Epub Jun 12, 2020

The Neotropical genus *Scleronema* is revised based on the re-examination of the type specimens and 1,713 newly collected specimens. *Scleronema* is diagnosed from other trichomycterids by the following unambiguous derived characters: fleshy flap at the base of the maxillary barbell; skin flap in the posterior margin of the opercle; articulation between the autopalatine and the vomer ventrally located, with the medial margins of the autopalatines very close to each other; and autopalatine with an interrupted or not interrupted ossified arch-shaped process on its dorsal surface forming a canal. *Scleronema minutum* and *S. operculatum* are redescribed, *S. angustirostre* is considered a junior synonym of *S. minutum*, and six new species are described. A lectotype is designated for *Trichomycterus minutus*. The type localities of *S. angustirostre*, *S. minutum*, and *S. operculatum* are reviewed in order to correct erroneous information cited in articles and catalogs subsequent to the original descriptions. Species of *Scleronema* are geographically distributed in the La Plata basin and Atlantic coastal drainages from Southern Brazil, Southern Paraguay, Northeastern Argentina and Uruguay. They inhabit rivers or streams with sand- or gravel-bottoms across the Pampa grasslands. We provide evidences to recognize two putative monophyletic units within the genus, namely the *S. minutum* species group and the *S. operculatum* species group, and discuss the distribution patterns of their species.

**Keywords:** Biodiversity, Identification key, Taxonomy, Trichomycterinae, Uruguayan savanna ecoregion.

O gênero Neotropical *Scleronema* é revisado com base na análise do material-tipo e outros 1.713 espécimes recentemente coletados. *Scleronema* é diagnosticado de outros tricomicterídeos pelos seguintes caracteres derivados não ambíguos: aba de pele na base do barbillão maxilar; aba de pele na margem posterior do opérculo; articulação entre o autoplatino e o vómer posicionada ventralmente, deixando as margens mediais dos autoplatinos muito próximas entre si; e o autoplatino com um processo com formato de arco na sua superfície dorsal. *Scleronema minutum* e *S. operculatum* são redescritas, *S. angustirostre* é considerada um sinônimo júnior de *S. minutum* e seis novas espécies são descritas. Um lectótipo é designado para *S. minutum*. As localidades-tipo de *S. angustirostre*, *S. minutum* e *S. operculatum* são revisadas com o intuito de corrigir informações errôneas citadas em artigos e catálogos após suas descrições. As espécies de *Scleronema* distribuem-se na bacia do rio da Plata e drenagens costeiras atlânticas no sul do Brasil, sul do Paraguai, nordeste da Argentina e Uruguai, habitando rios e riachos ao longo do Pampa com fundos de areia ou cascalho. Dois grupos de espécies supostamente monofiléticos, o grupo *S. minutum* e o grupo *S. operculatum*, são reconhecidos no gênero e os padrões de distribuição de suas espécies são discutidos.

## INTRODUCTION

Trichomycteridae is a monophyletic group of freshwater catfishes endemic to the Neotropical region which is classified into eight subfamilies: Copionodontinae, Glanapteryginae, Sarcoglanidinae, Stegophilinae, Trichomycterinae, Trichogeninae, Tridentinae, and Vandelliinae (de Pinna, Wosiacki, 2003). Trichomycterids are easily recognized by their highly modified opercular system, involving the interopercular and opercular bones equipped with odontodes (de Pinna, 1998; Adrians *et al.*, 2010), and comprise the second richest family of Siluriformes with 328 species (Fricke *et al.*, 2020). The subfamily Trichomycterinae contains the majority of these species, being composed of nine genera: *Bullockia* Arratia, Chang, Menu-Marque, Rojas, 1978, *Cambeva* Katz, Barbosa, Mattos, Costa, 2018, *Eremophilus* Humboldt, 1805, *Hatcheria* Eigenmann, 1909, *Ituglanis* Costa, Bockmann, 1993, *Rhizosomichthys* Miles, 1943, *Scleronema* Eigenmann, 1917, *Silvinichthys* Arratia, 1998, and *Trichomycterus* Valenciennes, 1832.

Though trichomycterines are usually known to preferentially occur in mountain rivers and rapids, species of *Scleronema* (Tab. 1) occupy areas of low altitudes in the subtropical region of the La Plata basin (Paraná, Paraguay, and Uruguay rivers) and coastal drainages from Southern Brazil and Uruguay. Their distributions encompass almost the entire area of the South American “Campos” – called “Pampa biome” in Brazil according to IBGE (2004, 2019) – an ecological region composed mainly of natural grasslands and herbs with sparse shrubs and tree formations generally in the banks of rivers and streams (Pallarés *et al.*, 2005). Among the Brazilian biomes, the

Pampa has the lowest percentage of legally protected areas and, according to ICMBio (2016), having had the fewest number of issued research permits.

*Scleronema* has long been defined by the large base of the maxillary barbel and by the presence of a skin flap in the posterior margin of the opercle, two unusual characters proposed by Eigenmann (1917) and corroborated by subsequent authors (e.g., Eigenmann, 1918; Tchernavin, 1944; de Pinna, 1989, 1998; Arratia, 1990). Hitherto, some phylogenetic analyses using morphological (Wosiacki, 2002) and molecular data (Ochoa *et al.*, 2017a; Katz *et al.*, 2018) recovered the monophyly of *Scleronema*.

Currently, the genus *Scleronema* encompasses three sand-dwelling species: *S. angustirostre* (Devincenzi, 1942), *S. minutum* (Boulenger, 1891), and *S. operculatum* Eigenmann, 1917. However, the diversity of the genus seems to be larger in view of the number of undescribed taxa listed for the genus in fish catalogs (de Pinna, Wosiacki, 2003; Becker *et al.*, 2013; Bertaco *et al.*, 2016). Even identifications of *Scleronema* species given in papers focused on higher-level relationships within Trichomycteridae (Wosiacki, 2002; Ochoa *et al.*, 2017a; Katz *et al.*, 2018), as well as some species recorded in local fish inventories (e.g., Burns *et al.*, 2015; Corrêa *et al.*, 2015) are uncertain due to the lack of a taxonomic review of the genus. To add some uncertainty to species definition and boundaries, information on type localities and vouchers for the three species of *Scleronema* given in checklists of trichomycterids or siluriforms (*i.e.*, de Pinna, Wosiacki, 2003; Ferraris, 2007; Wosiacki, de Pinna, 2007) are inaccurate, therefore requiring revisions.

**TABLE 1** Species of *Scleronema* with authors, name-bearing types and type localities.

Species	Author	Name-bearing type	Type locality
<i>Scleronema angustirostre</i>	(Devincenzi, 1942)	MHNM; holotype; not found	Uruguay; Paysandú; Cañada de las Piedras Blancas; tributary of río Queguay; lower río Uruguay; ca 32°05'09"S 57°53'13"W
<i>Scleronema guapa</i> , new species	Ferrer, Malabarba, 2020	UFRGS 23500; holotype	Brazil; Río Grande do Sul; Rosário do Sul; sanga Santo Antônio; tributary to río Ibicuí da Armada, río Ibicuí basin, lower río Uruguay; 30°17'41"S 54°59'17"W
<i>Scleronema ibirapuita</i> , new species	Ferrer, Malabarba, 2020	MCN 19470; holotype	Brazil; Río Grande do Sul; Santana do Livramento; río Ibirapuitá Chico; tributary to río Ibirapuitá, río Ibicuí basin, lower río Uruguay; 30°33'29"S 55°31'03"W
<i>Scleronema macanuda</i> , new species	Ferrer, Malabarba, 2020	MCN 20230; holotype	Brazil; Río Grande do Sul; Sentinela do Sul; irrigation water channel draining to arroio Velhaco; laguna dos Patos system; 30°43'13"S 51°39'28"W
<i>Scleronema mate</i> , new species	Ferrer, Malabarba, 2020	MCP 54183; holotype	Brazil; Río Grande do Sul; Venâncio Aires; stream tributary to arroio Castelhano; río Taquari basin, laguna dos Patos system; 29°33'S 52°17"W
<i>Scleronema milonga</i> , new species	Ferrer, Malabarba, 2020	MCP 54165; holotype	Brazil; Río Grande do Sul; Dezesseis de Novembro; arroio Lageado Araçá; río Ijuí basin; lower río Uruguay; 28°12'23"S 54°56'58"W
<i>Scleronema minutum</i>	(Boulenger, 1891)	BMNH 1891.3.16.84; lectotype	Brazil; Río Grande do Sul; São Lourenço do Sul; stream tributary of laguna dos Patos; ca 31°21'55"S 51°58'42"W
<i>Scleronema operculatum</i> , type-species	Eigenmann, 1917	FMNH 58080; holotype	Brazil; Río Grande do Sul State; Cacequi; río Cacequi; lower río Uruguay; ca 29°53'58"S 54°50'24"W
<i>Scleronema teiniagua</i> , new species	Ferrer, Malabarba, 2020	ZVC-P 14522; holotype	Uruguay; Artigas; arroyo Tres Cruzes; río Cuareim basin; lower río Uruguay; 30°35'31"S 56°37'34"W

In this paper, we provide a systematic revision of the genus *Scleronema*, advanced by the first author during his Doctoral Thesis (Ferrer, 2016), based on the examination of all available type specimens and on a dense sampling of new specimens from the entire geographical distribution of the genus, as well as other trichomycterids.

## MATERIAL AND METHODS

Specimens examined are housed at the following fish collections: AMNH, American Museum of Natural History, New York, U.S.A.; ANSP, Academy of Natural Sciences of Drexel University, Philadelphia, U.S.A.; BMNH, Natural History Museum, London, U.K.; FML, Fundación Miguel Lillo, Tucumán, Argentina; FMNH, Field Museum of Natural History, Chicago, U.S.A.; LIRP, Laboratório de Ictiologia de Ribeirão Preto, Faculdade de Filosofia, Letras e Ciências Humanas, Universidade de São Paulo, São Paulo, Brazil; MACN, Museo Argentino de Ciencias Naturales Bernardino Rivadavia, Buenos Aires, Argentina; MCP, Museu de Ciências e Tecnologia, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil; MHNM, Museo Nacional de Historia Natural y Antropología, Montevideo, Uruguay; MLP, Museu de La Plata, Instituto de Limnología, La Plata, Argentina; MPEG, Museu Paraense Emílio Goeldi, Belém, Brazil; MNRJ, Museu Nacional, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; MZUSP, Museu de Zoologia, Universidade de São Paulo, São Paulo, Brazil; UFRGS, Departamento de Zoologia, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; UMMZ, University of Michigan Museum of Zoology, Ann Arbor, U.S.A.; UNICTIO, Laboratório de Ictiologia, Universidade do Vale do Rio dos Sinos, São Leopoldo, Brazil; USNM, National Museum of Natural History, Smithsonian Institution, Washington D.C., U.S.A.; ZVC-P, Departamento de Zoología Vertebrados, Universidad de Montevideo, Montevideo, Uruguay.

Specimens identified by “c&s” were cleared and counter-stained for bone and cartilage according to protocol of Taylor, Van Dyke (1985); some of these were dissected on the right side of the head. Radiographs (“xr”) were taken of some specimens and additional ones were obtained in the Database of the All Catfish Species Inventory (Morris *et al.*, 2006). Osteological illustrations were prepared based on photographs of c&s specimens in a stereomicroscope with a Nikon AZ100M camera attached.

**Morphometrics.** Measurements were taken point-to-point using a digital caliper to the nearest 0.1 mm and presented as percentages of standard length (SL) or head length (HL) for its subunits. Measurements follow Tchernavin (1944) for barbel length; Bockmann, Sazima (2004) for total length, body width, distance between snout tip and posterior nare, intranarial length, anterior internarial width, and posterior internarial; Wosiacki, de Pinna (2008) for length and depth of the caudal peduncle and for supraorbital pore s6 distance; and Ferrer, Malabarba (2011) for scapular girdle width. Remaining measurements follow Costa (1992).

**Counts.** Vertebral count excludes those in the Weberian complex; the compound caudal centrum was counted as a single element. Abdominal vertebrae are those without haemal arch and haemal spine, *sensu* de Pinna (1998) explained by Datovo,

Bockmann (2010: 237). Counts of fin rays include the unbranched ones plus branched ones. Number of branchiostegal rays, odontodes, pterygiophores, ribs, teeth, vertebrae and procurrent rays (those anterior to unbranched rays of dorsal, anal, and caudal fins) were counted only in c&s and xr specimens. Rays of paired fins and branchiostegal rays were counted in both sides of specimens and, if variable, the counts of each side separated by a slash.

**Nomenclature.** Nomenclature and homologies of laterosensory canal system and associated pores follow Rizzato, Bichuette (2016). Nomenclature for caudal skeleton morphology follows Lundberg, Baskin (1969) and for remaining bones follows, whenever possible, de Pinna (1989) with few variations discussed by Arratia (1998), Bockmann, Sazima (2004) and Bockmann *et al.* (2004) who named the “lacrimal” as “antorbital” and the “supraoccipital” as “parieto-supraoccipital”. Nomenclature for bones not cited in de Pinna (1989) follows Bockmann, Sazima (2004).

**Species accounts.** All obtainable type specimens were measured and radiographed. Asterisk indicates lots with specimens measured for species descriptions. Number of specimens with each count given in parentheses, also noting the count observed in the holotypes, paratypes, lectotypes, or paralectotypes. The synonym lists were based on the analysis of the vouchers cited in the literature whenever possible. Alternatively, species identity was confirmed by photographs or illustrations provided in publications or through exclusive geographical distribution of some taxa. External characters have preference in the diagnosis rather than internal osteological traits observed only in c&s or xr specimens. If necessary, doubtful and incomplete geographical coordinates were corrected or estimated according to the available information and use of the Google Earth software. Type localities of *S. angustirostre*, *S. minutum* and *S. operculatum* are clarified following the recommendation 76A of the International Code of Zoological Nomenclature (ICZN, 1999), as well as a lectotype is designated for *Trichomycterus minutus* according to its Article 74.

## RESULTS

### *Scleronema* Eigenmann, 1917

*Scleronema* Eigenmann, 1917: 691.—Eigenmann, 1918: 260, 269 (distribution notes); 277 (relationships); 278 (diagnosis in key); plate 36 (distribution map).—Tchernavin, 1944: 234, 235, 272 (review).—Myers, 1944: 597 (diagnosis in key).—Gosline, 1945: 55 (listed).—Fowler, 1954: 37 (listed).—Myers, Weitzman, 1966: 278, 284, 285 (phylogenetic relationships).—Ringuet *et al.*, 1967: 351 (diagnosis in key).—Baskin, 1973: 79, 98 (listed, notes on mouth width).—Castello *et al.*, 1978: 124–125 (listed, diagnosis).—Burgess, 1989: 307, 313, 321 (listed, diagnosis in key).—Arratia, 1990: 400 (diagnosis).—de Pinna, 1989: 9, 24, 25, 28, 29; fig. 21, 30, 31, 35 (putative apomorphic characters, phylogenetic relationships, phylogenetic tree).—de Pinna, 1992: 213 (notes on dorsal-fin position).—Costa, Bockmann, 1993: 45 (phylogenetic relationships).—Arratia, Huaquin, 1995: 21; fig. 9b, 25, 27, 28, 29, 30 (notes on laterosensory canal

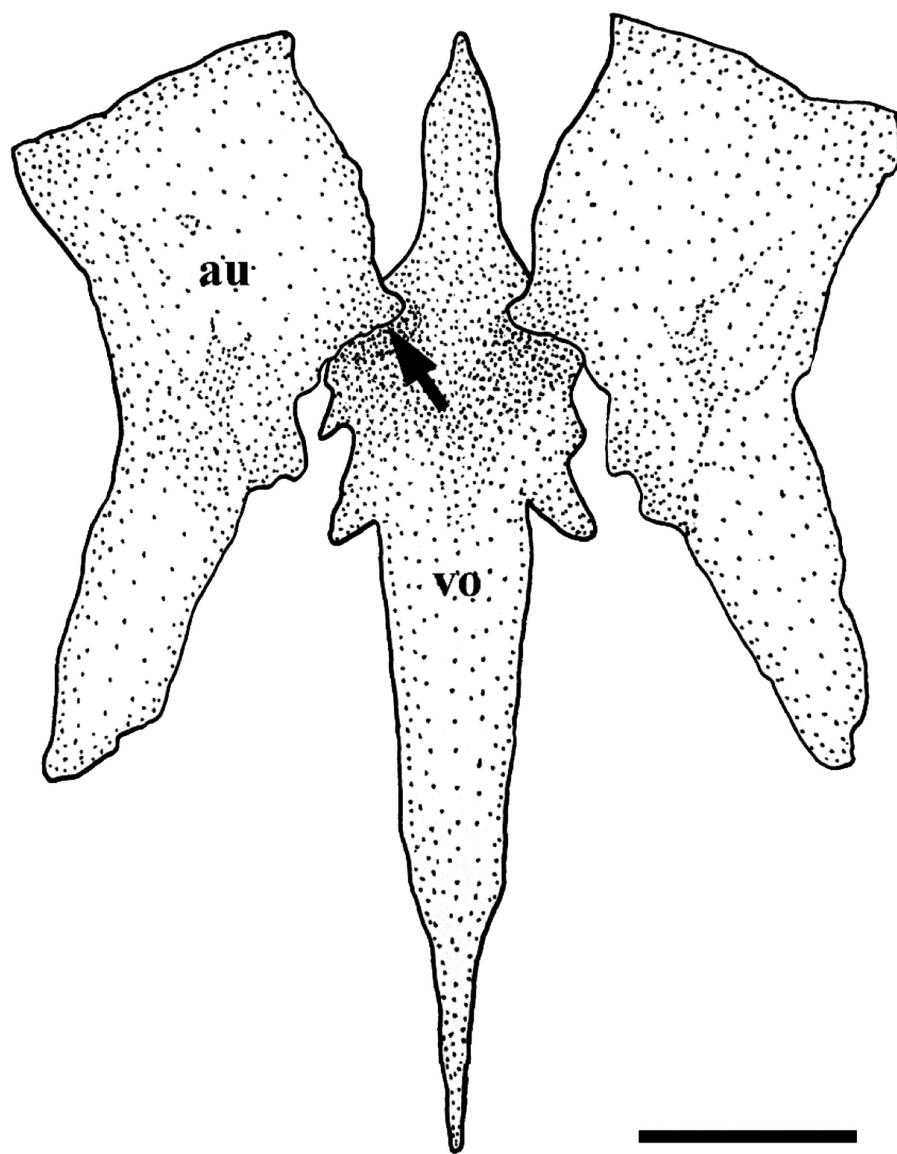

system; drawing of the neurocranium and laterosensory canal system from dorsal view). —Eschmeyer, 1998: 2123 (listed). —Arratia, 1998: 366, 367; fig. 14e, 368 (phylogenetic relationships, drawing of the neurocranium and laterosensory canal system from dorsal view). —de Pinna, 1998: 299; fig. 10 (phylogenetic relationships, synapomorphies). —Nion *et al.*, 2002: 15 (listed). —Wosiacki, 2002: 227, 324; fig. 87 (synapomorphies, phylogenetic relationships). —de Pinna, Wosiacki, 2003: 278 (listed). —Ferraris, 2007: 413 (listed). —Datovo, Bockmann, 2010: 233; fig. 37, 235–238 (phylogenetic tree, phylogenetic relationships). —Adriaens *et al.*, 2010: 349, 357; fig. 10 (notes on length of the interopercular odontodes and body elongation). —Do Nascimento, 2015: 938, 941, 943, 944, 951 (notes on osteological characters). —Fernández *et al.*, 2015: 6 (distribution in Argentina). —Nion *et al.*, 2016: 15 (listed). —Ferrer, 2016: 61–62; figs. 47–50 (synapomorphies, phylogenetic relationships). —Ochoa *et al.*, 2017a: 74–79 (phylogenetic relationships). —Katz *et al.*, 2018: 560–564 (phylogenetic relationships). —Ochoa *et al.*, 2020: fig. 3 (phylogenetic relationships).

**Type species.** *Scleronema operculatum* Eigenmann, 1917 (by original designation).

**Diagnosis.** *Scleronema* is phylogenetically diagnosed by four synapomorphies: 1) fleshy flap at the base of the maxillary barbel (Fig. 1) *vs.* fleshy flap absent or extending beyond the base of the maxillary barbel; 2) skin flap in the posterior margin of the opercle (Fig. 1) *vs.* skin flap absent or covering practically the entire opercle; 3) articulation between the autopalatine and the vomer ventrally located, with the medial margins of the autopalatines very close to each other (Fig. 2) *vs.* articulation between the autopalatine and the vomer situated laterally, with the medial margins of the

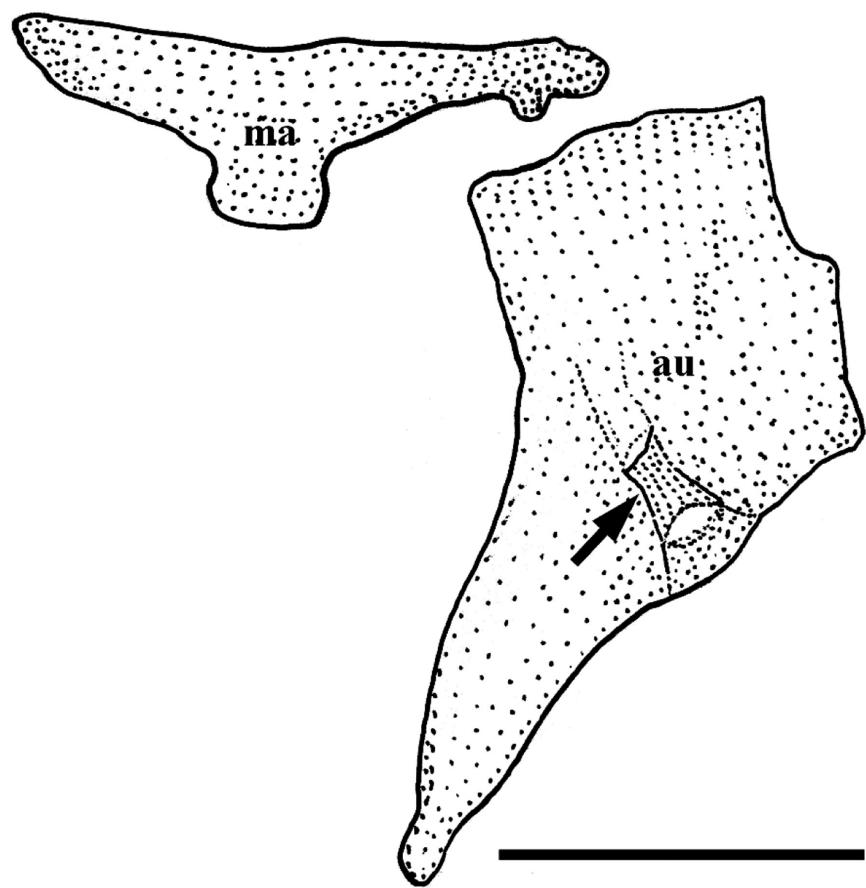

**FIGURE 1 |** Lateral view of **A.** *Scleronema macanuda*, new species, paratype (ZVC-P 9374; 74.5 mm SL) and **B.** *S. milonga*, new species, holotype (MCP 54165; 37.8 mm SL) showing the thick fleshy flap in the base of the maxillary barbel (red arrows), the skin flap in the posterior margin of the opercle (black arrows), the dorsal membrane in the caudal peduncle (white arrows), and the vertical black bar in the caudal fin (blue arrow).

**FIGURE 2** | Ventral view of the autopalatine (au) and vomer (vo) of *Scleronema operculatum* (UFRGS 19654) showing the articulation ventrally located between these two bones (black arrow). Scale bar = 1 mm.

autopalatines not close to each other; and 4) autopalatine with an interrupted or not interrupted ossified arch-shaped process on its dorsal surface forming a canal (Fig. 3) *vs.* arch-shaped process absent.

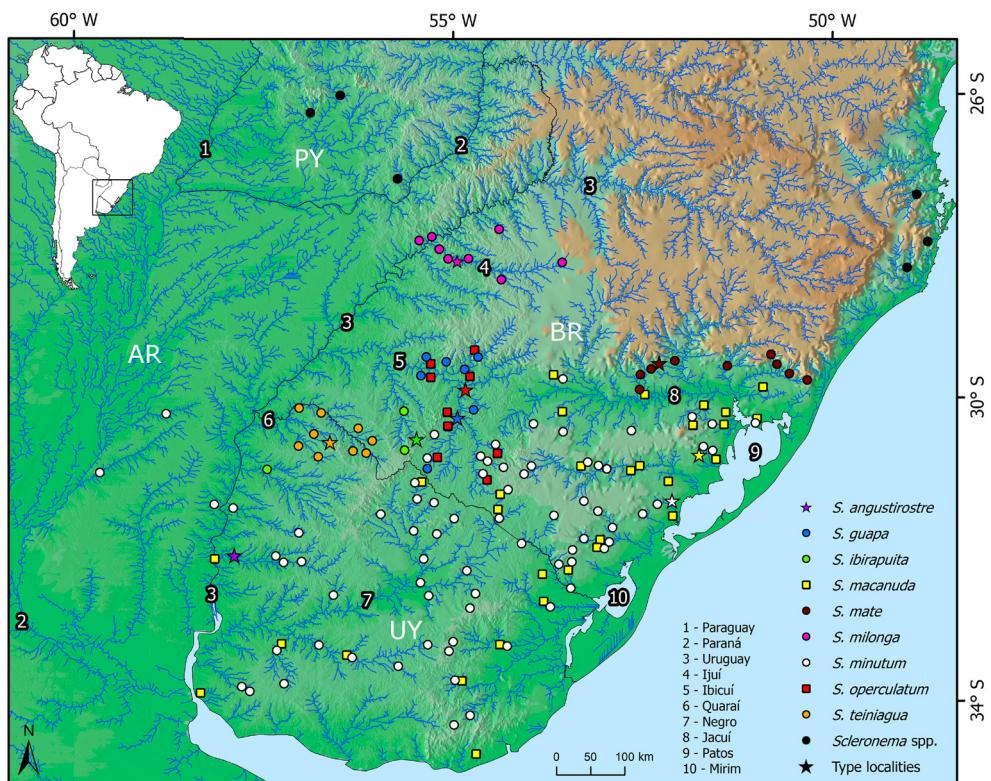

**Identification key.** The geographical distribution of the species in the key are given according to the names and limits of the freshwater ecoregions of Abell *et al.* (2008) and illustrated in the Fig. 4. The two species groups mentioned in key (*Scleronema minutum* species group and *S. operculatum* species group) are further commented in the Discussion section.

**FIGURE 3 |** Dorsal view of the autopalatine (au) and maxilla (ma) of *Scleronema minutum* (ZVC-P 12491) showing the arch-shaped process on its dorsal surface (black arrow). Scale bar = 2 mm.

#### Identification key to the species of *Scleronema*

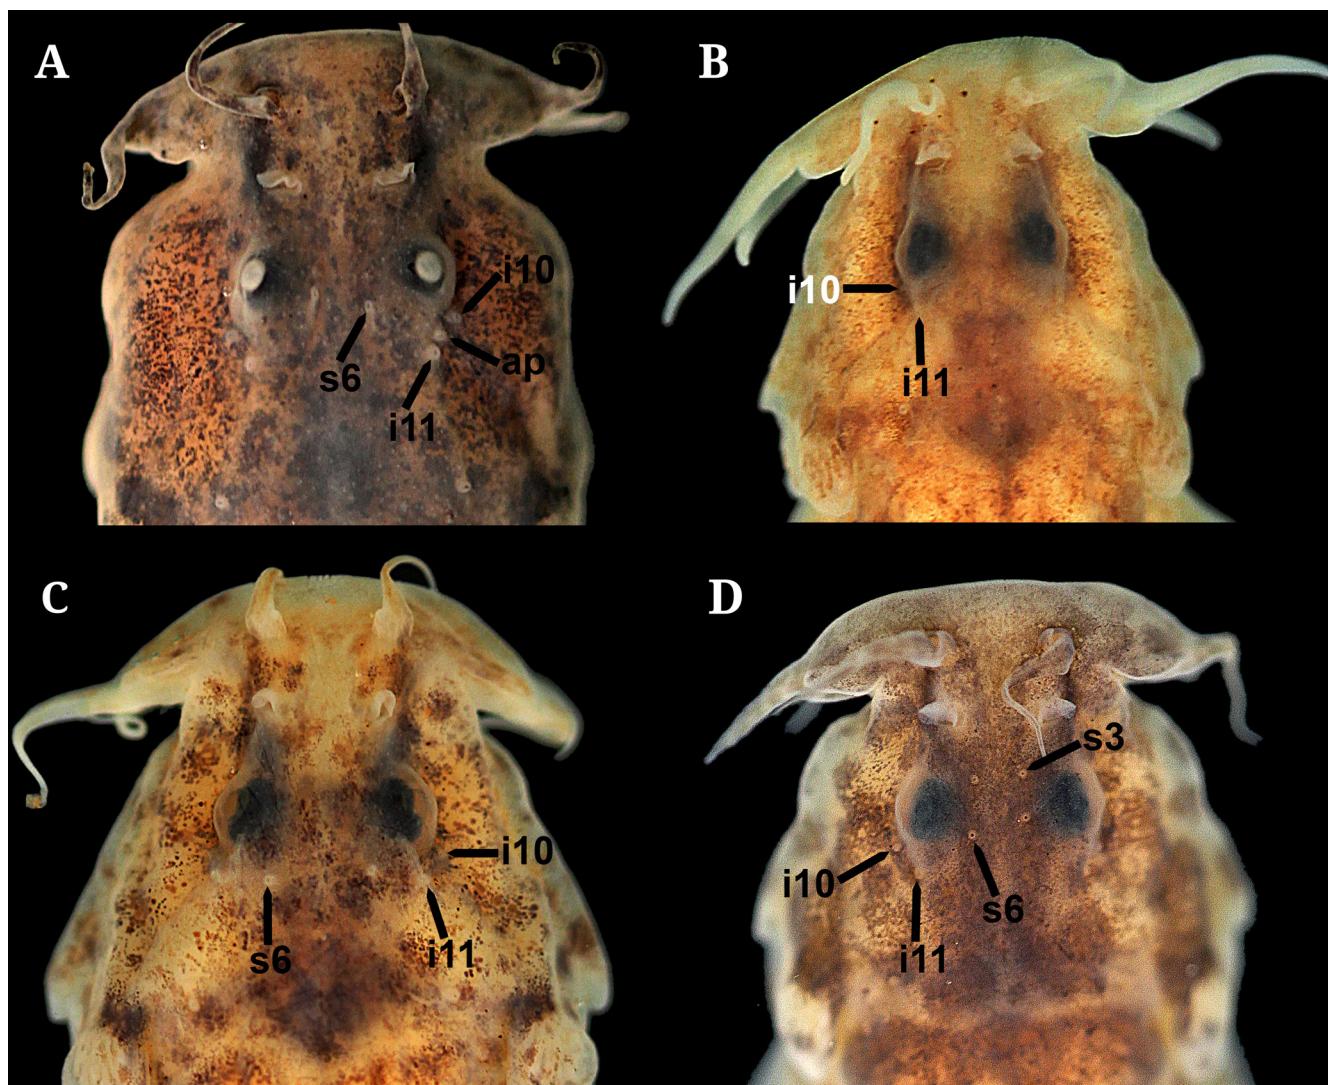

- 1a. Body compressed; maxillary barbel with thinner portion shorter than wider one; fleshy flap at the base of the maxillary barbel located anteriorly, thick, prolonged up to the snout and with distal margin straight; skin flap posterior to opercle pointed and long; caudal fin with a vertical black bar distally (Fig. 1A)  
.....2 (*Scleronema operculatum* species group)
- 1b. Body roughly cylindrical; maxillary barbel with thinner portion longer than wider one; fleshy flap at the base of the maxillary barbel located posteriorly, thin, restricted to the maxilla and with distal margin rounded; skin flap posterior to opercle rounded and short; caudal fin lacking a vertical black bar (Fig. 1B) .....  
.....3 (*Scleronema minutum* species group)
- 2a. Lateral surface of body with a midlateral series of 6–9 rounded black blotches larger than opercle (Figs. 1A, 9, 11); tip of maxillary barbel extending between anterior and posterior margins of interopercle .....  
.....*Scleronema macanuda* (Laguna dos Patos and lower rio Uruguay)
- 2b. Lateral surface of body with a midlateral series of 10–14 rounded black blotches

**FIGURE 4 |** Geographical distribution of the genus *Scleronema*. Circles and squares indicate species of the *S. minutum* group and *S. operculatum* group, respectively. Some symbols represent more than one collection locality. AR = Argentina; BR = Brazil; PY = Paraguay; UY = Uruguay.

- smaller than or equivalent in size to opercle (Figs. 21, 22, 25A); tip of maxillary barbel never surpassing anterior margin of interopercle .....  
..... *Scleronema operculatum* (lower rio Uruguay)
- 3a. Lateral surface of body with diffuse brown spots or rounded black blotches as large as or smaller than opercle ..... 4
- 3b. Lateral surface of body with rounded black blotches larger than opercle ..... 5
- 4a. Lateral surface of body with diffuse, scattered brown spots (Figs. 6, 7); infraorbital line of the laterosensory system with pores i10 and i11 and no additional pores associated ..... *Scleronema guapa* (lower rio Uruguay)
- 4b. Lateral surface of body with rounded black blotches (Figs. 12, 13A); infraorbital line of the laterosensory system with pores i10 and i11 and additional pores associated (Fig. 5A) ..... *Scleronema mate* (Laguna dos Patos)
- 5a. Pore i10 of the sphenotic canal of the laterosensory system absent; 8 pterygiophores in the dorsal fin ..... *Scleronema teiniagua* (lower rio Uruguay)
- 5b. Pore i10 of the sphenotic canal of the laterosensory system present (Fig. 5B-D); 9–10 pterygiophores in the dorsal fin ..... 6
- 6a. Pore s6 of the frontal canal of the laterosystem canal absent (Fig. 5B) .....  
..... *Scleronema ibirapuita* (lower rio Uruguay)
- 6b. Pore s6 of the frontal canal of the laterosystem canal present (Fig. 5C-D) ..... 7

- 7a. Pore s3 of the frontal canal of the laterosensory system absent (Fig. 5C); dorsal-fin origin located at vertical through origin of pelvic fin or slightly posterior ..  
..... *Scleronema milonga* (lower rio Uruguay)
- 7b. Pore s3 of the frontal canal of the laterosensory system present (Fig. 5D); dorsal-fin origin located at vertical through half-length of pelvic fin .....  
*Scleronema minutum* (Laguna dos Patos, lower rio Uruguay and lower rio Paraná)

**FIGURE 5 |** Dorsal view of the head of **A.** *Scleronema mate*, new species, paratype (UFRGS 17418; 34.9 mm SL), **B.** *S. ibirapuita*, new species, paratype (UFRGS 27402; 49.4 mm SL), **C.** *S. milonga*, new species, paratype (LIRP 16775; 35.3 mm SL), and **D.** *S. minutum* (UFRGS 19651; 46.4 mm SL) showing the pores of the laterosensory system. “Ap” = additional pore.

Hartmann, M. Dalmolin, R. B. Dala-Corte & T. Guimarães. UFRGS 19655\*, 10 (1 c&s), 29.8–42.3 mm SL, Alegrete, arroio Jacaquá,  $29^{\circ}51'39"S\ 55^{\circ}20'56"W$ , 1 May 2007, B. Klotzel, L. E. Lanés & M. Volcan.

**Diagnosis.** *Scleronema guapa* is distinguished from all congeners by the lateral surface of body with diffuse, scattered brown spots, sometimes grouped forming irregular and small marks at midlateral line (*vs.* lateral surface of body with a midlateral line of black or brown rounded blotches). *Scleronema guapa* is further distinguished from *S. macanuda* and *S. operculatum* by the maxillary barbel longer than half-length of the head (*vs.* smaller than half-length of the head); the tips of pectoral-fin rays not extending beyond the interradial membrane (*vs.* extending beyond the interradial membrane), the skin flap in the posterior margin of the opercle rounded and short (*vs.* skin flap pointed and long); the fleshy flap at the base of the maxillary barbel located posteriorly, thin, restricted to the maxilla and distal margin rounded (*vs.* fleshy flap located anteriorly, thick, prolonged up to the snout and with distal margin straight); and by the caudal fin uniformly brown (*vs.* caudal fin with a transversal black bar distally). *Scleronema guapa* is further distinguished from *S. ibirapuita*, *S. milonga*, and *S. teiniagua* by having the pore s3 of the supraorbital line of the laterosensory system (*vs.* pore s3 absent).

**Description.** Based on specimens ranging from 16.2 to 42.3 mm SL; 2 c&s (one dissected). Morphometric data for 20 type specimens in Tab. 2.

*External morphology.* Greatest height and width of body in half-length of trunk. Body elongate, trunk roughly cylindrical gradually compressed towards to caudal fin. Dorsal profile of trunk convex and ventral profile straight to slightly convex. Dorsal and ventral profiles of caudal peduncle straight. Dorsal margin of caudal peduncle with thin membrane, resembling adipose fin. Head depressed and wide, usually trapezoid-shaped from dorsal view, wider posteriorly; square-shaped in specimens with muscles of cheeks well developed. Dorsal and ventral profiles of head straight to slightly convex. Anterior snout profile usually rounded from dorsal view (holotype with anterior snout profile straight; Fig. 6). Nostrils of equivalent size, smaller than eye diameter. Anterior nostril surrounded by fleshy flap of integument, posterolaterally continuous with nasal barbel. Posterior nostril surrounded anterolaterally by thin flap of integument. Eyes rounded, dorsally oriented but also visible from lateral view; located behind posterior nostrils; orbital rim not free; eyes covered by thin and transparent skin.

**FIGURE 6 |** *Scleronema guapa* just after the fixation in formalin, holotype (UFRGS 23500; 36.4 mm SL), Brazil, Rio Grande do Sul State, Rosário do Sul, sanga Santo Antônio, tributary to rio Ibicuí da Armada, lower rio Uruguay.

**TABLE 2 |** Morphometric data of *Scleronema guapa*, new species (data of holotype included in the range). N = number of specimens; SD = standard deviation.

Barbels with large bases and tapering gradually towards tips. Nasal barbel long; emerging from posterolateral edge of anterior nostril extending between anterior and posterior margins of eye. Maxillary barbel long; emerging from edge of upper lip and extending between anterior and posterior margins of interopercle. Basal portion of maxillary barbel wide with thin fleshy flap dorsally and distal margin rounded. Maxillary barbel with thinner portion longer in length than wider one. Rictal barbel emerging from lateral lobe of lower lip and slightly shorter than maxillary barbel. Mouth subterminal with edges posteriorly oriented. Upper lip wider than lower lip. Lower lip with round fleshy lobes in corners. Ventral surface of lower lip with small papillae. Gill openings not constricted united with isthmus anteriorly forming free fold. Opercular patch of odontodes rounded, inserted in posterior region of head visible from dorsal and lateral views. Posterior margin of opercle with distinct skin flap short and rounded.

Interopercular patch of odontodes elongate inserted on posteroventral region of head visible from lateral and ventral views. Odontodes of opercle and interopercle barely visible, completely involved by flesh.

Pectoral fin with distal margin convex when expanded, 6(n = 5), 6/7(n = 9) or 7(n = 48; including holotype) rays; first ray unbranched and not prolonged as filament; fourth and fifth longest. Pectoral-fin insertion posterior to branchial aperture usually covered by branchial membrane anteriorly. Some specimens with intumescence above anterior portion of pectoral fin and axillary pore not visible. Pelvic fin with distal margin convex when expanded, 4(n = 1), 4/5(n = 2) or 5(n = 59; including holotype) rays; first ray unbranched. Pelvic-fin origin located at half-length of SL extending between urogenital papilla and anal-fin anterior insertion; tangentially inserted with inner margins separated by large interspace. Urogenital papilla located between last third of pelvic fins.

Dorsal fin with distal margin straight to slightly convex when expanded, 7(n = 2), 8(n = 5), 9(n = 46; including holotype), or 10(n = 9) rays; usually first two rays unbranched. Dorsal-fin origin located at vertical through half-length of pelvic fin. Anal fin with distal margin slightly convex when fin expanded, 5(n = 2) or 6(n = 60; including holotype); usually first two rays unbranched. Anal-fin origin located at vertical through last third of dorsal-fin base. Caudal fin with distal margin straight and corners slightly rounded, 11(n = 5), 12(n = 57; including holotype) rays; most-external rays of dorsal and ventral plates of caudal fin always unbranched and smaller than branched rays. Branched rays of caudal fin splitting up to twice. Caudal fin with 9(n = 1) procurent rays dorsally and 8(n = 1) procurent rays ventrally. Procurent rays of dorsal, anal, and caudal fins rarely visible.

**Osteology.** Premaxilla with 14–19(n = 2) teeth arranged in two rows. Dentary with 28–32(n = 1) teeth arranged in one to three rows. Opercle with 9–14(n = 2) odontodes and interopercle with 10–14(n = 2) odontodes. Hyoid arch with 6(n = 1) or 6/7(n = 1) branchiostegal rays. Free vertebrae 35(n = 1) or 36(n = 1); abdominal vertebrae 3(n = 1). Ribs 11(n = 2). First complete haemal arch in 4<sup>th</sup>(n = 1) free vertebra, first haemal spine in 12<sup>th</sup>(n = 1) free vertebra. Dorsal fin with 9(n = 2) pterygiophores; first one inserted anteriorly to neural spine of 16<sup>th</sup>(n = 2) vertebra. Anal fin with 6(n = 2) pterygiophores; first one inserted anteriorly to haemal spine of 20<sup>th</sup>(n = 2) vertebra.

**Laterosensory system.** Data for 61 specimens summarized in Tab. 3. Canals of laterosensory system with simple (non-dendritic) tubes and external pores. Supraorbital line with nasal canal usually absent and frontal canal usually with pores s3 and s6. Infraorbital line with antorbital segment invariably absent and sphenotic canal usually with pores i10 and i11. Posterior segment of frontal, sphenotic and otic canals fused to each other. Otic, posotic and scapular canals present with preoperculo-mandibular and pterotic branches short and usually with one pore each (po1 and po2, respectively). Trunk canal short usually with two pores.

**Coloration in alcohol.** Lateral surface of body with brown spots over light yellow background (Fig. 6). Occasionally, smaller specimens with spots grouped forming small blotches in midlateral line of trunk (Fig. 7). Dorsal surface of body usually with brown spots irregularly distributed or with vermicular brown marks extending ventrally to dorsolateral surface of trunk over light yellow background. Ventral surface of body light yellow with few brown blotches in caudal peduncle. Dorsal and laterodorsal surfaces of head with small brown spots over light yellow background. Anterior portion of opercle

**TABLE 3 |** Distribution of pores of the laterosensory system for the species of *Scleronema*. Asterisks indicate the pattern present in the type specimens of *Scleronema minutum* and *S. operculatum* and the holotype for other species. Additional pores are present in the infraorbital line or posteriorly to the pore s6 of the supraorbital line.

black. Ventral surface of body light yellow. Barbels uniformly yellow or intercalated with brown areas. Pectoral and dorsal fins hyaline or with rays of anterior portion faintly brown. Pelvic and anal fins hyaline. Caudal fin with rays faintly brown and distal margin hyaline. Caudal fin with vertical light brown stripe basally (Figs. 6–7).

**Coloration in life.** Coloration in life similar to that of specimens preserved in ethyl alcohol, but more intense (Figs. 6–7).

**Geographical distribution.** *Scleronema guapa* is endemic to the rio Ibicuí basin, a tributary to the left bank of rio Uruguay, State of Rio Grande do Sul, southern Brazil (Fig. 4).

**Ecological notes.** *Scleronema guapa* inhabits rivers and streams, with fine sand-bottoms. The species is usually collected syntopically with *S. operculatum*.

**FIGURE 7 |** *Scleronema guapa* just after the fixation in formalin, paratype (UFRGS 18087, 32.0 mm SL), Brazil, Rio Grande do Sul, Rosário do Sul, sanga Santo Antônio, tributary to rio Ibicuí da Armada, lower rio Uruguay.

**Etymology.** The species epithet “*guapa*” is a regional adjective used to describe a beautiful person, an allusion to the beauty of the new species.

**Conservation status.** *Scleronema guapa* has an Extent of Occurrence (EOO) less than 5,000 km<sup>2</sup>, but no specific threats were detected and the species can be classified as LC according to IUCN criteria (IUCN, 2019).

**Additional material examined.** 55 specimens from Brazil, rio Ibicuí basin, lower rio Uruguay: MCP 17436, 6, 24.6–29.5 mm SL, São Francisco de Assis, rio Jaguari. MCP 48738, 1 (c&s), not measured (specimen with axial skeleton and fins damaged), São Francisco de Assis, rio Jaguari. MCP 26866, 1, 38.8 mm SL, Rosário do Sul, arroio do Salso, tributary of rio Ibicuí da Armada. MCP 25192, 14, 20.0–21.7 mm SL, São Francisco de Assis, rio Inhacunda. MCP 27505, 1, 23.2 mm SL, São Francisco de Assis,

arroio Taquari, tributary of rio Miracatu. MCP 54170, 19, 17.6–27.0 mm SL, São Francisco de Assis, unnamed stream tributary of rio Inhaundá. MCP 54169, 13, 17.3–26.3 mm SL, Jaguari, arroio do Tigre, tributary of rio Jaguari.

of eye. Maxillary barbel long; emerging from edge of upper lip and extending up to posterior margin of interopercle or briefly surpassing. Basal portion of maxillary barbel wide with thin skin fold dorsally and distal margin rounded. Maxillary barbel with thinner portion longer in length than wider one. Rictal barbel emerging from lateral lobe of lower lip and slightly shorter than maxillary barbel. Mouth subterminal with edges posteriorly oriented. Upper lip wider than lower lip. Lower lip with round fleshy lobes in corners. Ventral surface of lips with small papillae. Gill openings not constricted united with isthmus anteriorly forming free fold. Opercular patch of odontodes rounded, inserted in posterior region of head visible from dorsal and lateral views. Posterior margin of opercle with distinct skin flap short and rounded. Interopercular patch of odontodes elongate inserted on posteroventral region of head visible from lateral and ventral views. Odontodes of opercle and interopercle barely visible, completely involved by flesh.

Pectoral fin with distal margin convex when expanded, 6(n = 1), 6/7(n = 3), or 7(n = 39; including holotype) rays; first one always unbranched and not prolonged as filament; fourth and fifth longest. Pectoral-fin insertion posterior to branchial aperture usually covered by branchial membrane anteriorly. Some specimens with intumescence above anterior portion of pectoral fin and axillary pore not visible. Pelvic fin with distal margin convex when expanded, 4/5(n = 2) or 5(n = 41; including holotype) rays; first one always unbranched. Pelvic-fin origin located at half-length of SL extending between urogenital papilla and anal-fin anterior insertion; tangentially inserted with inner margins separated by large interspace. Urogenital papilla located between last third of pelvic fins.

Dorsal fin with distal margin straight to slightly convex when expanded, 8(n = 2), 9(n = 39; including holotype), or 10(n = 2) rays; first two or three rays unbranched. Dorsal fin with 2(n = 2) procurent rays. Dorsal-fin origin located at vertical through half-length of pelvic fin. Anal fin with distal margin slightly convex when expanded, 6(n = 43; including holotype) rays; usually first two rays unbranched. Anal fin with 2(n = 2) procurent rays. Anal-fin origin located at vertical through last third to posterior edge of dorsal-fin base. Caudal fin with distal margin straight and corners slightly rounded, 11(n = 2) or 12(n = 41; including holotype) rays; most-external rays of dorsal and ventral plates of caudal fin always unbranched and smaller than branched rays. Branched rays of caudal fin splitting up to twice. Procurent rays of dorsal, anal and caudal fins rarely visible. Caudal fin with 12(n = 1) or 13(n = 1) procurent rays dorsally and 9(n = 1) or 10(n = 1) procurent rays ventrally.

**Osteology.** Premaxilla with 26–28(n = 1) teeth arranged in three rows. Dentary with 30–32(n = 1) teeth. Opercle with 12–13(n = 2) odontodes and interopercle with 16–18(n = 2) odontodes. Hyoid arch with 6(n = 2) branchiostegal rays. Free vertebrae 33(n = 1) or 35(n = 2); abdominal vertebrae 3(n = 1). Ribs 12(n = 3). First complete haemal arch in 4<sup>th</sup>(n = 1) free vertebra, first haemal spine in 12<sup>th</sup>(n = 1) free vertebra. Dorsal fin with 9(n = 3) pterygiophores; first one inserted anteriorly to neural spine of 14<sup>th</sup>(n = 2) or 15<sup>th</sup>(n = 1) vertebra. Anal fin with 6(n = 3) pterygiophores; first one inserted anteriorly to haemal spine of 18<sup>th</sup>(n = 1) or 20<sup>th</sup>(n = 2) vertebra.

**Laterosensory system.** Data for 43 specimens summarized in Tab. 3. Canals of laterosensory system with simple (non-dendritic) tubes and external pores. Supraorbital line with nasal canal invariably absent and frontal canal usually absent (Fig. 5B) (one of 43 specimens with pore s6). Infraorbital line with antorbital segment invariably absent and sphenotic canal with pores i10 and i11. Posterior segment of frontal, sphenotic and otic canals fused to each other. Otic, posotic and scapular canals present with preoperculo-mandibular and pterotic branches short usually with one pore associated each (po1 and po2, respectively). Trunk canal short with two pores.

**Coloration in alcohol.** Lateral surface of body with midlateral line of 5–8 round brown blotches larger than opercle over light yellow background (Fig. 8); blotches of some individuals becoming fade or absent towards caudal peduncle. Dorsal surface of body with 5–6 rectangular brown blotches extending ventrally to laterodorsal surface of body. Ventral surface of body light yellow with few brown blotches in caudal peduncle. Dorsal surface of head almost entirely black. Laterodorsal surface of head with numerous brown round blotches over light yellow background. Anterior portion of opercle black. Ventral surface of head light yellow with few small brown blotches in

lower lip, sometimes forming thin stripe. Barbels uniformly yellow or intercalated with brown areas. Pectoral and anal fins with rays faintly brown and distal margins hyaline. Pelvic fin hyaline. Dorsal and caudal fins with vertical light brown stripe basally, rays faintly brown, and distal margins hyaline (Fig. 8).

**Geographical distribution.** *Scleronema ibirapuita* occurs in the rio Ibirapuitã basin, a tributary to the left bank of rio Ibicuí (Brazil), and in the río Arapey (Uruguay; see remarks); lower río Uruguay basin (Fig. 4).

**Ecological notes.** *Scleronema ibirapuita* inhabits rivers and streams with sand- or gravel-bottoms. The species has not been collected with congeners. The stomach of one specimen had immature aquatic insects and unidentified plant remains.

**Etymology.** The species epithet “*ibirapuita*” is given in reference to the Conservation Unit “Área de Proteção Ambiental Ibirapuitã”, where the new species can be found and that includes its type locality. A noun in apposition.

**Conservation status.** *Scleronema ibirapuita* has an Extent of Occurrence (EOO) of less than 5,000 km<sup>2</sup>, but no specific threats were detected to the species. In addition, *S. ibirapuita* is widespread in streams and rivers draining a Federal Conservation Unit (Área de Proteção Ambiental Ibirapuitã). Thus, the species can be classified as Least Concern (LC) according to IUCN criteria (IUCN, 2019).

**Remarks.** *Scleronema ibirapuita* has only one record for the río Arapey basin collected in 1972, Uruguay (ZVC-P 5123; five specimens). Although these specimens have the diagnostic pattern of the laterosensory system for the species, they are listed herein as non-type specimens.

**Additional material examined.** ZVC-P 5123, 5, 26.1–32.2 mm SL, Uruguay, Salto, río Arapey Grande near Termas, lower río Uruguay.

**Diagnosis.** *Scleronema macanuda* is distinguished from all congeners with the exception of *S. operculatum* by the following external characters: maxillary barbel smaller than half-length of the head (*vs.* larger than half-length of the head); tips of the pectoral-fin rays extending beyond the interradial membrane (*vs.* not extending beyond the interradial membrane), skin flap in the posterior margin of the opercle pointed and long (*vs.* skin flap round or short); fleshy flap at the base of the maxillary barbel located anteriorly, thick, prolonged up to the snout and with distal margin straight (*vs.* fleshy flap located posteriorly, thin, restricted to the maxilla and with distal margin rounded); and the caudal fin with a transversal black bar distally (*vs.* caudal fin with black bar absent). *Scleronema macanuda* differs from *S. operculatum* by having a midlateral line of 6–9 rounded black blotches larger than opercle (*vs.* midlateral line of 10–14 rounded black blotches as large as or smaller than opercle); tip of nasal barbel usually extending beyond anterior margin of eye (*vs.* tip of nasal barbel never reaching anterior margin

of eye), tip of maxillary barbel extending between anterior and posterior margins of interopercle (*vs.* tip of maxillary barbel never surpassing anterior margin of interopercle).

**Description.** Based on types ranging from 15.8 to 93.6 mm SL; 11 c&s (3 dissected). Morphometric data for types and non-types in Tab. 5.

*External morphology.* Greatest height of body in trunk and greatest width of body in anterior portion of trunk. Body elongate and compressed. Dorsal and ventral profiles of trunk straight to slightly convex. Dorsal and ventral profiles of caudal peduncle straight to slightly convex up to anteriormost procurrent ray insertion. Dorsal margin of caudal peduncle with thin membrane, resembling adipose fin (Fig. 1A). Head depressed and wide, trapezoidal from dorsal view, wider posteriorly. Dorsal and ventral profiles of head straight. Anterior snout profile rounded from dorsal view. Nostrils of equivalent size, smaller than eye diameter. Anterior nostril surrounded by fleshy flap of

**FIGURE 9 |** *Scleronema macanuda*, new species, holotype (MCN 20230; 71.8 mm SL), Brazil, Rio Grande do Sul Sentinela do Sul, irrigation water channel draining to arroio Velhaco, laguna dos Patos system.

integument, posterolaterally continuous with nasal barbel. Posterior nostril surrounded anterolaterally by thin flap of integument. Eyes rounded, dorsally oriented but also visible from lateral view; located behind posterior nostrils; orbital rim not free; eyes covered by thin and transparent skin.

Barbels with large bases and tapering gradually towards tips. Nasal barbel short; emerging from posterolateral edge of anterior nostril and usually extending between anterior and posterior margins of eye (few specimens with nasal barbel surpassing posterior nostril and not reaching anterior margin of eye). Maxillary barbel short; emerging from edge of upper lip and extending between anterior and posterior margins of interopercle. Basal portion of maxillary barbel wide and with thick flashy flap dorsally with distal margin straight. Maxillary barbel with thinner portion smaller in length than

wider one. Rictal barbel emerging from lateral lobe of lower lip and slightly shorter than maxillary barbel. Mouth subterminal with edges posteriorly oriented. Upper lip wider than lower lip. Lower lip with round fleshy lobes in corners. Lower lip and corners of upper lip with small papillae. Gill openings not constricted united with isthmus anteriorly forming free fold. Opercular patch of odontodes rounded, inserted in posterior region of head and visible from dorsal and lateral views. Posterior margin of opercle with distinct skin flap, thin and pointed; some specimens with groove in skin flap. Interopercular patch of odontodes elongate inserted on posteroventral region of head visible from lateral and ventral views. Odontodes of opercle and interopercle barely visible, completely involved by flesh.

Pectoral fin with distal margin convex when expanded, 7 rays( $n = 41$ ; including holotype); first one always unbranched and not prolonged as filament; fourth and fifth longest. Pectoral-fin insertion posterior to branchial aperture usually covered by branchial membrane anteriorly. Rays of pectoral fin extending slightly beyond interradial membrane. Some specimens with wilted skin above anterior portion of pectoral fin or with intumescence, axillary pore not visible. Pelvic fin with distal margin convex when expanded, 5( $n = 40$ ) or rarely 6( $n = 1$ ) rays; first one always unbranched. Pelvic-fin origin located at half-length of SL extending between urogenital papilla and anal-fin anterior insertion; tangentially inserted with inner margins separated by large interspace. Urogenital papilla located between last third of pelvic fins.

Dorsal fin with distal margin straight when expanded, 10( $n = 9$ ), 11( $n = 9$ ), 12( $n = 15$ ; including holotype), 13( $n = 5$ ) or 14( $n = 3$ ) rays; first two rays unbranched. Dorsal fin with two( $n = 4$ ) or three( $n = 7$ ) procurent rays. Dorsal-fin origin located at vertical through first half of pelvic fin. Anal fin with distal margin slightly convex when expanded, 6( $n = 36$ ; including holotype) or 7( $n = 6$ ) rays; first two rays unbranched. Anal fin with one( $n = 1$ ) or two( $n = 10$ ) procurent rays. Anal-fin origin located at vertical through last third of dorsal-fin base. Caudal fin with distal margin straight and corners slightly rounded, 12( $n = 41$ ; including holotype) rays; most external rays of dorsal and ventral plates of caudal fin always unbranched and smaller than branched rays. Branched rays of caudal fin splitting up to twice. Caudal fin with 11( $n = 2$ ), 12( $n = 7$ ), 13( $n = 1$ ) or 14( $n = 1$ ) procurent rays dorsally and 9( $n = 9$ ), 10( $n = 1$ ) or 13( $n = 1$ ) procurent rays ventrally. Procurent rays of dorsal, anal and caudal fins rarely visible.

**Osteology.** Premaxilla with 19–29( $n = 3$ ) teeth arranged in three rows. Dentary with 34–38( $n = 1$ ) teeth inserted in one to three rows. Opercle with 9–13( $n = 3$ ) odontodes and interopercle with 14–19( $n = 3$ ) odontodes. Hyoid arch with 6( $n = 11$ ) branchiostegal rays. Free vertebrae 34( $n = 2$ ), 35( $n = 2$ ), 36( $n = 4$ ), 37( $n = 2$ ) or 38( $n = 1$ ); abdominal vertebrae 3( $n = 5$ ). Ribs 8( $n = 5$ ), 9( $n = 4$ ) or 10( $n = 2$ ). First complete haemal arch in 4<sup>th</sup>( $n = 5$ ) free vertebra, first haemal spine in 7<sup>th</sup>( $n = 1$ ), 8<sup>th</sup>( $n = 3$ ) or 9<sup>th</sup>( $n = 2$ ) free vertebra. Dorsal fin with 10( $n = 1$ ), 11( $n = 5$ ) or 12( $n = 4$ ) or 14( $n = 1$ ) pterygiophores; first one inserted anteriorly to neural spine of 13<sup>th</sup>( $n = 2$ ), 14<sup>th</sup>( $n = 2$ ), 15<sup>th</sup>( $n = 3$ ), 16<sup>th</sup>( $n = 3$ ) or 17<sup>th</sup>( $n = 1$ ) vertebra. Anal fin 5( $n = 2$ ) or 6( $n = 9$ ) pterygiophores; first one inserted anteriorly to haemal spine of 19<sup>th</sup>( $n = 1$ ), 20<sup>th</sup>( $n = 4$ ), 21<sup>st</sup>( $n = 4$ ) or 22<sup>nd</sup>( $n = 2$ ) vertebra.

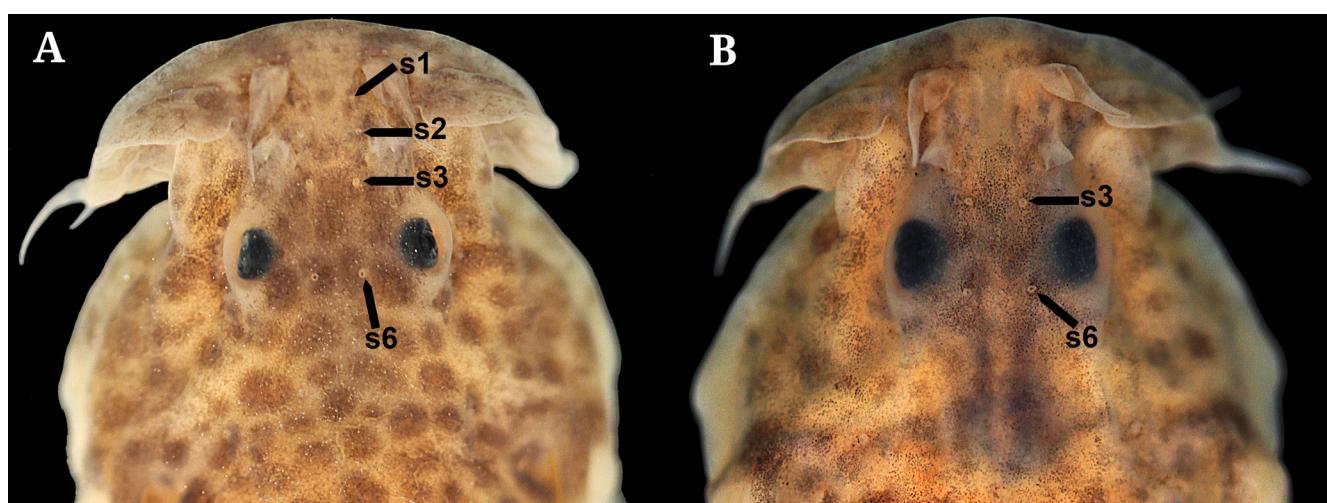

**Laterosensory system.** Data for 107 specimens summarized in Tab. 3. Canals of laterosensory system with simple (non-dendritic) tubes and external pores. Supraorbital line usually with two paired nasal canals (right and left; Fig. 10A); however, one or both canals can be absent. Nasal canal, when present, interrupted (not connecting

with frontal canal) with pores s1 and s2. Frontal canal usually with pores s3 and s6. Infraorbital line with antorbital segment invariably absent and sphenotic canal usually with pores i10 and i11. Posterior segment of frontal, sphenotic and otic canals fused to each other. Otic, posotic and scapular canals present with preoperculo-mandibular and pterotic branches short with one pore each (po1 and po2, respectively). Trunk canal short usually with two pores.

**Coloration in alcohol.** Lateral surface of body with two longitudinal lines (midlateral and laterodorsal) of 6–9 black rounded blotches (distinctly larger than opercle) over light yellow background (Figs. 9, 11). Occasionally, smaller individuals with blotches becoming fade or absent towards to caudal peduncle and larger individuals with scattered small blotches among larger ones (Fig. 11). Longitudinal line of laterodorsal blotches visible from dorsal view. Anterior portion of dorsal surface of body with numerous black rounded blotches. Ventral surface of body uniformly light yellow. Dorsal and lateral surfaces of head and nape area with numerous black rounded blotches or uniformly black. Ventral surface of head light yellow. Dorsal surface of maxillary and rictal barbels weakly black and ventral surface light yellow. Nasal barbel weakly black. Opercle with anterior and dorsal margins black; posterior fold light yellow. Pectoral, pelvic, dorsal and anal fins hyaline. Dorsal fin of some larger individuals with black stripe basally. Caudal fin hyaline with vertical stripe basally and vertical black bar in distal margin, which could extend up to mid-length of fin in larger individuals (Figs. 9, 11).

**Coloration in life.** Coloration in life similar to that of specimens preserved in ethyl alcohol, but more intense (Fig. 11).

**Geographical distribution.** *Scleronema macanuda* is widely distributed in rivers and streams that drain to laguna dos Patos (Brazil) and lagoa Mirim (Brazil and Uruguay); and in small Atlantic coastal drainages of Uruguay (Fig. 4). In the lower rio Uruguay

**FIGURE 10 |** Dorsal view of the head of **A.** *Scleronema macanuda*, new species, paratype (UFRGS 21635; 75.6 mm SL) and **B.** *S. operculatum* (UFRGS 19646; 56.1 mm SL) showing the pores of the laterosensory system.

**FIGURE 11** | Specimens in life of *Scleronema macanuda*, new species, paratypes, (UFRGS 21635; **A.** 75.6 mm SL, **B.** 65.7 mm SL), Brazil, Rio Grande do Sul, Bagé, rio Piraí, tributary of rio Negro, lower rio Uruguay.

basin, the species occurs in the rio Negro and tributaries (Brazil and Uruguay) and in arroyo Higueritas (Uruguay). The specimen figured by Vaz-Ferreira, Soriano (1960: fig. 1; ZVCP 170) from the mouth of río Queguay in the río Uruguay (Uruguay) was not analyzed, but can be identified as *S. macanuda*.

**Ecological notes.** *Scleronema macanuda* inhabits rivers and streams usually with sand-bottoms. The species is collected syntopically with *S. minutum* in some localities. The stomachs of 11 specimens were analyzed and six had immature aquatic Diptera (Chironomidae), Oligochaeta, unidentified plant fragments and sand. Individuals of *S. macanuda* larger than 35.0 mm SL are capable to spawn and considered adults by Carvalho (2017). The diet of immatures of *S. macanuda* is composed of Chironomidae and Ephemeroptera according to Carvalho (2017).

**Etymology.** The species epithet “macanuda” is a regional adjective to describe a “large and strong” person, an allusion to being the largest species of the genus.

**Conservation status.** *Scleronema macanuda* is frequent and abundant in the rio Negro basin and Laguna dos Patos system. In addition, no specific threats were detected and the species can be classified as Least Concern (LC) according to IUCN criteria (IUCN, 2019).

**Additional material examined.** 75 specimens. **Brazil:** FMNH 125684, 1, 13.1 mm SL, Santa Maria, rio Vacacaí-Mirim. MCN 12681, 3, 22.6–54.3 mm SL, São Lourenço do Sul, arroio Inhuquipá. **Diagnosis.** *Scleronema mate* is distinguished from all congeners, with the exception of *S. operculatum*, by having the rounded blotches at the midlateral line as large as or smaller than opercle (*vs.* rounded blotches larger than opercle or absent). *Scleronema mate* differs from *S. operculatum* by the maxillary barbel longer than half-length of the head (*vs.* shorter than half-length of the head); tips of the pectoral-fin rays not extending beyond the interradial membrane (*vs.* extending beyond the interradial membrane), skin flap in the posterior margin of the opercle rounded and short (*vs.* skin flap pointed and

**FIGURE 12 |** *Scleronema mate*, new species, holotype (MCP 54183; 49.3 mm SL), Brazil, Rio Grande do Sul, Venâncio Aires, arroio Grande, tributary of arroio Castelhano, rio Taquari basin, laguna dos Patos system.

long); fleshy flap at the base of the maxillary barbel, thin, restricted to the maxilla and with distal margin rounded (*vs.* fleshy flap located anteriorly, thick, prolonged up to the snout and with distal margin straight); and by the caudal fin uniformly brown (*vs.* caudal fin with a transversal black bar distally).

**Description.** Based on specimens ranging from 18.4 to 50.1 mm SL; 4 c&s (2 dissected). Morphometric data for 16 types in Tab. 6.

*External morphology.* Greatest height and width of body in half-length of trunk. Body elongate, trunk roughly cylindrical gradually compressed towards to caudal fin. Dorsal profile of trunk convex and ventral profile straight. Dorsal and ventral profiles of caudal peduncle straight. Dorsal margin of caudal peduncle with thin membrane, resembling adipose fin. Head depressed and wide, trapezoid-shaped from dorsal view, wider posteriorly; square-shaped in specimens with muscles of cheeks well developed. Dorsal and ventral profiles of head straight to slightly convex. Anterior snout profile usually rounded from dorsal view. Nostrils of equivalent size, smaller than eye diameter. Anterior nostril surrounded by fleshy flap of integument, posterolaterally continuous with nasal barbel. Posterior nostril surrounded anterolaterally by thin flap of integument. Eyes rounded, dorsally oriented but also visible from lateral view; located behind posterior nostrils; orbital rim not free; eyes covered by thin and transparent skin.

Barbels with large bases and tapering gradually towards tips. Nasal barbel long; emerging from posterolateral edge of anterior nostril extending up to posterior margin of eye or briefly surpassing. Maxillary barbel long; emerging from edge of upper lip and extending up to posterior margin of interopercle or briefly surpassing. Basal portion of maxillary barbel wide with thin fleshy flap dorsally and distal margin rounded. Maxillary barbel with thinner portion longer in length than wider one. Rictal barbel emerging from lateral lobe of lower lip and slightly shorter than maxillary barbel. Mouth subterminal with edges posteriorly oriented. Upper lip wider than lower lip. Lower lip with round fleshy lobes in corners. Ventral surface of lips with small papillae. Gill openings not constricted united with isthmus anteriorly forming free fold. Opercular patch of odontodes rounded, inserted in posterior region of head visible from dorsal and lateral views. Posterior margin of opercle with distinct skin flap short and rounded. Interopercular patch of odontodes elongate inserted on posteroventral region of head visible from lateral and ventral views. Odontodes of opercle and interopercle barely visible, completely involved by flesh.

Pectoral fin with distal margin convex when expanded, 7( $n = 14$ ; including holotype) rays; first one always unbranched and not prolonged as filament; fourth and fifth longest. Pectoral-fin insertion posterior to branchial aperture covered by branchial membrane anteriorly. Some specimens with intumescence above anterior portion of pectoral fin and axillary pore not visible. Pelvic fin with distal margin convex when expanded, 5( $n = 14$ ; including holotype) rays; first one always unbranched. Pelvic-fin origin located at half-length of SL extending between urogenital papilla and anal-fin anterior insertion; tangentially inserted with inner margins separated by large interspace. Urogenital papilla located between last third of pelvic fins.

Dorsal fin with distal margin straight to slightly convex when expanded, 8( $n = 1$ ), 9( $n = 3$ ), 10( $n = 5$ ; including holotype) or 11( $n = 4$ ) rays; usually first two rays

**TABLE 6 |** Morphometric data of *Scleronema mate*, new species (data of holotype included in the range). N = number of specimens; SD = standard deviation.

unbranched. Dorsal fin with one( $n = 1$ ) or two( $n = 1$ ) procurent rays. Dorsal-fin origin located at vertical through first third to half-length of pelvic fin. Anal fin with distal margin slightly convex when expanded, 6( $n = 13$ ; including holotype) or 7( $n = 1$ ) rays; usually first two rays unbranched. Anal fin with two( $n = 2$ ) procurent rays. Anal-fin origin located at vertical through last third to posterior edge of dorsal-fin base. Caudal fin with distal margin straight and corners slightly rounded, 10( $n = 1$ ), 11( $n = 1$ ), 12( $n = 10$ ) or 13( $n = 2$ ; including holotype) rays; most-external rays of dorsal and ventral plates of caudal fin always unbranched and smaller than branched rays. Branched rays of caudal fin splitting up to twice. Caudal fin with 13( $n = 2$ ) procurent rays dorsally and 9( $n = 2$ ) procurent rays ventrally. Procurent rays of dorsal, anal and caudal fins rarely visible.

**Osteology.** Premaxilla with 21–22(n = 1) teeth arranged in two to three rows. Dentary with teeth inserted in one to three rows. Opercle with 9–12(n = 3) odontodes and interopercle with 9–18(n = 3) odontodes. Hyoid arch with 5/6(n = 3) branchiostegal rays. Free vertebrae 34(n = 1) or 35(n = 2); abdominal vertebrae 3(n = 3). Ribs 11(n = 1) or 12(n = 1). First complete haemal arch in 4<sup>th</sup>(n = 3) free vertebra, first haemal spine in 12<sup>th</sup>(n = 2) or 13<sup>th</sup>(n = 1) free vertebra. Pelvic girdle with basipterygium with anterolateral process absent. Dorsal fin with 9(n = 4) pterygiophores; first one inserted anteriorly to neural spine of 14<sup>th</sup>(n = 1) or 15<sup>th</sup>(n = 2) free vertebra. Anal fin with 6(n = 4) pterygiophores; first one inserted anteriorly to haemal spine of 19<sup>th</sup>(n = 3) free vertebra.

**Laterosensory system.** Data for 34 specimens summarized in Tab. 3. Canals of laterosensory system with simple (non-dendritic) tubes and external pores. Supraorbital line with nasal canal invariably absent and presence of pores s3 and s6 of frontal canal variable (Fig. 5A). Infraorbital line with antorbital segment invariably absent and sphenotic canal usually with pores i10 and i11. Posterior segment of frontal, sphenotic and otic canals fused each other. Otic, posotic and scapular canals present with preoperculo-mandibular and pterotic branches short usually with one pore each (po1 and po2, respectively). Fifteen specimens of 34 with additional pores mainly in infraorbital line. Trunk canal short usually with two pores.

**Coloration in alcohol.** Lateral surface of body with midlateral line of 4–5 rounded brown blotches as large as or smaller than opercle over light yellow background; blotches becoming fade or absent towards caudal peduncle (Figs. 12, 13A). Dorsal surface of body with 5–6 rectangular brown blotches extending ventrally to laterodorsal surface of body. Ventral surface of body light yellow with few brown blotches in caudal peduncle. Dorsal surface of head almost entirely black. Laterodorsal surface of head with numerous brown rounded blotches over light yellow background. Anterior portion of opercle black. Ventral surface of head light yellow with few small brown blotches in lower lip, sometimes forming thin stripe. Barbels uniformly yellow or intercalated with brown areas. Pectoral, pelvic and anal fins with rays weakly brown and distal margins hyaline. Dorsal and caudal fins with vertical light brown stripe basally, rays weakly brown, and distal margins hyaline (Figs. 12, 13A).

**Coloration in life.** Coloration in life similar to that of specimens preserved in ethyl alcohol, but more intense.

**Geographical distribution.** *Scleronema mate* occurs in four tributaries of the rio Jacuí (rio Caí, rio Pardo, rio Taquari, and rio dos Sinos), laguna dos Patos system, Brazil (Fig. 4).

**Ecological notes.** *Scleronema mate* inhabits rivers and streams with sand- and gravel-bottoms. In the rio Pardo basin, the species is collected syntopically with *S. macanuda*.

**Etymology.** The species epithet “mate” is given in reference to the herb used as an infusion in a traditional drink (“chimarrão”) from South Brazil, Argentina, and Uruguay. Additionally, the type locality of the new species, “Venâncio Aires”, is known

**FIGURE 13 |** Small specimens of **A.** *Scleronema mate*, new species, paratype (UFRGS 17616; 34.3 mm SL) and **B.** *S. teiniagua*, new species, paratype (LIRP 16776; 29.3 mm SL).

as the “Terra do Chimarrão”. A noun in apposition.

**Conservation status.** *Scleronema mate* has an Extent of Occurrence (EOO) less than 5,000 km<sup>2</sup>. The arroio Castelhano in Venâncio Aires has suffered from siltation and is strongly impacted by domestic and industrial sewage, as well as excess of fertilisers and pesticides in the surrounding crops. A similar decline in the quality of habitat due to dense urbanisation and agricultural activity can be observed in other areas of occupancy of *S. mate*. Therefore, the species can be classified as Near Threatened (NT), approaching EN B1b(iii) according to IUCN criteria (IUCN, 2019).

**Additional material examined.** 15 specimens from Brazil, Rio Grande do Sul State: MCN 6252, 1, 38.7 mm SL, Três Coroas, arroio Quilombo, rio dos Sinos basin. **Diagnosis.** *Scleronema milonga* is distinguished from all congeners, with the exception of *S. ibirapuita* and *S. teiniagua*, by the absence of the pore s3 of the supraorbital line of the laterosensory system (*vs.* pore s3 present). *Scleronema milonga* differs from *S. ibirapuita* and *S. teiniagua* by the presence of the pore s6 of the supraorbital line of the laterosensory system (*vs.* pore s6 absent). Additionally, *Scleronema milonga* is distinguished from *S. mate* and *S. guapa* by having the rounded brown blotches at the midlateral line larger than opercle (*vs.* rounded brown blotches as large as or smaller than opercle in *S. mate* and absent in *S. guapa*).

**Description.** Based on specimens ranging from 17.5 to 39.2 mm SL; 3 c&s (one dissected). Morphometric data for 35 types in Tab. 7.

*External morphology.* Greatest height and width of body in half-length of trunk.

Body elongate, trunk roughly cylindrical gradually compressed towards to caudal fin. Dorsal profile of trunk convex and ventral profile straight to slightly convex. Dorsal and ventral profiles of caudal peduncle straight. Dorsal margin of caudal peduncle with thin membrane, resembling adipose fin (Fig. 1). Head depressed and wide, trapezoid-shaped from dorsal view, wider posteriorly. Dorsal and ventral profiles of head straight. Anterior snout profile usually rounded from dorsal view. Nostrils of equivalent size, smaller than eye diameter. Anterior nostril surrounded by fleshy flap of integument, posterolaterally continuous with nasal barbel. Posterior nostril surrounded anterolaterally by thin flap of integument. Eyes rounded, dorsally oriented but also visible from lateral view; located behind posterior nostrils; orbital rim not free; eyes covered by thin and transparent skin.

Barbels with large bases and tapering gradually towards tips. Nasal barbel long; emerging from posterolateral edge of anterior nostril extending between anterior

**FIGURE 14 |** *Scleronema milonga*, new species, holotype (MCP 54165; 37.8 mm SL), Brazil, Rio Grande do Sul, Dezesseis de Novembro, arroio Lageado Araçá, rio Ijuí drainage, lower rio Uruguay.

**TABLE 7 |** Morphometric data of *Scleronema milonga*, new species (data of holotype included in the range). N = number of specimens; SD = standard deviation.

and posterior margins of eye. Maxillary barbel long; emerging from edge of upper lip and extending between anterior and posterior margins of interopercle. Basal portion of maxillary barbel wide with thin fleshy flap dorsally and distal margin rounded. Maxillary barbel with thinner portion longer in length than wider one. Rictal barbel emerging from lateral lobe of lower lip and slightly shorter than maxillary barbel. Mouth subterminal with edges posteriorly oriented. Upper lip wider than lower lip. Lower lip with round fleshy lobes in corners. Ventral surface of lower lip with small papillae. Gill openings not constricted united with isthmus anteriorly forming free fold. Opercular patch of odontodes rounded, inserted in posterior region of head visible from dorsal and lateral views. Posterior margin of opercle with distinct skin flap short and rounded. Interopercular patch of odontodes elongate inserted on posteroventral region of head

visible from lateral and ventral views. Odontodes of opercle and interopercle barely visible, completely involved by flesh.

Pectoral fin with distal margin convex when expanded, 7( $n = 44$ ; including holotype) rays; first one always unbranched and not prolonged as filament; fourth and fifth longest. Pectoral-fin insertion posterior to branchial aperture usually covered by branchial membrane anteriorly. Some specimens with intumescence above anterior portion of pectoral fin and axillary pore visible. Pelvic fin with distal margin convex when expanded, 4/5( $n = 1$ ) or 5( $n = 43$ ; including holotype) rays; first one always unbranched. Pelvic-fin origin located at vertical through dorsal-fin origin or briefly anterior extending between urogenital papilla and anal-fin anterior insertion; tangentially inserted with inner margins separated by large interspace. Urogenital papilla located between last third of pelvic fins.

Dorsal fin with distal margin straight to slightly convex when expanded, 9( $n = 18$ ), or 10( $n = 26$ ; including holotype) rays; usually first two rays unbranched. Dorsal fin with 2( $n = 2$ ) procurent rays. Dorsal-fin origin located at vertical through origin of pelvic fin or briefly posterior. Anal fin with distal margin slightly convex when expanded, 6( $n = 40$ ; including holotype) or 7( $n = 4$ ); usually first two rays unbranched. Anal fin with 2( $n = 2$ ) procurent rays. Anal-fin origin located at vertical through last third of dorsal-fin base. Caudal fin with distal margin straight and corners slightly rounded, 10( $n = 1$ ), 11( $n = 1$ ) or 12( $n = 42$ ; including holotype) rays; most-external rays of dorsal and ventral plates of caudal fin always unbranched and smaller than branched rays. Branched rays of caudal fin splitting up to twice. Caudal fin with 10( $n = 1$ ) or 13( $n = 1$ ) procurent rays dorsally and 10( $n = 1$ ) or 11( $n = 1$ ) procurent rays ventrally. Procurent rays of dorsal, anal, and caudal fins rarely visible.

*Osteology.* Premaxilla with teeth arranged in three rows. Dentary with 21–27( $n = 2$ ). Opercle with 12–16( $n = 2$ ) odontodes and interopercle with 14–16( $n = 2$ ) odontodes. Hyoid arch with 6( $n = 2$ ) branchiostegal rays. Free vertebrae 34( $n = 2$ ) or 35( $n = 1$ ); abdominal vertebrae 3( $n = 2$ ) or 5( $n = 1$ ). Ribs 9( $n = 2$ ) or 11( $n = 1$ ). First complete haemal arch in 4<sup>th</sup>( $n = 2$ ) or 6<sup>th</sup>( $n = 1$ ) free vertebra, first haemal spine in 11<sup>th</sup>( $n = 2$ ) or 12<sup>th</sup>( $n = 1$ ) free vertebra. Dorsal fin with 9( $n = 1$ ) or 10( $n = 2$ ) pterygiophores; first one inserted anteriorly to neural spine of 14<sup>th</sup>( $n = 3$ ) vertebra. Anal fin 6( $n = 3$ ) pterygiophores; first one inserted anteriorly to haemal spine of 18<sup>th</sup>( $n = 1$ ) or 19<sup>th</sup>( $n = 2$ ) vertebra.

*Laterosensory system.* Data for 44 specimens summarized in Tab. 3. Canals of laterosensory system with simple (non-dendritic) tubes and external pores. Supraorbital line with nasal canal and pore s3 of frontal canal invariably absent; pore s6 of frontal canal usually present (Fig. 5C). Infraorbital line with antorbital segment invariably absent and sphenotic canal with pores i10 and i11. Posterior segment of frontal, sphenotic and otic canals fused each other. Otic, posotic and scapular canals present with preoperculo-mandibular and pterotic branches short and usually with one pore each (po1 and po2, respectively). Trunk canal short usually with two pores.

**Coloration in alcohol.** Lateral surface of body with midlateral line of 6–8 rounded black blotches larger than opercle over light yellow background; blotches of some individuals becoming fade or absent towards caudal peduncle (Figs. 14–15). Some individuals with lateral blotches in contact, almost forming continuous stripe (LIRP 16775). Dorsal surface of body with 5–6 rectangular black blotches extending ventrally

to laterodorsal surface of body. Anterior portion of opercle black. Ventral surface of body light yellow with few brown blotches in caudal peduncle. Dorsal and laterodorsal surfaces of head with numerous brown rounded blotches over light yellow background. Ventral surface of head light yellow with few small brown blotches in lower lip, sometimes forming thin stripe. Barbels uniformly yellow or intercalated with brown areas. Pectoral-, pelvic-, and anal-fin rays faintly brown. Dorsal and caudal fins with vertical light brown stripe basally, rays faintly brown, and distal margins hyaline (Figs. 14–15).

**Coloration in life.** Coloration in life similar to that of specimens preserved in ethyl alcohol, but more intense and with midlateral blotches of body brown (Fig. 15).

**Geographical distribution.** *Scleronema milonga* occurs in the rio Ijuí and rio Santa Rosa basins, two tributaries to the left bank of rio Uruguay, southern Brazil; and small tributaries of the right bank of the rio Uruguay, Misiones, Argentina (Fig. 4).

**Ecological notes.** *Scleronema milonga* inhabits rivers and streams with sand- and gravel-bottoms. The species has not been collected syntopically with its congeners. Individuals of *S. milonga* larger than 31.0 mm SL are capable to spawn and considered adults by Carvalho (2017). Its diet is composed mainly of immature, autochthonous and benthic insects (Ephemeroptera, Chironomidae, and Trichoptera), in both adults and immatures (Carvalho, 2017).

**FIGURE 15 |** Specimen just after the fixation in formalin of *Scleronema milonga*, new species, paratype (UFRGS 7685; 32.7 mm SL), Brazil, Rio Grande do Sul, São Nicolau, unnamed stream tributary to rio Ijuí, lower rio Uruguay.

**Etymology.** The species epithet “milonga” is given in reference to the musical rhythm popularized in Argentina and Rio Grande do Sul State (Brazil), both regions where the new species can be found. A noun in apposition.

**Conservation status.** *Scleronema milonga* has an Extent of Occurrence (EOO) less than 5,000 km<sup>2</sup> and a significant part of the original vegetation of the rio Ijuí basin in Brazil was converted to soybean crops. However, no additional threats were detected and the species occurs in well-preserved areas of Argentina. Thus, the species can be classified as Least Concern (LC) according to IUCN criteria (IUCN, 2019).

**Additional material examined.** MCP 13442, 1, 16.3 mm SL, Argentina, Misiones, Itacaruaré, arroyo Santa María, lower río Uruguay. UFRGS 27844, 8, 25.9–34.6 mm SL, Brazil, Santa Rosa, río Santa Rosa at the confluence with a stream, lower río Uruguay.

### *Scleronema minutum* (Boulenger, 1891)

(Figs. 5D, 16–18, Tabs. 3, 8)

*Trichomycterus minutus* Boulenger, 1891: 235 (original description, type locality: San Lorenzo district), plate 26; fig. 3 (drawing of one syntype from lateral view and drawing of the head and pectoral fins of one syntype from dorsal view). —Ihering, 1893: 110 (original description). —Burgess, 1989: 322 (listed). —Nion *et al.*, 2002: 15 (listed). —Eschmeyer, 1998: 2123 (listed in catalog). —Nion *et al.*, 2016: 15 (listed).

*Pygidium angustirostris* Devincenzi, in Devincenzi, Teague, 1942 **new synonym** 30–31 (original description, type locality: Cañada de las Piedras), plate 4, fig. 3 (drawing of a type from lateral view and head detail from dorsal view). —Olazarri *et al.*, 1970: 4 (type catalog of the MNHM). —Eschmeyer, 1998: 2123 (listed in catalog). —Loureiro *et al.*, 2016: 412 (notes on types).

*Pygidium minutum* —Ihering, 1898: 172–173 (notes on original description). —Eigenmann, 1910: 399 (listed). —Eigenmann, 1918: 340, fig. 20 (drawings of original description and original description with few modifications). —Gosline, 1945: 61 (listed).

*Scleronema* cf. *angustirostre* —Ochoa *et al.*, 2017a: 75, 76; fig. 2, 77; fig. 3, 79 (phylogenetic relationships, phylogenetic tree).

*Scleronema minutum* —Tchernavin, 1944: 236–237 (redescription). —Fowler, 1954: 37–38, fig. 639 (listed, drawing of one syntype from lateral view). —Burgess, 1989: 313 (drawing of Fowler, 1954). —Malabarba, 1989: 145 (listed). —Casciotta, Almirón, 1996: 51–53 (record to Argentina). —de Pinna, 1998: 300 (notes on vertebrae). —Wosiacki, 2002: 259; fig. 2, 260; fig. 3, 261; fig. 4, 262; fig. 5, 263; fig. 6 (phylogenetic relationships). —de Pinna, Wosiacki, 2003: 278 (listed). —López *et al.*, 2003: 38 (listed). —Menni, 2004: 82, 96 (listed). —López *et al.*, 2005: 336 (listed). —Liotta, 2005: 279 (distribution in Argentina). —Ferraris, 2007: 413 (listed). —Wosiacki, de Pinna, 2007: 69 (listed). —Arias *et al.*, 2013: 13 (listed). —Fernández *et al.*, 2015: 14 (catalog of the MLP). —Bertaco *et al.*, 2016: 421 (listed). —Ferrer, 2016: 111–121; figs. 47–50 (phylogenetic relationships, taxonomy). —Ochoa *et al.*, 2017a: 75, 76; fig. 2, 77; fig. 3, 79 (phylogenetic relationships). —Ochoa *et al.*, 2017b: 558, fig. 5 (phylogenetic tree). —Carvalho, 2017: 14 (diet, ecomorphology, and reproduction). —Ochoa *et al.*, 2020: fig. 3 (phylogenetic relationships).

*Trichomycterus angustirostris* —Nion *et al.*, 2002: 15 (listed). —Nion *et al.*, 2016: 15 (listed).

**Lectotype by present designation.** BMNH 1891.3.16.84, 32.4 mm SL, Brazil, Rio Grande do Sul, São Lourenço do Sul, stream tributary of laguna dos Patos, *ca* 31°21'55"S 51°58'42"W, H. Ihering (Fig. 16).

**Paralectotypes.** BMNH 1891.3.16.85–86, 2, 16.6–18.7 mm SL, Brazil, Rio Grande do Sul, São Lourenço do Sul, stream tributary of laguna dos Patos, *ca* 31°21'55"S 51°58'42"W, H. Ihering.

**Diagnosis.** *Scleronema minutum* is distinguished from *S. macanuda* and *S. operculatum* by the following external characters: maxillary barbel longer than half-length of the head (*vs.* shorter than half-length of the head); tips of pectoral-fin rays not extending beyond the interradial membrane (*vs.* extending beyond the interradial membrane), skin flap in the posterior margin of the opercle rounded and short (*vs.* skin flap pointed and long); fleshy flap at the base of the maxillary barbel located posteriorly, thin, restricted to the maxillary and distal margin rounded (*vs.* fleshy flap located anteriorly, thick, prolonged up to the snout and with distal margin straight); and by the caudal fin uniformly brown (*vs.* caudal fin with a transversal black bar distally). *Scleronema minutum* differs from *S. ibirapuita*, *S. milonga*, and *S. teiniagua* by having the pore s3 of the supraorbital line of the laterosensory system (*vs.* pores s3 absent). *Scleronema minutum* is distinguished from *S. mate* and *S. guapa* by having the rounded brown blotches at the midlateral line larger than opercle (*vs.* rounded brown blotches as large as or smaller than opercle in *S. mate* and absent in *S. guapa*).

**Description.** Based on specimens ranging from 14.5 to 53.9 mm SL; 7 c&s (2 dissected) and 4 xr (including lectotype and two paralectotypes). Morphometric data for types and non-types in Tab. 8.

*External morphology.* Greatest height and width of body in half-length of trunk.

**FIGURE 16 |** *Scleronema minutum*, lectotype of *Trichomycterus minutus* (BMNH 1891.3.16.84; 32.4 mm SL), Brazil, Rio Grande do Sul, São Lourenço do Sul, stream tributary to laguna dos Patos. Photograph taken by Sandra Raredon.

Body elongate, trunk roughly cylindrical gradually compressed towards to caudal fin. Dorsal profile of trunk convex and ventral profile straight to slightly convex. Dorsal and ventral profiles of caudal peduncle straight. Dorsal margin of caudal peduncle with thin membrane, resembling adipose fin. Head depressed and wide, trapezoid-shaped from dorsal view, wider posteriorly; square-shaped in specimens with muscles of cheeks well developed. Dorsal and ventral profiles of head straight to slightly convex. Anterior snout profile usually rounded from dorsal view. Nostrils of equivalent size, smaller than eye diameter. Anterior nostril surrounded by fleshy flap of integument, posterolaterally continuous with nasal barbel. Posterior nostril surrounded anterolaterally by thin flap of integument. Eyes rounded, dorsally oriented but also visible from lateral view; located behind posterior nostrils; orbital rim not free; eyes covered by thin and transparent skin.

Barbels with large bases and tapering gradually towards tips. Nasal barbel long; emerging from posterolateral edge of anterior nostril extending between anterior and posterior margins of eye. Maxillary barbel long; emerging from edge of upper lip and extending between anterior and posterior margins of interopercle. Basal portion of maxillary barbel wide with thin fleshy flap dorsally and distal margin rounded. Maxillary barbel with thinner portion longer in length than wider one. Rictal barbel

**FIGURE 17** | *Scleronema minutum* (MCP 17514; 39.8 mm SL), Brazil, Rio Grande do Sul, São Lourenço do Sul, arroio São Lourenço, laguna dos Patos system.

emerging from lateral lobe of lower lip and slightly shorter than maxillary barbel. Mouth subterminal with edges posteriorly oriented. Upper lip wider than lower lip. Lower lip with round fleshy lobes in corners. Ventral surface of lips with small papillae. Gill openings not constricted united with isthmus anteriorly forming free fold. Opercular patch of odontodes rounded, inserted in posterior region of head visible from dorsal and lateral views. Posterior margin of opercle with distinct skin flap short and rounded. Interopercular patch of odontodes elongate inserted on posteroventral region of head visible from lateral and ventral views. Odontodes of opercle and interopercle barely visible, completely involved by flesh.

Pectoral fin with distal margin convex when expanded, 6( $n = 2$ ), 6/7( $n = 1$ ) or 7( $n = 69$ ; including lectotype and two paralectotypes) principal rays; first one always unbranched

and not prolonged as filament; fourth and fifth longest. Pectoral-fin insertion posterior to branchial aperture usually covered by branchial membrane anteriorly. Some specimens with intumescence above anterior portion of pectoral fin and axillary pore visible. Pelvic fin with distal margin convex when expanded, 5(n = 71; including lectotype and one paralectotype) rays; first one always unbranched. Pelvic-fin origin located at half-length of SL extending between urogenital papilla and anal-fin anterior insertion; tangentially inserted with inner margins separated by large interspace. Urogenital papilla located between last third of pelvic fins.

Dorsal fin with distal margin straight to slightly convex when expanded, 9(n = 36),

10( $n = 33$ ; including one paralectotype) or 11( $n = 1$ ) rays; first two rays unbranched. Dorsal fin with 2( $n = 3$ ) or 3( $n = 3$ ) procurent rays. Dorsal-fin origin located at vertical through half-length of pelvic fin. Anal fin with distal margin slightly convex when expanded, 6( $n = 69$ ; including one paralectotype) rays (one anomalous specimen with 4 rays); first two rays unbranched. Anal fin with 2( $n = 6$ ) procurent rays. Anal-fin origin located at vertical through last third of dorsal-fin base. Caudal fin with distal margin straight and corners slightly rounded, 11( $n = 2$ ), 12( $n = 69$ ; including lectotype and two paralectotypes) rays; most-external rays of dorsal and ventral plates of caudal fin always unbranched and smaller than branched rays. Branched rays of caudal fin splitting up to twice. Caudal fin with 10( $n = 1$ ), 11( $n = 1$ ), 12( $n = 2$ ) or 14( $n = 2$ ) procurent rays dorsally and 8( $n = 2$ ), 9( $n = 2$ ) or 10( $n = 2$ ) procurent rays ventrally. Procurent rays of dorsal, anal, and caudal fins rarely visible.

**Osteology.** Premaxilla with 19–25( $n = 5$ ) arranged in two or three rows. Dentary with 23–24( $n = 1$ ) arranged in one to three rows. Opercle with 10–15( $n = 7$ ) odontodes and interopercle with 13–23( $n = 7$ ) odontodes. Hyoid arch with 6( $n = 6$ ) branchiostegal rays. Free vertebrae 34( $n = 1$ ), 35( $n = 3$ ) or 36( $n = 7$ ; including paralectotype and two paralectotypes); abdominal vertebrae 2( $n = 1$ ) or 3( $n = 6$ ). Ribs 10( $n = 3$ ), 11( $n = 5$ ; including one paralectotype) or 12( $n = 3$ ; including one lectotype and one paralectotype). First complete haemal arch in 3<sup>th</sup>( $n = 1$ ) or 4<sup>th</sup>( $n = 6$ ) free vertebra, first haemal spine in 12<sup>th</sup>( $n = 5$ ) or 13<sup>th</sup>( $n = 2$ ) free vertebra. Dorsal fin with 8( $n = 1$ ), 9( $n = 3$ ) or 10( $n = 4$ ) pterygiophores; first one inserted anteriorly to neural spine of 13<sup>th</sup>( $n = 1$ ) or 14<sup>th</sup>( $n = 6$ ; including lectotype) or 16<sup>th</sup>( $n = 4$ ; including two paralectotypes) vertebra. Anal fin with 6( $n = 8$ ; including lectotype) pterygiophores; first one inserted anteriorly to haemal spine of 18<sup>th</sup>( $n = 1$ ), 19<sup>th</sup>( $n = 4$ ) or 20<sup>th</sup>( $n = 6$ ; including lectotype and two paralectotypes) vertebra.

**Laterosensory system.** Data for 291 specimens summarized in Tab. 3. Canals of laterosensory system with simple (non-dendritic) tubes and external pores. Supraorbital line with nasal canal invariably absent and frontal canal usually with pores s3 and s6 (Fig. 5D). Infraorbital line with antorbital segment invariably absent and sphenotic canal usually with pores i10 and i11. Posterior segment of frontal, sphenotic and otic canals fused each other. Otic, posotic and scapular canals present with preoperculo-mandibular and pterotic branches short with one pore each (po1 and po2, respectively). Trunk canal short usually with two pores.

**Coloration in alcohol.** Lateral surface of body with midlateral line of 5–9 (rarely 4 or 10) rounded brown blotches larger than opercle over light yellow background; blotches of some individuals becoming fade or absent towards caudal peduncle (Figs. 16–20). Lateral surface of body with additional smaller brown blotches. Some smaller individuals (< 28.0 mm SL) with lateral blotches in contact, almost forming continuous stripe (UFRGS 8622 and UFRGS 13665). Dorsal surface of body with 5–9 rectangular brown blotches extending ventrally to laterodorsal surface of body; some individuals with blotches of dorsal surface discontinuous (UFRGS 19647). Ventral surface of body light yellow with few brown blotches in caudal peduncle. Dorsal and laterodorsal surfaces of head with numerous brown rounded blotches over light yellow background. Anterior portion of opercle black. Ventral surface of head light yellow with few small brown blotches in lower lip, sometimes forming thin stripe. Barbels uniformly yellow

or intercalated with brown areas. Pectoral-, pelvic-, and anal-fin rays weakly brown or completely hyalines. Dorsal- and caudal-fin rays brown. Caudal fin with vertical light brown stripe basally.

**Coloration in life.** Coloration in life similar to that of specimens preserved in ethyl alcohol, but more intense (Fig. 18).

**Geographical distribution.** *Scleronema minutum* occurs in the laguna dos Patos system, lower rio Uruguay basin and lower rio Paraná basin. In the former, the species is widely distributed in rivers and streams that drain directly to laguna dos Patos (Brazil) and lagoa Mirim (Brazil and Uruguay). The species is known from only one stream of the right bank of the lower rio Uruguay, the arroyo Yuquerí Chico (Argentina), and widespread in following drainages of its other side: rio Negro (Brazil and Uruguay), rio Ibicuí (Brazil), río Dayman (Uruguay), río Queguay (Uruguay), and río San Salvador (Uruguay). In the lower rio Paraná basin, the species has few records to two tributaries of its left bank, the arroyo Feliciano and río Guayquiraro, Argentina (Fig. 4). Other two possible records of *S. minutum* for Argentina (MLP 10557; arroyo Mármol, tributary of río Uruguay, and MLP 10649; río Gualeguay, tributary of río Paraná) could not be accessed and examined.

**FIGURE 18 |** Specimens in life of *Scleronema minutum* (A. UFRGS 22100; 37.4 mm SL, Santana da Boa Vista, arroio das Neves, B. UFRGS 22128; 39.4 mm SL, arroio Igrejinha), Brazil, Rio Grande do Sul.

**Ecological notes.** *Scleronema minutum* inhabits rivers and streams usually with sand or gravel-bottoms. The species is found syntopically with *S. macanuda* in the laguna dos Patos system and rio Negro basin and syntopically with *S. operculatum* in the headwaters of the rio Ibicuí. The stomachs of eight specimens were analyzed and seven had immature aquatic Diptera (Chironomidae), Ephemeroptera, and Plecoptera. Individuals of *S. minutum* larger than 29.0 mm SL are capable to spawn and considered adults by Carvalho (2017). Its diet is composed mainly by “organic matter indeterminate” and immature, autochthonous and benthic insects (Chironomidae, Ephemeroptera and Trichoptera) in adults and Chironomidae in immatures (Carvalho, 2017).

**Conservation status.** *Scleronema minutum* is frequent and abundant in the lower rio Uruguay and Laguna dos Patos system, also occurring in the lower rio Paraná. No specific threats were detected and the species can be classified as Least Concern (LC) according to IUCN criteria (IUCN, 2019).

**Remarks on the type locality of *Scleronema minutum*.** Boulenger (1891) quoted the type locality of *Scleronema minutum* as San Lorenzo District, in the state of Rio Grande do Sul, Brazil. Such a locality was erroneously interpreted by de Pinna, Wosiacki (2003) as “São Lourenço das Missões = 28°30'S 54°40'W”, also in Rio Grande do Sul State, Brazil, in the rio Uruguay drainage. Such mistake has been later repeated in subsequently published systematic fish catalogs (Ferraris, 2007; Wosiacki, de Pinna, 2007).

The actual type locality, however, has long been correctly referred by Ihering (1898: 172, 173), who collected those fishes and sent them to Boulenger. Ihering mentions the type locality of *S. minutum* as “arriios da colônia de S. Lourenço” (= creeks of the colony of S. Lourenço). The German colony called San Lorenzo by Boulenger (1891) or S. Lourenço by Ihering (1898) is currently the city of São Lourenço do Sul (31°21'55"S 51°58'42"W), which encompass two streams tributaries of the laguna dos Patos, the arroio São Lourenço and the arroio Cahará, possibly the localities where the type specimens were collected (Fig. 4).

Malabarba (1989) discussed the origin of several fish specimens collected in Rio Grande do Sul by Herman von Ihering that were sent to the collections of the British Museum (Natural History) and Indiana University (now at California Academy of Sciences), referring to Ihering (1898) who clearly stated that all fishes he collected come from laguna dos Patos drainage, and not from the rio Uruguay drainage: “It [the Rio Grande do Sul State] is divided, considering the freshwater fauna, into two perfectly distinct regions, that of the Uruguay River and that of the Lagoa dos Patos, one and the other comprising the respective slopes. Regarding the first, nothing is known about the tributaries and slopes of the Uruguay River born in the State of Rio Grande do Sul. (...) Only the works of Eigenmann bring some fish from Rio Grande do Sul that were not collected by Hensel, nor by me and that evidently belong to the collection made in Uruguayana [this is a reference to the collection made by Brazilian Emperor Dom Pedro II and donated to the Thayer expedition]. (...) In abstraction from them there remain fifty-nine species which were signaled by Hensel, by myself and others in the latter region [the laguna dos Patos drainage].”

Finally, it is worthy mentioning that the locality given by de Pinna, Wosiacki (2003) is not included in the area of distribution of *Scleronema minutum*. Instead, it is within the

distribution range of a distinct species, *S. milonga*.

**Remarks on type specimens of *Trichomycterus minutus*.** The three syntypes of *T. minutus* (BMNH 1891.3.16.84–86) are small in comparison with the maximum SL of the species (16.3–32.4 vs. 55.5 mm SL). The largest and better-preserved specimen among the three syntypes of *T. minutus* (BMNH 1891.3.16.84) is designated herein as lectotype according to the Article 74 of the ICZN (1999) (Fig. 16) and because *S. minutum* occurs sympatrically with two congeners, *S. macanuda* and *S. operculatum*. Rounded blotches in the dorsal and lateral surfaces of body are visible in the lectotype herein designated, but not clearly visible in the two paralectotypes (BMNH 1891.3.16.85–86). The lectotype is also uncharacterized by the broken fin rays (more evident in the dorsal and anal fins) and the cutted nasal barbels. However, the fleshy flap in the maxillary barbel, the skin flap posterior to opercle, and the membrane in the dorsal margin of caudal peduncle are easily visible in all type specimens. The lectotype has 5–6 odontodes in the opercle and 9–12 in the interopercle, but at least three odontodes are lost in both bones.

**Remarks on type specimens and type locality of *Scleronema angustirostre*.** The holotype and three paratypes of *Pygidium angustirostris* housed at MNHN (Montevideo) are lost (Olazarri *et al.*, 1970; de Pinna, Wosiacki, 2003; Ferraris, 2007; Loureiro *et al.*, 2016). The paratype sent to London (BMNH 1944.6.20.1; 34.5 mm SL) has the fins damaged (with rays broken and dyed of blue); the skin of the lower jaw was removed, possibly to observe the teeth, which are conical and directed inward; and odontodes dyed of blue and some missing (Fig. 19). However, the coloration of body is not faded completely and it is possible to observe the rounded blotches in the dorsal and lateral surfaces of body. Other important traits observed in the paratype are the papillae on lips, the posterior flap in the opercle, the thin membrane above caudal peduncle, and the pattern of pores in the laterosensory system compatible with that of *S. minutum*. The state of preservation of the two MNRJ 3605 paratypes of *P. angustirostris* (19.9–32.4 mm SL) is quite worse (Fig. 20) and few information could be obtained from them, such as in the laterosensory system. Coloration of specimens faded completely, barbels are broken, fins rays are broken or bent, and the skin over the head in the smallest specimen is damaged.

Devincenzi, Teague (1942) described the type locality of *S. angustirostre*, Cañada de las Piedras, in detail including photos and a map with the itinerary of its collector, Mr. Teague. The Cañada de las Piedras, also called by these authors as “Cañada de las Piedras Blancas”, is a stream tributary to the right bank of the río Queguay in Paysandú, lower río Uruguay (Fig. 4), near to a railroad bridge (*ca* 32°05'09"S 57°53'13"W).

**Material examined.** 899 specimens. Argentina, lower río Paraná: MACN 7130, 1, 27.5 mm SL, Corrientes, río Guayquiraró. MACN 7131, 1, 26.9 mm SL, Entre Ríos, arroyo Feliciano. MACN 7132, 3, 30.4–35.3 mm SL, Entre Ríos, puddles 1 km from arroyo Feliciano. Brazil, Rio Grande do Sul State, laguna dos Patos system: BMNH 1891.3.16.84, 32.4 mm SL, lectotype of *Trichomycterus minutus* Boulenger, 1891, stream tributary of laguna dos Patos, São Lourenço do Sul. BMNH 1891.3.16.85–86, 2, 16.6–18.7 mm SL, paralectotypes of *Trichomycterus minutus* Boulenger, 1891, collected with lectotype. FMNH 82728, 2, 12.5–13.5 mm SL, Santa Maria, río Vacacaí-Mirim. MCN

***Scleronema operculatum* Eigenmann, 1917**

(Figs. 10B, 21–24, 25A–B; Tabs. 3, 9)

*Scleronema operculatum* Eigenmann, 1917: 691–692 (original description, type species by original designation, type locality: Cacequy, Uruguay basin). —Eigenmann, 1918: 381; plate 44; fig. 1 (original description, drawing of the holotype from lateral view), 282; fig. 2d–e (drawing of the neurocranium, suspensorium, opercular apparatus, and inferior jaw from dorsal view of one paratype). —Henn, 1928: 81 (listed, type catalog of the Carnegie Museum). —Tchernavin, 1944: 235–236 (redescription based on original description). —Gosline, 1945: 55 (listed). —Fowler, 1954: 38, fig. 640 (listed, distribution, drawing of a type from lateral view). —Ibarra, Stewart, 1987: 78 (type catalog of the FMNH). —Burgess, 1989: 321 (listed). —Arratia, 1990: 399, fig. 2d (drawing of a specimen from lateral view). —de Pinna, 1998: 300 (observation on vertebrae). —Eschmeyer, 1998: 1243 (listed in catalog). —Wosiacki, 2002: 259; fig. 2, 260; fig. 3, 261; fig. 4, 262; fig. 5, 263; fig. 6, 291; fig. 38, 309; fig. 69, 312, fig. 73, 323; fig. 86 (phylogenetic relationships, drawings of characters). —de Pinna, Wosiacki, 2003: 278 (listed). —Ferraris, 2007: 413 (listed). —Wosiacki, de Pinna, 2007: 69 (listed). —Bertaco *et al.*, 2016: 421 (listed). —Ferrer, 2016: 66–76; figs. 47–50 (phylogenetic relationships, taxonomy).

*Scleronema minutum* [non Boulenger, 1891] —de Pinna, 1989: 4, fig. 22a, 23a (comparative material, drawings of the maxilla, premaxilla, and anterior portion of the mesethmoid from dorsal view).

**Diagnosis.** *Scleronema operculatum* is distinguished from all congeners with the exception of *S. macanuda* by the following external characters: maxillary barbel shorter than half-length of the head (*vs.* longer than half-length of the head); tips of the pectoral-fin rays extending beyond the interradial membrane (*vs.* not extending beyond the interradial membrane), skin flap in the posterior margin of the opercle pointed and long (*vs.* skin flap rounded and short); fleshy flap at the base of the maxillary barbel located anteriorly, thick, prolonged up to the snout and with distal margin straight (*vs.* fleshy flap located posteriorly, thin, restricted to the maxilla and with distal margin rounded); and by the caudal fin with a transversal black bar distally (*vs.* caudal fin uniformly brown). *Scleronema operculatum* differs from *S. macanuda* by having a midlateral line of 10–14 rounded black blotches as large as or smaller than opercle (*vs.* midlateral line of 6–9 rounded black blotches larger than opercle); tip of nasal barbel never reaching anterior margin of eye (*vs.* tip of nasal barbel usually extending beyond anterior margin of eye), and tip of maxillary barbel never surpassing anterior margin of interopercle (*vs.* tip of maxillary barbel extending between anterior and posterior margins of interopercle).

**Description.** Based on specimens ranging from 22.4 to 72.8 mm SL; 4 c&s (2 dissected) and 3 xr (holotype and two paratypes). Morphometric data for types and non-types in Tab 9.

**External morphology.** Greatest height of body in trunk and greatest width of body in anterior portion of trunk. Body elongate and compressed. Dorsal and ventral profiles of trunk straight to slightly convex. Dorsal and ventral profiles of caudal peduncle straight

to slightly convex up to anteriomost procurent ray insertion. Dorsal margin of caudal peduncle with thin membrane, resembling adipose fin. Head depressed and wide, trapezoidal from dorsal view, wider posteriorly. Dorsal and ventral profiles of head straight. Anterior snout profile rounded from dorsal view. Nostrils of equivalent size, smaller than eye diameter. Anterior nostril surrounded by fleshy flap of integument, posterolaterally continuous with nasal barbel. Posterior nostril surrounded anterolaterally by thin flap of integument. Eyes rounded, dorsally oriented but also visible from lateral view; located behind posterior nostrils; orbital rim not free; eyes covered by thin and transparent skin.

**TABLE 9 |** Morphometric data of *Scleronema operculatum* (data of type specimens not included in the range of non-types). N = number of non-types; SD = standard deviation.

Barbels with large bases and tapering gradually towards tips. Nasal barbel short; emerging from posterolateral edge of anterior nostril usually surpassing posterior nostril and never reaching anterior margin of eye. Maxillary barbel short; emerging from edge of upper lip and extending near to or reaching anterior margin of interopercle. Basal portion of maxillary barbel wide with thick fleshy flap dorsally and distal margin straight. Maxillary barbel with thinner portion smaller in length than wider one. Rictal barbel emerging from lateral lobe of lower lip and slightly shorter than maxillary barbel. Mouth subterminal with edges posteriorly oriented. Upper lip wider than lower lip. Lower lip with round fleshy lobes in corners. Lower lip and corners of upper lip with small papillae. Gill openings not constricted united with isthmus anteriorly forming free fold. Opercular patch of odontodes rounded, inserted in posterior region of head visible from dorsal and lateral views. Posterior margin of opercle with distinct skin flap, thin and pointed; some specimens (as the holotype) with groove in skin flap. Interopercular patch of odontodes elongate inserted on posteroventral region of head visible from lateral and ventral views. Odontodes of opercle and interopercle barely visible, completely involved by flesh.

Pectoral fin with distal margin convex when expanded, 7 principal rays ( $n = 51$ ; including holotype and three paratypes); first one always unbranched and not prolonged as filament; fourth and fifth longest. Pectoral-fin insertion posterior to branchial aperture usually covered by branchial membrane anteriorly. Rays of pectoral fin extending slightly beyond interradial membrane. Some specimens with wilted skin above anterior portion of pectoral fin (including holotype and one paratype) or with intumescence, axillary pore not visible. Pelvic fin with distal margin convex when expanded, 5( $n = 50$ ; including holotype and three paratypes) or rarely 6( $n = 1$ ) rays; first one always unbranched. Pelvic-fin origin located at half-length of SL extending between urogenital papilla and anal-fin anterior insertion; tangentially inserted with inner margins separated by large interspace. Urogenital papilla located between last third of pelvic fins.

Dorsal fin with distal margin straight when expanded, 11( $n = 28$ ; including holotype and one paratype), 12( $n = 20$ ; including one paratype) or 13( $n = 3$ ; including one paratype) rays; usually first two or three rays unbranched. Eight small specimens (< 33.4 mm) of 51 analyzed without branched rays in dorsal fin. Dorsal fin with 2( $n = 5$ ; including holotype and two paratypes) or 3( $n = 2$ ) procurent rays. Dorsal-fin origin located at vertical through first half of pelvic fin. Anal fin with distal margin slightly convex when expanded, 6( $n = 29$ ; including one paratype) or 7( $n = 22$ ; including holotype and two paratypes) rays; usually first one or two rays unbranched. Eight small specimens (< 33.4 mm) of 51 analyzed without branched rays in anal fin. Anal fin with 1( $n = 1$ ; paratype) or 2( $n = 6$ ; including holotype and one paratype) procurent rays. Anal-fin origin located at vertical through last third of dorsal-fin base. Caudal fin with distal margin straight and corners slightly rounded, 12( $n = 51$ ; including holotype and three paratypes) rays; most-external rays of dorsal and ventral plates of caudal fin always unbranched and smaller than branched rays. Branched rays of caudal fin splitting up to twice. Caudal fin with 12( $n = 2$ ) or 13( $n = 5$ ; including holotype and two paratypes) procurent rays dorsally and 8( $n = 1$ ), 9( $n = 1$ ; holotype), 10( $n = 1$ ) or 11( $n = 4$ ; including two paratypes) procurent rays ventrally. Procurent rays of dorsal, anal, and caudal fins rarely visible.

**Osteology.** Premaxilla with 25–42( $n = 2$ ) arranged in three to five rows. Dentary with

46–88(n = 2) teeth arranged in one to five rows. Opercle with 8–13(n = 4) odontodes and interopercle with 10–15(n = 4) odontodes. Hyoid arch with 6(n = 4) branchiostegal rays. Free vertebrae 35(n = 2) or 36(n = 5; including holotype and two paratypes); abdominal vertebrae 3(n = 4). Ribs 8(n = 1; paratype), 9(n = 3; including one paratype) or 10(n = 3; including holotype). First complete haemal arch in 4<sup>th</sup>(n = 4) free vertebra, first haemal spine in 7<sup>th</sup>(n = 3) or 9<sup>th</sup>(n = 1) free vertebra. Dorsal fin with 10(n = 2; including one paratype), 11(n = 4; including holotype and one paratype) or 12(n = 1) pterygiophores; first one inserted anteriorly to neural spine of 15<sup>th</sup>(n = 3; including one paratype) or 16<sup>th</sup>(n = 4; including holotype and one paratype) vertebra. Anal fin with 6(n = 7; including holotype and two paratypes) pterygiophores; first one inserted anteriorly to haemal spine of 20<sup>th</sup>(n = 5; including two paratypes) or 21<sup>st</sup>(n = 2; including holotype) vertebra.

**Laterosensory system.** Data for 43 specimens summarized in Tab. 3. Canals of laterosensory system with simple (non-dendritic) tubes and external pores. Supraorbital line with presence of nasal canals variable: with two paired canals (right and left), only one canal present or both canals absent (Fig. 10B). Nasal canal, if present, interrupted (not connecting with frontal canal) with pores s1 and s2. Frontal canal usually with pores s3 and s6. Infraorbital line with antorbital segment invariably absent and sphenotic canal with pores i10 and i11. Posterior segment of frontal, sphenotic and otic canals fused each other. Otic, posotic and scapular canals present with preoperculo-mandibular and pterotic branches short usually with one pore each (po1 and po2, respectively). Trunk canal short usually with two pores.

**Coloration in alcohol.** Lateral surface of body with two longitudinal lines (midlateral and laterodorsal) of 10–14 black rounded blotches (as large as or smaller than opercle) over light yellow background; blotches in trunk of some individuals become fade or absent towards caudal peduncle (Figs. 21–22). Some large individuals with smaller blotches among larger ones. Longitudinal line of laterodorsal blotches visible from dorsal view. Ventral surface of body uniformly light yellow. Dorsal and lateral surfaces of head and nape area with numerous black rounded blotches or uniformly black. Ventral surface of head light yellow. Dorsal surface of maxillary and rictal barbels weakly black and ventral surface light yellow. Nasal barbel weakly black. Opercle with anterior, dorsal and ventral margins black; posterior fold light yellow. Pectoral, pelvic, dorsal and anal fins hyaline; one large individual (UFRGS 19654; 70.1 mm SL) with black bar in distal margin of anal fin. Caudal fin hyaline with transversal stripe basally and transversal black bar distally, which could extend up to half-length of fin in larger individuals.

**Coloration in life.** Coloration in life similar to that of specimens preserved in ethyl alcohol, but more intense (Fig. 22).

**Geographical distribution.** *Scleronema operculatum* is endemic to the rio Ibicuí basin, a tributary to the left bank of rio Uruguay, State of Rio Grande do Sul, southern Brazil (Fig. 4).

**Ecological notes.** *Scleronema operculatum* inhabits rivers and streams usually with fine sand-bottoms. *Scleronema guapa* and *S. minutum* may be collected in the same

**FIGURE 21** | *Scleronema operculatum* (UFRGS 18086; 40.0 mm SL), Brazil, Rio Grande do Sul, Rosário do Sul, sanga Santo Antônio, tributary to rio Ibicuí da Armada, lower rio Uruguay.

**FIGURE 22** | Specimen in life of *Scleronema operculatum* (UFRGS 18086; 42.3 mm SL), Brazil, Rio Grande do Sul, Rosário do Sul, sanga Santo Antônio, tributary to rio Ibicuí da Armada, lower rio Uruguay.

microhabitat of *S. operculatum*. The stomachs of three specimens were analyzed and two had immature aquatic Diptera (Chironomidae), Odonata and grains of sand.

**Conservation status.** *Scleronema operculatum* has an Extent of Occurrence (EOO) less than 20,000 km<sup>2</sup> being found in specific habitats. However, no threats were detected and the species can be classified as Least Concern (LC) according to IUCN criteria (IUCN, 2019).

**Remarks on type specimens and type locality of *Scleronema operculatum*.** John Haseman collected the holotype and three paratypes of *Scleronema operculatum* in February 1909 in an expedition to South America. Haseman returned to USA one year later and the fishes were stored in the Carnegie Museum, Pittsburgh (Haseman, Eigenmann, 1911). Eigenmann described *S. operculatum* in 1917 and the FMNH purchased all fishes from the former Carnegie Museum collection in 1951 (Ibarra, Stewart, 1987) and, currently, the type specimens of *S. operculatum* are catalogued under the numbers FMNH 58080 (holotype; ex CM 7077) and FMNH 58520 (paratypes; ex CM 7539).

The coloration of the type specimens of *S. operculatum* faded and only one paratype has the black round blotches in the lateral surface of body (FMNH 58520; 58.6 mm SL) (Fig. 23). The caudal-fin rays of the holotype are slightly bent in their insertion and mid-length (Fig. 24). Additionally, the skin of the right maxilla in the holotype was ruptured making the bone exposed (probably by Eigenmann to analyze internally the structure of the conspicuous maxilla). Paratypes present faint wrapping marks in their bodies (Fig. 23). One of paratypes (FMNH 58520; 58.6 mm SL) has a longitudinal slit ventrally from abdomen extending to the lateral surface of trunk. The head of another paratype (FMNH 58520; not measured), osteologically studied by Eigenmann, was cut off and dissected dorsally making the bones exposed, which were drew in Eigenmann (1918; p. 282, fig. 2d–e; reproduced herein in the Fig. 25). In this same paratype, the anal-fin rays are broken.

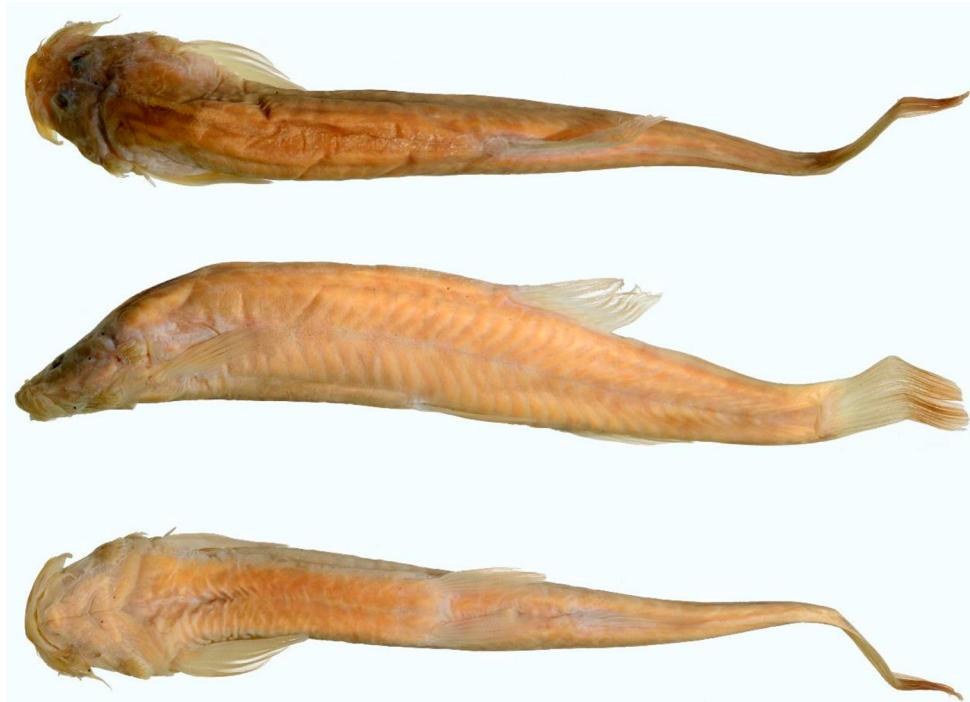

External synapomorphies of the genus could be observed in the type specimens of *S. operculatum*, such as the skin folds in the maxillary barbel and posterior to opercle. The membrane on the dorsal margin of caudal peduncle is present in all types. Diagnostic characters for the *Scleronema operculatum* species group (see discussion) are also observed in the types, such as the maxillary barbel shorter than half-length of the head. Additionally, all types present the tip of nasal barbel not reaching the anterior margin of eye, a diagnostic character for *S. operculatum*.

It is possible to count the principal rays of fins (see description). Through the skin is visible 3–5 branchiostegal rays and were counted 5–7 and 6–11 odontodes in the opercular and interopercular, respectively; with posterior ones longer and curved. However, these counts should be interpreted with caution considering the losses of some odontodes along the time and those completely covering by skin.

The type locality, based on notes accompanying the type material, “Cacequy, Feb 2 09, 2383” [sic], fits with John Haseman’s itinerary of expedition (*cf.* Haseman, Eigenmann, 1911: 308), and can be specified as Brazil, Rio Grande do Sul State, Cacequi, rio Cacequi, one mile from railroad station, rio Ibicuí basin, lower rio Uruguay, [*ca* 29°53'58"S 54°50'24"W].

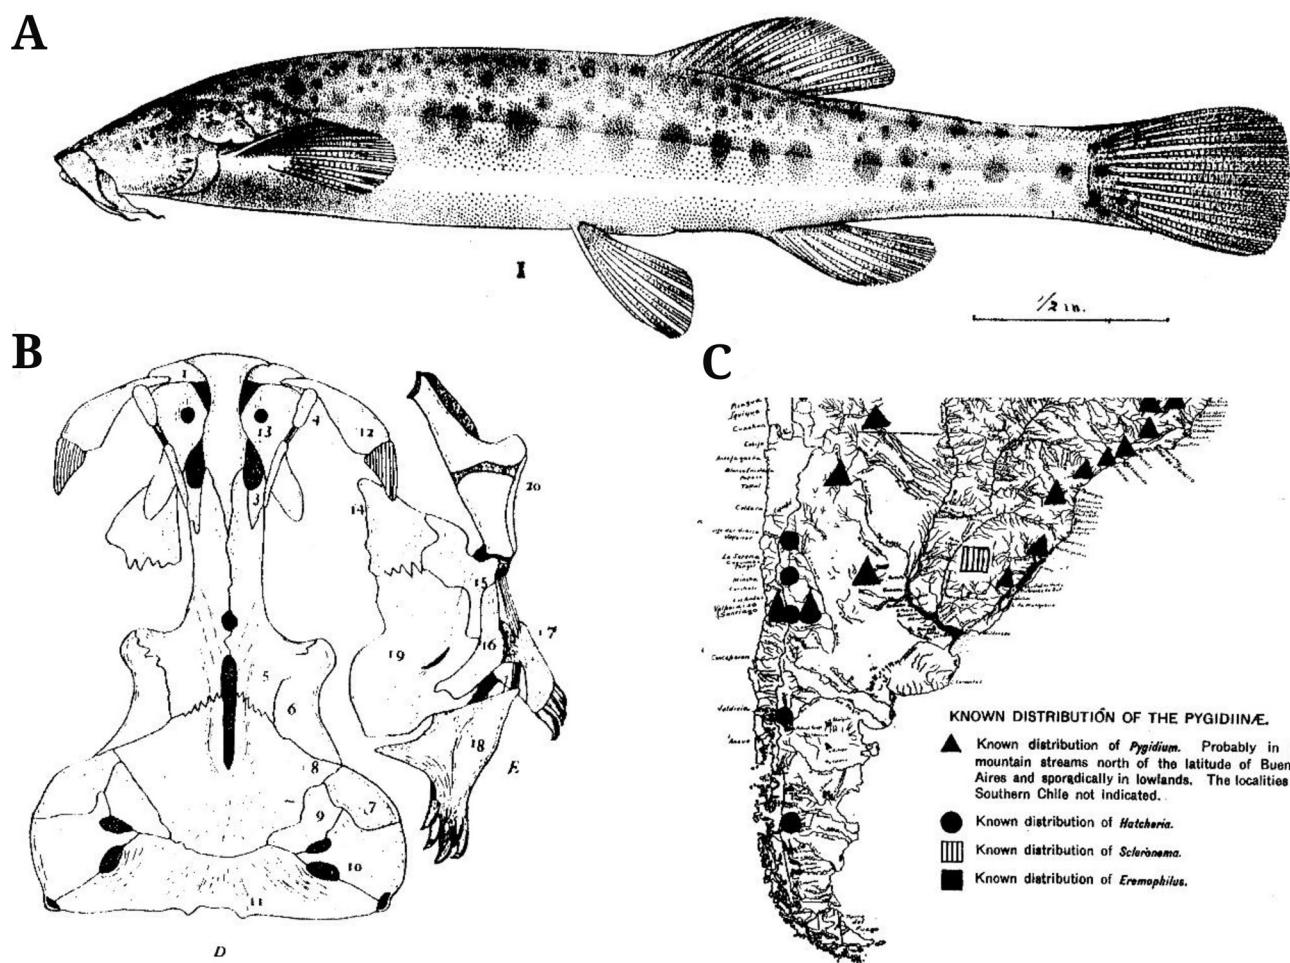

**FIGURE 23 |** *Scleronema operculatum*, paratype (FMNH 58520; 58.6 mm SL), Brazil, Rio Grande do Sul, Cacequi, rio Cacequi, tributary to rio Santa Maria, rio Ibicuí basin, lower rio Uruguay. Photograph taken by Sandra Raredon.

**FIGURE 24 |** *Scleronema operculatum*, holotype (FMNH 58080; 65.9 mm SL), Brazil, Rio Grande do Sul, Cacequi, rio Cacequi, tributary to rio Santa Maria, rio Ibicuí basin, lower rio Uruguay. Photograph taken by Sandra Raredon.

**Remarks on drawings of Eigenmann (1918).** Even though Eigenmann (1917) did not provide illustrations of *Scleronema operculatum* in his original description, one year later drawings of the holotype from lateral view and of the neurocranium, suspensorium, opercular apparatus, and lower jaw from dorsal view of one paratype were include in a revision of Trichomycteridae (Fig. 25; reproduced from Eigenmann, 1918: 381; plate 44, fig. 1 and 282; fig. 2d–e). However, some details of those figures do not correspond with the redescription above and deserve comments. The distal margins of the dorsal and caudal fins are straight in all types and non-types analyzed in opposition with the convex profile exhibited in the drawing of the holotype in Eigenmann (1918). Similarly, the anterior margin of the mesethmoid Eigenmann (1918) is convex whereas the c&s specimens observed have this margin straight to slightly concave. Lastly, the posterior process of the autopalatine in *S. operculatum* is long, overlapping almost the entire area of the metapterygoid, distinctly longer than the illustration in Eigenmann

**FIGURE 25 |** Original drawings published by Eigenmann (1918): **A.** lateral view of the holotype of *Scleronema operculatum*, FMNH 58080, (plate 44; fig. 1); **B.** neurocranium, suspensorium, opercular apparatus, and inferior jaw from dorsal view of one paratype of *S. operculatum*, FMNH 58520, (p. 282; fig. 2d–e); **C.** part of the distribution map (modified from original drawing) showing the occurrence area of *Scleronema* (dashed square) at that time (plate 36).

(1918). However, some characters diagnostic for *S. operculatum* or synapomorphic for the genus can be recognized in the drawings: the lateral surface with 14 round black blotches smaller than opercle, the long and pointed skin flap posterior to opercle and the conspicuous ventral flap in the ventral margin of the opercle.

**Material examined.** 54 specimens from Brazil, rio Ibicuí basin, lower rio Uruguay: FMNH 58080, 65.9 mm SL, holotype of *Scleronema operculatum* Eigenmann, 1917, Cacequi, rio Cacequi. FMNH 58520, 3, 53.3–58.6 mm SL (one specimen not measured), paratypes of *Scleronema operculatum* Eigenmann, 1917, collected with holotype. MCP 9315\*, 2 (1 c&s), 38.2–41.8 mm SL, São Francisco de Assis, rio Jaguari. MCP 27457\*, 4 (2 c&s), 24.2–41.3 mm SL, São Francisco de Assis, stream tributary of rio Inhacundá. MCP 27543, 5, 24.0–28.6 mm SL, Jaguari, arroio do Tigre, tributary of rio Jaguari. MCP 43904\*, 4, 22.5–34.2 mm SL, São Gabriel, arroio Jaguari, tributary of rio Santa Maria. **Diagnosis.** *Scleronema teiniagua* is distinguished from all congeners by a remarkable reduction in the laterosensory system lacking the pores s1, s2, s3 e s6 in the supraorbital line and pore i10 in the infraorbital line (*vs.* presence of, at least, the pore i10) and in the lower number of pterygiophores of dorsal fin (8 *vs.* 9–14).

**Description.** Based on specimens ranging from 15.5 to 45.2 mm SL; 2 c&s (one dissected). Morphometric data for 20 types in Tab. 10.

*External morphology.* Greatest height and width of body in half-length of trunk. Body elongate, trunk roughly cylindrical gradually compressed towards to caudal fin. Dorsal and ventral profiles of trunk slightly convex. Dorsal and ventral profiles of caudal peduncle straight. Dorsal margin of caudal peduncle with thin membrane, resembling adipose fin. Head depressed and wide, trapezoid-shaped from dorsal view, wider posteriorly; square-shaped in specimens with muscles of cheeks well developed. Dorsal and ventral profiles of head straight to slightly convex. Anterior snout profile usually rounded from dorsal view. Nostrils of equivalent size, smaller than eye diameter. Anterior nostril surrounded by fleshy flap of integument, posterolaterally continuous with nasal barbel. Posterior nostril surrounded anterolaterally by thin flap of integument. Eyes rounded, dorsally oriented but also visible from lateral view; located behind posterior nostrils; orbital rim not free; eyes covered by thin and transparent skin.

Barbels with large bases and tapering gradually towards tips. Nasal barbel long; emerging from posterolateral edge of anterior nostril extending up to posterior margin of eye or briefly surpassing. Maxillary barbel long; emerging from edge of upper lip and extending up to posterior margin of interopercle or briefly surpassing. Basal portion of maxillary barbel wide with thin fleshy flap dorsally and distal margin rounded. Maxillary barbel with thinner portion longer in length than wider one. Rictal barbel emerging from lateral lobe of lower lip and slightly shorter than maxillary barbel. Mouth subterminal with edges posteriorly oriented. Upper lip wider than lower lip. Lower lip with round fleshy lobes in corners. Ventral surface of lower lip with small papillae. Gill openings not constricted united with isthmus anteriorly forming free fold. Opercular

patch of odontodes rounded, inserted in posterior region of head visible from dorsal and lateral views. Posterior margin of opercle with distinct skin flap short and rounded. Interopercular patch of odontodes elongate inserted on posteroventral region of head visible from lateral and ventral views. Odontodes of opercle and interopercle barely visible, completely involved by flesh.

Pectoral fin with distal margin convex when expanded, 6/7( $n = 2$ ), or 7( $n = 21$ ; including holotype) rays; first one always unbranched and not prolonged as filament; fourth and fifth longest. Pectoral-fin insertion posterior to branchial aperture covered by branchial membrane anteriorly. Some specimens with intumescence above anterior portion of pectoral fin and axillary pore visible. Pelvic fin with distal margin convex when expanded, 4/5( $n = 1$ ) or 5( $n = 22$ ; including holotype) rays; first one always unbranched. Pelvic-fin origin located at half-length of SL extending between urogenital papilla and anal-fin anterior insertion; tangentially inserted with inner margins separated by large interspace. Urogenital papilla located between last third of pelvic fins.

Dorsal fin with distal margin straight to slightly convex when expanded, 8( $n = 5$ ), 9( $n = 30$ ; including holotype), or 10( $n = 2$ ) rays; usually first two rays unbranched. Dorsal fin with 2( $n = 1$ ) or 3( $n = 1$ ) procurent rays. Dorsal-fin origin located at half-length of pelvic fin. Anal fin with distal margin slightly convex when expanded, 6( $n = 23$ ; including holotype) rays; usually first two rays unbranched. Anal fin with 2( $n = 2$ ) procurent rays. Anal-fin origin located at vertical through last third of dorsal-fin base. Caudal fin with distal margin straight and corners slightly convex, 11( $n = 2$ ) or 12( $n = 21$ ; including holotype) rays; most-external rays of dorsal and ventral plates of caudal fin always unbranched and smaller than branched rays. Branched rays of caudal fin splitting up to twice. Caudal fin with 12( $n = 1$ ) or 13( $n = 1$ ) procurent rays dorsally and 9( $n = 1$ ) or 10( $n = 1$ ) procurent rays ventrally. Procurent rays of dorsal, anal, and caudal fins rarely visible.

**Osteology.** Premaxilla with 25–26( $n = 1$ ) teeth arranged in three rows. Dentary with 40( $n = 1$ ) teeth. Opercle with 14–15( $n = 2$ ) odontodes and interopercle with 17–21( $n = 2$ ) odontodes. Hyoid arch with 6( $n = 2$ ) branchiostegal rays. Free vertebrae 34( $n = 1$ ) or 35( $n = 1$ ); abdominal vertebrae 3( $n = 1$ ) or 4( $n = 1$ ). Ribs 10( $n = 1$ ) or 12( $n = 1$ ). First complete haemal arch in 4<sup>th</sup>( $n = 1$ ) or 5<sup>th</sup>( $n = 1$ ) free vertebra, first haemal spine in 11<sup>th</sup>( $n = 1$ ) or 12<sup>th</sup>( $n = 1$ ) free vertebra. Dorsal fin with 8( $n = 2$ ) pterygiophores; first one inserted anteriorly to neural spine of 14<sup>th</sup>( $n = 1$ ) or 16<sup>th</sup>( $n = 1$ ) vertebra. Anal fin with 6( $n = 2$ ) pterygiophores; first one inserted anteriorly to haemal spine of 18<sup>th</sup>( $n = 1$ ) or 20<sup>th</sup>( $n = 1$ ) vertebra.

**Laterosensory system.** Data for 40 specimens summarized in Tab. 3. Canals of laterosensory system with simple (non-dendritic) tubes and external pores. Supraorbital line with nasal and frontal canals invariably absent. Infraorbital line with antorbital segment and pore i10 of sphenotic canal invariably absent; pore i11 of sphenotic canal usually present. Posterior segment of frontal, sphenotic and otic canals fused each other. Otic, posotic and scapular canals present with preoperculo-mandibular and pterotic branches short with one pore each (po1 and po2, respectively). Trunk canal short with two pores.

**Coloration in alcohol.** Lateral surface of body with midlateral line of 5–9 rounded brown blotches larger than opercle over light yellow background; blotches of some

**FIGURE 26 |** *Scleronema teiniagua*, holotype (ZVC-P 14522; 45.2 mm SL) Uruguay, Artigas, arroyo Tres Cruzes, río Cuareim basin, lower río Uruguay.

individuals becoming faded or absent towards caudal peduncle (Figs. 13B, 26). Dorsal surface of body with 4–6 rectangular brown blotches extending ventrally to laterodorsal surface of body; smaller specimens with these blotches smaller, dorsally discontinuous (MCP 16179). Ventral surface of body light yellow with few brown blotches in caudal peduncle. Dorsal and laterodorsal surfaces of head with numerous brown rounded blotches over light yellow background. Anterior portion of opercle black. Ventral surface of head light yellow with few small brown blotches in lower lip, sometimes forming thin stripe. Barbels uniformly yellow or intercalated with brown areas. Pectoral-, pelvic-, and anal-fin rays weakly brown. Dorsal and caudal fins with vertical light brown stripe basally, rays weakly brown, and distal margins hyaline (Figs. 13B, 26).

**TABLE 10 |** Morphometric data of *Scleronema teiniagua*, new species (data of holotype included in the range). N = number of specimens; SD = standard deviation.

**Coloration in life.** Coloration in life similar to that specimens preserved in ethyl alcohol, but more intense with blotches better defined (Fig. 27).

**Geographical distribution.** *Scleronema teiniagua* is endemic to the drainage of the río Cuareim (Uruguay), also named río Quaraí (Brazil), a tributary to the left bank of lower río Uruguay (Fig. 4).

Only two lots identified on the basis of external characters as *S. teiniagua* were supposedly sampled outside of the río Cuareim basin: ZVC-P 3462 from arroyo Milano,

**FIGURE 27 |** Specimen in life out of the water of *Scleronema teiniagua* (ZVCP 13763), Uruguay, Artigas, arroyo Catalán Grande at Paso Santiño, río Cuareim basin lower río Uruguay. Photograph taken by Sebastián Serra.

Santa Lucía basin (collection date 1958) and ZVC-P 5592 (collection date 1971) from río Queguay basin. The ichthyofauna of the río Santa Lucía has been densely inventoried and none trichomycterid was recorded until now (Zarucki *et al.*, 2011; Marcelo Loureiro, 2014, pers. comm.). The unique specimen of the lot ZVC-P 5592 is originated from the type locality of *S. angustirostre*, Cañada de las Piedras, and all material analyzed from this locality and the río Queguay basin belong to *S. minutum* (senior synonym of *S. angustirostre*). The occurrence of *S. teiniagua* in the río Santa Lucía or río Queguay basins should be considered with caution and need to be confirmed by new samples.

**Ecological notes.** *Scleronema teiniagua* inhabits rivers and streams and has not been collected with its congeners. The stomachs of two specimens were analyzed and had immature aquatic Diptera (Chironomidae and Simuliidae) and Ephemeroptera.

**Etymology.** The species epithet “teiniagua” is given in reference to the character of a fictional tale entitled “Salamanca do Jarau” popularized in the Rio Grande do Sul State by the writer Simões Lopes Neto (Lopes-Neto, 1913). In this story, Teiniaguá was a princess transformed to a witch that lives in a cave at the hill “Cerro do Jarau”, which is inserted in the area of distribution of the new species. A noun in apposition.

**Conservation status.** *Scleronema teiniagua* has an Extent of Occurrence (EOO) less than 20,000 km<sup>2</sup>, but no threats were detected to the species. Thus, the species can be classified as Least Concern (LC) according to IUCN criteria (IUCN, 2019).

**Remarks.** Specimens of *Scleronema minutum* analyzed by Vaz-Ferreira, Soriano (1959) from Artigas probably belong to *S. teiniagua*. However, these authors did not provide the voucher numbers to confirm their identification.

**Additional material examined.** 30 specimens from Uruguay. ZVC-P 3462, 17, 23.6–41.7 mm SL, uncertain locality. ZVC-P 5592, 1, not measured, uncertain locality. Artigas, río Cuareim basin, lower río Uruguay: ZVC-P 412, 3, 18.0–22.3 mm SL, río Cuareim near mouth of arroyo Yacaré. ZVC-P 10588, 8, 20.1–38.4 mm SL, río Cuareim. ZVC-P 10590, 1, 31.9 mm SL, arroyo Catalán Grande. ZVCP 13763, 1, not measured, arroyo Catalán Grande at Paso Santiño.

## DISCUSSION

**Monophyly of *Scleronema*.** Eigenmann (1917) defined the genus *Scleronema* on the basis of following diagnostic characters: ventrals nearer snout than caudal; outer pectoral rays shortest, without a filament; opercle with a long dermal flap; interopercular spines in a much more restricted area than in species of *Pygidium* (species currently allocate in *Cambeva*, *Ituglanis*, and *Trichomycterus*); accessory rays of the caudal inconspicuous; maxillary barbel with a large osseous base (maxillary bone); teeth very narrow incisors; mouth wide, terminal. Eigenmann (1918) in a revisionary study of Pygididae (= Trichomycteridae) repeated all these traits and provided two new characters to recognize *Scleronema* in an identification key: maxillary bone longer than the attached barbel and anal short. Tchernavin (1944) contested the exclusiveness of these characters in *Scleronema* and mentioned that the genus should be placed in the synonymy of *Trichomycterus*. According to him, only two characters present in *Scleronema* were considered of generic significance: the relatively wider cleft of the mouth and the larger maxilla. Based on current knowledge on the family, the most of these characters (Eigenmann, 1917; 1918; Tchernavin, 1944) failed to diagnose unequivocally *Scleronema* from other trichomycterids, with the single exception of the dermal opercular flap (Fig. 1), as noted by de Pinna (1989; 1998), Arratia (1990), and Wosiacki (2002). Some specimens of *Cambeva*, *Ituglanis*, and *Trichomycterus* seem to have a thin opercular fleshy flap as mentioned by Tchernavin (1944) for many species of *Trichomycterus*: “variously developed but always smaller than *Scleronema*”. Nevertheless, this condition results from the odontodes strongly embedded in the integument and usually observed in specimens preserved for a long time or fixed directly in alcohol. The vandelliine *Plectrochilus machadoi* is the only trichomycterid, which has a notable flap of integument in the opercle, such as that of *Scleronema*. However, this flap has a thinner thickness than *Scleronema* and surrounds practically the entire circumference of the opercle, condition that resembles an “ear” according to de Pinna (2013).

Arratia (1990) proposed the long fleshy projections extending posterior to opercular teeth and other three characters as synapomorphies supporting the monophyly of *Scleronema*: skin of upper lip without epidermal papillae, transverse skin fold between anterior nostril and base of maxillary barbel, and three abdominal vertebrae. However, we observed epidermal papillae in the lips for all species of *Scleronema* rejecting this putative synapomorphy proposed by Arratia (1990) and posteriorly corroborated by de Pinna (1998) and Wosiacki (2002). On the other hand, our findings agree with the second character (*i.e.*, the skin fold on dorsal surface of the maxillary barbel) as a synapomorphy for the genus (Fig. 1), condition also suggested by de Pinna (1998) and Wosiacki (2002). Among trichomycterids, *Sarcoglanis simplex* also has a fleshy flap over the maxillary barbel; however, it is longer (extending to the anterior nare and the eye) and quite different in shape to the condition noted in *Scleronema*. Consequently, the characters are presently hypothesized as not homologous.

Wosiacki (2002) included four species of *Scleronema* in a phylogenetic analysis of the subfamily Trichomycterinae. As a result, *Scleronema* was supported by the two characters discussed above (*i.e.*, skin flap posterior to the opercle and fleshy flap at the base of the maxillary barbel), plus the maxilla elongated and expanded distally, the

autopalatines near each other articulating with the vomer ventrally, and the presence of a dorsal canal in the articulation process between the autopalatine and the lateral ethmoid. As proposed by previous authors (*cf.* de Pinna, 1989; Arratia, 1990) and confirmed by our observations, the third feature (concerning on the maxilla) is shared by sarcoglanidines and some trichomycterines. The condition of the autopalatines near each other, articulating with the vomer ventrally, is herein corroborated (Fig. 2) and by DoNascimento (2012).

Finally, Wosiacki (2002) observed the presence of a canal or foramen in the dorsal surface of the autopalatine in *Scleronema* and some species of *Trichomycterus* from Southern and Southeastern Brazil (some of them currently included in the genus *Camberra*). The author, however, noted different conditions in these genera: species of *Scleronema* have one or two canals oriented obliquely across the autopalatine whereas the species of *Trichomycterus* have various canals without any noticeable organization. We observed, exclusively in *Scleronema*, a unique canal forming an interrupted arch dorsally similar to the condition illustrated by Wosiacki (2002: fig. 73) or a conspicuous arch not interrupted (Fig. 3) placed exactly above the aperture of the second nare.

**Taxonomy and diversity.** So far, the single taxonomic revision of the species of *Scleronema* after the description of the genus by Eigenmann (1917, 1918) was that of Tchernavin (1944), which was based on the analysis of type material housed at the BMNH and on Eigenmann's papers. Tchernavin noticed that the diagnostic features described by Eigenmann (1917, 1918) to the genus and its type species, *S. operculatum*, were shared by two species formerly described as *Trichomycterus minutus* Boulenger, 1891 and *Pygidium angustirostris* Devincenzi, 1942. Consequently, the author suggested a new combination for these taxa: *S. minutum* and *S. angustirostris*.

Tchernavin (1944) also noted several features to distinguish *S. minutum* from *S. operculatum*, such as the posterior position of the pelvic fin, shorter pectoral-fin rays, larger head, narrower cleft of the mouth, soft part of the maxillary barbel longer, nasal barbel longer, and flap posterior to opercle shorter in the former. However, Tchernavin considered these differences were related to the size of the specimens available for each nominal species ("specimens of *S. minutum* are very small and probably young" [sic]) and that they belonged to a single species. Additionally, according to Tchernavin (1944), the third nominal species, *S. angustirostris*, also might have been included in the synonymy of *S. minutum* due to notable similarities. Based on present data, however, all characters mentioned by Tchernavin (1944) are valid to diagnose *S. minutum* and *S. operculatum* and actually these species reach distinct maximum sizes (55.5 mm SL and 72.8 mm SL, respectively). Posterior to Tchernavin's view, the comments regarding the taxonomy of *Scleronema* were focused on the need of a taxonomic revision of the genus (de Pinna, 1989; Casciotta, Almirón, 1996) and on the reference to undescribed species (de Pinna, Wosiacki, 2003; Becker *et al.*, 2013; Bertaco *et al.*, 2016).

*Scleronema angustirostre* is recognized herein as a junior synonym of *S. minutum* in the absence of morphological differences between their type specimens (Figs. 18–20) and between populations of the lower rio Uruguay drainage *versus* the laguna dos Patos drainage and coastal rivers from Uruguay, corresponding to the type localities and historically assumed as belonging to *S. angustirostre* and *S. minutum*, respectively. The similarity of both species was first noted by Tchernavin (1944) and posteriorly

by Casciotta, Almirón (1996). Despite of this synonymy, the diversity of *Scleronema* increased considerably in the present review, with the recognition of *S. minutum* and *S. operculatum* as valid, and the description of six new species: *S. guapa*, *S. ibirapuita*, *S. macanuda*, *S. mate*, *S. milonga*, and *S. teiniagua*. Additionally, two other undescribed species recognized along this study (Fig. 4) are focus of further taxonomic investigation yet incomplete due to the few specimens available.

**Interspecific relationships and comparisons.** Within the genus, Ferrer (2016) defined two species groups supported by striking morphological features: the *S. operculatum* species group, which includes *S. macanuda* and *S. operculatum*, and the *S. minutum* species group, which encompasses *S. guapa*, *S. ibirapuita*, *S. mate*, *S. milonga*, *S. minutum*, and *S. teiniagua*. Some diagnostic characters between these two species group are coincidental with those observed by Tchernavin (1944) when he provided a detailed comparison between *S. minutum* and *S. operculatum*, regardless his suggestion that these characters correspond to intraspecific variation due to body size and that the two species would constitute synonyms.

The most conspicuous morphological differences exhibited by these groups are related to those characters that define the genus. For example, the skin flap in the posterior margin of the opercle is pointed and long in the *S. operculatum* species group and rounded and short in the *S. minutum* species group (Fig. 1). The fleshy flap at the base of the maxillary barbel is located anteriorly, thick, prolonged up to the snout and with distal margin straight in the *S. operculatum* species group while it is posteriorly inserted, thin, restricted to the maxillary barbel and with distal margin rounded in the *S. minutum* species group. Lastly, the articulation of the autopalatine with the vomer is inserted more ventrally with its margins nearer each other in the *S. operculatum* species in comparison with that condition observed in the species of the *S. minutum* species group.

Moreover, species of *S. operculatum* group have the body compressed, the maxillary barbel shorter than half-length of the head, the caudal fin with a vertical black bar distally, the tips of pectoral-fin rays extending beyond the interradial membrane, the coronoid process of the dentary approximately four times wider than the coronoid process of the anguloarticular, one branchiostegal ray articulated with the anterior ceratohyal, and the first haemal spine inserted between the 7<sup>th</sup> to 9<sup>th</sup> vertebra.

In contrast, species of the *S. minutum* group have the body roughly cylindrical, the maxillary barbel longer than half-length of the head, the caudal fin lacking a vertical black bar, the tips of pectoral-fin rays not extending beyond the interradial membrane, the coronoid process of the dentary approximately two times wider than the coronoid process of the anguloarticular, two or three branchiostegal ray attached to the anterior ceratohyal, and the first haemal spine inserted between the 11<sup>th</sup> to 13<sup>th</sup> vertebra.

The two species included in the *S. operculatum* group (*Scleronema operculatum* and *S. macanuda*) are diagnosed by the color pattern of the lateral surface of body, composed of 10–14 rounded blotches in the midlateral line as large as or smaller than opercle in the former versus 6–9 round blotches larger than opercle in the latter. The two species also exhibit differences in the length of barbels: tip of nasal barbel never reaching the anterior margin of eye and tip of maxillary barbel never surpassing the anterior margin of interopercle in *S. operculatum* while the tip of nasal barbel usually extends

beyond the anterior margin of eye and the tip of maxillary barbel extends between the anterior and posterior margins of interopercle in *S. macanuda*.

Interspecific distinction within the *S. minutum* species group is less noticeable. *Scleronema guapa* and *S. mate* have unique color patterns (body with scattered spots and small rounded blotches, respectively) whereas the remaining species possess a similar color pattern, formed by larger rounded blotches.

Additionally, a remarkable reduction in the canals and pores of the laterosensory system observed in *Scleronema* is quite informative to diagnose its species (Tab. 3; Figs. 5, 10). As emphasized by Ferrer *et al.* (2015), characters related to the laterosensory system are useful to diagnose species when based on analyses of large samples. The nasal canal (pores s1 and s2) is usually present in *S. macanuda* and variably present in *S. operculatum* (Fig. 10), but always absent in the species of the *S. minutum* species group (Fig. 5), excepting for one specimen of *S. guapa* that has its right branch. The reduction in the canals and pores of the laterosensory system is still more conspicuous within the *S. minutum* species group. In *S. milonga* the pore s3 of the frontal canal is absent, in *S. ibirapuita* the entire frontal canal is absent (Fig. 5), and in *S. teiniagua* the frontal canal and the pore i10 of the sphenotic canal, are missing.

**Distribution patterns.** Species of the genus *Scleronema* are distributed in Southern Brazil, Southern Paraguay, Northeastern Argentina and Uruguay (Fig. 4), corresponding to the following freshwater ecoregions *sensu* Abell *et al.* (2008): Laguna dos Patos, Lower Paraná, Lower Uruguay, Paraguay, and Southeastern Mata Atlântica. Five species are found exclusively in the Lower Uruguay (*S. guapa*, *S. ibirapuita*, *S. milonga*, and *S. teiniagua*) and *S. mate* is restricted to the Laguna dos Patos ecoregion. *Scleronema minutum* is the most widespread species of the genus occurring in the Lower Paraná, Lower Uruguay and Laguna dos Patos ecoregions. Finally, *Scleronema macanuda* inhabits the Lower Uruguay and Laguna dos Patos ecoregions.

Interestingly, species that make part of each species group are always allopatric whereas it is noticeable several cases of syntopy of species of the *S. operculatum* group with species of the *S. minutum* group (Fig. 4). *Scleronema operculatum* is geographically restricted to the rio Ibicuí basin where it co-occurs with *S. minutum* in the headwaters and with *S. guapa* in the middle portion. Likewise, *Scleronema macanuda* co-occurs with *S. minutum* in the most localities of its distribution in the rio Negro basin and Laguna dos Patos system. In this latter drainage, *S. mate* is restricted to its north portion being found with *S. macanuda* only in the rio Pardo basin. It is likely possible that the two species group of *Scleronema*, with their different body shapes, represent adaptive morphotypes exploring different niches in sand-bottom environments as observed for *S. macanuda* and *S. minutum* in field observations, allowing their coexistence in syntopy. The results obtained by Carvalho (2017) demonstrated a strong relationship between diet and morphology for *S. macanuda*, *S. minutum* and *S. milonga*, which also presented distinct diet compositions although the three species are insenctivores with predominance of immature stages of autochthonous benthic preys.

The allopatric distribution among the species of the *S. minutum* group is evident in the distinct tributaries of rio Uruguay. *Scleronema milonga* is restricted to the rio Ijuí basin (Brazil) and arroyo Itacaruaré (Argentina), representing the northernmost occurrence of the genus in the rio Uruguay basin. *Scleronema guapa* is restrict to the

rio Ibicuí basin (Brazil), a downstream tributary to the left bank of the rio Uruguay. *Scleronema ibirapuita* also occurs in the rio Ibicuí basin, but is found uniquely in the rio Ibirapuitã basin, a small tributary. *Scleronema teiniagua* is endemic to the rio Quarai (Brazil) or río Cuareim (Uruguay), the next downstream large tributary to the left bank of the rio Uruguay after the rio Ibicuí. *Scleronema minutum* is widespread in the following southern affluents of the rio Uruguay, with the exception of the río Arapey. The only record of the genus for this basin is tentatively identified as *S. ibirapuita* (see remarks on the species).

The distribution pattern of the species of the *S. minutum* species group in the rio Uruguay drainage (Fig. 4) shows a clear resemblance with that described by Turcati *et al.* (2018: fig. 6) for *Gymnogeophagus gymnoenys* species group, in the same drainage, with separate species inhabiting the main tributaries (*G. constellatus* and *S. milonga* in the rio Ijuí, *G. tiraparae*, *G. mekinos* and *S. guapa* in the rio Ibicuí, *G. pseudolabiatus* and *S. ibirapuita* in the rio Quarai). Turcati *et al.* (2018) suggested that the main channel of river act as a physical or ecological barrier to dispersal of these species of *Gymnogeophagus* among rio Uruguay tributaries and it may also be true for the species of *Scleronema* cited above. It must be considered, however, that the absence of records of these species in the tributaries of rio Uruguay of Argentina may be associated with the lack of sampling in the western tributaries of rio Uruguay, in contrast to the most densely collected areas in the eastern tributaries of rio Uruguay in the Rio Grande do Sul state, Brazil (Bertaco *et al.*, 2016). It is also remarkable that the rio Ijuí and rio Santa Rosa to the north and rio Quarai to the South are embedded in a basaltic sediment and the rio ibicui in the middle in a sedimentary bed. Since both *Gymnogeophagus* and *Scleronema* habits are closely associated with the substrate for feeding, this is also a possible reason for such disjunct distributions.

*Scleronema macanuda* and *S. minutum* inhabit the lower portions of two isolated hydrographic systems, the rio Uruguay and Laguna dos Patos drainages (Fig. 4). Such fact was observed in some killifishes of the genus *Austrolebias* and *Cnesterodon decemmaculatus*, being inferred as a consequence of drainage rearrangements (González-Bergonzoni *et al.*, 2009; Loureiro *et al.*, 2011; Ramos-Fregonezi *et al.*, 2017).

**Conservation.** Species of *Scleronema* are strongly related to grasslands of the Pampa biome from Southern Brazil (IBGE, 2004, 2019) and the Uruguayan savanna ecoregion *sensu* Olson *et al.* (2001) that includes the entire country of Uruguay. Six species of the genus are found exclusively in this region (*S. guapa*, *S. ibirapuita*, *S. macanuda*, *S. minutum*, *S. operculatum*, *S. teiniagua*), whereas *Scleronema mate* and *S. milonga* occupy its limits with the Atlantic Forest ecosystem. Loureiro *et al.* (2013) suggested that the species of *Scleronema* have priority for conservation in Uruguay in view of some threats, such as habitat destruction and modification, use of fertilizers, pesticides and herbicides.

Similar threats are observed in the grasslands of Southern Brazil, mainly by the currently and rapid expansion of culture soybean in the region. Conservation of the non-forest ecosystems in Brazil have been neglected, although they have biodiversity levels comparable to forests and cover large parts of the country (Overbeck *et al.*, 2015). According to Malabarba *et al.* (in prep.), approximately 63% of the 422 freshwater

fishes from Rio Grande do Sul (Southern Brazil) recorded by Bertaco *et al.* (2016) distribute in the Pampa biome, and around 60 are endemic to this region, which encompass only 2% of the Brazilian territory. The Pampa has the lowest percentage of legally protected areas among the Brazilian biomes (ICMBio, 2016) and *S. ibirapuita* is the only species of the genus with occurrence in a Conservation Unit (“Área de Proteção Ambiental Ibirapuitã”).

## ACKNOWLEDGMENTS

We thank Richard Vari, in memoriam, Carlos David de Santana, Kris Murphy, Jeffrey Clayton, and Sandra Raredon (USNM), Aléssio Datovo (MZUSP), André Esguícero (LIRP), Carlos Lucena and Juliano Romanzini (MCP), Caleb McMahan, Kevin Swagel and Susan Mochel (FMNH), Doug Nelson and Andrea Thomaz (UMMZ), Emanuel Neuhaus, Fábio Pupo, Marcelo Britto and Paulo Buckup (MNRJ), James Maclaine (BMNH), John Lundberg, Mark Sabaj Pérez and Tiago Carvalho (ANSP), Juliana Wingert (UFRGS), Leo Smith and Gloria Arratia (KU), Marcelo Loureiro (ZVC-P), Marco Azevedo and Vinicius Bertaco (MCN), Pablo Lehmann and Thais Mumbach (UNICTIO), Radford Arrindell (AMNH), Ricardo Ferriz (MACN), Sebastián Serra (MHNM) for all support in the fish collections. Mário de Pinna (MZUSP), Tiago Carvalho (MPU) and Wolmar Wosiacki (MPEG) for valuable contributions on the PhD Thesis of JF. Flávio Bockmann (LIRP) for a detailed and critical review of the manuscript. We thank to Marcelo Camana (UFRGS) for the Fig. 4 (distribution map) and Sebastián Serra for the Fig. 27 (specimen in life). Sandra Raredon (USNM) gently made photographs of specimens used in this study (Figs. 18, 19, 23, 24). JF was supported in Brazil (Proc.142010/2012-0 and 152354/2016-6) and abroad by CNPq, being funded by the extinct exchange program “Ciências sem Fronteiras” (CNPq; Proc. 201215/2014-4) established in 2011 by the Brazilian federal government. JF also thanks for the “Böhlke Endowment” provided by ANSP. LRM is supported by CNPq (Proc. 307890/2016-3 and 401204/2016-2).
