INTRODUCTION

The vast majority of cultivated bananas originate from two wild species, *Musa acuminata* and *Musa balbisiana*, either directly or in various hybrid combinations (Simmonds 1995). While farmers domesticated bananas by selecting plants that were sterile and seedless, the fertile ones continued propagating, hybridizing amongst themselves and consequently creating further diversity. These wild relatives are found primarily in tropical regions, from India to Polynesia. The center of diversity is thought to be either Malaysia or Indonesia (Daniells *et al.* 2001). Unfortunately, there is little information about the accurate geographic distribution of each *Musa* section (Australimusa, Callimusa, Eumusa and Rhodochlamys). The traditionally accepted boundaries of each *Musa* section established by Champion (1967) (Figure 1) will have to be revised due to the presence of Callimusa in China (Liu *et al.* 2002) and of Australimusa in Borneo (Hotta 1967).

Figure 1. Distribution of *Musa* sections (Champion 1967, adapted by Guinard 2003).

Many researchers around the world, especially in Asia, have assembled germplasm collections. These can be found in field collections and consist mainly of cultivars from within the country, and to a lesser extent, of indigenous wild species. Wild species are underrepresented in collections for several reasons. Some missions did not collect any plants and only made observations (Argent 1976). Others brought back vegetal material that eventually withered away. For example, the suckers of *Musa ingens* and *Musa boman* collected at the end of the 80s in Papua New Guinea did not adapt to the place where they had been transplanted (S. Sharrock personal communication). Fortunately, the people in charge of collecting missions wrote reports that were sometimes published in scientific journals.

The purpose of this work was to initiate a bibliography on wild *Musa* species and analyse the information (new species, distribution, ecogeographic data, etc.) related to them for integration into the *Musa* Germplasm Information System (MGIS). This database already contains over 5000 records of accessions held in 16 collections throughout the world. It contains passport data and complementary information such as photographs, morphological characteristics, geographical information. Since data from the literature have not been included in the MGIS database, this report will give a number of recommendations regarding the future entry of this kind of data and its transfer to DIVA-GIS. This software produces maps and can be used to show the geographical distribution of *Musaceae* in a country, a province and even a region, thus helping researchers decide where to organize future collecting missions. Finally the report will try to identify sources of interesting metadata (cultivation intensity, deforestation, soil degradation, etc.) that can be downloaded for the use with DIVA-GIS.

METHODS

The first step was to build a bibliographic database (see Appendix C) using *Musalit*, *Agricola*, CAB-abstracts, Current Contents[®] and Internet websites. All the documents and articles discussing the distribution of wild *Musa* species in Southeast Asia were consulted as potential sources of information. Unfortunately some of the documents and articles ordered through documentation services were not received. In the end, only the articles published after the original grouping of the *Musa* genus into four sections by Cheesman (1947) and those that listed exact geographical data, like longitude and latitude, or a precise description of the site (village, valley, national park etc.), were selected. Only fifteen articles (see Appendix B) were retained for incorporation into the MGIS database (version 2.1). All the site coordinates were validated by a query in the GEOnet Names Server (GNS) (<http://gnswww.nima.mil/geonames/GNS/index.jsp>). Since this is a pilot project, all data were recorded on a single machine, not on the network, to avoid any corruption or loss of entries in the original MGIS database.

Since it was originally conceived to hold only the data given by curators of germplasm collections, and not data from the scientific literature, the MGIS software had to be adapted for this new purpose. First, the wild species and their specific locations listed in the literature were entered in a newly created a file named <LITERATURE>. Each of them was given an accession number that consisted of the code of the collection (LIT) followed by a four-digit serial number starting at 0001 to allow wild species to be treated in the same way as an accession in a collection. To record them, we used the “New accession” function in the “Accession” menu. This opened the “Passport data” window in which information like the scientific name and the status of the plants was entered (Table 1).

Table 1. MGIS data entry fields used under < New Accession >

Field	Description
Accession code	Unique code identifying the accession. Generated automatically. Three-letter code (LIT) followed by a four-digit serial number.
Name of species	Scientific name of the accession.
International code	A three-digit number that refers to the international classification at five levels (genus, section, species, sub-species, type or form). If a level is unknown, the number will be 500 and above.
Status of the plant	Type of plant. For this report, it will always indicate "wild".
Acquisition	It is mandatory to enter the previous location: Collecting mission.
Books	Bibliographical references about the articles.
Notes	Notes about the species (synonym, typical or atypical species, etc.)

The geographical data about collecting sites, like country, altitude and longitude, (Table 2), were logged in MGIS using "Collecting sites" in the "Accession" menu. When the "Find Collecting Sites" window was displayed, < LIT > was selected in the collection field. We clicked on the button "Creation" to make the "Collecting sites" window appear. A new code (LTx-xx) was assigned in the "Collecting number" field. The letters LT specify that the data come from the literature. They were followed by a number to identify the article and by the number attributed to each wild species mentioned in the scientific article. Other information can be recorded in the "Collecting sites" window (Table 2).

Table 2. MGIS data entry fields in "Collecting sites"

Field	Description
Collecting number	Code attributed to the wild species in the article or document
Province	Province of the collecting or observation site
Department	Department of the collecting or observation site
Location of the collecting site	Village, river, valley near the collecting or observation site
Location	Geographical situation. This specifies: Country of the collecting or observation site. Latitude and longitude of the site in DDMMC. Altitude in meters.
Destination	Specify the place where the sample was sent after having being collected.
Notes about the collecting site	Additional notes concerning the collecting site (agricultural area, allopathic or sympatric population etc.)

The "Passport Data" and "Collecting Site" fields from the accessions in the < LIT > collection were extracted from MGIS using a SQL query. The new file generated a dBase-IV file (.DBF) compatible with DIVA-GIS. Data from some collections were also extracted from MGIS: Queensland Department of Primary Industries of South Johnstone in Australia (SJR), Indonesian Research Institute for Fruits (RIF), South China University (SCU) and Vietnamese Pho Ho Fruit Crop Research Center (PHU). These collections were chosen because they contain a significant number of wild species as well as accurate coordinates of the collecting sites. The DBF file served in DIVA-GIS to

draw maps (Table 3). The ability of this software to serve this function was demonstrated in a previous report (Guinard *et al.* 2002b).

To visualize the extracted data in DIVA-GIS (version 2.5), a new Diva file was started from “New” in the “File” menu. The DBF file was converted into a shapefile (.SHP) using “Point to Shapefile” in the “Data” menu. The points obtained were superimposed over a map of Asia and also over maps of various Asian countries. Unless otherwise noted, each point represents a plant collected or observed. This map, as well as the administrative boundaries of 15 Asian countries (Bangladesh, Brunei, Bhutan, Burma (Myanmar), Cambodia, China, India, Indonesia, Japan, Laos, Nepal, Philippines, Papua New Guinea, Thailand and Viet-Nam), were downloaded from the DIVA-GIS website (<http://www.diva-gis.org/data/DataServer.htm>). The maps of Australia, Samoa and Sri Lanka are from ESRI website (<http://www.esri.com/data/download/basemap/index.html>).

For each map containing accessions, the command “Select records” with the variable “Section” under the “Theme” menu was used to distinguish each section of the *Musaceae*. The selected points were separated in a new shapefile using the “Selection to Shapefile” function under the “Data” menu. Wild species were represented as follows: a red cross for *Australimusa*, a pale blue square for *Callimusa*, a yellow circle for *Eumusa*, a green triangle for *Rhodochlamys*, a black circle for *Ingentimusa* or unclassified species, and a combination of forms for an hybrid (i.e. a yellow triangle for *Eumusa* x *Rhodochlamys* hybrid) using the function “Symbol” in the “Theme” menu. The location of each point was verified against the data in XXX_ADM2.SHP (XXX is the three letters code identifying a country) using “Check Coordinates” in the “Data” menu.

Table 3. Type of information entered in DIVA-GIS.

Column title	MGIS field	Column title	MGIS field
IDNUM	Internal code	SIT_LAT	Latitude
GENUS	-----	SIT_LGT	Longitude
SECTION	-----	SIT_ALT	Elevation
NAME	Scientific names	PVC_STAT	Province
ITNCOD	International code	DEP_CTRY	Department
TYPE	Status of plant	LOCATION	Location of the collecting site
ACC_NOTE	Notes about species	SIT_NOTE	Notes about the collecting site
COL_NUMB	Collecting number	DEST	Where the plants have been sent
COL_CTRY	Country	BIBLIO	Bibliography

RESULTS

The DBF file created contains 363 lines that correspond to 291 accessions that come from <LIT> and the rest from the germplasm collections mentioned above. The *Ensete* genus is present in the MGIS database but was not included for visualization with DIVA-GIS. Appendix D contains an edited DBF files of all the accessions. Unfortunately not every country situated in the traditionally accepted boundaries of the *Musaceae* distribution has data about of the wild species. The name of all the *Musaceae* listed in this report are in Appendix A.

Australia

Two varieties of wild bananas are native to Australia; both grow in the northern part of Queensland. The most common is *M. acuminata* ssp. *banksii* (Eumusa), which is found from Ingham to the tip of Cape York (Daniels 1991). The second, *Musa jackeyi* (Australimusa), has been reported only by Bellenden Ker and Cooktown (Daniels 1991) and the World Conservation Monitoring Center (WCMC) (<http://www.unep-wcmc.org/index.html>) considers it rare. Argent (1976) writes that this species most likely belongs within the *Musa maclayi* complex (Australimusa). The Flora of Australia (1987) mentions a third species: *Musa fitzalanii* (Australimusa) but specifies that it is known only from a type sampled in the 19th century near the Daintree River and being kept in a herbarium in Queensland.

However, we chose a single collecting mission by Simmonds (1956b) because he was the only one to give a precise description of the observation sites (Figure 2). His banana expedition reported five areas of *M. acuminata* ssp. *banksii* on the coast of Queensland, which is the wettest part of Australia (Simmonds 1956a). With his team, Simmonds searched in vain for *M. fitzalanii* along the Daintree River. He suggests that this species may well be extinct. On its website, the WCMC draws the same conclusion about *M. fitzalanii*.

Figure 2. Distribution of *Musa* sections in Australia (data from Simmonds 1956b).

Bangladesh

No map was produced due to the lack of information about the distribution of wild species in this country. According to Champion (1967), Bangladesh lies within the borders delineating the natural habitat of the Rhodochlamys and Eumusa sections. *Musa ornata* and *Musa rosea*, both from the Rhodochlamys section, have been recorded in Bangladesh (Häkkinen 2002). It is possible that three Eumusa live there, *M. balbisiana*, *Musa sikkimensis* and *Musa flaviflora*, since the three of them grow in the Indian province of Meghalaya (see the appropriate section below), which borders Bangladesh.

Bhutan

Three wild species - their botanical names listed as *Musa* ssp - grow in Bhutan's sub-tropical and temperate regions up to 1800 metres (Rinchen 2003). However, from Nortie's Flora of Bhutan quoted by Constantine (1999), the following Eumusa species are present: *M. balbisiana*, *M. flaviflora* and *M. sikkimensis*. Also from a single gathering, *Musa thomsonii* (Eumusa) and a new species with no description tentatively named *Musa griersonii* have been observed.

Brunei

This small country is part of the island of Borneo. Previous banana expeditions on this island surveyed mainly Sarawak and Sabah, two provinces of Malaysia. However, a few collecting missions were made in Brunei. Hotta (1967) observed species from the Callimusa and Australimusa sections. He found out that *Musa textilis* (Australimusa) grows in Brunei, as well as a new species, *Musa tuberculata* (Australimusa). His discoveries extended the boundary of the Australimusa section which, according to Champion, stops in the Philippines. Hotta also described a new Callimusa named *Musa flavida* and recorded the presence of two populations of *Musa campestris*, one in the province of Temburong and the other in the province of Tutong (Figure 3).

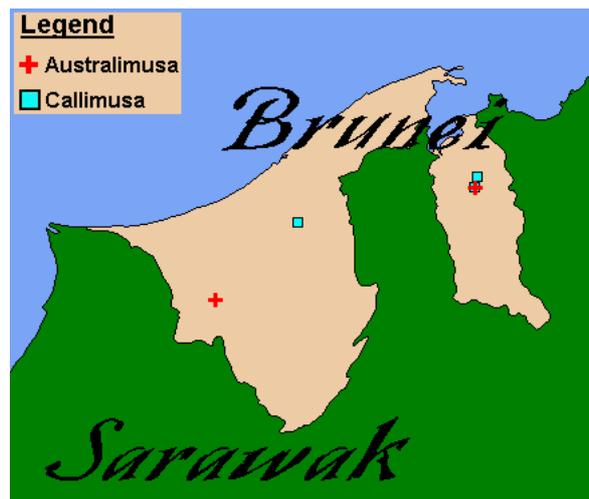

Figure 3. Distribution of *Musa* sections in Brunei (data from Hotta 1967).

More recently, Häkkinen (2003) made an exhaustive study of the section Callimusa. The author describes five varieties of *M. campestris* located in five different areas of the island of Borneo. Two of them, *M. campestris* var. *lawasensis* and *M. campestris* var. *limbangensis*, are partially located on the territory of Brunei (Figure 4).

Figure 4: Distribution of *M. campestris* var. *lawasensis* and *M. campestris* var. *limbangensis* in Brunei (adapted from Häkkinen 2003).

Myanmar (Burma)

This country has not been properly explored in the last decades, mainly because of the political situation. In the 50s, Simmonds (1956b) gave up on making field studies in this country for this reason. Like Bangladesh, Myanmar is the natural habitat for some *Rhodochlamys* species: *M. ornata*, *M. rosea*, *Musa laterita* and *Musa sanguinea* were all reported a century ago (Häkkinen 2002). Since some *Eumusa* species (*M. acuminata* ssp. *siamea*, *Musa itinerans*, *Musa nagensium* and *M. sikkimensis*) are found in Thailand and in China (see the appropriate section below), close to the border with Burma, it is likely that the same species grows there too.

Cambodia

Like Bangladesh and Myanmar, Cambodia is still waiting to be properly explored. The few available data are almost 100 years old. They come from the description of *Musa angcorensis* by Gagnepain (1907). According to the author, this species belonged to the *Rhodochlamys* section but later Simmonds (1960) referred to it as a *Callimusa*. It still awaits a modern description. Since Cambodia is situated at the center of *Callimusa* and *Eumusa* distribution, it is very likely that more species grow in this country.

China

A collecting mission of the South China University, sponsored by INIBAP, explored the provinces of Yunnan, Guangxi, Guangdong and the island of Hainan in 1997. The results of this expedition are stored in the MGIS database under the code SCU, with collecting numbers ranging from CHN1 to CHN4. More than 98 accessions are recorded, but only 17 concern wild species. Unfortunately, some of them contain errors. Three accessions were given a longitude and latitude that put them outside of China's boundaries (Table 4). Those mistakes were corrected by using new geographical coordinates based on the location of the nearest town listed in the collecting mission report.

Table 4. Corrections to the MGIS data points that fell outside China

IDNUM	COL_NUMB	COL_CTRY	PVC_STAT	DEP_CTRY	LOCATION	SIT_LAT	SIT_LGT	New_Lat	New_Long
SCU0004	CHN1-03	China	Yunnan	Hakou	Nanxi	22,5	104	22,63	103,93
SCU0016	CHN1-04	China	Yunnan	Hekou	Hekou	22,5	104	22,52	103,97
SCU0038	CHN4-29	China	Hainan	-----	Lingshui	18,1	110	18,5	110,02

Furthermore, 8 of the 17 wild species were located in the right provinces but in the wrong departments. For example, according to MGIS, SCU0011 lies in the department of Napo but the latitude and longitude from the database show that it is in the department of Malipo (Table 5). Unlike what happened for the errors of table 4, the location of the nearest town did not help clear up the matter. For this reason, the map shows only the provinces, not the departments.

Table 5. Wild accessions listed in the wrong department

IDNUM	COL_NUMB	Are located in	Should be located in	PVC_STAT	LOCATION	SIT_LAT	SIT_LGT
SCU0011	CHN2-05	Malipo	Napo	Guangxi	Bainan	23,08	106
SCU0013	CHN2-13	Malipo	Napo	Guangxi	Pinmao 10 Km	23,08	106
SCU0037	CHN4-18	Dan Xian	Qiongzong	Hainan	Songtao	19,3	109,58
SCU0049	CHN3-24	Huaxian	Guangzhou	Guangdong	Lufu Park	23,6	113,28
SCU0082	CHN2-04	Malipo	Napo	Guangxi	Pinmao	23,1	106
SCU0083	CHN2-01	Longzhou	Pingxiang	Guangxi	Pingxiang, Baiyun	22,25	106,75
SCU0084	CHN2-09	Malipo	Napo	Guangxi	Guilian village	23,08	106
SCU0088	CHN2-02	Longzhou	Pingxiang	Guangxi	Pingxiang	22,25	106,75

Despite those errors, useful data can be retrieved from this collecting mission (Figure 5). The researchers collected:

- Three species from the Eumusa section : *M. balbisiana*, *Musa basjoo* and *M. itinerans*
- One species from the Callimusa section : *Musa coccinea*
- One species from the Rhodochlamys section : *M. sanguinea*

Figure 5. Distribution of *Musa* sections in China.

Another source of information on China was an article recently published. It reported an expedition that studied the distribution of wild *Musa* species in China based on field observations, a literature review and herbarium research (Liu *et al.* 2002). Unfortunately, the researchers did not give any geographical coordinates but drew a map of the *Musaceae* distribution (Figure 6). This field survey found some of the same species as the collecting mission described above, along with a new species, *Musa paracoccinea* (Callimusa).

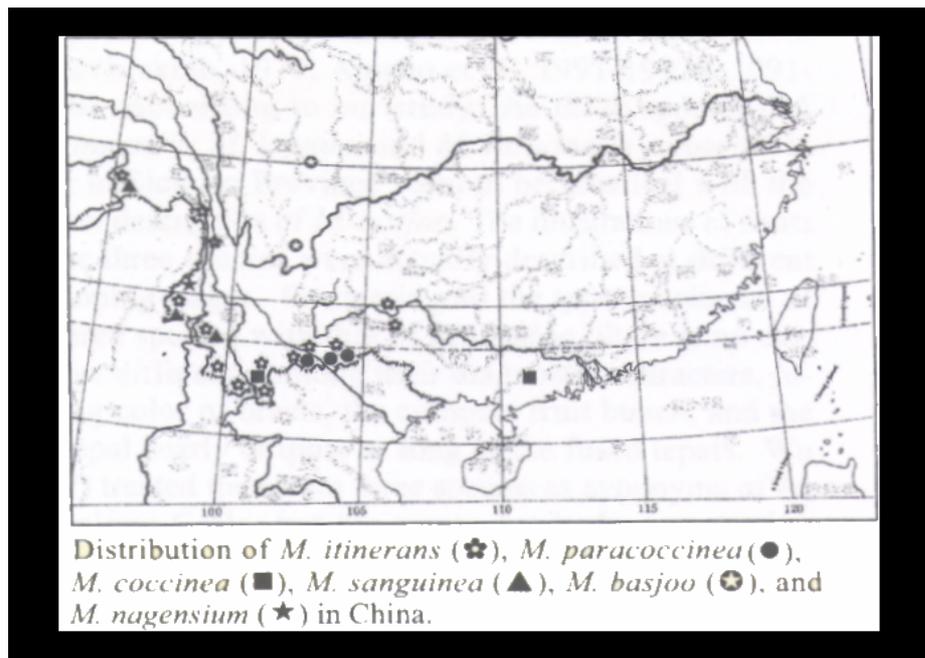

Figure 6. Distribution of *Musa* sections in China (Liu *et al.* 2002).

From the analysis of both maps, the following conclusion can be drawn: *M. balbisiana* and *M. itinerans* enjoy a wide distribution in China, from the island of Hainan to the province of Xizang Zizhiqu (Tibet). *M. basjoo* can be found as far as in the Sichuan province, which makes it the most septentrional species listed in this report. Liu (2002) writes that the previously described *Musa dechangensis*, *Musa luteola* and *Musa lushanensis* are all synonyms of *M. basjoo*. He adds that *M. basjoo* is now widely cultivated in China, while the wild populations appear to occur only in Sichuan. As for *M. nagensium*, it is grown only in the western parts of the Yunnan province. On Champion's map (Figure 1), the presence of *Callimusa* in China seems to be something new but it was not. A description from the Curtis Botanical Magazine, published in 1813, reports *M. coccinea* in Yunnan. In the past this species had a wide distribution, but human activity made it rare and it has become difficult to locate populations (Liu *et al.* 2002). As for the new species *M. paracoccinea* (*Callimusa*), it was observed in southeastern Yunnan. *M. sanguinea* (*Rhodochlamys*), about which we know almost nothing, was found in the evergreen forest of western Yunnan.

India

Recent explorations conducted by the National Research Centre of Banana in India (NRCB) led to the identification of several accessions (Uma 1999). The reports indicate species spotted in northeastern India: *M. balbisiana*, *M. itinerans*, *M. nagensium*, *M. sikkimensis* and *Musa cheesmani*. A study on the variability of *M. acuminata* revealed six subspecies, of which three were listed without any geographical data (*M. acuminata ssp. burmannica*, *M. acuminata ssp. burmannicoides* and *M. acuminata ssp. malaccensis*). The NRCB confirmed the existence of *Rhodochlamys* in Assam: *M. ornata* and an unidentified species. Unfortunately, almost all of the varieties listed in the annexes of the report are of landraces, not wild species.

Figure 7. Distribution of *Musa* sections in India.

An early exploration made by Simmonds (1956b) gives accurate information on the distribution of wild species in India (Figure 7). The researcher observed five *Eumusa* species: *M. itinerans* (not to be found in MGIS because of inaccurate location), *M. balbisiana*, *M. flaviflora*, *M. sikkimensis* and *M. cheesmani*. No pure *Rhodochlamys* population was reported, but Simmonds found a *M. flaviflora* × *Musa velutina* population in a small area of Assam. Two-thirds were constituted by apparently pure *M. flaviflora* and the remaining third, by an hybrid population. The absence of pure *M. velutina* is probably due to a dry season dieback, *Rhodochlamys* are more severely affected by rain shortfall than *Eumusa* (Simmonds 1956b). An interesting fact is the presence in Khasi Hill (at an altitude of over 1000 m) of *M. balbisiana*, which is generally distributed at low altitude throughout northeastern India (Simmonds 1956a).

Indonesia

Indonesia is the world's largest archipelago. Its major islands or island groups are Sumatra, Java, Kalimantan (Borneo), Sulawesi (Celebes), Papua (the western half of Papua New Guinea formerly known as Irian Jaya) and the Moluccas, a group of smaller islands. Indonesia is situated in the center of origin of *Musaceae* and has a large number of wild bananas growing throughout the country (Figure 8).

Since MGIS only uses degrees (DD) and minutes (MM) to indicate longitude and latitude, but not the seconds (SS), the banana accessions shown on the map are within 1 minute of their actual growing place. Sometimes it means that accessions are not in the right province (LIT 113-115-121) while others end up in water (LIT 123-130). But for RIF 198-199-200, this is another matter. These last three were 05DD from land. This error was due to the fact that 00DD05MM had been entered as 05DD00MM in MGIS and was easily corrected.

Almost 66% of the accessions come from Nasution's (1991) study of *M. acuminata*. He identified fifteen varieties of *M. acuminata*, 33% of them being described for the first time (Table 6). Only four are found in the *Musalogue* (Daniells *et al.* 2001) and are listed as subspecies and not varieties. Some of Nasution's observations were not entered in MGIS because of insufficient geographical data. For this reason, no entry is available in MGIS for Kalimantan (Borneo), although the expedition recorded wild species on all major islands. In this province, both *M. acuminata* ssp. *microcarpa* and *M. acuminata* ssp. *flava* were observed but they constitute the same species according to De Langhe *et al.* (2003). In spite of that, the variability of *M. acuminata* is important and far above the number of *M. acuminata* reported in neighbouring countries. Most *M. acuminata* described by Nasution are confined to Indonesia's lowland, except *M. acuminata* ssp. *halabanensis* and *M. acuminata* ssp. *malaccensis*, which also grow on mountains (Nasution 1991).

Table 6. *M. acuminata* varieties listed in Nasution's study.

#	Species	Status	#	Species	Status
1	<i>Musa acuminata</i> spp. <i>acuminata</i>	Not in Musalogue	9	<i>Musa acuminata</i> var. <i>malaccensis</i>	In Musalogue
2	<i>Musa acuminata</i> var. <i>alasensis</i>	New	10	<i>Musa acuminata</i> var. <i>microcarpa</i>	In Musalogue
3	<i>Musa acuminata</i> var. <i>bantamensis</i>	New	11	<i>Musa acuminata</i> var. <i>nakaii</i>	New
4	<i>Musa acuminata</i> var. <i>breviformis</i>	New	12	<i>Musa acuminata</i> var. <i>rutilifes</i>	Not in Musalogue
5	<i>Musa acuminata</i> var. <i>cerifera</i>	Not in Musalogue	13	<i>Musa acuminata</i> var. <i>sumatrana</i>	Not in Musalogue

8	<i>Musa acuminata</i> var. <i>longepetiolata</i>	New	--	----	----

Other botanical excursions (different from those mentioned in table 6) have spotted *Eumusa* in Indonesia. *Musa schizocarpa* and *M. acuminata* ssp. *banksii* have been collected by Allen at the beginning of the sixties (Rosales *et al.* 1999). The Indonesian Research Institute for Fruits (RIF) – where of the 76 accessions listed only eight were wild species - reported the same wild *Musa* as Allen in Papua. The RIF and the Allen collecting mission also observed species from the *Callimusa* and *Australimusa* sections. According to Allen, *M. textilis* and *Musa lolodensis* respectively grow in the Moluccas and in Papua. Recently, a researcher described a new *Australimusa* species in southwestern Papua, in the Timika area (Argent 2001). This species, *Musa johnsii*, grows at high altitude, above 1000 m. Argent writes that other *Musaceae* have rooted around the Timika area: *M. lolodensis* and *M. acuminata* ssp. *banksii*. As for the *Callimusa* section, *M. coccinea* grows on the island of Java (Rosales *et al.* 1999) and the presence *Musa salaccensis* (native to Java) has been reported in Sumatra and Java (Nasution 1993). The latter has not been uploaded in MGIS because the geographical information about it is limited to the islands. Häkkinen (2003) also reported the presence of *Musa hirta* and *M. campestris* var. *sarawakenis* near the border of Sarawak.

Figure 8. Distribution of *Musa* sections in Indonesia.

Japan

Only one species is known to grow in Japan. *M. basjoo* is found in southern Japan, in the Ryukyu Islands. Turner (2002) listed it as a native species whereas Liu (2002) argues that it was introduced from China. Its actual origin requires further investigation. A subspecies of *M. basjoo* is said to grow in Sakhalin, much further north than the Ryukyus Islands (Turner 2002). It seems unlikely that the species occurs this far north.

Laos

Like all the countries between China and Malaysia, Laos has been poorly explored for its *Musaceae* diversity. We might expect *M. acuminata* ssp. *siamea* to grow in the western part of the country, since it does in the Thai province of Nan, which borders it (Figure 13). In the north, Laos also shares a border with the Chinese province of Yunnan, where *M. itinerans* and *M. coccinea* are found (Figures 5 and 6). *M. balbisiana*, a species present in western Vietnam, is also thought to grow in Laos (Figure 14).

Malaysia

One part of this country is a peninsula attached to the Asian continent. The other part consists of two provinces (Sarawak and Sabah) on the northern coast of Borneo. Malaysia has been explored many times compared to other countries. This report has 68 accessions coming from eight articles.

Figure 9. Distribution of *Musa* sections in Malaysia.

The map shows that all the *Musaceae* sections are present in Malaysia, contrary to Champion who did not report any *Australimusa* or *Rhodochlamys* (Figure 9). *M. ornate*, which belongs to the latter section, has been observed in the Lagud Seberang Agricultural Park in Sabah. However, it is not native to Borneo Island and it is cultivated in this park as an ornamental. Simmonds (1956b) did mention a new *Rhodochlamys* species from northern Borneo that has characteristics between *Musa rubra* and *M. laterita*, but according to Häkkinen (personal communication), Simmonds based his

conclusion on herbarium samples from Singapore that turned out to be *Musa campestris*. Unfortunately no more information on this matter has been found. A non-continental *Rhodochlamys* other than the cultivated one has still to be recorded. As for *Australimusa*, two new species have been reported outside the range of the park. *Musa monticola* (Argent 2000) and *Musa muluensis* (Hotta 1967) respectively observed in Sabah and Sarawak, extending the range of the *Australimusa* section.

The *Eumusa* section is well represented in Malaysia, especially on the peninsula. The expeditions of Simmonds and Allen have found four subspecies of *M. acuminata* (*malaccensis*, *microcarpa*, *siamea* and *truncata*) most of them on the western side of the country. In the province of Sabah and Sarawak, only *M. acuminata* ssp. *microcarpa* has been reported in various places (Simmonds 1956b, Rosales *et al.* 1999, De Langhe *et al.* 2003). The presence of the *microcarpa* subspecies outside Borneo is currently being revised. De Langhe *et al.* (2003), citing Sheppard (1999), say that *M. acuminata* ssp. *microcarpa* is confined to Borneo and that *M. acuminata* ssp. *truncata* is typical of the Malayan Highlands. The possible presence of the subspecies *microcarpa* in northern Borneo contrasts with what was found in other parts of Southeast Asia, such as peninsular Malaysia, Sumatra and Java, where two or more subspecies seem to be sympatric (De Langhe *et al.* 2003). This fact is based on cytogenetics studies. An interesting fact about Allen's records of *M. acuminata* is that they contain information on Sigatoka resistance and 14 of the 17 resistant varieties recorded were situated in peninsular Malaysia. Previous work made at INIBAP (Guinard 2002b) suggests that climatic and environmental factors could explain this phenomenon.

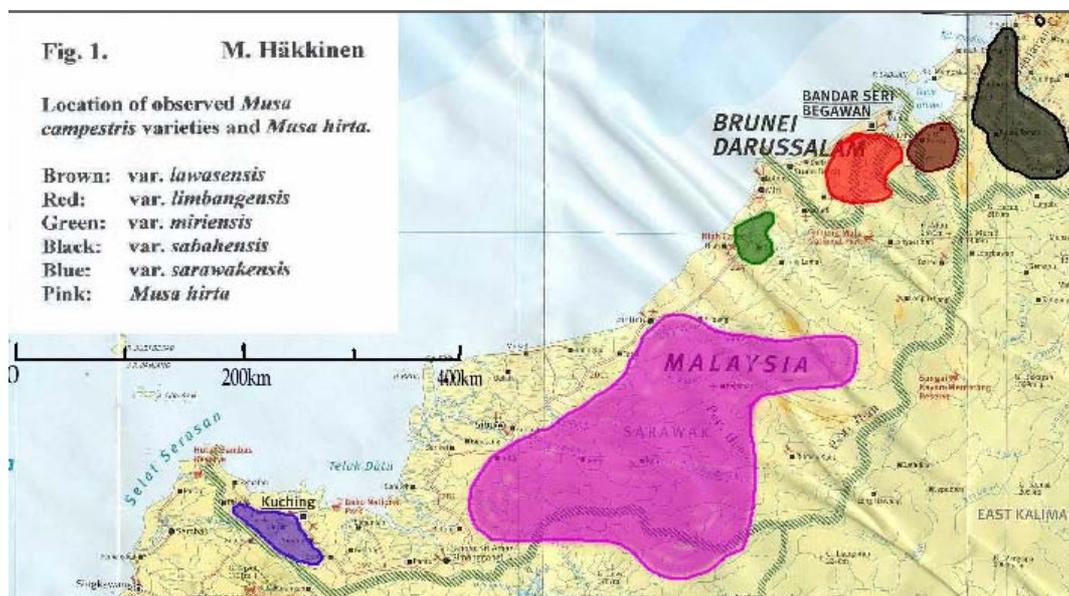

Figure 10. Observations of *M. campestris* subspecies and *M. hirta* (Häkkinen 2003).

With the recent expedition of Häkkinen in Borneo, we now have a better understanding of the diversity of the *Callimusa* section on this island (Figure 10). In the past, Hotta (1967) had reported the presence of *M. campestris* and *M. hirta*, but he had explored only small areas and could not evaluate the entire diversity of the section. Häkkinen (2003) observed *M. hirta* and five subspecies of

M. campestris mainly distributed in Sarawak (Figure 9). He also discovered a new species of Callimusa, *Musa bauensis* in the Bau limesonte area (Häkkinen and Meekiong 2003). Another new species is also being described (Häkkinen personal communication).

Two Callimusa species different from those in Borneo are found in peninsular Malaysia. They are *Musa gracilis* and *Musa violascens*. Both were observed by the Simmonds expedition in the 50s. Interestingly, the distribution of *M. violascens* is limited to the western part of the peninsula, while *M. gracilis* is found on the east side. No hybrid populations, where the two species overlap, was reported.

Finally, a new species was described by Argent (2000) as an intermediate between Australimusa and Callimusa. It was named *M. suratii* and one population was found in Sarawak and another in Sabah. The latter is rapidly shrinking as the forest is regrowing. The validity of this species should be investigated. If it belongs to the Australimusa section, it would be the most eastern native species of this section.

Papua New Guinea

With 158 accessions, this country is the best represented in this report. Many important collecting missions have been made in Papua New Guinea: Simmonds (1956b), Argent (1976), Allen in the 60s (Rosales *et al.* 1999) and finally the IBPGR project at the end of the 80s (Sharrock 1989). From the latter, 243 accessions (39 wild species) are recorded in MGIS under “Queensland Department of Primary Industries of South Johnstone in Australia” (SJR). The wild species belong to two of the four sections of the genus *Musa* (Table 7). The sections Callimusa and Rhodochlamys are not represented. Nine Australimusa, four Eumusa and one *Ingentimusa* have been observed on the main island or the smaller ones located in the eastern part of the country (e. g. Bougainville, New Britain, New Ireland.).

Unfortunately, the administrative boundaries of Papua New Guinea do not include divisions in provinces and/or departments. Moreover, 22 accessions end up in the water. Part of the problem is because MGIS uses only degrees (DD) and minutes (MM) to indicate longitude and latitude, and do not specify the seconds (SS), which means that the accessions end up within 1 minute from their true location. However, it is intriguing that a large number of points fell outside the country, given that it did not happen elsewhere on such a scale. One possibility is that the shapefile for Papua New Guinea is inaccurate. Another mistake involves MGIS. *M. boman* is listed as being in the Eumusa section, whereas Argent (1976) classified it as an Australimusa and *Musalogue* (Daniells *et al.* 1999) as an *Incertae sedis*. For the purpose of this report, MGIS was not corrected, but the DBF files used in DIVA-GIS was updated and *M. boman* is now under Australimusa. To determine in which section this species should be included, a chromosome count is currently being done. The same procedure was done with *M. ingens*, which is under *Ingentimusa*. Finally SJR0090 (PNG066) and SJR0138 (PNG176) are listed as landraces in the database, but are actually wild species (*M. acuminata* ssp. *banksii*). SJR0034 and SJR0059 both have the same collecting number (PNG220).

Table 7. Australimusa and Eumusa species found in Papua New Guinea

Section	Name	Section	Name
Australimusa	<i>M. boman</i>	Australimusa	<i>M. peekelii</i> ssp. <i>angustigemma</i>
Australimusa	<i>M. bukensis</i>	Australimusa	<i>M. peekelii</i> ssp. <i>peekelii</i>
Australimusa	<i>M. lolodensis</i>	Eumusa	<i>M. acuminata</i> ssp. <i>banksii</i>
Australimusa	<i>M. maclayi</i> ssp. <i>ailuluai</i>	Eumusa	<i>M. acuminata</i> ssp. <i>banksii</i> x <i>M. schizocarpa</i>
Australimusa	<i>M. maclayi</i> ssp. <i>maclayi</i> var. <i>erecta</i>	Eumusa	<i>M. balbisiana</i>
Australimusa	<i>M. maclayi</i> ssp. <i>maclayi</i> var. <i>maclayi</i>	Eumusa	<i>M. schizocarpa</i>
Australimusa	<i>M. maclayi</i> ssp. <i>maclayi</i> var. <i>namatani</i>	Ingentimusa	<i>M. ingens</i>

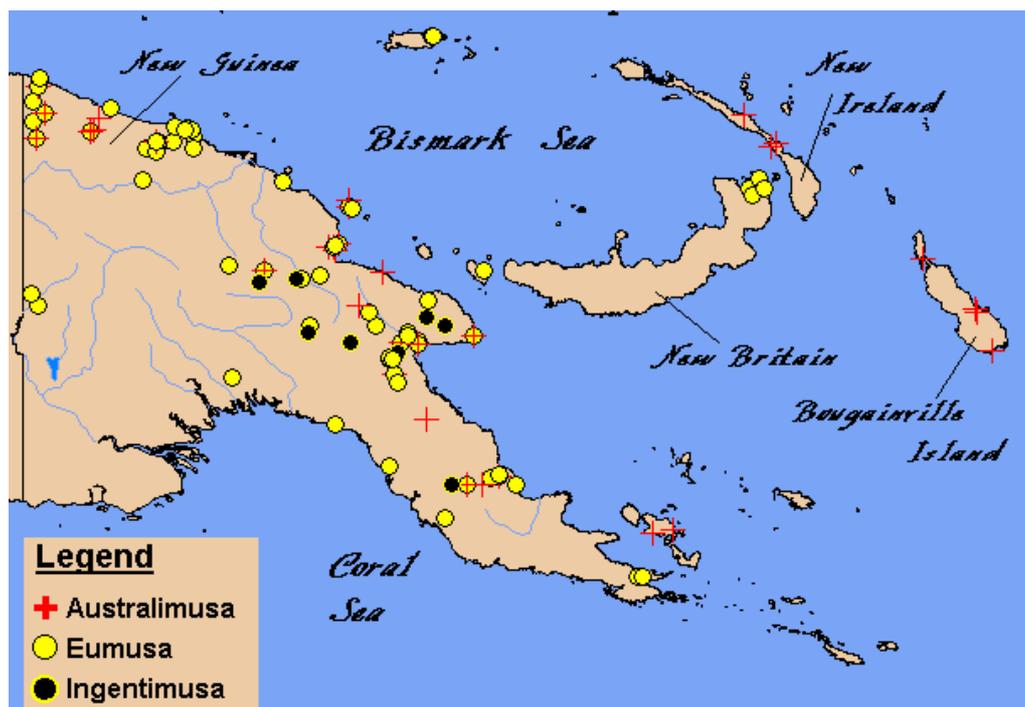

Figure 11. Distribution of *Musa* sections in Papua New Guinea.

Among the three *Eumusa* species, *M. acuminata* ssp. *banksii* is the most widespread in New Guinea (Argent 1976). Just as on the island of Borneo, there is the exclusive presence of an *acuminata* subspecies. The IBPGR even found it on Manus Island. This variety also enjoys the highest number of records in this report. *M. schizocarpa* is also widely distributed, even on the smaller eastern islands of New Guinea, but it is less common than the *acuminata* subspecies. Hybrids between the two *Eumusa* are known to occur (Argent 1976). Another species, *M. balbisiana*, is not as widely distributed and well adapted as the two other indigenous *Eumusa* (Sharrock 1988). The IBPGR expedition found it only in New Britain and in Oro Bay, on the main island, although they also searched the same province (Morobe) as Simmonds and Argent, who both observed the species in Markham Valley and/or the Wau/Bulolo Area (Sharrock 1988). Even in New Britain this species is growing rare, noted the IBPGR collecting mission. Whereas Simmonds (1956b) considers it native to PNG, Argent (1976) suggests that it may have been introduced as a wild species or as a primitive cultivar that later reverted to a wild type.

Papua New Guinea can boast of being the Asia-Pacific country with the greatest diversity of Australimusa. Nine species or subspecies of this section grow on the main island as well as on the smaller ones in the east. Their distribution pattern is clear. *M. boman* and *M. lolodensis* are found on the north-western part of Papua New Guinea. *M. peekelii* ssp. *angustigemma* seems to be limited to the province of Madang and the Eastern Highlands, while *M. maclayi* ssp. *maclayi* var. *maclayi* prefers the southern region, more precisely the Lae province. The other Australimusa varieties seem to grow only on the eastern islands: *M. maclayi* ssp. *maclayi* var. *namatani* in New Britain and New Ireland, *M. peekelii* ssp. *peekelii* in New Ireland, *M. maclayi* ssp. *maclayi* var. *erecta* and *M. bukensis* in Bougainville. These observations are based on the results of the collecting missions of Argent and the IBPGR.

Finally, *M. ingens* is common in the Eastern Highlands. This species does not belong to any of the four sections of *Musaceae*, because of its different number of chromosomes, which is $2n=14$ (Callimusa and Australimusa are $2n=20$, while *Musa* and *Rhodochlamys* are $2n=22$). A new section, *Ingentimusa*, has been created for this species; sometimes it is also included in the *Incertas sedis*. *M. ingens* is described as the world's largest herb of any type and its altitudinal range is from 1000 to 2100 m (Argent 1976).

Philippines

People from the Philippines cultivate bananas for their fibre as well as for their fruit. For ages, they have used the so-called "Manila hemp" to produce marine cordage whereas this type of hemp derives from the sheaths of abacá plants, *M. textilis*, an Australimusa (Simmonds 1995). There are a number of varieties of abaca (Valmayor *et al.* 2002). Unfortunately, none of the collecting missions mentioned in this report observed wild *M. textilis*. Constantine (1999) quoted Mabberley as opining that "*M. textilis* is a cultigen, meaning that it is a plant found only in cultivation or escaped from cultivation". However in a book on the wild bananas of the Philippines, a map of the Bikol peninsula shows the presence and natural habitat of *M. textilis* (Valmayor *et al.* 2002). The latter is not the only wild species found in the Philippines. Another Australimusa has been recently described: *Musa alinsanaya*. This indigeneous species was formerly mistaken for *M. textilis* (Valmayor 2001). On the Palawan island, the presence of *M. peekelii* was also reported (Valmayor *et al.* 2002), but the subspecies was not indicated. Species of the Eumusa section also grow in the country, such as *M. balbisiana* recorded by Allen in the 60s. A new subspecies of *M. acuminata* has been described and named *M. acuminata* ssp. *Errans*. It had previously been associated with the subspecies *banksii*, but detailed characterization revealed major differences (Valmayor 2001). It became necessary to reclassify it. In spite of all this information, the Philippines still wait to be explored in depth. Only a few observations have been made in Luzon and Mindanao, and none in the Visayas Islands (Figure 12).

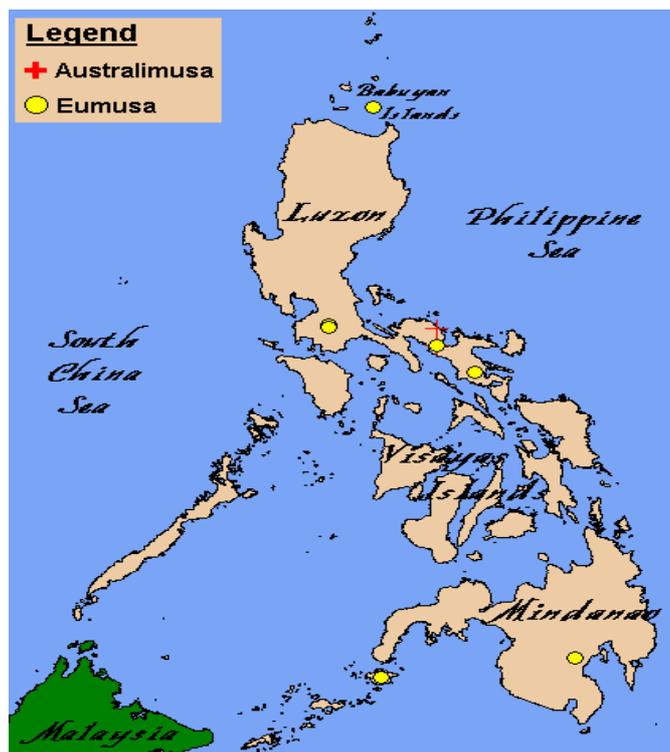

Figure 12. Distribution of *Musa* sections in the Philippines

Samoa

This country consists of two islands: Upolu and Savaii. Simmonds (1956b) made an expedition there and found that *M. acuminata* ssp. *banksii* was common. Specimens were collected on both islands. Unfortunately, the map is not shown because some accessions were in the water and it was not possible to locate and correct the source of this error.

Sri Lanka

The only information on wild species in Sri Lanka come from an IPGRI newsletter made in 1999. It mentions the existence of two wild species: *M. acuminata* and *M. balbisiana*. The subspecies of *acuminata* is not specified, but Constantine (1999) lists *M. acuminata* ssp. *burmannica* as present on this island.

Thailand

After Simmonds' (1956b) study of Thailand's wild species, no collecting mission and botanical study were carried out until De Langhe (2000). Both researchers explored the wilderness of northern Thailand and found two sections: Eumusa and Rhodochlamys (Figure 13). The former was represented by five species, while only one species was attested for the latter. A surprising fact is that Silayoi (1990) is the only one to have reported the presence of Callimusa in Thailand, even if this country lies at the center of diversity of this section. However he did not specify the species and the location.

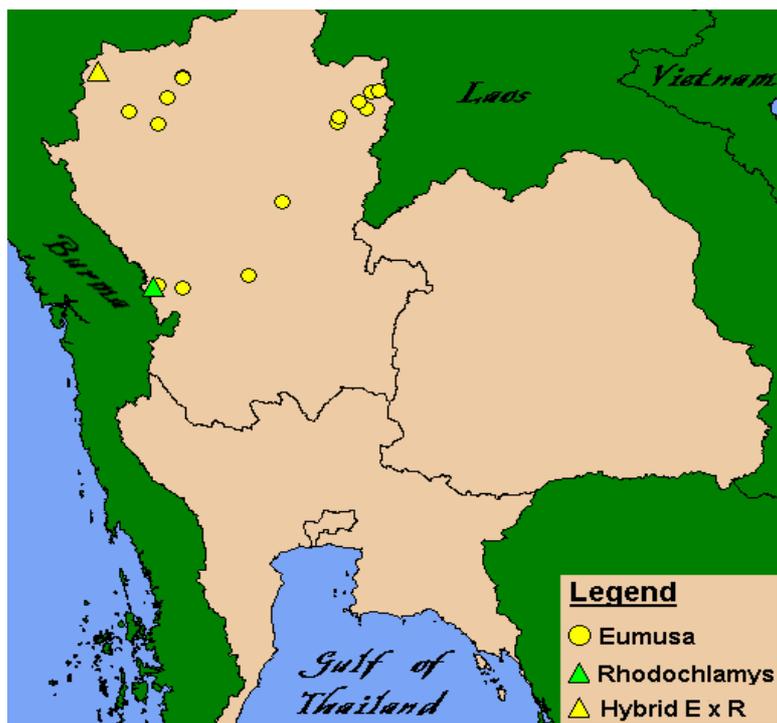

Figure 13. Distribution of *Musa* sections in Thailand.

M. acuminata ssp. *siamea* and *M. itinerans* have the largest distribution in the province. De Langhe noted that the subspecies *siamea* exists in two forms: one that is close to type and an atypical one. A specimen that looked very much like *M. acuminata* ssp. *malaccensis*, except for a few characters, was also recorded. It was tentatively named as a *pseudo-malaccensis* (De Langhe 2000). *M. nagensium* was observed by Simmonds (1956b) close to the borders of Burma. Despite active research, De Langhe (2003) could not find any traces of this species during his expedition. As for *M. sikkimensis*, it grows mainly in the northwestern part of the province. Unlike Simmonds (1956b), De Langhe (2000) gives it a putative status. If this accession is confirmed as *M. sikkimensis*, this species would enjoy a relatively large distribution (from the northwest of India to western Thailand). Finally, De Langhe (2000) found a population of wild *M. balbisiana*, although this species is more often observed in cultivated fields. Silayoi (1990) mentions that four subspecies of *M. acuminata* are found in Thailand, they are *malaccensis*, *microcarpa*, *siamea* and *burmannica* and their distribution is wide spread.

Only one species of *Rhodochlamys* was collected in Thailand, near the Burma border. De Langhe (2000) identified it as *M. laterita*, but his specimen was poor. However, a *Rhodochlamys* x *Eumusa* hybrid with a morphological *M. laterita* dominance was described. The *Eumusa* parent is probably *M. acuminata* ssp. *siamea*, since several plants of this species were growing nearby (De Langue 2000). Simmonds (1956b) also reports the existence of an undetermined *Rhodochlamys* hybrid with *Eumusa*.

Vietnam

Many of the accessions in the MGIS database come from the Vietnamese Pho Ho Fruit Crop Research Center (PHU). But given that the classification of the wild species is incomplete, it remains difficult to get a clear picture of which species grow in this country (Figure 14). Moreover, some accessions indicate an erroneous geographical situation. Five of the eight wild species were located in the right provinces, but in the wrong department (Table 8). This confusion could be due to the fact that the ADM Vietnam names were not spelled as suggested by the US Board on Geographic Names (GNS website). The same problem occurred with another country (see China). This time, the location of the nearest town did not clear up the matter. For this reason, the map shows only the provinces where bananas grow, not the departments. Another important mistake has found its way into MGIS. In the collecting site window under “Department/County”, the name Vietnam was entered and not the actual department, which was logged under “Location of the collecting site”. Someone probably confused the word “county” with “country”.

Table 8. Wild accessions of Vietnam listed in the wrong department.

IDNUM	COL_NUMB	SIT_LAT	SIT_LGT	Are located in	Should be located in	PVC_STAT	LOCATION
PHU0066	27	18,91	105,31	Do Luong	Tan Ky	Nghe An	
PHU0068	26	18,91	105,31	Do Luong	Anh Son	Nghe An	
PHU0071	54	21,45	105,23	Phong Chau	Doan Hung	Vinh Phu	
PHU0072	129	10,76	105,13	Chau Doc	Tinh Bien	An Giang	
PHU0075	155	18,91	105,31	Do Luong	Tan Ky	Nghe An	

An article published in the *InfoMusa* gives reliable information on the species observed in Vietnam (Danh *et al.* 1998). Unfortunately, it does not supply any accurate geographical data. During these five prospecting missions, which explored 30 of the 43 vietnamese provinces, two wild species were widely encountered growing side by side, *M. balbisiana* and *M. itinerans*. *M. acuminata* (subspecies not defined) and *M. coccinea* were observed in South Vietnam. A *Rhodochlamys* species was also found in gardens surrounding the temples, a domesticated plant cultivated for its ornamental value. This mission also yielded unidentified and undescribed species. One of them is *M. exotica* (*Callimusa*), which has been described by Valmayor (2001).

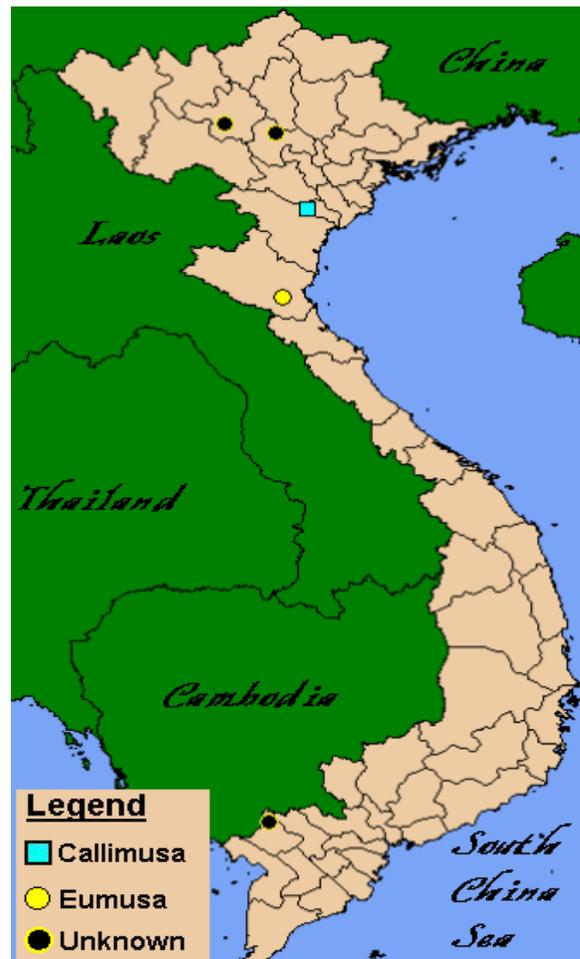

Figure 14. Distribution of *Musa* sections in Vietnam.

DISCUSSION

Recording information on wild species in MGIS

Quality control regarding the accuracy of data entry has already been reviewed in a previous report (Guinard 2003a). Consequently, this work will only formulate recommendations about how the information on wild species should be integrated to the database.

MGIS has proved to be an adequate tool to record data from literature. We only have to make some minor adjustments to the database. Firstly, a "Literature" menu should be created in the title bar. The passport data (Figure 15) has to be different from the one employed for the germplasm collection. The field "Status of the plant", being of no use, can be replaced by another one asking for the "Type of survey": observation only, collecting mission or other. A "Collector's name" field can be created to replace the "Curator's name" field. The action buttons "Notes", "Photos" and "Books" are useful and should stay, although the latter could be renamed "References". The "Acquisition" field remains useful as wild species can be collected. However, the new window onto which it opens should have more options to classify "The type of material received". In this field, terms like "flowers" or "leaves" could be added, since herbariums sometimes make collecting missions. On the

other hand, it would be wise to remove the “Hybrid” action button and replace it by “Synonyms” for the sometimes numerous names employed to designate a wild species. The “Location” button, to enter the location of an accession in the collection, should be replaced by a button that would open the collecting site window.

Figure 15. Current MGIS “Passport Data” window.

The collecting site window (Figure 16) is almost perfect. From it, it is already possible to enter ecogeographic data about the specific location of a species, where it was observed or collected. However, the action button “Situation”, which opens the “Geographical situation” window, should be updated. Latitude and longitude should include not only degrees and minutes, but also seconds. The location of a wild species specimen or population would then be more accurate. In the “Elevation” field, it would be better if it were possible to enter a range (i.e. 50 – 100 m) in addition to a discrete value. The “Destination” action button should stay because it shows whether the sample was treated during the mission, and then, the place to which the wild species was sent. The “Notes” action button is also very useful. It could be used to record more information about the population. For example, how many specimens are there in the population? Is the population allopatric (species growing in geographically isolated areas) or sympatric (two or more species growing in the same area or in areas that overlap)?

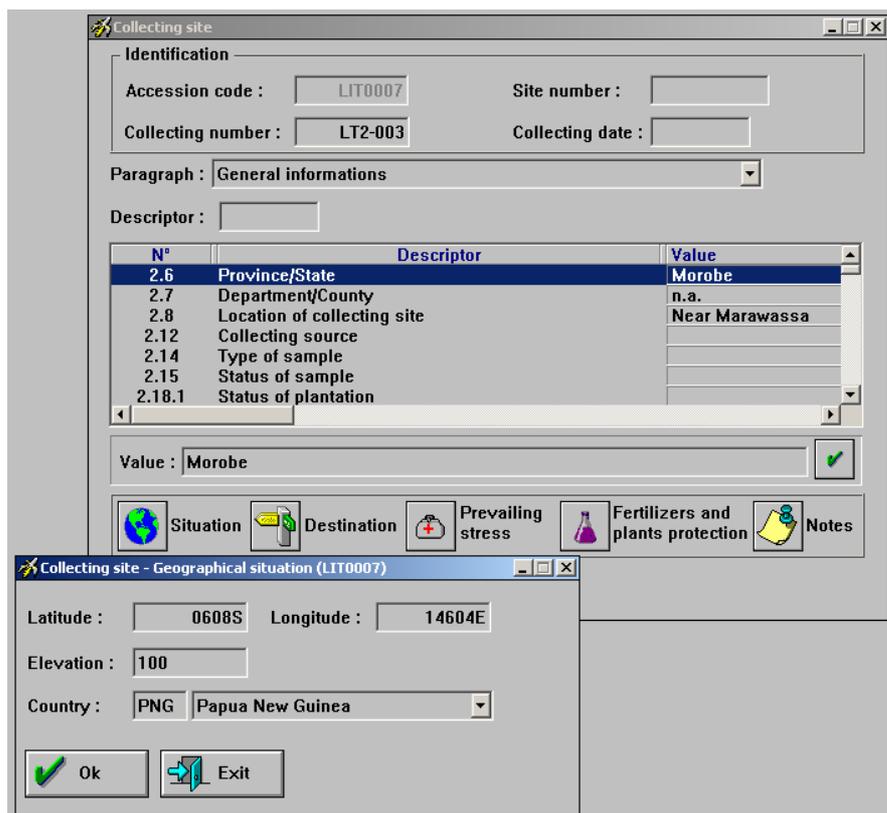

Figure 16. Current MGIS “Collecting Site” window.

Analysing *Musa* diversity using DIVA-GIS

The efficiency of this geographic information system has been analysed in a previous report (Guinard 2003b). Nonetheless, DIVA-GIS can be further exploited by using metadata. While studying climatic data sets, Guinard (2003b) found that wild *Musa* grow best where the average temperature is between 20 to 27°C and precipitations between 1300 to 4000 mm. We had less success in collecting additional data of interest, like cultivation intensity, soil degradation and deforestation. The reasons for this are various. For example, the Asia Pacific Spatial Data Project, an academic and applied research institution specializing in GIS databases for Asia, offers spatial data sets but these are licensed and sometimes cost over 1000 \$US. The GEO Data Portal, an online database, holds more than 400 geospatial data sets on freshwater, agriculture, health, forests, disasters and others. A potentially interesting data set about cultivation intensity was downloaded from this website but it was more than 10 years old. Moreover, the file format was not compatible with DIVA-GIS.

On the website of the Australian Center for International Agricultural Research an interesting document titled “Mapping Land Resource Potential and Agricultural Pressure in Papua New Guinea” (Hanson *et al.* 2001). On the website, only the report was available and not the shapefile, but it is possible to buy it from the center. Another possible interesting metadata for future integration in DIVA-GIS is the 2003 version of the World Database of Protected Areas (WDPA) CD-ROM. It has been prepared on behalf of the WDPA Consortium by the Center for Applied Biodiversity Science (CABS).

Data from Collecting missions

With GPS technology more accessible than ever, future collecting missions should use this tool to record the latitude and the longitude of a population. Accurate geographical data will facilitate mapping will help improve analysis with DIVA-GIS. In the last chapter of this report, we mentioned that some wild species observed or collected could not be added to MGIS because of insufficient information on their location. Since the collecting missions made 50, 30 or even 15 years ago did not have access to GPS technology, it is understandable that they could not always list accurate locations. Future expeditions should do everything in their power to avoid confusion. If they do not possess a GPS, they should record the exact locality in the following manner: XX km from XYZ village in the X direction (Moss and Guarino 1995). They should also explain how the site can be reached and describe its surroundings, if necessary. Recent collecting missions using a GPS, like the ones to northern Borneo (Häkkinen 2003) and Thailand (De Langhe 2000), did use a GPS and reported accurate locations. However, others (see the sections on China and Vietnam) had problems even when they used a GPS. In the future, field researchers would be well advised to enter their GPS data directly into a computer. Data editing would be easier and more secure and it would reduce the risk of making mistakes while entering the data. The subchapter on Papua New Guinea provides a good example of how this sort of errors can occur. In one instance, a person typed 0500 to indicate zero degrees and five minutes.

Collecting missions should record more ecogeographic data, especially since MGIS was originally conceived to store this type of information. An ecogeographic study is defined as a process of gathering and synthesizing taxonomic, geographic and ecological data (Maxted *et al.* 1995). The results can be used to assist future collecting missions and to set conservation priorities. Maxted and his collaborators are a good example of an ecogeographical study of annual legumes in Syria. They present a detailed analysis of the climatic and soil characteristics that influence the distribution of annual legumes in the country. They suggest that species diversity and seed production are related to annual rainfall and that populations in drier areas face a greater threat of genetic erosion. Based on their analysis of the ecogeographic data, they propose a detailed list of conservation priority (Maxted *et al.* 1995). Albeit very interesting, this kind of study may be difficult to realize on wild banana species, especially if the goal of the expedition is to get suckers, because those can only be stored for a limited time after collecting, especially if the conditions are hot and humid (Sharrock 1995). To overcome this problem, the collecting work should be carried out in a series of short missions. However, to gather taxonomic, geographic and ecological data takes so much time that it might prove incompatible with collecting suckers. More people could take part in the operation, but this would cost more money. Another solution is to collect wild species as seeds rather than suckers. Seed samples are easier to carry and store during collecting missions (Sharrock 1995).

Wild species status

Only Indonesia, Malaysia and Papua-New Guinea can boast of having near or over 50 records in the virtual "Literature" collection of MGIS. Australia, China, India, the Philippines, Thailand and

Vietnam all have around or fewer than 20. The situation is slowly improving due to the collecting missions that were undertaken recently. Bangladesh, Burma (Myanmar), Laos and Cambodia have no records at all. Moreover, all the information on wild *Musa* diversity in these countries is very old. One of the articles about the *Musaceae* in Cambodia dates back to the beginning of the 20th century. Much is to be expected when Burma (Myanmar) and its neighbours (Bangladesh, Cambodia and Laos) get properly explored, since all these countries lie within the center of diversity of the genus *Musa*. Unfortunately, the political situation prevailing in some of these countries makes it difficult and even dangerous to work there.

If some countries are underexplored, some sections of the *Musaceae* are also not well known. This is the case for *Rhodochlamys*. A recent review article (Häkkinen and Sharrock 2002) was largely based on descriptions made in the 19th and early 20th centuries. Even if the article had given up-to-date information, this section would still be poorly known. Only four records are found in the “literature” collection. Another species with few records is *M. balbisiana*; only 31, compared to 147 for *M. acuminata*. Of them, only 14 come from observations made in countries other than Papua New Guinea. Recently, 79 different wild *M. balbisiana* were collected in the Philippines and 45 in India (Anonymous 2003), but none of this data has yet been entered in MGIS. Collectors should publish their works more often or contact INIBAP for collaboration. INIBAP would then know about the countries or provinces being surveyed and eventually recommend regions that need to be sampled. In the case of *M. balbisiana*, even if the results in India and in the Philippines are encouraging, the diversity of this species does not limit itself to these two countries. New collecting missions should be made in China, Thailand, Vietnam, Bangladesh, Bhutan, Laos, Cambodia and Burma (Myanmar).

Finally, the genus *Musa* shows a great intraspecific variability. Earlier in this report it was mentioned that Nasution (1991) recorded 15 varieties of *M. acuminata* and Häkkinen (2003) five of *M. campestris*. In the future, for a more accurate classification, new species should be grown and botanically described under uniform conditions. With the help of multivariate analysis, or numerical analysis, it can be possible to determine how much variability is due to environmental conditions in the wild and which characters are stable or not. New species should also be submitted to the scrutiny of molecular markers. Ultimately, the goal is not to replace taxonomy by molecular biology, but to create a synergy between both in order to obtain a better understanding of the diversity of the *Musaceae*.

ACKNOWLEDGEMENTS

Many thanks to Markku Häkkinen and Edmond De Langhe for their kindness in answering questions and also for their critical reading of a previous draft of this report.

APPENDIX C. Bibliographic data on wild species

Journal	Author	Title	Year	Country	Species involved	Personal evaluation
Advancing banana and plantain R & D in Asia and the Pacific - Molina, A.B., Roa, V.N. (eds) p. 71-83	De Langhe, E., Wattanachaiyingcharoen, D., Volkaert, H., Piyapitchard, S.	Biodiversity of wild Musaceae in Northern Thailand	2000	Thailand	<p><u>Eumusa</u> <i>Musa acuminata</i> spp. <i>malaccensis</i> <i>Musa acuminata</i> spp. <i>siamea</i> <i>Musa balbisiana</i> <i>Musa itinerans</i> <i>Musa sikkimensis</i> <u>Rhodochlamys</u> <i>Musa laterita</i> <u>Incertae sedis</u> <i>M. acuminata</i> spp. <i>siamea</i> x <i>M. laterita</i> <u>Ensete</u> <i>Ensete glaucum</i> <i>Ensete superbum</i></p>	Data on wild <i>Musaceae</i> in Thailand. Localisation is limited to a province or a region.
Annals of Botany 90: 231 - 238	Wong, S., Kiew, R., Argent, G., Set, O., Lee, S. K., Gan, Y. Y.	Assessment of the Validity of the Sections in <i>Musa</i> (Musaceae) using ALFP	2002	Malaysia Philippines	<p><u>Eumusa</u> <i>Musa acuminata</i> spp. <i>burmanica</i> <i>Musa acuminata</i> spp. <i>malaccensis</i> <i>Musa acuminata</i> spp. <i>siamea</i> <i>Musa acuminata</i> spp. <i>truncata</i> <i>Musa balbisiana</i> <i>Musa nagensium</i> <i>Musa sikkimensis</i> <i>Musa itinerans</i> <u>Rhodochlamys</u> <i>Musa laterita</i> <i>Musa ornata</i> <i>Musa velutina</i> <u>Callimusa</u> <i>Musa suratii</i> <i>Musa borneensis</i> <i>Musa campestris</i> <i>Musa coccinea</i> <i>Musa violescens</i> <i>Musa gracilis</i> <u>Australimusa</u> <i>Musa baccarii</i> <i>Musa jackeyi</i> <i>Musa monticola</i> <i>Musa textilis</i> <u>Ensete</u> <i>Ensete glaucum</i> <i>Ensete superbum</i></p>	Knowledge about molecular markers (AFLP). <i>Musa suratii</i> and <i>Musa monticola</i> are defined in a section, Samples coming from collection botanical gardens and in wild. Location limited to a province or a village.

Journal	Author	Title	Year	Country	Species involved	Personal evaluation
Australian Plants 17: 264-266	Dick, H.	Wild banana - <i>Musa banksii</i>	1994	Australia	<u>Eumusa</u> <i>Musa acuminata</i> spp. <i>banksii</i>	Information about <i>Musa acuminata</i> spp. <i>banksii</i> in wild. Location limited to a region.
Biotropia 16: 28-38	Javed, M.A., Chai, M., Othman, R.Y.	Characterization of Malaysian wild banana's based on anthocyanins	2001	Malaysia	<u>Eumusa</u> <i>Musa acuminata</i> <i>Musa balbisiana</i> <u>Callimusa</u> <i>Musa violascens</i>	Characterisation of wild species using chemotaxonomy. Location limited to a province or a village. Subspecies not always defined.
Biotropica 23: 151-158	Itino, T. Kato, M. Hotta, M.	Pollination ecology of the two wild bananas, <i>Musa acuminata</i> subsp. <i>halabanensis</i> and <i>M. salaccensis</i> : chiropterophily and ornithophily	1991	Indonesia	<u>Eumusa</u> <i>Musa acuminata</i> spp. <i>halabanensis</i> <u>Callimusa</u> <i>Musa salaccensis</i>	Knowledge about pollinisation Little information about location
Botanical Bulletin of Academia Sinica 43: 77-81	Ai-Zhong Liu, De-Zhu Li, Xi-Wen Li	Taxonomic notes on wild bananas (<i>Musa</i>) from China	2002	China	<u>Eumusa</u> <i>Musa basjoo</i> <i>Musa itinerans</i> <i>Musa nagensium</i> <u>Callimusa</u> <i>Musa coccinea</i> <i>Musa paracoccinea</i> <u>Rhodochlamys</u> <i>Musa sanguinea</i>	Taxonomic studies of wild bananas in China. Localisation show through a map only,
Bulletin de la Société Botanique France 54:412-413	Gagnepain, F.	<i>Musa angcorensis</i>	1907	Cambodia	<u>Callimusa or Rhodochlamys</u> <i>Musa angcorensis</i>	Description of <i>Musa angcorensis</i> localisation is available
Bulletin Heliconial Society 10: 1-2	Bar-Zvi, D.	<i>Musella lasiocarpa</i> : A cinderella from China	2000	China	<i>Musella lasiocarpa</i>	Description of <i>Musella lasiocarpa</i> only,
Current Genetics 25:265-269	Fauré S., Noyer J.L., Carreel F., Horry J.P., Bakry F., Lanaud C.	Maternal inheritance of chloroplast genome and paternal inheritance of mitochondrial genome in bananas (<i>Musa acuminata</i>).	1994	Not specified	<i>Musa acuminata</i>	Knowledge about mitochondrial and chloroplastic DNA. Plants came from a research center in Guadeloupe. No information about the localisation of the wild species
