**Abstract** An annotated checklist of marine and freshwater fishes of Tanega-shima and Mage-shima islands in the Osumi Islands, Kagoshima Prefecture, southern Japan, was compiled from specimen and literature surveys. A total of 1,181 species (538 genera and 167 families), including 536 species that represent the first reliable records from the islands on the basis of collected specimens and/or underwater photographs, is listed with citation of literature, registration numbers, sizes, localities on the islands, and some remarks. A new standard Japanese name, Omeagoamadai, is proposed here for *Opistognathus megalops* Smith-Vaniz 2023 (Opistognathidae). Analysis of the species composition of fishes that occur on and off Tanega-shima and Mage-shima islands shows that the ichthyofauna of the islands is similar to that of the Pacific coast of southern Japan, including southern Kyushu, but significantly different from that of the neighboring island, Yaku-shima.

Motomura, H. 2023. An annotated checklist of marine and freshwater fishes of Tanega-shima and Mage-shima islands in the Osumi Islands, Kagoshima, southern Japan, with 536 new records. Bulletin of the Kagoshima University Museum, 20: 1–250.

## Introduction

Tanega-shima, a long and narrow island, measuring 57.2 km north to south and 5–12 km east to west, with an area of ca. 444 km<sup>2</sup> and a highest point of 282 m above sea level, is the second largest island in the Osumi Islands after Yaku-shima island. The Osumi Islands is located between Kyushu and the Tokara Islands, southern Japan (Fig. 1). The coastline of the island stretches about 186 km, with sandy beaches, mangrove tidal flats, rocky reefs, well-developed coral reefs, and there are numerous freshwater rivers and ponds on the island.

Mage-shima, a small rounded island, with an area of ca. 8.2 km<sup>2</sup>, circumference of 16.5 km, and a highest point of ca. 72 m above sea level, is the largest uninhabited island in the Osumi Islands (larger than the smallest inhabited island, Take-shima island), and located 12 km west of northern Tanega-shima island. The island has only rocky coastline, and there are no large freshwater rivers on the island (only few artificial small rivers and reservoirs). In 1951, agricultural pioneer groups began settling on the island as part of an Emergency Pioneering Project. At its peak in 1959, the island was home to 528 people in 113 households, who were engaged in sugarcane cultivation and dairy farming. In March 1980, the last of the islanders moved out of the island, and the island has been uninhabited since then. The Ministry of Defense has begun construction of the Air Self-Defense Force Mage-shima Base in 2023.

The history of research on the fish diversity of Tanega-shima island is relatively old, dating back more than 100 years. In 1904–1905, Roberto Anderson, a graduate student at Stanford University, collected many fishes in tide pools on Tanega-shima island and brought them back to the United States. Based on the specimens, *Praealticus tanegasimae* (standard Japanese name: Tanegimpo; named after Tanega-shima) and other species were described by Jordan and Starks (1906) as new species, and this paper was the first record of fish diversity on the island. In 1908, *Callogobius tanegasimae* (Tanehaze), also named after Tanega-shima, was described by Snyder (1908), and then a series of papers were published by foreigners. The first report on the fishes of Tanega-shima island by a Japanese was probably by Kuroiwa (1927). He recorded seven species of fishes from the freshwater areas of Tanega-shima island. Since then, many papers and books on fishes of Tanega-shima island, including Yoshigou (2014) and Kaburagi (2016), were published. Yoshigou (2014) reported 87 fishes from estuaries and rivers on Tanega-shima island on the basis of literature (e.g., Ogawa 1937; Sakai et al. 2001; Suzuki et al. 2004). Kaburagi (2016) provided color photographs of 287 species collected by himself from Tanega-shima island, and he donated 703 specimens, including some specimens used in Kaburagi (2016), to the Kagoshima University Museum. Most recently, in 2023, *Etelis boweni* Andrews, Fernandez-Silva, Randall and Ho 2021 and *Opistognathus megalops* Smith-Vaniz 2023 were recorded for the first time from Japan based on specimens from Tanega-shima island (Jeong et al. 2023) and described as a new species based on a holotype from the island (Smith-Vaniz 2023), respectively. As of July 2023, 645 species have been recorded from Tanega-shima island. In addition to the literature survey, 10,300 specimens from Tanega-shima and Mage-shima islands (deposited at the Kagoshima University Museum) obtained through donations by local people and field surveys led by the Kagoshima University Museum were examined during this study.

Examination of the above-mentioned specimens, published literature (plus examination of some specimens used in the literature), and unpublished underwater photographs taken at Tanega-shima and Mage-shima islands confirmed 1,181 species (538 genera and 167 families) of marine and freshwater fishes (plus one hybrid individual), including 536 new records, from the islands. All species are listed below. The islands have the third highest fish species diversity in Japan (Motomura 2016) after Amami-oshima (see Nakae et al. 2018) and Yaku-shima islands (see Motomura and Harazaki 2017), and further species discoveries from Tanega-shima and Mage-shima islands are expected through future surveys.

## Material and methods

Sampling methods were described and illustrated in Motomura and Matsuura (2010, 2014). Curatorial procedures for newly collected specimens followed Motomura and Ishikawa (2013). Standard length, total

length, and desk width are abbreviated as SL, TL, and DW, respectively. The systematic arrangement of families generally follows Nelson (2006). Scientific names generally follow Fricke et al. (2023), with some modifications given by Motomura (2023) following recently published or unpublished taxonomic studies. Within families, species are arranged in alphabetical order of the scientific name. Standard Japanese names generally follow Motomura (2023), having been transliterated using the Hepburn system. Each species record was compiled from voucher specimens, underwater photographs, and/or published literature. Registration number, number of specimens registered (if more than one), mm in SL, TL, or DW, and locality on Tanega-shima and Mage-shima islands (Fig. 2) are listed in each species record. These islands have one city and two towns: Nishinoomote City (on Mage-shima island and northern Tanega-shima island), Nakatane Town (middle of Tanega-shima island), and Minamitane Town (southern Tanega-shima island). Tanega-shima and Mage-shima islands are abbreviated as TSI and MSI, respectively. The localities of marine and freshwater fishes are indicated as names of “port or beach, town, island (e.g., Shimama Port, Minamitane, TSI)” and “river, town, island (e.g., Takeno River, Nakatane, TSI)”, respectively. The locality is expressed simply as “off TSI” or “off MSI” for fish(es) collected far off the island or if the precise locality on the island is unknown.

Institutional codes used in this paper are as follows: BMNH (Natural History Museum, London, UK), BSKU (Laboratory of Marine Biology, Faculty of Science, Kochi University, Kochi, Japan), CAS (California Academy of Sciences, San Francisco, USA), FAKU (Kyoto University Museum, Kyoto, Japan), KAUM (Kagoshima University Museum, Kagoshima, Japan), KPM (Kanagawa Prefectural Museum of Natural History, Kanagawa, Japan), NSMT (National Museum of Nature and Science, Tsukuba, Japan), USNM (Smithsonian Institution National Museum of Natural History, Washington DC, USA), and ZUMT (University Museum, University of Tokyo, Tokyo, Japan).

## Remarks

The number of species in the top 10 most speciose families occurring at Tanega-shima and Mage-shima islands is shown in Table 1. Comparable data for 20 localities in southern Japan, including the Sagami Sea, Osezaki (Suruga Bay), Kushimoto (Kii Peninsula), Kashiwa-jima island (Shikoku), Mishima, including Iwo-jima, Take-shima, and Kuro-shima islands (Osumi Islands), Yaku-shima island (Osumi Islands), Amami-oshima island (Amami Islands), Kikai-jima island (Amami Islands), Tokuno-shima island (Amami Islands), Okinoerabu-jima island (Amami Islands), Yoron-jima island (Amami Islands), Okinawa-jima island (Okinawa Islands), Ie-jima island (Okinawa Islands), the Miyako Islands, Ishigaki-jima island (Yaeyama Islands), Iriomote-jima island (Yaeyama Islands), Yonaguni-jima island (Yaeyama Islands), and the Ogasawara Islands, were presented in Motomura (2016: tables 1, 2), Koeda et al. (2016: table 2), Nakae et al. (2018: table 2), Mochida and Motomura (2018: table 1), Motomura and Uehara (2020: table 1), Fujiwara and Motomura (2020: table 1), Jeong and Motomura (2021: tables 2–5).

The ichthyofauna of the Nansei Islands from Yaku-shima to Yonaguni-jima islands is characterized by having the top three most speciose families being Gobiidae (1st), Pomacentridae (2nd), and Labridae (3rd) (Motomura 2016; Motomura and Uehara 2020; Fujiwara and Motomura 2020). The top three most speciose families in the Sagami Sea, Osezaki, Mishima, and the Ogasawara Islands are Gobiidae, Lab-

ridae, and Serranidae (the last family was replaced with Pomacentridae in the other localities) (Motomura 2016; Jeong and Motomura 2021), which are well consistent with those of Tanega-shima and Mage-shima islands (Table 1). In addition, Carangidae was included in the top 10 most speciose families only in the Sagami Sea (10th, 2.1%), Osezaki (10th, 2.5%), the Ogasawara Islands (7th, 3.6%), and Tanega-shima and Mage-shima islands (6th, 3.3%), the percentages being somewhat higher at lower latitudes in Japanese waters. Interestingly, in Japanese waters, Lutjanidae was included in the top 10 most speciose families only in the Ogasawara Islands (8th, 3.4%), and Tanega-shima and Mage-shima islands (7th, 2.8%). Thus, the ichthyofauna of Tanega-shima and Mage-shima islands (Table 1) is similar to that of the Sagami Sea, Osezaki, and the Ogasawara Islands among the 20 localities in Japan.

A recent fine scale cluster analysis, based on comprehensive ichthyofaunal surveys in the Ryukyu and Osumi islands and the Pacific coast of southern Japanese mainland, revealed that a major biogeographical boundary for southern Japanese marine fishes [Osumi Line *sensu* Motomura and Harazaki (2017: 182, fig. 1)] is located between Yaku-shima, and “Tanega-shima, Iwo-jima, and Take-shima islands” (Motomura and Matsunuma 2022), although the distance separating Yaku-shima and Tanega-shima islands is only about 20 km. The similarity between the ichthyofaunas of Yaku-shima island and the Ryukyu Islands is most likely due to the transportation of tropical fishes from Taiwan, China, and/or the Philippines to Yaku-shima island by the Kuroshio Current (Motomura et al. 2010; Motomura 2012; Motomura and Matsunuma 2022). Such transported fishes (including egg stages) are easily projected northward toward Yaku-shima island by the redirection of the Kuroshio Current from northward to eastward (Motomura and Matsunuma 2022: fig. 4.1). In contrast, fewer opportunities exist for transported fishes to arrive off Tanega-shima island since the latter is located inside the bend where the Kuroshio Current turns from eastward to northward, such fishes being more likely to be projected eastward into the Pacific Ocean (Motomura and Matsunuma 2022).

Tanega-shima island is the southernmost distribution limit for many temperate marine fishes, such as *Hemirhynchus akajei* (Dasyatidae), *Scorpaenopsis cirrosa* (Scorpaenidae), *Sebastiscus marmoratus* (Sebastidae), *Pagrus major* (Sparidae), *Halichoeres tenuispinis* (Labridae), *Acanthogobius flavimanus* (Gobiidae), and *Paralichthys olivaceus* (Paralichthyidae) (Motomura 2015; Motomura and Matsunuma 2022: fig. 4.10), which also supports the existence of a distinct biogeographical boundary between Yaku-shima and Tanegashima islands. The ichthyofauna of Tanega-shima island is very similar to that of southern Kyushu, as revealed by ongoing ichthyofaunal surveys. In fact, fishes of southern Kyushu may be transported to Tanega-shima island by the Osumi Branch Current, which occurs irregularly between Osumi Peninsula and the Osumi Islands. A further consideration, since Osumi Peninsula and Tanega-shima island were connected by land until ca. 130,000 years BP (Ôki 2000), is that some temperate fishes found at Tanega-shima island may represent relictual populations (Motomura 2012; Motomura and Matsunuma 2022).

Remarks: Although Kano and Tatsuzawa (2003) reported that two genetic populations of this species were found in Mage-shima island, DNA analysis of newly collected specimens from the island in 2022 by an environment assessment company showed that the two genotypes had become intermingled through interbreeding. The population size of this species on this island is quite large.

Remarks: This species recently described as a new species from the holotype collected off Urata, Nishinoomote at a depth of 103–107 m can be distinguished from all other congeners by having an upper jaw with a flexible lamina posteriorly, a relatively large oval supramaxillae, 11 segmented dorsal-fin rays, 11 segmented anal-fin rays, 38 total gill rakers in adults, 16 caudal vertebrae, and no ocellus in the dorsal fin (Smith-Vaniz 2023). English name Bigeye Jawfish was proposed by Smith-Vaniz (2023) for the species. Ome-agoamadai (オオメアゴアマダイ) is proposed here as the standard Japanese name for *Opistognathus megalops* on the basis of holotype of the species (KAUM-I. 97065).

Remarks: Although *Sphyraena japonica* Cuvier in Cuvier and Valenciennes 1829 has long been used for Yamato-kamasu, it is objectively invalid because it has been preoccupied by *Sphyraena japonica* Bloch and Schneider 1801 [unnecessary replacement name for *Silurus inermis* Houttuyn 1782 and currently regarded as a synonym of *Inegocia japonica* (Cuvier 1829) (Platycephalidae)]. Taxonomic status of Yamato-kamasu has been studied by Morishita and Motomura.
