The birds of Serra da Canastra National Park and adjacent areas, Minas Gerais, Brazil

Luís Fábio Silveira

É apresentada uma listagem da avifauna do Parque Nacional da Serra da Canastra e regiões próximas, e complementada com observações realizadas por outros autores. São relatadas algumas observações sobre espécies ameaçadas ou pouco conhecidas, bem como a extensão de distribuição para outras.

Introduction

Located in the south-west part of Minas Gerais state, south-east Brazil, Serra da Canastra National Park (SCNP, 71,525 ha⁸, 20°15'S 46°37'W)⁹ is regularly visited by birders as it is a well-known area in which to see cerrado specialities and a site for Brazilian Merganser *Mergus octosetaceus*. However, Forrester's⁶ checklist constitutes the only major compilation of records from the area. Here, I list the species recorded at Serra da Canastra National Park and surrounding areas (Appendix 1), with details of threatened birds and range extensions for some species.

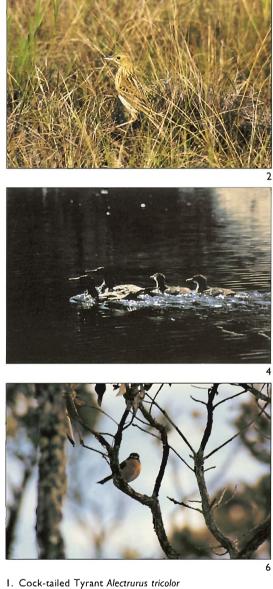

Material and methods

The dominant vegetation of Serra da Canastra National Park is cerrado *sensu lato*, but more than 90% of its total area is covered by subdivisions of this formation, known as *campo limpo* and *campo sujo*; the park has small portions of *campo rupestre*, and cerrado *sensu stricto*, and patches of gallery forest with Atlantic forest characteristics⁸. The relief is undulating, with streams in the valleys. The climate has a marked seasonality, with a rainy season in September–February and a dry season in March–August⁸.

I studied the avifauna during February 1996-February 1998, with most fieldwork conducted in April–December 1996, when I undertook population surveys and investigated the habitat requirements of Brazilian Merganser¹⁷. This project's methodology involved considerable activity in gallery forest adjacent to watercourses apparently suitable for *Mergus octosetaceus*. Over c.45 km of the river São Francisco-from its source as far as the village of Vargem Bonita-were surveyed. Downstream of the village, water conditions and environmental degradation have made the area unsuitable for Brazilian Merganser. Observations were made in both of the area's major drainage systems-the rios São Francisco and Paranáwithin and outside the park. I also undertook an avifaunal inventory, documenting most species recorded with photographs or tape-recordings, using a Sony TCM 5000EV and Sennheiser ME 66 directional microphone. Tape-recordings are deposited at Arquivo Sonoro Elias Pacheco Coelho, in the Universidade Federal do Rio de Janeiro, Brazil (ASEC).

A problem with many avifaunal lists concerns the evidence of a species' presence in a given area. Many species are similar in plumage and vocalisations, resulting in identification errors and making avifaunal lists the subject of some criticism¹. Several ornithologists or experienced birders have presented such lists without specifying the evidence attached to each record—in many cases it is unknown if a species was tape-recorded, or a specimen or photograph taken. However, Hayes⁷ provides a source for all species recorded in Paraguay, and in Brazil, Cohn-Haft et al.³ explicitly provided evidence for species' occurrences north of Manaus. These lists class evidence according to rank, the highest being a specimen and the lowest being a heard-only record. I did not collect specimens at Canastra, although this is undoubtedly the most surefire method of identification (and a specimen has considerable additional value¹²). In the list presented here, I rank evidence as follows: the highest evidence is a species cited in Forrester⁶ (1) also observed by me (two independent records), followed by a tape-recording (R), a photo which conclusively identifies a species (P), a sight observation (O) and, the lowest category, a record based only on a vocalisation and not tape-recorded (H) (Appendix 1). For some species more than one type of evidence is available, increasing the value of the record, if it was made only by me (e.g. Small-billed Tinamou Crypturellus parvirostris was observed and taperecorded). I accessed unpublished data from other ornithologists (see Appendix 1) who visited SCNP, and species recorded by more than one of these observers or for which specific documentation exists were included in the main list. Thirty-four species were recorded by only one author (26 in Forrester⁶---see Table 1) and these were considered hypothetical

- 2. Ochre-breasted Pipit Anthus nattereri
- 3. Brasilia Tapaculo Scytalopus novacapitalis
- 4. Brazilian Merganser Mergus octosetaceous
- 5. Lesser Nothura Nothura minor
- 6. Grey-backed Tachuri Polystictus superciliaris (All photos by Edson Endrigo)

because specific evidence was unavailable. Many hypothetical species are almost certainly present in the area, but better documentation is required.

Species recorded were classified with respect to threatened status⁵ or relative abundance (in suitable habitat), which was determined subjectively, and changes can be expected through further research. The taxonomy and species sequence follows Sick 1997¹⁵, except *Aratinga auricapilla*, which follows Collar *et al.*⁴.

Results and species accounts

Forrester⁶, through compilation of various unpublished reports, presents a list of 260 species recorded from Serra da Canastra National Park. The list presented here for the Serra da Canastra region includes 282 species (Appendix 1) for which some evidence for its occurrence is available.

Twelve species are endemic to the cerrado sensu latu¹⁶ and 13 species are endemic to Brazil¹⁵. Twenty-one species recorded in the region are classified as threatened or near-threatened⁴, nine of which occur in one of three categories: Critically Endangered (Brazilian Merganser), Endangered (Ochre-breasted Pipit Anthus nattereri) and Vulnerable (seven, e.g. Lesser Nothura Nothura minor, Dwarf Tinamou Taoniscus nanus and Crowned Eagle Harpyhaliaetus coronatus). According Wege & Long¹⁸, SCNP is one of the most important sites harbouring threatened species of the campos and cerrados of Brazil (habitats disappearing rapidly yet receiving comparatively little attention by conservationists, and which require urgent protection, as noted by Parker & Willis¹⁰).

Table I. Species recorded by only one author,and thus regarded as hypothetical at Serra daCanastra.

Podilymbus podiceps Leptodon cayanensis Accipiter striatus Spizastur melanoleucus Micrastur semitorquatus Falco rufigularis Bartramia longicauda Gallinago undulata Columba speciosa Columba plumbea Columbina picui Brotogeris tirica Asio flammeus	WDB BCF BCF BCF BCF BCF BCF BCF BCF BCF
Brotogeris tirica	BCF
Caprimulgus parvulus	RAR
Polytmus guainumbi Veniliornis spilogaster	BCF BCF

Furnarius figulus	BCF
Xiphocolaptes albicollis	BCF
Hemitriccus margaritaceiventer	BCF
Myiopagis gaimardii	BCF
Todirostrum plumbeiceps	BCF
Knipolegus cyanirostris	BCF
Arundinicola leucocephala	RAR
Casiornis rufa	BCF
Myiarchus tuberculifer	BCF
Schiffornis virescens	JFP
Turdus subalaris	RAR
Hemithraupis guira	BCF
Tachyphonus rufus	BCF
Pipraeidea melanonota	BCF
Euphonia cyanocephala	RAR
Oryzoborus maximiliani	BCF
Oryzoborus angolensis	BCF
Coryphospingus cucculatus	BCF

Observers are coded as follows: BCF = Bruce C. Forrester⁶; JFP = José Fernando Pacheco (pers. comm.); RAR = Rose Ann Rowlett (pers. comm); and WDB = Wolf Dieter Bartmann².

Species accounts

Species accounts are presented for those taxa for which I obtained new information from within SCNP or nearby. Each species is coded as follows: (C) = Critical; (E) = Endangered; (V) = Vulnerable; (NT) = near-threatened⁴; and (RE) = range extension.

Brazilian Merganser Mergus octosetaceus (C). My research at SCNP commenced with a population census of this species: six mature pairs and 22 individuals were found along the main rivers and streams of the region¹⁷. Below, I present observations on the six pairs found in the study area. Breeding in SCNP occurs in July². Mergus octosetaceus has two significant ecological requirements which limit its distribution: one is a lack of suitable trees, in much of the gallery forest, with holes of a sufficient size for the species to use for nesting. Some pairs studied since 1996 have not bred, probably because there are no suitable trees in the gallery forest adjoining their territories. The second requirement has meant a lack of vacant territories for juveniles to occupy. Mergus octosetaceus is a highy territorial species, and each pair requires a minimum of 8 km of river with high water quality (Silveira & Bartmann in prep.). Such conditions exist in few areas, all occupied by mature pairs. It is unknown what happens to fledged young. Other potential areas are disturbed by diamond mining and ecological tourism; local farmers are renting properties by the São Francisco river to tourists who increase water pollution and disturb the environment.

Pair 1. Studied by Bartmann², this pair occupies a territory on the São Francisco river, above the Casca d'Anta waterfall. Bartmann and I observed this pair with four small ducklings in September 1996. In February 1997, Henrique R. Nobre (pers. comm.) observed the same pair and its young in this area. I returned to the territory in April–June 1997 and failed to find any birds there, but in July 1998, Juan Mazar Barnett (pers. comm.) found the pair with two ducklings in the same place and I was also able to observe them there during 21–23 August 1998.

Pair 2. Also studied by Bartmann², this pair occupies a territory on the São Francisco river, between the Casca d'Anta waterfall and a point near São José do Barreiro village. Breeding was not recorded in 1996–1997.

Pair 3. A newly discovered pair on the São Francisco river which occupy a territory between São José do Barreiro to c.4 km downstream of there. No breeding records in 1996–1997.

Pair 4. Studied by Bartmann², this pair occupies a territory in an area known as Retiro das Pedras. In August 1997, the pair had four ducklings, and was seen regularly in this area.

Pair 5. Another newly discovered pair, which occupy the Ribeirão das Posses stream, part of the Paraná drainage basin. No breeding records.

Pair 6. This pair occupies a territory c.8 km dowsntream of pair 5; it had two ducklings in October 1996.

Brasília Tapaculo Scytalopus novacapitalis (V). Occurs in almost all humid forest where the fern Blechnum sp. is found, in densities of 1-2 pairs per patch. In October-December, pairs sing throughout the day (males and females have different songs), and are easily attracted to playback. S. novacapitalis is very common in and outside the park in areas with other typical cerrado species, e.g. Herpsilochmus longirostris and Antilophia galeata.

Dusky-tailed Antbird Drymophila malura (RE). Although mapped in Minas Gerais¹⁴, I have found no published records of the species from the state. Unpublished records have been made at several localities in Serra da Mantiqueira, e.g. a male taperecorded at Fazenda São Francisco do Jordão, near Delfim Moreira (22°30'S 45°16'W), in April 1994 (Flávio C. T. Lima pers. comm.). The species has been regularly recorded at Caraça Natural Park (20°08'S 43°30'W), Santa Bárbara municipality (J. F. Pacheco pers. comm.), and I have found it at Tripuí Ecological Station (20°17'S 43°30'W), where it is fairly common in secondary forest. At SCNP, I tape-recorded a pair in a gallery forest near Ribeirão das Posses in September 1996. This record represents a range extension of c.350 km west from Tripuí, the nearest traceable locality, and demonstrates the need to publish records clarifying the status and distribution of common birds.

Sharp-tailed Tyrant Culicivora caudacuta (NT) and Cock-tailed Tyrant Alectrurus tricolor (NT). C. caudacuta is easily found year-round, in small groups of 3-7 birds in tall grass. In December 1996, a family group with two dependent young was found. The young were similar in shape to that briefly described in Parker & Willis¹⁰. I have never seen Culicivora caudacuta in mixed groups of cerrado species, as noted by the last-named authors. Alectrurus tricolor is a migrant, arriving in mid-August-September and leaving in December-January. In December 1996, a female was noted feeding two young with small fruits. The structure of the immature birds was very similar to that of the female. In SCNP, Cock-tailed Tyrant utilises campo sujo and campo limpo, where the males perform the territorial displays described by Sick¹⁵.

Southern Bristle-tyrant Phylloscartes eximius (NT, RE). Inhabits mid-strata of humid forests in south-east Brazil, Argentina and Paraguay¹⁴. There are few recent records of P. eximius in Brazil (Silveira & Develey in prep.). In Minas Gerais, Pinto¹¹ documented a pair obtained by A. M. Olalla in Fazenda Boa Esperança, north of São José da Lagoa (now Nova Era, 19°45'S 43°03'W, at 530 m) in September 1940. Another pair was obtained in March 1926 by Snethlage at Fazenda Taveira, Mariana municipality (20°22'S 43°24'W, at 712 m) (retained at Museu Nacional do Rio de Janeiro: J. F. Pacheco pers. comm.). I found two pairs in the Atlantic forest below Casca d'Anta waterfall, in September 1996 and on all visits in 1997-1998. They were very responsive to playback (remaining in an upright position) different to typical Phylloscartes. Ridgely & Tudor¹⁴ draw attention to the fact that P. eximius may be declining substantially due to deforestation throughout its range, but many ornithologists are unfamiliar with this species' vocalisations. I have never recorded it following mixed-species flocks, and it often perches quietly and unobtrusively. More records will almost certainly be made once its voice becomes more widely known amongst fieldworkers in the region. The records at SCNP extend its known range c.300 km west. It is interesting to note that other typical Atlantic forest species occur at SCNP, e.g. *Pyroderus scutatus* and *Ilicura militaris*.

Ochre-breasted Pipit Anthus nattereri (E) (RE). This scarce species is known in Minas Gerais from Monte Belo (21°19'S 46°22'W), Alfenas (21°25'S 45°46'W) and Morro do Ferro, Poços de Caldas municipality (21°47'S 46°33'W)4. This record extends its distribution by c.100 km north-west from Monte Belo, the nearest locality. The species was identified by Juan Mazar Barnett, on 16 December 1997, and we tape-recorded at least three birds in a grassy field near the source of the São Francisco river. Following this, I found A. nattereri in other areas of the park. The species is easily identified by its vocalisations and display, which differ from those of A. lutescens and A. hellmayri, which are also present here. Displaying Ochre-breasted Pipit perform a spiralling descent while singing, unlike A. lutescens, which descends in a near-straight line, and A. hellmayri, which also makes a spiral descent but with a more open helix than A. nattereri. I also observed this phenonomen at Ibitipoca State Park (21°33'S 43°55'W) in January 1997. The three species' songs are easily recognisable. Open areas inhabited by A. nattereri are threatened by the development of pasture and agriculture¹⁰. Following grass-burning, Ochre-breasted Pipit would disappear, but was one of the first species to return once the grass had regenerated. Parker & Willis¹⁰ have also noted the species' preference for recently burnt areas. The area in SCNP where A. nattereri was recorded for the first time also supports other nearthreatened species: Taoniscus nanus, Coryphaspiza melanotis, Culicivora caudacuta and Alectrurus tricolor.

Rufous-rumped Seedeater Sporophila hypochroma (NT). In Brazil, this species was previously known from just two localities in the centre-west of the country⁴. I observed two males in a mixed flock of Sporophila bouvreuil and S. melanogaster (see below) in October 1996, when seeds are abundant. Important field marks are the rump and belly coloration, more rufous than in S. hypoxantha (the colour in Rufous-rumped is similar to that in S. b. saturata: specimens at Museu de Zoologia da Universidade de São Paulo) and providing more of a contrast with the greyish upperparts. It is interesting to note that the other Brazilian records were also in October⁴, and the birds I recorded did not vocalise. This suggests that Rufous-rumped Seedeater is an austral migrant in Brazil, as noted by Ridgely & Tudor¹³, and illustrates the conservation importance of grasslands in central-east Brazil, which are rapidly disappearing and are very important areas for migrant seedeaters.

Black-bellied Seedeater Sporophila melanogaster (NT). Sick¹⁵ recorded the species from three localities in Minas Gerais: Campanha (21°50'S 45°24'W)⁹ and Pocos de Caldas (21°47'S 46°33'W)⁹, without additional data, and Pirapora (17°20'S 44°56'W)⁹, in September. I saw four adult males in October 1996 in the same mixed flock with the S. hypochroma noted above. Mixed Sporophila flocks are frequent at SCNP in October, and always include resident S. bouvreuil. An additional record of S. melanogaster was one mist-netted (with two others seen) at Várzea do Rio Jacaré, near Morro do Ferro village (20°46'S 44°34'W), Minas Gerais, on 27 December 1997. This bird possessed significant abdominal fat, a clear sign of a migrant. Migration routes of Sporophila in Brazil require more accurate study before effective conservation measures can be designed.

Acknowledgements

I acknowledge Dr Wolf D. Bartmann (Dortmund Zoo, Germany), an enthusiastic researcher of Serra da Canastra's fauna, especially the Brazilian Merganser: his encouragement and experience were very important in the development of my work. The Zoologische Gesellschaft Frankfurt-Hilfe für die Bedrohte Tierwelt sponsored the Brazilian Merganser project in 1996 and partially funded the production of this paper. I thank Prof. Dra. Elizabeth Höfling (Universidade de São Paulo) for guidance and support, and my colleagues at the Ornithology Laboratory—Herculano M. Alvarenga, Andrés C. Mendéz, Renato G. Lima, Alex M. Santos and Marcos A. Raposo-for fruitful discussions during the preparation of the text. Pedro F. Develey, Flávio T. Lima (Universidade de São Paulo), Juan Mazar Barnett and José F. Pacheco (Universidade Federal do Rio de Janeiro) made important suggestions and corrections to the manuscript. Roberto Murta (Belo Horizonte), Édson Endrigo (São Paulo), Prof. Dr. Karin Werther (UNESP, Jaboticabal, São Paulo), Henrique Rocha Nobre (Belo Horizonte) and Líliam P. Pinto are thanked for their valuable assistance in the field. Juan Mazar Barnett identified the first Ochre-breasted Pipit at SCNP. José Fernando Pacheco kindly provided unpublished information from Rose Ann Rowlett, Derek Scott, Luiz

Antônio Pedreira Gonzaga and Bret Whitney. The staff of Instituto Brasileiro do Meio Ambiente e dos Recursos Naturais Renováveis (IBAMA) at Serra da Canastra National Park have provided facilities for my research and I thank the people of São Roque de Minas, Vargem Bonita and São José do Barreiro, principally Ms Paula (Faria's Hotel), Ms Ivanilde and her husband (Pousada São José), and Mr Ziro and his sisters, who are enthusiastic supporters of Brazilian Merganser conservation. This paper is dedicated to the memory of Mário Marcos F. Gonçalves, who made the official map of Serra da Canastra National Park, and gave me the opportunity to explore many areas.
