A redescription of *Hypostomus hermanni* is presented herein along with the description of a new species of *Hypostomus*, which is apparently endemic to the Ivaí River basin, a tributary of the Upper Paraná River basin, Brazil. *Hypostomus hermanni* is diagnosed from congeners mainly by having: usually large black blotches on body and fins; absence of keels on compound pterotic, on pre-dorsal plates, and on lateral series of bony plates; by having parieto-supraoccipital and predorsal region flat; and by having less than 46 teeth per each premaxilla or dentary ramus. The new species is distinguished from congeners mainly for lacking conspicuous blotches, parieto-supraoccipital non-carinate, and villiform bicuspid teeth.

Uma redescrição de *Hypostomus hermanni* é aqui apresentada, juntamente com a descrição de uma nova espécie de *Hypostomus*, que é aparentemente endêmica da bacia do rio Ivaí, afluente do alto rio Paraná, Brasil. *Hypostomus hermanni* é diagnosticada de suas congêneres principalmente por apresentar: geralmente grandes manchas pretas ao longo do corpo e nadadeiras; ausência de quilhas no pterótico-composto, nas placas pré-dorsais e nas séries laterais de placas ósseas; por ter as regiões do parieto-supraoccipital e predorsal planas; e por ter menos que 46 dentes por cada ramo premaxilar ou dentário. A espécie nova distingue-se de suas congêneres principalmente pela ausência de manchas conspícuas no corpo, e supraoccipital não quilhado e dentes viliformes bicuspídos.

INTRODUCTION

Hypostomus Lacepède, 1803 is the richest genus of the subfamily Hypostominae, comprising about 140 valid species (Zawadzki *et al.*, 2018) as well as the second largest genus within Siluriformes. Besides that, *Hypostomus* is one of the most diverse and complex genera of South American catfishes (Carvalho *et al.*, 2010; Tencatt *et al.*, 2014). Its representatives are mainly differentiated from other Hypostominae genera by lacking a strong eversible operculum, unexposed scapular bridge, and oval-shaped caudal peduncle (Weber, 2003). The same author suggested that through morphological and molecular shreds of evidence, one-third of the species of the genus were not yet described. Despite some recent descriptions of new species (Oliveira *et al.*, 2020; Zawadzki *et al.*, 2020), this scenario has not been substantially changed. Additionally, to the high diversity of *Hypostomus*, the brevity of the descriptions from the former centuries allied to the absence of knowledge of the distribution patterns of each species lead to a common high amount of misidentifications in literature, museums, and conservation status lists.

Ihering (1905) presented the original description of *Hypostomus hermanni* as *Plecostomus hermanni*, from the Piracicaba River, in the state of São Paulo, Brazil, based solely on the analysis of the holotype, which was reported to have 240 mm in total length. In the original description, he reported traces of dark blotches on the upper surface of the head; however, he did not cite blotches being present on trunk or fins. The author also mentioned the dorsal fin with the posterior part of each interradial membrane dusky. Other important remarks of Ihering's description was "snout moderately narrowed anteriorly; supraorbital edges not raised; parieto-supraoccipital nearly flat; temporal plates (compound pterotic) not carinate; scutes spinulose, not carinate; and a lower surface of head and abdomen in great part covered with small granular scales, with a naked area at the base of each ventral" (Ihering, 1905:560). However, the actual differentiation of *H. hermanni* from other congeners is commonly hampered by the relatively great ontogenetic and interspecific variation found in several species of the genus. Limits of a species sometimes superpose the limits of other species of the genus.

This scenario is especially seen in the Upper La Plata River basin. Some ancestral lineages of *Hypostomus* may have migrated to the basin to find an area relatively free from the competition of Amazonian algivorous/detritivorous fishes and this allowed them to experience adaptive radiation (Silva *et al.*, 2016). Therefore, the high species diversity creates great difficulty for most ichthyologists to identify species of *Hypostomus* in this basin. Then, as important as revealing the new species, redescriptions with emphasis on the morphological variability along the distribution area of each valid species from the La Plata River basin are needed.

Herein, a redescription of *H. hermanni* is provided based on the analysis of the holotype, and based on the analysis of a great amount of recently collect material of *H. hermanni* including some specimens from its type-locality, the Piracicaba River. A morphologically similar species to *H. hermanni* was also found. This species seems to be restricted to Ivaí River basin, a subbasin of the Upper Paraná River basin. This new species, which is syntopic to *H. hermanni* in the Ivaí River, is described in the present work.

MATERIAL AND METHODS

Meristic and morphometric data were obtained point-to-point with a 0.1 mm digital calipers according to the procedures of Boeseman (1968) with additions of Weber (1985) and Zawadzki *et al.* (2008, 2010). Bone and plate terminology followed Schaefer (1997) with modifications of Oyakawa *et al.* (2005), and Geerinckx, Adriaens (2006). *Hypostomus* super-groups are according to Queiroz *et al.* (2020). Vertebrae counts include five vertebrae of the Weberian apparatus and the ural complex was counted as one single structure. Some not well preserved specimens were considered as non-types.

Standard length (SL) is expressed in millimeters and all other measurements are expressed as percentages of the standard length or head length (HL), unless otherwise noted. RESULTS

Hypostomus hermanni (Ihering, 1905)

(Figs. 1–3; 9; Tabs. 1–2)

Plecostomus hermanni: Ihering, 1905:560 (original description; type-locality: Piracicaba River, São Paulo, Brazil). —Gosline, 1947:124 (brief description; *partim*).

Hypostomus hermanni: Isbrücker, 1980:24 (validation of *Hypostomus hermanni* (Ihering, 1905)). —Burgess, 1989:431 (checklist). —Gómez, Chebez, 1996:64 (checklist). —Isbrücker, 2001:28–31 (checklist). —Isbrücker, 2002:19 (revision of Loricariidae). —Weber, 2003:358 (checklist). —López *et al.*, 2003:51 (checklist). —Armbruster, 2004:79 (phylogeny). —Menni, 2004:81 (checklist). —Ferraris, 2007:254 (checklist). —Galves *et al.*, 2007:256 (checklist). —Langeani *et al.*, 2007:188 (checklist). —Bueno *et al.*, 2012:245 (check list cytogenetic data). —Bueno *et al.*, 2013:104 (cytogenetics). —Oliveira *et al.*, 2013:265 (checklist). —Paiva *et al.*, 2013:571–578 (allozymes; fig. 1c, p. 572). —Bueno *et al.*, 2014:3 (cytogenetics). —Frota *et al.*, 2016:6 (checklist). —Silva *et al.*, 2016:12 (phylogeny; fig. 7d, p. 14). —Zawadzki *et al.*, 2016:264 (reference to color pattern and comparative material). —Zawadzki *et al.*, 2018:257 (diagnosis from *Hypostomus latirostris* and from *H. renestoi*). —Dias, Zawadzki, 2018:394 (identification key; fig. 6, p. 401). —Zawadzki *et al.*, 2019:240 (cited as additional specimens examined). —Queiroz *et al.*, 2020:9 (phylogenetic relationship).

Diagnosis. *Hypostomus hermanni* is distinguished from the species of the super-group *H. cochlodon* Kner, 1854 by having viliform teeth and dentaries usually angled more than 100° (*vs.* spoon- or shovel-shaped teeth and dentary rami angled to each other up to 80°); from the species of the super-group *H. hemiurus* (Eigenmann, 1912) by having round dark blotches (*vs.* somewhat horizontally elongate dark blotches); from the species of the super-group *H. plecostomus* (Ihering, 1905) by lacking rows of odontodes on keels along lateral series of plates (*vs.* with moderate to well-developed rows of odontodes on keels); from *H. nematopterus* Isbrücker & Nijssen, 1984 by lacking elongate dorsal-fin ray (*vs.* extremely elongate dorsal-fin ray). From the congeners of the *H. auroguttatus* Kner, 1854 super-group *Hypostomus hermanni* is diagnosed from *H. alatus* Castelnau, 1855, *H. albopunctatus* (Regan, 1908), *H. arecuta* Cardoso, Almirón, Casciotta, Aichino, Lizarralde & Montoya-Burgos, 2012, *H. faveolus* Zawadzki, Birindelli & Lima, 2008, *H. fluviatilis* (Schubart, 1964), *H. francisci* (Lütken, 1874), *H. Krishnamurtii* Zawadzki, Penido & Lucinda, 2020, *H. luteomaculatus* (Devincenzi, 1942), *H. luteus* (Godoy, 1980), *H. margaritifer* (Regan, 1908), *H. meleagris* (Marini, Nichols & LaMonte, 1933), *H. microstomus* Weber, 1987, *H. multidens* Jerep, Shibatta & Zawadzki, 2007, *H. regani* (Ihering, 1905), *H. roseopunctatus* Reis, Weber & Malabarba, 1990, *H. strigaticeps* (Regan, 1908), *H. tietensis* (Ihering, 1905) and *H. variipictus* (Ihering, 1911) by having dark spots or blotches on a clear background (*vs.* pale spots or vermiculations on a darker background); from *H. asperatus* Castelnau, 1855, *H. brevicauda* (Günther, 1864), *H. johnii* (Steindachner, 1877), *H. leucophaeus* Zanata & Pitanga, 2016, *H. nigropunctatus* Garavello, Britski & Zawadzki, 2012, *H. renestoi* Zawadzki, da Silva & Troy, 2018 and *H. uruguayensis* Reis, Weber & Malabarba, 1990 by having large dark

blotches, that is, similar to or larger than eye diameter on trunk and fins (*vs.* small spots, similar to or smaller than eye pupil diameter); from *H. atropinnis* (Eigenmann & Eigenmann, 1890), *H. denticulatus* Zawadzki, Weber & Pavanelli, 2008, *H. freirei* Penido, Pessali & Zawadzki, 2021, *H. goyazensis* (Regan, 1908), *H. iheringii* (Regan, 1908), *H. macrops* (Eigenmann & Eigenmann, 1890), *H. latirostris* (Regan, 1904) and *H. ternetzi* (Boulenger, 1895) by having parieto-supraoccipital and predorsal region flat (*vs.* parieto-supraoccipital medially raised and with raised parallel keels on predorsal region); from *H. brevis* (Nichols, 1919), *H. garmani* (Regan, 1904), *H. goyazensis* (Regan, 1908), *H. lima* (Lütken, 1874) and *H. topavae* (Godoy, 1969) by having parieto-supraoccipital and predorsal region flat (*vs.* predorsal region high and convex in frontal view); from *H. denticulatus*, *H. jaguar* Zanata, Sardeiro & Zawadzki, 2013, *H. latirostris*, *H. mutucae* Knaack, 1999, *H. paulinus* (Ihering, 1905) and *H. ternetzi* by having tooth number less than 46 on each premaxillary or dentary (*vs.* more than 50); from *H. agna* (Miranda Ribeiro, 1907), *H. angipinnatus* (Leege, 1922), *H. isbrueckeri* Reis, Weber & Malabarba, 1990, *H. latifrons* Weber, 1986, *H. luetkeni* (Steindachner, 1877) and by having a single predorsal plate bordering parieto-supraoccipital (*vs.* two to three plates); from *H. perdidio* Zawadzki, Tencatt & Froehlich, 2014 by having bicuspid teeth (*vs.* unicuspids teeth); from *H. peckoltoides* Zawadzki, Weber & Pavanelli, 2010 by having dark large blotches on body and fins (*vs.* wide dark transverse bars on body and bands on fins); from *H. guajupia* Penido, Pessali & Zawadzki, 2021 by having conspicuous blotches or marks on body and fins (*vs.* lacking conspicuous blotches or marks); from *H. heraldoi* Zawadzki, Weber & Pavanelli, 2008 by having pectoral-fin spine length smaller than pelvic-fin unbranched ray (*vs.* larger than); from *H. nigromaculatus* (Schubart, 1964) by lacking curved club-shaped pectoral-fin spine (*vs.* curved club-shaped pectoral-fin spine); *H. wuchereri* (Günther, 1864) by having abdomen plated in specimens about 100 mm SL (*vs.* abdomen mostly naked in specimens up to 150 mm SL); from *H. yaku*

FIGURE 1 | *Hypostomus hermanni*, NUP 16526, topotype, 134.4 mm SL; Brazil, São Paulo State, Piracicaba, Piracicaba River, Upper Paraná River basin. Dorsal, lateral and ventral views.

Martins, Langeani & Zawadzki, 2014 by lacking hypertrophied odontodes on laterals of trunk (*vs.* mature males with hypertrophied odontods on laterals of trunk) and from *H. garmani* and *H. guajupia* by compressed caudal peduncle, almost triangular shaped, lateral surface of caudal peduncle straight (*vs.* oval-shaped caudal peduncle, lateral surface of caudal peduncle convex).

Description. Morphometric and meristic data are presented in Tabs. 1–2. Head broad and stout. Body width at cleithral region greater than head depth and approximately equal to head length. Snout and anterior profile of head rounded in dorsal view. Snout rising at approximately 40° from horizontal in lateral profile. Dorsal profile convex and sloped upward from snout tip to interorbital region, convex again from that point to dorsal-fin origin; sloped downward from dorsal-fin origin to region just anterior of dorsal procurent caudal-fin rays, then elevating again to caudal-fin insertion. Caudal peduncle deep, strongly compressed laterally and slightly flattened ventrally. Eye comparatively moderate to large, dorsolaterally positioned. Interorbital space straight in frontal view; orbit barely raised. Mesethmoid region with inconspicuous median ridge on dorsal surface of snout to nares. Pair of low rounded ridges on the dorsolateral surface of head, from lateral margins of nares to anterodorsal margin of eyes, and from that longitudinally through superior portion of compound pterotic. Cheek plates usually lacking developed odontodes even in larger specimens. Exposed surface of opercle large, its horizontal length usually slightly smaller than eye diameter. Parieto-supraoccipital generally flat anteriorly; with posterior weak median ridge; with short posterior process; and posteriorly bordered by large single plate. Dorsal and lateral surfaces of head and body covered with dermal plates, except for small naked patch on tip of snout and at dorsal-fin base. Dermal plates with slightly enlarged odontodes on posterior border. Predorsal region flat, lacking ridges. Body lateral surface with five longitudinal series of plates. Dorsal series of plates dorsally flattened from dorsal-fin base origin to caudal-fin origin. Mid-dorsal and median series lacking keels. Median series bearing complete lateral-line pores. Mid-ventral series with first four to five plates bent, without keels to caudal peduncle. Ventral series gently bent.

Mouth short to moderate, dentary width approximately 15–28% of cleithral width. Lips round, short to moderate, lower lip length 16.2–30.3% of lower lip width. Outer edge of upper lip with odontodes. Lower lip not reaching gill openings line. Lower lip inner surface covered with numerous small papillae, larger proximally to dentary. Maxillary barbel moderate in size, shorter than orbital diameter. Median buccal papilla moderately developed. Villiform bicuspid teeth. Teeth moderate to robust, with elongated main cusp and smaller and pointed lateral cusp. Teeth crown ventrally arched in lateral view. Intermandibular tooth row angle about 120°.

Lower surface of head mostly plated except beneath lower lip. Abdomen largely plated except moderate to large areas around pelvic-fin insertions and around urogenital openings. Dorsal fin II,7; moderate in size; its distal border slightly to moderately convex; when adpressed usually reaching azygous plate of adipose fin; spine flexible. Adipose-fin spine inflexible and well developed, slightly curved and posteriorly oriented, with distal tip of spine usually reaching first dorsal procurent caudal-fin ray. Pectoral fin I,6, its distal border straight; pectoral-fin spine inflexible, slightly curved with rounded tip, and usually with distally slightly developed hooked odontodes, especially in larger

FIGURE 2 | *Hypostomus hermanni*, BMNH 1905.6.9.5, holotype, 201.8 mm SL; Brazil, São Paulo State, Piracicaba, Piracicaba River, Upper Paraná River basin. Dorsal, lateral and ventral views.

specimens (about 150 mm SL, NUP 16526); when adpressed reaching from one third to half pelvic-fin spine. Pelvic fin i,5 with branched rays slightly decreasing in size posteriorly; its distal border straight to slightly convex. Pelvic-fin spine flexible, curved inward; when adpressed surpassing anal-fin insertion. Anal fin i,4; when adpressed, distal tip of posterior rays reaching sixth to seventh plate posterior to its origin. Caudal fin i,7,7,i; truncate to slightly emarginate.

Coloration in alcohol. Dorsal ground color of body and fins grayish brown. Body dorsolaterally covered with dark blotches; ventral region of body clearer and lacking blotches. Numerous blotches on head, slightly smaller than eye pupil diameter, equally set. Blotches on trunk and fins moderately spaced to each other, usually slightly larger than eye pupil. In some populations blotches on trunk and fins can be equal to eye diameter or even slightly larger (Fig. 1). In some specimens blotches inconspicuous towards caudal peduncle. Dorsal, pectoral, pelvic, and caudal fins with one series of blotches on each interradial membrane. Adult specimens with a narrow black line bordering distal margins of dorsal and caudal fins. Dorsal fin with longitudinal inconspicuous dark stripe anteriorly margining branched rays. Blotches on caudal fin transversely aligned to form four to five bands. Usually all spines and unbranched-fin rays with blotches or dark marks, except anal-fin unbranched ray. In specimens from the Piracicaba River, blotches on dorsal fin sometimes blurred or mottled. In specimens from other localities blotches usually sharply defined and very conspicuous. blotches on anal fin more faded than on other fins.

FIGURE 3 | *Hypostomus hermanni*, in life. NUP 16526, topotype, 134.4 mm SL; Brazil, São Paulo State, Piracicaba, Piracicaba River, Upper Paraná River basin.

Coloration in life. The same pattern which was described for alcohol preserved specimens, but with greenish background color tan and blotches darker (Fig. 3).

Sexual dimorphism. Not found.

Geographical distribution and type-locality. *Hypostomus hermanni* was described from the type-locality Piracicaba. The species is known from the Piracicaba River (Fig. 4), and the Tietê River basin in the state of São Paulo, Southeastern Brazil. Additionally, the species is herein also recorded in the Paraná River main channel and three of its left tributaries, Paranapanema, Ivaí, and Piquiri basin, in the state of Paraná, Southern Brazil (Fig. 7). As specimens of *H. hermanni* are mainly found in shallow to moderate shallow running waters, if Ihering (1911) referred the type-locality Piracicaba River as the Piracicaba city, the most probable collecting spot of the holotype was the Salto de Piracicaba, a single rocky rapid stretch in the Piracicaba River at Piracicaba city (Fig. 4).

FIGURE 4 | Salto de Piracicaba, Piracicaba River, tributary of Tietê River, Upper Paraná River basin. The most probable type-locality spot of *Hypostomus hermanni*. Brazil, São Paulo State, Piracicaba, 22°43'15"S 47°39'22"W, 474 m.

TABLE 1 Counts and morphometric data of *Hypostomus hermanni* from the Ivaí, Piquiri, Tibagi and Tietê river basins. H, holotype; SD, standard deviation; n = number of specimens.

Diagnosis. *Hypostomus robertsoni* is distinguished from the species of the super-group *H. cochlodon* by having viliform teeth and dentaries usually angled more than 100° (*vs.* spoon- or shovel-shaped teeth and dentary rami angled to each other up to 80°); from the species of the super-group *H. hemiurus* by having round dark blotches (*vs.* somewhat horizontally elongate dark spots); from the species of the super-group *H. plecostomus* by lacking rows of odontodes on keels along lateral series of plates (*vs.* with moderate to well-developed rows of odontodes on keels); from *H. nematopterus* by lacking elongate dorsal-fin ray (*vs.* extremely elongate dorsal-fin ray). From the congeners of the *H. auroguttatus* super-group *Hypostomus robertsoni* is distinguished from *H. alatus*, *H. albopunctatus*, *H. arecuta*, *H. faveolus*, *H. francisci*, *H. Krishnamurtii*, *H. luteus*, *H. luteomaculatus*, *H. margaritifer*, *H. meleagris*, *H. microstomus*, *H. multidens*, *H. regani*, *H. roseopunctatus*, *H. scabriceps* (Eigenmann & Eigenmann, 1888), *H. strigaticeps*, *H. tietensis* and *H. variipictus* by having dark blotches on a clear background (*vs.* pale spots or vermiculations on a darker background); from *H. asperatus*, *H. brevicauda*, *H. johnii*, *H. melanephelis* Zawadzki, Oliveira, de Oliveira & Rapp Py-Daniel, 2015, *H. nigropunctatus*, and *H. uruguayensis* by having faded dark blotches similar to or slightly larger than eye diameter on trunk and fins (*vs.* similar to eye pupil); from *H. denticulatus*, *H. iheringii*, *H. macrops*, *H. latirostris*, and *H. ternetzi* by having parieto-supraoccipital and predorsal region flat (*vs.* parieto-supraoccipital medially raised and with raised parallel keels on predorsal region); from *H. brevis*, *H. fluviatilis*, *H. goyazensis*, and *H. topavae* by having parieto-supraoccipital and predorsal region flat (*vs.* predorsal region high and convex in frontal view); from *H. denticulatus*, *H. freirei*, *H. kuarup* Zawadzki, Kullander & Lima, 2012 *H. latirostris*, *H. mutucae*, *H. paulinus*, and *H. ternetzi* by having tooth number less

than 46 on each premaxillary or dentary (*vs.* more than 50); from *H. agna*, *H. isbrueckeri*, and *H. luetkeni* by having a single predorsal plate bordering parieto-supraoccipital (*vs.* two to three plates in *H. luetkeni* and three in *H. agna* and *H. isbrueckeri*); from *H. guajupia* by having conspicuous blotches or marks on body and fins (*vs.* lacking conspicuous blotches or marks); from *H. heraldoi* by having pectoral-fin spine length smaller than pelvic-fin unbranched ray (*vs.* larger than); from *H. nigromaculatus* by having pectoral-fin spine slightly curved, with diameter almost homogeneous along its length (*vs.* curved club-shaped pectoral-fin spine); *H. wuchereri* by having abdomen plated in specimens about 100 mm SL (*vs.* abdomen mostly naked in specimens up to 150 mm SL); from *H. garmani* and *H. lima* by having triangular-shaped caudal peduncle, its lateral surface straight (*vs.* oval-shaped caudal peduncle, its lateral surface convex); from *H. guajupia* by having abdominal area mostly naked, larger specimens with transverse row of platelets in cleithral region and medially along abdomen (*vs.* abdominal area densely plated, from pectoral girdle to anus); from *H. hermanni* by lacking or with inconspicuous dark (faded brown) blotches on body and fins (*vs.* usually having conspicuous black blotches), and by having truncate caudal fin (*vs.* emarginate).

FIGURE 5 | *Hypostomus robertsoni*, holotype, NUP 22740, 127.9 mm SL; Brazil, Paraná State, Marialva, Keller River, tributary of Ivaí River, Upper Paraná River basin. Dorsal, lateral and ventral views.

Description. Morphometric and meristic data are presented in Tab. 3. Head broad and moderately depressed. Body width in cleithral region greater than head depth and approximately equal to head length. Snout and anterior profile of head rounded in dorsal view. Snout rising at approximately 30° from horizontal in lateral profile. Dorsal profile weakly convex and sloped upward from snout tip to interorbital region, and from that point to dorsal-fin origin; sloped downward from dorsal-fin origin to region just anterior of dorsal procurent caudal-fin rays, then elevating again to caudal-fin insertion. Caudal peduncle elliptically compressed, slightly flattened ventrally. Eye large, dorsolaterally positioned. Interorbital space straight in frontal view; orbit barely raised. Mesethmoid forming inconspicuous median ridge on dorsal surface of snout to nares. Pair of inconspicuous ridge on dorsolateral surface of head, from lateral margins of nares to anterodorsal margin of eyes, and from that longitudinally and softly through superior portion of compound pterotic. Exposed surface of opercle of moderate size. Parieto-supraoccipital flat, with short posterior process and bordered by a large single plate. Dorsal and lateral surfaces of head and body covered with dermal plates, except for a small naked patch on tip of snout and at dorsal-fin base. Dermal plates with very weakly hypertrophied odontodes mostly on posterior border. Predorsal region lacking ridges. Body lateral surface with five longitudinal series of plates. Dorsal series of plates dorsally flattened from dorsal-fin base origin to adipose-fin posterior edge. Mid-dorsal and median series lacking keels. Median series bearing complete lateral-line pores. Mid-ventral series with first four to five plates bent, without keels, to caudal peduncle. Ventral series gently bent, without rows of odontodes.

Mouth short to moderate. Median buccal papilla moderately developed. Lips moderate in size, transversely oval. Outer edge of upper lip covered by odontodes. Lower lip not reaching gill openings line. Lower lip inner surface covered with numerous small papillae, larger proximally to dentary. Maxillary barbel short, similar in length to eye pupil diameter, or even shorter. Villiform bicuspid teeth. Teeth moderate to robust, with lanceolated main cusp and smaller pointed lateral cusp. Teeth crown ventrally arched in lateral view. Intermandibular tooth row angle about 120°.

Lower surface of head with plated area anteriorly to gill opening. Abdomen usually mostly naked in specimens up to 130 mm SL. Larger specimens with transverse row of platelets in cleithral region and medially along abdomen. Dorsal fin II,7; moderate in size; its distal border convex; when adpressed posterior rays usually reaching azygous plate of adipose fin; spine flexible. Adipose-fin spine short, inflexible, moderately curved, and backward oriented, with distal tip usually not reaching first dorsal procurent caudal-fin ray. Pectoral fin I,6, its distal border straight; pectoral-fin spine inflexible, slightly curved with rounded tip, and usually with distally moderately developed hooklets, especially in larger specimens (*i.e.*, about 150 mm SL; NUP 8536); when adpressed reaching about one-third pelvic-fin spine. Pelvic fin i,5 with anterior branched rays slightly larger than posterior ones; its distal border straight to slightly convex; pelvic-fin spine flexible, slightly curved inward; when adpressed surpassing anal-fin insertion. Anal fin i,4; when adpressed, distal tip of posterior rays reaching fifth to sixth plate posterior to its origin. Caudal fin i,7,7,i; truncate to slightly emarginate.

Color in alcohol. Dorsal surface of head and trunk dark, varying between brown to grey (Fig. 5). Fins of the same color as body dorsal surface. Body surface usually

without blotches; some juvenile specimens with inconspicuous dark blotches of similar size on head. Compound pterotic usually without blotches. Dorsal fin without blotches; interradial membrane with inconspicuous dark stripe anteriorly margin each branched ray. Few small specimens with inconspicuous blotches at the base of dorsal-fin posterior rays. Adipose and caudal fins without blotches. Pectoral and pelvic fins usually without blotches; few specimens with inconspicuous dark blotches on the proximal region of both fins. Saddles sometimes present, which may be the so-called “stress color” saddles (Glaser, Glaser, 1995:63). Ventral region of body without blotches; whiter than dorsal region.

Color in life. Color in life similar to that on fixed specimens, but being more brown to grayish brown. Sometimes with faded dark blotches mainly on the dorsal region of head and trunk (Fig. 6). Black pupil bordered by a golden yellow ring.

FIGURE 6 | Specimens of *Hypostomus robertsoni* in life, with inconspicuous dorsal fin dark blotches.

Sexual dimorphism. Not found.

Geographical distribution. *Hypostomus robertsoni* is only known from the Ivaí River basin (Fig. 7). Specimens of the new species were found in some main tributaries as the Keller River (Fig. 8), the type-locality, Bonito River, and Água Fria River.

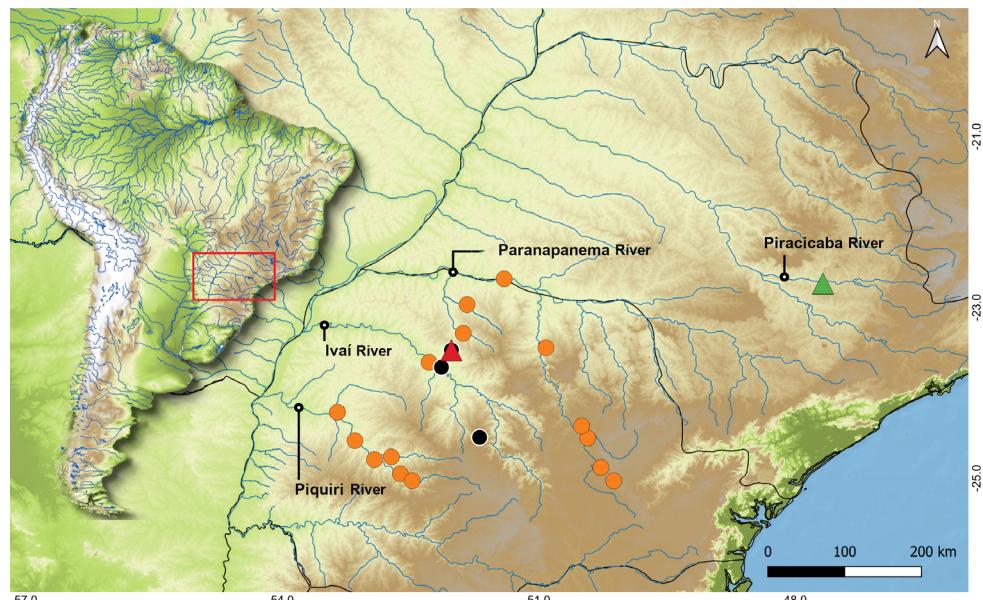

FIGURE 7 | Distribution of *Hypostomus hermanni* (green triangle, type-locality, and orange circles) and *H. robertsoni* (red triangle, type-locality, and black circles) among Upper Paraná River basin. Some marks may represent more than one record.

Ecological notes. The Ivaí River basin can be geographically divided into three portions. The upper portion with steep slopes ranging from about 1200 to 600 m a.s.l. is a high gradient system; from this section, the median portion goes down to about 400 m a.s.l. having strong to moderate declivities; and finally, the lower section of this river is marked by a very low declivity (Parolin *et al.*, 2010). *Hypostomus robertsoni* occurs syntopically with *H. hermanni* in this basin (*e.g.*, NUP 4842). However, while *H. hermanni* is most frequently captured in the Ivaí River main channel, *H. robertsoni* commonly occurs either in the Ivaí River and in smaller tributaries.

Etymology. The specific epithet is in honor of Robertson Fonseca de Azevedo due to his large and constant efforts to preserve natural landscapes in the Paraná State, Brazil. Robertson fought to prevent unnecessary small hydroelectric power plants in the high gradient stretches along two main Upper Paraná River left tributaries, the Ivaí and Piquiri Rivers.

Conservation status. *Hypostomus robertsoni* is not abundant in scientific collections and does not present a wide distribution in the Upper Paraná River basin. Up to now, the species is only found in the Ivaí basin, however it is possible that it occurs in adjacent basins. Furthermore, there are no known imminent threats that would put the species at risk of extinction. Therefore, this species may be categorized as Least Concern (LC), according to the International Union for Conservation of Nature (IUCN) categories and criteria (IUCN Standards and Petitions Subcommittee, 2019).

Comparative material examined. All from Brazil. DISCUSSION

Hypostomus hermanni is easily distinguished from congeners from the Upper Paraná River basin by its usually conspicuous, large and widely spaced dark blotches, its smooth body, without keels, and by its wide and somewhat depressed head. Ihering (1905) described *H. hermanni* based on a single specimen from the Piracicaba River, in the State of São Paulo and pointed out as main characteristics: snout moderately narrow anteriorly, supraorbital edges not raised, temporal plates not carinate, parieto-supraoccipital entirely bordered by a single scute, traces of dark blotches on the upper surface of the head and dorsal fin with the posterior part of each interradial membrane dusky.

The Fig. 9 shows some morphological divergences among populations of *H. hermanni*. The mains divergences are eye diameter, caudal peduncle length and caudal peduncle depth. However, no population from the studied localities was fully distinguishable from those of the *H. hermanni* type-locality basin, the Tietê River basin, as revealed by data from Tab. 1. Differences in color pattern were also found among populations, however, none of those were considered strong enough to support a species distinction. As stated by Ihering (1905) specimens from the Piracicaba/Tietê Rivers have dark blotches mainly conspicuous on the head, while those along the trunk and fins are larger and less conspicuous. In the light of the material collected recently, we found most specimens with the dorsal fin showing inconspicuous dark blotches (Fig. 6). Specimens from the rios Ivaí and Piquiri Rivers have dark blotches more conspicuous, their limits better defined and the blotches are closer to each other than those in the specimens from Piracicaba/Tietê Rivers. Therefore, the morphometric and color differences found among populations of *H. hermanni* do not corroborate the statement of Gosline (1947) that “this species is relatively lacking in variability”. Gosline’s (1947) incorrect assertion was very probably due to the smaller number of specimens of *H. hermanni* he had studied. We even doubt that specimens from the Mogi Guaçu River (Grande River basin) studied by Gosline (1947) were representatives of *H. hermanni*. This proposition is based on the analysis of the material (NUP 11769) from that region. The specific status of that population is to be further considered as more material is available for morphological and molecular taxonomy.

In this context, we can recognize *H. hermanni* as having large black blotches, which can be more or less conspicuous along the distribution of the species. Besides that, although the differences found herein indicate some degree of isolation among the populations, it was not considered strong enough to break them into different species. Finally, *H. hermanni* and *H. robertsoni* were surveyed by cytogenetic procedure techniques, and both species presented $2n = 72$ chromosomes. The specimens of *H. hermanni* from the

FIGURE 9 | *Hypostomus hermanni*, from different sub basins in the Upper Paraná River basin. From top to bottom: NUP 16526, 134.4 mm SL, Tietê River; NUP 14995, 152.2 mm SL, Tibagi River; NUP 5584, 128.1 mm SL, Piquiri River; NUP 5402, 175.1 mm SL, Ivaí River.

Piquiri River (Bueno *et al.*, 2013, 2014) and those from its type-locality the Piracicaba River (Rubert *et al.*, 2016) presented multiple sites of the 5S rRNA through the 5S rDNA-FISH technique, while Kamei *et al.* (2017) found to *H. robertsoni* (*Hypostomus* aff. *hermanni* in that work) a single 5S rRNA fluorescent site.

ACKNOWLEDGMENTS

The authors are grateful to Carlos Oliveira, Douglas Viana, Gabriel Zawadzki, Hector Alcaraz, Henrique Bueno Ruiz, Horálio Julio Jr, Hugmar da Silva, Hugo Message, Leonardo Mommenshon, Luiz Pesenti, Rafael Vieira, and Renata Ota for helping with the field surveys, Alessandro Bifi for helping with pictures, Iago Penido with map

and Bruno Melo for helping with the text. We are also thankful to Walter Lechner for review the English language and commenting the manuscript. Thanks are also due to Claudio Oliveira (LBP), Patrick Campbell and Gordon Howes (BMNH), David Catania and Tomio Iwamoto (CAS), Alexandre Ribeiro (CPUFMT), André Esguícero, Flávio Bockman and Ricardo Castro (LIRP), Gilmar dos Santos, Iago Penido and Tiago Pessali (MCNIP), Carlos Lucena and Margarete Lucena (MCP), Fernando Jerep and José Birindelli (MZUEL), Osvaldo Oyakawa (MZUSP), and Alexandre Ribeiro for the loan of comparative material and for hosting museum visits, and to Nupélia for provided logistical support. This study was partially supported by awards to CHZ from the US National Foundation (DEB-0315963) entitled Planetary Biodiversity Inventory: All Catfish Species (Siluriformes) – Phase I of an Inventory of the Otophysi, by Coordenação de Aperfeiçoamento de Pessoal de Nível Superior for the financial support to master's degree fellowship to ACD, and grants to CHZ from the Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq), Proc. 313623/2018-0.
