[3], R. Hajek[1,3,4];*
[1]Babak Myeloma Group, Department of Pathological Physiology, Faculty of Medicine, Masaryk University, Brno, Czech Republic, [2]Department of Experimental Biology, Faculty of Science, Masaryk University, Brno, Czech Republic, [3]Laboratory of Experimental Hematology and Cell Immunotherapy, Department of Clinical Hematology, University Hospital Brno, Brno, Czech Republic, [4]Department of Internal Medicine – Hematooncology, University Hospital Brno, Brno, Czech Republic.

Monoclonal gammopathy of undetermined significance (MGUS) is a premalignant stage of multiple myeloma. MGUS consists of phenotypically normal (nPCs; CD138+19+56-) and abnormal malign plasma cells (aPCs; CD138+19-

56+/-). Combination of fluorescence activated cell sorting (FACS) and interphase fluorescence in situ hybridization (I-FISH) allows monitoring of specific chromosomal abnormalities in separate PCs populations. We hypothesized that there should not be any chromosomal abnormalities in nPCs.

By I-FISH we examined following chromosomal alterations in nPCs and aPCs: del(13)(q14), del(17)(p13), IGH rearrangement, 1q21 gain and hyperdiploidy (+5, +9 and +15). In this study, we chose MGUS patients from whom it was possible to separate nPCs and aPCs and who had IGH rearrangement in aPCs (n=15). In the nPCs we found only IGH disruption. Total of 27% (4/15) and 73% (11/15) MGUS patients have more than 20% and 10% aberrant PCs bearing IGH rearrangement not only in aPCs, but also in nPCs, respectively. Other chromosomal abnormalities were detected only in aPCs: del(13)(q14) was found in 20% (3/15), 1q21 gain in 7% (1/15) and hyperdiploidy in 13% (2/15).

In conclusion, we found IGH rearrangement in phenotypically nPCs defined by CD138+CD19+CD56- and thus we assume that the separation according to this phenotype is not sufficinent to separate genetically nPCs.

Support: The study was supported by grants MSM0021622434, MSM0021622415, GAP304/10/1395, NT11154, NT12425, NT12130.

Combination of FISH and array-CGH technique provide powerful diagnostic toll in multiple myeloma: single centre experience

J. Smetana[1,2], *J. Frohlich*[2], *R. Zaoralova*[2], *V. Vranova*[2,3], *P. Nemec*[1,2], *H. Greslikova*[1], *R. Kupska*[1], *A. Mikulasova*[1,2], *M. Almasi*[1,4], *R. Hajek*[1,4,5], *P. Kuglik*[1,2,3];
[1]Babak Myeloma Group, Department of Pathological Physiology, Faculty of Medicine, Masaryk University,, Brno, Czech Republic, [2]Department of Experimental Biology, Faculty of Science, Masaryk University, Brno, Czech Republic, Brno, Czech Republic, [3]Department of Medical Genetics, University Hospital, Brno, Czech Republic, Brno, Czech Republic, [4]Department of Clinical Hematology, University Hospital Brno, Czech Republic, Brno, Czech Republic, [5]Department of Internal Hematooncology, University Hospital Brno, Czech Republic, Brno, Czech Republic.

Multiple myeloma (MM) is a hematological disease caused by malignant proliferation of clonal plasma cells (PCs). Identification of copy number aberrations (CNAs) in genome of PCs plays a key role in MM pathogenesis and is supposed to have important prognostic significance for MM patients. Combined utilization of array-CGH technique and FISH proved to be a powerful toll in MM diagnostic. There are two major genetic entities in MM. Hyperdiploid group (H-MM), which include about 50% of MM patients and have is commonly characterized by gains of odd-numbered chromosomes and lower prevalence of *IgH* translocations. Non-hyperdiploid (NH-MM) cases are connected with frequent incidence of one of several recurrent *IgH* translocations: 4p16 (*FGFR3* and *MMSET*), 11q13 (*CCND1*) or 16q23 (*MAF*) and are associated with adverse prognosis. Using combination of array-CGH and FISH technique, we found CNAs in 100% of cases (106/106). Most common CNAs were found in 1p, 1q, 6p, 8p, 13q, 14q, 16q and 22q along with gain of extra copies of odd-numbered chromosomes. Hyperdiploidy was found in nearly half of the cases (48%) with subgroup of cases with +11 and with gain(1q) and del(13q) Translocation t(4;14)(p16;q32) was found in 12% (14/81 cases)and it was more common in non-hyperdiploid cases (P=0.041), deletion *TP53* was observed in 14% (15/106). Most common homozygous deletions were found 1p32.3, 11q22, 13q14 and 16q22. We conclude that simultaneous utilization of FISH and array-CGH technique provides powerful toll for identification of CNAs in MM patients. This study was supported by grants LC06027, MSM0021622434, NS10207, NT11154 and NT12130

INTRODUCTION: Myelodysplastic syndromes (MDS) are a group of clonal haematopoietic stem cell diseases characterized by cytopenia(s), dysplasia in one or more of the major myeloid cell lines, ineffective haematopoiesis, and an increased risk of developing acute myeloid leukaemia (AML). Chromosomal abnormalities are detected in half of patients with the novo MDS. The infrequency of balanced translocations in MDS makes their identification and reporting imperative for the recognition of the recurrent ones. This increases the likelihood of identifying which genes are possibly involved in the pathogenesis of the neoplasia.

OBJECTIVE: Identify the frequency of balanced translocations in a series of 1,850 patients with MDS included in the database of the Spanish group of myelodysplastic syndromes (GESMD).

RESULTS: Two hundred and twelve (11%) balanced translocations were diagnosed in 1,850 SMD patients. The chromosomes more frequently involved were chromosome 1 (n=34), 2 (n=31), 3 (n=30) and 5 (n=16). All chromosomes were involved in the translocations, with the exception of chromosomes 19, 20 ,22 and Y. Half of the translocations were found as a part of a complex karyotype (>=3 chromosomal abnormalities). One hundred and seventy-six (83%) translocations were not previously described neither in MDS nor AML. Nine new apparently recurrent translocations were found in our series.

CONCLUSION: Balanced translocations were found in 11% of MDS patients, half of them being involved in complex karyotypes.

P07.29

The low level clones of BM cells with BCR-ABL fusion gene amplification have unfavorable influence on CML imatinib therapy outcome

S. Mordanov[1], *A. Zeltzer*[1], *E. Grankina*[1], *O. Ustaeva*[1], *T. Kungurova*[1], *Y. Shatokhin*[1], ***S. Kutsev***[2,3];
[1]Rostov State Medical University, Rostov-on-Don, Russian Federation, [2]Federal State Budgetary Institution "Research Centre for Medical Genetics" of the Russian Academy of Medical Sciences, Moscow, Russian Federation, [3]Russian National Research Medical University named after N.I.Pirogov, Moscow, Russian Federation.

Imatinib CML therapy have shown the high effectiveness but primary and secondary resistance is observed in some cases. The aim of this study was to elucidate the influence of low level clones of BM cells with BCR-ABL gene amplification (GA) to the results of CML imatinib treatment.

Bone marrow samples from 174 CML patients (pts) were analyzed by cytogenetic and FISH analysis. 200 interphase nuclei were analyzed after hybridization with dual color/dual fusion BCR-ABL gene probe ("Vysis") in each case. According to the ELN criteria (2009) 51 pts have achieved optimal or suboptimal response, 86 pts have failure and 37 pts have loss of achieved response.

FISH did not revealed BCR-ABL GA in pts with optimal and suboptimal responses. Additional copies of BCR-ABL gene (from 1 to 7) were found in 32 (37,2%) pts with primary resistance and in 12 (32,4%) pts with secondary resistance. The probability of complete cytogenetic response (CCyR) achievement in pts with BCR-ABL GA was significantly lower than in pts without it (31,6% vs. 63,8%, p=0,000025). All Pts with additional copies of BCR-ABL gene were subdivided in 4 quartiles (Q) in accordance with % of BM cells with BCR-ABL GA. The probability of CCyR achievements in pts of Q1-Q2 (1-6% BM cells with BCR-ABL GA) do not differ from pts of Q3-Q4 (7-72% BM cells with BCR-ABL GA) (p=0, 86454).

In conclusion, the pts with low level clones with BCR-ABL GA have the same unfavorable prognosis as well as pts with high level clones.

P07.30

The clone with trisomy 8 in the culturing bone marrow mesenchymal stem cells of healthy donors

V. A. Nikitina, *L. D. Katosova*;
Research Centre for Medical Genetics, Moscow, Russian Federation.

It has been clearly recognized that the hematopoietic microenvironment plays a key role in the physiology of the hematopoietic system. Mesenchymal stem cells (MSC) are key components of the hematopoietic microenvironment. Several studies have shown that MSC play important role in the genesis of some hematological disorders.

We have investigated the bone marrow MSCs from healthy donors (n=20), intended for allogeneic transplantations recipients with hematological disorders. We have analyzed the characteristics of bone marrow MSC including the growth pattern, the immunophenotype and their cytogenetic characterization by GTG-banding and FISH with centromere-specific DNA-probes for chromosomes X and 8.

Despite decrease proliferation possibilities from the third to the 12 passages, cells kept typical MSC immunophenotype. There were two bmMSC cultures with abnormal clones: clone with trisomy 8 and monosomy X. Culture with trisomy 8 was explored three times. In 4th passage 24% of all analyzed

cells had extra chromosome 8. In 6th passage their amount increased to 34% and in 12th passage it decreased to 16%. In other case the culture of bmMSC of healthy woman had clone with one X chromosome. The amount of such cells in 4th passage was 12% and increased to 91% in 10th passage.
Thereby, the cytogenetic analysis revealed the presence of genetic abnormal cells clones in early passages and persisted till late stages of cultivation. In one of the cultures of healthy donor's bmMSC was found the clone with trisomy 8, chromosomal abnormality, which is strongly associated with myeloid malignancies.

P07.31

Micronucleus (MNs) induction and FISH analysis in peripheral lymphocytes of Tunisian pathology and anatomy laboratory workers exposed to Formaldehyde (FA)

S. Bouraoui[1], *S. Mougou*[1], *A. Brahem*[2], *H. Benkhelifa*[1], *N. Bouali*[1], *R. Berguiga*[1], *I. Ben abdallah*[1], *S. Brahem*[1], *O. Mamai*[1], *M. Gribaa*[1], *D. Hmida*[1], *N. Mrizek*[2], *F. Tabka*[2], *H. Elghezal*[1], *A. Saad*[1];
[1]Department of Cytogenetic and Reproductive Biology, Farhat Hached University Teaching Hospital, Sousse, Tunisia, [2]Department of occupational and environmental medicine, Farhat Hached University Teaching Hospital. Sousse, Tunisia, Sousse, Tunisia.

Formaldehyde is an important industrial compound but it is also a naturally occurring biological compound present in all cells and body fluids. The International Agency for Research on Cancer (IARC) classified FA as carcinogenic to humans (group I) based on the studies indicating an increased incidence of nasopharyngeal cancer in populations occupationally exposed to FA.
A genotoxic effect of (FA), in particular micronucleus induction, has been shown in several studies. The aim of our study was to assess the frequency of (MNs) and to identify the type of chromosomal damage in Tunisian staff from pathologic anatomy laboratory of Farhat Hached hospital (Sousse, Tunisia).
Assessment of chromosomal damage was carried out in peripheral lymphocytes of 31 exposed to (FA). We used 31 controls from the administrative department of the same hospital. The clastogenic/ aneugenic effect of FA was evaluated using the standard MN assay in combination with the fluorescence in situ hybridization (FISH) technique.
The results showed a significant increase of the MN frequency in lymphocytes of exposed workers compared with the control group (25.35 ‰± 6.28 versus 7.08 ‰± 4.62).
As assessed by FISH, the frequency of centromeric micronuclei (C+MN) was higher in exposed subjects than in controls (18.38 ‰±5.94 versus 5.03‰±3.64). Among the (C+MN), the frequency of MN containing one centromere was significantly higher in pathologist/anatomists than in controls (15.35 ‰ ± 6.0 versus 3.33 ‰±2.74).
The increase of the frequency of centromeric micronuclei observed in exposed group may suggest a slight aneugenic effect of exposure to FA.

P07.32

Evidence for a pre-malignant cell line in a skin biopsy from a patient with Nijmegen Breakage Syndrome (NBS)

R. Habib[1], *H. Neitzel*[1], *B. Goryluk-Kozakiewicz*[2], *K. Chrzanowska*[2], *K. Sperling*[1];
[1]Institute of Medical and Human Genetics, Berlin, Germany, [2]The Children´s Memorial Hospital, Warsaw, Poland.

The chromosomal instability disorder, Nijmegen breakage syndrome (NBS), is characterized by microcephaly, growth retardation, immunodeficiency, hypersensitivity to X-irradiation, and predisposition to malignant tumours, especially lymphomas. Nibrin, the product of the *NBN* gene, is part of the MRE11/RAD50 complex, which is involved, amongst others, in the repair of DNA double strand breaks (DSBs). The majority of NBS patients are of Central and Eastern European origin and carry the common founder mutation in the *NBN* gene, 657del5. Skin fibroblasts, derived from a 9 year old NBS patient showed a mosaic of normal diploid cells and those with an unbalanced translocation, resulting in partial monosomy for 6q and 13q21→qter, and partial trisomy for 20q11.2→qter, as confirmed by G-banding, CGH and chromosome painting. The relative proportion of these aberrant cells increased during propagation of the cell line. This was due to a faster cell cycle, as shown after BrdU labelling and is paralleled by a shorter telomere length, as demonstrated by T/C-FISH (telomere/centromere-FISH). Moreover, after treatment with 0.5 and 1.0 Gy the aberrant cells showed significantly more chromosomal aberrations than the diploid cells in the same flask. This chance observation proves that the aberrant cell line has a selective advantage and thus may represent a first step in malignant transformation.

P07.33

Secondary acute myeloid leukemia after treatment for Neuroblastoma stage III. A Case Report.

M. Moschovi[1], *A. Athanasiadou*[1], *M. Adamaki*[1], *Y. P. Ktena*[1], *M. I. Rompola*[2], *A. Karytianou*[2], *A. Divane*[2];
[1]Hematology-Oncology Unit, First Department of Pediatrics National University of Athens, Aghia Sofia Children's Hospital, Athens, Greece, [2]"Life Code", Genetic Centre for Research and Diagnosis, Athens, Greece.

Introduction: Therapeutic advances in the treatment of pediatric neoplasms have improved the prognosis but increased the risk of developing second malignant neoplasms (SMNs). Acute myeloid leukemia (AML) is the most likely SMN to occur during the first 5 years following treatment.
Purpose: To describe the case of a pediatric patient with Neuroblastoma (NBL) stage III, who developed secondary AML at 4 years following cessation of treatment.
Material-Method: A 2,5-year-old boy was diagnosed with stage III NBL on the adrenal and received chemotherapy. No cytogenetic study to NBL was performed. The mass progressively decreased and 1 year later the follow-up was negative. Eight months after the cessation of treatment, a local relapse of NBL was revealed and treated with partial resection, radiotherapy and chemotherapy. One year later, a second local relapse was revealed and a total resectomy of the mass achieved complete remission.
Results: Four years following the cessation of treatment (eight years after NBL diagnosis), the patient was admitted with anaemia (Hb 7,3 gr/dl) and thrombocytopenia (PLTs 5000/μl). A secondary AML was diagnosed. FISH analysis revealed MLL rearrangement in 60% of the nuclei and cytogenetic analysis showed 46,XY,t(11;19)(q23;p13.3). The patient received chemotherapy according to AML-BFM-2004 protocol and MLL rearrangement was detected in 29.4% on the 15th day of treatment.
Conclusions: NBL is the most common solid tumors in childhood. However, little is known about the factors that determine the long-term risk of SMN following this type of cancer. The risk of AML was significantly increased after combined radiation and chemotherapy.

P07.34

T/C-FISH studies on telomere length of derivative chromosomes in HeLa cells

J. Döhla, E. Kornmann, ***B. Fritz****;*
Institut für Humangenetik, Marburg, Germany.

Telomeres play an essential role in preserving chromosomal integrity and genomic stability. To achive a better understanding of telomere length and its possible impact on development of chromosome aberrations, we analyzed the telomere length of the karyotypically well characterized HeLa cell line. HeLa cells have a hypertriploid chromosome number with specific numerical deviations and clonally abnormal chromosomes known as HeLa signature chromosomes. Karyotypic heterogenity is also present exhibiting 'shared' and 'unique' karyotypic alterations. To measure the telomere length of individual chromosomes we did sequential analysis of metaphase spreads using telomere/centromere fluorescence in situ hybridisation (T/C-FISH) as well as multi-colour-FISH (M-FISH) to identify the marker chromosomes unequivocally. In the present study, individual telomere length was highly heterogeneous. Telomere length was associated with both frequency and type of chromosomal aberrations. The telomere length of derivative chromosomes, which were present in almost all metaphases did not differ from the average telomere length. However, derivative chromosomes appearing only in few cells showed great variability in telomere length (0% up to +643%) compared to the average telomere length. Regarding the type of chromosome aberration small marker chromosomes and isochromosomes showed significantly longer telomeres than deletions and complex translocations.
Our results imply that recurrent aberrations have passed the point of short telomeres and high instability. Their telomeres may be stabilized and even increase in length possibly depending on the type of aberration.

P08.01

Tissue inhibitor of metalloproteinases-2 -418 G/C gene polymorphism and abdominal aortic aneurysm

J. Mikołajczyk-Stecyna[1], *A. Korcz*[1], *R. Słomski*[1], *M. Gabriel*[2], *K. Pawlaczyk*[3], *G. Oszkinis*[2];
[1]Institute of Human Genetics, Polish Academy of Sciences, Poznan, Poland, [2]2Department of Vascular Surgery, Poznan University of Medical Sciences, Poznan, Poland, [3]3Department of Hypertension, Internal Medicine, and Vascular Diseases, Poznan University of Medical Sciences, Poznan, Poland.

Objective and design. Pathogenesis of abdominal aortic aneurysm (AAA) is connected with abnormal extracellular matrix remodeling with the assistance of extracellular matrix metalloproteinases (MMPs). Tissue inhibitors of metalloproteinases (TIMPs) inhibit their activity. Any imbalance in the MMPs/TIMPs ratio may cause various disorders. A decrease of tissue inhibitor of metalloproteinases-2 (TIMP2) gene expression was detected in AAA patients. Recently, a -418 G/C (rs8179090) polimorphism of the TIMP2 gene promoter, influencing the transcription rate of the gene has been described. The aim of this study was to investigate whether -418 G/C gene polimorphism was associated with AAA in the Polish population.

Methods. TIMP2 gene promoter polymorphism was evaluated by polymerase chain reaction followed by restriction enzyme analysis and pyrosequencing in 128 patients affected with AAA and 180 individuals treated as references. The control group was directly matched to patients according to common risk factors of vascular diseases.

Results. The genotypes distribution was 17 CC, 5 CG, 106 GG in the 128 AAA cases and 12 CC, 0 CG, 168 GG in the 180 control subjects. The frequency of the C allele was significantly higher in the AAA patients than in the control group (P=.0005, OR=2.516). The distribution of genotypes also differed significantly between the studied groups (CC+CG vs. GG: P=.0037, OR=2.906) or was close to being significantly different (CC vs. GG+GC: P=.0501, OR=2.144).

Conclusion. This study supports the hypothesis that TIMP2 and -418G/C polymorphism located in promoter of TIMP2 gene are important in AAA pathophysiology.

P08.02

Analysis of polymorphisms in GABRA2 and AUTS2 genes in patients with alcoholism from Russia

G. Faskhutdinova, *A. Asadullin, E. Khusnutdinova;*
Institute of Biochemistry and Genetics Ufa Scientific Center of Russian Academy of Sciencies, Ufa, Russian Federation, Ufa, Russian Federation.

Family, twin and adoption studies have provided evidence of a genetic component (40-60%) in the origins of addictive disorders. One of very few confirmed genetic association findings differentiating alcoholics from non-alcoholics is with variants in the inhibitory gamma-amino butyric acid a2 receptor subunit (*GABRA2*) gene. Also according to the recent genome-wide association study variation in autism susceptibility candidate 2 gene (*AUTS2*) was strongly associated with alcohol consumption. Population stratification and ancestry differences within populations may compromise the success of association studies. Therefore analysis of genes variants in homogeneous ethnic groups is of great importance.

We designed a classical case-control association study for two polymorphisms: rs279858 in *GABRA2* and rs6943555 in *AUTS2* that were tested for association with alcoholism. 307 men with ICD-10 diagnosis of alcoholism (112 Russians, 91 Tatars, 100 Bashkirs), and matched control groups were typed for the above-mentioned gene variants using PCR-RFLP technique.

In Russian population the frequency of individuals carrying the **G* allele of rs279858 polymorphism was significantly higher in patients with early-onset alcoholism as compared with the healthy controls (p=0.03;OR=1.40). The carriers of *GABRA2*A/*A* genotype were found to be at low-risk of alcoholism development (p=0.04;OR=0,57). In Tatars the frequency of *AUTS2* rs6943555 **T* allele was higher in group of alcoholics with acute alcohol psychosis (0.74) as compared with controls (0.64). However observed differences were not statistically significant.

Our results suggest that *GABRA2* genetic variation might be involved in the development of alcoholism in Russians. This work was supported by Russian Foundation for Basic Research (#11-04-97032-r_povolzhye_a).

P08.03

Fine-mapping of the *PICALM* locus, CSF biomarker profile analysis and neurofibrillary pathology in a Flanders-Belgian Alzheimer cohort

C. Van Cauwenberghe[1,2], *K. Bettens*[1,2], *A. Sieben*[1,2,3], *S. Engelborghs*[2,4], *N. Le Bastard*[4], *R. Vandenberghe*[5], *P. De Deyn*[2], *J. Martin*[2], *C. Van Broeckhoven*[1,2], *K. Sleegers*[1,2];
[1]VIB Department of Molecular Genetics, Antwerp, Belgium, [2]Institute Born-Bunge, University of Antwerp, Antwerp, Belgium, [3]Department of Neurology, University Hospital Ghent and University of Ghent, Ghent, Belgium, [4]Department of Neurology and Memory Clinic, Hospital Network Antwerp Middelheim and Hoge Beuken, Antwerp, Belgium, [5]Department of Neurology, University Hospitals Leuven Gasthuisberg and University of Leuven, Leuven, Belgium.

Genome-wide association studies (GWAS) have identified significant genetic association of Alzheimer disease (AD) with genetic variations located 5' upstream of the gene *PICALM* gene. We used a high-density single nucleotide polymorphism (SNP) map of the *PICALM* locus in a Flanders-Belgian patient-control cohort and analyzed the effect of SNP genotypes on cerebrospinal fluid (CSF) biomarker profiles in AD patients. We additionaly investigated association with AD related neurofibrillary changes.

We have performed SNP genotyping in the PICALM locus in 1047 patients and 858 healthy control individuals. In addition CSF levels of β-amyloid peptide ($A\beta_{1-42}$), total tau protein (T-tau) and tau phosphorylated at threonine 181 ($P\text{-tau}_{181P}$) were available for 308 patients. Quantitative scoring of tau pathology was performed on immunohistochemical stained brain sections of autopsied AD patients. Our results show

two *PICALM* SNPs (SNP 2, SNP 4), both located in the 5' region, with nominal association with AD. Interestingly, SNP 4 showed borderline significance with T-tau in CSF of AD patients, while SNP 2 was significantly associated with $P\text{-tau}_{181P}$. No significant association could be identified for AD related neurofibrillary tau pathology, probably because of limited statistical power due to a small sample size (N = 24).

We were able to fine-map the GWAS *PICALM* association signal in the Flanders-Belgian cohort. Furthermore, this study strengthens the observation that genetic variations in *PICALM* affect AD risk and that these variations represent genuine AD susceptibility factors. Of specific interest, our study highlights a possible implication of *PICALM* in tau biology in AD.

P08.04

Association of Angiotensinogen M235T polymorphism in Tunisian patients with dilated cardiomyopathy

S. Mehri, *m. hammami;*
Laboratory of Nutrition and Vascular Health, Faculty of Medicine, monastir, Tunisia.

Background: Angiotensinogen (AGT) is a liver protein that interacts with renin to produce angiotensin I, the pro-hormone of angiotensin II (Ang II). The aim of this study was to determine the association of Angiotensinogen (M235T AGT) polymorphism with the risk of dilated cardiomyopathy in a Tunisian population.

Methods: A total of 73 patients with dilated cardiomyopathy was compared to 149 ethnically, age- and gender-matched controls.

Results: The frequencies of the TT genotype and T allele were significantly higher in patients as compared with controls, and were associated with increased risk of dilated cardiomyopathy (AGT TT versus MT and MM: OR = 4.1 (95% CI, 2.78-6.24; p = 0.018)); T versus M: OR = 1,3 (95% CI: 1.25-3.27; p = 0.008)). No association was found between the combined genotypes (TT+MT) or T allele and left ventricular end diastolic diameter in dilated cardiomyopathy patients with severe and moderate clinical phenotypes.

Conclusion: TTgenotype and T allele of Angiotensinogen (M235T) gene polymorphism are associated with increased risk of dilated cardiomyopathy in a Tunisian population but do not influence the cardiac phenotype severity

P08.05

Estimating the prevalence of TRIC gene mutations in 144 Iranian families with non-syndromic autosomal recessive hearing loss

M. Babanejad[1], *Z. Fattahi*[1], *N. Nikzat*[1], *N. Bazazzadegan*[1], *K. Kahrizi*[1], *R. J. Smith*[2], *H. Najmabadi*[1];
[1]Genetics Research Center , University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran, [2]2) Molecular Otolaryngology & Renal Research Laboratories, Department of Otolaryngology Head and Neck Surgery, University of Iowa, Iowa, IA, United States.

Hereditary hearing impairment is a genetically heterogeneous disorder, which affects about 1 in 1000 newborns. So far, over 90 loci and 40 genes have been mapped for autosomal recessive non-syndromic hearing loss (ARNSHL).

One of the loci related to ARNSHL, DFNB49, is located on the long arm of chromosome 5. The gene responsible for the hearing loss in this locus is *MARVELD2*, which encodes an essential protein called TRIC.

DFNB49 was first described in our neighboring country, Pakistan, and is estimated that approximately 1.06% of the causes of ARNSHL in this population, is due to *MARVELD2* gene mutations.

To determine the contribution of *MARVELD2* gene in Iranian deaf population, one hundred and forty four ARNSHL families with two or more affected individuals originated from different ethnic groups of Iran were chosen for the screening of this gene's mutations. Among these families, which were subjected to homozygosity mapping using flanking STR markers of *MARVELD2*, one family showed linkage to DFNB49. *TRIC* gene sequencing in this family led to the identification of a novel mutation (c.1543delA) in exon 6 which causes a premature stop codon [p. (Lys517ArgfsX16)].

According to our result, it is computed that 0.7% of families with ARNSHL in our country manifest hearing loss due to mutations in the *MARVELD2* gene and it shows the low contribution of this gene in Iranian population.

P08.06

MEFV gene mutations are associated with Behçet's Disease

A. Rüstemoğlu[1], *S. Yiğit*[1], *Ü. Gül*[2], *T. Taşlıyurt*[3], *Ö. Ateş*[1];
[1]*Gaziosmanpasa University, Medical Faculty, Department of Medical Biology, TOKAT, Turkey,* [2]*Ankara Numune Education and Research Hospital, Second Dermatology Clinic, ANKARA, Turkey,* [3]*Gaziosmanpasa University, Medical Faculty, Department of Internal Medicine, TOKAT, Turkey.*

Mutations in MEFV, the gene encoding pyrin, play majority role an autoinflammatory disease Familial Mediterranean Fever (FMF). Behçet's disease is a chronic inflammatory multisystemic disorder of unknown cause. In recent years, prevalence MEFV gene mutations in Behçet's disease (BD) has been reported significantly higher compared with general population. We were investigated prevalence of five MEFV gene mutations (M694V, M680I, V726A, E148Q and P369S) in BD patients and comparison with controls.

DNA samples were collected from 207 BD patients and 200 control subjects were used. MEFV gene mutations were detected by PCR-RFLP method. SPSS 16.0 Software was utilized to estimate OR and Chi-square tests.

All investigated mutations were detected higher in BD patients. But only two mutations, M680I and E148Q, were out of significantly higher than controls. Especially E148Q mutation found remarkable way higher in BD patients (14.49% in BD patients vs 4.50% in control; p=0.001; OR, 3.60; 95% CI, 1.66-7.77). This mutation contains approximately 35% of the observed total mutations in BD patients. Additionally, total mutation rate was detected higher in BD patients (p=0.00001; OR, 2.74; 95% CI, 1.75-4.29). On the other hand, compound heterozygosites were found higher in BD patients than controls (2.90% vs 0.50%), but statistically significant not found (p>0.05).

Our study showed that, MEFV gene mutations associated with BD. Especially E148Q and M680I mutations may play a role in BD susceptibility.

Breast Cancer Risk Assessment in a High Risk Cohort: Which covariates are associated with differential model performance?

A. S. Quante[1,2], *A. S. Whittemore*[3], *T. Shriver*[4], *J. Flom*[4], *M. Terry*[4,5];
[1]*Institut für Genetische Epidemiologie, Helmholtz Zentrum München, Neuherberg, Germany,* [2]*IBE, Ludwig-Maximilians-Universität München, München, Germany,* [3]*Department of Health Research and Policy, Stanford University School of Medicine, Stanford, CA, United States,* [4]*Mailman School of Public Health, Columbia University, New York, NY, United States,* [5]*Herbert Irving Comprehensive Cancer Center, Columbia Medical Center, New York, NY, United States.*

Background: Clinical prediction models estimating lifetime risk of breast cancer vary widely in their estimates. There is a need to communicate to the medical community this variation and reasons for the differences.

Methods: Using a NYC cohort (N=1,857 women) we evaluated the model performance between two prediction models including non-genetic and genetic risk factors (BCRAT and IBIS), by assessing accuracy through the Hosmer-Lemeshow goodness of fit statistic and discrimination by the area-under-the-receiver-operating (AUC) characteristic curve. We assessed differential model performance (accuracy and discrimination) in subgroups defined by broad covariates.

Results: We observed substantial difference between the two models in estimating lifetime-risk: IBIS was better calibrated and showed greater discrimination than BCRAT. Additionally we compared the discrimination and accuracy of the two models for covariate specific subgroups. The observed/ predicted ratio was better for IBIS than for BCRAT for all subgroups except those defined by race. In addition, IBIS was better than BCRAT in identifying women who went on to develop cancer except for the subgroup of women with at least one breast biopsy.

Conclusion: There is a need for a single accurate model that performs well for all women. In our cohort, we found that overall prediction was better in IBIS for almost all covariate-specific subgroups of women, including women who were not gene carriers and who had a more limited family history. Thus, enhancing existing models such as IBIS with additional risk factors (number of biopsies and race/ ethnicity) may further improve the performance.

Classic bladder exstrophy (CBE) is part of the bladder exstrophy and epispadias complex (BEEC), a spectrum of urogenital anomalies in which part or all of the distal urinary tract fails to close. Birth prevalence, including terminated pregnancies, has been estimated to be 1 in 37 000. Isolated BEEC is assumed to be multifactorial involving both genetic and environmental factors.

For the purpose of a genome-wide association study (GWAS) 127 CBE patients of Central European ancestry were genotyped using Illumina's Beadchips and compared to 525 ethnically matched population based controls. After standard Quality Control (QC) procedures the data set was subjected to imputing based on 1000 Genomes Project reference panels. After applying post-imputation QC, single marker analysis was conducted using a logistic regression (additive model). Our analysis yielded promising results, including a genome-wide significant finding ($P = 4.55 \times 10^{-8}$) for a SNP near the *SALL1* gene. Interestingly, mutations in *SALL1* have been reported to cause Townes-Brocks syndrome, a rare genetic disease with (among others) anorectal and urogenital/renal malformations. Currently, replication of the top associated SNPs (n=88) is been carried out in additional 200 cases and ethnically matched controls (n=500).

Our data provide the first GWAS for CBE patients in a reasonable large cohort with this rare malformation. While our top finding *SALL1* represents an excellent candidate for urogenital malformations, further studies are warranted to verify these findings.

Catechol-O-methyltransferase Val158Met polymorphism and uterine leiomyoma

O. Ates[1], *F. Demirturk*[2], *M. Toprak*[2], *S. Sezer*[1], *S. Yigit*[1];
[1]*Gaziosmanpasa University Medical Faculty Department of Medical Biology, Tokat, Turkey,* [2]*Gaziosmanpasa University Medical Faculty Department of Obstetrics and Gynecology, Tokat, Turkey.*

Uterine leiomyoma (ULM) is the most common gynecological benign tumors that affecting around 20% to %50 of women over age of 30 years. Although their molecular pathogenesis is still unknown, ULM has a multifactorial etiology determined by both genetics and environmental factors. The present study was designed to find out whether Val158Met polymorphism in the Catechol-O-methyltransferase (COMT) gene are associated with the risk of ULM.

We analyzed COMT Val158Met polymorphism in 105 ULMs patients and 105 healthy subjects by using polymerase chain reaction (PCR)-based restriction fragment length polymorphism (RFLP) assay. We found remarkably similar frequencies in ULM compared with controls for COMT Val158Met genotypes and alleles, and no association was found between ULM and this polymorphism (p=0.482). COMT 158 Met allele in patients with large (≥5 cm) fibroids was higher than in patients with small (<2 cm) fibroids, and significant association was found between fibroid size and COMT 158 Met allele (p=0.021 O.R 0.54 95%CI 0.30- 0.97).

Our results reflect that COMT Val158Met polymorphism is not associated with increased risk of ULMs but Val158Met polymorphism may be risk factor for development of large fibroids in Turkish patients with ULM.

Relationship between cytokine gene polymorphisms and graft-versus-host disease after allogeneic stem cell transplantation in an Iranian population

M. R. Noori-Daloii[1], *N. Jalilian*[1], *P. Izadi*[1], *M. Sobhani*[1], *Z. Rabii Gilani*[1], *M. S. Yekaninejad*[2];
[1]*Department of Medical Genetics, School of Medicine, Tehran University of Medical Sciences,, Tehran, Islamic Republic of Iran,* [2]*Department of Biostatics, School of Public Health, Tehran University of Medical Sciences,, Tehran, Islamic Republic of Iran.*

Despite advances in post-transplant immunosuppressive strategies GVHD is a major complication of allogeneic HSCT, leading to serious morbidity and mortality. In this retrospective, case-control investigation, 91 subjects were recruited, including Iranian patients and their HLA matched siblings.
