**ABSTRACT** — A checklist comprising 355 species and 190 genera of asexual microfungi associated with plant debris collected in different localities of the tropical montane cloud forest of Veracruz, Mexico, is presented based on literature and fresh specimens. Annotations (lists of studied material and locations) are accompanied by illustrations of 31 species. A total 101 taxa are recorded for the Mexican mycobiota for the first time.

**KEY WORDS** — biodiversity, systematics, tropical cloud forest, conidial fungi.

### **Introduction**

The Tropical Montane Cloud Forest (TMCF) is one of the world's most diverse biomes. In Mexico, this ecosystem covers less than 1% of the land surface, but contains 10–12% of the country's flowering plant species (Rzedowski 1991). Because of its climatological characteristics and the enormous variety of microhabitats of these forests, there is considerable fungal diversity. Unfortunately, TMCF is severely endangered and disappearing from Mexico and around the world.

For more than two decades, the authors have studied saprobic asexual microfungi (SAM) collected on plant debris from different localities of TMCF in the state of Veracruz (Arias et al. 2000, 2010, 2015, 2016; Castañeda-Ruiz et al. 2000a,b, 2001, 2010, 2011, 2012, 2013; Delgado et al.

2006; Heredia 1993, 1994; Heredia & Mercado-Sierra 1998; Heredia & Reyes 1999; Heredia et al. 1995, 1997, 2000a,b, 2002, 2004, 2006, 2013, 2014; Mena-Portales et al. 1995, 2009; Mercado-Sierra & Heredia 1994; Mercado-Sierra et al. 1995, 1997, 2002). Before the present contribution, about 227 taxa of SAM had been recorded for Mexican TMCF. Most of them belongs to the Veracruz state. Unfortunately, for other Mexican states with TMCF, information on these kind of fungi is scarce or non-existent.

Although studies on the species richness of SAM have increased in recent years, the magnitude of diversity of these fungi in the Mexican TMCF remains largely unknown. To improve our knowledge about these important and diverse fungi, in this contribution, in addition to record several species unknown for Mexico, we present a current state of the SAM species recorded to date for the TMCF areas of the state of Veracruz.

### **Materials and methods**

Samples of plant debris consisting of leaf litter, dead branches, rotten wood, palm rachides, petioles and submerged plant remains, were collected. Material were placed in paper bags, taken to the laboratory, and prepared according to Castañeda-Ruiz et al. (2016). Mounts were prepared in polyvinyl alcohol and lactic acid (PVL), measurements were made at a magnification of  $\times 1000$ . Micrographs were obtained with a Nikon Eclipse 80i microscope equipped with bright field. All specimens consisting in permanent slides were deposited in the fungus collection of the Herbarium of the Instituto de Ecología A. C. (XAL). To complete the information relevant literature was extensively reviewed for scattered records. For the quantification of the species registered in the TMCF, only species published in refereed journals and documented with specimens deposited in registered collections were considered.

The Index Fungorum (<http://www.indexfungorum.org/Names/Names.asp>) database was consulted for current nomenclature and author names.

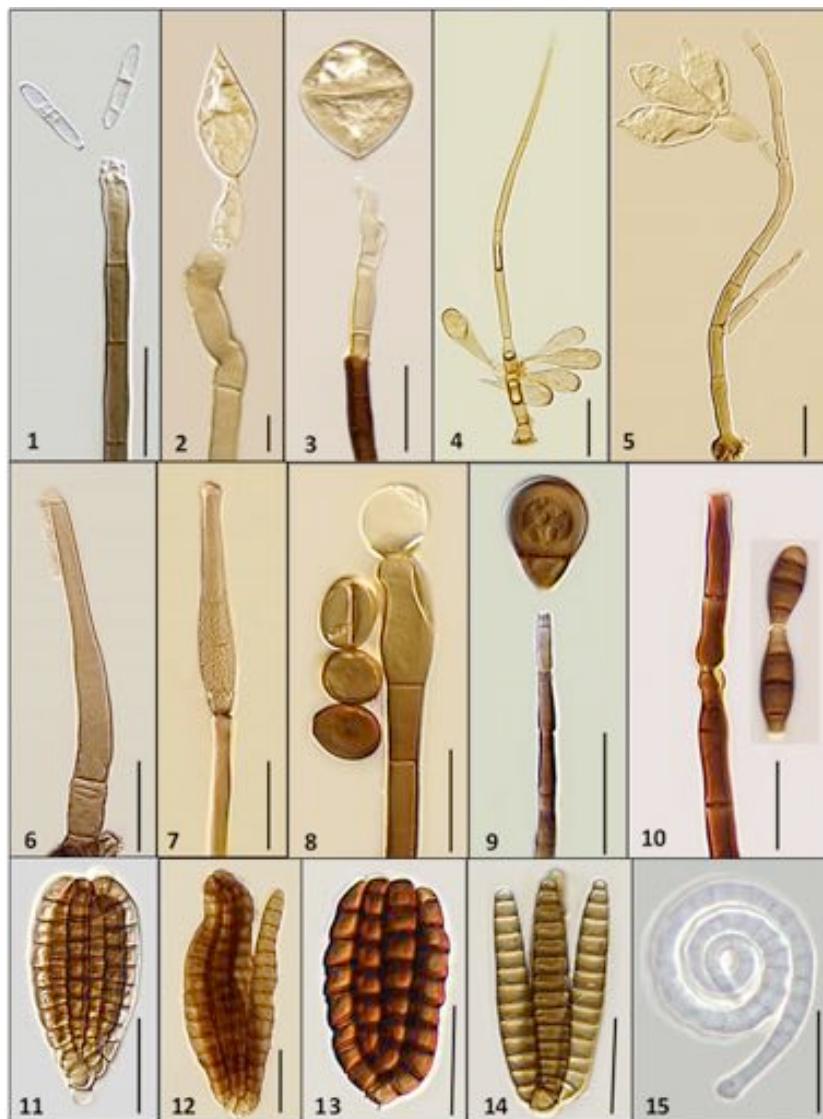

## Results

This contribution adds 42 genera and 129 species to the 148 genera and 226 species of SAM already known from TMCF in Veracruz State, taking totals up to 190 genera and 355 species.

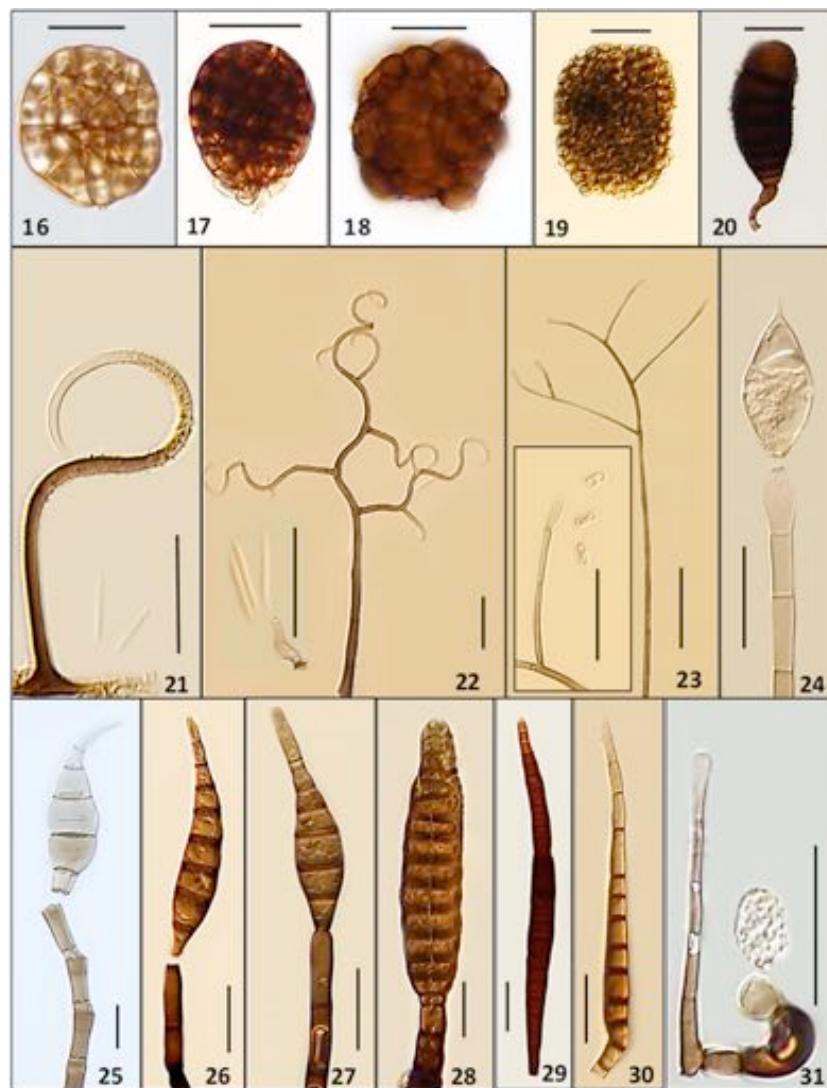

The genus with the highest number of recorded species was *Monodictys* S. Hughes with 30 species, followed by *Dictyochaeta* Speg. with eleven species, *Sporidesmiun* Link with ten, *Dictyosporium* Corda with eight species and *Endophragmiella* B. Sutton and *Chalara* (Corda) Rabenh, both with seven species.

Among the specimens we found six new genera and twenty-one new species. The new genera were: *Anaselenosporella*, *Anaseptoidium*, *Carrismyces*, *Helensiella*, *Minimelanolocus*, and *Veracruzomyces*. The new species were: *Acremoniula triseptata*, *Anaselenosporella sylvatica*, *Anaseptoidium mycophilum*, *Bactrodesmium simile*, *Belemnospora navicularis*, *Camposporium quercicola*, *Carrismyces proliferatus*, *Cylindrosympodium sosae*, *Dictyoaquaphila unisetulata*, *Endophragmiella mexicana*, *Helensiella rigidophora*, *Hermatomyces amphisporus*, *Lobatopedis kirkii*, *Minimelanolocus curvisporus*, *Minimelanolocus limpidus*, *Monodictys spinosa*, *Piricauda mexicana*, *Pseudobeltrania macrospora*, *Redbia inflata*, *Repetophragma paracambrense*, and *Veracruzomyces obclavatus*.

Species names are listed alphabetically including information of their herbarium number and localities. An asterisk (\*) before the name of the species indicates that the taxon is reported for the first time for Mexico, and the symbol § indicates a new record for TMCF. Illustrations are provided for 31 species.

#### Acknowledgements

The authors wish to thank PhD. David W. Minter (CABI, UK), Dr. Gregorio Delgado EMLab P&k) and PhD. Luís Fernando Pascholati Gusmão (UE de Feira de Santana)

for critical review of the manuscript. We are grateful to Biol. Magdalena Gómez Columna and M. Sc. Yamel Perea Rojas for their efficient help in searching bibliographic information and technical assistance. Funding for this research was provided by the National Commission for Knowledge and Use of Biodiversity (CONABIO) of Mexico through the financial support of the projects P030, B139 & IE004. RFCR is grateful to OSDE, Grupo Agrícola from Cuban Ministry of Agriculture for facilities.
