Marine Ecology Progress Series 592: 19-35 (2018)

Fig. S1. Acoustic transects (n = 6) collected between 2010 and 2014 along the transit between New Zealand and the Southern Ocean by fishing vessel Janas.

Fig. S2. Acoustic transects (n = 11) collected between 2008 and 2014 along the transit between New Zealand and the Southern Ocean by fishing vessel San Aotea II.

Fig. S3. Acoustic transects (n = 5) collected between 2010 and 2013 along the transit between New Zealand and the Southern Ocean by fishing vessel San Aspiring.

Fig. S4. Acoustic transects (n = 6) collected between 2008 and 2013 along the transit between New Zealand and the Southern Ocean by research vessel Tangaroa.

Acoustic transects split into three latitudinal regions to assist descriptive analysis. Regions were split to remove bottom depth effects on acoustic backscatter east and southeast of New Zealand, and overcome data limitation in the southernmost end of the area of study.

Fig. S5. Transects split into three latitudinal regions for spatial and temporal analysis: Northern region (dark yellow); Central region (red); Southern region (green).

Acoustic transect exemplifying the north-south decrease in acoustic backscatter.

Fig. S6. Distribution of vertically summed acoustic backscatter (s_a) in m² km⁻² per bin, collected at 38 kHz along the transit between the Southern Ocean (right) and New Zealand (SO-NZ) (left). Transect JAN 2014 SO-NZ. Bubbles represent 1 km bins.

Fig. S7. Transect mean acoustic backscatter ($m^2 km^{-2}$) in the epi- (a) and mesopelagic (b) zones in the central region. Shown in chronological order (see transect collection dates in Table S1) by vessel: Janas (orange), San Aotea II (green), San Aspiring (blue) and Tangaroa (black). Whiskers represent two times the standard error of the mean, and the red line transects mean s_a (Epipelagic = 2.5 and mesopelagic = 10.1 m² km⁻²).

Bootstrapping statistical tests

Fig. S8. Distribution of mean acoustic backscatter (s_a in $m^2 \text{ km}^{-2}$) in the central region by day and night (a and d), spring and summer (b and e), and epi- and mesopelagic (c and f), generated by bootstrapping with 95% confidence intervals.

Fig. S9. Distribution of mean acoustic backscatter (s_a in $m^2 \text{ km}^{-2}$) in the central region during the day and night in the epipelagic zone (a and c respectively), and mesopelagic (b and d respectively), generated by bootstrapping with 95% confidence intervals.

Vertical distribution of volume backscattering strength

Fig. S10. Summary of vertical distribution (between the surface and 1200 metres) of volume backscattering strength (S_v in dB) in the Central region by vessel and chronological order. Red line indicates day (between sunrise and sunset), and blue line indicates night (between sunset and sunrise). Dotted grey lines indicate the 90th confidence intervals (t-student, 0.90). Panels correspond to individual transects.

Cubic smoothing spline fitted to vertical distribution of volume backscattering by day, night and season

Fig. S11. Cubic splines smoothers fitted (CSS) to spring day vertical distribution (at 10 m resolution) of mean volume backscattering strength (S_v in dB) along the 38 kHz transects in the Central region. The grouping of the transects followed a subjective assessment of the shape of the CSS fitted to the backscatter profile.

Fig. S12. Cubic splines smoothers fitted (CSS) to spring night vertical distribution of mean volume backscattering strength (S_v in dB) (at 10 m resolution) along the 38 kHz transects in the Central region. The grouping of the transects followed a subjective assessment of the shape of the CSS fitted to the backscatter profile.

Fig. S13. Cubic splines smoothers (CSS) fitted to summer day vertical distribution of mean volume backscattering strength (S_v in dB) (at 10 m resolution) along the 38 kHz transects in the Central region. The grouping of the transects followed a subjective assessment of the shape of the CSS fitted to the backscatter profile.

Fig. S14. Cubic splines smoothers (CSS) fitted to summer night vertical distribution of mean volume backscattering strength (S_v in dB) (at 10 m resolution) along the 38 kHz transects in the Central region. The grouping of the transects followed a subjective assessment of the shape of the CSS fitted to the backscatter profile.

Boosted regression trees

Fig. S15. Relationship between the cubic-transformed mean s_a and temperature (cars_t_meso, from regional hydrographic climatologies using the CSIRO Atlas of Regional Seas (CARS)) fitted by the boosted regression trees in the mesopelagic zone. Grey lines represent 95% confidence intervals. Focal_rac_vect_brt = residual autocorrelation covariate used in BRT for accounting for spatial autocorrelation.

Migration of organisms into the mesopelagic zone from deeper waters

Fig. S16. Echogram of transects collected by vessels San Aspiring (SAS) in 2011 between New Zealand (NZ) and the Southern Ocean (SO) showing evidence of potential migration of organisms from deeper zones into and out of the mesopelagic zone. Each pixel represents mean volume backscattering strength (S_v) in decibels (dB) echo-integrated in 1 km long and 10 m depth bins. Echogram threshold -84 dB.

Table S1. Summary of the final set of transects analysed, including frequency used for its collection, the total number of bins (size = 1 km), date of start and end of data collection, mean acoustic backscatter (s_a), standard deviation (std. dev.), mean s_a in the epi and mesopelagic zones, and total s_a in m² km⁻² (as the sum of all the bins vertically summed s_a), per transect. Vessels name key: JAN – Janas, SAO – San Aotea II, SAS – San Aspiring, and TAN – Tangaroa. The start and end location of the acoustic transect is also indicated in the transect name: NZ – New Zealand, and SO – Southern Ocean.
