Under the term “paraphrenia” Freud proposed uniting the different clinical categories of dementia praecox, and then of schizophrenia. While maintaining the Kraepelinian distinction between paranoia and schizophrenia which includes paranoid dementia, he nevertheless stressed certain kinds of relation between the two conditions and the possibility of combinations of symptoms of the two types. He used, in some of his writings, the term “paraphrenia” to designate the paranoia-schizophrenia grouping. He emphasized more the underlying fixations and mechanisms than the criteria for systematization of the form of delusions. It was therefore the defense against homosexuality in the “Schreber case” (1911c [1910]) that led Freud to situate this clinical picture on the side of paranoia, in spite of a number of paranoid dementia aspects. He didn’t exclude forms of passage from one condition to another, situating fixation in schizophrenia at a theoretical level anterior to the closer development of autoerotism. For him, hallucinatory mechanisms prevalent in schizophrenia linked it rather to hysteria, while projection in paranoia evoked certain traits of obsessive neurosis.

Finally, the paranoid-schizoid position of Melanie Klein refers to fears of persecution, linked to primal sadistic-oral ambivalence, able to manifest itself subsequently in schizophrenia and paranoia.

## PARANOID-SCHIZOID POSITION

In the paranoid-schizoid position, first described by Melanie Klein in 1946, the earliest experiences of the infant are split between wholly good experiences with “good” objects and wholly bad experiences with “bad” objects. The ego protects itself from the bad ones by a mechanism that splits the ego itself.

Freud, at the end of his life, was interested in the splitting of the ego (Freud, 1940e [1938]). He had come, as it were, full circle from his earliest interest in dissociation in hysteria, via the manic-depressive psychosis, back to fragmenting processes that resemble schizophrenia. This was addressed too by Ronald Fairbairn (1941).

Working with severely disturbed patients, Klein identified the disintegrating forces within the early ego, and its struggle to develop a consistency within itself. This early dynamic of falling into pieces and pulling itself together again represented, for Klein, the conflict between the life and death instincts. So, the key anxiety-situation of this position is the fear of being destroyed from within. Klein and her followers (Rosenfeld, Herbert, 1950; Segal, Hanna, 1952) described this as the core anxiety of the schizophrenic, that which the schizophrenic feels to be overwhelming, that from which the schizophrenic is unable to recover. In contrast, the normal infant survives without the belief that it has been irretrievably fragmented. Usually the infant has various resources with which to keep this anxiety sufficiently mastered. In the first place the infant uses a number of primitive defense mechanisms—splitting, projection, introjection, identification, denial (annihilation), and idealization.

Central and above all is splitting. Already fearing itself under attack from within, the ego re-orders its senses of self and object. It reconstructs its reality into a coherent picture of good elements and bad ones, which are split apart. These collections of fragments can then be processed by the other primitive mechanisms. In particular, as Freud described, the bad parts of the self and the object are expelled and believed to be a property of the external world, leaving the ego to contain only the good elements.

These fantasies and mechanisms constitute narcissism from a Kleinian point of view, and involve projective identification and splitting as fundamental mechanisms of defense.

This set of fantasies is based upon the view that the infant, from the beginning, has a sense of the boundary between its internal world (self) and the external world. Contrary to Freud’s view, the death instinct is clinically visible in these states. The disintegration of the ego (under pressure to split off parts of itself) poses for the infant a struggle to master these disintegrating forces within. It may do so by directing the attacks of the death instinct toward the goal of forming coherent splits in the ego.

The death instinct, at first directed internally against the self, can, due to the projective processes, be partly redirected outwards against the now “bad” external objects. But in the process, the death instinct is also split, and the self-directed attacks are then seen as coming from outside, from the attacked object. This leads to illusions of a very persecutory nature. Such a projection of the self-attack into an external object creates an attacking external object. If introjected again that external object takes on the eventual form of a persecuting internal object, resembling a harsh super-ego.

Another capacity the infant has for combating the anxiety of fragmenting is its internalization of a good object. If the external object has some consistency in the external world, then when introjected it can form the basis from which an internal consistency can grow. This is Klein’s view of the origins of a coherent and relatively consistent sense of self. The achievement of a stable good internal object is the beginning of the depressive position, and represents a developmental move from the paranoid-schizoid to depressive position.

On the other hand, the failure adequately to develop this secure internal object gives a prolonged deficit in the development of the depressive position. This may later take the form of schizophrenia (Rosenfeld, 1965); or lead to a borderline state in which the anxiety situations of both positions are effectively avoided through a retreat into a pathological organization out of touch with any emotional life (Steiner, Riccardo, 1993). Some infants seem particularly prone to fail in introjecting a good external object and thus establishing a secure internal one. This may be due to various factors: a projection of the death instinct into the objects, good and bad, in the external world; or an intense envy of external good objects; or the actual absence of a consistent enough external good object; or indeed to a combination of all three.

The intricacy of the fantasy activity involved in these primitive processes is regarded by some as improbable. It is also questioned whether fantasy activity alone can be formative of the mind and of character. This position implies, to many analysts, that Klein viewed development advancing on the basis of internal states only and solipsistically remote from the external world.

## PARAPHRENIA

German psychiatrists in the 19th century employed the term *paraphrenia*, derived from the Greek *para*

(beyond) and *phrēn* (mind), as a nonspecific term for madness. In 1863 Karl Ludwig Kahlbaum used *paraphrenia hebetica* to designate a degenerative malady of puberty, later known as hebephrenia.

Emil Kraepelin, in the eighth edition of *Dementia Praecox and Paraphrenia* (1919), which was published in four volumes beginning in 1908, proposed paraphrenia to designate chronic delirious psychoses unaccompanied by intellectual decline; he suggested four different clinical types: *systematica*, *expansiva*, *confabulans*, and *phantasica*.

Freud believed paraphrenia to be a more properly descriptive term than schizophrenia, the term Eugen Bleuler suggested to replace Kraepelin's dementia praecox. He used it for the first time in his "Psycho-Analytic Notes on an Autobiographical Account of a Case of Paranoia (Dementia Paranoides)" (1911c). Although Bleuler's term became prevalent, Freud employed paraphrenia again in "The Disposition to Obsessional Neurosis: a Contribution to the Problem of Choice of Neurosis" (1913i) and in "On Narcissism, an Introduction" (1914c). Subsequently it came up again twice, first in the *Introductory Lectures on Psycho-Analysis* (1916–17a) and in the second published version of "The Disposition to Obsessional Neurosis." Strangely enough, the term did not surface at all in the long discussion of the mechanisms of schizophrenia in the metapsychological article on "The Unconscious" (1915e), nor in "A Case of Paranoia Running Counter to the Psycho-Analytic Theory of the Disease" (1915f). It was also missing from the two articles on "Neurosis and Psychosis" (1924b) and "The Loss of Reality in Neurosis and Psychosis" (1924e).

It is difficult to understand why Bleuler's term became preferred usage, although certainly this was due in part to the notion of "split" (*schizo*). However, although paraphrenia did not gain currency, on a nosological level Freud's reasoning, as developed particularly in the Schreber case, was quite remarkable and in line with his earlier attempts at diagnostic precision concerning neurosis. Freud maintained in effect that paranoia must be viewed as a clinical type distinct from schizophrenia, even if the overall clinical picture is complicated by schizophrenic-like characteristics. The two conditions can be distinguished by the central obsession and by a different mechanism of symptom formation.

## PARAPRAXIS

A parapraxis is an act that appears to be unintentional but can be understood, through psychoanalytic exploration, to be perfectly motivated and unconsciously determined. A brief and delimited disturbance that may be spontaneously explained as the result of chance or inattention, a parapraxis may be readily perceived by its initiator or by a third party to be a “mistake.”

Parapraxes include a wide range of events, including failures of memory, slips of the tongue or pen, mistakes, and bungled or accidental acts. A parapraxis cannot be explained by referring to the nature of the “slip” itself, but psychoanalytic hypotheses make it possible for it to

be described simultaneously as a mistake and not a mistake, depending on one’s point of view.

Parapraxes interested Freud as early as 1890. In letters to Wilhelm Fliess, he created a virtual collection of examples communicated to him by correspondents. Parapraxes represented, in fact, an important demonstration of disturbances created by the unconscious. As opposed to dreams, parapraxes tend to require fewer biographical details while providing valuable evidence—indeed, often with comical effect—that offers a popular audience an easy way to grasp psychoanalysis. Furthermore, parapraxes constitute one of the pillars of the psychopathology of everyday life, which Freud considered necessary to understand mental pathology in a broader context.

Freud discusses parapraxes in two of his major works: *Psychopathology of Everyday Life* (1901b) and *Introductory Lectures on Psycho-Analysis* (1916–17a [1915–17]).

Beyond the anecdotal nature of many of the examples in these two works, parapraxes clearly raise an issue fundamental for psychoanalytic thought—namely, the link between psychic determinism and the unconscious. Freud was led to clarify his position toward the notion of “chance” (as discussed in the review *Topique*, 1997) as differentiated from superstition: “I do not believe that an event in whose occurrence my mental life plays no part can teach me any hidden thing about the future shape of reality; but I believe that an unintentional manifestation of my own mental activity *does* on the other hand disclose something hidden, though again it is something that belongs only to my mental life [not to external reality]. I believe in external (real) chance, it is true, but not in internal (psychical) accidental events.” (Freud, 1901b, p328)

The link between parapraxes and psychopathology, moreover, is established, according to Freud, uniquely through the fact that, in the case of chance events in a real world, “slips” involve the most insignificant psychic events. By contrast, neurotic symptoms are related to the most important psychic functions from both individual and social perspectives. In both instances, however, the same processes enable such symptoms to be understood, that is, as compromise formations located between desire and defense, between a subject’s conscious intention and repression.

## **PARCHEMINEY, GEORGES (1888–1953)**

Georges Parcheminey, the French psychoanalyst, was born on April 21, 1888, at Ronchamp in the Haute-Saône department, and died in Paris on July 29, 1953.

Born of a music-teacher mother and a mining-engineer father, he was educated in a religious institution where he studied the classics, before going to Paris to study medicine. In 1917 he married a woman who shared his passion for music. Wounded during the First World War, he first practiced as a general practitioner and then as a neurologist.

During the 1920s he was analyzed by Rudolf Loewenstein and, having contributed in 1925 to the creation of *Évolution psychiatrique*, in 1926 he was one of the co-founders of the Paris Psychoanalytic Society (SPP). René Laforgue was president of the Society for its first four years, followed by Parcheminey for the period 1930–31.

Having worked as a Physician-Captain during the 1939 war, he was demobilized when Prof. Laignel-Lavastine appointed him laboratory director in the medical faculty where, in spite of the Occupation, he lectured on psychoanalysis in the Mental Health Clinic. Prof. Jean Delay, who then took over this department of the Sainte-Anne hospital, retained his position for him until after the Liberation.

He was training analyst for Maurice Bénassy and Maurice Bouvet from 1942 and was president of the short-lived National Syndicate of Psychoanalyst Physicians, created in April 1951. He played a leading role in the discussions preceding the creation of the Institute of Psychoanalysis and, as senior member, he resumed presidency of the SPP on the dramatic evening when the split occurred on June 16, 1953, three months before his death.

His knowledge of German enabled him to read Freud in the original and his writings focused mainly on neurosis—the subject of his lessons at the Institute of Psychoanalysis—and conversion hysteria. He studied the links between the psychic and the somatic and compared Pavlov’s work with that of Freud.

His first article, which appeared in the *Revue Française de Psychanalyse* (French review of psychoanalysis) in 1928, was co-authored with Édouard Pichon and was entitled “Sur les Traitements Psychothérapeutiques Courts d’Inspiration Freudienne chez les Enfants” (On short Freud-inspired psychotherapeutic treatment for children). Each of the two authors related a case in which the patient was “cured” in one session. In 1932, in his report to the sixth Congress of French-Speaking Psychoanalysts, he presented a critical study of the different conceptions of “conversion hysteria.” He compared the theories of Janet, Babinski, Dupré, Claude and Lhermitte, Kretschmer, and Pavlov, with those of Freud and Breuer, which he explained in detail.

In “La Problématique du Psycho-Somatique” (The problem of the psychosomatic), an article dating from 1948, he asserted that this term, created by Mrs. Dunbar and her school in the United States, was in fact a logical extension of Freudian notions concerning the theory of the neuroses and particularly the study of hysteria. Psychosomatic medicine did not exist for him, “it is only an artificially isolated section of an anthropological conception of medicine, a more synthetic vision of all human existence.”

At the time of his death in 1953, Michel Cénac wrote: “He was called on to act as president at difficult times, when it was essential to recover control of techniques that some had practiced with a greater or lesser degree of success. Under these circumstances he knew how to act in a balanced and wise manner and the unit came together thanks to his diplomacy and tact. . . . His love of harmony led him to sacrifice himself for its sake, although his own sensibilities may have suffered in the process. Moreover, his piano-playing showed the same taste and the same sensibility.”

At the end of his life he recovered his religious belief and practice in the company of Father Bruno de Jésus, a friend of Laforgue.

## **PARENTHOOD**

The term “parenthood” has acquired a semitechnical sense in anthropology and psychoanalysis, and it has the same connotations in both disciplines. Ethnologists began using the term in the 1970s (Goodenough, 1970; Carroll, 1970; Goody, 1971). It specifies one of three kinds of social relations that make up kinship: the relationship between parents and children (the other two kinds of kinship systems govern blood relations and relations by marriage).

The term “parenthood” also raises the issue of the child as “property.” To be recognized as a child’s parent, is it sufficient for a man to engender, or a woman to give birth to, the child? The English ethnologist Esther Goody, in her book *Parenthood and Social Reproduction: Fostering and Occupational Roles in West Africa* (1982), theorized about parenthood for the first time. She distinguished five groups of functions that individuals can or must take on in order to be considered as parents of children: (1) conceiving or engendering; (2) raising, feeding, protecting; (3) instructing, educating; (4) considering oneself responsible for what the child does; (5) endowing the child at birth with a status, a name, and a group of rights and duties. In different societies, these various functions may exist in combination or separately; adult responsibilities vis-à-vis the child are thus susceptible of broad variety of dissociation and division (the case of adoption is a classic example).

For psychoanalysis, parenthood consists of a process of psychic maturation that begins at conception for both mother and father. Therese Benedek (1973) and

G. Bibring-Lehner (1959, 1961), two American psychoanalysts, introduced the term “motherhood,” which they defined as all the affective processes that develop and are integrated in a woman when she becomes a mother. In France this notion was introduced by the psychiatrist Paul-Claude Racamier (1961).

In psychodynamic terms, insofar as motherhood is a mental process that cannot be reduced to physiology, the father too may be supposed to go through an identity crisis analogous to that of the mother. This is directly in line with the thinking of Therese Benedek, who showed that men and women share the same two sources of parenthood: their biological bisexuality and their common dependency on a mother or mother figure. Indeed, in men and women the urge to reproduce has a common origin (the pregenital stage); only its organization is different in each sex. Taking up a theme from “Totem and Taboo” (Freud, 1912–1913a), Theodor Reik, in his interpretation of the custom of *couvade* in “Die *Couvade* und die Psychogenese der Vergeltungsfurcht” (The *couvade* and psychogenesis of the fear of reprisals; 1914), emphasized that the attainment of fatherhood—the fulfillment of an oedipal wish—entails a thoroughgoing reorganization of the libido in men as well as in women. (*Couvade* is a custom where the father takes to bed during the birth of a child and submits to certain taboos.)

Some psychoanalysts have adopted the notion of fatherhood in connection with the psychoaffective changes that occur in fathers-to-be. Clinical experience has revealed that future fathers experience a normal crisis equivalent to that of motherhood (Carel, 1974; Delaisi de Parseval, 1981). Such crises, whose unpredictable outcome may have maturational value and may lead to a new equilibrium, should be understood by analogy with the classical psychoanalytical account of clashing instincts that eventually become integrated.

It is notable that in Western societies the lived experience of fatherhood is concealed, even denied, both in fantasy and on the psychosomatic level. These societies in effect promote an implicit ideology of parenthood in which essentially feminine moments such as pregnancy, giving birth, breast feeding, and the earliest relations between mother and infant are privileged as essential. The man, the father, remains a relatively unobtrusive presence in representations of parenthood.

## **PARRICIDE**

“Murder of the father” is a reference to the murder of the legendary king of Thebes by Oedipus, the Greek hero in Sophocles’ play *Oedipus Tyrannus* (King Oedipus). According to Freud, we were all, as young children, gripped by the “compulsion” embodied in the Greek legend: we were all, “once, in germ and in fantasy, just such an Oedipus” (1950a [1892–1899], p. 265). Analysts speak of “parricide” when the fantasy is acted out, when the murder of the father is no longer merely an imagined infraction of one of the two oedipal injunctions. The term refers both to a willful act of murder of the father (or, more generally, of a male progenitor) and to the murderer.

Freud introduced the hypothesis of parricide in the fourth chapter of *Totem and Taboo* (1912–1913a). The word “Vatermord” (murder of the father) conveys an element of intent in the crime committed by the son. In the case of a premeditated murder by the primitive horde, the homicide in question might be considered a form of assassination. According to the Freudian myth, “one day, the brothers who had been driven out came together, killed and devoured their father and so made an end of the patriarchal horde” (1912–1913a, p. 141). In a single sentence Freud thus summed up the “memorable and criminal deed” (p. 142) that served as the foundation and chief precondition of psychoanalytic thought and “the main source of the sense of guilt” (1928b [1927], p. 183).

When Freud first used the term “Oedipus complex,” he spoke of the moment when the boy “begins to desire his mother . . . and to hate his father anew as a rival who stands in the way of this wish” (1910h, p. 171). The hostile impulses that the child develops toward his father are the mental correlate of fundamental biological facts, namely the “prolonged period of [humanity’s] dependence in childhood” (1940a [1938], p. 185), which inevitably leads to a conflict-ridden relationship with the parents. In *Totem and Taboo* (1912–1913a), Freud noted the adventitious content of the two oedipal crimes—the two prohibitions forming the core of totemism—and the child’s two primal wishes. The institution of a prohibition hid the fact that those who punished transgression harbor the same desire as the transgressor. This, for Freud, was “one of the foundations of the human penal system” (p. 72).

In 1927, in his introduction to a German book on Dostoevsky, specifically on *The Brothers Karamazov*, Freud observed that this novel was one of “three masterpieces of the literature of all time” to deal with the manslaughter of the father (*Vatertötung*). His choice of the term “Vatertötung,” which implies no criminal intent on the part of the son, enabled Freud to assert that in the Greek drama, “the hero commits the deed unintentionally” (1928b [1927], p. 188). In contrast, in the Russian novel, as in Shakespeare’s *Hamlet*, someone else commits the murder. Two years later, in *Civilization and Its Discontents* (1930a [1929]), Freud again insisted that it is impossible to get “away from the assumption that man’s sense of guilt springs from the Oedipus complex and was acquired at the killing of the father by the brothers banded together” (p. 131). However, to

account for the action of the death instinct, discovered in the interim, Freud now stressed the inevitability of the feeling of guilt as an “expression of the conflict due to ambivalence, of the eternal struggle between Eros and the instinct of destruction or death” (p. 132). It follows that whether or not the father is actually killed is of no great consequence.

In “Some Character-Types Met with in Psycho-Analytic Work” (1916d), Freud had argued that many criminals suffer from a sense of guilt. Such guilt may predate the crime, which is in fact perpetrated as a way of seeking punishment. This claim was clinically demonstrated and developed by other authors during the last decades of the twentieth century. Referring to the important notion of guilt, Jean Laplanche defined the oedipal crime as “the first crime committed out of a feeling of guilt” (1992). Sophie de Mijolla-Mellor, who thinks that the fantasy of murder enables the child to accept the idea of death, defends the hypothesis that murder is part of a “sexual theory of childhood” (1996). Paul-Laurent Assoun has pointed out the resonance between the primal criminal act of patricide and a particular criminal metaphor of the unconscious: the work of repression, he writes, is simply an “effort to erase the traces of a primal crime” (1997). The risks stemming from the unconscious and associated with crime—notably with the murder of the father—raise the issue of the relations between law and psychoanalysis.

For Freud, myth indicates the path every child will have to travel as an individual. Certainly, the legend of Oedipus provided him with an opportunity to “‘fictionalize’ a mental truth” (Assoun, 1997). The myth of the murder of the father of the horde arguably constitutes a kind of distillation of the Yahweh myth, which Freud called the “Christian myth” (1912–1913a) and Lacan called the “myth of the apple.” The hypothesis that the murder of the father is criminal is in fact well suited to accounting for the primal fault (Freud incorrectly referred to it as “original sin”), which can be understood as a tragic split between humanity and God the Father resulting from the human wish to usurp God’s place. The discovery of correspondences between the mental life of savages and that of the early Jews makes it possible to identify the hidden origins of the oedipal myth in the stories of Genesis. But above all, this Freudian myth serves to confirm the relevance and universal nature of the finding that Freud summed up in the axiom that where there is prohibition, there

is a wish. Original guilt implicates the subject not in the primal fault but in desire itself.

## **PARTIAL DRIVE**

When Freud spoke of “a drive,” he was always referring to a partial drive. The first definition of this term is

found in the first of the *Three Essays on the Theory of Sexuality* at the opening of section five, “Component [Drives] and Erotogenic Zones”: “By [a drive] is provisionally to be understood the psychical representative of an endosomatic, continuously flowing source of stimulation, as contrasted with a ‘stimulus,’ which is set up by *single* excitations coming from without. The concept of [drive] is thus one of those lying on the frontier between the mental and the psychical. The simplest and likeliest assumption as to the nature of [drives] would seem be that in itself [a drive] is without quality, and, so far as mental life is concerned, is only to be regarded as a measure of the demand made upon the mind for work. What distinguishes the [drives] from one another and endows them with specific qualities is their relation to their somatic sources and to their aims. The source of [a drive] is a process of excitation occurring in an organ and the immediate aim of the [drive] lies in the removal of this organic stimulus” (1905d, p. 168).

Freud quickly conceived of the role of the sexual drive and the libido in the etiology of the neuroses, but the discovery of infantile sexuality took much longer. According to the “seduction theory,” the effects of sexuality in the infant were extrinsic and contingent. Freud abandoned this theory when he discovered fantasy and the Oedipus complex during his self-analysis. In its place, there appeared a general infantile sexuality that gives rise to fantasies, neurotic symptoms, perverse acts, and delusions. According to his letters to Fliess, this work was accomplished between September 21 and November 14, 1897. The anal and oral regions and “perhaps the whole surface of the body as well” are sexual zones that in infancy “instigate something that is analogous to the later release of sexuality” (1950a [1892–99], p. 269). These zones persist in perversion, but usually fall under “normal repression.”

Fueled by both clinical observation and Freud’s own self-analysis, the elaboration of infantile sexuality is found throughout *The Interpretation of Dreams* (1900a). The analysis of Dora’s cough (1905e [1901]), reveals a fantasy of sucking the penis. The morphogenesis of the fantasy is simple: the mouth is the “primary erogenous zone”; created by the act of nursing, it survives in the act of kissing. “So we see that this excessively repulsive and perverted phantasy of sucking at a penis has the most innocent origin. It is a new version of what may be described as a prehistoric impression of sucking at the mother’s or nurse’s breast—an

impression which has usually been revived by contact with children who are being nursed. In most cases, a cow’s udder has aptly played the part of an image intermediate between a nipple and a penis” (1905e [1901], p. 52). Stating that “Psychoneuroses are, so to speak, the *negative* of perversions” (p. 50), Freud sketched out the thesis that he would establish in the *Three Essays on the Theory of Sexuality* (1905d). “You will have no doubt heard . . . that in psychoanalysis the concept of what is sexual has been unduly extended in order to support the theses of the sexual causation of the neuroses and the sexual meaning of symptoms. . . . We have only extended the concept of sexuality far enough to be able to comprise the sexual life of pervers and children. We have, that is to say, given it back its true compass” (1916–17a, p. 319).

The synthesis of these concepts began in 1905. So-called normal adult sexuality, neuroses, and perversions all show the sexual drive to be aberrant if reproduction is its aim. But these aberrations are effaced if the innate germs of sexuality go through a complex morphogenesis in infancy and then succumb to repression, which creates amnesias and an ignorance comparable to those found in neurosis. These germs of sexuality develop along with the physiological needs and functions, the points on the body that interface with the external world each creating their own organ pleasure. Thus the partial drives find their source, their aim, and their object, “the thing in regard to which the [drive] is able to achieve its aim. It is what is most variable about [a drive]” (1915c, p. 122). If a drive finds its object in the subject’s own body, it is described as autoerotic. Sadoomasochism and mastery involve oral, anal, urethral, and muscular erotism. Voyeurism and exhibitionism involve the eyes. As for the skin, the “erotogenic zone par excellence” (1905d, p. 169), it involves the genitals, among other regions. Meanwhile, the infant is “polymorphously perverse.”

From this point on, Freud worked continuously on the theory of the partial drives and their vicissitudes. He elucidated the transformations that the primitive impulses of the drive undergo on account of their entanglement in language in terms of the development of the ego, education, and culture. He described psychoanalysis as “biological psychology: “[W]e are studying the psychical accompaniments of biological processes” (1933a [1932], pp. 95–96).

Diligently following up his clinical work, Freud devoted himself in 1931 to analyzing the myth of

Prometheus: a story of the urethral drive, or rather of how humankind's control over fire, acquired by repressing the wish to urinate on it, led to legends (1932a).

In the unconscious, the impulses of the drive—the primary energy and material of mental processes—appear as both ideational representative and quota of affect. These impulses have both active and passive aims that make them susceptible to ambivalence. Several impulses can share the same vicissitude, and the satisfaction of one can replace that of another. These transpositions of drives give rise to unconscious concepts such as feces-infant-penis. And the ego's defenses alter the ways in which impulses are expressed. Reversal into the opposite, turning around upon oneself, repression, regression, reaction-formation, isolation, undoing, projection, inhibition as to aim, and sublimation all testify to the malleability of drives. Moreover, infantile development goes through the stages of pregenital libidinal organization, which involve the choice of an object and the primacy of the partial drives: oral, anal-sadistic, and then phallic. These stages converge in the formation of character and can provoke regressions. Also, it is worth noting that all fantasy scenarios include the satisfaction of a drive.

The notion of the partial drive has given rise to more elaborations than criticism. For example, Karl Abraham, Sándor Ferenczi, and Lou Andreas-Salomé all added to the theory, as did the development of child analysis.

## **PASCHE, FRANCIS LÉOPOLD PHILIPPE (1910–1996)**

Francis Pasche, physician, psychiatrist, psychoanalyst, and full member of the Paris Psychoanalytic Society, was born in Paris on May 7, 1910, and died there on September 12, 1996.

His mother came from the Champagne region and his father from Switzerland. He was educated to be an atheist but was inculcated with moral principles that were imbued with Jansenist rigidity and Calvinist rigor.

In 1928–29 he began to study pharmaceuticals and graduated in 1934. In 1935 he completed his military service as an auxiliary pharmacist near Dole in the east of France. He had a simultaneous and passionate involvement with philosophy and esthetics. He thus began to work toward a primary degree in philosophy at the Sorbonne. His mentors were Victor Basch and Charles Blondel. He studied the great historians of philosophy from the 1930s: Henri Gouhier, Victor Brochard and Étienne Gilson.

His interest in psychoanalysis dates from the time when he began to study philosophy. Pasche had completed his first two years of medical studies when World War II broke out in 1939. He was mobilized as an auxiliary pharmacist at Vesoul on September 15, 1939. On November 20 he was posted to the Rouffach emergency unit. Imprisoned at Gérardmer on June 22, 1940, he was sent to Stalag II B.

As a member of the health services, he was allowed to return to France on January 28, 1941 and was posted to different Parisian hospitals. He was still a military prisoner, but under particularly favorable conditions that enabled him to complete his medical studies. He graduated in 1944. The Medical Faculty of the University of Paris awarded him a bronze medal for his thesis, conducted under Jean Delay and titled “Psychopathologie du cauchemar” (The psychopathology of the nightmare). In 1948 he was appointed director of the clinical laboratory for mental diseases. The French Medical Association officially recognized him as a psychiatrist in

1951 and as a neuro-psychiatrist in 1953. In 1961 he was appointed assistant consultant at the Sainte-Anne psychiatric center. He continued to work there for more than thirty years training young psychiatrists and as a consultant. His reputation crossed the Atlantic and many Canadians and Latin Americans came there to study under him.

Having been analyzed by John Leuba, he quickly became a member of the Paris Psychoanalytic Society. He was made a full member in 1950 and was president of the society from 1960 to 1964. He therefore witnessed the rift that took place in 1953, a rift that toward the end of his life he believed could have been avoided. In 1959 he married Maria Cléopas, a Greek woman, with whom he had two sons, Alexandre and Jérôme. Francis Pasche was a man of books and culture and for many years he directed a seminar at the Institute of Psychoanalysis: he discoursed with equal ease on philosophy, anthropology, metapsychology, and clinical practice.

To appreciate the full value of some of his writings, they should be read in counterpoint with those of Lacan, a man he both admired and criticized and with whom he had a fascinating but difficult relationship. His work comprises a large number of articles and papers for colloquia and national and international congresses. Some of it has been brought together in two volumes: *À partir de Freud* (Beginning with Freud; 1969), and *Le Sens de la psychanalyse* (The meaning of psychoanalysis; 1983). He made important and original contributions to the clinical treatment of the psychoses, and the theory and clinical treatment of depression. Equally remarkable are his writings on anxiety, the notion of the superego, the issues at stake in analysis, psychoanalytic ethics, and the role of the analyst. His deeply philosophical nature also led him to take an interest in Greek mythology and in the religions of the book.

## **PASS, THE**

Lacan invented the pass to clarify and formalize the transition between analysand and analyst: “This dark cloud that covers this juncture I am concerned with here, the one at which the psychoanalysand passes to becoming a psychoanalyst—that is what our School can work at dissipating” (Lacan, 1995).

Lacan's foundation of the École freudienne de Paris (Freudian School of Paris) on June 21, 1964, was marked by the originality of its membership categories. No longer were there permanent members or didacticians, since an analysis could be recognized as didactic only after the fact by the analysand in question becoming an analyst. There were three categories of membership: analyst of the school (a title initially given to all the former permanent members of the Société psychanalytique de Paris [Paris Psychoanalytic Society] and the Société française de psychanalyse [French Society of Psychoanalysis]), member analysts of the school (who were nominated by a reception committee that guaranteed the “competence” and “regularity” of the candidate's analytic practice), and practicing analysts (who declared their own practice to be analytic, although it was not guaranteed by the school).

Internal conflicts soon developed within the school over training and clinical ability. In an attempt to overcome this crisis, François Perrier proposed, on March 31, 1967, in an address to the analysts of the school, the formation of a college of analysts of the school, which would be devoted to “the clinic as a career and a vocation” (1994). This initiative did not receive any support from Lacan, who wrote up an alternative plan under the title “Proposition of 9 October 1967 on the psychoanalyst of the school” (1995). The procedure that Lacan proposed involved having a candidate give an account of an analysis in which the candidate was the analysand before three “passers,” who had been

nominated by their own analysts. The passers would then report about their sense of the analysis to an acceptance committee, which could then allow the candidate to pass from analysand to analyst.

This initiative gave rise to a lively debate within the school. As early as 1968, Piera Aulagnier, Maud Manoni, François Perrier, and Jean-Paul Valabrega made their objections known (later published in *Analytica*, 7 [1978]). And when Lacan put the proposal to a vote for inclusion in the school's statutes during the Lutetia (Paris) session, Piera Aulagnier, François Perrier, and Jean-Paul Valabrega resigned from the school.

Nevertheless, the pass was put into practice. It seemed that Lacan expected the pass to be not an "experiment in unconscious knowledge," but a "revelation." Thus the pass had nothing to do with analysis. In 1974, in a letter to three of his Italian adherents (Giacomo Contri, Muriel Drazien, and Armando Verdiglione), Lacan recommended that they create an Italian group, "including the principle of the pass for those who apply for it" (1982). In Italy the pass was thus proposed at the outset before the school was functioning.

On January 7 to 8, 1978, during the Deauville session on the pass experiment, Lacan heard much discussion on the value of the pass. He mostly heard objections to the procedure, notably from Ginette Raimbault and Serge Leclaire. So he closed the session with these words: "I had wanted to hear testimonials about how it's working. And obviously I didn't hear any. The pass really is a complete failure" (*Lettres de l'école*, April 1978).

Lacan's declaration that the pass was a failure seemed to indicate that it is impossible to pinpoint within the analytic situation the passage from analysand to analyst. Thus analysts must resort to the other way of recognizing a psychoanalyst, namely an ability to maintain the analytic position as verified by a supervised analysis. This leads to the hypothesis that one is an analyst only in the analytic situation.

## **PASSION**

Passion is the abandonment of the ego to an object (a person or abstract idea) that has taken the place of the ego ideal. The relationship is one of alienation, wherein the object of desire has become an object of need.

Although Freud made frequent references to passion—individual or collective—throughout his work, he did not distinguish it from the state of being in love, which for him found its extreme manifestation in passion. Subsequently, other authors examined the specific characteristics of this state, which resembles addiction in some respects.

In passion the psychoanalyst encounters both philosophical and psychiatric elements. Plato, in the Phaedrus, described the phenomenon as a burning condition, where the soul separates from the body. Marsilio Ficino saw the "divine fury" as an illumination of the soul, and Giordano Bruno saw in the "heroic fury" the alienation in which self-consciousness vanished. Hegel claimed that "nothing great is accomplished without passion." Similarly, Freud referred to the passionate abandonment to an abstract idea or ideal, even to research, as he found in Leonardo da Vinci (1910c)—and in himself.

The states of passion studied by psychiatry resemble paranoia more than love (Clérambault). Freud distinguished three types of passion: the passion that arises from being in love, the passion that corresponds to the cathexis of a sublimated activity, and the passion that has more in common with hate than with love (erotomania).

Concerning the passion associated with being in love (1921c), it is the degree of idealization of the object and the corresponding weakening of the ego that leads to the submissiveness of the subject. Freud used a model of the hypnotic relationship to describe the crowd's subjugation to its leader: "A primal horde

is the sum of individuals who have put a single object in place of their ego ideal and consequently, in their ego, have identified with one another." Freud's study of the *Gradiva* is situated at the border between love cathexis and passionate investment in an abstraction (1907a). The "delusion" consisted precisely in substituting the latter (the archeological revivification) for the living young girl whom the hero no longer recognizes. From the repressed memory to fantasy and delusion, there is a sense of continuity, similar to what Freud had found between love and passion.

The passionate cathexis of a sublimated activity is caused by a transposition, a redirection of drive. Leonardo, "having transposed his passion into the thirst for knowledge, now abandoned himself to the investigation with the tenacity, continuity, and penetration that are associated with passion" (1910c). The origin of the disposition to passion may relate to the intensity of the erotic relationship between mother and child ("My mother crushed my mouth with countless kisses," wrote Leonardo). In "Observations on Transference Love" (1915a [1914]), Freud associated the tumultuous passion of the patient for the analyst with resistance. Aside from the technical issue, he goes on to point out that this apparent abandonment to love is in fact a demand without any basis in reality. Those patients "would like, with their passion disconnected from any social bond, to keep the doctor at their mercy." This relation of subjugation, compared by Freud to the dangerous manipulation of explosive substances, is closer, in spite of his claims, to an erotomaniacal form of paranoia than to the state of being in love, even when intense.

Sándor Ferenczi spoke of the "language of passion" as opposed to "tenderness" (1932), emphasizing the traumatic force of the confusion of tongues between adults and the child, ranging from sexual rape to erotic punishment. He emphasized the "premature graft of the varieties of erotic love loaded with feelings of guilt onto an individual who is still immature and innocent." Years later, Daniel Lagache (1947) examined from a psychoanalytic viewpoint the clinical treatment of states of passion (jealousy, erotomania).

Piera Aulagnier (1979) developed a new approach to the concept of passion, which she defined as "a relation in which an object has become, for the I, another exclusive source of all pleasure and has been displaced in the hierarchy of needs." There are three prototypes for this: the relation of the drug addict to the drug, the

relation of the gambler to the game, the relation of an other to the I, that is, "amorous passion," which is qualitatively and not quantitatively different from being in love. Characterized by an asymmetry between the two partners, where one appears as unattainable, the personal relation assumes a desire for subjugation supported by an "inductor," or passion instigator, which uses the suffering of the other to control emotions.

Literature provides invaluable support for extending the psychoanalytic study of passion. In it can be found constant elements such as the fantasy of an opaque and explosive body, the negation of the natural rhythm of time, which is always present in its instantaneity, and the infinite extension of space in the representation of a fusion that is always situated in the future. The impassioned individual struggles to counter-cathect an impossible mourning and, more profoundly, to realize an absent narcissistic unity. The vital question embodied by passion is well illustrated in crimes of passion (Mijolla-Mellor, Sophie de, 1987).

## PAYNE, SYLVIA MAY (1880–1976)

Sylvia Payne, British physician, psychiatrist, and psychoanalyst was born on November 6, 1880 in Wimbledon, Surrey, England. She died on July 30, 1976 in Tunbridge Wells, Sussex, England.

Payne was the daughter of a clergyman and one of nine siblings. She went to Wimbledon High School. At thirteen she had taken the exams to enter a Musical College, but after her teacher died, she decided to study medicine instead. She trained at Westfield College and the London School of Medicine for Women (Royal Free Hospital). She qualified in 1906. In 1908 she married a surgeon, J. E. Payne, with whom she had three sons. During the 1914–1918 War she was Commandant and Officer in Charge of the Torquay Red Cross Hospital, and for her services there she was appointed CBE, (Companion of the order of the British Empire) in 1918.

It was while working with shell-shocked patients that she first heard about Freud's work. She started analysis in London with James Glover. In 1920 she went to Berlin to have analysis with Hanns Sachs. While there she learned enough German to read Freud's *Ego and the Id* for herself. She returned to London and was elected an Associate Member of the British Society on June 1922. She was elected a full Member in October 1924. Her husband, who was a general practitioner, sent her patients. She was thus independent of Jones or Glover for referrals. She held many important offices in the Society and was a trusted administrator and colleague. In 1926 she joined the staff of the London Clinic of Psychoanalysis and was Honorary Secretary of it until 1937. In 1927 she was elected to the Training Committee, on which she served for many years. In 1929 she replaced Rickman as Secretary of the Institute of Psycho-Analysis, and she was elected Business Secretary of the Society. As such she was responsible for arranging for the typed record of the Controversial Discussions that took place during the Second World War. She was elected President of the British Society in 1944, following the controversies. As president, she played an important role in facilitating the rapprochement between Anna Freud and the British Society in 1946, which resulted in a revised training scheme that offered two parallel training courses. She was again elected President of the Society from 1954–1956, during the Freud Centenary Celebrations. In 1962 she was elected an Honorary Member of the Society.

Payne did not publish many papers, but read fourteen papers to the British Society. These cover clinical problems, combining Freud's conceptual framework with her concern for training issues.

She believed that psychoanalysis flourished in an atmosphere of scientific controversy, and although a "moderate," she always valued contributions from colleagues from different theoretical orientations. It is largely due to her that there is one united psychoanalytical society in Britain today.

## PENIS ENVY

The little girl notices the strikingly visible and well-proportioned penis of a brother or playmate, immediately recognizing it as the superior counterpart of her own small and hidden little organ and from then on she is subject to penis envy. She has seen it, knows that she does not have it, and wants it. This is the way Freud describes penis envy in *Some Psychological Consequences of the Anatomical Distinction between the Sexes* (1925j).

The first allusion to envy in relation to the penis appears in *On the Sexual Theories of Children* in 1908; the little girl then declares "that she would rather be a

boy.” Freud uses the term *Penisneid* for the first time in *Observations and Analyses Drawn from Analytical Practice* (1913h). He uses it again in *On Narcissism* in 1914. It constitutes the girl’s castration complex whereas anxiety concerning the penis constitutes the boy’s castration complex. The castration complex leads to “masculine protest,” a term invented by Adler and which he attached to ego instincts and not to sexual instincts.

In *The Sexual Theories of Children* (1908c), Freud says that the little girl would rather be a boy but then the accent is put, not on the situation of boys in general, but on the possession of the male sexual organ in itself. The girl reproaches her mother with not having given her one and turns away from her to take the father as a love object. Penis envy and the castration complex thus bring her into the Oedipus complex out of which, unlike the boy, she will never emerge (cf. *The Dissolution of the Oedipus Complex*, 1924d). The desire for a penis is replaced by the desire for a child by the father. But, whereas the boy identifies with the rival and forbidding father and thus constitutes a solid superego, the girl does not manage to produce a superego of the same quality. The result is a series of feminine characteristics: the woman “displays a lesser sense of justice, a lesser inclination to submit herself to the great necessities of life,” “she more often allows herself to be guided in her decisions by tender and hostile sentiments.” In short, we must not allow ourselves “to be misled by the argumentations of feminists who want to impose on us a complete parity of position and appreciation between the sexes.”

Freud’s position is linked to his phallocentrism and he failed to assess the degree to which it derived from the patriarchal culture in which he lived. He studied only the case of boys in depth and deducted from it, *mutatis mutandis*, conclusions concerning girls. He could not conceive of women except in negative terms: in order to become a woman, a man would have to renounce his penis. He was unable to conceive of women in a positive manner, as equipped with organs in which the man is lacking. He could conceive that a man might be afraid of women who want to take his penis from him. He could not conceive of men desiring femininity, maternity, or breasts. Women could have the fantasy of being no more than castrated men. Freud asserted that the castration of women was a reality that they had to accept. He thus forced them into a

feeling of inferiority from which it is difficult to see a way out.

Children of both sexes are subjected to trauma when they learn that, whether boy or girl, neither one is the totality of the human being. Each one relies on their peer group for self-valorization and to devalorize the other. It is in this more general framework that we must situate castration anxiety and penis envy. Penis envy does not consist in wanting to change sex but fits into the narcissistic continuity: the girl would like to have the narcissistic and social advantages linked with the possession of a penis, rather than the organ itself (Horney, 1922), especially if she has the experience of her father and mother putting more value on the male child.

## PERALDI, FRANÇOIS (1938–1993)

François Peraldi, Canadian psychoanalyst and professor of psychoanalysis in the Department of Linguistics of the University of Montreal, was born on May 2, 1938, in Paris, and died in Montreal, on March 21, 1993. The son of Jean Peraldi and Denise Roger, François was the second child of a family of three boys. He was proud of his father's heritage as a Corsican mountagnard peasant. He attributed his close ties to his father to the double pneumonia he contracted when he was eighteen months old, which required constant care from his father for three months. When his father was mobilized in 1939, he lost the person he loved most in the world. "My first mother," he wrote, "was not my mother, but my father."

After studying medicine Peraldi turned to psychoanalysis, and underwent a teaching analysis with Simone Decobert, an analyst with the Société Psychanalytique de Paris (SPP) (Paris Psychoanalytic Society). After being rejected by the SPP, he was accepted by the École Freudienne de Paris (Freudian School of Paris), where he completed his training. During this period, Peraldi developed friendships with Françoise Dolto, Luce Irigaray, and Michèle Montrelay. Interested in child psychoanalysis, he began working as an institutional psychotherapist with young psychotics. Along with his psychoanalytic training, he completed a doctorate in linguistics with Roland Barthes.

In 1974 he emigrated to Montreal, where he practiced psychoanalysis until his death at the age of fifty-five. Peraldi claimed that what he called the "intellectual terrorism" then practiced in France had driven him from the country. His training in linguistics and psychoanalysis, which led to a teaching position in the Department of Linguistics at the University of Montreal, had made him receptive to the work of Jacques Lacan. Although Peraldi actively promoted Lacan's work, he himself refused to be labeled a Lacanian.

A gifted thinker, Peraldi introduced Lacan's clinical work into North America, where Lacan's influence had been limited to philosophy and aesthetics. To remedy this Peraldi created the Peraldi seminar, attended by intellectuals, clinical practitioners, and apprentice analysts of all persuasions and loyalties. The seminars were given for fifteen years, from 1976 to 1991, and were held every other Wednesday at the university. Attendees listened to presentations by Julien Bigras,

Josette Garon, Jean Imbeault, Mireille Lafortune, Jacques Mauger, Lise Monette, Régine Robin and other local practitioners, as well as by Jacques Hasoun, Françoise Dolto, Luce Irigaray, Chantal Maillet, Gérard Miller, Gérard Pommier, and Moustapha Safouan. Several of the speakers from Montreal were members of the Montreal Psychoanalytic Society and Peraldi developed close ties with some of them. His friendships with the local psychoanalytic community led to his contributions to the review *Interprétation*, edited by Julien Bigras. He also became a member of the editorial committee of *Frayages* and contributed to *Filigrane*, edited by Hélène Richard.

Because of his opposition to any form of institutionalization, in 1986 Peraldi established the Réseau des Cartels, an idea he had borrowed from Lacan, being careful to emphasize that he was not founding an institution. To the extent that its only function was to promote the transmission of psychoanalysis rather than become a recognized training school, the Réseau served as an alternative to the institutional framework. "This network," he noted, "is a place for exchange and analysis, without any power of recognition or control." He succeeded in obtaining, for a psychoanalytic fringe that rejected any form of institutionalization, a framework for meetings and exchanges in small groups of four—"three plus one"—to discuss clinical problems, the analyst's desire, and the group unconscious.

He used to joke that Lacan's ideas had helped him become an analyst and read Freud but that he was more Lacanizing than Lacanian. He was an original, if marginalized, thinker, who rejected leaders of all kinds, but he was more than an interpreter of Lacan's work, and developed his own approach to Lacanian ideas. For example, he developed a personal approach to sexuality, which he developed in his 1981 article "Polysexuality."

Because of his early death much of the work intended for his seminar remained incomplete, but the seminars themselves remained a focal point for independent psychoanalysts in Montreal. His work as a consultant to many other analysts also remained unfinished, and the Réseau des Cartels was disbanded after his death.

## PERCEPTION-CONSCIOUSNESS (PCPT.-CS.)

In the Freudian metapsychology of the period of the first topography, the “Perception-Consciousness System” designates the system located on the periphery of the psychic apparatus. Its function is consciousness, and Freud linked it to the preconscious system.

The theoretical constitution of the Pcpt.-Cs. (Perception-Consciousness) system dates from the time of the “Project for a Scientific Psychology” (1950c [1895]). Gradually the Pcpt.-Cs. system was assimilated into the ego, or at least considered as its “core.” Two clearly demarcated systems were needed to explain two contradictory functions—the inscription of (lasting) mnemonic traces and their renewal—and this is what led Freud, following Breuer’s observations, to distinguish between the Ucs.-Pcs. and the Pcpt.-Cs.

From the topographical point of view, the Pcpt.-Cs. system is attached to the Pcs. (preconscious) system but not to the Ucs. (unconscious) system—at least, not to the unconscious as an effect of repression, since Freud considers the unconscious of a consequence of the ego. Because consciousness belongs to the ego, which is in part unconscious in the expanded sense of the term (the ego manifests unconscious energy in resisting the transformation of its unconscious into consciousness), the Pcpt.-Cs. system is topographically related to the unconscious of the ego, which, unbeknownst to itself, has “overdetermined” the ego’s operations. The Pcpt.-Cs. system receives information externally as well as internally, which is provisionally inscribed on its surface. The preconscious involves the mnemonic alteration and fixation of verbal traces and conscious perceptions. Conscious perceptions are current and immediate, while verbal representations

“were at one time perceptions” (1923b, p. 20). Furthermore it is because they are past perceptions that “they can become conscious again.” Freud explained in *The Ego and the Id* (1923b) that principally it is acoustic perceptions and not visual perceptions that constitute a “special reserve for the use of the preconscious,” “so that the system Pcs, has, as it were, a special sensory source,” images not being very suitable for making “thoughts” conscious. On the other hand, the unconscious makes much use of images, which can symbolize thought in the absence of sensory information, and without these thoughts being manifest.

From the economic point of view, the Pcpt.-Cs. system poses a particular difficulty in that it causes a transformation in perception itself. It presupposes a hyper-cathexis on the level of energy (or quantity), and it adds a special qualitative dimension with the establishment of an “index of reality.” Attention describes the process of making perceptions conscious not as a simple focusing, since perception is already focusing, but as a hyper-cathexis causing an “intensive” transformation of the perceived into a qualitative given. Though Freud does not say it explicitly, we can see that the perceived would become, through the workings of the Pcpt.-Cs. system, a “determination”—that is to say, a qualified relation of the ego to reality, which obliges the ego in turn to assume a position. In *An Outline of Psychoanalysis* (1940a [1938]), Freud specified that these “positions” are so many “*characteristics of the ego*. . . the ego has voluntary movement at its command. It has the task of self-preservation. As regards *external* events, it performs that task by becoming aware of stimuli, by storing up experiences about them (in the memory), by avoiding excessively strong stimuli (through flight), by dealing with moderate stimuli (through adaptation), and finally by learning to bring about expedient changes in the external world to its own advantage (through activity). As regards *internal* events, in relation to the id, it performs that task by gaining control over the demands of the instincts, by deciding whether they are to be allowed satisfaction, by postponing that satisfaction to times and circumstances favourable in the external world or by suppressing their excitations entirely. . . . The ego strives after pleasure and seeks to avoid unpleasure” (pp. 145–46), which the id does not know how to do, with the result that the ego is sensitive to anxiety, being capable of reading its signals. Finally:

“From time to time the ego gives up its connection with the external world and withdraws into a state of sleep” (p. 146). It should be mentioned in this connection that Freud did not recognize the activity of thought as one of these possible positions of the ego in relation to reality, even though he always stressed the importance of attention in thought processes.

Finally, from a dynamic point of view, Freud’s ideas about the Pcpt-Cs. continued to evolve. In the beginning he claimed that it controlled repression, which suggested that Pcpt-Cs. was based on a voluntarist conception of consciousness. Gradually, defenses and resistances were themselves linked, at least partly, to the unconscious of the ego, so that the “decisions” of the ego were no longer considered as the conclusions of attention, and the will was no longer envisaged as something that attention could control. Consequently attention itself was over-determined, and the Pcpt-Cs. system no longer possessed within itself the means for exploiting its dynamics. Ultimately, the strengthening of the Pcpt-Cs. system, which psychoanalysis attempts to accomplish, according to Freud, means that analytical work should be understood not only as an active transmutation of the Ucs. into the Pcpt-Cs., but also as a working-through of the unconscious that belongs to the ego itself—which is precisely what limits the activity of the Pcpt-Cs. system.

## **PERCEPTUAL IDENTITY**

The Freudian notion of perceptual identity refers to the goal pursued by the pleasure-seeking primary process by means of hallucination. Perceptual identity is

opposed to thought identity, which thought seeks by means of the secondary process.

The notion of perceptual identity is essentially articulated in Freud’s “Project for a Scientific Psychology” (1950c [1895]) and *The Interpretation of Dreams* (1900a). Yet the clinical, developmental, and anthropological dimensions of Freudian thought help one to grasp its full import, beyond the defining opposition between primary and secondary processes. Indeed, the issue of perceptual identity brings into play that of hallucination, which is fundamentally related not only to psychopathology but also to analytic clinical practice as such.

By means of hallucination, the primary process seeks to forestall any schism between the id and reality, and so it seeks to neutralize the ego, since the task of the latter is to negotiate the inevitable conflicts between the two. Perceptual identity presupposes a foreclosure of meaning in the sense in which Jacques Lacan discussed it, a result of the identity, in representation or affect, between the aim of the drive and perception. In melancholia, perceptual identity unifies the absent or lost object and the aim of perception; this permits a substitution of the past for the present and future, and preserves the lost object as a substitute satisfaction. By contrast, thought identity presupposes an elaboration of the lost object—hence the detour inherent in the activity of thought.

Cogitative thought processes may seek thought identity in perceptual identity. The great mystics demonstrate this, as do intuitionist currents in philosophy (for example, intellectual intuition in German idealism). Perhaps perceptual identity enhances speed of thought and gives rise to flashes of brilliance, whose importance to creativity should not be underestimated.

## PERESTRELLO, DANILO (1916-1989)

Daniilo Perestrello, the Brazilian psychiatrist, psychoanalyst, and university professor, was born in Rio de Janeiro on February 28, 1916, and died there on February 10, 1989.

Perestrello practiced as a general practitioner for the first few years of his working life before becoming a psychiatrist. Late in 1946 he left for Buenos Aires in order to train as a psychoanalyst. When he returned to Brazil in 1949 he was already an associate member of the Asociación Psicoanalítica Argentina (APA) and became a full member in 1953. At the International Congress of Psychoanalysis held in London in 1953, Perestrello was the only Brazilian to present work that was published in the *International Journal of Psycho-Analysis*. In 1957 he was one of the founders of the Sociedade Brasileira de Psicanálise study group in Rio de Janeiro, which was recognized by the International Psychoanalytic Association (IPA). In 1959 he and his colleagues from the study group founded the Sociedade Brasileira de Psicanálise de Rio de Janeiro (SBPRJ). He became a training analyst in 1960. Perestrello presented many purely psychoanalytic studies in addition to those devoted to psychosomatic questions. For more than ten years he was in charge of the Institute's seminars based on Freud's work.

His interest in psychosomatic questions predated his becoming a psychoanalyst. In 1958 he published his work entitled *Medicina psicossomática* (Psychosomatic medicine), which was translated into Spanish and published in Buenos Aires.

In the same year he organized and directed the Center for Psychosomatic Medicine attached to the chair of clinical medicine in the federal university of Rio de Janeiro. In 1965 he was one of the architects and founders of the Associação Brasileira de Medicina Psicossomática (ABMP). The founding assembly held in São Paulo elected him as its first president.

In 1974 he published *Medicina da pessoa* (Medicine of the person), which became the conceptual source behind the teaching of psychosomatic medicine in

Brazil's leading medical faculties. The first edition of the *Revue psychosomatique* was devoted to him.

His university teaching was always based on clinical cases. Perestrello manifested an immense respect for his students and patients. He cut a peerless figure in the lecture hall. A brilliant orator, he never failed to capture the attention of his audience. After 1976, already ill and retired from active life, he was elected honorary president of the ABMPE and, in 1986, honorary president of the Brazilian Psychoanalytic Association (ABP). In 1987 his students, wife, and son selected and published his most important works.

As a humanist, Perestrello always exalted human beings; as a doctor, his patients; and as a psychoanalyst, the analyst-patient relation.

## PERRIER, FRANÇOIS (1922–1990)

The French psychiatrist and psychoanalyst François Perrier was born on July 25, 1922 in Paris and died on August 2, 1990, also in Paris, at the Hôtel-Dieu hospital.

His father, Martial, was a journalist and poet—his works were published by his friend Bernard Grasset—and his mother, a musician, taught him to play the piano when he was a very young child. He studied medicine and then psychiatry in Paris, and in 1951 defended his doctoral thesis directed by Jean Delay, titled “Les données apportées par la spectrographie dans l'étude du syndrome humoral de l'électrochoc”

(The contribution of spectographic data to the study of humoral syndrome in electroshock therapy).

In 1949 Perrier went into analysis with Maurice Bouvet, and in 1953 he participated in the student revolt in the Société psychanalytique de Paris (SPP; Paris Psychoanalytical Society). He followed the founders of the Société française de psychanalyse (SFP; French Society of Psychoanalysis), becoming an associate member at the same time as Vladimir Granoff and Serge Leclaire, in 1954, the year his first psychoanalytic text, “La psychothérapie des schizophrènes” (Psychotherapy for schizophrenics) was published.

Beginning in 1956 he provided psychoanalytic consultations at the Hôpital Sainte-Anne at the same time as presentations of the patients of Daniel Lagache and Jacques Lacan, as well as a seminar on analytic clinical practice with Leclaire and Granoff. In 1953 he undertook a period under Lacan’s supervision, and in 1956 began an analysis with him that lasted until 1963.

From 1960 Perrier, Granoff, and Leclaire (nicknamed “the Troika”) took part in various negotiations with the International Psychoanalytic Association (IPA), attempting to secure the integration of the SFP. After the failure of these attempts, Perrier joined the camp of Lacan.

It was in Perrier’s home that, on June 21, 1964, Lacan founded the École freudienne de Paris (Freudian School of Paris). Perrier was on the École freudienne’s first board of directors; he was also the first to resign from the board, on December 1, 1966, on grounds of disagreement over the training of analysts. On January 26, 1969, during the hearing on “the pass” at the Hôtel Lutetia, he resigned from the École freudienne, along with Piera Aulagnier and Jean-Paul Valabrega. Again at his home, the Quatrième Groupe (Fourth Group) was founded in February 1969; he became its first president. In 1969 he wrote an article on training analysis that appeared in the first two issues of *Topique*. He finally resigned from the editorial committee of this journal in 1974, following its refusal to publish his article, “Thanatol.” Thereafter he devoted himself to the publication of his work, with the collaboration of Jacques Sédât. He resigned from the Quatrième Groupe in 1981.

Perrier’s vast body of work shows an analytic and original approach to the totality of clinical practice, whether it is a question of phobias (1956), erotomania

(1966), schizophrenia and psychosis (from 1956), alcoholism, hysteria, or female sexuality. He also contributed to thinking about the training of analysts and training analysis (1969).

For many years Perrier taught a seminar in psychoanalysis. Some of his seminars have been published.

## PERROTTI, NICOLA (1897–1970)

Nicola Perrotti, an Italian psychoanalyst and physician, was born in Penne (Pescara) in 1897 and died in Rome in 1970. He was one of the pioneers of psychoanalysis in Italy. Perrotti, a humanist with considerable clinical sensitivity, after receiving his doctorate in medicine in Rome in 1922, turned to Freud’s new science. Even before he underwent psychoanalytic training, he defended the cause of psychoanalysis in the pages of *Il Saggiatore*, an avant-garde cultural review.

In 1932 he began analysis with Edoardo Weiss and soon became one of his close collaborators. Again with Weiss, in 1934 he participated in the International Psychoanalytic Congress in Lucerne, where he presented his “Psychoanalytic Considerations on Music.” In 1935 the *Internationale Zeitschrift* published one of his most original essays, “Die Righophobie” (Phobia of cold), confirming Freud’s predictions to Weiss (1970) that “his collaborator Perrotti had the potential to become a prize winner.”

After the Italian Psychoanalytic Society (SPI) was forced to dissolve in 1938 and following Italy's entrance into the War, Perrotti returned to the political movements he had followed in his twenties, when he was a militant in the Socialist Party, struggling alongside men such as Nenni, Saragat, and Pertini. He was elected deputy of the new Italian Parliament and appointed High Commissioner for Hygiene and Health, a position he left in 1950.

During this period of political engagement, Perrotti continued to take an interest in the status of psychoanalysis in Italy. In 1946, with Emilio Servadio and Cesare Musatti, he reestablished the SPI, of which he was president until 1951. Through his friendship with Maryse Choisy, he took advantage of his contacts in France to enter the European circuit of psychoanalysis. The subsequent Congress of Romance Languages Psychoanalysts provided Perrotti with an opportunity to work with distinguished representatives of French psychoanalysis and helped formalize his contacts.

In 1952, after his term as president of the SPI had ended, he founded the Istituto di Psicoanalisi di Roma (Rome Psychoanalytic Institute) and, in 1963, managed the newly reestablished review *Psiche*. His most important articles were published in *Psiche*, the *Rivista di psicoanalisi* and the *Revue française de psychanalyse*. During his lifetime, he published seventy articles, which were collected in a posthumously published anthology entitled *L'Io legato e la Libertà* (The bound ego and freedom), whose main topics were the identity crisis of contemporary man, the metapsychology of the self, depersonalization, and aggression.

## PERSECUTION

The term “persecution” derives from the vocabulary of religion and was used to describe the torture and

torments inflicted on the early Christians martyrs. In everyday usage, it characterizes all relationships in which one party, the persecutor, pursues the other, the persecuted, with malevolent intentions, cruelty, and hatefulness.

In the language of psychopathology, the term “delusions of persecution” has been used to refer to the ideas and feelings described in patients with various diagnoses, including paranoia, schizophrenia, melancholia, and hypochondria. Freud's hypothesis is that a delusion of persecution is the result of a defense against unconscious homosexual impulses.

Described since antiquity, feelings and ideas of persecution were noted in connection with various clinical entities until the second half of the nineteenth century, when new systems of psychiatric classification isolated them into a separate and independent category (Legrand du Saule, 1871). In the early twentieth century, German psychiatry characterized persecution in relation to “paranoia” while French authors dismissed what they called *folie raisonnante*; even though it was clear that other pathologies (for example, the paranoid form of dementia praecox) could include this type of delusional thinking.

Today, clinicians tend to recognize the persecution dimension in a number of conditions, including erotomania, delirious hypochondria, or delirious jealousy; these conditions do not actually reach the level of “delusions of persecution” in the strict sense of the term, but all involve essential aspects of the persecutory relationship— projection, passionate and one-sided attachment, and acting out.

In his commentary on Daniel Paul Schreber's autobiography (1911c), Freud described the mechanism of symptom formation, the underlying unconscious fantasy, and the level of fixation of a persecutory relationship. He saw the onset of the disorder in “sexualization of their social instinctual cathexes” (p. 62) and suggested that these cathexes are the result of inhibition of homosexual tendencies (the erotic component of friendship) arising from the stage when object choice is narcissistic. The unconscious fantasy of the persecutory relationship thus represents the fixation to this homosexual stage of the libido.

Finally, to explain the way that symptoms of persecution develop, Freud suggested the specific mechanism of “projection.” The impossibility of accepting “I (a man) love him (a man)” is unconsciously transformed into “I

*hate* him.” But this formulation, representing the return of the repressed, cannot become conscious in such form and Freud writes that, “thus the impelling unconscious feeling makes its appearance as though it were the consequence of an external perception. ‘I do not love him—I hate him, because he persecutes me’” (p. 63).

Delusions of persecution represented Freud’s first attempt to identify certain mental pathologies with reference to psychic mechanisms other than repression and the “return of the repressed.”

## **PERU**

The first reference to psychoanalysis in Peru dates from a thesis presented in 1914. The following year, Honorio Delgado published an article on the new discipline in the country’s most important daily. In 1918 he and Hermilio Valdizán founded the *Revista de psiquiatría y disciplinas conexas* (Review of psychiatry and associated disciplines), the first mouthpiece for psychoanalysis in Latin America. In 1919 he wrote the first Spanish work on the subject. That same year he received a letter from Freud, the first in an epistolary exchange that was to last until 1934.

Although Freud was interested in enlisting Delgado—whom he cited as an example of his influence in Spanish-speaking countries, and whose articles and reports appeared in *Imago*, the *Internationale Zeitschrift für Psychoanalyse*, *Psychoanalytic Review* and the *International Journal of Psycho-Analysis*—the Peruvian physician, on the other hand, manifested some reticence. He attended the Berlin Congress on Freud’s

invitation. He arrived late but nevertheless managed to meet the founder of psychoanalysis. In 1926 Delgado published Freud’s biography and paid homage to him in the National Academy of Medicine. Paradoxically, in 1927, just as he was beginning to manifest a much more critical attitude, he was made a member of the British Psychoanalytic Society (BPS), attended the Innsbruck congress, and visited Freud at Semmering.

Having been a major figure in Peruvian psychiatry for more than thirty years, Delgado changed position from that of an exponent to that of a detractor. He was the architect behind the enthusiastic welcome that psychoanalysis received in the 1920s, when the discipline was introduced into psychiatry lectures and when the most important reviews published translations of Freudian texts—in 1926 one of them devoted an entire issue to Freud and psychoanalysis. José Carlos Mariátegui, the most eminent Peruvian thinker of the 20th century and founder of the Peruvian Communist Party, devoted an article to psychoanalysis as well as a chapter in one of his books. In 1929, one year before his premature death, he wrote a psychoanalytically informed article on literature.

Delgado’s opposition in the 1930s was an obstacle to the expansion of the psychoanalytic movement, which was suspended for another four decades. With the exception of some isolated articles and a few theses, the psychiatric milieu lost all interest in the discipline. It disappeared from the scene for several years, until reintroduced through the influence of Carlos Alberto Seguin. The science journalist, Oscar Miró Quesada (RACSO), nevertheless devoted several articles to Freud and psychoanalysis, as well as a book in 1937.

In 1940 Seguin published a book in Buenos Aires on Freud. He later went into analysis and frequented the New York Psychoanalytic Institute. For many years he was director of the first psychiatry department attached to a general hospital in Latin America and contributed to promoting dynamic psychiatry and psychosomatic medicine on psychoanalytic bases. He was president of the psychoanalytic section of the Peruvian committee at the first World Congress on Psychiatry. His influence was of major importance: ninety percent of psychiatrist members of the Peruvian Psychoanalytic Society studied under him.

Saúl Peña’s return to Peru in 1969 marked the beginning of active work in university and clinical

circles, which continued with the returns of Carlos Crisanto in 1973 and Max Hernández in 1974, the year of the foundation of the Center for the Development of Psychoanalysis. In 1979 the International Psychoanalytic Association (IPA) recognized this institution as a provisional study group and appointed a sponsoring committee which admitted the three analysts as training analysts and selected the first candidates.

Founded in 1980, the Peruvian Psychoanalytic Society was accepted as a study group in 1981. Peña, Crisanto, Hernández and the new sponsors made up the joint training committee of the brand new Peruvian Institute of Psychoanalysis. In 1985 the group acquired the status of a provisional society and that of a member society in 1987.

With Sara Flores as president, the Society had forty-eight associate and full members as of 2004, to which we must add the twenty-two candidates and students from the Institute directed by Jorge Kantor, and the eleven candidates from the seventh group to begin training. The many influences from psychoanalysts trained abroad and the foreign personages associated with the society have contributed to representing very different schools (British-independent and Anna Freud, East and West Coast United States, Argentina, France, and Frankfurt).

The society has organized and/or sponsored eight national congresses and other events, mainly international and inter-disciplinary, which have contributed to forging a role in cultural life for psychoanalysis as well as having an influence on artists, specialists in the social sciences, educators, historians, writers, psychologists, and psychiatrists. The 1998 international conference "On the Threshold of the Millennium" and "At the End of the Battle" (2001), both co-sponsored by the IPA and UNESCO, also aroused the interest of politicians, economists, captains of industry, diplomats, and the general public.

Since 2001 the most prestigious private university of the country has a Master's Program in Psychoanalytic Theoretical Studies, organized by Max Hernández and Moisés Lemlij, whose second class is about to graduate. Also the most widely read weekly in the country has a column presenting a psychoanalytic point of view and a psychoanalyst heads a radio program where people seek advice and consultation.

Max Hernández is one of the leading intellectuals in contemporary Peru and a major personality in the

Peruvian Society. His influence extends beyond the discipline and his contributions have been rewarded with the Sigourney prize. During his presidency of the FEPAL, Saúl Peña, the first president and honorary president of the Peruvian society, organized the first Latin American Congress of Child and Adolescent Psychoanalysis and presented the contributions of Latin American psychoanalysis in the form of various publications.

César Rodríguez Rabanal, a former member of the Peruvian Society and an important leader of opinion, made a renowned contribution on the subject of how to approach marginalized and under-privileged populations. As an active promoter on an international level of culture in general and psychoanalysis in particular, Moisés Lemlij has twice been vice-president and treasurer of the IPA. Álvaro Rey de Castro, current President of FePAL, stands out for his active participation in the war against corruption.

The main psychoanalytically-informed institutions in Peru are: the Center for Psychosocial Development and Counseling (1976), the Lima Center for Psychoanalytic Psychotherapies (1983), the Association for Child Psychotherapy (1986), the Center for Psychoanalysis and Society (1986), the Interdisciplinary Seminar on Andean Studies (1987), the Center for Human Development and Creativity (1995), the Center for the Development of Art Therapy (1997), and the School of Applied Clinical Psychotherapy (1999). The Lacanian movement is still at an embryonic stage.

The leading works are published by the Biblioteca Peruana de Psicoanálisis and the Fondo Editorial SIDEA. Directed by Moisés Lemlij, these publishing centers have together published more than thirty works since the early 1990s. Also worthy of note is the *Libro anual de psicoanálisis* (Annual book of psychoanalysis), published by Gustavo Delgado (The Peruvian Society publishes a journal, *Psicoanálisis*, every two years).

## PERVERSION

To posit a “perverse” sexuality is to imply the existence of a “normal” variety with reference to which certain acts and object-choices are deemed deviant. In the *Three Essays on the Theory of Sexuality* (1905d), Sigmund Freud stated that the aim of adult sexuality was to reach orgasm by means of genital penetration, but he tempered this rather normative statement by observing that “the disposition to perversions is itself of no great rarity but must form a part of what passes as the normal constitution” (p. 171).

This was the basis of Freud’s celebrated formula according to which “neurosis is the negative of perversion” (pp. 165, 231). In his turn—or perhaps rather his return—to Freud, Jacques Lacan followed up by underlining the importance of the absence of the father in cases of perversion, and at the same time claimed that perversion was above all attributable to the mother’s putting her child in the place of the phallus (2002 [1955–56], p. 188). The pervert-to-be was thus chained to the desire/demand of the mother. It should be borne in mind, however, that Lacan was chiefly interested in the form of a “third structure” between the psychotic structure and the neurotic, so that for him perversion was a specific structural category rather than a class of sexual behavior to be set against an established norm.

It is difficult, from the psychoanalytical perspective, to frame a satisfactory definition of what, among adult sexual activities and object-choices, might constitute a symptom. Should homosexuality, for example, always be looked upon as a symptom? Or should it be viewed simply as a variation of male or female sexuality? Psychoanalysts are sharply divided on this clinical question.

First of all, the polymorphous features of adult sexuality hardly need underlining. Countless patients, whether heterosexual or homosexual, describe an infinite variety of erotic scenarios, fetish objects, masquerades, sadomasochistic games, and so on, which constitute private areas in their love lives, and which they experience neither as compulsive nor as indispensable to their sexual gratification.

Since every psychological symptom constitutes an attempt at self-cure intended to spare the sufferer painful mental conflict, this may be said equally of symptomatic sexuality (inasmuch as we are able to define it). Such a constructive approach to the meaning and aim of sexual symptoms, and of the reason for their formation, invariably leads to the conclusion that they embody infantile solutions to the confusions and anxieties attending sexual difference and sexual identity. The need to reinvent the sexual act often turns out to be closely tied to the parents’ unconscious, or to silent messages or deceptive communications from the parents concerning sexual identity, adult sexuality, and notions of “feminine” and “masculine.”

If some patients can achieve sexual satisfaction only by recourse to fetishistic, sadomasochistic, or other scenarios, the analyst might well wish that their sex life were less constrained, less subject to rigid conditions; yet if such erotic rituals are indeed for them the *sine qua non* of sexual relations, there is no justification for wanting these patients to abandon their erotic practices, whether or not other people consider them perverse.

As for the primal scene and the troubling fantasies to which it is apt to give rise, these tend—apart from their genital aspects and the phallic-oedipal conflicts they arouse well before the oedipal crisis proper—to bear the stamp of the pregenital: the fantasies in question feature *devoration*, or erotic and sadistic exchanges of an anal or fecal kind. When such fantasies predominate, they often fail to be integrated into genital eroticism and thus lead to so-called perverse sexual solutions.

Even more inhibiting than fantasies originating in the pregenital psychosexual stage are archaic fantasies involving vampirism, implosion, and fears of the loss of identity or of the sense of the boundaries of the body. When such fantasies, characteristic of early infancy, play a predominant part in the mental reality of adult individuals, sexual and love relationships are

liable to be experienced as a threat of castration, annihilation, or death.

In order to achieve a gratifying sexual or love life, individuals inhabited by such terrifying fantasies find themselves obliged by the force of their unconscious to invent means whereby their castration anxiety and fear of annihilation—to which may be added feelings of confusion as to sexual identity, of emptiness, and of inner death—can be transformed into eroticized games. As an absolute prerequisite to sexual relations, adults in this situation commonly require complex theatrics: constraining conditions, disguises of all sorts, pregenital sexual behavior including the exchange of excrement, and so on—all meticulously stage-managed.

Most patients who re-enact the primal scene in this way feel that their erotic acts and object-choices are conflict-free and consonant with their desires, even if other people adjudge them perverse. The specific form assumed by a person's sexual predilections becomes a clinical problem in need of solution only if it causes that person to suffer. The real question is not whether particular acts or preferences should be judged deviant, but when a given deviation should be considered a variation from adult sexuality within the context of a significant object-relationship and therefore be treated as symptomatic.

A good many authors continue to use the term "perversion" in a pejorative way, but only inasmuch as it connotes a proclivity towards evil. Thus Robert Stoller (1975) confines the use of the word, which he defines as "the erotic form of hatred," to any sexual act whereby a person seeks deliberately to hurt someone else. Joyce McDougall (1995) uses the term "neosexual" to qualify the kind of scenarios described above and suggests that "perverse" be applied exclusively to specific relations, notably sexual relations, imposed by one individual on another who does not consent thereto (as for instance a child or a mentally disturbed person): in other words, sexual relationships in which one of the partners is utterly indifferent to the vulnerability or the desire of the other. It is worth noting that these same acts belong more often than not to the class of behavior that is condemned by the law: sexual abuse of minors, rape, exhibitionism, and so forth. The sexual activity of consenting adults, whether or not it is considered deviant with respect to supposed norms, tends not to be treated as illegal.

In short, where neosexual practices do no harm to either partner, nor seem to display a relentless compulsiveness of which the subject him or herself complains, the analyst has no cause to wish another erotic perspective upon the patient. It should be remembered that neosexualities serve not only to repair breaches in the sense of sexual and subjective identity but also, unconsciously, to protect their internal objects from the subject's hate and destructiveness, which derive in part from the unworked-out oral and anal impulses characteristic of incorporative infantile love. In the course of an analysis, the meaning of the love relationships of sexual innovators is revealed. It transpires in fact that their "choices" represent the best solution that the sometime child was able to find in response to messages from the parents. The feeling of choice is nonexistent, whether the individual is heterosexual, homosexual, autosexual, and/or neosexual.

Thanks to the uncovering of neosexual scenarios, what had been nonsensical becomes significant and meaningful, and a feeling of vitality prevails, at least momentarily, over inner death. These same problems might otherwise have produced graver outcomes of a psychotic or psychopathological order. Despite the often constraining conditions imposed by patients' compulsions and anxiety, which so often define the repertoire of sexual deviations, the underlying self-curative intent in face of conflicts of a neurotic or psychotic kind means that Thanatos is bound and that Eros triumphs over death.

## PERVERSION (METAPSYCHOLOGICAL APPROACH)

The concept of perversion is a recent one, though the word has been in use since the beginning of the third century, when it meant “to invert” or “to make something go wrong.” Among Christians, it means “to corrupt, distort (minds).” Literary scholars use it to mean “to falsify a text.” The term developed and from the second half of the nineteenth century it entered everyday language, particularly in its sexual sense.

The Graeco-Roman world does not have a concept of perversion, whereas the Christian world considers sexuality in general as a sin. Curiously, the reference to alternative sexual practices and sexual practice without a reproductive purpose within psychiatry served to liberate sexuality from religion.

Perverse phenomena were beginning to be investigated in the clinical medicine of Freud’s time; Krafft-Ebing, in Germany, and Havelock Ellis, in England, were Freud’s precursors in this area. Freud, however, was the first to indicate the polymorphous perverse constitution of the child, breaking with the cherubic vision of the child that had prevailed until then and creating huge scandal. Freud’s revolution introduced a metapsychological approach to perversion; that is, an approach that comprises economic, topographical, and dynamic views of perverse practice and which does not separate it from normal sexual life. In *Three Essays on the Theory of Sexuality* (1905d), Freud writes: “Everyday experience has shown that most of these extensions, or at any rate the less severe of them, are constituents which are rarely absent from the sexual life of healthy people, and are judged by them no differently from other intimate events. If circumstances

favour such an occurrence, normal people too can substitute a perversion of this kind for the normal sexual aim for quite a time, or can find place for the one alongside the other. No healthy person, it appears, can fail to make some addition that might be called perverse to the normal sexual aim; and the universality of this finding is in itself enough to show how inappropriate it is to use the word perversion as a term of reproach” (1905d, p. 160).

The case that Freud defines as “severe” is when a “perversion, instead of merely appearing *alongside* the normal sexual aim and object, and only when circumstances are unfavourable to *them* and favourable to *it*—if, instead of this, it ousts them completely and takes their place in *all* circumstances—if, in short, a perversion has the characteristics of *exclusiveness* and *fixation*—then we shall usually be justified in regarding it as a pathological symptom.” He concludes: “This gives us a hint that perhaps the sexual instinct itself may be no simple thing, but put together from components which have come apart again in the perversions” (1905d, pp. 161–162).

Our interest now concerns these different components of sexual life, which may have originated from the erogenous zones but consist of something more than these. Later, in the same work, Freud writes: “It must, however, be admitted that infantile sexual life, in spite of the preponderating dominance of erotogenic zones, exhibits components which from the very first involve other people as sexual objects. Such are the instincts of scopophilia, exhibitionism and cruelty, which appear in a sense independently of erotogenic zones; these instincts do not enter into intimate relations with genital life until later, but are already to be observed in childhood as independent impulses, distinct in the first instance from erotogenic sexual activity” (1905d, pp. 191–192).

Accordingly, exhibitionism, voyeurism, sadism, and masochism are the first “partial drives.” Freud considered that it is these “partial drives” that require the presence of other people as sexual objects from the outset. Thus, a degree of distance is established between the sexual nature of the object and its capacity to satisfy the needs connected with the erogenous zones. Furthermore, because they require the integration of “other people,” exhibitionism and voyeurism and sadism and masochism form the basis of every identification and therefore of the formation of the

ego. This viewpoint is far removed from the simplistic theories based on a genetic approach.

Two problems arise concerning Freud's interest in the perversions. The first relates to his interest in masochism and the second to his interest in fetishism, which are in fact the only two perversions in which he seems to take a close interest. Freud explains his interest in masochism as a perversion in the 1919 article "A Child Is Being Beaten" (1919e). There he outlines the different stages that give rise to the masochistic fantasy: first, "My father is beating the child" and, above all, "My father is beating the child *whom I hate*"; second, "I am being beaten by my father"; third, someone is beating many people, a phase that corresponds to a return to the first fantasy, now reinforced, which becomes: "My father does not love this other child, *he loves only me.*" These fantasies correspond to residues of the oedipal elaboration and are one of the sources of the formation of the superego.

This text seems somewhat inaccessible today without a critical apparatus that takes into consideration both its connection with Anna Freud's text on "The Relation of Beating Fantasies to a Daydream" (1923) and the shared origin of both texts in Anna's analysis by her father and the presentation of this young woman as a member of the Vienna Psychoanalytical Society in that same year. These are complicating factors for their impact in explaining masochism in general.

Freud takes up this theme again in 1924 in "The Economic Problem of Masochism," a text that is of great theoretical and metapsychological interest, specifically for its identification of the death drive as the origin of masochism. Nevertheless, this text seems both to be overshadowed by the 1919 text and to introduce a methodological bias: Freud attributes a form of masochism to women that he explains in this text that he has only ever been able to observe clinically in men. The problem seems to be that Freud never entirely accepts the existence of two sexes and that he systematically reduces "femininity" to "underdeveloped masculinity" if not to "infantility" in its masculine form.

In the article "Fetishism" (1927e), Freud bases the essence of his theories on fetishism on the voyeuristic quest for the maternal phallus, in conjunction with the fears that are concealed by this quest. He remains cautious: "But I do not maintain that it is invariably possible to discover with certainty how the fetish was

determined" (1927e, p. 155). However, his theoretical association leads him to connect the formation of the fetish with the dead father on the one hand and with the splitting of the ego on the other and to the theories that he had already developed at the time concerning the differences and similarities between neurosis and psychosis.

The article poses some problems. Freud conflates "phallus" and "penis," making no distinction between the terms. The "maternal phallus" and "the mother's penis" are not interchangeable terms. The term "phallus" designates a representation of the erect penis that dates back to the Dionysian cults of Ancient Greece. During the Roman Empire, this term was linked more to fascination but it is not reduced to the symbol of the erect penis. Everything that appeals in terms of procreative capacity is called "phallic." The erection is only one of the possible states of the penis and by far the least ordinary, but Freud does not give any reasons why the child would expect to encounter an "erect penis" in his mother. Furthermore, if Freud is referring to the procreative capacity, the association with the penis is superfluous since the mother is just much a parent as the father.

Further, Freud rejects the concept of "scotomization" that was put forward by René Laforgue, and thus rejects his own concept of *Verwerfung* (foreclosure or repudiation), whereas Laforgue's proposition would have established a link between the perversions and the psychoses in accordance with Freud's theories concerning the definite presence of perverse fantasies in the psychoses as well as in the neuroses. If the neuroses are the negative of perversions, do perversions constitute their "positive" as in relation to the psychoses? Furthermore, it seems possible that clinical experience led Freud to abandon the long-established differences between neurosis and psychosis in favor of that new considerations he expounds in this text on fetishism.

Finally, at the dawn of the third millennium, the theory that designates the clitoris as "the normal prototype of inferior organs," the "woman's real small penis" (1927e, p. 157), is considered somewhat problematic. Freud had difficulty recognizing the existence of the two different sexes, and his formulation here considers the woman as deprived of a penis. In this respect, the theory is itself a fetishistic one.

It seems that on the subject of perversions psychoanalysis may not have progressed very far since Freud, but from 1967, structuralism questioned the degree of

variation between neurotic, psychotic, and perverse “structures.” The authors of *Le Désir et la perversion* (Aulagnier-Spairani, P. et al., 1967), several French psychoanalytic clinicians, mainly close to Jacques Lacan, claim to isolate perversion as an entirely separate entity that has no obvious connection with other mental or sexual disorders. Guy Rosolato forwards a “study of the sexual perversions based on fetishism” that essentially adheres to Freud’s framework. However, the dead ancestor becomes the fantasy of the murder of the father, and castration anxiety, attributed only to male individuals, forms the basis for the theory of a general perversion in women. The second article, by Piera Aulagnier, is based on the account of a clinical case but she seems to overlook Freud’s theories on the “universal bisexuality of human beings.” In her view, men would never be able to understand the specific characteristics of female *jouissance*, nor vice versa. Jean Clavreul is interested in the perverse couple but the essentially legalistic viewpoint that he held in 1966 impedes his contribution to an understanding of sexuality, which should consist in taking complete stock of forms of human behavior without any disqualifications. François Perrier takes up the traditional discussions in France and establishes a connection between erotomania as it appears in Clérembault’s first observations and Lacan’s much later contributions. In its implications for clinical practice and its great sensitivity throughout, this appears to be the most important essay of the collection.

The efforts to establish a form of “structuralism” in psychoanalysis, which usually take this back to the old psychiatric nosography, have proved persistent in France. However, the claim that “the apparatus of the soul” can be reduced to “psychic structures,” as in every form of psychopathology, involves a neglect of Freud’s theories concerning the dynamics and economy of formations of the soul that constantly forge links between “difficulties in thinking” and particularly between the psychoses, neuroses, and perversions. Their coexistence was established by Freud from the outset of his works. Neo-sexuality does not exist in this third millennium any more than in any earlier period. On the other hand, a form of neo-morality sometimes seems to emerge, which takes a different view of the eternal forms of erotism.

Furthermore, Freud’s characteristic conflation of femininity with infantility has been detrimental to the understanding of female fetishism and the perversions

in general. Thus it has been claimed either that a polymorphous perverse dimension was inherent in femininity or that there could be no such thing as female perversion because women were entirely devoted to sublimation. These are extreme and romantic theories.

In the United States and, less commonly, in France, psychoanalysts have been more concerned about clinical practice and have indicated the female perversions being exercised in a commonplace way in women’s relationships with children (Welldon). Exhibitionism is a further manifestation of female perversion and male voyeurism is integral to it, relating to any part of the body: men look at what women show them; women show what men want to see. The supposed “female masochism” is usually accompanied by a form of sadism and “male sadism” often abandons men to masochism. The opposed pairs of the partial drives as Freud conceived them are indissociable in clinical practice and are frequently interchangeable.

### **PFISTER, OSKAR ROBERT (1873–1956)**

Pfister was a Swiss pastor, teacher and psychoanalyst, he was born on February 23, 1873 in Zürich, where he died on August 6, 1956.

Born in his father's Zürich suburban parish (Wiedikon), young Oskar was strongly influenced by his father's liberal Christianity and his mother's Pietism. In the course of his early education Pfister was impressed by classroom group dynamics and the erotic power of sadism. After university studies in philosophy, theology, history, and psychology at Basel and Zürich (1891–1895), Pfister completed his education with a series of courses in psychiatry, psychology, and philosophy in Berlin (1896).

Pfister was pastor of Zürich's Predigerkirche (1902–1939), secondary school teacher (1906–1936), instructor at the Cantonal Teaching Academy (1908–1918), and lay psychoanalyst. He specialized in the application of psychoanalytic thought to theology, education, and the humanities and social sciences; he is also known for his passionate popularization of Freudian analysis. Pfister's life and work are intimately bound up with the city of his birth and death: Zürich.

Pfister's first documented encounter with Freud's work came via Carl Jung in early 1908. Freud's psychology fulfilled Pfister's decade-long search for a coherent and meaningful synthesis of psychological and theological thought. He devoured Freud's works and immediately set to work applying analytic insights to problems of pastoral counseling and teaching. Pfister authored the first popular exposition of Freud's ideas and pioneered psychoanalytic interpretations of history, religion, pedagogy, political science, art, and biography.

During the early years of psychoanalysis (1908–1914) Pfister worked closely with the psychoanalytic leadership (Eugen Bleuler, Carl Jung) and its most important early adherents. In January 1909 Pfister, possibly prompted by Jung, sent one of his first psychoanalytic papers to Freud and began their remarkable thirty-year correspondence. The Freud-Jung-Pfister triad became a leitmotif within Pfister's correspondence with Vienna, laden with political and theoretical implications. Jung collaborated with Pfister on at least two of the latter's publications, a 1909 paper detailing Pfister's first full-length analytic case study, and Pfister's comprehensive 1913 textbook *Die psychanalytische Methode*, prefaced by Freud himself. Jung contributed a section on child psychology to the first edition of Pfister's tome. It seems likely that the two collaborated on several other projects, such as Pfister's

1910 psychopathology of Count Zinzendorf. Pfister is mentioned no less than half a dozen times in Jung's 1912 *Wandlungen und Symbole der Libido*.

During the Freud-Jung schism Pfister's loyalties were sorely tested. Though Freud expressed to his closest colleagues Ernest Jones and Sándor Ferenczi his fears that Pfister would side with Jung against him, once the Zürichers officially withdrew from the International Psychoanalytical Association on July 10, 1913, Pfister took only five days before writing to Freud that he was prepared to join the Vienna Society. Pfister then became Switzerland's leading proponent of Freudian psychology, establishing in March 1919 the Schweizerische Gesellschaft für Psychoanalyse, jointly with Drs. Emil and Mira Oberholzer.

From 1908 until his death in 1956 Oskar Pfister authored hundreds of articles and books on psychoanalytic therapeutic technique, the advantages of analytic pedagogy, and his psychoanalytic theology. His most important works are the first psychoanalytic textbook for lay audiences, *Die psychanalytische Methode* (1913), his potent reply to Freud's 1927 attack on religious belief "Die Illusion einer Zukunft" (The illusion of a future; 1928), and the collection of essays in *Zum Kampf um die Psychoanalyse* (Some applications of psychoanalysis; 1920). Pfister's psychoanalytic pastoral care is detailed in *Analytische Seelsorge* (Analytic soul-searching; 1927). His magnum opus, *Das Christentum und die Angst* (Christianity and fear; 1944), systematically analyzed the concept and historical use of fear in order to expose what he perceived to be Christianity's fatal flaw and, if analytically mastered, perhaps its saving grace. The 1963 publication of the Freud-Pfister correspondence remains an important source of information on these men, though very few of Pfister's letters appear in the volume.

In addition to his written work, Pfister frequently toured Europe (particularly Scandinavia) giving dozens of lectures to large audiences of teachers, pastors, and laymen. Among his closest colleagues, were found Hermann Rorschach, Ernst Schneider, Hans Zulliger, and (before 1913) Carl Jung, Alphonse Maeder, and Franz Riklin. Under his tutelage Jean Piaget, among many students after 1909, first learned psychoanalytic technique. One of the first lay practitioners, among Pfister's many analysands were Henri Ellenberger, Emil Oberholzer, and Harold and Kristin Schjelderup.

Oskar Pfister's impact has been recognized by the American Psychiatric Association, which awards the annual Oskar Pfister Prize, for the finest work in religious psychology. The 1973 centennial celebration of his birth in Zürich produced a series of excellent monographs on his contributions to analysis, pastoral psychology, and education. Pfister did not establish a school, though Zulliger and Schneider in analytic pedagogy, and a small group of pastors in Zürich continued his work long after his death. Pfister's importance derives mainly from his thirty-year friendship with and impact upon Sigmund Freud. From his defiant choice to remain a Freudian when the body of the Zürich group left the IPA in 1913, to his role as anonymous interlocutor in Freud's *Die Zukunft einer Illusion*, Pfister served Freud and the psychoanalytic movement with total devotion and great skill.

## PHALLIC MOTHER

The so-called *phallic mother* is a mother who is fantastically endowed with a phallus. Among the male child's earliest sexual theories, he believes that all people have the male genital. By substituting the phallus for the organ that the child thinks the female is lacking, he tries to protect himself from the castration anxiety that arises from the primal fantasies of the mother. The fear of the phallic mother imago tacitly affirms the threat of castration, while at the same time defensively negating it along with all its oral and anal pregenital foundations.

A theory of the phallic mother existed in Sigmund Freud's work from his earliest formulations on the sexual theories of children (1905d, 1908c), and it played a constant role throughout later developments regarding the questions of feminine castration and the maternal penis (1909b, 1910c, 1923b). From 1905 to 1927, these questions were structured by the continuing Freudian exploration of fetishism. The fetishist fears castration excessively, and finds protection from it in a chosen object that serves as an equivalent for the maternal phallus. Further, Freud emphasized the role of the maternal phallic imago in masculine homosexuality (1910c) and its variations in feminine sexuality (1931b, 1933a [1932], 1937c).

Echoing the pioneering works of Freud, Sándor Ferenczi (1913, 1923) described the sexual organs of the mother both as a cavity and as penile. In another attempt to relativize the exclusive predominance that the Viennese gave the phallus, Ernest Jones (1927, 1932) made a case for a partial and secondary castration, an early identification with the mother that allowed for later orogenital bonds. Karl Abraham (1922)—anticipating Melanie Klein in this regard—proposed a “bad mother” as the bearer of the infant's sadistic projections.

Still following the direction indicated by Freud (1910), Melanie Klein marked a shift by locating the site of castration in the oral relation to the breast/penis, which served as a prototype for all others. She believed that within the framework of the pregenital stages of the oedipal conflict, the baby projected onto the maternal breast the destructive drives of its own penis (1926, 1927, 1928). According to Klein, the formidable weapons of the phallic mother are an absent breast that threatens the child's survival, an orally intrusive breast, a devouring mouth/vagina, and an anally penetrating phallus.

According to Klein's theory of early stages of the oedipal conflict, several key concepts are inseparable from that of the phallic mother: the symbolic analogy between breast and penis, projective identification, and the infantile sexual theory of the combined parent-figure (1932). The last term refers to the fantasy that the castrating mother is endowed with the paternal penis, which was incorporated during intercourse; thus it represents the mother and father in a menacing combination.

Today, understanding the investment in the imago of the phallic mother is clinically useful for understanding the pregenital basis of castration anxiety as related to early scenarios of triangulation. Nevertheless, care must be taken because "the relation to the phallic mother is not prior to castration, but rather signified through it" (Green, 1968). In other words, the archaic imago of the phallic mother is expressed in a secondary cultural image only retroactively. Thus there is a great risk of confusion between stages of development and regressive forms if the fantasy of the phallic mother is not understood as an attempt to translate into adult language (secondary process) the phenomenology of the enigmatic early years (primary process).

For Freud, it is the male genital organ alone that plays the central role for both sexes, and any account of this role privileges the masculine. The Freudian view of feminine sexuality, organized around penis envy, has given rise to countless polemics right up to the present day. These ongoing epistemological debates are what gives the question of the phallic mother its historical and cultural substance.

## **PHALLIC STAGE**

The phallic stage is an infantile organization of libido which follows the oral and anal stages and is characterized by a unification of the component instincts under the primacy of the genital organs. During this period the child, whether boy or girl, conceives, according to Freud, of but one genital organ, the male one, and the antithesis between the sexes is experienced by him or her as one between phallic and castrated. The phallic stage coincides with the culmination and decline of the Oedipus complex. It disintegrates under the pressure of the castration complex.

The phallic phase, according to Freud, precedes and ushers in problems attending the oedipal complex and the castration complex. It is connected with a relative unification of the component instincts under the primacy of the genital organs, and arises after the oral and anal pregenital phases, around the third year of life, along with the first manifestations of infantile sexual curiosity. This is the time when the child becomes aware of the anatomical difference between the sexes, that is to say, of the presence or absence of a penis (1923e).

At the same time, this phase is to be distinguished from the full (post-pubertal) genital organization in one essential respect: the child recognizes and sets store by a single genital organ—the male one. The little boy deals with the threat of castration by disavowing his perception of the female genitals and persisting in his belief that the mother possesses a penis; the little girl reveals her "penis envy" by imagining that she will later grow a penis of her own.

The phallic phase is thus still a pregenital stage. The penis is conceived of as a phallic organ embodying power and completeness rather than a narrowly genital organ: the phallic phase implies the primacy of the phallus, not of the genital.

The male organ is seen as a "small detachable part of the body" that may be lost after the fashion of the

contents of the bowel, and thus the difference between the sexes is interpreted in terms of the theory of castration. According to this pregenital logic, the activity/passivity polarity typical of the anal stage is transposed into the antithesis between phallic and castrated. Only with puberty will the masculine/feminine dichotomy be constructed.

For Freud, the phallic phase, which is also the phase of the Oedipus complex, is destined to disappear with the decline of that complex, which is brought about by the threat of castration. The phallic phase is then “submerged” and gives way to the period of latency (1924d, p. 174).

A phallic organization exists in girls. When the little girl notices the difference between the sexes, specifically, the woman’s lack of a penis, she develops a desire for a penis. This “penis envy” creates resentment toward the mother who has given her no penis and leads her to take her father as a love-object, inasmuch as he can offer her the symbolic equivalent of a penis: a baby.

The relative importance of the phallic phase, and especially of penis envy, a concept considered too phallocentric by some, has given rise to significant debates within the analytic movement.

Melanie Klein and a good number of other authors have postulated the existence of an early phase of female sexual development and, notably, related the vaginal sensations felt by the little girl as early as the second year of life to the development of orality and anality. This has led them to treat the phallic phase as nothing more than a secondary formation with a defensive function only. Thus penis envy, which Freud had placed at the center of his theory of female sexuality, was in Klein’s view (1975 [1957], pp. 199–200) merely a relatively late derivative of the primal wish for the breast and the counterpart of the male’s envious identification with the mother who bears children.

## PHALLIC WOMAN

The term *phallic woman* refers to the fantasmatic image of a woman (or mother) endowed with a phallus or a phallic attribute. It also refers to the fantasy of the woman (or the mother) retaining the phallus internally after coitus.

The expression “phallic mother” appeared in Freud’s work in 1933 in the *New Introductory Lectures on Psycho-Analysis*, in reference to Karl Abraham’s interpretation of the image of a spider. “According to Karl Abraham (1922),” Freud wrote, “a spider in dreams is a symbol of the mother, but the *phallic mother*” (1933a, p. 24). In fact, Abraham had not used the exact expression in 1922, but it could be inferred from what he wrote. Even though the term appeared quite late in Freud’s career, the idea itself was present a number of years earlier in Freud’s work.

In the essay on “Fetishism” (1927e), Freud returned to the idea that he had first advanced in 1910 in *Leonardo da Vinci and a Memory of His Childhood*. The small child believes that the woman (the mother) has a phallus and refuses to give up this belief. The “infantile hypothesis of the maternal phallus,” Freud argued, led to the dominant role that the young Leonardo gave to the vulture’s tail in his childhood fantasy (1910c,

p. 98). It also underlies the formation of a fetish, which is, according to Freud, a substitute for the maternal phallus, the absence of which is denied. The image of the phallic woman or mother is often found in dreams and fantasies, and also in mythology. This imaginary “form of the mother’s body” has its basis in the infantile theory of the maternal phallus and is maintained even after the recognition of the difference between the sexes.

The image of the phallic woman as Freud described it has only given rise to a few tentative elaborations, for example, those of Ruth Mack Brunswick (1940). But it should also be noted that since Felix Boehm brought attention to another version of the fantasy that came to light in his analyses of homosexuals (1926), the term “phallic woman” also refers to the fantasmatic image of a woman with an internal phallus, retained inside her body after coitus. In this version of the fantasy, the woman still “possesses” the phallus.

The notion of the phallic woman generally does not refer to the identification that a girl or woman has with either the maternal or male phallus, nor to the fantasy of possessing a phallus, on which the masculinity complex is founded. And even though women who present so-called masculine traits are often called “phallic,” this is not necessarily what is meant by the term “phallic woman (or mother).”

## **PHALLUS**

The term “phallus” designates the representation of an erect penis, which plays a key role both intra- and inter-subjectively. Freud barely distinguished between the fantasized phallus and the anatomical penis. He called the period between three and five years of age the “phallic stage.” At this stage, infants of both sexes are dominated by the question of who possesses a penis and the related issue of its masturbatory jouissance (gratification), which is clitoral in the case of girls. Up to this point, the mother is imagined as having a penis, and the discovery that she lacks a penis, after an initial denial, precipitates the castration complex.

Jacques Lacan chose to use the term “phallus” for the imaginary and symbolic representation of the penis in order to better distinguish the role of the penis in the fantasy life of both sexes from its anatomical role. Freud’s famous “symbolic equation” of breast, feces, penis, and baby (1916–1917a [1915–1917], 1918b, 1924d) already implied this distinction between the real penis and its phallic representations.

According to Lacan, the phallus at the outset represents what else the mother desires is in addition to the baby. Thus, a pre-oedipal triangle of mother, phallus, and infant arises. At first the infant tries to *be* the phallus for the mother until the moment of a crucial transformation when the child, after identifying the phallus as a static image of completeness and sufficiency, sees it as representing the mother’s desire, and thus her lack. From then on, the phallus takes the form of something missing ( $-\varphi$ ) within any imaginary, and hence libidinal, frame of reference. Thus the phallus comes to signify desire, Lacan says.

The intermittence of its erection, its ability to fade (compare Ernest Jones’s concept of aphanisis), and even the fact that half of all humans do not have it have made the erect penis eminently suited to symbolize the crucial issues of being (subject) and having (object) in both sexes. The penis constitutes the key element in the asymmetrical division that, according to Roman Jakobson, characterizes any symbolic system.

When the phallus takes on the role of signifier, this implies that the subject grasps it in the Other, the locus of the set of signifiers that determines the subject. There it signifies the Other’s desire, which is to say that the Other is marked by her own incompleteness. From then on, the phallus signifies the Other’s

submission to the laws of symbolic exchange, and such incompleteness frees up in the subject her own jouissance.

In his seminar on female sexuality (1998), Lacan further specified what he meant by the term “phallic jouissance.” He used the phallic signifier ( $\Phi$ ) in writing his “formulas of sexuation,” which posit that every human being has to be on one side or the other of the sexual divide. A woman always has something of the phallus (she is not entirely castrated), and the man is only supposed to “have” the phallus when he fantasizes his castration. In Lacan’s symbolic notation, the phallus takes on the formal role of a supplement, which adds to the castration complex the fact that “there is no sexual relation,” as Lacan said, referring to the impossibility of writing an equation of the relationship between the sexes.

## PHANTOM

In *The Shell and the Kernel*, published in 1978, Maria Torok and Nicolas Abraham attempted to provide a

revised metapsychological approach to their concept of the phantom. The work, which is presented as a collection of older or unpublished articles, is in fact the second volume of *Anasémies*, the first volume of which appeared in 1976 under the title *The Wolf Man’s Magic Word: A Cryptonomy*.

*Anasémies* is a relatively difficult theoretical-clinical work, “a psychoanalytic and transphenomenological space” with an important introduction by Jacques Derrida, “FORs: Les mots anglés de Nicolas Abraham et Maria Torok.” The work is one that signaled a fecund period of reflection about the processes of transgenerational transmission as they were initially addressed by psychoanalysts and later reconsidered by child psychoanalysts, especially from the point of view of so-called developmental psychoanalysis.

In the second volume of *Anasémies*, chapter four is devoted to the concept of the “crypt” and chapter six to the “work of the phantom in the unconscious and the law of ignorance.” The following lines appear at the head of the chapter: “The phantom is the work in the unconscious of the inadmissible secret of an Other (incest, crime, illegitimacy). Its law is the obligation of ignorance. Its manifestation, as anxiety, is the return of the phantom in bizarre words and acts and symptoms (phobic, obsessive, and so on). The phantom’s universe can be objectivized in fantastic stories. There then occurs a particular affect that Freud described as the ‘uncanny.’”

By reworking and somewhat demetaphorizing the concepts of incorporation, identification, crypt, and phantom, Abraham and Torok arrive at the following formulations: “The phantom is also a metapsychological fact. That is, it is not the dead that haunt us but the gaps left in us by the secrets of others. Although the phantom is not associated with the loss of an object, it could (therefore) be the result of a failed process of mourning . . . The phantom of popular belief merely objectivizes a metaphor that operates in the unconscious: the burial in the object of an inadmissible fact . . . The phantom is a formation of the unconscious, which is peculiar in the sense that it has never been conscious—and with good reason—and which results from the passage—whose mode remains to be determined—of the parent’s unconscious to the child’s unconscious . . . The phantom who returns to haunt is the witness of the existence of death buried in the other. . . . By extending our ideas about the phantom, we can see that, in all likelihood, the ‘phantom effect’

is attenuated during its transmission from one generation to another, ultimately extinguishing itself.”

These comments illustrate the drama of the “cryptophoric” subject and the dialectic that arises between incorporation and identification, to the extent that the fantasy of incorporation can play a role as a factor of identificatory refusal through the maintenance of the metapsychological status quo. Abraham and Torok’s *The Shell and the Kernel* concludes with a study of Hamlet’s ghost.

These essays are part of a line of research that has developed in France through the work of authors such as Alain de Mijolla, Haydée Faimberg, Jean-José Baranès, and Jean Cournot, who have assumed critical positions with respect to the theory of the phantom and suggested other approaches to so-called transgenerational phenomena. The work of Abraham and Torok was continued by Serge Tisseron, Didier Dumas, and Claude Nachin.

## **PHENOMENOLOGY AND PSYCHOANALYSIS**

The polysemous term “phenomenology” has been employed in philosophy since the late eighteenth cen-

tury and in psychiatry since the beginning of the twentieth. It is worth looking at its use in these two spheres before examining its relationship to psychoanalytic thought.

In philosophy, the word was introduced by the German Johann Heinrich Lambert as a designation for an empirical description of human experience devoid of all metaphysical presuppositions. This meaning is still current. Borrowing somewhat from the study of perception and from history, Hegel used the word in his *Phenomenology of Mind* (1931) to evoke the stages (consciousness, self-consciousness, reason) whereby human experience, after passing through the universal, appeared first as the experience of concrete singularity and then as the quest for the self-conscious subject. This quest, destined to fail, led humanity through the forms of stoicism, skepticism, and finally phrenology, for which the mind’s being in the world is literally a bone (the phrenologist Franz Joseph Gall claimed that bumps on the cranium corresponded to psychological functions). The dialectic of history, far from being imposed from without, manifested itself in and through this evolution of experience.

These two senses of “phenomenology” coexisted until 1913, when Edmund Husserl, in the first volume of his *Ideas: General Introduction to Pure Phenomenology* (1931), used the term to designate whatever clearly manifests itself after the problem of the existence of the world has been bracketed, in order to describe how the transcendent elements of the world, including other selves and cultural beings, appear in perception, in imagination, in memory, and as essences. Consciousness in this perspective is always consciousness of something, that is, intentionality; phenomenological description excludes introspection.

Husserl’s disciples were largely heterodox. In Germany, his descriptive method helped Martin Heidegger situate man’s existence as being for death, that is, as a derelict and inauthentic being in the world. Max Scheler, for his part, pressed Husserl’s phenomenology into service for his account of “the man of resentment.” In France, Maurice Merleau-Ponty used the term when discussing the incarnation of consciousness in the bodies of humans acting in history. Jean-Paul Sartre, in *The Psychology of Imagination* (1948), argued that consciousness does not present the subject to himself, and that one’s ego is an inhabitant of the world, on a par with the ego of the other.

In psychiatry, there is a similar dichotomy with respect to the use of “phenomenology.” For Karl Jaspers, the word meant the subjective aspect of clinical psychiatric practice, and he proposed a distinction between knowing (*erklären*) and understanding (*verstehen*), according to which knowing implied an objective and natural knowledge, whereas understanding referred to an intuitive feeling. Jaspers regarded the failure of such spontaneous understanding as the distinguishing mark of psychosis, thus incorporating a notion of process in his view of the disorder. Jaspers’s usage was quickly and widely adopted in Anglo-American psychiatry, where “phenomenology” tends to mean simply the lived experience of patients.

Another psychiatric acceptance, just as important, derives explicitly from Husserl and Heidegger. In German-language psychiatry, Viktor von Gebsattel, Erwin Straus, especially Ludwig Binswanger, and later Roland Kuhn and Wolfgang Blankenburg, despite their considerable divergences, were all concerned to show how each basic type of psychopathology corresponded to a particular mode of being in the world (Heidegger), or a particular mode of the transcendental ego (Husserl). *Daseinsanalyse* (being-in-the-world analysis) as a therapeutic technique belonged to this tendency.

Within French psychiatry too there were distinct positions with respect to phenomenology. Eugène Minkowski meticulously showed how various basic pathological situations expressed specific alterations in the subject’s relationships to time and space. Minkowski also recognized the part played by subjective impressions of the clinician in arriving at a diagnosis. Henri Ey built on phenomenology and existentialism in seeking to transcend clinical empiricism and arrive at an organic-dynamic synthesis and a conception of psychiatry as a pathology of freedom.

It is arguable that phenomenology should be expected not to furnish psychiatry with yet one more theory, but rather to describe the conditions that make psychiatry possible and to clarify the place and the roles of psychiatric knowledge without, however, reducing such knowledge to phenomenology.”

The relations between phenomenological attitudes and psychoanalysis, which are neither simple nor schematic, may be viewed from various angles. To begin with, for phenomenology, the existence of the unconscious is far from a central concern, as some in psychoanalysis have asserted. After all, as we have seen, con-

sciousness for phenomenology is defined in terms of intentionality, and introspection is barred as a source of knowledge. Also, if, as Sartre contends, the subject truly exists in the world in the phenomenological sense, and if the ego is not immanent, the phenomenological view (though it cannot speak of “the unconscious”) can acknowledge that the subject escapes his own grasp—a postulate readily embraced as early as the work of Hegel. The charge that the unconscious is reified in this context need not be taken seriously.

Phenomenological knowledge, being essentially descriptive, is hard put to achieve any clear standing within an economic perspective, the perspective of metapsychology. This is a very significant divergence between phenomenology and psychoanalysis.

Though they hail from cultural realms far removed from one another, psychoanalysis and phenomenology may be said to have at least one thing in common: neither is a humanist theory. Neither admits any assumptions prior to what is shown by clinical experience or phenomenological reduction; neither posits a priori that humanity is the measure, good or bad, of all things; neither in advance gives humanity sovereignty over itself; and both can acknowledge the role of conflicts and of seeking to avoid conflicts.

## PHILIPPINES

The U.S. dominance of the university educational system in the Philippines in the early decades of the twentieth century meant that Filipino doctors looked to that country for its medical models. Several physicians studied in the United States and imbibed psychoanalytic theory from the American tradition.

One of the first was Virgilio Santiago, who completed his medical training at the University of Santo Tomas in the Philippines in 1949. This medical training led him to psychoanalytic training under Robert Waelder, a student of Freud's. He then went on to study at the Menninger Clinic in Topeka, Kansas. This was an unusual route to follow, since most psychiatrists were trained in the dominant organic school of psychiatry. In the 1950s psychoanalysis was strictly forbidden by the conservative Catholic clergy. Santiago was also discouraged by his colleagues from pursuing the field. Nonetheless, in a private practice he found a clientele among the expatriate population, and a small minority of Filipinos suffering from psychosis also consulted him. Santiago's general criticisms of the poor quality of Filipino health care suggest that the average Filipino was unsuited to psychoanalysis (Santiago, 1966).

Two other early pioneers were Baltazar Reyes and Rudolfo Varias. Reyes graduated from the University of the Philippines and then did postgraduate training at the Langley Porter Institute in California before returning to the Philippines to teach and research. Varias trained in classic psychoanalysis in New York. He returned to teach at the institute of public hygiene (now the College of Public Health). In the 1970s he

returned to New York. His departure meant no further development of psychoanalytic psychotherapy at that time.

Not until the end of the 1960s, with the appearance of Lourdes Lapuz's *A Study of Psychopathology* (1969), was orthodox psychoanalytic theory again taken seriously. This groundbreaking book influenced a whole generation of psychiatrists, psychologists, and counselors, who remodeled the original psychoanalytic theory in which they had been instructed to suit the Filipino cultural mold. As in other Asian cultures, people's social and cultural expectations led them to view the doctor as an authority figure, and this required a more interactive role of the analyst. This book was followed by *Children of Oedipus* (Lapuz, 1973), which deals more fully with these issues. In her succeeding works she dealt with marital counseling and couple and family therapy (Lapuz, 1979).

In spite of these developments, however, the modern mental-health system remains poorly understood in the Philippines because of the low level of medical awareness of the population and the prevalence of alternatives to modern medicine, be they indigenous forms of herbal healing or even cult healing practices. These factors, coupled with a poor health-insurance system and a social need for gainful employment, have reduced the need for formal institutes of psychoanalysis and explain why the Philippines at the moment has no training analysts practicing psychoanalysis. Freud's work has not made a big impact in this predominately Catholic culture, where even today, teaching human sexuality from the point of view of psychology has not gained much ground in the academic world. Sex education consists largely of lectures on population control.

## PHILIPPSON BIBLE

Sigmund Freud's father Jakob Freud (1815–96) came from a Hassidic community in Tysmenitza, in Galicia. He familiarized his son Sigmund, from age seven, with Ludwig Philippson's Hebrew Bible, in a richly illustrated, bilingual Hebrew-German edition.

In all probability, he had acquired the second edition, published in 1858, at the establishment of Baumgärtner, a bookseller in Leipzig, during the family's trip from Freiberg to Vienna with little Sigismund, then three years old. Jakob inscribed in this Bible the date of the death of his own father, Schlomo, along with the following: "My son Sigmund Schlomo was born on Tuesday, the first day of Iar 616 at 6:30 in the afternoon, or 6 May 1856. He entered into the Jewish Covenant on Tuesday 8 Iar, or 13 May 1856. The Mohel was Rabbi Samson Frankl."

Jakob Freud had this Bible rebound in leather in 1891 and gave it to Sigmund for his thirty-fifth birthday with a dedication, written in Hebrew characters, that is a mosaic of sentences excerpted from the Bible, the Talmud, and the Jewish liturgy, showing that he was a learned Jew and an expert in biblical reading. According to a study by Yosef Hayim Yerushalmi, the heritage this dedication holds is a coded message from the father, seventy-seven years old at the time, advocating a return to the Bible as a source of creative inspiration. There is some discord between, on the one hand, the knowledge and meaning evident in the dedication, which display a biblical spirit; and on the other the rationalist tenor of the Philippson Bible, which is infused with the spirit of the Enlightenment, even if the Hebrew text itself, bears a traditional orientation. Freud himself, in a 1935 addendum to "An Autobiographical Study" (1925 [1924]), revealed the impact this early reading had on him: "My deep engrossment in the Bible story (almost as soon as I had learnt the art of reading) had, as I recognized much later, an enduring effect upon the direction of my interest." (p. 8).

The critique of religion elaborated in Freud's scientific writings originated in his youth, but his affirmations relating to his Jewish identity and his belonging to the Jewish people are an integral part of his life story, from his earliest years to his last days.

## PHILOSOPHY AND PSYCHOANALYSIS

The relations between psychoanalysis and philosophy are close, complex, and full of conflict. Freud, Lacan, and a few other writers assuming a psychoanalytic viewpoint persistently situated themselves in relation to philosophy, making use of it and explaining psychoanalytic terms by reference to it. For their part, philosophers have regarded psychoanalysis with a mixture of fascination and suspicion, and have subordinated it to the needs and objectives of philosophy, which has allowed them to contest or reject it.

The meaning and scope of Freudian enquiry have been evaluated differently by the two disciplines. For Freud, philosophy has repeatedly been concerned with the question of the unconscious. Indeed, thinkers before Freud have posited the unconscious. In the philosophic tradition, however, either the unconscious is mystic and impossible to grasp, so that its relation to the psyche remained buried in obscurity (Eduard von Hartmann and the Romantics), or the psyche was identified with consciousness (René Descartes, Franz Brentano), with the result that psychological investigation overlooked the unconscious. These philosophers misunderstood unconscious mental activity. They did not suspect to what extent unconscious "phenomena" (primary and secondary processes, the processes of the id and the ego) were similar to and yet different from conscious phenomena.

Freud exposed the paradox of the philosopher, caught between the wish for a totalizing and unifying vision and the need to put an individual stamp on his work. Freud believed that psychoanalysis could expose the subjective and individual motivations behind philosophical doctrines that claimed to result from an impartial effort of logic (see his derivation of systems from two sources in *Totem and Taboo* [1912–1913a]). Psychoanalysis can also demonstrate the weak points of a philosophical system. There is a link among these two findings, the singular focus of philosophy on “conscious awareness,” and the uncovering of philosophical paradox. To acknowledge unconscious processes is to recognize the impossibility of any pure transparent knowledge of the world and of thought to itself. Less negatively, on the interpretation of art proposed by Freud, philosophy could be considered an intellectual work of art.

Nonetheless, Freud maintained that psychoanalysis is a natural science with a specific object. For it has an empirical content that is experienced in everyday psychic phenomena and in analysis and that is manifested in ways governed by a determined protocol: unconscious mental processes, infantile sexuality and the Oedipal structure, transference, resistance, and repression. This same content can be grasped a posteriori in fundamental concepts and coordinated in a theory that Freud called “metapsychology.” As distinct from biology and psychology, metapsychology refers to a psychology that runs up against the unconscious. Freud did not hesitate to apply such conceptions to Immanuel Kant’s thought by suggesting, for example, that the superego is the metapsychological version of the categorical imperative. As for the death instinct, Freud noted the differences but also the proximity of his concept with that of Arthur Schopenhauer.

Yet psychoanalysis wanted to go further. It seeks to “translate metaphysics into metapsychology,” that is, not only to capture the subjective motivation of a philosopher but to propose a global interpretation of mental life, one of the most fundamental aspects of philosophy. For psychoanalysis, the mental process takes place in three stages: “endopsychic perceptions,” including unconscious psychic phenomena, supply an “obscure awareness”; this is objectified by projection onto the outside world and is reflected in the construction of a supersensible world; finally, metapsychology translates this supersensible metaphysical world into a psychology that takes unconscious processes into account (Assoun, 1976).

At the same time, Freud downplayed his knowledge of philosophers, especially Friedrich Nietzsche—whether from fear of being dispossessed of his discovery or from real ignorance, it is difficult to say, especially given the ambiguous link that connects Freud to philosophy and science. Freud, who was initially very interested in philosophical thought (1985), attempted to reconcile in metapsychology (which he called “the metapsychological sorceress”) his enthusiasm for speculation and the requirements of scientific practice.

It must be pointed out that Freud never contested the primacy of consciousness. For although the unconscious is located at the juncture of the psyche and the body, it is inaccessible via the body. Therefore, it must be approached by the only avenue left open to us: consciousness. It is through the data of consciousness, and principally language, that we are able to infer unconscious processes.

Throughout his life, the French psychoanalyst Jacques Lacan always engaged with philosophy and philosophers. The landscape and aims of psychoanalysis have changed since Freud, but a secret heritage remains. Lacan could rightly claim, “What I tried to do with my Borromean knot is nothing less than the first philosophy that seemed likely to me to hang together.” He referred to philosophy as an “irreparably mistaken path,” against which psychoanalysis affirms its belief in the unconscious. But his differences from Freud are considerable. Lacan’s originality can be traced, at least partially, to his unique learning. He was grounded in contemporary philosophy and possessed an understanding of modern science, especially linguistics, mathematics, mathematical logic, information theory, and game theory. Such science, profoundly connected to the nominalist current that appeared in European philosophy in the fourteenth century (William of Ockham) and was extended by Descartes and Gottfried Wilhelm Leibniz, tends to separate the sign from the referent, or signified, and to emphasize the value of the signifier. Even though he profoundly distorts the meaning of the concepts he borrows from philosophy and science, Lacan can be understood only if the origin of those concepts is properly situated: the concept of the signifier arose in linguistics and nominalist thought, that of the real in its opposition to the world arose from Martin Heidegger’s concept of being-in-the-world (*Dasein*), that of the other and the big Other (the primary caregiver) arose in reference to the work of Georg Wilhelm

Friedrich Hegel. Also important is philosophical thinking on alterity (otherness) in general (from Plato to Hegel and Emmanuel Levinas [1906–1995]).

Indeed, it is difficult to talk about desire (a concept foreign to Freud) without recalling the discourse of master and slave, about the subject without reference to Descartes, or about the thing without reference to Heidegger's or Kant's notion of the thing-in-itself. But aside from his concepts, Lacan's project, although not metapsychological, is to form a distinct psychoanalytic discourse that diverges from university discourse, to which philosophical discourse is assimilated (see Lacan's theory of the four discourses [1991]). Through the construction and study of Borromean knots, Lacan felt he was able to achieve what Freud had foretold: "There is a place beyond the Oedipal complex, where we enter into the reality test and where we experience a *jouissance* [enjoyment] beyond the pleasure principle." Lacan felt he had written the much sought-after philosophical discourse—a discourse that possessed, if not scientific rigor, at least philosophical rigor (Juranville, 1984).

We again face the ambiguity confronted at the start: the nature of the subject. Here the point of disagreement between philosophy and psychoanalysis has to do with the subject that engages in these discourses: even if the subject of the unconscious is the Cartesian subject (philosophical discourse), that subject, as conceived by Lacan, has been divided, separated, and split (psychoanalytic discourse). Lacan's relation to philosophy is original and singularly complex. It is impossible to adjust to the needs of psychoanalysis the logic of the signifier (for which Lacan's use of Borromean knots is the ultimate extension) and Freud's discovery of the unconscious without a misappropriation of philosophy, principally Descartes's "Cogito, ergo sum" (I think; therefore I am) (Lacoue-Labarthe & Nancy, 1992).

Psychoanalysis always appears to the philosopher as a source of the uncanny, which is difficult to integrate in rational thinking. How can one practice philosophy after Freud? asked Monique Schneider (1989). There has been a dizzying array of responses to this question; here it will suffice to sketch a few of the main arguments. The point of view generally adopted is that of the unconscious, which naturally cannot be introduced without placing limits on the question. Marxists (Georges Politzer, Herbert Marcuse), phenomenologists (Eugen Fink, Jean-Paul Sartre, Maurice Merleau-Ponty),

hermeneuticians (Paul Ricoeur), philosophers of the 1960s (Gilles Deleuze, Jean-François Lyotard, Jacques Derrida, Michel Henry), Ludwig Wittgenstein and his commentators (Jacques Bouveresse), philosophers of science (Karl Popper, Adolf Grünbaum), analytic philosophers (in France, Pascal Engel, Centre de recherche en épistémologie appliquée [Center for Research in Applied Epistemology]) have all developed a discourse on psychoanalysis and the unconscious. Some of their criticism is directed at the scientific status of psychoanalysis, which is violently rejected by Popper, Grünbaum, and Bouveresse. Others, such as Ricoeur, felt they could demonstrate its validity by treating it as a form of hermeneutics. Marcuse saw psychoanalysis as an instrument of sexual liberation. Deleuze saw it as an instrument of destruction: "In opposition to psychoanalysis I have claimed only two things: it breaks everything produced by desire, it crushes every utterance. By doing so it shatters both sides of the arrangement: the mechanistic articulation of desire and the collective articulation of utterance." Lyotard made brilliant use of the concepts developed by Freud in *The Interpretation of Dreams* (1900a) to construct an aesthetic philosophy. Others, like Henry in *Généalogie de la psychanalyse* (1985) or Jean-Marie Vaysse in *L'inconscient des modernes* (1999), attempt to demonstrate how Freud's thought derived from Descartes "Cogito, ergo sum," as it did for Benedict de Spinoza, Leibniz, Schopenhauer, and Nietzsche. Jacques Derrida is a separate case. Even though, like his predecessors, he feels that only his principal concepts (here *différence* [difference], *archi-écriture* [original writing], deconstruction) are capable of addressing the arguments of psychoanalysis, among philosophers he remains, together with Lyotard, one of the most knowledgeable about psychoanalysis and, since the 1970s, one of the most engaged with psychoanalysis.

The difficult relations between philosophy and psychoanalysis arise primarily from the fact that both investigate the same field, human experience (including sexuality, life, death, suffering, relations with the world in culture and work) but operate within this field according to opposite principles, consciousness in the case of philosophy and the unconscious in the case of psychoanalysis. The unconscious is expressed in everyday life but is especially present during analysis, where transference and resistance occur. Except for Derrida (1987; 1998), most authors do not really consider the reality of transference and its paradoxical nature. One thing is certain, however. A dialogue with philosophy and epistemology will enable psychoanalysis to better

understand its ambiguous status, which falls somewhere between science and fiction.

## **PHOBIA OF COMMITTING IMPULSIVE ACTS**

A phobia of impulsive acts is the fear of a sudden desire to commit an auto- or heteroaggressive act. This sudden desire is accompanied by anxiety stemming from a neurotic disorder within the sexual economy. Two types are generally described: defenestration phobias and phobias of knives; impulsive phobias of a sexual nature have also been described. The aggressive valence and symbolic nature of such phobias are obviously in the foreground.

In psychiatry, the term *phobia of impulsive acts* appeared at the end of the nineteenth century, in the midst of a catalog of more than two hundred phobias. Initially, phobias were not greatly differentiated from obsessive ideas. Philippe Pinel described “manias without delusions”; Jean-Étienne Esquirol placed them within the “monomanias” along with the notion of “obsessive fears.” The notion of phobia per se appeared only in 1871, with agoraphobia (Karl Westphal). At the beginning of the twentieth century, phobias, still largely undifferentiated from obsessions, were thought to arise from hyperemotivity. In *Les Obsessions et les Impulsions* (Obsessions and impulses; 1902), Albert Pitres and Etienne Régis emphasized the fact that any phobia can become obsessive and placed these phobias of impulsive acts in the category “obsessions-impulses.” The similarity between phobia and obsessional neurosis was pursued by Emil Kraepelin and Pierre Janet. Sigmund Freud, too, through his clinical examples, gave the impression of placing them alongside obsessional manifestations.

The syndrome of the phobia of impulsive acts is situated between hysterical anxiety and the modes of obsessive organization. The most frequent forms are defenestration phobia (“I’m afraid of wanting to throw myself out of the window”) and phobias of knives. The phobic subject consciously fears what he

unconsciously desires; he perceives his desires as being alien to himself. Sometimes it is objects that become phobogenic, dangerous, and to be avoided at all costs (“I’m afraid of hurting my child with a knife”). These phobias generate anxiety because they stage fantasies of narcissistic fusion with the forbidden oedipal object. If the primary object brings security, why not throw oneself into its arms, enter into it? If it is oedipal, sexually desirable, why not become one with it? (Bayle, Gérard, 1997). The failure of repression cannot mask feelings of ambivalence; defenses are formed against loss of identity and the threat of castration. But in contrast to simple phobias, the subjects of the phobia of impulsive acts fear actions coming from themselves. They feel inadequately protected against their own impulses, and to defend themselves, resort to avoidance tactics that use a protective third party, enabling them to bolster their weakened narcissism. In “Contribution à l’étude des phobies” (Contribution to the study of phobias; 1956), Jean Mallet showed that a perceived absence of parental protection is an essential component in the choice of phobia.

Phobias of impulsive actions are to be considered not so much a symptom as an element to be situated in relation to the structure, history, and fantasies of the subject. Their outcomes are variable, depending on whether they involve an oedipal conflict or issues that are more narcissistic in nature. The conflict of ambivalence is always present, and obsessions will appear if anxiety and aggression overpower the ego’s phobic defenses. Moreover, a phobia of obsessive acts may appear prior to a psychotic decompensation.

## **PHOBIAS IN CHILDREN**

A phobia (from the Greek *phobos*: “flight, fear, fright”) is an irrational fear aroused by an object, situation, or activity that does not involve real danger. Anxiety, the irrationality of which is generally consciously recognized by the person, results in various defensive strategies: flight, avoidance, or the use of an object or person that enables the subject to face the feared situation.

The term first appeared in the psychiatric literature of the late nineteenth century (Karl Westphal, in 1872, cited agoraphobia); French psychiatrists around the same time (Albert Pitres and Emmanuel Régis) described a very large number of phobias in terms of the triggering object or situation (claustrophobia, erythrophobia, zoophobia, etc.).

Pierre Janet, who linked phobic symptoms to psychasthenia, divided phobias into three categories that remain in use: object phobias, situation phobias, and function phobias. Object phobias involve pointed or cutting objects (scissors, knives, razor blades) associated with auto- or heteroaggressive fantasies that may take the form of phobias of impulsive acts and that are often integrated into obsessional neurosis. Similar to these are phobias of animals, which are very frequent in children but can continue into adulthood (fear of spiders, mice, snakes, birds, etc.).

Situation phobias involve open spaces (agoraphobia), enclosed spaces (claustrophobia), or high places (vertigo). In function phobias, manifest anxiety bears upon the functioning of the organism: fear of falling asleep or of swallowing. Similar to these are the fear of diseases (nosophobia) and social phobias: fear of speaking or blushing in public (erythrophobia), and phobias of touching or contact.

The term *pantophobia* is sometimes used to describe a diffuse anxiety aroused by several objects or

situations, but the absence of specific conditions for the emergence of anxiety makes the inclusion of such cases in the framework of the phobias questionable. Certain phobic behaviors can be likened to the rituals seen with obsessional neurosis (mixed, so-called phobo-obsessional forms).

The clinical study of phobias would be incomplete if it did not consider the behaviors that the person uses to fight against the anxiety associated with the phobogenic object. These behaviors derive from two types of defensive strategy: avoidance and reassurance. Avoidance can be expressed in maneuvers to flee or bypass the phobogenic situation or through varying degrees of restriction in the subject's activities. Reassurance enlists a person or object that makes it possible to face the phobogenic situation.

The understanding of phobias is one of the very earliest topics to engage Sigmund Freud's theoretical reflection, as early as 1894–1895. One of his first articles on this theme, "Obsessions and Phobias: Their Psychological Mechanism and Their Aetiology" (1895c [1894]), originally published in French, discussed Janet's conceptions and clearly separated phobias from obsessions: in particular, the relation to anxiety is specific to phobias. In these early works, Freud considered the phobias as a form of anxiety neurosis, which he classed among the "actual" or defense neuroses and whose etiology he explained in terms of an accumulation of endogenous excitation, "a veritable self-intoxication, by means of a sort of engorgement of the sexual substances."

In his later writings, he linked phobias to hysterical anxiety and thus to the transference neuroses that are accessible to analysis. In hysterical anxiety, the libido is unleashed in the form of anxiety and not converted as would normally happen in hysteria. Repression bears upon an instinctual impulse with projection onto an object; anxiety cannot be totally avoided except at the cost, as Freud noted, of "all sorts of inhibitions and restrictions" to which the person must submit him- or herself.

Freud developed his notion of the formation of phobias in the case of Little Hans, related in "Analysis of a Phobia in a Five-Year-Old Boy" (1909b), and in his return to that case in that of the Wolf Man in "Inhibitions, Symptoms and Anxiety" (1926 [1925]). The symptom results from mental work that aims to "fix once again the anxiety that has become free."

Freud showed how Little Hans's phobia of the horse staged the representation of the threat of castration by the father figure. At the same time, through the motor inhibition it entailed in the child, the phobia realized a compromise between the incestuous desires directed toward the maternal object and their repression (prevented by his phobia from going out, the boy could remain near his mother). Repression affects the totality of the components of the Oedipus complex.

Returning to this case in 1926, while maintaining the central role of castration anxiety, Freud placed greater emphasis on the repression of parricidal fantasies, as well as on the passive homosexual fantasy of the father figure. The phobia could be understood as an attempt to resolve the conflict of ambivalence: Little Hans's symptom was a compromise between love and hostility for the father. The displacement onto another object of the anxiety that results from a conflict of ambivalence protects the ego from instinctual danger. In this work Freud underscored the reversal that analysis of the formation of phobias had compelled him to make in his theory of anxiety: It is anxiety that is at the origin of repression, and not the reverse.

In the subsequent development of psychoanalysis, phobias in children have incited numerous theoretical debates. Anna Freud and her followers differentiated between phobias and the archaic fears that preexist all earlier experiences (fear of the dark, of storms, etc.). For these authors, these infantile fears, merely an expression of the ego's immaturity, were not phobias in the strict sense, in that they did not bring together condensation, projection, and symbolization. However, they considered such fears to be the precursors to phobias. These authors believed that was not possible to speak in terms of a neurotic organization before conflicts had been internalized at the end of the Oedipus complex.

According to Melanie Klein, the primitive Ego is subjected to experiences of intense anxiety. Phobia corresponds to the projection of the death instinct onto external objects; it comes about in relation to the forming of object relations and the emergence of a terrifying, archaic superego that is identified with the paternal penis. This destructiveness, projected onto the introjected parents, constitutes the internal threat that is the source of phobias. Archaic anxiety produces fantasies of being devoured; phobias of animals, especially, represent the fear of being devoured by the superego. However, the phobia also expresses a sadistic

destructiveness that is linked to aggression directed toward the paternal imago; the violence of this destructive impulse is the source for massive anxiety that, in turn, becomes a source of persecution.

In 1956–1957 Jacques Lacan introduced the notion of the phobic signifier, the equivalent of the paternal metaphor that makes it possible to symbolize the Real of phallic *jouissance*. The phobogenic object masks the subject's fundamental anxiety and comes to occupy an intermediate position between the phallic signifier and an appeal to the Name-of-the-Father. Whereas the fetish object, in perversion, is the absolute condition for *jouissance*, the function of the phobic signifier is to protect the subject from the disappearance of desire.

Although castration anxiety does indeed appear to be central in phobias, the affect that characterizes it seems to originate in the experience of separation. The absence of the mother, in the preverbal infant's situation of helplessness and distress (*Hilflosigkeit*), creates the traumatic conditions for terror (*Schreck*). The defensive mechanisms put into place to cope with this can be seen as the precursors to the organizing mechanisms of phobia. According to Annie Birraux in *Éloge de la phobie* (In praise of phobia, 1994), phobia is “a primitive structure of thought”: Projection, one of its fundamental mechanisms, is to be linked to the primitive movement of expulsion that Freud, in “Negation” (1925h), placed at the origins of the coming into being of the subject and the activity of thought.

From a clinical viewpoint, Jean Mallet, in “Contribution à l'étude des phobies” (Contribution to the study of phobias, 1956), described the development of phobias in children as a function of age. He showed the continuity between the child's archaic fears and the phobias proper of the oedipal period. The prototype of phobia can be seen at around eight months in the child's negative reaction to the approach of a stranger; according to René Spitz, this reaction expresses the child's accession to a total object relation and thus to the experience of separation. This issue becomes the basis for the organization of the fears and phobias (or prephobias, according to some authors) of the pregenital period.

Anxieties often manifest during sleep or at bedtime: fear and refusal to go to bed (the transitional object can be considered as a precursor to the counterphobic object), or nightmares, which Mallet linked to night

terrors. Around the age of two, dream imagery takes the form of large animals that can bite or devour, and which translate fantasies related to orality—the source, according to Mallet, of the phobias of large animals that often occur around this age. Later, the shift toward phobias of small animals—a source of repulsion rather than fear, and with which the child avoids visual or tactile contact—coincides with entrance into the genital stage. These phobias can be understood as an expression of the prohibition against the voyeuristic impulses and touching, and more generally against sexual curiosity.

School is one of the main places where phobic manifestations occur. While some intellectual inhibitions can be related to castration anxiety and oedipal issues, most anxiety disorders centering on school are connected to difficulties of separation, whether in the form of transitory—although sometimes extremely intense—reactions against the early experience of being in school, or more serious and persistent phobias relating to school. Serge Lebovici has emphasized that serious school phobias appearing later in life (in preadolescence or adolescence) are often congruent with a prepsychotic organization. This underscores the heterogeneous nature of phobic manifestations in children and the need for a psychopathological evaluation of the developmental and structural context in which these manifestations emerge.

## PHOBIC NEUROSIS

Phobic neurosis, referred to by Sigmund Freud as “anxiety hysteria,” is characterized by anxiety focusing on certain external objects, be they things, persons, or situations. It is essentially a castration anxiety caused by an oedipal scenario. This distinguishes phobic neurosis from other, less serious situations. Beginning with “The Neuro-Psychoses of Defence” (1894a), Freud gave a fairly clear definition of the phobias, which he connected, in part, to hysteria, and which he distinguished from obsessions. In contrast to the so-called “actual” neuroses, which have a contemporaneous sexual dysfunction in their etiologies, he related obsessions and hysterias to an intrapsychic conflict with roots in childhood sexual history. In the case of an obsession, the sexual idea is later divorced from the corresponding affect; in the case of “hysterophobia,” the sexual idea, because of repression, disappears from consciousness only to reappear in the form of anxiety linked to another idea. The sexual idea is maintained with the earlier one by means of surreptitious links, which psychoanalysis can reveal.

This first theory of anxiety, which Freud developed in the context of the first topography between 1895 and 1900, is, as Jean Laplanche pointed out (1980), an economic theory. In “Analysis of a Phobia in a Five-Year-Old Boy” (1909b), Freud stated that Little Hans’s phobia corresponded to a repressed libidinal longing and emphasized the irreversible character of this transformation. Even if the longing could later be satisfied, it “can no longer be completely retransformed into libido; there is something that keeps the libido back under repression” (p. 26). In an attempt to clarify this imprecise understanding, Freud, after elaborating the second topography and returning to his reading of the case of little Hans in “Inhibitions, Symptoms, and Anxiety” (1926d [1925]), reversed his earlier formulation: “The anxiety felt in phobias is an ego anxiety and arises in the ego, and ... it does not proceed out of repression but,

on the contrary, sets repression in motion” (p. 110). As to the origin of this anxiety, Freud concluded with a “Non liquet!” (“It is unclear”).

Melanie Klein further developed this line of thinking in light of the death instinct hypothesized by Freud in 1920. As Hanna Segal wrote in 1979, “For her part, Melanie Klein believes that anxiety is a direct response to the internal work of the death instinct.” The phobic defenses are erected against unconscious fantasies, which are linked to the death instinct, in an attempt to control the external objects; this attempt is proportional with other attempts to exercise omnipotent obsessive control over internal objects. Even a succinct discussion of the place of these concepts in Klein’s metapsychology would require developing other ideas, notably those connected with the hypothesis of the internalization of an early archaic superego. Klein’s case study of “Richard” illustrates this problem.

The category of phobic neurosis, under the heading “phobic anxiety disorders,” appears in the World Health Organization’s *Classification of Mental and Behavioural Disorders*, in *International Classification of Diseases (ICD-10)*, in a purely descriptive and behavioral formulation. Because of the polymorphism of phobias, this category brings with it a marked risk of imprecise diagnoses. By contrast, the *Classification française des troubles mentaux de l'enfant et de l'adolescent* (French classification of childhood and adolescent mental disorders, Roger Misès), appears to maintain clear distinctions among the different phobic symptomatologies and the related neurotic structures.

The existence of such a “neurotic phobic structure” has been contested by some authors, notably Jean Bergeret. On another level, Jacques Lacan, in his seminar on object relations (1994) based on the case of Little Hans, introduced the notion of the phobic signifier. This reflection led him to reject the idea of a “phobic structure” in favor of a conception that made phobia a crucial moment that can be turned into hysteria, obsession, or perversion.

René Spitz’s work on the “fear of strangers” as the “second organizer” in babies was also carried out from a perspective marginal to the current of thought supporting neurotic structures. In the 1990s there was an inquiry into metapsychologically extending the concept of the phobic to adolescents, as well as an inquiry into whether phobias are a primal structure (Birraux).

## PHYLOGENESIS

Freud used the term *phylogenesis* to encompass the process of human evolution from its earliest origins. He hypothesized that individual development (ontogenesis) repeats the main stages of evolution, with the

traumatic events in the history of humanity thus reappearing and having a structural influence on the individual. This would explain the universality of primal fantasies, the Oedipus complex, and, more globally, a general outline for the development and functioning of the human psychical apparatus (or psyche).

The idea owes much to Darwin, whom Freud admired from adolescence onward: “The theories of Darwin, which were then of topical interest, strongly attracted me, for they held out hopes of an extraordinary advance in our understanding of the world,” he wrote in “An Autobiographical Study” (1925d [1924], p. 8). The idea appeared with a reference to Darwin in *Studies on Hysteria* (1895d, p. 181) in which, while discussing the symptoms of Elisabeth von R., Freud comments that they “belong to the field of ‘The Expression of the Emotions,’ which, as Darwin has taught us, consists of actions which originally had a meaning” (“originally” here refers to the history of the species) but, Freud adds, civilization has reduced and transposed these expressions symbolically in language.

Freud had already begun reckoning with the axis of time in his early research on the pathways of nerve conduction. He continued to do so in his study of aphasia (where the influence of Hughlings Jackson is notable) and so he quite naturally placed it at the heart of psychoanalysis, in accordance with two axes that he claims to be complementary, ontogenesis and phylogenesis. For Freud, the ontogenetic explanation takes precedence, but reference to phylogenesis may be used to support it, albeit cautiously: “I regard it as a methodological error to seize on a phylogenetic explanation before the ontogenetic possibilities have been exhausted” (1918b [1914], p. 97).

In spite of this reservation, Freud made great use of Haeckel's hypothesis whereby “ontogenesis recapitulates phylogenesis,” and it is worth bearing in mind that his mentor, Carl Klaus, was a fervent disciple of Haeckel. Freud is very explicit in this regard: “Impressive analogies from biology have prepared us to find that the individual's mental development repeats the course of human development in an abbreviated form” (1910c, p. 97), and again (1913f).

Freud made frequent references to phylogenesis in his writings, but it is of central importance in two of them, in which he attempts to paint a vast picture that brings together both the history of the individual and that of humanity in general. In *Totem and Taboo* (1912–13a), which Freud based “upon a hypothesis of

Charles Darwin's upon the social state of primitive men": like apes "men, too, originally lived in comparatively small groups or hordes within which the jealousy of the oldest and strongest male prevented sexual promiscuity" (p. 125). Every human being retains a trace of this domination, which was broken when the sons killed the father: this is the Oedipus complex. And in *A Phylogenetic Phantasy: Overview of the Transference Neuroses* (1985 [1915]), Freud created a sweeping fresco in which he tried to coordinate three stories marked by three temporalities: that of a postulated succession of psychopathological states, that of ontogenesis, and that of phylogenesis (Perron, 1994). In this attempt, conducted jointly with Ferenczi, Freud was in fact more Lamarckian than Darwinian in spite of the discredit that came to bear on Lamarck in the scientific world at the time. Lamarckism informs many passages of his work: in fact, in order to support his hypotheses it was important to believe that individual acquisitions could be preserved and passed on from generation to generation. He often returned to this: "The phylogenetically inherited schemata [...] are precipitates from the history of human civilization [...] This instinctive factor would then be the nucleus of the unconscious" (1918b [1914], pp. 119–120), and again: "Affective states have become incorporated in the mind as precipitates of primaeval traumatic experiences, and when a similar situation occurs they are revived like mnemonic symbols" (1926d, p. 93).

Freud's positions here have received intense criticism for several reasons:

- A certain assimilation of prehistoric man with contemporary "primitive" man and with children, in vogue at the beginning of the twentieth century, is no longer acceptable;
- The "social Darwinism" from which it derives, even if it were based on Darwin's own propositions, has since seen such detestable developments that we are bound to distrust it;
- Most contemporary specialists refute the ethnological and anthropological bases for *Totem and Taboo*;
- Haeckel's hypothesis, which is only very approximately valid in terms of anatomy and physiology, cannot be transposed to behavior, culture, or psychic function without running great risks;
- On his own admission, Freud had recourse to the phylogenetic explanation only when the ontoge-

netic comprehension ran up against the "biological bedrock." When he writes, "All that we find in the prehistory of neuroses is that a child catches hold of this phylogenetic experience where his own experience fails him. He fills in the gaps in individual truth with prehistoric truth" (1918b, p. 97), it is tempting to parody him by saying: "The history of Freudian thought shows that Freud had recourse to the phylogenetic explanation only when the ontogenetic comprehension ran up against the inexplicable. He filled in the gaps in his construction of individual history with prehistoric elements";

- It is important to bear in mind that Freud used the word "phylogenetic" to designate the successive stages in human civilization (supposing, moreover, a single line of development), which implies intraspecific evolution, whereas the term is more usually used to designate interspecific evolution in the succession of living forms;
- Finally, it is difficult to see on what organic bases (postulated each time that Freud had recourse to the notion of "constitution") the transmission could be effected. In this respect, modern research into "intergenerational phenomena" opens the debate concerning means and modes of transmission that correspond more closely to psychoanalytic thought.

## PHYLOGENETIC FANTASY, A: OVERVIEW OF THE TRANSFERENCE NEUROSES

During World War I, Freud worked on a series of papers on fundamental theoretical issues, intending originally to publish them as a book entitled *Zur Vorbereitung einer Metapsychologie* (Preliminaries to a Metapsychology). He eventually published only five of these papers, including “The Unconscious” (1915e) and “Mourning and Melancholia” (1917e [1915]), in the *Internationale Zeitschrift für ärztliche Psychoanalyse*. From his correspondence, we know that Freud effectively finished the seven other texts, but the projected book never materialized.

Since the seven manuscripts had disappeared without a trace, it was long suspected that Freud had destroyed them. The surprise was general when a manuscript draft of the twelfth in the series was

discovered in 1983 among Sándor Ferenczi’s papers. The work was published in 1985—a facsimile reproduction of Freud’s own manuscript and a printed transcription of it—under the title *Übersicht der Übertragungneurosen. Ein bisher unbekanntes Manuskript* (Overview of the Transference Neuroses. A Hitherto Unknown Manuscript). An English translation followed in 1987.

Freud had sent this draft to Ferenczi for his opinion on July 28, 1915. In the accompanying letter, he specifically stated that the fair copy followed the draft as transmitted to Ferenczi sentence by sentence. The manuscript draft thus gives us a very accurate idea of the lost twelfth metapsychological paper.

The text is clearly divided into two parts. The first sets forth, in telegraphic style, a systematic comparison of the three transference neuroses (conversion hysteria, anxiety hysteria, obsessional neurosis) on the basis of the essential factors involved: repression, anticathexis, symptom-formation, relation to the sexual function, regression, and disposition. True to the promise implied by the title of the draft, this review is based on careful observation and strictly confined to the ontogenetic plane. But once at the sixth factor, namely the role of inherited disposition in the etiology of neurosis, which is almost entirely handwritten, Freud embarks on the speculative adventure of phylogenetic reconstruction (not to say construction). The title is likewise abandoned, as Freud extends his discussion to the “narcissistic neuroses”: dementia praecox, paranoia, and melancholia-mania.

This second part is unquestionably the most groundbreaking section of the draft. The phylogenetic fantasy outlined here may be read as a variation on a theme introduced by Freud in *Totem and Taboo*, the hypothesized murder of the tyrannical father of the primal horde by the sons, giving rise to the sense of guilt as the emotional foundation of emerging civilization. In order to explain the “archaic” inheritance of the mental life of modern man, which is in his view based not only on dispositions but also on actual contents, actual memory traces, Freud postulates a Lamarckian form of hereditary transmission. As scientifically unacceptable as this phylogenetic fantasy is, it presents the greatest interest today, for it may be interpreted as an attempt by Freud, in the context of the etiology of neurosis, to link the model of the drive to the model of trauma by claiming that what are normally considered primal fantasies belonging to psychic

(inner) reality are in fact the product of traumatic events that took place in external reality in prehistoric times.

The discovery of this draft also attests to the close collaboration between Freud and Ferenczi, at the time of its writing, especially with respect to metapsychology and, ultimately, with respect to “psychobiological” themes.

## PHYSICAL PAIN/PSYCHIC PAIN

---

Pain is not a concept, but rather a psychical state expressed through localized bodily sensation; as such it is a phenomenon that is currently distinguished from nociception (the electrochemical activity of receptors known as “nociceptors” that react only to bodily stimuli, perhaps of traumatic or inflammatory origin).

The properties of pain have continued to challenge the logical and complex corpus that is Freud’s psychic apparatus, right up to his final works. Thus is pain organic in origin? Is it perhaps the recollection of suffering or a mnemonic symbol for periods of conflict? Pain was also in fact a personal concern for Freud, as it accompanied most of the physical symptoms that afflicted him personally such as migraines, angina, and other cardiac symptoms, but above all the pain in his mouth that appeared around 1899 and which later proved to be cancer. This might explain why he was more interested in cocaine as an analgesic than as an anesthetic.

As early as the “Project for a Scientific Psychology” (1895), where Freud speculates on neuronal and quantitative theory, he acknowledges the limits of this dynamic system and the omissions to his concept of the contact barrier: “Is there a phenomenon which can be brought to coincide with the failure of these contrivances? Such, I think, is *pain*” (Freud, 1895, p.307). When he later directed his research toward the suffering of hysterical patients their physical pain appeared to him to be the product of the conversion of remembered ethical pain into physical pain, owing to their inability to tolerate, at a psychic level, the memory involved. Since it is not always attached to a representation, pain appears to disengage itself from the notion of the symptom in the “Studies on Hysteria” (1895) and consequently Freud decided to use it as a clinical “compass.”

Earlier that same year he had noted that “pain results from a loss” (letter to Wilhelm Fleiss dated January 7, 1895); it comes from a “fixation” (Letter 61, Draft L), and leaves behind “permanent facilitations” (Freud, [1895] 1950, p. 307). This key Freudian hypothesis appears again in his later writings, especially in “Mourning and Melancholia” (1916–1917g [1915]), where the adjective “painful” is characterized as a “mood of mourning” (p. 244). The term “pain,” however, is in fact associated with the two states in question in this text; that is to say, it transcends the categories of normal/pathological and the presence/absence of the lost object in external reality. Freud’s examination, in “On Repression” (1915d), of the fact that an external event produces an internal excitation led him to define pain as a “pseudo-instinct” (p.146). This hypothesis is crucial because it situates pain within the structure of the speaking subject. In “Beyond the Pleasure Principle” (1920) Freud poses the problem of what is bearable and what is unbearable in a radically different way; thus the “specific unpleasure of physical pain,” which “is the result of the protective shield having been broken through in a limited area,” generates an “anticathexis on a grand scale . . . for whose benefit all the other psychical systems are impoverished, so that the remaining psychical functions are extensively paralyzed or reduced” (Freud, 1920g, p. 30).

By virtue of the constancy of its influx, pain is indeed “like” a stimulus coming from within the apparatus that generates an attempt to psychically bind this energy. However, a substantial conceptual change had been effected in that, for Freud, the general problem of the instinctual forces was linked, fundamentally, to the notion of the psychical representative. Pain as a “pseudo-instinct” was thus freed from the economic model that had proven to be too limited, even in terms of its interrelationship with neuropsychology.

Despite his explicit return to the dualism of the instincts in 1926, he could again write: “Pain is thus the actual reaction to loss of object” (1926d [1925] Addendum C). It should be recalled, however, that for him there are no unconscious emotions or affects; it is not pain, but rather lack, that is unconscious.

From the numerous metapsychological reflections on pain it should still be remembered that Freud always insisted that pain should be separated from sadomasochism. For example, he notes here: “Psychoanalysis seems to show that the infliction of pain plays

no role in the primal aims of the instincts” (1926d [1925] Addendum C). To be sure, pain must be conceptualized beyond the pleasure-unpleasure principle, and these hypotheses can lead to the assumption that logically, pain must be anterior to fantasy and to the symptom in the genesis of unconscious formations.

Pain, as a phenomenon, reemerges not according to the processes of remembering (representation) or reminiscence (trauma), but rather from what might be called the “reliving” of an early experience of loss involving an unconstituted object. In this way, the subject would be restored to a state of insignificance.

### **PIAGET, JEAN (1896–1980)**

Psychologist and theoretician of cognitive development Jean Piaget was born in Neuchâtel, Switzerland, on August 9, 1896. He died in Geneva on September 16, 1980.

Although renowned for his research on the development of intelligence and for his “genetic epistemology,” Piaget was strongly influenced by psychoanalysis in his early career. In his autobiography, Piaget attributed this interest to his mother’s instability and her “rather neurotic temperament.”

By 1912, Piaget had already published taxonomic research on mollusks and developed a background in natural history; he then turned to philosophy. During World War I he went through a period of intellectual crisis dominated by Bergsonian mysticism, which

combined Christian and socialist ideas. One of his first encounters with psychoanalysis occurred in 1916 on the occasion of a lecture on religion and Freudian theory in which Théodore Flournoy stated his agreement with the analytic theory of sublimation while asserting that it must respect the mystery surrounding the ultimate nature of religious phenomena. In *Recherches*, an autobiographical novel about his intellectual apprenticeship, Piaget adhered to the criticisms of Flournoy and the Zurich psychoanalysts; and in his theoretical speculations and analysis of his own character (a young man he identifies as himself) he gave a central role to the concepts of “autism” and “complex,” terms that were originally defined and employed by Eugen Bleuler and the Zurich school. By recasting mystical thought in psychiatric terms, Piaget was able to claim that he both understood it and repudiated it.

Piaget spent the winter semester 1918–1919 at Zurich, where he attended lectures by Eugen Bleuler and Carl Gustav Jung and seminars led by Oskar Pfister. While in Paris in the fall of 1919 he gave a lecture, “Psychoanalysis in Its Relations with Child Psychology”; this became his first publication in psychology and made him one of the first to introduce psychoanalysis to France. He emphasized the importance of psychoanalysis in pedagogy and moral education, but insisted that “unconscious mechanisms” are “the first states of conscious activity.” He also indicated the direction of his early research: correlation of “unconscious development” and “mental development.” In a flattering article published in 1920, Oskar Pfister foresaw a bright future for Piaget as a psychoanalyst.

Piaget joined the Swiss Psychoanalytic Society in October 1920. In 1921 he was hired by the Institut Jean Jacques Rousseau in Geneva, founded by Édouard Claparède and managed by Pierre Bovet. His analyst was Sabina Spielrein, with whom he planned to do research (Vidal). Piaget attended the Seventh International Congress of Psychoanalysis in Berlin in 1922. Circa 1924 he analyzed a student pastor; he may have also have attempted to analyze the student’s mother. He also wrote reports of psychoanalytic works for *The Archives of Psychology*.

During the 1920s Piaget developed the analogy between infantile thinking and “symbolic” or “autistic” thinking, remaining rather closer to his teacher Pierre Janet’s psychology than to Freud’s psychoanalysis. In elaborating parallels between intellectual and emotional development, Piaget critiqued the Freudian

concepts of symbol, memory, and the unconscious. Near the end of his career, Piaget included “the cognitive unconscious” and “the affective unconscious” as a part of a generalized “unconscious” consistent with all that is not conceptualized (1973, p. 31ff).

Piaget retains a place in the history of psychoanalysis, especially in terms of the Genevan “genetic psychology,” and in varied and diverse efforts to link psychoanalysis and the psychology of intelligence—as, for example, in terms of developmental object relations and the concept of object constancy.

## PICHON, ÉDOUARD JEAN BAPTISTE (1890–1940)

Édouard Pichon, physician in Parisian hospitals, linguist and psychoanalyst, was born on June 24, 1890, at Sarcelles, just outside Paris, and died in 1940 (he was buried on January 23, 1940).

Originally from Burgundy, Pichon was the son of a notary public at Sarcelles. The family was marked by illness: diabetes on his father’s side and acute articular rheumatism on his mother’s side, from which he, like his sister, would also suffer. Cardiac complications, also shared by his sister, handicapped him throughout his life and were the cause of his death at the age of fifty.

His uncle, Jacques Damourette, who suffered from epilepsy and tuberculosis, also lived in the family

home and introduced his nephew to grammar. Over a period of thirty years they worked together on *Des mots à la pensée* [From Words to Thought], a seven-volume essay on French grammar, as well as a volume of tables and articles for the *Revue de la Philologie Française* [Review of French Philology].

Pichon was a brilliant student, with a special affinity for literature, but, on his father's recommendation, he enrolled for medical studies. At university he met and befriended Théophile Alajouanine. In May 1910, he passed the examination enabling him to become an extern in Parisian hospitals and in 1914 he qualified as an intern under Lereboullet. Louis Aragon, whom he met in the hospitals at this time, described him as "a great pale horse of a man with the typhoid-colored mustache of a thirteen-year-old." He was a lover of obscene songs and linguistics, and kept a notebook where he scrupulously noted all the expressions he heard.

He was a medical officer in the army during World War I and was awarded the Military Cross in 1916. It was during this period that his heart condition first appeared. He became seriously ill, was often hospitalized and handicapped by illness, the inevitable consequences of which were known to him. In 1924 he qualified as a medical doctor after presenting a thesis on "Progressive rheumatic heart disease and its treatment." In 1925 he was appointed clinical director for infantile medicine, first as an assistant at the Saint-Louis Hospital, then, in June 1931, physician to the Parisian hospitals, a prestigious title in which he took great pride.

Through Alajouanine he came to meet Adrien Borel and then René Laforgue, who introduced him to Eugénie Sokolnicka, with whom he began an analysis that lasted from 1923 to 1926. His clinical experience convinced him of the solid bases of psychoanalytic theories and he consistently defended psychoanalysis while hoping to "Frenchify" it. Along with the Sainte-Anne group of psychiatrists and the Minkowskis, good friends of his, he was one of the founding members of *L'Évolution psychiatrique* (Psychiatric Evolution) and its review in 1925, as well as of the Société psychanalytique de Paris in 1926 (of which he was several times president), and the *Revue française de Psychanalyse* (French Review of Psychoanalysis), going on to become its first general secretary (1927 to 1929).

In 1927 he married Hélène Janet, Pierre Janet's daughter. He tried in vain to organize an encounter between Freud and his father-in-law.

A highly talented man, a brilliant polemicist, a fervent Catholic, a supporter of the death penalty and medical and "national" psychoanalysis, he applied in 1927 to become a member of the Ligue de l'Action Française (a right-wing anti-Semitic organization). He believed that Catholicism was a factor in maintaining social order, in opposition to the Jewish or Protestant spirit. Seeing that "the Pope is becoming a Protestant," he approached Charles Maurras, the leader of Action Française, to join.

Some hundred or so articles bear witness to his medical and psychoanalytic activity in the field of childhood, psychosis and, of course, linguistics, which remained the strong point in all his thinking. In his article dated 1928, "Position du problème de l'adaptation réciproque entre la société et les psychismes exceptionnels" [Positioning the problem of reciprocal adaptation between society and exceptional psychisms], he abandoned the strict organicist definition of mental illness in favor of the theory of degeneration in terms of a failure to adapt, and delinquency. He crossed swords with Marie Bonaparte, whom he accused of denying the responsibility of the individual. Opposed to the man he ceremoniously referred to as "Monsieur Freud," and Princess Marie Bonaparte, he fought against "Laienanalyse" (lay analysis) and tried to use language to combat the internationalism of psychoanalysis. In 1927 he proposed to translate "libido" with the word "aimance" and the Es (id) with "infra-moi" (infra-self).

In three conferences dating from 1937, entitled "À l'aise dans la civilisation" [Civilization and the contented], in response to Freud's *Civilization and Its Discontents*, he defended, not without humor, the values of the manly man and the womanly woman, fought against feminism, and theorized on "How thought takes flesh." Praising the merits of Descartes, Roland Dalbiez, and Madame Borel-Maissonny, a specialist on language disorders, he criticized the arbitrariness of the sign in Ferdinand de Saussure, explaining the latter's error by the fact that he was anchored in the traditions of a country that lacked linguistic unity.

In two articles co-authored with Jacques Damourette and in his report to the International Psychoanalytic Association (IPA) in Paris in August 1938 entitled "La personne et la personnalité vues à la lumière de la pensée idiomatique française" [The person and the personality viewed in the light of idiomatic French thought], he studied the different forms of negation.

The paper stressed the value of the notions of “scotomization”—a concept forged with Laforgue and criticized by Freud — and “foreclosure,” which was to become one of the bases of Lacan’s theory.

In 1938, when Lacan’s article on the family appeared in the *Encyclopédie française*, he responded in polemical tone in the *Revue française de Psychanalyse* with “La famille devant Lacan” [The family before Lacan]. Recognizing the intelligence of Lacan who had read Karl Marx, he criticized him for his Germanism and his use of jargon, but acknowledged the importance of the discovery of the “mirror stage.”

In his *Journal* for August 23, 1945, Laforgue wrote: “Pichon was schizophrenic like his mother and uncle before him, and I knew it. This explains why I always tried to mount a vigilant guard at the demarcation line between reality and madness. But at the end of the day Pichon was the only person I could bring my patients’ dreams to when I could not understand them and for whom they seemed to be familiar. With good reason.” And when the time came, Jacques Lacan did not fail to salute “the late Édouard Pichon who, both in the indications he gave concerning the birth of our discipline and those that guided him through the darkneses of people, demonstrated a power of divination that we can only explain in relation to his practice of semantics” (*Écrits*, p. 258).

## **PICHON-RIVIÈRE, ENRIQUE (1907–1977)**

Enrique Pichon-Rivière, the Argentinean physician, psychiatrist, and psychoanalyst, was born in Geneva on June 25, 1907, and died in Buenos Aires on July 16, 1977.

He was three years old when his parents, originally from France, arrived in Argentina. The family settled in the heart of the Chaco forest and spent four years in this inhospitable region, under the obsessive threat of a fierce attack from the Guarani Indians who, apart from their group incursions, were otherwise hard-working and peaceful. This coexistence afforded the young Enrique an opportunity to familiarize himself with Guarani culture and to learn their language. When he was eight years old, his family left the region to move to the province of Corrientes, before settling in the city of Goya where he studied in the school founded by his mother. Sports, poetry, and painting were the great passions of his childhood, adolescence, and early adulthood. Pichon-Rivière readily admitted that his readings of Lautréamont, Rimbaud, and Artaud exercised a constant influence on his thought. In 1946 he published “Lo siniestro en la vida en la obra del conde de Lautréamont [The Sinister in the Life and Work of the Count de Lautréamont].

In Buenos Aires he studied medicine, worked as a journalist, and played an active part in the intellectual Bohemia of his day. He finally qualified as a physician in 1936.

He married Arminda Aberastury, who went on to become an eminent child psychoanalyst. As a result of his success in a competitive examination he was appointed psychiatrist at the Hospicio de las Mercedes. There he experienced something that was to have a decisive influence on his training: the creation of “operational groups.” Pichon-Rivière could be described as one of the greatest pioneers of modern psychiatry in Argentina.

Although he had read Freud since his youth and was driven by an intense intellectual curiosity, it was not until the end of the 1930s that he entered into contact with Celes Cárcamo, Angel Garma, and Arnaldo Rasovsky, with whom he founded the Asociación Psicoanalítica Argentina in 1942. He occupied an important position within this institution as the direct or indirect master for several generations of psychoanalysts.

Pichon-Rivière did not leave an abundance of writings behind him. He was more gifted at transmitting

his knowledge orally, his teachings being collected and elaborated by his disciples in what could be considered the most creative and the best defined contributions of Argentinean psychoanalysis. Among his most prominent disciples we find José Bleger and David Liberman.

One of the central notions in his work is the constitution of *Esquema Conceptual Referencial y Operativo* (ECRO; Referential and Operational Theoretical Schema) as an instrument for apprehending reality in a scientific manner. In a rising theoretical-practical spiral (praxis) he took a researcher's view of life experience and learning, as well as popular sources of knowledge.

In the scientific milieu his intellectual independence and his indomitable spirit of innovation caused conflict in his relations with institutions and people. His links with the Psychoanalytic Association were punctuated with difficulties and his family life was not renowned for its stability. In 1956 he divorced Arminda Aberastury. His second wife died in a road accident and he finished his days with the woman who helped him to organize and maintain what he claimed was the institutional foundation for his thinking: the School of Social Psychology.

His thinking and scientific development were characterized by his efforts to redefine psychoanalysis as a social psychology. It is no accident that the work that contains the greater part of his writing is entitled *Del psicoanálisis a la Psicología social* (1970, From Psychoanalysis to Social Psychology). In this volume we find work by Pichon-Rivière from the 1940–1969 period, work that clearly reflects the variety of interests and obsessions that focused his attention in different studies. Among those that stand out for their originality are the creation of “operational groups” and the notions of “mouthpiece” (*portavoz*) and “emergent” (*emergente*) that derive from this. For the author, the individual is emerging and therefore a mouthpiece for his or her family group, which is in turn the mouthpiece of the socio-cultural group of which it is a part. Hence his conception of the psychism as an “internal group” in interaction with and interdependent with external groups.

In the domain of psychopathology Pichon-Rivière posited that health and illness are not static categories but correspond rather to modes of reading and adapting to reality. “Active adaptation to reality” supposes a

transformational and a critical reading of it, a reading that in turn produces a transformation of internal structures. His theory of the “single illness” posits the existence of a central psychotic nucleus—a basic depressive situation—that is pathogenic, all pathological structures being attempts at an elaboration of or detachment from this nuclear situation. Among the factors that intervene in the configuration that structures adopt, we can list: polycasuality, phenomenal plurality (body, exterior world, and mind) and genetic and functional continuity.

## PICTOGRAM

The term *pictogram* was used by Piera Aulagnier to describe the primal form of representation that is shared by all subjects but retains a special force of attraction for psychotics. According to Aulagnier, a pictogram represents not an object but the uncompleted experience of an encounter between a sensory zone and an object capable of completing it. The term thus has no relation to the way in which Freud used it in *The Interpretation of Dreams* (1900a) in connection to writing with images (*Bilderschrift*) in the dream-work. A pictogram is a representation of an instantaneous action (introjecting/rejecting) whose principle

feature, in this stage when the psyche is still unaware of anything outside itself, is the specular relation that comprises it.

Aulagnier's theory of the primal may be held alongside what Freud wrote in "Negation" (1925h) about the workings of the activity of the judgment that attributes existence based on an evaluation of whether an object is good or bad: "Expressed in the language of the oldest—the oral—instinctual impulses, the judgment is: 'I should like to eat this,' or 'I should like to spit it out'; and, put more generally, 'I should like to take this into myself and to keep that out.' That is to say: 'It shall be inside me' or 'it shall be outside me'. As I have shown elsewhere, the original pleasure-ego wants to introject into itself everything that is good and to eject from itself everything that is bad." (p. 237) In Aulagnier's view, introjection and rejection entail consequences for the psychical agency involved. In *The Violence of Interpretation: From Pictogram to Statement* (1975/2001), she writes, "seen, heard, tasted will be either well perceived by the psyche as a source of pleasure of its own production, and therefore especially forming part of what is 'taken' inside itself, or as a source of pain to be rejected and this rejection *implies* that the psyche cuts off from itself what, in its own representation, brings into play the organ and the zone, the source and seat of excitation" (p. 22). The postulate of a self-procreation specific to the primal is logically deducible from the fact that at this stage the object, whether it is to be put inside or outside of the self, is not external to the self in question, which is nothing more than a collection of sensations.

Having thus defined the pictogram on the basis of the dichotomy between introjecting and rejecting, Aulagnier took yet another step toward structural definition, no longer of the represented, but of the representative—of the psyche itself—as she had done for the primary and secondary processes. At issue here was the definition of psychical agencies other than those posited by Freud but that do not replace the latter and, above all, whose origin is different because each case involves the reflection (in the literal sense) of mental activity onto itself. The influence of Jacques Lacan's mirror stage (1966/2004) is felt here, but Aulagnier retained from that model only the movement of specularization, which she viewed as a constant of mental activity from its very beginnings. In *The Violence of Interpretation* she wrote that "any creation of the psychical activity is presented to the psyche

as a reflection, a presentation to itself" (p. 24). This process becomes difficult to grasp, however, when the dichotomy between reflecting agent and reflected object does not yet exist; but whereas other authors had spoken of indissociability or fusion in these instances, Aulagnier adhered to the notion of the specular image. In the same book she wrote: "If one accepts that in this phase the world—the outside-the-psyche—has no existence other than in the pictographic representation that the primal makes of it, it follows that the psyche encounters the world as a fragment of specular surface, in which it mirrors its own reflection" (p. 24).

One might think that Aulagnier was begging the question when she asked us to consider a self (that is, a representing agency that is not yet either the Freudian ego nor what Aulagnier called the I) that can only know of the outside that which is given as a reflection of the self in question, and that can only know itself as that which has engendered the fragment that itself reflects it. The whole question, so thorny in Freud's work, of the outcome of primary narcissism is found again here, but here, too, it is appropriate not to conceptualize in realist terms what is presented as a theoretical fiction. What ensures that there is a way out of this play of mirrors is simply, as in Freud, the difference that exists between a representation of the object and the real object able to satisfy a need. The mind must thus face the obligation—and this from the beginning, even if the description of these mechanisms leads to evoking them in succession—to acknowledge that the breast is an object different from the mind's body itself, that it has an independence and is thus not self-generated.

What are the effects of desire and non-desire at the level of the primal representation constituted by the pictogram? To the extent the psyche engages in making representations, they point to the fact that it itself has produced the hated object and even—owing to the specular relation—that it at least partially identifies with the latter. "In this case," wrote Aulagnier in *The Violence of Interpretation*, "the agency that sees itself in the represented contemplates itself as a source of its own pain; it then tries to annul and destroy that image of itself" (pp. 19–20).

What Melanie Klein theorized as splitting between a "good breast" and a hated "bad breast" has been conceptualized in various ways. Freud for one asserted that the bad comes before the good to the extent that the obligation to desire disturbs an anterior mythical

state of quiescence that is actually prior to life itself. Aulagnier did not adopt this perspective, in the sense that she saw love and hate of the object as appearing simultaneously. Freud, however, viewed hate as the initial repudiation of the external world by the narcissistic ego; in “Instincts and Their Vicissitudes” (1915c), he wrote: “Hate, as a relation to objects, is older than love. It derives from the narcissistic ego’s primordial repudiation of the external world with its outpouring of stimuli” (p. 139).

To the extent that, according to Aulagnier, primary narcissism is not a closed unity but rather the reflection that the representative perceives of itself in its self-generated representations, there is always either simultaneously, depending on whether we side with Eros or Thanatos, the image of an encounter involving pleasure, or that of a delay or a lack that occasions unpleasure. Thus, in Aulagnier’s view, getting rid of the bad by rejecting it will require, since the bad is indissociably linked to a bad sensory zone that has engendered it, the destruction of the latter. “The wish to destroy the object,” she wrote in *The Violence of Interpretation*, “will always be accompanied, in the primal, by the wish to annihilate an erogeneous, sensory zone, as well as the activity of which that zone is the seat” (pp. 27–28). According to Freud, rejection allows a “purified pleasure-ego” to remain. In this instance it cuts off a part of the representative’s self, a process viewed by Aulagnier as the “archaic prototype of castration” (p. 28) that will be reshaped into a fantasm at a later stage. Where she is in agreement with Freud, on the other hand, is in the preeminence of Thanatos over Eros, since the latter can only win out by desiring an object that, by means of the satisfaction it brings, leads, at least momentarily, to a state of nondesire, of quiescence.

The analysis of the pictogram Aulagnier proposes amounts to developing, affirming, and complicating the notion of the drive and its representative. But where Freud spoke of excitation, need, or instinct, Aulagnier preserved the notion of a “body” that she described as being simultaneously—the provider of representational-models for the psyche, the irreducible proof of the existence of a “somewhere else,” the privileged object of a desire for destruction and, lastly, the source and locus of an erotogenic pleasure.

The originality and the fruitfulness of the notion of the pictogram derive from the fact that its structure is based on specularity. This notion also allows an approach to psychosis based on the fact that, for the

future psychotic, the experience of conjunction is most often one of violence and intrusion, and not one of a complementarity that occasions pleasure. This could be compared to the idea Winnicott furthered in “Psychosis and Child Care” (1952), of the need for “good enough” environment—that is, one that for a time preserves the illusion of omnipotence and thus an image of self-procreation formed under the influence of pleasure and Eros. As Aulagnier wrote in *The Violence of Interpretation*, a specific feature of psychosis is “to make possible the re-presentation between the primal space and the space outside-the-self of a state of specularisation” (p. 31).

## PLEASURE EGO/REALITY EGO

In his work on instincts, Freud introduced a distinction between those whose sole aim is the search for pleasure and the avoidance of unpleasure and those that tend to adapt to the realities of life, which cannot be done without renouncing pleasure to some degree. This discrepancy results in conflicts within the ego that are sometimes resolved by splitting.

The pleasure ego may adapt to the reality ego by postponing a yield of pleasure. This is the normal and the most usual course of things. It depends, however, on the ego's having reached a certain level of development.

During early childhood, the reality ego is still weak, while the pleasure ego has only two functions, namely to satisfy the oral zone and to cause the body-ego to be experienced as pleasurable. After breastfeeding comes sleep, after sleep breastfeeding once again—and the reaction to any disagreeable feeling is to cry. As soon as the anal stage is reached, conflicts arise between the reality ego and the pleasure ego. The pleasure ego demands only the evacuation of the bowels, which is accompanied by great pleasure. The reality ego for its part requires that this occur only at a particular time and place. Once this has been achieved, it further demands that pleasurable sensations in the anal zone be reduced to a minimum. This last requirement is probably not satisfied in all individuals, giving rise to the kinds of behavior that we call perversions.

So long as the sexual instinct stays in its infantile mode, it is relatively easy for the reality ego to fulfill its function of adaptation to reality. Which having been said, it is quite possible for the two egos to clash even during early childhood, for the reality ego maneuvers by contriving all kinds of displacements, so causing a set of symptoms to arise as a way of gratifying the pleasure ego. Many childhood illnesses attest to this, since they are often the consequence of a surrender by the reality ego. Such situations may even lead to serious psychosomatic illness. Generally, however, a strong reality ego and a developing superego or ideal ego will help the subject overcome the difficulties of this period and embark on a relatively conflict-free latency.

With the onset of puberty, the pleasure ego lays siege to the reality ego with extraordinary vigor. During this time, which may extend over several years, it easily happens that the pleasure ego gains the ascen-

dancy. As a rule, the consequence of the conflict between the reality ego and the pleasure ego is bizarre behavior, veering back and forth between the exalted to the depressive and punctuated by violent bouts of ill temper. Everything depends in this period on the strength of the superego; if the superego is absent or very weak, its role is perforce assumed by social organizations—by gangs or other kinds of groups. The kind of group chosen by the ego in puberty will depend on social opportunity. The social conditions under which the adolescent grows up are therefore of the greatest importance in determining behavior. A good social environment means that desires can more often be met in a social way, and it leaves far more room for the expression of the abilities (athletic, intellectual, artistic, and the like) that might strengthen young people who are striving as best they can to get through puberty. In any event, the primary goal during this period is to supply the reality ego with the resources to defeat the pleasure ego.

Should such favorable conditions be lacking, the pleasure ego is liable to realize its aspirations by errant means, as witness drug abuse, for example. In most cases, however, the reality ego carries the day and succeeds in imposing its dominance—in principle, as soon as adolescence comes to an end. The pleasure ego is left a certain amount of space, depending on the exigencies of social adaptation. The amount of satisfaction that the reality ego can grant the pleasure ego is largely a function of social and cultural circumstances. The capacity to sublimate has a significant role here. Thanks to sublimation, the reality ego, aided by the superego, manages to persuade the pleasure ego to expect a measure of gratification on a higher mental plane. In other words, the pleasure ego can experience a great deal of pleasure once the individual has reached a high social level and is able to tolerate long delays before reaching this goal. This represents an ideal form of cohabitation between the reality ego and the pleasure ego, one which, under auspicious social conditions, may begin to develop as early as childhood.

## **PLEASURE IN THINKING**

According to Sigmund Freud, “thought-processes are in themselves without quality, except for the pleasurable and unpleasurable excitation which accompany them, and which, in view of their possible disturbing effects upon thinking, must be kept within bounds,” (*The Interpretation of Dreams* [1900a], p. 656). However, the notion of sublimation allows us to consider the activity of thought and the partial processes that compose it as a libidinal investment, and as an offshoot of narcissism that offers a pleasure as limitless as knowledge itself.

For Sándor Ferenczi, in “The Birth of Intellect,” suffering is at the origin of intellect, which “is born not simply of common, but only of traumatic, suffering. It develops as a consequence of, or as an attempt at, compensation for complete mental paralysis. . . . *Pure intelligence* is thus a product of dying, or at least of becoming mentally insensitive, and is therefore *in principle madness, the symptoms of which can be made use of for practical purposes.*” (“Notes and Fragments,” [1931], p. 244–46).

This perspective on the relation between trauma and the development of intelligence was taken up again by numerous authors, for example by Kurt R. Eissler (1961), and Didier Anzieu and Matthew Besdine (1974). Nevertheless, the issue of decathexis or inhibition of thought would not arise if we did not assume that the subject had already developed a capacity to master trauma through thought and to feel

pleasure at this prospect. Rather than suffering in itself, it is confidence in the capacity to master suffering that can create cathexis in intellect. This evokes a fantasy of certitude, of a truth that is just on the horizon, aiming at an ultimate synthesis, like the absolute knowledge of Hegel, the third kind of knowledge of Spinoza, or the contemplation of the world of ideas of Plato.

The pleasure of thinking appears, however, not only as a goal, but also as the surplus pleasure produced by whatever the exercise of intellect puts into play through the sublimation of the partial drives of seeing and seizing. These two drives combine, as Nietzsche described the character of the scholar, to form “an ego with an unlimited avidity, which desires everything and would want to see with the eyes and take with the hands of a thousand people, an ego that recovers all the past and would lose nothing that could belong to it” (in Mijolla-Mellor, Sophie de, 1992).

Considered from the standpoint of intellectual development, pleasure and trauma might be equally necessary. The initial methodology of thought is to ignore perplexity and doubt, regarding what it discovers as unquestionably true; afterwards there comes a time when the basis of evidence collapses—whether this is regarded as a result of the primal scene, as for the Wolf Man, or a discovery; in whatever form it takes, whatever the child regarded as secure is fond to be an illusion. The pleasure that thought aims at experiencing consists in the attempt to recreate a basis for certainty that it will not fail again (Mijolla-Mellor). Pleasure in thinking will consist, from then on, in the encounter with points of certitude, effected through a construction of thought. The subject learns that these points of certitude are not fixed forever and that it is in their power to reconstitute them under other forms, if necessary. This experience of the pleasure of reconstructing points of certitude, which are capable of substituting for the kind of evidence available to sensation, is a condition for being able to cathex to thought, and should be distinguished from an exercise in obsessional intellectualizing defense. On the contrary, the visionary intuition of the researcher provides them with instants when thought not only operates through images to be captured in sensible form in the imagination, but itself turns into an image or schema fusing the primary and secondary processes. The desire for knowledge, in so far as it always pursues an object just out of reach, an enigma present in the

appearance of things, would be opposed to any renunciation of dissatisfaction. The desire for knowledge works against the force of Thanatos by keeping the will to question alive.

## **PLEASURE / UNPLEASURE PRINCIPLE**

The pleasure/unpleasure principle, often shortened to *pleasure principle*, requires the psychic apparatus to automatically discharge excitations when they accumulate above a certain threshold and are experienced as unpleasure. This principle governs the functioning of the primary processes and is the basis for the economic viewpoint in metapsychology.

The translation of the German *Lustprinzip* by “pleasure principle” in English warrants some comment. The German *Lust* actually has two meanings: that of pleasure, but also that of desire or want. *Lust haben auf* is the most common expression for “to want, to have a desire for.” The pleasure principle is thus also the “desire principle”: The psychic apparatus can do nothing else but desire, says Freud. Similarly, with regard to the rendering of *Unlustprinzip* as “unpleasure principle” in *The Interpretation of Dreams* (1900a), it should be kept in mind that *Unlust* in German also means “aversion.” Consciousness turns away from that which occasions aversion.

Although philosophers throughout the ages, notably Epicurus, have opposed pleasure and pain, or linked pleasure to the absence of pain, the concept of

the pleasure principle originated in John Stuart Mill’s *Utilitarianism* (1861), where pleasure and the avoidance of pain are posited as the two ends of life, and in the natural philosophy of Gustav Fechner, who in 1848 published an essay entitled *Über das Lustprinzip des Handelns*. Sigmund Freud is also known to have translated Mill’s essay on George Grote’s *Plato* (1866).

However, it was during their theoretical elaboration of the first analytic treatments in *Studies on Hysteria* (1895d) that Freud and Josef Breuer first discovered the role of pleasure and unpleasure as mental qualities that determine repression, and that they formulated the principle of constancy, which was inspired by the concept of homeostasis in physiology.

In Chapter VII of *The Interpretation of Dreams*, Freud estimates pleasure and unpleasure to be the only psychical qualities actually apprehended by consciousness, other than external excitations received by the perceptual system. The excitations of pleasurable and unpleasure are thus seen as almost the only elements that make it possible to describe a transformation of energy inside the psychic apparatus. It is “the releases of pleasure and unpleasure [that] automatically regulate the course of cathetic processes” (1900a, p. 574), which Freud calls the “unpleasure principle.”

Freud inaugurates his fictional depiction of the primitive psychic apparatus with the notion that the accumulation of excitation is experienced as a tension that elicits unpleasure, and that it activates the psychic apparatus in order to repeat the experience of satisfaction, which on previous occasions brought about a reduction in tension that was experienced as pleasure. Desire is thus defined as the current within the psychic apparatus that goes from unpleasure to pleasure; it alone sets the psychic apparatus in motion. The obtaining of pleasure is primitively sought in a hallucinatory mode in which perception becomes identical to the traces recorded in a primitive experience of pleasure: This is the mode of operation of the primary psychic processes. Moreover, the unpleasure principle prohibits the psychic apparatus from introducing painful elements during the course of its thoughts, and all mental acts liable to provoke a signal of unpleasure will be repressed.

However beginning with the “Three Essays on the Theory of Sexuality” (1905), Freud observes the need to differentiate between kinds of tension more clearly, and perhaps to not always associate tension with

unpleasure; since the tension involved in the state of sexual excitation cannot be ranked among the feelings of unpleasure. Pleasure and sexual tension are thus only indirectly related. He then delineates a preliminary pleasure, which he employs as the preliminary pleasure principle in *Jokes and Their Relation to the Unconscious* (1905c).

In “Formulations of the Two Principles of Mental Functioning” (1911b), the unpleasure principle is called the *pleasure/unpleasure principle* and then shortened to *pleasure principle*. It characterizes the functioning of the pleasure-ego, but undergoes a modification over the course of the development of the psychic apparatus: The reality principle imposes a detour upon the pleasure principle; it defers satisfaction, or eliminates certain possibilities for satisfaction, by subordinating it to a test as to whether conditions that are favorable to it exist in reality. But the reality principle also guarantees survival, since total submission to the pleasure principle would likely lead to death, even though the young infant, “provided one includes with it the care it receives from its mother” (pp. 219–220, n. 4) comes close to producing a psychical system of this kind; as Freud remarks in a footnote where Donald Winnicott would later locate the mother-infant unit upon which he based his theory of human development.

In *Beyond the Pleasure Principle* (1920g), Freud calls into question some of his own earlier theoretical conceptions when he discusses repetition compulsion. Clinically documented in dreams, traumatic neuroses, children’s games, and transference neurosis, the repetition compulsion is placed above the pleasure principle. Later, in “The Economic Problem of Masochism” (1924c), he dissociates the states of pleasure and unpleasure from the economic factors of relaxation and tension. Pleasure and unpleasure do not seem to depend upon this quantitative factor but instead on a qualitative aspect, some of whose traits Freud suggests: rhythm, the temporal flow of modifications, and rises and falls in the quantity of excitation. Although he reconfirms the tendency of the psychic apparatus to rid itself of tensions or reduce them to a minimum, he now calls this tendency, following Barbara Low, the “Nirvana Principle,” which consists in reducing to zero the general level of excitation of the psychic apparatus. What is involved thereafter is a tendency of the death drive; whereas the pleasure principle stems from the libido. As for the reality principle, its role is to

imposes a modification of the pleasure principle, which thereby takes into account the influence of the outside world.

## **POLAND**

Poland was divided between Germany, Russia, and Austria-Hungary when psychoanalysis came into being at the beginning of the twentieth century. Ludwig Jekels, a follower of Freud, practiced psychoanalysis in Austrian Poland in the clinic he directed outside Lvov, a city that has been Ukrainian since 1945 but was Austro-Hungarian at the start of the twentieth century. Jekels was joined by Hermann Nunberg until the latter emigrated to the United States. We also have to thank him for the first publications in Polish dating from 1908. Between 1911 and 1914, three titles appeared in the Polish Psychoanalytic Library.

After World War I psychoanalysis went through a dynamic period of development in the new Polish

state. As a result of its many publications and conferences, its influence extended to the medical world and the cultural life of the country. The majority of Polish analysts at the time were trained in the Berlin Institute. Two names stand out: Roman Markuszewicz and Gustav Bychowski. The first published an apologetic work in 1926 on psychoanalysis and its therapeutic function and, ten years later, a critical work: "Toward a Revision of the Fundamental Freudian Notion." Bychowski was trained in Berlin and published on metaphysics and schizophrenia there before returning to Poland to take up a position in Warsaw as a university professor. There he published on the psychoanalytic aspect of the psychoses. The following names are also worthy of note: Stefan Borowiecki, Maurycy Bornsztajn, Jan Kuchta, Rudolf Kesselring, Wladislaw Matecki, Joseph Mirski, Norbert Praeger, Adam Wisel, and Leopold Wolowicz.

Eugénie Sokolnicka deserves a special mention. She trained in Zurich, Vienna, and Budapest between 1911 and 1920 but, not being a physician, she failed to find her place in the Warsaw psychoanalytic milieu of 1920. Freud, who had been her analyst, advised her to go to Paris, where she arrived in 1921. She met with no better success in the Paris medical world, but she analyzed René Laforgue and Édouard Pichon. She did, however, take an active part in founding the Paris Psychoanalytic Society in 1926 and became its first vice-president.

World War II and the ensuing communist régime reduced this first development to dust and it took another ten years before the Polish psychoanalytic movement again showed signs of life. Three young psychiatrists went to train in Hungary and Czechoslovakia, where psychoanalysis was leading an underground existence. The first of these, Jan Malewski, went first to Prague and then, more importantly, to Budapest, where for ten years he alternated six months of analysis with Imre Hermann and six months of activity in Poland. The second, Zbigniew Sokolik, had Theodor Dosuzkov as his analyst in Prague. The third, Michael Lapinski, was analyzed in Prague by Otakar Kucera.

Greater freedom of circulation between eastern countries and later between them and the West fostered a new period of development for psychoanalysis: Young psychiatrists and psychologists in analysis went on to become the active practitioners of contemporary Polish psychoanalysis. In this climate the International Psychoanalytic Association (IPA) elected two direct

associate members at the 1989 Congress in Rome: Elzbieta Bohomolec, a psychiatrist who was analyzed by Michael Lapinski in Warsaw and who was in supervision in Berlin; and Katarzyna Walewska, a psychologist in analysis in Warsaw and then in Paris, and who was in supervision in Warsaw and London. They are at the root of two psychoanalytic groups. The first, the Polish Society for the Development of Psychoanalysis, was founded in 1991; the second, the Institute of Psychoanalysis and Psychotherapy, was founded in 1992. The names of these two groups clearly reflect the nuance that distinguishes them: increasing the number of practitioners for the first, the quality of the training for the second. Members from both groups work together in the Rąstów Center for Psychotherapy of Neuroses, founded in 1965 by Jan Malewski. Having been prohibited during and after World War II, psychoanalysis began to be taught in the psychology faculties of Warsaw, Krakow, and Lublin in 1961. Psychotherapeutic practice has developed in these cities and in Gdansk.

Only Zbigniew Sokolik has remained in Warsaw. Michael Lapinski emigrated to Australia in 1983 and became a member of the Australian Psychoanalytic Society. Jan Malewski settled in Heidelberg in 1975 and became a member of the German Psychoanalytic Association. At the same time émigrés who fled the Nazi persecutions, like Hanna Segal, have reestablished contacts with Poland. Analysts from the international analytic community have visited Poland to give clinical and theoretical training in psychoanalysis. The vitality of the Polish group was demonstrated in 1991 at Pototsk, near Warsaw, on the occasion of the third seminar for East Europeans, a seminar that was organized under the auspices of the European Federation of Psychoanalysis.

## POLITICS AND PSYCHOANALYSIS

Within the wide range of cultural and social interests that led to Sigmund Freud's "The Claims of Psychoanalysis to Scientific Interest" (1913j), politics appears as the poor relative. However, contrary to the rumor that claims Freud was "apolitical," or "politically inert," it can be shown that there are extremely close links between all of Freud's work—analyses, investigations, concepts, projects—and the sources and resources that constitute truly political thought. Together with the American ambassador William C. Bullitt, Freud put his name to a book of political psychoanalysis in the strict sense, *Thomas Woodrow Wilson, Twenty-Eighth President of the United States: A Psychological Study*, (1966 [1938]), that has received little comment. Freud's anthropological work is considerable. He questioned the origin and structure of society in *Totem and Taboo* (1912–1913a), unmasked illusions and dogmas in *The Future of an Illusion* (1927c) and *Civilization and its Discontents* (1930a), denounced Bolshevism in one of the *New Introductory Lectures on Psychoanalysis*—"On a Weltanschauung" (1933a), and described the foundation of a religion, a culture, and a people—the Jews—in *Moses and Monotheism* (1939a). In 1908 he strongly criticized "civilized sexual morality" (1908d), the source of "the nervous illness of modern times." His 1921 essay, *Mass Psychology and the Analysis of the Ego* (1921c), which dismantles the concepts of leader, crowd, and power, can be seen as the foundation of all political psychoanalysis.

In *The Interpretation of Dreams* (1900a), politics saturates the imagery of the "dream of Count Thun," the prime minister of the emperor. Quoting Beaumarchais, Zola, Panizza, and mobilizing the revolution of 1848, social-democracy, and anti-Semitism, Freud denounces the "nothingness" represented by Count "Nichtsthun" and celebrates his own "revolutionary humor." Although he is not committed to political action like his friend Heinrich Braun, at least he sees his foundational work, *The Interpretation of Dreams*, as a form of Promethean subversion: "Flectere si

nequeo Superos, Acheronta movebo"—"If I am unable to influence the Gods, I will shake up Hell." Aside from these lines of force of political thought, all Freud's psychological system is rich with political implications. Following Copernicus and Darwin, he lays claim to a true and grandiose ideological "revolution." In the unconscious the ego is no longer master in its own house and humanity must therefore drive it out. In the agency of the superego, Freud ascribed values, ideals, and imperatives associated with morality and society to the psyche.

No socio-political theory or practice can simply neglect the sovereign preeminence of drives and the unconscious, which various ideologies, especially totalitarian, have been able to exploit. The triptych of the sexual drive, the death drive, and the instinct for mastery exercises an implacable determinism throughout existence, social and political, individual and psychological. It is significant that the most heightened forms of political thought—Machiavelli, Hobbes, La Boétie, Marx, Weber, and others—intersect with and illustrate many of Freud's psychological ideas. The radical rejection of all forms of illusion, the will to lucidity based on a flexible rationality, the dismantling of connections within communities, the emphasis on the autonomy and responsibility of the individual subject—Freud's political thought remains an inexhaustible resource, even when contested or misused, for original psycho-political constructs. Some of these include the research and bold assumptions of Wilhelm Reich, often summarily categorized as "Freudian-Marxism," the "social-democratic" psychology of Alfred Adler, the anarchism of Otto Gross, the "Trotskyite" element in Otto Fenichel, the democratic and eclectic humanism of Erich Fromm, Herbert Marcuse's Orphic leftism, Deleuze and Guattari's libertarian schizoanalysis, and so on.

More recently the field of "psychohistory" has attempted to combine psychoanalysis and politics, but has managed instead to obscure and weaken what was so powerfully revolutionary in Freudian thought.

## POLITZER, GEORGES (1903–1942)

Georges Politzer, a French philosopher, was born May 3, 1903, in Nagyvarad, Hungary, and died on May 23, 1942, in Mont-Valérien, France, where he was shot by a firing squad. Born into a Jewish family, Politzer's father, a doctor, is said to have participated in the 1919 communist regime in Budapest. Young Politzer was soon confronted by the upheavals that shook Central Europe following World War I. Forced to leave Hungary, he stayed briefly in Vienna, where he appears to have embraced the work of Sigmund Freud, then moved to Paris in 1921.

Politzer majored in philosophy at the Sorbonne, where he studied with Léon Brunschvicg, whose rationalism had a profound effect on his thinking in spite of his later repudiation of the man. He became a naturalized French citizen in 1924 and received his philosophy degree in 1926. In 1930 he became a professor as well as a political militant, apparently losing all interest in psychology.

His interest in psychoanalysis can be traced to 1924 and the publication, in the review *Philosophies*, of two articles, "Médecine ou philosophie?" and "Le mythe de l'antipsychanalyse" (in Politzer, 1969). Two themes emerged from these publications: Freud had revolutionized the science of man by inventing a method that could be used to grasp the individual in his singularity while avoiding the abstraction that characterized contemporary psychology. But when Freud tried to establish a theoretical foundation for his general intuitions, he fell into the grip of classical psychology with its emphasis on formalism, abstraction, and realism. This is discussed in Politzer's *Critique des fondements de la*

*psychologie* (1928), where Freud's thought is used as a weapon against conventional psychology and as a model for the construction of the object of the concrete psychology of the future — the drama, or the dramatic life to the extent that it is the subject of a story. Politzer makes use of Freud's texts in a way no French philosopher had until then, especially *The Interpretation of Dreams*. The first six chapters are described to be exemplary for concrete psychology; the last, however, is strongly criticized, especially the passage in which Freud discusses regression, where Politzer sees a resurgence of psychological realism in the materialist concept of the psychic apparatus. He also felt that the concept of the unconscious belonged more to nineteenth-century philosophy and traditional psychology, and was an obscure concept that negated the real inspiration of psychoanalysis. He outlined the conflict between Freud's method and his theories, a dichotomy later picked up by many other philosophers.

Politzer became a member of the Communist Party in 1929. That same year he published "La crise de la psychanalyse" in *La Revue de psychologie concrète* and "Un faux contre-révolutionnaire, le freudo-marxisme," which appeared in 1933 in *Commune*, and in 1939, on the occasion of Freud's death, "La fin de la psychanalyse" in *La Pensée* (republished in Politzer, 1969). These articles articulate the split between a committed Marxist and psychoanalysis, which he condemned for its supposed dogmatism.

Politzer's 1928 book has influenced a number of French philosophers, especially Sartre and Merleau-Ponty, through the author's critique of the unconscious and the importance he gives to meaning in understanding human behavior. In 1946 Jacques Lacan wrote a glowing encomium to Politzer's life and work.

## PORTO-CARRERO, JULIO PIRES (1887–1937)

This Brazilian psychiatrist was born at Pernambuco in northeast Brazil on September 7, 1887, and died in Rio de Janeiro on December 30, 1937.

He studied medicine at Rio de Janeiro, specialized in psychiatry, and became a full professor of forensic medicine in the law faculty. A disciple of Juliano Moreira and “wild psychoanalysis,” he used Freud’s method as early as 1924 and was the most important precursor of the psychoanalytic movement in Rio. Sponsored by Durval Marcondes, he founded an affiliate society of the Sociedade brasileira psicanálise in 1928 with Juliano Moreira as president and himself as secretary.

Between 1929 and 1934 he wrote seven works on psychoanalysis. In the first, *Ensaio de psicanálise* (1929, *Essays on Psychoanalysis*), he displayed a good knowledge of the works of the great psychoanalysts. These essays consist of different articles and papers dating back to 1925. The first chapter, “The Concept and History of Psychoanalysis,” is very important in terms of historical data. In the article “Clinical Aspects of Psychoanalysis” (1925), he declared: “Sooner or later, it will become standard practice to apply psychoanalysis to daily life, to pedagogy, to trade even, to military training, to legal investigations and to penitentiary systems.” In “A Brief Notion of Psychoanalysis” (1927), he wrote: “Thanks to this concept, we have a better understanding than before of how civilization developed, the genesis of languages, the origin of myths and legends, the reason behind works of art and the motives for professional vocations.”

In his course, “Psychoanalysis Applied to Education” (1928), given with Deodato de Moraes, we read: “Although psychoanalysis was initially therapeutic [...] it has invaded the sphere of the mind sciences.” He demonstrated the evolution of Freudian ideas and responded objectively to Freud’s critics. Other articles revealed his researcher’s spirit. Finally, in “The Value of Psychoanalysis” (1931), he described his personal experience, his doubts and certainties, his positive and negative results. His limits, in terms of the technique he accepted, came from his lack of analytical training. He also translated Freud’s *The Future of an Illusion* (1927).

As a renowned professor of forensic medicine, he stressed the necessity of having a human and a psychoanalytic understanding of the criminal. He enjoyed

great influence in student circles and among the intellectual elite and paved the way for the future psychoanalysts of the 1940s.

He was in the habit of organizing musical receptions in which he played an active part. On the evening of December 30, 1937, just as his guests were arriving, he felt ill and suddenly died.

## PORTUGAL

Before psychoanalysis was institutionalized in Portugal, certain cultural events paved the way for the reception that Freud’s doctrines were later to receive. It is widely accepted that the birth of psychoanalysis in France and Austria was influenced by experiments relating to hypnosis (Mesmer and Charcot). Similarly, we can say that in Portugal José Custódio de Faria (1756–1819), known as Abbé Faria, was an important precursor. Born in Goa, he studied theology in Lisbon and Rome before becoming a priest. He was in Paris in the troubled days of the French Revolution and the Empire, and it was there that he became a disciple of the magnetists. He studied under Mesmer and Puységur, and the theories he presented in his book, *De la cause du sommeil lucide* (1819, *The Cause of Lucid Sleep*), were ahead of his time — he was the first to abandon theories of magnetic fluids and anticipated his contemporaries in his descriptions of post-hypnotic suggestion.

The impact of Freud’s discoveries began to be felt in Portugal at the beginning of the twentieth century. Egas Moniz (1874–1955) was the first to present the

bases for Freud's theory. Moniz had taken an interest in sexology early in his career, and in 1901 he published a book entitled *Sexual Life (Physiology and Pathology)*, which ran to several thousand copies in a few years. In 1925 he published a remarkable biography of Abbé Faria. Because Moniz was preoccupied with sexual life and hypnotism, it was only logical for him to take an interest in psychoanalysis also. In fact, between 1915 and 1925 he published several articles on psychoanalytic theory and method. In two of these articles Moniz described two long cures of neurotic patients, with whom he used the couch, free association, and dream interpretation. In both cases he managed to resolve the neurotic conflicts by having recourse to psychoanalytic psychotherapy. As time went by Moniz's activities centered increasingly on neurological problems. After he discovered cerebral angiography (1927), for which he won the Nobel Prize, he devoted himself entirely to neurology—to the exclusion of psychotherapy and the sexual life. We may well wonder how the psychoanalytic movement would have evolved in Portugal if Moniz, who really was a man of genius, had continued with his initial research and joined Freud's Viennese circle instead of going to work in Paris with Pierre Marie, Jules Déjerine, and Joseph Babinski.

Other psychiatrists, like Sobral Cid (1877–1941), a professor of psychiatry at the university of Lisbon, and Diogo Furtado (1906–1963), one of the most brilliant neuro-psychiatrists of his day, manifested great interest in the theory of psychoanalysis. But they did not continue Moniz's therapeutic work, nor his observations.

After these false starts, a Portuguese psychoanalytic movement finally saw the light of day in the 1950s. Portuguese physicians, beginning with Francisco Alvim and Pedro Luzes, went to Switzerland to train in Raymond de Saussure's Geneva group. They became full members of the Swiss Society and met in Geneva with Spanish analysts who were also in training there (Pedro Bofill, Pere Folch Mateu, and José Rallo Romero).

Together they decided to organize the Luso-Spanish Psychoanalytic Society, which the International Psychoanalytic Association (IPA) recognized as a study group at the Paris Congress in 1957. Two years later this study group was admitted as a component society at the Copenhagen Congress. The Luso-Spanish Society continued to grow, with the addition of ana-

lysts who were generally trained abroad, but training progressively came to be set up in Spain and Portugal.

In 1966, the Iberian group split because of problems of distance and other difficulties, giving birth to the Portuguese study group. Although the IPA may have granted the Luso-Spanish Society the status of a component society somewhat prematurely, too much time was allowed to pass before the Portuguese study group was recognized as a provisional society (1977) and then a component society (at the Helsinki Congress in 1981). This can largely be explained by the change in the IPA statutes, which became increasingly demanding in terms of the required number of members, with benchmarks being used to establish intermediary stages.

The title "Portuguese Psychoanalytic Society" nevertheless began to be used (locally) in 1971. Prior to 1981, several international meetings and congresses had already been held in Portugal. In 1968, the twenty-ninth Congress of Romance-Language Psychoanalysts was organized in Lisbon. Pedro Luzes presented a report entitled "Thinking Disorders in Clinical Psychoanalysis." It was one of the first works from outside Great Britain to stress the importance of Bion's research into thinking. In 1978 the second Conference of the European Federation of Psychoanalysis was held in Estoril on the theme: "The Narcissism of the Psychoanalyst." In 1980, again in Estoril, the First World Congress on Infant Psychiatry, dedicated to the memory of René Spitz, focused on normal and pathological aspects in the first two years of infant life. The forty-fourth and fifty-fourth Congresses of French-Speaking Psychoanalysts met in Estoril and Lisbon, respectively, in 1984 and 1994.

Since 1989, biennial Iberian congresses of psychoanalysis have brought together the Portuguese Society, the Spanish Society (with its headquarters in Barcelona), and the Madrid Psychoanalytic Association. Together these institutions publish the *Iberian Directory of Psychoanalysis* in the Castilian language.

In 1975, the Portuguese Psychoanalytic Society inaugurated an Institute of Psychoanalysis. As a center for psychoanalytic treatment its main function is to provide assistance. It is also active in providing psychoanalytic training. In addition to ten consulting chambers, the institute has several meeting rooms and an ample library containing all the most essential psychoanalytic books and reviews. The Society publishes

the *Portuguese Review of Psychoanalysis* every semester. The first issue appeared in 1985. In terms of scientific activities and dissemination of psychoanalysis, it is important to mention the scientific encounters that usually take place twice a year, called symposia (when predominantly clinical) and seminars (when predominantly cultural).

The problem of schools and divergent currents in psychoanalysis made its presence felt in Portugal, as everywhere else, though perhaps less acutely than in other countries, probably because in the context of a small society deep rifts and intense rivalries run the risk of destroying the analytic group. In the period between the 1940s and the 1980s, when the Portuguese Psychoanalytic Society was finding its feet, the opposition between so-called Freudian (also called “classical”) analysts and Kleinian analysts came to a head. In the Freudian camp were Francisco Alvim (who trained in Raymond de Saussure’s group in Geneva) and João dos Santos (who trained in Paris). Kleinian ideas were introduced to Portugal by Pedro Luzes who, while working in the same Geneva group as Alvim, was also analyzed by Marcelle Spira (a Swiss analyst who received Kleinian training in Argentina). The Freudian nucleus sought support from the Paris Psychoanalytic Society. Beginning in 1962, Pierre Luquet, its representative in Portugal, provided regular teaching for more than twenty years. The Kleinian group received more limited support from the British. Today the theoretical ideas of most of the members and students in the Portuguese Society are mixed, having both Freudian and Kleinian roots. This epistemological constitution is close to what the British call Group B. The Portuguese Psychoanalytic Society recently undertook the task of institutionalizing the training of child psychoanalysts among young analysts and candidates. To do so they relied mainly on French analysts (Florence Guignard, Annie Anzieu, Jean Bégoïn, Didier Houzel, Donald Meltzer, and Antonino Ferro).

Several tendencies claiming to have a dynamic model of the mental continue to evolve along parallel lines. Some, being analytical, take their inspiration from the teachings of Jacques Lacan. Others are influenced by the systemic current (group analysis and family therapy). The psychoanalytic trend as defined above nevertheless dominates all of these movements.

## **POSTNATAL/POSTPARTUM DEPRESSION**

The term *postnatal* (or *postpartum*) *depression* describes a condition occurring in a woman after giving birth to her child. The symptoms are depression, anxiety, lack of interest in the baby, and feelings of inadequacy and incompetence as a mother. It occurs among 10 to 15 percent of mothers after delivery, with onset at five to eight weeks after delivery. It is underestimated by professionals and often denied by women, who usually do not seek medical advice. It commonly lasts six months to a year or longer. It causes a lack of attunement in the mother and infant dyad and can lead to early developmental and psychosomatic problems in the baby, making diagnosis and treatment essential (Murray, L., et al., 1991; Mazet, P., 1997). Jeni Holden et al. (1989) demonstrated the therapeutic efficacy of nondirective psychological interviews; A. F. Henderson et al. (1991) note the positive effects of estrogen therapy; R. Channi Kumar et al. (1984) and Donald Meltzer emphasize the need for professionals to coordinate their efforts in treating this pathology, which is still poorly understood and is situated at the intersection of obstetrics, pediatrics, and health services.

B. Pitt (1968) gave the first description of an “atypical postnatal depression” that affected a minority of women, but occurred at a rate of 10.8 percent in a sample of 305 women after delivery. The Edinburgh Postnatal Depression Scale (EPDS), a questionnaire for mothers developed and validated by John Cox et al. (1987), John Cox and Jeni Holden (1994), and Nicole Guedeney et al. in France (1995), makes it possible to diagnose postnatal depression from the sixth week after delivery (when the postnatal obstetrical visit is usually scheduled).

Postnatal depression can be classed among other postnatal psychiatric conditions, ranging from the blues to postpartum traumatic neuroses (Bydlowski and Raoul-Duval, 1978) and the acute postpartum

psychoses that have been described since the nineteenth century (Marcé, L.-V., 1858). In a psychodynamic study, Paul-Claude Racamier et al. (1961) developed the concept of “maternity.” The event of childbirth occasions reversible changes in the psyche whose transparency has been described by Monique Bydlowski (1997). This involves, on the one hand, a reactivation of the themes of the young woman’s infantile neuroses, namely castration anxiety and the avatars of her pre-oedipal links to her own mother, and, on the other hand, a particular capacity for regression that enables her to achieve a psychic functioning that is more in tune with her newborn, as Donald Winnicott showed (1956). The conflicted development of this maternity is theorized as being the origin of some psychopathologies.

Postnatal depression differs from a depressive state in the strict sense, in that anxiety and the mother’s feelings of inadequacy it produces often dominate the picture. It should also be distinguished from postpartum blues (Yalom, I., et al., 1968; Kennerley, H., et al., 1989), a reaction whose peak frequency occurs on the third day after delivery and which affects half of all women; it is characterized by irritability, mood swings, and crying spells, with spontaneous resolution in one to ten days. A particularly lasting or intense case of the blues may be an indicator of the subsequent likelihood of true postnatal depression (Fossey, L., et al., 1997).

### **PÖTZL, OTTO (1877–1962)**

Otto Pötzl, the Austrian physician and psychiatrist, was born in Vienna on October 29, 1877, and died there on April 1, 1962.

His father, the writer Eduard Pözl, came from a Catholic family and was a freeman of the city. Otto Pözl finished his medical studies in the medical faculty of Vienna University in 1907 and specialized in psychiatry and neurology. From 1905 to 1921, he worked first as an assistant then as chief medical officer in Julius Wagner-Jauregg's neuro-psychiatric clinic in Vienna. In 1911 he took a qualifying exam for specialists in psychiatry and neurology and in 1919 he was appointed professor extraordinary at the university. From 1922 to 1928, Pözl was professor of psychiatry in Prague and in 1928 he succeeded Wagner-Jauregg in Vienna.

Pözl was one of the most respected representatives of the Viennese school of psychiatry. One of his lectures at Vienna University, in which he presented experimental research into dreams and thus confirmed the Freudian theory, led Freud to invite him to attend the sessions of the Vienna Psychoanalytic Society. In June 1917 he delivered a paper on the theme of "Experimentally provoked dream images as an illustration of Freudian dream analysis." Six months later he was admitted as a member of the society. Although some considered his attitude to psychoanalysis to be ambivalent, several of Freud's students were trained in his clinic and Pözl remained a member of the society until 1933. His scientific work, however, had no impact at all on clinical psychoanalysis.

He gave speeches at the ceremonies organized to celebrate the eightieth and hundredth anniversaries of Freud's birth.

In a letter to Freud, Pözl wrote: "[...] I cannot imagine my teaching work without psychoanalysis. My audience and I are your fervent supporters" (Jones E., 1953–1957, p. 255).

Pözl remained president of the university neuro-psychiatric clinic until 1945, when he retired.

## **PRECONCEPTION**

In the strict sense, the term "preconception" in the work of Wilfred R. Bion refers to a necessary antecedent to all forms of thought (be it a conception, concept, or deductive system). When a preconception is "realized," that is, comes into contact with sensory data close to it, it becomes a conception and a concept. Bion later greatly expanded and generalized this notion.

In Bion's theory, preconception functions like the categories in Emmanuel Kant's epistemological theory, that is, as an innate predisposition to receive certain information, as the form of thought. The term designates a state of expectancy.

This formulation theoretically grounds the innate character of preconception. The example of preconception that Bion repeatedly gives, the nursling's expectation of the breast that provides nourishment, suggests Freud's notion of primal fantasies. From this perspective, the infant need not receive, for example, a threat of castration to be subject to the castration complex, because the infant can have primal fantasies of sexual mutilation.

Later, in his *Elements of Psycho-Analysis* (1963), Bion readjusted the term and eliminated references to the innate and phylogenetic aspects of preconception. With regard to his grid, Bion explained that each element along the vertical axis functions as a preconception relative to the terms that follow on the same line, with the exception of the saturated beta elements. In addition, the grid as a whole functions as a preconception. The analyst's free-floating attention is also like preconception, in that it involves a state of expectation induced in the analyst by the analyst's personality and training.

With the aim of producing a more abstract and expanded formulation, Bion proposed representing preconception by means of a function (preconception) and an unknown variable (realization). Once a realization becomes known (agitation, curiosity, castration, etc.), it becomes a constant.

Bion developed the term “preconception” by generalizing and concretizing it, yet such development does not fully comport with the genetic importance that Bion attributed to it in the formation of thoughts or with its epistemological role in resolving certain conundrums of psychoanalysis (empiricism versus innatism).

## **PRECONSCIOUS, THE**

Already, in his 1896 letters to Wilhelm Fleiss (“Extracts from the Fliess Papers,” 1950a), Freud connected the preconscious associated with verbal representations as being the ego. The full definition of the preconscious emerged only within the delineation of the first topographical theory, although it was never precisely formulated.

The preconscious (*Pcs.*) can only be conceived in opposition to the unconscious (*Ucs.*): It is the very differentiation between the two that makes it possible to think of a topography of the mind. The *Pcs.* is the antagonist of the *Ucs.*; the former is separated from the latter by censorship, the barrier of repression. As the agent of repression, the *Pcs.* is what provides the forces necessary (anticathexes) to maintaining unconscious representations in the unconscious.

The modes of functioning of the *Pcs.* system are different from those of the *Ucs.* in that energy is bound there and that the secondary processes and the reality principle are dominant.

To understand the antagonistic function of the *Pcs.*, it is necessary to let go of the idea—which is nevertheless suggested by its name—of a sort of gradation in the capacity for material to become conscious. That idea was nonetheless present in Freud’s work when he adopted the point of view of a descriptive unconscious, defined relative to consciousness. What was preconscious was then considered as unconscious in the phenomenological sense, readily and by right accessible to consciousness. This usage of the term, most often as an adjective, was thus in contradiction with the notion of two opposing systems, with the preconscious preventing the penetration into consciousness of unconscious contents. The contradiction was only transcended within the context of analysis itself, when the process of becoming conscious was studied. Thereafter, the preconscious took on the role of an intermediary between unconscious contents and their coming into conscious awareness.

The specificity of the preconscious lies in its connection to language. In “The Unconscious” (1915e), Freud wrote: “The system *Ucs.* contains the thing-cathexes of the objects, the first and true object-cathexes; the system *Pcs.* comes about by this thing-presentation being hypercathexed through being linked with the word-presentations corresponding to it” (pp. 201–202). It is thus the perspective of treatment (the “talking cure”) that made it possible to grasp the specificity of the preconscious. Through the work of analysis, representations of things, that is, the contents of the unconscious, are put into relation with the word-presentations that can then make it possible for them to come into conscious awareness. The preconscious is the place where this transposition into words, this link between words and the unconscious thing, takes place.

This notion of the preconscious as the intermediary between the unconscious and consciousness, between thing-presentations and word-presentations, between the primary and secondary processes, was maintained and amplified in psychoanalytic work over the course of time. The preconscious is now considered a locus of exchange and psychic work. Attributed to it are qualities of richness and permanence that vary from one individual to the next and can be used as the criteria for analyzability.

While Freudian metapsychology, dominated by the idea of repression and its role in neurosis, does make it possible to conceive of an impoverished preconscious, cases of atypical, nonneurotic patients, in particular psychosomatic patients, drew the attention of the psychosomatic school of Paris under the aegis of Pierre

Marty. Marty gave the preconscious a central place in his conception of mental functioning, and as a result there is an emphasis in his theory on its role as an organizer, a regulator of not only psychic but also somatic balance. Marty's thinking concerned qualities that are present in varying degrees in the preconscious: its richness, breadth, mobility, and permanence. Richness and mobility refer to the multiplicity of symbolic derivatives in the unconscious capable of interacting in this intermediary zone with word-presentations, themselves multiple and available. The notion of breadth, evocative of the density of this network of representations, also leads to the idea of the preconscious playing the role of an internal protective shield that makes possible the protection of the ego against assaults from the drives and the external world. Permanence has to do with the capacity for lasting and stable functioning.

A sound organization of the preconscious goes hand in hand with sound mentalization, whereas occasional or long-term weakness can lead to what the French psychosomatic school called "operative" functioning, essential depression, or character and behavioral neuroses, as these are described in Marty's classification. By contrast, sound functioning of the preconscious guarantees a rich capacity for fantasizing.

## **PREGENITAL**

The term *pregenital* designates the libidinal phases prior to the definitive, genital organization of psychosexuality.

This adjective first appeared in Sigmund Freud's 1913 article, "The Disposition to Obsessional Neurosis: A Contribution to the Problem of Choice of Neurosis." The idea of a pregenital organization of the libido was introduced in the context of anal erotism. The qualifier "pregenital," which at this point in Freud's work generally defines the child's psychosexual organization, takes into consideration the play of the instincts that are not yet under the primacy of the erotism of the genital zones. Such instincts are called "component" instincts because they remain closely dependent on their somatic sources, they have partial aims, and they function independently of one another. Partial oral and anal sexual activities are supported by the corresponding physiological functions: eating and defecating. In other words, they rely anaclitically on those functions and are thereby instituted as erotogenic zones; their excitability will mark the later genital stage.

In the case of Little Hans, recounted in "Analysis of a Phobia in a Five-Year-Old Boy" (1909b), Freud described an infantile libidinal mode of organization under the sway of an erotogenic zone, namely the genital area. In the boy the Oedipus complex is born of castration anxiety, that is, the fear of being deprived of a precious organ, the penis (as punishment for masturbation). Freud maintained that at this stage, there is a primacy of the male organs for both sexes.

This model, however, based as it was on the boy's libidinal organization, made the case of the girl problematic for Freud and for many of his successors. In his paper on "The Infantile Genital Organization" (1923e), Freud nevertheless clearly assigned the phallic phase of libidinal organization to the pregenital

period. He also revised the general picture of the successive phases of libidinal organization and its polarities. That organization was characterized by the subject/object opposition and its beginnings in the ambivalence of the second stage of the oral phase; then by the opposition, in the anal-sadistic phase, between active and passive. In the next stage, the phallic or infantile genital organization, the phallic/castrated opposition emerged, but this preceded the masculine/feminine opposition. "The complete organization is only achieved at puberty, in a fourth, genital phase," wrote Freud in "An Outline of Psychoanalysis" (1940 [1938], p. 155).

Under these conditions, is it appropriate to call the phallic organization "pregenital"? The very title "The Infantile Genital Organization" invites a negative response; and indeed, the actual use of the term "pregenital" tends to embrace only the oral and anal organizations. However, this same paper of 1923 clearly defines phallic organization as preceding the ultimate genital organization. This question might appear to be purely formal, but it raises substantive issues about libidinal development and the obstacles it encounters, in both sexes, that are not easily clarified.

## **PREGNANCY, FANTASY OF**

An infantile fantasy in which the subject, whether masculine or feminine, has the unconscious wish to bear a child, the *fantasy of pregnancy*, which Sigmund Freud links to the enigma of the origin of children and to the fantasy of the primal scene, leads the child to elaborate sexual theories that stage it. In the work of Melanie Klein, this development relates to the creation of an internal object (good or bad). Over the course of psychosexual history, this fantasy has taken on different forms and different meanings.

Freud discusses this unconscious fantasy in connection with dreams in "On Dreams" (1901a); that of pregnancy and the wish for a child in connection with the earliest theories of infantile sexuality in *Three Essays on the Theory of Sexuality* (1905d) and with the Schreber case, in "Psycho-analytic Notes on an Autobiographical Account of a Case of Paranoia (Dementia Paranoides)" (1911c [1910]).

In girls, this fantasy develops in relation either to orality with incorporation, or to anality, where the child-feces becomes a gift given to the mother (between omnipotence and toxicity). The enigma of sexual difference and penis envy, at the genital turning point (penis = infant), feeding on identification with, and hatred of, the mother, cause her to address this fantasy to both parents. Freud situates it as coming second after the onset of penis envy, whereas in Klein's view the girl, through mental bisexuality, wishes to receive a penis from the father; the girl believes she contains children (image of a hollow interior), but may doubt her capacity to bear them. In the girl's oedipal phase, she turns away from her mother and toward the mother's object of desire, the father. The girl demands from him the infant-penis that would make her a mother and worthy of his love; he is supposed to give her what her mother has refused to give her. There is thus a movement from having to receiving, via passivity, and an external demand toward something internal.

Often confused or conflated in the adult woman, the fantasy of pregnancy and the desire for a child situate her within bisexuality: By means of this infant-penis, without renouncing masculinity, she is

inscribed within the feminine position, according to Julia Kristeva in *The Sense and Non-Sense of Revolt*. In feminine homosexuality, this fantasy can aim to neutralize the father, making him a mere progenitor. In boys, this fantasy, often activated by visual contact with the mother or a pregnant woman, is colored by a feminine attitude toward the father, as attested by some frequent themes: bearing embryos after swallowing fruit pits or seeds; escaping from sexual difference by equating feces with a child (a part of the self that must be renounced); aiming to achieve narcissistic completeness in the ambivalence between feminine and masculine, through an identification that passes from creative power to passivity and masochism. Persistence of these infantile traces is found in the traits of homosexuality; in hypochondria; in the fear of having been poisoned and carrying toxic material within oneself; in the notion of being chosen by the gods and impregnated, as in the case of President Schreber, to bring a new humanity into the world; or in the fantasy of self-engenderment (*sui generis*).

Occidental mythology includes various representations of this fantasy: Minerva springing from the head of Jupiter, or Eve being born from Adam's rib. It can happen that the companion of a pregnant woman may experience physical or mental malaise around the time of delivery. The *couvade* (a custom in which the father of a newly born infant engages in certain rites such as being in bed as if he has borne the child himself) is a variation linked to envy of women's creative functions.

## **PREHISTORY**

Freud used “prehistory” to refer to the most remote past, the “already there,” the psychically innate, and the time before the Oedipus complex. This notion, present in his writings as early as 1888, was made more explicit in chapter 7 of *The Interpretation of Dreams* (1900a). The idea runs through his entire work, and after 1912 (1912–1913a; 1913j; 1918b [1914]; 1985 [1915]) was transformed in a scientific quest to define psychoanalysis as an autonomous natural science of origins. Yet the notion of prehistory was also transformed into a ground for speculating and for pursuing an analogical approach.

From 1912 to 1915, a period of intensive metapsychological theorization, Freud pursued this quest in his investigations and hypotheses with Sándor Ferenczi, himself the exponent of a “metabiology.” Freud also definitively broke with Carl Gustav Jung and invited first-generation psychoanalysts to explore the object of anthropology and ethnology via the clinical method of psychoanalysis (Rank, Róheim). Without ever giving up his theoretical grounding in the drives and libidinal development, Freud introduced the evolutionary views of Charles Darwin, Ernst Haeckel, Jean-Baptiste de Lamarck, Fritz Wittels, and J. J. Atkinson for two primary reasons: to give a new orientation to the problem of how constitutional dispositions relate to individual history, and to make two points of view—ontogenesis versus phylogenesis, or development versus evolution—coherent with one another.

This is a bold hypothesis, fraught with theoretical and clinical consequences in that it affirms not only the universality of the psychic apparatus and the archaic heritage of its disposition and constitution, but also the transmission of content, that is, the lived experience of previous generations. This is not a biological theory, but rather a psychoanalytic theory of the history of the facts and acts that constitute the biological.

Freud asked the reader to abandon phenomenal knowledge in order to conceive of the primal, the genesis of primordial conflict, anxiety in the developmental processes, guilt in evolution, latency, and deferred action. Freud's notions of primitive, primary, primordial, ancient, archaic, and ancestral broaden the notion of prehistory and reveal not only Freud's strong adherence to the evolutionary ideas of his time, but also a need to conceptualize a prior period that defines the

subject's history and that the psychoanalytic process reactualizes during treatment. To explore the various borders encompassing the concept of prehistory, Freud entered into the domains of anthropology, ethnology, paleontology, linguistics, folklore, history of religion, and archaeology.

The notion of prehistory attempts to legitimize the systems of thought of primitive peoples, of children, and of adults to be compared, and also reorders the choices of neuroses inversely to the hypothetical phases of human mental development.

## **PREMATURE-PREMATURITY**

A *premature* or *preterm* baby (Voyer, Marcel, and Magny, Jean-François, 1998) is a baby born with fewer than thirty-seven weeks and six days of gestation.

Babies born before the thirty-third week of gestation are considered significantly premature; pregnancies that end earlier than the thirty-first week of gestation pose the greatest problems. Today, the vital and neurodevelopmental prognosis is very good for preterm babies born after thirty-three or more weeks of gestation.

Premature birth disrupts the conditions necessary for the normal development and physiology of the fetus. A new environment must take over the tasks of the maternal placenta, including respiration; the baby's genetically programmed maturation is henceforth dependent on postnatal maturation, prematurely exposed to the outer world (Soulé, Michel, 1992).

Beginning in the 1970s psychoanalysts began making their specific contribution with regard both to the premature baby as person and to parents and caregivers (Satgé, P., and Soulé, 1976). The preterm baby's specific modes of interaction (Di Vitto, Barbara, and Goldberg, Susan, 1979; Field, Tiffany, 1979; Minde, Klaus, 1980), as well as the child's capacities and competence, became better known (T. Berry Brazelton). The notion of the "interactive pattern," which describes different styles of parental interaction, also appeared.

Direct infant observation (that of Esther Bick, and Michel and Geneviève Haag), together with the work of the neo-Kleinians, was applied to hospitalized preterm babies (by Catherine Druon, Joyceline Siksou, and Yolaine Quiniou, among others) and contributed to a closer understanding of the baby's emotional life and bodily states during these first days of life, which are decisive for the foundation of mental life, according to Bernard Golse. Shared observation aims to support, or even treat, the interactive capacities of those participating: mother, father, and caregivers, any of whom may be impeded by the situation or their own personal state. Faced with this exceptional newborn, often closer to a "fetus out in the air" than to their fantasized, imagined baby, the parents find themselves in an almost experimental situation (Kreisler, Léon, and Soulé, 1995).

Psychic trauma can be serious when reality seems to authenticate the fantasies inherent in pregnancy, such as the birth of something strange, or a crisis in parental identity, which are magnified by the preterm birth (Aubert-Godart, Anne, 1998; Friche, Anne, 1998).

The baby's physical prematurity has as its correlate an unfinished pregnancy, mirrored by the prematurity

of the mental process of becoming a parent. The maturation of the internal object is brutally interrupted and the necessary imaginary work during pregnancy of dreams and fantasies regarding the expected baby is suspended. The “unanticipatable” and unrepresentable reality of the newborn, both strange and a stranger, can imprison its parents in a traumatic present.

The parents in the making, persecuted by an amputated pregnancy, a catastrophic birth, and an anxiety-provoking infant, develop intense and ambivalent feelings of strangeness, guilt, and shame, magnified by the necessary separation of hospitalization. The psychopathological risks they run are exacerbated if the parents have fragile personalities. Their mental difficulty in assigning the baby a place within the symbolic universe of the family and transmitting to the child what Serge Lebovici has called the “transgenerational mandate” expresses both their wounded narcissism and their current inability to enter into a relationship with their baby. Therapy sessions are necessary to support their emerging and vacillating sense of parenthood.

In such cases, the team of caregivers relies on a multidisciplinary effort to promote psychical working over, led by the psychiatrist, the psychologist, and the psychoanalyst. Caregivers work together, beyond strict medical or nursing care, to promote a gradual “revelation” of the parents’ nurturing abilities and the overall development of a newborn who is “good enough.”

## **PREMONITORY DREAMS**

A premonitory dream is a dream preceding a real event that seems to foretell its occurrence.

In *The Interpretation of Dreams* (1900a), Sigmund Freud alluded many times to the ancient belief that certain dreams predict the future. In an appendix he added to this work, he described and analyzed this kind of dream from the perspective of wish fulfillment. The following year he stated explicitly: “It is interesting in this connection to observe that the popular belief that dreams always foretell the future is confirmed. The future which the dream actually shows us is not the one which *will* occur but the one which we should *like* to occur” (1901a, p. 674). He later discussed so-called premonitory dreams in connection with the case of the “Rat Man” (1909d).

While obviously, in clinical practice, the belief in the premonitory character of certain dreams cannot be adhered to naïvely, it does make sense to pay very close attention to this belief, when it accompanies the recounting of a dream, often in connection with a sense of “the uncanny.” In the analysis of such dreams the hypothesis of a disguised realization of an unconscious wish has shown itself to be particularly fruitful.

## **PREPSYCHOSIS**

Prepsychotic states are characterized by precariousness of the neurotic mechanisms, that is to say, “secondary processes” that are too readily invaded by the “primary processes” (Sigmund Freud), resulting in the sudden

appearance of troubling and raw images that cause excessive anxiety and disorganization.

The notion of prepsychosis or prepsychotic states was introduced in 1969 by René Diatkine and Serge Lebovici to account for the lability of symptomatology and appearance of some worrisome clinical configurations in children; the term “prepsychosis” describes states that it would be imprecise, and also detrimental to the child, to try to situate as either neuroses or psychoses.

It was in the context of a psychoanalytic approach to the mental functioning of children that the notion of prepsychosis became necessary. In psychoanalytic clinical work with children as it developed in France between 1960 and 1980, diagnostic and prognostic assessment was not based on a collection of symptoms and behaviors but rather on a psychoanalytic exploration of the mental processes put into play in the child to ensure homeostasis in his or her mental functioning. From this point of view, “neurotic functioning,” as it is observed in “infantile neurosis,” is the most favorable form of psychic organization. “Infantile neurosis” (as part of the Oedipus complex) is thus opposed to “neurosis in children,” which encompasses various pathological conditions.

Clinical psychoanalysis attempts to penetrate beyond manifest symptomatology as exemplified by the psychoanalytic understanding of phobias, wherein a phobia ensures that the anxiety be associated with an avoidable situation and thus that it is an effort to disengage the child’s mental functioning from the risk of being flooded with an excess of anxiety that would be paralyzing. But if this attempt at fixation fails, the possibility of flooding by anxiety despite the phobia remains strong; in this situation large quantities of diffuse, unbound anxiety lead to the massive inhibitions and counterphobic behaviors that define prepsychotic states. But overwhelming anxiety inevitably restricts autonomous mental functioning. Only with difficulty can the mental structures necessary to their development be organized in such children, allowing for sublimations or pleasure in mental functioning that would enable them to ensure the regulation of their mental activity. Their current, apparent neurotic organization does not protect them from breaks in their equilibrium that may cause them to resort to psychotic or aberrant behavior.

Thus, in prepsychotic states the secondary processes are sufficiently developed to ensure, for certain periods

of time or under certain environmental circumstances, a relatively adequate mode of behavior in which the child shows a neurotic type of functioning. However, this functioning can easily be overwhelmed and again flooded by extremely debilitating anxiety and by the primary processes. In the absence of reinforcement by the neurotic mechanisms, a kind of fragility of psychic functioning sets in that will make it difficult for the child as he or she approaches the critical period of adolescence.

The prognosis with such states essentially depends upon the support and reinforcement of the child’s neurotic functioning that can be provided through the child’s social and family environments and psychotherapy treatment. Prepsychotic children’s vulnerability to disorganization also predisposes them to various developmental vicissitudes. Rather than evolving toward fixation in psychotic organization *per se*—which remains a possibility in the mid- or long term—most often such children begin to manifest behavioral disorders: perverse or psychopathic conduct, sexual behavior problems, somatization, substance abuse, and so forth. Another course of development, particularly in young children, is that of inhibited intellectual growth, where the mechanisms of isolation put into effect in an attempt to control being invaded by the primary processes result in impoverished mental functioning and restriction of developmental possibilities.

In itself, then, the term prepsychosis does not have a prognostic value relative to possible psychotic organization later on, but is instead intended to situate the functioning of these children between neurosis and psychosis. The choice of this term has thus often been criticized, and other authors faced with the same clinical reality have proposed such terms as “parapsychosis” (Jean-Louis Lang) or “developmental disharmony” (Roger Misès). The term “borderline conditions” applied to childhood, might also be suitable to describe these intermediary states.

The essential thing, more than the term itself, is the emphasis placed by Diatkine and Lebovici on the specifics of mental functioning in such children and on the need to envisage this phenomenon from a dynamic point of view and not merely from a perspective of diagnostic description.

## **PREREFLECTIVE UNCONSCIOUS**

The term “prereflective unconscious” refers to the shaping of experience by psychological structures (organizing principles, meanings, schemas, thematic patterns) that operate outside conscious awareness. Experience is shaped by organizing principles without this shaping ordinarily becoming a focus of self-reflection. The patterning and thematizing of experience is therefore said to be prereflectively unconscious.

George E. Atwood and Robert Stolorow first introduced this idea in 1980 and distinguished the prereflective unconscious from Freud’s preconscious, because the former can be made conscious only with great effort, whereas the latter can be made conscious by a simple act of attention. Unlike Freud’s dynamic unconscious, the prereflective unconscious is not the product of defensive activity such as repression. The defenses themselves are seen as a special instance of organizing activity that is prereflectively unconscious.

The prereflective unconscious became a central construct in the theory of intersubjectivity developed by Robert Stolorow, George A. Atwood, and Bernard Brandchaft. Prereflective structures of experience are pictured as crystallizing within the evolving interplay between the subjective worlds of child and caregivers. Recurring patterns of intersubjective transaction lead to the establishment of invariant principles that unconsciously organize subsequent experiences. These prereflective principles, forged within the child-caregiver system, are seen as the basic building blocks of personality development and as the quintessential focus of psychoanalytic investigation and interpretation.

The prereflective unconscious has features in common with Claude Levi-Strauss’s, Jean Piaget’s, and Jacques Lacan’s ideas about unconscious structures of thought.

The concept of intersubjectively derived prereflective organizing principles is an alternative to the classical notion of unconscious instinctual fantasy.

## **PRIMAL FANTASIES**

The term “primal fantasies” connotes those fantasy formations (observation of sexual intercourse between the parents, seduction, castration) which are typical in character in that they transcend individual variations and which in Freud’s hypothesis are part of a phylogenetic inheritance.

Though evoked in “A Case of Paranoia” (1915f), the notion of primal fantasies was essentially bound up with Freud’s reflections on the primal scene, as developed in connection with the “Wolf Man” case (1918b [1914]) and reviewed during the same period in the *Introductory Lectures* (1916–17a).

The subject of primal fantasies brings up three issues: the idea of “typical” mental formations analogous to the sexual theories of childhood; an “origin” of such fantasies antedating the individual’s direct experience (phylogenetic inheritance); and the matter of “origins” in a general sense (what Laplanche and Pontalis [1964] call “fantasies of origins”).

If fantasies arose simply from the individual's particular experience, the work of analysis would be exceedingly complicated; it is precisely the recurrent structures of fantasy narratives and their association with specific psychopathological formations that makes them analyzable. Without going so far as to create a taxonomy, we may say that fantasies are central to complexes with a general character. In the case of the primal fantasies, however, Freud posited their universality inasmuch as they were characteristic of "all neurotics, and probably of all human beings" (1915f, p. 269). It was for this reason, he argued, that primal fantasies must perforce belong to a shared phylogenetic heritage. "It seems to me quite possible that all the things that are told to us to-day in analysis as phantasy . . . were once real occurrences in the primaeval times of the human family, and that children in their phantasies are simply filling in the gaps in individual truth with prehistoric truth" (1916–17a, p. 371).

What is meant, then, are inherited mnemonic traces that the child calls up in order to account for the enigmas he or she encounters: the difference between the sexes, the nature of sexual relations, and so on. As Jean Laplanche and J.-B. Pontalis point out, Freud here found himself once again between the rock of actual events and the hard place of constitutional factors. Transmission may occur, however, via the unconscious of the parents (see "Identification Fantasies," Alain de Mijolla [1981]). Fantasies of this kind tend to echo myth or tragedy (Sophocles, Shakespeare), for the same questions addressed there about the origins of things invariably recur in them: "Fantasies of origins: the primal scene pictures the origin of the individual; fantasies of seduction, the origin and upsurge of sexuality; fantasies of castration, the origin of the difference between the sexes" (Laplanche and Pontalis, 1974, p. 19). The universality of primal fantasies is underscored by the anonymity of the persons involved (1919e), clearly marking such fantasies off from fantasies in which the subject plays a leading part, even from instances where analysis of a fantasy uncovers the presence of the fantasizing subject. This curious characteristic lends these fantasies a seeming incontestability suggesting that they indeed originate from a source other than the individual imagination.

The notion of primal fantasy constitutes a link between the psychoanalysis of social groups and that of individuals, between prehistory and the history of particular subjects.

Freud deployed the phylogenetic thesis as a counterargument to the Jungian idea of retrospective fantasies (*zurückphantasieren*), but in a sense he remained himself trapped by this antithesis. Indeed the psychoanalytical conception of the "primal," as later elaborated, notably by Melanie Klein, abandoned the argument from phylogenesis.

## **PRIMAL REPRESSION**

The term "primal repression" refers to a hypothetical process postulated by Freud as the originating moment of repression: certain unconscious ideas—the primal repressed material—constitute a "first unconscious nucleus," which then operates as a pole of attraction for elements to be repressed later. "Primal" repression thus complements the work of rejection performed by the censorship or the ego by way of

“repression proper” or “after-pressure” (1915d, p. 148).

The existence of primal repression is in essence inferred from its effects. For repression to succeed, in Freud’s view, some already repressed material must be present, material which, as a truly constraining force, will draw to itself those ideas now marked for repression. But such unconscious attraction cannot suffice. At the same time, and in tandem with it, a pressure must also come into play from the opposite direction—a truly “repressive” force. Thus “repression proper” is the outcome of the combined forces of attraction and repulsion as directed toward the psychical representatives of the instinct.

Its prerequisite is that other, older, “primal” repressions should have already deposited material that remains in the shape of unconscious ideas manifesting their presence by attracting—from consciousness into the unconscious—ideas deemed disagreeable or unwelcome. This earliest repressed material constitutes a “nucleus of the Unconscious,” a primordial nucleus that later “exerts an attraction” upon fresh items to be repressed (1926d, p. 94); in this sense the moment of its formation may well be described as “primal.”

In the German term *Urverdrängung*, “primal repression,” the prefix *ur-* denotes this primordial aspect, for it means “original,” “of the origins.” It does not, however, provide any key to the meaning of primal repression. In parallel with *Urvater*, primal father of the horde, and *Urszene*, primal scene, *Urverdrängung* designates the matrix, as it were, of the prohibition on knowledge of that which was formerly known. Seen in this light, primal repression is much more than a postulate; the concept has been described as “an epistemological coup de force” marking the tipping point between the unknowable and the first signs of mental functioning, and as “inaugural and structuring” (Menahem, 1986).

This “phylogenetic” thesis seemed necessary to Freud in respect of the process itself, which had to be explained as the result of both pressure and attraction. “The impelling force is in a sense driven from two extremities, being rooted on the one hand in [its] ‘patrimonial’ foundation and linked on the other to perceptions liable to be unpleasurable. It thus combines the current and the archaic” (Le Guen, 1992).

Treating the attractive force as necessary raises the question of when primal repression occurs: How can a

“first” repression take place before anything has yet been repressed? “We have reason to assume that there is a *primal repression*, a first phase of repression, which consists in the psychical (ideational) representative of the instinct being denied entrance into the conscious. With this a *fixation* is established; the representative in question persists unaltered from then onwards and the instinct remains attached to it” (1915d, p. 148).

Furthermore, repression “demands a persistent expenditure of force” (*ibid.*, p. 151). Freud invokes anticathexis as the mechanism “which represents the permanent expenditure [of energy] of a primal repression, and which also guarantees the permanence of that repression.” Anticathexis is the sole mechanism involved in primal repression; as for “repression proper” or “after-pressure,” the withdrawal of preconscious cathexis also plays a part (1915e, p. 181). During the primitive period when the unconscious itself is constituted, if a force can be directed to the task of counter-cathexis, this can be done only by a differentiated mental agency. Inasmuch as the superego is formed subsequent to primal repression, the ego must be assumed to be the agency responsible here. The establishment of the ego and that of primal repression would thus seem to be correlated.

Although the precise nature and the motor force of this initial anticathexis might be obscure, Freud did offer an economic hypothesis concerning its formation: “It is highly probable that the immediate precipitating causes of primal repressions are quantitative factors such as an excessive degree of excitation and the breaking through of the protective shield against stimuli” (1926d [1925], p. 94).

## PRIMAL SCENE

The expression “primal scene” refers to the sight of sexual relations between the parents, as observed, constructed, and/or fantasized by the child and interpreted by the child as a scene of violence. The scene is not understood by the child, remaining enigmatic but at same time provoking sexual excitement.

The term appeared for the first time in Freud's work apropos of the “Wolf Man” case (1918b [1914]), but the notion of a sexual memory experienced too early to have been translated into verbal images, and thus liable to return in the form of conversion symptoms or obsessions, was part of his thinking as early as 1896, as witness his letter of May 30 of that year to Wilhelm Fliess, where he evokes a “surplus of sexuality” that “impedes translation” (1950a, pp. 229–230). Here we are already close to the model of the trauma and its “deferred” effect. The following year, in his letter to Fliess of May 2, Freud gave the approximate age when in his estimation children were liable to “hear things” that they would understand only “subsequently” as six or seven months (*SE* 1, p. 247). The subject of the child's witnessing parental coitus came up as well, albeit in an older child, with the case of “Katharina,” in the *Studies on Hysteria* (1895d), and Freud evoked it yet again in *The Interpretation of Dreams*, with the fantasy of the young man who dreamed of watching his parents copulating during his life in the womb (1900a [addition of 1909], pp. 399–400).

Freud persistently strove to decide whether the primal scene was a fantasy or something actually witnessed; above all, he placed increasing emphasis on the child's own fantasy interpretation of the scene as violence visited upon the mother by the father. He went so far, in “On the Sexual Theories of Children” (1908c,

p. 221), as to find a measure of justification for this interpretation, suggesting that, though the child may exaggerate, the perception of a real repugnance towards sexual intercourse on the part of a mother fearful of another pregnancy may be quite accurate. In the case of “Little Hans,” however, the violence was explained in terms of a prohibition: Hans deemed it analogous to “smashing a window-pane or forcing a way into an enclosed space” (1909b, p. 41).

The fantasy of the primal scene, like the sexual theories of children, is typical in character: it may be encountered in all neurotics, if not in every human being (Freud, 1915f), and it belongs in the category of “primal” fantasies. It appears, however, not to have the same force for all individuals. The case history of the Wolf Man gave Freud the opportunity not only to pursue the issue of the reality of the primal scene, but also to propose the idea that it lay at the root of childhood (and later adult) neurosis: the sexual development of the child was “positively splintered up by it” (1918b [1914], pp. 43–44). Freud later would later assign a central place to the primal scene in his analysis of Marie Bonaparte, although in her case the scene took place between her nanny and a groom (Bonaparte, 1950–53).

Looked upon as an actual event rather than as a pure fantasy reconstructed in a retrospective way (as with Jung's *zurückphantasieren*), the primal scene had a much more marked traumatic impact, and this led Freud to insist on the “reality” of such scenes, thus returning to the debate over event-driven (or “historical”) reality versus psychic reality. Beyond the issue of the scene itself, however, it was the whole subject of fantasy that was thus raised (in Chapter 5 of the Wolf Man case-history [1918b, pp. 48–60]), discussed in terms that would be picked up by Freud again later in “Constructions in Analysis” (1937d).

It was not merely, in Freud's view, that the technique of psychoanalysis demanded that fantasies be treated as realities so as to give their evocation all the force it needed, but also that many “real” scenes were not accessible by way of recollection, but solely by way of dreams. Whether a scene was constructed out of elements observed elsewhere and in a different context (for example, animal coitus transposed to the parents); reconstituted on the basis of clues (such as blood-stained sheets); or indeed observed directly, but at an age when the child still had not the corresponding verbal images at its disposal; did not fundamentally alter

the basic facts of the matter: "I intend on this occasion," wrote Freud, "to close the discussion of the reality of the primal scene with a *non liquet*" (1918b, p. 60).

Melanie Klein's view of the primal scene differed from Freud's, for where Freud saw an enigmatic perception of violence, she saw the child's projective fantasies. Klein describes the primal scene in a way closely resembling Freud's definition of the sexual theories of childhood. These wishes of the infant abound in hostile and destructive tendencies, but the mother is pictured therein as just as dangerous for the father as the father is for her. The sexual relationship between the parents, fantasized as continuous, is also the basis of the "combined-parent figure."

The primal scene is inseparable from the sexual theories of childhood that it serves to create. This disturbing representation, which at once acknowledges and denies the familiar quality of the parents, excludes the child even as it concerns them, as witness the libidinal excitement the child feels in response. The particularity of the primal scene lies in the fact that the subject experiences in a simultaneous and contradictory way the emergence of the unknown within a familiar world, to which they are bound by vital needs, by expectations of pleasure, and by the self-image that it reflects back to them. The lack of common measure between the child's emotional and psychosexual experience and the words that could give an account of the primal scene creates a gulf that the sexual theories of childhood attempt to bridge. A sadistic reading of the scene combines the child's curiosity about both the origin and the end of life in a representation in which death and life are indeed fused.

## PRIMAL, THE

The term *primal* refers to the totality of representations produced at the very beginning of mental life before there is any differentiation between internal and external, psyche and soma.

The primal should not be confused with the origin of fantasy life, but is an early expression of it and has

its own contents and its own logic. Never directly observable, the primal and its functioning can only be inferred, notably in the processes characteristic of psychosis (although psychosis is not reducible to these).

The primal was not used as the name of a category by Sigmund Freud, who contrasted the primary processes, describing the unconscious system and the free flow of psychic energy, to the secondary processes, describing the preconscious-conscious system and the binding of energy that allows for postponement of satisfaction. Freud felt the need for a term to describe that which is prior to the primary processes and would precede individual life experience, constituting a sort of a priori framework in which the events in the psychic life of each unique individual would be inscribed. In his view, the “archaic heritage forms the nucleus of the unconscious mind” (1919e, p. 204), the equivalent of instincts in animals in that it is innate and inherited based on phylogenetic traces. The primitive phases of the human family thus survive in each individual subject and are rediscovered by the child according to his or her particular life experiences: “In the case of human being...this phylogenetic point of view is partly veiled by the fact that what is at bottom inherited is nevertheless freshly acquired in the development of the individual, probably because the same conditions which originally necessitated its acquisition persist and continue to operate upon each individual” (354–355) (*passim*) (*Introductory Lectures on Psychoanalysis* (1916–1917) [1915–1917]).

Thus, Freud’s thinking on the origins of psychic life did indeed involve a “primal” defined on both a historical level (humanity’s prehistory) and a biological level (the transmission of traces). With his notion of “primal fantasies,” Freud provided some elements of the contents of these traces, but their structure was considered identical to the one that generally exists between all events and their memory traces. The only difference lay in his hypothesis that what has become fantasy was a reality in primal times.

The notion of the primal was studied by later psychoanalysts, not as a phylogenetically inscribed prehistory, but rather as the point of emergence of the earliest representations. In a certain sense, psychoanalytic thinking on the primal has been mainly informed by the Freudian notion of hallucinatory wish-fulfillment (*The Interpretation of Dreams* [1900]). For example, that notion is found in the work of Melanie Klein, who distinguished an “unconscious fantasy” that is linked

to sensation and stems from the instinctual impulses themselves. These fantasies quickly become susceptible to being fixed in the form of visual, kinesthetic, tactile, gustatory, or olfactory images. Only secondarily can these fantasies become associated with representations of external reality, and later, under certain conditions (e.g., analysis or the child’s spontaneous play) capable of being verbally expressed. However, they remain very remote from both words and conscious relational thought, and they are governed by emotional logic (Isaacs). At this level, there is no differentiation between mind and body, since overall primitive experience and the corporeal schemata associated with it are the determining factors. Traces of this primitive functioning are found in psychosis and hypochondria. Working within a Kleinian theoretical model, Wilfred R. Bion in *Learning from Experience* (1962) described the primal as being “at the source of experience,” defining something prior to thought made up of sensory impressions translated into mnemonic traces (alpha elements). The psychotic, who cannot effect this translation, must contend with sensory impressions in a raw form (beta elements) that cannot be represented as thing-presentations or word-presentations. This situation constitutes not a primal functioning of thought but its failure. However, this failure makes it possible to locate what would otherwise have been unfathomable because it normally undergoes transformation.

Clinical experience with psychotic patients also provided Piera Aulagnier with the basis for her development of the notion of the primal. In Aulagnier’s theory, mental activity is made up of three modes of functioning: the primal with the pictogram, the primary with the fantasy, and the secondary with the idea. These three processes go into effect in succession (following a genetic perspective), but then remain active simultaneously. However, as she wrote in *The Violence of Interpretation: From Pictogram to Statement*: “The psychical ‘objects’ produced by the primal are as heterogeneous to the structure of the secondary, as is the structure of the objects of the physical world that the I encounters and of which it will only know the representation that it makes of it” (p. 4). The primal process has its own logic. By pictogram, Aulagnier means a representation corresponding to the requirements imposed by the body on psychic apparatus (cf. the Freudian definition of the instinct). But the pictogram’s main characteristic is that it is unaware of the duality between sensory organ and external object. It

is a relational schema in which the representative is reflected as identical to the world. This implies an extension of the Freudian notion of primary narcissism, but with an original theoretical adjunct. As Aulagnier explained in the same book: “What psychical activity contemplates and cathects in the pictogram is this reflection of itself, which ensures that, between psychical space and the space outside-the-psyche, there exists a relation of reciprocal identity and specularisation” (p. 25).

Aulagnier’s theory of the primal opened the way to a new understanding of psychosis. Psychosis can in no way be considered a regression to a primal mode, although in the destructiveness of the psychotic process we encounter modalities of functioning that are no longer prevalent in other contexts.

## **PRIMARY IDENTIFICATION**

“Whatever the character’s later capacity for resisting the influences of abandoned object-cathexes may turn

out to be, the effects of the first identifications made in earliest childhood will be general and lasting. This leads us back to the origin of the ego ideal; for behind it there lies hidden an individual’s first and most important identification, his identification with the father in his own personal prehistory. This is apparently not in the first instance the consequence or outcome of an object-cathexis; it is a direct and immediate identification and takes place earlier than any object-cathexis. But the object-choices belonging to the first sexual period and relating to the father and mother seem normally to find their outcome in an identification of this kind, and would thus reinforce the primary one (*primäre Identifizierung*.)” (Freud, Sigmund, 1923b, p. 31).

It is rare in Freud, and consequently worthy of special attention, to read in the third chapter of *The Ego and the Id*, the solemnity with which he writes of “an individual’s first and most important identification” (*die erste und bedeutsamste Identifizierung des Individuums* [GW, XIII, p. 259]). This identification is situated in a mythical era, outside of time, a source of the ego ideal; it is called as such here to demonstrate that “be like” comes first, before the interdiction of the superego: “not to be like your father.” The father is what is implied here, even if Freud added in a note at the bottom of the page: “Perhaps it would be safer to say ‘with the parents’; for before a child has arrived at definite knowledge of the difference between the sexes, the lack of a penis, it does not distinguish in value between its father and its mother” (Freud, 1923b, p. 31n).

These quotations underscore how deeply Freud’s work is marked by the notion of “Proton Psuedos,” from the *Project for a Scientific Psychology* (1950c [1895], p. 352ff), which notion is a precursor to the concept of “deferred action.” Father, mother, or parents are equivalent in the logic of the system of this identification, for which the qualification “ontological” might be suitable. One day, two or three years after the crucial moment of identification—it does not matter exactly when—the perception of the anatomical difference must confirm *a posteriori* that the only one who matters in this identification is the bearer of the penis, father or phallic mother (whose image, it should not be forgotten, is reassuring, before becoming frightening), as an avatar of the father. Eventual identifications with the father and mother as such, that is to say differentiated, will surface later only to “reinforce the primary one” (*primäre Identifizierung zu verstärken*).

Interestingly, no “*primary identification*” appears in the translation nor the index of the *Standard Edition*. James Strachey limits himself to speaking of “*first and most important identification*,” then, at the end of the paragraph, “[it] *would thus reinforce the primary one*” (1923b, p. 31). It might be wondered to what extent this omission contributed to the international use and dissemination of this expression with a meaning contrary to its Freudian conception by many authors whose sources were English-language texts.

In effect there have been many discussions of primary identification, which, from Edith Jacobson (1954) up to the current time, has generally been defined as the first phase of the union with the mother, in a still undifferentiated environment (Winnicott, Donald W., 1956); others have even thought of it as the “primal form of affective attachment to an object before an object relation” (Meissner, William W., 1970). León Grinberg (1976) interpreted it as a very archaic object relation of symbiosis, preceding the differentiation of the Self from the object—an idea which was developed further by Joseph Sandler (1960), who described a state of fusion/confusion between the *Self* and the *not-Self*. René Spitz (1957) used the term “primary identification” to signify the undifferentiated stage and the “acrobatics of identification”; the latter includes “identification with gestural language” (Bertha Bornstein), in which imitation is preeminent—as well as “reciprocal identification,” describing the mirror situation between mother and child.

It is evident that the notion of the “father,” so essential in all of the theory and practice of Freud, has been dropped from the concept of primary identification, the theoretical development of which has been especially pursued in the English-language literature, as is clear in the work of R. Horacio Etchegoyen (1985) on the first of the definitions of identification given by Freud in *Group Psychology and the Analysis of the Ego* (1921c): “Identification is the earliest and original form of an emotional tie” (p. 107). Yet authors generally neglect to mention that the first lines of Chapter VII, “Identification,” developed the above formula, to specify that the father is at its core, where is founded “personal prehistory,” in the wake of the murdered father of the primal horde.

Many misunderstandings, consequently, between European and English, American, or South American schools are rooted in different readings of Freud, and

the notion of “primary identification” is a particularly significant example of this.

## PRIMARY LOVE

*Primary love* is the term proposed by Michael Balint to designate the very first phase of mental development, characterized by a “harmonious relation to an undifferentiated environment” (Balint, 1952), a “mixture that is made harmonious through interpenetration” of the individual and his or her environment. This “inevitable” primitive phase, which is not associated with an erogenous zone, would become the matrix of all other object relations and leave “vestiges and residues . . . in all the later phases.”

This concept is outside the framework of object relations theory, which made its appearance during the thirties and considers the subject no longer isolated but an integral part of his environment. Michael Balint attempted to resolve the theoretical polemic between Vienna and London on the first stages of psychic life (primary narcissism or sadism), by continuing to carry out research in both directions indicated by Freud in *Three Essays on the Theory of Sexuality* (1905d) and *Totem and Taboo* (1912–13a), and by

treating “the development of the individual sexual function and the development of human relations” as inseparable.

Balint emphasized biology—the bond between the mother and the infant is described as a form “biological interdependence”—and object relations, “reactions to the real influence of the world of objects, primarily to the educational methods” that follow. In 1935 Balint made use of the work of Sándor Ferenczi (Ferenczi, 1924/1963) and the predominant role he gave to object relations, as shown in his *Clinical Diary* of 1932: “Life begins with a passive and exclusive love object. Infants do not love. They must be loved” (Ferenczi, 1988/1932). He identified transferences of this type in certain cures and inferred this primitive stage from them.

In 1937 Balint developed a more radical critique of “primary narcissism.” Postulating (with Sándor Ferenczi and Alice Balint) the idea that object relations exist from birth, he suggested replacing the Freudian perspective with the notion of “primary love.” This concept better accounts for subsequent clinical approaches to transference during the treatment of psychotic patients, as well as during treatment of the pre-oedipal material of neuroses: the demand for “primitive,” “naïve,” “innocent” gratification (Balint, 1952), and calm or passionate responses to gratification or frustration by the analyst. During the stage of “primary love” all the infant’s needs are satisfied, but those of the mother are as well; the two protagonists are equally satisfied and gratified. If this satisfaction is lacking (in the infant or the mother), “relational tensions . . . can result in the appearance of all kinds of ego distortions in the infant or neurotic phenomena in the mother.” Balint articulates this stage and its pathologies in a new theory of the “basic fault.” Although the term is not in widespread use and has even been neglected, and in spite of its restriction to dyadic relations, the changes in technique that it brings about in order to avoid “malignant regressions” has influenced analysts of borderline or psychotic patients.

## PRIMARY MASOCHISM

Primary masochism is identical to erotogenic masochism as defined by Sigmund Freud in “The Economic Problem of Masochism” (1924c). This name makes official masochism’s recognized primacy, at the time, over sadism, which is masochism projected outward.

In *Beyond the Pleasure Principle* (1920g) Freud had already challenged the anteriority of sadism to masochism: “The account that was formerly given of masochism requires emendation as being too sweeping in one respect: there *might* be such a thing as primary masochism—a possibility which I had contested at that time” (p. 55).

The reason for specifying the primary nature of masochism is to underscore an early fusion of the death instinct through and with the life instinct, occurring internally. Accordingly primary masochism also becomes primal in psychic and instinctual life, prior to any object. Benno Rosenberg further developed this Freudian conception by emphasizing masochism’s role as a “guardian over life” and the importance of being able to eroticize increases in tension, and thus unpleasure (1991). This step is indeed essential in tempering satisfaction, thereby opening the way for both hallucinatory wish fulfillment and the constitution of an early internal temporality. At issue, then, is a primary nucleus of the ego.

Primary masochism is opposed to secondary masochism, which is obtained by a double turning around (of sadism back onto the subject and of activity into passivity), as evident in the description of masochism in “Instincts and Their Vicissitudes” (1915c). Given this distinction, the introduction of primary masochism does not invalidate the earlier clinical descriptions. Rosenberg further emphasized that in psychosis, a striking excess of secondary masochism might result not from overly intense sadism, but instead from a far

more basic deficit of primary masochism for which secondary masochism attempts to compensate by means of quantity, in an attempt to complete a deficient instinctual fusion.

## **PRIMARY NEED**

As early as *The Interpretation of Dreams* (1900a), Sigmund Freud described the movement that leads from need to desire. In *Three Essays on the Theory of Sexuality* (1905d), he specified, “According to some authorities this aggressive element of the sexual instinct is in reality a relic of cannibalistic desires—that is, it is a contribution derived from the apparatus for obtaining mastery, which is concerned with the satisfaction of the other and, ontogenetically, the older of the great instinctual needs” (p. 159). In “Instincts and Their Vicissitudes,” he justified his choice of the term “needs”: “a drive stimulus does not arise from the external world, but from within the organism itself” and acts as a constant force (1915c, p. 118). He then added, “A better term for a drive stimulus is a ‘need.’ What does away with need is ‘satisfaction’” (p. 118–119). In other words, the concept of primary need refers to the endogeneity of the drive and its biological roots.

From then on in Freud’s work, the concept of need lay at the crossroads of two lines of reflection: on the one hand, the theory of anaclisis, and on the other, the question of primitive hallucination. In the theory of anaclisis, sexual life is grafted secondarily from the

satisfaction of the great needs of the organism (concerned with self-preservation). Thus, “Sucking at the mother’s breast is the starting-point of the whole sexual life, the unmatched prototype of every later sexual satisfaction, to which phantasy often enough recurs in times of need” (1916–17a [1915–1916], p. 314).

It is known, however, that primitive hallucination stems from lack and thus from the frustration of need. No doubt the first response to an unsatisfied need is indeed hallucination, it being understood that the acceptance of this response leads to the replacement of the pleasure principle with the reality principle.

Later developments in the attachment theory (Bowlby) gave rise to profound modifications to the concept of need, modifications that again put into question both the theory of anaclisis and the metapsychological theorization of the emergence of thought. Indeed, according to the theories of Bowlby and his followers, the social and relational link is not secondarily derived from the satisfaction of primary needs, but is in itself a need as primordial as the need for self-preservation. Furthermore, the emergence of thought is played out less in the absence than in the presence of the object, which causes schemas of attachment (internally functioning models) to form in the psyche of the infant.

## PRIMARY OBJECT

The notion of primary object corresponds to the constitution of the object of satisfaction of needs and wishes resulting from the first mother-infant encounter, even before questions of inside/outside, subject/object have been raised. Its incorporation constitutes the kernel of the ego.

Freud postulates the existence of this first encounter beginning in 1895 in the “Project For a Scientific Psychology” (1950c). Nevertheless, a full theory of the primary object would have to wait for Melanie Klein and especially Donald Winnicott in 1952 and Wilfred Bion in 1961.

Freud conceived of the primal psychic apparatus as undifferentiated, in a state of immaturity and distress necessitating maternal care. The object-breast which satisfies need creates the erogenous-oral zone through anaclysis or “leaning.” The inertia principle imposes its conditions on the pleasure/unpleasure principle through the effects of this encounter. Affect-feeling reigns supreme in this primal psychic space, and the experiences of satisfaction and/or dissatisfaction inscribe their traces in it, which makes possible the hallucination of satisfaction via the return [through the trace] and the [re]creation of the object.

For Freud, the “reality ego of the beginning” seeks to constitute itself as a “purified-pleasure-ego”; even though it is “born of hatred” (1915c), which is only apparently contradictory. Unlike Freud, Melanie Klein conceives of the primary psychic space as being from the very first the theater of a completed and active ego animated by drives already attached to their objects, engaged in relationships of love and hatred, desire and gratitude.

Wilfred Bion introduced the “capacity of maternal reverie” as an essential factor in the “alpha function,” whose task is to lend constancy and symbolization to the “beta elements” that the infant expels into it [the maternal reverie] through projective identification.

For Melanie Klein and Wilfred Bion, the drives and the ego are therefore active from birth. Winnicott’s use of the notion of “leaning” remains a bit closer to Freud. He describes a “transitional space” that allows him to suspend the decision between need and desire, internal and external, objective and subjective, primary narcissism and drive. This leads to the notion of the “subjective object,” product of the infant’s “primal

creativity,” which, when exposed to “primal maternal preoccupations,” secures for the experiences of illusion/disillusion necessary to the constitution of this object from the endlessly created and recreated breast.

## PRIMARY PROCESS/SECONDARY PROCESS

Freud’s terms “primary process” and “secondary process” designate two opposed yet nevertheless complementary modes of functioning within the psychic apparatus. The primary processes, directly animated by the drives, serve the pleasure principle and work to actualize a free flow of psychic energy. Secondary processes, which presuppose the binding of this energy, intervene as a system of control and regulation in the service of the reality principle. Psychical life is entirely regulated by the equilibrium between these two types of processes, which varies between subjects and at different points in time.

Freud raises the prospect of this fundamental duality as early as his “Project for a Scientific Psychology” (1950c [1895c]), where an entire paragraph is devoted to the complete enunciation of a schema that he would refine over the decades to come. Briefly put, desire or the wish (*le désir*) unleashes a process of discharge. But since in this “precocious phase” the psychic apparatus is not capable of distinguishing between the representation of a missing object and its perception in reality, the fulfillment of the wish is therefore hallucinatory and “requires a criterion from elsewhere in order to distinguish between *perception* and *idea*.” This mode of functioning may be “biologically detrimental”—a

regulation therefore intervenes which makes it possible for the psyche to “distinguish between a perception and a memory (idea)” (p. 324–325) by deferring hallucinatory satisfaction. Thus “wishful cathexis to the point of hallucination . . . which involve a complete expenditure of defense are described by us as psychical primary processes; by contrast, those processes which are only made possible by a good cathexis of the ego, and which represent a moderation of the foregoing, are described as *secondary psychical processes*” (p. 326–327).

This statement is made from within the framework of Freud’s attempt to account for psychic functioning on the basis of an economic hypothesis, that is to say by positing the existence of a specific energy, and, in neurobiological terms, by distinguishing between different types of neurons, and considering the circuits through which this energy circulates between them. He will quickly reject the second hypothesis, but the first will remain central, in that the energy in question, henceforth psychical, is to be re-baptized “libido,” and is given a major application in the case of the dream work, which is conceived from the first as an actualization of desire that transforms latent thoughts into dream images. “The intensities of the individual ideas become capable of discharge *en bloc* and pass over from one idea to another” (1900a, p. 595). Either in mutual displacement, or agglomeration via condensation, this play of unbound energy is characteristic of the primary processes of the dream: “The first wishing seems to have been a hallucinatory cathecting of the memory of satisfaction. Such hallucinations, however, if they were not to be maintained to the point of exhaustion, proved to be inadequate to bring about the cessation of the need, or, accordingly, the pleasure attaching to satisfaction. A second activity—or, as we put it, the activity of a second system became necessary . . .” (p. 598–599). Whereas the activity of the first system, that of the primary processes, is “directed towards securing the free *discharge* of the quantities of excitation,” the second system, that of secondary processes, “succeeds in *inhibiting* this discharge” (p. 599).

The influence of Jacksonian theses defining the neuropsychic apparatus as a hierarchical system of regulating and regulated structures is apparent in this kind of conceptualization. What is also apparent here is Freud taking sides against the positions held by both Josef Breuer and Pierre Janet simultaneously, in that both only tended to account for the weakening of

psychical functioning in the cases of hypnoid states or when the mental *tonus* had been reduced. According to Freud, it is ever indispensable to take an equilibrium between antagonistic forces into account.

This conception is at one and the same time both synchronic and diachronic or, in other terms, both structural and developmental. This is seen clearly in Freud’s commentary on the terms he chooses to designate this opposition-complementarity: “When I described one of the psychical processes occurring in the mental apparatus as the ‘primary’ one, what I had in mind was not merely considerations of relative importance and efficiency; I intended also to choose a name which would give an indication of its chronological priority. It is true that, so far as we know, no psychical apparatus exists which possesses a primary process only, and that such an apparatus is to that extent a theoretical fiction. But this much is a fact: the primary processes are present in the mental apparatus from the first, while it is only during the course of life that the secondary processes unfold” (1900a, p. 603).

Specifying the opposition between the pleasure principle and the reality principle, whereby he posits the pleasure principle as temporally primary, Freud would later write: “It will be rightly objected that an organization which was a slave to the pleasure principle and neglected the reality of the external world could not maintain itself alive for the shortest time, so that it could not have come into existence at all.” His answer which followed was to constitute the keystone of the contemporary development of theories of psychogenesis in their entirety, by bringing the mother-child relationship into consideration: “The utilization of a fiction like this is, however, justified when one considers that the infant—provided one includes with it the care it receives from its mother—does almost realize a psychical system of this kind” (p. 603).

The opposition-complementarity of the primary and secondary processes was therefore described first by Freud in economic terms. However he also accords it a topological dimension. In “The Unconscious” (1915e), he specifies that the Preconscious is the locus of the secondary processes and their regulating function over the primary processes characteristic of the Unconscious. It is this regulation that binds the cathectic energy used for representations, and therefore makes possible the development of thought, which occurs via the passage from thing-representations to word-representations. Indeed the work of

thought, which functions via the “displacement of small quantities of energy” requires that the representations upon which it is based remain stable and distinct. This would not be possible if the free flow of energy, and the condensations and displacements characteristic of the primary processes, prevailed.

## **PRIMITIVE**

The term “primitive” (sometimes “primeval” or “primal”) is close to “archaic,” but should be distinguished from the latter in that “primitive” refers not to origins but rather to an anthropological or historical description of cultural phenomena (myths, religions, legends) or modes of thinking that remain unconscious in modern, civilized humans.

Freud’s interest in the primitive was manifested as early as “A Project for a Scientific Psychology” (1950c [1895]), where he cited Charles Darwin. Thereafter, this notion is always found at the interface between, on the one hand, Freud’s preoccupation with biological evolution and phylogenesis and, on the other, his hypotheses on the formation of social groups, as presented in particular in *Totem and Taboo* (1912–1913a) and *Moses and Monotheism* (1939a [1934–1938]).

In Freud’s hypothesis, as outlined in “On the Universal Tendency to Debasement in the Sphere of Love” (1912d), “primitive” people, although they too live in a civilization remote from archaic times, are the equivalent of the childhood of “civilized” people. Thus everything about them is relevant to the study of

humanity as a whole. Among salient examples of Freud’s use of the term in his work are references to primitive religions and primitive sexual rites of worship (letter to Wilhelm Fliess dated January 24, 1897) and to primitive languages in which, as in dreams, there is no such thing as negation or contradiction (1900a), or in which a word is even systematically used with opposite meanings to express ambivalence (1910e).

In fact, thought itself, at these primitive stages, possesses original characteristics—such as conceptions of death, mechanisms of projection, and sexualized thought—as are found in magical beliefs or animism (1912–1913a). Freud hypothesized that social organization is initially patriarchal (the primal horde), then matriarchal (the divinization of woman as mother and the grouping of brothers into totemic clans), and finally once again patriarchal and patrilineal, with a unique God replacing the primal father. This conception constitutes a model for viewing collective life in general in its different, ever unstable configurations. The notion of the primitive always appears at the boundaries of myth, legend, and history, which are characteristic of the primitive style of writing history (1909d).

The primal scene (when a child is first emotionally aware of his parents copulating) also condenses certain epistemological questions that can be raised about the primitive, particularly concerning the reality of what the small child has seen or heard in connection with the parents’ sexual relations.

The notion of the primitive occupies a central place in Freud’s thought. It is the equivalent, at the collective level, to the infantile at the individual level. This aspect of Freud’s work provides the outlines for fruitful interaction between anthropology and psychoanalysis.

## PRIMITIVE AGONY

In psychosis, the original “unthinkable state of affairs that underlies the defense organization” (Winnicott, 1974).

In Winnicott’s developmental schema, the innate “maturational tendency” (of the baby to become integrated as a whole ongoing being) is effective insofar as there exists “a facilitating environment” (which both is and is not provided by an emotionally attuned mother) adapting and developing alongside the developing infant. The infant can then integrate, and eventually object-relate, proceeding from “absolute dependence” to “relative independence.” Winnicott describes “the fear of breakdown” as the fear of re-experiencing the conditions previously feared during failure of the environment, which are described as various degrees and types of “primitive agony,” associated with different defense systems, “disintegration” for example being a defense against unthinkable dread of a return to an “unintegrated state.” These unthinkable fears will be reached in analysis in the transference, and it is during analysis that the feared but not yet experienced (because the subject was not yet integrated enough to experience it) disaster can be known and understood.

Winnicott approached this formulation earlier (Winnicott, 1962) as “unthinkable anxiety,” and on different occasions, and while describing his concept of development used this earlier term. His purpose in using this term was to emphasize that psychotic illness, even “infantile autism” (Winnicott, 1967), is always a

defense organization, and to describe the conditions underlying the establishment of such organizations.

## PRIMITIVE HORDE

Charles Darwin and evolutionist sociologists of the nineteenth century used a term of Tartar origin, “primitive horde,” to refer to the simplest possible form of social formation in existence during prehistoric times. The horde was a link between the state of nature, ultimately unknowable, and the state of culture. The word has also been used by some ethnologists to characterize groups that engage in hunting and gathering in a given territory.

The notion of the primitive horde was described in Darwin’s *The Descent of Man* (1871). Freud, in *Totem and Taboo* (1912–1913a), wrote “Darwin deduced from the habits of the higher apes that men, too, originally lived in comparatively small groups or hordes within which the jealousy of the oldest and strongest male prevented sexual promiscuity.” James Jasper Atkinson returned to this hypothesis in *Primal Law* (1903). He referred to the horde as a “cyclopean family.” Andrew Lang, in *The Secret of the Totem* (1905), also acknowledged Darwin’s theory: “The first practice was that of the jealous Father: ‘no male can touch the females in my camp,’ which was accompanied by the expulsion of the adolescent sons.”

It was Freud, in *Totem and Taboo*, who provided greater insight and scope for Darwin's theory. In spite of the criticisms that appeared when the book was published, he maintained this idea and returned to it again in *Group Psychology and the Analysis of the Ego* (1921c), *The Future of an Illusion* (1927c), and *Civilization and Its Discontents* (1930a [1929]), and especially in his last book, *Moses and Monotheism* (1939a). The importance he assigned to this is reflected by a communication he had with Abram Kardiner in which he wrote, "Don't take this too seriously. It's something I dreamed up one rainy Sunday afternoon."

Freud's principal contribution was the idea of the murder of the Father of the primitive horde: "One day, the brothers who had been driven out, came together, killed and devoured their father and so made an end to the patriarchal horde. United, they had the courage to do and succeeded in doing what would have been impossible for them individually." The collective crime is correlative with the birth of a group and, later, the birth of humanity.

"One day" man was living in a primordial age. To leave it a foundational act was needed, one that was irreversible. Certainly, it is possible that, before this, one of the children in a horde may have succeeded in killing the father. He would then have taken his place and the group would have gone on as before. But it was the unanimous decision of murder ("the brothers came together") that enabled mankind to enter history. For the sons only became brothers when they were able to overcome their powerlessness—which could have (and should have) heightened rivalry among them—and achieve a sense of solidarity. This was a relation in which each recognized the other as an equal, which enabled them to escape the deadly fascination they experienced, that is, the admiration and fear they experienced before the omnipotent father.

Atkinson had already assumed that the "young troop of brothers" had finally acquired strength and had "taken from the paternal tyrant his wife and his life." But he did not see this as a new beginning. Moreover, he failed to make use of another theory that was crucial as far as Freud was concerned, that of William Robertson Smith. Smith, in his *The Religions of the Semites* (1894), had used the totemic meal, during which a sacrificial victim is put to death, as a central element in the ritual reestablishment of the clan, a celebration at which the clan experiences the solemn transgression of a prohibition, a transgression that can

only be justified "if the entire clan shares in the responsibility." For Freud the totemic meal, "which is perhaps mankind's earliest festival, would thus be a repetition and a commemoration of the memorable and criminal deed, which was the beginning of so many things—of social organization, of moral restrictions and of religion." The conspiracy, prepared long in advance, promoted group cohesion. The murder followed by the meal in common made brothers of the sons, a brotherhood of equals, united by the same blood, identifying with the father, and each appropriating, through the act of cannibalism, part of his strength.

However, it is important to remember that due to the ambivalence of feeling, the brothers loved their father as much as they feared him. Moreover, the brothers felt guilty for having killed the father. They then decided to reject the object of desire for which they had banded together: ("what had up to then been prevented by his actual existence was thenceforward prohibited by the sons themselves, in accordance with the psychological procedure so familiar to us in psychoanalysis under the name of 'deferred obedience.'") They idealized and mythified the father they had established as totem, experienced as the founder of the group and the bearer of symbolic law. The world of relations of force gives way to the emergence of a world of alliances and solidarity. In *Moses and Monotheism* Freud returns to this idea. But he insists on the monopolization of speech by the Father of the horde. By killing him, the sons appropriate nascent language (see P. Kaufmann [1979]). As a result of the act, great importance is given to the "omnipotence of ideas that will bring about such extraordinary progress in intellectual activity" and the development of spirituality.

*Totem and Taboo* was strongly criticized by anthropologists. Paul Radin (1929) felt it was a "deplorable performance," Alfred Louis Kroeber, in 1920, rejected Freud's hypothesis, which he denounced as a "conviction without substance." In 1939 he returned to the book and criticized the use of history to cloak a "psychological intuition." In contrast, Géza Róheim, an anthropologist and psychoanalyst, used Freud's grid in his work while focusing on the analysis of the "actual carriers" of culture and forgetting the "bewitching phylogenesis." Claude Lévi-Strauss (1949) took the hypothesis of the murder of the father seriously, not as a historical event but as a "durable and ancient dream" that has even more importance "since the acts it evokes

have never been committed because culture has always and everywhere opposed them.” It was a writer, René Girard, a man opposed to psychoanalysis, who in 1968 praised *Totem and Taboo* in the clearest terms, even though he contested its reasoning. Eugène Enriquez (1967) had already adopted the hypothesis of parricide to explore the notion of power; Serge Moscovici (1981) used Freud’s book to understand the role of the charismatic leader.

It is worth pondering why Freud invented this narrative. The unconscious desire for murder and fantasy would have been sufficient. Didn’t Freud himself say that the only currency used by psychoanalysis was fantasy? Yet, in spite of the clinical data (Sándor Ferenczi’s little man-rooster and Freud’s “Little Hans”), Freud wanted to tie the Oedipus complex to an event. He had always been sensitive to the “act.” (“In the beginning was the act,” as Goethe wrote.) He always believed that ontogenesis reproduced phylogenesis. For Freud it was necessary to inscribe the history of each subject within that of social organization. The work of Ernst Haeckel seemed to provide the best way of doing this. And, by linking this to the origin of religion, he knew that he risked a break with Carl Gustav Jung—a not altogether disagreeable possibility for Freud.

## **PRINCIPLE OF CONSTANCY**

The *principle of constancy* is the principle of psychic functioning that seeks to maintain the quantity of excitation contained in the apparatus at a low or constant level. This is accomplished through a discharge of the energy present in the apparatus or by avoiding its augmentation.

In 1892, Freud submitted a manuscript and letter to Breuer articulating their common position regarding the thesis of “holding constant the amount of excitation” (1940d). One year later, Freud spoke of a tendency to “shrink” or “diminish” the “amount of excitation,” and trauma was conceived to be a result of its augmentation.

The principle of constancy represented a point of view widely accepted in the sciences of the nineteenth century, such as Fechner’s equilibrium principle (Laplanche and Pontalis, 1967; Laplanche, 1970). Its workings were held to be furnished by mechanisms (in the Freudian sense of acts and behaviors) of avoidance of external excitations, of defense and of discharge (abreaction) in response to increased tension of internal origin.

The principle of constancy is a central feature of the theory developed between 1892 and 1895, introduced in order to account for phenomena observed in hysteria that contradicted this “precondition of health” (1940d). From this point forward symptoms were blamed on a lack of abreaction, and treatment offered adequate discharge. However, Breuer envisaged the law of constancy as optimal, allowing for a free circulation of kinetic energy. In his “Project” of 1895 Freud sought a principle unrelated to healthiness, by sketching out an operation that occurred simultaneously at the heart of and at the extremities of a specific portion of the nervous system. The principle of constancy was thereby supplanted by an inertia principle, according to which certain neurons tend to empty themselves totally of their quantity of excitation. The tendency to

constancy would become a secondary function—a modification of the inertia principle—demanded by the “exigencies of life.” It is confined to the secondary processes of the “ego” where energy is bound, meaning maintained at a certain level in the “psi system.”

In *The Interpretation of Dreams* (1900a) the opposition constancy/inertia serves as a backdrop. The principle of inertia regulated the functioning of the system Ucs. according to the laws of primary functioning. The principle of constancy worked at the level of the Pcs.-Cs. system through cathexes, diversion of inhibitions, and transformations into states of quiescence by raising excitation to even levels. Subsequently, the opposition between the two modes of functioning was most often assimilated to the opposition between the pleasure principle and the reality principle.

Freud finally formulated an explicit “principle of constancy” in *Beyond the Pleasure Principle* (1920g), as the economic basis of the pleasure principle, but he left open the question concerning what level should be aimed at: zero, constant, low, high, etc. However the tendency toward zero that later became the “Nirvana Principle” was considered fundamental. It was in this connection that Freud introduced the death drive. The latter tended toward the absolute reduction of tensions and was opposed to the life drive, which made use of heightened tension levels in its quest to forge and hold onto vital unities.

Freud’s thinking on this matter remains plagued by an unresolved difficulty. Is psychoanalysis limited to a narrow domain, or does it represent an attempt to create a general psychology, meaning a biology? In spite of the “self-preservation/sexuality” distinction, the overlap between vitality and sexuality remained a problem for Freudian theory to work through. Was the energy Freud envisioned energy in general, or sexual energy (cf. Jung)? Did everyday regulatory mechanisms encompass the phenomena of increased quantities of all kinds, or was the augmentation of psychic sexual energy controlled by a special sub-regulatory mechanism?

The principle of constancy was the basis of the conception of the pleasure/unpleasure principle, but the latter’s complexity (a pleasurable sensation may accompany an increase in tension), became increasingly evident to Freud, reopening the possibility of a confusion of the pleasure and constancy principles. The principle of constancy, which resembles the

principle of homeostasis that Walter Bradford Cannon would later introduce, served as kind of general principle of self-regulation, whereas the specifically sexual pleasure principle can (and must) detract from this general principle. This was an inextricable complexity that the conceptualization, in 1920, of the life drive attempted to resolve.

## **PRINCIPLE OF IDENTITY PRESERVATION**

The principle of identity preservation stipulates that human beings are motivated by the need to preserve and maintain their identity at all costs. Superseding adaptation and the reality principle, the principle of identity preservation governs the psychic apparatus, and the drives are a function of it.

Introduced in 1961 by Heinz Lichtenstein, this principle is the response to what he calls the “dilemma of human identity” in the book of the same title. Human identity is uncertain; the ego cannot guarantee its existence, and the subject must maintain it at all costs. This notion is in keeping with this author’s rejection of the idea of the dualism of the drives.

Human identity is formed through a specific use of nonreproductive sexuality during the dissymmetrical interactions between mother and child—mirroring experiences in which the mother’s seduction triggers an irreversible “identity theme” stemming from the impact of her unconscious messages and the child’s reactions. From this primary, irreversible identity there emerges a sense of the identity of the self, a

creation or variation on an invariant identity theme. Identity formation can suffer disturbances; the existence of impossible “themes”—such as that of nonseparation, which causes an oscillation between solitude and fusion—generates pathological sexual and aggressive manifestations.

The principle of identity preservation underscores the importance of the “preservation of identity” or the self based on the “feeling of identity”—Erik Erikson’s “ego identity.”

The formation of identity makes it possible to resolve Cartesian dualism by forgoing the concept of identification. A metapsychology of the self is established, to the detriment of the drives. Lichtenstein was the first to theorize the notion of identity in the sense of a principle. Robert Stoller used the notion of identity as the theoretical basis for his hypothesis regarding the core of “gender identity” and the inverted gender identity of the feminine boy as stemming from an irreversible early imprint left over from the infant’s symbiosis with the mother. Traces of Lichtenstein’s thought are discernible in Heinz Kohut’s self psychology, although he is not explicitly mentioned: The characteristics attributed to identity by Lichtenstein are close to those of the Kohut’s “Self,” and the principle of identity resembles the same type of conceptualization as the “principal Self” in Kohut’s *The Restoration of the Self* (1977)—the preservation of the Self as fundamental to the psyche.

The importance given to identity—that is, narcissism—in relation to the drives reverses Freudian priorities and presents the risk of a psychoanalysis that is more phenomenological than metapsychological.

## **PRINCIPLE OF (NEURONAL) INERTIA**

The principle of inertia is a principle of the functioning of the nervous system in which the  $\varphi$  neurones

tend to divest themselves completely of the quantities of energy that they receive. Freud presented it at the beginning of the *Project for a Scientific Psychology* (1950c [1895]).

The  $\varphi$  neurones receive external excitations, since they belong to consciousness. These neurones are described as “permeable” because their “contact barriers” (what we today would call synapses) permit quantities of energy to pass toward the, or perceptual, neurones. In the *Project*, Freud takes the general law of motion from physics as his basis, but then focuses on an active tendency of the system, which would oppose the principle of constancy; in effect, he creates a psychophysical fantasy in which it is the working of the system itself—and not the conservation of energy—that is the final goal. The Freudian model here is the reflex arc and, in particular, the “inclination to a flight from pain” caused by an exterior source.

Freud uses the notion of inertia in an ambiguous manner. In the physical sense, it is a property of what he calls “quantity,” which, transformed into “quality,” is retained by the memory belonging to the  $w$  system. The word *Trägheit* itself adds an unexpected element: in German it means both “inertia” and “laziness.” While it may be difficult to think of such an active principle as idle, Freud nonetheless used this ambiguity here to indicate the system’s fundamental tendency to retreat from life’s burdens. Elsewhere in his work Freud did use *Trägheit* to mean “laziness,” speaking of “mental laziness,” “intestinal laziness,” “dreams of laziness,” and so on. Later, influenced by Jung’s term “viscosity of the libido,” Freud used the word to mean “inertia,” particularly as a synonym for “fixation.”

While the “principle of inertia” does not appear again in Freud’s work after the *Project*, he does maintain a permanent equivocation between the different levels “constant,” “low,” and “zero” (1920g; Laplanche, 1970/1976).

Although it may represent a metaphor for free circulation in the unconscious, the principle of inertia can be considered as an eventual source of errors. Beyond its theoretical heir, the nirvana principle/death drive, it cannot account with any specificity for the encounter on the level of libido between adult and child. On the other hand, the principle of neuronal inertia does offer a certain resemblance to the free circulation of thing-representations that characterizes the

unconscious, and it might well describe the results of trauma.

## **PRINCIPLES OF MENTAL FUNCTIONING**

The term *principles* is used to refer to the fundamental postulates or hypotheses proposed by Sigmund Freud to describe the basic laws of the psyche; they provide the basis for ordering mental functioning as a whole and making it intelligible. The two main principles of the psychic apparatus are the pleasure/unpleasure principle and the reality principle; their dialectical relationship and composition explain the organization of psychic dynamics.

The concept of principle does not appear as such in psychoanalytic metapsychology; it is always articulated together with another notion whose essential and organizing characteristics are determined in accordance with it. Regardless of which principle is involved—the pleasure/unpleasure principle or the reality principle, or, as these are expressed in different forms, the nirvana principle or the principle of constancy (the latter being less conceptually important in the current and historical corpus of the theoretical practice of psychoanalysis)—a principle describes the orientation of the action of the psychic processes, which determines their direction and limits the conditions under which they are put into effect. Principles are thus both explanatory principles used in making

the psyche intelligible, and laws to which the psyche is subjected or must submit.

The first principle to appear in Freudian metapsychology is the unpleasure principle posited in *The Interpretation of Dreams* (1900), which states that the psyche aims to reduce or eliminate sources of tension that result in unpleasure. However, as early as the “Project for a Scientific Psychology” (1895), Freud postulated the existence of a psychic process that also aims to select memory traces of pleasurable experiences.

The pleasure/unpleasure principle as described by Freud in “Formulations on the Two Principles of Mental Functioning” (1911b) has two aspects: on the one hand, to reproduce and re-present to the psyche experiences that have produced pleasure in the past or are likely to produce pleasure in the present; and, on the other hand, to avoid or eliminate experiences that have resulted in unpleasure. This implies a principle of selection that is exercised either through hallucinatory wish-fulfillment, for pleasurable experiences, or through repression, for unpleasurable experiences. However, hallucinatory wish-fulfillment or repression cannot in fact cause intrapsychic tensions to disappear, and an organism limited to the pleasure/unpleasure principle alone could not survive.

Thus, when it goes into effect the pleasure principle encounters what could be called the “reality principle of pleasure”—that is, the principle of an effective reduction of tension that presupposes, at least initially, recourse to an external object. The reality principle thus does not override the pleasure principle; rather, it transforms its mode of expression and action by taking into account the conditions of internal and external reality.

It is the constancy principle that governs the fact that pleasure is no longer attained as a result of an absolute reduction of intrapsychic tensions, but rather through a reduction relative to a certain threshold or constant, and by submission to certain requirements of reality. The nirvana principle, on the other hand, expresses the psyche’s tendency toward an immediate and absolute reduction (to zero) of sources of tension. As can be seen, all of the principles evoked above can be inscribed within the orbit of the principle of pleasure/unpleasure; they are derivatives that integrate, to varying degrees, other characteristics of psychic life into their operations, but without calling into question

the primary and fundamental principle of the orientation of the psyche's action.

In "Beyond the Pleasure Principle" (1920) Freud began to describe processes that seemingly contradicted the pleasure/unpleasure principle. In this essay he emphasized the existence of mental impulses that reactivate experiences that had not produced any conscious or unconscious satisfaction, either at the time or through deferred action (*après-coup*). These exceptions to the pleasure/unpleasure principle are due to the repetition compulsion. In this way, with "Beyond the Pleasure Principle," the pleasure principle appears as a secondary principle; the primary or immediate or fundamental tendency is no longer the avoidance of unpleasure or the search for pleasure, but rather repetition of an earlier state, the tendency to return to an earlier state.

## **PRIVATION**

The concept of privation is essential for Freud. In *The Future of An Illusion* (1927c), he writes: "For the sake of a uniform terminology we will describe the fact that an instinct cannot be satisfied as a 'frustration,' the regulation by which this frustration is established as a 'prohibition' and the condition which is produced by the prohibition as a 'privation'" (p. 10). Later in the same essay, he defines more specifically the drive-wishes that result from privation: incest, the pleasure in and wish to murder, and cannibalism.

Melanie Klein and Jacques Lacan are the main authors to have taken up this concept. For Klein, privation is the basis for the paranoid position. She writes: "Persecutory anxiety, therefore, enters from the beginning into [the baby's] relation to objects in so far as he is exposed to privations" (Klein, 1932/1952b, p. 199). And elsewhere: "Feelings of frustration and grievance lead to phantasying backwards and often focus in retrospect on the privations suffered in relation to the mother's breast" (Klein, 1952a, p. 265). All feelings of privation or frustration originate in the subject's relationship with the mother, specifically with the maternal breast. These feelings are also articulated with persecution and fragmentation anxieties.

In "L'archaïque et le profond dans la pensée de Melanie Klein" (The Archaic and the Profound in Melanie Klein's Thought; 1982), Jean-Michel Petot discusses the constant slippage between the terms *privation*, *deprivation*, and *frustration* in Klein's work. He clearly shows Klein's difficulties with these notions, as well as the role played by Ernest Jones's translations of the German term *Versagung*.

For Jacques Lacan, archaic persecution or fragmentation anxieties are to be deduced from castration

anxiety and are not its precursors. Privation is what is inscribed in the Real and reveals its nature. Privation corresponds to the “hole” in the Real; it is the basis of the Symbolic Order, and the agent who deprives is always Imaginary. Lacan’s answer to the question concerning what is actually being deprived is that “It is especially the fact that the Woman does not have a penis, that She is deprived of it. [...] The very notion of privation, so tangible and visible in an experience such as that one, implies the symbolization of the object in the real. For in the real, nothing is deprived of anything. Everything that is real is sufficient unto itself. By definition, the real is full [*plein*]. If we introduce the notion of privation into the real, it is to the extent that we can already symbolize it adequately, or even completely. Indicating that something is not there means supposing its possible presence—that is, introducing into the real, in order to recover it and hollow it out, the simple symbolic order” (1956–57).

The reversal effected by Lacan, as compared to authors inspired by Klein, is striking, and it is the basis for his claim of making a rigorous return to Freud. However, his was a return to a particular Freud: In Freudian thought, while woman is indeed deprived of a penis, the male child is just as deprived of the breast. Although woman can aspire to replace what she lacks by bearing a child, man must replace that which he has been deprived of with “spiritual nourishment,” or thought.

## **PROCESS**

The term *process* is used extensively from within different perspectives, not all of which fall within the scope of psychoanalysis. The concept has been defined in the fields of philosophy, psychiatry, psychopathology, and psychoanalysis, with various meanings that, over time, have come to overlap one another, gradually expanding its scope.

Only the salient points of the term’s evolution can be given here. Etymologically, “process” is derived from the Latin *procedere*, which means “to move forward,” and reflects the dynamic aspect of the concept. In philosophy it designates “a succession of phenomena presenting a certain unity or that are reproduced with a certain regularity.” André Lalande notes that the term is often used to refer to physiological, psychological, or social phenomena, and much more rarely to mental phenomena.

In psychiatry, “process” indicates the dynamic and productive nature (of symptoms) of a given state or modality of mental operation. For example, we speak of a process, the psychotic active phase, to indicate that there is a particular evolutionary moment in mental pathology that is considered to give rise, more or less transiently, to the emergence of delusions or hallucinations.

In psychopathology it is the German school of the nineteenth and twentieth centuries—especially Karl Jaspers—that developed the distinction between “process” and “development.” At the time, existential philosophy and phenomenology had completely revitalized conceptions of psychopathology. Consequently, so-called quantitative disturbances (developments) were isolated from qualitative disturbances (processes). The first were associated only with an anomaly in the intensity of certain psychic mechanisms (fears,

inhibitions, rituals), which were relatively easy to understand, while the second implied a disturbance of mental operation that was currently incomprehensible to the outside observer. We can see how, from this point of view, the neuroses would be seen as developments (even though eventually an author like Pierre Marchais would introduce the concept of “neurotic process”) while the psychoses are processes, since they are associated with a break with external reality and the entrance of the suffering subject into a specific representational world.

In psychoanalysis the description of defense mechanisms associated with neurotic and psychotic mechanisms harmonizes fairly well with the above psychopathological viewpoint, since the neurotic subject is here considered as having recourse, in a quantitatively abnormal and rigid manner, to certain specific, but normal, defense mechanisms (repression during hysteria, isolation and retroactive cancellation in the case of obsessive neurosis, displacement in the case of phobias), while the psychotic subject has recourse to defense mechanisms (splitting, denial, projection, idealization) that are qualitatively different than those used by the so-called normal subject. The neurotic subject would thus have lost only the flexible and extensive use of the entire range of defensive mechanisms at the disposal of the normal subject, but the mechanisms used by him would be qualitatively normal (development). The psychotic subject, however, would make use of qualitatively abnormal defensive mechanisms (process).

In reality this approach needs to be modulated to the extent that extensive study of psychotic and archaic processes has shown that the mechanisms in question in this type of psychopathology can also be described at the so-called “primal” levels of mental functioning (Piera Aulagnier), especially in the infant, but prematurely and much too transiently.

It is in the “Project for a Scientific Psychology” that Sigmund Freud lays out for the first time his neuronal theory of primary and secondary processes. The primary process tends to discharge excitations (free energy), while the secondary process provides various means of discharge (bound energy) since it operates at the level of psychic attention and extends to the mechanisms of perception and intelligence: “Wishful cathexis to the point of hallucination [and] complete gratification of unpleasure which involves a complete

expenditure of defence are described by us as *psychical primary processes*; by contrast, those processes which are only made possible by a good cathexis of the ego, and which represent a moderation of the foregoing, are described as *psychical secondary processes*. It will be seen that the necessary precondition of the latter is a correct employment of the *indications of reality*, which is only possible when there is inhibition by the ego” (1950c [1895], pp. 326–327).

Freud would return to this distinction on several occasions in *The Interpretation of Dreams* (1900a), but it was in 1911, when he fully described the two major types of psychic function (unconscious and conscious), that he returned to this distinction. Here he clarifies the differences between primary processes (free energy, pleasure principle), governing our fantasies, neuroses, and “everyday psychopathology,” and secondary processes (bound energy, reality principle), governing the dynamics of rational thought, which is logical and desexualized (1911b).

Subsequently, Freud described positions anterior to and posterior to primary and secondary processes. The anterior processes have been extensively described by Piera Aulagnier, who distinguishes three successive registers that operate together: primal processes (the first level of embodiment of sensory experience by means of “pictograms”), primary processes (staging, staging of fantasies), and secondary processes (“vocalization” of so-called secondary thought experienced from a first-person point of view). The posterior processes have been investigated by André Green, who described “tertiary” processes as modalities of regulation (work of the preconscious) between primary processes and secondary processes or between thing-representations and word-representations.

Throughout these developments, the term “process” remains highly polysemic depending on the epistemological field in which it is used.

## PROCESSES OF DEVELOPMENT

The expression “processes of development” is used to describe all the processes and mechanisms that contribute to differentiating-organizing a living being from the start of life onwards. The result of these processes for any given organism at any given time corresponds to its “level of development.”

The different phenomena involved in development must be considered in terms of the somatic level (morphological growth, development of physiological functions), behavioral level and psychic level, the level of psychogenesis. The work of genetic (or *developmental*) psychology is defined in terms of this last level, but an essential aspect of psychoanalytic theory and clinical practice is also situated at this level.

Freud's interest in the processes of development appeared in his first scientific works, well before he created psychoanalysis. In an attempt to establish the pathways of nerve conduction he tried to grasp their development through comparative anatomical studies of fetuses. From the very beginning he thus posited a principle that he was to use in creating psychoanalysis itself: in order to understand a complex structure in an adult, the sovereign method is to grasp the successive stages in its construction. Moreover, as an ardent

Darwinian, he straightaway and ever after considered time as an essential part of the data.

The reason he became so excited by Josef Breuer's account of the case of Anna O. in 1885 was because he saw it as proof that when subjects themselves go back in time through their own history, this has a curative effect. The cases reported in *Studies on Hysteria* (1895d) are all built around this principle, as is the accompanying theoretical writing.

He thought he had found the psychopathological equivalent of the source of the Nile: every case of psychoneurosis, particularly hysteria, can be considered as a progressively constituted formation based on a traumatic incident in childhood, an incident that is always of a sexual nature and whose effect is deferred, not appearing until the subject reaches puberty. He nevertheless came to doubt that “seduction” of girls by their fathers was as frequent as the hysterics he treated would have had him believe. After a brief period of discouragement (“*they are only fantasies*”), he effected a remarkable recovery (“*they are fantasies*” that the patient places in the past and which must be analyzed). The analysis of the case of Little Hans in 1905 (the text was not published until 1909) offered him a live study of the development of such fantasies in the child, as well as their pathogenic effects.

This *developmental* point of view was to continue to have major importance in Freudian thought. He thus wrote his *Formulations on the Two Principles of Mental Functioning* (1911b) in the imperfect tense, as if he were telling a story. In 1913 he wrote that the psychoanalytic approach “consists in relating a psychic formation to others preceding it in time and from which it has developed [...] from the very beginning psychoanalysis has been led to look for processes of development” (1913i).

Freud had to have recourse to a general theory of development in order to account for mental pathologies: they were deviations from the normal pathways, fixations at any given stage that should have been surpassed, regressions to earlier formations, the whole culminating in repetitive, rigid, and irritating structures. It was in these terms that he analyzed the case of the Wolf Man. It was indeed, as its title indicates (*From the History of an Infantile Neurosis*), by reconstructing the past that he explained the pathology of the adult (text written essentially in 1914, was published in 1918).

In 1915, Freud wrote *Overview of the Transference Neurosis* (1985a) in a state of feverish agitation. He was trying to establish correspondences between three histories: the history of the succession of stages in normal psychogenesis; then, more hypothetically, the history of the layering of the psychoneuroses and neuroses (depending on the time of the fixation) in the course of those stages and, even more hypothetically, the history of the stages he refers to as being “phylogenic” in the course of the history of humanity (Perron, 1994). In doing so he based his reasoning, as he had already done on several occasions (particularly in *Totem and Taboo*, 1912–13a), on Ernst Haeckel’s hypothesis, “ontogeny recapitulates phylogeny.”

He finally developed a general theory of psychogenesis wherein the stages are considered to be “developmental phases” (today we prefer to speak of “modes of organization”) that are characterized by the primacy of an erogenous zone and an object-based mode of relation: the oral, anal, phallic stages and adult genital organization (Brusset, 1992).

Having formulated his second topography and his second theory of the instincts (1920–23), Freud devoted more time to structural considerations and allowed synchronic aspects to outweigh diachronic aspects. Others nevertheless devoted themselves to developing a direct approach to children and the psychoanalytic treatment of children. The pioneers, his daughter Anna Freud and Melanie Klein, took quite different stances on practical and theoretical questions, so much so that their opposing positions shook the foundations of the British Psychoanalytic Society.

Since then an important trend in research, supported by extensive experience of analyzing children, has stressed the pregenital phases of development and the processes of the first individuation, with direct observation of the baby and the interactions between the mother and baby (J. Bowlby, R. Spitz, D. W. Winnicott, D. Stern, B. Cramer, S. Lebovici), but also with regard to the serious alterations we find in cases of infantile autism and psychoses (M. Mahler, M. Klein, F. Tustin, D. Miltzer, R. Diatkine). It is worth observing that infant and child psychiatry owes a large part of its remarkable development over the last thirty years to psychoanalysts.

The developmental perspective in psychoanalysis calls for a certain number of comments:

- a. As we have seen, Freud was the first to try to go back through personal history to undo a fixation point; in order, according to a metaphor that was dear to him, to deconstruct a unit and then reconstruct it with a better balance from the vestiges thus revealed. He went on to considerably modify these oversimplistic views, admitting that traces of the past do not exist as such but are constantly remodeled retroactively.
- b. In which case, what history is in question (Le Beuf, Perron, Pragier, 1997)? Analysts cannot limit themselves to working on *factual* history, the history that any careful anamnestic investigation would reveal. The analyst’s only informant is the patient and the history he or she recounts is made up as much of fantasies as it is of memories of events whose reality is unverifiable; it is largely constructed retroactively and most of the materials are consigned to the unconscious (Viderman, 1970). In fact the history that the analyst is trying to reconstitute is the *psychic* history of the subject as revealed by the functioning of the subject’s mind. It may be very different from a “real” history as told step by step.
- c. But how is it grasped? *Direct observation* of the baby, which is supposed to provide first-hand objective material is far from being as conclusive as it might appear: the data has no meaning except when interpreted in the light of the psychoanalytic theory it is supposed to support.
- d. From a theoretical point of view, psychoanalysis was shaken by the great controversy on “structure or history?” which began to spread during the seventies from linguistics to all human sciences. We have seen and continue to see in this context the opposition between those who give pride of place to individual history (in currents as diverse as Hartmanian Ego-Psychology and the Kleinian school) and those who reserve it for structure (particularly Lacan and those who followed him).

## PROGRESSIVE NEUTRALIZATION

In 1963 Heinz Kohut and Philip Seitz proposed an alteration in Sigmund Freud's diagrammatic structural model of the mind (1923). In their revised model (see Figure 1), they expanded the diagram to include the unrepressed unconscious activities and infantile impulses in interrupted contact with the preconscious layers of the surface. They called this the "area of progressive neutralization." It is formed through the pro-

**FIGURE 1**

cess of transmuting internalization and consists of a drive restraining or neutralizing structure.

## PROHIBITION

The term *prohibition* has been borrowed by psychoanalysis from everyday language, where it is used either as an adjective to describe something we are not allowed to do, say, see, think, or be; or substantively to refer to the law, social constraint, moral education, and so on, on which this prohibition is based.

Psychoanalytic language gives a more precise meaning to the term, however. Prohibition can present itself to the subject as external, and be internalized as a result of its associated dynamic of conflict; it can also result from structural requirements inherent in the mind. In every case the formulation of the prohibition and its operation can be partially or totally unconscious, even when the resulting conduct and its justification are explicit.

The concept appears early in Freud's work and can be found in the *Studies on Hysteria* (1895d), where the subject, driven by desires prohibited by morality, consciously forms "representations that are irreconcilable" with that morality, and then refuses them satisfaction, doing away with them by making them unconscious through repression. Those desires are always, in the final analysis, sexual in nature, especially in the case of the "neuro-psychoses of defense." "The etiology of hysteria almost inevitably can be traced to a psychic conflict, an irreconcilable representation, which prompts into action the defense of the ego and provokes repression" (Freud, 1896b). From the very outset, then, the notion of prohibition is inseparable from the drive-defense conflict, which will constitute the core of psychoanalytic theory.

Initially, that is to say, within the framework of the first topography and the first theory of drives, Freud studied the libidinal origins of the conflict and its treatment through repression (these are the texts on metapsychology from 1915) as well as its educational

(“Little Hans,” 1915), sociological and ethnological (*Totem and Taboo*, 1912–1913a) origins. The formulation of the Oedipus complex then focused attention on the prohibition of incest.

Subsequently, the formulation of the second topography led to a redefinition of prohibition. Here, the ego appears as prey to conflicts where it is torn between “three masters”: the id and its libidinal demands, reality and adaptive requirements, and a superego that is essentially defined as an agent of prohibition. (However, to this must be added the more positive functions of the ego ideal, which condenses all the moral values the subject claims to hold.)

Although throughout his work Freud presents the incest prohibition as the heart of the conflictual dynamic, he also discusses prohibitions that affect other manifestations of sexuality, primarily masturbation and the satisfaction of the partial drives or compound instincts (voyeurism, exhibitionism, anal pleasure). Generalization of the limitations created by these prohibitions can lead to serious inhibitions of thought. Moreover, it has been shown how the repression of the drives can lead to serious reaction formations, especially when aggression is poorly integrated.

## **“PROJECT FOR A SCIENTIFIC PSYCHOLOGY, A”**

The “Project for a Scientific Psychology”—a title provided by the editors upon the manuscript’s first publication in 1950—is part of Freud’s correspondence with Wilhelm Fliess. Freud himself referred to it as

“Psychology for Neurologists,” or else as “ $\phi \psi \omega$ ” (his denominations for the three kinds of neurones described in the text). His two aims in this piece were to arrive at “a sort of economics of nerve forces” and “to peel off from psychopathology a gain for normal psychology” (Freud to Fliess, May 25, 1895, 1985c, p. 129).

Freud’s “Project” was first conceived in late March, 1895. In September, returning from a visit to Fliess in Berlin, where the two discussed it, he began the writing while still on the train, and on October 8, he sent Fliess two notebooks, holding back a third dealing with repression. These were followed by his letter to Fliess of January 1, 1896 and the attached “Draft K.” Even at this time Freud oscillated between feeling that the work we know as the “Project” was “delusional” and feeling that it was an excellent start on “the elucidation of the neuroses”; and if the “quantitative conception” would in fact never disappear from his work, it would always remain in the background.

The first part of the “Project” is devoted to the description of physical prototypes of repression. The model of the organism here seems to be the vesicle exposed to the very powerful energies of the “primal soup.” When flight is not available to the system, it resorts to its multiple protective survival mechanisms. Thus Freud begins his discussion by introducing the “principle of inertia” and then proceeds to describe two systems of neurones,  $\phi$  and  $\psi$ , soon to be joined by a third,  $\omega$ , concerned with perception. Presentation of the notion of “contact-barriers” gives him an opportunity to point up the distinction between perception and memory by which he would always subsequently abide (1925a).

To protect itself, the system is said to rely not only on the principle of inertia but also on “quantity-screens” constituted by “nerve-ending apparatuses” as a way of guaranteeing a first bulwark against the powerful stimuli of the outside world (*SE I*, p. 306). The outcome of a failure in this protective contrivance is pain, along with the intrusion of excessive quantities of excitation that “leave permanent facilitations behind” (p. 307). Consciousness, meanwhile, is defined by Freud as the locus of transformation of “quantity” into “quality” in the “x” system of neurones (p. 311). This is the context in which the “pleasure/unpleasure principle” is first framed in terms, here, of proportional fullness (analogous, arguably, to hunger’s proportionality to lack in the case of the

alimentary function): an excessive cathexis of neurones, according to Freud, generates unpleasure, while a lesser cathexis thereof gives rise to pleasure (p. 312).

After recapitulating “the functioning of the apparatus,” Freud goes on to describe the  $\Psi$ -system of neurones as exposed without protection to the quantity of endogenous stimuli, “and in this fact lies the *mainspring* [*Triebfeder*] of the psychical mechanism” (pp. 315–16). This first adumbration of the instinct or drive (*Trieb*) is followed in the “Project” by a discussion of the “experience of satisfaction”—a reaction to the “filling” (“*Erfüllung*,” which also means “fulfillment”) of the neurone by a pressure or urgency that results in a motor discharge, as for example screams. Being incapable of feeding itself, the infant succeeds in this way in calling up “extraneous help” (p. 318)—or in other words an adult, who satisfies the need for nourishment and subsequently becomes a “memory of the object” whose image may, should the need arise once again, be hallucinated (p. 319).

Having thus linked the vital and sexual spheres, in counterpoint to satisfaction, Freud turns to the “experience of pain,” in which the system perceives a “hostile object” (is Freud thinking of two distinct objects or of a single object “split” into “good and “bad”?) behind which we may discern the “seducer,” the idea of which (or of whom) gives rise to an increase in the level of excitation, and hence of unpleasure (p. 320). The organization of the apparatus is thereafter perfected thanks to the development of the “ego.” The ego is supposed to inhibit the system and to mobilize secondary against primary processes. This new way of functioning allows for the emergence of “indications of reality” (p. 325), of the capacities for judgment, remembering, thought, and so on. Freud returns to the issue of the primary process at the end of this ontogenetic itinerary, considering its role in sleep and dreams, which constitute a return to an earlier state and permit the “fulfillment”—comparable to the aforementioned “filling” of neurones—of “wishes.”

A description of the play of displacements, ideas, and quantities in dreaming provides Freud with an easy transition to the second, and unfortunately the shortest part of the “Project,” entitled “Psychopathology.” Here he explains “hysterical compulsion” by means of a very interesting theory of the symbol.

Whereas the displacements and substitutions that give rise to “symbols” in normal subjects are said to be the same in hysterics, in the case of hysterics, “The symbol has in this case taken the place of the *thing* [that has been repressed] entirely” (p. 349). The two preconditions of repression coming into play, Freud asserts, are that the idea affected be unpleasurable and that it be sexual (p. 350). But “the core of the riddle” of repression remains, for, in contrast with hysteria, “compulsive neurosis” can arise without symbol-formation (p. 352). Thus the “*proton pseudos*” is constituted by two premature scenes of a sexual nature whose impact is “deferred” until quantities of sexual excitation are released at puberty. The ego is then evaded by memories while it is preoccupied with defending itself against assaults coming from perception. The specific action of sexuality can be explained only by reference to its belatedness as compared with the rest of the individual’s development: “The retardation of puberty makes possible posthumous primary processes” (pp. 356, 359).

The third part of the “Project” is a long presentation of normal mental processes, in which Freud seeks to situate issues of general psychology—attention, judgment, thought, memory in relation to language, and so on—within the framework that he has been developing. One interesting idea is that the pleasure principle might be an inhibiting mechanism that pushes the ego to learn attentiveness and to cathect the wishful idea to a moderate degree (p. 361). In the later development of his work, Freud would make these considerations the basis of the reality principle, even though he would characteristically, given his predilection for over-rigorous oppositions, treat this as an absolute antagonist of the pleasure principle. His discussion here of “observing thought” (pp. 363–65), meanwhile, though it might seem off-putting, may well have led him to develop the technique of “free association.”

A final aspect of the “Project” that needs stressing is, according to James Strachey (*SE 1*, p. 291), the remarkable part played by sexuality in this early work. Freud was indeed rather too prone, later, to forget what he had described here as a cardinal aspect of repression—the fact that it affects only *sexual* ideas (p. 352); and he likewise paid insufficient attention to the impossibility for the child of metabolizing adult sexuality, of handling what in the “Project” are called “excessively intense” (*überstark*)

ideas (p. 347). Simultaneously indicated and masked by the metaphorization of the general development of the mental apparatus, this embryonic account of the advent of a sexual “program” in the child is presented solely from the point of view of the “receiver” and offers no parallel description of the “transmitter,” which would have introduced the interpersonal dimension. Precisely because of this omission, Freud would tend to espouse the idea of inborn sexual programming, in which context the primary process became proof of the unconscious as opposed to what it might have been if the view of the “Project” had been followed, namely a receiving area for an unconscious brought into being for its part by multiple encounters with the objects of childhood.

First published in 1950 in the original German, translated into English in 1954, the “Project” was greeted with enthusiasm by Freud’s admirers. A whole generation of physicians thought it promoted a new rapprochement between two forms of knowledge (medicine and psychoanalysis) that history had tended to set at odds. James Strachey, however, had already cautioned against an excessive reaction to the “Project’s” disinterment (*SE*, 1, p. 239). Today the enthusiasm has been much tempered, especially among “biologists,” who argue that what seemed like brilliant insights when the “Project” emerged have been much tarnished by the passage of time. All the same, for psychoanalytic researchers this work is still a cornucopia of discoveries yet to be made and of avenues past and future to be avoided.

## PROJECTION

In a general sense, the term *projection* refers to the displacement of something from one space to another, or from one part of a single space to another (the Latin word *projectio* translates as “throw forward”). More specifically, this term denotes an operation that consists of transporting a form, or certain elements of that form, onto a receptive support that may be real (as is the case with cinematographic projection) or imaginary (as is the case in projective geometry—for example, the projection of a cube onto a plane, which presupposes laws of transformation). Thus, the concept always involves a distinction between two spaces—the space of origin and the space of destination—that are complementarily defined by this very operation.

This basic definition is found in the psychoanalytic notion of projection, whose specifics raise difficult problems with regard to the two spaces thus distinguished, their distinction, and their complementarity. The spaces in question are known, following Sigmund Freud, as the space of mental reality and the space of the reality of the outside world, that is, internal and external reality.

From a psychoanalytic viewpoint, projection is an intrapsychic process that creates or shapes a percep-

tion (or a collection of perceptions) with reference to an object in the outside world, which, although the subject believes he or she is perceiving it “objectively,” is actually being perceived according to the subject’s own characteristics; the most interesting case is when this object is a real person (sometimes called an *external object*). Passing through all possible intermediary cases, this ranges from cases where the perception is entirely invented, in the absence of any concomitant sensory reference (as in hallucinations, but also nighttime dreams), to cases involving the subject’s “coloration” of an otherwise objective perception (for example, an unknown person’s attitude is perceived as being vaguely hostile by one person, while another perceives it as being fairly friendly).

Freud did not write any text specifically on this notion, although it seems he wrote such a draft in 1915, in the framework of his metapsychological writings of this period. In fact, the idea of projection was already well established in his work. It appeared, still in a very simple form, as early as “On the Grounds for Detaching a Particular Syndrome from Neurasthenia under the Description ‘Anxiety Neurosis’” (1895b [1894]): In anxiety neurosis, the psyche, to protect itself from excessive excitation, “behaves as though it were projecting that excitation outwards” (p. 112). What is described is thus a cathartic evacuation of an overflow of excitation. But it is in a letter to Wilhelm Fliess dated January 24, 1895 (Manuscript H) that the first version of what Freud would subsequently develop under the term *projection* is found. No longer is it merely this evacuation that is involved, but also the transposition outward toward an exterior support, of representations and affects that are linked to it. Freud defined this process as being characteristic of the paranoid subject: “[T]he purpose of paranoia is thus to fend off an idea that is incompatible with the ego, by projecting its substance onto the external world” (p. 209).

Freud returned several times to the problems raised by the notion of projection, in particular in his “Further Remarks on the Neuro-Psychoses of Defence” (1896b) and, later, in “Totem and Taboo” (1912–1913a). Above all, this notion took on a very special importance in his discussion of his case of Judge Daniel Schreber in “Psycho-Analytical notes on an Autobiographical Account of a Case of Paranoia (Dementia Paranoides)” (1911c [1910]).

From the outset, Freud distinguished two clearly distinct mechanisms in this regard. One corresponds to “normal” projection, defined by the following passage from “Totem and Taboo”: “Under conditions whose nature has not yet been sufficiently established, internal perceptions of emotional and thought processes can be projected outwards in the same way as sense perceptions; they are thus employed for building up the external world, although they should by rights remain part of the *internal world*” (p. 64). Thus, this “normal” projection is a component of perception itself and of construction of the real.

The other mechanism involves a “pathological” projection in which the process gets carried away, so to speak, and results in a construction of the real that is so distorted that mental functioning can indeed be considered pathological. This is seen in the phobias, as Freud noted on several occasions, notably in “Instincts and Their Vicissitudes” (1915c). But it is above all the workings of projection in the paranoiac, analyzed in connection with the Schreber case, that best illustrate this mechanism. Schreber’s initial, homosexual position, as constructed by Freud, is essentially: “I (a man) *love him* (a man)” (1911c, p. 63); but this basic proposition, actively combated, undergoes a double transformation that is in fact a double reversal. The inversion of subject/object and active/passive (it is not I who love him; it is he who loves me) and inversion of love/hate (I do not love him; I hate him) culminate in a justification: “I *hate* him because HE PERSECUTES ME” (p. 63). For Freud, Schreber’s entire delusion was constructed on the basis of this mechanism, which could be seen to involve denial, and, more generally, the figures of the negative, the workings of which have been thoroughly analyzed by André Green.

Several major problems arise at this point. The notion necessarily presupposes a distinction between “inside” (the intrapsychic) and “outside” (the outside world). Freud pointed out in “Instincts and Their Vicissitudes” that this distinction is fundamental and necessary from the very beginnings of biological life: The single-celled organism, for example the paramecium, constitutes a functional unit separated from its environment by a membrane; it must import from the environment the nutrients it needs and export the toxic metabolic by-products it produces. This dual, import/export movement, which, in biological terms, involves incorporation/excorporation, is extended and transposed to the level of mental functioning in the

form of introjection/projection. Freud in effect deemed it necessary to define introjection—a notion he borrowed from Sándor Ferenczi—as the necessary complement of projection. Thus, he wrote in this essay: “In so far as the objects which are presented to [the ego] are sources of pleasure, it takes them into itself, ‘introjects’ them . . . and, on the other hand, it expels whatever within itself becomes a cause of unpleasure” (p. 136).

From that point, we are led to consider the processes of identification, which have been defined, precisely, in terms of the pair introjection/projection. But if one goes back to the biological model, one observes that the paramecium, taking from its environment the substances it needs, runs the risk of reimporting the harmful metabolites that it itself has rejected. Similarly, the mind runs the risk of reincorporating from the outside the “bad” elements with which it has, in a sense, polluted it. The fantasmatic aspects of this dialectic between good and bad, in this continual coming-and-going between inside and outside, were in particular developed by Melanie Klein and her followers, based on this fundamental biological schema and within the perspective of Freud’s second theory of the instincts; the notion of projective identification developed by these authors becomes easier to understand in light of these considerations.

To what extent does this dual, inside/outside movement blur or, on the contrary, confirm, the boundaries between psychic reality perceived as such by the subject himself, and the surrounding world, conceived of as existing as a function of its own existence, beyond any omnipotence of thought? The question is clearly raised in the case of dreams, and more generally, that of the hallucinatory satisfaction of desire of which nighttime dreams are a particular case. Generally, day-dreams or reveries maintain a clear distinction between the two, and this is the source of the richness of the imaginary developments in the “transitional space” whose importance was so clearly shown by Donald Winnicott: Here the world is transformed, even created, by psychic reality, but by a psychic reality that is aware of this creative free play. Nighttime dreams thus involve a hallucination through which psychic reality creates illusory perceptions out of whole cloth, in the sense that they do not correspond to any “objective” sensory data. Is it possible, then, following the distinction that Freud consistently sought to maintain, to speak of “pathological” projection?

The question arises even more crucially in the case of the hallucinatory satisfaction of desire in the infant, whose disappointment, according to Freud, presides over the birth of the earliest representations, defined, precisely, by the feeling, “This is inside Me, and not currently and really outside of Me.” Clearly, in no case can such a foundational process of psychic life itself be considered “pathological.”

We are thus led to distinguish two different functions for projection, which, moreover, exist in tight complementarity. On the one hand, a defensive function that involves expelling from the intrapsychic space that which is unpleasurable, threatening, and so forth. On the other hand, an elaborative function in which this expulsion establishes and consolidates the indispensable inside/outside differentiation. From there, many different balances between the two modes of functioning can be established. If the defensive function predominates, projection occurs in the service of misapprehension, and the world thus constructed is inhabited by hostile figures: This is what Freud termed “pathological” projection, from its relatively minor operations in neurotics to the delusional constructions of psychosis. If the elaborative function predominates, this involves, through the extension of the earliest processes of individuation, maintaining and affirming a complementarity between the ego and what is given to it to know.

The notion of projection is among those, which, after Freud, underwent interesting further elaboration, in particular in the British School, in the work of Klein and her successors, with the related notion of projective identification. Wilfred Bion, in particular, distinguished between an excessive form of projective identification that serves the pleasure principle, and which essentially corresponds to what Klein was describing, and a “realistic” projective identification, a primitive mode of communication that serves the reality principle. The latter no longer involves fleeing reality but rather modifying it in order to be able to reintegrate bad projection without being harmed and to better accommodate introjection of good objects.

## PROJECTION AND “PARTICIPATION MYSTIQUE” (ANALYTICAL PSYCHOLOGY)

Carl Gustav Jung defined projection as an initial objectified representation of the contents of the unconscious beyond the states of so-called “*participation mystique*” (mystical participation) and “archaic identity,” and he showed how the individual can be led to see through the illusions of projection and yet, at the same time, to experience symbolic life.

As early as his psychiatric studies written between 1900 and 1908, and also in his thesis, “Psychology and Pathology of So-Called Occult Phenomena,” which he

defended in 1902, Jung was investigating the internal coherence and meaning of representational systems that were largely being ignored by his contemporaries. His conception of “highly charged emotional complexes” (*gefühlbetonte Komplexe*) and his contact with Sigmund Freud led him to analyze, in his “Psychology of the Unconscious. A Study of the Transformation and Symbolism of the Libido. A Contribution to the History of Thought” (1911–1912), the poems and fantasies of a young woman by comparing them to a whole series of myths and rites that stage the difficult process of detachment from one’s original attachments and inclusions. Jung’s subsequent elaboration of his theory of projection was based on the analysis of states of *participation mystique* (he borrowed this French expression from the anthropologist Lucien Lévy-Bruhl) or “archaic identity.”

In the states of *participation mystique* and archaic identity there is no differentiation between object and subject and no distinction between lived experience and what the subject believes he or she perceives about the world. However, projection, which is more specific, enables the subject to apprehend and potentially recognize contents that are still unconscious. Thus, analysis of the religions of our ancestors, the literature and iconography of alchemy and, more generally, the arts, as well as the fantasmatic universe of a given group or individual from the perspective of modern psychology can be quite valuable.

In fact, the Jungian Shadow, Anima, Animus, and Self, before being recognized as presences or inner agencies, are ordinarily projected onto typical figures or acquaintances of the subject, in the same way as they are projected onto the analyst in the transference relationship. The recognition and withdrawal of projections usually provokes a state of disenchantment or, conversely, elation and inflation of the ego; however, these processes can also open the way to a practice of the symbolic life and of human relations without too much alienation or mystification, especially through the experience and analysis of the transference.

Some feared that Jung was indulging himself in an imaginary universe without concrete support. However, his analyses of the history of our culture, his position with regard to various religions and also within the history of psychoanalysis, and above all his ways of conceiving and eliciting the work of the unconscious, not only in its compensatory effects but also its effects of contradiction, give the clinical

practitioner the means of avoiding this potential trap.

## **PROJECTIVE IDENTIFICATION**

In the paranoid-schizoid position described by Melanie Klein, the ego may split off intolerable experiences by dividing itself, and locating parts of the self in external objects. Typically, though not always, it is “bad” parts of the self which are expelled in this way, but they are then feared as “bad” objects. This process is called projective identification.

The term is first used in a footnote added in 1952 to Klein’s paper on schizoid mechanisms (1946/1952). The concept of projective identification arose from psychoanalytic treatments that she and certain colleagues were conducting with seriously disturbed schizoid and schizophrenic patients (Scott, 1946; Rosenfeld, 1950; Segal, 1950).

Klein described states of vagueness, blankness, apathy, and futility as a result of the mind being split up and parts of it annihilated. She distinguished splitting of the ego from the way repression may remove a word or memory from consciousness, typically in the parapraxes. Frequently she noted that something of what the patient has lost is still experienced by the patient, but as attributed to some external object, perhaps in the analyst. In that sense, a piece of the subject’s personal identity has been projected into someone else’s. She linked this self-directed annihilation of parts of the mind to the death instinct, and viewed it as clinical evidence of the death instinct in, for exam-

ple, the common schizoid experience of feeling that parts of the mind are missing. The associated form of projection very specifically interferes with the sense of self and identity.

As an expulsive process, unwanted bad objects are expelled in an anal phantasy; however, annihilated fragments of the self are also caught up in the expulsion. The result in phantasy is a complex situation in which the parts of the self give a special quality to the object into which these bad things are physically evacuated (the “lavatory mother”). The object retains a special reference to the self, and is not properly distinguished from the self. It is felt to *be* the bad self, and that means the self that is engaged in attacking itself. Projective identification is, therefore, characteristically the process by which the death instinct is split and displaced by projection into the external world. Klein regarded it as the prototype of the aggressive objective-relationship.

The term has been the focus of great attention in the years since it was first described clinically in psychotic patients. It has also been expanded considerably in meaning. Two features have been greatly investigated: firstly its interpersonal aspect; and secondly its normal occurrence in mild form in everyday life.

Not long after Klein’s description of this mechanism, it was realized that in the *interpersonal* dimension the patient re-finds that part of himself in another person. A process occurs in the object (introjection) in which their intrapsychic world actually takes on those aspects the patient has disowned. Then the relationship with the other person conforms to the phantasy that underlies projective identification. In the psychoanalytic setting this interaction between two intrapsychic worlds has revised the phenomenon of countertransference: Parts of the analyst come to be entangled with those parts of the patient’s own self which they seek to project into their psychoanalyst (Money-Kyrle, 1956; Brenman-Pick, Irma, 1985).

Projective identification is a core feature of the paranoid-schizoid method of defense; it has also come to be recognized as an invariable occurrence in the primitive stages of development. This normalization of the concept has enlarged the scope of the term “projective identification” until it now covers a whole catalogue of different phantasies, many of them widely divergent from the one Melanie Klein originally presented (Rosenfeld, Herbert, 1983).

In particular, the degree of violence by which the self is split and projected is variable. Loosely, the ego that is more mature, secure, and centered upon a good internal object, is less violent in projecting parts of the self.

Instead of using projective identification as a means of desperately expelling an internal catastrophe, it can become an unconscious method of communication, a non-symbolic communication aimed at making the object (the psychoanalyst) feel the experience of the patient very directly (Bion, 1962). In this view, it is the method by which an experience is passed directly on to others. In ordinary conversation, if someone lacks the emotional impact engendered by limited projective identification, they are regarded as flat and tedious.

Moving further along a conceptual axis toward a still lesser degree of violence, there is a relationship in which the ego no longer splits itself, but nevertheless can see itself in the other person. Insight is achieved through “putting oneself in another’s shoes.” This benign form of projection into someone else is the foundation of empathy. There is thus a spectrum of different “uses” of projective identification: expulsion, non-symbolic communication, and empathy (Hinshelwood, 1994).

The influence of one person (the patient) on the intrapsychic world of another has in time become accepted by psychoanalysts outside of the Kleinian group. Joseph Sandler (1976) has noted the way in which the patient mobilizes certain affects, and even behavior, in the analyst. He has called this “role-actualization,” and regards it as a formulation of projective identification in an ego-psychology conceptual framework.

In some schools of psychoanalysis (notably contemporary ego-psychology), the responsiveness of the object and the interpersonal interaction have been elevated to a position as the most important aspects of this concept, over and above the intra-psychic defensive aspects (Ogden, Thomas, 1982).

Melanie Klein’s own assessment was that these kinds of processes are so remote from consciousness that it is hard for people to grasp them. As phantasy activities, they are seen as, improbably, having a definite effect in the real world. The “omnipotence of fantasy” as described by Freud in the Ratman case (1909d) fell short of claiming a real effect in the interpersonal world. Such a claim for projective identifica-

tion is therefore disputed by many. However, the notion is accepted widely, and by psychoanalysts of varied schools, many of whom do not accept the theory of the death instinct on which Klein originally based her interpretation.

## PROTECTIVE SHIELD

In Freud's psychophysiological model, the term *protective shield* designates an essential function of the psychic apparatus and the mechanism responsible for it. This function is to protect the organism from potentially harmful excitations coming from the outside world. The protective-shield function, in the context of the theory of the ego, is the result of a complex, dynamic barrier between outside and inside—a barrier in which the protective shield is posited as the most superficial and inert element.

As early as 1895, in "Project for a Scientific Psychology," (1950c [1895]), Freud hypothesized the existence of a mechanism responsible for protecting the "phi neurons" from an excessive influx of exogenous stimuli. In the psychic apparatus, governed by the principle of constancy (elevated quantities produce unpleasure), the sudden irruption of large quantities causes pain. Thus the phi neurons, which receive stimuli perceptions from the external world, must allow only small "quotients" or quantities to pass, but at this point Freud did not specify how this shield quantity ("Q-screens") functioned.

From 1920 to 1926, granting the perceptual apparatus its full importance in relations between the ego and the outside world, Freud hypothesized as an adjunct to the *Preconscious-Conscious* system the protective shield, which constitutes its most superficial layer. This system is operative only with regard to excitations coming from the outside world, and its function overrides that of the layer that receives excitations. By con-

trast, excessive energies that come from within are received directly by the *Preconscious-Conscious* system, which projects them to the outside so that the protective shield can be used against them.

In *Beyond the Pleasure Principle* (1920g), in order to understand the phenomenon of painful repetition in traumatic events, Freud posited in human beings the equivalent of the cortical layer that receives stimuli in living cells. Owing to the constant impact of excitations, the substances of the *Preconscious-Conscious* system and its protective shield undergo a profound modification. To a certain extent, the substance of the protective shield abandons the structure characteristic of living entities and becomes a special membrane that usually keeps exogenous stimuli separate. This inert filter is combined with two other elements to finally make up a true dynamic barrier between outside and inside. In the first place, the sensory organs, which periodically filter out sufficient amounts of the excitations coming from the outside world, constitute another protective shield (a hypothesis taken up again in "A Note upon the 'Mystic Writing Pad,'" [1925]); and finally, there is preparatory anxiety, which is the most dynamic element of the protective-shield system. This line of defense, prepared by a hyper-cathexis to receive and bind the sums of excitation flowing in from the exterior, shields against breakthrough and trauma (a hypothesis confirmed in *Inhibitions, Symptoms and Anxiety*, [1926]). Here, on either side of the barrier that prevents the development of anxiety, consisting of the *Preconscious-Conscious* system and its protective shield, Freud differentiated between two types of anxiety: on one side, the automatic anxiety of the states of the immature ego, which corresponds to an uncontrolled energy and is closely connected with trauma; and on the other, signal anxiety, which depends on a strongly hierarchical mechanism of the ego, which warns it in cases of real, external danger or internal, pulsional danger and allows the ego to mobilize its defenses.

After Freud, the protective-shield function of external objects was emphasized in the work of Donald W. Winnicott and Wilfred R. Bion. In Winnicott's view (1958), the environment, and especially the mother, must present the external world to the infant in a way that preserves the illusion without which the child's encounter with the world would be traumatic. In Bion's view (1962), the mother's capacity for reverie plays a foundational role in the infant's thought processes.

In *Le Penser: Du Moi-peau au Moi-pensant* (1994), Didier Anzieu held that the Skin-ego and the Thinking-ego both fulfill the protective-shield function, each at its own level. The Skin-ego defends the psyche against endogenous pulsional breakthroughs and simultaneously contributes to satisfying the appetite for stimulation; the Thinking-ego protects the Reality-ego from being flooded by thoughts and at the same time ensures that there is continuity in thinking activity. Lastly, Claude Smadja and Gérard Szweg attributed a protective-shield function to the death drive and self-calming behaviors by way of the repeated actions of weak discharges that involve motricity and perception; this is particularly applicable in the case of psychosomatic structures.

Ultimately, since the aim of the psychic apparatus is control over excitations, it can be said that under normal conditions, all mental work fulfills the protective-shield function.

## **PROTECTIVE SHIELD, BREAKING THROUGH THE**

A tear in the protective shield occurs when excitations from the external world reach such a level of intensity that they overflow the protective systems, or when the

absence of signal anxiety means that external perceptions are not recognized as dangerous by the psychic apparatus. Breach of the protective shield is thus a trauma whose source may be external or instinctual.

In trauma, the excess of excitations that the ego cannot control and work through results in disorganization of the psychic apparatus. This involves an attack on the boundary between inside and outside, upheaval in the mind's topographies with instinctual flushing, development of anxiety, and discharge actions aimed at bringing psychic tension back down to a tolerable level. Freud explained mental breakdown in terms of anticathexes that limit the tearing of the protective shield. Summoning the energies of all the mental systems, these anticathexes impoverish those systems accordingly and produce a reduction or even paralysis of mental activity.

In *Le Penser. Du Moi-peau au Moi-pensant* (1994; Thinking: from the skin-ego to the thinking-ego), Didier Anzieu proposed that in the face of the economic disorder resulting from the breach of the protective shield, the response of the psychic apparatus depends upon the prevailing principle of mental functioning. With the principle of constancy, there is automatic discharge into the external world (acting out), the body (pain, affliction of an organ), or the mind (disturbance of a mental function). In the case of the nirvana principle, excitation itself is what is dreaded; decaathexis, withdrawal, and sometimes hallucinatory projections occur. On the other hand, the constraint of repetition impels the psyche to seek out, whether in dreams or in reality, situations in which a traumatic flooding of stimuli occurred, in order to repair the trauma. Here, repetition of the painful experience aims to bring about retroactive control over the excitation, aided by the development of the anxiety that was initially lacking. Using the protective-shield effects of the death drive, the self-calming behaviors described by Claude Smadja (1993) and Gérard Szweg (1993) counterinvest a traumatic reality that might emerge from within. It should be noted that these solutions all have in common that they are rapid, economical, and the opposite of thought.

Reference is also made to breach of the protective shield in the etiology of borderline and psychotic pathologies. In these cases, object deprivation and early trauma have interfered with the development of the protective-shield system. Moreover, the overwhelmed, malfunctioning, and intolerant ego is

particularly exposed to traumas. According to Donald W. Winnicott (1958), when the mother's holding fails to provide protection to the nursling's immature ego, contact with the external world or the instincts is traumatic. The risk is disintegration of the self.

## **PROTON-PSEUDOS**

In the second part (“Psychopathology”) of *Project for a Scientific Psychology* (1950c [1895]) Freud introduced *proton-pseudos* in relation to hysteria. The term relates to Aristotle and the theory of the syllogism, which describes the link between false premises and false conclusions: if the premises are false, if there is an original error, then the conclusion must necessarily be false in spite of the soundness of the intermediary reasoning. The *proton-pseudos* refers to those false premises, the original error.

As an example, Freud described the case of Emma, who at the age of thirteen fled the laughter of the sales staff in a shop, consciously believing that they were laughing at her clothes. However, Emma's reaction in the shop was triggered by a repressed first event from years before, a grocer who had sexually touched her when she was eight.

This example described Freud's whole theory of the two stages of traumatism. He emphasized the intermediary period between the two successive events and that of the psychic maturation at puberty, which

enabled a reconsideration and reinterpretation of the first event, which, when it occurred, could only be recorded psychically without any real integration or metabolization.

Freud described what he called the “determinant conditions for the first hysterical lie” (*πρωτου πσευδος*), stressing the role of puberty and its delayed onset in the human species, a two-stage evolution that he believed explained why “every adolescent must carry the germ of hysteria within him” (1950c, p. 356). This breakdown of trauma theory into two stages echoes the biological view of pubertal evolution, although Freud gradually came to admit in his later work that the time span separating the two stages of the traumatism could in fact be shorter than he had initially believed; the second stage could be prepubertal in certain cases.

Freud discussed Emma's story before the discovery of infantile sexuality, and it is important to put his views into perspective with his letters to Wilhelm Fliess dated May 20, 1896, and December 6, 1896, and Manuscript M, in which he reflected on the different levels at which mnemic traces are recorded and on the “process of stratification” underlying this recording. In France this line of thought resulted in Jean Laplanche's work much later on the mechanisms of “psychic translation and the theory of so-called “general seduction.”

## PROTO-THOUGHTS

The term “proto-thoughts” refers to primitive sensory and emotional material that has not been subjected to the mother’s alpha function or been manipulated by the infant’s thought-thinking apparatus. Proto-thoughts also correspond to what Wilfred R. Bion called “beta elements.”

In *Learning from Experience* (1962), Bion posited the realm of the protomental as corresponding to objects that are “bad” because they are not in the infant’s possession, and yet excite his or her desire. The infant (or the psychotic patient) tries to rid him- or herself of “bad” objects and proto-thoughts. At this time, at the beginning of mental life, there is no possibility of relief because there are as yet no alpha elements, nor a thought-thinking apparatus to process alpha elements. Bion indicated two later outcomes for proto-thoughts: either flight in the face of frustration, or modification of frustration. The end result is the same if the mother is incapable of receiving the baby’s projections and later returning them to him or her in a tolerable form. If there is failure of the alpha function in the infant or the mother, contact with reality or with living objects also fails. The infant cannot think when things are not present; he or she cannot generate ideas. He or she will tend to act out, and later, the child’s speech will represent an action to liberate the

psyche from an excess of stimuli. The infant’s personality has access only to beta elements, which have no subjective meaning, cannot be used, and are thus evacuated through the eyes, the mouth, the anus, and touching.

The modification of frustration implies the appearance of alpha elements, originating in the mother’s alpha function and later the child’s alpha function. Alpha elements have affective resonance and an associative “penumbra.” They digest proto-thoughts and enable the development of the functions of the personality: intelligence, memory, emotional experiences, dreams, or the distinction between conscious and unconscious. Without the alpha function or alpha elements, there can be no maturation.

## PSI ( $\psi$ ) SYSTEM

In his unfinished 1895 "A Project for a Scientific Psychology" Freud defines the psi ( $\psi$ ) system as a subdivision of the nervous system concerned with psychic processes (1950a[1895]). Later, in *The Interpretation of Dreams* (1900a) he used the term to refer to components of the "psychical apparatus."

In the "Project," Freud hypothesized two neuronal systems,  $\phi$  (phi) and  $\psi$  (psi), and employed the principle of inertia and the concept of permeability. Elements of what he called the system were permeable but retained nothing; while the impermeable neurons, equipped with resistance and retentive of quantity, are the vehicles of memory and psychic processes in general, and receive endogenous excitations. Subject to the principle of constancy, neurons that make up the system mitigate its impermeability by "facilitation" (*Bahnung*), creating a permanent alteration in "contact barriers." Freud here adumbrated the concept of the synapse and the idea of synaptic change.

In later work, Freud abandoned the nomenclature of the "Project." He only employed the term " $\psi$  system" in *The Interpretation of Dreams*, where it was used in the plural to describe the components of the psychic apparatus. (1900a, Chap. 7). The systems possess spatial and temporal qualities in terms of arousal, which begins with internal or external stimulation and ends in "innervation" or discharge.

After 1900, Freud employed the term " $\psi$  systems" without as much spatial precision, and made use of new subdivisions: the systems Pcpt. (perceptual), Cs (conscious), Ucs (unconscious), among others.

## PSYCHANALYSE ET LES NÉVROSES, LA

*La psychanalyse et les névroses* followed in the wake of Emmanuel Régis and Angélo Hesnard's important work on the psychoanalysis of the neuroses and psychoses (1914). René Laforgue and René Allendy's book offered the French public a series of writings on psychoanalysis that were replete with clinical examples. The chapters on symbolism and those written from a non-medical point of view were by Allendy.

On the title page, an epigraph from Joseph-Jules Déjerine situated the book firmly in the French medical tradition. The medical qualifications of the authors and a preface by Henri Claude, consultant to hospitals and asylums, emphasized this even further. This latter preface, however, does not mince words: "While I am happy to present Laforgue and Allendy's book on psychoanalysis and the neuroses to the medical public, I have not hidden from the authors that I intend no endorsement of their opinions thereby.... Some of their investigative methods will shock those with delicate feelings, and some of their outrageously symbolic generalizations, though they may possibly apply to those of other races, do not seem to me acceptable to

Latin clinical practice.” He nevertheless recommended the book because he knew, having seen the authors at work, that it was work written in good faith and based on direct experience.

After reading Claude’s preface, Freud wrote to Laforgue that, although he had not yet read the book, he thought that it must be good, since Claude’s reservations showed that the authors had made no compromises and had no fear of controversy.

Laforgue and Allendy indeed presented “the medical public” with the fundamental notions of psychoanalysis, the mechanism of the neuroses, and the technique of this new discipline. Clinical examples, often from their experience at Sainte-Anne Hospital, were adduced to support their arguments. Accordingly, female frigidity, homosexuality, and impotence were discussed. In the chapters on symbolism, Allendy demonstrated his eclecticism and erudition: philology, astrology, and studies of diverse civilizations and religious customs were all brought in to reinforce his argument. This book, by young French doctors who were also practicing psychoanalysts, was the first of its kind. Two years later they founded the Psychoanalytic Society of Paris.

## PSYCHANALYSE ET PÉDIATRIE [PSYCHOANALYSIS AND PEDIATRICS]

When Françoise Marrette, the young analyst in control with Sophie Morgenstern, was working in the Breton-

neau hospital under Dr. Édouard Pichon, she determined that she wanted to “heal with psychoanalysis.” And it worked. Symptoms disappeared, and family equilibrium was restored. It seemed as simple as that. If all pediatricians and general practitioners could benefit from this experience it would be a great day for medicine. She wished to direct the attention of her fellow physicians to the possible benefits of analysis to the patients who came to consult for a variety of ailments. Her thesis was addressed to her colleagues and presented in 1939.

Before recounting her beautiful stories, Marrette felt the need in the first part of her work to define for her lay audience some analytic concepts: instinct, castration complex, agencies of the personality, conscious, preconscious, unconscious, repression, resistance, transference—but this teaches us nothing: the essence is in the struggle between the agencies, the flow of libidinal energy. Human beings were not defined as speaking beings but as storehouses of libido. The author informs us that her first three chapters are theoretical in nature, such that some readers might prefer to go directly to the second “distinctly more concrete and clinical” part.

The first chapter, “Évolution des instincts,” clearly shows that we can describe the behavior and thinking of young children with reference to the breast, excreta, the penis, and without any reference to the father; only the mother is named. The father only appears when the mother goes away “to do the housework, to keep dad happy.” Finally, “the child abandoned by the mother” comes to realize that it is not the only center of its mother’s attention: there is a rival in the form of the father, when there are not extra rivals in the form of brothers and sisters. As is clear in the work of the first child psychoanalysts (Melanie Klein, Donald Winnicott, among others), the remarkably absent father plays only a late role, toward the age of four or five, and “is part of the ambience of the mother.” Analytical theory introduces the father only in a context of oedipal rivalry, when the boy plays the despot, “donning his father’s hat.” In the beginning the child and the mother are one in the child’s experience; for many analysts, they are one and the same flesh.

Marrette’s work contains original suggestions. She brings forth the notion of progressive weaning, at the age of four or five months, to be completed by the seventh or eighth at the latest. If too late, she warns, weaning is experienced as “punishment for oral

aggression,” an assertion that received legitimate criticism. Françoise Marette was more cautious when it came to educating the sphincter. Whereas many analysts claimed that children should receive potty training at the end of the first year, she waged war against abusive sphincter training: not before twenty-four months. In this she was innovative. Equally with regard to the discovery of sexual differences and the pleasure of masturbation.

The role of the father was also a problem when it came to the Oedipus complex and the castration complex. When her work was presented in 1962, mention was made of the fact that she had married Dr. Boris Dolto in 1942. When she became a mother she acquired “experience that made her one of the representative personalities of the contemporary French psychoanalytic movement.”

The second part of her thesis gives us a sense of this: in clinical vignettes and moving stories extolling the merits of psychoanalysis, sixteen children came to see her accompanied by their parents. She initially received the family all together, and then the parents withdrew to the waiting room. The children were then free to express themselves, to draw and use clay, to play and speak. But she did not see the parents again at the end of the session with the child. Some analysts and institutions immediately separate parents and children, which deprives the analyst of significant information that is indispensable for an understanding of what the child is experiencing and thus prevents the analyst from having an effective contact with the parents.

Through her account of these consultations, generations of physicians gained an increased understanding of the emotional lives of children and discovered that they had an educational role to play, whether they liked it or not. Marette, inventively, invited the children to use speech and play in order to free themselves from regressive or aggressive and poorly-adapted behavior. It is a pleasure to witness the children, determined workers, undertaking an analytic cure and inviting their parents to question the influences that condition them, all without their realizing it.

Attentive readers also discover the path that analysts must follow if they don't want to become obstacles in the way of the analysis. The thesis concludes with: “The castration complex is ineluctable in the course of human development [...]. This work has not enabled us to deal with the very many questions relating to the castration complex. Its aim is to inter-

est our non-psychoanalyst colleagues in the fundamental importance of the Oedipal stage in the history of individual development and its role in the etiology of functional symptoms and behavioral disorders in order to demonstrate the therapeutic interest of psychoanalysis.”

## PSYCHANALYSE, LA

The *Société française de psychanalyse* (SFP, French Psychoanalytic Society), was founded on June 18, 1953, following the resignation of Françoise Dolto, Juliette Favez-Boutonier, Jacques Lacan, Daniel Lagache, and Blanche Reverchon-Jouve from the *Société Psychanalytique de Paris* (SPP, Paris Psychoanalytic Society). The new group did not found a journal, but rather published a series of eight “notebooks” that came out according to no fixed schedule under the title of *La Psychanalyse*. The subtitle was *Freudian Research and Teaching of the Société Française de Psychanalyse*. The titles of the series, all published by Presses Universitaires de France, are as follows:

- I. On Speech and Language (1956)
- II. Clinical Miscellany (1956)
- III. Psychoanalysis and the Human Sciences (1958)
- IV. The Psychoses (1958)
- V. Critical Essays (1959)
- VI. Structural Perspectives (1961)
- VII. Feminine Sexuality (1964)
- VIII. Fantasy, Dream, Reality (1964)

The first volume contained Lacan's “Rome Report” from the new society's first congress in September 1953, as well as all the presentations made at that

conference. Volume VI, “Structural Perspectives,” published the acts of the international congress held at Royaumont in 1959. It included Daniel Lagache’s paper “Psychoanalysis and Personality Structure,” followed by Jacques Lacan’s “Remarks on Daniel Lagache’s Presentation: ‘Psychoanalysis and Personality Structure.’” It also included Lacan’s “The Direction of the Treatment and the Principles of Its Power” and Dolto’s “Personology and Body Image.” Volume VII included the proceedings of an international conference on feminine sexuality held in Amsterdam in 1960. It included “Guiding Remarks for a Conference on Feminine Sexuality,” by Lacan, and papers by Dolto on “The Destiny of Feminine Genital Libido” and by Wladimir Granoff and François Perrier on “Feminine Ideas and the Problem of Perversion in Women.” This volume also included numerous papers and translations of texts, such as Ernest Jones’s “Early Female Sexuality” and Joan Rivière’s “Womanliness as Masquerade.”

The members of the S.F.P. disbanded in 1963 and announced the group’s dissolution in 1964, shortly after the publication of the last volume of *La Psychanalyse*. The volumes were published without an editorial committee. Among the numerous French authors whose works were included were Piera Aulagnier, Serge Leclair, Maud Mannoni, Octave Mannoni, Gisela Pankow, Guy Rosolato, Mustapha Safouan, Daniel Widlöcher. Foreign authors published in *La Psychanalyse* included Michael Balint, Martin Grotjahn, Susan Isaacs, Jacques Schotte, and Alphonse de Waelhens.

## PSYCHE / PSYCHISM

In their most general sense, the words “psyche” and “mind” refer to phenomena and processes associated with the “soul,” understood empirically, without consideration of its content (conscious, unconscious, life principle) but excluding any metaphysical or religious meaning (unity of the soul, distinction between soul and body, immortality).

Although “psyche” and “mind” can, to some extent, be considered synonymous, the first is not

really a modern term (except, obviously, in modern Greek) and its use is based on the desire to allude to a context that is as much literary as philosophical. Freud rarely used it outside of such a context (however, see *An Outline of Psychoanalysis*, 1940a [1938]). Nonetheless, in *The Interpretation of Dreams* (1900a), he refers to the fact that “the Ancients . . . provided Psyche with butterfly wings.” The mythical character of Psyche—who, in a story by Apuleius, loses her husband, Eros, after having looked upon him as he slept—has been the theme of numerous works of literature and art. The fact that, as a common noun, the word “psyche” refers to a type of mirror, has led us to reconsider the concept of the soul as a narcissistic double.

The word “mind” on the contrary is—or claims to be—“scientific.” As such it can only be defined with reference to the science whose object it supposedly represents, namely psychology. While the concept of “consciousness” has escaped definition (we can only speak of lived experience), it is likely that any definition of mind will turn out to be circular, or simply limited: “Mind” is the object of psychology as a discipline distinct from metaphysics and biology. But since the limits and principles of psychology are themselves problematic, the difficulty remains.

Introducing the concept of the unconscious does nothing to alleviate the difficulty, since mind cannot be defined as the simple addition of conscious to unconscious. For Freud unconscious is not identical with non-conscious, and the question of just how mind should be defined remains. Hence a reliance on a history of the concept, a history in which, it should be noted, the problem of conscious versus unconscious has only marginal importance.

To vastly oversimplify the matter, we can say that for the early Greeks, “psyche” referred to the breath of life, and for Descartes the soul was identified with consciousness. In Homer the psyche, sometimes represented with butterfly wings, resembles a dream and an unreal image of a man, while the breath of life is called *thumos*. In the Pythagoreans and Plato the psyche appears as a reality belonging to the moral order. It is capable of good or evil, it will be judged, and it is immortal. But it is also in Plato that we find—following chapter 4 of the *Republic*—the celebrated distinction between intelligence, anger (*thumos*), and the base instincts, which Freud associated, in 1923, with the concepts of ego, superego, and id. This Platonic distinction enriched the notion of the soul with anthropological features and supplied the

foundation for a rational and empirical psychology, which was developed in Aristotle, who emphasized, although not exclusively, mental functions that were vital, if not biological (biology did not yet exist as an autonomous science). In fact the Aristotelian notion of the psyche covers a very broad range of functions (metaphysical, “psychological” in the modern sense, biological), while “mind” was not distinguished until the modern era.

The important milestones in this development are not those of the history of the unconscious but of the genesis of empirical psychology. The appearance in 1590, in the Latin title of a work by Rudolf Goeckel, of the word *psychologia*, in Greek (although the term did not exist in ancient Greek), indicates the tendency of Renaissance culture to use the term to delimit a specific field of thought and research. However, the decisive event was the distinction made by Christian Wolff, in 1732 and 1734, in two works respectively entitled *Psychologia Empirica* and *Psychologia Rationalis*. Even though Wolff’s first text remains highly speculative, the initial break with rational psychology has been made, through metaphysics, along with a top-down demarcation of the object that the term “mind” would designate. A bottom-up demarcation would take place in the nineteenth century with the development of scientific biology.

What of the unconscious? It is true that Descartes, by defining *mens* in terms of thought and by rejecting the scholastic concept of soul and its vital aspects, made it necessary to introduce, as early as the seventeenth century, the concept of the unconscious (the term itself did not appear until the eighteenth century and did not become popular until the nineteenth). But when, in German romantic philosophy, the concept was used to designate a form of foundation or first principle, the connection with representation would be broken. For example, Eduard von Hartmann, in his famous *Philosophy of the Unconscious* of 1869, describes a form of panpsychism that makes it possible to introduce the notion of psychism. Freud himself was familiar with this point of view. When, in a well-known passage from *The Interpretation of Dreams*, he wrote that “the unconscious is the true reality of the psyche,” he destroyed any possibility of defining mind in terms of representation (conscious or non-conscious) and left untouched the problem of the characteristics that could be used to distinguish the psychic from the biological, and from metaphysics.

It is only through an epistemology of psychology that the concept of mind can be defined. And since psychology, in its current form, comprises various disciplines whose epistemological foundations are difficult to reconcile, we must resign ourselves to the fact that the terms “psyche” and “mind” designate only those highly amorphous objects considered by psychology as understood in the broadest sense of the terms.

## **PSYCHÉ, REVUE INTERNATIONALE DE PSYCHANALYSE ET DES SCIENCES DE L'HOMME (PSYCHÉ, AN INTERNATIONAL REVIEW OF PSYCHOANALYSIS AND HUMAN SCIENCES)**

Founded in 1946 on the initiative of Maryse Choisy, *Psyché* is defined as an “international review of psychoanalysis and human sciences.” The first issue of this monthly review appeared in November 1946 and was followed by another 120 issues until 1963.

The idea for the review took root among a circle of intellectuals that Maryse Choisy brought together between 1944 and 1945. This group of poets, writers, philosophers, and theologians met to exchange ideas

on a variety of topics that sometimes included occultism, astrology, and clairvoyance. Philosopher Pierre Bachelard introduced the psychoanalytic element, as did psychoanalyst Juliette Boutonier, whose presence between 1945 and 1946 drew in other analysts like André Berge, Françoise Dolto, René Laforgue, and George Mauco.

In the course of time, a certain number of analysts from the Paris Psychoanalytic Society thus accepted Maryse Choisy's proposition to create the review *Psyché*. The *Revue française de psychanalyse* (French Review of Psychoanalysis) had not yet reappeared after the war and *Psyché*, with its vocation extending to include the "human sciences" was closer to the framework of applied psychoanalysis, being comparable in this respect to *Imago*.

Maxime Clouzet (Maryse Choisy's husband) was director of the review and the committee of patronage brought together some eminent personalities of the time, people like Louis de Broglie, perpetual secretary of the of the Academy of Science, Pierre Janet from the Institute, Pierre Teilhard de Chardin, the discoverer of the Sinanthropus, Charles Baudouin, Drs. John Leuba, René Laforgue, Angélo Hesnard, Louis Le Guillant, Charles Odier, and Édouard Toulouse.

Maryse Choisy directed a small team that included André Berge and George Mauco, both psychoanalysts, as well as other collaborators with artistic and literary vocations in charge of completing the "monthly chronicle" under headings like Painting, Books, Theater, Cinema, and a Review of Reviews. The copy desk was the responsibility of Jacqueline Massière (the future Jacqueline Cosnier), a young philosopher in analytic training.

The first issues enjoyed the benefits of a group of varied and competent collaborators. At the end of 1945, Maryse Choisy had managed to acquire the collaboration of the (rare) psychologists and psychiatrists who practiced psychoanalysis or who were beginning to take an interest in it, as well as eminent personalities from the worlds of science, literature, and philosophy.

In the course of the different issues we thus find the names of André Maurois, Edmond Jaloux, Louis de Broglie, Pierre Teilhard de Chardin, Marcel Griaule, Georges Dumézil, Karl Jaspers, Martin Heidegger, Claude Lévi-Strauss, Georges Heuyer, Serge Lebovici,

Françoise Dolto, Béla Grunberger, Juliette Boutonier, Octave Mannoni, René Laforgue, Charles Odier, René Allendy, Marie Bonaparte, and Angélo Hesnard. It is worth pointing out that the last five of these were among the seven authors in the first issue of the *Revue française de psychanalyse* in 1927.

Quickly enough, *Psyché* began to publish contributions by psychoanalysts from other societies in other countries: Emilio Servadio and Nicola Perrotti of the Italian Society, Igor Caruso from Austria, John R. Rees from London, Karen Horney and René Spitz from the United States, Heinrich Meng from German-speaking Switzerland, while the committee of patronage was completed with professors Jean Delay, Henri Gouhier, Daniel Lagache, and Jean Lhermitte.

Congresses came to be organized as an extension of the review: the Royaumont study week on "The fate of collective man" (1947), the International Congress of Catholic Psychiatrists, Analytical Psychotherapists and Educational Psychologists (1949). *Psyché* published the proceedings of these congresses as well as reports on the different meetings relating to the field of psychology. A supplement to the review also appeared with installments of the "Dictionary of Psychoanalysis and Psychological Technique," directed by Daniel Lagache, the outline of the future *The Language of Psychoanalysis*.

*Psyché* played a role in organizing and bringing together the psychoanalytic milieu immediately after World War II. However, the eclecticism and the "ecumenical" preoccupations of its instigator, combined also with the reorganization of the psychoanalytic societies and the reappearance of the *Revue française de psychanalyse* (in 1948), which was soon complemented by the creation of other specific reviews, led to two phenomena that were to reduce its importance in the analytic world: psychoanalysts had other places where they could exchange ideas, and because of this the review's para-analytic and extra-analytic cultural aspects assumed increasing importance. Moreover, from issue number 15 onward the initial sub-heading of the review, "International Review of Psychoanalysis and Human Sciences," changed to "International Review of Human Sciences and Psychoanalysis."

## **PSYCHE. ZEITSCHRIFT FÜR PSYCHOANALYSE UND IHR ANWENDUNGEN**

*Psyche. Zeitschrift für Psychoanalyse und ihr Anwendungen* (*Psyche: A Journal for Psychoanalysis and Its Applications*) is the most important and most widely distributed German-language psychoanalytic journal. Seven thousand copies of it are printed every month.

Founded in 1947 by Hans Kunz, Alexander Mitscherlich, and Felix Schottlaender, it first appeared with the subtitle *Jahrbuch für Tiefenpsychologie und Menschenkunde in Forschung und Praxis* (*Yearbook for Research and Practice in Depth Psychology and the Human Sciences*). It adopted its current name in 1966, thus leaving no doubt about its Freudian orientation.

In the beginning *Psyche* represented a mixture of the teachings of Carl G. Jung, Sigmund Freud, Alfred Adler, and the neo-analysis of Harald Schultz-Hencke. This eclecticism, which escaped the attention of the first editors, was a hangover from the period when National Socialism grouped together the most diverse therapeutic schools in the Deutsches Institut für psychologische Forschung und Psychotherapie (German Institute for Psychological Research and Psychotherapy). In the 1950s Mitscherlich managed to acquire contributions from emigrant Freudian authors like Michael Balint, Erik H. Erikson, Heinz Hartmann, and Edith Jacobson, thus establishing a Freudian tradition that still characterizes the journal in 2005.

From its first decades up until the early 1970s, the journal aimed primarily to repromote knowledge of Freudian psychoanalysis, which had been destroyed or brushed aside in Germany by National Socialism, and to raise the scientific level of German psychoanalysis to that of international standards. Moreover, its editor Alexander Mitscherlich (who worked alone after 1968) sought from the beginning to relate psychoanalytic questions to social and cultural questions and to give the periodical the interdisciplinary orientation that has become its hallmark. Problems raised by Freud's theory of culture were always given priority treatment, although not to the detriment of the theoretical and clinical aspects of psychoanalysis.

In the 1970s and 1980s the journal opened its pages to discussion of the tense relations between psychoanalysis and feminism, and to the prickly question of to what degree and with what consequences the German psychoanalysts who did not emigrate between 1933

and 1945 had compromised themselves in National Socialist health policy. This question, which relates to the historical and moral complicity of German psychoanalysts, was the subject of an intense several-year controversy between the editors of the review and representatives of the German psychoanalytic societies. This controversy showed *Psyche* for what it really was: a journal that never considered itself merely a mouthpiece for the German psychoanalytic community.

After the death of Alexander Mitscherlich in 1982, the new editors—Margarete Mitscherlich, Helmut Dahmer, and Lutz Rosenkötter—continued the well-tried editorial policy of the journal. Since 1990 Margarete Mitscherlich has been the sole editor.

## **PSYCHIC APPARATUS**

The notion of psychic apparatus (or of the intellect) is common in Freud's work from the very start (cf. for example, the article of 1898b, "The Psychological Mechanism of Forgetfulness"). It appears continuously from then on, and is the title of Chapter I of one of his last texts, *An Outline of Psychoanalysis* (1940a [1938]). It was borrowed from the vocabulary of nineteenth-century psychologists who were seeking to accord to animal and human mental functioning a representation conforming to the exigencies of the natural sciences (physiology and especially physics).

Considered from a static point of view, the Freudian versions of the psychic apparatus correspond to what was subsequently called the "topographies." The first one (yet to be designated by this word) appears in Chapter VII of *The Interpretation of Dreams* (1900a) and essentially comprises the distinction between the unconscious, the preconscious, and the conscious. The second topography (cf. *The Ego and the Id*, 1923b) distinguishes between id, ego, and superego, which are depicted in a diagram reminiscent of an egg, that was to be reworked into a slightly different form in Seminar XXXI of the *New Introductory Lectures on Psychoanalysis* (1933a [1932]).

Still from the start the notion of psychic apparatus also pointed to a dynamic perspective: it presupposed something that functions. The schema outlined in Chapter VII of *The Interpretation of Dreams* occupies a place within the time's general psychological framework concerned with the passage from perception to movement (to be found, for example, in Henri Bergson's *Matter and Memory* of 1896, and which corresponds with experimental psychology's stimulus-response pairing). Freud's aim was to demonstrate how "unconscious systems," which he was not yet referring to as "complexes," acted upon the information gathered by the perceptual apparatus to create representations and conscious movement, and in particular, in this respect, oneiric representations. Likewise the group comprising the three instances—id, ego, and superego—was also to have permitted an accounting of psychic functioning, in particular the resolution of certain difficulties regarding the unconscious and the non-conscious. Freud never specifically says whether the id, ego, and superego were to replace the schema in *The Interpretation of Dreams*, thus rendered obsolete, or only to add another perspective to it.

In more precise terms, the Freudian notion of psychic apparatus entails the idea—borrowed from physics—of a sort of "energetic economy." Although he never attempted to specify the precise nature of sexual energy (as would Wilhelm Reich), nor, even less, that of psychic energy in general, Freud, (inspired by Gustav Fechner), conceived the workings of the human psyche from the perspective of the flow, equilibrium, and transformation of a certain "energy." The "pleasure principle" articulated the idea that when tension in the psychic organism reaches a certain level, a release will ensue which is lived subjectively in the form of pleasure, but whose objective effect is to lower tension and avoid the dangers of overflowing. Although the pleasure principle itself derives from thermodynamics, the notion of sublimation, which envisions the transformation of a socially-incompatible sexual "energy" into socially-acceptable activities, originates in chemistry.

Finally it is worthwhile to note that some of the most suggestive representations of the psychic apparatus refer to models taken from optics (cf. for example the passage cited above from *The Interpretation of Dreams*, as well as the *Question of Lay Analysis*, 1926e). The fact that Freud sometimes uses the adjective *psy-*

*chisch* (psychic), sometimes *seelisch* (relating to the intellect), does not seem significant, as the two words may be considered synonymous.

The notion of psychic apparatus and the uses Freud puts it to raise the issue of the value models taken from the physical sciences have for psychoanalysis. Some, such as George Politzer and Jean-Paul Sartre, have concluded them to be an inexcusable misunderstanding of the psyche's specificity. Indeed as Sartre says in *Critique de la raison dialectique* (1960) concerning the notion of defensive mechanism, that such a representation "burdens the workings of the ego with an a priori inertia." If, as Georges Politzer reasons, the psyche as such is a kind of drama, no apparatus could represent it. These arguments could be countered by noting that these are metaphors—that topography—despite its etymology—does not imply the brain as locale, but only a "locus of the psyche" as such, and that from a dynamic point of view the flows and transformations of energy are not physiological or chemical processes. Freud was perfectly aware of these difficulties and explained himself clearly, for example concerning the problems posed by the visualization of the psyche (cf. *New Introductory lectures on Psychoanalysis*, 1933a, xxxi). Nevertheless for him, the representations he called "psychic apparatus" seemed to be much more than merely images, useful but misleading, which as Plotinus and Bergson have taught, should be employed with other images, incompatible with them, to avoid one's being duped by them. Freud seems to have tried to forge a path between the neurological perspective, where psychic functions are supposedly lodged in their cerebral headquarters (a view he no longer shared at the time he invented psychoanalysis), and the phenomenological perspective which excluded anything to do with topographical location, functioning, or mechanical operation. He adopted this perspective at times, furthermore, but not in those texts where the notion of psychic apparatus intervened. Still, this path seems so narrow we may wonder if it is navigable. Without going so far as to challenge its legitimacy, we may at least consider it—in Freud's own words—"provisional."

## **PSYCHIC CAUSALITY**

In Sigmund Freud’s work, the term “psychic causality” designates a group of unconscious psychic processes (conflicting drives, structural conflicts, narcissistic and object investments) and defensive mechanisms (repression, denial, splitting, rejection) that are assumed to be the origin of the phenomena of day-to-day life (dreams, slips, failed acts, creative acts) as well as of neurotic and psychotic symptoms. Operating according to the logic of psychic conflict and primary processes, psychic causality is said to be dissociated from the concept of “psychic reality,” and from Freud’s ongoing attempt to discover the etiology of neuroses, psychoses, and perversions.

The concept appears indirectly throughout Freud’s work but he never examined it at any length. It is known that Freud came upon the idea at the Salpêtrière, working with Jean Martin Charcot in 1885–1886. As he subsequently wrote, “[Charcot] succeeded

in proving, by an unbroken chain of argument, that these paralyzes were the result of ideas which had dominated the patient’s brain at moments of a special disposition” (1893f, p. 22). By 1890 Freud had extended this to all neuroses. In an article entitled “Psychical (or Mental) Treatment,” he claimed that “in some at least of these [neurotic] patients the signs of their illness originate from nothing other than *a change in the action of their minds upon their bodies* and that the immediate cause of their disorder is to be looked for in their minds” (1890a, p. 286). Based on the article, psychic causality is not yet explicitly linked to the unconscious mechanisms he would subsequently describe. However, very early in his work he postulated a “sexual etiology in all cases of neurosis but in neurasthenia the neurosis is actual; in psychoneuroses factors of an infantile nature are at work” (1896c). In 1898, in “Sexuality in the Etiology of the Neuroses” (1898a), he referred to “unconscious psychic traces.”

Psychic causality implies the ability to substitute for a set of apparently unrelated facts an explanatory system based on assumptions that provide them with consistency and can be used to describe the laws governing their interrelations. All of Freud’s work revolves around “two opposed conceptions of causal necessity” (Dayan, Maurice, 1985), one of which was responsible for integrating individual differences in a coherent structure, the other tending to emphasize the subject’s singularity and originality. There is a gradual complication of the notion of psychic causality in Freud. In 1895 he proposed two models simultaneously: a causality of psychic facts conceived as part of a system that we would now call cognitivist and neurobiological (see, “Project for a Scientific Psychology,” 1950c [1895]) and an “event-driven” traumatic conception of neurosis. His “neurotica” is supposed to comprise hysteria and obsessional neurosis based on the psychic traces of sexual aggression experienced during childhood and reactivated later on.

The (relative) abandonment of this etiology (letter to Wilhelm Fliess on September 21, 1897) would confirm the effectiveness of the unconscious fantasy as a psychic act. *The Interpretation of Dreams* (1900a) and the first topographical subsystem enabled him to describe the laws underlying the operation of unconscious processes for which time and contradiction have no meaning, which shift and condense to produce not only dreams but the lapses and parapraxes of

the “psychopathology of everyday life” (1901b), together with neurotic symptoms and delusions. Freud thus established the absence of a barrier or discontinuity between the normal and the pathological, a key idea in psychoanalysis. The same unconscious psychic mechanisms are responsible for both modes of existence.

From the first to the second topographical subsystem (1923), the Freudian notion of psychic causality was radically modified. The description of the mental apparatus became increasingly complex. Mental and psychopathological facts are now the result of relations of force between id, ego, and superego agencies, and the dualism between the libido and the death drive. Metapsychology, which combines topological, dynamic, and economic points of view is the final version of this new way of thinking about psychic causality. At the same time, the role of object relations and the weight of civilization on possible subject pathologies were substantiated. The *Versagung* (refusal) that social reality forces desire to confront, the privation (*Entbehrungen*) that someone like Judge Schreber, unable to have a child, experienced, or the disappearance of the love object are considered as helping to trigger neuroses and psychoses.

In 1933, in the *New Introductory Lectures on Psychoanalysis* (1933a), Freud proposes a general theory of neurosis based on the combination of three factors: a refusal of a reality that is unsatisfactory for the id, fixation at a stage prior to libidinal development, and idiosyncratic disposition to the conflict that characterizes the potentially neurotic subject. The neurosis is triggered by regression to the points of attachment; in the case of psychosis and perversion specific defense mechanisms—splitting, denial, rejection (“Fetishism,” 1927e, “Splitting of the Ego in the Process of Defence,” 1940e [1938])—are also involved. In his last writings, *Moses and Monotheism* (1939a) and *An Outline of Psycho-Analysis* (1940a), published after his death, Freud insists on the particular causal value of the superego that is associated with phylogenesis and the threat of castration, which “[the boy] experiences [as] the greatest trauma of his life and introduces the period of latency with all its consequences” (1940a, p. 155). Whatever the case, Freud reaffirms the continuity of the normal and the pathological: “[T]he neuroses do not differ in any essential respect from the normal” (1940a, p. 184). The normal, neurotic, or psychotic individual will die “of his internal conflicts” (p. 150).

Freud also again insists on the central importance of conflict between the body and the mind, and their interrelations, in his conception of psychic causality, which as we have seen had a number of “avatars.”

It could be said that, since Freud, all writers on psychoanalysis have tried to enrich the notion of psychic causality with their own theories, which are inspired by archaic fantasies and the individual’s traumas and personal history. Jacques Lacan’s work represents an original attempt to define psychic causality on a structuralist basis by identifying the unconscious with the chain of signifiers. “The only causality the analyst knows is always that of the cause,” he wrote in *Seminar XI*. At the end of his life, he attempted to systematize intrapsychic activity using mathemes. The contributions of psychosomatic analysts (Georg Groddeck, Franz Alexander) and those of the French school who followed the work of Michel Fain and Pierre Marty reopened the question of psychic causality by focusing on Freud’s initial question: the relationship between physical and mental disturbances.

For André Green “the term psychic causality is used by Freud rather loosely, without any genuine theoretical support” (1995). In spite of the lapidary nature of this claim, it must be acknowledged that disagreement over the nature of the concept was the origin of the split in the psychoanalytic movement. For example, Otto Rank believed he had discovered the cause of neurosis in the traumatism of birth. Wilhelm Reich focused on the idea of the sexual frustration imposed by civilization (*The Function of the Orgasm*, 1927). Sándor Ferenczi, after attempting to illustrate Freud’s phylogenetic theory and the concept of regression (*Thalassa*, 1924), reaffirmed the reality of sexual trauma experienced by the infant, and did so against Freud’s advice (“Confusion de langues entre les adultes et l’enfant. Le langage de la tendresse et de la passion,” 1933).

Epistemologists, making use of the criticisms that quantum mechanics and the theory of relativity had formulated concerning causality in physics, have contested the causal ambitions of psychoanalysis. Attacking Freud’s system of causal interpretation, Ludwig Wittgenstein referred to purely “aesthetic” relationships (*Cambridge Lectures*, 1932–1934). Karl Popper contested the scientific status of psychoanalysis, which was, according to him, a self-validating theory (*The Logic of Scientific Discovery*, 1934).

André Green, in his *La Causalité psychique* (1995), supplied a masterful criticism of the attempts of biology, neuroscience, and anthropology to invalidate the concept of Freudian causality. Nonetheless, in the realm of physics, measurement can be used to provide uniform descriptions of the natural universe. As far as we know, the relative force of mental drives does not lend itself to any precise form of measurement. Psychoanalysts are content to state that “it works. . . .” As Piera Aulagnier wrote, we are forced to recognize that psychoanalysis can lay claim to “necessary” but never “sufficient conditions” as these are understood by philosophy and mathematics.

## PSYCHIC ENERGY

The hypothesis of a psychic energy constitutes a fundamental postulate of psychoanalytical theory. It is omnipresent, from the theory of sexuality to that of the dream, of anxiety, of drives, and of affects. Of the three great metapsychological points of view, the economic one is directly founded on it, but the dynamic and topographical points of view imply it also. Any psychic movement can, in the last analysis, be linked to a phenomenon of energy. Nevertheless, this economical point of view, this “energy metaphor,” has often been criticized, put into question, and even abandoned by some.

The notion of psychic energy has its source in the works of neurophysiologists at the end of the 19th century, Sigmund Exner in particular, or in the psychophysics of Gustav Fechner, and it is present in the psychiatry of that epoch. In psychoanalytical writings, it surfaced first under the pen of Josef Breuer in *Studies on Hysteria* (1895d). He described this energy as a “nervous tension,” or “Intracerebral Tonic Excitations” (p. 192), contained in the reservoir of the nervous fibers. This “quiescent” energy can be put into movement and become active.

Sigmund Freud, starting with *Studies on Hysteria*, introduced the idea of a tendency “to maintain cerebral excitation at a constant level,” a principle of constancy that will become a principle behind the balance of pleasure and unpleasure. He first developed the notion of psychic energy in the “Project for a Scientific Psychology” (1950c [1895]) in a neuronal version; in *The Interpretation of Dreams* (1900a), the neurophysiological model disappeared and psychic energy was inserted into a theory of thought. The energy could be “free,” in the case of “primary processes,” or “bound,” as in “secondary processes.” In the latter, the binding or connecting of psychic energy is related to the linking of representations and to the “taming” of the tendency for “discharge.” “Thought must concern itself with the connecting paths between ideas, without being led astray by the *intensities* of these ideas” (p. 602). The quantities of energy conveyed by these

two kinds of thought are different; secondary processes of thought only convey much weaker quantities of energy, while a surfeit of non-bound energy can occur, to weaken these thought processes.

For Freud, with the theory of drives, the equating of psychic energy and the libido was reinforced; the libido constituted, therefore, the essence of psychic energy. However, he always remained reticent about Carl Gustav Jung's proposition of conflating psychic energy totally with the libido, and he held onto the idea of a psychic energy distinct from the libido, attached to ego drives and self-preservation, all the while continuing to wonder about its provenance, and admitting that this could be a desexualized energy. In *The Ego and the Id*, he constructed the hypothesis of a "displaceable energy, which, neutral in itself, can be added to a qualitatively differentiated erotic or destructive impulse, and augment its total cathexis. . . . It seems a plausible view that this displaceable and neutral energy. . . proceeds from the narcissistic store of libido—that it is desexualized Eros" (1923b, p. 41).

Most post-Freudian authors recognize no other psychic energy than the libido, except for the school whose source is *Ego Psychology*, which developed the Freudian idea of a displaceable, neutral energy; for them, this was a "neutralized" energy, participating in the functioning of an ego that had been "liberated from conflicts." With Melanie Klein, the evolution of the stages of the libido was prominent at the beginning of her work; later, the importance accorded to unconscious fantasy and the object relation would force her, in fact, to abandon the economic point of view altogether. On the contrary, the notion of psychic energy and the economic point of view would be very important to the perspective opened up by Pierre Marty and the work of the psychosomaticists of the School of Paris. The notion of the libido and that of psychic energy will be rejected by Jacques Lacan, who replaced the drives with "desire" and spoke ironically of the theory of the libido as an "astral myth"; he allowed absolutely no room for the economic point of view.

## **PSYCHIC REALITY**

A concept developed by Freud to denote the level of reality specific to unconscious processes, psychic reality, from an epistemological standpoint, refers to the "object" that psychoanalysis attempts to characterize, understand, and explore.

In *The Interpretation of Dreams* (1900a), the concept referred to the force of reality associated with the subject's internal fantasy life, which could oppose and even dominate perception of external reality; it could, in other words, seem more "real" than reality itself. From the outset the emphasis was on the objective nature of subjectivity, the reality of subjectivity for the psychical apparatus—even at the expense of its relationship to external reality.

The cultural context in which Freud worked tended to devalue or deprecate the character of subjective mental activity and, in particular, unconscious mental activity. He needed to assert the objective character of unconscious psychic entities in the face of opposition that would prefer to relegate them to the realm of the "imaginary" and unreal.

In an article devoted to hysterical paralysis (1893c), Freud had presented the problem of the "objective" nature of hysterical conversion symptoms and their significance. The difference between biological reality, especially in terms of anatomy, and the "psychic" reality expressed by hysterical symptoms prefigured the objective character of the unconscious, as Freud was to

understand it. The nature of symptomatic manifestations—anesthesia, paresthesia, and so on—demonstrated that hysterical patients could not be “malingerers.” Existence of an autonomous realm of psychical life and the unconscious psyche, including the reality of fantasies, could henceforth be asserted with growing confidence.

Another aspect to the emergence of psychical reality was sexual trauma and its value in terms of etiology in the debate around the role of real-life events as opposed to fantasy. The early *neurotica* that Freud developed tended to assign to some “real” traumatic event—childhood sexual seduction, for example—a determinative role in the etiology of hysteria and of neuroses, more generally. However, treatment gradually revealed that it was impossible to say whether the remembered scenes of traumatic seduction had actually taken place or were “invented.” The infantile and sexual fantasies that such scenes represented replaced the traumatic etiology of neurosis. These fantasies, an important type of psychical reality, impacted the psychic apparatus with all the force of “reality” and more.

Thus, the concept of psychical reality was advanced initially to point out the imperious nature of fantasy with its hallucinatory quality, which could somehow dominate external reality. Any trace of opposition between external and internal as the concept is currently employed is complicated further by the question of how to determine the source or basis of the subjectively “real” character of psychical reality.

Two kinds of hypotheses can be advanced in this regard. Not necessarily antagonistic, they represent two major strands in psychoanalytic thought that need to be considered together. The first type relates psychical reality to the impact of external reality, summarized at a preliminary level by the Freudian aphorism, “Nothing in thought that was not first in the senses.” Psychical reality in this sense would indicate a previous encounter with reality; it would represent a reality that has become psychical through trace of impact. The character of reality itself would bear witness to the psychical heritage of encounters with the external world. Fantasies, according to this view, are “hybrid” structures that contain a core of reality, a kind of transformed reminiscence, the source of which lies at a remote point in time. Beyond hallucination, what is actualized and acts upon the psychic apparatus refers to a past reality—for example, cruel acts of childhood retained in feelings of guilt.

The second type of hypothesis relates psychic reality to the constraints intrinsic to psychical activity, to its laws and operational principles. Thus, older representations of desire can be reactivated via the pleasure principle through hallucination, creating the perception of a wish fulfilled, even to the possible detriment of perception of the real world.

However the psychic apparatus develops, do awareness and symbolization of lived experience obey the rhythm and laws specific to psychic reality? Its own requirements cannot be ignored. Constraints are imposed by the external world, while others arise from the psychical apparatus itself. Psychical reality makes demands with the same limitations and categorical imperatives as instincts and external reality. This has led some contemporary psychoanalysts to formulate the existence, alongside the pleasure principle and the reality principle, of a “principle of psychical reality.”

An epistemological point of view would distinguish three types of reality: material reality generally, that aspect of material reality characterized by biological reality, and another aspect, independent of biological reality, to be known as psychical reality. This last is the special province of psychology. Psychoanalysis would be characterized as providing an account of “unconscious psychical reality” and its impact on psychical reality.

The concept of psychical reality thus unfolds in a paradoxical way. It types reality and constrains subjectivity; it indicates the psychical objectivity of the action of subjectivity and its preeminent concern for the intelligibility of psychical facts. These arise not only from the earliest subjective experiences, from what Freud called the “psychic raw material,” but also from the requisite transformation of this material in the course of development, aiming at integration necessary for acceptance at higher levels of consciousness and in consonance with laws that govern there.

## PSYCHIC REPRESENTATIVE

Sigmund Freud used the term *psychic representative*—*psychische Repräsentanz*, the expression of an instinct in mental life—almost synonymously with *Triebrepräsenzanz*, or “instinctual representative.” The distinction seems to be that the latter term emphasizes the thing that is expressed (the instinct), whereas the former emphasizes the process of expression. In fact, this possible discrepancy raises the problem of the instinct as a “frontier-concept” between the psychic and the somatic. Controversies over this point have pit authors who have attempted to dispense with this notion and its uncertainties, such as Jean Laplanche (1987/1989) and Daniel Widlöcher (1986), against others who, like André Green (1995, 1997), have vigorously defended its position within the metapsychological edifice and who attempt to specify its status.

It was in the “metapsychological” articles of 1915 (“Instincts and Their Vicissitudes,” “Repression,” and “The Unconscious”) that Freud posed this question the most clearly, by defining two components of this expression of the somatic in the psyche: the “ideational representative” and the “quota of affect.” However, he had already outlined the issue as early as 1895, in the “Project for a Scientific Psychology,” and above all in *Three Essays on the Theory of Sexuality* (1905), to which he substantially added in 1915 based on his then current thinking. He later reformulated these issues in his second theories of the instincts in *Beyond the Pleasure Principle* (1920) and *The Ego and the Id* (1923).

## PSYCHIC STRUCTURE

Psychic structure defines the dominant organization of an individual’s mind, manner of establishing relationships, and way of dealing with conflicts. Structure must consequently be seen as a whole. It must also be seen as fundamental, registering its influence at a level deeper than what is apparent in the individual’s personality, character, and manner. It is not innate, however. Individual psychic structure history is combined with hereditary or biological factors, since structure and genetics are not mutually exclusive.

Structure retains a unity and an immutable form, according to Freud in *New Introductory Lectures on Psycho-Analysis* (1933a [1932]), where he compares the ego to a crystal that is formed and also breaks along certain lines. Yet it is not invariable, because it is

a living organization that is constantly adapting, and because it can fail to maintain its equilibrium in certain modes of decompensation.

In effect, components of the dominant conflict—castration anxiety, loss of the object, or problems of identity—simultaneously explain the origins of psychic structure, its points of fragility, and the form of breakdown, through neurosis, depression, or psychosis. Depending on the structure in question, the defenses put into play will take on different meanings while sometimes retaining the same form: projection in the phobic subject is not the same as in the delusional subject. Also, symptoms insufficiently define the psychic structure, according to Jean Bergeret in *La violence et la vie* (Violence and life; 1994). While obsession occurs more frequently in depressed patients, it is also present in many cases of psychosis, where it plays a different role, and it is also capable of becoming dominant in an obsessive structure, just as protest or the demand for vindication can be permanently inscribed in a paranoid structure.

The typical stability of neurotic, psychotic, or perverse structures contrasts with the uncertainty of borderline organizations, where a narcissistic fragility produces a specific type of instability—“unstable states, stable structure,” as Daniel Widlöcher put it in his foreword to Otto Kernberg’s book on borderline conditions. Lastly, psychosomatic breakdown is caused by lack of structure, unless structure is considered at the level of organic function, which is no longer exactly a mental phenomenon.

In all cases, the unity of psychic structure can be defined according to different perspectives, which may converge at various points but do not completely overlap. For example, there are pregenital structures, with their archaic, oral, or anal relational modalities, and genital structures, with their more refined oedipal apprehension of the object. Taken together, these different notions of structure offer a less nosographic, more dynamic approach to the notion of structure, as Maurice Bouvet (1967) explained.

## **PSYCHIC TEMPORALITY**

The expression “psychic temporality” does not appear as such in the writings of Sigmund Freud. In fact, it is difficult to conceive of any other kind of temporality than psychic temporality, insofar as human time is concerned, whether or not it can be readily represented to the individual subject. Psychoanalytically, psychic temporality may be defined as the way psychic processes create their own time management and sense, according to three possibilities: regression, fixation, and anticipation.

Freud often argued the point that in dreams time is represented through space. He gives the example of a personage, who, in dreams, appears very diminished, as if seen the wrong way through binoculars, a figuration that he interprets not as an estrangement in space, but one in time (1933a [1932]). Reciprocally, the temporal contiguity of the associations of the patient is to be understood as spatial contiguity, recalling in its turn a relation of cause to effect (1905e [1900]). The succession in time of two consecutive dreams can even be upset without altering the causal relation, since it is the respective length of the dreams that then matters (1900a). From all these considerations, it emerges clearly that spatial representation is more important than temporal representation, and allows the latter to be expressed. This is explained by the fact that the visual is the mode of inscription of the infant’s memory.

Fantasy, said Freud, treats chronology with even more indifference, insofar as fantasy “hovers, as it were, between three times—the three moments of time which our ideation involves” (1908e, p. 147). A current impression is necessary, to reawaken an instinctive movement linked to an event from childhood and to create, in imagination, a situation relating to a future when the desire would be realized.

However, in a more general sense, it is the entire psychic life that proudly ignores time. “Neurotics,” wrote Freud, “suffer from obsession or regression” (1912–13a). Whether because it is unaware of the passage of time, or even returns to the past when the present becomes too frustrating, every psychopathological form (hysteria, paranoia, and so forth) takes, in its own way, this flight out of time that is also a flight from reality. Even more profoundly, psychic life combines simultaneously the three forms of topical, temporal, and formal regression found in dreams and in neuroses. Freud writes: “All these three kinds of regression are, however, one at bottom and occur together as a rule; for what is older in time is more primitive in form and in psychical topography lies nearer to the perceptual end” (1900a, p. 548).

Freud noted the total absence of the sense of time in psychosis (1900a), but did not try to explain this. Piera Aulagnier has been concerned with demonstrating the incapacity of the psychotic to conceive of a future time that is not just a pure repetition. She emphasized, on the one hand, the work of auto-historicizing incumbent on the ego, a veritable laying hold of the past and even of the prehistory of the subject; and on the other hand, the identificatory project that allowed the ego, at every moment of its trajectory, to imagine itself in a different place, implying the possibility of change. In psychosis, where repetition dominates, the ego does not succeed in transforming the fragmentary evidence concerning it into a temporal continuity, implying a before and an after. In this regard, the question of identity and the ability to conceive of temporality seem profoundly linked.

## PSYCHOANALYSE DES NÉVROSES ET DES PSYCHOSES, LA

*La psychoanalyse des névroses et des psychoses* (The psychoanalysis of neuroses and psychoses), by Emmanuel Régis and Angélo Hesnard, was the first book on psychoanalysis ever published in French. Prior to its publication, Freud mentioned it in a letter to Karl Abraham dated January 2, 1912: “Today I received a letter from a pupil of Régis at Bordeaux written on his behalf apologizing in the name of French psychiatry for its neglect of psycho-analysis and announcing his willingness to publish a long paper about it in *Encéphale*” (Freud and Abraham, 1965, p. 111). To Ernest Jones he wrote more specifically twelve days later:

“There is some stir in France even now, another man Hesnard a pupil of Régis at Bordeaux presenting in the name of his master to me ‘the excuses of the French nation’ for so continued a slighting and declaring himself prone to work for  $\Psi$ A [psychoanalysis] in the French papers” (Freud and Jones, 1993, p. 126)

Régis and Hesnard published two articles in *L'encéphale* in April and June 1913 on “the doctrine of Freud and his school” (1913a; 1913b). They were introduced as follows: “Freud’s system, whatever may be said of it, seems to constitute one of the most important scientific movements of our psychological times. Irrespective of whether its renown, now worldwide, is justified or not, we must surely be shocked and rightly so, that this system is almost completely unknown in our country.”

Régis and Hesnard’s book recapitulated and expanded on the two articles. Based on a reading of Freud and written with the collaboration of Oswald Hesnard, Germanist and brother of Angélo, the book presented the basics of Freudian theories as faithfully as possible at the time. The authors were very clear in their preface, dated May 1, 1914: “Possibly some will be shocked to see this popularization of a German theory that is at once so widely endorsed, so contested, and in certain ways so foreign, undertaken by French psychiatrists who are far from partial to the current fashion for German science. There is no cause for surprise, however. It is one thing not to accept blindly whatever comes from outside, another to ignore or misunderstand it. Impartiality and independence regarding what comes from elsewhere should not turn into xenophobia.”

The first part of the work (“The Theory of Psychoanalysis”) has six chapters: “Description and History of Psychoanalysis,” “The Dynamic Psychology of Freud,” “The Sexual Theory of Freud,” “The Morbid Sexual Constitution,” “The Technique of Psychoanalysis, Dream Analysis,” and “The Psychoanalysis of Associations of Ideas and Daily Life” (titles are translated from the French).

The second part (“Applications of Psychoanalysis”) has five chapters: “Extramedical Applications of Psychoanalysis,” “The Psychoanalysis of Neuroses,” “The Psychoanalysis of Psychoses,” “The Therapeutic Role of Psychoanalysis,” and “The Critique of Psychoanalysis.” There followed a bibliography listing the works of Freud, various books and articles in French, and some non-French works on psychoanalysis.

Sándor Ferenczi (1915) quickly recognized the significance of the book, but nevertheless found serious fault in it because it lacked the notion of the unconscious and repeated throughout the error of deriving almost all emotional tendencies from the sexual instinct. Ferenczi also challenged the judgments of the last chapter, which he correctly attributed to Régis. He vigorously stated his objections: the book lacks scientific value; it depends on “mystical concepts” and “teleological conceptions” that are more philosophical than medical; and it bases psychoanalysis on “ingenious hypotheses” and “fragile, uncertain techniques” whose “symbolic interpretation is sometimes an insult to common sense.”

One statement from Régis and Hesnard’s book served as a leitmotif for a good number of authors in the decades that followed: “Freud’s method and conceptions are based on those of Janet, by whom, it seems, he was constantly inspired. Changing Janet’s ‘psychological analysis’ to ‘psychoanalysis’ changed nothing as far as the method common to both students of Charcot was concerned.” For his part, Freud, in his “On the History of the Psychoanalytic Movement” (1914d), merely noted, “Régis and Hesnard (Bordeaux) have recently [in 1913] attempted to disperse the prejudices of their countrymen against the new ideas by an exhaustive presentation, which, however, is not always understanding and takes special exception to symbolism” (p. 32). Freud never forgave Hesnard for his ambivalence, which he let pass only around 1926, and then only partially.

The First World War put an end to any serious discussion in France about psychoanalysis, and hence Régis and Hesnard’s work, until 1920 (an exception being André Breton’s discovery of Freud in 1916). Régis died in 1918, and Hesnard alone was responsible for the new edition of 1922, where he wrote, “Science without scientific nationalism can be neither alive or fruitful. Freud’s teaching, which derives not, as has been claimed, from the French genius of Charcot, but rather from Germanic philosophy could have no more deniable adversary than moderation, a trait of Latin genius, from one point of view of the search for truth.” Freud did not much appreciate this remark, and four years later he spoke sarcastically to René Laforgue about such “bowing and scraping before Latin genius.”

In the third edition, appearing in 1929, Hesnard revealed that the chapter critical of psychoanalysis had been written by Régis, even if Hesnard had agreed at

the time. “At present,” Hesnard added, “with the benefit of five years of daily experience of it, we are in a better position to confirm the great value and significance of psychoanalysis. It is a therapeutic—and especially an exploratory—method that is indisputably superior to all others, in this, despite the drawbacks, it inevitably shares with all ‘heroic treatments.’”

## PSYCHOANALYSIS

Sigmund Freud himself provided the most complete, and now most classical definition for his invention, psychoanalysis: “Psycho-analysis is the name (1) of a procedure for investigating mental processes which are

almost inaccessible in any other way, (2) of a method (based upon that investigation) for the treatment of neurotic disorders and (3) of a collection of psychological information obtained along those lines, which is gradually being accumulated into a new scientific discipline” (1923a [1922], p. 235). This definition, intended for the *Encyclopaedia Britannica*, is still widely used today by many psychoanalytic training institutes.

Freud also wrote that the best way to understand psychoanalysis was to study its history. Its origins could be traced to the young Viennese doctor’s medical practice. He frequently treated “nervous” patients, for the most part described as suffering from “hysteria,” a field he came to specialize in after his return from Paris and his work assisting Jean Martin Charcot. He needed to heal these patients and develop a clientele large enough to support his growing family, even though therapeutic procedures at the time were practically nonexistent. The available techniques—electric shock, isolation in medical clinics, and sedatives—were soon abandoned. Hypnosis appeared to him at first to produce miraculous results, but it turned out to be a dead end, and he decided to apply the “cathartic method” that his mentor, Joseph Breuer, had discovered during the treatment of the patient known as Anna O. Taking the symptom as its starting point, this method strove to have the patient recall the circumstances of its first occurrence, and a successful outcome depended on this recollection by means of talk, which was supposed to make the symptom disappear.

Freud then discovered the “resistance” that patients would put up during the search for pathogenic “primal scenes,” as if they wanted to keep the origin of their illness secret. The material that was “repressed” in this way always involved old memories associated with specific events related to the earliest sexual activity of children. His suggestion that such a sexuality even existed greatly shocked many of his contemporaries. His patients soon began drawing his attention to their dreams, which he encouraged them to recount. In keeping with his belief in determinism, Freud concluded that dreams fulfilled a function—the safeguarding of sleep through the fulfillment of wishes that had been ignored by consciousness—and consequently had an “unconscious” content, a meaning that could be deciphered. The analysis of resistance and the interpretation of dreams, together with the method of “free association,” became the pillars of the psy-

chotherapy to which Freud, in 1896, gave the name “psychoanalysis.” The term appeared for the first time in an article written in French, “Heredity and the Aetiology of the Neuroses” (1896a).

By the first years of the twentieth century, the principal features of psychoanalytic treatment that still define it at the beginning of the twenty-first had been established: The patient was placed on a couch and the therapist remained out of sight. The patient was asked to say whatever came to mind. Sessions were fairly long, frequent, and expensive, so that the treatment would become an important part of the patient’s life and so that the bond with the psychoanalyst—the “transference”—would become the principal engine of the attempt to reconstruct the past and weaken the defenses the patient had set up against the pressure from contradictory drives. But the initial therapeutic successes were not as consistent or as long-lasting as Freud had hoped. The transference could become hostile and give rise to a “negative therapeutic reaction,” leading to the discontinuation of treatment or its indefinite extension.

Freud was less a therapist than a researcher, something he often recognized; it was primarily his students and successors who introduced improvements to his methods, or different but connected methods, to make the “therapeutic” aspect of psychoanalysis more effective.

Thus Carl G. Jung and Hermine von Hug-Hellmuth worked with psychotic patients, and Anna Freud and Melanie Klein with children. Otto Rank and Sándor Ferenczi sought to improve psychoanalytic therapy and make it more effective. They introduced so-called “active” techniques and tried to shorten the length of therapy, even exploring a form of “mutual analysis.” Traces of these early initiatives can be found in psychotherapeutic methods developed years later. Similarly, the extension of psychotherapy to patients presenting problems of psychosis or addiction, and the development of group analysis and psychodrama all tended to point up the therapeutic value of psychoanalysis. Some psychoanalysts sought to render their approach more effective by forging links with the neurosciences.

Following Freud, however, who quipped about the profession’s “*furor sanandi*,” other psychoanalysts emphasized the research implications of treatment. Thus Jacques Lacan, who in 1957 spoke of curing patients as merely an “extra” benefit of psychoanalysis, and who in 1964, when he founded the *École freudi-*

*enne de Paris*, described training analysis as “pure”—as opposed to simply “therapeutic”—psychoanalysis, clearly represents the tendency that embraces the third of Freud’s three basic definitions of psychoanalysis.

In his daily practice, however, Freud never differentiated between what he experienced and what he theorized later. His letters to Wilhelm Fliess allow us to follow, almost day by day, the theory-building that turned psychoanalysis into the “depth psychology” Freud hoped would supplant academic psychology. A work of construction then—but also of deconstruction—Freud considered his ideas to be superstructures whose existence was necessarily ephemeral, and anticipated new discoveries better adapted to the knowledge obtained from clinical practice. A first model, developed in 1900, which described a psychic apparatus formed of three agencies—the unconscious, preconscious, and conscious—was replaced in 1923 by another conceptual scheme comprising the id, the ego, and the superego. And while Freud remained firmly committed to the Oedipus complex, he had, over a period of forty years of work, fleshed out the speculative aspects of his metapsychology with new concepts that improved and sometimes reversed his earlier hypotheses: narcissism, the death instinct, the phallic stage, the splitting of the ego.

Alfred Adler, in 1911, and Jung, in 1913, made their final breaks with Freud over theoretical disagreements and formed their own schools. The first psychoanalytic theory to be developed that broke with Freud’s theories while also claiming to further the Freudian tradition was Melanie Klein’s, developed between 1930 and 1962. Klein radically revised the Freudian view of the first moments of the formation of the mental apparatus, on the basis of her clinical experience with very young children and her interest in psychoses. Her theoretical model invoked very early stages she referred to as “depressive” or “paranoid-schizoid” positions, and she held that the Oedipus complex originated at a much earlier age than Freud thought. Her opposition to Anna Freud, who insisted on strict fidelity to the spirit and letter of her father’s theories, gave rise to several important “controversies” (1941–1945) that determined the orientation of the British Psycho-Analytical Society after the Second World War. Following Klein, Donald Winnicott, Wilfred Bion, and Ronald Fairbairn helped develop British psychoanalytical theory and practice. In the United States a number of derivative psychoanalytic theories came into being,

some of which parted ways with classical Freudian theory. The theory of ego-psychology was introduced by Heinz Hartmann, Ernst Kris, and Rudolph Loewenstein, and was for years the major reference point of American psychoanalysis. Heinz Kohut developed a theory of narcissism, and Karen Horney and Harry Stack Sullivan were cofounders of a “culturalist” approach. Erik Erikson’s work was also notable.

In France, Jacques Lacan, under the banner of the “return to Freud” in November 1955, proposed new models that in his view could better account for the constitution of the “subject” and the relationship between the subject and the unconscious. The three categories of the real, the imaginary, and the symbolic; the primacy of the phallus; the object *a*; Borromean knots; and mathemes were so many milestones in an evolving theory that Lacan developed week by week, from 1954 to 1981, in his famous seminars. His idiosyncratic use of the findings of modern linguistics, inspired by Ferdinand de Saussure, of structuralism, and of logical and mathematical models, enabled him to make an audience of even communities like the Catholic Church and the Marxist orthodoxy, which had previously rejected “Freudian doctrine” as “unscientific.”

Whether or not psychoanalysis is a science has been debated for years, and the issue reappears regularly in the news. For epistemologists like Karl Popper and a host of other critics, the statements made by psychoanalysis cannot be considered scientific since they cannot be “falsified” and because the theory cannot be “refuted.” For Freud, the scientific status of his theory was never in doubt, and he considered his metapsychological hypotheses no more implausible than those of contemporary physics. Psychoanalysis, as far as he was concerned, was a “natural science” (“*Naturwissenschaft*”). Despite holding a position deemed by some close to “scientism,” Freud clearly distinguished his belief in a scientific ideal and the consistency of his hypotheses concerning the unconscious from a *Weltanschauung*, a “vision of the world” whose totalizing tendencies and illusory nature he feared. In *The Question of Lay Analysis*, he wrote: “Science, as you know, is not a revelation; long after its beginnings it still lacks the attributes of definiteness, immutability and infallibility for which human thought so deeply longs. But such as it is, it is all that we can have” (1926e, p. 191).

Freud also insisted on the importance of psychoanalysis as a cultural phenomenon and a special instrument for studying and understanding other cul-

tural phenomena. On July 5, 1910, he wrote to Jung: “I am becoming more and more convinced of the cultural value of psychoanalysis, and I long for the lucid mind that will draw from it the justified inferences for philosophy and sociology” (p. 340).

His letters to Wilhelm Fliess already illustrate the extent to which his psychological discoveries provided new insights for the understanding of literature and visual art, and how their study provided him with new ideas or proofs of the correctness of his views. It was Sophocles who provided Freud with the name for his “Oedipus complex,” discovered during his self-analysis in October 1897. In 1913 he indicated the fields of knowledge he felt would benefit (1913j) from psychoanalytic concepts. Aside from psychology, he listed the science of language, philosophy, biology, the history of the development of civilization, aesthetics, sociology, and pedagogy.

He confirmed this interaction in the *Introductory Lectures on Psychoanalysis*: “In the work of psychoanalysis links are formed with numbers of other mental sciences, the investigation of which promises results of the greatest value: links with mythology and philology, with folklore, with social psychology and the theory of religion. You will not be surprised to hear that a periodical has grown up on psychoanalytic soil whose sole aim is to foster these links. This periodical is known as *Imago*, founded in 1912 and edited by Hanns Sachs and Otto Rank. In all these links the share of psychoanalysis is in the first instance that of giver and only to a less extent that of receiver” (1916–1917a, p. 167–68).

Despite the charge that Freudian concepts cannot be applied outside the framework of the treatment and notwithstanding the superficial way they have indeed too often sometimes been used, the fact is that “applied psychoanalysis” has profoundly modified our view of literature and the fine arts, of biography, and of sociological and political realities. Freud set the example by the way he approached Wilhelm Jensen’s story “Gradiva,” Leonardo da Vinci’s life, and Michelangelo’s sculpture, to mention only a few of his contributions. But on several occasions he expressed his reservations about the value of the psychobiographies produced by some of his followers and successors.

Toward the end of his life his clinical work took a secondary position to his writings on the great problems of religion and culture: *The Future of an Illusion* (1927c), *Civilization and Its Discontents* (1930a

[1929]), and especially his last work, *Moses and Monotheism* (1939a [1934–1938]), which expands upon the anthropological ideas he had extensively covered in *Totem and Taboo* (1912–13a).

Later, the spread of Freudian ideas attracted the interest of writers, artists, and critics, who made use of them to enrich their own work. The Surrealists were among the first, but novelists, painters, and dramatists borrowed from psychoanalysis as well. Created at the same time as cinematography, psychoanalysis has inspired filmmakers from the early days. One has only to think of *Secrets of a Soul* (*Geheimnisse einer Seele*), the film G. W. Pabst made in 1926 in spite of Freud's reservations; or of the films of Alfred Hitchcock, *Spellbound* and *Vertigo*; or of *Freud, the Secret Passion*, by John Huston, prepared with the help of Jean-Paul Sartre and released in 1962, in which Montgomery Clift plays the role of Freud; or, for that matter, of the comic treatment of psychoanalysis by Woody Allen.

Throughout the twentieth century, the discoveries of psychoanalysis and its theory of the unconscious have profoundly modified the rules mankind has established concerning its behavior and sexual taboos, its relation to guilt, to femininity, and more generally to other people, about whom a whole new unconscious aspect was now apprehended. Obviously, however, the wide dissemination and renown of psychoanalysis were themselves the product of the twentieth century. Psychoanalysis was inspired and carried along by that century, with its excesses, its political ideologies, its economic and religious ups and downs, and above all, its terrible conflicts, which despite all claims to civilized behavior mobilized the darkest and most barbaric of human impulses just as Freud had understood and feared (1915b, 1933b [1932]).

In so many ways—the liberalization of behavior, the advancement of the status of women (both inside and outside feminist movements and in spite of their virulent criticisms of Freudianism), the dawning recognition of sexual minorities (even though in Freudian theory their preferences have been explained as arrested libidinal development and more or less archaic fixations), a different approach to the subject and its relation to itself and the other—psychoanalysis has become a part of everyday life throughout the so-called “Western” world and is not about to simply disappear, despite all the wild swings of fashion.

Its expansion toward other cultural sensibilities, like the multiplication of the often contradictory theories

and techniques that claim allegiance to it, as demonstrated by this *Dictionary*, show that psychoanalysis has never been a dogma or the kind of closed theory caricatured by dishonest critics. In his own time Freud defined those “cornerstones,” which seemed to him to provide the foundation that his successors would trace back to him: “The assumption that there are unconscious mental processes, the recognition of the theory of resistance and repression, the appreciation of the importance of sexuality and of the Oedipus complex—these constitute the principal subject-matter of psycho-analysis and the foundations of its theory. No one who cannot accept them all should count himself a psycho-analyst” (1923a [1922], p. 247). Nothing has really changed regarding the basic principles, in spite of the considerable diversity found in theoretical research and methods of practice, which has enriched the great network of the global psychoanalytic movement.

The recent rapid development of the neurosciences does not signal any decline in the value of the listening procedure that psychoanalysis has offered for more than a century in its attempt to understand and treat mental suffering. Apparently contradictory theoretical systems will eventually intersect and enrich each other, and the pessimism of the Cassandras can be answered with Freud's remarks, written in 1914: “At least a dozen times in recent years, in reports of the proceedings of certain congresses and scientific bodies or in reviews of certain publications, I have read that now psychoanalysis is dead, defeated and disposed of once and for all. The best answer to all this would be in the terms of Mark Twain's telegram to the newspaper which had falsely published news of his death: ‘Report of my death is grossly exaggerated’” (1914d, p. 35).

## PSYCHOANALYSIS OF CHILDREN, THE

Melanie Klein's first work, this book is the thoroughly worked-out result of her substantial clinical experience in applying psychoanalytic treatment to children. Though there had been other attempts to use psychoanalysis in treating children, notably Sigmund Freud's work with the father of Little Hans, reported in "Analysis of a Phobia in a Five-Year-Old Boy" (1909), *The Psychoanalysis of Children* is free of adult-centered biases and is a pioneering work.

Klein's freedom of thought, in terms first of technique and then of theory, came from her discovery of a new methodology: the use of the play technique had opened a new field of investigation of the unconscious. She had observed that children's play expressed their fantasies and anxieties. Gradually, she realized that children's play could be situated within the framework of the ego's attempts to defend itself from instinctual conflicts in order to work them out. This led to her conception of symbolism, a psychic mechanism that is essential for development of the ego.

This book can be divided into two parts. The first and technical part is based on six lectures given by Klein in London at the invitation of Ernest Jones in 1925 and 1927. In these chapters, Klein emphasized the clinical signs indicative of children's transference fantasies, which, in her view, made it possible to interpret them in a way that was similar to analytic work with adults. In fact, she demonstrated the technical value of an early interpretation of the transference resistances of certain children, in order to facilitate the

establishment of the therapeutic bond and a psychoanalytic process.

The second, more theoretical part of the book was written later. Here Klein developed her ideas on the early stages of the Oedipus complex, manifested in the phase of maximum sadism, where the child's aggressive instincts are directed toward parental part-objects: the mother's breast, the father's penis, and in particular the mother's body and its contents. Fixations of this kind can produce hypochondriacal fantasies about the child's own body, or else various inhibitions, especially in relation to toilet training. In Klein's conception, the early forms of the superego result from introjection of the persecutory breast and penis, which function as internal persecutors.

In this work Klein gradually became more oriented toward a theory of psychic conflict in which aggression plays the greatest role. The destructive omnipotence of aggressive fantasies stems from the child's immaturity in his or her struggle against the death instinct, as Klein argued in greater detail in her later theoretical work.

## PSYCHOANALYSIS OF DREAMS, THE

In 1940, in order to obtain the equivalent, in Argentina, of his medical degree from the University of Madrid, Angel Garma presented his book, *Psicoanálisis de los sueños*, for his doctoral thesis. Considered a classic of psychoanalytic literature, this work has gone through a number of editions in which Garma

has gradually elaborated upon his differences from the Freudian interpretation of dreams as wish fulfillments.

According to Garma, the dreamer's thoughts, originating in repressed content, present hallucinatory characteristics. In becoming conscious, these thoughts inform the manifest dream. They are related to highly traumatic psychic content. The ego seeks to protect itself by masking such contents. It transforms them into what appear to be wish fulfillments, but which are in fact satisfactions more characteristic of mania.

This theory maintains that the traumatic situation that causes dreams ends up as a hallucination when the charge of the repressed content is stronger than the weakened counter-charge of the sleeping ego. These contents give the ego the impression that they correspond to current situations in the real world. In Garma's view this is a phenomenon that occurs in a way diametrically opposed to that described by Freud describes it in his theory of reality-testing.

## PSYCHOANALYSIS OF FIRE, THE

*The Psychoanalysis of Fire* was published by Gaston Bachelard in 1938, before *Water and Dreams: An Essay on the Imagination of Matter* (1940), *Air and Dreams: An Essay on the Imagination of Movement* (1942), and *Earth and Reveries of Will* (1945). This essay was part of an effort that reconnected research on pre-Socratic philosophy with the question of the fundamental constituents of the world, the "elements."

Bachelard was both a theoretician of modern science (*The New Scientific Spirit*, [1934]; *Le Rationalisme appliqué*, [1949]) and a philosopher of poetics,

in the sense that while demonstrating the need for systematization associated with all rational thought, he insisted on the collapse of any system in the face of the infinite richness of experience. He also attempted to circumscribe existence with a profound imagination imbued with poetic experience that transcends the individual imagination of the subject.

For Bachelard the phenomenon of fire is situated at this crossroads of science and poetry. In his preface, he writes, "I am going to examine a problem in which objectivity has never held sway, where the initial seduction is so compelling that it deforms the most rational minds and leads them to the cradle of poetry, where daydreams replace thought, where poems hide theorems. This is the psychological problem presented by our convictions about fire. The problem is so directly psychological that I have no hesitation in speaking of a 'psychoanalysis of fire.'"

The work is broken down into seven chapters: 1. Fire and Respect: The Prometheus Complex; 2. Fire and Reverie: The Empedocles Complex; 3. Psychoanalysis and Prehistory: The Novalis Complex; 4. Sexualized Fire; 5. The Chemistry of Fire: History of a False Problem; 6. Alcohol and Water that Flames. Punch: The Hoffmann Complex. Spontaneous Combustions; 7. Idealized Fire: Fire and Purity. The two chapters that most directly concern psychoanalysis are obviously chapters three and four.

It is interesting that Bachelard, who here attempts an anthropological study of the birth of fire in human history and an approach to the libidinal components represented by fire, quotes Carl Jung on several occasions but never Sigmund Freud. He also quotes James George Frazer's *Myths on the Origin of Fire*, even though Freud himself referred to Frazer's work (in 1911 Freud read *The Golden Bough*), which was partly responsible for his interest in prehistory.

We also know that in 1930, in *Civilization and Its Discontents* (1930a [1929]), Freud discussed his famous hypothesis on the origins of the mastery of fire associated with a rejection of the impulse to urinate on the flame to extinguish it: "It is as though primal man had the habit, when he came in contact with fire, of satisfying an infantile desire connected with it, by putting it out with a stream of his urine. . . . The first person to renounce this desire and spare the fire was able to carry it off with him and subdue it to his own use" He also wrote an entire article on this, "The Acquisition and

Control of Fire” (1932a [1931]), in which he provides a brilliant analysis of the myth of Prometheus.

Therefore, the lack of any reference to Freud in Bachelard’s text is surprising, for the direction of their thought converges at many points even though it arises from different epistemological viewpoints. As far as we know Freud never met Bachelard, an existential non-event that may characterize, in its own way, Freud’s profound ambivalence toward philosophy, even when it was highly compatible or consistent with metapsychology.

## PSYCHOANALYST

“Whoever has admitted that transference and resistance constitute the linchpins of treatment forever belongs in our untamed horde,” Freud wrote to Georg Groddeck on June 15th, 1917. He would later add: “The acceptance of unconscious psychical processes, the acknowledgement of the doctrine on resistance and repression, the taking into consideration of sexuality and the Oedipus complex are the principle tenets of psychoanalysis and the bases of its history, and whosoever is not prepared to subscribe to all of them should not count himself among Psychoanalysts” (1923a).

Since then, disputes have run to the heart of the various psychoanalytic institutes over didactic analyses and training. The absence of a consistent code, compounded by inconsistent statutory regulations which governmental authorities have and have not have enacted in different region, has further multiplied the number of pronouncements as to what each institute reckons should best define what a psychoanalyst is.

Freud had already stated a few of his own prescriptions: “It is therefore reasonable to expect of an analyst, as a part of his qualifications, a considerable degree of mental normality and correctness. In addition, he must possess some kind of superiority, so that in certain analytic situations he can act as a model for his patient and in others as a teacher. And finally we must not forget that the analytic relationship is based on a love of truth—that is, on a recognition of reality—and that it precludes any kind of sham or deceit” (1937c, p. 248).

The work of the psychoanalyst has been described as being quite similar to that of the patient. First of all he or she should be committed to the relationship and to analyzing his or her own motivations for being in it. He or she must also engage in interpretive listening, including to the manifestations of their own defenses. In short, a “free-floating” or “evenly-suspended” attention must be paid when dealing with the processes inevitably evoked or generated by the highly-charged affective moments to which psychoanalytic activity leads.

The term counter-transference has been considerably expanded upon since it first appeared in 1910, and the various meanings attributed to it attest to the intricacies that develop within the analytic situation (Sandler, Joseph, et al., 1973; Blum, Howard, 1986). These conceptual responses, like the so-called “neutrality” intended to make the analyst into a “mirror,” attest to the receptiveness with which personal analysis, often called a “didactic” or “training analysis,” was meant to equip the psychoanalyst. In the event, only a presumptive judgment may be made in this respect. It should be recalled that language is the analyst’s fundamental operation medium. The psychoanalytic candidate must have mastered the unique system of language that a psychoanalytic dialogue will engage him in, as this language is far from being something that unfolds through one voice alone.

The “Rules and Procedures of the Training Committee, Representing the French SPP [Société psychanalytique de Paris],” composed in France in 1949, in which the style of Jacques Lacan is very much in evidence, detailed the criteria for the selection of candidates for apprenticeship in psychoanalysis in France in the wake of the Second World War: “Only through clinical examination may light be shed upon the deficiencies which disqualify the candidate as an aide to memory or judgment: traits pointing to future intel-

lectual frailty, latent psychoses, cognitive difficulties compensated for otherwise; or as a guiding agent: psychical difficulties in the form of crises and mood swings including epilepsy, meaning Cyclothymia.”

The “Rules and Procedures” also advise: “Among other disqualifying elements should be included such problems as might impair the basis of imaginary support the person of the analyst may furnish to transferential identifications in the generic homeomorphism of his body image: shocking deformities, visible mutilations and overt functional impairments . . . Secondly, the examiner should consider the candidate’s cultural education, which is evidenced in the special kind of intellectual open-mindedness that grasps the meanings of words and inspires their usage.”

Freud, relying less on specifics and caricatures in his catalogue of counter-indications, emphasized above all the characteristic element of commitment to the activity, which “cannot well be handled like a pair of glasses that one puts on for reading and takes off when one goes for a walk. As a rule, psycho-analysis possesses a doctor either entirely or not at all” (1933a, p. 153). The arguments that have taken place surrounding whether it is possible to practice psychoanalysis part-time, on the margins of other medical or university activities, are extensive.

While Freud regretted the fact that “It cannot be disputed that analysts in their own personalities have not invariably come up to the standard of psychical normality to which they wish to educate their patients” (1937c, p. 247), he also added: “It almost looks as if analysis were the third of those ‘impossible’ professions in which one can be sure beforehand of achieving unsatisfying results. The other two, which have been known much longer, are education and government” (p. 248).

## **PSYCHOANALYTIC EPISTEMOLOGY**

The notion of psychoanalytic epistemology incorporates the epistemology specific to psychoanalytic knowledge as well as the psychoanalysis of mental processes required in the construction of knowledge.

Epistemology refers to the critical examination and logical analysis of scientific knowledge. Traditionally viewed in France as the philosophy and history of science, epistemology is distinguished from the theory of knowledge, which also includes non-scientific knowledge. This distinction is not found in Anglo-American philosophy and, as a result, epistemology is frequently confused with the theory of knowledge, Freud’s *Erkenntnistheorie*. More recently, the concept of genetic epistemology (Jean Piaget) introduced the

analysis of the mental processes of knowledge within a developmental perspective.

The term “epistemology” is fairly recent. It was introduced in France at the beginning of the twentieth century, at the time when the relationship between philosophy and the sciences was reversed: it was no longer philosophy that lent its stature to science but science that became an object of philosophical study. This change in perspective reflected a crisis that had two sources: first, the foundations of mathematics and physics were being called into question by the scientific community itself; and second, the claims of philosophical systems, in particular Hegelian systems, of being able to account for rationality without the need for practical applications or experiential data were being discredited.

The concept of epistemology does not appear in the index to the *Gesammelte Werke*, and the *Concordance to the Standard Edition of the Complete Works of Sigmund Freud* indicates only three occurrences of the term “epistemological” in the *Standard Edition*, where it appears as a translation of the adjective *erkenntnistheoretisch*. The word appears for the first time in the English translation of the obituary of Viktor Tausk. Freud wrote in 1919: “These writings exhibit plainly the philosophical training which the author was able so happily to combine with the exact methods of science. His strong need to establish things on a philosophical foundation and to achieve epistemological clarity compelled him to formulate, and seek as well to master, the whole profundity and comprehensive meaning of the very difficult problems involved” (1919f, p. 274). But the use of the term “epistemological” in the English and French translations obliterates the distinction between “epistemology” and “theory of knowledge.” Yet Freud’s judgment of Tausk can only be fully appreciated when viewed as re-establishing this distinction. It is not, as the translations state, “epistemological clarity” that Freud reproaches Tausk for, but his overestimation of the logico-deductive operations of philosophy. Tausk went too far in trying to prematurely establish psychoanalysis on the basis of a theoretical system that was philosophical in its need for coherence.

Although the term “epistemology” is rarely found in Freud, a Freudian epistemology is nonetheless present. For Freud the epistemic identity of psychoanalysis remained that of the empirical sciences of his time, which are unrelated to the sciences of mind. He relies on observation and inductive logic to rebuff the

demons of metaphysics and goes so far as to claim for psychoanalysis a “specific right to become the spokesman” for the vision of the scientific world. He defends the ideal of science against anarchist and nihilist doctrines that contested the criteria of truth found in scientific knowledge. Psychoanalysis was said to possess the heuristic means to show that science required a determined attitude that rejected “wish fulfillment” through acceptance of observation and methodically programmed experiment, the only path capable of leading us to a true knowledge of reality. He wrote, “it would be illegitimate and highly inexpedient to allow these demands [wish fulfillments] to be transferred to the sphere of knowledge. For this would be to lay open the paths which lead to psychosis, whether to individual or group psychosis. . . .” (1933a., p. 160).

In Freudian discourse the scientific ideal assumes the function of a regulatory idea and barrier for knowledge in general and psychoanalytic knowledge in particular. Freud’s rationalism and positivism were consequently subverted by his discovery: by taking as its subject the gaps, contradictions, and distortions of our mechanisms of observation, language, and reason, psychoanalysis reveals what the constructions of positivist science owe to repression. In keeping with his discovery Freud recognized the anticipatory role of art and philosophy, acknowledged the historical truth of religion, and affirmed the mythopoetic element in every scientific theory. His literary style, his references to historical, philological, and ethnographic works, his interest in Moses and Shakespeare, his sense of doubt concerning thought transference, all temper the image of a realist and positivist Freud. Freud’s psychoanalytic epistemology presents the paradox, analyzed by Paul-Laurent Assoun, of sabotaging the language of science while claiming it as one’s own.

The path of Freudian discovery traces the passage from a therapeutic technique to an *episteme* through the implementation of a method employed within the context of a specific practice. Psychoanalytic epistemology appeared to be essential as much to define and circumscribe the conditions and legitimacy of his approach as it did to respond to the epistemological criticisms to which it was subject. In both cases it is a matter of relating and analyzing whatever is resistant to his method. The criticisms of Karl Popper, Ludwig Wittgenstein, and Adolf Grünbaum cast doubt on the psychoanalyst to the extent that they reveal the risk

psychoanalysis runs whenever it tends to transform itself into an ideology. Yet such objections have the merit of constraining the psychoanalyst to treat his concepts dialectically and be more attentive to precisely defining their use value within a specific framework. Such criticisms also indirectly reveal the limitations of the phenomenological, doctrinal, and hermeneutic revisionism of men like Ludwig Binswanger, Roland Dalbiez, or even Paul Ricoeur, for trying to save psychoanalysis by means of auxiliary hypotheses. For such thinkers, psychoanalysis could only confirm its results by borrowing from other fields of knowledge (phenomenology or neuroscience, for example) or through the addition of extraneous methods (such as surveys or experimental protocols).

Quite the contrary. It is by repatriating the value and scope of discoveries where they originate—the psychoanalytic situation—that psychoanalysis can verify the consistency of its theorizations. Psychoanalysis does not consist of the analyst's knowledge of the analysand's unconscious or a grid for reading the world, but is based on a transsubjective knowledge created as much as revealed by a particular situation of interactive dialogue whose transference and analysis are operators. Outside that field it loses all epistemological validity.

Such methodological operationalism enables psychoanalysis to participate in the ongoing epistemological debate, which tends to reject the ideal of accuracy for a concern for truth that is conceived as revelation as well as creation.

## **PSYCHOANALYTIC FAMILY THERAPY**

Psychoanalytic family therapy is based on the observation that for any group that calls itself a family in a given culture, there is an objective interdependence between the subjects comprising it, owing to the hierarchy of generations and the distribution of roles within it. There are also areas of subjective interdependence.

Difficulties concerning the treatment of some patients led therapists to become interested in these individuals' families, which were viewed as pathogenic; the family and the mental patient were examined as a whole, and their specific modes of functioning highlighted. In the 1950s, researchers at Stanford, influenced by systems theory (Ludwig von Bertalanffy), described the kinds of communication that occur in the families of schizophrenics. From this arose a vast area of research that came to be applied to "systematic family therapies."

Concurrently, research on groups was conducted in the field of psychosociology (Jacob-Levi Moreno) and from a psychoanalytic perspective (Sigmund H. Foulkes, Wilfred Bion, Henry Ezriel). In France, Jean-Bertrand Pontalis, Didier Anzieu, and René Kaës proposed new concepts such as the group mind, inter-fantasizing, and group transference.

Family groups whose members had a life in common, both past and present, have been the object of a number of specific experiments conducted by psychoanalysts. Freud suggested the concept of "psychic apparatus" to account for the existence of mental factors associated with this apparatus's ability to distribute and transform psychic energy. Borrowing this model, René Kaës forged the concept of "group psychic apparatus," which he defined as "an efficacious and transitional fiction—that of a psychic group,

backed up by a mythical group, which is seeking to become real by the construction of a concrete group.”

In this connection, family therapists conceptualized a family group mental apparatus, one which originated archaically in the individual psychic “deposits” and the psychic contents of the transgenerational heritage. Their fusion created an unconscious psychic basis, common to members of the family group, inducing a specific experience of belonging, with “a feeling of familiarity,” unlike anything else. Individual fantasies were articulated on this psychic basis, from which they derive some of their content. The family psychic apparatus (FPA) is a conflicting co-construction formed from the elements of internal group feeling of each family member, and elements of a common psyche and of the social group. The FPA, as a category, includes the sexual nature of the roles active in family relations.

In therapy, this psychic organization of the family group is realized within the framework proposed by the therapist. The therapist ensures psychic security, allowing the deployment of the therapeutic process through the free verbalization required, the stability of temporal-spatial conditions, the fact that the duration of the cure is not determined *a priori*, and the rule of abstinence. In their observations and interventions therapists focus especially on group aspects as based on the transference/counter-transference. The essential goal of therapeutic work lies on the level of the paradoxical narcissism-antinarcissism duality that is active from the very beginning in each subject and primal component of the familial psychic apparatus. This objective transcends the treatment of the symptomatology of the “designated patient.” The goal is autonomy for the individual psyche and access to the oedipal conflict, through a sufficient development of the couple/group tension that is always conspicuous within the family group. However, René Kaës has expressed doubts about the “accepted name, Analytical Family Therapy,” thinking it should rather be known as “Psychoanalytical Psychotherapy of the Family.”

Family therapy requires preliminary work to allow the family group to accept this unusual situation. Maurice Berger developed a “new theoretico-clinical field,” in which reference to the group and to psychoanalysis was preserved. He drew on Winnicottian concepts, and developed the idea that the framework could not be determined ahead of time by the therapist, but had to be constructed with the family. At the

limit, the very notion of therapy was eschewed (but not the goal of treatment).

The training of family therapists requires a personal psychoanalysis, but how necessary it is to have psychoanalytical experience with members of one’s own family is, as of 2005, still open to debate.

## **PSYCHOANALYTIC FILIATIONS**

In addition to intellectual, theoretical, and professional reasons, more personal ones usually play a part in the decision to take up an interest in psychoanalysis. Inextricably bound up with the former, but usually not as readily acknowledged or clearly understood as an influence on an individual’s choice of intellectual orientation, such psychoanalytic filiations run like a perpetual current through the life and work of the individual con-

cerned, for which reason questions about who analyzed him or her, when, how, why, and with what effect will continue to attract much attention both inside and outside the psychoanalytic community.

If collected and used properly, information about psychoanalytic filiations can help illustrate aspects of individual development, as may also be true when that individual does not subsequently engage with psychoanalysis professionally. However, where professional work follows, the psychoanalytic filiations between analyst and trainee acquire an additional significance, for in addition to involving conscious and unconscious processes at highly charged transference and counter-transference levels, they will themselves be an object of study during and after training, and their outcome, whether in the form of a resolution or not, will have an influence on the current and future work of both analyst and analysand.

Akin to and as powerful as—indeed repeating—characteristics of family life, such filiations have held the psychoanalytic community together as often as, when excessively active, they have threatened to tear it apart. Consequently, knowledge of the extent, nature and resolution of such psychoanalytic filiations is important for an understanding of individual psychoanalysts as well as of the movement as a whole.

Historically, psychoanalytic filiations preceded other forms of preparation for and involvement in psychoanalytic work (study of theory and work under supervision), and their explosive nature, particularly when not attended to psychoanalytically, showed in early dissensions and break-aways, as well as in expressions of excessive loyalty. But though seen by Freud and some early analysts as potentially too powerful, they did not lead to the adoption of a personal analysis as an obligatory part of training, but instead to the foundation in 1910 of international media (the International Psychoanalytical Association [IPA], the *Zeitschrift*, and congresses) to coordinate and assist local groups and coordinate the defense of psychoanalysis against outside critics. In fact, by the time the Secret Committee was formed (1912), only two of its members (Sandor Ferenczi and Ernest Jones) had had themselves been analyzed (and Ferenczi's plan that all should be analyzed by Freud was not realized). An analysis was not made an obligatory part of training until 1922. However, once accepted, it was clearly perceived both as a valuable support for trainees and as a potential threat to their independence, for which reason the

Berlin training model, which the IPA was then (Homburg Congress 1925) accepting as its benchmark, stressed “the same analyst should not conduct the instructional analysis of the candidate and later supervise him in the practical part of his training.”

As subsequent dissensions have shown, neither the Homburg nor any other principles have been able to prevent periodic recurrences of destruction or adulation within the psychoanalytic family. On the contrary, whether or not in the grip of unresolved problems, some training analysts have continued to create pro-selytes, and some trainees continue to use their psychoanalytic genealogy as legitimization of their own position and work, or as a weapon against others. On the other hand, since the institution of a personal analysis as an obligatory part of training, members of various groups have increasingly been able to explore disagreements, tolerate differences, and establish working alliances across divisions, both at local level, through the IPA, and by means such as exchange lectures, transfer of analysts, international conferences, and discussions at many levels about matters at times highly controversial.

However, openness at the level of psychoanalytic filiations remains a problem, not least because of a tendency in some analysts as well as some archivists, editors, and historians to withhold or misrepresent such highly personal information either in part or as a whole, typically with references to propriety or confidentiality. As a result, a crucial area of knowledge has not only been left open to speculation, but has been used by supporters and opponents of psychoanalysis alike to idealize or demonize institutions or individuals, to drive psychoanalytic thinking in the direction of dogma and petrification, and turn the writing of its history into an ideological act.

The problem of how, if at all, to use such information as can be obtained, remains. Clearly, simply refusing to consider it, either because it is incomplete or too difficult, is not an option for psychoanalysts who, by the same token, would indeed brand their profession as an impossible one. On the other hand, any decision on the part of psychoanalytic institutions to bring about change would be controversial, as it would involve the suspension of strict adherence to the principle of confidentiality where analysts and their trainees are concerned.

Obviously, disclosure of details about past and present psychoanalytic filiations, perhaps even by

putting the information into a database for psychoanalytic practitioners and historians to use, would greatly assist understanding and research, and it is encouraging that several present-day scholars seem interested in such a project. Naturally, only when—in each case—the effects of a person's psychoanalytic filiations have been validated, can they be truly useful to serious historians of psychoanalysis. The inevitable consequence—that there will also be richer pickings for the prurient—need deter no one, as experience shows that nothing inhibits speculation more than disclosure of facts, and that in cases where that does not work, nothing short of a thorough personal analysis will.

## **PSYCHOANALYTIC NOSOGRAPHY**

Is there a psychoanalytic nosography in the etymological sense of a rewriting and reorganization of psychopathology on the basis of psychoanalysis? And if so, is that nosography restricted, in its form and boundaries, to the sphere of psychoanalytic thinking and practice; that is, is there a psychoanalytical symptomatology for internal use only that does not coincide exactly with that of psychiatry? In answer to these questions, it is arguable that dynamic psy-

chology sought at first to dismantle several established clinical pictures and to erode the boundaries between the normal and the pathological, but that then, having exhausted the possibilities of this approach, it abandoned the efforts.

Alternatively, can psychoanalytic theory, or more precisely, metapsychology, perhaps be said in a more ambitious way to have revised the whole of psychopathology and placed it in a perspective where, reordered, it attained a new coherence? Indeed, psychoanalysis grew out of a questioning of psychiatry, and in particular, the neurological or mental nature of hysteria. Also, before writing *Studies on Hysteria* (1895d), Freud thoroughly scrutinized the normal clinical treatment of patients at that time.

Freud's study of dreams, his study of the development of sexuality, his model of the mental apparatus, and his positing of the unconscious all implied a broad transcendence of the clinical data from which he set out. Yet his quest for a new understanding of the neuroses nevertheless led him back to familiar categories: conversion, phobia, obsession, and anxiety. Freud found that, in the context of the interaction between affects and ideas, the mechanisms of defense could be most effectively differentiated on the level of symptoms, for this level yielded the greatest degree of explanation.

Yet even on this level, the level of Freud's first topography, the classical syndromes tended to reassume their old forms rather than to break down as their outlines came into clear view. A specific set of conflicts could be confidently aligned with parapraxes, with phobias, or with confused or delusional states. These diverse conditions were explicable by reference to a dynamic that the earlier categories of traumatic neurosis, transference neurosis, and actual neurosis had initially tended to define too narrowly—in terms that for this very reason have fallen out of use. All the same, Freud failed sufficiently to explore the vicissitudes of the interaction between primary and secondary processes (the affective and thought processes) in trying to better understand, on the basis of conflict, the various disturbances of consciousness that challenged the existence of the object. Accordingly, what Freud called “reality-testing” and described as an “institution of the ego” (1916–1917f [1915], p. 233) became an object of study alongside the still relevant material addressed in the clinical treatment of acute mental disorders.

Other questions had already arisen for Freud when he found it necessary to introduce narcissism into his theory (1914c). These questions obliged him to consider the withdrawal of libido from the object and redirection toward the ego, as well as its restitution. This consideration brought in, in different ways, the notions of depression, psychosis, and delusion. Clinical and therapeutic experience with such pathology demonstrated that its organization was too complicated to be adequately explained by its unconscious meanings alone. Here too the idea of narcissistic neurosis was not up to the task of circumscribing nuances and distinctions, and this remained true even after the category of narcissistic neurosis was subsequently limited to depression alone. At this point Freud focused on hypochondria as the main decompensatory tendency: “The relation of hypochondria to paraphrenia is similar to that of the other ‘actual’ neuroses to hysteria and obsessional neurosis” (p. 84).

To go more deeply into what, in 1895 in Draft G of the Fliess Papers (1950c), he had had to say about the essential nature of depression, Freud took classical melancholia as the basis for what he characterized as the withdrawal of the conflict into the ego (1916–1917g). Such narcissistic identification with the lost object already implied a second topography that would overturn earlier mental agencies and offer even the most “endogenous” psychiatry a vast range of possible dynamic explanations.

Furthermore, the heterogeneous borderline states, which have since achieved so much importance in clinical practice, can perhaps be unified only within the psychoanalytical perspective of seeing them as a narcissistic failure in dealing with conflict and avoiding depression by mobilizing a set of defenses against reality: negation, splitting, idealization, and so on.

As for psychosis, beginning with his discussion of the Schreber case (1911c [1910]), Freud suggested that it had roots deeper than merely the various projective modalities of the homosexual drive, deeper than merely the repression of reality (1924b, 1924e). Though loath to challenge the established German-language nosography of the day with regard to what he would have preferred to call “paraphrenia,” Freud felt that the subject’s the return to autoeroticism short of narcissism, the failure of thing presentations, and the opacity of the symbol in instances of “organ-speech” (1915e, p. 198) raised questions about what was at

stake in psychosis, namely the integrity of the ego and the objects that were incompatible with it.

Consideration of the psychic context of breakdowns of mental life, of Freud’s earliest questions concerning the actual neuroses, and of the development of psychosomatic medicine support the idea that, even though psychoanalysis has not invented a new nosography, it has nevertheless cast an incomparably clear light across the whole field of psychopathology and has provided a firm foothold to understand the field.

## “PSYCHO-ANALYTIC NOTES ON AN AUTOBIOGRAPHICAL ACCOUNT OF A CASE OF PARANOIA (DEMENTIA PARANOIDES)”

This paper is one of Freud’s great theoretical-clinical studies. It deals with the autobiography, published in

1903, of Daniel Paul Schreber, a mental patient whom Freud never met personally.

Schreber was the son of a physician who was a great believer in rigid educational methods. The young man studied and later practiced law. After a political setback, however, he fell victim to a depression accompanied by hypochondriacal ideas and spent six months (1884–1885) in a Leipzig psychiatric clinic run by Paul Emil Flechsig. In 1893 he was offered a significant promotion, but six months later he was admitted once again to Flechsig’s clinic, then transferred to an asylum, directed by Doctor Guido Weber, where he would remain for the next eight years after being diagnosed as suffering from “paranoid dementia.”

During this eight-year period, he first went through a phase of intense hallucinatory delusion characterized by an extremely disorganizing anxiety; he then organized his delusions somewhat, eventually achieving a degree of stability that allowed him (at his own request) to argue for his freedom (with great legal talent) and to regain it by a judgment of the Royal Appeal Court of Dresden dated July 14, 1902.

Over the years Schreber had taken occasional notes, and toward the end of his internment he made these the basis of a book, which he succeeded in having published in 1903 under the title *Denkwürdigkeiten eines Nervenkranken* (Memoirs of a neuropath). Many passages were excised at the behest of the publisher—and, one may suspect, at the behest of Schreber’s family to conceal the family’s great sexual crudity. It is essential to read Schreber’s book, translated as *Memoirs of My Nervous Illness* (1955), in order fully to appreciate the commentary Freud offered on it a few years later. It provides a very eloquent description of the sensory hallucinations to which Schreber fell prey, along with his own explanation of them. According to this explanation, these sensations were imposed on him by God, by means of “divine rays” connected directly to his body, and specifically to his nerves. Schreber strove mightily to satisfy God by procuring the “voluptuous sensations” that God demanded, yet at the same time he waged a ferocious, superhuman struggle to free himself from the rays.

Schreber’s God was a strange, capable of this terrifying kind of possession, yet at the same time pitiful, inasmuch as God understood nothing about humans and ardently sought to become acquainted with their sensations. In Schreber, God found a unique being

who gave God an ardently wished-for connection. This God, who had a dual nature (Schreber evoked the dualism of Ahriman and Ormuzd found in Zoroastrianism), had created a replica of himself in Flechsig (who was also divided into two, but who was liable to shatter into many pieces at certain moments), and Flechsig had been God’s agent with regard to Schreber. The incoherence of this account is immediately apparent, yet it is a poignant testimony to a sick man’s desperate struggle to establish a level of meaning that he could accept and that would free him from his incoherent anxiety about disintegration.

Little by little, Schreber’s explanation organized itself into a vast theological cosmogony: The world was coming to an end, and for a whole stretch of time Schreber was the sole survivor, surrounded by shadows, semblances of men, mere apparitions. A new humanity would supposedly be born from Schreber himself, provided that he is transformed into a woman and offered God the voluptuous feelings of women’s pleasures.

Schreber published his book to enlighten psychiatrists. Granted, he was mentally ill (as indicated in the title of his autobiography), but the causes of his illness were quite different from what the psychiatrists attributed it to. Schreber, above all, wanted to convey his message to people at large in order to enlighten humanity about essential truths.

It is instructive to read the clinical reports of Dr. Weber appended to Schreber’s narrative (1955, pp. 267ff.), for they offer a remarkable description of how a calming delusional system can cure anxiety. Also of great interest is the wise judgment passed by the appeals court in Dresden (Schreber, 1955, pp. 329–356), which discharged Schreber in 1902. The court forcefully declared, in effect, that Dr. Schreber was completely mad, but that his worldview was interesting, and that he no longer represented any danger to himself or others. Indeed, after his release Schreber passed several uneventful years before being recommitted and dying in an asylum in 1911, the very year in which Freud published his study of the case.

When he worked on this text, Freud had been engaged for two or three years in a sustained discussion of the psychoses with Carl Jung. From these discussions Freud he expected much of value to emerge, though the first signs of Jung’s coming break with Freud were already beginning to appear. Freud made no attempt here to account for all the psychopatholo-

gical phenomena and processes characterizing Schreber's illness. Rather, as in all of Freud's great clinical writings, his purpose was to prove something. In this case he set out to demonstrate that the motor of the paranoiac's persecution anxiety and delusional worldview is related to issues attending homosexuality, as was strikingly revealed by Schreber's delusions.

The first part of Freud's discussion, "Case History," though it hews close to Schreber's *Memoirs*, nevertheless presents the material that will serve to illustrate the thesis set out in the second part, "Attempts at Interpretation." In Freud's view, Flechsig, as a doctor admired by Schreber, is the privileged object of Schreber's homosexual desire, a desire justified and indeed sanctified by his delusional system. Yet the roots of Schreber's homosexual desire must be sought in his relationship with his father, Daniel Gottlieb ("God's love") Moritz Schreber, a relentless educator who promoted absolute submission to God's will. In this case the father, it would seem, was the bane of his children's lives (an elder brother of Daniel Paul killed himself, while a younger sister was a confirmed mental patient).

In the third and last section of his study, "The Mechanism of Paranoia," Freud analyses the process of projection that constitutes the paranoiac's chief defense and organizes the paranoiac's delusions of persecution: the basic homosexual desire, "I (a man) love him (a man)," is negated into "I do not love him—I hate him," which then, as a result of projection, becomes "He hates (persecutes) me," and from this the paranoiac derives the justification "I do not love him—I hate him—because he persecutes me" (1911c [1910], p. 63). What we have is a system of transformations to defend against homosexuality. Freud presents two more variants of such systems, one being the mechanism at work in erotomania and the other the mechanism mobilized in delusions of jealousy. (A fourth possible mode of defense against homosexual desires embraces the formula "I do not love at all—I do not love anyone.")

This work of Freud's spawned a large number of discussions and commentaries, the most notable of which are cited in the bibliography below.

## PSYCHOANALYTIC QUARTERLY, THE

*The Psychoanalytic Quarterly* was founded in 1934 by four analysts: Bertram Lewin, Gregory Zilboorg, Dorian Feigenbaum, and Frankwood Williams. Their editorial policy, enunciated explicitly in the first issue, was directed at a specific task. Psychoanalysis was becoming quite popular in North America, and while the enthusiasm was welcome, it also gave rise to a certain amount of confusion. The founders of *The Psychoanalytic Quarterly* wanted to establish a forum for the discussion of psychoanalytic ideas that have *clinical* relevance.

*The Psychoanalytic Quarterly* has always addressed the interests and concerns of the analytic practitioner. Theoretical and applied analytic studies are welcome, but only if they generate hypotheses a clinical analyst can bring back to the treatment situation and test against observations made there. An empirical, pragmatic orientation informs the journal's editorial policy.

*The Psychoanalytic Quarterly* also directs itself against the inevitable parochialism of local analytic subcultures by exposing its readers to work done from an array of theoretical perspectives. For example, *The Psychoanalytic Quarterly* was the first journal in the United States to publish an article by Jacques Lacan. Special issues have taken up such topics as “Knowledge and Authority in the Psychoanalytic Relationship” and “The Psychoanalytic Process,” featuring papers by a variety of analysts from widely differing schools of thought.

In addition to original scientific contributions, *The Psychoanalytic Quarterly* includes a comprehensive Book Review Section. It also has an Abstracts Section, in which summaries of selected articles from other journals—virtually the entire non-English language psychoanalytic literature, as well as the neural sciences, philosophy, sociology, infant observation, political science, and so on,—are presented.

*The Psychoanalytic Quarterly* is a free-standing, self-published journal. It contains no advertising, and is supported by subscription fees. It is not accountable to any psychoanalytic organization. Therefore, *The Psychoanalytic Quarterly* has been able to maintain a tradition of complete editorial independence alongside intellectual rigor and fine scholarship.

## PSYCHOANALYTIC RESEARCH

Research, whether to create scientific advances or investigate historical and epistemological issues, is generally supported by the state and is often carried out by specialized institutions or in laboratories. In psychoanalysis, research with a view to theoretical and clinical advances has sometimes been conducted in such settings, but it has also been conducted by individuals and psychoanalytic associations. Freud’s hope, that analysis would find a place in the university in ways that would ensure its status as a separate discipline, has been partially fulfilled: from the 1960s, dissertations in the field of psychoanalysis

have begun to appear in countries around the world.

Psychoanalytic research implies scientific standing, and a persistent issue has been whether analysis is a science. If science is limited to experiment and the use of mathematical tools, the answer is no. This has been the view of such prominent philosophers as Karl Popper and Alfred Grünbaum, for whom psychoanalysis presents a body of claims that cannot be falsified or refuted. But the scientific nature of psychoanalysis has also been questioned by those who prefer to see it as an art, not so much to be taught as transmitted. It thus escapes the objective criteria on which the sciences, whether physical or social, are based.

For Freud, psychoanalysis has a place among the sciences and shares its worldview: it is above all a method of investigating unconscious processes and could be adapted for use in fields unrelated to therapy. In this sense, psychoanalytic theory comprises a set of hypotheses and concepts subject to constant revision. Therapy is one possible application of psychoanalytic method and is also to a great extent its source, because therapy provides the link between theory and clinical practice, the space in which the principal hypotheses are developed and tested.

Freud distanced psychoanalysis from religion and philosophy, from unverifiable constructions in general, and from medical pragmatism. In 1911 he signed a manifesto, together with Albert Einstein, David Hilbert, Ernst Mach, and about thirty others, that appealed for the creation of a society to disseminate positivist philosophy in order “to outline a vast vision of the world on the basis of positive facts that each science has accumulated” (quoted in Hoffmann, 1995).

Psychoanalysts have developed a relatively independent network by which they exchange ideas and information at professional seminars and colloquia. While university research provides new and original perspectives and is designed to address questions by reexamining them within the context of history and the critical perspective of previously published work, independent researchers often come up with their own clinical findings of the type they believe the clinical setting can provide. Some of these researchers may formulate more general hypotheses, which they then test in various clinical situations.

The actual content of psychoanalysis also affects how research is conducted. In terms of theory, psycho-

analysts have produced a body of notions and concepts—two terms that should not be confused. In psychoanalysis, fundamental concepts (*Grundbegriffe*), or even keystones (*Grundpfeiler*), are not a priori categories but result from investigations into mental processes. These create the scaffolding that Freud called “metapsychology,” the theoretical superstructure that includes such useful fictions as the psychical apparatus. For Freud, metapsychology was necessary for advancing new ideas but could always be modified or revised.

The “fiction” of a “psychic apparatus,” noted in *The Interpretation of Dreams* (1900a), was followed by the first theory of the instincts with its dualities of the self-preservation and sexual instincts and of the pleasure/unpleasure principle. Freud introduced narcissism in 1914, which led to a revision of the theory of the ego and ego ideal, and in 1920, in *Beyond the Pleasure Principle*, he introduced the dualism of the life and death instincts. Although these theoretical developments, advanced through clinical practice, did not require a reconstruction of the metapsychology, revision did arise from certain particularly innovative notions in psychopathology.

Ongoing clinical work, with its infinite diversity of patients and variety of psychological facts, vastly added to the number of notions in psychoanalytic theory. Not all notions fared equally well. Some met a clinical need, while others fell into such disuse as to interest only historians of psychoanalysis, who sometimes resuscitate lost notions or bring forth new ones that originated in forgotten antecedents.

Psychoanalytic theory and investigation have produced an abundant literature, often a surfeit that makes it impossible to read everything written in any particular area. For this reason, the division of research between academicians and individual practitioners would appear to be complementary and desirable.

## **PSYCHOANALYTIC REVIEW, THE**

The contemporary *Psychoanalytic Review* can trace its lineage to two disparate yet converging journals in the history of American psychoanalysis.

The original *Psychoanalytic Review* was founded in 1913, making it the first English-language journal dedicated to psychoanalysis, and as the oldest continuously published psychoanalytic journal in the world. Smith Ely Jelliffe (1866–1945), one of the journal's founders, was a neurologist who became interested in psychoanalysis through the influence of Abraham Arden Brill. He was also influenced by the writings of Adler and Jung, and advocated for the journal a general psychodynamic perspective on behavior, free of sectarian bias. The other founder, William Alanson White (1870–1937) was superintendent of the Government Hospital for the Insane in Washington, D.C., and one of the pioneers in psychoanalytic psychiatry.

*Psychoanalysis*, the other parent of the present journal, was founded in 1952 by the National Psychological Association for Psychoanalysis (NPAP), the first publication of its time situated and representing a non-medical training institute. Theodor Reik was Editor-in-Chief, and the editors were John Gustin and, later, Clement Staff. In 1958, *Psychoanalysis* absorbed *The Psychoanalytic Review* and for the next five years appeared as *Psychoanalysis and The Psychoanalytic Review*, under the direction of Marie Coleman Nelson as managing editor and Murray Sherman as assistant editor and later as co-editor and editor.

The name *Psychoanalysis* was dropped for the first issue of 1963 and henceforth the journal has been known as *The Psychoanalytic Review*, having been edited by Marie Nelson, Murray Sherman, Leila Lerner, and Martin Schulman.

*The Review* has occupied a unique niche in the history of the psychoanalytic movement, both in the United States and in the international arena. It has always represented a non-sectarian, open venue for all psychoanalytic perspectives. This openness, and refusal to see psychoanalysis as a finite body of truism analogous to a religion led Ernest Jones, in 1924, to call it a "refuge of all malcontents." Schulman sees it, rather, as a forum for those, not malcontent, but discontent with orthodoxy, sectarianism, dogma, and exclusionism. While scholarship and literary style are the prerequisites for the acceptance of articles, the journal is a setting for all legitimate perspectives within the psychoanalytic movement.

It has published representational articles by classical Freudians, Ego psychologists, object-relations theorists, Kleinians, self-psychologists, Lacanians, and even contemporary Jungian theorists.

It has continued to be committed not only to clinical psychoanalysis, but to a psychoanalytic exploration of general culture, seeing psychoanalysis as informed by other disciplines, rather than reducing all discourses to a superordinate psychoanalytic frame. It is representative of the general philosophy of critical inquiry, and psychoanalytic scientific humanism, the historical foundational core of psychoanalysis.

MARTIN A. SCHULMAN

## PSYCHOANALYTIC SEMIOLOGY

Semiology, the science of signs, gains its meaning from being communicable within a given field of science. The same holds true for somatic medicine, following what Michel Foucault described in 1963 as the "fundamental isomorphism of the structure of disease and the verbal form that describes it." The sign indicates the symptom, just as a wheeze indicates pneumonia. Woven into the mesh of concrete banality and everyday life, psychiatric symptomology lends itself less easily to a system of directly meaningful and unchanging references. From this viewpoint psychoanalysis appears to escape any form of semiology that might be useful in treatment. But metapsychology, which theorizes experience and justifies procedure, does supply a form of semiology that is both specific to it and appropriate in certain situations.

The only semiology useful to the clinical situation is specifically context dependent, belonging solely to a particular analyst/analysand relation. The observer, the analyst, is involved in a unique relation involving the dynamic of transference and counter-transference. Therefore the reality involved in analysis, even when it concerns external facts, can only serve as a reference frame for a fantasy that supports the narrative at a particular moment, for reasons that are specific to it alone. At most the reality of analysis, its framework and the patient's attitude can, from one case to another, present some invariant elements. At all other times the sign will depend only on the context; to this extent, the symbol can express the contrary to what it might indicate elsewhere. We know that defenses can take the form of a movement of the drive and that interpretation provides no truth, but reveals a pathway of associations and reroutes energy between two signposts without any absolute value. And finally, nothing can at the same time be experienced and understood other than in small doses (Strachey, 1934).

Nonetheless, metapsychology can shape a semiology that can be applied in three areas. During the evaluation, it can help to understand psychic structure and function, and thus indicate modes of therapy. The ability to associate, observed during the interview, or their various avatars, the defensive methods of repression, denial, projection, and so on, the expression of affects, and regressive forms, are all elements that can constitute a system of signs for evaluating the manifestations of the unconscious and their dynamic in the organization and operation of psychic agencies. Similarly, one

can read the inconsistencies and weak points in a conflict, where the risks of depressive or delusional decompensation are present. A semiotic method is perhaps even more useful in cases where a breakdown is manifested through psychosomatic symptoms. These same semiological data could be used by psychotherapy, in which the patient apprehends external reality. Such data can clarify fears of the phobic patient with regard to oedipal positions. The splittings and idealizations of the borderline patient can split, or idealize, for reasons of archaic violence and narcissistic fragility.

Finally, psychiatry as a whole can be entirely revised in light of psychoanalytic semiology, which intersects psychiatric semiology, introducing the dynamic of metapsychology into clinical situations, where the unconscious reveals its presence in the most biological manifestations and the most external events.

## **PSYCHOANALYTIC STUDY OF THE CHILD, THE**

In 1945 there appeared a new journal, four hundred pages long, titled *The Psychoanalytic Study of the Child*. Due to its editors (Anna Freud, Heinz Hartmann,

Ernst Kris) and its contributors (such as Edward Glover, Ernst Kris, René Spitz, Phyllis Greenacre, and Rudolph Loewenstein), the journal immediately enjoyed huge success and prestige. Ever since, the journal has appeared regularly every year, always in the same format and always just as thick. More than fifty volumes stretch along the bookshelves of psychoanalytic institutions throughout the world.

Right from the start, its intellectual and political mission was clear. Heinz Hartmann had just immigrated to New York. In London, the disciples of Anna Freud and Melanie Klein were emerging from several years of intense and sometimes violent quarrels. While one could hardly say that Anna Freud's star was fading, that of Melanie Klein was shining ever brighter. But this was in Britain. On the other side of the Atlantic, the situation was different. The United States still appeared as a vast and as yet wide-open field, professionally shapeless and ill-defined. In particular, it still needed an infusion of Klein's new teaching. Hence the value not just of creating an English-language journal, but also of publishing it in New York.

The 1945 volume contained declarations on the part of Hartmann, Anna Freud, and Edward Glover, among others. They stated their thinking in the most trenchant terms: the psychoanalysis of children was a success, and its principles should be based on the later metapsychology of Sigmund Freud or, more precisely, on Freudian metapsychology as interpreted by Hartmann and Anna Freud.

The threat from Klein was staved off by a cunning ploy. In volume 1, Klein was the subject of detailed discussion, and her "deviations" were denounced. After this discussion, there was near silence. In the following years, her name was rarely mentioned. Even in 1952, when she made a brief reappearance in the journal, it was as the author of a mere three-page heavily criticized commentary (7, pp. 51–53) of a paper given by Hartmann at the 1951 congress of the International Psychoanalytical Association. As for Jacques Lacan, his existence was never even recognized during his lifetime (the first article on Lacan, critical but nonetheless well intentioned, appeared in 1993 [48, pp. 115–142]). Despite the international tone of the first volume (which included articles by Marie Bonaparte and Raymond de Saussure), during the following years *The Psychoanalytic Study of the Child* militantly limited its horizons to the Anglo-Saxon world.

Such doctrinal parameters might have paralyzed original thought, but this was far from the case. On the contrary, the 1950s saw an upsurge of creativity. Anna Freud and Hartmann, in articles exceptional in their quality, consolidated and refined their shared perspective. During the same period, a new line of thinking started to emerge. In 1952 Margaret Mahler published “On Child Psychosis and Schizophrenia: Autistic and Symbiotic Infantile Psychoses” (7, pp. 286–305), which drew a huge response. Then in 1954 came Edith Jacobson’s “The Self and the Object World” (9, pp. 75–127). Structural psychology, as the theoretical framework of Anna Freud and Hartmann came to be known, then had to reach a compromise with the new object-relations theory. Ironically, one of the strengths of object-relations theory lay in the sophisticated way in which Klein’s key concepts had been reworked—for instance, the role of so-called primitive defenses during the pre-oedipal period.

At the end of the 1960s and during the 1970s, the wave of object-relations theory continued to develop: case studies were more and more frequently labeled “separation-individuation,” “fusion anxiety,” “object permanence,” and the like. During the 1980s, object-relations theory became more important than structural psychology. Nonetheless, both viewpoints managed to coexist in the review and have continued to do so. Even after her death in 1984, Anna Freud remained a powerful presence. A good example of her unflinching authority is an excellent article by Clifford Yorke, “Anna Freud’s Contributions to Knowledge of Child Development,” published in 1996 (51, pp. 7–24). In this paper Yorke endeavored to produce the most detailed investigation of all the journal articles written from the perspective of Anna Freud.

One significant result of the increasing space given to “representations of the self and the object” was the rise in importance of the Anglo-Saxon version of parent-infant psychotherapy. Selma Freiberg was the main innovator here, and the journal has continued to support this current (Liebermann and Pawl, 39, pp. 527–548; Seligman, 49, pp. 481–500).

Another subsidiary development emerged with the publication, in 1978, of “Trauma and Affects,” by Henry Krystal (33, pp. 81–116). Krystal argued for a more rigorous definition of the concept of trauma and recommended that greater attention be paid to the consequences of this notion for the psychoanalysis of

the child. In 1979 and 1984 there appeared two widely-read articles by Lenore Terr: “Children of Chowchilla: A Study of Psychic Trauma” (34, pp. 547–623) and “Time and Trauma” (39, pp. 633–665). *The Psychoanalytic Study of the Child* was one of the main journals to grant an important place to the subject of trauma, which later became a major focus of interest in the world of child therapy.

As might have been expected, what remained problematic for the journal was its relation to research on child development. In the first years, a simple solution seemed to suffice. In the first volume (1945), the hope was forcefully expressed that research might become more central. In practice, this intention amounted to almost nothing. For a long while, the sole empirical studies recognized by the journal were those practiced by its own editors and a few key contributors: Anna Freud’s diagnostic observations at the Hampstead Clinic, Margaret Mahler’s investigations on day nurseries, René Spitz’s studies on hospitalization, Ernst Kris’s observations at Yale University. In 1959, John Bowlby read a paper before a large audience during a meeting of psychoanalysts in New York. His presentation, “Grief and Mourning in Infancy and Early Childhood,” published in the 1960 volume (15, pp. 9–52) was vehemently attacked by Anna Freud (15, pp. 54–61).

At the end of the 1970s, this state of affairs changed radically. “Outstanding Developmental Progress,” a longitudinal study by Bertrand Cramer (who was working in New York at the time) appeared in 1975 (30, pp. 15–48). “Four Early Stages in Development of Mother-Infant Interaction,” an important article by T. Berry Brazelton and Heidelise Als on video studies of mothers and infants, was published in 1979 (34, pp. 349–369). Even more revealing, the main specialists in early infancy in the 1990s, such as T. Berry Brazelton, Daniel Stern, and Edward Tronick, began to be cited frequently by various authors in the journal in the 1970s. This tendency, which continued during the 1980s and 1990s, represents a praiseworthy movement toward more openness. Yet the most surprising thing is that investigators seemed to imagine they could assimilate the new discoveries to the existing metapsychology without raising some rather complex questions. One would expect more objections, such as those of Fred Pine, who, in a fine 1992 article, “The Separation-Individuation Concept in Light of Infant Research” (47, pp. 103–116), brought out the existing disagreements between Mahler and Stern.

Despite the reservations one may have on its omissions, *The Psychoanalytic Study of the Child* has maintained a high level of professionalism. Few journals in the history of psychotherapy have managed as well as this one to retain their influence while remaining lively, dynamic, and provocative in theoretical matters.

## **PSYCHOANALYTIC THEORY OF NEUROSIS, THE**

Otto Fenichel's *The Psychoanalytic Theory of Neurosis* is widely considered the standard reference work on this subject. It also offers a systematic summary of the literature of psychoanalysis up to the Second World War. With its seven hundred pages and its 1,600-entry bibliography, the work has contributed significantly to its author's reputation as a first-rank theorist and "encyclopedist" of psychoanalysis.

In a brief Preface, Fenichel describes how the book was conceived. After many years of activity in a training capacity and as a lecturer in various psychoanalytical institutes in Europe and America, and of vigorous participation in internal debates on theoretical deviations and on the internal practices of psychoanalysis, he had decided not to work on a second edition of his earlier *Outline of Clinical Psychoanalysis*, first published in two volumes by the Internationaler Psychoanalytischer Verlag in Vienna in 1931, and in English translation in 1934, but rather to produce a completely new work.

Fenichel began writing *The Psychoanalytic Theory of Neurosis* in Prague, and Freud proposed the work to the Verlag. In May 1943, the author made a formal statement about his project at the Meeting of the American Psychoanalytic Association in Detroit. In view of all the misunderstandings, obscurities, and deviations then besetting psychoanalysis, and in view of the continual temptation to revive resistances within the movement, it was much to be desired, he felt, that the essential part of Freud's dynamic psychology be set forth in the clearest way. He hoped to

contribute to this task by writing a "Psychoanalytic Theory of the Neuroses."

In his introductory chapters, Fenichel sets forth his scientific position, stresses his views on changes noted in psychoanalytical theory, and defines his goal, namely to understand and institute Freudian psychoanalysis as a psychology, as a natural science. In this way he hoped to keep at arm's length psychoanalysts who confined themselves to a partial view of psychoanalytic theory, reducing it in a psychologizing or biologizing way, and hence overvaluing or neglecting one or another of its aspects. Part One of Fenichel's book is devoted to an account of general mental development from the psychoanalytical point of view; Part Two describes the various defining characteristics and forms of the neuroses.

Fenichel was very conscious of the cultural import of psychoanalysis, and conceived it as his "vital duty" to work for "the conservation, extension, and correct application" of Freud's discoveries. Against this background, Fenichel's book was designed to preserve the clinical basis of psychoanalysis, its libido theory, the foundations of its theory of the instincts, and its account of the perpetual conflict and interaction between the frustrations of the outside world and the demands of the instincts.

## **PSYCHOANALYTIC TREATMENT**

The psychoanalytic treatment is a method for treating psychic suffering that advances self-knowledge. It is characterized by the interpretation of the free associa-

tions of a patient, who in becoming aware of feelings and forgotten memories, can thus resolve or express differently the unconscious conflicts behind his/her neurotic symptoms. The way sessions are structured—couch and armchair—and their frequency and regularity facilitate this process through the transference onto the psychoanalyst of affects and childhood fantasies.

From 1886, when he set himself up in private practice to 1909, the year of the “Rat Man” analysis, Freud gradually developed the system of psychoanalytic treatment. In fact the method emerged from the hypnotic treatments that he used after his recognition of the failure of medicinal and physical therapies in vogue at the time. Sessions in which the patient relaxed on a couch in an atmosphere of calm and comparative sensory deprivation resulted from the conditions imposed by somnolent suggestion and later by the “cathartic method” developed by Joseph Breuer to treat his patient, Anna O. Patients themselves contributed towards the maturation of the structure of the treatment, beginning with Emmy von N’s command at their first encounter on May 1, 1889, to “Keep still! Don’t say anything! Don’t touch me!” and her angry demand that he stop interrupting and let her speak freely.

The abandonment of hypnosis in favor of an interrogatory technique, and the application of pressure to the forehead to release ideas, repressed through resistance, introduced a decisive turn in method, even though Freud appears to have taken a particularly active role, insisting patients surrender the pathogenic secrets buried in their unconscious, as the chapter entitled “The Psychotherapy of Hysteria” in *Studies on Hysteria* demonstrates (1895d).

*The Interpretation of Dreams* (1900a) introduced the innovation “free association,” which would become the “fundamental rule” of all psychoanalytic treatment. At the same time the therapist was required submit to the principle of “evenly suspended attention” which entails the scrutiny of even the most apparently insignificant detail (Freud, 1904a).

Freud could thus describe his “psychotherapeutic method” in 1904 as follows: “Without exerting any other kind of influence, he invites them to lie down in a comfortable attitude on a sofa, while he himself sits on a chair behind them outside their field of vision. He does not even ask them to close their eyes, and

avoids touching them in any way, as well as any other procedure which might be reminiscent of hypnosis. The session thus proceeds like a conversation between two people equally awake, but one of whom is spared every muscular exertion and every distracting sensory impression which might divert his attention from his own mental activity” (1904a, p. 250). Through the transference, whose importance Freud had discovered with his patient Dora, resistance became common, both as an obstacle to treatment and as its major driving force.

There remained one last significant innovation in technique, which Freud reported to his disciples at a meeting of the Vienna Society on November 6, 1907, via an account of the early stages of his treatment of the “Rat Man.” Otto Rank noted in *The Minutes of the Vienna Psychoanalytic Society* that “analytic technique has been modified to the extent that the psychoanalyst no longer actively seeks to obtain material that interests him, but rather allows the patient to follow the unprompted and natural course of their thoughts.”

Hereafter the framework was determined and has remained to the present day. The features that Freud was to recall in “On Beginning the Treatment” (1913c) include the analyst’s position outside the reclining patient’s line of vision, regular sessions of a prescribed duration, and terms for the payment of fees. These conditions create the setting for a “psychoanalytic situation” in which, for Jacques Lacan (1953) and his followers, the principal, indeed the exclusive role, would be one given to speech; but a speech and an aural attention going beyond words to include silences, expressions of affect, and even minuscule movements. Freud had observed this when treating Dora: “If his lips are silent, he chatters with his fingertips; betrayal oozes out of him at every pore. And thus the task of making conscious the most hidden recesses of the mind is one which it is quite possible to accomplish” (1905e, p. 78).

Even when supplemented by professional motives (as in training analysis), it is psychical suffering that compels individuals to consult a psychoanalyst. After one or more preliminary interviews, which Freud advised should not be repeated and in relation to which he preferred “a trial treatment of one to two weeks” (1913c), the direction of the treatment is set out; the two protagonists then decide whether to embark on this venture whose initial temporal duration is indeterminate but whose eventual length is

assured. “To speak more plainly,” added Freud, “a psycho-analysis is always a matter of long periods of time [...] of longer periods than the patient expects. It is therefore our duty to tell the patient this before he finally decides upon the treatment” (p. 129).

Since Freud some features of this initial framework have changed; thus the six hour-long sessions per week were reduced to five, then to four, and eventually to three and the length of sessions has been cut from one hour to forty-five minutes. Following his lead, disciples of Lacan have instituted short sessions, and even sessions whose variable length is based on the analyst’s attention to the scansion effect in his patient’s discourse, a practice that has been keenly disputed. Some analysts believe that two sessions per week is possible, others, that the couch advocated by Freud is in no way an absolute requirement.

The notion of a “standard treatment” (Bouvet, 1954), which was similar to descriptions of the medical standard that characterized the manuals of the 1950s, was counterbalanced by what were described as its “variants” (Lacan, 1955); it has now been replaced by the “classic” or indeed the “orthodox” treatment for those who see themselves as liberated from its formal constraints.

It is essential that a “psychoanalytic process” be established and that it is encouraged to advance through the development of the transference neurosis, whose infantile origins are revealed in analysis, but that it is also always jeopardized by the initiation of a “negative therapeutic reaction” which would counter the original love-based “therapeutic alliance.” The analyst’s “abstinence” in the face of the patient’s demands for affective gratification is a requirement for this development, as is his capacity to manage conflicts that may engender “secondary gains” from the illness and, once the initial honeymoon period is over, a transference and countertransference relationship that is as intense as it is unusual. According to Freud: “the therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id” (1937c). Analytic interventions address this aim, but more importantly so too do interpretation, construction, and reconstruction (1937d) as well as the analysis of resistances and the dispelling of amnesia that masks infantile sexuality. Active periods alternating with inactive phases, which for Freud were occasionally indicative of a patient’s “working through” (*Durcharbeitung*) of the material analyzed, mark the stages of what has been

described as “autohistorization” (P. Aulagnier) and highlights the journey towards autonomy which will determine the treatment’s cessation.

The termination of analysis has occasioned a number of studies since Freud’s own (1937c) and is dependent on the aims that the psychoanalyst and the analysand have given themselves. Curing the symptom has never been the most important function of the treatment and so Jacques Lacan could speak of the “cure as surplus.” However, patients do have every right to expect relief from the psychic suffering that led them to analysis in the first place, alongside the capacity to better manage the pathological responses that the vagaries of life engender through the repetition compulsion.

The extension of psychoanalytic treatment to more severe pathologies, to borderline conditions and psychotic disorders, has altered both the notion of its outcome and the means by which it is reached. Freud’s formulation “Where id was, there shall ego [or ‘I’] be (*Wo Es war soll Ich werden*)” and its possible translations has produced a range of possible interpretations according to whether the Freudian *Ich* is translated as “ego,” as in ego psychology for example, or as “I,” as in the “subject.”

However, the termination of treatment does not mark the end of the analytic process; its ongoing working-through continues in self-analysis and in the return to the couch, of either the same psychoanalyst or of another, or to an analyst of the other sex or to one from a different school.

## PSYCHO-ANALYTICAL TREATMENT OF CHILDREN, THE

This book brings together three works written during the years 1926–1945. It thus offers a longitudinal and dynamic view of Anna Freud's basic theoretical positions regarding the technique of child analysis and, in Anna Freud's own words, “attempts to summarize some of the advances in the understanding and evaluation of the infantile neurosis which the author has made in the [last] nineteen years of work on the subject” (p. ix). Inevitably, this volume reflects the controversies and conflicts that opposed the author's

approach to that of Melanie Klein, who is in fact cited repeatedly throughout.

The first part of *The Psycho-Analytical Treatment of Children* is comprised of four lectures given at the Vienna Institute of Psycho-Analysis in 1926 under the general title “Introduction to the Technique of the Psycho-Analysis of Children.” Here Anna Freud exposes her views of that time on the preparatory phase of child analysis (Lecture 1), on technique (Lecture 2), on the role of transference (Lecture 3), and on the relationship between the analysis of children and their upbringing (Lecture 4). The second part of the book, “The Theory of Children's Analysis,” a paper read to the Tenth Psycho-Analytical Congress at Innsbruck in 1927, takes up the same theme, while the third part, the latest, is mainly concerned with indications for the psychoanalytic treatment of children.

Three main themes can be identified in this work. The first concerns the techniques used in child analysis, where, in contrast with adult analysis, free association does not play a central role; nor does dream interpretation, which in the case of children is therefore not the “royal road” to the unconscious. Play and drawing are considered to be indispensable tools, though she conceives of them far more as techniques for “observing” the child than as sources of directly interpretable material. Indeed the analyst is described by Anna Freud as an “observer,” very close to the child, who relies on the words of the parents and their wish for the child to be treated. The child is not considered capable of being conscious of its illness, nor, therefore, of asking for help, whence the need for the analyst actively and deliberately to induce the young patient to accept “a tie between us which must be strong enough to sustain the later analysis” (p. 11).

The issue of the child's participation in the analysis raises the problem—a central one in the dispute between Anna Freud and Melanie Klein—of the child's ability to establish a transference during analytic treatment, and this question is the second essential theme of this book. Despite some evolution in her thinking, and even if she acknowledged the possibility of some manifestations of transference with children, Anna Freud always maintained that it was impossible for a childhood neurosis to be supplanted by a transference neurosis, that is, by a new neurotic formation in which the analyst replaces the “original objects” in the child's emotional life, namely the parents (p. 34). Inasmuch as the child continues to experience its parents as love-

objects in reality, the analyst can play a role only as an addition to, and not as a replacement for, those relations.

The third and last main theme here, dealt with mainly in the last part of Anna Freud's book, in her discussion of the indications for child analysis, concerns the distinction between normal and pathological development, between transient symptoms and real obstacles to development, between the equilibrium of defense mechanisms and the overwhelming of those mechanisms, and, finally, the relations between infantile neurosis and the formation of the ego. These are matters also discussed elsewhere by Anna Freud, as for example in *The Ego and the Mechanisms of Defence* (1936) or *Normality and Pathology in Childhood* (1965), along with, notably, the idea of "lines of development." Anna Freud thus contributed to the attenuation of an over-mechanical view of the Freudian "stages" of emotional development, laying the stress instead on a more dynamic and less linear vision of the child's mental functioning. She also emphasized the part played by reality in the psychoanalytic treatment of children, notably the importance of an alliance with the parents and of their evolving attitudes and support during the course of their child's treatment—ideas that have lost none of their present-day relevance.

## PSYCHOANALYTISCHE BEWEGUNG, DIE

In 1929 Adolf J. Storfer founded the review *Die Psychoanalytische Bewegung* (The psychoanalytic movement) as one of the publications of the Internationaler Psychoanalytischer Verlag. As its title suggests, this bimonthly periodical was intended to open the frontiers of the institutionally contained psychoanalytic world to a broader non-specialist public. As a link between the science of psychoanalysis and a public with an interest in the literature, this periodical saw itself as a forum for somewhat unorthodox propositions and ideas.

This orientation was already clear in Thomas Mann's contribution to the first issue, "Die Stellung Freuds in der modernen Geistesgeschichte" (The place of Freud in the history of modern thought). Mann described Freud as a writer and scientist with a worldwide reputation whose scope and range far exceeded the universe of specialist psychologists and who was well on the way to revolutionizing all sciences of the mind. In addition to contributions from applied psychoanalysis, the review also brought together reviews of contemporary literature in the domain, as well as short literary or scientific works dating from an earlier period and considered to be precursors of psychoanalysis. In this category of genealogical precursors it published extracts from poets, such as Boccaccio, or thinkers and philosophers like Plato, Kierkegaard, Montesquieu, and Montaigne. It also presented critical points of view from contemporary writers like André Maurois, Italo Svevo, Arnold Zweig, and Stefan Zweig. The section entitled "Das Echo der Psychoanalyse" provided information on events in the world of psychoanalysis and reviewed recent political and scientific critiques of psychoanalysis in various sectors.

After Storfer resigned from the Internationaler Psychoanalytischer Verlag, Eduard Hitschmann took over the publication in August 1932. The number of subscribers to the periodical dropped after the National Socialist party came to power in Germany,

when many German analysts and intellectuals close to analytic circles fled the country. The economic and political situation caused the publication of *Die Psychoanalytische Bewegung* to be suspended in December 1933.

## PSYCHOBIOGRAPHY

The term *psychobiography* in its broadest sense designates any approach to biography that emphasizes inner life and psychological development, but in the more specific sense, it means the use of a formalized psychological theory and concepts in writing biography, and it received its decisive impetus from psychoanalysis. Psychobiography in the broad sense goes back at least to Plutarch, but Freud's book on Leonardo's childhood (1910) is often seen as one of the first to apply a formalized metapsychology.

Although many biographies in the past had dealt with psychological development, the arrival of psychoanalysis in the twentieth century has offered a comprehensive psychological theory of early human development that explains the shaping of the life course. Psychobiography generally focuses on the formative early years of life in an effort to uncover the relational dynamics, traumas, or complexes that might explain later behavior.

Psychobiography is a major instrument of psychohistory for the study of leading historical figures. But the two are not identical since psychohistory is especially concerned with group behavior.

The focus of psychoanalysis on the first few years of life has led to the sharpest criticisms of psychoanalytic psychobiography. The most often heard objections center around the charge of reductionism. First, psychobiography is criticized for its focus on psychological factors to the exclusion of cultural, social, economic, and other external factors. Psychoanalytic psychobiography in particular is often accused of reducing the subject's life to determination by complexes established in the first few years of childhood, e.g., fixation on the oral or anal stage or to a failure to successfully pass the oedipal period. Critics also point out that reliable evidence on early childhood is often almost impossible to obtain. As a result of the absence of data,

many psychoanalytic biographers have used theory to project an image of what the subject's infancy must have been like. This practice has brought especial discredit on the psychoanalytic approach since it is accused of inventing facts. A fourth objection holds that psychoanalytic biography lacks the central tool of psychoanalysis in the clinical setting—free association. Finally, there is the moral objection that psychoanalytic approaches have often denigrated the memory of great men and women by portraying them in terms of pathology or unresolved infantile conflicts.

Obviously, the more sensible and cautious psychobiographers have avoided reductionistic claims. The best psychobiographies also avoid over-confident assertions about the existence of childhood events based only on the evidence of adult behavior. The absence of a living subject's "free association," however, is viewed as less of a handicap than critics assert because the psychoanalytic biographer can often draw upon an abundance of diaries, letters, and other writings as well as sound recordings, photographs, and films for more recent subjects. Finally, to the objection that psychobiography maligns the reputation of exemplary figures, one may reply that the same objection can be made to any critical biography which explores the determination of character.

Many of the standard objections to psychoanalytic biography are also mitigated by the application of those psychoanalytic theories which place greater emphasis on ego development. In some versions of ego psychology the personality is said to continue to develop across the life span with the possibility that later experiences can modify processes rooted in early childhood. According to such perspectives there are important psychological stages and tasks to be accomplished beyond the oedipal period, as illustrated in Erik Erikson's *Gandhi's Truth*, which deals with a crisis in Gandhi's mature years. In the early twenty-first century, psychoanalytic theories provide a variety of perspectives that can illuminate all stages of the life span, accounting for psychological health and triumph as well as the persistence of destructive traits fixed in infancy.

## **“PSYCHOGENESIS OF A CASE OF HOMOSEXUALITY IN A WOMAN, THE”**

The treatment that Sigmund Freud relates in the article “The Psychogenesis of a Case of Homosexuality in a Woman” was a short one, lasting four months. He had broken it off one year or so earlier, upon recognizing the force of his patient’s negative transference towards him.

Then aged nineteen years old, the young girl did not consider herself to be in any way ill and had only agreed to begin an analysis at her father’s insistence. Her father was worried not only about his daughter’s overt homosexuality but in particular about a recent suicide attempt; after he had encountered her in the street in the company of the woman with whom she was in love, she had thrown herself over a parapet wall on to a suburban railway line.

The second child and sole daughter of a family of four children from the Jewish bourgeoisie in Vienna, “assimilated” by baptism, the young girl had fallen passionately

in love with a “*cocotte*” who was ten years older than she. In desperation, the family had decided to appeal to Freud, despite what he describes as the low esteem in which psychoanalysis was then generally held in Vienna.

This is the only case of female homosexuality that Freud reports and the analysis was conducted during a period when his daughter Anna, then aged twenty-four years old, was also in analysis with him. This text could be considered as the starting-point for a development in Freud’s study of femininity, as he later elaborated it in “Some Psychical Consequences of the Anatomical Distinction between the Sexes” (1925j), “Female Sexuality” (1931b), and “New Introductory Lectures on Psycho-Analysis” (1933a).

“The Psychogenesis of a Case of Homosexuality in a Woman” is noteworthy in that it simultaneously concerns:

- Clinical questions: homosexuality in women but also in men; the concept of object-choice in relation to the Oedipus complex; the status of dreams with regard to the unconscious; adolescence and passage to the act; and suicide.
- Technical observations on the treatment: the negative therapeutic reaction; the transfer of oedipal hostility onto the analyst; the therapeutic alliance; and the difficulty with analysis conducted at the request of a third party.
- Epistemological developments: causality in the analysis and its unpredictability; innate and acquired characteristics; and the connections between psychoanalysis and biology.

It therefore becomes apparent once again how it is difficulty or even failure in clinical practice that lead Freud to reflect in a productive way, as is characteristic of scientific investigation.

Freud addresses the question of homosexuality from the outset of his work in many texts. He emphasizes here that “it is not for psycho-analysis to solve the problem of homosexuality” (1920a, p. 171); that is, he considers it to be a variant of the sexual organization that in common with heterosexuality represses the other part of the original bisexuality. For him, the analytic attitude consists in re-establishing the full bisexual function in a way that leaves open the subsequent choice.

The complex relations between object choice and identification with the object are demonstrated here:

disappointed in her oedipal love by the birth of a new brother when she is in the throes of the pubertal resurgence of the Oedipus complex, the young homosexual girl turns away from her father and from men in general. She identifies with her new brother and takes first her mother and then another woman as love object in place of her father.

Rather than the oedipal competition, Freud emphasizes here the negative consequences of the “libidinal withdrawal” as a convenient position that avoids the conflict. He also resumes and continues his analysis of the origin of the compulsion to fall in love with women of “ill repute” who need to be “saved” (1910h).

Previously analyzed (1910g), suicide is emphasized here in its primary murderous and other-directed nature, which is secondarily turned back on the subject herself by identification. It is surprising, however, that the young girl’s passage to the act, which she explains by her despair in love following her rejection by the woman who evidently did not want any trouble with the family, is not discussed any further by Freud—particularly in its dual character of destructiveness both toward the mother, represented by the loved and rejecting woman (who “drops” her), and toward the father against whom the act is directed as a supreme act of defiance.

The idea that the patient is attempting to mislead him with lying dreams leads Freud to an important observation that the dream is not the “unconscious” but the form into which a thought left over from conscious or preconscious waking life is recast.

This is to be understood in the context of the patient’s negative transference and resistances, which he likens to Russian military tactics of encouraging the enemy to advance in order to ambush him later. Realizing that the patient has transferred to him “the sweeping repudiation of men which had dominated her ever since the disappointment she had suffered from her father” (1920a, p. 164), Freud breaks off the treatment and advises that she should resume it with a woman analyst.

In his view, the young girl has therefore proved incapable of successfully completing the second phase of the analysis, which follows the period in which information is obtained and is supposed to lead the patient herself to grasp hold of the material placed at her disposal. These technical observations had already

appeared in another form in the concept of working-through (1914g).

Finally, the question of homosexuality leads Freud to distance himself from the received idea of a congenital homosexuality and to emphasize, alongside the somatic sexual characteristics and the type of object-choice, the importance of the psychic sexual characteristics—that is, the “masculine and feminine positions”—leaving the rest to biological research.

This article is therefore an important clinical, technical and epistemological work.

The therapeutic failure is productive not only because it leads Freud to reconsider the procedure of both analyst and analysand in the treatment, particularly in its beginnings, but also because it leads him to identify in part with the question posed by the parents: what should be done with regard to this young girl’s homosexuality and, above all, could it have been foreseen and therefore avoided?

This concerns a fundamental question for psychoanalysis, to which Freud gives a firm answer: “Hence the chain of causation can always be recognized with certainty if we follow the line of analysis, whereas to predict along the line of synthesis is impossible” (1920a, p. 168).

There are so many causal factors at work that it is impossible to know in advance which will prove to be the strongest. The concept of “deferred action” that characterizes the specific nature of temporality in psychoanalysis emerges here in its epistemological dimension: prediction is impossible because it is only in deferred action that it can be said which elements were the strongest, for the sole reason that it is these that have prevailed. Although it may seem a truism, this observation is nevertheless of fundamental importance for child and adolescent psychology and it conflicts with primary pseudo-determinism.

On the ethical plane, it is also a perspective that leads to an active attitude of confidence in the possibility that psychic destiny is not fixed for all time. In fact, Freud does not take the view that homosexuality is a sexual pathology, although he does emphasize that female homosexuality is “much less glaring” than male homosexuality and that it is beyond the purview of the law.

Despite his annoyance at not managing to get through his young patient’s defenses and polite con-

tempt, Freud in fact appears respectful of her choices and firm with regard to the ethics of the analytic position, in which there is no question of defining a “good” sexuality to be imposed on the ailing “deviant.”

A fascinating biography of the patient, Sidonie Csillag, was published in 2000 by Ines Rieder and Diana Voigt. It provides us with a useful reminder of the context of female homosexuality in this period and bisexuality as a phenomenon that accompanied women’s emancipation. The book sheds light on the unusual fate of this woman, who was to die a centenarian, after leading a life that was as free, non-conformist, and adventurous as the one that had led her to Freud against her will at the age of nineteen.

## PSYCHOGENESIS/ORGANOGENESIS

The notions of *psychogenesis* and *organogenesis* come out of a classic debate in the field of psychology—a debate that, throughout history, has taken the form of

a dichotomy between innate and acquired or subjective and objective. Today, its most radical form is illustrated in the opposition between neuronal and mental. These two notions are usually associated with causal deterministic or etiopathogenic types of mental disorders.

Classically, *psychogenesis* of a mental problem is understood to mean an etiological or etiopathogenic process that is exclusively supported by events or mechanisms of a mental nature and outside of any organic factor, especially those affecting the nervous system or the brain. Psychoanalysis, as a theory of the human mind based on exploration of the unconscious, for a long time represented and illustrated the psychogenetic point of view within psychology by emphasizing the dynamics of unconscious conflict. Some doctrinal trends within contemporary psychoanalysis, such as the current informed by the work of Jacques Lacan, radicalized this viewpoint through the use of a formalization of the structures of language in relation to the unconscious.

By contrast, *organogenesis* of a mental problem is understood to mean an etiological or etiopathogenic process grounded in an organic dysfunction. While in the late nineteenth and early twentieth centuries organic dysfunction was conceived in terms of lesions of certain areas of the brain according to an anatomical model, present-day contributions from molecular biology, genetics, and, above all, the neurosciences have instead situated such dysfunction within the neuronal connections that make up the structures of the brain. Certain currents within psychology, such as those derived from neuropsychobiological, experimental, or cognitive approaches, by privileging the objective dimension within observation protocols and data collection, illustrate this organogenic point of view.

From a psychoanalytic point of view, the debate between psychogenesis and organogenesis can no longer be treated schematically and exclusively. This debate raises the question of psychic causality, the affirmation of which is indissociable from psychic reality. According to Freud’s conception, mental life is necessarily grounded in organic life, but there is a limit beyond which psychoanalytic inquiry can no longer be relevant. Following up from that viewpoint, today one can say that mental functioning is grounded in brain functioning, but that it does not derive directly from, nor is it reducible to, brain functioning. The logic of

the mental thus remains heterogeneous to the logic of the neuronal, as is shown, in particular, by its theoretical referents. Notions such as the drive—with its two polarities, somatic and psychic—or representation, as well as modern psychoanalytic studies on borderline states or psychosomatic states, which emphasize symbolic transformations (meaning) and economic transformations (force) attest to a specifically mental reality that has its own causality.

At the margins of the psychogenetic and organogenetic points of view, one current of doctrine, the organodynamic current, attempted to make a synthesis between the two. An outgrowth of the work of the neurologist John Hughlings Jackson, and based on a hierarchical, evolutionary conception of the structures of the nervous system, this trend was applied in the field of psychopathology, specially by Henry Ey and others. In this conception, it is posited that mental disorders are linked to dissolution or disorganization at a certain level of mental organization, by means of damage of organic origin that generates negative symptoms, and to reorganization at an inferior level, linked to mental life's characteristic dynamism and ability to generate positive symptoms. In the field of psychosomatic phenomena, Pierre Marty applied this model in an original and personal way to the psychosomatic economy and its disorders.

## **PSYCHOGENIC BLINDNESS**

Psychogenic blindness, whether it arises from too great a desire to see or from a refusal to see, had psychological causes for Freud. Here, as elsewhere, hysteria was Freud's guide: it was apropos of hysteria that he broached the subject of conflict between the various visual functions, and he placed the eye (the source of visual pleasure) and the act of looking itself at the center of his thinking.

His study "The Psycho-Analytic View of Psychogenic Disturbance of Vision" (1910i) dealt specifically with blindness that had its origin in hysteria. He noted that hypnosis could be used to induce blindness experimentally by suggesting to the subject not to see anything, but that in hysterical patients the idea of being blind did not proceed from third-party suggestion but arose spontaneously from autosuggestion. Hence his question: when and under what conditions does an idea become so powerful that it behaves like a suggestion and becomes a reality? For Freud "hysterically blind people are only blind as far as consciousness is concerned; in their unconscious they see" (p. 212): the stimuli reaching the blind eye arouse unconscious affects.

Certain ideas associated with vision remain separate from consciousness: they have succumbed to repression because they conflict with other, stronger ideas that dominate the ego. Such conflicts between ideas are simply an expression of the conflict between instincts, especially between the sexual instincts and the ego instincts, both of which use the same organs of the body. Thus the eyes perceive not only the modifications to the outside world that are important for preserving life, but also the characteristics and attractions of the love object. But it is not easy to serve two masters: the more that an organ with this dual function enters into an intimate relation with one of the two great instincts, the more likely it is to refuse itself to the other. This can have pathological consequences if the two basic instincts are disunited, if, for example, the partial sexual instinct that uses the eyes makes excessive demands. These excessive demands disturb the relation of the eyes and the act of seeing to the ego, because the ideas linked to these demands succumb to repression and are excluded from consciousness. This circumstance may attract a counterattack from the ego instincts.

When the sexual interest of sight, *Schaulust*, becomes too insistent, the ego no longer wants to see anything,

and the visual organ, using its power to separate, puts itself entirely at the disposal of the sexual instinct in the unconscious. Because the ego then no longer has conscious control over the organ, the repression miscarries, and a substitute mechanism converts the repression into blindness. This blindness seems to be the result of an implacable psychic logic: by seeking to misuse the visual organ for purposes of sexual pleasure, subjects condemn themselves to see only the sexual on the unconscious stage and otherwise to see nothing.

When Freud tackled the question of the uncanny (1919h), he mentioned E. T. A. Hoffmann's tale *The Sandman*, in which a character plucks out children's eyes to graft them onto automatons. This story, he felt, lent support to his view that the feeling of uncanniness is directly related to the sight of the female genitals, particularly those of the mother. He stressed the frequent unconscious equivalence between the eyes and the genital organs, and between blindness and castration. Blinding oneself, like Oedipus, is an attenuated form of self-castration, but it also makes one the bearer of a blind eye, which represents the other sex while disfiguring the face. In his theory, Freud, with a single word, *übersehen*, which means both to look and to overlook, successfully condensed the story of Oedipus.

Blindness is thus the result of a punishment, but what is the nature of the offense? The hysteric's blindness seems to play out the Oedipus complex quite literally. For one, it chooses a substitute organ, the eye, which stands at once for the castrated sexual organ and the desired sexual organs of the mother. Moreover, it makes the eye into the special object of the desire to see, as though it were obliged to reduce the sexual organ to the eye and were subject to the autoerotic need for the eye to derive pleasure from the eye.

## **PSYCHOHISTORY**

Psychohistory may be defined as the application of formal psychological models in historical research. The modern field known as psychohistory is usually dated from the appearance of Freud's book on Leonardo (1910), although the term *psychohistory* did not come into use until the 1960s. Although scattered attempts at the application of psychoanalytic theories to history were made between 1910 and 1940, the rise of Hitler and National Socialism led to a renewed interest in understanding irrational motivation. This was particularly true in the United States, where William L. Langer became president of the American Historical Association in 1958 and called for psychoanalytic methods to replace amateur psychologizing in historical research. That same year Erik Erikson published his widely read *Young Man Luther: A Study in Psychoanalysis and History*. As a result of Langer's and Erikson's influence many younger scholars turned to psychohistory, as the new field was soon nicknamed.

Although the fields of psychohistory and psychobiography are closely related, psychohistory limits itself to important historical figures like Richelieu, Hitler, or Wilson, and attempts to go beyond individual psychology to group behavior. Many historians regard the real test of the utility of psychoanalysis for history to be its success in explaining group behavior. A number of recent psychoanalytic studies, such as Robert Jay Lifton's *The Nazi Doctors*, have attempted to explain group behavior in extreme historical situations. The witchcraft trials of the seventeenth century have also provided a fruitful subject for the study of group behavior, as in John Demos's *Entertaining Satan* (1982) on New England or Lindal Roper's *Oedipus and the Devil* (1993) on southern Germany.

Psychohistory has been controversial within the history profession from its beginnings, but particularly after it became a prominent sub-field within academic history in the United States. Attacks on psychohistory have been of two kinds. One kind assails the careless research methods and hasty conclusions reached by some authors, particularly by clinicians not trained in historical method or by historians who misunderstand and misapply psychoanalytic concepts. The second

kind of objection to psychohistory involves specific problems such as the role of individuals in history compared to larger social and economic forces, the charge of reductionism and the importance of acknowledging possible alternative explanations, the difficulty of “analyzing” the dead from scant evidence of childhood experiences, and, finally, questions concerning the validity of psychoanalytic theory itself. Although there are reasonable answers to each of these problems, some academic historians remain hostile to psychohistory.

Perhaps the most important reply to the general antagonism toward psychohistory is that since history has accepted models and theories drawn from the other social sciences (sociology, anthropology, economics), historians should not continue to use amateur psychology but draw on explicit psychological models. Of course, there can be a non-psychoanalytic psychohistory and even among those historians sympathetic to psychoanalysis there are many differences in approach, some following traditional instinctual models, others some form of object relations, and an increasing number pursuing ego psychology models like that of Heinz Kohut.

Some have suggested that methodological problems could more easily be avoided if psychohistorians received professional training in both history and psychoanalysis and there are a number of present-day historians who not only have doctoral degrees in history but are certified by one of the psychoanalytic institutes. In the United States a number of psychohistorians hold teaching and research positions in universities and offer doctoral training to younger scholars. Two journals exist, *The Journal of Psychohistory*, which primarily publishes the work of practicing clinicians, and *The Psychohistory Review* which publishes the work of historians and clinicians concerned to meet the standards of academic history. Despite some continuing resistance, psychohistory in the broadest sense is an established part of academic history in the United States and to a lesser degree in Germany and Israel. It has made its way more slowly in Britain and France.

## PSYCHOLOGICAL TESTS

Psychological tests are those that are designed to reveal individual modes of psychological functioning. Some of these are subject to strict codification and numerical evaluation that afford an assessment of individual performance in relation to a standard. Others use more flexible techniques and do not have recourse to quantification: the expression “projective personality assessment” is often then used rather than “test.” This expression is applied to so-called expressive and “projective” evaluations, the only ones to bear—often, though not always—the mark of some aspect or another of psychoanalytic theory.

Hermann Rorschach, a Swiss psychiatrist trained in the Burghölzli clinic directed by Eugen Bleuler, was the first to imagine this type of test when he had the idea of asking his patients what they saw in inkblots. This test, which has given rise to innumerable publications, is the most commonly used. In his theoretical views, Rorschach himself was no doubt more influenced by Bleuler and Gustav Jung than by Sigmund Freud, although some of his successors have tried to fit him into coherent psychoanalytic thinking (Anzieu and Chabert, 1997).

Another type of assessment derives from the line of approach begun by Henry Murray in 1935 with the Thematic Apperception Test, or TAT. In these thematic tests the subject is presented with plates (or photographs) presenting one or more characters engaged in a situation and an action that the subject is asked to imagine. Leopold and Sonya Soral Bellak constructed a version for children in which the plates represent humanized animals (Children's Apperception Test, or CAT). Many other evaluations using the same principle have been put forward (like Louis Corman's Black Paw, Roger Perron's Personal Dynamic and Images).

A great many assessments have been imagined using different principles, almost always in a psychoanalytic context: sentences to complete and stories to complete (Madeleine Thomas); fables in which the person being tested has to comment on the moral (Louisa Düss); stories to create and tell with the material support of dolls (Gertrude von Staabs), characters, elements of a village (Henri Arthus, Pierre Mabile); interpretation of the expressions on human faces in photographs (Leopold Szondi). Saul Rosenzweig's Frustration-Aggression test no doubt deserves special mention because it is built explicitly on the basis of a hypothesis derived from psychoanalysis ("frustration produces aggression"). It met with great success in the world of American experimental psychology between the two wars.

Lastly, we must accord a special place to "expressive" techniques that interpret the content and style of speech, walking, gestural behavior, but most of all graphic behavior: writing, but above all drawing, a procedure that Françoise Dolto in particular demonstrated (*Le Dessin de l'Enfant*, 1996).

These techniques are said to be "projective," based on the hypothesis that what the subject "perceives" of the material presented (which is preferably ambiguous and open to multiple interpretations in terms of graphics, situation, and so on) is in fact indicative of the subject's representations of the world, people, interpersonal relations and, definitively, of the subject's own psychic functioning. This often supposes a fairly psychologized and simplified definition of the psychoanalytic notion of projection, although certain authors prefer to use the notion of *identification*, which is also every bit as complex in psychoanalytic theory. Theoretical simplification always runs the risk of resulting in relatively simplistic interpretation procedures. Correct use of these techniques presupposes a solid grounding in clinical psychology and psychopathology, as well as specialized training.

Under these conditions, projective tests constitute an important instrument for contributing to psychological and psychopathological diagnostics.

## **PSYCHOLOGICAL TYPES (ANALYTICAL PSYCHOLOGY)**

Carl Jung's discrimination of human consciousness according to its functions (thinking, feeling, sensation, and intuition) and habitual attitudes (extraversion and introversion) was his attempt to provide a psychology of experience with a critical orientation in sorting out the empirical material of psychic dispositions, tendencies, and convictions. Jung's first presentation of the idea of psychological types was in a lecture delivered at the Psychoanalytical Congress in Munich during September 1913. He noted the striking difference in attitude toward the external world between patients diagnosed with hysteria and those diagnosed with schizophrenia in terms of intensity of feeling, the former displaying an exaggerated emotivity with regard to the environment and the latter an extreme apathy. He also noted characteristic differences in thought content: the fantasy life of the patient with hysteria may be accounted for in a natural and

human way by the antecedents and individual history of the patient, whereas the patient with schizophrenia consciously experiences fantasy closer to dreams than to the psychology of the waking state in having a distinctly archaic character, with mythological creations more in evidence than the personal memories of the patient.

From these facts, Jung concluded that hysteria is characterized by a centrifugal movement of libido, which he called *extraversion*, and schizophrenia by a contrary movement, which he called *introversion*, toward the core of the personality (which he later called *the self*). Although Jung recognized that in these two clinical syndromes he was witnessing regressive extraversion and regressive introversion, he nevertheless concluded that there was in the development of consciousness a normal distinction between the two movements of libido. Extraversion, he postulated, tends naturally to bond and even merge with objects in the outer world, while introversion naturally turns away from such objects in order to link up with the internal objects that Jung eventually called archetypes. Kenneth Shapiro and Irving Alexander have subsequently noted that these two movements of libido are constitutive of experience itself for the different types, experience only being experience for the extravert when it is shared with another person or object in the outer world and, for the introvert, when it matches up to some a priori archetypal category or capacity to experience just that type of thing. The theory of psychological types itself is an introverted way of thinking about experience and making it real, which may account for its difficulty for psychologists using an extraverted attitude.

In the years between 1913 and 1921, when the book *Psychological Types* finally appeared, Jung developed the theory to include what he called the functions of consciousness, which he named sensation, thinking, feeling, and intuition. Whether deployed toward objects in the outer world or toward the inner world of archetypes, sensation gives consciousness the practical sense that an object is really being presented to it; in other words, that it is, thinking gives it a name, feeling assigns it a value (for which reason Jung's *feeling* is sometimes replaced by analytical psychologists with the word *valuing* or with *feeling valuation*) and intuition grants consciousness a direct, uncanny perception (from the perspective of the "absolute knowledge" of the unconscious) of the

origin and fate of the object, as Jung puts it "whence it arises and where it is going."

For Jung sensation and intuition are irrational functions in being functions of perception which are irrationally "given." Thinking and feeling, by contrast, are rational functions, being choices, in the sense of judgments by consciousness, as to how to discriminate among objects that are perceived.

That individuals develop consciousness in different ways, according to their preference for using certain functions over others has led the theory of psychological types to be used to type people and to predict their likelihood to succeed in certain professions. A test based on Jung's model, known as the Myers-Briggs Type Indicator (MBTI), has had widespread use in the United States. The MBTI uses categories of judging and perceiving to distinguish Jung's rational and irrational extraverted functions. In typing the preferred mode of consciousness of an individual, an attempt is made to define the person's typical "superior function" according to whether it is extraverted or introverted, whether it is most characterized by sensation, thinking, feeling, and intuition, and whether it is rational or irrational.

There will normally be an auxiliary function that is "different in every respect" providing the individual with an alternative mode of consciousness with which to meet inner and outer situations. In depth psychological work, it is also important to define the "inferior function" which, though much less easily differentiated into a conscious competence, is the place one most often experiences unconscious complexes and conflicts.

## PSYCHOLOGY AND PSYCHOANALYSIS

It is important to stress the point that for Freud himself psychoanalysis was a psychology. In 1923 he wrote: "Psychoanalysis is the name (1) of a procedure for the investigation of mental processes which are almost inaccessible in any other way, (2) of a method (based upon that investigation) for the treatment of neurotic disorders and (3) of a collection of psychological information obtained along those lines, which is gradually being accumulated into a new scientific discipline" (1923a, p. 235).

Rarely in his writings did he make any mention of contemporary work in "academic" psychology, however. He sometimes cited authors who wrote in German (Wundt, Hering, and Ehrenfels), French (Binet and Claparède), or English, like Darwin and his cousin Francis Galton, or Stanley Hall, whom he met in 1909 on his voyage to the United States, but such references remain episodic. The two most frequently cited authors are Fechner, from whom he borrowed the principle of constancy in the framework of his energy approach to psychic function, and Pierre Janet, with whom he had a long controversy based both on a conflict of prestige and priority and on a fundamental theoretical divergence: Janet explained hysteria in terms of reduced "psychic tone," whereas Freud saw the effects of conflictual tension in it.

One could therefore consider Freud to be ill informed about work by psychologists in his own time. This would probably be completely false: his interest in memory and perception fits readily into the framework of a "psychology of the faculties," which was still very much present in *Project for a Scientific Psychology* (1950c [1895]), the main points being reviewed in *The Interpretation of Dreams* (1900a). Over the years, however, his concepts, which were initially strongly influenced by the dominant empiricist associationism of the late nineteenth century, progressively evolved toward a radically different approach to memory and perception that allows for the effects of deferred action and also focuses on the psychoses and delusions (Perron). This provides a

new solution to the whole problem of the relations between the "reality of the external world" and "psychic reality," a solution that has nothing in common with the views developed elsewhere in psychology.

We must also bear in mind that while he was still at school it was from a psychologist, albeit an amateur, Herbart, that Freud acquired the fundamental ideas of psychoanalysis, ideas such as repression, the threshold of consciousness, and the unconscious (Andersson)—these were the origins of the topical model of metapsychology. The origins of the economic model can be found in the "energetic" trend that included, among others, Brücke, his mentor, and Fechner. The "dynamic" model is specifically psychoanalytic. There is also what is sometimes referred to as a "fourth point of view," the developmental perspective: case studies analyzing the stages in the development of a given child were very much in vogue in psychology between 1880 and 1930, from Baldwin and Binet to Piaget himself. With the cases of "Little Hans" and the "Wolf Man" Freud fit into this stream of ideas in his own way.

After Freud, what were and what are the influences of psychology on psychoanalysis? And conversely, what are the influences on psychology of psychoanalysis? The asymmetry is patently clear. Although certain psychoanalytic developments are deliberately based on ideas and facts coming from disciplines such as psychiatry, biology, linguistics, sociology, and ethnology, it is not easy to cite analogous importations from psychology or any of its so-called scientific branches (experimental psychology and differential psychology, for example). Perhaps the epistemological (in terms of basic postulates) and methodological gap is such that this type of importation seems unacceptable to psychoanalysts, who dread a "psychologization" that would empty metapsychology of its essential substance. In Europe, at any rate, the opposition to Hartmannian "Ego Psychology" has often been justified in this way. However, psychoanalytic theories on memory, perception, and thought processes would gain by being better informed about the current work of psychologists and neuropsychologists on these questions, and it is regrettable that they are still too often discussed in psychoanalysis in the same terms in which Freud posed them.

This discrepancy could be attributed to the "narcissism of minor differences," the separation between things that are too similar. However, it is obvious that,

seen from the reverse point of view, the influences of psychoanalysis on psychology are of major importance, in at least three respects:

- In terms of theories. Certain research trends have developed in experimental and differential psychology based on hypotheses that have been imported from psychoanalysis (albeit with distortions and simplifications): work on selective forgetting of unpleasant experiences and on aggressive behavior caused by frustration.
- In terms of techniques. Here we are referring mainly to so-called “projective” and “expressive” trials. It is important to remember that Rorschach, a psychiatrist at the Burghölzli asylum (directed by Bleuler, and where Jung also worked), created his famous ink blot test in the context of psychoanalytic ideas, as they were accepted in that institution around 1920. It is patently obvious that in recent years psychoanalytic theory has had a strong effect on this Rorschach test, as well as so-called thematic tests (Murray’s TAT), both in terms of research work and its interpretation in individual clinical practice. As for children’s drawings (classified among the “expressive” techniques), it has become commonplace though nevertheless still pertinent to interpret them in psychoanalytic terms, as Françoise Dolto illustrated particularly well.
- In more general terms, a whole new sector of psychology has developed in a context where many consider psychoanalytic references to be dominant, which creates no small difficulties for the professionals in question (Perron).

In fact, no valid questions concerning the relations between psychology and psychoanalysis can be posed without first asking: which psychology, which psychoanalysis? In both fields questions are being asked concerning the permanently threatened unity of the respective disciplines. There is no doubt very little in common between the “pure” experimental psychologist working on the memorization of meaningless syllables and the clinical psychologist who is trying to understand the dynamics of phobic behavior leading to a total inability to work. In a similar vein, apart from very general principles, there is very little common ground to be found between Jacques Lacan, Heinz Hartmann, Melanie Klein, Heinz Kohut, Wilfred Bion, and numerous others.

Can these gaps between and within each of these disciplines one day be reduced? Such an effort presupposes an analysis of the epistemological bases of each approach, and it seems doubtful that such an analysis would produce any unified theory.

## **PSYCHOLOGY OF DEMENTIA PRÆCOX, THE**

*The Psychology of Dementia Præcox* dates from the period when Carl Gustav Jung was conducting clinical research at the Burghölzli university clinic in Zürich (1900–1909). Encouraged by Eugen Bleuler, he took an interest in *Dementia præcox* (schizophrenia) although he had distinguished himself for years

through his work using the association test and aimed at acquiring a better comprehension of psychodynamic processes in normal and hysterical subjects. It was first published in book form by Carl Marhold Publishers at Halle.

The work breaks down into five chapters. After a critical review of the existing literature on the subject, Jung starts out from Freudian psychology and his own research and establishes the concept of the complex, demonstrating its general influence on the psyche and the validity of associations. In chapter 4 the author describes the parallels between hysteria and *Dementia præcox*, their symptoms and their psychodynamic foundations. As an illustration he then provides a complete analysis of a case of paranoid dementia.

In both pathologies Jung discovers one or several complexes in the depths of the patient's being. In the case of hysteria these are linked to the symptoms in an obvious way and have never been completely overcome, while in the case of *Dementia præcox* they are fixed in a lasting fashion and the causal link with the symptoms cannot be determined. For Jung there was a powerful affect at the beginning of the disease. The author postulates the existence of a factor X, a metabolic toxin for example, that would create a directly harmful effect of the complex, or a predisposing factor, like a sort of organic cerebral disposition.

His most acerbic critics reproached Jung with trying to provide a psychological explanation for an affection with an undeniably organic cerebral origin in order to present an apology for Freud's ideas. But Jung never had any such intention. In any case, his work is perfectly consistent with the research at the Burghölzli asylum, which also helped Bleuler to situate patients' often-incomprehensible symptoms in a meaningful context of individual psychology. Bleuler paid his respects to Jung and to Freud in his important work on schizophrenia.

### “PSYCHOLOGY OF THE UNCONSCIOUS, THE”

An article by Théodore Flournoy on the poems, reveries, and visions of an American student named Miss Miller inspired Jung to compare these products of the imagination with mythology and the history of religions. It was an opportunity for him to differentiate himself from Freud by laying the foundations for his theoretical constructions. Several powerful ideas were developed: the libido is not uniquely sexual; some unconscious content is a condensation of the collective history of psychic evolution; certain fantasies are recurrences of ancient beliefs—they cannot enable us to understand mythology but by finding the source of myths we can gain access to the psyche; and incest is first of all a psychic reality before it begins to concern the real mother. The article “The Psychology of the Unconscious” contains the seeds of all the Jungian concepts before he actually formulated them explicitly. It cost him his friendship with Freud and was followed by a long period of internal crisis.

In 1950 he reworked and updated the article in the light of his research over the intervening decades, though he did not deny any of its original contents. It was published under the title *Symbole der Wandlung* (Symbols of transformation).

In the first part Jung analyzes the religious sentiment and the difficulty of differentiating between human love and love of God or the divinity. By studying the interplay of the archetypes in the collective unconscious he reveals the psyche's capacity to rediscover in the present, and in relatively new forms, experiences and ideas that marked the history of humanity. The second part intro-

duces his concept of the libido, which he bases on his work on schizophrenia and which appears radically different from Freud's concept. Jung then goes on to describe his concept of incest, which is one of the pivotal points of his theory. Symbolically, incest signifies an ebbing of the libido (Jung speaks of regression) toward ancient layers of the unconscious located well beyond the genetic mother. For Jung the unconscious is a place of becoming, the locus of encounter with the "Great Mother." This return to origins is symbolized by the hero's combat with the monster. In his quest the hero aspires to being reborn but he must nonetheless renounce this incestuous attraction in order to be liberated from the maternal, otherwise he risks being engulfed by it. Jung thus develops the question of sacrifice. In the process of individuation, the organizing influence of the Self underlies this movement and actualizes itself through the Self's confrontation with ancient unconscious content.

## PSYCHOLOGY OF WOMEN, THE. A PSYCHOANALYTIC INTERPRETATION

*The Psychology of Women. A Psychoanalytic Interpretation* consists of two volumes. The first, entitled "Childhood and Adolescence," appeared in 1944, followed in 1945 by the second, with the sub-heading "Motherhood." This breakdown corresponds to what Helene Deutsch called "the fundamental dualism of femininity," which opposes individual development and personality with the role of "servant of the species." She was trying to shed a psychoanalytic light on the conflicts that are born of this dualism, which is only surpassed and transcended through the reconciliation of the antagonistic goals of the individual and the species, a point Freud stressed in "On Narcissism: An Introduction" (1914c).

Published at the end of World War II, *The Psychology of Women* reviews and develops, in the light of new observations, the author's first conclusions concerning the different problems of female psychology described in her first book, *Psychoanalyse der weiblichen Sexualfunktionen* (Psychoanalysis of the sexual functions of women), published by the Vienna Verlag in 1925. This, together with her work on female homosexuality, was based on clinical material gathered over a twelve-year period. As her biographers have pointed out (Roazen), *The Psychology of Women* is also influenced by the author's personal experiences. The book was born of her double desire to put her ideas to the test of time, and to compare them with those of Freud.

Although certain concepts have aged, some of her theses are still pertinent: the "secondary" character of penis envy in girls; the slowness of the construction of femininity (the opposite position to that of Freud, who believed the fate of femininity was prematurely sealed at the phallic stage), which explains her decision to study the psychology of women only from the latency period onward; and the psychic importance of the phenomena of "expectancy" (linked to late anatomico-physiological

female maturation) and identifications. Deutsch described the development of the female personality as a process that takes place through a series of intermediary identifications that correlate with modifications affecting her objects and the links to them. Equally striking is her assertion that the rape fantasy is universal and non-pathological, being a veritable organizer of female sexuality.

There was no shortage of criticism for *The Psychology of Women*, either from the feminists, who reproached her for her Freudian orthodoxy, or from psychoanalysts, for the converse reason. Very few of those who welcomed Winnicott's ideas with enthusiasm were able to recognize similar ideas expressed in *The Psychology of Women*, particularly in volume 2, "Motherhood." Deutsch's great mistake is no doubt the fact that she named this vast psychoanalytic study of more than seven hundred pages *The Psychology of Women*.

## PSYCHOPATHOLOGIE DE L'ÉCHEC (THE PSYCHOPATHOLOGY OF FAILURE)

Written between 1935 and 1939, the first draft of René Laforgue's manuscript *Psychopathologie de l'échec* (The psychopathology of failure) contained a chapter on Hitler, which the author is said to have destroyed because he felt threatened by the Gestapo. The first French edition of the book was published in Marseilles in 1941. In the same year, hoping to see his work translated into German, Laforgue appealed on several occasions to Matthias Göring, director of the Institute of Psychotherapy in Berlin. Having read the manuscript, a Professor von Hattenberg passed a negative judgment on the grounds that it "trots out Freud's doctrine in an utterly uncritical manner." In the last version, published after the author's death, the publisher acknowledged Mrs. Délia Laforgue, who had made changes and corrections in accordance with her husband's wishes and instructions.

Laforgue's book was a study of failure neurosis and the influence of what he called the "Super-I." "One day," he wrote, "we will find a better term for it, for example, 'Ductorium' as proposed by Edouard Pichon." By way of example, Laforgue took the Jewish "minority" (the word was replaced by "collectivity" beginning with the edition of 1944). The Jews, he argued, "harbor an obsessive fear of persecution which they frequently associate with an atmosphere, even should that atmosphere no longer justify the fear" (1941; the edition of February 1944 has: "an atmosphere which no longer justifies that fear"). The "Super-I" of the Jews ("Super-Ego" in the 1950 and 1963 editions) "collaborates in the persecution, and if need be provokes it... Its opposition determines ["may determine" in the editions of 1944 and 1953] in them a more or less pronounced infantilism and a more or less powerful latent homosexuality." According to Laforgue, that homosexuality was always reflected by a tendency to be a victim rather than a victor.

Laforgue also described collective and class-specific superegos, powerfully influenced by education and religion. Changing social class, specifically moving from the working-class to the bourgeoisie, produced individuals prone to failure on account of the unconscious influence exerted by a proletarian superego (comparable to the superego of ghetto Jews) reacting to the betrayal implied by upward social mobility.

In the second edition of Laforgue's book, famous patients and personalities like Rousseau and Robespierre, along with Napoleon, were scrutinized from a psychobiographical point of view. Chapter 12 of the first edition, "On Professional and Affective Orientation," in which he leaned heavily on the work of Professor Reiter, President of the German Health Institute, on the subject of the social value of an individual for the community, was removed from later editions and replaced by Laforgue's long study of Napoleon's failure neurosis.

Historians, like those who lived through the war years in France, have great respect for Laforgue's abilities as a clinician. But inasmuch as this some time member of International League against Anti-Semitism supported Marshal Petain, his psychoanalytical theories of collective psychology—and indeed his political judgment—should, to say the very least, be treated with great circumspection.

## PSYCHOPATHOLOGY OF EVERYDAY LIFE, THE

Sigmund Freud's lively book, *The Psychopathology of Everyday Life*, has some unique characteristics. Freud discusses psychoanalytic matter in the context of everyday life, sidestepping the experience of neurosis. He abandons his customary process, that of discussing the normal in terms of the pathological. Everyday psychopathology is discussed with few allusions to infantile

sexuality and its impact on adult pathology. The theoretical aspect is practically nonexistent, although Freud does compare the interpretation of everyday life to dream theory, another banal psychopathological phenomenon familiar to everyone. He emphasizes the importance in life of displacement, condensation, over-determination, and the creation of compromise formations. He makes use of his knowledge and interest in literature to provide many examples by writers, poets, and dramatists, reinforcing his position by emphasizing their intuitive understanding of the meaning of parapraxis.

The book contains twelve chapters on forgetting (proper names, words belonging to foreign languages, series of words, impressions, and projects); childhood memories and screen memories; slips of the tongue (spoken and written); mistakes, clumsiness, symptomatic acts, errors, associations of several "parapraxes"; and the determinism of the unconscious, the belief in chance and superstition.

All these forms of behavior are grouped under the heading of "slips of the tongue": "I almost invariably discover a disturbing influence [in slips of the tongue] . . . which comes from something *outside* the intended utterance; and the disturbing element is either a single thought that has remained unconscious. . . . or it is a more general psychical motive force which is directed against the entire utterance" (p. 61). To belong to this category they must not exceed "the limits of the normal state" and they must "have been previously accomplished correctly."

Freud's description emphasizes various aspects of these phenomena: These are mental functions that "cannot be justified by an explanation of the representation of the goal toward which they are directed." This demonstrates the importance of the psychic determinism associated with unconscious desire and rejection. He notes, for example, the forgetting of a proper name, which is linked with a disturbance of a thought, due to an internal contradiction, arising from a repressed source (the name of the painter Signorelli replaced by the names Botticelli and Boltraffio). The use of free will assumes a distinction between conscious and unconscious motivation; accordingly, some motor acts are disturbed on account of the unconscious—for example, the loss or destruction of an object that has meaning either in terms of the person who has given it to us or because a symbolic association with something else has been shifted toward this

object. Our errors of judgment acquire a sense of certainty and remain convincing for us, precisely to the extent that they express a repressed content. This is, at the very least, the same reasoning used by the paranoid who rejects any accidental element in the psychic manifestations of other people, such as incorrect statements.

The meaning of symptomatic actions is sometimes difficult to determine; repressed ideas and tendencies remain hidden from the individual, as internal resistance presents an opposing force. Technically, slips of the tongue and bungled actions are made possible by the shifting of nervous excitation. In the example of the *lapsus linguae*, there can exist, between the intended word and the spoken word, a phonetic resemblance (a “contamination”) or psychological associations connected with the person’s history. As in dreams there is a disturbing element (which is repressed) that makes itself felt through “deformations, mixed formations, or compromise formations,” or, again as in dreams, a word may be replaced by its opposite. These phenomena reveal two factors simultaneously: a positive one (free association) and a negative one (relaxation of the inhibitory action of attention).

What mental factors are thus expressed? The disruptive idea arises from innate tendencies and should not be confused with the intentional idea, or an association exists between the two, or the disruptive idea is unconscious and comes into play when activity is undertaken, thus revealing itself by indirectly disturbing the intentional idea. This is the case with slips of the pen, where there can exist, in a waking state, a phenomenon of condensation, in which conscious and unconscious ideas overlap as in dreams. This is also the case when we forget past events that are associated with a memory likely to awaken a painful sensation from a different time (in keeping with the idea that the “unconscious is outside time”); or when we forget certain things because of a conflict associated with an opposing wish; or likewise when we make a mistake, or a strange impulse is manifested that contradicts an intended action. This is equally true of other kinds of acts, which are often symbolic representations of dreams or desires.

*The Psychopathology of Everyday Life*, one of Freud’s best known works, is an excellent introduction to psychoanalysis. His observation of the psychopathology of normal life has not, however, had the

subsequent theoretical development it deserves. Work on orality, anality, femininity, or sibling relations in everyday life would benefit from new investigations of metapsychology.

## PSYCHOSES, CHRONIC AND DELUSIONAL

In psychiatry the term *psychosis*, first used to refer to mental illnesses in general, was later restricted to the major clinical forms: schizophrenia, chronic and delusional psychoses, and manic-depressive psychoses. Unlike the neurotic, the psychotic subject does not “criticize” the disorders of his or her thought. In 1845 Baron Ernst von Feuchtersleben used the term *psychosis* to refer to mental illness in his manual of medical psychology. At the end of the nineteenth century, alienists defined psychosis as the loss of reason and mental alienation.

Psychoanalysis seeks less to categorize mental illnesses than to identify their structures and mechanisms. A structural and dynamic definition of psychosis must be conceived on the basis of a primary disturbance of the libido’s relationship to reality, through splitting and the reconstruction of an alternative, delusional reality. Eugen Bleuler, influenced by psychoanalysis, characterized schizophrenia as a dissociation of thought through withdrawal into the self, or autism. He posited as its basis splitting, linked to a loosening of associative texture. Skirted around by Sigmund Freud, who preferred the term *paraphrenia*, the notion of schizophrenia nevertheless became standard within psychiatry and psychoanalysis. A second variety of chronic psychosis, paranoia, is characterized by systematic delusions (delusions of persecution, jealous delusions, erotomania, delusions of grandeur), the

predominance of interpretation, and the absence of intellectual deterioration.

In Manuscript H (1894), Freud designated three conditions as psychoses: hallucinatory confusion, paranoia, and hysterical psychosis (which he distinguished from hysterical neurosis). In his texts on the neuro-psychoses of defense (“The Neuro-Psychoses of Defence” [1894a] and “Further Remarks on the Neuro-Psychoses of Defence” [1896b]), he took the distinction between neurosis and psychosis as given. From his earliest writings, he undertook to characterize the psychopathology of the psychoses through his successive theories of the psychic apparatus. His only study of a case of psychosis is his commentary on Daniel Schreber’s *Memoirs of My Nervous Illness*. Freud’s correspondence with Carl Gustav Jung illustrates the development of Freudian doctrine between 1909 and 1911, and the essays “On Narcissism: An Introduction” (1914), “Fetishism” (1927), and “The Loss of Reality in Neurosis and Psychosis” (1924) show the further elaboration of his theories.

Freud examined the individual’s relationship to reality from the vantage point of a consideration of the libidinal cathexes. In the psychoses, the loss of reality—and the changed relationship to others following a radical decathexis of the objects of everyday reality (“the end of the world,” for Schreber)—must necessarily be considered in a way other than descriptive, taking into account the attempted reorganization of reality by the psychotic processes.

All psychoses are characterized by the coexistence of two attitudes: one that takes reality into account, and another that “this same ego, under the influence of the id, withdraws from a piece of reality” (1924e, p. 183). Delusions affirm the subject’s belief in the existence of an alternative reality that restores the primitive cathexes that archaically linked childhood awareness with an early love object. The reconstruction of reality in accordance with the “desires” of the id expresses both a defensive cancellation and a reparative force. This entails a process whose psychotic manifestation in no way excludes rearticulation in terms of the mechanisms defined by psychoanalysis. Thus, in Freud’s view, hallucinatory psychosis could be considered as the expression of an imaginary maintaining of an early reality whose loss the ego finds unbearable. This theorization requires the refinement of concepts such as regression, which is above all conceived as a function of development of the ego and of the libido:

In the one case, regression leads to primary narcissism, and in the other, to hallucinatory wish fulfillment.

Initially, Melanie Klein, like Karl Abraham, tended to base her clinical work on a psychopathological theory of the points of fixation and temporal regression of the libido. In addition to this temporal regression, Freud distinguished a topographical regression that made it possible to compare the mechanisms of dreams with those put into play in psychosis. “In schizophrenia, it is words that become the object of elaboration by the primary process; in the other, the dream, it is the thing-presentations: representations of things to which the words have led.” In schizophrenia, circulation is cut off between the preconscious cathexis of words and unconscious thing-presentations. The fundamental mechanism of paranoia is projection. The feeling of hatred toward the object is projected outward and then turned back onto the subject in the form of persecutory hatred.

In the final stage of his work, in describing the splitting of the ego, Freud was on the way to defining an original mechanism of the repudiation of reality in psychosis: denial of the reality of castration. This notion of the *Verleugnung* (denial) of castration, which he opposed to repression, goes back to the primal experience of loss. Thus, Jacques Lacan, taking up the term *Verwerfung* (rejection) in his discussion of the “Wolf Man,” translated the German *Verwerfung* as *foreclosure* and, on the basis of this notion of a primordial excision of a fundamental signifier, elaborated his conceptualization of psychosis. The phallus as the signifier of castration is not inscribed within the symbolic order. Not integrated into the psychotic’s unconscious, it returns to the real, especially in the phenomenon of hallucinations. Through Lacan’s paternal metaphor, it can be considered that foreclosure of the Name-of-the-Father is the hole in the symbolic that is inherent in all psychoses.

The psychoanalytic elaboration of a theory concerning chronic and delusional psychoses runs up against the difficulty and complexity of a concrete approach. It becomes diversified into a theoretical eclecticism bringing together the considerations through which each school of thought, and indeed each analyst, refines and consolidates the foundations of the transference relationship. For all the intrinsic interest of the original viewpoints of John N. Rosen, Frieda Fromm-Reichmann, Marguerite Sechehaye, Gisela Pankow, Gaetano Benedetti, or Piera Aulagnier, among others, it is

impossible to recognize their particular relevance without having access to the specific techniques used in their respective therapeutic approaches.

Through a “psychotic transference” that moves from extreme avoidance to a relationship that is almost one of merging, demands are placed on the analyst that touch his or her own archaic unconscious dispositions; “falling in love-hate” and the preponderance of narcissistic investment over object investment make it difficult to manage. What place does this relationship have within the complexity of medication-based, institutional, or readaptive approaches? Analytic theory must certainly be remembered in a variegated context (families, caregivers, recipients of care) if one wants to maintain a certain structural coherence. José Bleger’s notion of *framework*, Lacan’s of *historization*, and the understanding of transference and counter-transference—both individual and institutional—must always be implemented when the challenge of treating the psychoses is undertaken.

## **PSYCHOSEXUAL DEVELOPMENT**

Psychosexual development is the progressive evolution of infantile sexuality as it passes through the different stages or phases of psychic organization (oral, anal, phallic) with due regard for a prevalent erogenous zone, which organizes fantasies, and a certain type of object relation. Complete psychosexual organization is not reached until the arrival of puberty and a final phase of libidinal development, the genital phase.

Freud saw infantile sexuality as being active from the beginning of life. This broadened the notion of sexuality, giving it a range of extension that is specific to psychoanalysis.

In the *Three Essays on the Theory of Sexuality* (1905d), Freud initially saw infantile sexuality as a sort of precursor of adult sexual perversions and a blueprint for pubertal genitality, but he later described it as the mainspring of psychic development. He used the term *infantile sexuality* in an effort to acknowledge the existence of the stimuli and the needs for satisfaction that involve specific body zones (erogenous zones) that seek pleasure independently of exercising a biological function. He therefore described the sexual instinct as becoming separate from the vital functions that ensure the preservation of the organism in accordance with the anaclitic model (whereby the sexual instincts initially depend on those vital functions). The pleasure bonus provided alongside the accomplishment of the function would, in a second stage, be sought for its own sake. Freud thus considered anaclysis, the erogenous zone, and autoeroticism to be three intimately linked criteria for the definition of infantile sexuality.

The Freudian scheme of the phases of libidinal development links two essential components at each stage: on the one hand, an organizing erogenous zone, along with the excitations and instinctual movements for which it is both the link and the source, and on the other, the modalities of the object relation linked to development of the ego.

In the *Three Essays*, Freud stressed the existence and importance of oral and anal erogenous zones (in addition to the genital which is the primary erogenous zone in adults), describing them as pregenital and

highlighting the autoeroticism that is linked to them: sucking in relation to oral activity, retention/expulsion for anal erotism.

The specification of infantile genital organization as phallic organization nevertheless shows clearly that the prevalence of one erogenous zone is inseparable from a certain mode of symbolic organization. The Oedipus complex is organized around the idea of castration, which is represented in the unconscious as castration of the penis (Perron and Perron-Borelli, 1996). The loss of the breast and feces that are specific to the oral and anal stages can also be considered as early symbolic forms of genital castration.

The relationship between weaning—as implementing the absence of the mother—and the Oedipus complex introduces the structural point of view, which relativizes the developmental model of the stages and gives it its best perspective (Brusset, 1992).

In the normal evolution of sexuality the component instincts of childhood are progressively integrated into the genital sexuality of the adult. What remains of them is found in the foreplay that precedes the sexual act proper.

The potential for stimulation of these pregenital erogenous zones remains present in the body and in the mind and they tend to be reactivated on the occasion of later sexual experiences. Their degree of erotism is integrated into the genital sexuality of the adult. Excessive repression of these residues from the infantile period can lead to neurotic symptoms. Similarly, what persists in a prevalent and manifest manner in the perversions is repressed in neurosis. Hence Freud's famous aphorism: "Neurosis is the negative of perversion."

The phases Freud described between 1905 and 1923 correspond to successive organizations of the sexual instinct under the primacy of a given erogenous zone: the oral phase, sadistic anal phase, infantile genital or phallic phase, followed by the genital phase after puberty. He also distinguished at the same time the different stages leading from autoerotism to full object love, that is, the progression from autoerotism, narcissism, toward the homosexual or heterosexual object choice.

Three points deserve to be raised here in order to provide a better definition of the notion of psychosexuality as envisaged by Freud.

1) The body is first and foremost considered as the seat of the instincts (drives) and the source of the exci-

tations aiming for satisfaction. In the *Three Essays* he makes a point of defining infantile sexuality as a criterion for organ pleasure and autoerotic satisfaction. However, in the course of the following years he integrated his earlier discoveries about the role of fantasies into this. He showed, specifically, how the fantasy works "by integrating the attachments of infantile sexuality can, depending on the case, result in conscious formations (daydreaming, for example) or, on the contrary, formations that are repressed into the unconscious" (Perron and Perron-Borelli, 1996).

2) It should be noted that these infantile manifestations of sexuality only come to play their full role "après coup." The adult pervert's exclusive fixation on certain components of infantile sexuality must be understood as a regression and a return to pregenital fixations.

3) Finally, infantile sexuality culminates toward the fourth or fifth year of life, the age when sexual tumult gradually enters a latency period, and is not reactivated until puberty when it leads to adult sexuality in the context of general maturity. There is therefore at this stage a halt, a decline in psychosexuality, and this period is then subjected to the infantile amnesia of the latency period. Freud related this diphasic establishment of sexual life, which can be observed only in human beings, to events in humanity's prehistory.

In any case, it is during the period of latency "that are built up the mental forces which are later to impede the course of the sexual instinct and, like dams, restrict its flow" (1905d, p. 177).

After the *Three Essays*, Freud gave the oedipal conflict its full organizational value, normal libidinal development being defined in psychoanalytic theory as the integration of the polymorphously perverse aspects of infantile sexuality under the primacy of the genital organization.

Following the *Three Essays*, Freud's successive contributions (1913–24) continued to expand on the general outline of the stages of libidinal development.

Karl Abraham tried to find the etiopathogenic basis for all of psychopathology in this model. He distinguished two stages within each of the first two phases (oral and sadistic oral, anal and sadistic anal) and he further stressed the link existing between the specific erogenous zone and the modalities of object relation particular to it.

Many authors after him, such as the proponents of Ego-Psychology (Heinz Hartmann, Ernst Kris, and Rudolph Loewenstein), used the outline of libidinal development and made it a major element in a genetic psychology that could be integrated into a general psychology. Others, on the contrary, particularly in France (Jean Laplanche and Jean-Bertrand Pontalis; Brusset, 1992; Perron, Perron-Borelli, 1996) insisted on the importance of the notion of organization. Each stage or phase of development creates a structure, in the modern sense of a self-regulated functional system tending toward equilibrium. Each of these phases in psychosexual development organizes not only the present state of mental functioning but also its future state. Infantile genital organization therefore defines the oedipal phase as the great organizer of mental functioning, laying down in the infantile phase of sexuality what will become the genital organization of the adult.

## **PSYCHOSOMATIC**

It is difficult to provide an exact definition of *psychosomatics*. To some extent the term itself already indicates a theoretical bias. It joins together the normal or pathological dynamics of both mental and somatic structures and assumes their close interaction. According to Pierre Marty, psychosomatics is the clinical observation of individual mental or somatic organization, disorganization, and reorganization, the attempt to draw from those observations theoretical findings, and the practical application of those findings to the therapeutic situation. If considerably broadened, *psychosomatics* would involve a global understanding of what it is to be human.

The term *psychosomatics* appeared in 1818 in the work of J. C. H. Heinroth, a German psychiatrist, and reflects a naturalist and vitalist approach to medicine. The context was formalized in 1945 by British psychologist James L. Halliday. The word has been in use since then among a wide range of practitioners, often with different interests. In the United States it is often referred to as psychosomatic medicine.

Prior to these developments, the interaction of *psyché* and *soma*, both within and beyond the context of philosophy and religion, reflected a vague association of the term with organic disease. It has been said (Kamieniecki) that “the history of medicine has written the prehistory of psychosomatics.” This prehistory has gradually distinguished psychosomatic medicine, in various socio-cultural contexts, from its philosophical, mystical, and religious corollaries, the *Corpus Hippocraticum* being a good example. Since then there has been a continued effort to identify the links between “the ontological unity of being and the phenomenological duality of its operation.”

This project, which has become for some researchers an original and fundamental discipline, can be considered part of a psychoanalytic framework, for it “consists in subjecting the somatic to the same dynamic and the energetic considerations that govern the life of individuals undergoing analysis,” according to the authors of *L'investigation psychosomatique* (Psychosomatic investigations; Marty, M'Uzan, and David). It must be noted that this project has generated no consensus, since it is a matter of applying these principles to the field of organic disease from the standpoint of psychoanalysis, a concept that has its detractors. Psychosomatics relates to the human indi-

vidual in its concrete being, living and sexual, acting through its own body and mental organization—including the conflict within the individual movements between life and death (Marty)—and where illness is an incarnation of the logic governing the living being.

In the area of organic disease, where research in psychosomatics has been directed, what has been referred to as the “psychosomatic phenomenon,” the interaction of psyché and soma, remains problematic and has led to numerous claims that have further confused the concept: psychogenesis, generalized conversion, somatization, and so on, not all of which have the same heuristic value. Somatization, seen as the result of a process in which mental causality (in the broad sense) plays a role, has become a doctrine for some. However, the real problem and focus of interest for the psychosomatic psychoanalyst, aside from any reactive mental disturbances, remains the discovery of a process for understanding and interpreting the reality of the disease, any possible exacerbation, and its resurgence in times of crisis. This entails the question of causal factors, while at the same time giving medical factors their due. It therefore includes the notion of a possible psychic causality that would interweave two histories of pathological alteration that belong to different orders but whose interactions are not purely random. When the two fields do not interact, there is no psychosomatic phenomenon, only the evolution of somatic morbidity along biological lines. The possible psychic causes remain an open question; these may be neither necessary nor sufficient but cannot be overlooked, even if we do not believe in psychogenesis or a limited determinism, and even if we feel that the “constructed meaning” of a symptom is not the cause or the origin of the disturbance.

Freud was not overly concerned with a strictly psychosomatic approach to disease, but in 1923 he wrote, “According to the indications of some analysts, the psychoanalytic treatment of obvious organic disturbances is not without a future, since it is not unusual for a psychic factor to play a role in the genesis and persistence of these affections” (1923a [1922]). The libidinal organization points to the somatic as a source; the description of actual neurosis and its underlying hypotheses (for some this is related to the so-called process of somatization); the idea of libidinal stasis identified in the organic disease; and the emergence of the id (the term originates with Groddeck, a

precursor of psychosomatics according to some authors)—all these theoretical hypotheses, after being reworked, have led to the conclusion that Freud was also a pioneer in this field.

More recent interest in psychosomatics can be traced to the investigations of the American researchers Helen Flanders Dunbar and especially Franz Alexander during the 1940s. Their work helped develop later research and elements of it can be found, in modified form, among psychosomaticians and clinical psychologists. The so-called New York School (Dunbar) was associated with the culturalist movement of the time. They related organic pathology to pre-morbid “personality profiles,” specific to certain clinical symptoms: the structure of the personality would expose a specific part of the organism to external aggression and would prepare the way for somatization. Dunbar also hypothesized an emotional dynamic, derived from Darwin, who assigned a defensive goal to the emotions, coupled with the affective repercussions within the body itself. Dunbar was one of the first to take a neovitalist approach—the degradation of vital energy—to developing an understanding of psychosomatics. For him, the exclusion of conflict outside consciousness would result from a short-circuiting of the mental (though he does not use this word), through subcortical mechanisms. This school of thinking concluded that psychoanalysis alone would provide a deeper understanding of the processes in question.

Franz Alexander believed that the personality profile alone was not sufficient to determine causality. He centered his hypotheses on the notion of a “specific psychodynamic constellation.” This constellation was based on basic reactions that ensued following an increase in tension within the psychic apparatus, reactions that encompassed the autonomic nervous system and the subcortical stem, along with basic dispositional characteristics. The idea of psychosomatic medicine (the title of his first book) was both established and subject to criticism because of its over-reliance on biology. But internal conflicts and emotional reactions culminating in physical changes also played a role. This sequence led to the concept of “organ neurosis,” corresponding to the abnormal stagnation of a quantity of energy in an organ or system. These connections between affective states and somatic behaviors resulted in “psychosomatic patterns” that, from functional disturbances, could produce organic symptoms. One finds in his work profound intuitions that have con-

tributed to contemporary theory in spite of his overly biological approach and pertinent suspicion about the concept of organodynamics, a concept picked up by Henri Ey.

During the 1960s, two approaches to psychosomatics appeared in France. These were the sources of a number of subsequent developments that altered, weakened, and expanded certain hypotheses, and modified the clinical and therapeutic approach to the field. Jean-Paul Valabrega promoted an approach to somatic symptoms through a model of generalized conversion isolation, whose rediscovered source in fantasy would give meaning to the symptom. For Valabrega the isolation of the conversion phenomenon from its source and its specifically hysterical environment resulted in the development of manifestly visceral symbolizations, which originated in conversion phenomena and were unexplained by reference to a hysterical kernel common to all neuroses. In this context of “psychosomatic conversion,” Valabrega insisted on the resurgence of the fantasy at the very site from which it had been expelled, a hypothesis associated with the general problem of the accessibility of the symptom to symbolization and meaning. The psychosomatic symptom was said to constitute a physical barrier that had to be crossed by separating it from its hidden fantasy elements, which had been kept in check. “In other words, according to the hierarchical etiology, the specificity is defined less by physiopathological or psychopathological mechanisms than by the singular mode of organization which underlies both mechanisms” (1966/1974).

In 1963, the so-called psychosomatic school of Paris (Pierre Marty, Michel de M'Uzan, Christian David, Michel Fain) formalized its approach, based on the notion of deficit, where a mental loss (fantasy, oneiric, associative, the loss of mental defenses) was seen as paradigmatic. This concept meshed satisfactorily with the findings of psychoanalysis, especially in the area of psychic economy, where the somatic symptom is asymbolic and does not produce meaning. Their approach gave rise to a number of developments. After Pierre Marty introduced the concept of *operative thought*, other clinical concepts emerged, such as *essential depression* and *chronic disorganization*, and Marty insisted on the reorganizing value of the regression/fixation system. The process of disorganization, triggered by trauma and incapable of stopping the regression/fixation system, became the crux of the “somatization process.” However, regression can also be pathogenic and reversible

illnesses are conceivable, in terms of points where disorganization is halted at various stages of somatic fixation. This model, based on monist, evolutionist, and neovitalist principles, and extensively described in Marty's writings, presents an internal coherence that has made it a classic, although not always accepted, reference in the field.

## **PSYCHOSOMATIC LIMIT/BOUNDARY**

The term *psychosomatic limit* (or *psychosomatic boundary*) designates the virtual demarcations and separations between the space of the body and that of the psyche. At the same time this boundary serves as a contact barrier where, if the person has good mentalization, psychic phenomenon take on symbolic or metaphorical significance at the somatic level or, conversely, somatic excitation is registered in the psyche.

This concept cannot be grounded in a monistic account of the *psyche-soma* (Pierre Marty, the Paris

School), but should rather be understood as André Green explained in *Somatization, psychanalyse et science du vivant* (Somatization, psychoanalysis, and the science of the living; 1994), in terms of a “structural dualism that comes out of a de facto monism . . . in which the psychic apparatus is posited as being rooted in the nervous system but as developing its own distinct properties from there, which data based on biological structures alone cannot account for.” The concept of the psychosomatic limit is present but seldom explicit in the work of Sigmund Freud. The notions of the drives, conversion, and the ego bring this concept into play. One of its synonyms, the word *frontier*, appeared for the first time in *Three Essays on the Theory of Sexuality* (1905d) in connection with the instincts; there Freud described an instinct as “the psychical representative of an endosomatic, continuously flowing source of stimulation. . . . The concept of the instinct is thus one of those lying on the frontier between the mental and the physical” (p. 168). Instinct, representing a source of internal excitations, thus becomes one of the forms of the body’s language. In “Instincts and Their Vicissitudes” (1915c), Freud again used the word *frontier* to convey the idea of a limit or boundary: “An ‘instinct’ appears to us as a concept on the frontier between the mental and the somatic . . . as a measure of the demand made upon the mind for work in consequence of its connection with the body” (pp. 121–122). The psyche works only because of its link with the corporeal, because without this virtual contact barrier, the psyche would be nothing and the body would be only an object.

In *Studies on Hysteria* (1895d), Freud dealt particularly with conversion, but that concept was defined for the first time in “The Neuro-Psychoses of Defence” (1894a): “In hysteria, the incompatible idea is rendered innocuous by its *sum of excitation* being transformed into something somatic. For this I should like to propose the name *conversion*” (p. 49). The psychosomatic limit is crossed and there is the mysterious “leap from the psychical into the somatic” that conversion involves owing to “motor innervation” (p. 49).

The ego, as described in the second theory of the psychic apparatus (1923d [1922]), is above all a bodily ego; it is not only a surface being, but it is itself the projection of a surface. It represents the surface of the mental apparatus. If the ego is a surface with both psy-

chic and somatic limits, it can be ruptured, as when physical pain results in a heightened narcissistic cathexis of the body that empties the ego and leads it to defend and reconstitute itself.

Notions related to the psychosomatic boundary can be found. For example, there are the “transitional phenomena” described by Donald Winnicott (1971), an internal space and external reality where body and language, which together support this space, establish an intersection between psyche and soma. Babies experience burps and anal noises. “It can be supposed,” Winnicott writes, “that thinking or fantasies acquire a link with these functional experiences.” In his definition of *holding* (1965), Winnicott linked tonus (the physical holding of the body) to processes that may appear to be physiological but that in fact originate in the infant’s psychology.

The concept of the psychosomatic limit, though not fully developed in Freud’s writings, nevertheless turns up there in an essential way. In his 1994 book, Green described the concept as implicitly present whenever the body expresses itself directly within the framework of the psyche: in functional signs, conversion, actual neuroses, and psychosomatic pathology.

## **PSYCHOTERAPIA (PSIXOTERAPIJA-OBROZRENIE VOPROSOV LECENIJA I PRIKLADNOJ PSIXOLOGII)**

In Moscow in 1909 the military physician Nikolai A. Vyroubov founded the review *Psychoterapia, A Review of Questions of Therapy and Applied Psychology* with a view to introducing Russian practitioners to western schools of psychotherapy.

The thirty issues of the review (which appeared from January 1910 to the end of 1917) focused increasingly on psychoanalytic theories but they also presented the work of Freud's great rivals, like Paul Dubois and Johannes Marcinowski. Readers were also informed of the split brought about by Alfred Adler (1911). The review enjoyed the support of the very influential Moscow Psychiatric Circle and the eminent psychiatrist Vladimir P. Serbski (1858–1917), who had decided to dissociate himself from the nosological and purely organicist orientation of Kraepelin's school.

Completing the work of the "Library of Psychology and Psychoanalysis," also organized by Vyroubov and which published Freud's major works, *Psychoterapia* translated no fewer than twelve of Freud's short technical texts. It also introduced its readers to the works of Adler, Ferenczi, Jung, Rank, Reik, Sachs, and Stekel. The orthodox tendency of the review, directed by doctors Nikolai Ossipov and Mosche Wulff, gave an account of the first Russian attempts to apply the method of free association to clinical neurosis. But it also published works of psychoanalysis applied to subjects as diverse as political jousting, stage fright in actors, and folklore. Supporters of the breakaway Adlerian school, being more politicized, criticized the "monoetiology" (sexual) of the neuroses.

Just before it disappeared, the review had begun to manifest great openness to the medical and scientific culture or the West, and also to its literary and artistic culture. There was no other Russian review of psychoanalysis until 1991—not even during the short and amazing period of Bolshevik psychoanalysis (1920–1930). As a mouthpiece for democratic and liberal ideals, *Psychoterapia* was of capital importance for the peaceful acceptance of psychoanalysis in Czarist Russia.

## **PSYCHOTHERAPY**

Psychotherapy is a method for the treatment of psychological problems, which are often expressed somatically.

Therapies can be classified following various models. In the cathartic model, the patient is urged to speak, in order to expel or get rid of his suffering. The therapist favors the act of communication over the content of what is expressed. In the reparative model, the therapist tries to help the patient by bringing love and understanding to cancel out the prejudice he has been victim of or to make up for some internal deficit. With the educational model, the therapist guides the patient in the "right" direction, advising him as to his life choices. He "corrects" the mistakes of nature, parental education, or social environment.

Freud demarcated himself dramatically from hypnosis and cathartic post-traumatic abreaction in developing an original psychotherapeutic dimension, centered on the exploration of the unconscious, the study of psychic functioning and intrapsychic conflicts, and transference-counter-transference relation (Ellenberger, 1970). He emphasized psychic reality understood through the reality of narrative. Accordingly, the psychotherapy to be discussed here is psychoanalytic psychotherapy, situated within the context of the theory, technique, and framework of psychoanalysis.

The term *psychotherapy* surfaced for the first time in 1872, while the term *psychoanalysis* came to be known only in 1896. But it wasn't until 1905, in his article "On Psychotherapy" (1905a [1904]) that Freud clearly distanced himself from hypnosis by opposing the cathartic method to the analytic method. For a number of decades, he had used the terms *psychoanalysis* and *psychotherapy* interchangeably, but shortly before 1920 he abandoned the term *psychotherapy* definitively, qualifying his method from then on as *psychoanalysis*. This abandonment occurred after the defections of Alfred Adler, Wilhelm Stekel, and Carl G.

Jung and, in a second stage, his differences with Otto Rank and Sándor Ferenczi. In effect, some of those in Freud's circle were advocating a more active attitude on the part of the psychoanalyst to accelerate the psychoanalytic process as well as to shorten its duration. A reaction was not long in coming: Ernest Jones and Edward Glover emphatically denounced any deviation from a traditional treatment, and any psychotherapeutic approach, such as a return to pure suggestion of the preanalytic period (Robert Wallerstein). This traditional position was the "official" one of the psychoanalytic movement for a very long time. Nevertheless, in the 1950s the term *psychoanalytic psychotherapy* gained currency among psychoanalysts themselves, who came to believe that certain changes had to be made in the framework of the classical psychoanalytic model, which was not appropriate for the psychopathology of some patients.

As of 2005, questions about the differences between psychoanalytic psychotherapy and psychoanalysis are still posed in terms of process: how, for example, could the psychoanalytical process be influenced by reworking the framework? The face-to-face position implies seeing the analyst, being able to observe his gestures and unconscious corporal reactions, to hang onto his every word and look into his eyes. Likewise, not being seen by the analyst can result in the patient's feeling lost, cast into the abyss, or on the contrary allow him to feel emotions that would be blocked by a face-to-face expression. However, these differences in formal framework (frequency of sessions, face-to-face or couch-armchair, more or less active position of the psychoanalyst, etc.) are insufficient, in themselves, to characterize the type of process underway. In any event, according to René Roussillon (1986), a psychoanalytic approach can only explore certain portions of the psyche. Even where the choice of the framework (psychotherapy or psychoanalysis) favors a psychoanalytical approach, this is not always necessarily the same one. Finally, the psychotherapeutic process is characterized by a transference of partial objects to the psychoanalyst while, in the psychoanalytical process, these partial transferences would be worked through until there was a full development of the transference neurosis.

Other authors have brought out differences in therapeutic aims. Ideally, in psychoanalysis the framework should allow exploration of the patient's unconscious with the psychoanalyst following the patient as far as

he is able to go. According to this very strict definition, psychoanalysis does not, a priori, aim at a therapeutic goal. Instead, the therapeutic result emerges from the psychoanalytic process. By contrast, psychotherapy does imply a goal: to diminish the suffering of the patient, allowing him to return to work, and so on. However, these differences are not always so clear-cut in the reality of practice among psychoanalysts and psychotherapists. Whatever technique is chosen, standard treatment or face-to-face, the psychoanalyst has a "psychoanalytic function," so that any psychotherapeutic approach undertaken by the psychoanalyst involves psychoanalytical work.

Psychotherapy cannot be isolated from its social context. After the Second World War, the development of social health care programs allowed compensation for psychiatric care and the establishment of a variety of facilities for the treatment of specific pathologies. Many of the professionals practicing in these institutional settings were trained in psychoanalytic psychotherapy by psychoanalysts working in the field, or else were educated in teaching institutes that structured their curricula in accordance with psychoanalytic psychotherapy. These professionals engaged in personal psychoanalytic work without, necessarily, matriculating in the training courses of psychoanalytic societies; but very often a veritable analytical process developed with patients that they were treating in their institutions.

Accordingly, the wish of Freud (1919a [1918]) has been fulfilled, "to alloy the pure gold of analysis freely with the copper of direct suggestion" (p. 168) to create "a psychotherapy for the people" (p. 168), and to alleviate a greater portion of "the vast amount of neurotic misery which there is in the world" (p. 166), which the small number of psychoanalysts cannot greatly affect. Clearly Freud wanted to see the traditional treatment adapted to treat a greater number of patients as soon as "the conscience of society will awake" (p. 167). The concern to preserve psychoanalytic thought in some institutional form has led national societies of psychoanalytic therapy to create organizations like the European Federation for Psychoanalytic Psychotherapy (EFPP).

Psychoanalysis and psychoanalytic psychotherapy, and their particular adaptations (child psychoanalysis, group psychoanalysis, analytical psychodrama, psychoanalytical couple or family therapy, etc.) constitute a

“psychoanalytic field,” very different in nature from therapeutic techniques. The latter, basically anti-analytic, may be considered as “an ensemble of ready-made counter-transference approaches meant to function as institutional defenses, as a system of alleviating anxieties prompted by the relation to the other,” representing “group-oriented ideologies” (Roussillon, 1986).

The psychoanalytical approach often requires much time since it favors the process rather than the suppression of symptoms, which is the case with non-analytical therapeutic techniques. In the interest of budgetary considerations, social agencies that reimburse psychic treatment try to limit its duration or the amount of compensated sessions, or else to favor approaches that aim to eliminate symptoms very quickly, without taking account of their function in the overall psychic economy of the patient. The psychoanalytical approach runs the risk of losing its liberty and revolutionary quality in submitting overly to social constraints. Countries that seek to integrate the psychoanalytic approach in the master plan of their treatment policies risk making it shed its special and irreverent identity, becoming increasingly therapeutic, in the sense of “suppressing symptoms” (Frisch, 1998). The notion of *conflict*, central in psychoanalysis, has consequently been introduced in the psychoanalytic movement on issues relating to its future and its identity: it must either evolve toward isolation to maintain its purity (psychoanalysis), or adapt to social constraints to survive (psychoanalytical psychotherapy), but at the risk of losing its soul.

## PSYCHOTIC DEFENSES

Psychotic defenses are psychic processes involving unconscious, or more-or-less conscious, attempts to deal with reality. They take the form of disavowal or withdrawal as the subject tries to avoid or circumscribe conflicts encountered in his relationship with the external world.

In “The Neuro-Psychoses of Defense” (1894a), Freud wrote: “There is, however, a much more energetic and successful kind of defense. Here, the ego rejects the incompatible idea together with its affect and behaves as if the idea never occurred to the ego at all. But from the moment at which this has been successfully done the subject is in psychosis” (p. 58)—to which he added in 1896 that “*projection*,” as a “defensive symptom,” signified “*distrust of other people*” (p. 184).

The chief psychotic defenses in Freud’s view were *foreclosure* (*Verwerfung*, reformulated by Lacan in 1956), *projection*, and *delirium*. All of these were in evidence in Freud’s analysis of the case of President Schreber (1912a). The *disavowal* (of reality) as a defense (1927e) was described in the context of the castration complex, particularly in the case of fetishism.

The work of Melanie Klein underscored the major role of the defense mechanism of projective identification in psychotic functioning. Such post-Kleinian authors as Wilfred R. Bion and Donald Meltzer viewed it also as an essential mechanism of psychic growth. Later, other mechanisms became the subject of important conceptual developments: projection, splitting (of ego or object), and the disavowal/idealization pair.

Psychic defenses are not confined to psychotics. Since Bion, they have been deemed a part of the mental functioning of every individual, as long as they have not yet acquired an invasive and systematic quality.

## **PSYCHOTIC/NEUROTIC**

The relationship between the neuroses and the psychoses, or between the neurotic sphere and the psychotic one, cannot be studied from a psychoanalytical point of view without clarifying the meaning of the two terms, considering their reciprocal ties as described in the work of Sigmund Freud and Karl Abraham, and, lastly, reviewing their status today.

With regard to the term *neurosis*, the idea that medicine ought to set aside a nosological and etiopathogenic category to cover conditions presenting functional impairments, in the absence of manifest lesions, which affected the nervous system but not the

brain or any other organ, arose in the classical period in the work of Thomas Willis (1622–1675) and Thomas Sydenham (1624–1689). These authors included as neuroses hysteria, to which they denied a uterine origin, and hypochondria, to which they denied the hepatic genesis attributed to it since antiquity. The word *neurosis* itself was coined in 1777 by William Cullen (1710–1790) to identify a class of generalized as distinct from localized disease which along with the neuroses included fevers and cachexias. Defined as sensory and motor attacks without fever or local disorder, Cullen's "neuroses" encompassed comas, adynamias (to which he assigned hypochondria), spasms (including hysteria), and vesanias.

Nineteenth-century usage veered back and forth between a narrow definition of neurosis limited to hysteria and hypochondria and a broader meaning that embraced syncope, tetanus, epilepsy, chorea, paralysis agitans, and neuralgias. During the last quarter of the century, however, in part due to the advent of dynamic psychology (Pierre Janet, Sigmund Freud) and of semiological neurology (Jules Déjerine, Joseph Babinski, Gordon Holmes), a new system of classification began to take form. Matters were helped, too, by the new discipline of clinical neurology, which laid claim to epilepsy, chorea, Parkinson's disease, and cerebellar syndromes while recognizing psychiatry as the sole proprietor of the neuroses (with the exception of hysterical paralyses, which called for cooperation between the two specialties). Thenceforward the neuroses were understood either in a simple way, as by Pierre Janet, who distinguished only between hysteria and psychasthenia, or in the more elaborate manner of Freud, who contrasted the actual neuroses (anxiety neurosis, neurasthenia, hypochondria) with the so-called defense or transference neuroses (conversion hysteria, phobic neurosis, obsessional neurosis), using criteria that were certainly descriptive but also psychopathological in character.

The term *psychosis* appeared later. Introduced in 1845 by Ernst von Feuchtersleben (1806–1849), it was at first a very general designation for illnesses of the mind ("*Geisteskrankheiten*") as opposed to the neuroses, attributed at the time to malfunctions of the peripheral nervous system. Psychosis thus became synonymous with mental alienation in the most general sense. During the last quarter of the nineteenth century and the first half of the twentieth, when psychiatry started emphasizing the irreducible variety of

mental illnesses, *psychosis* covered all cases within that domain which were clearly not of the nature of neurosis, of dementia, or of mental retardation—in other words, the label was applied to almost all institutionalized mental patients. Psychoses were considered either acute (confusional states, delusional episodes, mania, melancholia) or chronic (schizophrenia, paraphrenias, paranoia), but no answer was offered to the question whether these categories were discrete or whether they were variations expressing a single underlying (psychotic) disease process. (Not to mention issues of etiology or the inflated role assigned to general paralysis.)

In the development of psychoanalysis, the relationship between the psychotic and the neurotic was at first considered a relationship of exclusion, a veritable gulf separating the one from the other, just as, in zoology, vertebrates were radically separated from invertebrates. Little by little, however, a more nuanced view prevailed: for one thing, the two realms were brought much closer together; for another, the question was raised whether a particular place should not be set aside for perversions. Even greater difficulty was met with later, when a pigeonhole had to be found for the borderline states identified in apparently neurotic subjects who, after being accepted as such for psychoanalysis, decompensated during the treatment in a psychotic manner (Kernberg, 1975).

In Freud's early works, those collected in the first two volumes of the *Gesammelte Werke*, a radical distinction between neurosis and psychosis was of a piece with his inaugural discoveries: the neuroses were said to reflect conflicts within the subject whose original sense escaped him, conflicts echoing others in earliest childhood, repressed but accessible in general through a transference relationship and hence accessible to psychoanalysis; the psychoses, by contrast, were related to conflicts between the subject and the outside world, hardly or not at all accessible via a transference relationship, and for that very reason contraindicating psychoanalytic treatment, even though the discourse of psychotic patients might bring directly to light aspects of the unconscious that emerged in neurotics only after many psychoanalytic sessions.

Freud continued to maintain this point of view a little later, in the third part of his commentary on Daniel Paul Schreber's *Memoirs* (Freud, 1911c [1910]), when he put forward the idea that the pathological process common to the various chronic delusional conditions

was denial of homosexual wishes—a mechanism very different from those met with in neurosis.

The work of Karl Abraham presents what is probably the most careful psychoanalytical account not only of the relationship between the neuroses and the psychoses, but also of the relationships between each of them and libidinal fixations and regressions, as well as those of individual neuroses and psychoses to one another (1927 [1924]). Abraham showed in the clearest way, albeit in a nuanced and quite unschematic way, how the received clinical distinctions between schizophrenia, paranoia, mania, and depression might be seen as corresponding to the subdivisions of the oral and anal stages, and how likewise the neuroses related, each after its own fashion, to the genital stage; thus the empirical level of clinical experience could find theoretical support in the psychoanalytic knowledge of libidinal development. This standpoint tended therefore to buttress the view that the neurotic and psychotic spheres should continue be treated as separate, because their respective connections with the libidinal stages were quite distinct. At the same time, as Abraham noted, especially with respect to melancholia and obsessional neurosis, links had to be recognized between particular psychoses and particular neuroses, as for instance the link between schizophrenia and hysteria.

Later on, both the relative simplicity of the neurosis/psychosis distinction and its tendency to become absolute were contested, and the dividing-line was once more brought into question. This clear-cut division had long served a didactic purpose in the professional training of analysts, but even for the most vociferous partisans of the primacy of the totality—of the Germanic *Ganzheit*—training could hardly be founded on a complete absence of distinctions; indeed it was arguable that the usefulness of this clear opposition resided solely in its educational value, and that it should therefore be discarded once training was successfully completed.

The development of his conception of the perversions led Freud to abandon the idea of the primacy of fixation to infantile sexuality (1905d), along with the corresponding view of perversion as the reverse of neurosis, and to assign a major role to the disavowal of reality and the splitting of the ego (1940a [1938]). Since these processes were closely akin to those in play in the psychotic realm, this meant the end of the tidy arrangement that had prevailed hitherto. A difficult choice remained between two possible revisions: to

reincorporate the perversions into the psychoses, or else to abandon the neurosis/psychosis dichotomy by giving the perversions their own category between the other two. The latter course was liable to jeopardize any strict distinction, for it is well known that the only good opposition is a binary one.

## **PSYCHOTIC PANIC**

In the psychotic part of the personality, according to Wilfred Bion, anxiety changes into psychotic panic.

Earlier, Melanie Klein (1935) had put forward the view that the first anxieties are psychotic in content and that in the normal development of infants there is a combination of processes by which primitive anxieties of a psychotic nature are bound, worked through, and modified.

Bion investigated the nature of the processes by which anxiety is modified during the 1950s and 1960s. He saw projective identification as the means by which the infant communicates primitive anxieties and emotions to the mother, and her reverie, that is, her containment with alpha function, as the process that modifies her infant's anxieties. If there is a pathological matrix between infant and mother of an adverse endowment and adverse nurture so that the infant's primitive and violent emotions find no container, a primitive disaster is felt to have occurred in which the container has been destroyed and anxiety has turned into psychotic panic. A nameless dread, as Bion also calls psychotic panic, is returned to the infant which threatens to suffuse and annihilate the personality, and from then on development takes a divergent course.

Psychotic panic is the origin, the O, of the ensuing transformation in hallucinosis, rather than, as in the neurotic personality, transformation in thought. Defenses are adopted to avoid the experience of panic by the evacuation of ego functions capable of the experience, and there is an explosive projection of ego pieces, images, beta-elements, and objects, into a space that has no limits.

## **PSYCHOTIC PART OF THE PERSONALITY**

Clinical discoveries made in work with psychotic patients enabled Wilfred R. Bion to formulate a set of

highly original hypotheses about psychosis. He states these in a classic paper “Differentiation of the psychotic from the non-psychotic personalities” (1957). His hypotheses are that the psychotic part of the personality arises from “a minute splitting of all that part of the personality that is concerned with awareness of internal and external reality, and the expulsion of these fragments so that they enter into or engulf their objects.”

In this way the psychotic personality constructs a universe of bizarre objects in which he is unable to think and suffers existence in a state of hallucinosis. The psychic preconditions in the psychotic personality are: a preponderance of destructive impulses, a hatred of internal and external reality, and the dread of imminent annihilation, all of which lead to the precipitate formation of thin object relations tenaciously held.

The psychotic personality develops “in a manner markedly different” from the neurotic personality. In the same paper Bion continues: “The difference hinges on the fact that this combination of qualities leads to minute fragmentation of the personality, particularly of the apparatus of awareness of reality which Freud described as coming into operation at the behest of the reality principle, and excessive projection of these fragments of personality into external objects.” Because of the destructive attacks on his ego and on any thought that could serve as a link between two objects, and, in addition, the bizarre nature of his world, he feels unable to restore either himself or his objects.

In the psychotic personality projective identification, the primitive defense mechanism discovered by Melanie Klein (1946), is not merely excessive, but has also a different role in that it becomes the predominant psychic operation: It replaces the processes of introjection and regression, and the structuring of the mind performed by repression in the neurotic personality.

In Bion’s view, contact with reality, at least in those patients who are able to attend for analysis, is never entirely lost. He considers it is important clinically to find the neurotic personality which is concealed by the psychotic personality, and also to find the psychotic personality, which exists in everyone.

## **PSYCHOTIC POTENTIAL**

The notion of *psychotic potential* was created by Piera Aulagnier, who contributed significantly to the study of the sources of psychosis. Opposing the idea of a seed of psychosis that supposedly exists in every person, she explored the necessary conditions for the psychotic “solution” to be “chosen” by the subject. These conditions were necessary, but not sufficient in themselves, to produce an out-and-out psychosis, the latter being dependent on chance happenings in the life of the subject. Meanwhile, the psychosis would be “potential.”

The notion of predictability is present on two levels in psychotic potentiality. Firstly, it can be understood as a link between, on the one hand, the history and prehistory of a particular subject (on the level of both reality and fantasy), and, on the other hand, the subject they have become by the time they have been characterized in terms of psychopathology. Potentiality is then understood in the temporal sense: as the relation between a past and a present. It then leads, following the same line of argument, to the question of whether the future is predictable on the basis of the present.

Further, psychotic potentiality can also be understood not just in terms of psychogenesis but also in terms of the Aristotelian opposition between potentiality and act: we can be something potentially without this ever being actualized. The idea of psychotic potential is not the result of a diagnosis made on the basis of observable criteria: it is, first and foremost, a counter-transferential feeling, an extremity or an appeal for help that is felt as strange, even dangerous, by the analyst who is able to empathize. It is particularly important that attention be focused on this dimension, right from the first sessions, for the purpose of forestalling

the risk of failure of certain functions linked to the progress of the treatment itself. Aulagnier emphasized the partial character of this process: It is as if the psyche of the patient could function normally, that is to say without being in flagrant contradiction with the common mindset of other subjects in the same culture, while at the same time containing zones of shadow in which a totally different and original kind of functioning operates.

In *La Violence de l'interprétation* (*The Violence of Interpretation*), of 1975, she defined this concept as “the result of the fixation of a primal delirious thought, whose function it is to attempt to reconstruct a fragment missing in the discourse of the other.” It seemed then that psychotic potential would constitute a “solution” to a conflict experienced by the subject in childhood—a conflict that was too early and intense, causing so much suffering that the psychic work involved in surviving turned into “madness.” This is not the only solution. Aulagnier offers three others: the choice of death, in the form of Thanatos triumphant; the development of infantile autism; and the attempt to flee from any thought, any desire which would lead back to the conflict that was the cause of so much suffering. This latter solution is a partial mutilation, but it is not really constructed like a psychotic delirium. Because of this third possibility, the notion of psychotic potential transcends the childhood/age opposition. Rather than harboring, from childhood onwards, such delirious thoughts, the subject can try to whitewash everything that could prompt suffering or conflict. Yet this avoidance itself, which is to say the delirious “solution” itself, which may be understood as preferable to suicide, nonetheless establishes that such deeply troubled thoughts do exist.

Psychotic potential involves not only the setting up of a premature and primal, delirious kind of mentality, which can develop into psychosis in adulthood. It also suggests the idea of a flaw itself created by pushing away the delirious solution—a fault line that constitutes an invitation to delirium anytime the conflict situation is reactivated by events.

The theorization of psychosis by Piera Aulagnier is very different from that of Sigmund Freud, for whom the call to delirium is an attempt at reparation and reconstruction following a rupture between the self and reality (1924b [1923]). This rupture, according to Freud, is based on the “frustration, a non-fulfillment, of one of those childhood wishes which are for ever undefeated”

(p. 151). Contrary to neurosis, where the reparation is carried out at the expense of the id, reparation in psychosis occurs at the expense of the relation to reality. For Aulagnier, the conflict generating psychosis is not located on the level of desire, but on the level of the thinkable, that is to say of self-identification.

Behind the conditions of possibility for psychotic potential to be established, whether it turns into open psychosis or not, lies a particular situation that imposes on the subject a prohibition and/or an obligation to think something that contradicts the logic of the discourse of society. It is not society that transmits the contents of such thoughts; they result from a compromise that allows one to continue to cathect with reality, and to love objects. They amount to so many *para-decathexes*, a term coined by Aulagnier on the model of para-excitations. In extreme cases, the choices are limited: either real death, or psychic death; a decathexis such as the victory of Thanatos, or a delirious reconstruction.

To sum up the essence of psychotic potential, as Aulagnier defined it: at the source of delirious thinking there lies, on the one hand, an intolerable frustration, whose significance is linked to the question of the origin of the subject, the world, pleasure, and so forth; and, on the other hand, an unconquerable desire, which refuses to be reduced to silence and is connected with the identificatory needs proper to the self.

From her earliest texts until her most recent, Aulagnier has emphasized the fundamental quality of this need in these terms: Every self needs to think that its existence makes sense, that it is not, as Shakespeare says, “a tale, told by an idiot, full of sound and fury, signifying nothing.” If such meaning is lacking in the discourse of the one supposed to impart meaning, the father, delirious thinking will, in its primordial way, attempt to accomplish the reconstruction of the missing fragment. This reconstruction will be illusory, but it will be in conformity with the identificatory demands of the self.

## PSYCHOTIC TRANSFERENCE

The term *psychotic transference* describes the intense and primitive feelings experienced by some patients during analytic sessions; such experiences occur during periods marked by a deep regression, and they are totally real to the patient, which is why a number of authors speak in this connection of delusional or regressive transference.

The concept of psychotic transference is often used to evoke very intense, primitive or undifferentiated experiences and emotions based on part-objects. Some authors use this model in working with patients presenting psychotic crises. Others use it with neurotics, when the relation with the therapist displays primitive and regressive features which are taken to be “psychotic aspects of the personality.”

Freud at first argued, apropos of transference in psychosis, that in psychotics the libido had been withdrawn from the outside world, and that consequently no transference was possible (1914c). Later, however, he moderated this view: “Since then analysts have never relaxed their efforts to come to an understanding of the psychoses. Especially since it has been possible to work with the concept of narcissism, they have managed, now in this place and now in that, to get a glimpse beyond the wall... [T]he mere theoretical gain is not to be despised, and we may be content to wait for its practical application. In the long run even the psychiatrists cannot resist the convincing force of their own clinical material.” Freud noted in this context, in connection with those aspects of psychosis which allow for transference, that “Transference is

often not so completely absent but that it can be used to a certain extent; and analysis has achieved undoubted successes with cyclical depressions, light paranoiac modifications, and partial schizophrenias” (1925d [1924], pp. 61, 60).

In his treatment of psychotic patients, Herbert Rosenfeld (1965) discovered that they did in fact establish a transferential link with the therapist, and he called this phenomenon “transference in psychosis” or “psychotic transference.” He was the first to take an interest in this question after the fashion of Hanna Segal and Frieda Fromm-Reichmann. As for Wilfred R. Bion, when he discussed the psychotic personality, he was referring, in effect, to psychotic transference or delusional transference: “Since contact with reality is never entirely lost, the phenomena which we are accustomed to associate with the neuroses are never absent and serve to complicate the analysis, when sufficient progress has been made, by their presence amidst psychotic material” (1957, p. 267). Bion described the relationship to the analyst as premature, precipitate, intense, tenacious—and founded on projective identification (p. 266).

## PUBERTY

Puberty was originally defined anatomically and physiologically as the appearance of secondary signs of

sexual maturation that mark the beginning of the adolescent process which will put an end to the period of childhood that had been prolonged by the period of latency. The concepts of puberty and adolescence have been increasingly considered as belonging to the field of psychoanalysis only progressively.

Of course the chapter on the “Transformations of Puberty” in *Three Essays on the Theory of Sexuality* (1905d) is the essential text by Freud on this subject, but to ascertain the reason for the key place this stage assumes in metapsychological development, it is necessary to go back to the early hypotheses on trauma. The seduction theory formulated in the *Studies on Hysteria* (1895d) assumed in effect two distinct scenes separated by puberty. It is this breakthrough from the presexual (albeit already oriented by the phallus to the genital) which gives both chronological and logical meaning to the twin ideas of latency and deferred action.

For Freud therefore, above and beyond the impact it has on the body and the psychological implications of this, puberty is something that *operates*: initially as a real trauma, then later as a logical operand in the seduction-fantasy, where it served to delineate boundaries. That being said, the 1905 essay on puberty and all the preceding work was to be enriched by later discoveries, such as the 1914 theory of narcissism and, in 1924, the second topology and the death drive hypothesis.

What is at stake in puberty is clear from the outset: “With the arrival of puberty, changes set in which are destined to give infantile sexual life its final, normal shape. The sexual instinct has hitherto been predominantly auto-erotic; it now finds a sexual object” (1905d, p. 206). Freud then raises five questions, all of which are still being asked, on the nature of puberty: First of all, how is the erotic destiny of each person, perversion aside, determined by the way in which the pregenital drives are simultaneously placed in submission to and in the service of genitality, which is the sign of normality? Secondly, what is the role, necessary but not sufficient, of the “chemical” factor in causing sexual tension and pleasure, given that even neurosis “greatly resembles” a state of intoxication and want? Thirdly, according to the theory of narcissism how will ego libido and object libido be fused in this moment of anticipated tension and complementarity between the currents of love and sex? Fourthly, how is, in a final renunciation of bisexuality, the man’s “more logical”

development going to then be differentiated from the “involution” of the young woman who willingly rejoins her initial, oral sexual orientations at the same time as she accedes to genitality? Fifth and finally, in what way is the new sexual object, a semblance of the Other sex, at once both new and rediscovered on the basis of the primal objects, the ancestors of the Other sex? In his conclusion devoted to the risks associated with homosexual inversion occasioned by both familial and social milieus, Freud alerts us to the fact that this accession to a sexual relationship which assumes responsibility for the difference between the sexes, does not occur automatically.

For a long time after Freud puberty remained a secondary preoccupation for psychoanalysts. Instead, under the influence of child analysts and fueled in particular by the debates between Anna Freud and Melanie Klein, interest tended to focus on the relationship between earliest infancy and the oedipal period, with adolescence being considered as little more than the outcome of precocious determinants. On the other hand in the field of psychopathology, the side of adolescence, dissociated from puberty, concerned with the trials of socialization and its psychopathological failures, became the privileged focus of study in the texts on this period (Siegfried Bernfeld, August Aichhorn).

Only recently, and especially in Great Britain and France, has interest been renewed in puberty as distinct from the ensemble of adolescent processes, and designated as such as being their origin. Donald Winnicott was the first to recall that it is sexual maturation, not only social exigencies, which reactivate oedipal difficulties, giving rise to murderous and incestuous feelings which were all too easily repressed in childhood when they were unrealizable, and calling for a second oedipal working-through, subject to new ups and downs. Moses Laufer has elaborated on this approach by explicating the more-or-less pathological crises of adolescence using the concept of *breakdown*, reworked from Winnicott, but which is for Laufer a developmental fracture in the integration of the body image which, following puberty, needs to then incorporate the genital organs and allow for a new compromise between masturbatory fantasy and the demands of the superego. With this Philippe Gutton was able to produce the concept of the “pubertal, which is to the psyche what puberty is to the body.” Although he left room for debate, Gutton distinguished distinctly and

chronologically between the category of feelings that refashion the aim of the drive from the phallic to the genital and are oriented towards a new, complementary, part object—and the *adolescens* process, which is a reconstruction of referents and ideals that this genital identity imposes.

On the Lacanian side, which has proved more reticent with respect to the psychogenetic approach, the texts are few and far between: For Françoise Dolto, puberty is a third “moment of synthesis” (after the mirror stage and the Oedipus complex), in the construction of an unconscious body image. Jean-Jacques Rassial views puberty in its somatic, but also psychic aspects, as the Real blow that necessitates an Imaginary reconstruction and a new Symbolic foundation, insofar as this is an adolescent function.

The production of the concept of puberty points toward a certain number of theoretical modifications: First off (and this is borne out by clinical experience), the topological status of puberty, be it individual or social, and which affects not only the ego but also the id and the superego, affirms the autonomy of the psychical from the somatic and the social, because psychic puberty does not always occur at the same time as these two other puberties. Secondly, from a dynamic point of view, Freudian precepts hold that the conflicts taking place during this time are not only the repetition of earlier conflicts, and therefore all psychogenesis, and particularly the pre-pubertal function of the latency period, needs to be rethought. Thirdly, the economic function of the phallus, between drive and representation, is put into question by its separation during this period from the genital that cannot, after all, be reduced to just its imaginary employment.

As is already apparent in Freud’s texts, the transformations of puberty are not a simple issue of psychogenetics, but raise the question of the function of sexuality as a whole. In other words, behind the story that goes from infantile sexuality to so-called adult normality there lies another, about the infantilism of a sexuality that destines the sexual relationship to its failures, which diverge according to the sexual genital in question.

## **PUERPERAL PSYCHOSES**

Derived from the Latin *puerpera* (“woman in childbirth”), *puer* (“child”), and *parere* (“to give birth”), the term *puerperal psychoses* conventionally comprises all the psychiatric conditions with onset during pregnancy and in the year following it. In a more restricted sense, the same term is used as the equivalent of *post-partum psychoses*, in which case it concerns only major, acute problems that occur during the days or first month immediately after delivery.

Puerperal disorders have been known since antiquity (Hippocrates, Galen). Puerperal psychoses were singled out in the mid-nineteenth century, with the work of Jean-Étienne Esquirol (1838) and Louis-Victor Marcé (1858). Still relevant from that time are questions that treat the specificity of these morbid states: Are they an autonomous clinical entity of which childbirth is the causal agent? Or, instead, is childbirth merely an event that precipitates the emergence of a psychiatric syndrome in an already vulnerable woman?

Psychoanalysis very early on became interested in this pivotal stage in a woman’s life. Paul-Claude Raca-

mier, in “La mère et l’enfant dans les psychoses du post-partum” (Mother and child in the postpartum psychoses; 1961), defined puerperal disorders as accidents in the psychoaffective “process” of motherhood—a process that can be understood in light of concepts developed by Sigmund Freud: the castration complex, its impact within narcissism, and its clinical consequence, penis envy, which becomes the desire to have a child by the father during the oedipal phase. Above all, Freud discovered the strength of the bond uniting the little girl with the preoedipal mother and its articulation with the central problem of identification.

Beginning in the 1970s analytic understanding of the processes of motherhood and its avatars was opened up to contributions from other disciplines, such as developmental psychology, ethology, or the practice of observation. A number of theoretical and/or clinical concepts have since become available: primary maternal preoccupation (Donald Winnicott), the capacity for maternal reverie (Wilfred Bion), projective identifications (Melanie Klein, Bion), behavioral and fantasmatic mother-child interactions, transgenerational transmission (Mary Ainsworth, Serge Lebovici), or the motherhood constellation (Daniel N. Stern).

## PUNISHMENT, DREAM OF

In punishment dreams, the dreamer is explicitly or implicitly punished for a fault, often indicated as excusable or unknown to the dreamer.

In the 1911 revision of *The Interpretation of Dreams* (1900a), Freud included an analysis of a dream of the famous Austrian poet Peter Rosegger. Freud associated the dream with his own memories of a time when, working in the physiological laboratory under the German physician Ernst Brücke, he admonished himself in a dream for boasting about his scientific and social success.

In another emendation, in 1919, Freud introduced the theme of punishment dreams into chapter 7, on the fundamental psychology of the dream processes. The painful quality of dreams of punishment seems to contradict the theory that a dream represents a gratification of a wish. Freud asserted that dreams of punishment indeed represent precisely the wish to be punished, to expiate a fault. In this process, there is no return of a repressed wish but rather a need for punishment that originates with the ego or rather (as he soon would call it, in a note added in 1930) the superego.

In *Introductory Lectures on Psycho-Analysis* (1916–1917a [1915–1917]), Freud explored the relationship between punishment and dreams in the chapter devoted to wish fulfillment. In “Some Additional Notes on Dream-Interpretation as a Whole” (1925i), Freud, in discussing the content of dreams in terms of moral responsibility, laid stress on the ego’s censorship of the wishes of the id. In *New Introductory Lectures on Psycho-Analysis* (1933a), in the chapter on the revision of the theory of dreams, Freud emphasized the superego’s role of repression. The questions Freud posed apropos of punishment dreams are also related to repetition compulsion, discussed in *Beyond the*

*Pleasure Principle* (1920g) and *The Economic Problem of Masochism* (1924c).

## **PURIFIED-PLEASURE-EGO**

In 1911 Freud, in “Formulations on the two principles of mental functioning” (1911b [1910]), distinguished between a *pleasure-ego* “that can do nothing but *wish*, work for a yield of pleasure, and avoid unpleasure,” and a *reality-ego* that “need do nothing but strive for what is *useful* and guard itself against damage” (p. 223), then, in 1915 he described a “purified-pleasure-ego” (p. 136) in the course of his metapsychological reflections on “Instincts and Their Vicissitudes” (1915c).

The purified pleasure-ego is the result of a distinction between an ego and a non-ego, and the splitting of both the external and internal world into what is pleasurable and what is not. Certain instincts are considered to be unpleasant and are then rejected or rather “projected” outside, whereas objects that are a source of satisfaction are “introjected.” “The original reality-ego, which distinguished internal and external by means of a sound objective criterion, changes into a purified ‘pleasure-ego’, which places the characteristic of pleasure above all others. For the pleasure-ego the external world is divided into a part that is pleasurable,

which it has incorporated into itself, and a remainder that is extraneous to it. It has separated off a part of its own self, which it projects into the external world and feels as hostile” (p. 136).

We find these same distinctions unchanged in the article entitled “Negation”: “The original pleasure-ego wants to introject into itself everything that is good and to eject from itself everything that is bad. What is bad, what is alien to the ego and what is external are, to begin with, identical” (1925h, p. 237).

Following the example of Melanie Klein, who was inspired by this notion to describe projective identification (Manual Furer, 1977; James Grotstein, 1994), the majority of Anglo-Saxon writers who have described the first phases in the development of the mind have referred to this “purified pleasure-ego” as linked to the splitting into “pleasant” and “unpleasant” which becomes “good” and “bad.” The symbiotic phase described by Margaret Mahler is very close to this (Julio Granel, 1987). And Heinz Kohut goes so far as to indicate in a footnote in *Forms and Transformations of Narcissism* (1966) that “The purified pleasure ego may be considered as a prestage of the structure which is referred to as the narcissistic Self in the present essay” (p. 246n).

## PURPOSIVE IDEA

Sigmund Freud used the term *purposive idea*, above all in his early psychoanalytic writings, to refer to the orienting role of an idea when it is conducive to the sudden appearance of a train of thought (ideas, affects, representations, fantasies, and so on). The stages in this train of thought converge in the direction of this idea, which thus itself seems to be the goal of all of this psychic work.

Freud's main discussion of this notion is found in *The Interpretation of Dreams* (1900a; chapter 7, section 1); thereafter he returned to it only sporadically. His aim in this passage was to refute an objection that had been raised against his method of dream analysis by means of free association; his critics contended the material produced in this way could consist only of isolated fragments and could have no overall meaning. This objection came out of an understanding of associationism in which, at the time, ideas that thus appeared "by chance" could only be brought together based on formal criteria (synonymy, assonance, and so on) or chance (temporal coincidence, for example). It is remarkable that Freud, who elsewhere made extensive use of these formal or contingent factors in association, in this passage challenged the idea of a train of thought occurring by chance. He pointed out that conscious thought is always directed toward a goal to be reached (solution of a problem, preparing for an action, and so on). The same is true, he said, when a train of thought is unconscious and/or bears upon representations that are themselves unconscious: It is always directed toward a goal, even if the subject is unaware of it. Thereafter, when someone was asked, after relating a dream, to proceed by free association, the sequence of the dreamer's evocations followed an orientation homologous to the one that presided over the dream-work, a process in which the goal to be reached was the fulfillment of a wish. The same applied in the analysis of a symptom, homologous to the work of producing this symptom, which could thus be decrypted.

Thus, although Freud subsequently returned to this term only intermittently in his later works, he based the notion on two essential principles: First, the elements of thought, notably representations, are linked together in an ordered sequence (the analysis of several such trains of thought leading in general to a "nodal

point" at the heart of the subject's problematics); and, second, this sequence is ordered by a finality.

## PUTNAM, JAMES JACKSON (1846–1918)

American physician and neurologist James Jackson Putnam was born on October, 3, 1846 in Boston, where he died on November 4, 1918.

His family belonged to New England's professional aristocracy. Both his father and grandfather were prominent physicians. His mother admonished him to be good, honest, and not to entirely neglect his social obligations. He studied medicine at Harvard University. In 1870, he went to Europe to learn about electrotherapeutics and neurology, concentrating on anatomy and pathology—whose proponents believed that mental diseases were due to defective heredity, and that brain and mind were parallel systems. He became one of America's most distinguished specialists in nervous diseases.

By the mid-1890s, with, among others, William James, Josiah Royce, and Morton Prince, Putnam experimented with hypnosis and psychotherapy. His practices were rooted in the ideas of Janet, Bernheim, and Charcot, as well as in the virtue and belief in progress that, habitually, was taught to the members of New England's professional aristocracy. He was aware of Freud's work, and after meeting Ernest Jones (who then was in Toronto), he began to think that early experiences and childhood sexuality might be important elements in later neuroses and psychoses. Thus, he came to psychoanalysis at the age of sixty-three.

Together with William James, Putnam went to hear Freud's lectures at Clark University in 1909. He was impressed and invited Freud (along with Carl Jung and Sándor Ferenczi) to his camp in the Adirondacks. Nathan Hale (1971b, p. 25) demonstrates that there they forged a friendship, and Putnam became "convinced of Freud's integrity and sincerity, and from then on marshalled all his energies, prestige, and elo-

quence, on behalf of psychoanalysis.” Until his death, he lectured on psychoanalysis at Harvard and published twenty-two papers on the subject.

In that period, Putnam and Freud exchanged eighty-eight letters, and Freud analyzed Putnam during psychoanalytic congresses. At Freud’s urging, Putnam initiated the founding of the American Psychoanalytical Association in 1911, and the Boston Psychoanalytic Society in 1914. He fiercely defended psychoanalysis against scurrilous attacks. However, Putnam rejected Freud’s bent toward materialism and determinism, and Freud objected to Putnam’s idealistic and philosophical formulations—which led him to urge his patients to ennoble their minds—and to the belief that individuals are ruled by an inherent principle of growth.

In *Totem and Taboo* Freud particularly rebutted the religious elements of Putnam’s book *Human Motives*, although already before then Putnam’s ideas allegedly had influenced him. Putnam’s convictions originated in his Unitarian upbringing; in Bergson’s belief that memory images are not “stored” in the brain but called up by the sensory-motor system; in his patient’s, Susan Blow’s, argument that “self-activity” expresses the self-determining energy of life; and in Royce’s faith in an unseen ideal.

Throughout his life, Putnam was concerned with the moral crises which, in America, were arising out of an ingrained “civil morality”—that engendered hidden conflicts due to expectations of religious purity in upwardly mobile men who were having illicit affairs. Because Putnam’s case notes were destroyed, we do not know how he conducted his therapies. But his stature and esteem, and his dedication to psychoanalysis, were decisive in establishing the discipline on the North American continent.

# Q

## QUANTITATIVE/QUALITATIVE

*Qualitative* and *quantitative* are two indissociable adjectives applied to the concept of affect in psychoanalytic theory. From Sigmund Freud to André Green, affect has been approached in terms both of its dynamic (quantitative) and subjective (qualitative) dimensions.

The relationship between these two terms evolved in Freud's work at the same time as the relationship between representation and affect. Initially, representation took priority over affect, the latter being assigned a function of mere coloring, and the emphasis was on the quantitative dimension. As subsequent theoretical revisions were effected, affect took on importance and was no longer studied only in terms of its relationship to representation, and the qualitative dimension thus was given growing prominence.

*Quantity* was the term that appeared first, in an article written by Freud for Villaret's Encyclopedia (1891). In *Studies on Hysteria* (1895) Freud took up the term again and used it in an economic sense in his description of the excitation present in the nervous system and its vicissitudes. He took his inspiration from the scientific model of thermodynamics: The psychic apparatus seeks to maintain the sum of excitation at the lowest possible level, either by spreading it out by means of association, or by discharging the surplus.

Freud approached the quantitative and qualitative dimensions together for the first time in "Project for a Scientific Psychology," which was written in 1895 but never published during his lifetime. Although what was at issue was not yet affect but rather psychic energy, the fundamentals of Freud's future hypotheses

can be discerned in this text. He had not yet abandoned the idea of a scientific career in biology, and, as he explained in the introduction, was seeking to bring psychology into the framework of the natural sciences. He divided the psychic apparatus into systems ( $\phi$  system of permeable neurones,  $\psi$ -system of impermeable neurones, and  $\omega$ -system of perceptual neurones) in which the psychic processes are quantitatively determined states of material particles, the neurons. The  $\phi$  system refers to exogenous and physical quantities, while the system  $\psi$  refers to internal, mental quantities. The quantity  $Q$  derives from hypotheses he had already proposed in an article written the previous year, "The Neuro-Psychoses of Defence," (1894) in which he distinguished measurable quantity, its variations, the movement associated with this quantity, and its discharge.

The affects are thus, according to Freud, internal, secreted discharges. The taking into account of quality is subordinated to this dynamic conception. He had difficulty in approaching this dimension, and for this purpose introduced the third system,  $\omega$ , which he linked to perception. This system is aroused by perceptions, and it is the discharge of this excitation that produces a quality. Further on, he specified that quality appears where the quantity  $Q$  has been reduced beforehand. All this thus amounts to the transformation of an external quantity into a quality. Qualitative phenomena are brought back to the vicissitudes of quantity, an idea that Freud expresses in his statement that the tendency to avoid unpleasure is blended with the primary tendency toward inertia. This implies communication between the  $\psi$  and  $\omega$  systems.

Freud put considerable emphasis on the sensation of a psychic modification giving the impression of an

internal movement, in this way relating indices of quality to information about discharge. Attention is thus brought to bear both on indices of quality belonging to the external properties of the object and on the internal processes of the passage of a psychic quantity,  $Q$ . Because he did not allude on this occasion to the  $\omega$  system, it is impossible to say whether it is this system that provides this perception of movement. The confusion grows even further in a correction Freud sent to Fliess, in which he specified that the  $\omega$  system serves only to excite, that is, it is limited to indicating the path to be followed; this would imply that unconscious processes remain unconscious and can acquire only a secondary and artificial consciousness by being linked to processes of discharge and perception.

With *The Interpretation of Dreams* (1900), Freud effected an epistemological break and renounced the biological model, but he nevertheless remained unclear about the qualitative, which remained subordinated to the quantitative. He stressed the quantitative, dynamic aspect of the repression of representations. Affect, independent of the latter, is not transformed in dreams; its quality remains unchanged, although its content is suppressed.

Up until his metapsychological writings of 1915 (“Instincts and Their Vicissitudes,” “Repression”), Freud distinguished two very different things: representation (or ideation) on the one hand, and on the other, the quota of affect representing the instinct. The two have very different vicissitudes. The quota of affect corresponds to instinct that is detached from representation and that finds expression, proportionate to its quantity, in processes that are experienced as affects. This amounts to saying that there are only quantitative differences between different instincts that are qualitatively alike. Freud then pursued this line of thinking and posited a duality between the quantitative factor with representation, on the one hand, and the qualitative factor with affect, on the other. He distinguished the ideational representative from the representative of affect, with the two having different fates. The first disappears from consciousness under the effects of repression. The second has three possible outcomes: suppression of the instinct, expression of a qualitatively defined affect, or transposition of the psychic energy of the instincts into affects.

Not until 1924, with the article “The Economic Problem of Masochism,” did Freud come to recognize the relative independence of quantity and quality. At

this point he dissociated states of pleasure and unpleasure from the economic factors of relaxation and tension, and distinguished the Nirvana principle, on the one hand, from the pleasure principle, on the other. The former has the purely quantitative task of reducing the level of psychic energy to zero. The latter is responsible for the qualitative avoidance of unpleasure and the search for pleasure. Affect is thus found in an intermediate position between annihilation by means of discharge, and the desire to transcend it.

After Freud, others continued to investigate the connection between the quantitative and qualitative aspects of affect. There remained, however, a tendency to approach affect only in its quantitative dimension, neglecting its qualitative dimension. Only with Green’s book, *The Fabric of Affect in Psychoanalytic Discourse* (1973/1999), in which he attempted to develop a metapsychology of affect and representation, was the relationship between quantitative and qualitative significantly reexamined. Green described two poles of affect, one economic and the other psychic, that are most often complementary. In its economic aspect, affect can be considered as a quantity of dischargeable energy. This is the primary dimension of affect, closer to the id than to representation, but difficult to distinguish from the latter. In its psychic aspect, the movement of discharge is only incipient, and is overridden by the qualitative dimension. It is found in the form of the pleasure/unpleasure dichotomy, which for Green is “the principle of primary symbolization.”

## QUASI-INDEPENDENCE/TRANSITIONAL STAGE

In Fairbairn's revision of classical developmental theory, based in object-relationships rather than libido theory and underlying his theories of psychopathology, quasi-independence, or transitional stage, occurs between the stages of infantile dependence and mature dependency, and is characterized by dichotomy and exteriorization of the incorporated object.

Fairbairn's view of the ego as inherently object-seeking rather than pleasure-seeking, and invested with its own energy, facilitated his move away from instinct/libido theory and psycho-sexual development as delineated by Freud and later Abraham, and allowed him a revised theory of development based on object-relations. He proposed an early stage of infantile dependence, or primary identification, the object, while still part of the relationship, not yet being differentiated, and the aim (libido) being incorporative, "taking."

Fairbairn described the gradual transformation of quasi-independence into an object-relationship in which the subject and object are fully differentiated, and the aim is "giving," the stage of mature dependency. In the transition between these stages the object has split into the accepting (loved) and the rejecting (hated) object, attached to the libidinal and antilibidinal egos respectively, and increasing differentiation results in attempts to "exteriorize" these objects, modelled on the known physiological experiences of defecation and urination.

The characteristic conflict of the transitional/quasi-independent stage is between the developmental urge towards mature dependence and the regressive reluctance to relinquish infantile dependence, and Fairbairn described four transitional stages, or rejective techniques, the paranoid, obsessional, hysterical, and phobic, each consisting of different internal relationships and mechanisms, and each underlying specific psychopathologies.

Based neither on the sequence of erotogenic zones, nor on "positions," Fairbairn's developmental theory is a more psychological and object-related theory than

that of either Freud or Klein, and allows considerable flexibility of theoretical and clinical approach. These ideas have been particularly useful to British Independent analysts, and those interested in self-psychology and intersubjective analysis.

## QUATRIÈME GROUPE (O. P. L. F.), FOURTH GROUP

The Quatrième groupe (Fourth group) of the Organisation psychanalytique de la langue française (O. P. L. F., French-Language Psychoanalytic Group) is one of the larger psychoanalytic groups in France. It claims to follow principles and methods that have opened up a third way between Lacanism and the standards of the International Psychoanalytical Association.

The Quatrième groupe was born out of the third split in the French psychoanalytic movement, which occurred in March 1969. This was after the 1953 split, which gave rise to the Société française de psychanalyse (French Psychoanalytic Society), and the 1963 split, which divided the Société française de psychanalyse into the Association psychanalytique de France (French Psychoanalytic Association) and the École Freudienne de Paris (Freudian School of Paris), created by Jacques Lacan.

The founders of the Quatrième groupe—Piera Aulagnier, François Perrier, and Jean-Paul Valabrega—had been members of the first board of directors of the École Freudienne de Paris, but very soon, with the

resignation of Perrier in 1967, followed by that of Valabrega, they reproached him for setting up institutional formations that he had previously criticized. In addition to this criticism of Lacan's leadership, the direct cause of the split was their rejection of new modes of psychoanalytic training (the "pass") that Lacan had just put in place in December 1968.

The first of the meetings that would result in the formation of the Quatrième groupe took place in Ermenonville, north of Paris. The group was officially founded on March 17, 1969, and at first included only ten people. Its officers were François Perrier, president; Jean-Paul Valabrega, vice-president; Piera Castoriadis-Aulagnier, psychoanalytic secretary; Evelyne-Anne Gasquères, scientific secretary; Jean-Paul Moreigne, administrative secretary; and Gabrielle Dorey, treasurer.

The Quatrième groupe was founded on considerations of both the essence of psychoanalysis and the form of institution most likely to sustain the principles of its practice and transmission. These considerations resulted from the experience of the Société française de psychanalyse, in which Lacan was the major driving force, but also from a critique of both the institution and practice of Lacanism (most notably, the short sessions). This critique lent its tone to the Quatrième groupe's declaration of principles and methods: "Between the idealism of principles and the authoritarianism of ideologies, it is appropriate to pinpoint difficulties and to define the impossible. . . . It will be found that the three terms of 'ability,' 'membership,' and 'training' are a source of insoluble conflicts and the sticking points of post-Freudianism" (*Topique*, 1 [1969]).

The issue of ability was linked to that of the effects of the training analysis, which is particularly dangerous if the training analysis is defined as Lacan did, that is, as aiming at "pure," as opposed to "applied," analysis. The issue of membership opened up the possibility of feudal loyalty based solely on analytic affiliations. And the issue of training raised the risk of basing the status of analyst on the attainment of a diploma or on the rituals of collegial recognition. This triple preoccupation can be summed up as a concern over whether an analytic society can manage to banish "alienation" (Mijolla-Mellor, 1996), and it is the basis of a functional mechanism for coping with this difficulty.

The Quatrième groupe's declaration of principles and methods ultimately made up what would be called the "Blue Notebook," that is, the founding charter of 1969 (*Topique*, 1 [1969]), along with later modifica-

tions to that charter in 1970 (*Topique*, 6 [1971]), in 1983 (*Topique*, 32 [1983]), and in 1985 and 1986 (*Topique*, 38 [1986]). These successive modifications were aimed at "refounding" the institution (during "refounding" sessions) in order to avoid ossification.

The two main points of its principles and methods were the following: First, the composition of the group was limited to two categories of membership. Those in the first category were successively called *tenured* members, then *subscribing* members, and finally *member analysts*. Those in the second category were called *candidates*, then *contributors*, and then *participants*. They were not considered *trainees*, and their status did not guarantee their potential careers as analysts. They were defined as *guests*—either as colleagues already authorized by other societies or as *auditors* in the midst of their analyses who wanted to attend the Quatrième groupe's scientific events (such as seminars and lectures) or participate in its institutional activities (as observers). Passage from the status of participant to that of member analyst posed difficult issues of recognition and the process of authorization.

Second, at the end of a personal analysis, which was not distinguished from a training analysis, whether with a member of the Quatrième groupe or not, the candidate analyst, who was usually a participant member, could decide to undertake a "fourth analysis" (*analyse quatrième*) with a member analyst. The fourth analysis is a private act based on an agreement between the person who requests it and the analyst who agrees to it. After one or more fourth analyses, during which the applicant not only develops an analytic ear (under supervision) but also learns to pinpoint the effects that identification with one's own analyst can have on one's practice, the candidate begins a process of authorization that takes place in between analyses. This process consists of a series of meetings with member analysts who have been chosen by the candidate and have agreed to the request. The "fourth analyst" may or may not be among them. During these interanalytic meetings there is discussion of a case or any analytic question posed by the participants. After at least two or three of these meetings, there are more meetings with other analysts, always chosen by the candidate. At the end of this usually long process, one of the meetings is declared to be "authorizing" by the member analysts in attendance. They have the responsibility,

with the agreement of the whole group, of deciding on the authorization of the new member analyst and reporting it to the ratifying assembly. At any time, the candidate can request the participation of an “analytic secretary,” a member elected by the officers of the Quatrième groupe, if the candidate thinks it would be useful. The secretary has no decision-making power over the candidate. Obviously, this procedure does away with training analysts and the status of trainee. Yet it is strictly codified so that candidates can be authorized only through this process.

This procedure has several advantages. Even if there were no committees, commissions, or boards of admissions, the analytic and scientific secretaries would still provide applicants the possibility of discussing the soundness of their interests and abilities. Moreover, member analysts, merely by being chosen to participate in interanalytic meetings, also contribute to advancing the process of recognition. Consulting analysts thus fulfill their roles as institutional representatives, as opposed to the collective lack of responsibility favored by centralized bureaucracies. In addition, whether it is a matter of the interanalytic meetings or of the authorization itself, any conclusions reached or decisions made must be discussed in the presence of the candidate. Finally, the several fourth analyses and several interanalytic meetings guarantee the principle of multiple references in the process of training so that authorization is not reduced to a kind of feudal initiation based on personal loyalty. Naturally, at every step in the process the candidate's own analyst is prohibited from intervening.

In its earlier formulations, the process of authorization also included a final step in which the candidate would write a memoir to be presented to the whole group at a scientific assembly. This presentation marked the moment of the candidate's acceptance. Even though this practice is no longer followed in quite the same form, candidates, over the course of the long process of authorization, still present their work in meetings of working groups and also possibly at conferences or in scientific journals.

The mechanisms that the Quatrième groupe has put in place aim at responding to a major problem in analytic societies and the principle cause of their dissolution, namely the question of training and authorization. The status of analyst is problematic in that it can only be put to the test during treatment, in the face of an ungraspable entity, the unconscious.

A statement added to the “Blue Notebook” in 1983 concludes, “Our model of analytic training and authorization does not pretend to be permanent or perfect. It would be good if Winston Churchill's statement about democracy could be applied to it: that it is ‘the worst form of government, with the exception of all the others.’”

## **QU'EST-CE QUE LA SUGGESTION? [WHAT IS SUGGESTION?]**

The questions raised in the nineteenth century concerning hypnosis and suggestion continue to preoccupy. It is part of the legend that Freudian psychoanalysis grew out of these practices and distanced itself from them, and Freud himself was careful to establish this part of the legend. In daily life the fascination of these states of mind remains, similar to the state of being in love, and the various other seductions that operate in the social realm. However, psychoanalysts continue to question the nature of Freud's concept, which associated hypnosis with the wielding of influence. Some feel that psychoanalysis is no longer dependent on the all-seeing eye of one person; is manipulation necessary in the therapeutic relation, or suggestion the guide along the path to freedom?

Is suggestion necessary or best avoided? Is it a method of control, or a forced passage toward true reappropriation of the self? The concerns confronting

Charles Baudouin are still present in the early twenty-first century. Initially he published a study, *Suggestion and Autosuggestion* (1920/1962). This he followed in 1924 with the basic question: *What Is Suggestion?*

Baudouin questioned the power of suggestion and the different conceptions of it at the time. He did not believe it was purely an outside influence; he was absolutely convinced that all effective suggestion is basically autosuggestion, that it is part of the psychology of the subject and not constructed of some social psychology in which several different individuals are in relation with each other.

For a while he seemed to draw closer to Émile Coué. He always believed in the power of autosuggestion for the development of the subject, particularly in the context of education. His book develops landmarks in working with the problems posed to him. Is suggestibility in a person normal or pathological? Can there be suggestion without hypnosis? Why should autosuggestion be truly preferable?

## QUESTION OF LAY ANALYSIS, THE

Freud wrote *The Question of Lay Analysis* as an occasional piece in support of one of his friends, Theodor Reik, who had been accused of practicing medicine

illegally (he was not a physician). He cast it in the form of an informal conversation with an “impartial interlocutor,” probably Julius Tandler, the Viennese city councilor for welfare, with whom he had in fact discussed the Reik case.

The question of “lay” analysis had been of concern to Freud and his students for a long time because not all of them were physicians. The gap had progressively widened between those who, like Freud, felt that sound training as an analyst was all that mattered, regardless of any previously acquired diplomas, and those (particularly Abraham A. Brill and the Americans) who, considering analysis to be a medical discipline, wanted to prohibit non-physicians from practicing. Ernest Jones launched a major survey of the analytic community before the Innsbruck International Congress in September 1927, at which twenty-eight contributions on the subject were discussed without any agreement being reached. Freud wrote a “Postscript” for the occasion, maintaining his claim that analysis could be practiced by non-physicians.

Freud opens the imaginary conversation of *The Question of Lay Analysis* by describing disorders for which the ordinary physician can offer no real help, then proceeds to outline the methods of free association, dream analysis and so on, which seek to shed light on unconscious processes. He provides his putative interlocutor, whose supposed criticisms and questions frequently punctuate the exchange, with some notion, from the dynamic point of view, of his structural theory of the mind, of the instincts and, from the economic point of view, of repression and anxiety, of childhood sexuality, of the Oedipus complex, and so on. This metapsychological overview is followed by an account of the procedures of analytic therapy (transference, resistance, and the art of interpretation). Neither general medicine nor psychiatry prepares the physician for any of this, Freud declares; they may even constitute an obstacle. Special training is required, beginning with a personal analysis, without which even a physician may be no more than a quack. Any legislation on the subject would therefore be more of a hindrance than a help. Freud therefore concludes that analysis may perfectly well be practiced by non-physicians. Such an analyst would nevertheless need the help of a physician, prior to the analysis, in order to settle diagnostic questions or, in the course of the analysis, to take over in the case of disorders beyond the scope of the analyst: but the same holds for the

physician analyst. Freud concludes by tracing the program of what the ideal analytical training might involve (p. 246).

This work has had considerable influence on the debates that continue to this day on the “question of lay analysis” and the training of analysts. On the whole—though with noticeable variations from country to country—the International Psychoanalytical Association has adopted Freud’s position.

## QUOTA OF AFFECT

Affects are modes of expressing impulses, manifesting internal states of psychic life based on the two primitive polarities of pleasure and unpleasure, which play an essential role in the totality of mental functioning, especially in the defensive organization of the ego. The concept of affect can be found in the earliest examples of Freud’s psychoanalytic writings (1895d [1893–95]), where it is used to explain hysterical symptoms as a quantity of energy that cannot be discharged and, as a result, remains attached to memory. Therapy involves a recovery of this memory. Language, which is equivalent to the act, enables abreaction and the discharge of affect.

Originally, affect was considered by Freud to be a variable amount of excitation, a quantum of affect closely associated with memory traces. André Green

(1973) elucidated the concept when he spoke of the *ideational representative of the impulse* and its *affective-representative*. The idea of affect is also very close to the concept of libidinal energy; whenever the libido is repressed, it can be transformed into anxiety (the first Freudian theory of anxiety). This is perhaps the best-known example of affect.

In 1915 Freud wrote, “For this other element of the psychical representative the term *quota of affect* has been generally adopted. It corresponds to the instinct in so far as the latter has become detached from the idea and finds expression, proportionate to its quantity, in processes which are sensed as affects” (1915d, p. 152). Here, Freud seems to postulate that repression most deeply weighs upon the *ideational representatives*, which become unconscious, while affects are not found in the unconscious. They are excluded from consciousness through repression.

This vision of affects as charges capable of undergoing conversion (conversion hysteria), displacement (obsessional neurosis), transformation (anxiety neurosis), and being manifested through internal discharges that produce changes in the body of the individual, was substantially modified in Freud’s second theory of anxiety (1926d [1925]). Here, the ego becomes the seat of affects, especially anxiety. Anxiety automatically arises whenever the ego of the nursing child is overwhelmed by an instinctual excitation that it is unable to discharge on its own; gradually, the newborn realizes that the mother will help to dissipate this experience of danger. Subsequently, the ego experiences the loss of the mother as an alarm signaling the arrival of these dangers (signal anxiety). In this same work, Freud also describes other affects, such as psychic pain and sadness. Later, following the *Metapsychological Papers*, he emphasizes the importance of unconscious feelings of guilt that are part of the affects residing in the ego. These are complex affects that are made manifest through fantasies, such as those mentioned concerning the loss of the mother, in which “ideational representations” and affects are closely intertwined.

Melanie Klein (1948/1952) adhered to, and further developed, the Freudian concept of affects. Starting from annihilation anxiety, a primitive affect she conceived as the ego’s reaction to the internal threat caused by the death impulse, more complex affects associated with paranoid-schizoid and depressive positions came into being: persecution anxieties

and anxieties of depression, sadness, and guilt. Anxieties, therefore, become organized as a modality of fantasies that serve as prototypes of possible interactions of the ego with objects according to basic polarities: pleasure-unpleasure or annihilation experience-security experience. These help organize and determine the ego's relations with objects through mobilization of the various defense mechanisms that structure the mental life of the individual.

## RACAMIER, PAUL-CLAUDE (1924–1996)

The French psychiatrist and psychoanalyst Paul-Claude Racamier was born on May 20, 1924, in Pont-de-Roide, and died on August 18, 1996, in Besançon.

The youngest of three brothers, Racamier had solid roots in his native Franche-Comté by way of his father, who came from a Catholic family in the Drôme and worked as an engineer at the Peugeot factory, and his mother, who came from a Protestant family in the Montbéliard region. Racamier's mother considered her son's health to be delicate and home-schooled him until the age of nine; this experience imparted a life-long stance marked by a passion for very individualistic ideas and a refusal of all conformism. After receiving a good secondary education in Montbéliard, he studied medicine in Besançon and then in Paris; he passed the medical exam qualifying him to practice in the psychiatric hospitals in 1952.

Racamier spent the first part of his career at the psychiatric hospital in Prémontre, where he worked from 1952 to 1962. Shocked by the dehumanizing conditions there, he established an improved setting for patients in his ward and gradually developed the therapeutic services of the institution itself. He then followed the same course of action in Switzerland, at the clinic of Rives de Prangins (1962–66), and subsequently at La Velotte, a treatment facility he created near Besançon in 1967, which would become his life's work. A limited number of patients (twelve at most), as many caregivers as patients, places for daytime activities and treatment, clearly separated from tastefully decorated and furnished, family-style living quarters, maintaining close contact with families, and so forth—such were the facility's prin-

ciples. They were based on Racamier's original theories.

These theories were nevertheless closely linked to Racamier's psychoanalytic training and activity. After undergoing analysis with Marc Schlumberger (and later with Evelyne Kestemberg), he worked with Sacha Nacht and Francis Pasche. He became a member of the Société psychanalytique de Paris (SPP; Paris Psychoanalytical Society) in 1958 and was elected to permanent membership in 1962. He taught at the University of Lausanne from 1962 to 1967, and then at the faculties of medicine and human sciences in Besançon. At the same time, he conducted many psychoanalytic and psychiatric training seminars; he served as director of the SPP's Institut de psychanalyse (Institute of Psychoanalysis) from 1975 to 1982.

Racamier's collaboration with colleagues who created and ran the mental health services of the 13th arrondissement in Paris (Philippe Paumelle, Serge Lebovici, René Diatkine, René Angelergues) led to a collectively authored book entitled *Le Psychoanalyste sans divan* (The psychoanalyst without a couch; 1970). In this book Racamier stressed an idea he would often return to: the need to simultaneously “care for” patients, caregivers, the group they form, the institution where they live, and families. The key word is to fight against the repetition compulsion that tends toward a routine where everything becomes fixed.

His theoretical writings originated in his practice working with adult psychoses: in *Les Schizophrènes* (Schizophrenics; 1980), he sought to show the “paradoxality” at work in these disorders. But his ideas went further. So did the ideas that came out of his work with patients suffering from postpartum psychoses.

Developing the notions of “mothering” and “motherhood,” he found close links between maternal psychosis and the child’s development; beyond this, he showed that in such situations, the entire process of “personation,” the sense of being an autonomous, coherent, and continuous person, is disturbed.

The same spirit of “going further” is evident in the notion of the *Antoedipus* (1989), a key element in Racamier’s thinking. In coining this term, Racamier intended to refer to both the “anti-oedipal” (that which is an obstacle to the oedipal organization) and the “ante-oedipal” (that to which the psyche is thus sent back); thus, in a “world of non-object objects,” the “anti-fantasy fantasies,” the “fantasies of self-procreation” that radically cancel out sexual and generational differences and the like, lead, according to the vicissitudes of this “shattered Antoedipus,” to psychosis or narcissistic perversions. However, the outcome of the Antoedipus is not necessarily so tragic: it remains present but discreet in the oedipal structures, contributing to their fluctuations and necessary reequilibrations.

This central notion is taken up anew in *Le Génie des origines: Psychoanalyse et psychoses* (The genius of origins: Psychoanalysis and psychoses; 1992), where Racamier articulated it, on one side, with the notion of primal mourning (renunciation of total possession of the object), and on the other, with a eulogy to ambiguity (to be distinguished from ambivalence), the condition for a psychic life that is sufficiently flexible, rich, and creative.

Racamier’s final work, *L’Inceste et l’incestuel* (Incest and the incestuous; 1995) returns to and broadens these ideas by going back to the very bases of his theorization, with the “incestuous,” that is, the totality of parent-child relations (particularly mother-child relations) that, by way of multiple substitutions, aim to maintain the eroticized narcissistic union of mutual seduction and block the oedipal organization.

Throughout, this succession of works shows the development and blossoming of a lively and original way of thinking that inevitably resonates with that of Donald W. Winnicott, Wilfred Bion, or even Jacques Lacan, even though Racamier, firmly anchored in his own practice, was not greatly concerned with backing it up with the theories of other authors. Racamier left behind a substantial life’s work, through his creation of institutions for the care of adult psycho-

tics and his practice there, through the theoretical contributions that were both the fruit of and the support for that practice, and, finally, through his teaching.

## **RACISM, ANTI-SEMITISM, AND PSYCHOANALYSIS**

The word *race* is derived from the Italian *razza* (fifteenth century, “sort or species”); the concept of racism arose from the nineteenth-century development of anthropology and the life sciences, notably genetics. A naturalist, zoologizing scientific tendency led to the classification and hierarchical arrangement of human groups according to their specific history and their morphological, cultural, or psychological characteristics, which were deemed to be hereditary. Against this backdrop, an ideological application of the term *race* came to justify discrimination, segregation, exploitation, expulsions, and ultimately the twentieth century’s industrialization of mass murder and extermination camps.

Pierre-André Taguieff (1998) has pointed out that “protoracist” social phenomena grounded in xenophobia and ethnocentrism antedated the coining of

the word *racism*. He adduces three instances of such protoracism:

1. The myth of “pure blood,” in fourteenth-to-seventeenth-century Spain and Portugal, which underlay the statutes of 1449 (*estatutos de limpieza de sangre*) barring all honors, privileges, public positions, or employment to converted “new Christians” and their descendants; such Moors or Jews (in practice, mainly Jews) were decreed to be “unclean,” smirched (*maculados*), and carriers of foul infections.
2. The colonial slave system and the exploitation of “colored peoples”—black and Indian—in the West Indies and the Americas in the sixteenth and seventeenth centuries, which nourished fears of contamination associated with the color of the “skin” and “blood.”
3. The French aristocratic doctrine of an antagonism between “two races”: nobles with “clear and pure” blood and “commoners” whose blood was “vile and abject.”

The “purity of the blood” and its corollary, the shame associated with contamination, which was feared to bring about a transmissible degradation or degeneration, gave rise to a phobia of interbreeding, of any mixing of races or misalliance with respect to lineage. The groundwork of racism was thus laid before any of the modern taxonomies of race appeared.

The distinction between humans and “subhumans” gives rise to feelings of fear, hatred, and rejection, to fantasies of dangerousness and absolute possession projected onto the “uncanny” stranger. The ideology of race purification is founded on such feelings. The associations of the defense mechanisms involved (purifying, purging, purifying, cleaning, disinfecting, and so on) reflect an underlying fantasy of absolute autonomy that embodies violent ideas and hostility toward structures of kinship.

The ideology of racism had its master thinkers. In France, Arthur de Gobineau, in *The Inequality of Human Races* (1853–55), distinguished three main races: the black, the yellow, and the white. He extolled “race consciousness” and, thanks to Richard Wagner among others, found a growing audience in Germany. Georges Vacher de Lapouge’s *L’Aryen, son rôle social* (The Aryan and his role in society; 1889–90) subdivided the white race into the superior “dolichocephalic” Aryans and the inferior “brachycephalic” variety,

which included Jews. Spurred on by the Dreyfus Case, Édouard Drumont, in his *La France juive* (Jewish France; 1886), held the Jews to account for the “devastating calamities” of socialism, internationalism, and nihilism. Richard Wagner’s son-in-law, Houston Stewart Chamberlain, whose *Foundations of the Nineteenth Century* (1899) was to bring grist to the mill of the Nazis, further exacerbated the rift between Germans and Jews by taxing the latter with the notorious blood libel: *die Blutschande*, literally “blood shame”—a charge ideally designed to project onto the Jews a perverse fantasy of transgression of the prohibition against incest. And in 1895 Alfred Ploëtz brought in the expression “racial hygiene,” echoed later in the German *Rassenhygien*. So many words bear witness to the eugenic obsession that underpins all xenophobic and racist thinking.

*Anti-Semitism* itself is a word that was coined in Germany by Wilhelm Marr, founder of the Antisemitic League, in a pamphlet on “the victory of Judaism over Germanism” (1879).

The bloody tradition of anti-Jewish sentiment comes all the way from the ancient world down to what Roberto Finzi (1997/1998) has called the “tragic epilogue of the Shoah.” (*Shoah* is Hebrew for “catastrophe,” and denotes the Nazi genocide of the Jews; the term *genocide* was for its part introduced by Raphaël Lemkin in 1944 in his *Axis Rule in Occupied Europe*.)

On the ever-fecund dunghill of anti-Jewish stereotypes bequeathed by the collective imaginings of medieval Christianity, which deemed “the Jew” a “deicide” and a perfidious contemner of the word of Christ the Savior, the Jews of Central Europe were subjected to senseless demonization and accused of the “ritual murder” of children during Passover. Forced to live in restricted areas under discriminatory laws, they were the frequent victims of boycotts and pogroms (a Russian word meaning destruction)—explosive and bloody outbursts reflecting the envious and fearful animosity that they aroused. The culture of antisemitism, whose denunciations of the supposed “Jewish race” sometimes had a left-wing tinge to them (as witness, in France, Pierre-Joseph Proudhon, Charles Fourier, and Alphonse Toussenel—who inspired Drumont—or, in Germany, Werner Sombart), was buttressed by an “economic” dimension which threw suspicion on the Jews as putative promoters and developers of the capitalist system. This calumny

reached its acme in 1920 with the legend of a worldwide Jewish-Masonic conspiracy founded on the spurious *Protocols of the Elders of Zion* (1894–1905), forged by the Czar's secret police.

National Socialism carried anti-Semitism to its apotheosis. As dictator of the Third Reich, Hitler reintroduced the medieval ghetto and, taking his cue from the massacre of the Armenians in 1915, planned the genocide of the Jews (the idea was broached by him as early as 1925, in *Mein Kampf*), to whom he later added Gypsies and homosexuals. Germany, for Hitler, had to become *judenfrei* ("Jew-free") and *judenrein* ("cleansed of Jews"). This will to genocide was enshrined as a doctrine of state in the Nuremberg laws (1935), later imitated in Italy (1938) and in Vichy France's Jewish statutes of 1940–41. After World War II, new legal concepts became indispensable in order to conduct the Nuremberg Trials (1945–46), among them "crimes against humanity," "crimes against peace," and "war crimes."

Racism and genocide cannot help but oblige us to consider the epistemological underpinnings of an obsession with eugenics: genesis, gene, generation, genealogy, genus engendering eugenics, genocide.

From the Freudian perspective, the differences between human beings, between the sexes, and between generations, lying as they do at the heart of the hominizing process, lie in the development and sublimation of murderous, parricidal, and incestuous wishes, and hence too the structuring recognition of heredity, otherness and civilization.

Beginning in 1912, with *Totem and Taboo* and his formulation of the myth of the murder of the primal father, as well as with the watershed or pivotal work that underlay "On Narcissism" (1914c), Freud broadened his thinking from the field of the individual to that of humanity in a collective sense. He was especially interested, against the background of World War I, in the narcissistic stakes in play for the libido and for power in mass-psychological phenomena, as he was, too, in the relationship to death. These concerns were evident in "Thoughts for the Times on War and Death" (1915b), *Group Psychology and the Analysis of the Ego* (1921c), and *Civilization and Its Discontents* (1930a [1929]). Meanwhile, he pursued his reflections on the function of the individual psyche, and almost simultaneously, he produced works raising questions about the enigma of the "Uncanny" (1919h)

and about the repetition compulsion and the death instinct (*Beyond the Pleasure Principle* [1920g]). The attention Freud paid to the "uncanny" stranger who is at the same time "secretly familiar," and who may in fact be understood as an "internal enemy," was in fact the core of his thinking about racism and anti-Semitism.

In *Moses and Monotheism* (1939a [1934–38]), Freud stressed the part played by the Oedipus complex in Judaism, "a religion of the father," as in Christianity, "a religion of the son" (p. 88). He brought up the issue of circumcision, suggested that the claim of the Jews to be the chosen people was a cause of jealousy, and evoked the "narcissism of minor differences," which, by exaggerating the sense of belonging, constituted an obstacle to the effective sublimation of the instincts, to the formalizing role of the superego, to the greater sense of sanctity vouchsafed by monotheism and ethics.

Rudolph Loewenstein dedicated his *Christians and Jews: A Psychoanalytical Study* (1952) to Christians who sacrificed themselves for persecuted Jews. In his view Judeophobia was a form of demonophobia, and as such an incurable "hereditary psychosis" that had existed since antiquity. The "Nazi religion," which preached the supremacy of the Aryan race, exalting earth and blood, the primacy of force over right, and the revolt of the instincts against the universal value of the superego, was certainly anti-Jew, but it was also anti-Christian.

According to Imre Hermann (1945), anti-Semitism is a collective sickness that is endemic as well as epidemic in nature. In Hermann's theory of attachment, the "clinging instinct," coupled with the instinct for knowledge, was the foundation of the mother/infant dual unity. Basing himself on the "clinging instinct/dermic system" combination, which he saw as the beginning of social contact, he saw the unconscious roots of the Nazi thesis that equated non-Aryans, and especially Jews, to vermin, germs or vampires in a specific kind of cathexis of the "skin" of the social body. The pleasure obtained by masses of people clinging in regressive fashion to a gigantic nourishing mother would account, in Imre's view, for the fascination with a leader who promised the "miraculous" destruction of the people that invented monotheism.

Drawing on his biopsychic and prenatal theory of narcissism, Bela Grunberger (1997) has described

specifically Christian anti-Semitism as a grandiose narcissistic aspiration to purity, as the rejection of an anality unintegrated into the self and its projection onto Judaism, which, being an authentic moral system underpinned by the oedipal paternal principle, has done away with the narcissistic maternal principle.

“Desolation,” a major concept in Hannah Arendt’s reflection on the origins of totalitarianism, may be said to correspond, on the level of political philosophy, to what Freud, in *Inhibitions, Symptoms and Anxiety* (1926d) and *The Future of an Illusion* (1927c), and other psychoanalysts after him, referred to as “*Hilflosigkeit*,” meaning a state of helplessness (that of the human infant). The view that heredity informs totalitarian racism in general and the genocide of the Jews in particular implies a systematic attack on the links of kinship and marriage and tends towards the structural actualization of what Pierre Legendre (1989) has called a “slaughter-house theory of heritage.”

The psychoanalytical reflections of Janine Altounian and H el ene Piralian on the Armenian “catastrophe” or those of Jacques Ascher on the “extermination of extermination” likewise testify to the gravity of the injuries sustained. The genocide carried out by the Nazis was the outcome of a “culture of extermination” (Gillibert and Wilgowicz). This pure culture of the death instinct, characterized by collective phenomena of adherence to a leader who has replaced the ideal ego, is constitutive of what Wilgowicz has described as a “historic mass vampirism” founded on infanticide and matricide/parenticide and on a disavowal of both birth and death, which destroys the narcissistic bases of identity in the survivors. As of 2005, three generations after the Shoah, the repercussions were still being felt.

### **RACKER, HEINRICH (1910–1961)**

Heinrich Racker, a doctor of philosophy, was born in Poland in 1910 and died in Buenos Aires on January 28, 1961.

When World War I broke out his family sought refuge in Vienna. In the course of his youth he acquired a solid grounding in general culture: He took an interest in literature, discovered psychoanalysis, and became an excellent pianist. In 1935 he obtained a doctorate in philosophy and one year later he was

admitted to the Vienna Institute of Psychoanalysis, where he was analyzed by Jeanne Lampl-de Groot. In 1937 he enrolled as a medical student. One year later the Anschluss took place.

Racker fled from Vienna, finally emigrating to Buenos Aires in 1939 after many vicissitudes. In spite of his financial difficulties he commenced analysis with Ángel Garma, who generously received him. He later did his training analysis with Marie Langer and in 1946 he completed his training in the Argentine Psychoanalytic Association (APA). In 1947 he became a subscribing member of the Association and a full member in 1950, becoming a training analyst one year later.

Racker was very young when he presented his first work on countertransference, a subject that was to confirm his reputation as one of the most original analysts in the history of the discipline. Presented at an APA conference in September 1948, “La neurosis de contratransferencia” (The countertransference neurosis) made a very strong impression. In this paper, which was not published for another five years, Racker emphasized the dialectical relation that exists between the transference and the countertransference. He revolted against the myth of the impersonal analyst and pointed out that countertransference reactions can give the analyst an indication of what is happening for the analysand. This was the essential point in the new theory of the countertransference that came into being in the middle of the twentieth century.

Simultaneously, at the sixteenth International Congress (Zurich, 1949) Paula Heimann presented her study *On Countertransference*, which was published in 1950. Without any consultation between them, Racker and Heimann had reached the same conclusions. But, as Cesio (1961) pointed out, whereas Racker developed the subject without delay and succeeded in interesting the scientific community, it took Heimann ten years to reconsider the question and her work had only a small impact.

In the 1950s Racker produced fundamental work. “Observaciones sobre la contratransferencia como instrumento técnico” (Observations on the countertransference as a technical instrument), presented to a conference in 1951 and published one year later, and “Los significados y usos de la contratransferencia” (Meanings and uses of the countertransference), in 1953, published in the *Psychoanalytic Quarterly* in 1957.

Apart from his studies of the countertransference, Racker wrote essays on music, art, and literature, which were published in book form in 1957. Psycho-pathological stratification was another of his interests, on which he published an article in the same year.

Although his publications and his work as an analyst and teacher were the most remarkable aspects of his activity, Racker also shone through his participation in the life of the Argentinean Association. With the publication of his work on psychoanalytic technique, Racker was appointed Sloan Visiting Professor at the Menninger School of Psychiatry, as well as being made a member of the symposium “The factors of healing in psychoanalysis” at the Edinburgh International Congress in 1961. Death did not leave him the time to complete these tasks. But in November 1960 he gave a conference entitled “Psychoanalysis and Ethics,” which was published 1966, after his death. It was the crowning glory of a noble life and a message of love for science, psychoanalysis, and humanity. He died in 1961, aged fifty, at the height of his creativity.

## RADÓ, SÁNDOR (1890–1972)

Sándor Radó, a Hungarian psychoanalyst and physician, was born in 1890 in Kisvarda, Hungary, and died on May 14, 1972, in New York City. Radó grew up in a middle-class business family 100 miles from Budapest. He studied at the Universities of Berlin, Bonn, and

Vienna, completing a political science degree in Budapest in 1911. He then enrolled in medical school in Budapest.

In 1913, Radó became, with four others, one of the founding members of the Hungarian Psychoanalytic Society. He first met Freud before World War I, due to an introduction from Radó's mentor, Sándor Ferenczi. In 1924, when Radó was already prominent in Berlin, Freud chose him to replace Otto Rank as editor-in-chief of the most important analytic journal, the *Zeitschrift*. Radó was known as an outstanding theoretician, and in Europe analyzed people of the stature of Wilhelm Reich, Heinz Hartmann, and Otto Fenichel.

When the New York Psychoanalytic Society was establishing its first Training Institute in 1931, Radó was invited to be the founding director. In 1935 difficulties arose between himself and Freud. The Viennese analysts around Freud were a palace guard of advisors who long envied Radó's special position. Freud resented the way Radó had been helping analysts to leave the continent for the United States. Radó had opposed Freud's plan to build a new international institute in Vienna after Hitler came to power.

The crisis between Freud and Radó in 1935 was occasioned by a critical review of one of the Radó's monographs written by Jeanne Lampl-de Groot, then a current patient of Freud's. The review appeared to be published with Freud's tacit endorsement. Then, shortly after Karen Horney had been demoted by the education committee of the New York Psychoanalytic Society, Radó was deposed as educational director.

In 1944, just as Radó was to found the Psychoanalytic Clinic at Columbia University's medical school, he was thrown out of the New York Psychoanalytic Institute as a training analyst. Even before then he was viewed as a traitor. Unlike other so-called dissidents within Freud's movement, who chose to make their appeal to the general reading public, Radó wanted to go deeper into university medicine.

Radó had been from the outset of his career in Berlin especially concerned with establishing standards of education and training. Some of his papers from those years, on melancholia and drug addiction for example, continue to seem outstanding. As time went on Radó, like other rebels in analysis, worked out new terms for old concepts. For some years he was a member of the New York State Mental Hygiene Council, and both

Governors Averell Harriman and Nelson Rockefeller supported his work with state grants. Radó retired from Columbia in 1955, after which he helped to create the New York School of Psychiatry at the State University of New York, where he was director for ten years.

Radó came to oppose the idea that the removal of repressions and the emergence of buried memories can necessarily be expected to have good therapeutic effects. Also, he thought that the provoking of transferences was a clinical mistake, since regression undermined a patient's capacity for autonomy and self-reliance. In addition, Radó was prescient enough to have emphasized the significance of genetics for the future of psychoanalytic psychiatry.

Radó was a sophisticated European man of letters, who belongs to the radical left within the history of analysis; but it has remained a fragmented tradition of so-called dissenters. Although Radó was for a time allied with New York's Abram Kardiner, and Radó's work on therapy was similar to the ideas of his fellow Hungarian Franz Alexander, these critics of the "mainstream" in analysis have rarely hung together. None of them would have dreamed of citing approvingly such earlier "heretics" as Carl Jung, Alfred Adler, or Rank. The nonconformists have been the ones with the original ideas, even though their position has so far won them inadequate recognition. It is hard to become educated in the real story of analysis because of the sectarianism that has afflicted the movement. As of 2005, some of the most persuasive present-day critics of Freud are only now reinventing concepts that were first advanced many years ago.

Radó's later writings can be hard to follow. He disdained popularizations and put his faith in medical science. Like Freud himself, Radó was a spell-binder who spoke like a book. Yet Radó underestimated Freud's contribution to the humanities, and was intolerant of the significance of analysis for philosophy and the social sciences. Within psychiatry itself, though, Radó may well turn out to have been prophetic.

## **RAIMBAULT, ÉMILE (1923–1998)**

Émile Raimbault, a French physician, psychologist, psychoanalyst, and member of the École Freudienne de Paris, was born in Anjou on October 21, 1923, and died at Saumur on August 21, 1998.

He first studied psychology, then, on the advice of Jacques Lacan, with whom he commenced his psychoanalysis, he also began to study medicine. He followed Lacan into the Société française de psychanalyse on the occasion of the split in 1953. Michael Balint, the first guest of this society, encouraged him and his wife, Ginette Raimbault, to regularly attend the “training cum research” seminars (“training seminars for physicians on the therapeutic relationship”) that he gave at the Tavistock Clinic in London under the auspices of the National Health Service. The Balint and Raimbault families became close friends.

Along with his wife and Jacques Gendrot, Émile Raimbault soon started one of the first “Balint groups” in France. This mixed group (physicians, interns, physiotherapists, an odontologist, and trainee psychoanalysts) met in the Raimbaults’ home in Paris. Known by the name of their street, the “Marignan group” became a reference for those that followed.

Raimbault also practiced as an analyst under Raoul Kourilsky in the Saint-Antoine hospital, where the pneumologist began to experiment in 1949 with a new type of consultation conducted by a “therapeutic pair”: an organicist physician and an analyst. Raimbault then introduced, in addition to listening to the patient’s unconscious, listening to the suffering of the medical team treating dying patients: he created the first Balint group in the hospital department. His experience resulted in his being appointed director of the psycho-oncology team in the Institut Gustave-Roussy, a position he occupied for fifteen years.

Along with Raoul Kourilsky and Jacques Gendrot, Raimbault co-edited the proceedings of the first congress in France, after the Brighton congress, of Balint leaders, held in the Paris medical faculty in 1964 and at the Trianon in Versailles. He was also responsible for a report on the leaders’ meeting, published in the same volume. He also wrote an essay on death with the title *La Délivrance*.

## **RAMBERT, MADELEINE (1900–1979)**

Madeleine Rambert, a Swiss psychoanalyst, was born in 1900 in Lausanne, where she died on May 17, 1979. The daughter of a pastor in the Free Evangelical Church of Vaud, she trained to be a teacher and soon specialized in handling backward children. She opened a facility for such children in Croix-sur-Romainmôtier. To improve her training she moved the facility to Lausanne and enrolled in classes at the Institut Jean-Jacques-Rousseau, where she studied psychoanalysis.

She was psychoanalyzed by Raymond Saussure and, after being supervised by Philipp Sarasin in Basel, she began practicing child psychoanalysis and became a member of the Société Suisse de Psychanalyse (Swiss Psychoanalytic Society) in 1942. That same year, Lucien Bovet founded the Office Médico-Pédagogique (Medical Training Center) in Vaud. Rambert worked at the Center, training the doctors and psychologists who came to practice there.

She is best known for her use of puppet therapy. She published a description of the technique in 1938, and again in 1945 in *Children in Conflict, Twelve Years of Psychoanalytic Practice*, which included a preface by Jean Piaget. The book became an international success. Observation of the child at play led to the identification and interpretation of standard behaviors, which the game triggered. Rambert was closely associated with the Vienna school and described three phases in

the treatment of the child: exteriorization of conflict; conscious realization and elimination of the neurotic conflict; and re-education.

During the 1960s and 1970s, she continued her training activities with teachers at the Pestalozzi School (Switzerland) and worked with delinquent women. In this way she was able to perpetuate her educational and social work, which characterize her role as one of the first clinicians in the field of child psychoanalysis in Switzerland.

## **RANK-MINZER (MUNZER), BEATA (1886–1961)**

Psychoanalyst Beata Rank was born on February 16, 1886, in Neusandetz near Krakow, Poland, then part of the Austrian-Hungarian Empire. She died on April 11, 1961, in Boston. Her life can be divided into four distinctive periods in different countries, which in turn delineated her professional career.

Originally named Beata Minzer (or Munzer), she was born into a middle-class, assimilated Jewish family. Early on she chose for herself the name Tola, used by family and friends, but never professionally. Her mother was one of 12 children, several of whom became professionals or business people. Beata's interest in psychology and the arts was encouraged by an aunt who had studied in Vienna and is credited with introducing her to her future husband, Otto Rank. Otto had been drafted into the army and stationed in Krakow where he was the editor of the *Krakauer Zeitung* from 1916 to 1918. Beata and Otto were married in a Jewish ceremony on

November 7, 1918, a week before the armistice. The young couple moved back to Vienna soon thereafter.

Vienna, 1918–1926: This period covers the last years of the Rank-Freud relationship, culminating with the well-documented, yet still not completely understood, final break. Beata and Otto's only child, Helene, was born on August 23, 1919. With Freud's and her husband's encouragement, Beata attended meetings, seminars, and lectures on psychoanalysis. She worked with Otto in the Verlag. Her interest in dream work led to her translation into Polish in 1923 of Freud's book *Über Träume* (*On Dreams*), and a later inquiry into the dreams of six-year-old schoolchildren. Also in 1923 she presented a paper to the Vienna Psychoanalytical Society which served as her ticket of admission to the group. It appeared in *Imago* in 1924 in the original German. An English translation of the title would be "The role of woman in the development of human society." The *Imago* paper was meant as an introduction to a large three-part study on the subject, which was never completed.

Paris, 1926–1936: In 1924 Otto began visiting the United States, teaching, lecturing, and seeing patients. By 1926 the relationship with Freud had seriously deteriorated, and the Rank family moved to Paris. This was seen as a compromise since Beata did not want to move to the United States, while artistic and cultural Paris had great appeal. As for Otto, Paris was a rest stop. He would build an American practice and earn a good income while increasing his American visits. Beata did not engage in clinical work during her Paris years, but continued research at the Bibliothèque Nationale on the role of women. In 1933, Otto, with the encouragement of some American colleagues, developed the Psychological Center and Summer Institute, a training, teaching, and general education center, and Beata worked with him primarily as an administrator. In 1934 there was a "de facto" dissolution of their marriage when Otto emigrated to the United States. This was also the time when he and Anaïs Nin became involved. Beata remained in Paris while their daughter Helene completed her French baccalaureate. Then, with Fascism extending its power, she decided to leave.

Boston, 1936–1969: Beata, still legally married to Otto, was able to enter the United States with Helene in the fall of 1936 as permanent residents under Otto's visa. Beata came to Boston where she was quickly accepted in the Boston psychoanalytic community,

due especially to the help of her longtime close friends from Vienna, Helene and Felix Deutsch. She came into her own as a prominent child analyst, as well as a highly respected supervisor and training analyst at the Boston Psychoanalytic Institute, where she was chair of the education committee for several years. Her influence reached far in the Boston community as diverse mental health professionals, as well as pediatricians and social scientists, sought out her teaching, while psychiatrists from many other countries also came to study with her. She was an honorary Professor of Psychiatry at Boston University School of Medicine, a consultant and supervisor at Judge Baker Guidance Center, and with Marian C. Putnam, co-founded and co-directed the James Jackson Putnam Children's Center in 1943. This center was a pioneering day-treatment facility for pre-school children and their parents. It simultaneously offered day-care and/or psychological evaluation and treatment for children with emotional and cognitive developmental problems, and their parents. Research was an integral part of the program and the staff published numerous papers, including Beata Rank's papers on atypical development. Beata Rank's contributions to child analysis live on through the many people she influenced through her teachings.

## **RANK (ROSENFELD), OTTO (1884–1939)**

Otto Rosenfeld Rank, an Austrian psychologist and psychoanalyst, was born on April, 22, 1884, in Vienna and died on October 31, 1939, in New York.

He was the son of Simon Rosenfeld, an artisan jeweler, and Karoline Fleischner. His older brother studied law while Otto became a locksmith: the family could not afford higher education for both. Close to his mother but alienated from his alcoholic father, Otto adopted the name “Rank” in adolescence and formalized it a few years later, symbolizing self-creation, a central theme of his life and work.

Of Jewish background, growing up in Catholic Vienna, Rank was a religious skeptic who wrote his own Ten Commandments, among them “Thou shalt not give birth reluctantly.” He read deeply in philosophy and literature, loved music, and considered himself an artist, writing poetry and a literary diary. Before he was 21, he read Freud's *Interpretation of Dreams* (1900). He applied psychoanalytic ideas in an essay on the artist; the manuscript came to Freud (probably through Alfred Adler, Rank's physician) which led to Rank's appointment as secretary of the Vienna Psychoanalytic Society in 1906. With Freud's financial and moral support, Rank obtained his PhD from the University of Vienna in 1912, the first candidate to do so with a psychoanalytic thesis subject.

Rank became the acknowledged expert on philosophy, literature, and myth in the Vienna Psychoanalytic Society and kept the minutes (1906–1918; later published in four volumes). He became the most prolific psychoanalytic writer after Freud, with *Der Künstler* (1907; expanded editions 1918 and 1925), *Der Mythos der Geburt des Helden* (1909), *Die Lohengrin Sage* [his doctoral thesis] (1911), and *Das Inzest-Motiv in Dichtung und Sage* (1912, 2nd edition 1926), a 700-page survey of world literature. Except for the posthumous *Beyond Psychology* (1941), Rank's books were written in his native German. Translations, mostly of his early psychoanalytic works, exist in English, French, Italian, and Spanish.

Other works important in Rank's Freudian period include “Ein Beitrag zum Narcissismus” (*Jarbuch*, 1911), *Die Bedeutung der Psychoanalyse für die Geisteswissenschaften* (1912, with H. Sachs), *Psychoanalytische Beiträge zur Mythenforschung* (1919), *Die Don Juan Gestalt* (1922), *Der Doppelgänger* (1925), *Eine Neurosenanalyse in Traumen* (1924), *Sexualität und Schuldgefühl*

(1926), *Technik der Psychoanalyse* (I. *Die Analytische Situation*, 1926; II. *Die Analytische Reaktion*, 1929; III. *Die Analyse Des Analytikers*, 1931; II and III translated as *Will Therapy*, 1936), *Grundzüge einer genetischen Psychologie* (I. *Genetische Psychologie*, 1927, II. *Gestaltung und Ausdruck der Persönlichkeit*, 1928; III. *Wahrheit und Wirklichkeit*, 1929, translated as *Truth and Reality*, 1936).

Rank was a member of Freud's Committee, or "Ring" of Seven and his closest associates (1906–1925). Of the founders of the International Psychoanalytical Association, Rank was closest to Freud geographically, professionally, and personally. He helped edit and contributed two chapters to Freud's *Die Traumdeutung* (editions 4–7, 1914–1922; "Traum und Dichtung" and "Traum und Mythos"). He and Hanns Sachs edited the journal *Imago*, beginning in 1912, with Freud and Sándor Ferenczi he edited *Die Zeitschrift für Psychoanalyse* beginning in 1913. Rank witnessed the vicissitudes and bitter endings of Freud's relationships with Wilhelm Stekel, Alfred Adler, and Carl Jung; Rank's tenure with Freud lasted much longer—two decades, exceeded only by that of his friend Sándor Ferenczi and his foe Ernest Jones.

Freud, who had discouraged young Rank from pursuing a medical career, after 1912 always addressed him as "Dr. Rank" and referred patients to him. This was consistent with his support of non-medical or "lay" analysis. Freud and Rank agreed on another controversial issue: the eligibility of homosexual candidates for analytic training.

Rank served in the Austrian army in Poland during World War I, where he met and married Beata "Tola" Mincer in 1918; she became a noted lay analyst and practiced in Boston after their separation in 1934. The birth of their only child, Helene (1919), enhanced Rank's interest in the pre-oedipal phase of development (birth to age 3) and the mother-child relationship.

He was co-founder of the International Psychoanalytical Association in 1910, honorary member of the American Psychoanalytic Association (1924–1930). Freud and Rank established the Internationaler Psychoanalytischer Verlag in 1919, which became Rank's major responsibility along with training psychoanalytic candidates from around the world. In 1924 Rank published *Das Trauma der Geburt*, emphasizing the importance of separation and individuation, with their attendant and inevitable anxiety in the pre-oedipal

period. Until then psychoanalysis had been father-centered, with oedipal conflict at the center. Rank meant only to balance and extend Freud's work but this book, and his work with Ferenczi on active therapy—*Entwicklungsziele der Psychoanalyse* (1924)—led to a final break with his mentor and virtual foster father. That same year Rank turned 40 and visited the United States for the first time. He was honored as Freud's emissary, although his ideas were beginning to challenge established Freudian doctrine.

Over the next decade Rank lectured, taught, wrote, and practiced a briefer form of psychoanalytic therapy with a more egalitarian relationship between therapist and patient. Rank modified the open-ended analytic process by using termination as the focus for separation and independent development. In this respect his work anticipated the innovations of Franz Alexander (brief analytic therapy, and the corrective emotional experience).

Orthodox Freudians condemned Rank as a deviant. The American Psychoanalytic Association expelled him and required his former analysands to undergo re-analysis. Although Rank suffered from poor physical health and occasional depression, assertions that his departure from the psychoanalytic fold were a result of mental instability (by Ernest Jones and A. A. Brill) are not supportable. The work of Rank and his colleague, Ferenczi, is being studied and discussed more objectively by psychoanalytic scholars in the twenty-first century.

Rank's creativity continued to flourish in his post-Freudian period. Between 1926 and 1931 he wrote major works on developmental psychology and therapeutic technique which are considered forerunners of object relations theory and ego psychology (Rudnytsky, 1991). He emphasized conscious experience, the present, choice, responsibility, and action, in contrast with the (classical Freudian) unconscious, past history, drives, determinism, and intellectual insight. *Seelenglaube und Psychologie* (1930) and *Art and Artist* (1932) are psychoanalytically informed major works of social psychology and cultural history addressing religion and creativity, respectively.

Rank's emphasis on will, relationship, and creativity appealed to psychologists Rollo May, Carl Rogers, Esther Menaker, Paul Goodman, and Henry Murray. Noted psychiatrists influenced by Rank include Frederick Allen, Marion Kenworthy, Robert Jay Lifton, Carl Whitaker, and Irvin Yalom; writers

and critics include Ernest Becker, Maxwell Geismar, Max Lerner, Ludwig Lewisohn, Anaïs Nin, Carl Rakosi, and Miriam Waddington.

Some of Rank's ideas which seemed radical in his time have become the mainstream of psychoanalytic thought: the importance of the early mother-child relationship; the ego, consciousness, the here-and-now, and the actual relationship—as opposed to transference—in therapy. He anticipated and influenced interpersonal, existential, client-centered, Gestalt, and relationship therapies. As a social psychologist he contributed to our understanding of myth, religion, art, education, ethics, and organizational behavior.

Rank's companion in the last four years of his life was Estelle Buel, an American of Swiss descent whom he married just three months before his death. He had applied for United States citizenship when a kidney infection led to fatal septicemia; he died in New York City at 55.

The Butler Library at Columbia University in New York holds the Otto Rank papers in its rare book and manuscript collections. *The Journal of the Otto Rank Association* appeared twice annually from 1966 to 1983, publishing works by Rank and many others who knew him or his writings. A collection of his American lectures (1924–1938) has been published as *A Psychology of Difference* (Robert Kramer, Ed., 1996).

### **RAPAPORT, DAVID (1911–1960)**

David Rapaport, a Hungarian psychoanalyst with a PhD in philosophy, was born in Budapest on September 30, 1911, and died December 14, 1960, in Stockbridge, Massachusetts. Born into a middle-class Jewish family, he quickly became active in the Zionist movement and, after studying mathematics and physics at the university, spent two years in a kibbutz in Palestine. There he married Elvira Strasser; their first child, Hanna, was born shortly after. Upon returning to Hungary in 1935, he ran the Young Zionist movement and began studying psychoanalysis with a relative, Samuel Rapaport, about whom he wrote two books. He was analyzed by Theodor Rajka from 1935 to 1938, and obtained his doctorate in psychology at the Royal University of Hungary, Petrus-Pazmany, in 1938, with a dissertation on the history of the concept of association from Bacon to Kant.

In December 1938, with the help of the Emergency Committee on Relief and Immigration of the American Psychoanalytic Association, he and his family traveled to the United States. He worked in New York as a psychologist at Mount Sinai Hospital, then at Osawatomie State Hospital, Kansas, for a year. In 1940 he joined the Menninger Clinic, in Topeka, Kansas, where he became director of the School of Clinical Psychology, then head of the Research Department. His *Emotions and Psychology*, which appeared in 1942, is a record of his early research, as is *Diagnostic Psychological Testing* (1945–1946), published in collaboration with Roy Schafer and Merton Gill.

In both books Rapaport refers to the theories of ego-psychology. In August 1948 he left Topeka for the Austen Riggs Center in Stockbridge, Massachusetts, leaving behind his wife, a mathematician, and

his two daughters Hanna and Juliette (born in 1943). He worked at Austen Riggs until his death from a heart attack at the age of forty-nine.

Although he never worked as a psychoanalyst, Rapaport was interested in treating schizophrenics and borderline cases, and soon became an eminent theoretician of psychoanalysis. His classes and conferences on affects, activity-passivity, and memory, his comments on chapter 7 of Sigmund Freud's *The Interpretation of Dreams*, his translations of Otto Fenichel, Paul Schilder, and Heinz Hartmann, provided him with many students and material for several books, including *Organization and Pathology of Thought* (1951), and many articles, which were collected after his death and are often cited. A member of the Western New England Psychoanalytical Society, he was an at-large member of the International Psychoanalytical Association and, shortly before his death, in September 1960, received a prize from the American Psychological Association's division of clinical psychology.

His close collaborator Merton Gill said of Rapaport that "he spoke of metapsychological abstraction with the fervor of a political orator and the thunder of a Hebrew prophet." Gill also recalled Rapaport's desire to create a general psychology that would include ego psychology and social psychology while retaining Freud's revolutionary intuitions about the id.

## **RASCOVSKY, ARNALDO (1907–1995)**

Arnaldo Rascovsky, an Argentinean physician and psychoanalyst, was born in Córdoba, Argentina, on January 1, 1907, and died on May 1, 1995.

He graduated from the Medical School of the University of Buenos Aires when he was 22 years old, and became a pediatrician, much interested in neurology, endocrinology, and psychosomatic medicine. He became acquainted with Freudian ideas in 1936 and started his personal analysis with Angel Garma, who came to Argentina in 1938. Rascovsky was one of the pioneers of psychoanalysis in Argentina and in Latin America. He was the co-founder of the Argentine Psychoanalytic Association in 1942, first director of the *Revista de Psicoanálisis*, still appearing more than 50 years later in 2005. He was twice president of the Argentine Psychoanalytic Association and then honorary member of this association. He was the co-founder and president of COPAL/FePAL (Latin American Psychoanalytic Federation), founder and president of Filium (Interdisciplinary Association for the Study and Prevention of Filicide) and several times president of the Society of Psychological Medicine, Psychoanalysis and Psychosomatic Medicine, a branch of the Argentine Medical Association.

Rascovsky made important contributions to the understanding of the emotional troubles related to psychosomatic disease. His most original contribution to Psychoanalysis was his study of early psychic development and his theoretical and clinical approach to fetal psychism (*El psiquismo fetal*, 1960). The papers on feminine psychology written in collaboration with his wife Matilde Rascovsky (also a psychoanalyst) threw new light on the complex phenomena taking place in different moments of the feminine life cycle.

His numerous writings deal with the psychoanalytic understanding of psychosomatics, the conceptualization of fetal psychism from the metapsychological point of view, and the understanding and prevention of filicide (*El filicidio*, 1973; *La Universalidad del filicidio*, 1986). A gifted communicator, his lectures on television and radio stimulated psychoanalytic thought throughout Latin America. He is the author of more than 50 psychoanalytic papers and several books. He knew how to address parents, pediatricians, teachers, and the community in general in defense of childhood, mother-father-child relations, and to condemn sadism in teaching, and filicidal behavior.

He was a training analyst and teacher of the Argentine Psychoanalytic Association and full member of the International Psychoanalytical Association. He is considered to be one of the main pioneers of the Argentine Psychoanalytic Movement, highly cultivated, gifted, and generous in his teaching.

## RATIONALIZATION

A rationalization is a logical or moral justification for an action or attitude that is provided by a subject whose (unconscious) motives are inaccessible. Two examples are justifying a fear of cancer by referring to other family members who suffered from the disease and justifying one’s compulsive washing by offering sanitary concerns. The term was introduced in psychoanalysis by Ernest Jones (1908).

Rationalization is not really a symptom. It is more a way of masking and denying the symptom. Nor is it a compromise formation, since within certain limits it satisfies the drive. Nor is it a defense mechanism, since it is not directed toward any libidinal satisfaction. It is more of a way to keep from recognizing neurotic conflicts. It is the conscious secondary thought process of covering the symptom with a screen.

Rationalization is primarily found in cases of neurosis: “Compulsive acts [that occur] in two successive stages, of which the second neutralizes the first, are a typical occurrence in obsessional neuroses. The patient’s consciousness naturally misunderstand them and puts forward a set of secondary motives to account for them—rationalizes them, in short” (Freud 1909d, p. 192).

Can the notion of rationalization be applied to delusion in particular, the logical delusion of paranoiacs? Some psychiatric studies have made use of an analogous concept to show how megalomania is caused by a need to explain and justify the feeling of persecution. In his essay on Judge Schreber, Freud rejects this formulation: “to ascribe such important affective consequences to a rationalization is, as it seems to us, an entirely unpsychological proceeding; and we would consequently draw a sharp distinction between our opinion and the one which we have quoted from the textbooks. We are making no claim, for the moment, to knowing the origin of the megalomania” (1911c [1910], p. 49).

Rationalization is sometimes compared to intellectualization, but the two concepts must be distinguished. In intellectualization, one distances oneself from psychic processes by cathecting one’s own intellectual processes and thought. Rationalization, in contrast, primarily finds support in systems of thought, representations, and beliefs that are socially constituted and accepted.

## REACTION-FORMATION

“Reaction-formation” refers to an attitude or a character-trait that responds to an unconscious (repressed)

wish or desire by evoking the opposite of such a desire. For example, generosity covers or conceals avariciousness and hoarding; modesty may replace megalomania; kindness or reluctance to engage in conflict can mask sadistic tendencies. Reaction-formation is thus also a symptom of a psychic conflict and a defense against instinctive reactions.

Even though it occurs in various pathologies, reaction-formation is most readily apparent in cases of obsessional neurosis. In his early writings, Freud described the mechanisms of obsessive patients, discerning in them clear signs of conflicts of ambivalence through regression from tender to sadistic impulses. In “Instincts and Their Vicissitudes” (1915c), he distinguished between reaction formation and similar concepts, such as *substitute formation and compromise formation*, by showing that repression is carried out differently in each case. Thus, a hostile impulse towards a loved one is subject to repression, such an impulse itself being the result of regression of the erotic drive. At first the work of repression succeeds—that is, contents of the representation vanish and the associated affect disappears. A substitute formation would entail a modification of the ego through establishment of scruples of moral conscience, distinct from the symptom per se, that involves a compromise formation.

Reaction-formation, by contrast, serves repression by intensifying the opposite. However, although conceptually and chronologically distinct, reaction formation and substitute formations are not unrelated. The former distinguishes itself by the antithetical choice of the substitution, which at least indirectly implies ambivalence. And, contrary to compromise formation, the instinct inhibited with respect to a reaction formation is not represented. In fact, it remains active and in evidence in various situations, in the subject’s defensive rigidity and in specific contradictions to the reactive stance.

In *Three Essays on the Theory of Sexuality* (1905d), Freud gave reaction-formation a more extended meaning. He suggested it as a pathway to sublimation inasmuch as the instinct is diverted from its aim. Unlike sublimation, however, with reaction formation the instinctual aim is not merely different but is diametrically opposed to the original. On the other hand, reaction formation does not entirely succeed in this diversion, and the inhibited desire attempts constantly to resurface.

Reaction-formation can also become a permanent character trait and its significance can grow more

general; it can become not just a symptom of a specific pathology, but it heralds the process of socialization. We become social beings by acquiring, as permanent character-traits, “virtues” which move counter to our sexual goals. “A sub-species of sublimation is to be found in suppression by reaction-formation,” wrote Freud (1905c), “which...begins during a child’s period of latency and continues in favourable cases throughout his whole life. What we describe as a person’s ‘character’ is built up to a considerable extent from the material of sexual excitations and is composed of instincts that have been fixed since childhood, of constructions achieved by means of sublimation, and of other constructions, employed for effectively holding in check perverse impulses which have been recognized as being unutilizable. The multifariously perverse sexual disposition of childhood can accordingly be regarded as the source of a number of our virtues, in so far as through reaction-formation it stimulates their development” (pp. 238–239).

Reaction-formation is not restricted to character and moral virtues, but also includes the domain of thought and intellect. The counter-cathexis of the system of conscience, organized as a reaction formation, supplies the first repression (Freud, 1915d). In “Thoughts for the Times on War and Death” (1915b), Freud showed how altruism may originate from selfishness, and compassion from cruelty. “Noble” motives can have the same effect as “non-noble” motives. We cannot divine the instinctual life of a subject, however; we only can observe his or her behavior.

Humankind’s capacity to reshape instinctual selfishness is otherwise known as its aptitude for culture. People have unequal abilities in this regard, and the most solid among them may prove the least well-defended. This explains how instinctual remodeling can be more or less thoroughly undone by circumstance—war being an event that puts culture most completely at risk—and how acquired civility, or the capacity to conduct oneself towards others according to ethical considerations, may entirely unravel. Reaction-formation thus exposes the fragility of morality and suggests how repressed instincts are able to return with a great intensity, as acts of barbarism and cruelty.

### **REALITY PRINCIPLE**

The reality principle is one of the two major principles that govern the workings of the mind. It designates the psyche's necessary awareness of information concerning reality and stands in contradistinction to the pleasure/unpleasure principle, which seeks the discharge or elimination of drive tension at all costs. Although the reality principle was formally introduced into the Freudian vocabulary in 1911 ("Formulations on the Two Principles of Mental Functioning"), it can be found in latent form in his thought as early as the 1895 "Project for a Scientific Psychology."

The need for such a concept arose at that time as a result of an internal contradiction in the pleasure principle, or more specifically, in the notion of hallucinatory wish fulfillment, which tends to mislead the mental apparatus and leave it traumatized by producing a satisfaction that is hallucinated rather than real.

It is therefore only by siding with the reality principle that the mental apparatus gives up the hallucinatory wish-fulfillment carried out by holding onto and binding its cathexes of traces of previous pleasures. It must be satisfied by representing what it wishes for, and engaging in the specific acting needed to make this wish a reality. This confirms why the reality principle is the effect of an internal transformation of the pleasure/unpleasure principle, because it arises first and foremost from the question of whether a pleasure is real, and because adaptation to reality is not its primary function. This transformation brings together both the question of external reality, concerning whether the object of satisfaction is present or absent,

and the question of internal reality, concerning whether pleasure is real.

As soon as it is in place, however, the reality principle comes into conflict with the pleasure principle, insofar as the latter seeks hallucinatory, immediate, wish-fulfillment. The reality principle, therefore, is the domain of the most "secondary" layers of the psychical apparatus. In the first topography it is expressed as the preconscious, and assumes its various qualities (perception, judgment, etc.).

However, in 1920 Freud in effect reversed the respective positions of the pleasure principle and reality principle when he overtly located a "beyond the pleasure principle"—a repetition compulsion—at the root of the psychical apparatus itself. The impact of early reality—whether "pleasurable" or not—becomes primary ("primitive" reality-ego), and the pleasure/unpleasure principle appears as secondary ("pure" pleasure-ego). Paradoxically, it would then be necessary to depict primary reality as falling under the primary of the reality principle ("definitive" reality-ego), due to the intervention of the external object.

### **REALITY TESTING**

"Reality testing" is defined as the process through which the psyche gauges the difference between the internal and external worlds. Freud first defined this process as founded on perception and motility, but as

he progressively elaborated his theory of the ego, reality testing became one of the functions of the ego.

Freud's most complete description of this concept occurs in "A Metapsychological Supplement to the Theory of Dreams" (1916–1917f [1915]), where it appears in tandem with another concept, the "reality-indicator," which makes it possible for the psyche to determine whether the experience it is undergoing is present or is the recall of a previous one. The need for both of these concepts in psychoanalysis stems from the psyche's proclivity to hallucinate. If a previous experience is hallucinated, meaning made present to perception by the action of intense instinctual cathexis, this may fog up the ego's capacities to differentiate between past and present, internal and external, and thus require it to refer to the intensity of the cathexis to differentiate between actual perception and hallucination.

In Freud's inaugural texts, the ego's capacity to make and change cathexes devolves upon reality testing. In the texts that followed, this capacity was assumed by perception, which conveys external reality inward (1911b), then motility, which enables flight from extreme sources of excitation and thereby enables the ego to differentiate the excitation from internal sources (1916–1917f).

However, all of these processes assume means that cannot be used in the psychoanalytic session, where motility and perception are in large part suspended. Freud's successors, Winnicott in particular, have therefore emphasized another process that contributes to distinguishing the realm of fantasy and differentiating internal and external realities. This process is based on the fact that external reality resists fantasized destruction and is not destroyed by it. Reality, or rather externality, can thus be discovered by its capacities to resist the subject's destructiveness. This confers upon the analysis of negative transference a preponderant role in treatment.

## **REALIZATION**

Implicit in Wilfred R. Bion's concept of inherent pre-conceptions is the notion of the future of the preconception in a realization in actual experience with its anticipated counterpart; thus, the infant's inherent preconception of a breast becomes mated with the actual breast that is found and becomes *real-ized* as a conception. Repeated confirmatory experiences of that kind eventually confirm the anticipated experience as a concept. Thus, *realization*, in its capacity to confirm that which has already been autochthonously predicted or expected, bestows confidence, faith, and security to the infant's sense of survival and thriving.

The concept of realization becomes even more ratified when the infant is able to tolerate frustration and thereby allow for the experience of the absence of the breast in the context of having faith in its return. Otherwise, in the case of the infant who cannot tolerate frustration, the experience of the absent breast is eclipsed by the negative experience of the "nobreast present," a concrete image of a bad, persecuting breast.

The concept of realization belongs to Bion's epistemological forays into the fundamental understanding of thinking and is associated with his notions of projective identification, alpha function, and container/contained. The inherent preconception of a breast searches for the realization of the breast in the context of felt neediness if there is an allowance for an absence of a breast that awaits fulfillment and exploratorily and projectively identifies itself in the realized breast. The object of the search who possesses the needed breast is the maternal container who is summoned by the outcry of the infant and his preconception of the

breast. The container must appose itself accommodatingly so as to contain the infant's anxiety of non-confirmation (negative realization).

**REAL, SYMBOLIC, AND IMAGINARY FATHER**

As Freud had already emphasized, the rather complicated paternal function is not assumed only by the real father, the progenitor, and the mother's partner. In his seminar on *Object Relations* (1956–57), Lacan proposed, based on his rereading of Freud's case of "Little Hans," a distinction between the actual father and the function of the father in its real, symbolic, and imaginary instances. In the reality of the child's life, these instances are incarnated by a variety of actual agents.

From the Lacanian perspective, the instance of the *real father* (a term that Lacan sometimes uses in the sense of the "father in reality") is not only embodied by the biological father or even the man who lives with the mother, that is, by a "Dad" with his own history, qualities, shortcomings, and psychic structure. The real father—insofar as "he" desires the mother and is the object of her desire—is also, and even primarily, embodied by anything that carries out the child's symbolic castration, that is, both the renunciation and the realization of the child's incestuous desire. Moreover, because he finds *jouissance* in a woman, this father does not seek an incestuous *jouissance* in the child. Still more broadly conceived, the real father is any being that, either in reality or by means of its reality, leads the child to give up being the mother's phallus, on the one hand, and leads the mother to give up trying to make the child into her phallus, on the other. This symbolic castration determines the way in which the boy and the girl will

**FIGURE 1**

<b>Real of the father</b>		
<b>Symbolic father</b>		
<b>Real father</b>	<b>Symbolic mother</b>	<b>Imaginary father</b>
Real father(s) or father(s) in reality	Real mother(s) or mother(s) in reality	Real child or child in reality

assume their masculinity and femininity. Insofar as fathers in reality are always somehow lacking as an embodiment of the symbolic father and cannot measure up to the imaginary father, to which they are inevitably compared, the real father also partially represents for the child the category of the impossible (Figure 1).

It should be noted that Lacan sometimes uses the term *real father* in a completely different way (in the sense of the "real of the father") to designate that which is impossible for us to say concerning the father. This is the unthinkable father, the primal father that Freud was unable to bring to light except in the myth that he developed in *Totem and Taboo*.

The imaginary father is the product of the child's imagination and finds support in the various cultural representations of the father as terribly tyrannical or immensely good, execrable or adorable, terrifying or fascinating. Inevitably, the child makes the actual father wear the masks and disguises of one or the other of these imaginary fathers. Even though the imaginary father can in some ways be a source of suffering, usually neurotic or masochistic, he is not entirely without beneficial effects, because he gives weight to the symbolic father and thus protects the father against the ravaging effects of the all-powerful archaic mother.

The *symbolic father* includes the two others. This more general instance of the father, also called the Name-of-the-Father, protects the child against psychosis. He imposes castration through the intervention of the real father (embodied in the actual father), frustration through the intervention of the symbolic mother, and privation through the mediation of the imaginary father. This all-encompassing instance of the father installs a definitive gap between the child and the mother, just as it institutes a distinction between the sexes and the generations.

The *symbolic mother*, as embodied by any particular mother, participates by her speech and acts (her

absences, for example) in making present the Law of the father.

## **REAL, THE (LACAN)**

The real, a category established by Jacques Lacan, can only be understood in connection with the categories of the symbolic and the imaginary. Defined as what escapes the symbolic, the real can be neither spoken nor written. Thus it is related to the impossible, defined as “that which never ceases to write itself.” And because it cannot be reduced to meaning, the real does not lend itself any more readily to univocal imaginary representation than it does to symbolization. The real situates the symbolic and the imaginary in their respective positions.

In 1953, in a lecture called “Le symbolique, l’imaginaire et le réel” (The symbolic, the imaginary, and the real; 1982), Lacan introduced the real as connected with the imaginary and the symbolic. The real, insofar as it is situated in relation to the death drive and the repetition compulsion, has nothing to do with Freudian reality (*Wirklichkeit*) or with the reality principle. Lacan wrote, “One thing that is striking is that in analysis there is an entire element of the real of the subject that escapes us. . . . There is something that brings the limits of analysis into play, and it involves the relation of the subject to the real” (1982). Right away, Lacan raised the question of the real in relation to analytic training, and in 1953 more specifically in relation to

the choice of candidates for training analysis. The issue concerned the fact that the real is defined not solely by its relation to the symbolic but also by the particular way in which each subject is caught up in it.

Lacan was able to extract this notion of the real from his meticulous reading of Freud. In *La relation d’objet* (Object relations; 1994), his seminar of 1956–1957, Lacan, taking up the case of “little Hans” (Freud, 1909b), explained the boy’s mythical constructions as a response to the real of sexual jouissance (enjoyment) that had erupted in his field of subjectivity. Thanks to his imaginary constructions and his phobia, little Hans avoided the issue of castration. In his seminar *The Ego in Freud’s Theory and in the Technique of Psychoanalysis, 1954–1955* (1988), Lacan presented a detailed reading of Freud’s dream of Irma’s injection (Freud, 1900a). He emphasized that the terrifying image that Freud saw at the back of Irma’s throat revealed the irreducible real and designated a limit point at which “all words cease” (1988, p. 164).

Lacan returned regularly to *The Interpretation of Dreams* (Freud, 1900a) to indicate how the real is located at the root of every dream, what Freud called the dream’s navel, a limit point where the unknown emerges (1900a, pp. 111n, 525). It is here, at the dream’s navel, that Lacan located the point where the real hooks up with the symbolic (Lacan, 1975). Lacan approached the real through hallucination and psychosis by careful study of Freud’s “Wolf man” case (1918b [1914]), Freud’s commentary on Daniel Paul Schreber (1911c [1910]), and “Negation” (Freud, 1925h). If the Name of the Father is foreclosed and the symbolic function of castration is refused by the subject, the signifiers of the father and of castration reappear in reality, in the form of hallucinations. Hence the Wolf Man’s hallucination of a severed finger and Schreber’s delusions of communicating with God. Thus, in developing the concept of foreclosure, Lacan was able to declare, “What does not come to light in the symbolic appears in the real” (1966, p. 388). Lacan reconceived Freud’s hypothesis of an original affirmation as a symbolic operation in which the subject emerges from an already present real and recognizes the signifying stroke that engages the subject in a world symbolically ordered by the Name of the Father and castration. In his seminar *The Four Fundamental Concepts of Psychoanalysis* (1978), Lacan took up Freud’s *Beyond the Pleasure Principle* (1920g) and approached the real in terms of compulsion and

repetition. He proposed distinguishing between two different aspects of repetition: a symbolic aspect that depends on the compulsion of signifiers (automaton) and a real aspect that he called *tuché*, the interruption of the automaton by trauma or a bad encounter that the subject is unable to avoid. Engendered by the real of trauma, repetition is perpetuated by the failure of symbolization. From this point on, Lacan defined the real as “that which always returns to the same place” (Lacan, 1978, p. 49). Trauma, which Freud situated within the framework of the death drive, Lacan conceptualized as the impossible-to-symbolize real.

The concept of the real also allowed Lacan to approach questions of anxiety and the symptom in a new way. While his early teaching was devoted to the primacy of the symbolic, in later seminars (from 1972 to 1978) he argued that the real (R), the symbolic (S), and the imaginary (I) are strictly equivalent. In effect, the symbolism that Lacan borrowed from logic failed to formalize the real, which “never ceases to write itself.” Thus Lacan attempted, by borrowing from the mathematics of knot theory, to invent a formulation independent of symbols. By affirming the equivalence of the three categories R, S, and I, by representing them as three perfectly identical circles that could be distinguished only by the names they were given, and by knotting these three circles together in specific ways (such that if any one of them is cut, the other two are set free), Lacan introduced a new object in psychoanalysis, the Borromean knot. This knot is both a material object that can be manipulated and a metaphor for the structure of the subject. The knot, made up of three rings, is characterized by how the rings (representing the real, the symbolic, and the imaginary) interlock and support each other. From this point on in Lacan’s teaching, the real was no longer an opaque and terrifying unconceptualizable entity. Rather, it is positioned right alongside the symbolic and tied to it by mediation of the imaginary. Thus, whatever our capacity for symbolizing and imagining, there remains an irreducible realm of the nonmeaning, and that is where the real is located (see Lacan, 1974–1975).

In the final years of his teaching, Lacan took up the question of the symptom and the end of the treatment (1975; 1976). If the symptom is “the most real thing” that subjects possess (1976, p. 41), then how must analysis proceed to aim at the real of the symptom in order to ensure that the symptom does not proliferate in meaningful effects and even to eliminate the symptom?

For analysis not to be an infinite process, for it to find its own internal limit, the analyst’s interpretation, which bears upon the signifier, must also reach the real of the symptom, that is, the point where the symbolically nonmeaningful latches on to the real, where the first signifiers heard by the subject have left their imprint (Lacan, 1985, p. 14). According to Lacan, to reach its endpoint, an analysis must modify the relationship of the subject to the real, which is an irreducible whole in the symbolic from which the subject’s fantasy and desire derive.

This notion of the real has given rise to numerous misunderstandings. Some have interpreted its resistance to formalization as a slide into irrationality. Others, by identifying the real with trauma, have made it a cause of fear and anxiety. Yet we all have an intuitive experience of the real in such phenomena as the uncanny, anxiety, the nonmeaningful, and poetic humor that plays upon words at the expense of meaning. Thus, when the framework of the imaginary wavers and speech is lacking, when reality is no longer organized and pacified by the fantasy screen, the experience of the real emerges in a way that is unique for each person.

## REAL TRAUMA

A real trauma has an exogenous cause and its disturbing, even disruptive effect is immediate and manifest.

This has been the usual definition of *trauma* ever since its adoption in a surgical context in 1855: The word always denoted a bodily injury, but its meaning was soon expanded to alone cover the state of shock or stupor induced by that injury. The adjective *real* has no meaning save by way of contrast with the psychoanalytic notion of psychical trauma. Freud used it to qualify not the trauma per se but rather those childhood scenes of seduction, which according to his theory of seduction, constituted the first moment of the trauma.

Although he abandoned this theory, thereby promoting the ideas of unconscious fantasy and psychic reality, Freud argued unwaveringly for the existence of real violent events and their pathogenic effects. By contrast, the majority of his immediate followers, failing to assimilate the oscillation throughout Freud's work between reality and fantasy, gave precedence to fantasy, to the omnipotence of thought, and evinced a distinct distrust of reality. Present-day analysts tend to pay more attention to the real event in its traumatic brutality, while recognizing that this does not free them from the task of thoroughly following the fantasy activity which that reality sets in motion; they espouse the eco-

nomic view of the trauma, as set forth by Freud in 1920, according to which the nature and intensity of a traumatic event can make it highly disruptive in its effects.

The underlying problem here, so often debated, is the nature of internal as opposed to external reality, an issue that occasioned a profound disagreement between Freud and Ferenczi. Even if the impact of reality—of the “bedrock” of biology and of event-governed history—is inescapable, there can be no question, despite all that, of reducing the trauma to a strictly objective reality.

Talk of real trauma might suggest that there is such a thing as fictitious, imaginary, or even “fraudulent” traumas. The term is somewhat questionable therefore, and is in fact little used in psychoanalysis. Quite obviously, any trauma, whatever its origin, is distinctly “real” in its effects.

## RECIPROCAL PATHS OF INFLUENCE (LIBIDINAL COEXCITATION)

The expression *reciprocal paths of influence* refers to routes that lead from a nonsexual function to a sexual function, but that can be traversed in both directions.

In *Three Essays on the Theory of Sexuality* (1905d) Sigmund Freud added to the somatic sources of sexual excitation (erotogenic zones) other sources that are unlimited in number, since they involve any internal process that has surpassed a certain quantitative threshold.

Two aspects of this notion of reciprocal paths of influence must be distinguished.

- First, the anaclitic relationship of the sexual function to a given physiological function sexualizes the latter (Laplanche, 1976). Thus the lips or the tongue intervene in the act of taking nourishment, but also in the pleasure that is taken in this act (or repudiated, as in anorexia), and that which can be found outside of the vital function. This aspect makes it possible to understand the alteration of physiological functions (somatization) that in and of themselves do not have a sexual character, but have taken it on secondarily and can thus undergo the process of repression.
- Second, a nonsexual activity such as intellectual effort, for example, can, if a sufficient amount of concentration accompanies it, create a related sexual excitation. This case does not, therefore, involve an anaclitic dependence on a bodily function, but rather an indirect source of sexual excitation that is in fact linked to the degree of cathexis at stake. In *Three Essays on the Theory of Sexuality*, Freud concluded that “it may well be that nothing of considerable importance can occur in the organism without contributing some component to the excitation of the sexual instinct” (pp. 204–205).

This hypothesis is extremely important because it makes it possible simultaneously to account for sublimation (attraction of the sexual toward the nonsexual) and symptom formation (attraction of the nonsexual toward the sexual). In fact, it considerably broadens the notion of sexuality to encompass the notion of “pleasure in thinking,” a very different perspective from the one that equates thinking with labor.

## “RECOMMENDATIONS TO PHYSICIANS PRACTISING PSYCHOANALYSIS”

“The technical rules which I am putting forward here have been arrived at from my own experience in the course of many years, after unfortunate results had led me to abandon other methods” (1912e, 111). Thus began Sigmund Freud’s “Recommendations to Physicians,” which is, together with “The Handling of Dream Interpretation in Psychoanalysis” (1911e) and “The Dynamics of Transference” (1912b), among the rare technical essays that resulted from Freud’s 1908 attempt to write a “general methodology,” a project he abandoned in 1910.

Freud went on to specify that these recommendations were the result of his own methods and that it was possible that another physician would assume a different position. But he insisted on their common goal, which was to establish for the analyst conditions that paralleled the “fundamental rule” imposed on the patient. It was in line with this that he recommended an attitude of “evenly suspended attention,” the use of “unconscious memory” rather than notes, the absence of a preconceived research “plan,” and therefore the adoption of an attitude of “distance” similar to that of a surgeon.

“The doctor should be opaque to his patients and, like a mirror, should show them nothing but what is shown to him” (1912e, p. 118). We know the fate of this metaphor, as we do that of the other metaphor that Freud would later return to: “To put it in a formula: [the analyst] must turn his own unconscious like a receptive organ towards the transmitting unconscious of the patient. He must adjust himself to the patient as a telephone receiver is adjusted to the transmitting microphone. Just as the receiver converts back into soundwaves the electric oscillations in the telephone line which were set up by sound waves, so the doctor’s unconscious is able, from the derivatives of

the unconscious which are communicated to him, to reconstruct that unconscious, which has determined the patient's free associations" (1912e, p. 115–116). It was to Ludwig Binswanger, who was surprised at a recommendation so similar to telepathy, that, on February 22, 1925, Freud made the following comment: "The statement that the unconscious of the analysand must be seized with one's own unconscious, that we must so to speak hold out the unconscious ear as a receiver, was one I made in an unassuming and rationalistic sense, although I grant that important problems are concealed behind that formulation. I simply meant that one must eschew the conscious intensification of certain expectations and so set up in oneself the same state one requires of the analysand. All ambiguities disappear once you assume that, in the sentence in question, the unconscious is meant purely descriptively. In a more systematic formulation, unconscious must be replaced with preconscious."

In order for this balance to occur, the analyst must first undergo an "analytic purification." This is the inception, by Freud himself, of the "training analysis," intended to help the analyst avoid the temptation of using his own life as an example or trying to educate the patient.

It is clear from this essay that Freud is responding indirectly to the errors that the first psychoanalysts inevitably made in their eagerness to understand or heal. It also shows how difficult it was for physicians to adopt the psychoanalytic attitude when, as a result of their training and professional experience, they had developed an active attitude, if not that of a miracle worker, the very attitude that characterized Freud in the *Studies on Hysteria*. Have the times really changed? Freud's "Recommendations" has continued to be read and, as Freud wrote to Ludwig Binswanger on May 28, 1911, "In truth there is nothing for which man's disposition befits him less than occupying himself with psychoanalysis."

### REES, JOHN RAWLINGS (1890–1969)

A British physician and psychiatrist, John Rawlings Rees was born on June 25, 1890, in Leicester and died on April 11, 1969, in London. He was a Commander of the British Empire and a Fellow of the Royal College of Physicians.

Rees came from a religious background, his father having been a Wesleyan Methodist minister (non-conformist Protestant). He had thought of becoming a missionary, but instead studied medicine. His sense of mission was fulfilled by his leadership at the Tavistock Clinic before World War II, later as chief psychiatrist to the British Army and, after the war, founding and becoming the first president of the International Federation for Mental Health. Rees served as a doctor in World War I, in France, Mesopotamia, and India. There he saw soldiers with nervous breakdowns who were not well treated. He ensured that good treatment was available in World War II. He wrote that it was through his military experiences that he grew up emotionally.

At first he was interested in public health, but moved into psychiatry through meeting with Hugh Crichton-Miller, a pioneer psychotherapist who had founded Bowden House, an in-patient clinic for the early treatment of psychiatric illness. Later Crichton-Miller founded the Tavistock Clinic. Rees did not train as a psychoanalyst, though he had a personal analysis with Morris Nicoll, a Jungian. He was a fine administrator and teacher, who recognized his limits as a therapist. Crichton-Miller resigned in 1932, having grown out of sympathy with developments at the Tavistock, and Rees succeeded him as director. Under his leadership the clinic grew to becoming the main center for psychoanalytic psychiatry in the United Kingdom, in opposition to the Maudsley Hospital at the University of London.

Rees encouraged training in psychiatric social work and child guidance. In the 1930s the clinic was eclectic, with Jungian, Adlerian, and other psychotherapists of many persuasions. Its leading figures were James Arthur Hadfield and Ian Suttie, whose 1935 book *The*

*Origins of Love and Hate* had an important impact in British psychotherapy. Both John Bowlby and Donald Winnicott acknowledged this influence. Suttie attempted to integrate the individual, the social, and the spiritual. Among the staff in the 1930s was Wilfred R. Bion, who treated Samuel Beckett. Henry V. Dicks, for many years his colleague, described Rees “as a natural unself-conscious leader and originator.”

Rees was surprised to be invited in 1939 to take command of British Army psychiatry. He found that there were hardly any psychiatrists in the army at that time and quickly assembled a team, many of whom had served under him at the Tavistock. Rees was able to cooperate with the military hierarchy and to persuade and to show them the value of psychiatry in the selection and allocation of soldiers to work appropriate to their personality and intelligence; in the rehabilitation of psychiatric casualties; and in the maintenance of good morale. He was ably assisted by Ronald Hargreaves. Through their work senior psychiatrists were appointed to army groups and were recognized as valuable advisors.

The education and training of soldiers with limited intelligence was a major innovation in wartime which cleared the way to post-war developments in this field. By 1945 there were 300 trained army psychiatrists and Rees had been promoted to brigadier. After World War II the Tavistock was a changed institution as the younger generation had experienced power and influence in the armed forces, and they were enthusiastic to train in psychoanalysis and to use psychoanalytic knowledge in their work with the clinic. Rees was out of tune with this development and felt pressured to give up as director in 1947.

At the age of 57 he was at the height of his powers and devoted himself to organizing the first Mental Health Congress in London in 1948. He became the leading figure in the movement to maintain and develop wartime international cooperation among psychiatrists. His mission then became the research and treatment of mental illness in its social roots. He was a leading figure in the formation of the World Federation for Mental Health of which he was director for many years. The Federation brought modern psychiatry to undeveloped countries, trained their personnel, and stimulated research. He was indefatigable in his travels, and his London home was always a place of welcome for colleagues worldwide.

Rees published an autobiographical volume, *Reflections*. His own writings were not original, but he was

able to explain psychotherapy in straightforward terms to the general public, and his work in exploring society was influential.

## RÉGIS, EMMANUEL JEAN-BAPTISTE JOSEPH (1855–1918)

Emmanuel Régis, a French physician, was born on April 29, 1855, in Auterive (Haute-Garonne) and died on June 21, 1918, in Bordeaux. He studied medicine in Paris, where he was taught by Baillarger, Lasègue, Motet, Falret, and Ball, and became a professor at the Sainte-Anne psychiatric hospital, where he became assistant physician in 1881. In 1883 Régis was back in Bordeaux. Asked to teach a course on mental illness in 1892 by Albert Pitres, he became head of the department of medicine, then associate professor in 1905. In 1913 Régis was appointed to the new chair of mental pathology, which he held until his death.

Régis is the author of several works in the field of criminal psychology and mental illness. His approach to etiology is based on the notion of degeneration and the importance of an accidental toxic-infectious factor, ideas that were consistent with his training and oriented his important work in medical hygiene. Under the influence of Pitres, a well-known student of Charcot, he explored the study of neuroses and, like him, was forced to

confront the paradoxes of hysteria. It was while studying hysteria that both men encountered the ideas of Sigmund Freud, whose nosographic conceptions they shared without accepting his hypothesis of an underlying sexual etiology.

The article “Séméiologie des obsessions et idées fixes” (Pitres and Régis, *Archives de neurologie*, 1897) reflects this critical rapprochement. *Les Obsessions et les Impulsions* (1902) followed, developing points of view that Régis would again return to in the four editions of his *Précis de psychiatrie*. Régis’s opinion of Freudian theory is ultimately negative, but Freud continued to arouse his curiosity. Thus, in 1913, together with his assistant Angélo Hesnard and his brother, a learned German linguist, he initiated a project of reading all of Freud’s works. This resulted in the article, “La doctrine de Freud et de son école” (Régis and Hesnard, *L’Encéphale*, 1913) and *La Psychanalyse des névroses et des psychoses* (1914).

This book, in which Régis challenges the scientific value of psychoanalysis while recognizing its heuristic usefulness, has the merit, as Ferenczi acknowledged in his 1915 polemic, of describing Freudian theory accurately, supported by an exhaustive bibliography. The book marks the official entry of psychoanalysis in France.

## **REGRESSION**

The Latin equivalent of *regression* means “return” or “withdrawal”; it also signifies a retreat or a return to a less-evolved state. There is no very precise psychoanalytic definition of the concept of regression. It is useful to introduce the idea of temporality. It could be said to represent an articulation between the atemporality of the unconscious, the primary processes, and the temporality of the secondary processes. Some analysts assign this notion a metaphoric value; it retains the connotations of a journey through time and the changes that will be necessary in psychoanalytic treatment.

Sigmund Freud introduced the notion of regression in *The Interpretation of Dreams* (1900a). The concept was necessary for his description of the psychic apparatus in terms of a topographical model, represented by an instrument whose component parts are agencies or systems with a spatial orientation. Excitation traverses the system in a determined temporal order, going from the sensory end to the motor end. In hallucinatory dreams, excitation follows a retrograde pathway. Dreams have a regressive character due to the shutdown of the motor system; the trajectory goes in the reverse direction, toward perception and hallucinatory visual representation. This regression is a psychological particularity of the dream process, but dreams do not have a monopoly on it. In the section of the last chapter of *The Interpretation of Dreams* titled “Regression,” Freud wrote that “in all probability this regression, wherever it may occur, is an effect of a resistance opposing the progress of a thought into consciousness along the normal path.... It is to be further remarked that regression plays a no less important part in the theory of the formation of neurotic symptoms than it does in that of dreams” (pp. 547–548). In this last chapter Freud already distinguished between three types of regression: topographical regression, in the sense of the psychic system; temporal regression, in the case of a return to earlier psychic formations; and formal regression, where primitive modes of expression and representation replace the usual ones. He also noted: “All these three kinds of regression are, however, one at bottom and occur together as a rule; for what is older in time is more primitive in form and in psychical topography lies nearer to the perceptual end” (p. 548). This basic unity is central to his metapsychological use of the concept.

In *Three Essays on the Theory of Sexuality* (1905d) Freud implicitly invoked the idea of fixation, which is inseparable from regression. In “A Metapsychological Supplement to the Theory of Dreams” (1916–17f [1915]), he underscored the distinction between “temporal or developmental regression” (of the ego and the libido) and topographical regression, and the fact that “[t]he two do not necessarily always coincide” (p. 227). Then, in the twenty-second of the *Introductory Lectures on Psychoanalysis* (1916–17a [1915–17]), he distinguished two types of regression affecting the libido: a return to the earliest objects marked by the libido, which are of an incestuous nature, and a return of the entire sexual organization to earlier stages. Libidinal regression is only an effect of temporal regression, with a reactivation of old libidinal structures preserved by fixation. At that point he asserted that regression was a “purely descriptive” concept, adding: “we cannot tell where we should localize it in the mental apparatus” (pp. 342–343). In making this assertion, he retrenched from his earlier position and denied regression its metaphysical status, which it would regain only after 1920 with the second theory of the instincts. It then becomes constitutive of the death instinct and can threaten to destroy psychic structures, but also becomes a mechanism that can be used by the ego.

According to Marilia Aisenstein’s article “Des régressions impossibles?” (Impossible regressions?), “Freud’s reticence around the notion of regression in 1917 was linked to its relation to the first theory of the instincts and the first topography. He had difficulty in situating and formulating regression not only in topographical terms, but above all in terms of the libido and the instincts of the ego. . . . It then became necessary to separate regression from disorganization, as the latter was envisioned by Pierre Marty and the psychosomaticians of the Paris School. . . . If the retrograde movement is not stopped by regressive systems involving fixations, the end result can be a process of somatization.” Regression is indispensable to the work of psychoanalytic treatment; it implies the notion of change and is part of the healing process, according to Donald W. Winnicott (1958). Regression is a form of defense and remains in the service of the ego. From the analyst’s point of view, formal regression provides another way of listening.

## REICH, ANNIE (1902–1971)

Austrian physician and psychoanalyst Annie Reich (née Pink) was born on April 9, 1902, in Vienna and died on January 5, 1971, in Pittsburgh, Pennsylvania.

Reich was the third child of Theresa Singer, a primary school teacher, and Alfred Pink, a Viennese merchant; Annie’s father remarried shortly after her mother’s death from influenza, during World War I. Her older brother, Fritz, was killed during the war, and her other brother, Ludwig, emigrated to

Australia in 1939. Reich studied medicine at Vienna University from 1921 and obtained her medical degree in 1926.

In 1921 she began an analysis with Wilhelm Reich, which was interrupted six months later when, in 1922, they were married. Two daughters, Eva and Lore, born in 1924 and 1928 respectively, issued from this marriage. Reich began another analysis with Hermann Nunberg and, years later, with Anna Freud. A member of the Vienna Psychoanalytic Society from 1928, she worked at the proletariat-oriented sex-counseling clinics founded by Wilhelm Reich and Marie Frischauf. After moving to Berlin in 1930, she became involved in the “Kinderseminar” for young, left-wing analysts that was founded by Otto Fenichel, and joined the Berlin Psychoanalytic Society.

In 1933, Reich and her husband separated. Reich emigrated to Prague where she established a practice and helped constitute the new psychoanalytic community there; as a member of the Vienna Psychoanalytic Society, she served as a training analyst until 1938. That year, she married Thomas Rubinstein and emigrated with him and her children to the United States, where she was quickly admitted into the New York Psychoanalytic Society; she served as its president from 1960 to 1962. She was also active in the International Psychoanalytical Association from 1938 until her death.

Reich’s publications include some of the first psychoanalytic works dealing with pedagogical aspects of sexuality, including “Zur Frage der Sexualaufklärung” (On the question of sexual enlightenment) in 1929. In addition, she wrote numerous theoretical and clinical articles, including key papers on counter-transference and female psychology. A collection of her papers was published posthumously in 1973.

## **REICH, WILHELM (1897–1957)**

Wilhelm Reich was an Austrian physician and psychoanalyst. He was born March 27, 1897, in Dobrzycynica, a part of Galicia belonging to the Austro-Hungarian Empire, now a part of Poland. He died November 3, 1957, at the Lewisburg penitentiary in Connecticut. Reich’s parents were assimilated middle-class Jews, who had emigrated after his birth to Jujinetz, in the Ukrainian region of Austria-Hungary. His father owned an extensive tract of land, on which he raised cattle. Two teachers were responsible for the young Reich’s education. At the age of fourteen he entered the local high school in Czernowitz. He was an officer in the Austrian army during the war and began his medical studies upon his return to Vienna.

In 1919 he was admitted to the local psychoanalytic society. In 1921 he married Annie Pink, a brilliant student who became a famous psychoanalyst. Reich had important responsibilities as a teacher and in clinical psychoanalysis, and in 1924 ran a seminar on psychoanalytic technique. At the same time he was working with Austrian socialists. In 1927 he published *The Function of the Orgasm*, which established the existence of a sexual economy focused on the power of the orgasm and genitality. He enrolled in the communist party in 1928 and, the following year, created the Socialist Society of Sexual Advice and Sexual Research. In 1929 he traveled to the USSR, where he familiarized himself with the work of Vera Schmidt, a Russian teacher who made use of psychoanalysis in her school for children.

In 1930 he left Vienna for Berlin, where he continued working to promote communism and psychoanalysis. In 1931 he founded the German Association for a Proletarian Sexual Policy, known as SEXPOL for short, which at one point had several thousand members. In a 1931 brochure, *The Sexual Struggle of the Young*, he promoted a radical liberation of individual behavior. In 1932 he published *The Invasion of Compulsory Sexual Morality*, a sociological study based on the work of the ethnologist Bronislaw Malinowski. Reich lived with Elsa Lindenberg, a dancer who was active in the same cell as he.

In 1933 Hitler was in power and Reich was thrown out of the German communist party. He fled to Denmark, where he published two of his most important works, *Character Analysis* and *The Mass Psychology of Fascism*. In 1934 he settled in Malmö, Sweden, and

founded the *Review of Political Psychology and Sexual Economy*. At the Lucerne Congress a decision was made to exclude Reich from the International Psychoanalytical Association (IPA). He took refuge in Oslo, Norway, where he continued to train psychoanalysts and conducted research on organic electricity. A campaign of defamation—he was referred to as a “Jewish pornographer”—led by a man named Quisling, led Reich to accept the invitation of Theodore Wolfe to move to the United States to teach “character-analytic vegetotherapy.”

He arrived in New York in 1939, rented a cabin in Maine and had several buildings constructed, which he called the “Orgonon.” Here he conducted research, taught, and performed clinical work. It was a period of intense creative activity for Reich. In politics he denounced the “emotional plague,” the source of fascism, and developed the principles for a “democracy of work.” He also became interested in newborns following the birth of his son Peter to his third wife Ilse Ollendorff in 1944. He investigated the problem of cancer and, at the same time, struggled to determine orgone formations in the atmosphere and the cosmos. He successfully practiced vegetotherapy. Preoccupied by the problems of the environment, he explored the Arizona desert (“operation Orop Desert”). He continued to publish and republish at a steady rate: in 1948 *The Function of the Orgasm*, an autobiographical work, and the *Biopathy of Cancer, The Sexual Revolution, and Listen, Little Man*; in 1951 *Ether, God, and Devil*, and *Cosmic Superimposition*; in 1953 *The Murder of Christ and People in Trouble*, published by the Orgone Institute Press.

A campaign of lies and vilification in the tabloid press resulted in Reich being called in for questioning by the police. After refusing to cooperate with the court he was convicted and sent to prison, where he died. A year earlier, as a result of a court decision, nearly all of Reich’s books were burned at the Gansevoort Street incinerator in Manhattan (New York City).

## REIK, THEODOR (1888–1969)

Lay analyst Theodor Reik was born on May 12, 1888, in Vienna, and died on December 31, 1969, in New York.

He was the third child of four born to the cultured, lower-middle-class Jewish family of Max and Caroline Reik. Reik’s father was a low-salaried government clerk who died when Theodor was aged 18. Freud became a father figure for the rest of Reik’s life. He attended public schools in Vienna and entered the University of Vienna at the age of 18, where he studied psychology and French and German literature. He received his PhD in 1912, writing the first psychoanalytic dissertation, on Flaubert’s *The Temptation of St. Anthony*. He met Freud in 1910, and two years later became a member of the Vienna Psychoanalytic Society. From 1914 to 1915 he was in analysis with Karl Abraham in Berlin and, with the outbreak of World War I, served as an officer in the Austrian cavalry from 1915 to 1918, seeing combat in Montenegro and Italy and being decorated for bravery.

Following the resignation of Otto Rank, Reik became the Secretary of the Vienna Psychoanalytic

Society. For ten years he practiced in Vienna and began to write so extensively that Freud asked him: “Why do you piss around so much? Just piss in one spot” (Natterson, 1966). Freud wrote “The Question of Lay Analysis” in defense of Reik, who had been prosecuted under the quackery laws of Austria for practicing medicine.

Reik moved to Berlin, where he lived and practiced from 1928 until 1934 and again was a celebrated teacher at the psychoanalytic institute. Fearing the rise of the Nazis, he left for The Hague, where he continued practicing and teaching. During this time his first wife Ella, mother of his son Arthur, died, and he married Marija. Two children were born of this marriage, Theodora and Miriam.

Still fearful of the Nazis, he moved to New York where, as a non-medical analyst, he was denied full membership in the New York Psychoanalytic Society. Reik would not accept the position of research analyst, although he could have made a “charade” of agreement and practiced, as many did. Reik experienced financial difficulties for many periods in his life. He was treated gratis by both Karl Abraham and Freud and for a time he received financial support of 200 marks a month from Freud. After he wrote for help in 1938, Freud wrote back: “What ill wind has blown you, just you, to America? You must have known how amiably lay analysts would be received there by our colleagues for whom psychoanalysis is nothing more than one of the hand-maidens of psychiatry” (Hale, 1995). Reik persevered, however, building a practice, and soon a group of colleagues centered around him and, in 1948, the National Psychological Association for Psychoanalysis was founded.

Reik’s influence on the development of nonmedical analysis in the United States was great. Not only did his many books have a profound effect on the general reading public but his influence through the NPAP (National Psychological Association for Psychoanalysis) and the institutes that split from it suggest that Reik was the major promulgator of non-medical analysis in the United States.

Reik’s psychoanalytic studies include discussions of such writers as Beer-Hofmann, Flaubert, and Schnitzler as well as Shakespeare, Goethe, and Gustav Mahler, to name but a few. He had a unique way of communicating and his writing and conversational style was free associational. His autobiography is to be found in his many works. Among his better known

are: *Listening with the Third Ear* (1948); the monumental *Masochism in Modern Man* (1949); *Surprise and the Psychoanalyst* (1935); his recollection of Freud, *From Thirty Years with Freud* (1940); an autobiographical study, *Fragment of a Great Confession* (1949); applied psychoanalysis of the Bible in *Mystery on the Mountain* (1958); anthropology in *Ritual* (1958); and sexuality in *Of Love and Lust* (1959), *Creation of Woman* (1960), and *The Psychology of Sex Relations* (1961); and music in *The Haunting Melody* (1960).

Toward the end of his life Reik, who grew a beard, resembled the older Freud and lived modestly, surrounded by photographs of Freud from childhood to old age. He died on December 31, 1969, after a long illness.

Natterson says, of Reik: “In many ways, Reik is the epitome of the sensitive aesthete, the pleasure-loving, erotic, highly intellectual, secular Jewish scholar. These characteristics are to be treasured” (Natterson, 1966).

Theodor Reik, disciple of Freud, Secretary of the Vienna Psychoanalytic Society, author of over 20 books and hundreds of papers on literature, music, religion, analytic technique, and masochism, founder of the National Psychological Association for Psychoanalysis (NPAP) in New York, an analyst in four major cities who wrote in a confessional way about his life, loves, failures, and triumphs, occupies a unique place in the history of psychoanalysis.

## RELATIONS (COMMENSALISM, SYMBIOSIS, PARASITISM)

In his book *Attention and Interpretation* (1970), Wilfred R. Bion conducted a parallel study of the relations between the mystic and the group, between the container and the contained, and between a new idea and the psychism in which it appears. He used the same relations model to describe these three situations with three types of relations: commensal, symbiotic, and parasitic.

Bion uses the relation of the mystic to the group as a springboard for his developments. The mystic, whom he also calls the genius or messiah, is the individual who brings new ideas to the group. He is opposed to the establishment, whose role is to maintain the cohesion and stability of the group. The mystic and the establishment need each other. By maintaining the stability of the group, the establishment enables the advent of the mystic who is engendered by the group to which the mystic gives life (psychic, spiritual, or scientific); the mystic needs the group, therefore the establishment, in order to introduce new ideas to the greatest number of people, for example the benefits of Newton's physics or Freud's psychoanalysis.

But together the group and the mystic maintain relations which, although they include a charge of creativity, also imply a charge of destructiveness. The new idea introduced by the mystic always threatens the existence of the group or one of its sub-groups.

These are the definitions that Bion gives of the three types of relations he describes: "By 'commensal' I mean a relationship in which two objects share a third to the advantage of all three. By 'symbiotic' I understand a relationship in which one depends on another to mutual advantage. By 'parasitic' I mean to represent a relationship in which one depends on another to produce a third, which is destructive of all three" (p. 95).

In the commensal relation there is coexistence on each side of the relation in such a way that each is inoffensive to the other. In the symbiotic relation "there is a confrontation and the result is growth-producing" (p. 78). In the parasitic relation the product of the association destroys the two associated parties; it is a relation that is marked by envy that "cannot be satisfactorily ascribed to one or other party; in fact it is a function of the relationship" (p. 78).

Bion gives different examples of these three types of relations, sometimes drawn from the relations of the mystic and the group, sometimes from the relations of the contained, noted ♂, to the container, noted ♀: "The container," he writes, "is represented by a mouth or a vagina, the contained by a breast or a penis" (p. 95). He illustrates the parasitic, symbiotic, and commensal relations with the example of a man who wants to communicate his annoyance but who is submerged by the emotion and who begins to stutter and becomes incoherent: "Such a failure is the outcome of a 'parasitic' relationship between the contained (or rather, not contained) material and the speech devised to contain it: 'container' and 'contained' have produced a third 'object'—incoherence—which makes expression and the means of expression impossible. In so far as the imaginary episode led to a development of powers of expression and of the personality that strove to express itself, the relationship could be described as symbiotic. 'Commensal' is illustrated by supposing that the episode occurred in an age and society (as in Elizabethan England) in which language had reached a point of development where the ordinary man was inspired to speak it well: that which was to be expressed and the vehicle for its expression profited from the culture to which they belonged" (p. 96).

## RELAXATION PRINCIPLE AND NEO-CATHARSIS

The relaxation principle and neo-catharsis is an element in analytic technique that complements the principle of frustration and makes it possible to reach moments of self-hypnotic analytic trance. For Ferenczi this represented technical progress because, along with

the analysis of the transference, this relaxation made it possible to reach very deep zones of the intrapsychic *teratome* consequent to precocious traumatizations (he uses a metaphor from embryology, the teratome being a tumor whose appearance evokes the different stages of embryonic development). A laissez-faire principle establishes the relaxation that is already implicit in the notion of free association.

Ferenczi describes how, with the help of this relaxation and this trust, the patient reaches trance states, transitory fits of veritable hysteria that have the great advantage of “giving a feeling of reality and objectivity that is closer to a real memory.” Moreover, these states of autohypnosis relate back to the old catharsis “long thought to be buried following the development of such successful theoretical constructions.”

In 1929 he read a paper entitled “Progress in Analytic Technique” to the eleventh congress of the International Psychoanalytical Association, held in Oxford. The following year he continued in the same vein with “Principle of Relaxation and Neo-Catharsis.” In his 1929 paper he referred to the work of Reich, Severn, Groddeck, and Simmel, as well as to treatment projects in clinical psychiatry. He also reported a discussion with Anna Freud, to whom he felt very close because of the techniques she used for psychoanalyzing children.

Dating from early psychoanalytic practice, this concept appears to be quite different from what has since come to be known as relaxation. The new catharsis he speaks about is more, as he wrote: “A confirmation from the Unconscious, a sign of our laborious work of analytic construction, of our technique in relation to the resistance and the transference which have finally succeeded in achieving etiological reality.” These two notions deserve their place in modern psychoanalysis, although they imply a new development in traumatic theory in order to explain the grave pathologies observed when prepubescent shock leads to a “passing psychosis,” which later results in the adult patient having the equivalent of an “intrapsychic twin” or “teratome.” Ferenczi progressively came to perceive the “incestuous tendency of repressed adults who don the mask of tenderness.” Two years later he developed these notions in his famous text “The Confusion of Tongues between Adults and the Child,” as well as in his *Clinical Diary*, which did not appear until fifty years later.

Many of the notions expressed here have been increasingly used by psychoanalysts dealing with patients in great difficulty, although some resist the

integration of this dynamic theory. It is worth remembering that a psychoanalyst like Georges Devereux developed the notion of the counter-Oedipus in a comparable vein.

## **RELAXATION PSYCHOTHERAPY**

At the urging of eminent neuropsychiatrist Julian de Ajuriaguerra, in the early 1960s a small group of psychoanalysts, all members of the Paris Psychoanalytic Society, attempted with certain patients to employ *autogenic therapy*, a technique inspired by hypnosis. Developed originally by German psychiatrist Johannes Schultz (1884–1970), autogenic treatment involved training a patient to experience well-being and comfort induced by hypnosis, more or less independently of a therapist.

Work with autogenic therapy soon led the group (Michèle Cahen, Jorge García-Badaracco and Marianne Strauss) to develop a psychoanalytic technique that aimed not so much to induce relaxation as to listen to bodily sensations. The observation that each patient experiences their own body in a unique way shifted emphasis toward resistances, perception of body image, and examination of the experience of relaxation itself. The principal psychotherapeutic tool became what Ajuriaguerra (1959) called the *tonic dialogue*. Spontaneous modifications of muscle tone develop in the course of any emotional relationship but almost always go unnoticed. These variations reveal the body's role in distinguishing pleasure-unpleasure and represent the first

“language” of the mother-infant dyad. The goal of relaxation psychotherapy is not primarily to soothe the patient but rather to lead them toward “verbal expression of the states of one’s own body.” (Roux, 1968). Such states, rather than the patient’s fantasies or stories, become the “signifiers” in relaxation psychotherapy.

The work of relaxation therapy takes place along two axes. First of all, it helps the patient to become aware of bodily sensations as experienced in the therapist’s presence, and also helps the patient to formulate descriptions of them and to facilitate verbalization in terms of secondary-process thinking. At the same time, the therapist illuminates the role of the earliest objects in formation of the ego as revealed by bodily reactions in terms of the transference, which is more clearly in evidence. It seems apparent that the therapeutic work can take into account “behavioral” reactions without serious risk of inflicting narcissistic injury. Relaxation therapy produces in the patient a “passive” attitude towards endopsychic functioning and instinctual movements which are ordinarily in a “discharge” mode.

Unlike other similar techniques, relaxation psychotherapy does not employ suggestion. The therapist remains in the patient’s line of sight and seeks to observe “what’s happening with the body” while confining participation to helping the patient describe, in their own words, associated thoughts and feelings. The “tonic-emotional responses” thus discovered are reflected in the relationship with the therapist. This “detour” via the body places the therapist in the position of a primitive transitional object, introducing a third party into the relationship. Therapeutically, this facilitates recapture of secondary-process thinking, development of insight, and integration of behavioral phenomena that can be meaningfully interpreted.

Indications for relaxation psychotherapy include cases with severe underlying weakness in ego structure, whether with evidence of psychosomatic disorder or in patients suffering from narcissistic pathology.

## **RELIGION AND PSYCHOANALYSIS**

Religion is a body of beliefs and practices shared by a given social group and connecting it to a higher agency, generally a divinity or divine human. Interestingly, the word *religion* is the same in most western languages, Latin or Germanic. However, the origin of the term has, for more than two thousand years, been the object of an intense debate that is of interest to psychoanalysis. According to the Latin authors Lactantius and Tertullian, the word is related to the Latin verb *religare*, “to reconnect, to bind again.” Religion would, therefore, involve a twofold connection—among humankind and between humankind and God. In Cicero, religion is associated with the verb *relegere*, “to gather.” In this case religion is said to be a gathering together, an interiority, some scruple that prevents or delays action and entails the performance of certain rites. In this sense we agree with philosopher Michel Serres and the linguist Émile Benveniste that the opposite of religion is negligence.

The topic of religion was initially examined by Freud and Breuer in the *Studies on Hysteria* (1895d), where hysteria could be considered a reaction to mental suffering associated with religious doubt. Freud’s first detailed examination of religion, “Obsessive Actions and Religious Practices,” appeared in 1907. The first book in which he discussed religious themes was *Totem and Taboo* (1912–1913a).

Freud saw religion in its collective and individual forms. On the one hand he viewed the church as the prototype of an artificial crowd (as the army), where each individual must love his leader (Christ, for example) as a father and other men as his brothers. Religion helped maintain the cohesion of a human group threatened with disintegration if there was a loss of faith (1921c). On the other hand, he also saw religion, with its ceremonies and detailed rites, as a universal neurosis, where scruples were transformed into obsessive acts.

Religion would contribute to humankind's transition from a natural state to a cultured one through the sacrifice of human drives. But the progress of civilization also implied a return to the irrational and the maintenance of illusions that maintained the individual within the confines of his infantile neuroses (1927c).

The Freudian approach to religion has more to do with anthropology than with theology: Religion is a part of civilization and the discussion of its dogmas is less important than its hold on society and the individual. From this point of view Freud, who claimed to be an atheist, had to confront the criticisms of his friend, Pastor Pfister, along with those of his former student Carl Jung. Moreover, Freudian conceptions of religion relied on the knowledge available during the early twentieth century, which has since often been challenged by the findings of archeology and epigraphy. Thus the character of Moses leading the people of Israel through the desert and out of Egypt in *Exodus*, a figure magnified by Freud, seems in the early twenty-first century to have more to do with myth than with history. And, unlike Jung, Freud rarely made reference to the religions of the Far East, which are so unlike Hellenistic and Middle Eastern cultures.

## **REMEMBERING**

The term *remembering* designates the specific psychic action of producing a memory and is to be distinguished

from reminiscences, flashbacks, and all other elements of the past that might be seen to constitute other types of representation. Freud, together with Josef Breuer, introduced this notion in their preliminary communication (1893a) as part of their cathartic therapy and Freud's initially trauma-based theory of hysteria. Freud stressed that simple recollection of memories with no accompanying affect, and so reduced to pure ideas, would have no therapeutic value. Remembering that is efficacious, and therefore of interest to psychoanalysis, involves the subject's reliving traumatic events with all their original affective intensity. Here Freud, while also stressing conditions of therapy, was already distinguishing purely narrative ideas that have affective energy discharged and that remain blocked in a split-off part of consciousness.

The recollection of memories in treatment introduced the difficulty of distinguishing between childhood memories and "screen memories" (1899a), despite certain clinical characteristics pertaining to the latter. Freud noted that the disparity between screen memories and other memories from childhood remained ultimately problematic. Did conscious screen memories originate in childhood or simply relate to it?

This question, raised as early as 1899, remains very much alive, because there is no guarantee that the recollection of even the most authentic memories travel a direct route from the past of childhood to the present of analytic treatment, and the total reliability of such remembering is certainly open to doubt. Inevitably, childhood memories are subject to the happenstance experience of the subject, leading to unconscious distortions, infidelities, maskings, false leads, and so on. The analyst who maintains that such memories are genuine, even those with the best claim to being authentic, is either naive or is laboring under a narcissistic illusion of omniscience.

In the area of remembering, psychoanalysis has to defend its sphere of authority by distinguishing itself from neurobiological, neuropsychological, and cognitive approaches to memory. Remembering remains a key element of psychoanalytic treatment. As in other relations that psychoanalysis has with proximate scientific disciplines, the issue is generally one of a cross-disciplinary misunderstanding, which it would be proper to resolve. This is what motivated Jean Laplanche to evoke Freudian pseudo-biology, pseudo-neurology, and pseudo-psychology. Unconscious

phenomena, the area specific to psychoanalysis, inevitably pervert, or at least distort, the various types of positive knowledge about humans.

Remembering in psychoanalysis can only be pertinent, therefore, when such remembering imitates the mechanisms that govern the recall function of memory, whose incredible complexity contemporary science is just beginning to plumb. Conversely, because of the necessary positivism of its project, the scientific approach to remembering cannot account for the negativism and emptiness in the psyche's dialectic between meaning and meaninglessness. Everything—from birth to death—that constitutes the enigmatic and singular design of an individual's destiny escapes, for the most part, from the individual's consciousness. Hence, there are limits to remembering.

To see how remembering functions in analysis, it is appropriate to chart a history of the aims of analytic treatment:

- The original memory model of psychoanalysis aimed at recollecting a childhood past that was buried but is likely to be brought to light.
- A subsequent model yielded increasingly to structures not subject to the internal history of the subject's life (the death drive, the Oedipus complex, repetition), in other words, to elements introduced by Freud in his second conceptualization of the psychic apparatus and to advances made in psychoanalysis since around 1930. Because psychoanalysis depends on the chance elements of the transference, this substantially relativized hope for a "spontaneous tendency towards a return of the repressed." As a result, the unrepresentable, the repetition compulsion, and various forms of psychic breaching have taken on a prominent role in the transference (Baranès).
- Finally, since the 1970s, psychoanalysis has been extending and openly accepting its own theoretical and practical divisions.

Remembering should be regarded essentially as reconstructing a certain historical truth together with ceding to what is sometimes referred to as "structural truth" (truth concerned with mental organization). Remembering and the freedom to rediscover one's own history, along with the de-centering that this entails, carves out a space that accords with some modulations of fantasy play and with the necessary mythology of origin. Analytic treatment—woven from

the memorable, the infantile, the repeatable, while encountering limitations to meaning and meaninglessness and the absence of temporal references—would be lost if the analyst's constructions and interpretations of the transference were not subordinate to the analysand and his freedom.

An individual engages in analytic treatment to effect change. An assemblage of memories, even an organized one, that does not benefit from the work of composition and that does not take into account the inherent constraints of the psychic apparatuses, whether grouped or corporeal, would be nothing but a dead letter, destined to be neither interpreted nor recreated. It is the fabric of the transference that facilitates, for both analysand and analyst, the energetics of transformation. As a result, while memories and historical working through might not be enough in themselves to move the analysis forward, they are nevertheless a *sine qua non* of analysis. In this respect, individuals are like nations: a community that has forgotten its history is condemned to servitude.

## “REMEMBERING, REPEATING AND WORKING-THROUGH”

Written and published in 1914, “Remembering, Repeating and Working-Through” clearly established Freud’s position on analytic technique, in which the cathartic method had yielded to the associative method. It thus deserves notice as one of the few technical writings to complement the great metapsychological edifice of 1915.

Freud begins the essay by citing the cathartic method, without doubt in order to mention how much he owed to it for having “acquainted him with certain analytical processes,” but above all so that the reader could recognize how much technical progress had been made with the new associative method. During this period, 1914–1915, treatment began to involve real psychic work for the patient for whom passive hypnosis is no longer clinically effective. The goal of this effort is to *remember*, “to fill in gaps in memory,” as Freud states, and to “overcome resistances due to repression” (p. 148). The growing complexity of analytic technique was opposed to the simplicity of the hypnotic technique, which responded only to the simplest form of remembering.

This required that forgetting, a psychic fact that had been previously thought to be negligible, be reconsidered in all its amplitude and complexity. “Impressions” and “experiences” (p. 148), insofar as they have a rapport with forgetting, were opposed by Freud to psychic reality, that is, to “phantasies, processes of reference, emotional impulses, [and] thought connections” (p. 148). From this point on, memory, a favorite theme of Freud’s since his work on aphasia, was to become an extensive subject for investigation. Yet remembering is not a straightforward process; thus, while the encounter between analyst and analysand might stimulate the repetition of the past, it does not always take the form of a memory, but might reside also in actions.

Repetition as action rather than as memory led Freud to examine the links between the three concepts of transference, repetition, and resistance. Transference is simply a “piece of repetition” (p. 151), and repetition is only the “transference of the forgotten past” (p. 151) onto the analyst but also onto “all the other aspects of the current situation” (p. 151). Freud then identified a further type of repetition, “the compulsion to repeat,” which replaced the “impulsion to remember” (p. 151) exposed by the analyst and which

demonstrated the powerful resistance to analysis mounted by the defenses. Respect for this resistance, and an acknowledgement of it in analytic technique, is necessary if the work of analysis is to comprehend the full extent of the psychic apparatus; hypnosis, conversely, totally suppresses this resistance. The psychoanalyst’s interest is in the contents of memory and the meaning that he can attribute to them, but he must remain particularly attentive to the means by which these memories are recalled.

The handling of the transference then becomes an essential task for the analyst while the treatment is underway. Too intense an amorous transference, or, conversely, a hostile transference toward the analyst, will bolster the resistance, causing the analysis to slide into repetition (as act). In this case, repression is the customary defense mounted by the resistance, which deprives the analysand’s thought of memorable ideational content and displaces the corresponding quota of affect onto the act.

It is clear in this article that the instinct’s quantitative potency can be made to signify so long as resistance to it is not excessively powerful, an *a priori* structuring, then, of the psychic apparatus around the transformation of instincts. Freud also provides some technical advice on how to advance the treatment towards a successful conclusion. Some of these recommendations are represented in the figure of the analyst and the analysand struggling against a common enemy: a state of morbidity. Freud wrote that the task of the analyst consists in treating the illness “not as an event of the past, but as a present-day force. . . . which consists in a large measure in tracing it back to the past” (p. 151). This approach should lead to “a change in the patient’s conscious attitude to his illness. . . . [and allow him to] find the courage to direct his attention to the phenomena of his illness.” (p. 152); so that it can ultimately “become an enemy worthy of his mettle” (p. 152). So long as the analyst continues to observe “the fundamental rule of analysis” (p. 155), neither the framework of the analysis nor its influence on the transference will be affected.

Freud admits that it is not always easy to derive ideational mnemonic content from acting out. Thus near the end of the text he writes that occasionally, “it is bound to happen that the untamed instincts assert themselves” (p. 153–154), the effects of which can be witnessed in the repetitive act whereby “the bonds which attach the patient to the treatment are broken”

(p. 154), or through other instances of negative therapeutic reaction. Freud advised that in these difficult cases “The main instrument [...] for curbing the patient’s compulsion to repeat and for turning it into a motive for remembering lies in the handling of the transference. We render the compulsion harmless and indeed useful, by giving it the right to assert itself in a definite field. We admit it into the transference as a playground in which it is allowed to expand in almost complete freedom” (p. 154). In order to transform the morbid state into “an artificial illness, which is at every point accessible” (p. 154) to analytical intervention, the analyst should not rely only on the “working-through” of the patient, but rather on an extension of his knowledge of metapsychology, as well as an acquaintance with aspects of his own character that might pose an obstacle to the cure.

Freud’s conception of the psychic apparatus in 1914 was still based on the first topography; however, in order to properly account for treatments whose virtually unassailable resistances obstruct the progress of the treatment, by mobilizing an entire procession of negative phenomena, he had to wait for the introduction of the “death drive” and the further complication of the psychic apparatus by the second topography.

Thus, while Freud spoke of rendering “the compulsion harmless, and indeed useful, by giving it the right to assert itself in a definite field” (p. 154), he ended the article on a less optimistic note only a few lines later. The demonstration to a patient of their resistance is often not enough to overcome it, and indeed frequently intensifies it, which is why Freud stressed the importance of “working in common” (p. 155) and the continuation of analysis, even if the endeavour eventually becomes “a trial of patience for the analyst” (p. 155). This advice, in a form more suited to the realities of the analytic treatment, was reiterated and endorsed by the theoretical developments introduced in his 1937 article “Analysis, Terminable and Interminable.”

Freud’s emphasis on the repetition compulsion from 1914 onwards might make it the precursor of the repetition compulsion of 1920, the consequence of an instinctual dualism between the life instincts and the death instinct. The compulsion to repeat of 1914 differs from that of 1920 in that the former is under the sway of the pleasure principle. In *Beyond the Pleasure Principle* (1920g), Freud identified compulsive instinctual phenomena that repeated psychic formations foreign to the pleasure principle, thus placing the repe-

tion compulsion of 1920 in an entirely different relationship to the pleasure principle.

## REMINISCENCES

Reminiscences are special forms of memory that rise up from the past, confused, vague, involuntary, distorted, or rendered unrecognizable by unconscious mental activity. They also entail a relaxation of the psychic apparatus such that the subject does not necessarily recognize these “rememberings” as belonging to his own past.

The concept entered into the field of psychopathology in Sigmund Freud and Josef Breuer’s “Preliminary Communication” (1893a). The phrase “*der Hysterische leidet grösstenteils an Reminiszenzen*” (“the hysteric suffers for the most part from reminiscences”) represents both a break with earlier psychopathology and an introductory maxim for psychoanalysis. This phrase, linking hysteria and reminiscence, introduced a new field of exploration by showing that hysteria consists in alterations of remembering, that is, the concrete affect of the past that will be lastingly expressed in symptoms.

The concept of reminiscence, like its use in psychoanalysis, turned out to be both incontrovertible and difficult to identify. This difficulty has to do with

the variety of the relationships between patients and analysts and their own pasts, their histories, and conceptions of reality, as well as the appearance, from 1896 until now, of new concepts and ideas. Given growing experience with therapy and theoretical research, these factors require continued attention to terminological accuracy. In 1996, following the refocusing of interest on reminiscence, the notion seemed to be more difficult and problematic to identify because of its increasingly generalized nature.

Initially the use of the term *reminiscence* referred to both the nature of the psychogenesis of hysteria and the effectiveness of cathartic therapy. Freud and Breuer associated hysterical symptoms with old psychic traumas whose memory had remained unconscious—in a space that had been split off from consciousness; in their attempt to transform these pathogenic reminiscences into true memories, the therapists showed they were capable of suppressing both the symptoms and healing the splitting from consciousness that had produced them. This, together with the notion of pathogenic psychic trauma, prefigured the notion of the unconscious.

The different attempts to model the psychic apparatus (homeostatic models, memory models, linguistic models) were so many constructions needed to articulate different realities: infantile reality and its effects, sexuality, dreams, the container and content of psychoanalytic therapy. Reminiscences, which are inherent in all the analyst's material, appear as the veiled echo of a reality that is itself problematic. The products of constructions and interpretations, these are situated between a so-called “mystic writing pad” or primal writing surface, and the decentering of a subject who reappropriates their own history.

The clearest manifestation of reminiscences, which extends beyond the Freudian context of 1893, is found in the psychotraumatic syndromes or “traumatic neuroses.” Here the patient suffers from an implacable repetition of the traumatizing situation in dreams and in the production of flashbacks, which are either reproduced with cinematic accuracy or distinctly transposed. This pathology, which is fairly common and sometimes appears during the analysis of a “classic” neurosis, closely resembles Freud and Breuer's 1893 discovery: the metaphor of the internal foreign body and the irruption of mnemonic material that does not consist of memories but of images of an almost persecutory past. It is extremely difficult to transform these reminiscences

into memories. Freud and Breuer themselves noted that the psychic trauma did not only involve Jean Martin Charcot's traumatic hysteria, but the traumatic neuroses more generally. In the early twenty-first century, the concept of reminiscence can provide psychoanalysis with an opportunity to return to the investigation of “psychic trauma” with greater accuracy.

## REPARATION

Reparation is a form of sublimation connected, in the depressive position, with putting right damage done to good objects.

The pain of depressive anxiety (or guilt) starts as a deeply persecuting demand for a punishment—the talion law of an eye-for-an-eye and a tooth-for-a-tooth. As this position is worked through, new feelings (*pining*, Melanie Klein called it) appear towards the object, and are associated with specific impulses to repair the damage done by aggressive phantasies or acts. Development in the depressive position along this axis depends on the capacity to sustain a feeling of love towards the object despite the impulses of hating and, in phantasy, wanting to attack the good object.

Love takes the form of a kind of penance or atonement to a loved one, creating a mixture of sadness, regret, and activity. This is reparation.

In the characteristic manic defenses the ego takes up a position in which the object is degraded, so that damage to it becomes a matter of indifference. At first reparation may be strongly colored by these defenses (manic reparation) and then reparation is not yet based on regret but is a demonstration of a strength and energy superior to that of the object.

The depressive position is founded primarily on the relations to the internal good object, and reparation is a means of securing it. Though reparation may often be directed to external objects, the latter represent the internal object to which the ego is dedicated.

Like sublimation, reparation is deeply dependent on the social context to provide useful directions for the effort to be channeled. Klein described reparation as a powerful impetus to creativity (1935). Aesthetic achievements are examples of the most touching and loving devotions to recreating the beauty of the loved object (Segal, 1991). Reparation without the sadness and regret betrays itself in a technical perfection of prettiness, distinct from beauty. Hanna Segal (1991) has greatly expanded the understanding of the Kleinian views on the aesthetic process based in reparation; and to some extent her descriptions of the aesthetic process compliment Donald Winnicott's theory of the aesthetic object (as transitional object). As a further addition to the psychoanalytic theory of aesthetics, Donald Meltzer has pointed to the place of the infant's primary "worship" of the breast, and of the parental creative couple, conflicted though that is.

Sublimation is a similar drive toward the use of libido in acceptable ways, though it is conceived in terms of the quantitative distribution of the libido while reparation is in terms of object-relations. Because it is an attempt to repair the effects of aggressiveness, reparation also links with undoing.

Reparation might be included within the term *sublimation*. However, reparation is not the result of desexualized and rechanneled libido. Instead it is the mobilization of the libidinal impulses in the context of a relationship with an object (especially an internal one) to contest the aggressive ones.

## **REPETITION**

A characteristic expression of unconscious psychic processes, repetition drives the subject, more or less regularly, but inflexibly, to reiterate systematically certain experiences, thoughts, ideas, and representations.

Discovering and accounting for repetition opened up one of the most fertile areas of study for Freudian psychoanalysis. Whereas others emphasized hereditary, physiological, traumatic or circumstantial causes, Freud stressed that what was involved was the automatic repetition of memories and experiences that are no longer conscious, according to modalities that vary with the circumstances and individual case. The technique adopted from the time of *Studies on Hysteria* (1895) favored placing this process of repetition within the special framework of the psychoanalytic relation, wherein the idea or affect that was blocked from conscious manifestation could be expressed (catharsis). Freud pointed out, all the same, that if the memory was blocked in the unconscious, this was because it was comprised of elements that had taken the turn of "deferred action." Consequently, repetition does not mean similitude, which contrasts it from the symptom properly speaking, particularly the obsessional symptom, where it is repeated as such.

The notion of *repetition* was originally introduced by Karl Groos, for whom *recognition* was the basis of ludic and aesthetic pleasure, and also by Gustav Fechner, who defined pleasure as the result of an economy of psychic effort, leading to a lowering of tension.

Repetition provokes the return of the already-known, “reunion with the object” and the tranquility of a satisfaction whose experience is deeply rooted in the psyche. This can take two possible directions: regression pure and simple, which, when it is engaged, imposes the repetition of the same on the entire psychic life; or conversely, that of an alternating rhythm of falling into a rut and coming out of it, which becomes the indispensable basis for new experiences.

In the subsequent work of Freud, there were two distinct periods, separated in 1920 by *Beyond the Pleasure Principle*. Until this time, when repetition was mentioned, in various contexts, it was always in the same sense and often conjoined with other notions such as recall, abreaction, construction, and working through. After 1920, it almost never came up again except in the form of a “repetition compulsion.” Here the focus will be, essentially, on repetition of the first period, and its extensions.

In the first meaning of the term, repetition was equivalent to reiteration. In *The Interpretation of Dreams* it was a significant primary process: “The temporal repetition of an act is regularly shown in dreams by the numerical multiplication of an object” (1900a). In *Jokes and Their Relation to the Unconscious* (1905c), it was the source of the comic, by reason of the economy of concentrated effort and the effect of pleasure thus obtained. With a child this pleasurable effect of repetition is quite evident. But for an adult, when something is repeated, what was first pleasurable arouses anxiety and a feeling of abnormality, especially when the repetition emerges from an encounter or an experience where it was least expected. Freud cited a few examples of this in “The ‘Uncanny’” (1919h), such as the repetition of the same number, the same place, or the multiplied encounter of the same face—all of which can become the source of considerable anxiety. Freud was known to harbor quasi-superstitious feelings about certain times of the year, the repetition of numbers, or about coincidences. In his *Leonardo da Vinci and a Memory of His Childhood* (1910c), he called a repetition that occurred in the context of the death of the father *perseveration*, adding that “It is an excellent means of indicating affective colour.”

In his article “Remembering, Repeating and Working-Through” (1914g), Freud described the role of repetition in the analytic cure, considerably narrowing its significance by linking repetition to acting out. Repetition matters only when the subject “does not remember anything

of what he has forgotten and repressed, but *acts* it out” (p. 150). In which case, “We soon perceive that the transference is itself only a piece of repetition” (p. 151). This accounts for the rule that no serious decision should be made in the course of the analysis. Insofar as it is only purely and simply repetition, transference is a resistance, since it is marked by the anachronism of repeated contents and aims to disguise the effects of deferred action.

In clinical practice, the most typical example of this is the fate neurosis, which produces ineluctably the translation of memories or repressed events into acts, a process discussed in “Remembering, Repeating and Working-Through” (1914g). In transference neurosis, the repetition intervenes basically on the level of affects or representations, which constitute undeniably for Freud evidence of early repressed pleasures that the subject has not been able to renounce, to the point that his thoughts are invaded by the repetitions, or he becomes fixated and obsessed. The problem here then is to limit the fascination they exert, so as to make it possible to break free of them, which can only be done in the framework of a transference-neurosis type of repetition—but one made flexible by means of interpretation. With perversion, the repetition is focused essentially on the scenario, the practice or means utilized in the search for pleasure, which leads to stereotyping and systematizing.

Daniel Lagache placed much emphasis on the role of repetition in the transference: “In the course of the sessions of psychoanalysis, as in the course of life, the patient draws from his repertoire of habits,” and on this basis, “the liquidation of the transference should be understood as a liquidation of the transference neurosis, that is to say of neurotic repetitions, inadequate for present-day reality.” This assimilation of “repetition” with “inappropriate” characteristics was echoed a few years later by Ralph Greenson (1967). Jean Laplanche criticized this conception of repetition, which he considered too adaptationist, opposing it to a repetition such as is manifested in “full transference,” which is a positive repetition of infantile images or relations—or the kind of repetition such as is behind the “hollow transference,” whereby the infantile repeated relation rediscovers its enigmatic quality, with meaningful questions surging to the surface when this occurs (1987).

In childhood the role of repetition is decisive. Through the first articulation of meaningful phonemes, primitive gestures or initial mimicry, it results in the establishment and gradual reinforcement of

signs, rhythms, and habits that will shape the being of the subject, his physiognomy and rapport with the world.

However, in the form of tics, stereotypes, stammering, etc., repetition signals real blockages; but when repetition turns into swayings, rictus, suckings, cries, and so on, it constitutes a valuable sign of early autism (Leo Kanner) or of anaclitic depression (René Spitz). These repetitions are evidence, in effect, of a progressive withdrawal of the child into a regressive internal world where his tendency is to lose himself. In this sense, childhood is a privileged period for observing the relation to others and situating oneself: as long as the other person remains a partner, there are progressive clarifications that result in a relatively stable habitus, one that it is possible to build on. However, when the partner is distant, unknown, mysterious, enigmatic, and silent, then sometimes obstructions and inhibitions occur that require external intervention. On the other hand, when real stereotyping ensues, it can only mean that the other has been confused with an internal object.

Repetition plays an especially important role in all activities centered on sublimation, and consequently in literary or artistic creation. In analyzing the *Gradiva* of Jensen (1907a), or meditating over *Leonardo da Vinci and a Memory of his Childhood* (1910c), Freud isolated a form of repetition that not only becomes renewal, but also metamorphosis or creation: in the case of *Gradiva* there was a risk of alienation from reality, while repetition clearly allows, in the case of Leonardo, for a very special way of working with reality. Freud's intuition was applied later to the subject of music, where repetition becomes rhythm, which is probably its source, engendering irreplaceable drive pleasures and satisfactions at the deepest levels of psychic functioning (Guy Rosolato).

## **REPETITION COMPULSION**

Repetition compulsion is an inherent, primordial tendency in the unconscious that impels the individual to repeat certain actions, in particular, the most painful or destructive ones. The repetition compulsion occupies a significantly more prominent role in French psychoanalysis than in North American psychoanalysis.

Freud introduced this notion in chapters 3 and 4 of *Beyond the Pleasure Principle* (1920g), making it one of the new foundations of his theory. In the first lines of chapter 4 he presented this idea as being a “speculation, . . . an attempt to follow out an idea consistently, out of curiosity to see where it will lead” (p. 24). At the same time, he stressed that he wanted to base it solidly on analytic experience, especially that of treating “traumatic neurosis” (p. 24). Just as the unconscious mind reacts to an external trauma by repeating it—a paradox, since the trauma is a frightening experience—the conscious mind resorts to repetition when unpleasurable unconscious contents surface and threaten the equilibrium of the ego as a whole. Repetition compulsion is thus initially a defense, an attempt to bind, assimilate, and integrate undesirable experiences that are incompatible with other experiences. Freud saw this as “a function of the mental apparatus which, though it does not contradict the pleasure principle, is nevertheless independent of it and seems to be more primitive than the purpose of gaining pleasure and avoiding unpleasure” (p. 32). Thus “excitations from within . . . often occasion economic disturbances comparable with traumatic neuroses” (p. 34).

Freud considered the repetition compulsion as a largely dominant “universal attribute . . . of organic life in general” (p. 36). Modifications and development take place only because external factors regularly force the living organism to adapt to new life conditions. In this regard, he wrote, “The aim of all life is death” (p. 38). In “ever more complicated *détours* . . . these circuitous paths to death . . . would thus present us to-day with the picture of the phenomena of life” (p. 39). Unconscious instincts are also subject to this law, this aim of life, and would be completely submerged in repetition were it not for the environment and its countless demands, on the one side, and sexuality and its potentialities, on the other. “These germ-cells, therefore, work against the death of the living substance and succeed in winning for it what we can only regard as potential immortality” (p. 40). In human

beings, these cells were posited as being at the source of what Freud later called the “life instinct,” while the compulsion to repeat, which is primary, is associated with the death instinct.

Freud thereafter continually tried to give a more precise account of this initial insight. The phenomenon of positive transference helped substantiate the idea of a repetition compulsion, which could prove stronger than the pleasure principle, he explained in “Remarks on the Theory and Practice of Dream-Interpretation,” (1923c [1922]). In “An Autobiographical Study” (1925d [1924]), Freud wrote that “the essentially conservative character of instincts is exemplified by the phenomena of the *compulsion to repeat*” (p. 57). In *Civilization and Its Discontents* (1930a [1929]), he explained that the repetition compulsion involves a resistance of the id. And in 1930 he explained why he preferred the term *compulsion to repetition automatism*.

In his late work, Freud emphasized the destructiveness of the repetition compulsion. In “New Introductory Lectures to Psychoanalysis” (1933a [1932]), he wrote, “And now the instincts we believe in divide themselves into two groups—the erotic instincts, which seek to combine more and more living substance into ever greater unities, and the death instincts, which oppose this effort and lead what is living back into an inorganic state. From the concurrent and opposing action of these two proceed the phenomena of life which are brought to an end by death” (p. 107). Repetition compulsion thus became synonymous with destructive impulses. Finally, Freud associated it with primary masochism, in which the subject turns violence against himself and subjugates his libido to it, endlessly repeating certain damaging patterns based on experiences rooted at the deepest levels within the self. He theorized that this is a way of tolerating feelings of guilt. The individual manifests a tendency to destroy and suffer, which brings with it feelings of overwhelming satisfaction, all of which are vestiges of a time when the individual did not yet have a sense of reality. In the famous text “Analysis Terminable and Interminable” (1937c), Freud revealed his greatest pessimism noting that instead of “permanently disposing of an instinctual demand [through analysis].... we mean something else, something which may be roughly described as a ‘taming’ of the instinct” (p. 224–225)

As on the dichotomy between the life and death instincts, psychoanalysts have been divided on the issue of repetition compulsion. As a result, it has been reinterpreted in several ways. Among the most influential

interpretations is that of Jacques Lacan (1978), who saw repetition compulsion as one of the four major concepts of psychoanalysis, along with the unconscious, transference, and the instincts. He used it as the basis for his distinction between *jouissance* (enjoyment) and pleasure, with *jouissance* being situated “beyond the pleasure principle” as the desired result of repetition of the worst carried to its extreme. Jean Laplanche, by contrast, emphasized that the “repetition compulsion and the death instinct are not at all synonymous”: it is the message of the Other as such that is traumatic, and repetition is the first way of giving it meaning.

The concept of the repetition compulsion turned Freudian theory on its head. It introduced the death instinct, opened the way to the second theory of the instincts, and led to modifications in clinical practice and analytic technique that are still going on in the early twenty-first century. Analysts no longer focus on deciphering slips of the tongue or dreams, or on resolving a particular symptom, but instead try to find ways to halt repetitive behavior patterns by opening up diversionary pathways for them. From a theoretical point of view, the evolution of the notion of repetition compulsion and the constant shifts it underwent in Freud’s thinking has received far more consideration than one would expect. In the beginning, the main role of the repetition compulsion was to account for the psyche’s conservative tendencies, its reactions in the face of anything that might invade it. Only at a second stage did Freud emphasize the compulsive, systematic, instinctual aspects of the repetition compulsion and bring out its fundamentally destructive side. This shift is problematic. To get beyond the resulting contradiction, which emerges in the opposing positions of Lacan and Laplanche (1980), one must return anew to one of Freud’s statements in the metapsychological articles of 1915, according to which all instincts are fundamentally active, willed, and enacted by the subject alone. And one must note in addition that the subject exists in relation to others and is the product of relationships. Subjects repeat what they internalized during their earliest relationships, in order to actively exploit this initial lived experience by all means at their disposal. This repetition turns into automatism pure and simple and becomes destructive when it runs up against some of life’s obstacles. Then repetition is completely beyond the control of the subject, who is held hostage to it.

## REPETITIVE DREAMS

The repetitive dream is a dream that is dreamt repeatedly and more or less identically during one's life.

Freud first thought that “a dream contains elements from childhood... where the dream is of what has been called the ‘recurrent’ type” (1900a, p. 190); subse-

quently he was of the opinion that symbolic interpretation was indispensable for an analysis of this kind of dream (1901a). He undertook a comprehensive analysis of such a repetitive dream in the case of Dora (1905e), then later, in that of the “Wolf Man” (1918b).

Taking into consideration the traumatic underpinnings of such dreams, he later changed his position, especially as it related to anxiety dreams. In “Dreams and Telepathy” (1922a) he discussed a dream, cause of much anxiety, that pursued the dreaming woman “like a ghost” (p. 209) for many years. This revision of his view of the repetitive dream occurred in the general context of metapsychological modifications resulting from his reflection on repetition itself, “beyond the pleasure principle” (1920g). Ferenczi (1931/1955) was influenced by it in writing: “Every dream, even the most disturbing ones, attempt at mastery and resolution of a traumatic experience” (p. 238).

Subsequently, the repetitive dream has been generally discussed from the perspective of the symptomatic repetition of a trauma (Rabain, 1988), as well as within the framework of metapsychological reflections on time (Seulin, 1997).

## REPRESENTABILITY

*Representability* is a sensory capacity of the psychic apparatus that makes it possible for an object that is

absent to be made present in the form of an image. It is active in the process of hallucination, artistic creation, and the dream work, where latent and abstract thoughts are transformed into visual images.

The notion of representability appears in chapter 6 of *The Interpretation of Dreams* (1900a) titled “The Dream Work,” in which Sigmund Freud explores the relationship between manifest content and latent thoughts, and the psychic means used in the selection and transformation of abstract thoughts into visual images. It is also found in chapter 7, “The Psychology of the Dream-Processes,” where the focus is on the dream’s instinctual force, understood as a wish-fulfillment by means of regression to sensory images.

In the mind’s use of representability, abstract thoughts are transformed into pictorial language. Among the means involved are condensation through selection of overdetermined elements, and displacement of psychic intensities along associative chains. The omission of logical and causal relationships that cannot be represented is reminiscent of the plastic arts, but the reduction to condensed terms also resembles the work of poetry, and the ambiguous syntax obtained by plays on words. The aim of this work is to make it possible for free-flowing energy to be attracted to visual images while at the same time satisfying the mind’s endopsychic censorship by means of these distortions. Primary representation-compulsion, noted in Herbert Silberer’s account of self-symbolization, should not lead us to overlook the aim of this formal regression governed by the primary process: putting an end to internal tension and “re-finding” the sensory trace of the object and the illusion of its presence. In so doing, the dream hallucinatorily fulfills a wish, and the regression is both temporal and topographical insofar as the wish is unconscious and dates from childhood.

In “A Metapsychological Supplement to the Theory of Dreams” (1916–17f [1915]), his perspective expanded by metapsychology, Freud delineated the hallucinatory process in its topographical and psychopathological dimensions. Representability involves a conscious cathexis of an instinctual demand; a negative hallucination makes it possible to deny the perception of reality.

In “Du langage pictural au langage de l’interprète” (From pictorial language to the language of the interpreter; 1980), with regard to psychosis, Piera Aulagnier returned to the idea that a consideration of representability is necessary for the analyst’s interpretation to be

dynamically effective, with regard to particular modes of thought that remain fixed to thing-presentations.

The term *representability* poses the same problems of translation as the term *representation*, which is used to render two different German terms: *Darstellung* and *Vorstellung*. Indeed the English terms do not capture the connotation, inherent in the German *Stellung-da*, of the presence of the object that is associated with all hallucinatory productions.

## **REPRESENTATION OF AFFECT**

The term *representation of affect* can be defined as that which constitutes the medium for the affect’s expression, in a sense serving as its vehicle in mental dynamics.

This expression, which is found in some psychoanalytic texts, is nevertheless of dubious value for metapsychology as it was expressed in Sigmund Freud’s 1915 texts brought together under that title. In those texts he clearly established that instinct, situated at the “frontier” between body and mind, is expressed in mental dynamics by means of two components: on the one hand, the ideational representative, and on the other, an energy charge, the “quota of affect” (*Affektbetrag*), whose fate can be distinct. This energy charge, when it is temporarily without a representational support, can be qualitatively transformed into various emotions (fear, pleasure, anxiety, etc.) and, under certain conditions, can cathect ideational representations awaiting the arrival of such a charge that will embody and validate them.

This is the case, for example, when anxiety “without an object” (that is, without a conscious object) becomes focused on a clearly identifiable phobogenic object; this process was clearly demonstrated in the case of “Little Hans,” related in “Analysis of a Phobia in a Five-year-old Boy” (1909), whose castration anxiety was found to be embodied in horses.

Thus, if we speak about representation of affect, it is in the sense in which a traveling salesman “represents” a product, delegated by his or her employer to perform this function for the clients (in this analogy, the instinct would be the employer, and consciousness would be the client). This usage of the term can be deemed to be congruent with one of the terms used by Freud to denote representation, *Repräsentanz*, which has precisely this meaning of “delegate,” “deputy,” or “representative” in the commercial sense.

## **REPPRESSED**

The repressed is constituted by the operation of repression, which rejects and maintains in the unconscious representations deemed incompatible with the ego.

The repressed is not directly knowable, since it pertains wholly to the unconscious. It can be known only by its effects and by what it produces through deferred action, in particular “derivatives” of the unconscious.

Sigmund Freud always insisted on the unalterability of the repressed, while at the same time recognizing that it could be rearranged or even modified, especially in the course of psychoanalytic treatment. Initially, Freud considered the notion of the repressed as a correlative to that of an unconscious still distinguished by its dynamic role. In his early works Freud attributed an “intentionality” to the mind that seeks to forget and maintain outside of consciousness a certain number of unpleasurable representations (thoughts, images, memories). He posited that these representations are isolated in a “second psychical group” that is separated from the mainstream of thoughts. The psyche then becomes “dissociated,” the unpleasurable idea being relegated to another place, repressed, thus blocking any discharge of the emotion associated with it.

It can be seen that the notion of repression, as originally set forth, is correlative to that of the unconscious. For a long time—until he put forward the idea of unconscious ego defenses—Freud used the term *repressed* as a synonym for the unconscious.

However, the term *intentionality* used by Freud in 1895 must be understood in a nuanced fashion. As Jean Laplanche and Jean-Bertrand Pontalis underscored in *The Language of Psychoanalysis* (1967; trans. 1974), the “splitting of consciousness” is only “initiated” by an intentional act (p. 353). Indeed, as a “separate psychic group” repressed contents escape the subject’s control and are governed by the laws of the primary processes. The repressed representation in and of itself is an initial “nucleus of crystallization” capable of attracting other intolerable representations, without the intervention of any conscious intention.

Repression is thus conceived as a dynamic process that involves maintaining a counter-cathexis; it is always susceptible to being thwarted by an unconscious wish seeking to return to consciousness. Freud called this process “the return of the repressed.” Repressed wishes are not annihilated in the unconscious; rather, they constantly tend to reappear in consciousness through the intermediary of more or less unrecognizable derivative formations that Freud generically called “derivatives of the unconscious” or “derivatives of the repressed.” In “Repression” (1915d), Freud explained

that these derivatives can return to consciousness in the form of substitutive formations or symptoms.

The repressed is not directly knowable, since it pertains wholly to the unconscious. Just as only the products of the unconscious can be known, we can only know the derivatives of the repressed, its formations under the effects of deferred action. According to Claude Le Guen in *Le Refoulement* (1992; Repression): “The repressed is indeed a constituent part of the id, but the only thing that can make it comprehensible to us has to do with the fact that it is a product of the ego.”

Freud pointed out in “Repression” that “repression does not hinder the instinctual representative from continuing to exist in the unconscious, from organizing itself further, from putting out derivatives and establishing connections.” The instinctual representative “proliferates in the dark . . . and takes on extreme forms of expression” that “not only . . . seem alien” to the neurotic, but “frighten him” (p. 149). The repressed undergoes distortions in and by means of the derivatives that represent it, until, thus disguised, it can elude censorship and gain access to consciousness. The repressed, therefore, is anything but inert. Moreover, it “exercises a continuous pressure in the direction of the conscious, so that this pressure must be balanced by an unceasing counter-pressure. Thus the maintenance of a repression involves an uninterrupted expenditure of force, while its removal results in a saving from an economic point of view” (p. 151). Finally, the repressed that returns is never identical to what was originally repressed, because in the meantime it has been distorted—it has “worked.” Indeed, such changes are mandatory in order for the censorship to give its authorization.

For a long time Freud privileged the study of the repressed per se. His interest in the repressing agency, the ego, only took shape later. What he described in *Beyond the Pleasure Principle* as “the aim which had been set up—the aim that what was unconscious should become conscious” (1920g, p. 18) proved to be a more difficult task than he had supposed in the early days of interpreting dreams and parapraxes. Analysis ran up against repetition compulsion, and the need for punishment. The repressed could thus not explain everything, and beginning in 1923 Freud shifted his focus toward the repressing agency. In *Civilization and Its Discontents* (1930a [1929]), he wrote: “Alterations in [analytic theory] seemed essential, as our enquiries

advanced from the repressed to the repressing forces, from the object-instincts to the ego” (p. 118).

In *Beyond the Pleasure Principle*, Freud posed the problem: “We shall avoid a lack of clarity if we make our contrast not between the conscious and the unconscious but between the coherent ego and the repressed. It is certain that much of the ego itself is unconscious, and notably what we may describe as its nucleus; only a small part of it is covered by the term ‘preconscious.’ Having replaced a purely descriptive terminology by one which is systematic or dynamic, we can say that the patient’s resistance arises from his ego, and we then at once perceive that the compulsion to repeat must be ascribed to the unconscious repressed” (1920g, p.p. 19–20). It is therefore appropriate to analyze the resistances rather than bringing to light the repressed (which always represents the dynamic unconscious). In the words of Claude Le Guen (1992): “The opposition is no longer to be situated between the systems, but rather between the agencies.”

Unconscious resistance is thus a product not only of the repressed, but also of the ego, which does not want to eliminate repression. “We may say that repression is the work of this super-ego and that it is carried out either by itself or by the ego in obedience to its orders,” wrote Freud in *New Introductory Lectures on Psycho-Analysis* (1933a [1932], p. 69). The question of the fate of the repressed remains crucial, above all in relation to psychoanalytic treatment and the possibilities for change it promises. Freud always insisted on the “indestructibility” of unconscious contents. In *The Interpretation of Dreams* (1900a) he described unconscious repressed wishes as being “ever on the alert and, so to say, immortal” (p. 553). The adjective *immortal* was used again in the lecture “The Decomposition of the Psychical Personality” in *New Introductory Lectures on Psycho-Analysis*.

In the metapsychological writings of 1915, the derivatives of the repressed are said to continue to become organized, to work, and to undergo distortion in the unconscious, but these transformations in service of the defenses are not real “changes.” Freud subsequently envisioned them in terms of the treatment. Returning in the *New Introductory Lectures* to the problem of the effects of treatment on the repressed, he noted that “in certain cases the repressed instinctual impulse can subsist unaltered in the id, albeit under constant pressure from the ego. In other cases, it seems, it can

undergo a complete ‘destruction’ during which its libido is definitively directed toward other pathways.” He had already postulated the “decline” (*Untergang*) of the oedipal repressed in “The Dissolution of the Oedipus Complex” (1924d).

Returning to the question of the effects of treatment on the repressed in “Analysis Terminable and Interminable” (1937c), Freud wrote: “Psychoanalysis leads the ego, which has matured and grown stronger, to revise its formerly repressed contents; some are destroyed, while others are recognized but newly constructed out of more solid materials.” He spoke here of eliminating, destroying, and rebuilding with more solid materials. Does this not imply true change, rather than a mere distortion? “Despite the explicit repetition of statements about the unalterability of the repressed, the idea of its possible change remains implicitly present,” noted Le Guen.

Freud again took up this question of the possibility of modification of the repressed in a footnote in *Inhibitions, Symptoms and Anxiety* (1926d): “Since the differentiation of the ego and the id, our interest in the problem of repression, too, was bound to receive a fresh impetus. Up till then we had been content to confine our interest to those aspects of repression which concerned the ego—the keeping away from consciousness and from motility, and the formation of substitutes (symptoms). With regard to the repressed instinctual impulses themselves, we assumed that they remained unaltered in the unconscious for an indefinite length of time. But now our interest is turned to the vicissitudes of the repressed and we begin to suspect that it is not self-evident, perhaps not even usual, that those impulses should remain unaltered and unalterable in this way. There is no doubt that the original impulses have been inhibited and deflected from their aim through repression. But has the portion of them in the unconscious maintained itself and been proof against the influences of life that tend to alter and depreciate them? In other words, do the old wishes, about whose former existence analysis tells us, still exist? The answer seems ready to hand and certain. It is that the old, repressed wishes must still be present in the unconscious since we still find their derivatives, the symptoms, in operation. But this answer is not sufficient. It does not enable us to decide between two possibilities: either that the old wish is now operating only through its derivatives, having transferred the whole of its cathectic energy to them, or that it is itself

still in existence too. If its fate has been to exhaust itself in cathecting its derivatives, there is yet a third possibility. In the course of the neurosis it may have become re-animated by regression, anachronistic though it may now be” (p. 142n).

In “Le refoulement (les défenses)” (1986), Le Guen gave a long analysis of this footnote and the new metapsychological perspectives it can provide. Only Freud’s third hypothesis seemed to Le Guen to correspond to the experience of treatment. The old, repressed wish, having disappeared as such after expending its libidinal energy for the purpose of cathecting its derivatives, can be revived by these derivatives along a regressive pathway. This involves not a meeting up, but instead a reconstruction. By reviving the past, the present acts via deferred action (*après-coup*). By organizing the past, deferred action thus serves the function of facilitation, with the most recent derivatives facilitating the older ones.

The question envisioned here—is the repressed subject to modification?—and the proposed answer—old wishes are “re-animated by regression,” with current events reviving and transforming the past—are important, in that both theory and clinical practice are closely related to our views on the fate of the repressed. Is analysis a mere bringing to light of repressed contents (Freud’s first hypothesis of a closed, inert system), does it provoke a new, defensive arrangement of them (the second hypothesis of a closed, dynamic system), or does it have a transformative role and aims (the third hypothesis of an open, dynamic system)? These three viewpoints influence the techniques used in treatment. Indeed, they indicate actual practices as well as the implicit theories of the analyst.

## REPRESSED, DERIVATIVE OF THE; DERIVATIVES OF THE UNCONSCIOUS

The term *repressed* was used by Sigmund Freud in the context of his dynamic conception of the unconscious. Repressed elements, which remain active in the unconscious, constantly tend to reappear to consciousness in derived formations that are unrecognizable to varying degrees: These are the “derivatives” of the unconscious that also appear in the forms of symptoms, fantasies, or free associations in the course of analysis.

It would be impossible to conceive of repression without the return of the repressed, and vice versa. The point of articulation of this process is provided by the “derivative of the unconscious” or “derivative of the repressed.” That which has been repressed in the unconscious tends to resurface in the conscious mind in the form of derivatives that, in turn, become the object of new defensive measures.

Freud used this expression, especially in the metapsychological texts of 1915, to refer to the symptoms, fantasies, and associations during the session that are connected to repressed ideas. In “The Unconscious” (1915), Freud compared these unconscious formations, these derivatives, to “individuals of mixed race”: “Thus *qualitatively* they belong to the system *Pcs.*, but *factually* to the *Ucs.* Their origin is what decides their fate. We may compare them with individuals of mixed race who, taken all round, resemble white men, but who betray their coloured descent by some striking feature or other, and on that account are excluded from society and enjoy none of the privileges of white people. . . . To this species belong the fantasmatic formations of normal men as well as neurotics, in whom we have recognized the preliminary degrees of the formation of the dream and the symptom” (p. 191).

This dual, Preconscious-Unconscious affiliation, together with their situation anterior to censorship, makes these derivatives into “necessary places of transition” through which the repressed can effect a return and through which repression can act, according to Claude Le Guen in *Le Refoulement* (Repression; 1992).

According to Freud in “The Unconscious,” the most highly organized unconscious derivatives include the

“substitutive formations” (*Ersatzbildungen*), which “succeed in breaking through into consciousness when circumstances are favorable—for example, if they happen to join forces with an anticathexis from the *Pcs.*” (p. 191). The substitutive formations (“parapraxes,” “jokes”) are nothing other than evolved derivatives that replace unconscious contents. In *Inhibitions, Symptoms and Anxiety* (1926 [1925]), Freud likened neurotic symptoms to substitutive formations put into the place of the instinctual process that has undergone the action of the defense.

The economic factor is what determines the various possible fates of the derivative. A reinforcing energy must retroactively intervene (for example, at puberty) for a mnemonic trace from childhood, reinforced by an unconscious cathexis and having become a “tolerable” derivative, to thereafter be perceived as bearable. Its relationship to action is what seals the fate of the derivative of the repressed. The derivative is condemned in its capacity as a precursor or representative of a possible putting into action.

The function of repression, which Freud in “Repression” (1915) described as “something between flight and condemnation” (p. 146), is to enlist the derivative in situations that render impossible the direct realization of unconscious desire—putting it into action.

## REPRESSION

Repression is the operation by which the subject repels and keeps at a distance from consciousness

representations (thoughts, images, memories) that are disagreeable because they are incompatible with the ego. For Sigmund Freud repression is the privileged mode of defense against the instincts.

Closely linked to the discovery of the unconscious, the notion of repression accompanies all the developments of Freudian theory. It is one of its major points, “the corner-stone on which the whole structure of psychoanalysis rests” (“On the History of the Psycho-Analytic Movement” [1914d], p. 16).

Initially described in conjunction with hysteria, repression plays a major role in other mental disorders as well as in normal psychic activity. It can be considered a “universal” psychic process insofar as it is constitutive of the unconscious, itself conceived of as a separate realm of the psyche.

More generally, repression is one of the defenses (in fact the primary one) mobilized by the mind to deal with conflicts and to protect the ego from the demands of the instincts.

Four main phases relating to the development of the notion of repression can be schematically described in Freud’s writings. Until 1895, based on the idea of the “intentionality” of forgetting in the neuroses, Freud assumed the existence of “unconscious motivation.” From 1895 to 1910, his research into the repressed and its contents led to the great discoveries of this period: infantile sexuality and the Oedipus complex. Repression became the mainspring of ordinary psychic functioning. From 1911 to 1919, Freud reconsidered the process of repression in terms of the threefold metapsychological viewpoint, and he described a “primal repression.” From 1920 to 1939, with the second topography (instinctual theory), repression became one “defense mechanism” among others, but at the same time remained a “separate” process. It remained at the center of analytic discourse.

Although the word had already been used in Johann F. Herbart’s psychology, it stood out to Freud as a clinical fact. He deduced from his treatment of hysterics that forgetting is an active, intentional phenomenon, since the return of forgotten memories under hypnosis and their abreaction caused the symptoms to disappear. In *Studies on Hysteria* (1895d) Freud and Josef Breuer explained that it was “a question of things which the patient wished to forget, and therefore intentionally repressed from his conscious thought and inhibited and suppressed” (p. 10).

The term *repression*, borrowed from everyday language, thereafter followed a remarkable trajectory. Not only did it return to common speech with a different meaning, but it became one of the four main concepts of psychoanalysis.

Freud showed the existence of a veritable intentionality of the mind that seeks to forget, to cause certain disagreeable representations to disappear. These representations are isolated in a “second consciousness, a *condition seconde*” (p. 12) separated from the mainstream of thought. The psyche is thereafter “dissociated,” the unpleasant idea having been relegated to another place, “repressed,” thus blocking any discharge of painful emotion that might be associated with it. It can be seen that the notion of repression, here seized at its origins, from the outset appears as a correlate to that of the unconscious. For a long time in Freud’s work, until his positing of the idea of unconscious ego defenses, the term *repressed* was essentially synonymous with the action of the unconscious.

Moreover, the term *intentionality* used by Freud in 1895 must be understood in a nuanced way. As Jean Laplanche and Jean-Bertrand Pontalis emphasized in *The Language of Psycho-Analysis* (1967; trans. 1974), the splitting of consciousness is only “introduced” by an intentional act. As a “second consciousness,” repressed contents elude the subject’s control and are governed by the laws proper to the primary processes. The specific processes of the unconscious thus mark the operation of repression. The repressed representation in itself constitutes what Freud described in *Studies on Hysteria* as an initial “nucleus and centre of crystallization” (p. 123) that can attract other unbearable representations, without any conscious intention having to intervene. From the outset, then, repression is conceived as a dynamic process involving the maintenance of a counter-cathexis; it is always capable of being stymied by unconscious desire that seeks to return to conscious awareness, which is what is meant by “return of the repressed” (“Repression,” [1915d], p. 154).

Moreover, representations are what are repressed, but it is affect, or rather its conversion from pleasure to unpleasure, that is the *raison d’être* of repression. The vicissitude of the affect is far more important than that of the representation, for it is affect that determines the judgment bearing upon the process of repression. If the vicissitude of the representation is to disappear or be held back from consciousness, the

vicissitude of the affect, the quantitative factor of the instinctual representative, is somewhat independent.

An instinct may be suppressed, or else the affect may be affirmed under a given qualitative coloring, or, in yet another case, affect itself may be transformed into anxiety. The difference, Freud explained in “Repression,” stems from the fact that representations are cathexes, whereas affects correspond to processes of discharge whose final manifestations are perceived as sensations.

The term *repression* appeared in Freud’s writings for the first time in the “Preliminary Communication” (1893a). It was identified as a cause of pathogenic amnesia, an etiological explanatory principle leading to the envisioning of a therapeutic method that would put an opposing tendency into action. At this early date, repression was still presented as “intentional” and was not well distinguished from simple suppression. A representation appears to be painful because it is incompatible with an ego that, at this time, is still synonymous with consciousness. The ego thus treats the disagreeable idea as a “non-arrival” by repressing it.

This repression is thus posited as being a mechanism common to all mental disturbances, to hysteria, obsessional neurosis, and hallucinatory confusion. It affects only the representation; the vicissitude of the affect, for its part, determines the specificity of the disorder: conversion, isolation, or rejection (“The Neuro-Psychoses of Defence” [1894a]).

With the metapsychological writings of 1915, Freud distinguished different phases in the process of repression: fixation, “repression proper” (“Repression,” p. 148) and finally, the “return of the repressed” (p. 154), which occurs at the point of the fixation itself.

Freud described several stages in the organization of repression, for if “repression and the unconscious are correlated” (p. 148) there was a good basis for accepting the idea of a “primal repression” (*Urverdrängung*, p. 148) that represents its earliest stage. This repression does not affect the instinct, the limit concept between the psychic and the somatic, but rather its “representatives,” which thus do not gain access to consciousness. An initial unconscious nucleus is created that will function as a first pole of attraction about which elements will be repressed. This is accompanied by a “fixation,” and the so-called representative “persists unaltered” (p. 148), along with the instinct attached to it, in the unconscious.

The second stage of repression is that of “repression proper” (*eigentliche Verdrängung*) or “after-pressure” (*Nachdrängen*, p. 148), which occurs through deferred action. It involves the psychic derivatives of the repressed representative, or else a given associative chain, a predetermined train of thoughts that is related to it by association. This is a double process that joins to the attraction of the primal repressed (the earliest unconscious nucleus) a force of repulsion (*Abstossung*) that comes from consciousness and acts upon material that is to be repressed. These two forces act in tandem, with “something previously repressed ready to receive what is repelled by the conscious” (p. 148). In a note added in 1915 to the *Three Essays on the Theory of Sexuality* (1905d), Freud compared this dual process with “the manner in which tourists are conducted to the top of the Great Pyramid of Giza by being pushed from one direction and pulled from the other” (pp. 175–176, note 2). Finally, the third stage is that of the “return of the repressed” (*Wiederkehr der Verdrängten*) (p. 154), expressed in the form of symptoms, dreams, slips of the tongue, or parapraxes.

Repression does not entail the destruction or disappearance of the repressed representation. As Freud explained in “Repression,” it does not prevent the instinctual representative “from continuing to exist in the unconscious, from organizing itself further, putting out derivatives and establishing connections. . . . [T]he instinctual representative develops with less interference and more profusely if it is withdrawn by repression from conscious influence. It proliferates in the dark, as it were, and takes on extreme forms of expression, which when they are translated and presented to the neurotic are not only bound to seem alien to him, but frighten him by giving him the picture of an extraordinary strength of instinct” (p. 149).

Thus Freud in 1915 envisioned the operation of repression from a threefold metapsychological perspective. From the topographical point of view, repression is initially described, in the first theory of the instincts, as being maintained outside of consciousness. Censorship is what ensures the role of the repressing agency. In the second topography, it is posited as a defensive operation of the ego that is considered to be partially unconscious.

From the economic point of view, repression presupposes an interplay of opposing forces—of cathexis, decathexis, and anticathexis—that affect the instinctual representatives. “We may suppose that the

repressed exercises a continuous pressure in the direction of the conscious, so that this pressure must be balanced by an unceasing counter-pressure. Thus the maintenance of a repression involves an uninterrupted expenditure of force, while its removal results in a saving from an economic point of view" ("Repression," p. 151). Similarly, in "The Unconscious" (1915e), Freud specified that the preconscious protects itself from the drive of unconscious repression by means of an anti-cathexis: "It is this which represents the permanent expenditure (of energy) of a primal repression, and which also guarantees the permanence of that repression" (p. 181). The fate of the instinctual representative is to disappear from consciousness and to be kept apart from the conscious mind, but the fate of the affect, which, according to Freud, represents the quantitative factor of the instinctual representative, is different. The instinct can be suppressed, or else affect can be either expressed under a given qualitative coloration or transformed into anxiety.

Finally, from a dynamic point of view, the main question is that of the reason for repression. According to Freud, the process of repression is linked to the group of defensive processes whose goal is to reduce, or even eliminate, any modification that might endanger the integrity and constancy of the psychobiological individual. Repression is one of the great "vicissitudes" of the instinct (along with sublimation and double reversal). Freud considered it a mode of defense against the instincts.

This dynamic conception of the repressed and the unconscious is not without consequences. The unconscious tends to produce material that is connected with it to varying degrees, which Freud calls "derivatives of the unconscious" (*Abkömmlinge des Unbewussten*) ("Repression," p. 152), and which reemerge in conscious life and behaviors. These derivatives encompass, for example, symptoms, fantasies, slips of the tongue, or meaningful associations during the analytic session. They are thus also "derivatives of the repressed" (p. 149) that become, in turn, the object of new defensive measures. In his essay on repression Freud stressed that "it is not even correct to suppose that repression withholds from the conscious *all* the derivatives of what was primally repressed. If these derivatives have become sufficiently far removed from the repressed representative, whether owing to the adoption of distortions or by reason of the number of intermediate links inserted, they have free access to the

conscious. It is as though the resistance of the conscious against them is a function of their distance from what was originally repressed" (p. 149).

In analytic practice, the analyst constantly invites the patient to produce these so-called derivatives of the repressed, which, following their distancing or distortion, can pass through the censorship of consciousness. Based on the patient's associations, "we reconstitute a conscious translation of the repressed representative" (p. 150).

Freud explained that "Neurotic symptoms, too . . . are derivatives of the repressed, which has by their means finally won the access to consciousness which was previously denied to it. . . . Repression acts, therefore, in a *highly individual* manner. Each single derivative of the repressed may have its own special vicissitude" (p. 150).

Thus, repression sometimes appears as a generic term, and sometimes as a specific term. At times it is the concept on which all of psychoanalysis rests, and at other times it above all describes the mechanism of hysterical neurosis. Sometimes it is just one defense among others, and at other times it subsumes all the defenses. In psychoanalytic treatment, the stage of repression identified as "the return of the repressed" is the basis for a clinical approach aimed at the lifting of repression itself.

## “REPRESSION”

Freud’s paper “Repression” is part of a larger work that was to be called *Preliminary Essays on Metapsychology* and that was to have included twelve essays; only five of these were published. Other titles were considered, notably “Introduction to Metapsychology” and “Overview of the Transference Neuroses” (Jones, 1955, p. 185). *Metapsychology* was conceived as a group of conceptual models that did not come directly from clinical experience, but which aimed to explain clinical experience in terms of mechanisms or fictional perspectives. Freud’s project in these essays was to introduce and synthesize its main elements. In “On the History of the Psycho-Analytic Movement” (1914d) he had defined the theory of repression as “the corner-stone on which the whole structure of psychoanalysis rests . . . the most essential part of it” (p. 16).

In this paper Freud returned to the idea of repression that had previously, in *The Interpretation of Dreams* (1900a), been conflated with the idea of the defense, which he had developed beginning with the “Neuro-Psychoses of Defence” (1894a). Here repression is the only defensive modality, whereas after 1920 repression would be seen as one defense among others. Freud believed that he had found an absolutely original idea in repression, and he did not acknowledge having encountered it in the work of Schopenhauer when Rank told him of analogous perspectives in the latter’s work (Gay, 1988).

In “Repression” Freud described repression as “something between flight and condemnation” (p. 146) and said that “it is a concept which could not have been formulated before the time of psycho-analytic studies” (p. 146). His argumentation in this essay is developed step by step, by reviewing all the possibilities of this

vicissitude of the instinctual impulse. First of all, given that instinctual satisfaction is by definition pleasurable, it was necessary to posit a conflict that “would . . . cause pleasure in one place and unpleasure in another” and the condition that “the motive force of unpleasure shall have acquired more strength than the pleasure obtained from satisfaction” (p. 147).

However, this mechanistic explanation is followed by another that is dynamic in nature. Repression and the unconscious are “correlated” (p. 148), and “We have reason to assume that there is a *primal repression*, a first phase of repression, which consists in the psychological (ideational) representative of the instinct being denied entrance into the conscious. With this a *fixation* is established; the representative in question persists unaltered from then onwards and the instinct remains attached to it” (p. 148). This fixation will constitute a point of attraction for other, later repressions that are thus said to occur through “after-pressure” (p. 148).

The same dynamism affects the instinctual representative that is fixed in the unconscious, where derivatives are formed and connections established. In “Repression” Freud explained that “Repression acts . . . in a *highly individual* manner. Each single derivative of the repressed may have its own special vicissitude; a little more or a little less distortion alters the whole outcome” (p. 150). If these derivatives are sufficiently distorted, they can freely enter into consciousness. Such occurrences provide the basis for psychoanalytic treatment, in that the repressed contents can emerge through free association, enabling a conscious reconstitution of these contents through psychoanalytic interpretation. Mentioned in passing here is the issue of fetishism, which was already alluded to in *Three Essays on the Theory of Sexuality*, and to which Freud would return much later (1940a [1938]). Here he proposed, as the origin of fetishism, a division of the instinctual representative into two parts, one of which is subjected to repression while “the remainder, precisely on account of this intimate connection, undergoes idealization” (p. 150).

The distinction that Freud then proposed between representation and quota of affect enabled him to refine his ideas on the vicissitude of the instinct. One possibility is its “*transformation* into *affects*, and especially into *anxiety*, of the psychological energies of *instincts*” (p. 153). The repressed thus remains active, and returns indirectly through these substitutive formations, but

also in the form of various symptoms. The “success” of repression is often mitigated: A given representation may indeed be eliminated, but something else has been substituted for it, and “it [repression] has failed altogether in sparing unpleasure” (p. 153).

In terms of the three major categories of neurosis— anxiety hysteria, conversion hysteria, and obsessional neurosis—Freud pointed to the links that can be established between the workings of repression and the formation of neurotic symptoms. However, he added in conclusion that further research in this area needed to be done.

## REPRESSION, LIFTING OF

*Lifting of repression* is the name for the process by which gaps in memory are eliminated, notably during psychoanalytic treatment, allowing for access to formerly unknown material.

While psychoanalysis is indeed an ensemble of theoretical conceptions that make up a metapsychology, and while it is a method of investigation of psychic processes, it is first a method of treatment (see Sigmund Freud’s article “The Libido Theory,” 1923a [1922]). From this perspective, Freud often reiterated his aim: “extracting the pure metal of the repressed thoughts from the ore of the unintentional ideas” (1904a [1903], p. 252). In “Lines of Advance in Psycho-Analytic Theory” (1919a [1918]), he wrote that “our task [is] to bring to the patient’s knowledge the

unconscious, repressed impulses existing in him” (p. 159). And in “An Outline of Psycho-Analysis” (1940a [1938]), he wrote that “the psycho-analyst is the one who is in a position to guess at repressed material.”

All of these formulations refer to what Freud usually called the “lifting of repression.” He used many different formulations to remind readers of this essential aspect of treatment. In *Introductory Lectures on Psycho-Analysis* (1916–17a [1915–17]), he wrote: “We can express the aim of our efforts in a variety of formulas: making conscious what is unconscious, lifting repressions, filling gaps in the memory—all these amount to the same thing” (p. 435).

At the time of his early discoveries, Freud observed that the sudden emergence of forgotten memories during hypnosis sessions caused symptoms to disappear. He concluded from this that forgetting was active and pathogenic, and that being cured had to be the result of the recollection and abreaction of traumatic memories. It was as if the symptom appeared in place of the memory, as if the symptom itself were a way of remembering: “The hysteric suffers from reminiscences.”

The observation of the revival of memories under hypnosis enabled Freud to theorize that a repressed representation could preserve a trace of that which had been repressed. He then shifted his focus toward resistance to remembering, the correlate of a repression that was still considered to be “intentional,” and thus onto resistance to the lifting of repression. In this way the obstacle (resistance) became a new means of unearthing meaning. The “talking cure” and the method of free association supplanted hypnosis. Memories no longer had to be rediscovered directly, but were now to be found indirectly, through the resistance that provided access to the repression.

“Suppressing gaps in memory,” that is, “eliminating resistance,” is reaffirmed in the metapsychological writings of 1915 with the expression “making the unconscious conscious.” But what in the unconscious becomes conscious? “This question remains flawed and is dependent upon a metapsychological conception in which the unconscious is largely equivalent to an immobilized past and is scarcely distinguishable from the repressed,” commented Claude Le Guen in 1992.

The central theory and the assertion “*Wo Es war, soll Ich werden*” (“Where id was, there ego shall be”) in

*New Introductory Lectures on Psycho-Analysis* (1933a [1932]) meant revisiting this issue. In 1923 Freud showed that the question was less that of bringing the repressed into consciousness and the “lifting of repression” than that of the paths to follow to be able to lead the repressed into the preconscious-conscious. The work of analysis is to put in place these preconscious intermediary terms without the unconscious having to “come up” into consciousness. Thus the unconscious, as it is activated in the id, remains indestructible and constantly active, without being affected by the unconscious impulses taken into the ego, which are capable of coming into consciousness due to the lifting of repression. It is in this way that the ego becomes the locus par excellence of conflicts between the instinctual impulses and the defensive processes, beginning with the first among them, repression. Analysis of the resistances is the essential means that must henceforth be used in treatment to bring about conscious awareness of the repressed and a lifting of repression. In the words of Le Guen, “The lifting of repression, with the liberation of libidinal energy it emanates and the unification of the ego it provokes, remains the touchstone of change in treatment and its main goal.”

## **REPUDIATION**

The term *repudiation* is the most literal translation of the terms *Verwerfung* (“foreclosure”) and *Verleugnung*

(“denial-disavowal”) that Sigmund Freud used to refer to a psychic act he wanted to distinguish clearly from repression.

In his commentary on the “Wolf Man” he declared that “A repression [*Verdrängung*] is something different from a repudiation [*Verwerfung*],” (1918 [1914]). Indeed, repression, while it erases an unpleasurable idea from consciousness, cannot prevent this idea from “working” to produce symbolic derivatives in the form of symptoms. Repudiation, by comparison, consists in invalidating a perception or mental representation, and thus is a way that allows it to remain conscious, but emptied of meaning; it is thus unable to have a role in the subject’s fantasy life.

The ultimate form of repudiation exists in what Jacques Lacan called *foreclosure*, where the representation is incapable of playing any symbolic role whatsoever (foreclosure in the Name-of-the-Father). But it can manifest itself elsewhere in a paradoxical manner by becoming inscribed within the individual topology of the split ego. In that case it will effect the kind of repudiation-disavowal seen in the so-called perverse structures. In any event, to varying degrees, such failure to symbolize an idea makes it impossible for the mental representation to be a part of the subject’s mental and fantasy life.

## **RESCUE FANTASIES**

In “A Special Type of Choice of Object Made by Men” (1910h), Sigmund Freud describes a type of man who repeatedly falls in love with a woman who is “of bad repute sexually” and “to whom another man can claim right of possession.” What is striking in such men is “the urge they show to ‘rescue’ the woman they love.”

Freud interprets the fantasy of rescue in light of the Oedipus complex: The boy initially believes his mother to be a saint and refuses to accept, when he begins to

become aware of sexual relations between adults, that his parents could behave in such a way. When the boy accepts this, the figure of the mother switches from that of the saint to that of the whore; the child is jealous of the father and regrets that the mother has not preferred him instead. “[H]e comes, as we say, under the dominance of the Oedipus complex,” and if “these impulses do not quickly pass, there is no outlet for them other than to run their course in fantasies: that of saving the beloved woman in order to win her love and obtain a baby from her, and, as a reaction to his hostility toward the father, the fantasy of saving him from a life-threatening danger by some heroic action.

Freud concludes this article by evoking imaginary scenes in which the mother is saved from drowning, a symbolic translation of the birth of a child. The following year, he added a brief reference to this theme in the 1911 edition of *The Interpretation of Dreams*. He returned to the topic at greater length in “Dreams and Telepathy” (1922a).

Although this theme is often encountered in clinical practice, it does not seem to have been further elaborated either in Freud’s work or thereafter.

## **RESISTANCE**

Psychoanalysis understands resistance as something that stands in the way of the progress of analytic work during treatment. The term appeared for the first time in Sigmund Freud’s writings in the *Studies on Hysteria* (1895d), where he reported—in connection with the case of Lucy R.—how he had given up testing the degree of hypnosis of his patients because “this roused the patients’ resistances and shook their confidence in me, which I needed for carrying out the more important psychical work” (p. 108). During his treatment of Elisabeth von R., already mindful of his own role in the clinical work, Freud perceived this resistance through the efforts he had to make in order to get his

patient to remember certain painful representations. In the Freudian psychodynamic approach, this concept refers to the psychic force that the patient opposes to the bringing into consciousness of certain unpleasurable representations during treatment: the psychic force developed to maintain repression.

If the topographical theory led to the idea that psychoanalysis was, in Freud’s words, an interpretative art that consisted of making the unconscious conscious, the analyst’s task was henceforth to “lead the patient to recognize his resistance and to reckon with it.” Analysis of the resistances thus became one of the cornerstones of analytic technique; analysis of the transference was soon linked with it.

In “The Dynamics of Transference” (1912b), Freud wondered why transference, the most effective among the factors of success, could become the most powerful agent of resistance. He was thus led to distinguish between positive and negative transference, and to conclude that “transference to the doctor is suitable for resistance to the treatment only in so far as it is a negative transference or a positive transference of repressed erotic impulses.”

Freud agreed that nothing in analysis is more difficult than overcoming the resistances. However, these phenomena are valuable because they make it possible to bring to light patients’ secret and forgotten emotions of love; above all, by endowing these with a sense of immediacy, the resistances facilitate the recognition of these emotions, because, as Freud put it in a well-known formulation, “it is impossible to destroy anyone *in absentia* or *in effigie*” (1912b, p. 108). Instead of remembering, the patient reproduces attitudes and feelings from his or her life, which, through the transference, can be used as means of resistance against the treatment and against the therapist. It is as if the patient’s intention to confound the analyst, make him feel his impotence, triumph over him, becomes more powerful than his or her intention to bring an end to his or her illness.

The article “Remembering, Repeating and Working-Through (Further Recommendations on the Technique of Psycho-Analysis II)” (1914g) marked a turning point where the discovery of repetition compulsion put an end to an illusion: Freud admitted that naming the resistance still did not make it disappear immediately. Analytic technique purported to be an art of interpretation that focused above all on recognizing the resistances and communicating them to the patient.

Discovering that “The greater the resistance, the more extensively will acting out (repetition) replace remembering” (p. 151), Freud recognized the importance of the need for working-through (*durcharbeiten*) “One must allow the patient time to become more conversant with this resistance with which he has now become acquainted, to *work through* it, to overcome it, by continuing, in defiance of it, the analytic work according to the fundamental rule of analysis” (p. 155). Freud constantly reiterated that it is the working-through of the resistances that offers the patient the greatest chance of change.

In the chapter “Resistance and Repression” in *Introductory Lectures on Psycho-Analysis* (1916–17 [1915–17]), Freud underscored the forms of the resistances, which are very diversified, extremely refined, and often difficult to recognize, and their protean character—attributes that require the physician to be cautious and to remain on guard against them. Thus, during treatment, phenomena such as gaps in memory, screen-memories, overabundant production of dreams, cessation of free association, avoidance of causal links, judgments about the insignificance of thoughts that come to mind, or even flight into treatment may all be understood as forms of resistance. But it was the most paradoxical forms of resistance—repetition compulsion and the negative therapeutic reaction—which Freud linked to unconscious feelings of guilt, that gave his study of the resistances its full amplitude.

In *Inhibitions, Symptoms and Anxiety* (1926d), Freud returned to the forms of the resistances and distinguished those of the ego, the id, and the superego. The first type is under the aegis of the pleasure principle and includes three possibilities: resistance to the lifting of repression, resistance to the loss of secondary gains from illness, and transference resistance, which aims to maintain repression. The second, resistance of the id, corresponds to “the power of the compulsion to repeat” (1926d, p. 159) and necessitates working-through. The third, resistance of the superego, comes out of the feeling of guilt and the need for punishment, which stand in the way of successful treatment; this type was later described as a negative therapeutic reaction, itself linked to the death instinct.

If Freud remained reticent on the intrinsic nature of the resistances while underscoring their variability, richness, and solidity, he always believed that the patient’s work on his or her own resistances was indis-

pensable to the success of the treatment, even positing in his last writings that this work alone carried in it the potential for real and lasting change in the ego.

Analysts after Freud have done relatively little further work on the manifestations of resistance during treatment. However, Melanie Klein, by seeing resistance essentially as a manifestation of negative transference, paved the way for a certain number of other studies, notably those of Wilfred Bion, who described psychotic resistance as “attacks on linking.”

## RESOLUTION OF THE TRANSFERENCE

The *resolution* or *dissolution* of the transference means the end-point of a transference neurosis and the full recognition by the analysand that his or her relationship to the psychoanalyst is based primarily on the repetition of earlier relationships, namely those of childhood.

Freud's first explicit mention of the resolution of the transference was in "Recommendations to Physicians Practising Psycho-Analysis," where he described it as "one of the main tasks of the treatment" (1912e, p. 118). The introduction of this idea, implying as it did an overall view of the transference, was part of Freud's conceptualization of the transference neurosis, and of the analytic treatment as a process: "on the whole, once begun, it goes its own way and does not allow either the direction it takes or the order in which it picks up its points to be prescribed for it. . . . A man can, it is true, beget a whole child, but even the strongest man cannot create in the female organism a head alone, or an arm or a leg. . . . He, too, only sets in motion a highly complicated process, determined by events in the remote past, which ends in the severance of the child from its mother. A neurosis as well has the character of an organism" (1913c, p. 130).

The "resolution of the transference" is one of the most important issues of all for psychoanalytic technique. The transference is at once the motor of the treatment and a means for combating resistances, but it may also itself be the source of resistances to the progress of the analytic work. It can be seen as the manifest content where the latent content is the infantile neurosis. Transference is not just a kind of "acted-out" repetition whose elucidation opens the way to the patient's remembering; it is at the same time a new experience—"a piece of real experience, but one which has been made possible by especially favorable conditions, and it is of a provisional nature" (1914g, p. 154). The resolution of the transference (or its "overcoming" by the analysand) necessarily subsumes all this, as well as the patient's eventual detachment from the analyst once this "piece of experience," with its "provisional nature," has come to an end.

Freud was always much concerned with the proper handling of transference phenomena, with restricting the power of suggestion to what would advance the analytic work, and with the danger of embarking on some kind of mutual analysis or love relationship, even in the most limited sense. As he wrote in "The Dynamics of Transference," "We take care of the patient's final independence by employing suggestion in order to get him to accomplish a piece of psychical work which has as its necessary result a permanent improvement in his psychical situation" (1912b, p. 106). Freud's view was that the intensity of the transference neurosis must be limited, so that the patient could "recognize that what appears to be reality is in fact only a reflection of a forgotten past" (1920g, p. 19).

Freud viewed the resolution of the transference as an imperative in psychoanalysis, which was properly so called solely "if the intensity of the transference has been utilized for the overcoming of resistances. Only then has being ill become impossible, even when the transference has once more been dissolved, which is its destined end" (1913c, p. 143). That this resolution had to occur by degrees, along with the progress of the treatment, was something that Freud indicated implicitly—as for example when he recommended that "the transferences" (considered here by analogy with symptoms) be destroyed one by one, as the work proceeded, or when he observed that negative aspects of the transference "in good time" (1905 [1901], p. 118). The "dissolution" of the transference, which coincided necessarily with the end of the treatment—"At the end of an analytic treatment the transference must itself be cleared away" (1916–17a [1915–17], p. 453)—was possible only if its progress towards resolution had paralleled the evolution of the analysis itself.

Thus the resolution of the transference was not just an ethical necessity for Freud, it was also an intrinsic aspect of the treatment; the patient's presenting neurosis was transformed into a transference neurosis, a kind of relay condition whose cure by means of the resolution of the transference secured a general therapeutic outcome: "All the patient's symptoms have abandoned their original meaning and have taken on a new sense which lies in a relation to the transference. . . . But the mastering of this new, artificial neurosis coincides with getting rid of the illness which was originally brought to the treatment—with the accomplishment of our therapeutic task. A person who has become normal and free from the operation of repressed instinctual impulses in

his relation to the doctor will remain so in his own life after the doctor has once more withdrawn from it” 1916–17a [1915–17], pp. 444–445).

James Strachey (1934) introduced transference interpretation, a method of relating current transference experience to the past as a way of helping resolve the transference; he saw this method as a model of “mutational” interpretation and as a specifically psychoanalytical therapeutic approach.

## **RETURN OF THE REPRESSED**

The return of the repressed is the process whereby repressed elements, preserved in the unconscious, tend

to reappear, in consciousness or in behavior, in the shape of secondary and more or less unrecognizable “derivatives of the unconscious.” Parapraxes, bungled or symptomatic actions, are examples of such derivatives.

Beginning with *The Interpretation of Dreams* (1900a), Freud always emphasized the “indestructible” nature of unconscious material, as likewise the irreducible character of memory traces. If we have no memories of events during the first years of life, this is because of the repression that affects them. In a sense, all memories may be said to be retained, their recollection depending solely on the way in which they are cathected, decathected, or anticathected.

In the thirty-first of his *New Introductory Lectures*, “The Dissection of the Psychical Personality,” Freud posited the unalterability of the repressed in the following terms: “impressions, . . . which have been sunk into the id by repression, are virtually immortal; after the passage of decades they behave as though they had just occurred” (1933a [1932], p. 74). In *Moses and Monotheism*, he added: “What is forgotten is not extinguished but only ‘repressed’; its memory-traces are present in all their freshness, but isolated by ‘anticathexes’ . . . they are unconscious—inaccessible to consciousness” (1939a [1934–38], p. 94).

Thus for Freud repressed wishes are not destroyed in the unconscious: rather, they are forever re-emerging in the form of what are generically called derivatives of the unconscious, some of which “become conscious as substitutive formations and symptoms—generally, it is true, after having undergone great distortion as compared with the unconscious, though often retaining many characteristics which call for repression” (1915e, p. 193). Such derivatives include not only symptoms but also fantasies, slips of the tongue, and parapraxes in general, and even certain character traits. They are expressions of the unconscious manifesting themselves in consciousness without this necessarily implying that what has been repressed becomes conscious: The repressed returns, but often remains unrecognizable. Such returns of the repressed are par excellence the material that the psychoanalyst works on, and they may refer as easily to the transference as to associations produced in the analytic session that are connected to the repressed ideas.

Freud links “symptom formation” (*Symptombildung*) to the return of the repressed: “it is not the repression itself which produces substitutive

formations and symptoms, but that these latter are indications of a *return of the repressed*” (1915d, p. 154). Broadly speaking, symptom formation encompasses not just the return of the repressed by means of “substitutive formations” or “compromise formations” but also “reaction formations” created as bulwarks against repressed wishes.

The return of the repressed was considered by Freud to be a “specific” mechanism (Freud to Ferenczi, December 6, 1910), a view he reiterated in his paper on “Repression,” where it is portrayed as a third distinct phase in the overall process of repression, following “primal repression” and “repression proper” or “after-pressure” (1915d, p. 148).

In a section of *Moses and Monotheism* dealing with the return of the repressed, Freud evokes the re-emergence of the “impressions” of early childhood and the instinctual demands that can erupt into the life of the subject, orientating his actions and subjecting him to constraining impulses. The instinct “renews its demand, and, since the path to normal satisfaction remains closed to it by what we may call the scar of repression, somewhere, at a weak spot, it opens another path for itself to what is known as a substitutive satisfaction, which comes to light as a symptom, without the acquiescence of the ego. . . . All the phenomena of the formation of symptoms may justly be described as the ‘return of the repressed.’ Their distinguishing characteristic, however, is the far-reaching distortion to which the returning material has been subjected as compared with the original” (1939a, p. 127).

The repressed thus retains its initial impulse, its urge to penetrate consciousness. It may achieve this, according to Freud, under three conditions: “(1) if the strength of the anticathexis is diminished by pathological processes which overtake the other part [of the mind], what we call the ego, or by a different distribution of the cathectic energies in that ego, as happens regularly in the state of sleep; (2) if the instinctual elements attaching to the repressed receive a special reinforcement (of which the best example is the processes during puberty); and (3) if at any time in recent experience impressions or experiences occur which resemble the repressed so closely that they are able to awaken it. In the last case the recent experience is reinforced by the latent energy of the repressed, and the repressed comes into operation behind the recent experience and with its help.” Freud adds that “In

none of these three alternatives does what has hitherto been repressed enter consciousness smoothly and unaltered; it must always put up with distortions which testify to the influence of the resistance (not entirely overcome) arising from the anticathexis, or to the modifying influence of the recent experience or to both” (1939a, p. 95).

### REVERCHON-JOUVE, BLANCHE (1879–1974)

Blanche Reverchon-Jouve was a French physician and psychoanalyst, a member of the Société psychanalytique de Paris and the Société française de psychanalyse, and a translator of Freud. She was born in 1879 and died January 8, 1974.

She studied in France, and later specialized in neurology under Babinski. She practiced psychiatry in Geneva and was one of the women celebrated in *La Garçonne* (Margeuritte, 1922). In 1921 she met the poet Pierre Jean Jouve. She and Jouve were invited by Stefan Zweig to participate in two of the conferences he gave in Salzburg. In 1923, after traveling to Bavaria, they began living together in Paris. They were married in 1925, following Jouve's divorce.

Reverchon-Jouve was analyzed by Eugénie Sokolnicka and became a member of the Société psychanalytique de Paris. She appears on the 1932 list as an associate member, then on a second, corrected list as a full member.

In 1923 Gallimard published *Trois essais sur la théorie de la sexualité* by Sigmund Freud, a translation she completed with the help of Bernard Groethuysen. With Jouve she wrote an article for the *Nouvelle Revue Française* of 1933 entitled "Moments d'une psychanalyse." Although a clinical study, it did not resemble those published by her peers. It was the work of an analyst and writer, and its formal beauty as literature casts doubt on the authenticity of the narrative.

On February 3, 1931, in Paris, she was presented as a member the French section of the Soroptimists, the international women's association. She did not train any students and her patients, often wealthy, provided her and her husband with a good income. They created a small circle around themselves, primarily centered on her husband. Olivier, Jouve's son by his first wife, married a woman in their circle, a dancer, in spite of his stepmother's advice to the contrary.

Reverchon-Jouve participated in the 1950 World Psychiatric Congress organized by Henri Ey and, at the time of the 1953 split, she joined Daniel Lagache when he founded the Société française de psychanalyse.

## **REVERIE**

The term *reverie* refers to an imaginary representation created to help realize a desire. The term *Phantasie* was used by Freud to designate such mental activity collectively, whether conscious or unconscious. In French the term *fantasme* prevailed in psychoanalytic use, for it was felt that the term *fantaisie* was too marked by current usage, where it connotes the idea of capriciousness or gratuitousness. However, following Daniel Lagache (1964), the term *fantaisie* came to refer to imaginary conscious or preconscious creations, without ignoring their continuity with the unconscious fantasies they reflect.

Daydreams, which everyone experiences, are the clearest examples of conscious or preconscious reveries. In general they explicitly satisfy a desire, providing some form of imaginary satisfaction, whether it be erotic, aggressive, ambitious, self-aggrandizing, or uplifting. It is not even unusual for people to visualize painful or humiliating experiences to their own advantage. In all these cases the narcissistic dimension of the process is obvious.

There are references to such daydreams in the *Studies on Hysteria* (1895d), primarily in the case study of Anna O., written by Josef Breuer. Freud wrote about daydreams in *The Interpretation of Dreams* (1900a). For example, when analyzing his dream about the "botanical monograph," he relates a daydream during which he imagines that, afflicted by glaucoma, he travels incognito to Berlin for an operation and experiences considerable pleasure in listening to the surgeon extol the anesthetic qualities of cocaine (thus being compensated for the pain Freud experienced through being too late to be recognized as the one who discovered its properties). The "phantasies or day-dreams are the immediate forerunners of hysterical symptoms. . . . Like dreams they are wish-fulfillments; like dreams, they are based to a great extent on impressions of infantile experiences; like dreams, they benefit by a certain degree of relaxation of censorship" (p. 491–492)

According to Freud, a daydream is initially the expression of an unconscious fantasy; then, it is used as available material among the latent thoughts used by dreams. However, as he noted, there is an essential

difference between night dreams and daydreams: the first is hallucinatory, the second is not, and the person remains more or less clearly aware that his daydream is an escape from a reality that is not completely suspended.

This distinction can be blurred or even disappear entirely. Freud analyzes this phenomenon in his detailed commentary on Wilhelm Jensen's *Gradiva* (1907a). In the same period, in "Creative Writers and Daydreaming" (1908e [1907]), he discusses the function of daydreaming in the genesis of the literary work, and later, in "Family Romances" (1909c [1908]), he foresees the situation where daydreams are used by the child to avoid the oedipal conflict by imagining himself to be adopted, to be really the child of a king and queen.

Robert Desoille (1961) developed an original method of psychotherapy based on the development and analysis of the patient's daydreams during therapy. For some patients and under certain circumstances, analytic psychodrama can create scenarios that are related to daydreams.

## **REVERSAL INTO THE OPPOSITE**

The expression *reversal into the opposite* refers to the transformation of an idea, a representation, a logical figure, a dream image, a symptom, an affect, or the like into its opposite. It is a process that affects the fate of the instincts, notably in the transformation of love into hate, and was more clearly described in Freud's discussion of the notion of turning around.

Freud first described this type of transformation with regard to dream images. Such reversals are used to create the disguises that enable the translation of latent thoughts into acceptable thoughts (which are thus able to cross the barrier of censorship). He gave numerous examples of this in *The Interpretation of Dreams* (1900). This process can affect characteristics of objects or people; thus, a small object can appear to be very large in a dream; someone whose intelligence is envied appears stupid in the dream, and so forth. Often a reversal of actions into their opposite is involved: Climbing a staircase expresses the idea of descending or falling; the latent idea of a heavy burden is translated in the dream by the action of carrying a light woman, and so on.

In the dream "Non vixit," the dreamer (Freud himself) with the intensity of his gaze melts a person whose blue eyes are growing paler: This expressed a reversal into its opposite of the fear that he had experienced, when he was young, under the gaze of Brücke's "terrible blue eyes" (1900a, p. 422). He gave a detailed analysis of a particularly interesting instance of reversal into the opposite in the case of the "Wolf Man"'s dream (related in "From the History of an Infantile Neurosis" [1918b]), in which the scary immobility of the wolves was a reversal of a violent movement (that of his parents' coitus). Reversals of the dream protagonists' roles may occur, such as the hare chasing the hunter, or the dreamer punishing his father.

Certain logical relationships can also be expressed in this way. Contradiction, for example, may lead in a dream to a condensation in which opposites are blended together in a depiction marked by a sense of absurdity. Temporal reversal of dream episodes is particularly interesting: "The outcome of the incident or the conclusion of a line of reasoning is the introduction to the dream, and the premises of the reasoning or the cause of the incident is found at the end."

But reversal into the opposite does not only affect representations or relationships between representations, it can also apply to affects: "There is yet another way in which the dream-work can deal with affects in the dream-thoughts... It can *turn them into their opposite*" (1900a, p. 471). Thus, a depressive feeling of self-devaluation can inspire a dream of brilliant success, or, on the contrary, a feeling of triumph may provoke a dream that recalls a humiliating failure. In the dream of the "uncle with the yellow beard," Freud's "warm dream feeling of affection [for his friend R.] in

the dream” masked the wish that R. be a “simpleton” (p. 140–141).” R. was a possible rival for nomination to the title of professor. The analysis of such transformations is a valuable tool for understanding the dream-work.

According to Freud in *The Interpretation of Dreams*: “[R]eversal [*Umkehrung*], or turning a thing into its opposite [*Verwandlung ins Gegenteil*], is one of the means of representation most favoured by the dream-work and one which is capable of employment in the most diverse directions. . . . [R]eversal is of quite special use as a help to censorship” (p. 327). From this it can be deduced that in this function as a process or a subterfuge to circumvent censorship, reversal clearly comes into play beyond the realm of the dream-work. This is the case in many myths: for example, those in which birth (emergence from water) is represented either by rising from the waves (as in the birth of Venus) or, on the contrary, by an episode in which the hero enters the water (as in the story of Moses).

This play of opposites is found in certain linguistic expressions that, according to context, can take on opposite meanings: Thus, the Latin word *sacer* means both “holy” and “damned”; the German *Boden* refers both to that which is highest and that which is lowest in a house, and so forth. According to Freud in “The Antithetical Meaning of Primal Words” (1910e), where he invoked the (now-contested) authority of the linguist Karl Abel, this phenomenon was frequent in “primitive languages” that were supposedly still poorly differentiated and thus often used condensations. In the eleventh lecture in the *Introductory Lectures on Psycho-Analysis* (1916–1917a [1915–1917]), Freud explicitly compared this play of opposites in language with its function in the dream-work. But this is not limited to the semantic level: Figures of speech can be subjected to such a mechanism, the most obvious case being that of negation, discussed in “Negation” (1925h), in which a thought is expressed in inverse form, accompanied by a projection that makes it possible to attribute it to someone else (“‘You ask who this person in the dream can be. It’s *not* my mother.’ We emend this to: ‘So it *is* his mother’” [1925h, 235].)

Symptom formation often makes use of this mechanism. The hysteric who is simulating rape tears her dress with one hand and clutches it around her body with the other; the fantasy in which she holds her sexual partner against herself is translated into her hands clasped behind her back, and coitus itself is expressed via hyperextension in a circular arc (“Some

General Remarks on Hysterical Attacks” (1909a [1908]), and so on. In such cases, what the hysteric acts out is an idea or image of an action—that is, a fantasy that corresponds to one of the received meanings of the idea. The same reversal of action is seen in dreams that center on a given idea or image.

Reversal into the opposite, especially in the case of a reversal of affect, involves a process very similar to those referred to as *turning [a]round*. The terminology is not very clear: Freud himself, moreover, in “Instincts and Their Vicissitudes” (1915c), used the term *reversal* to designate both processes, the turning around of activity into passivity and the reversal into opposite of the “contents” of the love/hate pair. However, it seems judicious to distinguish the two notions and to use the notion of turning around with reference (a) to expressions of drives as affects (love into hate, or the reverse); (b) to aims of drives (the active aim “turning around” into a passive aim); and (c) to the objects of drives. This also applies to the whole notion of the sadism/masochism pair. The notion of reversal into the opposite should be used, as is evident from the preceding, when formal aspects of transformations affecting representational contents are involved.

Both notions, however, can be subsumed into the broader category of “pairs of opposites” frequently found in Freud’s work, culminating in his second theory of the instincts with the oppositional pair Eros/the death instinct.

## REVISTA DE PSICOANÁLISIS

The Argentine Psychoanalytic Association was founded in 1942. The *Revista de Psicoanálisis*, its official organ, appeared only seven months later, in 1943. Its first editor was Arnaldo Rascovsky, one of the pioneers of the Argentine psychoanalytic movement.

The *Revista* has appeared continuously ever since, without interruption; it is thus the oldest psychoanalytic journal in the Spanish language, as well as one of the oldest psychoanalytic journals in the world. From its beginning until 1976, the *Revista de Psicoanálisis* appeared four times a year; since 1977 it has appeared six times yearly. These circumstances, plus its edition (print run) of 2,000 issues, its scientific quality, its prestige, and the important role it has played in the diffusion of psychoanalysis in Latin America, have caused the International Psychoanalytical Association (IPA) to choose the *Revista* to publish its *Bulletin* in Spanish whenever it was required, to publish the “pre-published” Congress papers, and to have the first right to choose the Congress papers it wishes to publish. In return, the Argentine Psychoanalytic Association sends an adequate number of the issues, containing the *Bulletin* and the pre-published Congress papers, to each of the IPA’s Spanish-speaking component societies.

At first, the *Revista* contained more translated papers than local productions. Long ago this situation was reversed, however, and the scientific production of Argentine analysts has come account for the vast majority of papers in a given issue.

Many of Freud’s papers appeared in Spanish for the first time in the *Revista*; for instance, “Analysis Terminable and Interminable,” in 1946. The Freudian tradition has remained continuous through the years. All “classic” authors and their continuators have had a place in the *Revista*. Also all contemporary schools or frames of reference have found their place there, either in their original authors’ publications, or through the papers of local followers.

Argentina is equally far from both Europe and the United States. This circumstance has many disadvantages but some advantages, that is: psychoanalysts from Argentina have been able to maintain a relative independence of thought, have been exposed to all frames of references, and have been able to avoid compromises, political or otherwise, with a given system of thought. This pluralism is reflected in the *Revista de*

*Psicoanálisis*; the titles and authors who have appeared in it offer a balanced view of current psychoanalytic thinking. Also, in the bibliography of the papers of Argentinian analysts, it is usual to find references to European, North American, and Latin American authors. Some decades ago the Kleinian School was preponderant, as European authors have become somewhat preponderant.

Following an international trend, the *Revista* has begun to publish issues with a given theme. In addition, a “Special International Issue,” also with a given theme, has appeared, but with the collaboration of invited and interested prominent analysts from many countries.

In spite of its respectable age, the *Revista de Psicoanálisis* remains an extremely active, contemporary, and purposely pluralistic publication.

## REVISTA DE PSIQUIATRIA Y DISCIPLINAS CONEXAS

Hermilio Valdizán and Honorio Delgado founded the review *Revista de psiquiatria y disciplinas conexas* in Lima in 1918. The subtitle highlights its interdisciplinary vocation: “A quarterly publication on psychiatry, psychoanalysis, pedagogy, sociology, forensic medicine, criminology and the history of medicine.” By 1924 five volumes had appeared in quarterly issues. The review achieved the objective it had set for itself: it was the first modern review of psychiatry in Peru.

The psychoanalytic content of the publication is remarkable in comparison to the dates of appearance of the dedicated psychoanalytic reviews of the time: *Imago* (1912), *Internationale Zeitschrift für Psychoanalyse* (1913), and *The Psychoanalytic Review* (1913) are the only ones to precede it. *The International Journal of Psycho-Analysis* and the *Revue Française de Psychanalyse* did not appear until 1920 and 1927 respectively. In a country as isolated from the international psychoanalytic community as Peru, and exposed to the difficulties of communication and the prejudices of a Catholic society, such an event is all the more remarkable.

With the appearance of the third issue (January, 1920) the review became militant, with an editorial signed by Delgado, "Freud and the psychoanalytic movement," illustrated with a full-page portrait of the founding father. Sigmund Freud mentioned the publication on two occasions: in a footnote added in 1923 to "On the History of the Psychoanalytic Movement," (1914d) and in a note added in 1924 to *The Psychopathology of Everyday Life* (1901b).

These facts confirm that Freud read the review attentively. In a letter dated 1924 he complained about its disappearance and asked Delgado if he intended to introduce another publication. In a report on Spanish-language psychoanalytic literature, Karl Abraham quotes from and comments on different works by Delgado and authors writing in the review. In 1922 an agreement was reached to publish a Spanish version of *Die Don Juan Gestalt*, but the project was hindered by the length of the work. The content of the review with regard to psychoanalytic books and publications proved to be top quality; it published timely comments on recent works by Freud, Abraham, and Sándor Ferenczi, and reports on the journals *Imago*, *Internationale Zeitschrift für Psychoanalyse*, and *The International Journal of Psycho-Analysis*.

Honorio Delgado figures with Paul Wilson and Hermilio Valdizán among those who published most on psychoanalysis in Peru at the time. Wilson, who always published in English, is most noteworthy for "The Imperceptible Obvious," on which Freud commented in detail in the above-mentioned note in *Psychopathology*. The article that appeared under the pseudonym "A. Z." in volume 2, number 1 (July, 1919): "Psychoanalytic treatment of a case of compulsive neurosis," constitutes the first Spanish-language account of psychoanalytic treatment.

It is difficult to determine the impact of the review. Its authors lacked analytic experience and made excessive claims to therapeutic success. Their theories were eclectic: a blend of ideas from Freud, Adler, and Jung. In spite of this, the review played a pioneering role in Latin America and in the Spanish-speaking community, contributing in a remarkable fashion to the spread of knowledge about psychoanalysis.

### REVUE FRANÇAISE DE PSYCHANALYSE

At the founding of the Société psychanalytique de Paris (SPP; Paris Psychoanalytical Society) on November 4, 1926, "it was decided to create a French journal of psychoanalysis, the medical part of which would be edited by MM. Laforgue and Hesnard, possibly joined by MM. de Saussure and Odier after their acceptance into the society, and the nonmedical part of which would be edited by the Princess Marie Bonaparte. M. Éd. Pichon accepted in principle the responsibilities of general secretary of this publication."

From the very inception of this publication, which could not have come into being without the financing of Marie Bonaparte, René Laforgue, and Prynns Hopkins, a very wealthy former patient of Ernest Jones, disputes arose around the issue of whom it belonged to. Even its title was contentious in this regard, for while Laforgue presented it to Sigmund Freud on November 27 as the "*Revue internationale de psychoanalyse*," the spelling *psychanalyse*, associated with the habits of the Swiss and the Jungians, was finally chosen. There was another, more serious problem that had to do with ambivalence on the part of the young psychiatrists who had created the journal *Évolution psychiatrique* (Developments in psychiatry) the previous year and who dreamed of a "French-style" psychoanalysis: the exclusion of the phrase "under the patronage of Professor Freud" from the title page, on the pretext that its presence might "gravely offend"

Henri Claude. Writing to Laforgue from Vienna on November 12, Marie Bonaparte expressed her indignation over this: “But I feel we are cowards, triple cowards, if we do not dare to put the name of the founder of the science we represent on the first journal in France devoted to his work.” She added: “Freud made a comment to me that I must pass on to you. It was that we should not name our journal the ‘Revue internationale de psychanalyse,’ because it is not international at all. If the British journal uses that name, it is because it is only a reproduction of the German journal. . . . Freud believes that we should go back to one of our first titles: ‘Revue française de psychanalyse,’ with, below it, ‘organ of the Paris Psychoanalytical Society,’ French section of the International Psychoanalytical Association (and I say) published under the patronage of Sigm. Freud. And nothing else on the title page. All our names on the back of the page, written in the smallest possible characters! If Claude takes offense, he is really too stupid.”

Finally, the French opted for “Revue française de la psychanalyse, organ of the S.P.P., published under the patronage of Professor Freud” in the first issue, which appeared on June 25, 1927. “We believe that today French psychoanalysis is ripe to have its own organ of expression. It will be the mirror of the young Paris Psychoanalytical Society, born this winter,” said the editorial. Alongside original pieces by Laforgue, Charles Odier, René Allendy, Angélo Hesnard, Félix Deutsch, and the First Conference of French-Speaking Psychoanalysts, and the administrative minutes of the nascent SPP, the issue included Freud’s “Moses and Michelangelo” and Bonaparte’s “The Case of Madame Lefebvre.” By way of a contribution, Freud did not ask for any royalties for his text, which was translated by the princess, and even provided an unpublished addendum. The phrase “section of the International Psychoanalytical Association” did not appear until the second issue.

It was the nationalistic contingent, enamored of a “Latin” mindset tinged with anti-Semitism and led by Édouard Pichon, that was behind these acts of pettiness—to the great anger of Bonaparte, who would not rest until she saw him removed from the editorship of the journal; at one point she wanted to withdraw it from the publisher Doin in favor of Gaston Gallimard. In late October 1929, opposition to the International Psychoanalytical Association by a “very active minority” that wanted to take control of the journal, since it

was referred to as the “Official Organ of the French Group,” again raised the idea of “transforming the French Journal into an International Journal of Psych.” (letter from Laforgue to Freud, October 26, 1929). The princess was opposed to this and succeeded in having Rudolph Loewenstein appointed editor in place of Pichon. By contrast, Ernest Jones deplored the label “French Journal” because it allowed the Americans to use this precedent for *The Psychoanalytic Quarterly*, which was a competitor to his *International Journal*.

Publication went on, sometimes very irregularly, as attested by the fact that there were only three issues, rather than eight, for the year 1930–1931. It resumed under a new publisher, Denoël & Steele, in 1932. In 1939 only a single issue was published, with a new blue cover. It contained Freud’s “Analysis Terminable and Interminable,” translated by Ann Berman.

Publication of the journal was interrupted for eight years, despite John Leuba’s announcement to Jones on December 31, 1944: “I have prepared two complete issues of the journal of psychoanalysis. Our printer has disappeared. We need to study the issue of a publisher. In any case, it would be impossible for us to publish until several months from now, since owing to the shortage of paper the number of journals that are authorized for publication is extremely limited.” The princess, on her side, explained to Loewenstein on July 2, 1945: “As for the *Revue*, I can no longer support it, either. Besides, it never really took off. Perhaps Rodker could start up a journal in London that would revive *Imago* in three languages, where we could publish our articles in French. The only risk would be problems with Jones, who only wants his English journal with ultra-Kleinian articles” (Bertin). Negotiations for the journal’s resumed publication with the Presses Universitaires de France took place only in 1947.

In fact, beginning with volume eleven, published in 1948, the SPP took over the publication of its “official organ,” underwritten by means of systematic subscription of its members. Authors gave up all potential royalties in exchange for disbursement by the publisher of a global sum intended to cover editorial costs. Despite discussions over the advantages and disadvantages of contracts that were renegotiated over time, the journal became sufficiently profitable to ensure its ongoing publication.

During the split of 1953, no disputes arose over the journal, which remained in the hands of the SPP and unfailingly published all information that was unfavorable to its competitor, the Société française de psychanalyse (SPF; French Psychoanalytical Society). It also disseminated the works arising out of rivalries with the secessionists, and owing to its regular publication—something other groups could not achieve—it became the most stable reference work of French psychoanalytic thinking during these decades.

Of anecdotal interest is the fact that in April 1960, at the age of seventy-eight, the indefatigable Bonaparte had a telegram sent to herself “accrediting her as a reporter for the *Revue française de psychanalyse*,” in order to visit Caryl Chessman in his cell prior to his execution, which she tried in vain to prevent (Bertin).

In the 1960s the problem arose of how to handle the publication of the proceedings of the Congress of Romance-Language Speaking Psychoanalysts, which the journal had undertaken from the outset. The growing importance of these proceedings had inflated the number of pages required for them, and a series of solutions were found. From 1961 to 1964 the congress proceedings were printed in a separate volume, but this practice was not maintained. Just as ineffective was the reiterated wish of the Teaching Committee of the Institute of Psychoanalysis that “the number of pages of the reports and papers hereafter be limited.” Denise Braunschweig and Jean Kestenberg obtained permission from the Presses Universitaires de France to return to the practice of publishing the proceedings in a special number of the journal. The value of this publication as a reference work must be underscored; each year it treats in depth a well-defined theoretical or practical point, and, beyond its historical perspective, inaugurated during the 1951 Congress with Daniel Lagache’s report on transference, it offers readers a broad spectrum of research and discussions. Since 1991 the *Bulletin de la S.P.P.*, created in October 1982 by Michel Fain, has undertaken advance publication of reports and papers.

After Maurice Bénassy’s resignation as editor of the *Revue française de psychanalyse* in April 1969, Christian David, Michel de M’Uzan, and Serge Viderman were chosen by the tenured members of the society in January 1970, in an informal vote, to take over editorship of the journal, with Jacqueline Adamov as copy editor. They attempted to make the journal more inde-

pendent of the SPP so that it would not appear to be a mere scientific brochure, but rather a publication unto itself. Their effort, from 1970 to 1975, to have the phrase “Official Organ of the S.P.P.” changed to “Published under the aegis of,” if it had the merit of raising the issue of a separation of objectives, was called into question during negotiations for a new contract with the Presses Universitaires de France. Beginning with the first issue of 1976, the words “Official publication of” reappeared. Overall it continued to run at a deficit, despite undeniable editorial success: In November 1977, there were 2,382 subscriptions, 684 of these from foreign subscribers, plus 1,022 copies sold by the issue.

In March 1980, Jean Gillibert, Claude Girard, and Evelyne Kestenberg were named co-editors. They in turn experienced problems and resigned three years later. They were held responsible for a decrease in subscriptions, even though the total readership had increased. They cited as a reason for the decrease in subscriptions the competition of the *Bulletin de la S.P.P.*, which nevertheless was the response to their often-expressed wish to be relieved of the burden of systematically publishing lectures and administrative information.

The idea of thematic issues seemed sound, as Claude Le Guen stressed in May 1983. After proposing his own candidacy, he left the new editorship of the journal to a team made up of Ilse Barande, Claude Girard, Marie-Lise Roux, and Henri Vermorel. They remained on the job beyond their mandate, which ended in 1986, and were replaced only in February 1988.

The merger of the SPP and its Institute of Psychoanalysis had taken place two years earlier when André Green, then president of the SPP, announced on July 8, 1988: “The Board of Directors has entrusted the editorship of the *Revue* to Claude Le Guen. The new editor has presented to the Board of Directors the new policy he intends to implement. Articles published by the journal will be divided into two categories, each of which will be entrusted to an adjunct editor. One category, headed by J. Cornut, will bring together publications and articles of a scientific nature. The other, headed by G. Bayle, will bring together publications of a more topical, critical, or even polemical nature, as well as those focused on training: clinical, technical, or theoretical points, in the form of regular columns. The editorial staff will also include J. Adamov, C. Athanassiou, J. J. Baranès, J. Begoin, T. Bokanowski, P. Denis,

M. Gibeault, C. Janin, R. Menahem, J. F. Rabain, J. Schaeffer, H. Troisier. The first issue of the R.F.P. produced by the new team will appear in October 1988 with a new format and a new cover design.”

The choice of presenting thematic issues definitively prevailed and led to a marked increase in the readership of this journal, which is both the oldest and the most widely read French psychoanalytic journal. The same year, 1988, Le Guen, assisted by Gilbert Diatkine, also created the “Monographies de la R.F.P.” (Monographs of the R.F.P.), a series in which each volume, focused in a specific theoretical or practical issue, was a sure-fire editorial success. “Débats en psychanalyse” (Issues in psychoanalysis), with Jacqueline Schaeffer as adjunct editor, was created in 1995 for the purpose of publishing papers from colloquia and scientific meetings, which the *Bulletin* could no longer handle on its own.

Since 1996 Paul Denis, creator of the series “Psychanalystes d’aujourd’hui” (Psychoanalysts of today), has been the editor of the *Revue française de psychanalyse*.

## RICHARD, CASE OF

Melanie Klein’s case of Richard is published in two forms: (a) “The Oedipus complex in the light of early anxieties” (Klein, 1945) and (b) *Narrative of a Child Analysis* (published posthumously, Klein, 1961).

In 1939, Klein moved out of London because of the war, and settled eventually in the small Scottish town of Pitlochry between June 1940 and September 1941. She used this time, away from colleagues, to reflect on her work; to plan further writing, especially on technique, and to conduct an exemplary analysis of a 10-year-old boy, Richard, six sessions each week from April to August 1941. She kept process records of the play and conversations—for example, Richard’s associations, and Klein’s interpretations of them—during each of the sessions.

The theoretical conclusions from this case, especially about the early form of the Oedipus complex in a boy, were presented as a paper in 1945.

The book, *Narrative of a Child Analysis*, is a detailed presentation of the case. The ten-year-old boy Richard was treated in 1941. Each of 93 sessions is described in a brief process record, and each is followed by a commentary written much later, just before Klein’s death in 1960. It was intended as a supplement to her early book *The Psycho-Analysis of Children*, and to present her technique in detail. The fact that it was not published for nearly 20 years is due to a number of reasons, including the fact that her interests had moved on to the urgent need to present her developing theoretical conclusions. But Klein believed this record represented her technique at the time and that it had not changed very much by the time the record was published.

She wrote this case history for presentation as a paper, “The Oedipus complex in the light of early anxieties,” to the British Psycho-Analytical Society in 1945. It is a very detailed account of the early stages of the Oedipus complex as it had emerged in her early work with children, and then subsequently revised in the light of her theory of the depressive position which she had described five years before. She believed this significantly added to Freud’s descriptions of the Oedipus complex, though she was clear that it did not replace Freud’s work.

As far as the boy’s complex is concerned, development through the Oedipal conflicts is propelled not only by the boy’s fear of castration from his vengeful father, but the boy’s love for his father and wish to protect him from his own damaging hatred. As to the little girl, she concluded that Freud was only partly right in his notion of penis envy, which he over-rated. More prominently, the little girl is occupied by the phantasy

of father's penis residing inside mother with the future babies there. The little girl is as preoccupied with the desire for father's penis inside her, and her internal babies, as she is with the hopeless wish for a penis of her own. The anxiety that little girls suffer most is therefore the fear of a retaliatory mother arising out of the girl's wish to steal the penis from inside her mother. Her conclusions were not new and are found in her earlier book (Klein, 1932).

Klein's wish to write a thorough account of her technique was only partly realized in a paper in 1955 on "The Psycho-Analytic Play Technique: Its History and Significance." Towards the end of her life she returned to the full set of process notes she had made of Richard's analysis, and began the task of annotating every session. She completed this just before her death, and the work was published a few months later as *Narrative of a Child Analysis*. This was her very last word on child analysis and is a major statement on her technique.

What the book does is to explore in careful detail the ways in which these configurations of objects are worked out for the 10-year-old boy in an analytic setting. In particular she concentrates carefully on the location of the objects; felt by the boy to be inside him, often accompanied by physical sensations, or in the external world and represented by actual things and people which interact in ways that make them suitable to incorporate into his play, his phantasies, and his dialogue.

The book is of fascinating and major interest for its portrayal of a child analysis in detail. It is written with considerable poignancy and charm, and with an obvious affection for Richard, a frightened but quite courageous little boy. At the time it attracted great interest because it revealed Klein at work, and it has remained an important complement to her often complex theoretical writings.

By the time she published her first account of Richard, in 1945, the technique employed by Klein and her colleagues was about to change in significant ways as she and her colleagues explored the fragmented and part-object world of schizoid and schizophrenic patients. Technical aspects of Anna Freud's method of child analysis had also changed by this time (Geleerd, 1963).

### **RICKMAN, JOHN (1880–1951)**

John Rickman, a doctor of medicine, psychiatrist, and psychoanalyst, was born on April 10, 1880, at Dorking, Surrey, England, and died on July 1, 1951, in Regent's Park, London. He was the only child of Quaker parents, and his father died when he was two. He went to Leighton Park, a Quaker boarding school in Reading. He fulfilled the requirements of a Natural Science Tripos at the University of Cambridge, and he completed his medical degree and qualified in 1916 at St. Thomas's Hospital in London. He joined the Friends War Victims Relief Unit in Russia (Rickman, 1949). In 1918 he met and married Lydia Lewis, an American. He then studied psychiatry at Cambridge, where Dr. William H. R. Rivers advised him to see Freud in Vienna. Freud agreed to see him for two guineas.

Freud asked him to work on what was published as *The Development of the Psycho-Analytical Theory of the Psychoses* (Rickman, 1928a). He returned to London and was elected an associate member of the British Psycho-Analytical Society in 1920 and a member in 1922. He played a key role in the early years of the society and its Institute of Psycho-Analysis, especially in administration, publication activities, and links with allied professions. In this regard, it was particularly helpful that he was an editor of the *British Journal of Medical Psychology* for 14 years.

He was elected to the council and to the first training committee in 1926. In 1929 he went to Budapest to have analysis with Sándor Ferenczi, and later, prior to the Second World War, he underwent some analysis with Melanie Klein and supported her approach.

After 1936 the Spanish Civil War convinced him of the need to oppose the Nazis. He was often asked to write editorials for *The Lancet* during periods of politi-

cal crisis. In 1939 he joined the Emergency Medical Services, later becoming a major in the Royal Army Medical Corp. He met Wilfred R. Bion when he worked in Wharncliffe and Northfield Hospitals. He was then posted to the British Army War Officer Selection Board to select officers. Impressed by his approach, some colleagues later applied to be trained as psychoanalysts.

After the war he took an active part in the British Psycho-Analytical Society and in its new training arrangements. He also facilitated the rapprochement between the Tavistock Clinic and the society. In 1948 he was elected president of the society. At that time he was considered a member of the Middle Group, not a Kleinian. His thoughts as president are contained in his seminal paper on the functions of a psychoanalytic society (Rickman, 1951).

In 1928 he published *The Development of the Psycho-Analytical Theory of the Psychoses, 1893–1926* and also *Index Psycho-Analyticus*. He edited the Psychoanalytical Epitome Series and wrote over a hundred papers and reviews. In 1957 his *Selected Contributions to Psycho-Analysis* was published.

His early death in 1951 was a loss to the British Psycho-Analytical Society, which missed his ability to act as a bridge between colleagues in other disciplines and analysts exploring the contributions that psycho-analysis could make to the understanding of group relations and the structure of society.

## RIE, OSKAR (1863–1931)

The Austrian pediatrician Oskar Rie, friend and physician to Freud and his family, was born on December 8, 1863, in Vienna, where he died on September 17, 1931.

The Ries were a Jewish family from Prague; Isidor Rie was a gem merchant. Oskar, the second of five children, studied in Vienna and received his medical degree in 1887.

Rie was one of Freud's most faithful friends. From 1886 to 1896 he served as Freud's assistant at the Kassowitz Institute in Vienna (*Öffentliches Kinder-Krankeninstitut*), where Freud held consultations in pediatric neurology several times each week. Together they published a monograph on cerebral palsy in children, *Klinische Studie über die halbseitige Cerebrallähmung der Kinder* (Clinical study of cerebral paralysis of children [1891a]), which won considerable influence and insured Freud's reputation as a specialist. Rie also served as family physician to Freud's children and sister-in-law Minna Bernays. While often acknowledging his devoted friendship, Freud viewed Rie with antagonism around the end of his friendship with Wilhem Fliess.

In the psychoanalytic literature Rie is known above all for his appearance as "Otto" in Freud's famous "dream of Irma's injection" in *The Interpretations of Dreams* (1900a). In the manifest dream, he is Freud's friend and the doctor who injected the patient with "a preparation of propyl, propyls ... propionic acid ... trimethylamin" (Freud 1900a, p. 140)—that aggravated her condition. Free associations clearly indicated Freud's ambivalence toward Rie, who was also taken to task in correspondence with Fliess. Freud took Rie's resentment concerning the revelations in *The Interpretation of Dreams* and "his lack of understanding for my findings" (Freud 1985, p. 447) to be another illustration of his observation that "[a]n intimate friend and a hated enemy have always been indispensable to my emotional life; I have always been able to create them anew, and not infrequently my childish ideal has been so closely approached that friend and enemy have coincided in the same person; but not

simultaneously, of course, as was the case in my early childhood” (1900a, p. 483).

But Rie would remain a close friend. He accompanied Freud on vacations in the mountains, including the sojourn at the Alpine retreat where Freud “treated” Katharina, one of the cases presented in *Studies on Hysteria*. Rie instructed Fliess (his brother-in-law) to insist that Freud stop smoking. On Saturdays, he played tarok with Freud and his brother Alfred, and often accompanied Freud to the theater. On January 5, 1898, together they saw Theodor Herzl’s play *The New Ghetto*, then later met Herzl at a meeting of B’nai B’rith, of which he became a member in 1901, the same year as Alexander Freud.

A member of the Wednesday Evening Society, Rie was admitted to the Vienna Psychoanalytic Society on October 7, 1908, at the same time as Sándor Ferenczi, and numerous traces of his presence can be found in the Society’s minutes.

Rie’s marriage to Ida Fliess’s sister, Melanie Bondy, on November 10, 1896, generated further connections in the history of psychoanalysis. In addition to a son, Norbert (b. Oct. 30, 1897), his daughter Margarethe (b. March 25, 1899) would marry Hermann Nunberg in 1929 and be analyzed by Freud in the 1920s (about the same time as her friend, Anna Freud). Marianne (born May 27, 1900) would marry Ernst Kris in 1927 and become a well-known analyst in the United States. Especially known for her work in psychoanalysis with children, among her adult patients were Marilyn Monroe and Diana Trilling; one of her closest friends was Anna Freud.

On August 4, 1921, Freud wrote to Rie: “Your friendly words about me have done me good although they didn’t tell me anything new because I have been looking upon your friendship for more than a lifetime as an assured possession. I have been able to give something to many people in my life; from you fate has allowed me only to receive” (Freud 1960, p. 335).

## RITE AND RITUAL

Rites and rituals have been studied from antiquity: Western philosophers pondered these practices, which in modern times have become an object of study in anthropology, ethnology, and sociology. The diversity of practices makes an authoritative definition problematic, but certain general descriptors apply: A rite is a well-ordered, obligatory action or group of actions that is performed precisely and repetitively; it often moves to an individual or collective rhythm; its meaning and aims are generally opaque, and of no obvious practical purpose. Rites and rituals are related to the sacred: religion, magic, purification, and so forth—the notion of the rite of passage remains in use. Sigmund Freud’s writings on the ritual can be included among the great variety on the subject, although, but he privileges the German word *Zeremoniell*, meaning ceremonial or ceremonious; in so doing, he underscores the sacred character of these practices.

From 1894 to 1896 Freud developed the idea of obsessional neurosis. In “Further Remarks on the Neuro-Psychoses of Defence” (1896b), in the context of the trauma theory, he interpreted the ceremonials it can entail. These derive from the idea of obsessive actions, which are among the defenses and result from repression. Freud cited ceremonials associated with the anal zone and with infantile masturbation in, respectively, *Three Essays on the Theory of Sexuality* (1905d) and the case of Dora, related in “Fragment of an Analysis of a Case of Hysteria” (1905e [1901]). The article “Obsessive Actions and Religious Practice” (1907b) was devoted to this topic and, according to Freud’s “Short Account of Psycho-Analysis” (1924f [1923]), marked the beginning of his work on religious psychology. The deepening of the analogy of the dynamics between obsessional neurosis and collective ritual practices, by way of the notion of primal ambivalence and its expression toward the father, in *Totem and Taboo* (1912–13a), is the basis for Freud’s perspective on individual and collective ceremonials.

In “A Short Account of Psycho-Analysis,” written in 1923, Freud presented this study in a broad context: “If

the psychological discoveries gained from the study of dreams were firmly kept in view, only one further step was needed before psycho-analysis could be proclaimed as the theory of the deeper mental processes not directly accessible to consciousness—as a ‘depth-psychology’—and before it could be applied to almost all the mental sciences. This step lay in the transition from the mental activity of individual men to the psychical functions of human communities and peoples—that is, from individual to group psychology; and many surprising analogies forced this transition upon us... To take an instance... It is impossible to escape the impression of the perfect correspondence which can be discovered between the obsessive actions of certain obsessional patients and the religious observances of believers all over the world. Some cases of obsessional neurosis actually behave like a caricature of a private religion, so that it is tempting to liken the official religions to an obsessional neurosis that has been mitigated by becoming universalized. This comparison, which is no doubt highly objectionable to all believers, has nevertheless proved most fruitful psychologically. For psycho-analysis soon discovered in the case of obsessional neurosis what the forces are that struggle with one another in it till their conflicts find a remarkable expression in the ceremonial of obsessive actions. Nothing similar was suspected in the case of religious ceremonial until, by tracing back religious feeling to the relation with the father as its deepest root, it became possible to point to an analogous dynamic situation in that case too” (pp. 205–206).

In the *Introductory Lectures on Psychoanalysis* (1916–17a [1915–17]), after noting an economic difference between ceremonials in obsessional neurosis and those of communities, the former expressing a defense against repressed sexuality and the latter against narcissistic and aggressive impulses, Freud granted the importance of “extremely strong sadistic impulses” in obsessional neurosis. The taboo against touching, whether actual or metaphoric, that is evident in the phenomenology of ceremonials thus becomes intelligible. In fact, the fundamental theme of any ritual having to do with “touching” is the “first aim of object-cathexis, whether aggressive or tender,” wrote Freud in *Totem and Taboo* (1912–13a). If we add that the psychic position necessary for any ritual is narcissistic, or animistic from the collective point of view, and that it presupposes the omnipotence of wishes and thoughts, it becomes apparent that the underlying obsession in any ceremonial is that of the

contagion of instinctual impulses; this explains the prevalence of magical actions and thoughts having to do with contagion—by contiguity, similarity, isolation, and retroactive annulment.

Throughout his writings Freud described and gave a detailed analysis of various rituals: scatological, money-related, rituals of washing, for going to sleep, or for beginning something. Collective rituals such as those governing relations between son-in-law and mother-in-law, rituals relating to the dead, to chiefs or enemies who have been killed, and rituals relating to defloration and marriage have been extensively studied, in addition to the totemic meal and its repetition in the Christian sacrament of Communion, based on the idea of the murder and consumption of the primal father of the horde.

Ceremonials, as compromise formations, presuppose a repression, and the primary processes thus play a part in their creation. Displacement and the condensation of a multiplicity of fantasies in the ceremonial lead to overdetermination; an absence of contradiction that enables the ceremonial to actualize both wish and defense. In addition, the abundance of symbolism is unmistakable. From an economic point of view, the pleasure principle prevails, and Freud emphasized the sexual excitation that occurs during ceremonials. In *Inhibitions, Symptoms and Anxiety* (1926d) Freud explained that from a topographical and dynamic point of view, regression, linked to powerful aggressive impulses, results in “the erotic trends being disguised” and that accordingly, “the struggle against sexuality will hence-forward be carried on under the banner of ethical principles” (p. 116). The ego “recoils in astonishment” from suggestions of cruelty emanating from the id, and “[t]he overstrict superego insists all the more strongly on the suppression of sexuality, since this has assumed such repellent forms” (p. 116). The theme of guilt is omnipresent, which phenomenology alone reveals, as is the theme of punishment. There is thus continuity between ceremonials and taboos. Moreover, the persistence of unconscious wishes and their fulfillment in ceremonials, no matter what the defenses have undertaken, provokes excessive scruples in their enactment and systematic doubt as to their propriety. The ceremonial’s common compulsion to repeat seems to depend on the same factors.

In *Inhibitions, Symptoms and Anxiety*, written in 1925, Freud lamented the fact that “no one has as yet collected [ceremonials] and systematically analysed

them” (p. 116). With regard to their emergence, often during the latency period, he noted: “Why this should be so is at present not at all clear; but the sublimation of anal-erotic components plays an unmistakable part in it” (p. 116). Sublimation remains a lively issue in psychoanalysis. The compulsion to repeat, as linked to the death instinct and to masochism, is another. Lastly, the generalization of the obsession with touching or not touching, in our ostensibly secular culture, seems more misunderstood than acknowledged. Thus, ceremonies, rites, and rituals are an area that awaits further study.

## **RITTMEISTER, JOHN FRIEDRICH KARL (1898–1943)**

John Rittmeister, a German neurologist and psychoanalyst, was born in Hamburg on August 21, 1898, and was guillotined in Plötzensee prison, outside Berlin, on May 13, 1943. The last of three children in a long-established and well-to-do family of merchants, he studied the humanities before joining the armed forces in 1917 during World War I and serving on the Italian and French fronts. From 1920 to 1925 he studied medicine at the universities of Göttingen, Kiel, and

Hamburg. He specialized in neurology with Max Nonne and received his state doctorate at Hamburg. After three years of neuropsychiatric training in the hospitals of Munich, he began practicing psychotherapy there. He gave conferences and demonstrations of hypnosis and familiarized himself with the teachings of Carl Gustav Jung.

In 1929 he settled in Zurich, staying there for two years before acquiring a post as a voluntary physician at the polyclinic for nervous diseases of the Burghölzli Psychiatric Clinic, under the directorship of Erich Katzenstein, where he also conducted neurological research. From 1935 to 1937, with a few interruptions, he worked as an assistant psychiatrist at the Münsingen cantonal hospital under Max Müller, where he developed an excellent personal and philosophical relationship with senior lecturer Alfred Storch, who had been driven out of Germany.

During his stay in Switzerland, he joined socialist groups for students and workers, went on a study trip to the Soviet Union, and became a convinced Marxist, for which the Swiss authorities often threatened to deport him. In Zurich he quickly distanced himself from Jung’s psychology club because of its “suffocating, mystical and obscure atmosphere.” He explained his position in a scientific lecture titled “Voraussetzungen und Konsequenzen der Jung’schen Archetypenlehre” (The presuppositions and consequences of teaching Jungian archetypes; 1982). In 1922, while still a student in Munich, he sought psychological help from Hans von Hattingberg, and in 1935 he commenced his analysis with Gustav Bally in Zurich. In “Die psychotherapeutische Aufgabe und der neue Humanismus” (Psychotherapeutic duty and the new humanism), published in Holland in 1936, he advocated a comparison between the Freudian and Jungian schools and “a humanism of decision, which establishes joint, concrete goals.” He attacked, in a barely disguised way, the political situation of National Socialist Germany, and he returned to this theme at the end of 1937.

In Berlin he was chief medical officer in a psychiatric clinic. He trained in psychoanalytic work group A of the Göring Institute, more formally known as the Deutsches Institut für psychologische Forschung und Psychotherapie (German Institute for Psychological Research and Psychotherapy), doing his training analysis with Werner Kemper. After he married Eva Knieper in July 1939, he obtained a position in the

polyclinic in September and later became its director. He played an active part in the scientific life of the Göring Institute, giving lectures and conferences for candidates. His report on the current state of the polyclinic appeared in the *Zentralblatt für Psychotherapie* in 1941, and his last conference in the spring of 1942, “Die mystische Krise des jungen Descartes” (The mystical crisis of the young Descartes) was published as late as 1961, when it appeared in *Confinia psychiatria*.

During the last years of his life in Berlin, he gathered around him a circle of young people (mainly his wife’s fellow students), teaching them philosophy and politics and organizing them to help Jews and foreign workers recruited by force. On Christmas 1941, with the help of Harro Schulze-Boysen, he managed to join the Red Orchestra, a resistance group organized around Schulze-Boysen and Arvid Harnack. Rittmeister participated in clandestine political work, designing and distributing pamphlets and propagandizing for foreign workers, but he did not spy for the Soviet Union, as was claimed. After being arrested on September 26, 1942, he was condemned to death by the war tribunal of the Reich, along with most of the members of his group, and was executed in May 1943.

## **RIVALRY**

Etymologically, the word *rival* refers to people who live by the river and draw their water from the same stream. From a psychoanalytic point of view, rivalry is not simply a struggle for possession of the object, but can also be understood as having sexual, identificatory, and narcissistic aspects.

The ensemble of partial drives directed toward the mother, once she is perceived as an object that is differentiated from the self, is accompanied by hostile rivalry toward the father. This oedipal rivalry is extended to the hostile relationships that occur among siblings.

The object of rivalry can change in relation to bisexuality. Wishes for the rival’s death are repressed, and the formerly hated rival becomes a homosexual love-object. In “Neurotic Mechanisms in Jealousy, Paranoia and Homosexuality” (1922b), Sigmund Freud posited an analogy between this mechanism and the process that is the basis for social bonds: “In both processes, there is first the presence of jealous and hostile impulses which cannot achieve satisfaction; and both the affectionate and the social feelings of identification arise as reactive formations against the repressed aggressive impulses” (p. 232).

Freud thus attributed the decline of rivalry to repression, which results from the establishing of the superego and from the confrontation between hostile wishes and the child’s impotence.

Rivalry creates a link of ambivalence between the subject and an other who can always become the subject’s alter ego, because the object of desire is the same for both. Putting himself in the place of this other, the subject imagines himself as being dispossessed of a source of enjoyment (*jouissance*) that tolerates no sharing. The subject’s hatred is all the stronger because unconsciously, this struggle is for possession of an object that bears the narcissistic illusion of perfect continuity between self and other. The destructiveness of the tendency away

from differentiation is thus transformed into hatred and suspended through triangulation.

Rivalry, which tends toward repetition and acquires its various layers through reaction formations, is one component in the structuring of human desire.

## **RIVIERE-HODGSON VERRAL, JOAN (1883–1962)**

British psychoanalyst Joan Riviere was born Joan Hodgson Verrall in Brighton, England, June 28, 1883, and died in London, May 20, 1962.

A founding member of the British Psycho-Analytical Society, she used her highly accomplished literary skills and sensitivity to meaning in her translations of Freud’s work and the writings of other psychoanalysts. As translation editor of the *International Journal of Psycho-Analysis* she was responsible for the translation of all papers from its inception in 1920 until 1937, after which she gave more time to her teaching and writing.

As a friend, colleague, and collaborator of Melanie Klein, she was an articulate proponent of Klein’s ideas, probably the most able among Klein’s colleagues to express her theories incisively and convey them with subtlety. Most important, Riviere contributed many original ideas to the body of psychoanalytical knowledge that was being developed during the more than 40 years of her professional life.

Her education was irregular, even for late Victorian times: school in Brighton, a seaside town in Sussex where she was born, was followed by some unhappy

years in a girls’ boarding school. Then, at 17, she spent a year in Gotha, Germany, where she gained the remarkable command of German that was to play such an important part in her translations.

She was married in 1906 to Evelyn Riviere, a barrister, and her only child, Diana, was born in 1908. In the following years she struggled to find a place in the professional world. She was involved in various movements for social change, such as divorce reform and suffragette activity. However these efforts did not alleviate the considerable emotional distress from which she suffered, and this led her to a therapeutic psychoanalysis with Ernest Jones in 1916. The latter was so impressed with her deep and sensitive understanding of psychoanalytic principles and processes that he made her a founding member of the British Psycho-Analytical Society, formed in 1919.

The analysis with Jones was difficult and, reaching an impasse, he recommended her to Freud for further psychoanalysis. This took place in 1922 with evident success. On her return to London from Vienna, Riviere became actively involved in the work of the British Psycho-Analytical Society, becoming a training analyst in 1930. She was the analyst of such well-known individuals as Susan Isaacs, John Bowlby, and Donald Winnicott. She was reported by those she supervised, such as Hanna Segal, Herbert Rosenfeld, and Henri Rey, to be an excellent supervisor.

Her original contributions to psychoanalysis are to be found in her papers: “Femininity as a Masquerade” (1929) examines an area of sexual development, in which the femininity of certain women is found to be the mask assumed to hide phallic rivalry and hatred of men. “Jealousy as a Mechanism of Defence” (1932) shows remarkable originality in that she finds jealousy to be a defense against envy aroused by the primal scene. Her most original work is “A Contribution to the Analysis of the Negative Therapeutic Reaction” (1936). In it she incorporates Klein’s findings on the depressive position, and describes for the first time the concept of a “defensive organization” as a protection against a psychic catastrophe. In the same year she showed her ability to put Klein’s theories in a context of Freud’s discoveries with “The Genesis of Psychological Conflict in Earliest Infancy,” delivered in Vienna in 1936 in honor of Freud’s 80th birthday. The richness of her thinking about our unconscious drives is apparent in the inner world in Ibsen’s “Master-Builder” (1952), where she describes how the forces

that shape the world find expression on the stage as in life.

## **RIVISTA DI PSICOANALISI**

*La Rivista di psicoanalisi* has been the official organ of the Italian Psychoanalytic Society (SPI) since 1955, when this quarterly review was first published. Each volume contains approximately 180 pages, for a total of 720 to 760 pages per year. The articles are organized by section: theory and clinical practice, current issues ("Reflections on Psychoanalysis and Science"), ethics, technique, and social issues ("Beyond the Couch"), discussions of work in progress, reports of congresses and meetings, reviews, reports of foreign-language publications, reviews of studies and trials, and obituaries.

Since being founded in 1925 and its subsequent revivals (1932 and 1945), the SPI has always attempted to publish a review that would serve as an instrument of scientific understanding and the diffusion of knowledge. In 1925, professor Marco Levi Bianchini, the society's founder, transformed the review he had created in 1920, *Archivio generale di neurologia e psichiatria*, into the official publication of the SPI with the

title *Archivio generale di neurologia, psichiatria e psicoanalisi*. In 1938 Italy's racial legislation forced him to sell the publication to Agostino Gemelli, who changed the title to *Archivio di neurologia, psichiatria e psicoterapia*.

After re-establishing the SPI in 1932, Edoardo Weiss provided it with a new official publication, the *Rivista italiana di psicoanalisi*, the first issue of which was published that same year. The Fascist government suspended publication, and the first issue of 1934, which had already been printed, was never distributed. In addition to articles by Edoardo Weiss, Nicola Perrotti, and Emilio Servadio, the first issue contained contributions from foreign authors including Heinrich Meng, Ernest Jones, Franz Alexander, Ludwig Jekels, Paul Federn, Sophie Morgenstern, Sigmund Freud ("The Moses of Michelangelo," 1914b), and Marie Bonaparte. Two other articles defended psychoanalysis against the attacks of the literary critic Francesco Flora and the philosopher Guido De Ruggiero. The second volume published Sigmund Freud's *New Introductory Lectures on Psychoanalysis* (nos. 29–35), along with contributions by Weiss and Servadio, and two articles by Cesare Musatti.

*La Rivista di psicoanalisi*, which has primarily promoted Italian authors, has also published several special issues: "Psychoanalysis of Psychiatric Institutions" (1971), "Aggression" (1972), "Interpretation" (1974), "Creative Processes" (1975), "Wilfred R. Bion" (1981). In 1986, in a supplement to volume 32, there appeared a general index covering the years 1932–1933 and 1955–1984, which provided information on authors, titles, and keywords.

## **ROBERTSON, JAMES (1911–1988)**

A psychoanalyst, filmmaker, and influential researcher at the Tavistock Clinic on the impact of early separation on child development, James Robertson was born in Rutherglen, Scotland, on March 22, 1911, and died in London on December 31, 1988.

Robertson was the eldest child of five in a working-class Scottish family, and left education at 14 to work in a Glasgow steelworks. From 19 to 27 years of age he attended various part-time Glasgow University Extension Courses on literature, history, economics, and philosophy, and in 1939 spent a year at Fircroft College for the Higher Education of Working Men in Birmingham, studying the humanities. From 1941 to 1945 he studied for the External Diploma in Social Studies at London University. In 1946–47 he completed the Mental Health Certificate at the London School of Economics. He trained in the British Psychoanalytical Society, attaining associate membership in 1952, and full membership in 1970. Robertson met his future wife and colleague, Joyce, while studying in Birmingham. A Quaker, he registered as a conscientious objector during the war, and joined his wife to work with Anna Freud as the only male social worker at the Hampstead War Nurseries. He was accepted for psychoanalytic training on the recommendation of Anna Freud, being analyzed by Barbara Lantos.

In 1948 he joined John Bowlby at the Tavistock Clinic to do research on the effects on separation from the mother in early childhood. This research was conducted in children's hospital wards at the time when national policy was weekly visits. He could not forget the unnecessary unhappiness of the children and was concerned at the time that harm was being done. He and his wife made a series of important films illustrating these effects vividly, and actively campaigned for change. Later films, about institutionalization, foster care and substitute mothering, were influential in promoting the use of fostering rather than children's homes.

Robertson's untiring campaigning over 30 years was critically important in changing the United Kingdom National Policy on recognizing and meeting the emotional needs of children in hospital. Parents are now expected to stay with their young children in hospital. The vivid illustration on film of increasing disturbance in young children separated from their families initially shocked many pediatricians and nurses, and Robertson came under attack, but finally, following the first two films, the Platt Report in 1959 recommended that practice should change. In the 1960s, the National Association for the Welfare of Children in Hospital was formed, with the help and support of both Robertson and his wife. Robertson's pioneering use of film has been developed using video,

particularly by those in the field of attachment, and in recent studies of infant and child development.

## **RÓHEIM, GÉZA (1891–1953)**

Anthropologist and psychoanalyst Géza Róheim was born in Budapest on September 12, 1891, and died in New York on June 7, 1953.

Born to a prosperous family of Jewish merchants, as a child Géza had a passion for folk tales and while a high school student he delivered a paper before the Hungarian Ethnological Society. At the University of Budapest he studied geography, linguistics, philosophy, law, and literature; then, in Berlin and Leipzig, anthropology and the history of religion. Because anthropology was not yet a fully developed discipline, when he received his doctorate in 1914 his examination was in geography. As an assistant librarian in 1917 in the Széchenyi Library of the Hungarian National Museum, Róheim essentially specialized in folklore. In 1918 he married Ilona, who would become his partner in anthropological research.

Róheim had become acquainted with psychoanalysis while a student, and his first article "Dragons and Dragon Killers," published in 1911, brought a psychoanalytic perspective to the explanation of myths. In 1916 he began analysis, first with Sándor Ferenczi and later with Vilma Kovács. In *Spiegelzauber* (Mirror Magic), first

published in 1919, Róheim made extensive use of Freud's recently developed theory of narcissism.

During Béla Kun's short-lived communist revolution in 1918, Róheim helped reorganize the Hungarian National Museum, where he held the first chair of anthropology at the University of Budapest. But when the regime failed after just three months, Róheim lost his academic position. Henceforth he made a living through analytic practice and by giving occasional courses in English.

In 1921, Róheim received the Freud Prize for his study "Das Selbst" ("The Self") and for his paper on Australian totemism delivered at The Hague Congress in 1920. In 1927, when Bronislaw Malinowski famously contested the existence of the Oedipus complex in matrilineal societies, Róheim had the task of gathering material to refute the ethnologist's arguments. Several expeditions, beginning in 1928 and sponsored by Marie Bonaparte, enabled Róheim to do field work in Central Australia, New Guinea, Normanby Island, and in Arizona among the Yuma.

From this work in the field Róheim developed his major themes. In 1932 he published "Psychoanalysis of Primitive Cultural Types" and arguably his central work, *The Riddle of the Sphinx*, appeared in 1934. He emphasized the significance of the primal scene and, relying on work in comparative anatomy by German physiologist Ludwig Bolk, attempted to demonstrate the role of fetal characteristics in human mental life, which he believed had important and to some extent pathogenic consequences.

In the autumn of 1938, after the rise of fascism and with war fast approaching, Róheim emigrated to the United States. He first settled in Worcester, Massachusetts, where he practiced as a psychoanalyst at the State Hospital for the Insane; he subsequently settled in New York. As a non-medical analyst, Róheim was not accepted into the New York Psychoanalytic Society, nor could he find an academic appointment. His work, based on a systematic human psychology, found little support among the functionalist ethnologists then predominant in the universities, while he himself remained critical of cultural anthropology. Ever creative and intrepid, Róheim organized a seminar in his home that brought together, among others, anthropologists Weston La Barre, Werner Münsterberger, and Georges Devereux. In 1947, he undertook a new expedition among the Navajo.

Róheim left a considerable body of work that includes some one hundred fifty studies and a dozen books on a host of topics in anthropology, sociology, history, mythology, folklore, and psychoanalysis. To him is owed a method of applied psychoanalysis buttressed by field investigation. He developed an ontogenetic theory of culture and, citing Ferenczi, he contended that a foundational trauma lies at the root of each culture. Also, influenced by Melanie Klein, Róheim offered an account of basic human activities, emphasizing the significance of fantasies of destruction and reparation. Marked by a deep cultural pessimism, Róheim always pointed to the cultural superiority of "primitive" people while viewing Western societies as dominated by anal retentiveness and reaction formations.

## **ROLLAND, ROMAIN EDMÉ PAUL-ÉMILE (1866–1944)**

The French author Romain Edmé Paul Émile Rolland was born on January 26, 1866, in Clamecy, a small town in Burgundy, and died on December 30, 1944, in the old village of Vézelay.

Freud held Rolland in high esteem for his insight into the mind of a child, and he called *The Enchanted Soul* “a most beautiful novel.” André Malraux thought Rolland was “the last of the great French romantic novelists.” Quite unlike Freud, Rolland was musical to the core and the seven volumes of his *Beethoven the Creator* were published between 1928 and 1943. He was awarded the 1915 Nobel Prize for literature for his novel *Jean-Christophe*.

A politically engaged intellectual from the time of the Dreyfus Affair at the turn of the twentieth century, Rolland aroused Freud’s admiration for the anti-war stance he took in 1914 with his essay “Au-dessus de la mêlée” (Above the Battle), in which he argued for international brotherhood instead of mutual destruction. Rolland denounced Hitler as early as 1933 and condemned Jewish persecution as a “crime against humanity.” Indeed, Rolland declined the Goethe Prize after the Nazis came to power. After lending critical support to the Soviet Union as a part of anti-Hiterlian strategy, Rolland’s idealism moved him for a time in the direction of non-critical communist fellow-traveler. Rolland’s correspondence shows his introspective side and his value as an eyewitness to history. (Duchatelet, 1976).

Aware of trends in German culture, Rolland read Freud as early as 1909. The two men would exchange about twenty letters from 1923 to 1936; Freud’s first communication was written the same week he was diagnosed with cancer of the jaw. Rolland visited Freud only once, on May 14, 1924.

The highly idealized intellectual and emotional relationship between Freud and Rolland suggests a veritable epistolary transference that served Freud as a sounding board for self-analysis during his later years, and several of his major works found their point of departure in exchanges with his “venerated” alter ego.

Despite differences of background and culture, powerful affinities joined these two romantic heroes. Freud admired the poet and “apostle of love for mankind” (Freud, 1960), while Rolland viewed Freud as a “conquistador” of the new world of the mind. In Spinoza they shared a common thread of influence—Rolland, the Christian without a church, inspired by “the enlightened Spinoza” and Freud the “Jewish heretic.” Both were critical of the dogmas of organized religion but differed over the role of religious feeling. Rolland reproached Freud for not having analyzed the

“oceanic feeling” associated with religiosity. Rolland’s pantheism led him to view mysticism, by contrast, as a path to knowledge of the human mind; this represents an element of Spinoza’s intellectual heritage and contrasts with the uncompromising nineteenth-century atheism of David Friedrich Strauss and Ludwig Feuerbach, to which Freud was heir.

In the first chapter of *Civilization and Its Discontents* Freud located the “oceanic feeling” in the primitive, undifferentiated ego; he pursued the dialogue with Rolland by searching for the causes of civilized unhappiness, which he attributed to excessive repression of sexual and aggressive drives and to the loss of collective ideals. Close to Rolland in his critique of Nazi anti-Semitism, Freud differed with him in showing that quasi-religious idealization of communist dogma masked its underlying violence.

*The Journey Within* (1942), a kind of self-analysis, which Rolland began after his visit to Freud, reveals an unconscious communication with him: he wrote about mourning his two-year-old sister, Madeleine, who died when he was five. In a mirror transference, with twelve years in age between them, Freud analyzed his own childhood grief, associated with the death of his infant brother Julius, when he was about two years old, in his “A Disturbance of Memory on the Acropolis” (1936a), addressed to Rolland on the occasion of the latter’s seventieth birthday. Capping their correspondence and transference relationship, several of Freud’s last writings developed themes first sketched in this final burst of self-analysis.

## ROMANIA

On returning from training courses in France and Germany, Gheorghe Preda (1879–1965), a medical officer in the Romanian army, published his considerations on psychoanalysis in a Romanian journal of medical sciences in 1912. Without any personal experience of psychoanalysis, he encouraged the interest of his collaborators, who were the first to propagate Freud's work. Later, in 1923, one of Jean Martin Charcot's students, Gheorghe Marinescu, contributed to making psychoanalysis known to Romanian intellectuals by publishing two articles: an introduction to the study of psychoanalysis and a critique of Freudian theory. Several psychologists and psychiatrists then took an interest in psychoanalysis. One of them, Ion Popescu-Sibiu, entered into correspondence with Freud and became the author of a very complete book on the theory and practice of psychoanalysis: *Conceptia Psihanalitica* (1947). In 1932 he won a Romanian Academy prize for this book. It was in fact a revision of the thesis he presented in 1927, with an addendum of "medico-psychological vocabulary." It was first published in three thousand copies. Around this time more than ten books and theses were published dealing with the applications of psychoanalysis to psychotherapy, forensic medicine, literature, the study of dreams, spiritualism, and career guidance. In a setback, in 1932 an application of psychoanalysis to the work of the Romanian national poet Mihai Eminescu (1850–1889) was considered iconoclastic. In 1934, and again in 1935, attempts to start a journal of psychoanalysis resulted in the appearance of one issue and no follow-up.

Over the next few decades the development of psychoanalysis was limited by the economic crisis of 1929, the rise of the fascist Iron Guard party, which aligned Romania with Nazi Germany, and the communist takeover of the country. In 1946, just after the Second World War, Ion Popescu-Sibiu and Constantin Vlad (1892–1971) founded the Romanian Society for Psychopathology and Psychotherapy. They rallied

around them all those who had been interested in analysis before the war. But psychoanalysis was prohibited in 1948, as it was in all communist countries. Not until 1973 and the new directions opened up by the political head of state Nicolae Ceausescu did a clinical psychological circle organize regular meetings of practitioners. This breach in the wall was short lived, however, and in 1977 it was forbidden to teach psychology. People nevertheless continued to study psychoanalytic texts. The first volume of a translation of Freud's *Introductory Lectures on Psychoanalysis* (1916–1917a [1915–1917]) was published in 1980. But the almost total absence of personal and training analysis was detrimental to any real development of psychoanalysis.

Not until after the fall of the Ceausescu regime could a group of psychotherapists, largely nonphysicians, found the Romanian Psychoanalytic Society in 1990. This society publishes an internal bulletin and a journal that appear on a regular basis. The desire of Romanian analysts to improve themselves professionally is manifest in the numbers that have gone abroad for training and by the 1995 Conference for Eastern Europeans at Constanza, organized with the help of the European Federation for Psychoanalysis.

## RORSCHACH, HERMANN (1884–1922)

Swiss psychoanalyst and creator of the projective test that bears his name, Hermann Rorschach was born in Zurich on November 8, 1884. He died in Herisau on April 3, 1922, probably from acute appendicitis, at the age of thirty-seven, nine months after publishing his seminal work, *Psychodiagnostik*.

From childhood Rorschach evinced considerable artistic skill and while in secondary school he hesitated between fine art, natural science, and medicine, opting finally for the latter. In Zurich, where Rorschach principally studied, Eugen Bleuler had created a revolution in

hospital psychiatry by introducing Freud's theories, while his colleague, Carl Gustav Jung, had worked out a word association test on psychodynamic principles. Rorschach obtained his medical license in 1909 and his medical degree in 1912, from the University of Zurich.

From 1909 to 1913, Rorschach worked as an assistant in the psychiatric hospital in Münsterlingen, and there prepared his doctoral thesis, "On Reflex-Hallucinations and Kindred Manifestations." At the same time, he conducted some early experiments on children and adults in which he compared verbal associations with associations aroused by blots of ink, but did not elaborate on this work at the time. Rorschach developed an interest in psychoanalysis about 1911, the date of his first publication. He contributed short articles, reports, and book reviews to the *Zentralblatt für Psychoanalyse* from 1912 to 1914.

After visiting Russia in 1913, Rorschach returned to Switzerland to assume a position as assistant in Waldau, a psychiatric clinic near Bern; his main interest during this period were several unusual Swiss religious sects. In 1915 he was appointed associate director of the asylum at the small town of Herisau, where he would remain until his death.

While at Herisau, Rorschach rekindled his earlier interest in the use of inkblots in psychiatric diagnosis. Over the course of three years, beginning in 1918, he developed a series of cards through experiments with patients to develop a projective test that could indicate the presence of certain personality traits and characteristics. The Rorschach test is an example of a scientific advance due as much to artistic talent as to intellectual rigor.

Published in 1921, *Psychodiagnostics* was not yet a definitive text when Rorschach died the following year. The test won acceptance over time, and by the 1930s it had garnered considerable attention in the United States. The Rorschach Institute was founded in New York in 1939, and Henri Ellenberger, with his biographical essay in 1954, restored Rorschach's stature and significance. In the United States, although the test was widely criticized from the 1950s and remains a controversial assessment tool, a revision by John Exner in the 1970s brought the Rorschach renewed and continuing attention.

In 1919, when the Swiss Society of Psychoanalysis was founded by Oskar Pfister and Emil and Mira Oberholzer, Rorschach was one of its eight members, and served as vice-president. He practiced psychoanalysis with a small number of patients. Training analyses

were not then required, and Rorschach himself was never analyzed. A selection of Rorschach's articles was published in Germany in 1965.

## **ROSENFELD, EVA MARIE (1892–1977)**

The psychoanalyst Eva Rosenfeld was born in Berlin in 1892 and died in Great Britain in 1977.

Her father, Theodor Rosenfeld, an impresario and a member of Berlin's wealthy Jewish bourgeoisie, died in 1907, when she was fifteen, leaving her with a mother who went into mourning until her death in 1942. Shortly after her father's death, she decided to look after the Zellerhaus, an institution for poor young orphan girls. At the age of seventeen she became engaged to her cousin Valentin, a young lawyer who knew Freud, and having married him in 1911, she moved to Vienna to live. She had three children, the first two of whom, both boys, died of dysentery in 1918.

She then created an establishment for adolescent girls in difficulty, which Siegfried Bernfeld recommended to Anna Freud in 1924 when Anna was seeking a home for a patient in difficulty. This was the beginning of a friendship between the two young women that lasted until 1932. In July 1927 the death of her fifteen-year-old daughter, Rosemarie (Mädi), in a mountain accident, again drove her to care for children in order to overcome her heartbreak. With the help of Dorothy Burlingham and under the pedagogical and psychoanalytical authority of Anna Freud, she then founded the Burlingham-Rosenfeld Heitzing School, named after the district where the garden of Eva's house was home to the school.

Encouraged by Anna Freud, she commenced analysis with Freud in March 1929, an analysis that lasted until 1932, of which she later said that the “transference was intense and passionate.” She also exchanged abundant correspondence with Anna while the latter was staying with her father in the clinic at Tegel. Ernst Simmel, who needed help to manage this disorganized clinic, appealed to Rosenfeld in 1931. As bursar, she was in charge of organizing its dissolution.

When Eva moved to Berlin, it marked the end of the school and her intense friendship with Anna Freud, which was further accentuated by her departure for Great Britain in 1936. She met Melanie Klein shortly after her arrival in London and, fired with enthusiasm for her personality and her work, she commenced analysis with her in 1938, an analysis that was to last in fits and starts until 1941, when Klein left for Scotland and Rosenfeld went to Oxford. Their relationship ended with a break: “You have sacrificed your analysis for the friendship of Anna Freud!” Eva and Anna, in fact, remained in contact until the very end.

There are few details concerning the rest of Rosenfeld’s long life, and her career as an analyst. Throughout her life she remained in contact with Anna Freud, although it was obvious that as soon as she left Vienna her place with Anna was taken by Dorothy Burlingham.

## **ROSENFELD, HERBERT ALEXANDER (1910–1986)**

Psychoanalyst Herbert Alexander Rosenfeld was born in Nuremberg, Germany, on July 2, 1910, and died in London on October 27, 1986.

Rosenfeld came from a middle-class Jewish family. He studied medicine at several German universities and became interested in psychiatry while at Munich University, from which he graduated in 1934. In 1935, due to the anti-Jewish racial laws, Rosenfeld emigrated to England, where he worked in several hospitals after having taken all his medical examinations again in Glasgow. During this period he became interested in the possibility of treating severely psychotic patients using psychotherapy instead of drugs. In 1942 he began his training analysis with Melanie Klein at the British Psycho-Analytical Society in London. He qualified as an associate member in 1945, became a full member in 1948 and a training analyst in 1949. In 1972 he became a F. R. C. Psych, fellow of the Royal College of Psychology.

For decades until his death, Rosenfeld practiced in London and taught at the Institute of Psycho-Analysis as well as abroad, being particularly interested in the psychoanalytic treatment of psychotic and severely disturbed patients. Together with Wilfred Bion and Hanna Segal, he widened the teaching of Melanie Klein and became a world-wide acknowledged authority in his field. In 1947, using the clinical material from his first training case, he published his first psychoanalytical contribution, “Analysis of a Schizophrenic State of Depersonalisation.” The case became one of the landmarks in the history of the psychoanalytical treatment of psychosis, because it was the first case of an adult psychotic patient being successfully treated by a purely interpretative psychoanalytic method. In this paper Rosenfeld used Klein’s seminal concept of projective identification, which he widened and clarified in successive papers.

Another important observation already present in his first paper was that of transference psychosis, which Rosenfeld differentiated from that of transference neuroses in order to describe the massive projection of unconscious fantasies of the psychotic patient on the analyst and the primitive nature of his object relations.

Another important paper related to the problems faced in treating psychotic patients was Rosenfeld’s research into what he called “confusional states” (1949). Although mainly related to processes characteristic of chronic schizophrenia, Rosenfeld’s observations help to better understand the problem of the impossibility or difficulty in normal splitting between bad and good aspects of the self and of the external

and internal objects which massively characterize chronic schizophrenia but to a certain degree can be found even in less disturbed patients. He collected his first set of papers in 1965 in a book *Psychotic States*, which soon became a classic. Later, Rosenfeld became increasingly interested in the study and treatment of narcissistic disturbances and personalities. Particularly important is his paper “A Clinical Approach to the Psychoanalytic Theory of the Life and Death Instincts: An Investigation into the Aggressive Aspects of Narcissism,” published in 1971, where he stressed the link between narcissism and the death drive.

During the last years of his life Rosenfeld became interested in problems related to the difficulties in communication and the impasse in the psychoanalytic treatment of severely and less severely disturbed patients, and on the role played by the analyst in creating those impasses. (See *Impasse and Interpretation*, published in 1986.)

## **ROSENTHAL, TATIANA (1885–1921)**

Tatiana Rosenthal, a Russian psychoanalyst, physician, and specialist in neurology, was born in Saint Petersburg in 1885 and committed suicide there in 1921.

Coming from a Jewish family, she emerged from childhood with an uneasy disposition coupled with a passionate temperament. During the Russian revolution of 1905, she embraced the cause of the workers' movement. In 1906 she settled in Zurich, where she studied medicine. When she read *The Interpretation of Dreams* (Freud, 1900a), she was inspired with the idea of combining the ideas of Freud and Marx.

After she finished her studies, she moved to Vienna. She became a member of the Vienna Psychoanalytic Society in 1911, and the following year she began to attend the Wednesday meetings. After the outbreak of World War I, she returned to Saint Petersburg and the Psychoneurological Institute there, devoting considerable energy to interesting Vladimir Bechterev, head of the institute, in psychoanalysis. Fighting to have psychoanalysis used in the education of children, she was a precursor of Vera Schmidt at the Moscow Detskiy dom (Children's Home). In 1919 she became director of the polyclinic for the treatment of psychoneuroses attached to Psychoneurological Institute. In 1920 she was appointed director of the clinic for neuropathic children.

One year later Rosenthal, mother of a young child, committed suicide. Her death at her own hand becomes less enigmatic when placed in its historical context: Bolshevism, having repressed the workers' strikes in Saint Petersburg and crushed the Cronstadt uprising, was beginning to show its terrorist face. Her suicide, at the age of thirty-six, may have been the reaction of a personality whose idealism was strained to breaking point.

Rosenthal's only published work is the essay “Stradanie i tvortchestvo v Dostoievskoni” (Suffering and creation in Dostoyevski), published in Russian in 1920 in the journal *Voprosi psichologiiu litschnosti*. The second part of this essay and two other articles, on war neuroses and Alfred Adler's individual psychology, have never been published. In her Dostoyevski essay, Rosenthal dealt with the psychology of the artist and unconscious influences in the genesis of artistic work. To do so, she had to clarify what psychoanalysis can contribute to understanding works of art. For Rosenthal, certain insufficiently sublimated pathological components of the artist's psychology detract from artistic works. Dostoyevsky's three youthful novels are a case in point.

## **ROSS, HELEN (1890–1978)**

Helen Ross, a psychoanalyst and administrator, was born March 16, 1890, in Independence, Missouri, and died August 10, 1978, in Washington, D.C.

One of seven children, Helen Ross was born into a family that highly valued education. Her older brother supported her college education, and after her own graduation from the University of Missouri in 1911, she worked for five years as a school teacher to enable her younger siblings to continue their education. During this period she augmented her income by teaching English to immigrants in a Jewish settlement night school in Kansas City. In 1916 she began graduate work in sociology and economics at Bryn Mawr. Ross gave up her graduate studies, however, at the urging of Pauline Goldmark, one of the famous Goldmark sisters, whose sister Alice was married to Supreme Court Justice Louis Brandeis, to accept a job as a field agent for the U.S. Railroad Administration, whose women's division was headed by Pauline Goldmark. For two years she traveled all over the United States, investigating the working conditions of women working on the railroads and, she emphasized in a memoir, making sure they were getting equal pay for equal work.

In 1914 she and an older sister established a summer camp for girls in Michigan, which they ran together for the next thirty-four years. Ross later wrote that the constant contact with “the everyday problems of normal children” sharpened her interest in human development and made her eager to deepen her understanding of personality development. This led her to an interest in psychoanalysis, and in 1929, at the urging of Franz Alexander who had recently arrived in Chicago, she went to Vienna. There she was analyzed by Helene Deutsch and began a lifelong friendship and

collaboration with Anna Freud. In particular, Ross was instrumental in the establishment of the Hampstead Clinic through her efforts to secure ongoing financial support for the clinic from the Marshall Field Foundation in Chicago. She also assisted in the translation of August Aichhorn's *Wayward Youth*.

After returning to Chicago in 1934, she began a private practice and acted as a consultant to a number of social agencies. She also wrote a newspaper column, *About Our Children*, for the *Chicago Sun-Times*. Ross used her influence as a consultant to social welfare agencies and her newspaper column to convey in clear and intelligent language the insights of psychoanalysis to teachers, social workers, and parents. In 1942 she began a fourteen-year tenure as the administrative director of the Chicago Psychoanalytic Institute. In 1956, at the request of the American Psychoanalytic Association, she and Bertram D. Lewin undertook an extensive survey of the training programs of seventeen American psychoanalytic institutes. The resulting book, *Psychoanalytic Education in the United States* (1960), reviewed, among other topics, the history of psychoanalytic education, presented a detailed analysis of candidates in training and how they were selected, analyzed curriculums for both adult and child analysis programs, and discussed the role of the teaching and supervising analyst in psychoanalytic training. The thoroughness of their survey, combined with its dispassionate tone, created a climate that allowed many institutes to closely examine and make changes in their educational programs. This was a considerable achievement and the success of the survey probably owes something as well to the deep respect and affection that their colleagues felt for Ross and Lewin.

After completing this project Ross moved to Washington, D.C., and became a faculty member and supervising child analyst of the Washington Psychoanalytic Institute, and also served as a psychoanalytic consultant, teacher, and supervisor at other institutes. Helen Ross's contributions to psychoanalysis as a supervisor, writer, consultant, and administrator were considerable. Anna Freud, in a touching letter to one of Ross's sisters after her death, described her own sense of deep loss by gracefully noting the personal qualities that made Ross such a formidable and beloved figure. “For me it means that something inexpressibly precious has gone and will never come again. Helen's rare combination of goodness and cleverness, firmness and gentleness, tolerance and sharpness of

judgment, friendship and undemandingness was hers alone. I hope she knew how much not only I, but many other people felt about her.” These personal qualities were accompanied by an indomitable intellectual curiosity and a determination that took her from the Midwest of Missouri and Kansas east to Bryn Mawr and finally to Europe and Vienna, where she found her vocation in one of the most vibrant intellectual movements of the twentieth century.

## **RUBINSTEIN, BENJAMIN B. (1905–1989)**

American physician Benjamin B. Rubinstein was born on December 3, 1905, in Helsinki and died on December 7, 1989, in New York City. He grew up in a warm, moderately affluent family of Finnish Jews. After attending a gymnasium in Copenhagen, he graduated from the University of Helsinki Medical School in 1936. He worked as an undergraduate research assistant to the neurophysiologist Ragnar Granit, gaining a lasting appreciation of scientific research and neurophysiology. His residency in psychiatry and neurology, begun in London, was interrupted by military service in the Finno-Russian wars, and completed at the University Hospital, Helsinki, in 1947.

In 1940 he married Dinorah Rosenthal (who later became a well-known photographer). David Rapaport recruited him as a psychiatric research fellow at the Menninger Foundation (Topeka, Kansas) in 1947. From 1948 to 1953, he was a staff psychiatrist and received psychoanalytic training. On graduating he moved to New York, where he remained in private practice until his death. He and his wife became American citizens in 1957; they had no children.

Rubinstein had strong interest and talents in music, poetry, and the theater, having been an actor and composer, principally of songs. He held teaching positions at the Albert Einstein College of Medicine and at Bronx Municipal Hospital Center, and served as a consultant to the Research Center for Mental Health, NYU. For several years, with Hartvig Dahl, he led a research seminar on clinical inference at the New York Psychoanalytic Society.

Because of the traumatic reception of his first psychoanalytic paper in 1952 (on the psychoanalytic concept of sexuality), he was slow to attempt other publication. He began with a paper on “Psychoanalytic Theory and the Mind-Body Problem” (chapter 1 of the *Collected Papers of Benjamin B. Rubinstein*; 1997). His final published work was “The Experience of Tragedy, Expectations, and the Moral Order” (chapter 17). All but a few discussions of papers were collected in a posthumous volume, plus several previously unpublished manuscripts.

Rubinstein had no peer among working clinical psychoanalysts in his expert grasp of the philosophy of science and his ability to apply it to psychoanalysis. His contributions to the juncture of these disciplines were warmly appreciated by such outstanding philosophers of science as Adolf Grunbaum (University of Pittsburgh) and Robert Cohen (Boston University). He contributed to the training and inspired the work of philosophers (Robert Shope), psychoanalysts (Hartvig Dahl, Emanuel Peterfreund), and psychologists (Morris N. Eagle, Robert R. Holt) alike, though his works and via informal seminars on psychoanalytic theory. His unpublished first paper anticipated many of the most cogent criticisms of Freud’s metapsychology that have appeared in the past four decades. His clarification of the clinical theory, its basic assumptions, and its hierarchical organization makes it more easily convertible into a workable, cumulative, and testable scientific theory. Rubinstein was first to demonstrate the probabilistic nature of the theory’s propositions, with profound implications for its verification—for example, Karl Popper’s model of testability is shown to be inapplicable. It is difficult to predict the eventual impact of his work, but if psychoanalysis makes major progress toward becoming a true science it will have been made possible as much by his work as by that of anyone else.

## **RUSSIA/USSR**

Psychoanalysis was introduced into Russia in 1905 when Nikolai Osipov (1877–1934) returned to Moscow after training with Carl G. Jung, about the same time as Moshe Wulff (1878–1971) settled in Odessa after studying with Karl Abraham. Like their teachers, neither man underwent a personal analysis. Osipov and psychiatrist Osip Feltzman carried out the first psychoanalytically-based treatments and taught Freudian theory at a university clinic directed by Vladimir Serbski who, although critical of the significance accorded sexuality in psychoanalysis, recognized therapeutic successes of the approach.

Near the beginning of the First World War, Sigmund Freud (1914d) wrote: “In Russia, psychoanalysis has become generally known and has spread widely; almost all my writings, as well as those of other adherents of analysis, have been translated into Russian. But a really penetrating comprehension of analytic theories has not yet been evinced in Russia; so that the contributions of Russian physicians are at present not very notable. The only trained analyst there is M. Wulff who practices in Odessa” (p. 33). That Wulff was considered an exception is explained by the quality of his publications in German; he was also the chief translator of Freud’s works into Russian.

Among the early Russian analysts, Wulff and Sabina Spielrein (1882–1941) produced the most innovative clinical and theoretical work, but they wrote in German. Spielrein’s important paper, “Destruction as the Cause of Becoming,” influenced Freud’s development of the theory of the death instinct. Articles by Osipov and Alexander Luria (1902–1977) discussed applied psychoanalysis while revealing their authors’ lack of training and clinical experience.

The advent of the communist regime after the 1917 revolution upset the development of psychoanalysis,

both ideologically and institutionally. The Communist Party, with Nietzschean aspirations to create the “new man,” at first lent its indispensable imprimatur to the creation of the Russian Psychoanalytic Society in 1922, presided over by Serbski’s successor at the State Psychoanalytic Institute, Ivan Ermakov. These organizations shared offices in a beautifully appointed Art Nouveau mansion in Moscow.

Following in the footsteps of Tatiana Rosenthal, who in 1911 had introduced psychoanalysis to St. Petersburg, Vera Schmidt (1889–1937), a physician and pedagogue, opened a psychoanalytic “children’s home” (*Detski Dom*) in 1921. In 1922 her husband, Otto J. Schmidt (1891–1956), although a mathematician, began to supervise the Psychological and Psychoanalytic Library, an imprint of the State Publishing House; he made possible the publication in Russian of Freud’s works.

In spite of such developments, conflicts inside the Soviet Union proved lethal for analysis both as a profession and a psychological theory even as it gained international recognition. Although at the Berlin Congress in 1922 Freud seemed pleased with progress, Ernest Jones was more cautious, especially as regards the Moscow group; he supported a group based in Kazan and headed by Luria. The International Psychoanalytical Association (IPA) requested that the Russian Society have at least two “instructors”; Spielrein thus returned to Moscow from Switzerland, joining Wulff, who had been in the city since 1919. The Kazan group relocated to Moscow and the IPA recognized the Russian Society at the Salzburg Congress in 1924.

But all was not well from the start. Osipov had already fled communism to settle in Prague, and after just eighteen months in Moscow, Spielrein retired to her birthplace, Rostov-on-Don, where she and her family met a tragic end at the hands of the Nazis during World War II. In 1927, Luria turned to neuropsychology and Wulff fled to Berlin.

By the end of the 1920s, when physicians were compelled to solemnly renounce private practice, training analyses were no longer available in the Soviet Union. The Russian Psychoanalytic Society, which formally existed until 1933, was vitally dependant upon the whims of various “red professors” who were controlled by the Communist Party; this would have made training with Wulff or Spielrein impossible in any event. This situation went unappreciated by Wilhelm Reich

when he visited Russia in 1929 under the auspices of the IPA. Reich paid no attention to Wulff and Spielrein; he was instead duped by the communist professors to such an extent that he reported that analysts occupied important posts in the Soviet Union.

Psychoanalysis required the approbation of the Communist Party, and initially received it most especially from the revolutionary leader Leon Trotsky. The fortunes of analysts in the Soviet Union declined upon Trotsky's fall from grace and political exile to Alma-Ata (now Almaty, Kazakhstan) in 1928, shortly before the Psychoanalytic Institute closed its doors and the Psychoanalytic Society became inoperative. In 1930, a year after Trotsky was exiled from the Soviet Union altogether, all psychoanalytic publications stopped. Otto Schmidt had not awaited the inevitable; he retrained to become a noted Arctic scientist and explorer.

In *Civilization and Its Discontents* (1930a [1929]) Freud commented, apropos Russian communism: "One only wonders, with concern, what the Soviets will do once they have wiped out their bourgeois" (p. 115). In 1931, the great proletarian writer Maxim Gorky (1868–1936) settled into Ryabushinsky Mansion, where Stalin met with him and famously called writers "engineers of human souls." Freud's works were consigned to "special storage" in public libraries; they might be consulted, but propagation of Freudian ideas was in this way greatly limited.

The Cold War saw development of a powerfully anti-psychoanalytic establishment in the Soviet Union. In 1950, at the Pavlov Conference, sponsored by the Soviet Academy of Sciences and the Academy of Medical Sciences, psychoanalytic concepts were criticized in a welter of attacks, with many participants obliged to repent for having previously voiced positive comments about analysis.

The official anti-psychoanalytic stance was modified somewhat three decades later when, at the end of East-West detente, participants at the Tbilisi Congress, held in Georgia in 1979, promoted a theory of "unconscious behavior" proposed by the Georgian experimental psychologist Dmitri Uznadze (1887–1950). The congress was preceded by publication of three long volumes on "the unconscious" that included a significant number of articles by Western authors such as André Green and Daniel Widlocher; these texts, however, were not translated into Russian. For fear of ideological manipulation and compro-

mise, well-known psychoanalysts from the IPA did not attend, although Leon Chertok and others, and especially Lacanians such as Serge Leclaire, accepted the invitation in the hope of starting a dialogue that was expected to be difficult in any event due to linguistic and political barriers. The Western articles were not included in the fourth volume, which appeared in 1985, concerning "Results of the Discussion." Some present-day Russian analysts consider the Tbilisi Congress the first step in the renewal of Russian psychoanalysis.

During *perestroika*, from 1985 to 1991, Russians were allowed to organize psychoanalytic meetings. In 1987, a first encounter with French analysts from the Institute of the Freudian Field took place in Moscow, followed by meetings with representatives of the School of the Freudian Cause. In 1988, a meeting seems also to have taken place with representatives of the American Psychoanalytic Association. Two new academic societies were created, the members of which almost all belonged to the Society of Moscow Psychoanalysts. The Franco-Soviet Group of the Freudian Field, founded in 1988, became the Russian Circle of the European School of Psychoanalysis from 1991 until 1995; its orientation was Lacanian and it was established without official statutes or stable direction. The Soviet Psychoanalytic Society, founded in 1989 and in 1991 renamed the Russian Psychoanalytical Association, did have official statutes and was presided over by Aron Belkin (1927–2003), who had a special interest in the social uses of psychoanalysis. The IPA welcomed Belkin at its congresses in Rome in 1989 and in Buenos Aires in 1991, and gave his group the special status of guest study group.

The historic events of August 1991, during which Russia separated from the Soviet Union (which itself was dissolved several months later), created prospects for travel and genuine psychoanalytic training. Thus, in 1992, Pavel Katchalov was able to undergo a personal analysis and training in Paris, helped by a grant from the French government and an alliance between Hopital Esquirol in Saint-Maurice, a suburb of Paris, and the Serbski Center in Moscow. Alexander Khoshtov, of Lomonosov University, and Victoria Potapova traveled to Paris in 1994. All three joined the Paris Psychoanalytical Institute; others followed suit. When, in 1995, Lola Komarova left to train in London, it was the end of the Russian Psychoanalytical Association. Some former members, decided to create

a new group following an IPA curriculum, the Moscow Society of Psychoanalysts. Several of its members had classical or shuttle analysis; the French influence was dominant. Since 1995, an annual Franco-Russian debate has been held every fall by Katchalov and Hervé Benhamou, a member of the Paris Psychoanalytic Society, with the support of the French Embassy.

The Moscow Psychoanalytic Society was founded due to Boris Kravtsov, who in the 1970s ran a psychoanalytic seminar that was attended by a number of psychologists, including Pavel Snejnevsky, Julia Alyoshina, and Sergei Agrachev. In 1988 he established a psychoanalytic section of the Association of Practicing Psychologists, and by 1990 contacts were established with IPA members in the United States, Germany, the Netherlands, and the Czech Republic, where several members were trained. Alyoshina and Snejnevsky were trained in the United States and decided to remain there. In 1995, this group became the Moscow Psychoanalytic Society, over which Agrachev presided until his death in 1998, promoting a training program for psychoanalysts with IPA support. Publications of this group soon included translations of works by Otto Kernberg, the three volumes of the *Modern Psychoanalysis* by Helmut Thomä and Horst Kächele, and Melanie Klein's *Envy and Gratitude*. The institute's subsequent director, Igor Kadyrov, was the first Russian to be elected a direct member of the IPA; he was trained by shuttle analysis, as were the other members of the society, which by 2004 included six members of the IPA.

In 1998 the St. Petersburg Society of Child Psychoanalysis was founded, the result of productive exchanges between psychoanalysts at the Anna Freud Centre in London and a Russian group that included Svetlana Chaeva and Nima Vasilieva, the society's president at that time.

Problems of quackery and imposture have plagued recent psychoanalysis in Russia. Institutes and societies of dubious origin have sprung up throughout the country, which train ersatz therapists without personal analysis, "certifying" them to take profitable advantage of psychosocial misery. With the decree of June 19, 1996, concerning "the revival and development of philosophic psychoanalysis, clinical and applied," President Boris Yeltsin made possible establishment of the controversial East European Institute of Psychoanalysis in St. Petersburg. The Russian intelligentsia and general public alike have grown more distrustful of

untrained or quack psychoanalysts. As a countermeasure, the two Moscow Institutes have combined forces to provide training and to improve awareness through yearly psychoanalytic seminars.

### **RYCROFT, CHARLES FREDERICK (1914–1998)**

Psychoanalyst and psychiatrist Charles Frederick Rycroft was born on September, 9, 1914, in Basingstoke, England, and died on May, 24, 1998, in London.

Rycroft grew up in Hampshire. His father, Sir Richard, was a country squire and the fifth Baronet in a family that traced its ancestry to before the Norman Conquest. When Charles was eleven his father died, and an elder half-brother succeeded to the title and the estate. Charles was educated at Wellington College, and then Trinity College, Cambridge, from which he graduated with honors in 1936 in economics and history. Charles had briefly been a Communist at Cambridge, where the Bloomsbury analyst Karin Stephen encouraged him to apply for psychoanalytic training. Ernest Jones thought that Charles should become a qualified physician; accordingly he started his psychoanalytic and medical training in 1937. He was analyzed first by Ella Sharpe, and after her death by Sylvia Payne. He finally qualified in medicine in 1945.

For almost three decades Rycroft was the leading intellectual force in independent British psychoanalytic circles. Within the British Psychoanalytic Society he became an associate member in 1949, a full member in 1952, and a training analyst in 1954. He was joint librarian (1952–54) with Masud Khan, served on the editorial board of the *International Journal of Psychoanalysis* (1953–54), and was scientific secretary (1956–59). He began to write reviews and essays for *The Observer* and *The New York Review of Books*, and beginning in 1965 started to withdraw from the British Society. Rycroft was bored and alienated by the long-standing ideological quarrels within the British Society.

Nonetheless he analyzed such notable figures as R. D. Laing, Peter Lomas, and Alan Tyson, in addition to a series of eminent people within British intellectual life. He also became one of the most well-known public expositors on psychoanalytic matters, best known for his *A Critical Dictionary of Psychoanalysis* (1968) and his book *The Innocence of Dreams* (1979). He remained in private practice until a week before he died.

Rycroft's special contribution to psychoanalysis stemmed directly from his being broadly well-educated and cultured. Out of his aristocratic background he succeeded in being a distinctive and original voice. He always stressed the constructive power of imagination, and he tried to steer clear of the reductionism and negativism that characterized so much of the early psychoanalytic thinking. Psychoanalysis belonged, he felt, within the humanities and moral sciences, not the natural sciences. He felt particularly inspired by the examples of Donald Winnicott and Erik Erikson, both of whom he considered kindred spirits. Rycroft took a special interest in the problem of creativity, and wrote on how analysts tended to rely on the "ablation" of their biological pasts, substituting instead their lineage in analytic training. The illusion of having created oneself was, he proposed, a defensive reaction characteristic of analysts, an ahistorical or

anti-historical tendency that could be good individually but was not desirable for the field as a whole. Idealizations of the training analysis and the so-called apostolic succession follow from such use of ablation. Ablation as a concept can help understand why it has unfortunately been so often a case of *lese-majesté* to talk about Freud—who had his own difficulties acknowledging his antecedents—within the regular categories of intellectual history. Rycroft's spiritual daring was in a sense an extension of Freud's own historic independence, even though that common trait had inevitably to lead in different directions.

Rycroft, widely acknowledged for his general brilliance, represented the best tradition of British free-thinking within psychoanalysis. He not only interpreted dreams independently of Freud, but took an individual slant on Freud's whole legacy. Rycroft expressed himself in careful, understated prose that is rewarding for its subtleties.

### SACHS, HANNS (1881–1947)

The Austrian psychoanalyst and doctor of law Hanns Sachs was born on January 10, 1881 in Vienna and died on January 10, 1947 in Boston.

Sachs was the son of a Jewish lawyer whose family roots were in Bohemia. After studying law at the University of Vienna, he earned his doctorate in 1904 and began to practice as a lawyer.

The same year was marked by the determining experience of his life, his reading of Sigmund Freud's *The Interpretation of Dreams* (1900), which made a very strong impression on him. He made contact with Freud and, in 1909, was admitted to the Wednesday society. He then participated in the "Committee," the limited circle of the first psychoanalysts around Freud.

Sachs had artistic and literary gifts. He translated Rudyard Kipling's poems into German, and had a sustained interest in the possibilities of applying the views and methods of psychoanalysis to cultural phenomena. Together with Otto Rank, with whom he was closely linked until Rank's break with Freudian psychoanalysis, he published *The Significance of Psychoanalysis for the Mental Sciences* (1913), and co-directed the journal *Imago*, created the previous year, whose title Sachs himself had chosen with reference to Carl Spitteler's 1906 novel.

In 1918 Sachs abandoned his legal practice to become a professional analyst in Zürich. In 1920 he became a training analyst at the Berliner Psychoanalytisches Institut (BPI; Berlin Psychoanalytic Institute) headed by Karl Abraham. The analysts who trained with him included, notably, Franz Alexander, Michael Balint, Erich Fromm, Rudolf Löwenstein, and Karen

Horney. In 1932, anticipating the full magnitude of political developments, he left Germany and emigrated to the United States. He taught at the Harvard Medical School in Boston, where he was one of the few analysts without a degree in medicine. Despite his authority as a training analyst in the Boston Psychoanalytic Society (BoPS), and despite the esteem in which he was held as someone close to Freud, his role was not universally accepted, mainly because of the issue of lay analysis. In 1939, following in the footsteps of the Austrian journal, he founded *American Imago*, which is still published today. He died on January 10, 1947, on his sixty-sixth birthday, in Boston.

Sachs always showed himself to be a loyal disciple of Freud. His *Freud: Master and Friend* (1944) presents a portrait of Freud that is dominated by loyalty, respect, and sympathy. In his presentations on clinical analysis, dealing with various themes, he always remained within the framework of Freudian theory. In works intended for the general public, such as *Zur Menschenkenntnis: Ein psypsychoanalytischer Wegweiser für den Umgang mit sich selbst und anderen* (Contribution to the knowledge of man: psychoanalytic guide to relations with oneself and others, 1936), he attempted to popularize psychoanalysis. He and Abraham advised Georg Wilhelm Pabst on *Mysteries of a Soul* (1926), a cinematic translation of Freud's world and ideas. Sachs took an interest in all realms—political, social, cultural, and, in particular, literary—whose understanding he believed could be enhanced by psychoanalysis. He wrote essays on Otto von Bismarck, the psychoanalysis of films, and kitsch. In 1930 he published a historical psychoanalysis of the Roman emperor Caligula, entitled *Bubi Caligula* (Little Caligula). He was also interested in Shakespeare, Schiller, and Baudelaire, among others.

In *Gemeinsame Tagträume* (Collective daydreams), published in 1924, Sachs developed a remarkable theory of literary creation that even today remains under-appreciated. Its argument is as follows: The determining factor is not talent or the individual effort of the artist, but rather the social character of the work. Sachs saw literary production first and foremost as a social performance: Literature, he argued, creates a social bond in the form of a recognized discourse, in which the unconscious and the repressed, which cannot express themselves otherwise, come into language. The condition for this is the literary form of the work of art, which he interpreted as a social compromise in which repressed instinctual needs are worked through. This theory of the work of art as a collective daydream was further reworked in his later works. His last book, *Masks of Love and Life*, published posthumously in 1948, broadens these conceptions by considering philosophical problems in the light of psychoanalysis.

### SADGER, ISIDOR ISAAK (1867–1942?)

Austrian physician and psychoanalyst Isidor Isaak Sadger was born in Neuzandec, in Galicia, on December 29, 1867, and died, probably in a Nazi concentration camp, during the Second World War.

An important figure in early psychoanalysis, Sadger began his career as a specialist in nervous diseases who, in 1894, began publishing a series of articles on psychophysiology. One such article, which vaunted the discoveries of Paul Flechsig (who would become physician to Daniel Paul Schreber), was noted when Freud, after reading it, dreamed of the sentence: “It’s written in a positive style” (1900a, p. 296).

A proponent of degeneracy theory, Sadger defined this hereditarian concept as an abnormal reaction of the central nervous system, and he investigated its incidence in the lives of significant writers. In his early writings, Sadger alluded to Freud in discussions of hysteria. He also appears to have attended some of Freud’s university lectures in the late 1890s, about the time he began to practice the various neuropsychiatric therapies. In addition to employing the degeneracy concept, Sadger also evinced considerable interest in Freud’s seduction theory.

In 1906, Sadger joined the group of analysts then gathering around Freud. His disregard for psychoanalytic conventions with patients earned him the disdain of colleagues; he took notes in shorthand during sessions and published them. However, he was regarded by Freud as a “good worker” for his varied research and particularly for his contributions concerning narcissism and homosexuality.

Some of Sadger’s publications were devoted to the medico-legal defense of homosexuality, and he analyzed homosexuals with a view to curing “perversion.” Such patients had to promise—indeed, certify—that they would undergo treatment even if the law did not punish their sexual behavior, and to admit that they possibly already had experienced some feeling for the opposite sex (Sadger, 1908). From these analyses emerged an etiology. The homosexual had a dominating mother and weak, sometimes absent father. Sadger regularly claimed that his homosexual patients recovered childhood memories of a precocious love for a woman, most often the mother. Sadger’s biography of Heinrich von Kleist, published in 1910, took up this theme. While Freud accepted this discovery, and made

use of it in his study of Leonardo da Vinci (Freud, 1910c), he rejected most of Sadger's ideas about narcissism (Sadger, 1908).

Sadger was the first Viennese analyst to employ the term "narcissism," bringing together Wilhelm Fliess's theory of bisexuality and the word "Narzissmus" which had been invented by Paul Näcke about 1899. He developed a theory of the ontogenesis of sexuality based on the concept of childhood seduction, in which sexuality manifested by the adult toward the child is taken up by the child and transformed into a closed circle of adoration. By contrast, Freud created a theory of narcissism in which the role of the object remains to a great extent concealed (Vichyn, 1984).

Sadger ended his work with, and his participation in, the Vienna Psychoanalytic Society about 1930. He may have written a biography of Freud but the manuscript has never been found. Sadger alone among Viennese analysts was either unable or unwilling to profit from his relationship with Freud in order to escape Austria after the German annexation in 1938. He died in the Theresienstadt camp in about 1942.

## **SADISM**

*Sadism* is pleasure derived from inflicting cruelty on another person. Richard von Krafft-Ebing coined the term in reference to the writings of the Marquis de Sade. In "Three Essays on the Theory of Sexuality" (1905d) Sigmund Freud described sadism as the active form in a pair of opposites, masochism being the passive form of the same sexual perversion.

Two pregenital libidinal phases are described, the oral-sadistic (or cannibalistic) stage, and the anal-sadistic stage, which remains active during later libidinal development. During the genital stage sadism becomes linked with the masculine position, owing to the active character of both. In neurotic organization, particularly of the obsessional type, sadism plays an important part, both as an instinctual impulse to be repressed, and because of the ambivalence of the instinctual investment. The case of the "Rat Man," related in "Notes Upon a Case of Obsessional Neurosis" (1909d) is particularly illustrative of sadism, as is the case of the "Wolf Man," described in "From the History of an Infantile Neurosis" (1918b [1914]), which shows that the child often interprets the primal scene as sadistic.

Sexual sadism is propped analytically on certain developmental events: the coming in of the teeth during the oral stage, during which satisfaction coincides with destruction of the object; mastery of the anal sphincter muscles; and muscular development that brings the genitalia under the control of reproductive functions. Freud in addition took into account from the outset a nonsexual type of aggression, in which a need to eliminate an obstacle to instinctual satisfaction also allows the instinct for mastery to be satisfied.

Thus, as he wrote in "Instincts and Their Vicissitudes" (1915c): "Psycho-analysis would appear to show that the infliction of pain plays no part among the original purposive actions of the instinct. A sadistic child takes no account of whether or not he inflicts pain, nor does he intend to do so" (p. 128). It is in this article that Freud gave his most complete account, within the framework of the first theory of the instincts, of the links between sadism and masochism. Sadism, first, can be transformed into masochism by

means of a double reversal, wherein activity is transformed into passivity and the subject is substituted for the object. The same outcome is found in the other pair of opposites described, voyeurism and exhibitionism. Nevertheless, Freud noted that the sexual sadistic component presupposes a prior knowledge of masochism, and that it therefore entails the following contradiction: “The enjoyment of pain would thus be an aim which was originally masochistic, but which can only become an instinctual aim in someone who was originally sadistic” (p. 129).

This contradiction was resolved in 1924 in “The Economic Problem of Masochism,” in which Freud confirmed his earlier intuition from “Beyond the Pleasure Principle” (1920g) of a masochism that could be primary. He posited an erotogenic primary masochism that binds the part of the death instinct remaining within the organism. Sadism in effect results from the diversion outward, through the intermediary of the musculature, of the libidinally bound destructive instinct onto objects. “It is appropriate, then, to call it the destructive instinct, the instinct for mastery, the will to power. Part of this instinct is directly placed in the service of the sexual function, where it has an important function to fill. This is sadism, properly speaking.”

Even in his second version accompanying the introduction of the death instinct, Freud allowed for consideration of sadism in a broad and not necessarily sexual sense, as representing the destructive instinct directed outwards toward the objects. Analysts who deem it unnecessary to adhere to the second theory of the instincts are thus justified in equating sadism and destructiveness, all the more so in that anality, for all its abundant potential for instinctual erotization, also lends itself to the metaphorization, by means of fecalization, of the most radical forms of deanimation (Béla Grunberger). Some authors, such as Jean Bergeret, have even maintained that sadism exists as a fundamental narcissistic violence, well before the emergence of sexuality is clinically revealed in narcissistic structures, and that it is inaccurate to describe it in terms of objects, even pregenital ones. Paul Denis has reassessed the element of mastery present in any instinct, with respect to the aim of satisfaction.

Like Karl Abraham, whom Freud also followed in his conceptualization of sadism and the libidinal stages, Melanie Klein adopted the second theory of the instincts and their dualism, but in her clinical work

she focused on sadism as the main expression of the destructive impulse, giving it considerable and early importance. Its turning back against the subject is what puts him or her in danger.

Other authors, such as André Green and Benno Rosenberg, have taken further Freud’s conception of the fusion of life and death instincts prior to any sadism, which thus becomes a projected masochism, and accordingly they see sadism as a protection against the threat of the death instinct and its deobjectivizing aim, particularly in borderline states in which primary anality (Green) intervenes against disintegration and its destructive consequences (Rosenberg). In such a view, sadism protects the individual just as masochism does, but with a more secure external object. This is not always the case, however, since in melancholia incorporation of the object endangers the subject’s life and illustrates the threat of the superego’s sadism toward the ego, which is also present, in a less severe form, in self-punishment.

## **SADOMASOCHISM**

Sadism and masochism represent contrasting forms of pleasure derived from sexual excitation linked to cruelty and the infliction of pain. While both currents

are present in any given individual, they also represent pregenital links in an intersubjective context in which one partner is the sadist and the other the masochist. Sadomasochism may have an oral component but takes on characteristic form during the anal sadistic stage.

In *Three Essays on the Theory of Sexuality* (1905d), Freud pointed out that sadism and masochism, terms that first gained currency in the work of Richard Krafft-Ebing, “are habitually found together in the same individual” and “occur together regularly as pairs of opposites” (pp. 159–60). Freud eventually generalized this dynamic to psychic structures as a whole, when he posited the relations governing the mental agencies in his second topography. Thus the superego’s sadism toward the ego figures prominently in the idea of self-punishment and moral masochism. Sadomasochism may also characterize relationships between individuals, regardless of gender, and even if the context is a normal sexual relationship.

Sadomasochism may be viewed as a regression in the face of castration anxiety, provoked by the oedipal conflict and associated with the perception of the anatomical differences between the sexes. This interplay can be seen in cases of obsessional neurosis—for example, with the “Rat Man” in “Notes upon a Case of Obsessional Neurosis” (1909d). Freud also found sadomasochistic aspects to the oedipally tinged autoerotic fantasies discussed in “A Child Is Being Beaten: A Contribution to the Study of the Origin of Sexual Perversions” (1919e). In general, Freud’s original conception of sadomasochism developed from his early instinct theory, which included a drive to mastery without a sexual aim.

However, in terms of the genesis of the sadism and masochism, Freud eventually gave pride of place to the latter, which he discussed first in 1915 in “Instincts and Their Vicissitudes” in terms of the presence of sexual excitation, and then formulated more generally in “The Economic Problem of Masochism” (1924c), written after the introduction of the death instinct.

In Freud’s later theory, sadomasochism derives its importance and power, so to speak, from a singularly effective form of instinctual fusion that protects the individual from the death instinct by diverting it outward (sadism) or binding it either internally or to an object (masochism). This amounts to a profound explanation of the human capacity to hurt oneself and one another, with both sexual and survival benefits.

This idea can elicit at least as much if not more resistance than infantile sexuality. In dealing with sadomasochism, the analyst may confront resistances that are especially rigid, together with fixations on pregenital object relations, moral masochism, and negative therapeutic reaction.

Freud’s conception of sadomasochism can be clinically validated by role reversal found among sadomasochistic couples, in the establishment of reverse relationships with another partner, and in the special durability of such relationships. The masochist’s victory lies in the fact that the master cannot free him- or herself from the ties that bind.

For analysts who remained faithful to Freud’s first theory of instincts, sadomasochism expresses mental destructiveness, sometimes in the most extreme fashion. For those who preferred the death instinct, sadomasochism instead offers protection from instinctual destructiveness, both internally and through cathexis of a particularly solid object relationship, albeit a pregenital one. Both camps are in agreement in referring to sadomasochism clinically in the analysis of borderline or narcissistic situations in which triangulation gives way to dyadic relations, but they view it differently, as either negative or positive, with regard to destructiveness. This difference would tend to dissolve if it were specified whether internal destructiveness or external destructiveness was involved, because only the latter is taken into account in terms of aggression.

## **SAINTE-ANNE HOSPITAL**

In an edict issued on July 30, 1863, Napoleon III “state approved” that an asylum be established in Paris for

the treatment of mental illness. This hospital was built on a plot of land that was formerly a farm called Saint-Anne, which was in a remote district, but provided forty-four acres that would allow for the construction of a model facility based on the ideas of Jean-Étienne Esquirol and able to accommodate up to 500 patients of both sexes.

The program set out by the committee established by Baron Haussmann included plans for a central admissions office, which was intended to replace immediately the “city madhouse,” where patients would be observed and then redirected to one of ten buildings constructed around the periphery. Work was quickly begun by Charles Auguste Questel, the architect who had drawn up plans for the project under the direction of alienist Girard de Caillaux, and construction was completed in 1866. The chief administrator of the central office was Valentin Magnan, but the “madhouse” was made a special infirmary under the prefecture of police, and when it was decided in 1875 that a clinical chair for mental illness and the study of the brain was to be created, Benjamin Ball won the appointment with the support of Charles Lasègue, under whom he served at the infirmary.

Sainte-Anne maintained a long tradition of competition between academic teaching sponsored by the chair and clinical lectures or seminars given by notable teachers who attracted large audiences. Henri Claude, who held the chair from 1922 to 1939, opened a public clinic (which Édouard Toulouse turned into the Henri-Rousselle Hospital in 1926). From 1936, Claude entrusted consultations in psychoanalysis to René Laforgue, and in 1926 sponsored a series of lectures on psychoanalysis at Sainte-Anne. Under his chairmanship Henri Claude allowed only doctors who had psychoanalytic training to practice at the clinic.

When the war began, Claude was replaced by M. Laignel-Lavastine, but in 1942, the faculty council installed Lévy-Valensi, who was prohibited from teaching under Vichy laws. He was arrested on September 15, 1943, and deported to Auschwitz where he died in the gas chamber three days later. Jean Delay, who served as acting chair after Lévy-Valensi, was named permanent chair in 1946. An analysand of Édouard Pinchon, Delay allowed only analysts to practice in the clinic. Lacan held his seminar in the departmental amphitheater until November 1963, while Henri Ey spoke at the Magnan Amphitheater at Henri-Rousselle Hospital.

But the advent of psychopharmacology, heralded by the International Conference on Thorazine at Sainte-Anne, was to make the hospital one of the birthplaces of neuroleptic treatment, in effect eliminating its role in the development of clinical psychiatry and psychopathology enriched by psychoanalysis.

## SALPÊTRIÈRE HOSPITAL, LA

On the site of a former gunpowder warehouse for the military, the “Salpêtrière,” Louis XIII constructed a building that would become part of the General Hospital of Paris and used to house beggars. The project was part of the general cleanup of the city that resulted from the edict published in 1656 by Louis XIV.

For more than two decades the Salpêtrière Hospital was used to house women. They lived in different buildings depending on the reason for their confinement (beggars, prostitutes, criminals, the ill). Gradually the facility was transformed into an asylum. Shortly before the Revolution of 1789, Philippe Pinel, who had arrived from the Hospital of Bicêtre (the men's asylum), working with the director, Cusin, introduced patient control methods similar to those he had already put into effect at Bicêtre.

When, in 1862, Jean Martin Charcot joined the General Hospital, it became his job to care for the women in the asylum. He began conducting clinical and anatomical-pathological research, which led to the foundation of rheumatology and neurology in France.

While conducting research on neuropathology (the anatomical study of infantile brain diseases), Freud, in 1895, requested a grant to study at the Salpêtrière.

Coincidentally, Charcot had just begun a critical revision of the pathogenesis of hysteria. Although Charcot had long believed in the organic nature of full-blown neurosis and in animal magnetism, when Freud came to attend his lectures (October 1885-March 1886), his approach was based on the psychological nature of hysteria, where the symptom was believed to result from a voluntary refusal to function. Hypnosis had no therapeutic advantage. It could, however, “experimentally” produce symptoms illustrating the role played by suggestion in their pathogenesis.

Freud was deeply influenced by Charcot and his ideas. Extremely disappointed by his welcome in Paris (which perhaps led to his life-long antipathy for the French), he idealized Charcot to the extent of calling one of his sons Martin in his honor. In 1889 he stopped in Nancy (the rival school) to deepen his understanding of hypnosis. However, he remained faithful to the teachings of the Salpêtrière, which held that the effect of hypnotic suggestion is observed only in subjects who are predisposed to it and that hysteria is the result of this predisposition. On his return to Vienna, Freud found that Joseph Breuer maintained the same position regarding hysteria.

Several years later, in 1890, Pierre Janet, with Charcot’s support, opened a psychopathology laboratory that allowed him, in spite of the organicist revisionism of Joseph Babinski and Pierre Marie, to continue his own clinical work, until Jules Déjerne had him replaced in 1910.

## SAN FRANCISCO PSYCHOANALYTIC SOCIETY AND INSTITUTE

Psychoanalytic training came to the United States first on the Atlantic seaboard during the 1930s with the establishment of institutes connected with societies in New York, Boston, and the Baltimore-Washington area and then, in one extension westward, in Chicago. A decade later, in the early 1940s, a society and institute were established for the first time west of the Mississippi River, in Topeka, Kansas, by Karl and Will Menninger,

who had been trained psychoanalytically by commuting to Chicago during the 1930s. The Topeka institute was authorized to sponsor all training in the western part of the United States, including California.

The San Francisco Psychoanalytic Institute was established in 1942 as part of the combined California Psychoanalytic Society (a joint society of Los Angeles and San Francisco), both branches being under the direction and supervision of the Topeka society and institute. The initial ten charter members of the new society (in Los Angeles and San Francisco, with one even in New York) were William G. Barrett, Bernhard Berliner, Otto Fenichel, George Gero, Bernard A. Kamm, Jascha Kasanin, Donald McFarlane, Douglass W. Orr, Ernst Simmel, and Emanuel Windholz. Because of the strictures of the American Psychoanalytic Association at that time against the training or membership of nonphysicians (lay analysts), the local nonmedical members of the analytic community (Frances Deri in Los Angeles and Siegfried Bernfeld, Erik Erikson, and Anna Mänchen in San Francisco) had to be designated as honorary members in the local society, not eligible for membership in the American Psychoanalytic Association. Almost all of these charter members in the new California society were refugees from Hitler’s Europe who had immigrated to America in the 1930s. In the latter half of the 1930s they started an informal psychoanalytic study group in San Francisco. This group was open to all interested medical or academic individuals, whether they had been psychoanalytically trained or not. One of the most prominent and active participants of the group was Robert Oppenheimer, the famed nuclear scientist, then at the University of California at Berkeley.

From these initial members, soon joined by others (such as David Brunswick, Ralph Greenson, Norman Reider, and May Romm), the California Psychoanalytic Society grew rapidly in the post-World War II boom years, and soon separated into two organizations. With candidacy limited at the time to psychiatric physicians, the San Francisco Society and Institute drew some candidates from among those in psychiatric training at the two local medical schools, Stanford University and the University of California at San Francisco, but the Departments of Psychiatry at both these medical schools, despite having a number of psychoanalysts on their clinical teaching faculty, were quite unfriendly to psychoanalysis and thus furnished fewer psychoanalytic candidates than the next source.

The greater bulk of the candidates came rather from the Department of Psychiatry of the Mt. Zion Hospital, a local independent Jewish clinical and teaching hospital. Its Department of Psychiatry was established when, in the late 1930s, it recruited as chief the psychoanalyst Jascha Kasanin from Chicago (who was, as stated above, one of the charter members of the California Psychoanalytic Society). Over a three-decade period, he was succeeded as chief by psychoanalysts Norman Reider, Edward Weinschel, and Robert Wallerstein. During this same period the department grew in scope in its training of residents in adult and child psychiatry and also, in accord with its multidisciplinary commitments, in its training of graduate and postgraduate students in clinical psychology and psychiatric social work, growing to a size and prominence that rivaled the training programs at the two medical schools.

This deeply psychoanalytic Department of Psychiatry became so well-known nationally that internship applications to this regional Jewish hospital came from all over the country, with the majority of the interns coming so that they could vie for acceptance into specialty training in the Department of Psychiatry, often to the dismay of the medical and surgical specialties, which competed for interns. Over a fifteen-year period (1973–1988), the Mt. Zion Department of Psychiatry conducted a Doctor of Mental Health program, a five-year experimental program for psychoanalytically informed mental-health practitioners, in content an amalgam of the most relevant aspects of separate disciplinary training in clinical psychiatry, clinical psychology, and psychiatric social work. This program furnished a substantial additional cadre of applicants for full psychoanalytic training at the San Francisco Institute (see Wallerstein, 1978, 1991, for a detailed account of the Doctor of Mental Health).

Until the early 1960s the San Francisco Society and Institute had no building. Its seminars and supervisions were held in institute instructors' and supervisors' private offices, which were primarily in the clusters of medical office buildings surrounding Mt. Zion Hospital, and the monthly scientific meetings were held in the hospital auditorium. When the San Francisco Society and Institute did erect a building, on the site where it still stands, it was kitty-corner from Mt. Zion Hospital. About half the training analysts in the institute, plus other graduate analysts, held part-time salaried administrative and teaching positions on the Mt. Zion Hospital staff, and the Department of Psy-

chiatry at the hospital served much like a prep school for the institute. Psychiatric trainees hoped to enhance their chances to be accepted as a candidate at the institute by impressing their psychotherapy supervisors and their clinical and theoretical seminar leaders who were also institute faculty members.

During the 1960s and 1970s, serious tensions over training issues arose within the Education Committee and threatened to split the institute. One of the principle protagonists in these battles regularly urged Robert Wallerstein, as chief of psychiatry at Mt. Zion Hospital, to join him and other training analysts on the Mt. Zion staff and split from the San Francisco society to found an alternative and rival Mt. Zion Psychoanalytic Society. One of Wallerstein's periodic tasks was to block this move. The internecine difficulties at the institute were finally resolved by the end of the 1970s, and the integrity of the society and institute has not been threatened since.

During the 1980s the long-simmering struggles within the American Psychoanalytic Association came to a head over the issue of accepting nonmedical mental-health professionals (for the most part, clinical psychologists and psychiatric social workers) for full clinical psychoanalytic training. In early 1985 four clinical psychologists, on behalf of a presumed class of many thousands, instigated a lawsuit against the American Psychoanalytic Association for its restrictive training and membership policies, a suit based on Sherman Antitrust grounds. They had the full backing of Division 39, the psychoanalytic division, of the American Psychological Association. (See Wallerstein, 1998, for a detailed accounting of the almost century-long struggle over this issue until its final resolution with the settlement of the lawsuit in 1988.) Many of the leading figures in the San Francisco society and institute had long been in the substantial minority within the American Psychoanalytic Association, who favored opening its doors to full clinical training of nonphysicians. As early as the early 1970s, Stanley Goodman, then the chairperson of the Education Committee of the San Francisco institute, led a finally successful effort to get the American Psychoanalytic Association to accord membership to the dozen or so nonmedical training analysts in institutes around the country, who, to that point, had not been allowed as members, though those they trained were, of course, eligible. This enabled Anna Mänchen, the one nonmedical analyst from the original nonmedical trio of founding

members of the psychoanalytic group in San Francisco and a long-time training analyst at the San Francisco Institute, to become an official member of the American Psychoanalytic Association.

While the 1984–1985 countrywide planning for the lawsuit against the American Psychoanalytic Association was underway, a group of nonmedical mental-health professionals in the San Francisco Bay Area were planning a similar suit, and they were actually given moral and financial support by a significant number of members of the San Francisco institute, including the then chairperson of its Education Committee, Daniel Greenson, even though those who supported the effort were at the same time members of the American Psychoanalytic Association, the parent organization that was planning a vigorous resistance to the lawsuit.

The lawsuit was settled in October 1988, and under the terms of the settlement, nonmedical mental-health professionals became eligible for candidacy, and later membership, in the institutes and societies of the American Psychoanalytic Association, and organized psychoanalytic training centers outside the American Psychoanalytic Association could qualify for membership in the International Psychoanalytical Association if they met its standards. Before the settlement of the lawsuit, membership in the International Psychoanalytical Association was possible in the United States only through the American Psychoanalytic Association.

Although the local group in the San Francisco Bay Area never filed a lawsuit separate from that of Division 39, the individuals involved in the lawsuit went on in 1989 to create a new and separate entity, the Psychoanalytic Institute of Northern California, with strong assistance from some senior members of the San Francisco Psychoanalytic Society and Institutes. The Psychoanalytic Institute of Northern California has had a thriving history of over a decade and in 2004 is in the process of working out membership in the International Psychoanalytical Association, outside the American Psychoanalytic Association. During the rise of the Psychoanalytic Institute of Northern California, several dissident members of the San Francisco Psychoanalytic Society and Institutes also established a new entity, the San Francisco Institute and Society for Psychoanalysis and Psychotherapy, and it too, now more than a decade later, is in the process of working out membership in the International Psychoanalytical

Association outside the framework of the American Psychoanalytic Association.

Thus San Francisco now has three mainline psychoanalytic societies and institutes: the San Francisco Psychoanalytic Society and Institute (since 1942 a member of the International Psychoanalytical Association through the American Psychoanalytic Association), and in addition the Psychoanalytic Institute of Northern California and the San Francisco Institute and Society for Psychoanalysis and Psychotherapy (two recent groups that became members of the International Psychoanalytical Association outside the American Psychoanalytic Association). San Francisco has also been one of the few American cities with a functioning Jungian Psychoanalytic Society and Institute, with a history of more than a half century. For the last decade it has also had a Lacanian training program inaugurated by two Belgium-trained Lacanian analysts, one from Greece and the other from Germany. In 2004 this amounts to five psychoanalytic groups in the San Francisco Bay area, all seemingly thriving and living together in relative harmony. On occasion, scientific events are organized across more than one of them (usually the San Francisco Psychoanalytic Society and the Psychoanalytic Institute of Northern California), and at times, scientific and social events are held for candidates of all five groups.

Yet none of these developments have in any way diminished the intellectual vigor or activity of the original San Francisco Psychoanalytic Society and Institute. With the 1988 opening of training possibilities for nonmedical mental-health professionals, there was a fresh burst of applications from individuals who had for years been hoping for just this opportunity, and the San Francisco Psychoanalytic Society and Institutes has offered a steady curriculum of active classes for candidates through the years since then. This is despite the decline in candidate applications that has beset most institutes of the American Psychoanalytic Association and around the world during these years. This is also despite the collapse of the renowned Department of Psychiatry at Mt. Zion Hospital after the School of Medicine of the University of California at San Francisco took over Mt. Zion Hospital. After Robert Wallerstein left the chair of the university's Department of Psychiatry, which he held from 1975 to 1985 after holding the chair of the Mt. Zion department, his successor as department chair at the university was a biological psychiatrist and neuroscience

researcher not friendly to psychoanalysis. Nonetheless, the flow of psychoanalytic candidates from medical and nonmedical sources has continued unabated.

Morale in the society and institute has been consistently high: the educational program has been pointed to in many circles of the American Psychoanalytic Association as a model for the nation; a supportive San Francisco Psychoanalytic Foundation has been established; and plans are now in the final phase for an improved and enlarged physical headquarters for the society and institute on the same site. Such developments promise to continue. Although the San Francisco society is only middle-sized, and not among the larger groups within the American Psychoanalytic Association, two of its members, William Barrett and Robert Wallerstein, have been presidents of the American Psychoanalytic Association, and two other members, Stanley Goodman and Edward Weinschel, have been chairpersons of the Board on Professional Standards, the educational arm of the American Psychoanalytic Association. And from 1985 to 1989, Robert Wallerstein was president of the International Psychoanalytical Association and Edward Weinschel was secretary.

## **SAN FRANCISCO PSYCHOTHERAPY RESEARCH GROUP AND CONTROL-MASTERY THEORY**

The San Francisco Psychotherapy Research Group (formerly called the Mount Zion Psychotherapy Research Group) was founded in the early 1970s by Joseph Weiss, M.D., and Harold Sampson, Ph.D., both analysts at the San Francisco Psychoanalytic Institute.

A large number of professionals have been associated with the group, which is one of the few in the United States engaged in programmatic research of the therapeutic process and development of a full-scale psychoanalytic theory. The theory is informally known as Control-Mastery Theory, from two of its assumptions: (1) people exercise considerable unconscious *control* of their mental lives (an assumption that contrasts with the view that the unconscious serves only as a repository of drives, blindly seeking expression), and (2) patients enter treatment seeking to *master* their difficulties, although they may be unaware of significant parts of their treatment goals (an assumption that contrasts with the perspective that sees patients as seeking to continue infantile gratifications and resisting modification even of partial symptomatic expression of such impulses). Symptoms stem from “unconscious pathogenic beliefs,” which are inferences about traumatic events, often involving fear of harm to a loved one as a consequence of trying to meet a normal developmental goal (Weiss, 1990; 1993).

These assumptions and several others have been articulated in many publications, in case examples, and especially in formal research. An early phase of the research examined psychoanalytic cases, especially the case of Mrs. C (see Weiss, Sampson, et al., 1986). Among other things, it was shown that patients test their therapists, often unconsciously, by (1) transferring (acting toward the therapist as they had acted toward a parent earlier in life) and (2) turning passive into active (acting toward the therapist as a parent had acted toward them earlier). In both cases, the patient unconsciously hopes that the therapist will not be traumatized as the patient was earlier. When the therapist responds in a way that passes the test, the patient improves immediately (as measured by standard psychotherapy progress measures, as well as several measures developed specifically by the researchers). Other research has investigated short-term psychodynamically oriented psychotherapy, short-term therapy conducted from other theoretical frameworks (for example, cognitive-behavioral therapy), and therapy with elderly clients and several other patient populations. It has been shown that explicit plan formulations can be developed for patients. The more congruent that a therapist’s interventions are with this plan, the greater the improvement (Silberschatz, Fretter and Curtis, 1986).

### SANDLER, JOSEPH (1927–1998)

Joseph Sandler, English physician, psychoanalyst, and psychologist, was born in Cape Town, South Africa on January 10, 1927 and died in London on October 6, 1998.

Sandler's family was Jewish. He received his Master's degree in psychology at age nineteen, from the University of Cape Town. He moved to England in the late 1940s to further specialize in psychology, and received his PhD from London University at age twenty-three.

He then began his medical education at University College London, and applied to become a psychoanalyst. In 1952 he qualified as psychoanalyst of the British Psychoanalytical Society, having been trained by the classical Freudian psychoanalyst Willie Hoffer, and then by his wife, Hedwig Hoffer. He became a training analyst at the age of twenty-eight, and specialized also in child analysis. Subsequently he was awarded both a MD and a D.Sc. Sandler had a outstanding career both as theoretician and clinician, but also as an administrator in psychoanalysis. He is considered a central figure in the second half of twentieth century psychoanalysis.

He was editor of the *British Journal of Psychology* (1959–1963), and then became the editor of the *International Journal of Psycho-analysis* from 1969 to 1978, and he founded the *International Review of Psychoanalysis*. He was the first Sigmund Freud professor of psychoanalysis at the Hebrew University of Jerusalem. He then became the first full-time Sigmund Freud professor of Psychoanalysis at London University, until

his retirement in 1992, the year in which was nominated Professor Emeritus.

He held several honorary degrees. He held more than twenty visiting professorships, and was elected President of the International Association of Psychoanalysis in 1989.

As a theoretician, Sandler is remembered for his effort to reexamine and update the theoretical and clinical issues of classical psychoanalysis. He was the leader of the so-called Hampstead Index Project, working with Anna Freud and her colleagues for many years at the Hampstead Child Therapy Clinic during the 1960s and the 1970s. He became more and more interested in trying to bridge the gap between classical Freudian psychoanalysis and the British school of object relations. His close friend Arnold Cooper described his work as “the silent revolution in psychoanalysis.”

Sandler was the author of more than 200 papers and author, editor, or co-editor of forty-four books. The most important of his papers are collected in *From Safety to Superego* (1988), *The Patient and the Analyst*, written in collaboration with Christopher Dare and Alex Holder (1973), and particularly in *Internal Objects Revisited* (1998), which he wrote together with his wife, Anne Marie Sandler.

In addition to being a prolific author, Sandler was also a great facilitator of the work of colleagues and young psychoanalysts. He also pioneered the rapprochement between psychoanalysis and empirical research, creating the annual research conference of the IPA at University College, London. This annual meeting of researchers has been given in his name since his death.

Sandler was married twice, having lost his first wife, and he had three children.

## SARASIN, PHILIPP (1888–1968)

Philipp Sarasin, the Swiss physician, psychoanalyst, and specialist on psychiatry and psychotherapy, was born at Basel on May 22, 1888, and died there on November 28, 1968.

He came from an old Huguenot family that played an important role in the cultural and economic life of Basel. Having first hesitated between studying Greek or botany, he finally opted for medicine. When he finished his studies in 1915 he worked as a volunteer physician with Eugen Bleuler in Zürich, where he commenced his first Jungian analysis with Franz Riklin. From 1916 to 1921 he worked under Ris as an assistant physician in the Rheinau clinic.

After a short period of analysis with Hanns Sachs, he had the opportunity to encounter Freud at the 1920 congress in The Hague. In spring 1921 he began his analysis with Freud, and in 1924 he set up his own practice in Basel as an independent psychoanalyst.

He was a member of the Swiss Psychoanalytic Society (SGPsa) from its foundation and, following the breakaway of president Emil Oberholzer he replaced him as president from 1928 to 1961. Thanks to his unstinting devotion to Freudian orthodoxy and the fact that he never pushed himself to the fore, he succeeded in saving the SGPsa from crisis and maintained its cohesion through difficult circumstances. Although his contribution was limited in terms of publications and lectures his main activity consisted in adopting "positions that were constantly renewed through considered comments in the course of hundreds of discussions on the scientific and practical questions that arose.... Through his enlightened mind, his rigorous thinking and honesty he formed

the scientific conscience of our country's psychoanalysts" (Parin).

His only psychoanalytic writing of import, on Goethe's *Mignon*, was in his own words the result of his discussions with Freud in the course of his analysis. It is also based on a good knowledge of Goethe's life and work. In it, he analyzes the character of the androgynous young woman, Mignon, who dies as a result of being separated from her beloved, fatherly friend, and the old Harfner, who grows violent in the course of a melancholic episode, as a reworking of the poet's youthful memories.

## SARTRE AND PSYCHOANALYSIS

French philosopher, novelist, and playwright Jean Paul Sartre (1905–1980) attended the École Normale Supérieure, received his accreditation in philosophy, and was a resident at the Institut Français in Berlin during 1933–34. He was awarded, but declined, the Nobel Prize for literature in 1964.

Sartre's first major work, *The Transcendence of the Ego* (1936–1937) published in English in 1957, called into question the interiority of consciousness and, based on Edmund Husserl's phenomenology, he wrote that "the ego is neither formally nor materially in consciousness: it is outside, in the world. It is a being of the world, like the ego of another." The subject does

not possess himself and consciousness, “defined by intentionality,” provides no privileged self-knowledge because, as Sartre writes, “My I, in effect, is no more certain for consciousness than the I of other men. It is only more intimate.” These ideas formed the springboard for a radical critique of introspection, self-knowledge, and inner life.

Sartre developed his ideas further in *Being and Nothingness* (1943). In this text he suggested that Sigmund Freud’s work (which he characterizes as “empirical”), in his estimation, represents a provisional formulation, subject to critique, of what he calls (more by reference to Søren Kierkegaard than to Ludwig Binswanger) “existential” psychoanalysis. He postulates the principle that the human being is a totality, expressed completely through fortuitous conduct. “In other words there is not a taste, a mannerism, or a human act which is not revealing” (p. 568). The goal, to elucidate the actual behavior of human beings, is based on “the fundamental, preontological comprehension which man has of the human person” (p. 568). All conduct symbolizes and conceals, in various ways, the basic choice of every individual subject. Each person must be unveiled and revealed, as Sartre himself would attempt to do with Jean Genet (1952) and Gustave Flaubert (1971–72). With this as a starting point, Sartre moves on to discuss the similarities and differences between Freudian psychoanalysis and what he calls existential psychoanalysis.

In terms of similarities, both analysis and existential psychoanalysis “consider the human being as a perpetual, searching, historization. Rather than uncovering static, constant givens they discover the meaning, orientation, and adventures of this history” (p. 569). With knowledge anterior to logic, the subject has absolutely no privileged capacity for self-knowledge, while conflicts and projects can be apprehended only from the point of view of the other.

But there are also radical differences. Most decisive, according to Sartre, is that for Freud the libido is an irreducible psychobiological given. By contrast, Sartre suggested that the subject’s own demarche is centered on choices that cannot be constituted in advance and which vary with each individual. “For human reality there is no difference between existing and choosing for itself” (p. 572) because “consciousness is a being, the nature of which is to be conscious of the nothingness of its being” (p. 47).

In sum, from a somewhat dated view of Freud’s work, Sartre fashions a critique that views psychoanalysis as an acceptable albeit awkward and provisional expression of what will become existential psychoanalysis, while on a practical level it is more successful. “Empirical psychoanalysis, to the extent that its method is better than its principles, is often in sight of an existential discovery, but it always stops part way” (p. 573).

### **SAUSSURE, RAYMOND DE (1894–1971)**

Raymond de Saussure, the Swiss psychoanalyst, was born in Geneva in 1894 and died there on October 19, 1971.

Descending in a direct line from a number of Geneva scientists, Raymond was the son of Ferdinand de Saussure, the founder of modern linguistics. He studied medicine in Geneva and Zürich from 1914 to

1920, then trained as a psychiatrist in Paris, Vienna, and Berlin.

While still very young, Saussure took an interest in psychoanalysis, and in 1919 he became a member of the newly-founded Swiss Psychoanalytic Society. In 1921 he met Freud at the conference in The Hague and began analysis with him in 1921. He then set up in Geneva, practicing essentially as a psychoanalyst until 1937. During the 1920s he began another analysis with Franz Alexander in Berlin. Spreading Freud's ideas to France, he and Charles Odier were among the founders of the Paris Psychoanalytic Society in 1926, the *Revue française de psychanalyse* and the Congress of French-Speaking Psychoanalysts. In 1937 he left Geneva for Paris, where he began a new analysis with Rudolph Loewenstein, but returned to Switzerland in 1939 because of the war. In 1940 Saussure was sent to the United States as part of the Swiss American Fund for Scientific Exchanges. He lived in New York until 1952, became a member of the New York Psychoanalytic Society, took an active role in the training activities of the New York Institute, was Associate Professor at Columbia University, and taught in the Free France university.

Upon returning to Geneva in 1952, Saussure put all his experience and energy into developing psychoanalysis in French-speaking Switzerland. He organized clinical and theoretical training seminars in collaboration with Germaine Guex in Lausanne, with Michel Gressot in Geneva, as well as with Marcelle Spira, a Swiss psychoanalyst trained in Argentina. He also lectured in psychotherapy in the medical faculty of Geneva University. He continued his efforts to promote the development of psychoanalysis not only in his own country—he was president of the Swiss Society for several years—but also internationally, and was one of the vice-presidents of the International Psychoanalytic Association (IPA) from 1955 to 1961. In 1966 he helped found the European Federation for Psychoanalysis. In the late 1960s Saussure lent his support to a movement, coming mainly from candidates in French-speaking Switzerland, for the creation of a psychoanalytic training center. This movement resulted in the inauguration of the Centre Psychanalytique Raymond-de-Saussure (Raymond de Saussure Psychoanalytic Center) in Geneva in 1973, two years after his death. This center for exchange and encounter played a leading role in the expansion of psychoanalysis in French-speaking Switzerland that began in the early 1970s, particularly in Geneva.

*La Méthode psychoanalytique* (The psychoanalytic method; 1922), with a preface by Freud (1922e), surprised the public of the time and was prohibited. "Les fixations homosexuelles chez les femmes névrosées" (Homosexual fixations in neurotic women), a report to the Conference of French-speaking Psychoanalysts, puts forward the original notion of "hermaphroditic narcissism," in order to shed light on identity problems in homosexuality (1929). "Psychologie génétique et psychanalyse" (Genetic psychology and psychoanalysis), a congress report, attempts to reconcile the ideas of Freud and Jean Piaget (1933). *Le Miracle grec* (The Greek miracle; 1939), a psychoanalytic study of the century of Pericles, was burned by the Nazis. In 1959 at the IPA Congress in Copenhagen he presented "The Metapsychology of Pleasure," a reflection on desire, pleasure, and happiness, in their relationship to the conscious and unconscious ego. His bibliography numbers about ninety publications.

Raymond de Saussure was intimately involved in the foundation and development of the Swiss society in 1919 and the Paris society in 1926, as well as the European Foundation for Psychoanalysis in 1966.

## SCHIFF, PAUL (1891–1947)

Paul Schiff—French physician, psychoanalyst, psychiatrist, and neuropsychiatrist known for his work with prisoners—was born in Vienna on August 5, 1891, and died in Paris on May 17, 1947.

Though Austrian by birth, Schiff was culturally French. His father, a foreign correspondent for an Austrian newspaper, settled in Paris when his son was a month old. At the Collège de France, Schiff studied philosophy and was especially influenced by Henri Bergson's lectures on Spinoza (1632–1677). He subsequently studied medicine. During World War I, Schiff, not a French citizen but unwilling to fight in the Austrian army, moved to Switzerland, where he became friends with the novelist Romain Rolland and the poet Pierre-Jean Jouve. Returning to France, he interned in psychiatry at the Asiles de la Seine (Asylums of the Seine) and later served as chief of the psychiatric clinic at Sainte-Anne Hospital in 1927. He married Suzanne Wertheimer, an ophthalmologist.

Analyzed by Eugénie Sokolnicka, Schiff became a member of the Société Psychanalytique de Paris (Paris Psychoanalytic Society) in 1928. He was also a founding member of Évolution psychiatrique, a medical organization for French psychoanalysts. He worked with Édouard Toulouse at the Henri-Rousselle Pavillion, where he directed a clinic for sex-related disorders until 1936.

Increasingly drawn to criminology, Schiff was appointed neuropsychiatrist of prisons in 1935. The same year, at the Ninth Conference of French-Speaking Psychoanalysts, he presented the paper "Psychoanalysis and the Paranoias." In his work on criminality, Schiff established an intellectual foundation for cross-disciplinary research employing a range of different perspectives, including the biological bases of behavior and the role of unconscious conflict. But World War II intruded, and his projected treatise on criminology remained unpublished. In 1938, with Daniel Lagache and others, Schiff founded the publication *Psychologie Collective* (Collective psychology), which terminated with the war.

Schiff enlisted as a battalion physician before returning to Paris after the 1940 defeat of the French forces. He and his wife both entered the Resistance and then joined the Free French in Algeria; he was later taken prisoner in Germany. Back in Paris after the end of the war, he immediately returned to his work with

prisoners, published actively, but suddenly died of a stroke just two years later.

## SCHILDER, PAUL FERDINAND (1886–1940)

The Austrian psychiatrist and psychoanalyst Paul Schilder was born in Vienna on February 2, 1886, and died in New York on December 7, 1940.

He was the son of Ferdinand Schilder, a Jewish silk merchant who died when he was three, and Berta Fürth, who favored him over his brother. He attended secondary school and received his medical training in Vienna. He became a medical doctor in 1909, but he also always maintained an interest in philosophy; he earned a doctorate in that field 1922 and in 1928 published *Gedanken zur Naturphilosophie* (Reflections on natural philosophy).

Schilder turned his attention toward neurology and psychiatry and became the assistant of Gabriel Anton in Halle, and later of Paul Flechsig in Leipzig. At this time he published an article on *Encephalitis periaxialis diffusa* (a syndrome that thereafter bore his name), that made him famous in the field of neurology from 1912. In 1914 he published *Selbstbewusstsein und Persönlichkeitsbewusstsein. Eine psychopathologische Studie* (Consciousness of self and personality: a psychological study), a work informed by Edmund Husserl's phenomenology, before serving as a doctor in the First

World War. But it was *Wahn und Erkenntnis. Eine psychopathologische Studie* (Delusion and knowledge: A psychological study), published in 1922, that marked his first real approach to psychoanalysis, despite the fact that on March 22 Sigmund Freud wrote to Karl Abraham: “Today I received—after the Simmel—a monograph extracted from the *Lewandowskysche Sammlung* (notebook number 15): *Delusion and knowledge* by Paul Schilder (Leipzig), which, in its results, is already thoroughly analytical, and which only leaves aside, as is appropriate, the Oedipus complex. Of course, Sch. acts as if these gentlemen had discovered everything themselves, or almost everything. In short, this is how German clinicians are going to ‘appropriate’ our discoveries. All things considered, I vow, it is of no importance.”

In fact, in 1919 Schilder was elected to membership in the Psychoanalytical Society of Vienna, and on March 7, 1920, he presented his first paper, on identification, there. During the same time, he became the assistant, at the Vienna Hospital, of Julius Wagner-Jauregg, who took a somewhat dim view of his interest in psychoanalysis. He was nevertheless appointed *Privatdozent* in 1921 and professor in 1925.

Although his book *Über das Wesen der Hypnose* (On the nature of hypnosis) led Paul Federn to accuse him of plagiarism in 1922, Schilder’s works were nonetheless known and recognized by Freud and psychoanalytic circles. In 1923 he began to elaborate his theory of “body image,” an expression borrowed from the psychiatrists Arnold Pick and Henry Head, in *Le Schéma corporel. Contribution à l’étude du corps propre* (The corporeal schema: contribution to the study of the individual’s own body). He developed Freud’s suggestion that the ego is derived from bodily sensations (elaborated in Freud’s 1923 encyclopedia article, “The Libido Theory”), and he made the body image a formation under construction that brings together perceptions, affects, fantasies, and thoughts, and that plays a fundamental role in human behavior and relations with others. In 1935 Schilder published his most famous work, *The Image and Appearance of the Human Body*. Donald Winnicott, Esther Bick, Piera Aulagnier, Gisela Pankow, Françoise Dolto, and Didier Anzieu are among the many psychoanalysts who subsequently further developed this notion, which is particularly useful for understanding certain psychotic states.

In 1923 he had also published *Seele und Leben* (Soul and life), a prelude to the many works that made him one of the most original and productive thinkers in his

generation of psychoanalysts—but he remained a relatively isolated man, because he did not wish to become linked with Freud, as was attested by his repudiation of the death instinct. However, although Freud, according to Fritz Wittels (1941) reproached him for working in “overly broad dimensions” instead of limiting himself to a microscopic psychoanalysis, he continued to hold him in esteem and in 1927, for example, he advised Marie Bonaparte to attend Schilder’s visits and lectures at the Vienna Hospital. Before her, Anna Freud had gone to learn the essential basics of psychiatry from him and from Heinz Hartmann, Wagner-Jauregg’s other assistant. Schilder was consistently hostile to the practice of psychoanalysis by non-physicians, attached as he was and would remain to his hospital-based psychiatric practice. He also refused to undergo training analysis and publicly maintained its uselessness. Still, his book *Entwurf zu einer Psychiatrie auf psychoanalytischer Grundlage* (Outline for a psychoanalytically based psychiatry), published in Leipzig in 1925, was a pioneering work on psychoanalytic approaches to the psychoses and has been too often neglected by his successors.

In 1928 he traveled to the United States at the invitation of Adolf Meyer and taught for three months at the Henry Phipps Psychiatric Clinic. He left the Vienna Hospital in 1929 and emigrated to the United States, in 1930 becoming medical director of the psychiatric division of Bellevue Hospital and research professor of psychiatry in New York University’s College of Medicine. He married his collaborator Lauretta Bender in 1937. Although he resigned from the New York Psychoanalytic Society that same year, his contributions continued to influence American psychoanalytic thought.

Struck by a car as he was leaving the hospital where his son had been born a few days earlier, Paul Schilder died in New York on December 7, 1940, a short time after the accident.

As Hartmann wrote, “In my view, Schilder’s conception of the psychic apparatus is very close to the ideas that have been developed in recent years in another field, the psychoanalytic psychology of the ego” (cited in Ziferstein). He also stated, in “The Psychiatric Work of Paul Schilder”: “Schilder did more to spread psychoanalytic discoveries among European psychiatrists than, with the exception of Freud, any other psychoanalyst.”

## SCHILLER AND PSYCHOANALYSIS

Johann Christoph Friedrich von Schiller, the German poet and dramatist, was born on November 10, 1759 in Morbach and died on May 9, 1805 in Weimar. He was the last and most exemplary representative of the Sturm und Drang movement before evolving—always in the company of Johann Wolfgang von Goethe, whose friend he became in Weimar—toward the aesthetic humanism of his classical period. He was a fundamental model for Sigmund Freud, whose identification with the poet was so strong that Schiller was a familiar figure in his dreams: for example, the dream about Hollthurn, in which Schiller's birthplace was the object of scorn, analyzed by Freud in *The Psychopathology of Everyday Life* (1901b).

In difficult periods in his self-analysis, Freud's dreams referred to the plays of Schiller, whose sensibility is darker and more violent than Goethe's. Freud had been familiar with these works since his adolescence, and at age fourteen, with his nephew John, had performed an act from Schiller's *Brigands* (1781) depicting the murder of Caesar by his adoptive son, Brutus; he evoked this memory in his associations with the dream "Non vixit" to analyze his rivalry with his brother. Schiller's modernity exalts the "deviltry of

freedom," the main theme of the play that earned its author honorary citizenship in the French Republic.

The twenty-seven quotations from Schiller in Freud's work, as identified in the *Concordance*, attest to his intimate knowledge of the writer, who was also a *Dicterphilosoph* (poet-philosopher) who articulated a theory of the drives: "The animal drives [*Triebe*] awaken and develop the spiritual drives"; he opposed the material drive (*Stofftrieb*) to the form drive (*Formtrieb*). The *Spieltrieb* (play-drive)—which expresses play, the beautiful, freedom, and the total man—is posited as an ideal nexus between the two *Triebe*. It is also the force that drives creation: "It is union of the unconscious and reflection that makes the poetic artist."

In 1910, Freud situated himself in Schiller's wake by distinguishing the sexual instincts from the ego instincts, acknowledging in 1930 that Schiller, with hunger and love, had provided him with an initial "foothold." The poet was again called to the rescue to provide the words to complete an elaboration, dealing with the oceanic feeling that was being held in abeyance: Freud alluded to the poem "Der Taucher" (The diver) to evoke the dangers of the maternal body inhabited by monsters, citing only the diver's ascent toward "the rosy light," to justify his avoidance of submersion in the maternal unconscious. Elsewhere, he used Schiller's poem "The Ring of Polycrates" as an illustration in "The Uncanny" (1919).

Ultimately, Freud considered the age of Goethe to be a prehistory to psychoanalysis, and he credited Schiller for his emphasis on free association as the basis for literary creation.

## SCHIZOPHRENIA

For psychoanalysis, as for medical research and the entire field of mental health, schizophrenia is a complex, baffling, and frustrating disorder. It is not particularly rare, affecting about 1 percent of the population; its distribution is worldwide. A century after Emil Kraepelin created the diagnosis of dementia praecox and its extensive symptomology—renamed schizophrenia by Eugen Bleuler—it remains poorly understood. In spite of revolutionary advances in biology and neuroscience, no treatment or combination of therapies offers a reliable cure.

Like all the psychotic disorders, schizophrenia was thought from the start to have an organic basis, but Kraepelin was forced describe it as a “functional disorder.” Early age of onset and absence of brain lesions such as might be found in epilepsy or tertiary syphilis, for example, encouraged early analysts to attempt treatment, especially in light of the limitations of other therapeutic modalities. It became plausible to suggest, at least tentatively, that schizophrenia was a psychological disorder that originated, like neurotic conflicts, in infancy and early childhood. The fact that some small but significant percentage of patients experienced full or partial recovery made it a target for therapies of all kinds, including psychoanalysis.

Although Freud himself was skeptical about prospects for successfully treating schizophrenia, the disorder was central to the activity of many early analysts, who often were associated with hospitals for the insane. Karl Abraham’s first letters to Freud concerned psychosis; like Carl Jung, he worked at the Burgholzi Central Asylum and University Clinic in Zurich, which Bleuler directed. In the United States, where psychiatry only gradually became a primarily office practice beginning about 1920, psychiatrists influenced by Freud also worked in asylums. Adolf Meyer and William Alanson White were both hospital-based psychiatrists, as was Harry Stack Sullivan, who reported impressive results with his analytically oriented treatment beginning in the 1920s. Particularly influential, Sullivan’s work led to the creation of a psychoanalytic enclave at Chestnut Lodge in Rockville,

Maryland, devoted to the treatment of patients with schizophrenia and related disorders.

The rapid growth of psychoanalysis as a medical specialty in the United States after World War II affected the way that schizophrenia was perceived, understood, and treated. The broad theoretical reach of psychoanalysis, with its ambitious aims to provide a general psychology, extended to schizophrenia both as an explanatory tool and treatment modality. In retrospect it is clear that as a treatment it was not successful and that the early-childhood environmental deficit model that analysts proposed could not be sustained. At the time, however, without benefit of drugs or a significant knowledge base in neurochemistry, and in the wake of a period during which biological explanations of mental disease had favored eugenics, psychoanalysts appeared to be modern and forward-looking professionals who were making an earnest and humane effort to understand severe psychopathology in terms of developmental deficits.

Psychoanalysis was not seriously affected by the introduction of phenothiazine in the mid-1950s. But the narcoleptics and their successor drugs set the stage for the de-institutionalization of the mentally ill that began a decade later and also opened the way for the dopamine hypothesis, the first of various neurochemical pathways to be implicated in schizophrenia. By the late 1960s the authority of psychoanalysis was eroding, both as therapy and theory, and it had to compete with a diversified marketplace of competing treatments. As psychoanalysis in the United States entered a period of steep decline in the 1980s, its efforts on both a theoretical and clinical level were often held to be of no account. However, one positive outcome of analytic interest in the severe mental disorders, in fact, was a sophisticated and durable typology of what became known as the borderline and narcissistic disorders (Kernberg 1975), which developed along separate lines and found a respected place in clinical psychiatry and mental health practice more generally.

The list of analysts who studied and wrote about schizophrenia is long and includes interpersonalists, ego psychologists, Kleinians and their successors, together with any number who might be described as individualistic or idiosyncratic. Key texts included papers by Paul Federn, Melanie Klein, Harold Searles, and many others. Some analysts published books on schizophrenia that remained in print for decades, such as Frieda Fromm-Reichman’s *Principles of Intensive*

*Psychotherapy* (1950) and Silvano Arieti's *The Interpretation of Schizophrenia* (1955). Arieti served for years as editor of the voluminous *American Handbook of Psychiatry*.

Today, psychoanalysts view schizophrenia through a diversity of lenses. Many if not most would acknowledge the medical consensus that it is essentially a biological disorder and would not recommend the kind of intensive therapeutic efforts employed in the past. Analysts seeking an in media res would hold that analytic therapy can be beneficial while giving up earlier etiological views. A minority of analysts, post-Kleinians and others, continue to view schizophrenia as amenable in a global sense to therapeutic intervention and theoretical elaboration. Although the classic psychoanalytic model of the etiology of schizophrenia is definitively obsolete, all these currents can coexist and develop alongside the diathesis-stress model of the disorder, currently dominant in psychiatry and medicine.

## **SCHLUMBERGER, MARC (1900–1977)**

Marc Schlumberger, the French physician and psychoanalyst, was born in Mayenne on July 26, 1900 and died in Paris on June 26, 1977.

Son of the writer Jean Schlumberger, whose homosexuality he had difficulty in coming to terms with, and a British mother who died prematurely, he studied medicine purely with a view to becoming a psychoanalyst. Dissatisfied with his first training analysis with René Laforgue, he began a second round of analysis with Sacha Nacht. He became an associate member of the Paris Psychoanalytic Society (SPP) on October 17, 1933, and a full member on March 2, 1937. He was secretary of the *Revue française de psychanalyse* from 1934 to 1936. He continued to practice discreetly during the Occupation, forming, along with André Berge, Françoise Dolto and Juliette Boutonier, what they called the "Sainte-Geneviève Quartet." He also contributed to Georges Parcheminey's lectures on psychoanalysis, given at the Sainte-Anne hospital. In 1946 he became secretary of the first bureau of the SPP under John Leuba as president, a position he retained until 1951. He remained true to Sacha Nacht during the 1953 rift and became president of the Society in 1957–1958. While occupying various positions within the SPP and in the training Commission he continued to practice as psychoanalyst until his death.

He stated without reserve that the future of psychoanalysis depended on women and "non-physicians." (Chasseguet-Smirgel J., 1978) Although his colleagues recognized him as an excellent practitioner, the fact that he never overcame his reluctance to write prevented him from being among the leading figures of the SPP. In his first lecture to the SPP in November 1936 he described a case of masculine impotence that improved greatly after the patient admitted to using a dildo as a penis substitute. Although the analysis

was very satisfied with this “cure” and terminated the treatment shortly afterward, the analyst went on to outline elements that could have been brought more to the fore while stressing the unconscious aggressive instinct and the insufficiently explored transference.

The few articles he wrote illustrate his interest in interpreting dreams and studying the transference in the analytic process. He wrote a report: “Introduction à l’étude du transfert en clinique psychanalytique” (Introduction to the study of the transference in clinical psychoanalysis) for the fourteenth Conference of French-Speaking Psychoanalysts in 1951 and, with Serge Lebovici and Maurice Benassy, for the SPP colloquium in Paris in 1958.

An article entitled “Paul,” written directly in English, recounts the short therapy and death of a young epileptic; in it, the depth of Schlumberger’s psychoanalytic thinking combines with the esthetic sense of a talented writer. In his obituary Janine Chasseguet-Smirgel saw the article as the sublimated elaboration of the author’s mourning for his young patient. She also stressed his “great independence of spirit, his humor and the total absence of conformism that his reserve, his courtesy and discretion at first belied.”

His training couch was very much in demand. He analyzed Wladimir Granoff, Evelyne Kestemberg, Pierre Marty, Ruth Lebovici, Moustapha Safouan, Joyce McDougall, Conrad Stein, Georges Devereux, and many others.

## **SCHMIDEBERG-KLEIN, MELITTA (1904–1983)**

Melitta Schmeideberg-Klein, physician, psychiatrist, and psychoanalyst, was born on January 17, 1904 in Rosenberg, Slovakia. She died in London on February 10, 1983, at seventy-nine.

Melitta was the oldest child and only daughter of Arthur and Melanie Klein. Before the 1914–1918 war, the family moved to Hungary and Melitta grew up and was educated in Budapest. After the war Arthur Klein moved to Sweden and Melanie Klein moved to Rosenberg, where Melitta matriculated in 1921. She joined her mother in Berlin. Melitta worked for and obtained her MD in 1927 from Wilhelms-Universität in Berlin.

In 1924 she met and married Walter Schmeideberg, who was an Austrian psychoanalyst and a friend of Freud, and who had joined the Berlin Society. In 1929 she started her analytic training with Karen Horney at the Berlin Institute, qualifying as an associate member of the Berlin Society in 1931.

In 1927, Melanie Klein moved to London and joined the British Society. In view of the growing anti-Semitism in Germany, the Schmeidebergs also moved to London and joined the British Society. Schmeideberg-Klein was elected an associate member in 1932 and a full member the next year. She wrote many papers and eventually became a training analyst.

Initially she often made use of her mother’s ideas in her papers (1930, 1935). She then went into analysis with Edward Glover in order to deal with her dependence on her mother, whom she hoped would understand. However, following the death of her elder brother Hans in 1934, and her mother’s reaction to it, she became increasingly critical of both her mother’s contributions and her behavior in the Society, as was her analyst, Glover.

As Melitta increased her criticisms, the atmosphere in scientific meetings worsened. With the arrival of numerous colleagues from Vienna in 1938, the theoretical differences became more obvious, together with the fear that the essentials of psychoanalysis were in danger.

When Schmideberg-Klein addressed the “extraordinary business” meetings to discuss these issues, her main contribution was concerned with the effect of Kleinian proselytizing on the conduct of the affairs of the Society, rather than concern about theoretical issues (1942). When Glover resigned from the training committee and from the Society in 1944, Melitta also withdrew from active participation in the Society, and she concentrated on her other interest—the treatment of delinquents.

In 1945 she went to America. There she helped to found the Association for the Psychiatric Treatment of Offenders in New York. After the death of her mother in 1960, she decided to return to Europe. In 1962 she resigned her membership of the British Society, having developed her own form of psychotherapy (1938).

In addition to many scientific papers and reviews, in 1948 she published her book *Children in Need* (1948). In 1957 she started *The International Journal of Offender Therapy and Comparative Criminology* of which she was managing editor.

She died in 1983, unfortunately unable to make a rapprochement with her family or with other psychoanalysts in the British Society.

## **SCHMIDT, VERA FEDEROVNA (1889–1937)**

Vera Schmidt, the Russian educationist, was born in Odessa in 1889 and died in Moscow in 1937.

She was one of the leading figures of the “Silver Age” of psychoanalysis in Russia. Her parents were both physicians and she was particularly attached to her mother, Elisaveta Yanitskaia, who treated children who suffered from neurological disorders. Vera was later to say that her mother had a determining influence on her choice of career.

In 1908 Vera enrolled in the Bestoujev classes in Saint Petersburg. This prestigious establishment was reserved for young girls: it specialized in training educationists and physicians. In 1912 she was brilliantly successful in completing her studies and graduated as a teacher. In 1913 she met Otto Youlievitch Schmidt and they married in the same year. Early in 1917 she worked Kiev in the supplies Committee. It was also at this time that she developed a passion for reading Freud, her perfect German enabling her to read him in the original.

Otto Schmidt shared his wife’s passion for psychoanalysis and in this respect his role merits our attention. He was the only member of a large family of originally German peasants to have a university education. The brilliant young mathematician became a *Privatdozent* (university lecturer) while preparing his PhD thesis in order to become a professor. An enthusiastic supporter of the 1917 Revolution, he enlisted his talents as a scientist and organizer in support of the Soviets. He was a high-ranking functionary in several ministries ranging from public education to finance and the *Gosplan* (State Planning Committee), as well as being vice-president of the USSR Academy for Science. As a scientist he conducted several polar expeditions, exploits that won him a place in schoolbooks.

However, the man had another passion: psychoanalysis. In 1921 and 1926 as vice-president of the coordinating committee of the Moscow Psychoanalytic Society and the Psychoanalytic Institute (with Ivan Ermakov as the head), he financed the publication of the “Library of Psychology and Psychoanalysis,” an important collection, under the directorship of the same Ermakov. Still via the Coordinating Committee, and thanks to his government posts, Otto Schmidt provided the necessary means for psychoanalytic institutions. In 1917 the committee moved from Petrograd to Moscow and the Schmidts moved also. Vera worked in the Childhood department of the Ministry for Public Education. She applied herself to an in-depth reading of Freud’s works, as well as writings by other western psychoanalysts.

August 1921 saw the opening of the experimental child laboratory Home (Detski Dom), which was to be her life's work. Vera had no psychoanalytic training, but her publications on the experiment and the work methods of the Home (which she herself translated into German for foreign reviews) were greatly appreciated by her colleagues in the West. Moreover, Vera kept a day-to-day detailed diary of the development of her son, Vladimir Schmidt, born in 1920. He was nicknamed Volik, not Alik, as erroneously indicated by certain publications on psychoanalysis in Russia. This immense monograph has never been published in Russian, nor translated into any other language.

In early 1923 the Schmidts went to Vienna where they met Freud, with whom they discussed the children's Home and psychoanalytic activities in Russia. They also visited other analysts, most notably Otto Rank and Karl Abraham. Discussions focused mainly on psychoanalysis and the organization of the collective educational system. This constituted a veritable apotheosis for the Russian Psychoanalytic Association, which became an associate member of the International Psychoanalytic Association (IPA) in 1924.

However, as early as mid-1923 problems began to arise for the Home. The threat of ideological censorship cast its shadow over psychology and child education. On August 14, 1925 the ministry for public education decreed the definitive closure of the children's Home. Until 1929 Vera Schmidt was a researcher at the nervous system Study Center attached to the Academy of Science, where she worked on conditioned reflexes. From 1930 to 1937 she conducted research, in the cerebral pathology Experimental Center, into innate illnesses of the nervous system in young children. But she was already seriously ill with a thyroid tumor and her participation in the Tchelouskine polar expedition organized by her husband only contributed to hastening her demise. On July 17, 1937, Vera Schmidt died on the operating table.

### **SCHNEIDER, ERNST (1878–1957)**

A psychoanalytically oriented Swiss educator, Ernst Schneider was born on October 17, 1878, near Liestal, and died in 1957 in Muttenz, near Basel.

A member of a large family living in the countryside around Basel, Ernst entered the Protestant Normal School of Muristalden, near Berne, at the age of sixteen. For five years he was a teacher in a one-room schoolhouse, then pursued studies at the University of Berne. During a year he spent in a pedagogical seminar at the University of Jena, his attention was drawn to the new currents of thought circulating in Germany. Back in Switzerland, in 1903 he headed a course in continuing education for teachers and thereafter, from 1905, the Hofwil-Berne Normal School. There Schneider put into practice his ideas on school reform, wrote instructional manuals for use in the primary grades, and in 1907 founded the *Berner Seminarblätter*, a renowned pedagogical journal that was later renamed *Schulreform*, which he headed until 1920.

Schneider first learned of psychoanalysis in 1910. He then entered into contact with the Swiss Society of Psychoanalysis, underwent analysis with Oskar Pfister and later with Carl Gustav Jung, and participated actively in the summer courses organized by Pfister in 1912 on the relationship between pedagogy and psychoanalysis; he introduced Sigmund Freud's science into his courses at the Normal School, where Hans Zulliger was his student. Recalled from his post as director in 1916, he taught psychoanalysis to educators at the Institut Jean-Jacques Rousseau in Geneva, then, from 1920 to 1928, taught general psychology, psychopathology, and characterology at the University of Riga (Latvia). He then established himself as a therapist in Stuttgart. On his return to Switzerland in 1946, he taught at the Institut de psychologie appliquée (Institute of applied psychology) in Zürich.

In 1926, together with Heinrich Meng, whom he had met in 1922 at the Berlin Congress (where he also met Freud), he founded the *Zeitschrift für psychoanalytische Pädagogik* (Revue of psychoanalytic pedagogy). He was an active contributor, publishing numerous articles on the relationship between the two sciences and on teacher training.

An independent thinker who was passionate about pedagogy and open to new ideas, Schneider was more a practitioner than a theorist. Still, his institutional activity promoting an educational model informed by Freud's discoveries is worth remembering.

## **SCHREBER, DANIEL PAUL (1842–1911)**

Daniel Paul Schreber, the subject of Freud's famous retrospective case history, was born on July 15, 1842, in Leipzig, and died in April 1911 in the state mental asylum at Leipzig-Dösen.

In 1893 Paul was at the zenith of his legal career, having just been promoted to presiding judge at the Dresden Higher Regional Court, when he suffered a severe mental breakdown. Thereafter he spent about thirteen years of his life in mental institutions, and while at the Sonnenstein Asylum he composed his only book, *Memoirs of My Nervous Illness* (1988), a masterpiece that has since inspired scholars in diverse fields. Freud (1911c [1910]) used the book to illustrate his theory of the causal link between homosexuality and paranoia. This heuristically important essay was an exercise in applied, not clinical, psychoanalysis; it was a hermeneutic, not historical, account of a paradigmatic case of paranoia; it was not about Schreber's life.

Paul's father, the son of Moritz Schreber and Pauline (née Wenck) Schreber, was a physician who specialized in exercise therapy for skeletal and muscular disorders, both with and without appliances. He attained fame with his 1855 book, *Illustrated Medical In-Door Gymnastics*, which may be considered a forerunner of modern rehabilitation medicine. Moritz also published works on child rearing and education and was posthumously immortalized by the eponym "Schrebergarten," or community garden, which he advocated as part of healthful living.

After completing his studies at the well-known Thomasschule (Thomas school), in 1860 Paul began studying law at the University of Leipzig, obtaining his doctorate in jurisprudence in 1869. Two years earlier he entered the ministry of justice and served as judge in a variety of cities in Saxony. In 1878 he wed Otilie Sabine Behr (1857–1912), the daughter of operatic director Heinrich Behr. His family considered the bride unsuitable. A diabetic, Sabine suffered six miscarriages or stillbirths.

Schreber was hospitalized three times with depressive illnesses, all following real and symbolically important losses: in 1884, after he was defeated in elections to the Reichstag; in 1892–1893, after he was made presiding judge and his wife gave birth to a still-born boy; and in 1907, when his mother died and his wife suffered a stroke. He functioned normally after the first (moderate, nonpsychotic) depression, and between the second and third (severe, psychotic) episodes, during which time he raised an adopted daughter.

The second depression (the first psychotic episode) began as a prodrome in the summer of 1893. He experienced anxiety dreams about his illness returning and had a fantasy of what a woman might feel during intercourse. By the fall he had a dramatic explosion of symptoms, including insomnia, agitation, hypochondriacal and nihilistic delusions, and attempts at suicide. He voluntarily returned to the Psychiatric Hospital of Leipzig University, under Paul Flechsig, director of the hospital. Months after admission, his agitated depression evolved into a syndrome that involved prosecutory hallucinations and delusions of sexual abuse and hostile human and divine influences, which Schreber described as soul murder. The human influences he attributed mainly to Flechsig. He also developed elaborate ideas of a fantastic cosmology and religion.

By June 1894, with his wife's consent and collaboration, Schreber was transferred by Flechsig to Sonnenstein. There major depression abated by 1897 but his wishes to be allowed to go home went unheeded. Superintendent Guido Weber (using Emil Kraepelin's taxonomy) diagnosed him with incurable paranoia, and he was declared mentally incompetent, yet his wife remained hesitant. Schreber continued to express rage, and he elaborated fantasies that he was to be transformed into a woman to redeem the world. But he was lucid and able to get along socially. He was also able to write his book and to conduct his own defense

in court, setting a legal precedent and regaining his freedom in 1902.

However paranoia and schizophrenia might be parsed in the history of psychiatry, in psychoanalysis the former came to signify a delusional defense against homosexuality. Freud followed Kraepelin's classification but was more interested in syndromes and character than in psychiatric diagnoses. He developed his dynamic formulation in collaboration with Sándor Ferenczi and in 1908 shared his ideas with Carl Gustav Jung, from whom he learned about Schreber in 1910. Locked into his theory, the universality and validity of which have since been challenged, Freud hypothesized that Schreber had a passive-negative oedipal constellation. He suggested that Schreber experienced through transference a passive sexual desire for Flechsig, transformed into the delusion of soul murder. This conflicted wish, Freud claimed, was pathogenic in Schreber's second illness. It had previously appeared in the prodromal fantasy of what a woman feels during intercourse, a fantasy that occurred before Schreber had any personal dealings with Flechsig. In his delusion of soul murder, Schreber intended the soul murder to indicate that Flechsig betrayed him by banishing him to Sonnenstein.

One should differentiate what may be valid in Freud's dynamic ideas from what remains correct in his interpretation of Schreber. Focusing on Schreber's so-called paranoia, Freud did not seem to consider the possibility of what today would be called a mood disorder; his own "Mourning and Melancholia" would not appear until 1917, after analytic contributions by Karl Abraham and Alphonse Maeder.

Subsequent studies of the Schreber case have brought to light much new material. Zvi Lothane (1992) extended work by William G. Niederland (1974) and Hans Israëls (1989). Schreber's fears of sexual abuse were a result of the psychotic process, not the cause; he suffered from repressed and manifest envy, aggression, and rage. In his illness, his real conflicts and transference relationships were decisive. These included conflicts with his mother (not mentioned by Freud), his relationships with the psychiatrists Flechsig and Weber, his career choice and work as a judge, and conflicts with his wife (which included serious disputes over money). In addition, there was the transfer to Sonnenstein and the incompetency ruling, which doomed his legal career.

On the other hand, Freud did acknowledge that the fantasy of being transformed into a woman, completing the trajectory of the prodromal feminine day-dream, was a self-healing rediscovery of a lost human relatedness. Lothane discovered that Schreber engaged in *nonhomosexual* cross dressing, a vehicle for dealing with heterosexual conflicts by means of diffusion of gender identity arising from identification with woman, mother, and wife.

Although Niederland developed a heuristically fruitful formulation, he departed from Freud significantly by reading Schreber's symptoms as determined not by endogenous wishes but by childhood trauma: paternal sadism alternating with physical seduction. These ideas are unsupported by the extant biographical evidence. For Niederland, Schreber's father was a tyrant who tortured his son with terror-inspiring "machines." In reality, these were rather innocuous appliances. Lothane showed a lack of support for Niederland's inference of such trauma taking place when Paul was three to four years old, or for the idea that the father made use of antimasturbation devices. Israëls first pointed out that the father was unduly demonized. Niederland (1974) suggested that some of Moritz Schreber's ideas were "useful in our effort to unravel a few among the many obscure features of the clinical picture and to make the hitherto incomprehensible aspects of Schreber's delusional system accessible to further investigation" (p. 206). A psychoanalytically informed longitudinal case study supports a reappraisal of the basic facts, premises, diagnoses, and dynamics of Schreber's story. Generally, psychoanalytic method, to be clinically valid, must combine hermeneutics and history.

## SCHULTZ-HENCKE, HARALD JULIUS ALFRED CARL-LUDWIG (1892–1953)

Harald Schultz-Hencke, the German general practitioner, was born in Berlin on August 18, 1892 and died there on May 23, 1953.

His father, Dankmar Carl Sigbert Schultz-Hencke, a physicist and chemist, founded an Institute of Photography (Lette-Verein) in Berlin, where he taught. His mother, Rosalie Adelaïde May Zingler, a graphologist, claimed to be the natural daughter of Edward VII. She died of tuberculosis in 1902. Schultz-Hencke had a sister, Luanna Asträa, a half-sister, Hanna, and a brother, Walter, who was killed during World War I (on May 29, 1915).

In 1911 he began to study: medicine at Fribourg-en-Brigau (doctorate in 1917), philosophy with Heinrich Rickert, Edmund Husserl, and Martin Heidegger, and psychiatry with August Hoche and Ferdinand Kehler. He volunteered as an army physician in 1914 and in 1915 he joined the Freideutsche Jugend, a German youth organization. Having somewhat mediocre health, he set about perfecting his knowledge of biology (studying fish from the Cichlidae family) and philosophy.

Influenced by Siegfried Bernfeld, he “resolved” to shed light on schizophrenia “with the help of Freud.” In 1922 he did his training analysis with Sándor Radó, then trained in the Berlin Psychoanalytic Institute (BPI). In 1927–28 he lectured there and created, with Otto Fenichel, the Clinical Seminar for “young analysts” (Kinderseminar). His critiques of metapsychology and libido theory, as well as his relatively active therapeutic methods, resulted in his being forbidden to teach, and made him an “enemy within” for the German Society.

First married to Frieda von Brixen, who suffered from acute nephritis, he left her and, after her death, married one of his patients, Gerda Bally, a Swiss half-Jew and former wife of analyst Gustav Bally. They

divorced in 1945. Neither union resulted in any children.

In 1934 he was one of the founding members of the Deutsches Allgemeine Ärztliche Gesellschaft für Psychotherapie (General German Society for Psychotherapeutic Medicine) under Matthias H. Göring, and developed “neoanalysis.” In 1942–43, though not a member of the NSDAP (the Nazi party), he was chief medical officer to the army, before being freed from this to do therapeutic work in the Göring Institute, founded in 1936.

On May 4, 1945, he founded the Institute for Psychopathology and Psychotherapy (IPP) with Werner Kemper, and became its director. The Institute practiced “neopsychoanalysis” (*Neopsychoanalyse*), supposed to be an amalgamation of all psychoanalytic schools, which Schultz-Hencke had created in opposition to classic psychoanalysis. On November 7 of the same year he created the Neopsychoanalytische Vereinigung (Neopsychoanalytic Association). The IPP was then transferred to the Zentralinstitut für psychogene Erkrankungen der Versicherungsanstalt Berlin (Berlin Social Security Central Institute for Psychogenic Diseases), which united the social security and retirement authorities under the directorship of Werner Kemper. The Institute for Psychotherapy was then founded on May 9, 1947.

At the sixteenth Congress of the International Psychoanalytic Association (IPA) in August 1949, a controversy broke out, in which Schultz-Hencke found himself in total opposition to Carl Müller-Braunschweig and he refused to resign from the German Psychoanalytic Society (DPG) because he was convinced that he enjoyed the support of the “progressive forces” in the IPA. This resulted in Müller-Braunschweig creating the Deutsche Psychoanalytische Vereinigung (DPV, German Psychoanalytic Association) on June 10, 1950.

Schultz-Hencke’s request for a chair of psychotherapy at the Charity was refused because of opposition from the DPG (September 26, 1949) which, in accordance with a directive from the Berlin court, opposed his appointment because the candidate already had financial revenues both in East Berlin (Charity) and West Berlin (director of the Institute for Psychotherapy). A brilliant and much respected professor, he was extremely disappointed by this lack of international recognition for his neopsychoanalysis. But in the GDR

his psychoanalysis was the only form recognized until the end of the fifties and the DPG remained under the influence of his teachings until the sixties.

His most outstanding works are: *Einführung in die Psychoanalyse* (Introduction to psychoanalysis; 1927), *Schicksal und Neurose* (Fate and neurosis; 1931), *Der gehemmte Mensch* (The inhibited being; 1940), and *Lehrbuch der analytischen Psychotherapie* (Treatise on analytical psychotherapy; 1951).

## SCHUR, MAX (1897–1969)

Austrian physician Dr. Max Schur was born September 26, 1897 in Stanislaw, then in the Austro—Hungarian Empire and today part of the Ukraine. He died in New York on October 12, 1969.

He completed his high school education in Vienna after his family moved there in 1914 to escape the advancing Russian army. After attending medical school at the University of Vienna from 1915 to 1920, he had most of his postgraduate training at the Vienna Poliklinik. He remained there as an associate in internal medicine until he left Vienna in 1938.

His psychoanalytic education was less direct. As a medical student he attended Sigmund Freud’s intro-

ductory lectures, which kindled a lifelong interest in psychoanalysis. He had a personal analysis with Ruth Mack Brunswick from 1924 to 1932 and was accepted into the Vienna Psychoanalytic Society in 1932. It was this combination of psychoanalytic orientation and internal medicine that led to his becoming Freud’s physician in 1929, a position he fulfilled admirably until Freud’s death in 1939. In the “biological study,” *Freud: Living and Dying* (1972), Schur tells the full story of this relationship and traces the theme of death in Freud’s life and writings.

After Freud’s death the Schur family emigrated to the United States. Schur resumed his medical practice and obtained a position at the Bellevue Hospital in New York. While there he analyzed several patients with chronic skin disorders and in 1950 published a series of papers on the psychopathology and psychoanalytic treatment of psychosomatic disorders. In 1953 he became a training and supervising analyst and teacher at the Psychoanalytic Institute at the Downstate Medical Center of the State University of New York, where he was appointed Clinical Professor of Psychiatry. His scholarship and critical skills led to an editorial career that included three terms on the editorial board of *The Journal of the American Psychoanalytic Association*, and positions as editor of *Drives, Affects, Behavior Volume 2* (1965), an anniversary volume dedicated to Marie Bonaparte, and co-editor of *Psychoanalysis—A General Psychology* (1966), a volume to honor Heinz Hartman on his seventieth birthday.

He was a founding member Psychoanalytic Association of New York and was its President in 1967 when the officers and board presented him with a festschrift as the most suitable gift for a man with his love of knowledge and learning. He died before it was published as *The Unconscious Today: Essays in Honor of Max Schur* (1971).

By 1950 he had published more than fifty papers on medical subjects, rarely with psychological emphasis. From then on he published a series of clinically detailed and theoretically reasoned psychoanalytic articles and books. The first group of papers, on symptom formation and the development of affects, explored the implications of structural theory, especially from a genetic and adaptive perspective. “The ego in anxiety,” “The ego and the id in anxiety,” and “Comments on the metapsychology of somatization” were instantly influential and his concepts “somatization,” “desomatization,” and “resomatization” have entered the psychoanalytic lexicon. Studying the development of the instinctual drives, Schur compared

ethological and child developmental concepts, as can be seen in his critical discussion of Bowlby's *Grief and Mourning in Infancy* (1960) and "The Theory of the parent–infant relationship." (1962) His monograph, *The Id and the Regulatory Principles of Psychoanalysis* (1966), argues firmly for a structured id and clarifies the pleasure/unpleasure principle. He felt that the idea of the repetition compulsion as a regulatory principle was superfluous.

Schur was a major contributor among those analysts who in the 1950s and 1960s worked to elaborate, integrate, and systematize the theoretical and clinical implications of the later work of Freud, working to expand the ideas in *Inhibitions, Symptoms and Anxiety*, Anna Freud's *The Ego and the Mechanisms of Defense*, and Heinz Hartmann's *Ego Psychology and the Problem of Adaptation*.

## SCHWEIZERISCHE ÄRZTEGESELLSCHAFT FÜR PSYCHOANALYSE

The Swiss Psychoanalytic Society (SGPsa), consisting of physicians and non-physicians, was created in 1919.

The Swiss Medical Society for Psychoanalysis, or *Schweizerische Ärztgesellschaft für Psychoanalyse*, is the result of a rift that took place within the first society in 1928.

In 1928 Emil Oberholzer and Rudolf Brun founded a medical society for psychoanalysis, which admitted only physicians as full members, non-physicians being considered as no more than "scientific collaborators or collaborators in their specialty." This new society applied to be admitted to the International Psychoanalytic Association (IPA) in 1929. The central committee of the IPA rejected the application in the following terms: "After careful consideration of the question the central committee feels obliged to reject this application because it deems the reasons given in justification of this new foundation to be insufficient. It deeply regrets the fact that the differences that appeared could not be resolved otherwise than through a rift of the old group." The wording is Anna Freud's.

Oberholzer and Brun explained the reasons for the foundation of the new 1928 society in a very long memorandum. The rift was born out of a desire to reorder and was introduced in opposition to "the membership of non-physicians in the Swiss Psychoanalytic Society," but also in rejection of "pseudo-analysts and physicians to whom psychoanalysis is in fact unknown." The difficulties with regard to the non-physician fraction of the old society crystallized around Oskar Pfister. He was reproached with a variety of things: contenting himself with short treatment periods; being essentially preoccupied with symptoms to the detriment of defenses; practicing propaganda; receiving into the society people who claimed to be psychoanalysts when they had in fact been insufficiently trained; being unable to discuss deep theoretical matters; working insufficiently on his own self-analysis; and using religious faith as a therapeutic lever.

This difficulty seems to have existed from the foundation of the SGPsa. The division of the society into two sections, one medical, the other non-medical, had already been suggested in 1926. It was quite probably Freud's 1926 text on lay analysis (1926e) that led to this foundation.

Sigmund Freud, Max Eitingon and Johan H. W. Van Ophuijsen took the side of the old society. In 1936 the Swiss Medical Society for Psychoanalysis renewed its application for membership of the IPA. Philipp Sarasin, as president of the SGPsa, set up a commission,

comprising Pfister, Kielholz, Zulliger, Christoffel, and Blum, which proposed to recognize the members of the medical Society on condition that they request it and that they accept “Freud’s point of view on the question of lay analysis and upon their agreeing to accept the Oxford ruling by non-physicians.” This report seems to have remained unanswered.

In 1938 some members of the medical Society joined the SGPSa individually just as Oberholzer was emigrating to the United States.

## SCIENCE AND PSYCHOANALYSIS

Sigmund Freud defined psychoanalysis as the “science of the unconscious” (*Wissenschaft des Unbewussten*). The use of the German term *Wissenschaft* suggests a particular mode of understanding: *Wissenschaft* is constituted as a system of knowledge organized into a coherent and ordered arrangement of fundamental concepts (doctrine), capable of accounting for empirically observed phenomena (the objects of possible experiments) by means of a method that ensures their intelligibility and verification through controlled reproduction of the experiment. This view of science, which was dominant in the nineteenth century, characterizes a form of rational experimentalism that gradually reduced the meaning of the word “science” to a narrowly defined “phenomeno-technique” (in the coinage of Gaston Bachelard).

Freud’s project to scientifically account for psychic processes appears clearly in 1895 in the introduction to the *Project for a Scientific Psychology*: “In this ‘Project’ the intention is to furnish a psychology that shall be a natural science: that is, to represent psychical processes as quantitatively determinate states of specifi-

able material particles, thus making those processes perspicuous and free from contradiction” (1950c [1895]). At this time he situated his discovery within the field of positivist materialism, where psychic processes are represented by means of the concepts of neurophysiology and the empirical data of clinical research; described, ordered, and reconstructed according to the method of the natural sciences (*Naturwissenschaften*). The construction of a metapsychology, a set of concepts specific to psychoanalysis, would lead Freud to abandon the neurophysiological representations found in the “Project” without renouncing his ideal of science.

Freud’s belief in a “scientific conception of the world,” his fidelity to the positivist ideals of his masters (especially Ernst Brücke) led him, in 1911, to cosign, along with Albert Einstein, David Hilbert, and Ernst Mach, an appeal (*Aufruf*) in favor of the creation of a society to help develop the awareness of positivist philosophy. This belief in the ideals of science can be found throughout his work, up to and including the *Outline of Psychoanalysis* (1940a [1938]), in which he writes: “Whereas the psychology of consciousness never went beyond the broken sequences which were obviously dependent on something else, the other view, which held that the psychical is unconscious in itself, enabled psychology to take its place as a natural science like any other. The processes with which it is concerned are in themselves just as unknowable as those dealt with by other sciences, by chemistry or physics, for example; but it is possible to establish laws which they obey and to follow their mutual relations and interdependences unbroken over long stretches—in short, to arrive at what is described as an ‘understanding’ of the field of natural phenomena in question.”

Freud’s adherence to the ideals of science is tempered by an epistemological relativism remote from a “scientific catechism.” He writes: “It is a mistake to believe that a science consists in nothing but conclusively proved propositions, and it is unjust to demand that it should. It is a demand only made by those who feel a craving for authority in some form and a need to replace the religious catechism by something else, even if it be a scientific one. Science in its catechism has but few apodictic precepts; it consists mainly of statements which it has developed to varying degrees of probability. The capacity to be content with these approximations to certainty and the ability to carry on

constructive work despite the lack of final confirmation are actually a mark of the scientific habit of mind” (1916–17a). In other words, science demands that we renounce beliefs like magic, globalizing visions of the world, and absolute knowledge of metaphysics and religion. The work of the scientist entails the sublimation of epistemophilic sexual drives, which are present in the primal paradigm of the theories and techniques of infantile sexual investigation. Freud raised science to the level of a perfect model of the renunciation of the pleasure principle.

Freud’s need to preserve psychoanalysis from the grip of religion and philosophy did not result in his abandoning it to physicians and scientists. As early as *The Interpretation of Dreams* (1900a) and the *Psychopathology of Everyday Life* (1901b), he took the side of antiquity and popular knowledge against the exclusivity of official science. Throughout his work he manifested this oscillation between art and science, which he discovered that he shared with Leonardo da Vinci. On several occasions he pays homage to the poets and novelists, the true precursors of his own discoveries: “The authors of works of the imagination are valuable colleagues and their knowledge should be held in high esteem, for they have the gift of understanding many things that occur between heaven and earth and of which we have no idea. As for knowledge of the human heart, they exceed us considerably, we humble mortals, for they appeal to sources that are not yet accessible to science” (1908e [1907]).

Freud recognized the role of the imagination in scientific work. This element of fiction within any theory leads him to speak of a “mythology of drives” and the metapsychological “sorcerer.” He identifies a dream element at work in science itself and shows, especially in *Delusions and Dreams in Jensen’s “Gratidiva”* (1907a [1906]), the overdetermination inherent in scientific discourse: science, as a whole, can be used for fantasy. Science, with its origins in dream and fantasy, can withdraw only temporarily behind respect for its methodological protocols and critical rationalism. Psychoanalysis can only maintain its scientificity through the implementation of a method within a given form of practice. This epistemological option appears constant over the development of Freudian thought: “What characterizes psychoanalysis, as a science, is less the material on which it works, than the technique of which it makes use” (1916–1917a).

The ideal of Freudian epistemology has gradually given way to the ideal of analysis, which has sometimes been referred to as an ethic. The scientific ideology to which Freud clung has shown itself to be dated, and has been rejected by modern epistemology. Freud’s initial belief in the positivist demands of science has been beneficial: It has situated the specificity of psychoanalysis within a method capable of elevating resistance and transference, along with their analysis, to the rank of operators of knowledge of the unconscious. Freud refused to construct and describe a particular structure in which concepts, as well as objects, would remain inseparable from a method. But his positivist and realist prejudices sometimes prevented him from recognizing that the psychoanalytic system created its objects as it discovered them.

With Freud, psychoanalysis, by recognizing its debt to poets and scholars, continued to enjoy the prerogatives of one and the privileges of the other, and vice versa, inscribing its praxeological specificity within the interstices of the traditional loci of knowledge. Having done so, and notwithstanding the classical and modern culture of its founder, it participates indirectly in the decompartmentalization of discourse characteristic of postmodernity.

## SCILICET

The first issue of the review *Scilicet*, under the direction of Jacques Lacan, appeared in May, 1968 from Seuil, the same publisher that two years earlier had brought out his *Ecrits*. Just seven issues would appear in all, counting two double numbers (2/3 and 6/7), over the next eight years.

The Latin adverbial *Scilicet* (scire licet) means “it goes without saying”; Lacan translated it, as he stated in the first issue of the review, as: “You are permitted to know.”

Beginning with the observation that he had “failed in a teaching project over the course of a dozen years which addressed only analysts,” Lacan added that during four years of teaching at the Ecole Normale Supérieure he had taken an interest in notions of formal mathematics. He wrote, “This review is one of the ways by which I expect success in my school, which operates differently from the so-called Societies, over resistance I encountered elsewhere”

Thus, *Scilicet* was not addressed to analysts but to novices. That was why, punning on the English word *bachelor*, he stated, “I’ve decided to call you *bachelier*, to remind you of your place in this empire of pedantry, now so prevalent that actually entering this world will guarantee you nothing except a cultural sewer.” This comment may be viewed as a harbinger of the revolutionary period of May, 1968.

Texts published in *Scilicet* were to be unsigned, “at least by anybody who would publish as a psychoanalyst.” The no-signature rule appeared to Lacan as “a radical solution... the right one to disentangle the

contortions by which in psychoanalysis experience is forced to reject anything that might change it.”

The decision to publish *Scilicet* was announced in the “Proposition of October 9, 1967...” that introduced the idea of the *passe*, a test that Lacan designed to evaluate students as they advanced from being analysands to becoming analysts. He also made reference to “Nicolas Bourbaki,” the pen name that an influential group of French mathematicians lent to their collective work beginning in the 1930s. “Let us be clear,” Lacan added: “*Scilicet* excludes no one, but that who ever does not appear in it will not be recognized as one of my students.”

Although Lacan listed the names of analysts who wrote for the journal in the next issue (2/3), anonymity for individual articles was maintained. Lacan published a number of interventions in *Scilicet*; these would later be republished in *Autres Ecrits* (2001). Around the same time, another review, *L’Ordinaire du psychanalyste*, also appeared, also with anonymous contributions, under the direction of Francis Hofstein and Radmila Zygouris. Although inspired by Lacan, these analysts had no allegiance to him and their review was a forum in which they could freely discuss clinical matters, providing a counterweight to *Scilicet* that proved a great critical success.

After *Scilicet* ceased publication in 1976 due to Lacan’s loss of interest, it was followed by the first issue of *Ornicar?* in which Lacan published “Peut-être à Vincennes...” Here he reaffirmed his aspirations for the department of psychoanalysis at the University of Vincennes and reiterated his confidence in Jacques-Alain Miller: “Hopefully, the curriculum at Vincennes will include teachings that Freud considered fundamental, enabling the analyst to confirm the findings of his personal analysis, to understand not so much the ends it served as the knowledge of which it made use.” By this time, Lacan seemed to be counting on the school to advance the foundations he laid down. He had furthered efforts to bring to bear mathematically-inspired formulas on psychoanalysis, with a lecture by Jean-Toussaint Desanti, “Reflections on the Concept of Mathesis,” which he introduced at a conference at Sainte Anne on “Psychoanalytic Knowledge,” on December 2, 1971.

## SCOPTOPHILIA/SCOPOPHILIA

The term *scoptophilia*, subsequently replaced by *scopophilia*, took its place in Anglophone psychoanalytic literature as a translation of the Freudian notion of *Schaulust*, “pleasure in looking,” in the sense of both seeing and being seen, as well as “curiosity.” Freud distinguished between two frequently encountered forms of this partial drive: one active, “voyeurism,” and the other passive, “exhibitionism,” neither of which he would necessarily rank among perversions (1910a [1909]).

As early as 1936, Ernest Jones wrote a critique of Howard C. Warren’s *Dictionary of Psychology* in which he noted that the *Glossary of Psychoanalytical Terms*, which Jones edited in 1924 in preparation for the planned Standard Edition, contained “an important mistake . . . , one which has been widely copied in psycho-analytical literature, namely, the incorrect term *scoptophilia*, which should be *scopophilia*” (p. 247). In 1963, James Strachey gave a more detailed explanation: “I must admit that the Glossary Committee disgraced itself lamentably over at least one word. The question was how to translate ‘*Schaulust*’—the pleasure in looking. Greek terminology was all the rage, and the word ‘*scoptophilia*’ was suggested and accepted with acclamation. It certainly looked a little odd; but nevertheless it passed into all the four volumes of the *Collected Papers* uncriticized. You might have imagined that we should have remembered telescopes and microscopes and so have suspected that the Greek root for looking was something like ‘scop.’ Actually there is a Greek root ‘scopt,’ but what it means is ‘to make fun of.’ And so to this day you may still come upon references to the component sexual instinct of pleasure in derision” (p. 229).

In fact, just as Bruno Bettelheim wrote in *Freud and Man’s Soul*, both terms are wrong and “the monstrosity contrived by Freud’s translators and perpetuated in the *Standard Edition*—“*scopophilia*”—certainly conveys nothing at all” (p. 91). He comments moreover that this seems a betrayal of Freudian thought: “It would admittedly be difficult to find a single English word to express what Freud had in mind with *Schaulust*—a term that combines the German word for lust,

or sexual desire, with that for looking, seeing, or contemplating—but a phrase on the order of ‘the sexual pleasure in looking’ would make his meaning clear; or since ‘lust’ is the near equivalent of the German *Lust* and has the further advantage that it can be used both as a noun and as a verb, it might be preferable to ‘sexual pleasure.’ In either case, the reader would know immediately what is meant. Since we have all repeatedly experienced great pleasure in watching something, in taking it in with our eyes, and have occasionally been ashamed of doing so, or even been afraid to look, although we wished to see, it would be easy to have both a direct intellectual and emotional understanding of Freud’s concept” (p. 90–91).

Several hundred articles by the most illustrious names in psychoanalysis nevertheless testify to the persistence of the use of these two suspect terms up to the present day—a particularly striking example of the absurd errors that can be passed on from text to text.

## SCOTOMIZATION

The term *scotomization*, borrowed from ocular pathology, where *scotoma* refers to a spot in the visual field in which vision is deficient or absent, came into use by young psychiatrists in the 1920s to refer to a lack of awareness of others. René Laforgue, who refers to this origin for the term, proposed the notion in the context of his thinking on schizophrenics and “schizonoia” at the time of his earliest work in psychoanalysis. He believed it would account for his patients’

misapprehension of reality, and explained in a letter of June 10, 1925, to Sigmund Freud that “scotomization corresponds to the wish that is infantile, and therefore not repressed, not to acknowledge the external world but to put the ego itself into its place. In these conditions, the process of repression seemingly has not overcome the primitive stages in the normal way, but, on the contrary, has allowed them to persist.”

Freud was puzzled and rather opposed to this innovation, which seemed to him a bit too “French” in its tendency toward simplification. In a letter to Laforgue dated May 1925, he argued: “A very important point seems to me that in repression (*Verdrängung*) you distinguish a scotomization. I do not believe there are any grounds for this. We have stated that repression means that an instinct is suppressed and that the fact of being conscious is withdrawn from its ideational representation. Why split this unitary process in two? As for the other differences you establish between repression and scotomization, I do not understand them.” He nevertheless accepted Laforgue’s presentation of the notion in the article “*Verdrängung und Skotomisation*” (Repression and scotomization), which appeared in 1926 in the *Internationale Zeitschrift für Psychoanalyse*.

However, he criticized it in a letter of February 18, 1926: “I read your article in German on scotomization from start to finish. I now understand why this concept and its relationship to repression pose such difficulties for me. I note that on one point you have abandoned me. You do not accept the metapsychological view that tries to characterize a psychical event in terms of its dynamic, topographical, and economic aspects—in terms of three coordinates, so to speak. It is especially by disregarding the topographical coordinate that you give up a sort of certainty, whereas it makes itself felt in the whole. You are not concerned with what happens in the three layers of the conscious, preconscious, and unconscious, and phenomena are therefore ambiguous. No doubt you have not dared to present to your compatriots this element of complication and speculation.”

Freud returned to the topic in “Inhibitions, Symptoms and Anxiety” (1926d), citing Laforgue’s notion as an example of the hysterical mechanism “which, by means of restrictions of the ego, causes situations to be avoided that would entail such perceptions, or, if they do occur, manages to withdraw the subject’s attention from them”. But his reflections on lack of awareness

continued in the article “Fetishism,” where he wrote: “If we wish to separate in it [repression] more clearly the vicissitude of the representation from that of the affect and reserve the expression ‘repression’ for the affect, for the vicissitude of the representation it would be correct to say in German *Verleugnung* (disavowal). The term ‘scotomization’ seems to me to be particularly improper, for it evokes the idea that perception has been completely swept away, as in the case where a visual impression strikes the blind spot of the retina. On the contrary, the situation which we are describing shows that perception remains and that a very energetic action has been undertaken to maintain its denial.”

Laforgue attempted a further refinement the following year in “*Überlegungen zum Begriff der Verdrängung*” (Considerations on the notion of repression), but the notion of scotomization did not withstand Freud’s commentaries for long, even in France, where Édouard Pichon had been extremely receptive to it.

If this notion is no longer used today, we can imagine that the discussions to which it gave rise, before the war, and Freud’s refusal to believe that a perception could be purely and simply suppressed, without conflict or any permanent psychic modifications, such as a splitting of the ego (1938), were no doubt not unrelated to what Jacques Lacan based on his translation of *Verwerfung* called “foreclosure.”

## SCREEN MEMORY

A screen memory (like forgetting and amnesia) is a compromise between repressed elements and defense against them. A paradoxical feature of recollections of this kind is they are less childhood memories than memories about childhood, characterized typically by their singular clarity and the apparent insignificance of their content. Important facts are not retained; instead, their psychic significance is displaced onto closely associated but less important details. Displacement is indeed the main mechanism here, as it is in the case of mnemonic symbols or in the forgetting of a proper name, although to some degree condensation may also be present.

The notion of screen memories was first presented by Freud in his paper so named (1899a), an extension of his work on mnemonic symbols and the recollection of trauma in hysteria, a paper written as he was beginning to develop the idea of unconscious fantasy. Later, he concluded that such memories, so long as one knew how to interpret them, supplied the best available source of knowledge about the “forgotten” childhood years (1914g, p. 148). Any memory could be a screen memory inasmuch as one aspect of it screened out something unacceptable to the ego.

In the “Project for a Scientific Psychology” (1950c [1895]), Freud told of Emma, who attributed her phobia to an insignificant scene recalled from adolescence while repressing a more important childhood event. The scene from adolescence, described by Freud as *pseudos*, was in effect a screen memory serving to negate the unacceptable fact of the traumatic seduction of a child by an adult, the memory of which was transformed into age-appropriate amorous feelings of adolescence (pp. 352–54). Freud clarified his notion of the defensive and idealizing falsification of memories in his account of the “Rat Man” case, where he noted “that people’s ‘childhood memories’ are only consolidated at a later period, usually at the age of puberty, and that this involves a complicated process of remodeling, analogous in every way to the process by which a nation constructs legends about its early history. It at once becomes evident that in his phantasies about his infancy the individual as he grows up “endeavours to efface the recollection of his auto-erotic activities” (1909d, p. 206n). The adolescent’s memories concerning his or her childhood thus sought to negate an infantile sexuality incapable of oedipal victory and

replaced it with more heroic ideas by means of a process that Freud compared to the creation of legends and myths.

In “Remembering, Repeating and Working-Through” (1914g), Freud compared screen memories and dreams, observing that their common trait of visual representability enabled them to contain mnemonic traces, albeit in the form of “dream-thoughts.” He added that the analysis of dreams and screen memories facilitated access to the reality of the direct experience of the past just as effectively as the analysis of simple memories: screen memories, he wrote, retained “all of what is essential. . . . They represent the forgotten years of childhood as adequately as the manifest content of a dream represents the dream-thoughts” (p. 148). Could screen memories conceivably be considered a more faithful representation than memories per se? A note added in 1920 to the *Three Essays on the Theory of Sexuality* drew an analogy between screen memories and the fetish which conceals female castration (1905d, p. 154n); and in *Leonardo da Vinci and a Memory of his Childhood*, memory covers up a fantasy of the mother with a penis (1910c, p. 98). This fetishistic aspect of screen memories, as likewise of sensorily intense mnemonic symbols and images, clearly foreshadows Freud’s later view of fetishism.

The key reference here nevertheless remains “Screen Memories” (1899a). In this paper Freud evoked one of his own memories of childhood (though he ascribed it to someone else), in which he saw himself playing with other children in a very green meadow across which vivid yellow flowers were sprinkled; analysis led to a later memory, from adolescence, in which he was in love with a girl in a yellow dress. Thus the childhood memory was in this case screening off a later sexual wish: “there was *no* childhood memory, but only a phantasy put back into childhood” (p. 315). The displacement was flagged by the intensity of sensory representability (a gauge of the persistence of the wish). Sensory representability was not always primary, however: figurative elements could sometimes reflect wishful verbal connections, as, in the present context, when the delicious taste of bread in memory could be interpreted as reflecting the adolescent wish to “earn one’s bread” like an adult.

As early as 1899, then, Freud suspected that any memory that presented itself to consciousness with great intensity might be a screen, so creating a theory of memory as a realm deeply affected by elements of

fantasy: “There is in general no guarantee of the data produced by our memory” (p. 315). Without such a guarantee, psychoanalytical interpretation would place its hopes in the study of repetition (1914g) or on the evidence from analytic constructions (1937d).

Inasmuch as screen memories cover up that which is unacceptable to the ego, they may be considered essentially defensive in nature. Their illusory aspect tends to infect all remembering, which thus may always be suspected of having a screen function. The notion tends to subvert the idea of historical reality, for it prompts the question whether such a reality is the outcome of creative interpretation or of genuine access to mnemonic traces. In analyzing his own screen memories, therefore, Freud developed an idea that implied a new epistemology of time and of the complexity of reality: “as though a memory-trace from childhood had here been translated back... at a later date” (p. 321). “The recognition of this fact must diminish the distinction we have drawn between screen memories and other memories derived from our childhood” (p. 322).

## **SECHEHAYE, MARGUERITE (1887–1964)**

Swiss psychologist Marguerite Secheyaye was born on September 27, 1887, and died in Geneva on June 1, 1964.

The child of an authoritarian mother and an egalitarian father, Marguerite Burdet received a Protestant education, attended a secondary school for girls, and graduated with a diploma in literature and pedagogy. While at the university, she attended Ferdinand de Saussure’s lectures on linguistics and, thanks in part to her notes from that course, Charles Bally and Albert Secheyaye, her husband, established the famous Course in General Linguistics. She also studied psychology and professional orientation at the Institut Jean-Jacques Rousseau, which was directed by psychologist Édouard Claparède. After graduation, she became Claparède’s assistant and opened a private practice as a psychologist.

Psychoanalyst Raymond de Saussure was friends with Marguerite and Albert Secheyaye and, according to their adoptive daughter, Louisa Secheyaye-Duess, “Saussure once asked Marguerite why she would not undergo psychoanalysis. She refused on the pretext that psychoanalysis was too concerned with sexuality and that her religion forbade it. When Saussure replied that she ought not judge a method without having experienced it, Secheyaye quickly admitted as much and the next day began a training analysis with Saussure. According to her own emotional reactions at the time, she seems not to have considered it a serious analysis. This was during 1927–28. Soon thereafter, Saussure advised her to take on cases of her own, to analyze them first under control, then he let her practice on her own.”

A group of analysts used to meet, during the 1930s, at the homes of Saussure and the Secheyayes, including Charles Odier, Henri Flournoy, Gustave Richard, and Georges Dubal. This gathering represented the first circle of analysts in Geneva after those of Charles Baudouin and Sabina Spielrein, who had analyzed Jean Piaget. Louisa Secheyaye-Duess wrote that Secheyaye “had a special influence among this group, gained by daring to show her ignorance while proposing very modern ideas. Everybody admired her mind and her beauty, knowledge, and modesty.”

Marguerite Secheyaye was an attentive reader of Freud and Piaget. Analytic practice with schizophrenic patients led her to develop an original method of psychotherapy. When Freud learned of her research, he wrote her an encouraging note, but also informed her of his doubts. The method she called “symbolic realization” would become her tool in psychotherapy with schizophrenics. In 1950, she published her major

work, *Autobiography of a Schizophrenic Girl*, in which she demonstrated, directly and indirectly, the essentials of her method applied to her patient Renée, whom she would eventually adopt and who would later become a psychoanalyst. Marguerite Sechehaye agreed with Melanie Klein on many issues. For both, the quality of mothering was essential. They corresponded on the decisive importance of the earliest stages of psychic development. Sechehaye had also frequent contacts with renowned analysts such as Marie Bonaparte, René Spitz, Anna Freud, and Donald W. Winnicott.

In 1951–52, at Zurich University, assisted by her daughter, she gave a series of lectures to the physicians of the Burghölzli Psychiatric Clinic. She examined several schizophrenic patients in the presence of the house physicians and taught them the steps of her psychotherapeutic method. Sechehaye also published articles and refined her concept of symbolic realization. In 1962, psychiatrists in Milan honored her with a gold medal. On January 1, 1964, several months before her death, Christian Müller honored Sechehaye with a stirring homage before the Swiss Psychoanalytic Society, noting her influence upon young Swiss psychiatrists and psychoanalysts.

## **SECOND WORLD WAR: THE EFFECT ON THE DEVELOPMENT OF PSYCHOANALYSIS**

The Second World War, like the First and in spite of the upheavals it caused in the psychoanalytic movement, was the origin of the international expansion of psychoanalytic theories and practices. Three principal factors were involved: The Nazi persecutions, by forcing Jewish psychoanalysts to emigrate and by elimi-

nating all references to Freud in occupied Europe, shifted the international core of the movement to America. Freud's death in the first weeks of the world conflict made all psychoanalysts responsible for what would or would not be considered "psychoanalytic," leading to the gradual evolution from an autocratic to a democratic structure within the movement. The Allied victory in 1945, by spreading American culture abroad, promoted interest in liberated Europe in a certain conception of psychoanalysis, understood as a liberalization of behavior and a new understanding of the individual in a "free" Western world, essentially opposed to Soviet totalitarianism.

Anna Freud and Ernest Jones made a determined effort to organize the emigration of Jewish analysts from Europe to countries willing to receive them (Steiner). Once Hitler came to power in Germany in 1933, persecutions against Jews forced many of them to leave professional organizations, emigrate from Germany and leave the famed Psychoanalytic Institute in the hands of Matthias Göring. The "German Institute of Psychological Research and Psychotherapy" attempted to eradicate psychoanalytic theory and practice, and the majority of therapists who remained in Germany compromised themselves during the twelve years the Nazi regime was in existence, although a few of them resisted. John Rittmeister attempted to, and was guillotined in 1943. Karl Landauer died in the Theresienstadt camp, Salomea Kempner in the Warsaw ghetto. In Austria the situation was similar after the *Anschluss*, when analysts were forced to emigrate. Freud and several family members and friends left Austria in 1938. In Italy Mussolini's fascists had, less brutally but just as efficiently, muzzled publishing and destroyed psychotherapy and helped to eradicate support for Freud in Europe, where psychoanalysis had come into being and flourished. There were a number of Hungarian analysts, for example, who had to flee to South America or Australia, where they became active proponents of Freudian theories.

In France, where several psychoanalysts like René Spitz and Heinz Hartmann had gone before the war and where Rudolf Loewenstein and Marie Bonaparte had emigrated after closing their institute and discontinuing the *Revue française de psychanalyse*, some psychoanalysts continued to practice, although discreetly. Only René Laforgue, originally from Alsace, tried to collaborate with the Göring Institute, an attempt that was ultimately unsuccessful. Sacha Nacht joined the

Resistance movement and Paul Schiff joined the Free French forces with whom he fought until the Allied victory.

But it was among the Allies that psychoanalysis found the greatest support, and it was in Allied countries that it flourished to an unprecedented degree. In Great Britain the controversy between Melanie Klein and Anna Freud gave the British Psychoanalytic Society the tripartite structure it subsequently retained. Just as important were the contributions by psychoanalysts to the war effort through selection and psychological care of English soldiers. John Rickman and Wilfred Bion, among others, developed techniques that were the origin of group therapy practices such as the application of psychoanalytic practices to social problems.

In America the influx of refugees disturbed the equilibrium of the American Psychoanalytic Society (APSA), the number of members rising from ninety-two in 1932 to one hundred ninety-two in 1940 and to two hundred forty-seven in 1945. Obviously there were conflicts. In 1941 Karen Horney left the New York Psychoanalytic Society to found, with Harry Stack Sullivan and Clara Thompson, the Association for the Advancement of Psychoanalysis. The European analysts and their students took the reins of the APA and continued the discussions and quarrels that had characterized their behavior prior to emigrating. Some, like Otto Fenichel, who had been politically militant in the past, had to keep their opinions to themselves and adapt to an "American way of life," of which, with the passage of generations, they became the most ardent defenders. We know that the APSA's requirement of a medical degree led to the exclusion of many highly capable analysts, like Theodor Reik, from traditional psychoanalytic organizations; others, like Géza Róheim, were not allowed to teach.

The International Psychoanalytic Association was in turn "Americanized," with Freud's prestigious students taking an increasingly greater part in its management. Their responsibilities also grew through the global expansion of psychoanalysis that emigration had caused and which accentuated the popular vogue for Freudian ideas in the United States. The 1945 Allied victory put an end to the dominance of German as the language of psychoanalysis, and English became the principle vehicle for Freudian theories. This was secured by the publication, between 1953 and 1974, of

the twenty-four volumes of the *Standard Edition of the Works of Sigmund Freud*.

The Cold War, and the time it took for traditional European psychoanalytic organizations to resume their activities in countries not subject to Soviet control, resulted in the unchallenged dominance of Anglo-American ideas for nearly fifty years in both international politics and psychoanalysis.

### **SECONDARY REVISION**

Secondary revision first appears in *The Interpretation of Dreams* (Freud, 1900), at the end of the section in Chapter 6 describing the mechanisms of the dream work.

Viewed strictly with respect to dreams, secondary revision is a rearrangement of the seemingly incoherent elements of the dream into a form serviceable for narration. This involves logical and temporal reorganization in obedience to the principles of noncontradiction, temporal sequence, and causality which characterize the secondary processes of conscious thought. Above all, it is instrumental dream censorship and may produce omissions or additions.

But this process, Freud goes on to explain, is also at work in daydreams, which organize remembered materials by “threading them onto the string of desire, between past, present, and future.” Furthermore, dreams may rework such fantasies, since they are just nearby in the Preconscious. Secondary revision may also be found in the symptoms of various afflictions, neurotic or otherwise, involving rationalization, the most extreme instances of which may be seen in obsessional neurosis.

Secondary revision is a concept that has been studied relatively little since Freud (except for rationalization in obsessional neurosis), because analysts have preferred to explore the mechanisms of condensation, displacement, and symbolic representation. However, there is no shortage of promising avenues of research in this realm.

First of all, we might consider its most important modes of operation: the act of putting into words, the translation of dream images into verbal images, and the transformation into narrative structure. This is somewhat akin to the rhetorical modes that effect the translation of visual images into figures of speech or style and, inversely, produce images in the mind of the listener. The difference is that the rhetoric of secondary revision serves the ends of censorship more than those of the drives and the primary processes of the unconscious (Duparc, 1995).

Secondary revision seems to be more or less constituted of ready-made, second-hand rhetorical figures that are already stored in a dictionary of such images without occasioning the emergence of much in the way of the affect or desire of the person using them, in contrast to the novel and creative images produced by the representation of unconscious wish. The images in secondary revision are like the prefabricated fantasies that the dream disposes of like the day’s residues. They might also be compared to symbols, impersonal or collective materials described by Freud as the remains of ancient linguistic identities and cultural artifacts that work against the emergence of the dreamer’s individual unconscious.

For some, the construction of the dream’s narrative is one of its most important aspects, perhaps even its driving force. Dreams are always meant to be told, even if only to oneself, and it is the moment of awakening itself, accompanied by the waning of the paradoxical sleep observed by neurobiologists, that triggers

the transformation of reactualized remembered material into instinctual manifestations and finally into an organized narrative (Dejours, 1986). Moreover, dreams that have undergone secondary revision are, as Freud puts it in *The Interpretation of Dreams*, “dreams which might be said to have been already interpreted once, before being submitted to waking interpretation” (p. 490). This aspect might lead us to reflect upon the deferred effect of intellectual revision which analytic treatment aims for and which assumes, insofar as secondary revision is concerned, the somewhat dubious form of constructions involving a significant temporal element.

As for pathology, the predominance of secondary revision over the other mechanisms of representation in dreams and language produces a hypermanifest discourse, in contrast to living discourse that is capable of breathing and resonating with the various levels of representation and figuration (rhythms of speech, mobile shapes, visual images, living rhetorical figures, and contemporary fantasies tied into a network of primal fantasies).

This discourse is composed of what could be called “manifest mechanisms,” as opposed to representations with multiple meanings that allow for glimpses of latent thought and the return of the repressed. These mechanisms are a caricature of the mechanisms of dream representation: incessant displacement leading to acceleration, a manic flight by thinking, flooding-dreams (manic defense); massive metaphorization that produces uninterpretable symbolic dreams (for example symbolic equations in the dreams of paranoid patients), major ellipses, or traumatic repetitions in the operative thought of certain psychosomatic patients.

## SECRET

A secret is a form of hidden knowledge. The word is etymologically related to excrement and seduction. Secret and excrement are both derived from the Latin verb *cernere* (*crevi*, *cretum*) which means: 1) to sift, to separate, to sort; 2) to discern or distinguish an object from a distance. The prefix “ex” relates to the idea of evacuation by sifting (excrement), the prefix “se” to the idea of separation, setting aside, and preserving (secretion, secret).

The secret has a positive, necessary side and a negative, destructive side. Freud referred to it periodically throughout his work, but gave it a central place that anticipated his later research in “The Uncanny” (1919h). In 1892 the term appeared in his writings with an anal connotation whenever it brought to mind “foul words, those secrets we all know, knowledge of which we force ourselves to hide from others” (“A Case of Successful Treatment by Hypnotism” (1892-93a)). The secret was then associated with unhealthy obsessions in the neuro-psychoses of defense (1894a). In 1900, in *The Interpretation of Dreams* (1900a), Freud interpreted dreams of exhibitionism as a desire to “keep a secret.”

In his discussion of Dora’s secret, masturbation, Freud wrote, “He who has eyes to see and ears to hear knows that mortals cannot keep any secret” (1905e [1901]). In 1906, in “Psycho-Analysis and the Establishment of Facts in Legal Proceedings,” (1906c), Freud distinguished the criminal’s conscious secret from the unconscious secret of the hysteric. In “Infantile Sexual Theories” (1908c), he demonstrated the importance of the parents’ lying and secrecy regarding the question of the child’s origins, which allows the infant to access the secret in turn. “Children, once they have been deceived (the stork theory) . . . begin to suspect that there is something hidden that grownups keep for themselves and for this reason they surround their later research in secrecy.” The parents’ secret is an enigmatic message triggering the birth of thinking in the infant.

In 1919, in his article “The Uncanny” (1919h), Freud gave considerable space to secrets and their transmission. He discussed the various meanings of the secret and its connections with the familiar, meetings, love affairs, sin, intimate organs, commodes, and *oubliettes*. He also quotes Friedrich Schelling, who writes: “We call *unheimlich* anything that must remain secret and which becomes manifest.’ *Heimlich* also designates a ‘place without a ghost.’” Freud goes on to study the theme of the double, and its analysis strangely anticipates the ideas of Nicolas Abraham and Maria Torok on the phantom, the crypt, and the intrapsychic cave, and all the later work on the transmission of the secret across generations: “Doubling of the ego, splitting of the ego, substitution of the ego—the constant return of the similar, repetition of the same traits, characteristics, criminal acts, even the same names in several successive generations.”

Abraham and Torok make an analogy between the work of the phantom and the work of the death drive, both working in silence without being mediated in words. In their article, “De la topic réalitaire: Notations sur une métapsychologie du secret,” they define the phantom as “a formation of the unconscious that is unique in never having been conscious. It is a result of the transition, whose method remains to be determined, from the parents’ unconscious to the child’s unconscious.” They add that the phantom is the “work in the unconscious of another’s inadmissible secret.” The phantoms that haunt the living are “the holes left in us by the secrets of others.” For these authors the phantom is associated with a preservative repression that fixes, immobilizes, and “the present past forms a block of buried reality, incapable of coming back to life without crumbling into dust.”

After 1970 research on the role of the secret and non-symbolization in alienating transgenerational transmission increased. Clinical work increasingly helped illuminate concepts such as non-transmission, the transmission of the inert (with Micheline Enriquez and the heritage of psychosis), the leaping of generations and alienating unconscious identification (Alain de Mijolla, Haydée Faimberg), and failed blocked mourning (Jean Cournut). Incorporation, encryption, psychic fossilization, and unfulfilled mourning are reflections of the work of the negative that is active in the transmission of secrets across several generations. The work of Daniel Stern on affective tuning may, perhaps, serve as an explanatory link to account for this

intergenerational psychic transmission, which continues to remain enigmatic.

Systemic family therapy is also relevant to secrets and their relation to family myths. The oedipal myth is already a history of a family secret. In families it is guilt that creates secrets and all the pathogenic rules that follow from them. Many American family therapists have shown that family secrets (divorce, suicide, madness, incest) can mask an implicit narcissistic wound, a devaluation of self image and family image leading to abnormal behavior in a descendant.

We must not forget that our psychic life can only develop against a background that remains silent, secret—the secret Self of which Winnicott speaks. And along with negative and positive secrets, living transmissions exist alongside deadly transmissions of the secret.

## **SECRET COMMITTEE**

The “Secret Committee” was the name given by Freud to the intimate circle of his closest collaborators. Its members were Karl Abraham, Sándor Ferenczi, Otto Rank, Ernest Jones, Max Eitingon, and Hanns Sachs.

Hanns Sachs revealed its existence for the first time in 1944 in *Freud, Master and Friend*. Since Sachs was himself a member of this mysterious group, which had a profound effect on the construction and extension of the “psychoanalytic movement,” his memoirs must be taken with a grain of salt, especially when it concerns the image of his “hero Freud.” Nonetheless, the information is invaluable for understanding the significance of this group for the psychoanalytic movement and the institutionalization of psychoanalysis.

The “psychoanalytic movement” achieved its organizational goals through the drafting of its first by-laws in 1910 by Freud and Ferenczi. What appears to be an alternate process of institutional development was initiated in 1912 with the formation of the secret committee. The creation of an informal organization within the organization was the result of tension between Sigmund Freud and his Swiss “dauphin” Carl Gustav Jung. Between 1910 and 1912 Jung had begun to distance himself from Freud, not only in terms of theory and clinical practice, but also in terms of their personal relationship (Schröter, Michael, 1995).

The history of the secret committee took place in three phases: from 1912 to 1920, from 1920 to 1927, then from 1927 to 1936 (Wittenberger, Gerhard, 1995). Details about the committee’s first period—from its creation during the summer of 1912 until the Hague congress in 1920—are provided in five *Komiteebriefe* (committee letters), which do not yet present all the characteristics of the *Rundbriefe* (circular letters). These letters illustrate how, at this time, members of the committee discussed and jointly worked out the policies of the International Psychoanalytic Association (Wittenberger, 1996). The second phase covers the actual history of the institution. From this time, September 20, 1920, until March 14, 1926, there is an extensive correspondence of 361 circular letters.

The significance Freud gave to the creation of the secret committee and the importance of each of its members in the struggle for “the thing” (die Sache) held in common, is reflected in the symbol of the ring bearing a Greek inscription, which he offered to each of his colleagues as a sign of recognition and esteem. Those who were so honored wore the ring as a mark of their intimacy. The uncertainty about when the exchange of circular letters ended is an indication that the secret committee had been disbanded. This was the result of the dynamic of the group as well as the

relational dynamic between Otto Rank and Sigmund Freud and between Rank and his rival colleagues.

There is a break in the circular letters (April 1924 to November 1926) corresponding to the period between the gradual cessation of letter writing among the members, following Rank's break with Freud and his colleagues and ultimately from psychoanalysis, and the official renewal of correspondence. At the same time there was an increased exchange of private letters among the members of the secret committee and Freud, which had been noted by Ferenczi in a letter to Freud in March 1924. Because of the important role played by Rank during the peak years of the "international psychoanalytic movement" (Lieberman, E. James, 1985), his departure (end 1924–beginning 1925) and Abraham's death (December 1925), together with Freud's cancer (1923) all contributed to the destabilization and final breakup of the committee. It was only after the appearance of a circular letter, dated November 23, 1926, written by Anna Freud under her father's dictation, that a new agreement was reached to reintroduce the circular letters.

This initiated the third period of the former secret committee, which now functioned as the "central governing body of the International Psychoanalytic Association." Jones relates how "After the Innsbruck Congress (1927), we modified the structure of the committee by establishing our private group at the head of the International Psychoanalytic Association. Eitingon was named president, Ferenczi and myself, vice presidents, Anna Freud secretary, and van Ophuijsen treasurer" (1957). Hanns Sachs left the committee. The governing body resumed writing the circular letters. The eighty-three letters whose existence we are currently aware of provide a glimpse of the problems facing those who were forced to emigrate during the rise to power of National Socialism.

## **SECRETS OF A SOUL**

A silent film about the talking cure which tells the story of the outbreak, psychoanalytic treatment, and cure of a knife phobia in a man, who has been living for some years in a happy but childless marriage. A murder next door and the return of his wife's cousin from abroad release in him a desire to murder his wife, which he does in a nightmare, but which a sudden inability to touch knives of any kind prevents him from carrying out in reality. Distressed to the point of suicide, he flees to his mother's house where he remembers a psychoanalyst, who had previously recognized his state of mind, and whose help he now seeks. During months of treatment, telescoped into three sessions of intense dream interpretation, the analyst takes the analysis through the presenting problem back to the original childhood trauma and forward into health via a cathartic abreaction as unconscious processes are made conscious.

Originally conceived as an educational film (Lehrfilm) with a booklet explaining the basic tenets of psychoanalysis in simple yet scientifically correct language, and based on an actual case history supplied by Karl Abraham and Hanns Sachs, the film developed into a full-length feature film with a cast of famous actors directed by Georg Wilhelm Pabst. Hailed as a masterpiece on its first showing in Berlin on March 24, 1926 it remains a milestone in the history of European cinema.

By contrast, it sparked off an intense controversy among psychoanalysts. Siegfried Bernfeld and Adolph Joseph Storfer used Vienna and the *Verlag* to publicly accuse their Berlin colleagues of bringing psychoanalysis into disrepute by presenting it in a facile and bowdlerized version and tried, unsuccessfully, to launch a

rival project of their own. Freud, who from the outset had expressed his doubts about the feasibility of the Berlin project, was supported in his opposition to the making of any psychoanalytic film by Max Eitingon, Sándor Ferenczi, and Ernest Jones.

The even-handed review printed in the *Internationale Zeitschrift für Psychoanalyse*—but not in the International Journal of Psychoanalysis—praised Abraham and Sachs for what they had achieved within the limitations imposed by the medium, and Sachs's booklet as a textbook on the essentials of psychoanalysis. But it also made the point that the resolution to psychic conflict as presented was similar to the cathartic abreaction as described by Freud in his first two American lectures, and concluded that the film did not represent psychoanalysis as a whole, but the quintessence of “psychoanalytic therapy.”

## SEDUCTION

The “scene of seduction” connotes attempts at seduction, real or fantasied, in the form of advances, incita-

tions, manipulations, or suggestions that are actively initiated by an adult vis-à-vis a child who is passive, even frightened.

The “theory of seduction” was a metapsychological model worked out by Sigmund Freud between 1895 and 1897 and then abandoned; it assigned an etiological role in the production of psychoneuroses to memories of actual seduction attempts. In 1893, bolstered by the accounts given him by his patients, Freud spoke of seduction as a clinical discovery. During the period 1895–1897, based on these clinical observations, he worked out a theory designed to explain the repression of infantile sexuality. On September 21, 1897, in a well-known letter to Wilhelm Fliess, he laid out his reasons for abandoning this model (1950a, pp. 259–260). This whole episode is eminently instructive from an epistemological as from a heuristic point of view, and is worth reviewing.

On May 30, 1893, Freud wrote to Fliess: “I believe I understand the anxiety neuroses of young people who must be regarded as virgins with no history of sexual abuse” (1950c, p. 73). This was his first allusion to the role of sexual seduction, still very broad in its application. In “Draft H,” dated January 24, 1895, he presented the following narrative: “He had called her up to the bed, and, when she unsuspectingly obeyed, put his penis in her hand. There had been no sequel to the scene, and soon afterwards the stranger had gone off. In the course of the next few years the sister who had had this experience fell ill. . . . I endeavored to cure her tendency to paranoia by trying to reinstate the memory of the scene. I failed in this. . . . She *wished* not to reminded of it and consequently intentionally repressed it. . . . She had probably really been excited by what she had seen and by its memory. . . . The judgment about her had been transposed outwards: people were saying what otherwise she would have said to herself” (1950a, pp. 207–209). Here then we have seduction, repression, and the foreshadowing of rejection, or what would much later be called foreclosure. On October 15, 1895, Freud wrote enthusiastically to Fliess: “Have I revealed the great clinical secret to you, either in writing or by word of mouth? Hysteria is the consequence of a presexual *sexual shock*. Obsessional neurosis is the consequence of a presexual *sexual pleasure* later transformed into guilt. ‘Presexual’ means before puberty, before the production of the sexual substance; the relevant events become effective only as *memories*” (1895c, p. 127). On May 30, 1896, he

distinguished the periods of life in which the event occurred from those in which repression came into play (1950a, pp. 229–231); and on May 2, 1897, with reference to fantasies in hysteria, he elaborated: “all their material is, of course, genuine. They are protective structures, sublimations of the facts, embellishments of them, and at the same time serve for self-exoneration. Their precipitating origin is perhaps from masturbation fantasies” (p. 247). The references to “structures,” “embellishments,” and “fantasies” indicate clearly that Freud was becoming increasingly dubious. In “Draft L,” an attachment to this last-cited letter, he went on: “The aim seems to be to arrive [back] at the primal scenes. In a few cases this is achieved directly, but in others only by a roundabout path, *via* phantasies. For phantasies are psychical façades constructed in order to bar the way to these memories. Phantasies at the same time serve the trend towards refining the memories, towards sublimating them” (p. 248). Truth to tell, the great revision was already under way.

In the famous letter to Fliess of September 21, 1897, Freud wrote: “I will confide in you at once the great secret that has been slowly dawning on me in the last few months. I no longer believe in my *neurotica*. This is probably not intelligible without an explanation. . . . Then came surprise at the fact that in every case the father, not excluding my own [a phrase long censored by successive editors of the Freud-Fliess papers], had to be blamed as a pervert . . . though such a widespread extent of perversity towards children is, after all, not very probable” (p. 259). Freud now realized that scenes of seduction could be the product of reconstructions in fantasy whose purpose was to conceal the child’s autoerotic activity. This was a historic moment in the shaping of psychoanalysis, rich in lessons about Freud’s creative functioning and typical of the tendency of his innovative thinking to be overtaken by its own development, often changing course when faced by contrary evidence but always anchored in clinical experience. Freud’s self-analysis, undertaken in the preceding months, following the death of his father, certainly made it possible for him to carry through this radical break, to approach the discovery of the Oedipus complex, and eventually to reject his seduction hypothesis as false. Much later, in 1924, he would write the following in a footnote to his “Further Remarks on the Neuro-Psychoses of Defence” (1896b): “At that time I was not yet able to distinguish

between my patients’ phantasies about their childhood years and their real recollections. As a result, I attributed to the aetiological factor of seduction a significance and universality which it did not possess. When this error had been overcome, it became possible to obtain an insight into the spontaneous manifestations of the sexuality of children which I described in my *Three Essays on the Theory of Sexuality* (1905d)” (p. 168n). A return to clinical observation was thus mandatory, and Freud had no theoretical alternative in the end but to assign seduction to the category of those primal fantasies whose origin he ascribed to the prehistory of humanity.

In the first Freudian clinical doctrine, the child at birth was naïve, innocent, and when confronted by the sexuality of the other perceived it as external, foreign, and strange: this was the context of the seduction theory; in Freud’s second clinical doctrine, the child was acknowledged to be the “polymorphously perverse,” inherent possessor of a primitive sexuality, destined to unfold in its interactions with its human surround. But while, historically speaking, infantile sexuality thus replaced seduction (scene and theory), it never obliterated it completely, and both clinical views continued to be discernible within psychoanalytic treatment, as Freud himself frequently pointed out from the *Three Essays* to the *Outline of Psycho-Analysis* (1940a [1938]).

## SEDUCTION SCENES

Seduction scenes are real or imaginary situations of a sexual character involving a child, whether as a spectator or forced participant. During the first period in his work, Freud placed under the rubric of “seduction scenes” both the child's observation of sexual relations between adults (generally the parents) and sexual advances made by an adult (often the father) or by an older child.

Freud early on had the idea of seeking the cause of the neuroses in traumas brought on by premature sexual experiences imposed on a child by an adult. In a letter to Wilhelm Fliess dated May 30, 1893, he reported having “analysed two such cases, and the cause was an apprehensive terror of sexuality, against the background of things [a child] had seen or heard and only half-understood; thus the aetiology was purely emotional, but still of a sexual nature” (1950c, p. 73).

This theme was central to Freud's contribution to *Studies on Hysteria* (1895d), written in collaboration with Josef Breuer. The case of Katharina reported there (pp. 125–134) is typical: Freud related the young woman's trouble to the fact that she has been a furtive witness to sexual relations between her elder sister and their father and then herself suffered similar assaults from him (in Freud's original account, the father was discreetly described as an uncle).

To begin with, Freud believed that such “seductions” were imposed upon children still in an asexual state. Their fright arose from incomprehensible scenes that they interpreted as violent and from their mystification by the adults' apparent excitement. The imma-

ture child thereafter retained a trace of an event whose traumatic character emerged only later, at puberty, when new events revived it.

Freud's initial misapprehension of childhood sexuality gave rise to two major psychoanalytic notions: the idea of the diphasic character of sexuality (the notion that psychosexual development occurred in two steps) and the idea of deferred action (according to which a mental event could derive its meaning and force from later events, by which it was reorganized retrospectively). From the outset, Freud faced the problem of how such a potential trauma could actually be deferred in this way. He first attempted to delineate an obscure “sexual-presexual” period (1950c, p. 127). He acknowledged that excitement and pleasure in response to a scene of seduction could exist in boys, if not in girls. Boys, he argued, being more active, tended toward obsessional neurosis, whereas girls, who experienced such scenes passively, were more likely fated to relive them in a hysterical mode (1950a, pp. 223–224, 228). The unsatisfactory nature of such attempted solutions led Freud, in his *Three Essays on the Theory of Sexuality* (1905d), unequivocally to accept the role of infantile sexuality.

A correlated major revision is foreshadowed in Freud's letter to Wilhelm Fliess of September 21, 1897. There he conceded that the scenes of “seduction” by the father that his hysterics recounted probably related “in every case” not to real events but to fantasies (1950a, p. 259). Although this startled Freud at first, he made a swift recovery, as he later recounted in vivid terms in his *Autobiographical Study* (1925d [1924]). The psychic implications of fantasies were much more important than the real event, he there claimed, and fantasies could be nourished by apparently banal or minor incidents (for example, the copulation of animals might be related in the child's imagination to sexual activity between the parents).

Freud never disavowed his theory of trauma, but in his second period, in which he focused his attention on the “primal scene” (the real or fantasized observation of sexual relations between the parents), he returned again and again to the issue of the relationship between “psychic” and “historical” (event-governed) reality. In his account of the “Wolf Man” case (1918b [1914]), the following question forms a veritable leitmotif: did the eighteen-month-old child really see his parents engaged in *coitus a tergo* (vaginal penetration from behind), with the trauma making its appearance by way of a dream

only when he was four, or was the entire scene merely a “product of the imagination” (p. 49)? Freud was thus led to postulate that primal scenes, bequeathed to every individual by the history of humanity itself, helped form the psychic apparatus (1912–1913a).

Sándor Ferenczi (1955), who fully acknowledged the role of childhood sexuality, emphasized the traumatic character not of the seduction itself but rather of the frustration that the child dramatically experiences when an adult, in the wake of exciting solicitations, disappoints the child by a rejection that points up the child’s powerlessness. This is perhaps inevitable if, as Freud himself emphasized, the mother, as the earliest caregiver, is, by force of circumstance, the first seductress (psychoanalytically conceived). Along similar lines, Jean Laplanche has made his “general theory of seduction” the centerpiece of his *New Foundations for Psychoanalysis* (1989).

### SELECTED FACT

The expression “selected fact” was borrowed by Wilfred R. Bion from the French mathematician Henri Poincaré to refer to the element that makes it possible to give coherence to a group of scattered data.

In *Science and Method* (1908), Poincaré considered the “selection of facts” that enabled science to discover laws of general validity—that is, facts that introduce order and coherence into the complexity of the world. Bion, elaborating his ideas in “A Theory of Thinking” (1962), initially placed emphasis on the container-contained relationship, taking as his paradigm the mother-infant dyad: The baby projects unassimilable “bad” elements of its own psyche onto the maternal psyche, and the mother bears the responsibility of restituting this material to the baby in a form that is psychically assimilable. Bion denotes this relationship using the conventional female and male symbols: ♀ ♂.

Bion later became interested in the process by which the mind transforms a chaotic, persecutory experience into an experience that is integrated, representable, and thinkable. This corresponds to the passage from what Melanie Klein calls the schizoid-paranoid position, in which the elements of the psyche are split and projected, and thus dispersed, to what she calls the depressive position, where these elements can come together and become stabilized in a stable configuration. Bion proposes the equation PS [ $\leftrightarrow$ ] D, where PS represents the schizoid-paranoid position and D represents the depressive position. The selected fact is the element that allows for passage from the first position to the second; it serves as a starting point for interpretation by the psychoanalyst, who becomes aware that a multitude of aspects of the patient’s material come together and make sense, beginning with a given element of the transference.

Although he borrows the notion of the selected fact from scientific methodology, Bion establishes an essential difference between the scientific approach that seeks the laws of nature and the psychoanalyst exploring the psychic reality of their patient. The scientist is searching for logical connections among the objective data collected, whereas the psychoanalyst is interested in the emotional links that seem both to dominate the transference relationship and to create interconnections among the disparate elements of associative material: “Selected fact is the name for an emotional experience, the emotional experience that

consists in discovering coherence; its meaning is thus epistemological, and the relation among selected facts must not be considered logical," writes Bion in "A Theory of Thinking."

## **SELF**

The term *self* is used in several different senses. It can refer to the ensemble of the psychic agencies, the narcissistic organization of the psyche, or the conscious part of the psyche that enables the individual to recognize himself or herself as an agent and a subject endowed with reflexive consciousness.

The German *Selbst* is sometimes encountered in Freud's writings to refer to the person. Beginning in the 1940s, Melanie Klein used the word *self* in the general sense of representation of the inner world. We can attribute the first psychoanalytic usage of the term to Heinz Hartmann, who in 1950 used it to refer to the ensemble of the psychic agencies, all of them being the object of the narcissistic drive.

The concept of self was partly included in the term *Ich* ("I"), in the sense that Freud used it until 1920. *Ich* was both the person in his or her totality and subjectivity, and the organizing portion of the psyche. From the time of the second topography, the ego became a specific structure. To avoid ambiguity, some English-speaking psychoanalysts began to use the word *self*, already in use in philosophy and social psychology (William James, George Herbert Mead, Gordon William Allport), to refer to the whole person.

The term *self* evolved in three different directions. During the 1950s it was used with similar meanings by the two British schools. In "Our Adult World and Its

Roots in Infancy" (1959), Melanie Klein proposed this definition of it: "The self is used to cover the whole of the personality, which includes not only the ego but the instinctual life which Freud called the id" (p. 249). Anna Freud also used it to refer to the totality of the psyche, but preferred to use it in reference to the self understood as the object of narcissistic investment.

In the theories of Heinz Kohut, the self is no longer the object of narcissistic libido but instead an organizing structure of the mind. In his "generalized" conception (1978), the self is a "superordered" center, constructed outside of the action of the drives through the relationship with the self objects. The self objects (ideal, mirroring, or alter ego), which are manifested by the corresponding narcissistic transferences, create the major components of the self: the pole of ideals, the pole of ambitions, and the pole of knowledge (1984). The cohesion of the self, which depends on the empathy of the self-objects, determines the capacity to overcome the conflicts linked to the drives. The self is a structure, but Kohut also often alluded to self-representation and self-consciousness.

The mind's reflexive function was not particularly explored by psychoanalysis, although in *The Interpretation of Dreams* (1900) Freud defined consciousness as "a sense organ for the perception of psychological qualities" (p. 615). Edith Jacobson described the self as the source of internal subjective reality and referred to the representations of self that are manifested in analysis (1964). Donald Winnicott (1961) considered this subjective perspective obvious. He attributed to the self the feeling of the reality, continuity, and rhythm of mental life, at the same time emphasizing that it is rooted in bodily sensations. In "Ego Distortion in Terms of True and False Self" (1960), he contrasted the true self, whose positive aim is "the preservation of the individual in spite of abnormal environmental conditions" (p. 143), to the false self, which is constructed in conformity to parental expectations and throughout life takes on the role of protecting the true self.

Formation of the self is an aspect of psychic development, whether in terms of an epigenetic conception of development (Erik Erikson, Heinz Lichtenstein), a psychic skin (Esther Bick, Didier Anzieu), or precursors to the self (Daniel N. Stern). Kohut's followers proposed an intersubjective theory of the analytic process that attributes a structuring role to the self's reflexivity (Robert D. Stolorow, George E. Atwood,

Bernard Brandschaft). A similar orientation is found in the work of Thomas Ogden, a post-Kleinian who developed the notion of the “analytic object” (André Green) in a theory of a third, subjective space, the locus of the relationship between patient and analyst.

The use of *self* in a specific sense is often criticized for potentially depriving the word *ego* of the richness of its multiple meanings. Yet clearly, this concept has been instrumental in the formation of several important developments in psychoanalysis. However, owing to the very breadth of the term *self*, it only has a heuristic value if the sense in which it is being used is specified.

## **SELF-ANALYSIS**

Self-analysis consists of interpreting one’s own preconscious and unconscious material (such as dreams, parapraxes, memories, fleeting thoughts, and intense emotions).

Psychoanalysis is to a great extent a result of Freud’s self-analysis between 1895 and 1902. The analysis of his own dreams brought him confirmation of what he found in the dreams of his patients and, reciprocally, he better understood their dreams on the basis of his own. Freud’s self-analysis only became systematic after

the death of his father in October 1896, and that it complemented and sustained his project of writing a book on the interpretation of dreams.

The method of self-analysis developed by Freud included four steps: writing down the material obtained; breaking it up into sequences; free associating on each of the sequences; and finally, forging links based on the associations produced, these links thus taking on an interpretive significance.

In his first conception of psychoanalytic training, Freud assumed that what was needed was a preliminary experience of self-analysis based on his model. Later, he took the position that the experience of a personal analysis should be required of future analysts. The risk of self-analysis is that it favors narcissistic self-satisfaction or obsessional rumination. Self-analysis could never be a purely solitary mental activity: Freud developed it in the course of a scientific, emotional, and fantasy exchange with his friend Wilhelm Fliess from Berlin. An active self-analysis takes place within the context of interrelations (with family or patients, for example). Furthermore it presupposes a subjective commitment to remain in analysis despite the development of personal crises.

Self-analysis can be fruitful if it prolongs the psychoanalytic work of which it is an echo. The main difficulty is the neglect of transference/countertransference relationships. One solution to this problem might be an introjection of the image of the analyst as an ideal object with whom an interior dialogue may then be pursued. This is probably what occurred in the case of Samuel Beckett after the interruption of his analysis with Wilfred Bion. His subsequent novels *Mercier and Camier*, *Molloy*, *Malone Dies*, and *The Unnamable* may thus constitute fictional sessions with a fictional analyst.

## SELF-CONSCIOUSNESS

Self-consciousness is the mental activity through which the subject feels a sense of being or existing as a unique and total individual. Although it does not obviate the idea of the unconscious, this notion comes out of reflexive philosophy and its derivatives that hold that the human faculty of consciousness, apparent to itself and having itself as its object, marks the primacy of consciousness in the definition of the human psyche. This sense of identity, this initial subjective stance, is established gradually, being linked with the general development of the human mind in its relationship to itself and the outside world.

This notion has taken on different forms throughout intellectual history, beginning with René Descartes's insistence on the primacy of consciousness in the human mind. In the nineteenth century, after Georg Wilhelm Friedrich Hegel's work but before that of Edmund Husserl, Franz von Brentano posited self-consciousness as being secondary to consciousness or intentionality toward the object. Husserl inverted that order, positing a reflective unit that is the mental locus of the relationship between subject and world, a pronominal form in which the subject, through discourse, identifies with what it believes it is or would like to be. This internal perception is also linked to the specular image of the body.

Finally, this notion is found in the work of Ludovic Dugas, a late-nineteenth-century semiologist. Drawing from the work of Hippolyte Taine and Théodule Ribot, Dugas approached the idea of self-consciousness from a negative perspective by looking at its dysfunction: "state[s] in which the subject feels estranged from his being and from things and begins to doubt that all that he is feeling is real." Such states entail alienation and the ego's inner loss of meaning—a loss of the immediate grasp of the ego's own inner states and the sense of existing. This sense of self-estrangement when the subject, in a state of indifference, feels his acts and emotions eluding him, is called *depersonalization* or *loss of self-consciousness*.

The idea of mental activity that supposedly situates the individual as being self-present and in an unmediated state in relation to himself, first attacked by Friedrich Nietzsche, was to be further diminished by Sigmund Freud and psychoanalysis. Jacques Lacan showed how Freud's discoveries decentered the subject

from the self-consciousness heretofore upheld by Hegelian philosophy and the solipsism of the Cartesian cogito. In "The Mirror Stage As Formative of the *I* Function" (1949/2002), Lacan describes the conditions for the appearance of self-consciousness: the moment when the infant, first in its mother's arms and later, once the baby is physically able, by itself, can "already recognize his own image as such in a mirror. This recognition is indicated by the illuminative mimicry of the *Aha-Erlebnis*" (p. 3). This jubilatory assumption on the part of the infant situates the ego and the recognition of the bodily imago within the necessary mediation of the gaze and the desire of the other, initially represented by the mother. Without letting himself be caught up within the fiction of this movement, Lacan emphasizes "the imaginary capture of the self through specular reflection within the function of misrecognition [*méconnaissance*] that remains attached to it" since alienation is the fact of the subject who is not "a being conscious of itself." Jean Laplanche later called this mental activity the "capability or incapability of consciousness."

Child psychoanalysis (Donald Winnicott, Serge Lebovici, and Michel Soulé) defines the child's sense of existing within the movement of his or her constitution of an inner universe, a container that makes possible relations with the self and the outside world. This container is elaborated gradually beginning with the child's experience with the mother, which is never totalizing, and it keeps the subject from being absent from itself. The child's rudimentary ego, after a period where there is no distinction between it and the world, creates a boundary where the *I* and the not-*I* are distinguishable, just as the image of the body takes on wholeness.

Didier Anzieu emphasizes in *The Skin-Ego* (1985) that "all mental function, in its development, is supported by a bodily function whose workings it transposes onto the mental plane." This implies that all ego feeling is both mental and corporeal. Involved here are the subject's sense of continuity in time, of proximity to self, of causality (the *I*), and of boundaries of which the subject is not always conscious, but which are revealed when normal mechanisms fail (depersonalization and certain states of mystical ecstasy). Carl Gustav Jung, although he prefers to speak in terms of "ego-consciousness," also links this mental activity to the child's progressive individual differentiation. If the mother is the condition for the appearance of ego-

consciousness, she is also that from which the child must distinguish itself. The process of individuation becomes merged with self-consciousness and “affect enables us to experience consciousness of ourselves with greater acuity and intensity.” Finally, in Freud’s work the notion of self-consciousness is not often used. In *The Interpretation of Dreams* (1900) he emphasizes that self-consciousness is suspended in dreams. In “On Narcissism: An Introduction” (1914) he links it to, on the one hand, moral consciousness, which serves philosophical introspection, and, on the other, to the self-perception that nourishes self-esteem. In “Group Psychology and the Analysis of the Ego” (1921) this sense of continuity that the individual acquires through his traditions, habits, and sphere of activity, this conscious personality, this “voice of consciousness” will be overtaken by the force of suggestion and hypnosis or, alternatively, will be deemed to be temporarily lost to the individual “following his absorption into the crowd.”

Expanded knowledge about children, neurology, and the study of failures of self-consciousness can provide a better approach. It should also be noted that the distinctions between the self (in the various usages of that term) and the ego can help to establish with precision their locus and movement.

Overall, the notion of self-consciousness remains marked by its philosophical origins. There can be no complete assurance of its consistency within psychoanalysis.

## **SELF-ESTEEM**

Esteem for the self consolidates the sense of one’s own value or, more mundanely, one’s pride. Hence Freud’s interest in it in “On Narcissism” (1914c): “One part of self-regard is primary—the residue of infantile narcissism; another part arises out of the omnipotence which is corroborated by experience (the fulfillment of the ego ideal), whilst a third part proceeds from the satisfaction of object-libido” (p. 100). As the effect of ego demands on the “narcissistic” ego ideal and “moral conscience,” the feeling of self-esteem is at the origin of repression: “In paraphrenics self-regard is increased, while in the transference neuroses it is diminished” (p. 98). It is nevertheless the narcissistic part that proves to be determinant: when self-esteem is threatened, the result is shame rather than guilt. It therefore depends, in each individual life and in the different psychopathological cases, on the quality of the subject’s narcissism and thus on the modalities of the subject’s cathexis by and of the object, as it depends for its regulation on its relations with the ego ideal (Janine Chasseguet-Smirgel). All situations of existential crisis shatter it particularly, adolescence being an example, but especially melancholy because, according to Freud (1916–17g), what differentiates it from “normal mourning,” over and above the common loss of object that characterizes them both, is the fact that it calls itself into question.

## **SELF-HATRED**

Self-hatred is a reflexive notion: In it, the subject is the hating person and at the same time the hated person.

The concept of self-hatred appeared in Sigmund Freud's "Mourning and Melancholia" (1916–17a [1915–17]): "If the love for the object . . . takes refuge in narcissistic identification, then the hate comes into operation on this substitutive object" (p. 251).

This concept was thus initially understood as the vicissitude of identification with the object of loss: "The self-tormenting in melancholia . . . signifies . . . a satisfaction of trends of sadism and hate which relate to an object, and which have been turned round upon the subject's own self" (p. 251). Later, in "The Ego and the Id" (1923), it was developed in connection with obsessional neurosis and melancholia, but this time within the framework of the second topography. At this point, the superego was theorized as replacing the object that persecutes the ego: "The fear of death in melancholia admits of one explanation: that the ego gives itself up because it feels itself hated and persecuted by the super-ego, instead of being loved" (p. 58). Revealed here is the degree to which self-hatred is infiltrated by sadomasochism, and to which the superego, in this context, can become the "culture of the death instinct" (1923b, p. 53).

In *Language and Insight* (1978), Roy Schafer emphasized the idea that the persecutor and the victim can unconsciously be persons other than the self, "say, one's father in the act of hating one's mother; here, 'I hate myself' translates into 'In this way I enact, experience, and perpetuate my father's hating my mother'" (pp. 123–124). In (1990), André Green introduced the interesting idea of the logic of despair, in which self-hatred is posited as reflecting "a compromise between the inextinguishable desire for revenge and concern for protecting the object from the hostile desires directed against it."

## **SELF-IMAGE**

The term *self-image* has entered common usage. Initially referred to by psychologists, it was then taken up

by psychoanalysts without really being theorized. The self-image is ostensibly the representation that everyone has of themselves, in physical as well as physiological, sociological, and mental terms, envisioned through the prism of each individual self-evaluation at different stages of development and in different situations.

Formerly, this notion was often considered to be the equivalent of the body scheme, postural scheme, somatopsyché, image of body-ego, or even somatognosia, although each of these notions had its own characteristics in terms of both its limits and its basic conception. Within this current of thought, the self-image can be seen as the representation of one's own body, as both body-object within one's environment and body in relation to others; or as the totality of a body that is initially experienced as being fragmented; or, finally, as a body that is experienced as autonomous, upon emergence from the period of non-differentiation.

When used in psychoanalysis, the self-image brings together the notions of body image, self-consciousness, the concept of the self, self-identity, and ego-identity. Self-image is constructed through imitations of (for psychology), or identifications with (in psychoanalysis), people around the subject or real or heroic imaginary figures, throughout the development of narcissism and the setting up of the ideal ego, the ego ideal, and the superego. The self-image is dependent as well upon the type of object relations established.

The notion of the self-image emerged in and was refined through the work of a number of authors, in particular that of Henri Wallon, who described the emergence, during the fifth stage of development (personalism), of self-awareness, which can only occur if the child is capable of having a self-image. This ability is related to the test in which the child recognizes itself in a mirror, whereas previously it had mistaken its specular image for another person. Heinz Hartmann, founder of the ego psychology movement, introduced the distinction between the ego, as psychic agency, and the self, in the sense of the person or personality proper. Paul Schilder posited that the formation of body image plays a determining role in the genesis of the representation of self that follows organization of the ego and the evolution of narcissism. In the view of Donald Winnicott, the mother and the primary mothering environment mirror (or do not mirror) back to the child an image of itself with which the child can (or cannot) identify. In this view, the self is

an agency of the personality in the narcissistic sense, a representation of self for the self, a libidinal investment of self. Heinz Kohut, in self-psychology theory, proposed the self as a notion that relates to the personality in its entirety, to psychic functioning as a whole, to the bodily self, as well as to more clearly defined elements such as self-representation. Jacques Lacan returned to the “mirror stage” to show that the young child’s recognition of its own specular image founds the dual relation, the dimension of the imaginary, and the ideal ego. In the view of Françoise Dolto, body image plays a part in the subject’s identification and determines the possibility of a feeling of self—of self within a body. Here, the body is the basis for the construction of the subject’s identity in relation to others, and the unconscious image of the body is the forgotten (repressed) bodily foundation for the feeling of self.

It is important, too, to make clear that the self-image also depends on how others see and assess us. We should perhaps add to the notion of the self-image the feeling of competence that is the cognitive construction corresponding to the opinion that each of us is subject to on the cognitive, social, and physical levels, and the relational feeling of self-esteem.

## **SELF-MUTILATION IN CHILDREN**

In psychiatric usage the term “self-mutilation” (auto-mutilation), a combination of the Greek root *autos* (self) and the Latin verb *mutilare* (mutilate), refers to behavioral forms characterized by acts of physical injury initiated by the subject; such acts are subject to various interpretations. Some authors have suggested the use of the expression “unintentionally self-inflicted injury,” which avoids the assumption of intentionality (Carraz, Yves, and Ehrhardt, Raymond, 1973).

The term “self-mutilation” was first used to describe physical injuries that schizophrenic patients or those suffering from melancholia sometimes inflicted on themselves. These were frequently directed at the genital organs, but the hands and eyes were also affected, especially in schizoid patients experiencing a period of mystical delirium. Karl A. Menninger in 1935 wrote a psychoanalytic study on the question. Menninger considered these signs of self-mutilation to be acts of self-punishment, which symbolized castration.

Self-mutilation has also been described in other psychopathological contexts: in relation to masochistic compulsions or within the context of some perversion; such behavior has also been described during states of heightened or chronic anxiety.

A particular and relatively frequent aspect is represented by the repetitive scarification or carving resorted to by some adolescents. The meaning of such behavior is difficult to interpret, especially since the subjects themselves do not associate any mental imagery with it. Aside from serving as a discharge designed to temporarily eliminate psychic suffering and short-circuit the activity of thought (Delarai-Chabaux, Catherine, and Roche, Jean-François, 1996) common to the majority of such behavior, this type of self-mutilation involves questions about the psychic status of the body in the adolescent.

In the infant, self-mutilation is observed in children who are severely mentally retarded or autistic, and especially when both types of pathological organization are combined. The most severe forms occur in children who cannot speak. In this clinical context, several authors have attempted to identify the different psychopathological interpretations of self-mutilation. Salem A. Shentoub and André Soulairac refer to motor discharges, possibly “self-offensive,” that can arise during normal development, especially between the ages of twelve and eighteen months, during the activity of sensory-motor exploration, although these have no pathological value. This primitive self-mutilation decreases rapidly with the development of the bodily schema and the differentiation between ego and not-ego. The infant perceives the causality of the pain; aggressive behavior towards others may then appear. In infantile psychoses self-mutilation is associated with the inability to modulate relational distance and the failure of defense mechanisms, which leads to a massive regression to undifferentiated stages of psychic

organization, where the ego is confused with the non-ego.

F. Dumesnil attempted to differentiate self-mutilating behavior in different forms of autism and infantile psychosis. Referring to the work of Frances Tustin and Margaret Mahler, he distinguished between “internal shell autism,” “external shell autism,” the “regressive autistic position,” “symbiotic psychosis,” and “moderate retardation.” In internal shell autism, self-mutilation appears to be a ritualized self-injurious gesture intended more for protection than destruction, in which the mutilatory aspects appear to be accidental. In external shell autism, self-mutilation, which is less mechanical but more violent than in the previous group, can be considered a self-destructive gesture without any specific intentionality. According to Dumesnil, its appearance is determined by an “experience of conflict” and must be understood as “the acting out of an intensely difficult emotion,” probably of a depressive nature. In the regressive autistic position, self-mutilation corresponds to a “discharge of hostility and anxiety” that occurs in connection with an anxiety-causing situation of internal or external origin, and which can be directed, in an undifferentiated manner, towards others or the self, because of the absence of a defined bodily limit. In symbiotic psychoses, where the mechanisms of splitting are prevalent, self-mutilation appears in situations where hostility gives rise to an “intense discharge of hatred.” Again, according to Dumesnil, these violent acts of self-mutilation, which specifically affect certain parts of the body, involve “an interplay of introjections and projections enabling the person to actualize the bad object within himself” and to maintain the feeling that the outside is completely good. Finally, in moderate retardation, self-mutilation results in a relatively disorganized discharge of anger triggered by some kind of frustration; it does not appear to be “directed” toward an object.

Some self-injurious behavior observed in cases of autism or mental retardation seems to fall within the framework of the auto-sensory phenomena described by Frances Tustin. These serve to maintain the child in a “constant bath of stimuli” that helps to form a “psychic skin” (Esther Bick), protecting the child from environmental discontinuities. The attempt to damage corporal integrity here appears to be an unintentional consequence of self-stimulation. The physiological phenomenon of habituation likely contributes to their

gradual intensification. In other cases, the deliberate search for a more or less violent contact with hard objects evokes what Tustin has described as an “autistic object.” The sensation of hardness serves to ensure a corporal limit while avoiding separation from the nipple. The distinction observed in clinical psychoanalytic work between the repetitive search for experiences of pure stimulation—which are aimed, well below the threshold of autoeroticism, at “feeling that one exists”—and a very real self-destruction can be compared with the opposition between life narcissism and death narcissism introduced by André Green.

Self-mutilating behavior can also occur when relations involve a form of partial object cathexis, which gives rise to attempts at omnipotent control of the object; separation then leads to violent displays directed toward another or toward the infant himself. The intentionality of self-mutilating behavior appears more clearly here since it reflects a form of aggression turned against the self, as a response to frustration, or because it represents an appeal or request, possibly reinforced by the responses provided by those in the subject’s immediate environment.

On another level self-mutilation raises the question of pain and its perception in the autistic child. Is there an elevation in the threshold of pain perception in these infants, as some neurobiological theories claim (endorphins)? Or is this apparent insensitivity the expression of an “intractable interweaving of pleasure and pain,” leaving the observer with the impression of a “desperate pleasure” (Jean Ochonisky)?

There also exist a number of forms of rhythmic behavior, most notably head banging, which can result in lesions of varying severity. It is known that these symptoms are particularly frequent in situations of separation or emotional deprivation. It can be hypothesized that for the infant rocking plays the role of maternal holding, or that the self-mutilation is a substitute, in the body of the child, for the missing object.

These attempts at psychopathological understanding are important for ensuring proper institutional care of such pathologies. Self-mutilating behavior arouses strong feelings of powerlessness and guilt, and sometimes even depression, in caregivers as well as parents.

## SELF-OBJECT

The term *self-object* refers to any narcissistic experience in which the other is in the service of the self, the latter being defined as a structure that accounts for the experience of continuity, coherence, and well-being. It is a source of narcissistic feeling.

The notion of selfobject appeared in the work of Heinz Kohut as early as his 1968 article, “The Psychoanalytic Treatment of Narcissistic Personality Disorders,” in his discussion of the narcissistic transference, in which the analyst is an archaic selfobject function in the narcissistic pathology. It was further developed in *The Analysis of the Self* (1971) in Kohut's reconceptualization of narcissism. It refers to a normal narcissistic function that evolves in stages. The selfobject can be the object of a fixation that is the basis for a narcissistic transference. When the object is narcissistically invested, the narcissistic object relation is opposed to object-love.

The hyphen (*self-object*) disappeared in *The Restoration of the Self* (1977), because the selfobject is

not reducible to the archaic configurations of narcissism, but is rather defined as a dimension of experience. In 1979, Kohut generalized a selfobject that is inseparable from the self, of which it is the existential correlate and the source. At the beginning, Kohut reminded us in his 1980 article, “Selected Problems of Self Psychological Theory,” the descriptor *selfobject* was reserved for pathology in the sense of an archaic fixation, with the emphasis being placed on the grandiose self or the omnipotent selfobject. Like the object, the selfobject is at first replaceable, before becoming meaningful. In the mature self/selfobject relationship, the archaic selfobjects continue to exist at a deep level and to resonate as leitmotifs at various times.

In *How Does Analysis Cure?* (1984), the selfobject became a dimension of experiencing another person whose functions are related to the self. The selfobject can thus be archaic or mature, anachronistic or appropriate. A support for the vulnerable self, it is the appropriate medium of the healthy self, like the oxygen that is necessary for life. The self is a feeling of unity, strength, and harmony if, at each stage of life, it receives the appropriate responses from the selfobject environment: availability and receptivity, the conditions for all mental life. The selfobject is an intrapsychic experience. In times of temporary vulnerability, the better equipped the subject is to find the selfobjects he or she needs, the healthier he or she will be. The selfobject is not necessarily a person; it can be music, an outing, a talent, culture, and so forth.

It is often difficult to distinguish between that which comes from the object and that which comes from the selfobject, especially in adults. In pathologies or in the context of treatment, the distinction is easier to make. The object is recognizable through representation and comes from desire. The selfobject is an archaic or mature function that comes from need. If the other is the target of desire, anger, love, or aggression, that other is an object. If the other maintains cohesion, strength, and personal harmony, it is a self-object. Object-loss results in mourning; the relationship to the selfobject cannot be lost but can instead undergo transformation.

Kohut's successors disagreed about the generalization of this term. In the view of some, the selfobject reflects vulnerability, even if it is temporary, in the self. An intact Self, according to this view, does not need a selfobject and the notion should be reserved for pathology. However, Kohut's view is clear: The

selfobject is the oxygen that we are only aware of when we think about it. Deficiencies in the self result from the self/selfobject relationship. What was once limited to pathologies is generalizable to every subject and every course of treatment, and pathology stems from narcissism alone. The selfobject preserves the ambiguity of being simultaneously both a relationship and an experience. The metapsychology of the self underlying this concept can be criticized.

## SELF-PRESERVATION

The term *self-preservation* in its simplest definition describes both the set of behaviors by means of which individuals attempt to preserve their own existence and the psychical processes that establish these behaviors.

In an initial period of his work Freud associated these behaviors with the sexual instincts. He claimed that a person's life is conditioned by two major forces: self-preservation instincts, by means of which people preserve their own existence, and sexual instincts, by means of which they ensure the survival of the species. This, he asserted, was fundamental biological data, adding that, as simple observation illustrates, they can

be opposed in conflicts that result in the essentials of psychic dynamics.

Although the notion of “self-preservation” itself did not appear until later, we find it foreshadowed as early as 1895 in “A Project for a Scientific Psychology” (Freud, 1950a), in which Freud accords major importance to attention viewed as the cathexis of perception and thought processes by the ego for the purpose of adaptation. He did not however explicitly formulate his thesis until 1910 in an article on “The Psychoanalytic View of Psychogenic Disturbance of Vision” (1910i, pp. 209–218), where he evoked “the undeniable opposition between the instincts which subserve sexuality, the attainment of sexual pleasure, and those other instincts, which have as their aim the self-preservation of the individual, the ego instincts” (p. 214). He was to return to this question and discuss it in greater detail in “Instincts and their Vicissitudes” (1915c, p. 124): “I have proposed that two groups of such primal instincts should be distinguished: the ego, or self-preserved, instincts and the sexual instincts.” He added cautiously—and somewhat short of his earlier affirmation that it was “fundamental biological data”—that it was merely a working hypothesis.

In this passage we notice that in accordance with the approach opened up in the “Project,” he considers “self-preserved instincts” and “ego instincts” as being equivalent terms and that they are indeed instincts. However, “As the poet has said, all the organic instincts [...] may be classified as ‘hunger’ or ‘love’” (1910i, p. 214–215). This brings up the question as to what is a purely organic need (*Berdürfnis*), what is instinctive behavior (*Instinkt*, in the sense of preformed and automatically executed behavior), and what is drive (*Trieb*, in the sense of a “borderline-concept” between the organic and the psychic). Freud was to be much more explicit on this question in relation to psychosexuality than in relation to self-preservation, which was relegated somewhat to the rear of his theoretical preoccupations. This opposition-complementarity nevertheless plays an important role in the theory that the sexual instincts are connected to the self-preservation instincts, based on the first case of sucking (1905d), and in the opposition between the pleasure principle and the reality principle: the ego instincts force the way to the reality principle, whereas the sexual instincts remain much more durably in the service of the pleasure principle (1911b).

With the arrival of the structural theory and the second theory of instincts opposing life instincts and death instincts, the question takes on new dimensions. All instincts are now seen as libidinal whereas the ego—at the expense of its largely unconscious function—more clearly takes charge of all adaptive functions (in the service of one of its “masters,” the reality of the external world, though simultaneously tyrannized by the other two, the id and the superego). The result is that, in the structural theory with the notion of conflict among the agencies, the status of the notion of “self-preservation” becomes relatively uncertain and the expression “ego instincts” tends to disappear from Freudian vocabulary.

However, several post-Freudian trends have again highlighted the value of the notions of self-preservation instincts and ego instincts, particularly the Paris psychosomatic school (Marty, 1990).

## **SELF PSYCHOLOGY**

*Self psychology* is the name Heinz Kohut chose for his psychoanalytic theory, which focused on narcissism.

Beginning with his new metapsychology of the Self in *Restoration of the Self* (1977), Kohut distinguished between the limited form of self psychology proposed in *The Analysis of the Self* (1971), in which he maintained the classical theoretical formulations, and a generalized self psychology that formed a system, albeit a replaceable one. The application of self psychology to other pathologies was the result of further clinical and theoretical elaboration, and also of criti-

cisms leveled against Kohut that may have led him to adopt more or less extreme positions.

Kohut presented the limited form of self psychology as both a complement to Freudian psychoanalysis and a critique of Heinz Hartmann's ego psychology. He held that uncovering narcissistic transference makes it possible to analyze narcissistic personalities, just as transference neuroses do for neurosis. The rehabilitation of narcissism against the ideal of health and maturity led to a preoccupation with development of the self and its defects. Soon, however, postulations concerning the self as a narcissistic structure came into conflict with the theory of the drives. Without eliminating the latter, Kohut considered them to be secondary to the structural defects in the self. The status of neurosis always remained ambiguous in Kohut's work, where it was seen both as a nosological entity unto itself and as being included among the disorders of the self. Neurosis is seen as resulting from oedipal conflicts and castration, but the self is deemed either to be whole at this phase of development, or else already weakened and incapable of resolving the difficulties of the oedipal phase, which then becomes a complex.

Self psychology, through the empathic method advocated by Kohut from 1959, focuses on the self and its fluctuations. It considers microstructures, in contrast to the analysis of neuroses, which focuses on macrostructures—the agencies of the psyche. Self psychology represented an epistemological turning point in which the analyst was no longer, or no longer only, a screen for the patient's projections, but rather a participant in treatment, which the analyst influences; the impact of the analyst's presence and, of course, his or her attitudes and interventions on the patient's narcissism, becomes an object for analysis.

The emergence of self psychology can only be understood in relation to ego psychology, in which the ego, as an agency endowed with functions, is distinguished from self-representations that are the object of narcissistic cathexis. Self-representations are supplanted by representations of the Self, and the Self thus becomes a structure within the psychic apparatus, a reflection of the state of the subject's narcissism.

Self psychology is sometimes considered to be a major deviation from metapsychology. Its focus on a psychology of defects and not only on instinctual conflict has generated a great deal of controversy.

## **SELF-PUNISHMENT**

Self-punishment (or the “need for punishment”) is a tendency, postulated by Freud, which drives certain subjects to inflict suffering upon themselves and search out painful situations, for the purpose of neutralizing a feeling of unconscious guilt. In the framework of the second topography of the psychic apparatus, Freud later attributed self-punishment to the activity of an especially intransigent superego, to which the ego submits.

Freud utilized the two notions “need for punishment” and “self-punishment” throughout his work. The emphasis in the former was on the feeling of unconscious guilt, and on the masochism proper to the ego, which demands punishment, whether it comes from the superego or from the outside, whereas the latter stressed the punishing activity of the superego, to which the ego submits—the superego in turn draws its energy from the reversal of sadism into auto-sadism. Punishment then was applied with no recourse to an external object, through the intervention of internal topographical duality of the ego-superego.

Very early in his career, Freud began noticing a certain number of phenomena and symptoms which conveyed a dimension of self-punishment. In manuscript N (May 31, 1897, in 1950a) he discussed the question of symptom formation and postulated that it constituted a compromise between the libido and the desire for punishment, based on hostile feelings towards the parents: “The motives of *libido* and of *wish-fulfillment as a punishment* then act by summation.” In *The Interpretation of Dreams* (1900a), he distinguished certain “punishment dreams,” whose punitive value allows the lifting of censorship and thereby the realization of certain desires.

Subsequently, the whole field of pathology and all the suffering connected with it came to be looked at through the perspective of self-punishment, whose goal was to satisfy feelings of unconscious guilt:

- in obsessional neurosis, where self-reproach and self-punishing behavior were connected to repressed, aggressive, hostile, and cruel feelings.
- in melancholia, where the self-punishment compulsion can lead to suicide. In a fit of melancholia there is introjection of the lost object and the possibility of unleashing sadism against the object. Without introjection, the guilt of the melancholic prevents the sadism from emerging. After the introjection the sadism can reign unchecked because it is also an attack on the subject, becoming self-punishment (1916–17g [1915]).

Within the second topography, Freud attributed to the superego the punitive role to which the ego submits, and culpability became a tension between the two entities. He emphasized also that some behavior can be motivated by the quest for punishment. For example, the transgressing subject, by obtaining punishment, is looking to gratify a desire for masochistic satisfaction (1928b [1927]). Freud was especially interested in what he called the negative therapeutic reaction, where the repressed sadism of the patient inclines him to sabotage the cure, combining revenge against the therapist with self-punishment.

More recent works have attempted to distinguish more clearly between guilt and moral masochism. Schematically, it can be averred that in neurotic guilt, the sadism of the superego is in control, while in moral masochism, the ego eroticizes the feeling of guilt. The desire for punishment is then resexualized

in a regressive way, becoming the source of masochistic satisfactions.

## **SELF-REPRESENTATION**

Self representation is the image the subject has of him or herself based on his or her own interpretation. It is one of the factors of the ego and its representation as termed “an individual, differentiated, real, and permanent entity” (Racamier) particularized by a distinctive history and modes of feeling, thinking, and doing.

This accounts for Heinz Hartmann’s distinction between, on the one hand, the ego as a function and

the self as the object of narcissistic investment, and, on the other, “object representations” and “self representations,” meaning the unconscious, preconscious, and conscious representations of the corporeal and mental self within the system of the ego, representations that are invested with both libidinal and destructive energy to become love objects and objects of hatred.

Jacques Lacan took a different approach. In “The Mirror Stage as Formative of the Function of the I as Revealed in Psychoanalytic Experience” (1949/2004), he described the mirror stage as “a drama whose internal pressure pushes precipitously from insufficiency to anticipation—and, for the subject caught up in the lure of spatial identification, turns out fantasies that extends from a fragmented image of the body to what I call “orthopedic” form of its totality—and to the finally donned armor of an alienating identity that will mark his entire mental development with its rigid structure” (p. 6).

Thus self representation is just of one aspect of the subject’s representations, marked by its belonging to the ego—that is, its insertion into reality, the aim of a substantial coherence with its narcissistic dimension and the lure it implies. To varying degrees it can be destabilized, called into question, unmasked by desires and conflicts, or seriously disturbed. The latter may take the form of the radical self-depreciation of melancholia, the overvaluation of self in mania, or a collapse into schizophrenia, where a more or less delusional new self representation is reconstituted as savior of the world, self-creator of all human lineages, of other such variant. Other less dramatic but particularly trying forms occur when the self representation is called into question in borderline states or transformed into transsexualism.

Any existential crisis, particularly in adolescence, can challenge or cause serious disturbances in self representation. These occur in anorexia, bulimia, dysmorphophobia (fear of deformity), or psychotic decompensation, all considered by American authors as defects in self-representation or as pathologies of identity (Erikson). Among the various elaborations proposed by authors who espouse Hartmann’s conception, Edith Jacobson’s has the merit of showing the correlation between the self and the object world, between identity and the feeling of identity within a framework that combines individuation and identification, and thus grants a determining role to the unconscious.

### SELF-STATE DREAM

Heinz Kohut believed that there were two types of dreams: the first expresses verbalizable latent contents, such as conflicts; the second expresses efforts to bind the nonverbal tensions of traumatic states. In the first type, the analyst can follow the free associations of the patient to uncover unconscious meaning. In the second, free associations do not lead to unconscious layers of the mind; rather, the imagery remains on the same level as that of the manifest content. Examination of the manifest content reveals that the healthy sectors of the psyche of the patient are reacting to a changed condition of the self, either overstimulation or depletion or a threatened dissolution. This second type of dream is called a “self-state dream” and is similar to dreams occurring in traumatic states. The correct interpretation of such dreams is to recognize the patient’s specific and general vulnerabilities.

Other writers after Kohut have expanded on his idea, stating that nearly all dreams can be seen as representing the state of the self in that they all express some vulnerability and/or psychoeconomic imbalance. On this view, a dream may be interpreted both as to its latent content and as to its portrayal of the self. These authors see no inherent contradiction in Kohut’s dualistic view of dreams, though some have suggested that patients have limited capacity for association.

### SELF, THE

The concept of the Self that was proposed by Heinz Kohut in *The Analysis of the Self* (1971) is not a Freudian concept and it does not appear as such in the *Vocabulaire de la psychanalyse* (Laplanche and Pontalis); nor does another concept of self that refers to the narcissistic axis of the psyche. When Freud spoke of the instinctive mechanism of “turning around upon the subject’s own self” in “Instincts and Their Vicissitudes” (1915c, p. 126), he did not mean the subject’s own self as an intrapsychic entity, but rather an equivalent of the subject’s own body, upon which the second phase of the drives was founded.

The concept of “Self” is really the invention of Heinz Kohut: the Freudian idea of the “splitting of the ego,” through the Kleinian idea of the splitting of the object molding the ego, by way of the mechanisms of introjection and projection, finally to the Kohutian idea of a Self, which becomes the object of all the narcissistic cathexes.

Understanding Kohut’s model is only possible within the context of the history of ideas. In the 1960s the nosographic concept of limit-states and *borderline* pathologies, belonging neither to neurotic nor psychotic structures, surfaced. This resulted in the progressive delineation of hybrid or composite disorders, centered on issues linked to representation or identity of the Self—that is to say, in the last resort, to narcissistic personality disorders (Otto Kernberg).

Researchers and clinicians had swung back-and-forth from the oedipal to the narcissistic axis. This seesawing may be what is behind the emergence of the concept of Self. In effect, Heinz Kohut proposed a new theory of the ego, adding a notion of the Self, partially of Winnicottian provenance (c.f. Winnicott’s false self) to the Freudian *Ich*.

In any case, the Kohutian theory of the Self has shown itself to be quite fecund. It has had considerably more of an impact in the Anglo-Saxon world than in Europe, especially in France, where it has been often understood as an attempt to desexualize psychopathology, or even as something similar to the ego psychology of Heinz Hartmann, Ernst Kris, and Rudolph M. Loewenstein. Even Kohut has been very critical of the so-called psychology of the ego. Anxious to purify psychoanalysis of any notion foreign to its domain, Kohut first defined empathy as specific to psychology, thinking of it as a technique of vicarious introspection

enabling knowledge of another's psyche. He did this as part of the larger project of extending psychoanalysis to types of personalities previously thought unanalyzable.

Having defined two particular transferences, the "mirror transference" and the "idealizing transference," he reconsidered the question of narcissism, which, according to him, could not be understood as a simple libidinal retreat into the ego. For Kohut, the quality of lived experience defines narcissism, which he then opposes to what he termed a "Self-object" relation, in which other people seem to exist predominantly in roles defined by function. In the cure, as in psychic ontogenesis, narcissism and object love develop conjointly and interactively, with Self-object roles finding themselves gradually interiorized in the form of internal regulatory structures (there is a hint of a goal of adaptation in this model).

On this basis, in *The Analysis of the Self* (1971), Heinz Kohut proposed what he called a restricted theory of the Self and, later, what he called a general theory of the Self. This was presented as complementary to Freudian theory, but in reality it attempted to subsume the latter into a larger model. The Self became progressively a relatively autonomous principle of motivation, integrating the drives, and accorded its own program of realization; it no longer was separate from the Self-object, a concept that was enlarged to include the entire narcissistic dimension of experience. A third kind of transference was described as "alterego transference," where the controlling element is the need for a peer, particularly someone of the same sex. For Kohut, the Self is something very much different from intrapsychic entities like the ego, id, or superego.

Beyond a certain number of notions, like the corporal or archaic Self, the nuclear Self, the consistency of the self, the permanent disintegration of the self, the fragmented self, and self-esteem, Kohut has particularly emphasized the notion of the grandiose Self to try to account for "the child's solipsistic vision of the world and the manifest pleasure he derives from the admiration he receives from it." However, his descriptions of the grandiose Self cover a wide range of phenomena, from "paranoiac delirium and the crudely sexual acts of the adult pervert, to certain kinds of simple, sublimated satisfaction that adults derive from what they are, what they do, and what they succeed in."

Some authors have attempted to deal with the concept of Self from a more topical point of view.

Among them is Jean Bergeret, who describes the ego ideal as originating in the maternal, rather than the paternal, attachment. Finally, the concept of the Self, in spite of all ambiguity and the criticism directed at it, has been shown to be of heuristic value; it has influenced many works, including *The Privacy of the Self* (1974), by Masud Khan, and, more recently *The Forces of Destiny* (1989) by Christopher Bollas. For Bollas, the destiny of the subject is the result of an encounter with an object; certain objects favor the emergence of the true Self, while others obstruct and condemn the individual to organize himself around a false Self.

Donald W. Winnicott has also used the notion of the Self in developing his work on the "false self." Both concepts, however, invite questions about the status of the Freudian theory of drives, which runs the risk of being somewhat obscured.

## **SELF, THE (ANALYTICAL PSYCHOLOGY)**

Jung originally defined his concept, "the Self," (Selbst), as follows: "As an empirical concept, the Self designates the whole range of psychic phenomena in man. It expresses the unity of the personality as a whole."

“But insofar as the total personality, because of its unconscious component, can only be partly conscious, the concept of the Self is, in part, only potentially empirical and is to that extent a postulate. In other words, it encompasses both the experienceable and the unexperienceable (or the not-yet experienced). From an intellectual point of view it is only a working hypothesis. Its empirical symbols, on the other hand, very often possess a distinct numinosity, that is, an emotional value. It thus proves to be an archetypal idea . . . which differs from other ideas of the kind in that it occupies a central position befitting the significance of its content and numinosity.”

Of the content and development of his ideas, Jung wrote: “The Self appears in dreams, myths, and fairy tales in the figure of a ‘supra-ordinate personality,’ such as a king, prophet, or savior, etc., or in the form of a totality symbol, such as the circle, square. . . . When it represents . . . a union of opposites it can also appear as a united duality in the form, for instance, of Tao as the interplay of Yang and Yin.” Related ideas pertaining to Self-symbolism were initially described by Jung: “The Self is not a philosophical idea since it does not predicate its own existence.”

By way of critical appraisal the *Journal of Analytical Psychology* published a symposium on the self in 1985. In Joseph L. Henderson’s contribution it is written: “I am impressed with how much serious thinking by Jungian analysts has gone into clarifying the multifaceted subject. For the most part the theoretical basis as expressed by Jung himself has been reaffirmed, namely that the Self as a symbol of totality of psychic life and as a central archetype of order equally exist.”

But if we place metaphor to one side and look at the manifestation of self-hood in action we may find our centering totality at work in more humanly understandable forms, as in analysis where analyst and analysand enter into a common ego-self relationship.

The self in this context approaches the concept of the self in other psychologies, such as Kohut’s self-psychology. Perhaps Jungians are in general becoming more comfortable with self as a psychological concept only and less in awe of the self as an archetype with its metaphysical aura.

Knowing the danger that too much emphasis upon the self may have an inflationary effect on the ego (grandiosity), or that too little emphasis upon it may aggrandize the importance of ego consciousness over

the unconscious, normal self-definition is found where ego and self are separate but inherently related. Jung writes: “Sensing the Self as something irrational, as an undefinable existent, to which the ego is neither opposed or subjected, but merely attached, and about which it revolves very much as the earth revolves around the sun—thus we come to the goal of individuation.” The individuated ego senses itself as the object of an unknown and supra-ordinate subject. It seems that a psychological inquiry might come to a stop here.

## **SELF (TRUE/FALSE)**

Donald Winnicott used the term “self” to describe both “ego” and self-as-object. He describes the self in terms of a psychosomatic organization, emerging from a primary state of “unintegration” by gradual stages. The true self, which in health expresses the authenticity and vitality of the person, will always be in part or in whole hidden; the false self is a compliant adaptation to environmental impingement.

This characteristically fluid use of the term can be traced throughout his work, evolving in terms of true and false selves. The first paper to clarify the existence of true and false selves as entities is “Aggression in Relation to Emotional Development” (1950–55). Winnicott, from within his own object-relations

theory, postulates the necessity for the innate maturational tendency to operate within the facilitating environment (1960). This is expressed in terms of the individual baby's need for an environment allowing uninterrupted continuity of being, which lays the foundations for psychosomatic integration, aliveness, and the beginnings of awareness of self, true self being "the summation of sensori-motor aliveness." In several papers, notably "Primary Maternal Preoccupation" (1956) and "Ego Distortion in Terms of True and False Self," (1960) he describes the exquisite adaptation, or primary maternal preoccupation in the new mother, whose handling (and in particular, holding) of her infant, protects the baby from "impingement," or environmental failure. Within such holding, which must involve both physical contact and empathic attunement, "going on being" is supported, and this allows the beginning of individuation. Environmental failure at this stage, when primitive agonies threaten, can result in psychosis, which Winnicott thought of as an environmental deficiency disease (1949).

Later, careful maternal adaptation must of necessity fail, gradually, and in stages (good-enough mothering), at such a pace that the developing infant can manage each stage, and replace each environmental lack with mental activity. Early on, the "good-enough mother" succeeds repeatedly in meeting and realizing the infant's sensory hallucination, or "gesture," thus allowing in infantile sense of omnipotence and the development of the later capacity for symbolization. With gradual failures of response from mother, the infant's experience of omnipotence can then be gradually relinquished, and recognition of reality, together with spontaneity and authenticity, becomes possible—the "true self."

The "not-good-enough mother" cannot respond sensitively and empathically, and fails to "meet the infant's gesture." While the infant can adapt to this up to a point, filling the gap with hallucination, eventually this mechanism fails and the infant loses touch with their own needs, responds excessively to the environment, and becomes "impinged upon," traumatized, and incapable of symbol-usage. At this point the infant, seduced into compliance, develops a "false self," reacting to environmental demands and relinquishing or hiding the remnants of spontaneity, the "true self." The existence of the "false self" is a defense against the feared annihilation of the true self, and becomes a

"caretaker self," taking over those functions unfulfilled by mother.

In some infants, particularly those well endowed with intellectual potential, the mind becomes the "caretaker self," over-valued and in conflict with the psyche-soma (1949). Winnicott described five degrees of false self formation, from severe limitation of spontaneity and liveliness with convincing imitation of normality, to those ordinary social adaptations necessary for life in human society. False self personalities may be superficially successful, but empty; they may become caretakers of others while being unable to allow dependency in themselves.

Winnicott believed that in psychoanalysis regression was a necessary phase for "false self personalities," in order to work through the earliest environmental failures. He advised against inexperienced analysts taking on this kind of work.

Winnicott's work has been usefully adapted in several ways. For Ronald Fairbairn, the "schizoid personality" derives from his understanding that the infant's primary need is for intimacy. In his reading environmental failure leads to splitting and to defenses against it. Michael Balint's "harmonious mix-up" can be seen as an early undifferentiated phase; his ideas about the "basic fault" relate to primary position of the infant's desire to be loved by its mother. Heinz Kohut develops a "psychology of the self" and describes "maternal self-object functioning." Margaret Mahler locates in early childhood a "symbiotic fusion" with the mother, and describes separation/individuation phases. Daniel Stern compares the "core self" and the "self with other."

Winnicott, while not abandoning drive theory, stresses the importance of relationships from the beginning. His writing is elusive, idiosyncratic, and often cryptic. Unlike Melanie Klein, whose concern was with the infant's internal, often instinctual struggles, his focus was on the emergence of the individual from the earliest relationship, an emergence which could be adversely affected by either impingement or deficiency of provision.

## SEMINAR, LACAN'S

In contrast with Freud, whose work was primarily written, Jacques Lacan's work was for the most part an oral improvisation from notes delivered as an ongoing seminar that he held in Paris from 1953 to 1980. From 1953 to 1963, Lacan's seminar was held at the Sainte-Anne Hospital in Paris. From 1964 to 1969, starting with seminar 11, it was held at the École Normale Supérieure on rue d'Ulm. And finally, from 1969 to 1980, starting with seminar 17, it was held before a much larger audience in the amphitheater of the law school at the Panthéon.

Even during Lacan's lifetime, the seminar circulated in the form of photocopies of diverse and unreliable written versions of the spoken text. Beginning in 1973, Lacan entrusted the transcription of the seminar to Jacques-Alain Miller. In an editor's note to *The Four Fundamental Concepts of Psychoanalysis*, the first of his publications of Lacan's seminars, Miller wrote, "My intention here was to be as unobtrusive as possible and to obtain from Jacques Lacan's spoken work an authentic version that would stand, in the future, for the original, which does not exist" (p. xi).

The individual seminars that make up Lacan's seminar are as follows:

a) Seminar 1 (1953–1954): *Freud's Papers on Technique*. (John Forrester, Trans.) New York: W. W. Norton, 1988.

b) Seminar 2 (1954–1955): *The Ego in Freud's Theory and in the Technique of Psychoanalysis*. (Sylvana Tomaselli, Trans.) New York: W. W. Norton, 1988.

c) Seminar 3 (1955–1956): *The Psychoses*. (Russell Grigg, Trans.) New York: W. W. Norton, 1993.

d) Seminar 4 (1956–1957): *La relation d'objet* (Object relations). Paris: Seuil, 1994.

e) Seminar 5 (1957–1958): *Les formations de l'inconscient* (Formations of the unconscious). Paris: Seuil, 1998.

f) Seminar 6 (1958–1959): *Le désir et son interprétation* (Desire and its interpretation). Unpublished.

g) Seminar 7 (1959–1960): *The Ethics of Psychoanalysis*. (Dennis Porter, Trans.) New York: W. W. Norton, 1992.

h) Seminar 8 (1960–1961): *Transfert* (Transference). 2nd ed. Paris: Seuil, 2001.

i) Seminar 9 (1961–1962): *L'identification* (Identification). Unpublished.

j) Seminar 10 (1962–1963): *L'angoisse* (Anxiety). Paris: Seuil, 2004.

*Name-of-the-Father* was to be the next seminar, but only a single session was given, on November 25, 1963, at Sainte-Anne Hospital. Lacan stopped giving this seminar when he learned that the International Psychoanalytical Association had refused to reinstate him as a training analyst.

k) Seminar 11 (1964): *The Four Fundamental Concepts of Psychoanalysis*. (Alan Sheridan, Trans.) New York, W. W. Norton, 1978.

l) Seminar 12 (1964–1965): *Problèmes cruciaux pour la psychanalyse* (Crucial problems for psychoanalysis). Unpublished.

m) Seminar 13 (1965–1966): *L'objet de la psychanalyse* (The object of psychoanalysis). Unpublished.

n) Seminar 14 (1966–1967): *La logique du fantasme* (The logic of fantasy). Unpublished.

o) Seminar 15 (1967–1968): *L'acte psychanalytique* (The psychoanalytic act). Unpublished.

p) Seminar 16 (1968–1969): *D'un Autre à l'autre* (From one Other to the other). Unpublished.

q) Seminar 17 (1969–1970): *L'envers de la psychanalyse* (The other side of psychoanalysis). Paris: Seuil, 1991.

- r) Seminar 18 (1970–1971): *D'un discours qui ne serait pas du semblant* (On a discourse that might not be a semblance). Unpublished.
- s) Seminar 19 (1971–1972): ... *ou pire* (... or worse). Unpublished.
- t) Seminar 20 (1972–1973): *On Feminine Sexuality: The Limits of Love and Knowledge, Encore*. Translated by Bruce Fink. New York: Norton, 1998.
- u) Seminar 21 (1973–1974): *Les non-dupes errent* (Those who are not duped err). Unpublished.
- v) Seminar 22 (1974–1975): *R.S.I. Ornica? 2–5*.
- w) Seminar 23 (1975–1976): *Le sinthome* (The sinthome [an archaic spelling of the word “symptom”]). *Ornicar? 6–11*.
- x) Seminar 24 (1976–1977): *L'insu que sait de l'une bévue s'aile à mourre*. *Ornicar? 12–18*.

The punning French title of this seminar is based on a fanciful French translation of the German word for the unconscious, “Unbewusste,” as “une-bévue,” which means a blunder or a mistake. As written, the title might be translated as “The unknown that knows about the one-blunder chances love.” But as spoken, with written puns ignored, the French title might be rendered most simply as “L'insuccès de l'une-bévue, c'est l'amour,” which means “Love is the failure of the one-blunder.”

- y) Seminar 25 (1977–1978): *Le moment de conclure* (Time to conclude). Unpublished.
- z) Seminar 26 (1978–1979): *La topologie et le temps* (Topology and time). Unpublished.
- aa) Seminar 27 (1980): *Dissolution*. *Ornicar? 20–23*.

Because Lacan was old and ill, seminar 27 was not delivered publicly but only published. It dealt with the dissolution of his school, École freudienne de Paris (Freudian School of Paris).

## SENSE/NONSENSE

Unlike meaning (*signification*), which unites a signifier, the material manifestation of the sign, to a signified, the concept to which it corresponds, sense (*sens*) has an axiological dimension: It is a sense “for” and orders a behavior by linking an object to a desire. Jacques Lacan (1966) and Piera Aulagnier (*The Violence of Interpretation: From Pictogram to Statement, 1975/2001*) showed that the preverbal infant's manifestations of needs are interpreted by the mother as signs that have a sense. She will consequently respond to them according to her own desire, which will or will not be in agreement with the sense that she has given to the infant's demand. The latter's responses will in turn take on sense and value for her. Sense later corresponds to a need for causality that constitutes, in the realm of thought, the equivalent of a rediscovery of the earliest experience of satisfaction.

In Lacan's work there is a specific theory of sense that will not be treated here. In the work of Sigmund Freud, this issue was essentially addressed in connection with jokes and the pleasure of sense in nonsense. Traces of the issue are nevertheless present elsewhere, particularly in all of the manifestations of the unconscious that the subject takes to be absurd or devoid of sense. However, Freud was much more specific about absurdity in dreams, which is not just a product of its noninterpretation. In *The Interpretation of Dreams* (1900), he wrote: “A dream is made absurd, then, if a judgement that something ‘is absurd’ is among the elements included in the dream-thoughts—that is to say, if any one of the dreamer's unconscious trains of thoughts has criticism or ridicule as its motive. Absurdity is accordingly one of the methods by which the dream-work represents a contradiction. . . . Absurdity in a dream, however, is not to be translated by a simple ‘no’; it is intended to reproduce the *mood* of the dream-thoughts, which combines derision or laughter with the contradiction” (pp. 434–435). This is the laughter of irony, the oedipal game par excellence, for it perverts the identification that is supposedly necessary to the edification of the superego by

identifying not with the manifest level of what is given as an example, but with its latent, infantile, and instinctual content. In this, the joke converges with the art of the ellipsis characteristic of ironic persiflage, by actualizing what Freud, in “Jokes and Their Relation to the Unconscious” (1905), calls an “omission without a substitute” (p. 77), in which the forbidden representation disappears.

How does nonsense become a joke? The nonsense contained in a joke is in fact a criticism; it imitates a supposedly profound proposition that in reality is ridiculous or a sophistry, and, precisely in doing so, reveals the nonsense behind its respectable appearance. Hence Freud’s formulation in “Jokes and Their Relation to the Unconscious”: “[I]n jokes nonsense often replaces ridicule and criticism in the thoughts lying behind the joke” (p. 107). However, the tendentious joke also uses a technique characteristic of jokes in general, which is “pleasure in nonsense” (p. 125), a relic of the pleasure of playing with words for their assonance alone, independent of meaning. Children, like adults, give themselves up to this pleasure, fully aware of its absurdity, just for the sake of the attraction of fruit forbidden by reason. Inherent in this is a perspective that goes beyond tendentious wit, since the capacity for rational thought is what is challenged here.

In “Jokes and Their Relation to the Unconscious” Freud associated this pleasure of untrammelled nonsense with adolescence, but also with adults in a relaxed state, especially as a result of drinking alcohol. He cited as examples the “cheerful nonsense of the *Bierschwefel* (a ludicrous speech delivered at a beer party)” and the *Kneipzeitung* (literally, “tavern newspaper”; a comic set of minutes), and noted: “Under the influence of alcohol the grown man once more becomes a child, who finds pleasure in having the course of his thoughts freely at his disposal without paying regard to the compulsion of logic” (p. 126). Pleasure in nonsense, a challenge to the constraints of reason and a narcissistic claim to being the omnipotent master of meaning, appeared to Freud to be the basis for the “sense in nonsense” factor: “The psychogenesis of jokes has taught us that the pleasure in a joke is derived from play with words or from the liberation of nonsense, and that the meaning of the joke is merely to protect that pleasure from being done away with by criticism” (p. 131). In the mind, nonsense appears as an end unto itself, and “the intention

of recovering the old pleasure in nonsense is one of the joke-work’s motives” (p. 176).

However, we can wonder about the function of this challenge, precisely because it allows sense to subsist. More than a destruction, at issue here is a condensation that brings to light contradictions, and this process could be compared to what Freud wrote in “The Antithetical Meaning of Primal Words,” emphasizing, with the linguist Karl Abel, that “our concepts owe their existence to comparison” (p. 157) and in consequence they simultaneously express contradictory images, each of them ensuring its pregnancy by its relational dependence on the other.

For sense constitutes a fundamental need, and when the a-sense of psychosis develops, this again involves a sense in revolt against another that has been unduly imposed upon the subject. Aulagnier showed how psychosis does not stem from a revolt of the id against reality, as Freud stated, but rather from “the struggle the infantile psyche puts up each time it is confronted with the powerlessness of the maternal discourse to make sense of lived experience and with the overwhelming power of the mother’s desire to appropriate the ‘thinking activity’ of the child.” Aulagnier, like Wilfred Bion (1963), showed how the mother substitutes for the a-sense of the real a reality that is cathected and thought by the mother, who retransmits it to the baby. This work of sense-making is later incumbent upon the I itself, and accordingly, causal explanations are a part of what is necessary for thought. This sense is not abstract, for it is initially a libidinal sense, all acts of knowledge being preceded by an act of cathexis. Constructing sense makes the I’s relationship to reality coherent; such, then, is the primary function of the activity of thinking and, accordingly, delusions themselves will have as their function the creation of a meaningful interpretation of the violence undergone by the subject (Mijolla-Mellor).

## SERVADIO, EMILIO (1904–1994)

Emilio Servadio, an Italian physician and psychoanalyst, was born in Sestri (Genoa) in 1904 and died in Rome in 1994. Servadio was born into a Jewish family and studied in Genoa, where he received a law degree. He wrote his dissertation on forensic medicine, specifically about hypnosis. It was the beginning of his interest in paranormal phenomena, which became one of his primary areas of research throughout his life.

Servadio was the editor of the *Enciclopedia italiana Treccani* in Rome, where he settled in 1929. He met Edoardo Weiss and asked him to write several articles on psychoanalysis for the encyclopedia. Weiss, in turn, began analyzing Servadio, who became a devoted student of psychoanalysis. After his departure for America, he remained in contact with Servadio, who was always grateful to Weiss for the role he played in his training.

In 1934 at the Lucerne Congress, in which the Italian contingent, led by Weiss, participated for the first time, Servadio made his first appearance on the international psychoanalytic scene by presenting a study on the links between psychoanalysis and telepathy. His paper, “Psychoanalysis and Telepathy,” was subsequently published in *Imago*. For the time it was an innovative and courageous work, in which he tried to relocate the telepathic phenomena that occur during the course of a séance within the framework of the patient-analyst relationship.

Far from leading Servadio to abandon an original field of research, his encounter with psychoanalysis—as his most brilliant student, Eugenio Gaddini, has written—enabled him to “investigate as fully as possible his initial aspirations and make use of an investigative method appropriate to the study of paranormal phenomena.”

Servadio’s use of psychoanalysis was unconventional and could have had an influence on psychoanalysis through his focus on the scope of counter-transference phenomena, which he wrote about in 1962 in an article that appeared in the *Rivista di psicoanalisi* (VIII, [2]). In 1939, because of the race laws then in effect in Italy, he was forced to leave the country. He settled in India, attracted by Asian cultures and ancient religions.

After his return to Italy in 1946, Servadio was, together with Nicola Perrotti and Cesare Musatti, one of the principal protagonists in the rebirth of psychoanalysis in the country. In 1962 he created a center for psychoanalysis in Rome and was president of the Italian Psychoanalytic Society (SPI) from 1964 to 1969.

Servadio was highly esteemed within the International Psychoanalytic Association (IPA) and was a friend of Anna Freud, Marie Bonaparte, and Ernest Jones; within the Italian psychoanalytic movement he played the role of institutional tutor. At the end of the 1950s, he visited Weiss, then in America, to request that an audit committee from the IPA come to Italy to ensure that its training regulations were consistent with international norms. In 1992, leading a minority group that had broken with the SPI, he helped form a second Italian Psychoanalytic Society, which was recognized by the IPA in 1993.

Although Servadio was intransigent in institutional matters and a brilliant writer and popularizer of psychoanalysis, he was very open-minded in matters of behavior and current events. He was a prolific writer, primarily in the field of applied psychoanalysis, with essays on a wide range of topics. They include his “Funzione dei conflitti preedipici” (Functions of pre-oedipal conflicts), published in 1953 in the *Rivista di psicoanalisi* (republished in issue 20 [3], 1974, devoted to Servadio), which remains his most important contribution to metapsychology.

## “SEVENTEENTH-CENTURY DEMONOLOGICAL NEUROSIS, A”

In this work Sigmund Freud examined the case of Christopher Haitzmann, a painter whose story he had learned from documents preserved in the sanctuary at Mariazell (in Lower Austria).

According to these documents, in 1668 Haitzmann wrote and signed in his own blood a pact with the Devil, thereby becoming his son and, in addition, vowing to belong to him body and soul nine years later. In 1677, when the nine years were almost up, Haitzmann was seized with remorse and terror, asked for help from monks, and was freed from his promise through the intercession of the Virgin Mary. Among the documents preserved at Mariazell are his diary, relating the apparitions of Satan, paintings by Haitzmann himself illustrating these scenes, and texts written by monks who witnessed or were commenting on the miracle. These documents were the basis for Freud’s analysis.

Freud emphasized the evidence of the psychopathological problems afflicting this man. He further noted that the “pact with the Devil” had been concluded at a time when Haitzmann, having no commissions and suffering from serious inhibitions in his work, had been reduced to poverty. This distress grew more acute at the death of his father, and shortly thereafter he declared himself to be Satan’s son, thus instituting Satan as a father substitute—although in Haitzmann’s paintings Satan was depicted with monstrous breasts. Referring back to the Schreber case, published twelve years earlier, Freud interpreted this “demonological neurosis” as stemming from Haitzmann’s homosexual position in relation to his father, and from the castration anxiety linked to such a position (cf. Malcapaine and Hunter; Urtubey).

## SEX AND CHARACTER

Otto Weininger began to draft *Sex and Character* in 1900, at the time when Hermann Swoboda informed him of Freud’s interpretation of bisexuality, and the book was elaborated concurrently with an exchange of ideas between the two friends. In 1901, having registered his manuscript, then called *Eros and Psyche*, in order to preserve his intellectual property rights, he wished to have it published and to this end this he met with Freud who took an unfavorable view of it. In 1902 Weininger successfully presented his reworked manuscript for his doctoral thesis in philosophy. He converted to Protestantism and then presented a third version of the book, which was characterized by the addition of chapters on Jews and women and the fact that he extended the metaphysical system.

First published in 1903 by a major publisher, Braumüller, the book became a bestseller after its author’s suicide. It ran to twenty-eight editions between 1903 and 1947 and was translated into ten languages. Many articles in *The Torch* (*Die Fackel*) contributed to the success of the book, as did accusations of plagiarism, by Paul J. Moebius in 1904 and most of all by Otto Fliess in 1906. Otto Rank was convinced by the work, each of its arguments reflecting his personal experience: “They were even expressed in my own terms,” he said. In a footnote to Herbert Graf’s (“Little Hans”) analysis, Freud wrote that “Being a neurotic, Weininger was completely under the sway of his infantile complexes; and from that standpoint what is common

to Jews and women is their relation to the castration complex" (1909b, p. 36).

Although consisting of multiple philosophical digressions, Weininger's book does in fact revolve around a central question that brings it closer to psychoanalytic research, the impossibility of establishing a definite group relation between the sexes. For Weininger there were two ideal types, M and F, which are analogous to Platonic types. Real individuals were intermediary bisexual states, defined by their proportions of M and F. There was no break in nature between masculine and feminine but a bisexual structure in varied proportions which, because of psycho-physiological parallelism, involved both the microscopic body and the mind. This Male/Female mosaic explains sexual attraction, which seeks to achieve complementarity: a man with the equation  $3/4M+1/4F$  seeks a woman with the equation  $3/4F+1/4M$ . It thus transpires that the ideal relation would be between a homosexual man and a homosexual woman. However, men and women who are attracted to each other are corporally individuated; they are not types. Weininger realized that: "In spite of the infinite gradation of the intermediary forms, the human being is definitively either man or woman," but diverges from the point when he postulates a substance that he used as the basis of his characterology. The permanent confusion between the outline of substantialized types and empirical experience gives his statements about women a shocking character—"The absolute female has no ego" (p. 186). The same holds true for his comments on Jews, whom he compares to women, speaking of Judaism as a "Platonic idea" (p. 311). For this reason he sometimes has to explain that he does not wish to "lend the faintest support to any practical or theoretical persecution of Jews" (p. 311). Jewish himself, Weininger's thesis is a testament to what he calls "self hatred."

## SEXUAL DIFFERENCE

Sexual difference refers to recognition by the child of the difference of the sexes. This recognition is related to the Oedipus complex and the castration complex.

In 1908 (1908c) Sigmund Freud presented for the first time the notion of the castration complex, centered on fantasies of castration and closely linked to the drives. Through this complex, whose framework is the "theory of infantile sexuality," the child is able to acknowledge sexual difference. In the same text Freud indicated that before the question of castration becomes important for the child, the child is capable, through the use of external signs, of making a (gender) distinction between men and women. Of its own initiative, the child will develop a sense of gender identity—male or female. This distinction is not dependent on the drives or the genitals. It is only with the "primacy of the phallus" (1923e) that the genital organ will be taken into account for both sexes, based on the presence or absence of the male genital organ. It is this awareness that leads to the question of castration. Moreover, it is through identification with the father and mother during the oedipal period that the child acquires the symbolic cues for masculine and feminine, whose dynamic will not be completed until adolescence. At that time, the material reality of the penis-vagina duality will replace the apparent reality of the phallus-missing phallus duality.

By separating penis and phallus and emphasizing symbolic castration, an operation through which the subject is formed, Jacques Lacan provides a very different interpretation for the castration complex, which now becomes dependent on phallic logic. If human sexuality is immediately subverted by language and if "the imaginary function of the phallus completes the challenge to sexuality through the castration complex in both sexes" (1958), then understanding what differentiates the sexes becomes problematic. Lacan then developed his idea of sexuation—a term borrowed from biology—to show the subject's modes of inscription in

the phallic function. This refers to the way in which both sexes recognize and differentiate themselves in the unconscious.

Since Freud recognized that his description related only to boys and for Lacan the relation to the phallus “was established without regard for the anatomical difference of the sexes,” we are led to the conclusion that psychoanalytic theory on sexual difference and, in particular, on what a woman is, remains highly incomplete.

Finally, it is important to point out that sexual difference, which enables the subject to relate to its own anatomical sex and position itself as man or woman, introduces important questions in psychoanalysis, as important as the problematic of identification/identity.

## **SEXUAL DRIVE**

“... The sexual [drive] does not originally serve the purposes of reproduction at all, but has as its aim the gaining of particular kinds of pleasure. It manifests itself in this way in human infancy, during which it attains its aim of gaining pleasure not only from the genitals but from other parts of the body (the erotogenic zones)... We call this stage the stage of auto-erotism... The development of the sexual [drive] then proceeds from auto-erotism to object-love and from the autonomy of the erotogenic zones to their subordination under the primacy of the genitals which are put at the service of reproduction” (Freud, 1908d, p. 188). The psychoanalytic movement is a revolution of “The sexual [drive]—or more correctly, the sexual

[drives], for analytic investigation teaches us that the sexual [drive] is made up of many separate constituents or component [drives]” (p. 187).

Thus Freud dissociated reproduction and sexuality. The innate sexual drive appears in earliest infancy. Its composite origin accounts for its perverse, neurotic, and normal adult manifestations, which appear in a vast synthesis. The importance of its dynamic manifestations in the psyche is well recognized in the form of libido, which is the fixed point in psychic conflict. The libido is opposed first to the drives of self-preservation or the ego drives, and then to the death drive. In this latter case, the libido goes under the name of “life drives” or Eros.

The term *Geschlechtstrieb* (sexual drive) appeared in 1894, at the same time as “libido” (1895b [1894]). In 1895, Freud published a review of a lecture entitled, “Der Geschlechtstrieb,” and denounced the underestimation of the sexual drive (1895i). He noted the importance of sexuality in the etiology of the neuroses and referred to “the participation of sexual motive forces as an indispensable premise” (1896c, p. 200). The discovery of infantile sexuality and its synthesis with the diversity of adult sexual life was announced in 1905 in the *Three Essays on the Theory of Sexuality* (1905d).

The *Three Essays* can be credited with “enlarging the concept of sexuality” (1905d, p. 134). Insofar as it is supported by all the other vital functions, the sexual drive in infancy is perverse, ubiquitous, and a composite of partial drives. Education and the development of the ego are able to modify the sexual drive: with no predetermined object it is entirely plastic, except for fixation. When its energy is deflected, libido can be invested in the interests of the ego and of culture. This view of the sexual drives (though disturbing) accounted for the essentials of psychic energy with repression playing a central role and is to be modified through the next two steps. Libidinal investment in the ego makes its appearance as an original contribution, necessary and essential to the sexual drive for survival. And then it is only the sexual drives that have the power to stand against the death drive.

As the very paradigm of the drive, the sexual drive is so central that there could be no conception of psychoanalysis without it. As Freud stated at the time of his break with Carl Jung in 1913, to dispute the importance of the sexual drive is tantamount to rejecting psychoanalysis.

## **“SEXUAL ENLIGHTENMENT OF CHILDREN, THE”**

This short text by Freud was written in the form of an open letter addressed to Dr. Fürst for publication in a journal on social medicine and hygiene. “The Sexual Enlightenment of Children” is contemporaneous with the *Three Essays on Sexuality* (1905d) and “Little Hans” (1909b), in both of which this same question of infantile sexual curiosity is developed. However, in this essay Freud discusses the ethical and epidemiological (with regard to the prevention of neuroses) aspects of a question he will examine from a more relativist perspective thirty years later in “Analysis Terminable and Interminable” (1937c).

Freud’s question has three components: “Can we, in general, supply explanations to children about sexual activity? At what age and how?” Freud strongly rejects the relevance of the first question, arguing that any possible refusal will only lead the child to obtain the withheld information from a different source and consider sexuality as something dirty. His principal argument is related to the existence of infantile sexuality as revealed in the *Three Essays* and he concludes that “refusal” only deprives the child of the ability to

intellectually overcome the exploits for which he is psychically prepared and somatically ‘adjusted’ except with respect to reproduction.”

Freud addressed the two major problems that preoccupy the child: the difference between the sexes and the origin of children, and he refers to infantile sexual theories, which are first discussed in a short essay that would be published later on (“On the Sexual Theories of Children,” 1908c). He concluded with these words: “What is most important is that children never develop the idea that we prefer to hide from them the facts of sexual life rather than other facts that are not yet accessible to their understanding.” The question of how to express this is resolved in the suggestion of adapting knowledge of sexual matters to knowledge of animal life in general, depending on the age and aptitude of the child.

This short essay is a precious example of how concepts in ethics and pedagogy can be spontaneously generated by the process of psychoanalytic discovery.

## **SEXUAL THEORIES OF CHILDREN**

In Freud’s view, children’s sexual theories arise neither in response to “some inborn need for established causality” nor out of an interest in sex that assumes a theoretical dimension. Rather, they are the product of a life need (*Lebensnot*) that encourages the child to master in thought, and perhaps even to avert, the feared arrival in the family of a new, younger sibling with whom the parents’ love will have to be shared.

Such theories seek to explain the differences between the sexes and the origins of sexual relations. Three aspects may be considered for each theory: its content, the modalities of its development, and the sexual (not theoretical) cathexis that the child can thereby mobilize. In this last aspect, the child’s sexual

theories closely resemble fantasies in that they are largely excluded from the demands of critical reasoning. Freud describes children's sexual theories as the direct expression, uninhibited and untransformed, of infantile sexual component instincts. This explains why children can maintain "accurate" theories, imparted by adults, alongside their own, for which they have a preference of an instinctual kind. "For a long time after they have been given sexual enlightenment [children] behave like primitive races who have had Christianity thrust upon them and who continue to worship their old idols in secret" (Freud, 1937c, p. 234).

More generally, the sexual fantasies of adults, especially masturbatory fantasies, may be looked upon as remnants of childhood theories. They are never abstract, for they are accompanied by a sexual excitement that supports the ideational content.

The sexual cathexis of a "theoretical" realm offers the best possible example of the origin of the sublimating function, which makes possible a diversion of sexual excitation to a theoretical activity dissociated from sexual questions (investigation and the invention of answers to riddles). This process, however, may be eliminated, impeded (as in inhibition), or aborted (as in obsessional rumination). According to Freud, the construction of childhood sexual theories is based on information provided by adults and other children and also on the sensations of the child's own body that accompany the work of thinking: "If children could follow the hints given by the excitation of the penis they would get a little nearer to the solution of their problem" (Freud, 1905d, p. 218). Observation of the animal world can also be a source of "exact" knowledge and the basis of projections, as with "little Hans" and the horse (Freud, 1909b).

It is fair to say, even though Freud does not theorize matters thus, that the case history of little Hans reveals the role of language in how children work out their theories. Before it is possible to speak of a theory, and not merely of a fantasy, what is being represented must be capable of attaching itself to words. If in general the naming of affects always falls short of reality, this is especially flagrant when a child has to relate direct experience as murky and violent as that associated with the primal scene (adults engaged in sex) or birth. So the child sets up a divide: the child reacts to experience by either abdicating or else relentlessly pursuing a quest for a theory that no

setback can stop, since it merely supplies another motive for research.

The content of childhood sexual theories, as described by Freud, is confined to a few typical ideas that can also be found in folklore and that constitute the basis of complexes (as for example the castration complex). However, the subject matter of these theories is just as varied as the content of ordinary fantasies (as distinct from primal fantasies). The content depends on whatever elements the child happens to come across: magical words, formulas, distorted words given a sexual meaning by the child (like the phrase "horse way" for Little Hans), or obscenities (Ferenczi, 1910).

At first sight, the term "sexual theories" might seem open to objection, but the great utility of the notion has been demonstrated by the link it makes between abstract theorizing and the sexual origins of such theorizing. These theories are clearly marked by a childish manner of thinking, a cumulative logic in which one causal explanation can be superimposed upon another without creating any contradiction overall. The child's research does not proceed by making use of known elements in order to master other, unknown elements, which is the usual form of the theoretical approach; instead, the child collects heterogeneous clues, because one mystery may stand for another and can therefore be conjoined with it (Mijolla-Mellor, 1999).

## SEXUAL TRAUMA

The term *sexual trauma* refers to a sexual situation that causes intense fear because the subject, a child, is exposed to it in a state of passivity and unpreparedness.

Classical psychiatry was already interested in traumas when Freud was developing his ideas. He borrowed the term, but replaced the psychiatric notion of a shock from a serious accident causing a fear of death with that of the impact of sexual aggressions against children. In a letter of October 15, 1895, he wrote to Wilhelm Fliess: “Have I revealed the great clinical secret to you?... Hysteria is the consequence of a presexual *sexual shock*” (1954a [1887–1902], p. 127). The notion of sexual trauma was here implicitly evoked for the first time; it would play a fundamental role in the history of psychoanalysis.

In the early days of his practice, Freud concluded from the frequency with which his patients recounted sexual scenes that such adult seductions of children were real, and that psychical traumas were always sexual in nature. Based on these clinical observations, Freud developed a theory, in 1895–1897, of the two-step effect of the trauma. According to this view, an initial event left traces that would be awakened a later time, usually at puberty, and lead to a flooding of the psyche with libidinal energy and a corresponding generation of anxiety.

With the discovery of infantile sexuality (1905d), Freud realized that scenes of seduction were often fantasy reconstructions; nevertheless, despite the abandonment of what he called his “*neurotica*,” he never stopped worrying about the question of just how fictitious and how real such scenes were. What was traumatizing in Freud’s view was not the event per se but the affects and representations, including fantasies, to which it gave rise. Its impact was a function of the

time it occurred relative to the child’s ego development and ability to metabolize the excitation thus initiated and relative to the effects it had on the child’s fantasy organization. For a trauma to be represented on an inner stage, and in more than one phase—and so to “offer by far the more favorable field for analysis” (Freud, 1937c, p. 220)—it must be neither premature nor too strong.

Sexual trauma, as defined by Freud in his first topography, cannot be understood independently of the notions of seduction, repression, deferred action, and internal versus external reality. At this phase of his thinking Freud did not yet consider the narcissistic injury caused by such traumas. And in his concern to locate scenes of seduction at an ever earlier date and to study their much later pathological effects—a concern that necessarily put the spotlight on the mechanism of deferred action—he paid scant attention to sexual aggressions suffered in adulthood or to their traumatic effects.

## SEXUALITY

Sexuality as understood by Sigmund Freud is “psycho-sexuality,” and should be taken “in the same comprehensive sense as that in which the German language uses the word ‘*lieben*’ (to love).” (1910k, pp. 222–23)

In his clinical work during the closing years of the nineteenth century, Freud noticed how significant a role sexuality played in the mental conflicts of his patients, eventually concluding that it was invariably one of the poles of any symptom-generating conflict. In *The Interpretation of Dreams* (1900a), he evoked the importance of childhood sexuality solely in connection with neurotics, but beginning with the first edition of the *Three Essays on the Theory of Sexuality* (1905d) he asserted its presence and its essential role in all children. Thereafter Freud conceived of human sexuality in a broadened sense that included childhood and perverse sexuality. Childhood sexuality had three main characteristics: it was autoerotic, subject to the primacy of erotogenic zones and component instincts, and anaclitically dependent on the self-preservation instincts or ego-instincts.

It would take twenty or so years for Freud to arrive at the theory of the four stages of psychosexual development that we now find in the manuals. Each stage was characterized by the dominance of a different erotogenic zone: oral, anal, phallic, genital. The child was polymorphously perverse in that the primacy of the genital zone and of the relationship to the object was not yet established. The pervert remained fixated in, or regressed to, a subordination to one or other of the non-genital zones, ruled by component instincts. Despite this broadening of the concept of sexuality, Freud continued to define a so-called normal sexuality, reached at the end-point of development and characterized by the primacy of the genital zone and of the relationship to the object. But he had trouble completely detaching normal sexuality from the goal of procreation, something he had been able to do in the cases of infantile and perverse sexuality (see the twentieth of the *Introductory Lectures* [1916–17a]).

Another point, often insufficiently stressed, is the distinction Freud drew between two currents, the affectionate and the sensual, “whose union is necessary

to ensure a completely normal attitude in love” (1912d, p. 180).

The whole of childhood sexuality falls under the rubric of the “Oedipus complex,” a term first used by Freud in “A Special Type of Choice of Object Made by Men” (1910h, p. 171), even though he had referred to Sophocles’ *Oedipus Rex* as early as 1897 in a letter to Fliess. The Oedipus complex was at first presented by Freud from the young boy’s point of view, and in a simplified form: the little boy is in love with his mother and so becomes his father’s rival. In the complete form, bisexuality came into play: the boy also wants to take his mother’s place vis-à-vis his father (inverted Oedipus complex). The Oedipus complex of the girl was not in Freud’s view symmetrical with that of the boy, for the girl did not experience the tragic conjunction of love for the mother and a rivalry with the father provoking murderous wishes.

A sexuality that could be called perverse inasmuch it activated erotogenic zones other than the genital nevertheless had a place in normal sexuality in the shape of “fore-pleasure.” What characterized perverse sexuality proper was the rigidity and exclusiveness of the manner of achieving orgasm.

Until 1920 Freud described mental conflict as a clash between the sexual instincts and the self-preserved instincts, also known as ego-instincts. Beginning with *Beyond the Pleasure Principle* (1920g), however, a new opposition came to the fore in Freud’s thinking, though without eradicating the earlier: that between Eros (life instincts or sexual instincts) and Thanatos (death instincts). This was yet another broadening of the concept of sexuality: Eros—love—sought to hold things together, while Thanatos—death—strove to tear them apart and destroy them. As noted above, Freud gave sexuality the same extension as the verb “to love”; since one side of the conflict is always sexuality, it may reasonably be deduced that all mental disturbance has a connection with sexuality conceived as love, as a tie to an object.

Freud was accused by some of “pansexualism.” It is true that sexuality was present everywhere in his theory, yet it was always seen as in conflict with other instinctual forces, so that Freud was surely right to defend himself against this charge.

On the other hand, the issue of the relationship between sexual disturbances and psychopathology is not simple. It is quite possible to encounter dysfunctional

sexuality in the strict sense in a person who presents no particular mental symptoms in other areas, while a perfectly satisfactory orgasm may occur in otherwise deeply disturbed individuals. But the libidinal tie and the relationship to the object are always implicated in the organization of the personality and in mental pathology. In psychoanalytic treatment, the transference instates a relationship of libidinal dependence with the analyst that repeats the relationship with parental figures. The transference—the motor of psychoanalysis—may become an obstacle to treatment if it takes a totally eroticized form.

For Freud, then, human sexuality was psychosexual, and individual and cultural ideas played an important role therein; yet in his view it was also biological, and he was certainly not mistaken in this. The object of the instinct is not given with the instinct itself. The history of the individual, which is to say the history of that individual's relationships with his mother, father, and other key people in the entourage, contributes to the constitution of his particular sexuality. Freud wrote that the infant's relationship with the mother who gave it the breast supplied the prototype for the adult's later love relationships. Weaning brought about the loss of the breast as libidinal object, and thereafter the individual would seek to rediscover that lost object. But some infants are not breast-fed, in which case weaning will not have the same character, and may not be so late. The breast has become a metaphor for all bodily attentions from the mother (Donald W. Winnicott), or else as a part-object (Melanie Klein). In language, and for the infant—even an infant which has not been breast-fed—the breast symbolizes the mother, and is an object of desire. Freud seems never to have heard little boys crying because they cannot have breasts like their mother, and he retained only the little girl's penis envy as a mark of the child's confrontation with the anatomical difference between the sexes. Freud's patriarchal and phallogocentric assumptions echo his culture, and he was unaware of them. Only rarely do we now see the typical neuroses and disturbances of sexuality that Freud described in his "Contributions to the Psychology of Love" (1910h, 1912d); and when we do, patients usually come from families where they have received a traditional patriarchal upbringing.

Freud never suggested that unbridled sexual activity could remedy sexual and mental problems. Certainly, he at first emphasized the conflict between sexual

wishes and the external world, and made "civilized sexual morality" responsible for "modern nervous illness." (1908d). But later on he located the essential conflict—that between the forces of binding and the forces of unbinding—within the psyche. A strong superego, constituted by means of identification with the father as prohibitor of incest—and also (as something of an afterthought on Freud's part) by the mother—he judged necessary not only to morality but also to creativity, to sublimation, that is to say to the inhibition and diversion of strictly sexual instinctual aims. Libido seemed to Freud to be masculine in essence, and he considered the woman's superego—and hence her moral sense and creativity—to be weaker than the man's. Women were destined to passivity, or at least to activities with passive aims. Freud rejected feminist aspirations to equality between men and women.

## SEXUALIZATION

Heinz Kohut has a view of sexualization that differs from Freud's. In fact, he sees it not so much as a defensive structure, but rather as the indication of a structural deficit. From the point of view of the drives, this deficit appears as an insufficient neutralization. From the point of view of the Selfobject [SIC], one might say that there is a lack of a necessary relation with another source of responsiveness. There is another idea involved, too: it is possible to attenuate or to dissipate sexualization by establishing a Selfobject transference. Independently of the theoretical perspective, sexualization becomes, in practice, an activity that imbues the whole personality and contributes, in an episodic or regular way, to the maintenance of psychological equilibrium. It procures pleasure and helps to obliterate painful feelings. It can also help to stem regression and enable the establishment of a relation that, while it may appear infantile, still helps to develop the Self's cohesion. Given all the psychological gains that it implies, it often resists analytical intervention without the elaboration and working-through of a Selfobject transference.

The way the diverse forms of sexualization are considered consists in translating behavior into a narrative that represents individual psychodynamics. Thus the exhibitionist or the pedophile is expressing a specific psychological configuration that can be read as a manifest content. This is most probably an exaggerated simplification, since many forms of sexualization are more a matter of fortuitous circumstances, or even of biology, than of psychological meaning. Sexualization is essentially perpetuated by vertical splitting. Any treatment of difficulties involving sexualization needs to study this particular structural problem.

## SEXUATION, FORMULAS OF

According to Jacques Lacan, *sexuation*, as distinct from biological sexuality, designates the way in which the subject is inscribed in the difference between the sexes, specifically in terms of the unconscious and castration, that is, as “inhabiting language” (Lacan, 1998, p. 80).

Lacan presented the complete table of the formulas of sexuation on March 13, 1973, during one of the lectures of his seminar *Encore* (1972–1973), but as early as 1971 he began to use his own symbols for the logical quantifiers and the function  $\Phi x$  (figure 1).

Lacan's choice of the term *sexuation*, and not *sexuality*, indicates that being recognized as a man or woman is a matter of the signifier.

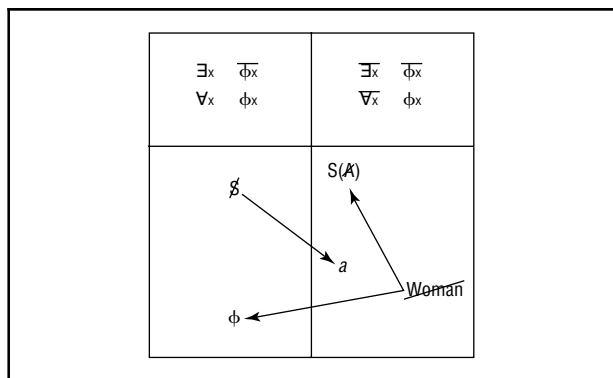

The phallus is situated as a symbol, the signifier of castration and thus also of desire. The Law that is transmitted by the father and that states the prohibition against incest is also the foundation of desire. And this is the Law of castration, which Lacan designated in his graph as the phallic function,  $\Phi x$ .

To construct these formulas, Lacan relied on the Aristotelian logic according to which propositions are categorized in four classes: the universal affirmative, the universal negative, the particular affirmative, and the particular negative. But Lacan adopted modern symbols for these categories, which are based on the universal quantifier,  $\forall$ , and the existential quantifier,  $\exists$ .

On the left side of the table, there appears the formula  $\forall x \Phi x$ , for all  $x$   $\Phi$  of  $x$  (all men are submitted to the phallic function, that is, castration). But modern logic has demonstrated the necessity of a particular negative,  $\exists x \neg \Phi x$  (there exists at least one that is not submitted to the phallic function), in order to found the universal affirmative. This is the hypothesis that Sigmund Freud developed in his myth of the primal father in *Totem and Taboo* (1912–1913a), and also in his argument that Moses was not a Jew in *Moses and Monotheism* (1939a): there always exists one who is an exception. This is how man is inscribed: by the phallic function, but on the condition that this function “is limited due to the existence of an  $x$  by which the function  $\Phi x$  is negated” (Lacan, p. 79). This is the function of the father.

The other side of the table concerns the “woman portion of speaking beings” (p. 80). The upper line is

FIGURE 1

read as follows: there does not exist any  $x$  that does not fall under the phallic function. In other words, castration functions for all women. But on the lower line Lacan introduced a negation marked by the barring of the universal quantifier, which is quite inconceivable from the perspective of formal logic. Lacan proposed that it be read as “not-whole.”

The woman’s side of the table “will not allow for any universality” (p. 80). Woman is not wholly within the phallic function. On this side there is no exception that could serve as the basis for a set of women. It is from this fact that Lacan derived the formula, “Woman doesn’t exist.” This formula leaves no room for any idea of an “essence” of femininity.

Below the table of formulas, there is a “scanded indication of what is in question” (p. 80). On the masculine side, there is the barred subject “and the  $\Phi$  that props him up as signifier” (p. 80). For the male is only able to reach his partner, the Other, through castration and the mediation of the object  $a$  as its effect. This is indicated by the arrow that crosses from the male side to the female side, which also reproduces the Lacanian formula of fantasy. On the feminine side, woman is doubled: she has a relation with  $\Phi$ , insofar as a man incarnates it for her. But she is not wholly in that relation. She also has a relation to the signifier of  $A$ , the signifier that the Other would need if a set of women were going to be formed. Woman’s jouissance is thus divided between phallic jouissance, linked to castration and appearing on the graph as  $\Phi$ , and an Other jouissance that is unique to her. Thus there is neither symmetry between the two sides of the table, nor any complementarity between the sexes.

## SHADOW (ANALYTICAL PSYCHOLOGY)

In Carl Gustav Jung’s analytical psychology, the shadow as a concept comprises everything the conscious personality experiences as negative. In dreams and fantasies the shadow appears with the characteristics of a personality of the same sex as the ego, but in a very different configuration. It is presented as the eternal antagonist of an individual or group, or the dark brother within, who always accompanies one, the way Mephistopheles accompanied Goethe’s Faust.

The role of the shadow within is sometimes hidden, and sometimes rejected or repressed, by the conscious ego. In the latter case it is pushed into the unconscious, where, because of its energy, it acts as a complex. People can, for example, be fully aware that they are avaricious, greedy, or aggressive and still manage to hide these truths from others beneath the mask of the *persona*. But they can also repress those characteristics. Then they are no longer conscious of them at all, and their moral ego is reestablished.

The shadow in everyone varies considerably depending on the guidelines in force within the family, the community, and the culture in which they grow up. Moreover, the shadow is not only made up of aspects of personality experienced as disagreeable or negative, but it can also have a positive side.

When the shadow is not integrated into the conscious personality and remains unconscious, it can manifest itself in two different forms. On the one hand, it can project itself onto another person in one’s immediate or distant circle, leading to serious conflicts among siblings, couples, or colleagues that have a tendency to recur and lead to lasting misunderstandings. On the other hand, it can also cause deflation, so that those involved find themselves subjugated and thus inferior, bad, or clumsy. In fact, the shadow corre-

sponds to what one does not want to become but still is, within the self. It is even something necessary, for just as a painting needs shadow to give it life and depth, each human needs a shadow—as illustrated by Peter Schlemihl de Chamisso (1824)—to become a true human being with all the genuine weaknesses and defects, qualities which can even make them likeable.

Jung developed and enriched the concept of the shadow throughout the 1930s, when he began studying closely alchemical literature and iconography in relation to his experience and conception of the process of individuation. He compared the “black work” of the alchemists (the *nigredo*) with the often highly critical involvement experienced by the ego, until it accepts the new equilibrium brought about by the creation of the self.

In the work he did after World War II, Jung developed the distinction between the personal shadow and the collective shadow, emphasizing the fact that while recognition and analysis of the shadow lead to a confrontation with the drives and the most intimate representations, they also lead to a confrontation with the collective unconscious. It is this that gives rise to projections of the shadow onto other cultures, other peoples, and other races—something that occurred during the twentieth century to an alarming extent.

## **SHAKESPEARE AND PSYCHOANALYSIS**

Throughout the century, psychoanalysts have studied Shakespeare’s works to deepen their understanding of psychic conflict and to hone their interpretive skills. Literary scholars have turned to psychoanalysis to solve perennial problems in interpreting Shakespeare’s text.

In a letter to his friend Wilhelm Fliess (15 October, 1897), Sigmund Freud sketched out his first formulation of what he would come to call the Oedipus complex, then promptly went on to show how this notion could be used to interpret some notorious cruxes in *Hamlet*. Freud linked, through the triangular structure of the Oedipus complex, Hamlet’s hesitation to avenge his father, his pangs of conscience, his hostility to Ophelia, the sexual disgust expressed to Gertrude, and his final destruction (1900a, 4: 264–266). “There are more things in heaven and earth Horatio, than are dreamt of in your philosophy” (1910c, 11: 137n.): Freud’s favorite quotation from any source, according to Jones, was this tribute to the complexity of existence, from *Hamlet*.

The nature of Freud’s attachment to Shakespeare’s work is also conveyed in his association of a “special cadence” in his own dream speech, with a cadence in Brutus’s speech of self-justification in *Julius Caesar*. “As Caesar loved me, I weep for him; as he was fortunate, I rejoice at it; as he was valiant, I honor him; but, as he was ambitious, I slew him.” (1900a, 5: 424) Freud shed light on the unconscious conflict over gender and ambition that fractured Lady Macbeth’s psyche, and on Shakespeare’s technique of splitting a character in two “she becomes all remorse and he all defiance” (1916d, 14: 324).

In Shakespeare criticism, after classic papers by Ludwig Jekels, Ernest Jones, Theodor Reik, Hanns Sachs, Wangh (Faber, M., 1970) and others, there has been a proliferation of essays, applying various aspects of psychoanalytic theory to Shakespeare’s texts: dream theory, the structural model, incest fantasies, primal scene fantasies, and the symbolizing and creative functions of the psyche itself. There are several English bibliographies that catalogue these works, including those by Norman Holland (1964), D. Wilbern (1978), and Murray Schwartz and Copelia Kahn (1980). “On the

Universal Tendency to Debasement in the Sphere of Love" (1912d, 11: 179–190) has featured in the discussion of obstacles to love regularly encountered in comedy. "Mourning and Melancholia" (1916–1917g, 14: 239–258), has been used in thinking about ambivalence toward the lost object and severe depression in tragedy or in a comedy like *Twelfth Night*. Freud's "On Narcissism" (1914c, 14: 69–91), and the thinking that grew out of it on the structure of the psyche and its roots in infantile development, have influenced many recent interpretations of Shakespeare's plays. "Negation" (1925h, 19: 235–239) has been useful to Shakespeareans as it explores one way in which the psyche negotiates its own internal contradictions.

Beyond Freud, Jacques Lacan's "mirror stage," Donald Winnicott's "transitional object," Margaret Mahler's "separation/individuation," and Erik Erikson's "basic trust" have generated new psychoanalytic readings of Shakespeare's plays. Of the classic psychoanalytic essays on Shakespeare, Ernst Kris's essay, "Prince Hal's Conflict" (Faber, 1970) has remained a model of sophistication. Integrating elements of the play's language, characterization, and plot with corresponding elements of psychic structure, Kris, examining the play's sources and speeches, recognizes Shakespeare's exceptional genius for historical and psychological observation. More recently, psychoanalysis has influenced the critics who see Shakespeare as a dramatist whose "plays and poems do not merely illustrate his identity but are in each instance a dynamic expression of the struggle to re-create and explore its origins" (Schwartz, 1980, xv–xvi). In this spirit, Janet Adelman (1992) has analyzed masculine identity and "fantasies of maternal power" and of "the maternal body" in Shakespeare.

Psychoanalytic criticism of Shakespeare has dominated the application of psychoanalytic theory to the arts and has articulated debates over the nature of applied psychoanalysis. One side insists that Shakespeare's text be treated with respect for its genre, for its formal and aesthetic properties, for its artifice, so that we must not invent an unconscious or an infantile neurosis for a character, or do wild analysis on the author; we must not go beyond the language of the text. Another position responds that a text is the product of the human psyche, which always uses the unconscious and its desires in creativity. Perhaps the most fruitful psychoanalytic interpretations of Shakespeare occupy a middle ground wherein the text is

evidence and arbiter, but where the characteristically Shakespearean illusion that a stage person has interior being, with motives that he himself does not fully understand, is recognized and explored.

## SHAME

The word *shame* encompasses: 1) the raw emotion linked to a loss of one's bearings; 2) judgment about this state (the perception of shame as such resulting from the comparison of oneself with a model); and 3) judgment about both this emotion and the possible

causes of shame (implying possibilities for action). In all cases, shame is a sense of anxiety about being excluded, that is, not only fear of a withdrawal of love, but even withdrawal of any form of interest.

In “Three Essays on the Theory of Sexuality” (1905), Sigmund Freud linked shame to the action of the forces of repression (what was initially an object of pleasure becomes an object of modesty, disgust, or shame). By contrast, in “La honte comme angoisse sociale” (Shame as a Social Anxiety; 1929), Imre Hermann described shame as a “social anxiety” linked to attachment.

Shame always has two aspects: one relating to individual mental functioning (anxiety about mental disintegration), and the other relating to relations with the group (anxiety about being excluded). Pathological shame is to be distinguished from shame as a signal of alarm. Coping with shame involves both naming it and reinforcing the secondary processes to limit its disintegrative effects. It can be displaced or masked, especially by resignation, anger, guilt, or hate.

To a certain extent, shame was a “blind spot” for Freud and, in his wake, for many psychoanalysts who reduced it to a pathological affect linked to the ideal ego and opposed to the guilt associated with the oedipal superego. However, it is a concept that is essential to the understanding of the dynamics of social bonds (it protects people from engaging in nonhuman actions) and intergenerational secrets.

### **SHARPE, ELLA FREEMAN (1875–1947)**

British teacher and psychoanalyst, Ella Freeman Sharpe was born in Haverhill, Suffolk, England, on February 22, 1875, and died in London on June 1, 1947.

Ella Sharpe was the eldest of three daughters. Her father, who read Shakespeare to her as a child, died when she was in her teens, and she took over responsibility for the family. She studied English at Nottingham University, but turned down a position at Oxford University in order to take a teaching job to support her family. She was then co-head and English mistress of Hucknall Pupil Teachers Training Centre for boy and girls from 1904–1916.

Ella Sharpe became depressed at the death of friends and pupils during the First World War and suffered anxiety attacks. She went to the Medico-Psychological Clinic in Brunswick Square, London, was treated successfully by Jesse Murray and James Glover, and became interested in Psychoanalysis. In 1917 she gave up teaching to study psychoanalysis at the clinic.

In 1920 she went to Berlin to be analyzed by Hanns Sachs, who shared her interest in art and literature. On October 13, 1921, she was elected an Associate Member of the British Psycho-analytical Society and a Full Member two years later, in 1923.

She took an active role in the administration of the Society and Institute, and was elected to the Board and Council a number of times, being a director of the Institute when war broke out. She was first elected a member of the Training Committee in 1930, and served on it for many years. She was soon involved in teaching analytic technique, and her experience as a teacher enabled her to present her material in a lively and clear way. She was one of the first British Analysts to work with children, and she supervised both child and adult patients.

She read her first paper to the Society in 1923 on the work of Francis Thompson. At the Oxford Congress in 1929, she read a paper on sublimation and delusion, and at the Lucerne Congress in 1934, she read a paper on sublimations underlying pure art and pure science (Sharpe, 1935), using ideas from Klein's work. She was particularly interested in those artists,

including Shakespeare, who used words to express themselves. Her paper on her examination of metaphor and poetic diction shows her own rich understanding of words and the link between metaphor and instinctual tension (Sharpe, 1940).

Her lectures on technique (Sharpe, E., 1930/1931) were published in the *International Journal of Psycho-Analysis* (vols. 11 and 12) and later in book form together with her other papers (Sharpe, 1950). Her lectures on dreams were also published as a book (Sharpe, 1937).

Ella Sharpe's main impact was that she could apply Freud's technical concepts to her clinical experience and communicate it to others, and she alerted readers to the importance of understanding, more deeply, the language of patients.

## SIGMUND FREUD ARCHIVES

The Sigmund Freud Archives, incorporated in the United States in 1952 by the leading analysts of that period, developed under the leadership of Dr. Kurt R. Eissler, who was the chief administrative officer until 1985. Dr. Harold P. Blum succeeded him as executive

director of the archive. The other officers in 2005 were Drs. Alexander Grinstein, president; Bernard L. Pacella, secretary and treasurer; and Sidney S. Furst.

The goal of the archive is to discover, collect, and preserve all of Freud's publications, letters, and other documents and to maintain an archive of these materials. The archive also facilitates research, writing, publishing, and other activities relating to the work of Freud and other pioneers of psychoanalysis. The Sigmund Freud Collection comprises Freud's letters, publications, first editions, personal documents, photographs, movies, and other personal items. Letters and papers of Anna Freud and many other renowned psychoanalysts are in separate collections, coordinated with the Sigmund Freud Collection. The archive has a continuing contract with the Library of Congress under which the Freud Collection is protected and preserved at the Library of Congress in Washington, D.C. The Freud Collection was almost completely derestricted as of 2005, and is accessible to all scholars upon application to the Library of Congress.

As a co-trustee, the archive is also responsible for the administration and development of the Freud Museum in London. The Freud Museum opened in July 1986 and contains a major collection of Freud's personal effects, including his extensive library, antiques, study, and consulting room. The Freud Museum displays Freud's professional and working environment, and sponsors relevant education, writing, and research.

A nonprofit organization, the archive offers all scholars equal access to all unrestricted documents. For more than a decade, the archive has steadily been derestricting documents in its control. Most of the Freud correspondence that has recently become available has been released by the archive. The goal of total derestriction was reached the year 2000, when documents under Anna Freud's will were scheduled for derestriction. Then only documents legally restricted, in writing, by the donor, will still be unavailable to scholars.

Documents are released at the Library of Congress for reading and research, but such release does not entail permission for publication. Documents are released completely unaltered and unexpurgated, with the single exception of the names of psychoanalytic patients. Patients' names are deleted to protect anonymity and confidentiality, but to facilitate scholarly research,

names are available to editors of correspondence upon special application to the Sigmund Freud Archives. In such cases, the editors are bound to maintain the confidentiality of patients' identities. Everyone using the documents in the Freud Collection is obligated to abide by the rules of the Library of Congress.

Dr. Harold Blum proposed a "Freud Exhibit" to the United States Library of Congress. Developed over several years, relying mainly on the Freud Collection of the Library of Congress, it opened in 1998 at the Library of Congress in Washington, DC. It was the largest exhibit of the life and work of Sigmund Freud ever held. The exhibit traveled to venues in four continents, including several additional major American cities, Vienna, Rio de Janeiro, and Tel Aviv.

The Freud Archives continues to support Freud scholarship and research. Plans are under consideration to digitize the Freud collection and as many other Freud documents as possible. In 2004 the Sigmund Freud Archives constructed its own web site, which will eventually be linked to the Library of Congress. An outline of the Freud Collection and its contents can be viewed on the web site. Derestriction of the small number of still classified correspondence and interviews is proceeding, consistent with legal and ethical requirements.

HAROLD P. BLUM

---

## SIGMUND FREUD COPYRIGHTS LIMITED

Sigmund Freud bequeathed the income from this world copyrights, which was seen as "pocket money," to five of his grandchildren, who were still all minors at the time of his death in 1939. His will appointed three of his children, Ernst, Martin, and Anna as trustees.

After World War II, the trustees decided that a limited company should be formed to handle the copyrights, promote publication and translations, and collect royalties and distribute them to the grandchildren. The company was incorporated April 15, 1946, and acquired from the trustees the copyright in all Sigmund Freud's works and other writings, letters, and so on, by an agreement of April 5, 1947.

The company was managed for many years by Ernst Freud, operating from his home in St. John's Wood, London, where he also continued to carry on his architect's practice. With his wife, Lucie, Ernst was also closely involved with editorial work, dedicating himself wholeheartedly to keeping his father's name before the public. He acquired an intimate knowledge of his father's vast correspondence and one of the earliest volumes of these letters, a selection of various correspondents, published under the title *The Letters of Sigmund Freud 1879–1939* (1960) was entirely Ernst's idea and his almost unaided achievement. Several other volumes followed, such as *Psych-analysis and Faith; The Letters of Sigmund Freud and Oskar Pfister* (with Heinrich Meng) in 1963; *A Psycho-analytic Dialogue; The Letters of Sigmund Freud and Karl Abraham 1907–1926* (with Hilda C. Abraham) in 1965; and *The Letters of Sigmund Freud and Arnold Zweig* in 1970. It had also long been Ernst's dream to publish a picture biography of his father, using letters and other documents and photographs mainly from the family's private collection. He worked on this for many years, together with his devoted wife, Lucie. The work remained uncompleted when he died in 1970, when the German scholar and psychoanalyst, Ilse Grubrich-Simitis, took on the task of finishing it. It finally appeared as *Sigmund Freud: His Life in Pictures and Words* in 1976 and was translated into many languages.

Although in 1960 he had passed the work of administering most German and foreign language rights in his father's published works (except English, Spanish, and Portuguese) to the S. Fischer publishing house in Frankfurt, by the mid-1960s Ernst Freud's health was failing and he was seeking someone to help him. At this point the literary agent, Mark Paterson, was asked by an American publisher to clear the rights in one of Freud's pre-analytic works. He contacted Anna Freud, who referred him to her brother Ernst. The two men met and warmed to each other immediately, and Paterson was appointed as a consultant. Shortly after Ernst's death he took over as Director.

The company continued to thrive, promoting new editions of Freud's works and many more editions of correspondences. The limited company became dormant in 1987 but the name "Sigmund Freud Copyrights" continues to be used as the collective name of the literary heirs of Sigmund Freud and its affairs are handled by Mark Paterson and Associates, 10 Brook Street, Wivenhoe, Essex, GB-C07 9DS.

This company also handles the works of many other psychoanalysts, including those of Anna Freud, and in conjunction with administering the Freud copyright, maintains a small archive comprising letters and other documents, many of them originals, relating to the history of psychoanalysis.

THOMAS ROBERTS AND MARK PATERSON

## SIGMUND FREUD INSTITUTE

Located in Frankfurt, Germany, the Sigmund Freud Institute is a state-supported research institute for psychoanalysis and its various applications. Research covers three broad areas: psychoanalytic therapy, foundations of psychoanalysis, and psychoanalysis and society; investigators target aspects of psychological health and illness in the context of economic development, and they study the theoretical and practical bases of psychoanalysis. The institute's psychoanalytically-oriented psychotherapy clinic focuses on treatment and research alike.

The institute is closely identified with its founder and first director, Alexander Mitscherlich (1908–1982). In the summer of 1956, Mitscherlich organized a series of conferences at the Institut für Sozialforschung (Institute for Social Research) with the support of Max Horkheimer (1895–1973). With the intention of restoring contacts with the international psychoanalytic community, Mitscherlich invited the participation of analysts who had left Germany prior to the Second World War. Somewhat later, on April 27, 1960, the Institut und Ausbildungszentrum für Psychoanalyse und Psychosomatische Medizin (Institute and Training Center for Psychoanalysis and Psychosomatic Medicine) officially opened. After moving to new quarters in West Frankfurt on October 14, 1964, it was rechristened the Sigmund Freud Institute.

Psychoanalysis originated in Frankfurt with the Frankfurter Psychoanalytisches Institut, which opened in 1929 but met an abrupt end when in 1933 the National Socialists expelled its first director, Karl Landauer, who would later die at the Nazi concentration camp at Bergen-Belsen. Heinrich Meng (1887–1972), the institute's second director, was forced to

emigrate along with colleagues Frieda Fromm-Reichmann (1889–1957), Erich Fromm (1900–1980), and Siegmund Heinrich Fuchs (S.H. Foulkes, 1898–1976).

The considerable achievement of the Sigmund Freud Institute under Mitscherlich's direction was to train new analysts with the help of analysts from abroad and to mount and maintain a conceptual and institutional forum for psychoanalysis in Germany. During the Cold War, the Sigmund Freud Institute became the most important psychoanalytic teaching institute in West Germany; its training protocols conforming to guidelines set by the German Psychoanalytic Society (DPV/API).

In addition to Mitscherlich, who led the institute from 1960 to 1976, its other directors include Clemens de Boor (1976–1983), Hermann Argelander (acting director, 1983–1985), Dieter Ohlmeier (1985–1992), and Horst-Eberhard Richter. Since 1995, in addition to providing treatment on an outpatient basis, the institute has supported research and education programs. The training of analysts, however, was transferred from the Freud Institute to the newly-created Frankfurter Psychoanalytisches Institut in 1994. Werner Bohleber became president of the Frankfurter Institut in 1994.

The Sigmund Freud Institute, state supported and independent of the university system, has greatly contributed to reestablishing psychoanalysis in Germany, with its unique dual role as a research center and training institute. It has developed an original approach to research projects and brought psychoanalytic investigations to bear on questions of social psychology.

## SIGMUND FREUD MUSEUM

In 1971 in Vienna, with Anna Freud present at inaugural ceremonies, the Sigmund Freud Museum opened in Berggasse 19, the apartment house where Freud had lived and worked from 1891 until 1938. Originally the museum consisted of the rooms on the first floor (second floor in American usage) that housed Freud's office; it subsequently expanded to include Anna Freud's consulting room and the family apartment, which opened to the public in 1996. The Sigmund Freud Museum, managed by the Sigmund Freud Foundation, is private. It shares the bulk of Freud's legacy with the Freud Museum in London and the Library of Congress in Washington, D.C.

Visitors enter the museum through the entrance hall of the family's private apartment. In the lobby that leads to Freud's office, the original wood paneling with bast covering has been preserved; several of Freud's belongings are on display and his diplomas hang on the wall.

Freud's patients and visitors entered his consulting room from the waiting room, which was restored in accordance with the memories of Anna Freud and Paula Fichti, the Freud's housekeeper. Furnishings, donated by Anna Freud, comprise a wooden table, three armchairs and a dark red couch. Objects from her father's collection of antiquities are also displayed in a glass case, a selection that offers a sampling of Freud's taste and his passion for archeology. Some bookcases have been replaced by pictures from Freud's scientific career.

Patients entered Freud's offices through soundproof padded double doors; his consulting room opened onto a separate study. On the walls, photomontages by Edmund Engelman, taken in 1938, show the way the rooms were furnished just before Freud left Austria. Beginning in the consulting room and continuing through the study, documents and memorabilia line the walls. Showcases include more items from Freud's collection of antiquities; first editions of his books and offprints, some signed by him; handwritten inscriptions; and various other documents and personal

memorabilia. Photographs provide a visual and chronological account of the founder of the psychoanalysis from his birth and early childhood in Freiberg through his decades in Vienna and the final months of his life in London. Freud's education, his cultural milieu and personal relationships throughout his career are highlighted; scenes from his private life, which Freud attempted to keep strictly apart from his professional life, are also on view.

In a media room located in an adjoining room, formerly the kitchen, a documentary film, *Freud 1930–1939*, features a commentary by Anna Freud, who helped produce it just prior to her death. It includes footage of Freud from 1930 to 1939 in Vienna, Paris, and London with family, friends, and close collaborators. The original print of the film remains at the Anna Freud Center in London; the museum has exclusive rights to its use in continental Europe. Another film, by Philip R. Lehrman and Lynne Lehrman Weiner, *Sigmund Freud. His Family and Colleagues, 1928–1947*, finished in 1985, is also shown at the museum.

Anna Freud's consulting room, dedicated in her memory, opened in November 1992 on the occasion of the tenth anniversary of her death; furniture from the Freud family private apartments and part of Anna Freud's library are on view. A multipurpose room (three former bedrooms) has been appointed for exhibitions and lectures. A library, which opened in the museum in 1991, has holdings of over 30,000 items, the largest collection of its kind in Europe.

In 1996, the Sigmund Freud Museum celebrated its twenty-fifth year; on this occasion, the new exhibition room and lecture hall were inaugurated. Together with the exhibition and lecture rooms they provide suitable spaces for temporary exhibitions. In 2002, a show called "Freud's Lost Neighbors" was put on; it showed the history of the residents of the house at Berggasse 19 from 1939 to the present. The Foundation for the Arts, Sigmund Freud Museum Vienna, a collection of contemporary art, has been on display in the exhibition rooms since 1997; the theme is the relationship between psychoanalysis and artistic production. In 2003, the Museum opened another exhibition space on the ground floor, with a display window facing the street. This is used for the mounting of art installations.

## SIGNAL ANXIETY

In the *Three Essays on the Theory of Sexuality*, written in 1905, Sigmund Freud saw the anxiety of separation as a special case of anxiety based on the phenomenon of “unused libido.” The absence of the mother (due to separation) prevented the infant from binding its affects to the maternal representation and it was these affects, together with their libidinal energy, that were transformed into anxiety. Otto Rank (1924) saw anxiety as rooted in the trauma of birth, which constitutes the quintessential separation experience (biologically, in fantasy, etc.).

In *Inhibitions, Symptoms and Anxiety* (Freud, 1926d [1925]), which, to a large extent, is a response to the position taken by Otto Rank two years earlier, Freud developed the theory of signal anxiety, which represents a kind of evolutionary progress since it involves anticipatory behavior. The infant no longer experiences anxiety when faced with the loss of an object but when faced with the fear of the loss of love from the object. There Freud developed different models of anxiety that, rather than being mutually exclusive, probably refer to different types of anxiety and different maturational steps. The conceptual transition from automatic anxiety to signal anxiety involves a profound reworking of his thinking about repression. In the case of automatic anxiety Freud made anxiety a direct consequence of repression. Repression, by ejecting the instinctual representation from consciousness, leaves a certain amount of libido unused, which is immediately transformed into anxiety. “One of the most important results of psycho-analytic research is this discovery that neurotic anxiety arises out of libido, that it is the product of a transformation of it, and that it is thus related to it in the same kind of way that vinegar is to wine” (1905d, note of 1920). When discussing signal anxiety, repression is no longer the origin but the consequence of the anxiety.

When an instinctual representation becomes dangerous, threatening, or guilt-ridden, it gives rise to anxiety within the ego, leading to repression. Anxiety now serves to alert the subject to the dangers associated with the possible separation and is no longer simply the expression of an instantaneous and automatic anxiety reaction to loss or separation.

## SIGNIFIER

As it is understood today, the notion of the signifier is attributed to Ferdinand de Saussure, founder of linguistics and semiology and author of the influential *Course of General Linguistics* (1907/1960). For Saussure, the linguistic sign was a mental entity with two aspects: the signified (the “concept”) and the signifier (the mental impression of the sound). The relationship between these two aspects, which Saussure compared to the recto and verso of a sheet of paper, was considered “arbitrary” in that what linked signifier to signified was merely a convention: the signifier “sister” and the signifier “soeur,” for instance, both refer to the same signified element, even though they belong to two different linguistic systems. At the same time, signifier and signified were connected syntagmatically and paradigmatically, and these connections—and not the designation of a referent or external object—were the basis of the meaning of statements. In the wake of Saussure, structural linguistics from Roman Jakobson to Émile Benveniste built extensively on his work. This account of the structure of the sign supplied the chief algorithm of the science of semiology, whose mandate was to assess and decipher all the sign systems generated by a given society, linguistics being merely a part of this whole—and a model for it.

Critical thinking about the signifier centered at first on what was called the priority of the signifier relative to the signified. Inasmuch as the material nature of signifiers was highly diverse (including sounds, images, objects, text, and so on), semiology opened onto all fields of expression—art, fashion, discourse—to the point where it came to be defined as the science of the signifier, or rather, of signifying practices (Kristeva). Claude Lévi-Strauss’s structural anthropology is a magisterial demonstration of this linguistics-inspired approach.

In psychoanalysis, Jacques Lacan, invoking both Freud and Saussure, as well as linguistic and anthropological structuralism, took the discussion beyond the signifier to what he called “the signifying chain.” Deeming that “the unconscious is structured like a language,” Lacan borrowed the methodology and operating concepts of Saussurian linguistics and applied them in an idiosyncratic way to psychoanalysis. In his view the discovery of the unconscious coincided with the discovery of a subject whose position, decentered (or “ex-centric”) relative to consciousness, was established solely by virtue of the retroactive operation of certain signifiers. Accordingly, the definition of the signifier as a component in a signifying chain was worked out on the basis of three notions:

- *Vacillation*: The signifier can fulfill its purpose of engendering meaning only by ceding its place to another signifier with which it is linked in the chain of signifiers.
- *The subject*: Located nowhere before the advent of the signifier, nor anywhere outside the signifier, the subject receives its place from the signifier, yet can occupy its own place only as a function of the *lack* whose place a signifier fills; the subject thus becomes the *extra* signifier that supports enunciation as it proceeds. This is the basis of Lacan’s formula according to which the order of the signifier is founded on the fact that “a signifier is what represents a subject to another signifier” (*Écrits*).
- *The object*: The object is that towards which discourse qua desire is directed; it governs the signifying chain and its operation. The object of enunciation too is always decentered relative to the one designated by an utterance. That object is also always lacking, for the subject is never finished with the work of signifying that desire entails. For Lacan, that work is orthonormal, both vertically by virtue of metaphor (condensation or substitution of signifiers), and horizontally by virtue of metonymy (displacement or contiguity of signifiers).

The idea of the signifier is cardinal in Lacan’s theory, determining as it does the very definition of the unconscious, of the subject, of the oedipal law, of castration, and of desire. It lies at the intersection of a reformulation of the Oedipus complex conceived of as the subjugation of the subject to the law (of language)

and a consideration specific to Lacan (and only hinted at by Freud) of the effects of speech on the subject as revealed by analysis. To say that the unconscious is a “signifying chain” is the same thing as saying that the “symbolic function” is what superimposes the rule of culture (Oedipus) on the rule of nature. The Other was viewed by Lacan from the outset as the logical empty place where the laws of language and speech are laid down; he described the Other as a “treasure trove of signifiers.” The fact remains that Lacan’s system retained aspects not subsumed by the linguistic realm: the “subject” (of the unconscious) qua “signifier effect,” the object of desire as alien to the sphere of need and even to that of demand, desire as inseparable from speech effects. This independent realm of the signifier was anchored to that “pure signifier,” the Name-of-the-Father: the three clinical categories of neurosis, psychosis, and perversion were viewed as three possible variants of the relationship of the subject of the unconscious to this paternal signifier. Later in his work, Lacan would in fact insist that his teaching was not akin to linguistics; before his final “knot” theory, he proposed an account of “the letter” as an element linking the three orders of the Real, the Imaginary, and the Symbolic—as distinct from his first theory of the signifier, which seemed to concern itself solely with the order of the Symbolic.

Saussure’s account of the structure of the sign (signifier/signified) and Lacan’s thinking on the signifier prompted a philosophical critique of the notion of the signifier that took Freud’s idea of “facilitation” as its starting-point and developed the concept of “trace” (Derrida). The resulting deconstruction of the Saussurian sign led in turn to the deconstruction of metaphysics and opened up the question of the truth of meaning from the point of view of Derrida’s “grammatology”—a perspective of distinct relevance to psychoanalytical interpretation. In the light of psychoanalytical discourse, though also in that of poetic language, Julia Kristeva has suggested another way of understanding the Saussurian signifier: first, in “semiotic” terms, taking into account the infralinguistic indications of the drive, as discernible in the language of poetry and also in the discourse of psychotic or depressed patients—indications excluded from the realm of the signifier as understood by Lacan; and, secondly, in “symbolic” terms, opening up the dimension of signs and syntax.

## SIGNIFIER/SIGNIFIED

A signifier, an element of language, is a material representation of a linguistic sign. In psychoanalysis, it is a phonemic sequence of the discourse that intervenes in conscious and unconscious processes to determine the subject engaged in the discourse. A signified is the idea or concept associated with a signifier, which together constitute the linguistic sign.

These elements, which come from Ferdinand de Saussure's linguistic theory, were introduced and problematized in the field of psychoanalysis by Jacques Lacan during his "return to Freud" phase in early 1950s. Lacan relied on the following main points of Saussure's structural model. The linguistic sign, which belongs to language, establishes a relationship between an acoustic wave form, or signifier, and a concept, or signified (Figure 1).

The directed and temporal sequence of an articulation presupposes the division of language into two axes: the *syntagmatic axis*, which refers to a system of speech as a system of signs capable of being combined and concatenated, and the *paradigmatic axis*, which refers to a system of language as a system of signs selected and substituted for particular meanings.

A sign taken in isolation does not define a meaning: a signifier can refer to several signifieds. Each sign thus gains its value by being placed in the context of other

FIGURE 1

signs. The "break" between a flow of sounds and a flow of thought associates the signifier with a signified.

Freud's definition of psychoanalysis as a treatment through speech led Lacan to propose that the "unconscious [is] structured like a language." This theory, advanced and developed on the basis of Freud's work, led Lacan to assign to the signifier and to the structure of language a fundamental role in the unconscious processes of the speaking subject.

At the level of the primary processes, Lacan posited an analogy between condensation and metaphor, as a substitution of meaning, and between displacement and metonymy, as a connection in meaning. At the level of the expressions of the unconscious, the elaboration of symptoms appears to be analogous to the mechanisms of metaphor, while witticisms and slips of the tongue appear to be analogous to metaphorical condensation and/or metonymic displacement.

The dynamic of desire in the speaking subject is expressed in an indefinite sequence of signifiers operating metonymically. However, this notion only holds because Lacan transformed Saussure's definition of the linguistic sign and, more specifically, that of the signifier in the structure of language. He referred to this as his "linguisteria" (*linguistérie*).

Analysis of the neuroses, the structure of unconscious formations, and the discourse of psychotics led Lacan to believe that the signifier is autonomous and dominant over the signified, which he symbolized as shown in Figure 2.

The bar that separates S from s shows the relationship between the subject and the language. The subject is thus subordinated to signifiers, without always having access to the meaning that they delimit. This is seen clearly in psychotic discourse, which unleashes the signifier.

The primacy of the signifier implies that signifieds draw their coherence only from a network of signifiers. The relationship between signifier and signified can come undone at any time. Lacan replaced Saussure's "break" (*coupure*), Saussure's correspondence between the flow of signifiers and the flow of signifieds, with

FIGURE 2

the *point de capiton* (literally, “quilting stitch”), the operation that stops the indefinite slippage of meaning by making a deferred limitation.

The logic of the signifier thus defined by Lacan calls for a change in how the unconscious processes are analyzed. Lacan focused on how the unconscious expresses itself in the patient’s language, as revealed through meter, punctuation, and interpretative breaks. Within this logic, certain signifiers, such as “phallus”, “Name-of-the-Father”, and “lack in the Other”, are invested with a fundamental metapsychological value.

## SIGNIFYING CHAIN

Inspired by the notion of facilitation, which was central to Freud’s description of the functioning of the psychic apparatus, Jacques Lacan defined the signifying chain as an association and combination of signifiers, connected in diverse ways, like the “links by which a necklace firmly hooks onto a link of another necklace made of links” (Lacan, 2002a, p. 145). The unconscious activity of desire is expressed through the associative and combinatory links of the signifier and is repeated in a kind of succession that sets up a chain reaction.

The signifying chain originates in the process of primal repression, during which the Name-of-the-Father signifiers are substituted for the signifier of the desire for the mother. From then on, conscious and unconscious signifiers are woven together through metonymy and metaphor, the two functions that generate signifieds.

The signifying chain has only one destiny: to insert the subject’s unconscious desire in the subject’s utterances. Thus it constitutes the design and the weave of the speaking subject’s psychic fabric. More generally, it is involved in all psychic causality.

## SILBERER, HERBERT (1882–1923)

Austrian psychoanalyst Herbert Silberer was born on February 28, 1882, in Vienna, where he ended his life by suicide on January 12, 1923.

Victor Silberer, his father, was a self-made man who ran a sports newspaper and a publishing house. A sportsman himself, Herbert was one of the pioneers of Austro-Hungarian aeronautics. He came to psychoanalysis self-taught, with a view to resolving his personal conflicts.

After receiving Silberer's observations on the intermediary stages between waking and sleep, Freud advised Jung (July 19, 1909) to publish the paper, remarking, "Silberer is an unknown young man, probably a better-class degenerate; his father is a well-known figure in Vienna, a member of the city council and an 'operator.' But his piece is good and throws light on an aspect of dream work" (p. 242).

In 1909, Silberer's "Report on a Method of Eliciting and Observing Certain Symbolic Hallucination-Phenomena" was published in the second volume of the newly launched *Jahrbuch*; it eventually appeared in English (Silberer 1951). In this article, Silberer described the hypnagogic states and explained the formation of symbols as revealing affects and emotions in a "functional" way and personalizing various states characteristic of the dreamer's psychic processes. In "On Narcissism: An Introduction" (1914c), Freud wrote that this was "one of the few indisputably valuable additions to the theory of dreams," adding that Silberer had "thus demonstrated the part played by observation—in the sense of the paranoiac's delusions of being watched—in the formation of dreams" (p. 97).

In October 1910, Silberer became a member of the Vienna Psychoanalytic Society. Articles published over the next several years showed Silberer's increasing interest in esotericism and mysticism. Freud recognized his contributions to symbolism, as did Wilhelm Stekel, with whom Silberer would maintain a close relationship after the latter's rupture with Freud.

Silberer's major work, *Problems of Mysticism and Its Symbolism*, published in 1914 and translated into English three years later, distinguished Freud's views on the dream from his own. Freud criticized his concept of "anagogic" interpretation, describing the evolution of dreams during treatment toward more general and universal symbolization, and he also noted Silberer's

deemphasis of sexuality and tendency to rationalize. Similarly, Ernest Jones wrote to Freud (February 8, 1911), "As to Silberer, I don't know what to make of him. He seems to be badly infected by the philosophic virus." Jones subsequently elaborated still stronger criticism of Silberer in his 1916 paper on "The Theory of Symbolism." Although it left Freudian colleagues more than skeptical, Silberer's comparison of transference to the alchemical reactions between male and female elements in nature inspired both Theodor Flournoy and, in particular, Carl G. Jung.

With Wilhelm Stekel and Samuel Tannenbaum, Silberer directed a review published in the United States, *Psyche and Eros*. Despite resigning after the publication grew increasingly hostile to Freud and psychoanalysis, his association with the journal further damaged his relations with the Vienna Society. Paul Roazen (1976) published a letter of Freud dated April 17, 1922: "Most Honored Sir, I ask you not to make your intended visit to me. After my observations and impressions of recent years I no longer desire personal contact with you." Roazen believes this letter was addressed to Silberer and became one of the motives for his suicide nine months later. Bernd Nitzschke (1989) does not share Roazen's conviction; based on the obituary by Stekel (1924), he believes the letter was addressed to Silberer's father, Viktor. In fact, Stekel, who was surprised by Silberer's suicide, stressed the Vienna Society's unfavorable reaction to his lecture on dreams on November 1, 1922.

Forty years after his death, Carl G. Jung wrote: "Herbert Silberer has the merit of being the first to discover the secret threads that lead from alchemy to the psychology of the unconscious" (Jung, 1955–57, p. 792).

## SILBERSTEIN, EDUARD (1856–1925)

Eduard Silberstein, an intimate friend of Freud's when he was an adolescent and young adult, was born on December 27, 1856, in Iasi, then the capital of Romania, and died in Braïla, Romania, in 1925. Freud's eighty extant letters to Silberstein, part of their steady correspondence from 1871 to 1881, have been preserved and published.

His father, Osias Silberstein, was a prosperous merchant, Orthodox Jew, and father of four. He sent Eduard and his brother Adolf to a local heder, but they soon rebelled against the narrowly religious education. Eduard then pursued his studies in Vienna, where he was one of Freud's classmates in the gymnasium. They were friends by 1870.

Tongue in cheek, Freud and Silberstein founded a secret "Spanish Academy" (*Academia castellana*), of which they were the sole members. In correspondence Freud often signed using the nickname "Cipión, dog of the hospital at Seville"; Silberstein was "Berganza," another canine hero from Cervantes's *Exemplary Stories*.

Freud's letters paint a lively picture of Freud's adolescence: the two students' academic worries, readings,

and early infatuations with girls. During the summer of 1871, when Freud was fifteen, Silberstein and Freud went to Freiberg, where Freud had a very brief meeting with Gisela Fluss, a girl almost twelve years old. This encounter was important enough to Freud that he recalled it while writing "Screen Memories" (1899a) and again in a slip of the pen in preparing his "Notes on a Case of Obsessional Neurosis" (1909d, p. 209).

During his first stay in Great Britain in 1875, at the Manchester home of his half-brothers Emanuel and Philipp, and during his stay in Trieste, Italy, at the experimental zoological station, Freud confided to Silberstein his impressions, youthful desires, and ambitions. Freud's last preserved letter to Silberstein dates to January 1881, when Freud was preparing to receive his medical diploma.

On February 7, 1884, Freud wrote to his fiancée, "We became friends at a time when one doesn't look upon friendship as a sport or an asset, but when one needs a friend with whom to share things. We used to be together literally every hour of the day that was not spent on the school bench. . . . [We] compiled a great mass of humorous work which must still exist somewhere among my old papers" (1960a [1873–1939], pp. 96–97). Those papers probably disappeared in the fire of April 1885.

As for Silberstein, after his exams he left for Leipzig to study jurisprudence, later moving to Vienna, where in 1875 he attended classes in law and Franz Brentano's lectures on philosophy. He took his doctorate in law in 1879, but would never practice. After a reversal in his family's financial situation, he was compelled to work in banking, then in the grain trade.

Silberstein's first marriage, with Pauline Theiler, ended sadly. According to his granddaughter Rosita Braunstein Vieyra, this young woman "became mentally ill, was treated unsuccessfully by his friend Sigismund Freud, and threw herself from a window in Freud's apartment building" (Freud, 1989a [1871–1881, 1910], p. 192). By other accounts, published at the time of the incident in 1891, she did not actually see Freud before committing suicide. Silberstein subsequently remarried and had a daughter, Theodora.

A socialist, Silberstein, together with fellow student Heinrich Braun, initiated Freud into social-democratic politics. Throughout his life Silberstein was politically active and played an important role in the Jewish community, fighting for the right of Jews to become

Romanian citizens and for their right to vote. He was president of the Hebrew Immigrant Aid Society, the Alliance Israélite universelle, and B'nai Brith.

Three years after Silberstein's death, Freud recalled him a final time in a letter to the president of B'nai Brith in Braila: "I was deeply touched to learn of the honor your Lodge has bestowed on my late childhood friend, Dr. Eduard Silberstein. I spent many years of my boyhood and young manhood in intimate friendship, indeed in fraternal fellowship, with him. . . . Later, life and physical distance separated us, but early friendship can never be forgotten" (1989a [1871–1881, 1910], p. 186).

## SILENCE

Silence in the course of an analytical session, whether it comes from the patient or the analyst, has constantly posed problems for the theorists of psychoanalytical technique.

According to certain authors, silence is to be interpreted as a resistance (Karl Abraham, Sándor Ferenczi, Sigmund Freud, Wilhelm Reich, Otto Fenichel, Anna Freud, Stephen Weissman). Edward Glover was the first to emphasize the counter-transference positions involved in it, and noted the role of the super-ego. Karl Abraham, Sándor Ferenczi, Edmund Bergler, Ella Sharpe, Robert Fliess and Kata Levy make of it a particular mode of instinctual expression, while Rudolph Loewenstein and Leo S. Loomie approach it as the

translation of a distortion of the ego. Silence has also been studied as an object relation by Jacob Arlow (defense or discharge) and by Ralph Greenson (resistance or communication), as an object relation properly speaking (Carel Van der Heide, Meyer A. Zelig) and as a particular mode of object choice (Robert Barande).

According to Freud ("The Dynamics of Transference," 1912b, p. 101): "If a patient's free associations fail, the stoppage can invariably be removed by an assurance that he is being dominated at the moment by an association which is concerned with the doctor himself or with something concerned with him. As soon as this explanation is given, the stoppage is removed, or the situation is changed from one in which the associations fail into one in which they are being kept back." And elsewhere, in "The Theme of the Three Caskets" (1913f, p. 295): "in dreams dumbness is a common representation of death." He also says in "Remembering, Repeating and Working-Through" (1914g, p. 150) that when the patient "is silent and declares that nothing occurs to him," this, "of course, is merely a repetition of a homosexual attitude which comes to the fore as a resistance against remembering anything," while Sophie Morgestern, in "A Case of Psychogenous Muteness" (1927), gave us the first work known in France to use drawing, in place of speaking, as a method of child analysis.

Other authors have added to these views: silence is "a state of restoration of primary narcissism, it is the realization of desire" enabling one to "re-experience narcissistic omnipotence" (Pierre Luquet, Béla Grunberger), or a sign of "good maternal care that provides the ego with a silent but vital support" (Donald W. Winnicott). The sense of the ego's inability to mask instincts from the super-ego in discourse may explain the very frequent silences that are encountered in child therapy. In the analytical couple, of whatever kind, "the support of the amorous exchange as the patient lives it is indeed silence [. . .] It's within the crucible of the therapist's silence that the patient's spoken words will be revealed as fantasy" (Robert Barande).

Luisa de Urtubey, in her report on the "work of the counter-transference" (1994), sets out the theories of a great number of authors who discuss silence. For her, "silence—as well as speech, its interpretations, its emphases, the links it weaves—is the expression of counter-transference in this analytical space and at this precise moment." Pearl Lombard expresses an aptitude for the silent maternal counter-transference: "speech is

silver, silence is golden” (“The Silence of the Mother, or: Twenty Years Later”, 1986). She remarks that “a succession of images wells up in the analyst’s mind as she or he accompanies a silent patient: astonishment, anxious questioning, an experience of depression and an obligation to imagine if we are to survive, but also if our patients are to survive psychologically. There are long periods in which the exchange between patient and analyst, although it is very intense, happens in both directions, in the mysterious depth of silence. The way these analyses evolve depends to a large extent on the existence of counter-transferential movements that are sufficiently intense to arouse representations of highly personal images or things, related to the analyst’s narcissism—representations that can invigorate the treatment only insofar as they can be linked and bound to a moment in the patient’s history, either in narrative form, or in the shape of images visualized on the basis of that narrative. Thus the vital bridge between word representations and thing representations is created or recreated in the analyst himself or herself. This bridge is highlighted by interpretation, the invigorating effect of which fulfils the silence and makes it speak.”

The evaluation of “silence” is possible only if each case—patient and analyst—is taken on its merits.

## **SIMMEL, ERNST (1882–1947)**

Neurologist and psychoanalyst Ernst Simmel was born on April 4, 1882, in Breslau, Germany (now Wrocław, Poland) and died in Los Angeles on November 11, 1947.

From a Jewish background, Simmel was the youngest of nine children. His father, Siegfried, was a banker; his mother, Johanna, managed an employment agency for domestic servants.

After studying medicine and psychiatry in Berlin and Rostock, Simmel received his medical degree in 1908; his dissertation concerned the psychogenic etiology of dementia praecox. Early in his career he worked as a general practitioner in Berlin. During World War I, however, he served as military doctor and chief of a hospital for psychiatric battle casualties in Posen. There he introduced the use of psychodynamic principles; at the time, he was still self-taught in psychoanalysis.

Returning to Berlin after the war, Simmel underwent a didactic analysis with Karl Abraham in 1919. Together with Abraham and Max Eitington, he helped establish the Berlin Psychoanalytic Institute in 1920. He served as president of the Berlin Psychoanalytic Society from 1926 to 1930, and founded and served as chief physician of the Tegel sanatorium at Schloss Tegel, outside Berlin, in 1927. The sanatorium, the first ever designed to employ psychoanalytic principles in treating patients who might benefit from observation, went bankrupt and closed in 1931.

In 1910, Simmel married Alice Seckelson, and the couple would have two sons. In 1929 he married his second wife, Hertha Brüggemann.

Simmel, a liberal who had helped to found the Society of Socialist Physicians and served as its president from 1924 to 1933, ran afoul of Nazi authorities soon after Hitler came to power in 1933. Emigrating to the United States in 1934, he moved to Los Angeles after a brief period at the Topeka Psychoanalytic Institute. He was instrumental in founding the Los Angeles Psychoanalytic Institute soon after the Second World

War; he also helped establish the San Francisco Psychoanalytic Society, and served as its first president.

Simmel published both clinical and theoretical papers. *On the Psychoanalysis of War Neuroses* (1921) became a classic. His 1927 lecture at the Innsbruck Congress on the use of psychoanalytic principles in treating institutionalized patients was also highly original. A major theoretical contribution is "Self-Preservation and the Death Instinct," published in 1944. Another significant contribution to theory was Simmel's hypothesis concerning the existence of pre-oedipal anal libido, germane to certain psychosomatic and psychotic disorders. These ideas would find resonance in the work of Melanie Klein, Wilfred Bion, and Donald Meltzer.

Simmel also published some thirty original works on social issues, clinical problems, and matters of mental health policy. He is important both as a founder of the institutions noted above and for establishing a place for psychoanalysis in health care and suggesting its applications to clinical medicine. Many of his works concern psychosomatic medicine, including his "Über die Psychogenese von Organstörungen und ihre psychoanalytische Behandlung" (The Psychogenesis of Organic Disturbances and Their Psychoanalytic treatment") from 1931. He edited the anthology *Anti-Semitism. A Social Disease*, published in 1946. *Psychoanalyse und ihre Anwendungen* [Psychoanalysis and its applications], a collection of numerous abstracts, lectures, and unpublished manuscripts, appeared in 1993.

## SKIN

The skin is of interest to psychoanalysis because it is anaclitically related to narcissism, because it is an erotogenic zone, and because it is the object of particular kinds of assaults. Manifestly, the skin is a potential vector for the main instincts (attachment, libido, destructive impulses).

At the end of the first essay of *Three Essays on the Theory of Sexuality* (1905d), in connection with his notion of polymorphous component instincts, Freud treated the skin as an erotogenic zone specifically excitable by the sadism/masochism "pair of opposites," in contrast with the eyes, which he conceived of as the bodily seat of the voyeurism/exhibitionism antithesis. Later, in his paper "A Child Is Being Beaten" (1919e), he described and analyzed the basic scene in masochism: an active adult beats a passive child, while another child bears silent witness to the event.

The skin has a particular place in the evolution of living beings: while the husk characterizes the vegetable realm and the membrane the animal realm, the skin is peculiar to vertebrates. In the development of the embryo in vertebrates, the ectoderm gives rise to both the skin and the cortex, so that the skin is in a sense the surface of the brain. The structure of the skin is complex in that it is a sense organ that contains the other sense organs. It comprises several interlocked layers of greatly varied structures. The skin and the sense organs that it envelops constitute an interface ensuring the individual's contact with the outside world. Like most outer coverings or membranes, the

skin has a twofold nature: it is a protective shield and it facilitates the communication of meanings. Freud mentioned this nature in his discussion of the “mystic writing pad” (1925a [1924]), on which traces and signs are inscribed. The skin helps give the body its form and coherence. The human body can more readily assume a vertical posture because the skin protects and holds in the skeleton and musculature. The unity of the individual thus depends on the skin.

Certain areas of the skin (mucous membranes, erectile tissue, hair on the head, pubic hair, hollows) are especially sensitive to sexual arousal (in comparison with overall presexual skin-to-skin contact). Didier Anzieu has advanced the hypothesis of a fantasy of a skin common to mother and child, and on that basis he developed the idea of a skin ego—an idea that converges with Esther Bick’s notion of a psychic skin and Wilfred R. Bion’s concept of container/contained. For Anzieu, this fantasy of a common skin contributes both to the narcissistic foundation of the individual and to the anaclitic reinforcement of the sexual instinct.

In sadism and masochism, humans experience a mixture of pleasure and pain. Here the fantasy of a common skin is replaced by the fantasy of its being ripped off, which is necessary if the individual is to progress toward autonomy but also is a source of guilt feelings. Mother’s and child’s joint cathexis of the newborn’s skin is immediate and is sometimes a source of sexual pleasure. Indeed, if the mother does not spontaneously cathect this first contact, any of a large number of pathologies, ranging from asthma to autism, may result.

Psychodermatology has shown a correlation between flaws in the ego and skin disorders. The greater the impairment of the ego, the more seriously the skin seems to be affected.

## **SKIN-EGO**

The term “skin-ego” designates a mental representation that the child forms on the basis of its experience of the surface of its body and uses to picture itself as the vessel of mental contents. The skin-ego belongs to the period in development when the psychic ego differentiates from the body ego on the practical level while remaining indistinguishable from it in the imagination. Intermediate between metaphor and concept, the notion of the skin-ego was worked out by Didier Anzieu and first presented in 1974.

According to Anzieu, the ego encloses the psychic apparatus much as the skin encloses the body. The chief functions of the skin are transposed onto the level of the skin-ego, and from there onto the level of the thinking ego. The functions of the skin-ego are to maintain thoughts, to contain ideas and affects, to provide a protective shield, to register traces of primary communication with the outside world, to manage intersensorial correspondences, to individuate, to support sexual excitation, and to recharge the libido. In brief, the skin-ego is an interface between inside and outside, and is the foundation of the container/contained relationship.

The skin-ego develops and is enriched by integration into the various envelopes of the sensorimotor system. It has two functional aspects, with one aspect focused on excitations of either internal or external origin and the other oriented toward communications with its entourage.

An important part of psychoanalytic work with borderline patients is the reconstruction of the earliest

phases of the skin-ego and their consequences for mental organization. This task calls on the techniques of transitional analysis.

## **SLEEP/WAKEFULNESS**

Unlike being awake, a vigilant consciousness, sleep corresponds to a withdrawal of cathexis from the outside world accompanied by a suspension of motor activity. It is an active phenomenon, and although at the beginning of life the opposition wakefulness/sleep is closely dependent upon that of satisfactions and needs; wishes, the capacity for regression, and the nature of the infant's relations to the mother soon modify this binary rhythm. In the waking state, excitation begins with sensory perception and in a sense traverses the psychic apparatus to emerge any motility; whereas during sleep the reverse happens: excitation passes from ideation to sensory perception, the dream.

Sigmund Freud approached the issue of waking and sleep through the analysis of dreams. In *The Interpretation of Dreams* (1900a), he advanced the hypothesis that dreams are the guardians of sleep. Unconscious excitation, linked to previous day's residues, is liable to disturb sleep. The dream is responsible for bringing this free energy under the control of the Preconscious; it diverts this energy, serves as a safety valve, and thus, with a minimal effort of vigilance, ensures sleep.

Freud did not modify this hypothesis, but later did flesh it out, most notably in the article "A Metapsychological Supplement to the Theory of Dreams" (1916–1917 [1915]), where he introduces the concept of a wish to sleep emanating from the ego, a veritable sleep drive that impels the sleeper to return to intrauterine

life. Sleep must be understood as a period of withdrawal toward primary narcissism: The mind renounces most of its acquisitions via a return to its developmental starting point as a way of reliving of its stay in the maternal body, some of the conditions of which are reproduced in sleep. It is as if a kind of inversion happens in sleep: The subject turns toward his or her inner world by almost totally withdrawing interest in the outer world of waking reality.

As Freud pointed out in the introduction to his "supplement," sleep, like mourning or being in love, can be considered the normal prototype of a pathological state. Regression and backward steps in development are observed. There are two types of regression. First, a temporal regression involving the organization of the ego, which, through this step backward, moves closer to the id. Second, a regression of libidinal development at the level of the drives which goes so far as to restore primary narcissism during sleep. Associated with a relaxation of repression during sleep, which is conducive to the emergence of the Id's drive energies, this state leads to the formation of dreams through hallucinatory wish-fulfillments. The dreamer is only interested in external reality to the degree it may threaten to bring about an end to the sleeping state by awakening.

After Freud, and until the early 1950s, this conception of the opposition sleep waking remained unchanged, and made enriched by concepts such as Bertram D. Lewin's 1949 postulation of the "screen dream," the result of introjecting the good maternal breast, which opens up "the dream space" and actualizes the matrix in which the dream's binding activity can occur. In 1953, when electroencephalographic images revealed the alternation between periods of slow sleep (also called non-rapid eye movement, or NREM sleep), which has a reparative function, and periods of paradoxical sleep (or REM sleep), in which dreams occur, attempts were made to distinguish between the somatic and psychic aspects of hypnic phenomena. As André Green emphasized, it appears to be essential to not transpose concepts from one domain to the other. However, it is both legitimate and productive to explore points of convergence between the two.

Authors do agree that sleep plays an organizing role in the case of both the physiological paradoxical sleep, and the psychological dreams. Dream phenomena seem to have binding functions: maintaining the continuity of sleep, connecting waking mental life to

sleeping mental life, and integrating lived experiences by binding them to libidinal needs. Masud Khan called this linking function the “capacity for dreaming,” and Didier Houzel suggested that this involves a process of stabilization, not in the form of a return to a fixed energy level of zero, but rather as a form of “structural stability,” that is, a dynamic equilibrium that assumes constant exchange with the environmental milieu.

## SLIPS OF THE TONGUE

Slips of the tongue are errors involving the uttering (*Versprechen*), or hearing (*Verhören*), or writing (*Verschreiben*), or reading (*Verlesen*) of a word and which entail an involuntary parody of the word, assuming the word is known. This kind of slip is an ordinary occurrence but is structurally related to the paraphasias found in pathological conditions.

Freud became interested in slips and word play in 1890, and discussed them in his correspondence with Wilhelm Fliess. Both resemble dreams in that

they are part of normal behavior although they introduce an incongruous and, in the case of slips of the tongue and dreams, an involuntary element. Freud’s interest arose from his conviction that it would be impossible to understand psychopathological processes without having a clear notion of their relation to normal mental processes. It was in *The Psychopathology of Everyday Life* (1901b) that he provided the first and most complete discussion of slips of the tongue, but he discussed them again at length in the *Introductory Lectures on Psychoanalysis* (1916–1917a [1915–1917]).

In *The Psychopathology of Everyday Life*, Freud made use of an earlier, essentially functionalist work on slips of the tongue and reading errors (Meringer and Mayer, 1895), which he contrasted with his own theory. He eliminated two hypotheses: that of the “contamination” of the sound of one word by another and that of “wandering” speech images, which interested Freud to the extent that these disturbances were located below the threshold of consciousness (1901b, pp. 57–58). Using numerous examples, some of which are undeniably comical, Freud illustrated the way in which repressed drives return in the disturbance of language.

Slips during reading and writing are not structurally different from those that occur in hearing or speaking, and the same motives are found in both, either libidinal or hostile. But slips provide infinite forms of expression for those drives, while disguising them, and some require a complex effort of interpretation that presupposes familiarity with the life and memories of their author. In general, slips of the pen are not as readily noticed by their authors as slips of the tongue.

Freud sums up the character of slips of the tongue as follows in the *Introductory Lectures on Psychoanalysis*: “the suppression of the speaker’s intention to say something is the indispensable condition for the occurrence of a slip of the tongue.” However, the intention can be conscious or unconscious and still produce a slip. “In almost every case in which a slip of the tongue reverses the sense, the disturbing intention expresses the contrary to the disturbed one and the parapraxis represents a conflict between two incompatible inclinations.”

Slips are especially interesting when they lead us, in trying to understand them, to dissociate the sound (the signifier) from the meaning contained in the

word (the signified). The same was true for the most famous parapraxis made by Freud, forgetting the name Signorelli, to which Jacques Lacan (1966) devoted an entire essay. We find in both word play and jokes, as in slips or the forgetting of names, a complex dynamic and the same processes (displacement and condensation) that Freud showed to be operative in dreams, whose relevance for the study of the unconscious he recognized. Listening for slips of our own often has an immediate revelatory component, similar to that of the patient who hears himself say things that are unknown and yet familiar during the course of analysis.

## **SMELL, SENSE OF**

Throughout his writings, Sigmund Freud made explicit reference to the role of the sense of smell in mental sexuality. “Olfactory substances...are disintegrated products of the sexual metabolism. . . . At time of menstruation and of other sexual processes the body produces an increased number of these substances and therefore of these stimuli,” he wrote to Wilhelm Fliess on January 1, 1896. Later, in his “Three Essays on the Theory of Sexuality” (1905d), he added that the repression of a coprophilic olfactory pleasure governs fetish choice: “Both the feet and the hair are objects with a strong smell which have been exalted into fetishes after the olfactory sensation has become unpleasurable and has been abandoned” (p. 155, note 3).

This inhibition of the sense of smell in humans, under the sign of the repression of the pleasure that it can bring, can play a major role in the development of certain neuroses; this is what Freud maintained in the case of the “Rat Man,” recorded in “Notes upon a Case of Obsessional Neurosis” (1909d). “The ‘organic’ repression of smell is also a factor in civilization,” he told his students at the Psychoanalytic Society of Vienna in a lecture delivered on November 17, 1909. Soon thereafter, in “On the Universal Tendency to Debasement in the Sphere of Love” (1912d), he posited this as a consequence of the fact that the human sensory organ had been raised up off the ground with the appearance of the upright stance. The coprophilic instinctual components then became incompatible with the esthetic demands of human civilization. He further elaborated this line of thought in “Civilization and Its Discontents” (1930a), where he speculated that the role of the olfactory sensations “was taken over by visual excitations, which, in contrast to the intermittent olfactory stimuli, were able to maintain a permanent effect. The taboo on menstruation is derived from this ‘organic repression’, as a defence against a phase of development that has been surmounted” (p. 99, note 1).

## SMIRNOFF, VICTOR NIKOLAÏEVITCH (1919–1995)

The French psychoanalyst and neuropsychiatrist Victor Smirnoff was born on November 27, 1919, in Petrograd and died in Paris on November 5, 1995.

The child of doctors belonging to the social-democratic intelligentsia, he emigrated with his parents in 1921 after the Bolsheviks came to power. He spent some early years in Berlin before moving to Paris in 1929. After medical training, he worked as a psychiatrist under Georges Heuyer. In 1950, a grant from the Rockefeller Foundation took him to the United States on a fellowship in child psychiatry. There he came into contact with the pioneers of the Child Guidance movement, while his cultural interests and love of books led him into artistic and literary avant-garde circles.

Back in Paris in 1954, he undertook an analysis with Jacques Lacan at the suggestion of Wladimir Granoff. Much involved in the internal debates of the Société Française de Psychanalyse leading up to the split of 1963, Smirnoff was one of those, when that split occurred, who opted for rejoining the International Psychoanalytical Association and distanced themselves from Lacan's practical procedures while acknowledging the value of his teaching.

As a child psychoanalyst, Smirnoff took part in the organization of teaching at La Salpêtrière with Jean-Louis Lang and Daniel Widlöcher, and founded the psychotherapy clinic of the fifteenth arrondissement of Paris, known as "La Rue Tiphaine," where the psychoanalytical approach predominated. He was very active in the founding and running of the Association Psychanalytique de France (APF), contributing most importantly to training issues through his writings and his many control analyses. He was the association's president in 1975 and again in 1984. He took part in numerous conferences and built up the association's external relationships as much in France (notably with the Quatrième Group) as abroad. Smirnoff's friendship with Masud Khan in London and his desire for cultural expansion led to his translation into French of several essential texts, including Winnicott's "Transitional Objects and Transitional Phenomena" (1953) and Klein's *Envy and Gratitude* (1955).

Smirnoff's book *The Scope of Child Analysis*, first published in 1966, has been widely translated and frequently reprinted, and in 1992 it was completely revised. It is a basic work of reference in its field.

A member of the editorial board of the *Nouvelle Revue de psychanalyse*, Smirnoff also contributed many articles to other journals, among them *Topique*, *L'Esprit du Temps*, and *L'Inactuel*. The titles of his books attest to his eclecticism: *Et Guérir de plaisir*, *De Vienne à Paris*, *Une Ténébreuse Affaire*, and *Les Limbes de la répression* (written in collaboration with Marie-Claude Fusco, his partner of many years).

Victor Smirnoff contributed broadly to the development of the psychoanalysis of adults as well as that of children, and he never cordoned child analysis off, preferring to integrate it into an overall theoretical perspective.

He liked to refer to himself as *ein analytischer Wandersmann*, an analytic journeyman, and his personal itinerary indeed enabled him to maintain a cosmopolitan cultural openness and a wide acquaintanceship with a variety of analytical tendencies without wavering in his commitment to the APF and his position within it.

The legacy of Victor Smirnoff is that of a humanist for whom psychoanalysis was a true passion, a way of thinking, and indeed a way of living.

## SOCIAL FEELING (INDIVIDUAL PSYCHOLOGY)

After long emphasizing feelings of inferiority and their consequences, Alfred Adler came to grant more and

more importance to the social feeling found in the notions of bonds or attachments that had been studied by such authors as René Spitz, John Bowlby, and Hubert Montagner.

At birth, the infant is extremely vulnerable because of its physiological immaturity. The mother-child relationship is thus vital for the newborn. In Adler's view, preestablished schemes are triggered in the interactions between mother and child: "The mother, taken as the nearest kin at the threshold of development of social feeling, is the source of the first impulses enjoining the child to enter into life as an element of the whole," he wrote. He thus considered the act of suckling the mother's breast as an act of cooperation. The socialization of the infant is a potentiality that represents an evolutionary acquisition of the species: "The evolutionary acquisition of maternal love is generally so strong in animals and human beings that it can easily outweigh the instinct for food and the sexual instinct."

Social feeling is not simply adaptation to the group, which itself can be a form of compensation for feelings of insecurity, as can be seen in cults or in totalitarian systems. This notion extends to both the political and economic dimensions of the object-relations that ensure the subject's autonomy. In the child, compensation for feelings of inferiority is modulated by the harmonious development of social feeling, in which the mother plays an essential role. According to Adler in *Problems of Neurosis: A Book of Case Histories* (1929/1964), it is she who "effects the first major and specifically human changes in the infant's behavior. Under her influence, the infant, for the first time, inhibits its desires and organic instincts and introduces delays and indirect methods into the pursuit of what it desires . . . it is also the mother who interests the infant in other people and enlarges its social circle."

This potentiality is not expressed automatically. The mother may reject the child from birth, as happens in puerperal psychosis. A fusional relationship, by contrast, will prevent any possibility of autonomy. René Magritte's painting *The Spirit of Geometry* illustrates this type of relationship, in which the mother can see herself as the son she would have liked to be. Fernando Botero's painting *Melancholy* represents one of its consequences. Compensation for feelings of inferiority mobilizes aggressive impulses, expressed in the form of antisocial behaviors that may develop in the direction of delinquency or criminality. It is the

development of social feeling that directs these aggressive impulses toward socialized behaviors or sublimation. In the neurotic, the aggressive behaviors are only masked. They are expressed in a systematic tendency toward devaluation.

In *The Practice and Theory of Individual Psychology* (1920/1951), Adler likened melancholia to paranoia. This is not surprising if we think in terms of compensation for feelings of inferiority and the degree of social feeling—that is, the relationship to the other in the two cases. The melancholic expresses a narcissistic breakdown resulting from a loss of love, for which he or she blames the other. The paranoiac hallucinates this feminine other, which enables him to idealize himself at the price of homosexual feelings of persecution, since he becomes both God and the wife of God. The annihilation of the other in the schizophrenic culminates in an all-pervasive self in a delusional world.

## **SOCIÉTÉ FRANÇAISE DE PSYCHANALYSE**

The Société française de psychanalyse (SFP; French Society of Psychoanalysis) was born in 1953 out of the first split in the French psychoanalytic movement. The reasons for its creation, already present within the Société psychanalytique de Paris (Paris Psychoanalytic Society), involved disagreements about the criteria for the selection and training of future analysts. The conceptions of Sacha Nacht, among other points of disagreement, were concretized in the statutes of the new Institut de psychanalyse (Institute of Psychoanalysis), and these were opposed by Jacques Lacan. At the administrative session of the meeting of the Paris Psychoanalytic Society on June 16, 1953, Lacan resigned after his presidential mandate was withdrawn in favor of Vice President Daniel Lagache. Lagache then

announced his own resignation. Also resigning were Françoise Dolto and Juliette Favez-Boutonier, soon followed by Blanche Reverchon-Jouve. Lacan joined forces with them to found the SFP, which André Berge and George Mauco also joined, though they concomitantly remained members of the Paris Psychoanalytic Society.

During the ten or eleven years of its existence, the SFP proved to be singularly active, productive, and open to other disciplines under the influence of, in particular, Lagache, Lacan, Dolto, Favez-Boutonier, and Georges Favez, seconded by the “troika” of Serge Leclaire, Vladimir Granoff, and François Perrier, who were to play a major role. Among the successes of the society, especially noteworthy are the Royaumont Colloquium of 1961 and the creation in 1956 of the journal *La psychanalyse*, which was active until 1964, eight issues later.

Meanwhile, a setback came to light. The founders of the SFP did not realize that by leaving the Paris Psychoanalytic Society, they were also, ipso facto, relinquishing their membership in the International Psychoanalytical Association. Thereafter, successive presidents of the society—Lagache, Lacan, and Angélo Hesnard—repeatedly approached the International Psychoanalytical Association to get the association to recognize the SFP.

The history of the second split, for anyone who did not actually experience it, is difficult to reconstruct. Those in charge of the future Association psychanalytique de France (French Psychoanalytic Association), except perhaps for Vladimir Granoff in veiled form, have not given their versions of events, while those in rival societies, except for Alain de Mijolla, gave only approximate glimpses often lacking in objectivity, or even obviously biased, imprecise, and polemical.

The reasons for this second split appear to be twofold and intertwined: recognition of the SFP by the International Psychoanalytical Association and the issue of training, in particular, training analysis. After a defeat on the former goal at the 1959 Congress of the International Psychoanalytical Association in Copenhagen, which had dispatched an investigative commission, the next congress, in Edinburgh in 1961, recognized the SFP with the provisional status of a study group and named Lagache, Leclaire, and Favez-Boutonier as members at large, but it combined these decisions with a series of “recommendations”—all

technical in nature, dealing with training, and challenging the practices of Lacan and Dolto.

The approach of the Stockholm congress in 1963, which was supposed to rule on the request for affiliation, sparked intense discussion, both within the SFP and with members of a new investigative commission. These discussions, not always devoid of misunderstanding or naïveté, mainly involved attempts at reconciliation, notably through the mediation of Granoff and Leclaire. A motion for relative reconciliation was thus presented to the International Psychoanalytical Association on July 11, 1963, by six of Lacan’s analysands, dubbed the “motionnaires”: Piera Aulagnier, Jean-Louis Lang, Jean Laplanche, Jean-Bertrand Pontalis, Victor Smirnoff, and Daniel Widlöcher; with the support of Didier Anzieu and Jean-Claude Lavie (also analysands of Lacan) and Granoff. But the executive committee of the association, though it added Granoff to the previously recognized members at large, further hardened its requirements, demanding that Lacan and Dolto be excluded from all training activity.

From then on, the split gradually solidified between the two groups: one around Lacan, with Leclaire and Perrier, and the other with Lagache, Favez-Boutonier, Favez, and Berge. The representatives of the first group, until then in the majority in the administration of the SFP, resigned in October 1963 and in December created, around Jean Clavreul, a “psychoanalysis study group” not recognized by the SFP. The second group, which became the majority in November, was recognized by the International Psychoanalytical Association only as a “French study group.” The split was then inevitable. The statutes of the Association psychanalytique de France were registered on June 9, 1964, and Lacan, on June 21, announced the founding of the *École française de psychanalyse* (French School of Psychoanalysis), which quickly renamed itself the *École Freudienne de Paris* (Freudian School of Paris). In January 1965 representatives of the two societies announced the dissolution of the SFP, whose membership at the time included 20 permanent members, 25 associate members, 4 corresponding members, and 80 candidates.

## **SOCIÉTÉ PSYCHANALYTIQUE DE GENÈVE**

The Geneva Psychoanalytic Society was founded in September 1920, its creation being announced in the *Internationale Zeitschrift für Psychoanalyse* (1921), although it never figured among the component societies recognized by the International Psychoanalytic Association. It was founded shortly after the Swiss Psychoanalytic Society, which was constituted in Zurich in 1919.

The Geneva Psychoanalytic Society brought together both physicians and non-physicians, as well as people who practiced psychoanalysis and others who took an interest in it without practicing it. Its president was Édouard Claparède, physician and professor of psychology at the science faculty of Geneva University. Although not a psychoanalyst, Claparède took a great interest in psychoanalysis from 1906 onwards and regularly kept the readers of *Archives de psychologie* up to date with Freud's latest discoveries. In 1920 he wrote the preface to the first French translation of Freud's *Five Lectures on Psychoanalysis* (1910a), which he first published in the *Revue de Genève*. Alongside Claparède we find Pierre Bovet, director of the Jean-Jacques Rousseau Institute, as well as Henri Flournoy and Charles Odier, who were among the first to practice psychoanalysis, and Raymond de Saussure,

who joined the society a little later. Also active in the society was Dr. Ferdinand Morel, who later abandoned psychoanalysis, Dr. William Boven, from the Lausanne medical faculty, and Sabina Spielrein. One of Jung's former patients, Sabina Spielrein came to Geneva in 1920 and was Jean Piaget's analyst. We know little enough about the life of the society or how it came to be dissolved. It is easy to imagine that after 1928 the Swiss Psychoanalytic Society, reorganized by its new president, Philipp Sarasin, had a greater attraction for psychoanalysts in French-speaking Switzerland.

## **SOCIÉTÉ PSYCHANALYTIQUE DE MONTRÉAL**

Around 1968 and 1969 it became obvious that for linguistic and geographic reasons, among others, sections based on a federal model were needed within the Canadian Psychoanalytic Society. In the Francophone community, the growing number of candidates and the emergence of a strong nationalist sentiment meant that the training program in English had become an anachronism. In and around Toronto, with the increase in the number of psychoanalysts between 1959 and 1969, there was no longer any reason why candidates should have to travel every week from Toronto to Montreal for their training, as had been the case for ten years.

The Canadian Psychoanalytic Society thus created Francophone and Anglophone sections for Montreal, called respectively the Société psychanalytique de Montréal (SPM) and the Canadian Psychoanalytic Society/Quebec English. A third section was created for Ontario: Ontario Branches. As early as May 1965, the Canadian Institute of Psychoanalysis communicated its intention of setting up a training program in

French, beginning in 1967. Initially, the three sections used the same training program that the institute had established in 1959, which corresponded to the program used by the British Institute of Psycho-Analysis. This four-year program consisted of conferences; clinical, technical, and theoretical seminars; and three supervised analyses. Considering the program to be too classical, the new wave of French-speaking psychoanalysts trained in Paris in the 1960s began to question it toward 1970.

In September 1969 a few Paris-trained French-speaking psychoanalysts created the *Groupe français de Montréal* (Montreal French Group). Some English-speaking colleagues quickly saw this as a desire for separation that was inspired by the political movement *Souveraineté-Association*. After the initial euphoria, the new group quickly found itself confronted with the harsh political realities of the Canadian Psychoanalytic Society: the requirements, programs, and traditions of the Canadian Institute of Psychoanalysis were very different from what they had known in Paris, and they aspired to greater autonomy than their Anglophone colleagues were willing to grant them. The *Société psychanalytique de Montréal* diverged from the other two sections of the society mainly over training issues: differences in the teaching program, a refusal to allow the institute to intrude in personal analyses, a non-evaluative concept of training, ongoing seminars that could be run by nontrainers, and above all, the creation of the category of authorized analysts, which allowed nontrainer analysts to analyze candidates after five years of membership.

It is important to point out that as early as 1965 those concerned had agreed on how the three Canadian sections would be constituted, and that in the winter of 1965/1966 the three future sections had established a common ground. At this stage the Francophone members of the institute expressed their fears that “due consideration for the needs of the sections in terms of geographic and cultural autonomy was hardly compatible with the maintenance of organizational unity.” Nevertheless, in 1968 the three sections of the institute were created, and in 1969 those of the society were created. On October 9, 1969, the members of the Francophone group unanimously adopted the name *Société psychanalytique de Montréal* (Psychoanalytic Society of Montreal), although the name was not officially adopted by the Canadian Psychoanalytic Society until 1972. At this point some members favored a

complete separation in the Canadian Psychoanalytic Society, while others feared the isolation that such an early separation might lead to. Another attempt to launch the idea of a separation was again rejected by the members in the mid-1990s.

In the fall of 1967, the first monolingual French training program got its start. There were 8 analysts and 9 students. Twenty-one years later (1988), 95 students had completed their training in French. The first elected council of the *Société psychanalytique de Montréal* held its inaugural meeting on November 24, 1969. Dr. Jean-Louis Langlois was the first president. During this meeting Roger Dufresne put forward the idea of ongoing seminars with a view to enhancing collaboration between the institute and the society, and the members voted in favor of an annual scientific colloquium to be held every spring, an idea that was dear to André Lussier.

The teaching at the institute was initially didactic and continued the tradition of the 1959 program. This situation continued until 1972, when ongoing open seminars directed by both members and nonmembers of the institute were made available to candidates. Work in such small groups best fostered the free and open exchange of ideas. The great originality of these seminars was that they consisted of older members, younger members, and students. The only requirement retained was study of Freud's texts, spread out over four years, the training being dispensed by any member who expressed the desire to do so, whether a training analyst or an ordinary member. In addition, stress was placed on supervision (which was seen as more helpful than evaluation) and particularly on the training analysis, later considered to be the core of training. For this reason the position of reporting analyst was abolished, in order to protect the transference of the training analysis from third-party institutional interference. In this context, the training analysis was considered a personal analysis in which the desire to become an analyst also had to be analyzed. As part of the commitment of candidate analysts, as soon as candidates are accepted, they are required to attend all scientific meetings.

This teaching model became the obvious choice among alternatives as the result of debate at international pre-congress meetings on training, the influence of the Francophone analytic groups, and the workshop “The current situation for psychoanalysis,” launched in February 1970 by four Paris-trained members: Jean

Bossé, Claude Brodeur, Roger Dufresne, and Jean-Louis Saucier. Every second Wednesday they reflected on the nature of the analytic process and on the relationships between psychoanalysis and society, psychoanalysis and medicine, psychoanalysis and psychoanalytic institutions, free treatment and direct payment by insurers, training analysis and personal analysis, training seminars and ongoing seminars, and supervision as assistance versus evaluation. Also important was the first annual scientific congress of the French section, in June 1970, on the theme “the transmission of psychoanalysis.” The reflections arising from these debates led to many policies later adopted at administrative meetings. Even in 2005 the structures of the Société psychanalytique de Montréal remain profoundly marked by the principles that made their appearance at that time.

Early on, the society found itself confronted with considerable challenges, particularly the establishment of the Quebec social security system. Psychoanalyst-physicians in Quebec had to decide on the medical or nonmedical character of psychoanalysis. At stake was the issue of state payment for analyses conducted by psychiatrists and whether there would be two categories of analysts: analysts with medical degrees and those without. Sufficiently aware of the obstacles that arise when the state interferes in treatment and because a second-class status would make it practically impossible for nonphysicians to practice, the French and English Quebec societies, after intense debate, bravely affirmed the nonmedical character of psychoanalysis. The Toronto Psychoanalytic Society made the opposite decision. This is one indication that many Canadian analysts, as well as many American analysts, considered psychoanalysis a subspecialty of psychiatry, and it provides a glimpse of the cleavage existing in the Canadian Psychoanalytic Society with regard to the nature of psychoanalysis.

The questioning was then extended to society-institute relations, to training in accordance with the Anglo-Saxon model (so different from the prevalent models in Paris), and to the centralizing influence of the Canadian Psychoanalytic Society, which delegated only the scientific program to sections, without providing any financial resources to organize scientific life or set up a library. During the three decades from 1967 to 1997, the financing and administration of the sections was partly autonomous and partly centralized. Up until the foundation of the Société psychanalytique de Montréal, all theoretical references were to works in

English, with the exception of Freud’s works, which had to be read in English. The authors to whom Paris-trained analysts referred seemed to be unknown. The difficulty of establishing a French-language library was the beginning of a long and arduous struggle toward administrative and financial autonomy for the sections—a struggle that reached its conclusion only in 1997 when they acquired complete autonomy in these domains.

The Société psychanalytique de Montréal was distinctly different from other Canadian psychoanalytic societies. First, it was open to diverse influences, but gravitated toward French psychoanalytic thinking. When founded in 1969, the society had 29 members, 13 of whom had trained in Paris, 3 in the United States, 1 in London, and 12 in Montreal. Second, it choose an open training program, unlike what was practiced in the other sections of the Canadian Psychoanalytic Society and in the United States. The Société psychanalytique de Montréal, like the Canadian Psychoanalytic Society/Quebec English, is the fruit of diverse contributions arising from several theoretical models following in the wake of Freud. As a result, points of dissent and rupture tend to be situated more around language and culture, or around questions of training and modes of transmitting psychoanalysis, rather than around schools and the theoretical rifts that found them. From a long cohabitation with English-speaking analysts, Francophone analysts have developed the arts of compromise and gentlemen’s agreements, which have enabled them so far to avoid the rifts that are so common in Europe. As a North American Francophone society, the Société psychanalytique de Montréal serves as a point of convergence between European and American influences.

The Société psychanalytique de Montréal and the Canadian Psychoanalytic Society/Quebec English share the same building, which is also the headquarters of the Canadian Psychoanalytic Society. Relations between the two sections have always been characterized by respect and courtesy. Some members of each section are greatly esteemed by those of the other. Ever since the establishment of the sections and in varying ways, there have always been candidates on either side who have gone to the other side for their supervision or analysis, just as from time to time some analysts, after their training, request transfers to the other section. Moreover, members of the French section attend

meetings of the Anglophone section more frequently than the converse.

In spite of all this, apart from differences over common issues that were resolved for a time, relations between the two sections have long been characterized by mutual incomprehension and distance. Though not applicable to all members, the most tenacious preconception is that the Francophones indulge in abstract philosophy and literature and are not clinically oriented, whereas the Anglophones are pragmatically engaged in psychiatry and psychology, but not psychoanalysis. These prejudices have not, however, prevented friendships and collaborations from developing between individuals. Moreover, by incarnating an external enemy against which cohesion had to be maintained, each society may perhaps have enabled the other to avoid internal divisions. Scientific relations with other sections are more tenuous. Even so, some members of the Société psychanalytique de Montréal are regularly present at the annual scientific congresses of the Canadian Psychoanalytic Society and play an active part in the different study committees of the umbrella organization.

Thirty years after its foundation, the Société psychanalytique de Montréal has more than quadrupled in size despite the inevitable departures. The society prides itself on having opened its doors to nonphysicians, which has enriched it with points of view from associated disciplines and consequently has enabled it to get a clearer grasp of the specific nature of psychoanalysis. The ongoing seminars of the society have exceeded the wildest hopes. They have enabled analysts, after their training is complete, to remain in contact with reflective networks of analysts of all ages. These seminars also serve to counterbalance the more impersonal relations that set in as the society grew larger. Analysts thus have a forum where they can discuss questions that arise in individual practice. Unfortunately, the society has not succeeded in providing an analytical presence in Quebec's main regions outside of Montreal and Quebec. As a result, the society has often been reproached for being closed.

In spite of the risks involved, the Société psychanalytique de Montréal, always supposing that its window onto society is compatible with its nature, has sought in the 1990s to maintain a higher social profile. The public conferences (Françoise Boulanger conferences, Julien Bigras roundtables), the open-house days, the project for an institutional psychoanalytic clinic, and

the creation of a permanent communications committee are all signs of a new desire to be open to society.

## **SOCIÉTÉ PSYCHANALYTIQUE DE PARIS AND INSTITUT DE PSYCHANALYSE DE PARIS**

From its creation in 1926 until the split of 1953, the history of the Société psychanalytique de Paris (SPP; Paris Psychoanalytical Society) practically coincides with the history of psychoanalysis in France, and since 1954 the society's history has been indissociable from that of the Institut de psychanalyse de Paris (Paris Institute of Psychoanalysis).

“On November 4, 1926, Princess George of Greece, née Marie Bonaparte, Mme. Eugénie Sokolnicka, Professor Angelo Hesnard, the two Drs. Allendy, A. Borel, R[ené] Laforgue, Rudolph Löwenstein, Georges Parcheminey, and Édouard Pichon founded the SPP. The goal of this Society is to bring together all the French-speaking doctors qualified to practice the Freudian therapeutic method and to give doctors who wish to become psychoanalysts the opportunity to undergo the training analysis that is indispensable to the practice of Freud's method.”

This was a fairly heterogeneous group of young psychiatrists (their average age was around thirty) who, after founding the group Évolution psychiatrique (Psychiatric Development) in 1925, were led to join forces with the non-physicians Eugénie Sokolnicka, a Polish-born emigrant; Freud's “legitimate representative” Marie Bonaparte, the main instigator of the organization (de Mijolla, 1988); and another emigrant of Polish origin, Rudolf Löwenstein, who had trained at

the Berliner Psychoanalytisches Institut (Berlin Psychoanalytic Institute) and would become their main training analyst. Although they were united around projects such as continuing the conferences of French-speaking psychoanalysts, initiated in August of the previous year, the launching of the *Revue française de psychanalyse* in 1927, or the formation of a Linguistic Commission for the unification of French psychoanalytic terminology, there were also a number of points of opposition that were exacerbated over the years. Two clans formed: One was made up of those who were faithful to Freud and to the International Psychoanalytical Association (IPA); the other consisted of those who, like Angélo Hesnard, or following Professor Henri Claude, who brought them together in his ward, were hostile to non-physicians. The latter group wished to invent a psychoanalysis purged of the “Germanic mystique,” adapted to the needs of psychiatry and, tellingly, to the French “mentality”—Édouard Pichon, after all, was a disciple of Charles Maurras of the right-wing Action Française.

The two factions nevertheless continued to pull in tandem, for better or for worse, until World War II, ensuring the publication of the *Revue*, the translation of a number of Freud’s works (many of these thanks to the efforts of Marie Bonaparte), and the introduction into the medical community of Freud’s theories, which had been rendered more than a little suspect by the vogueish effects that had accompanied their dissemination in France by way of the literary milieu of the *Nouvelle revue française* and surrealism.

When the society was created, René Laforgue was elected president (a post he held until 1930), Eugénie Sokolnicka vice president, and Rudolph Löwenstein secretary-treasurer. The first permanent member to be elected was Dr. Henri Codet, on December 20, 1926; Anne Berman, at the time Marie Bonaparte’s secretary, became the first regular member on January 10, 1927. Ernest Jones came to give a lecture on April 5 (Hanns Sachs was invited to lecture in 1928 and Hanz Prinzhorn in 1929, despite Édouard Pichon’s opposition to those who did not speak French), and in May it was announced that “Messieurs Codet, de Saussure, and Odier will be known as founding members.” In 1927 Sacha Nacht, as a “guest of the society,” presented “Quelques considérations sur une psychanalyse chez une schizophrène” (Some considerations on a psychoanalysis of a schizophrenic woman); he was elected to [membership on January 17, 1928, and to permanent

membership on October 21, 1929. A week later, the Second Congress of French-speaking Psychoanalysts discussed Charles Nodier’s report, “Obsessional Neurosis,” the first official manifestation of the SPP and the first in the long series of these Conferences (later called Congresses) that continue even today to bring together Europe’s French-speaking psychoanalysts and to put on their agenda various theoretical and clinical aspects of Freudian psychoanalysis: “Psychoanalytic Technique” by René Laforgue and Rudolph Löwenstein in 1928 and Eugénie Sokolnicka’s presentation on the same topic, also in 1928; “Les processus de l’autopunition en psychologie des névroses et des psychoses, en psychologie criminelle et pathologie générale” (The processes of self-punishment in the psychology of the neuroses and the psychoses, in criminal psychology and general pathology) by Angélo Hesnard and René Laforgue in 1930; “L’hystérie de conversion” (Conversion hysteria) by Georges Parcheminey in 1931; “La psychanalyse et le développement intellectuel” (Psychoanalysis and intellectual development) by Jean Piaget in 1933; and “Le masochisme, étude historique, clinique, psychogénétique, prophylactique et thérapeutique” (Masochism: a historical, clinical, psychogenetic, prophylactic, and therapeutic study) by Sacha Nacht in 1938, the last lecture before the war.

After discussions and revisions, which would often recur over the years, the statutes of the society, whose headquarters had been established at René Laforgue’s home, were officially registered on October 25, 1927. In 1928 the bureau saw Angélo Hesnard become vice president, Marie Bonaparte treasurer, and René Allendy secretary. In 1929, however, there was a crisis, because, as Laforgue wrote to Freud on October 26: “A very active minority of our group is against the International Psychoanalytical Association and against lay analysis.” The conflict was resolved, but at the price of Laforgue’s giving up the presidency.

On January 10, 1934, the first Institut de psychanalyse de Paris was inaugurated. Marie Bonaparte, who had made its creation possible, was named director. On July 13, 1937, Daniel Lagache was elected to permanent membership, as Jacques Lacan would be in December 1938.

Beginning in 1933 the issue arose of what welcome should be extended to analysts fleeing the threat of Nazism, first from Germany and then from other Central European countries. It was essentially Marie Bonaparte, supported by Anne Berman, René Laforgue, and

Paul Schiff, who pleaded in favor of these analysts and attempted to integrate them into a society whose nationalistic members—together, moreover, with the French population as a whole—wanted it to be more closed. René Spitz and Heinz Hartmann, among others, passed through Paris before emigrating across the Atlantic. The SPP offered no official welcome to Freud when he passed through Paris on June 5, 1938.

The beginning of the war in 1939 did not stop courses at the Institut de psychanalyse, but the German occupation brought all psychoanalytic activity to a halt. The *Revue française de psychanalyse* ceased publication.

The society's activities gradually resumed after 1946 under the presidency of John Leuba. In the wake of Sacha Nacht, wreathed in the laurels of his resistance activities, there appeared newcomers such as Serge Lebovici, the first among those who would soon form the core of his team. Discredited by his attempts at collaboration with Matthias Göring, René Laforgue was excluded, and those who had undergone analysis with him—Juliette Favez-Boutonier, Françoise Dolto—suffered from this discrediting. However, the *Revue française de psychanalyse*, published by the Presses Universitaires de France, was reborn in 1948, the same year that the Eleventh Congress of French-Speaking Psychoanalysts in Brussels saw joint presentations by Sacha Nacht and Jacques Lacan: “L’aggressivité en psychanalyse” (Aggressiveness in psychoanalysis).

This theme presaged the conflicts that would crystallize around the issue of the training of new candidates, for Freud had again become fashionable in France, and the prisonlike structures of psychiatric institutions were being called into question by young psychiatrists. The SPP, which no longer knew where to hold meetings, had no library and no means of accepting students (there were seventy of them in 1950), and needed to establish premises for its operations. Sacha Nacht was elected president in 1949 and took in hand the future of the institute of psychoanalysis that everyone was determined to create. Although there was unanimity around the contents of the “Rules and Doctrine of the Commission on Teaching Delegated by the SPP,” drafted by Sacha Nacht and Jacques Lacan in September 1949, Daniel Lagache quickly became opposed to its authoritarian views and convinced a number of René Laforgue’s analysands, and then Lacan himself, to take his side. After three years of internecine struggles, Lacan was shown, on June 16,

1953, to have minority support as president of the SPP and resigned, while Daniel Lagache announced the founding of the Société française de psychanalyse (SFP; French Society of Psychoanalysis). Meanwhile, legal proceedings filed in 1950 against a non-physician colleague, Mrs. Clark-Williams, for the “illegal practice of medicine,” had established that a psychoanalytic society had a the collective responsibility to civil society. There were thus ample arguments to support Nacht’s imposition of strict, medically-oriented standards for training, applying the criteria of co-option defined by the IPA with regard to the number, frequency, and duration of sessions in the “training analysis” or the “supervised treatments” required of candidates.

For some thirty years, issues related to training took center stage in French psychoanalysis; at the same time, they stimulated unprecedented emulation in the theoretical, clinical, and institutional creativity of members of an SPP that was spurred on by rivalry with the SFP and later, increasingly, by the renown of Jacques Lacan and the growing number of his students.

The June 1954 inauguration of the Institut de psychanalyse, headed by Nacht until 1962, created a split that was not transcended until 1986. Although the SPP, in the eyes of the IPA, remained the sole representative of psychoanalysis in France until 1965, it was then reduced to the rank of a mere scientific society, without decision-making powers with regard to training policies or the dissemination of Freud’s theories. To be sure, the society still played a determining role in the organization of “Romance-language congresses” (a new appellation suggested by Lacan before the split, and of which Pierre Luquet became permanent secretary in 1956), on commissions, and in international congresses, but the dynamism of the society was concentrated around the team that directed the Institut de psychanalyse (Serge Lebovici, René Diatkine, Maurice Bénassy, Henri Sauget). They formed the core of the “Commission on Teaching,” whose members were co-opted from among the permanent membership, and where choices and decisions were made regarding candidates for various posts. While dual membership in both societies may have been mandatory, the importance given to the criteria for training and selection was such that soon the public no longer spoke of the “Society,” but instead referred to the group as “the Institute.”

Sacha Nacht’s leadership style was autocratic, and he implemented a number of changes that remained

after his departure, such as the professional development seminar for analysts from the provinces. His students and partisans were quickly elected to permanent membership to replace those who had left as a result of the split: Béla Grunberger in November 1953, Michel Fain and René Held in early 1954, and others thereafter. Above all, Nacht created a mindset and a way of conceiving of psychoanalysis that are evident in the works published during his tenure, such as *La Psychanalyse d'aujourd'hui* (Psychoanalysis Today, 1956). At the Twentieth Congress of the IPA in Paris at the end of July 1957, he was elected vice president of that organization. His work was a central reference in almost all the scientific papers presented in meetings of the SPP, and he was the preferred target for attacks by his former friend Lacan and his followers, although Maurice Bouvet, before his death in 1960, was another such victim, particularly with regard to his work on object relations. In 1962 a prize was created in memory of this analyst; until 1978, when it went to Micheline Enriquez, a member of the Quatrième Groupe O.P.L.F., it was awarded only to analysts from the SPP.

During the 1960s new names appeared in the ranks of the permanent membership, such as Conrad Stein, Serge Viderman, Robert Barande, and André Green, who would represent the next generation of the SPP and build bridges of scientific communication with psychoanalysts from “enemy” organizations. In 1962 a minor revolution displaced Sacha Nacht from the leadership of the institute in favor of Serge Lebovici, assisted by Michel Fain, with Francis Pasche responsible for the presidency of the society. The autocracy of Nacht and his restricted Commission on Teaching gave way to an oligarchy, that of the “permanent members” (there were thirty of them in 1963). By way of elections held within the society, this group for a number of years maintained their control over what was always the living part of the society, the institute and its Commission on Teaching, on which they all secured ongoing membership in 1965. This was also the terrain of after-conflicts, since over time the play of politics led to the election of about one-third dissenting voices, which, although they never managed to impose the liberal reforms they wished to promote, gradually caused movement in the ponderousness of this large, two-headed institution.

The 1964 election to permanent membership of Evelyne Kestemberg, the first nonphysician since the times of Marie Bonaparte (who had died in 1962), provided proof of the thorough expunging of the poli-

cies of Sacha Nacht, who had always opposed this. Others followed, such as Janine Chasseguet-Smirgel and Joyce McDougall in 1965, and then Salem Shentoub in 1966, providing the SPP with the openness and diversity that gradually came to characterize it and cause it to lose its monolithic aspect. It was also the year of the rapprochement between the society and the Association psychanalytique de France (APF; Psychoanalytical Association of France), which was recognized by the IPA in July and in 1970 fully participated for the first time in a Congress of Romance-language-speaking Psychoanalysts, with a presentation by Didier Anzieu entitled “Éléments d’une théorie de l’interprétation” (Elements of a theory of interpretation).

The founding in October 1966 of the European Federation of Psychoanalysis, in which societies’ representation was proportionate to their membership base, led to a broadening of the SPP, the consequences of which were crucial for its development. This was the creation, in November 1967, of the category of “affiliated members,” which was to serve as a screening stage between the completion of the curriculum at the institute and election to full membership in the society upon submission of a clinical thesis, which henceforth was the only path of access to membership. This new category would not be the last thing to agitate the tumultuous meetings of May 1968, where institutional constraints were called into question within the Commission on the Degree Program and Hierarchy—although without immediately producing any spectacular modifications. A January 1969 report by Jean-Luc Donnet on behalf of this commission set forth a proposed degree program, the first in a long series, for discussions, counterproposals, meetings, conflicts, and open letters addressing the problems of training which thereafter took center stage in most of the meetings and general assemblies of the SPP and the institute.

A new reform of the statutes promoted by Pierre Marty, who was elected president in 1969, that aimed to create an administrative college was voted in on June 16, 1970, on the condition that the problem of the “affiliated members” be set aside. Indeed, this category considerably changed the numerical ratio of the membership in an association where, by law, each dues-paying member was supposed to have administrative power and the right to vote: there were 43 affiliated members when the category was created and 81 in 1969, but there were 214 by 1986, while during

the same time period the ranks of the regular members grew from 44 to 49 and then 79, and the number of permanent members grew from 35 to 38 and then to 66. The college thus represented a first step toward expanding institutional responsibilities over the three categories of members, even though initially only the regular members were allowed to play a role, for example, on the candidature commissions and the election of their peers. The area of training analysis (in French, *analyse didactique*), although the word “didactic” discreetly disappeared from usage, like the election of permanent members, remained a closed field reserved only for members of the Commission on Teaching. Only twenty-four years later, on September 27, 1994, would the permanent members modify the conditions for admission to the degree course and agree to allow any person who had been in analysis for more than three years with a member of the SPP to ask to be received by the Commission on the Degree Program. This measure put an end to the struggle that had underlain all the episodes of administrative turbulence that had beset the society and the institute from 1970.

A new attempt to reform the statutes to integrate the affiliated members into the institute failed in 1974 because of a negative vote from the permanent members, among whom a conservative majority continued to prevail. A gentleman’s agreement was nonetheless adopted that provided for a three-year trial of a board of directors made up of the three categories of members, but this was followed by a series of discussions and votes that were aborted because one or several categories did not have a quorum.

In 1974, René Major had to resign in a climate of hostility from his post as director of the institute because he was not French and his naturalization remained blocked for an unusually long time. André Green, who succeeded him, proposed in a letter of December 19, 1974, an idea that would run its course, that of the “merger of two associations into a single one, with that society taking responsibility the totality of our psychoanalytic life in the three institutional sectors related to it: the scientific sector, the training sector, and the therapeutic sector, which currently go by the names of the Société psychanalytique de Paris, the Institut de psychanalyse, and the Centre de consultations et traitements psychanalytiques [Center for Psychoanalytic Consultation and Treatment].”

This idea was taken up anew by Pierre Luquet, president of the SPP after 1975, but nothing was settled,

and the conflicts intensified to the point where in 1979 another split might have occurred had the dissidents been united around anything other than their opposition to the majority in place. The proposal for a training program with two tracks, one “classic,” proposed by Serge Lebovici, and the other more “liberal,” supported by Serge Viderman, was presented and in turn buried. The institutions held together only because of “moratoriums” whose end-dates were contested and extended, for no one could come to an agreement.

The IPA then intervened, dispatching its president, Edward Joseph, on a visit on October 6, 1980, to attempt to clarify the situation and encourage the SPP to find a solution to the conflicts. Raymond Cahn, elected president of the society, decided on November 25 to create a joint society-institute committee charged with presenting, within four months, a proposal for global revision of the statutes of the society and the institute. This proposed merger was voted in by the SPP on June 23, 1981, but rejected the following week at the level of the institute, essentially by the college of the affiliated members. At the Thirty-second International Congress in Helsinki the following month, the IPA decided to nominate an external committee charged with investigating the SPP’s problems. It proposed a six-month moratorium, but nothing had been resolved as of June 18, 1982, when Adam Limentani, who had become president of the IPA, went to Paris. There had still been no resolution by March 1984, when conflicts between the offices of the SPP, under Michel Fain’s presidency, and the Institut de psychanalyse, headed by Claude Girard, nonetheless precipitated the end of the crisis.

In a letter dated May 21, 1984, Adam Limentani noted that no one wanted to succeed Michel Fain, and announced that the SPP had to be placed under oversight, and that the institute had to transfer to the society all of its training activities. Daniel Widlöcher was a member of the oversight committee. In October 1984, Augustin Jeanneau was elected president, and he was determined to bring to its conclusion this reform that had been dragging on for ten years. He nevertheless had to wait almost another year and a half before the SPP, on May 6, 1986, voted to accept the new proposal for a merger that he had elaborated with the active help of Michèle Perron-Borelli; an extraordinary session of the Institut de psychanalyse on June 3 in turn formally ratified it.

The merger at last took place, and the SPP reclaimed the ground that it had lost with the creation of the Institut de psychanalyse in 1953. The institute remained its “training organ,” but the autonomous organization that constituted it was dissolved. The price of this compromise was that the problems relating to training analyses were not taken into account in drawing up the statutes, but instead left to the initiative and responsibility of the institute’s Commission on Teaching—that is, the permanent members. The society, meanwhile, was henceforth managed by a general committee made up of all the members, represented by an administrative board of forty-five members elected by the college in a system of parity representation. The society put an end to the unsound, two-headed functioning that was also in violation of French laws on associations.

On December 2, 1986, André Green was elected president of the new bureau of the organization whose creation he had set in motion exactly twelve years earlier. Simone Decobert became the first director of the new institute and remained in this post until 1996, when she was replaced by Paul Israël.

Suddenly, everything calmed down, or almost. There was an influx of candidates for permanent membership, and the SPP, four hundred and fifty members strong, encouraged the formation of groups in the provinces that brought together former students and attracted new ones: the Groupe lyonnais, the oldest of these (1958), the Groupe toulousain (1980), and the Groupe de travail méditerranéen (1984) were followed by other groups in Bordeaux, Brittany, the Loire region, Normandy, Pas-de-Calais-Picardy in the north, Grenoble, and Savoy. The creation of the Journées occitanes de psychanalyse (Occitan Days of Psychoanalysis) in 1978 gave the signal for regional initiatives.

Certain personalities, such as Robert Barande, Conrad Stein, or Serge Viderman more or less distanced themselves from the society’s activities, but on the whole the members appeared to be relieved by the outcome and determined to show the outside world that all that these years of dispute had brought much that was ultimately constructive for the discipline. They had been schooled in the exercise of democracy, with its contradictions, but also with the possibility of the confrontation of contradictory opinions, without any new “autocrat” having taken the dominant ideological position, and without another

split occurring to bring a brutal resolution to the apparent incompatibilities.

Moreover, work in the field of psychoanalysis had never ceased, even though too much time and energy had been tied up in the endless statutory discussions. The Tuesday evening scientific meetings maintained their monthly schedule and the Saturday Encounters continued to be held twice each month, providing a proving ground for the next generation of analysts. The society’s colloquium, started by René Diatkine in 1964, took place regularly in Deauville every autumn, focusing on theoretical and clinical topics. In March 1998, responsibility for organizing the colloquium was entrusted to André Green, and it was named the René Diatkine Colloquium in honor of its founder. The Congresses of French-speaking Psychoanalysts, under the guidance of Augustin Jeanneau, who succeeded Pierre Luquet in 1989, and Pearl Lombard, and then, beginning in 1997, that of Gérard Bayle and Georges Pragier, held in alternating years in Paris and a neighboring region, continued to serve as a forum for annual presentation of reports as a way of taking stock of advances in psychoanalytic theory in France and worldwide. From 1989, Franco-Italian colloquia confirmed the need for meetings between neighboring societies. The precursors of a trend toward openness that would increase over time, the Rencontres psychanalytiques d’Aix-en-Provence (Aix-en-Provence Psychoanalytic Meetings), placed under the aegis of the society by Jacques Caïn and Alain de Mijolla, from 1982 to 1991 brought a member of the SPP together with a psychoanalytic personality from another group and a non-psychoanalyst specialist from the field of the chosen common theme, ranging from “Languages” to “The Body and History,” “Autobiography,” and “Music.” Christian David, Jean Guillaumin, André Green, René Diatkine, Francis Pasche, Joyce McDougall, Michel Fain, Jean Cournut, Michel Neyraut, Claude Le Guen, and Conrad Stein thus met with Piera Aulagnier, Jean-Bertrand Pontalis, Pierre Férida, Olivier Flournoy, Michel Artières, Marie Moscovici, and Michel Schneider, and compared their psychoanalytic point of view with the perspectives offered by non-psychoanalysts such as Maurice Olender, Edmond Jabès, Eugène Enriquez, Philippe Lejeune, Isabelle Stengers, Marcel Détienne, Yves Hersant, and André Boucourechliev.

Begun on a modest scale beginning in the 1960s, when it was handled by Louis Dujarrier and distribu-

ted in the form of galleys duplicated by Roneo ®, information for the membership became a major necessity that was concretized in the creation of a journal, the *Bulletin de la S.P.P.*, the first issue of which was published in 1982, introduced by Michel Fain. Jacqueline Schaeffer took over as head of the journal in 1985. The society's library, which had a wealth of holdings thanks to the bequest of Marie Bonaparte and the accumulation of other consignments and acquisitions over the years, was housed, under the direction of Roger Perron (who succeeded Gérard Bayle), in new quarters in the Rue Vauquelin in 1994; named the Bibliothèque Sigmund Freud, it became France's most comprehensive repository of psychoanalytic works. Its computerized catalogue was made available to researchers by means of the Internet under the leadership of Ruth Menahem, who was succeeded by Eva Weil. For several years the library published a bulletin of reviews of works, *Lectures*, headed by Perel Wilgocz. Meanwhile, the creation of a Department of Archives and History, decided on in January 1988, and headed by Alain de Mijolla, then by Alexandra Munier, and then, after 2002, by Nicolas Gougoulis, witnessed the constitution of an audiovisual archive devoted to some eminent members of the society. The Archives de France took responsibility for the cataloguing and archiving of all the administrative documents that had accumulated since the 1950s.

Relations with the government were marked by intense discussions around the 1982 proposal presented by Maurice Godelier to the minister of Research and Industry with the aim of creating a center for the development of psychoanalytic research. Supported at the SPP by Gérard Mendel and discussed at length, the proposal in the end did not lead anywhere, but the issue of the "status of psychoanalysis" regularly came up in government debates and at the instigation of certain people, such as Serge Leclaire in December 1989; however, this did not lead the SPP to abandon its reserve and go back on its refusal to sanction the official recognition under the label "psychoanalysts" certain, essentially Lacanian, groups whose training criteria it viewed as inadequate. Not that the SPP was excessively rigorous on this matter, as its frays with the IPA had continually shown. The SPP recognized three sessions per week as the minimum for a training analysis, instead of the four sessions required by the international organization. The society, under the leadership of Sacha Nacht, had been one of the first in the

world to totally exclude a candidate's analyst from discussions and decisions concerning his or her accreditation. As early as the 1950s the SPP had implemented "collective supervision," which was unknown in the other IPA member organizations, and, around 1965, the "trial assessment." In terms of relations with the government, after successfully fighting against the 1981 decision of the Ministry of Finance to subject non-physician psychoanalysts, and subsequently those who did not have a degree in psychology, to the value-added tax (VAT), the society's only official step was its 1997 request for recognition as a public service organization, a possibility that had been raised as early as 1967—at the time, there were rumors that Jacques Lacan had requested this—but that had been ruled out owing to the society's desire to remain independent of any control by the state. In the fall of 2003, the tumult occasioned by the threat of an "amendment" intended to regulate the practice of psychotherapy enabled the SPP to state its position clearly: "Psychoanalysis, which includes what is known as 'psychoanalytic psychotherapy,' is the purview only of psychoanalytic organizations accredited to guarantee the training and qualification of their members."

Thus, from 1987, under the presidency of André Green and his successors, the SPP practiced a policy of communication with the outside, a different image from the slightly outmoded one of a conservative "orthodoxy" that had been associated with the institute. Already, the Thursday lecture series, open to the public simply by registration, had made it possible to transmit the basics of Freudian theory and clinical practice to listeners from all walks of life. The two days for reflection organized on January 14–15, 1989, in the UNESCO building, on the theme of "Psychoanalysis: Questions for Tomorrow," under André Green's presidency, were a major success in this direction, mobilizing the media and making it possible to disseminate to some 950 registered listeners documents that clearly explained the goals and mode of operation of an organization whose previous desire to remain outside of the public realm had resulted in its being misunderstood and misjudged. Two additional days of meetings, organized by André Green and Alain Fine on November 23–24, 2002, created a forum for dialogue on the theme of "The Work of Psychoanalysis" between practitioners and the principal French psychoanalytic societies.

This was also a way of responding to the media attention garnered by the many groups and micro-

groups born of the dissolution of the *École freudienne de Paris*. Other colloquia open to the public were organized by Gilbert Diatkine in 1994, on the “Powers and Limits of Psychoanalysis,” and by Marilia Aisenstein in 1996, on “Ill-Being: Anxiety and Violence.” At the same time, internal colloquia were held, such as “The Drives,” organized by André Green in 1995; “The Object in Person,” organized by Paul Denis in 1996; and “Psychotherapeutic interpretation, psychoanalytic interpretation,” organized by Gilbert Diatkine in March 1997.

Among the institutions linked to the SPP that continued their work throughout these years, mention must be made of the Centre de consultations et de traitements psychanalytiques, which, from its creation in 1954, made psychoanalytic treatment available free of charge for the most economically disadvantaged. Under the leadership of Michel Cénac and René Diatkine, Jean Favreau and Robert Barande, Jean-Luc Donnet and Monique Cournut, and, from January 2000, Jean-Louis Baldacci, it also provided for the clinical training of several generations of psychoanalysts. It was renamed the Centre Jean-Favreau in December 1993.

The *Revue française de psychanalyse*, meanwhile, continued in its efforts to present the work of members of the SPP. The journal made no further changes in publisher after 1947, when it was taken on by the Presses Universitaires de France, and the successive managing and editorial teams, despite not-infrequent conflicts, first and foremost sought to ensure the regular publication of the congresses of the French-speaking psychoanalytic community and the work coming out of the various conferences, colloquia, and other scientific meetings. However, from 1988, under the direction of Claude Le Guen, assisted by Gérard Bayle and Jean Cornut, the journal’s autonomy in relation to the society, which had tried in vain to obtain the previous directorships, intensified, the latter having found a place for expression in its *Bulletin*, which, from 1991, also published texts from the congresses. The decision henceforth to produce thematic issues led to a clear-cut increase in the readership of the *Revue*, which was both older and the most widespread of the French psychoanalytic journals. That same year, 1988, Claude Le Guen, assisted by Gilbert Diatkine, created the Monographies de la *R.F.P.* (Monographs of the *R.F.P.*), a series in which each issue, focusing on a specific theoretical or practical point, was an assured publishing success. The series *Débats de psychanalyse* (Debates in Psychoanalysis), of which Jacqueline

Schaeffer was the assistant director, was created in 1995 with the aim of publishing the proceedings of colloquia and scientific meetings, which the *Bulletin* alone could no longer handle. In March 1996 Paul Denis took over the direction of the *Revue française de psychanalyse* and created the series *Psychanalystes d’aujourd’hui* (Psychoanalysts of today).

The Society’s membership in and faithfulness to the IPA were concretized—following the lead of Marie Bonaparte, vice president after the war and honorary president from 1957—by Sacha Nacht, vice president from 1957 to 1969, by André Green from 1975 to 1977, and, above all, by Serge Lebovici, vice president from 1967 to 1973, and up to that point the only Frenchman to have been elected president of the IPA, from 1973 to 1977, and then by Haydée Faimberg and Paul Israël, each of whom served in turn as vice president. The SPP, however, was never subservient to the IPA, as attested to by the numerous disagreements that marked the history of relations between the two institutions, from the criteria for training analysis to the creation of the Chamber of Delegates announced in 1993. The SPP also maintained links with the European Federation of Psychoanalysis, in which a number of its members played important roles, such as Alain Gibeault, who was president from 1995 to 1999 before being named secretary general of the IPA alongside Daniel Widlöcher.

Citing the names of members of the SPP throughout this article makes it unnecessary to say more about the organization’s scientific resonance and the place that the work of its members ensured within the psychoanalytic landscape in France and internationally. Whether in terms of readings of psychoanalytic texts, reflections on metapsychology, studies on the psychoanalytic process and situation, on psychoanalytic conceptions in the areas of psychopathology or therapeutics, child psychoanalysis, individual or group psychoanalytic psychotherapy, psychodrama, psychosomatics, research on the history of psychoanalysis, or the relationship between science and psychoanalysis, the number of institutional creations or original theoretical contributions by members of the SPP is considerable, as is the list of collections of reference works or journals that they head or in which they participate.

André Green’s successors to the presidency of the society, Michèle Perron-Borelli (elected in January 1989, she resigned in February 1990 after a dispute with the board of directors over policies regarding Serge Leclair’s proposed “ordinal authority”), Paul

Israël (1990–94), Gilbert Diatkine (1994–96), Marilia Aisenstein (1996–98), Jean Cournot (1998–2002), and Alain Fine (1998–2004) have pursued the policies of openness initiated by the 1986 reforms, in a spirit of rigor attested to by the creation in 1995 of a Commission on Deontology charged with elaborating and enforcing a code of ethics. A report by Paul Denis on behalf of the Socioprofessional Commission, supported by Michèle Perron-Borelli, petitioned beginning in 1989 to ask for recognition as a public service organization; in January 1996 a general assembly of the SPP voted in favor of requesting such recognition. A new modification of the statutes followed to make the necessary adaptations for this change in status, which was granted by a degree published in the *Journal officiel* of August 20, 1997.

With nearly 600 members extensively trained in psychoanalytic theory and practice (109 permanent members, 82 members, and 383 affiliated members), the SPP provides, for the diversity in thinking implicit in such a gathering, an open forum for discussion and developments that nevertheless remain within the strict framework of Freudian thought. Plans are under study for a federation-type organization that would bring together the psychoanalysts in France who would feel linked to such an entity, for the importance of regional groups has only grown over the years, making up for the lag that occurred from the 1960s to the 1980s, to the benefit of other psychoanalytic organizations, particularly those coming out of the *École freudienne de Paris*. The Institut de psychanalyse de Lyon's move to become autonomous in 1996, with Françoise Brette as its first director, is a testament to this. Doubtless one of the next tasks of the SPP will be to organize this mode of affiliation on a national scale, since there is such lively demand from those who identify with the currents of thought and the institutional building that have characterized, with the many vicissitudes that are synonymous with life and many democratic debates, its long historic pathway and the place it has been able to take and maintain for almost eighty years in the French psychoanalytic movement.

## **SOCIOLOGY AND PSYCHOANALYSIS/ SOCIOPSYCHOANALYSIS**

Sociology is the methodological study of social facts, processes, and actions. Depending on the author, it is a general nomothetic science of society (Émile Durkheim), a science of the social forms resulting from the interaction among individuals (Georg Simmel), a discipline that strives to comprehend social activity (Max Weber), or “the living aspect, “the living aspect, the fleeting moment when society, or men, become sentimentally aware of themselves and of their relation to others” (Mauss M., 1923/1990, 80). Psychoanalysis is a method of investigating the individual psychic apparatus and a psychotherapeutic method that uses the transference that occurs during treatment as a powerful means of healing. Sociopsychanalyse (a term not yet fully accepted) is a discipline that aims to articulate the relationship between the psychic and the social. In this respect, sociopsychanalyse continues in the tradition of Freud's sociological and anthropological efforts.

The term “sociology” was created by Auguste Comte, who used it in volume 4 of his *Cours de philosophie positive* (1847). It replaced the term “social physiology,” put forward by Henri de Saint-Simon (1813). Yet it did not take on its modern meaning until Durkheim's *Rules of Sociological Method* (1895). The French terms “sociopsychanalyse,” “socioanalyse,” and

“sociothérapie” were used by different French authors after World War II (André Amar, Guy Palmade, Max Pagès, Jacques and Maria Van Bockstaele, Gérard Mendel, among others). It seems that the Englishman Elliott Jaques was the first to use the English term “socio-analysis,” in 1947, in his work of rehabilitating soldiers back from the war.

The desire to establish a link between psychoanalysis and sociology appears very early on in Freud’s work. The articles “Obsessive Actions and Religious Practices” (1907b) and “‘Civilized’ Sexual Morality and Modern Nervous Illness” (1908d) are evidence of this. In 1913 in “The Claims of Psychoanalysis to Scientific Interest,” Freud stressed the contributions that psychoanalysis could make to all the previously constituted psychological and social sciences, the unconscious often playing a role of primordial importance in all sorts of human behavior. In his later works, from *Totem and Taboo* (1912–1913a) to *Moses and Monotheism* (1939a), Freud analyzed the events that presided over the foundation and modification of social links, the advent of civilization, and the rise of its current discontents.

Many authors have followed in the path opened up by Freud in an effort to understand the evolution of civilization. Wilhelm Reich, the founder of “Freudo-Marxism,” analyzed the role of the family in the creation of authoritarian behaviors and the role of capitalist-patriarchal society in suppressing the instincts. Herbert Marcuse stressed the excessive suppression engendered by the capitalist system and the capacity of the most alienated classes to fight against the modern state and its tendency to make the individual into a “one-dimensional man.” By studying various types of societies and analyzing many different myths and legends, the anthropologist and psychoanalyst Géza Róheim succeeded in demonstrating that Freud’s fundamental hypotheses (the primitive horde, murder of the father, the Oedipus complex) are pertinent to all cultures, regardless of how different they might be.

Other researchers have taken a greater interest in the relations between psychoanalysis and politics and the phenomenon of power in modern societies. Theodor W. Adorno attempted to define the authoritarian personality, the source of all fascisms. Norman Brown tried to demonstrate the role of the life and death instincts in social functioning. Serge Moscovici studied crowds and the role of the leader, thus paying homage to the pioneering character of Freud’s *Totem*

and *Taboo* (1912–1913a) and *Group Psychology and the Analysis of the Ego* (1921c). Eugène Enriquez found in Freud’s work the elements necessary for his theory of the social link, and Cornelius Castoriadis used this theory to define the primary role of the imaginary in the institution of society. Pierre Legendre highlighted underdogs’ love for superiors, and Pierre Ansart focused on how political passions are managed.

Moreover, psychoanalysis has contributed to the creation of an original school of psychology and clinical sociology by analyzing the unconscious processes at work in groups, organizations, and institutions. First British authors (Wilfred R. Bion, Elliott Jaques), then French authors (Max Pagès, Gérard Mendel, Didier Anzieu, René Kaës, Jean-Claude Rouchy, André Lévy, and Eugène Enriquez), contributed new elements on the fantasies, projections, and identifications constantly at play in these groups, as well as on the organizational imaginary and on the processes of repression, suppression, and idealization at work in organizations. In South America, a school was formed to conduct a “social clinic.”

Undergoing particular development since 1990 have been “psycho-sociology,” the science of groups, organizations, and institutions (Kurt Lewin and the French authors mentioned above), and clinical sociology (Louis Wirth), particularly in Quebec and in France. In fact, clinical sociology was recognized as a branch of sociology by the International Sociological Association in 1993. It seeks to create a sociology that is close to lived experience and that makes the subject and the subject’s splitting and contradictions central elements in social construction.

Efforts to link sociology and psychoanalysis have yielded varied results. While some authors have defined original approaches, enriched analytic theory, and furthered the comprehension of social phenomena, others in France, intoxicated by the success of analysis, have indiscriminately applied psychoanalytic concepts to social reality and have succeeded only in bastardizing psychoanalysis (making it a management tool) and disfiguring social processes.

## **SOKOLNICKA-KUTNER, EUGÉNIE (1884–1934)**

Eugénie Sokolnicka-Kutner, the Polish psychoanalyst who introduced psychoanalysis to France, was born in Warsaw on June 14, 1884 and died in Paris on May 19, 1934.

Eugenia Kutner came from a Jewish bourgeois family that had demonstrated its political attachment to the Polish nation. Having been reared by a French governess, she naturally turned to France at the end of her secondary education with a view to enrolling in the Sorbonne to study biology and majoring in science. She also attended Pierre Janet’s lectures and established friendships in literary circles that she would rediscover fifteen years later.

She met M. Sokolnicki there and they got married when she returned to Poland. She devoted herself exclusively to family life until 1911 when she went to study at the Burghölzli asylum in Zurich, where she met Carl Gustav Jung. At the time of Jung’s break with Freud, she decided to go to Vienna and began her analysis with Freud; this lasted about one year and provoked a rather hostile counter-transference in Freud. She and Sokolnicki divorced at this time.

Also at this time she attended a few sessions of the Vienna Psychoanalytic Society (Nunberg H., Federn E., 1962–75) before settling in Munich on Freud’s advice. It may have been during this period that she analyzed Felix Boehm. The First World War forced her to return to Warsaw until the threat from the Germans and the Russians caused her to again flee, this time to Zurich in 1916. She became a member of the Zurich Psychoanalytic Society and was also elected to the Vienna Psychoanalytic Society on November 8, 1916.

Toward the end of 1917 she returned to Poland, and Freud wrote, in a letter to Sándor Ferenczi dated January 19, 1918 that “Sokolnick seems to be founding a psychoanalytic society in Warsaw.” For six weeks in 1919 she treated a little Jewish boy from Minsk who was suffering from an obsessional neurosis, the cure being classically centered round the transference and the interpretation of dreams, although a pedagogical attitude made its appearance, mainly with regard to sexuality (Ferenczi described it as an example of the “active technique”). It is, however, one of the first examples of a child analysis being conducted under conditions similar to those used for adults. She published the case the following year under the title: “Analysis of a Case of Infantile Obsessional Neurosis.”

At the start of 1920 she went to Budapest, and in January she began an analysis lasting about one year with Sándor Ferenczi who, sometimes as if in a kind of supervision, described its progression in his correspondence with Freud. She was not an easy patient, suffering from personality problems, mainly irritability, and describing Ferenczi as incapable compared to Freud, whom she nevertheless accused of putting an end to her analysis because she had no money as a result of her divorce. She also complained that Otto Rank had wounded her. These so-called paranoid characteristics were linked to depressive tendencies and accompanied by disturbing suicide threats. Alongside all of this, Ferenczi stressed her talent as a psychoanalyst and the quality of her interpretations.

In September 1920 she took part in the sixth International Congress at The Hague, presenting a paper on “Diagnosis and symptoms of neuroses in the light of psychoanalytic doctrines” and, in January 1921, expressed her intention of joining her brother in Paris. Ferenczi then asked Freud to recommend her to his Payot editor and his translator Samuel Jankélévitch, a request that Freud deferred granting until later, adding: “Besides, we *both* don’t like her, whereas you obviously have a weakness for this disagreeable person” (letter dated January 16, 1921). She again visited Freud between February and March and, upon finally receiving his approval, left for Paris.

Her relations were then in the literary milieu, particularly around the *Nouvelle Revue française*. There, as soon as she arrived in the fall of 1921, she found a public that was passionate about the “Freud sessions” she organized and which were attended by Jacques Rivière and André Gide. The latter is thought to have had a few analysis sessions with her and have depicted her in 1925 as “Doctoress Sophroniska” in *The Counterfeiters*.

During the winter of 1922–1923 she delivered several lectures at the *École des hautes études en sciences sociales*, meeting Georges Heuyer there through Paul Bourget. Heuyer, who ran the mental illness clinic of the Sainte-Anne hospital before the arrival of Henri Claude, invited her to attend the meetings and case presentations in his department. There she met young psychiatrists who, like René Laforgue for a few months or his friend Édouard Pichon for three years (1923–1926), were to go through the experience of training analysis with her. She soon either fled the hospital before Georges Dumas’s sarcasm, or was pushed out by Henri Claude who would have nothing to do with non-physician psychoanalysts. She failed to become the leader of a French psychoanalytic movement, abandoning that position to Laforgue and Marie Bonaparte, in spite of her support from Freud, who took her side rather than trust Laforgue, to whom he wrote on January 15, 1924: “We would have very much appreciated your working in cooperation with Mme Sokolnicka because we have known her for a very long time and we cannot help seeing her as our legitimate representative.”

She was appointed vice-president at the founding of the Paris Psychoanalytic Society in November 1926 and her teaching activity continued to increase con-

stantly. In June 1929 she presented a report to the fourth Conference of French-Speaking Psychoanalysts on “Some problems in psychoanalytic technique.” She analyzed Paulette Laforgue after her hysterectomy, Blanche Reverchon-Jouve, and Paul Schiff, but her clientele diminished over the years, leading her to practice shortened cures that barely earned her enough to live. Perhaps her turbulent sexual life was to blame, or the manifestations of the quick temper that Ferenczi described to Freud on February 11, 1921: “Actually she has suffered and is suffering not from a typical neurosis but from pathological sensitivity.”

It may be that from 1931 onward she progressively came under the influence of a state of depression. Having been announced for the opening of the Paris Psychoanalytic Institute in 1934 as speaking from May 2 to 23 on the “psychoanalysis of the character,” she died of what was probably a deliberate case of gas poisoning on May 19, 1934, less than a month from her fiftieth birthday.

## SOMATIC COMPLIANCE

The notion of somatic compliance was introduced by Sigmund Freud within the framework of certain so-called somatic symptoms found exclusively in the hysteric, pointing toward what he calls “conversion phenomena.”

Freud uses this expression for the first time in the case of Dora (“Fragment of an Analysis of a Case of Hysteria” [1905e]): The hysterical symptom requires input from both sides, and “cannot occur without the presence of a certain degree of *somatic compliance* offered by some normal or pathological process in or connected with one of the bodily organs” (p. 40). It is this “compliance” at the somatic level which “may afford the unconscious mental processes with a physical outlet” (p. 41) and which, accordingly, becomes a determining factor in the choice of neurosis. Meanwhile, this somewhat enigmatic notion of somatic compliance helps explain the equally enigmatic leap from the mental to the somatic level. “Conversion” is posited as one of the outcomes of unconscious processes, providing a privileged medium for the symbolic expression of unconscious conflict and especially well able to signify the repressed. Conversion is thus part of the framework of symbolization, in contrast to the somatic symptom properly speaking. Freud provides examples of somatic compliance, and thus of the phenomenon of conversion, in the case of Dora. In the same context he mentions “secondary gain from illness” and “flight into illness.”

Aside from hysteria, somatic compliance in a more general sense raises the question of the expressive power of a given organ or body area that is in some sense hysterical or erogenized, as indeed of the whole body as a means of expression—as a vicissitude of the narcissistic cathexis of the body.

Can the notion be used, as in the conception of Jean-Paul Valabrega, to buttress a theory of psychosomatic phenomena as the outcome of a general process of conversion occurring outside the realm of hysteria, but clearly investing somatic symptoms with meaning? If so, the notion of compliance would take on another dimension altogether.

## **“SOME PSYCHICAL CONSEQUENCES OF THE ANATOMICAL DISTINCTION BETWEEN THE SEXES”**

This paper, finished by Freud in 1925 and read by his daughter Anna at the International Psycho-Analytical Congress in Hamburg on September 3, first appeared in the *Internationale Zeitschrift für Psychoanalyse* in the same year.

Freud began by noting that he could no longer afford, as in his early days when he had no fellow researchers, to put off publication of new discoveries made on the basis of a mere handful of cases, even though they might not as yet have been confirmed. Then, starting out (as usual) from consideration of boys, Freud drew several new conclusions concerning girls. During the phallic phase, he argued, the boy remains attached to his mother and experiences his father as a rival whose place vis-à-vis his mother he wishes to usurp; at the same time, he would like to replace his mother as his father’s love object. The Oedipus complex is thus described as having two forms, active and passive—a duality consonant with the bisexual constitution of humans. When the boy first sees the girl’s genital area, he denies his perception that she has no penis (only later will the threat of castration arouse an emotional storm in him). In contrast, when the girl discovers the penis of the boy, “she has seen it and knows that she is without it and wants to have it” (1925j, p. 252). She falls victim to penis envy and to a masculinity complex. Consequences include a feeling of inferiority, jealousy (1919e), and a loosening of the girl’s tender relationship with her mother, whom she blames for her lack of a penis (1925j, p. 254).

For Freud, clitoral masturbation is masculine in character, and the mutilated aspect of the organ in question explains why women tolerate masturbation worse than men. The unfolding of femininity is based on a desire to eliminate clitoral sexuality. Under the sway of the Oedipus complex, the girl abandons her desire for a penis and replaces it by the desire for a child, and with this in mind takes her father as love object: “Whereas in boys the Oedipus complex is destroyed by the castration complex, in girls it is made possible and led up to by the castration complex” (1925j, p. 256). Indeed, the Oedipus complex never really disappears in women (1924d). This, according to Freud, accounts for characteristically feminine traits linked to a weaker and less perfectly

formed superego. In this connection, Freud refused to see the sexes as equal.

It should be noted that Freud's description of women as castrated beings who "refuse to accept the fact of being castrated" is hardly endorsed by all psychoanalysts.

## SOMNAMBULISM

Somnambulism (or sleepwalking) describes an apparently aimless nighttime walking in an unconscious state, accompanied by motor activity of varying degrees of complexity. The next day, the sleeper has no memory of the episode. Sleepwalking episodes, which occur during the first part of the night, last from a few seconds to around thirty minutes. They begin in the latency period and generally stop after puberty.

Owing to the amnesia that follows episodes of sleepwalking, no secondary revision can be made by the sleeper. This did not prevent Sigmund Freud from taking an interest in the phenomenon. In 1907 he spoke about it to the Vienna Psychoanalytic Society (Nunberg and Federn): He believed that sleepwalking was related to the fulfillment of sexual wishes and was thus surprised that there could be mobility without

interruption of the dream life. Finally, at that time, he suggested that the essence of this phenomenon was the desire to go to sleep where the individual had slept in childhood.

Ten years later, he again speculated about somnambulism in the article "A Metapsychological Supplement to the Theory of Dreams" (1916–17 [1915]). In this essay, where he proposed to clarify and expand his hypothetical ideas on dreams, the dream is a fragile equilibrium that is only partially successful: first, because the repressed unconscious impulses of the unconscious system, which do not obey the wishes of the ego and maintain their counter-cathexis, mean that "some amount of the expenditure on repression (anticathexis) would have to be maintained throughout the night, in order to meet the instinctual danger" (p. 225); and second, because certain preconscious daytime thoughts can be resistant, and these, too, retain a part of their cathexis. It is thus apparent how unconscious impulses and day residues can come together and result in a conflict.

Freud then wondered about the outcome of this wishful impulse, which represents an unconscious instinctual demand and which becomes a dream wish in the preconscious. Further, he envisioned the case in which this unconscious impulse could be expressed as mobility during sleep. This would be what is observed in somnambulism, though what actually makes it possible remains unknown.

More recently, based on data from electrophysiological sleep studies showing that sleepwalking episodes occur in the early phases of sleep (phases III and IV), the psychoanalyst Didier Houzel has leaned in the direction of the Freud's hypotheses, positing that the slow sleep phase, by interfering with the phase of paradoxical sleep that follows and interrupts the latter, prevents the possibility of dream work. Somnambulism thus results from a blocking of the possibilities of mentalization and a diversion of the instinctual energy onto paths of motor discharge. Houzel's viewpoint posits equivalences between night terrors, sleepwalking, and nocturnal enuresis, all of which have the same relationship to paradoxical sleep.

## SPAIN

In February and March 1893, one month after its appearance in the Viennese journal *Neurologisches Zentralblatt*, two Spanish journals, the *Revista de ciencias médicas* in Barcelona and the *Gaceta médica* in Granada, published *On the Psychical Mechanism of Hysterical Phenomena* by Josef Breuer and Sigmund Freud (1893a). It was, in the words of James Strachey, “the very first publication in the world of a translation of a psychological work by Freud.”

In 1911 José Ortega y Gasset, the well-known intellectual, published a long article titled “Psicoanálisis, ciencia problemática” (Psychoanalysis, a problematic science), in which he recognized the importance of a great number of Freud’s contributions. This article provoked the publication of Freud’s works in Spanish. At Ortega’s suggestion, the publisher Ruiz Castillo acquired the rights to publish all existing and future works by Freud and commissioned López Ballesteros to translate them. The publication of the first translation in the world of Freud’s complete works in seventeen volumes appeared over ten years (1922–1932).

The most eminent psychiatrists of the time published various works in which they analyzed Freud’s work and assessed the value of his contributions, but they also criticized what they considered “the omnipotent unconscious sexuality in all psychical phenomena” and the subjectivity of the therapeutic method. Psychoanalytic ideas exercised a considerable influence on judges, teachers, and thinkers. Writers and artists also felt attracted by Freud’s discoveries. A group of intellectuals invited Freud to Spain to give conferences, but his illness prevented him from realizing this project. Sándor Ferenczi nevertheless went to Spain in October 1928 and conducted the communication program Learning

Psychoanalysis and Psychoanalytic Transformation of the Character.

The discourse on psychoanalysis, already present in Spanish psychiatry, prompted two psychiatrists, Ramon Sarró and Angel Garma, to acquire psychoanalytic training. Garma trained at the Vienna Psychoanalytic Institute. He returned to Madrid in November 1931 and left Spain for good in 1936. For the five years between 1931 and 1936, motivated by the desire to create a psychoanalytic movement in Spain, he worked intensely to promote the discipline. The Spanish Civil War broke out in July 1936 and put an end to his hopes. He then emigrated to Argentina, where he participated in the creation of the Asociación psicoanalítica argentina (Argentine Psychoanalytic Association).

The Civil War (1936–1939) and the years of dictatorship imposed silence on many cultural and scientific sectors, particularly psychoanalysis. It was not until the end of the 1940s that two small groups of psychiatrists and intellectuals, one in Madrid and the other in Barcelona, took steps to train as psychoanalysts and to introduce psychoanalysis to Spain. In 1949 the Madrid psychiatrist R. del Portillo turned to the Deutsche psychoanalytische Gesellschaft (German Psychoanalytic Society) for training. He was analyzed by M. Steimback, whom he invited to Madrid to act as a training analyst. Steimback accepted and, until 1954, the year of his death, participated in training such analysts as Drs. R. del Portillo, Ma Teresa Ruiz, Carolina Zamora, J. Pertejo, and Julio Corominas.

During this same period Drs. Bofill, Folch, and Nuria Abelló from Barcelona turned to the Swiss Psychoanalytical Society for training. There they came into contact with Drs. Rallo from Madrid and F. Alvin from Lisbon. Drs. Pertejo, Zamora, and Corominas organized the Grupo Luso-Español de psicoanálisis (Portuguese-Spanish Group for Psychoanalysis), which, sponsored by the Swiss and Paris societies, was recognized by the International Psychoanalytical Association (IPA) in 1957. In 1958 R. del Portillo and Ma Teresa Ruiz joined the group. During the International Congress in 1959 the International Psychoanalytical Association admitted the group as a member. Following the break with the Portuguese group in 1966, the Sociedad Luso-Español de psicoanálisis (Portuguese-Spanish Society for Psychoanalysis) became the Sociedad Española de psicoanálisis (Spanish Psychoanalytical Society).

In 1973 psychoanalysts practicing in Madrid decided to form an independent group, and in 1979 the International Psychoanalytical Association recognized the Asociación de psicoanálisis de Madrid (Madrid Psychoanalytical Association) at the thirty-first congress. From then on the two IPA-affiliated societies together contributed to the development of psychoanalysis in Spain.

The scientific activity of the two societies proved to be intense and prolific throughout the years. Publications by Drs. León Grinberg, Folch, Bofill, Coderch, Torres de Bea, Spilka, Cruz Roche, Manuel Pérez Sánchez, Utrilla, Paz, Olmos, Loren, Guimón, congresses, symposia, schools, conferences; the publication of the journals *Revista catalana de psicoanálisis* and the *Revista de psicoanálisis de Madrid*—all bear witness to ongoing reflections on psychoanalytic theory and clinical practice. In these and other ways the two societies were active in both the medical and academic spheres, thus contributing to the dissemination of psychoanalytic thought.

In 1975 Oscar Masotta, an Argentinean philosopher and member of the Freudian School of Paris, introduced Jacques Lacan's ideas in Spain. In 1977 the library *Biblioteca Freudiana* was created in Barcelona, thus embodying the first institutional form of Lacan's ideas in the country.

After Masotta's death (1979), the dissolution of the Freudian school of psychoanalysis (1980), and the death of Lacan himself (1981), the Lacanian groups broke up and dispersed. In 1990, a group of eminent personalities, among them Jacques-Alain Miller, Eric Laurent, and Colette Soler, founded the European School of Psychoanalysis and the first section of the branch school in Barcelona. Later in the 1990s, different sections have come together in the European School of Psychoanalysis—Spain. Other Lacanian groups also exist and are directly linked to various French groups.

One hundred years after the first publication in Spain of a work by Freud, a great many psychoanalytic ideas have taken hold in psychiatry, medicine, psychology, teaching, and ethics, and many psychoanalysts are actively working to relieve psychic pain and contribute to a better knowledge of human development, both normal and pathological.

### **SPECIFIC ACTION**

The purpose of specific action is to permit the release of tension in ways comparable with the instinctual aim. This term appeared in Freud's earliest writings, but he rarely used it afterwards.

The term “specific reaction” (*spezifische Reaktion*) was used by Freud in “Draft E” of his correspondence with Wilhelm Fliess, which dates probably to June 1894, and which he entitled “How Anxiety Originates” (in 1950a). He sketched an answer to this question from the point of view of an energetics of somatic-mental functioning, an approach that went on to play a major role in the development of his thought: anxiety resulted from an accumulation of tension (biological tension, in the sense that need was involved; but also mental tension, for it implied a wish in search of an object), when there was no way for this tension to be released. Tension could be released in two ways: in the form of violent cries, emotional outbursts, destructiveness, and so forth; or in a way adequate to the need—as for example, the ingestion of food for a baby, or engaging in coitus for an adult. Such adequate kinds of releases are what Freud called “specific reactions.” Freud developed these views in other writings of the same period (1894a [1895]), particularly in the “Project for a Scientific Psychology” (1950c [1895]).

The notion of “specific action” is sometimes deemed obsolete, or tainted by a naïve behaviorism. In fact, as early as 1894, Freud very plainly stressed the need to distinguish between the *biological* tension of need and the properly *psychic* level, where specific

action presupposes “preparations,” a whole “psychical working-through,” in the framework of the conflictual dynamic specific to the subject (Perron-Borelli). Much later, when Freud reframed his conception of anxiety, he added a “signal of anxiety”—a testimony to, and outcome of those working-through processes—to his earlier “automatic anxiety,” generated by the accumulation of tension.

## **SPIELREIN, SABINA (1885–C. 1941)**

Sabina Spielrein, a Russian psychoanalyst, was born in 1885 in Rostov, and died in the city of her birth, in the Soviet Union, in 1941 or 1942, during World War II.

Born into a wealthy Jewish middle-class family, Sabina at age nineteen was taken to Zurich to be treated for severe hysteria. She was hospitalized at Burghölzli, the famous psychiatric university hospital run by Eugen Bleuler. There Carl G. Jung became her physician and succeeded in alleviating most of her symptoms. Within a year, by 1905, she was able to begin medical studies. She continued an analysis with Jung that he described as “Freudian” and that offered him an opportunity to initiate a relationship with Freud, from 1907.

The therapeutic relationship between Jung and Spielrein evolved into a personal relationship, probably a brief affair, after which Jung appears to have distanced himself from her and then called for Freud’s

help. The two men, who by then had been friends for two years, discussed the relationship in their correspondence, and at Jung’s request Freud wrote to Spielrein’s mother. In spite of what the two men thought, however, Freud’s intervention did not end Sabina’s passion for Jung, a passion documented in her diaries. Nonetheless, in 1911 she finished her studies in psychiatry under Jung’s direction with the thesis “The Psychological Content of a Case of Schizophrenia.” As Freud and Jung moved toward the rupture of their friendship and collaboration, Spielrein went to Vienna, where, in 1911, she presented her paper “Destruction as the Cause of Becoming” (1995), which received a mixed reception in the context of much anti-Jung sentiment.

After the break between Freud and Jung, in which she could not clearly decide which side to take, Spielrein’s life and career becomes more difficult to follow. In 1912 she married a Russian physician, Paul Scheffel, with whom she had a daughter in 1913; he returned to Russia in 1915. Spielrein could not settle down, moving successively to Zurich, Munich, Lausanne, and Geneva. She worked as an analyst but appears to have been uncertain whether her real calling was to psychoanalysis, art history, or music. A second daughter was born in 1926.

By 1923, with Freud’s encouragement, Spielrein had returned to Soviet Russia. She was admitted to the new Moscow Psychoanalytic Institute and taught psychoanalysis until it was prohibited in 1927. After returning to her birthplace, Rostov, during World War II, Spielrein was murdered by the Nazis, together with all the Jewish inhabitants of the city, in 1941 or 1942.

Spielrein published about thirty articles, the best known being her 1995 paper, which develops original ideas on female sexuality and is sometimes said to adumbrate Freud’s concept of the death instinct. It is unfortunate that a love affair and the troubled relationship between Freud and Jung played a role in her early disappearance from the intellectual ferment of psychoanalysis.

In spite of more shadow than light, her story retains an indisputable fascination. A series of fortuitous discoveries rescued Spielrein from oblivion. In 1977 a carton was discovered containing her diary and some of the letters she exchanged with Freud and Jung. A second cache, then a third, were recovered. These documents revealed the details of the long-suppressed

secret—an analysand seduced and abandoned by her analyst—which would have embarrassed Jung first and foremost, but also Freud, who had helped minimize the affair.

An intriguing and original figure in the early years of psychoanalysis, Spielrein subsequently became the object of considerable attention and the subject of several books.

## **SPINOZA AND PSYCHOANALYSIS**

In the history of psychoanalysis, several philosophers became subjects of a privileged confrontation with Freud. One such philosopher was Baruch Spinoza (1632–1677). From the 1920s intellectuals noted correspondences between Freudian thought and Spinoza's philosophy (Smith, 1924; Alexander, 1927). This discussion continues to more recent times (Bodei, 1991; Ogilvie, 1993).

Freud himself rarely spoke of Spinoza. Although he referred to Spinoza in *Leonardo da Vinci and a Memory of his Childhood* (1910c), he did not explicitly mention Spinoza anywhere else. In the work of Jacques Lacan, Spinoza is often present in the background and occasionally cited. For instance, proposition 57 of part 3 of Spinoza's *Ethics* appears as an epigraph to Lacan's medical dissertation (1932).

Authors who have tried to situate Spinoza vis-à-vis psychoanalysis have pondered several different kinds of questions. W. Aron (1977) asked about the overall influence of Spinoza on Freud's thought. C. Rathbun (1934) noted that the libido, a fundamental concept of psychoanalysis, is adumbrated in Spinoza's concept of *conatus*, an inborn drive that leads to striving and persisting. On Walter Bernard's reading (1946), it is perhaps closer to eros or desire. But what, according to these authors, were Spinoza's therapeutic principles? These works today appear dated, indicative as much of the intellectual state of psychoanalysis, particularly in Anglo-Saxon countries, as of a poorly informed reading of Spinoza. Some authors, such as Abraham Kaplan (1977) recall that Spinoza's philosophy was not a proto-psychoanalytic science, but a very knowledgeable metaphysics. Francis Pasche (1981) discusses the idea of "practical psychoanalysis." Gilles Deleuze's work on Spinoza, *Expression in Philosophy* (1992), has opened the way toward a confrontation between Spinozistic and psychoanalytic ethics. Finally, several psychoanalytic authors (Bertrand, 1984; Ogilvie, 1993; Burbage and Chouchan, 1993) have discovered unconscious implications in Spinoza's philosophy.

## SPITZ, RENÉ ARPAD (1887–1974)

Hungarian psychiatrist and psychoanalyst René Arpad Spitz was born in Vienna, Austria, on January 29, 1887, and died in Denver, Colorado, on September 14, 1974.

From a wealthy Jewish family background, Spitz spent most of his childhood in Hungary. While studying medicine in Budapest—he became a physician in 1910—he discovered the works of Freud. During the First World War, he served in the army as a military physician. Encouraged by Sándor Ferenczi, he became one of the first to undergo a training analysis with Freud himself. Between 1924 and 1928, he participated in the Vienna Psychoanalytic Society and, subsequently, worked in Berlin, where he became member of the German Psychoanalytic Society (DPG).

Between 1932 and 1938 Spitz lived in Paris, where he taught psychoanalysis and child development at the elite *École Normale Supérieure*, and he frequently attended conferences of the Paris Psychoanalytic Society. In 1939 he emigrated to the United States and found work as a psychiatrist at Mount Sinai Hospital in New York (1940–1943). He served as a visiting professor at several universities before settling at the University of Colorado, where he conducted much of his research on infant development.

He served as president of the Denver Psychoanalytic Society (1962–63).

At the end of World War II, Spitz (1945, 1946) published his influential research with infants and young children in various settings, including a founding home and a penal nursery. Serious developmental pathologies, as he documented with careful research, arose in infants who, though adequately nourished, were deprived of maternal care and emotional sustenance. Through direct observation he developed the diagnoses of “hospitalism” and “anacletic depression,” two pathologies that led him to further study mental and emotional development from birth to two years of age.

Spitz is best known for his books on the infant and the mother-infant dyad, including *No and Yes: On the Genesis of Human Communication* (1957); *A Genetic Field Theory of Ego Formation* (1959); and *The First Year of Life* (1965). According to Spitz, infants pass through three stages corresponding to stepwise developments in object relations: (1) the objectless stage (three first months of life), characterized by “non-differentiation” between baby and its mother; (2) the stage of “the precursor of the object” (from three to eight months) in which the smiling response indicates the beginning of object relations; and (3) the stage of the libidinal object (from eighth to fifteenth month), by which time the mother is recognized as a real partner and the infant can distinguish her face from strangers’ faces. From the fifteenth month, the child enters into semantic communication with gesture and the use of “no,” indicating the emergence of the autonomous ego.

Spitz was the first of a small number of distinguished psychoanalysts to actively pursue research in child development by employing methods commonly used in experimental psychology; his use of films was particularly influential. In contrast to behavioral psychologists, however, Spitz believed that deep psychic process, while not directly observable, may be identified by surface “indicators” such as the smile. These reveal “the organizers of the psyche” that serve as evidence of the child’s maturation.

## **SPLIT OBJECT**

The concept of the splitting of the object was elaborated by Melanie Klein. This is a defense mechanism deployed by the ego against anxieties concerning the destructiveness of the death drive, and which is directed at maintaining the separation between a good object and a bad object to safeguard the security and integrity of the ego.

The object that is split in this way is the internal object; Klein developed this concept of internal object on the basis of the concept of introjection. In fact, according to Freud, the ego introjects external objects that are sources of pleasure, and expels outside of itself that which causes unpleasure. For Melanie Klein, splitting, introjection, and projection constitute the first defense mechanisms. In his “phantasies,” the child introjects parts of his parents’ bodies (the breast, the penis, and so on), and the parents are split into gratifying good objects and frustrating bad objects.

The infant’s first relationship is a relationship to part-objects, principally to the mother’s breast, which is split into the ideal breast and the persecuting breast. In this relationship, the ego projects the death drive outwards and introjects an ideal object that is the product of the projection of the life drive. Historically speaking, Melanie Klein described the depressive position first, but it was the elaboration of the concept of the paranoid-schizoid position that then enabled her to study the mechanism of projective identification, as the result of primitive projections. Projective identification consists in the identification of the object with the part of the self that has been projected, and it concerns both the good and the bad parts of the self and the object. The paranoid-schizoid position, which is characterized by the fragmentation of the ego and the splitting of the object, is followed by the depressive position, in which the ego is integrated but is in the grip of the conflict between opposed drives; repression then gradually takes over from splitting, and projective anxiety gives way to guilt. In the paranoid-schizoid position, splitting therefore relates to part-objects, whereas in the ensuing depressive position it relates to a total object.

The interest in the internal object and its splitting has led Kleinian analysts to develop an entire conceptual apparatus concerning the genesis, evolution, and position of the object in the psychic apparatus and in the dynamics of the object relationship. Also deserving mention here are Wilfred Bion’s beta-elements and alpha-elements and “K” and “O,” Frances Tustin’s sensation-objects and Donald Winnicott’s transitional object, as well as the role of dimensionality in Donald Meltzer’s work.

In clinical practice, these concepts provide a better understanding of the way in which the line of the splitting protects and maintains the idealized object, by separating it from the frustrating object that bears the hallmark of castration (particularly in perverse, depressive, or obsessional neurotic structures).

The concept of the splitting of the object, based on the concept of the splitting of the ego introduced by Freud, has made it possible to focus attention on the importance of the internal object and of the phantasy, and has opened up some productive perspectives concerning intersubjectivity.

## **SPLITS IN PSYCHOANALYSIS**

Since its beginning, the psychoanalytic movement has been plagued by conflicts and has given rise not only to numerous splinter movements, but also to adversarial sub-groups and internal divisions within its larger institutions. Some see this as an indication of the psychoanalytic movement's tendency towards dogmatic organizations that practice exclusion and "excommunication." But others see signs of what they call "heteroglossia," noting that with conflict, propositions that were once judged to be inconsistent with the general theory of psychoanalysis are later reincorporated into it.

The breakup of Freud's friendship with Wilhelm Fliess could be called, albeit a bit arbitrarily, the first psychoanalytic "split." The way they split seems almost paradigmatic: two passionate researchers who seemed similar were able to collaborate in spite of profound contradictions between them that remained hidden until the moment one of them began to assert himself.

The 1912 break between Freud and Alfred Adler could be described in just the same way, and likewise that of Freud and Carl Jung in 1913. Neither of the two came to Freud empty-handed. They each had their own theoretical ideas and their own body of research. And their encounters with Freud were for a time more like those between like-minded individuals. They were not waiting for any kind of illumination, which they believed they already possessed, but rather supplement-

tal clarifications, or better still, Freud's approval. Both followed theoretical tendencies that diverged from Freud's own ideas and personality and that indicated orientations characteristic of their time: Adler emphasized social factors, under the influence of the Marxist movement that unfolded for most of the twentieth century; Jung was preoccupied with mysticism and the esoteric tradition from which Freud, in spite of his curiosity, kept a distance in his theorizing, if not in private life. Each of them founded parallel movements that refused to take any advantage of their connections to psychoanalysis even by virtue of their names: Adler's "individual psychology" and Jung's "analytical psychology." Wilhelm Stekel, who left the psychoanalytic movement after Adler in 1912, remained a marginal figure and only had a few disciples who followed him personally without constituting a group.

The first true psychoanalytic split was that of Otto Rank in the aftermath of the publication of his book *The Trauma of Birth* in 1924. Rank was educated with Freud's help and even somewhat under Freud's wing, and he was a crucial player in the conception and the organization of the psychoanalytic movement. On the basis of Freudian premises, and by claiming to be their true inheritor, Rank separated himself from the very person to whom he owed his entire career. In contrast to others who moved up the Freudian ranks for a time and then took a divergent path only to disappear forever after, Rank did not remain alone, and only his early death prevented him from developing a school with successors to carry on his ideas. His ideas on trauma, the primal relation to the mother, and the shortening of the duration of the treatment are some of the themes that later emerged to take an increasingly important place in contemporary psychoanalysis. Sándor Ferenczi's influence in psychoanalysis followed a similar trajectory, and he only narrowly avoided a break with Freud over the experimental techniques of his late career, as detailed in his article on the "Confusion of Tongues" (1932). His death prevented a break with Freud, which would have been one of the last to have a theoretical cause. The same can be said of Wilhelm Reich, who was thrown out of the psychoanalytic movement in 1934, though his political activism was a precursor of the Freudian-Marxist movements that would appear some decades later.

Problems of training increasingly came to overtake theoretical disputes as the primary motive for splits. This shift was signaled in 1926 by the trial of Theodor

Reik for quackery, by Freud's commentary on the case in *The Question of Lay Analysis*, and by the discussion that ensued within the International Psychoanalytic Association in 1927. Training was confirmed as the new topic of debate by the creation of the Swiss Medical Society for Psychoanalysis in Zurich in 1928. The new society excluded non-physicians, a measure aimed specifically at Oskar Pfister. The debate intensified when, in 1938, the American Psychoanalytic Association's refusal to admit non-physicians to their membership led to the brink of a split with the International Psychoanalytic Association (I.P.A.). But as Ernest Jones said in all seriousness, "the advent of the Second World War altered the whole situation . . . and the Americans . . . cordially cooperated with [the I.P.A.]" (Jones, Vol. 3, p. 300). But it was actually the death of Freud in September 1939, along with the disruptions that accompanied the exodus of Jewish analysts from Europe, that would radically alter relations among analysts (Mijolla). This led to the codification of the qualifications for the status of "psychoanalyst," which Freud had held the supreme right to confer while he lived.

One of the last great theoretical debates was the controversy between the partisans of Anna Freud and those of Melanie Klein from 1941 to 1945. The debate almost provoked a split, with each of the parties considering themselves to be more faithful to Freud's thought, but in the end the crisis was averted by a compromise that allowed the British Psychoanalytic Society to split into three subdivisions that have managed to coexist as well as could be expected. Meanwhile, in the United States, Karen Horney was kept out of the New York Institute, also for theoretical differences. In 1941, along with others who shared her "culturalist" views, she founded the Association for the Advancement of Psychoanalysis and the American Institute of Psychoanalysis. A series of splits followed, in Washington, Boston, and Los Angeles, while at the same time a number of associations for lay analysts were founded, such as the National Psychological Association for Psychoanalysis, founded by Theodor Reik in 1948. In 1987, this association was, after a long struggle, the cause of a reversal in I.P.A.'s policy on lay analysts.

In Germany after the war, theoretical grounds were used to settle scores for the positions that some had taken during the Nazi era. The German Psychoanalytic Society (*Deutsche Psychoanalytische Gesellschaft*, D.P.G.), which was reestablished in 1945 under the

strict leadership of Carl Müller-Braunschweig and Harald Schultz-Hencke, was a heterogeneous assembly that had hardly any conceptual or practical relationship with I.P.A.'s conception of psychoanalysis as represented at the Zurich Congress in 1949. Harald Schultz-Hencke advocated a "neo-psychoanalysis," and several of the group's members were more Jungian than Freudian. Thus Carl Müller-Braunschweig, in spite of the fact that his past did not inspire much confidence, was encouraged by those who held more orthodox views to found the German Psychoanalytic Association (*Deutsche Psychoanalytische Vereinigung*, D.P.V.), which was the only German group to be recognized by the I.P.A. as authorized to train analysts. The two groups would coexist until the German Psychoanalytic Society was eventually readmitted into the international psychoanalytic community.

Increasingly, problems of recruitment and training caused crises and splits within the international psychoanalytic movement. After World War II, the growing popularity of psychoanalysis and its geographical expansion linked to the exodus of analysts from Europe led to an increased demand for analysts and trainers in the western world.

The example of France is significant in this context. Young psychiatrists were already interested in psychoanalysis, but the creation of a bachelor's degree in psychology by Daniel Lagache in 1947 broadened this interest considerably. The decision to found a psychoanalytic institute in Paris triggered a struggle both for leadership and for authority over the candidates who began to flock to it. The outcome was the split of 1953, which left the Psychoanalytic Society of Paris (*Société psychanalytique de Paris*, S.P.P.) under the control of Sacha Nacht and led to the creation of the French Psychoanalytic Society (*Société française de psychanalyse*, S.F.P.) and a "free institute" co-directed by Daniel Lagache and Jacques Lacan. The new group then requested membership in the I.P.A., which, with an unprecedented intensity, took on the role of arbiter and even supreme authority in matters of training. Excluded from the I.P.A. by their own secession, the analysts of the S.F.P. fought for twelve years before their credentials as training analysts were granted. This recognition came at the price of excluding Jacques Lacan, who refused to comply with the norms that the I.P.A. imposed on analysts all over the world, such as the quantity and frequency of sessions in a

training analysis, the length of sessions, and the rituals concerning the required supervised analyses.

But conflicts over training reemerged after the foundation of the Freudian School of Paris (*École freudienne de Paris*, E.F.P.) by Jacques Lacan in 1964. A case in point was the split of 1969, when Piera Aulanger, François Perrier, and Jean-Paul Valabrega left to form the Quatrième Groupe (“Fourth Group” or O.P.L.F.). After Lacan dissolved the E.F.P. in 1980 and died the following year, the Lacanian movement suffered split after split, giving rise, in fact, to a plethora of small groups, most of them not very long-lived. In spite of its violent internal conflicts, the School of the Freudian Cause (*École de la Cause freudienne*, E.C.F.), the successor to the E.F.P., remained the most stable institution. Its longest lasting contemporary, the Center for Psychoanalytic Training and Research, broke up in 1995.

Psychoanalytic splits are often political, like the formation of the Psychoanalytic Seminar of Zurich in 1977, and often emotional, like the divisions over Kleinian theory in the Argentinean Societies. In the end, they are too numerous for a comprehensive overview. It has been impossible to give more than the most significant examples here. Nevertheless, they do have common features, among them emotional breakups, rebelliousness, and ideological schisms. Each split presents a mixture of these features in different proportions. Splits resemble emotional breakups insofar as old friendships are broken, transference bonds are brutally cut, and choices must be made. “It reminds you of parents who are divorcing,” as Anna Freud said in 1953 (Lacan, p. 72). As for “rebelliousness,” its traces are to be found in the new structures and regulations that arise, with much of the focus being on the functions of training, supervision, and so on. And ideological schisms, though generally masked by administrative operations, are always present. The fact that debates over ideas rarely reflect contrasting theoretical visions does not mean that they are any less vital. This is evident from the fact that every split is followed by a burst of creative activity on both sides.

It is possible to see in this last feature the invigorating potential of splits, which might otherwise seem like a kind of destruction. New, often formally unstable ideas can cause a definitive break, yet later they may reemerge in the mainstream of a psychoanalysis that is in perpetual evolution.

## SPLITTING

Splitting is a form of dissociation that results from a conflict that can affect the ego (splitting of the ego) or its objects (splitting of the object). It is a very general intrapsychic process to the extent that it also forms the basis of the capacity in the psychic apparatus for dividing itself into systems (cf. first topography: unconscious, preconscious, conscious) and into agencies (cf. second topography: id, ego, superego).

The term “splitting” has some long-established uses in psychiatry and goes back to the general concept of a capacity for psychic splitting in the human being. These usages are precursors of the concept of splitting as defined by Freud. They are found in the nineteenth century in relation to hysteria and hypnosis (splitting

of the personality, multiple personalities, dissociation) and in Pierre Janet's work, in which the concept of a deficiency of psychological synthesis plays an important role. Freud and Breuer return to the concept of splitting in relation to "splitting of consciousness" and from 1894 ("The Psycho-Neuroses of Defence"), Freud provides a causality for this process: "For these patients whom I analysed had enjoyed good mental health until the moment at which *an occurrence of incompatibility took place in their ideational life*—that is to say, until their ego was faced with such an experience, an idea or a feeling which aroused such a distressing affect that the subject decided to forget about it because he had no confidence in his power to resolve the contradiction between that incompatible idea and his ego by means of thought-activity" (1894a, p. 47).

However, the splitting mentioned here goes back to neurotic repression. Now, Freud, writes, "There is, however, a much more energetic and successful kind of defence. Here, the ego rejects the incompatible idea together with its affect and behaves as if the idea had never occurred to the ego at all" (1894a, p. 58). This describes another form of splitting, that which Jacques Lacan later translates as foreclosure (*forclusion—Verwerfung*), which is characteristic of the psychoses and results in the foreclosed element returning in the real in the form of a hallucination. With the concept of "denial of reality," Freud introduces another form of splitting that demonstrates the proximity of the mechanisms of perversion to psychotic mechanisms without actually conflating them, as is evident from the creation of a substitute for the absent reality (the female penis) that occurs in the fetish, which differs from a hallucination.

The concept of splitting does not only concern this possibility of dissociation from reality or internal rift in the ego, but also relates to the object of the drive. Based on Freud's hypotheses concerning the life drive and the death drive, Melanie Klein demonstrated the force with which the latter operates in generating infantile anxiety when confronted with frustration. The splitting between a "loved good breast" and a "hated bad breast" therefore constitutes a way of simultaneously preserving a good object and constructing a bad object as the receptacle of the destructive drives. This situation corresponds to what the author terms the paranoid-schizoid phase. The support that the ego draws from the good object and the process of repairing the destroyed object subse-

quently allow this splitting to be partly overcome. However, the splitting of the object is inextricable from a splitting of the ego into a "good" and a "bad" ego, according to the introjection of the corresponding split objects. Splitting can prove difficult to overcome when it is established between a very bad object and an idealized object. The entire pathology of idealization opens up here with its multiple clinical facets.

Melanie Klein's successors, Wilfred Bion and Donald Winnicott, amplified and deepened the concept of splitting. For Bion, splitting in the form of dissociation precedes the work of elaboration in loss. For Winnicott, who takes up Helene Deutsch's concept of "false self," a distortion in the initial relationship between the mother-environment and the baby creates a false self that protects the true self but also isolates it from contact with reality. For Winnicott, splitting can also take the form of dissociation or disintegration as responses to being confronted with a psychotic fear of disintegration.

## SPLITTING OF THE EGO

The term “splitting of the ego” refers to a division of the ego into two coexisting parts, one of which satisfies instinctual demands while the other heeds the objection, in the shape of a symptom, which reality raises to that satisfaction. This process, which Freud described as a “ruse,” constitutes a temporary response to the conflict, but the price paid is an inner rent in the ego that can only get worse with time.

For Freud the most striking instance of the splitting of the ego was to be observed in the perversion of fetishism, but it was also at work in the psychoses, and to a lesser degree in neurosis. It represents a position with respect to reality more complex than denial (or disavowal [*Verleugnung*]), for it implies the coexistence of two contradictory attitudes. The notion of the splitting of the ego was probably already present in embryo in Freud’s mind well before his paper on “Splitting of the Ego in the Process of Defence” (1940e [1938]). Thus the idea of a “plurality of psychical persons,” identifications, and in a more general sense the institution of the ideal mental agencies (superego, ego ideal) are so many forms of splitting of the ego—although it should be noted that in the last case the outcome is the formation of a new agency rather than the maintenance of a split within the ego itself.

It was above all in the context of the psychoses that Freud developed this idea, and especially with regard to paranoia and delusions of reference. Viktor Tausk also worked in this context in his discussion of the genesis of the “influencing machine” in schizophrenia (1919/1949). Similarly, Sándor Ferenczi (1933) pointed out that traumas experienced by the child might give rise to a dissociation of a kind that would enable the adult, later, to present an appearance of perfect adaptation concealing an ego in ruins. In Freud’s view, psychosis implied a break with reality caused by an irreconcilable idea: thanks to the mechanism of delusional projection, what had been abolished within the mind reappeared in the outside world in the shape of a hallucination.

The full dynamic complexity of the splitting of the ego emerged, however, only in the context of fetishism. Unlike a hallucination, a fetish was created not by a denial of reality but rather by a subtle avoidance of it, thanks to the symbolic transfer of the absent penis onto some other part of the body. This was the dividing-line between perversion and psychosis. But the

splitting of the ego also signaled the ego’s failure to build constructively on reality-testing by interpolating, between the instinctual demand and its gratification, the consequences of the envisaged course of action, whether the repression of the demand or the postponement of its satisfaction.

## “SPLITTING OF THE EGO IN THE PROCESS OF DEFENCE”

This short essay, dating from January 1938, was published after Freud’s death. In this work Freud returned to an issue that he had previously discussed in “Fetishism” (1927e) and that he was to take up again in *An Outline of Psychoanalysis* (1940a [1938]).

The subject of ego splitting surfaced also in other much earlier texts, particularly those concerned with psychosis, which is why Freud hesitated between “whether what I have to say should be regarded as something long familiar and obvious or as something entirely new and puzzling” (1940e [1938], p. 275).

In the paper, Freud described as “cunning” (p. 277) the solution found by the child simultaneously to satisfy his instincts and respect reality. (It is surprising here that what Freud called a “real” danger was just the fact that the child had been threatened with castration.) Through the mechanism of splitting, the child “takes over the fear of that danger as a pathological symptom and tries subsequently to divest himself of the fear” (p. 275). The displacement of confrontation anxiety (onto a phobia, for example) allows for a particular solution, namely the creation of a fetish.

Freud goes on to describe how the “reality” of the threat is confused with the reality of the absence of a penis in the woman, falsely interpreted as a castration. Displacing the absent penis onto an object chosen as a fetish allows the child to disbelieve the threat of castration, since a substitute for the penis exists. However, this is only possible at the price of “a turning away from reality” (p. 277), an erroneous conception of female anatomy. Demarcating this mechanism from psychotic functioning is the fact that the substitute is not hallucinated but chosen in a regressive manner—that is, from a pregenital perspective. “Success,” Freud wrote, “is achieved at the price of a rift in the ego which never heals but which increases as time goes on” (p. 276).

This text has been much discussed, notably for its innovation in seeing the splitting of the ego as a process involved not only in fetishism and psychoses, but also in neuroses. Freud further developed this idea of ego splitting in *An Outline of Psychoanalysis* (1940a [1938]), where he described the splitting of the ego as “a universal characteristic of neuroses that there are present in the subject’s mental life, as regards some particular behaviour, two different attitudes, contrary to each other and independent of each other” (p. 204).

## SPLITTING OF THE OBJECT

The early ego relates to its objects in partial ways; that is, it splits the object. This process creates objects characterized by a particular function (feeding, holding, and so on) or objects that frustrate or gratify (“bad” or “good” objects). The notion of splitting of the object appears for the first time in the article “Personification in the play of children” (Klein, 1929).

Melanie Klein in her earliest observations noted the wide discrepancies of children’s feelings toward objects in their attention. She was most impressed, and alarmed, by the strength of children’s aggressive and violent feelings toward objects they played with. Sometimes the child’s mood changed to aggression, anger, or fear very suddenly. In panics or tantrums this reaction could reach a rapid crescendo. Klein interpreted these hangovers from early infancy as the loss of the reality of the object. The object was no longer a person capable of mixed feelings of love and hate, and therefore of mixed intentions, beneficent or harmful. Instead, it became an object that was wholly loved or wholly hated. She regarded the early ego as not fully able to integrate the impressions of its first object. The breast, for example, is a good feeding object, or it is a frustrating one filled with hate and bad intent toward the infant.

As the ego matures, it becomes capable of recognizing that one and the same object can have good and bad aspects, as well as multiple functions. This perceptual development may, however, be distorted by emotional factors, with the result that the child, in its ways of relating, retains partial objects into childhood and later. Many prejudicial attitudes of race, class, gender, and so on, rely on distorted perceptions that enhance

one or another function, or the “good” or “bad” intent, to the exclusion of others. The capacity to integrate objects in accord with reality brings in powerful new emotional problems for the infant, who must harbor both hatred of a frustrating mother with love and gratitude toward her as a feeding mother. This integration leads to the depressive position and characteristic experiences of insecurity, guilt, pining, and reparation (Klein, 1935, 1940).

Melanie Klein derived her notion from Karl Abraham’s concept of partial object-love (1924). A splitting of the object is connected with a splitting of the ego; Klein (1946) thought that both must occur together. Freud’s last important theoretical contribution (1940e [1938]) concerned a splitting of the ego in connection with gross distortion of perceptions of the loved erotic object.

Anna Freud (1927) and Edward Glover (1945) have doubted that Klein could accurately describe the very early stages of development prior to the infant’s acquiring language. Klein, however, believed that her extrapolation from the analysis of young children back to infancy was no different from Freud’s extrapolation from the analysis of adults back to childhood.

Another dispute concerned the nature of objects. In classical psychoanalysis, objects are represented in the minds of adults and infants alike. However, Melanie Klein followed Karl Abraham in positing a level where objects are related to as real entities in psychic reality, be they concretely within the ego or outside.

## **SPLITTING OF THE SUBJECT**

“Splitting” (in French, “refente”) is one of the translations Jacques Lacan proposed for the German “Spaltung” when he discussed how the subject is divided in subordination to the signifier.

In 1958, at the end of *Les formations de l’inconscient* (1998), book 5 of his seminar, Lacan introduced the written symbol to refer to the effects of the signifier on the subject. He proposed the French term “refente” some time later to translate the English term “splitting,” itself a translation of the term employed by Freud, “Spaltung,” which, in Lacan’s view, indicated this same dimension.

As early as 1953 Lacan emphasized an initial division “that precludes . . . any reference to totality in the individual.” This division differentiates the ego from the subject and consciousness from the unconscious. A person does not speak about the subject; the id speaks about it. A signifier represents the subject, but before disappearing under this signifier, the subject is nothing.

The signifier represents the subject for the signifier that exists in the Other (the primary caregiver). This operation alienates the subject, and through alienation produces the subject. The second operation is separation. It results in the splitting of the subject. There is no answer in the Other to the question of the subject’s being. Instead, the subject encounters the desire of the Other, that is, its own lack, the juncture where the subject’s fantasy will form.

The “division of the subject,” the term that Lacan used most frequently to translate “Spaltung,” corresponds to the written notation. Other words have also been proposed for this notion: not only “refente,” but also “coupure” (cut) and “évanouissement” (disappearance, vanishing) in French, as well as “eclipse,” “fading,” and “aphanisis” in English.

## **SPLITTING, VERTICAL AND HORIZONTAL**

The psyche is often depicted metaphorically as an image, and this image can be further represented as whole or split. A horizontal splitting is used to bring out a division between upper and lower sectors. A vertical splitting suggests a separation of sectors that lie side by side. There is a psychoanalytic tradition that suggests that the first splitting (horizontal) represents repression, and the second (vertical) can be considered as a representation of denial.

A horizontal splitting, the barrier of repression, separates unconscious material from preconscious contents, while a vertical splitting basically partitions material that is more or less accessible to consciousness. While many are familiar with Sigmund Freud's ideas about repression and the forces that maintain it, the idea of vertical splitting is rather less well known. According to Heinz Kohut (1971), it is characterized by the existence, side by side, of attitudes operating on different levels—different structures of goals, aims, and moral and aesthetic values. Generally speaking, one side of this parallel existence is judged to be more in accord with reality, while the other can be judged infantile or turned towards immediate gratification.

One of the ways of considering these parallel attitudes of the personality consists in saying that the realist attitude is better structured and/or more neutralized, while the infantile attitude is relatively unstructured and/or not neutralized. This less structured sector is sometimes involved in a fantasy, but with even less structure it can issue in manifest action. Such is the case with behavioral disturbances such as addictions, delinquency, and perversions. With horizontal splitting, the infantile and unstructured material is kept at bay. With vertical splitting, it succeeds in expressing itself. Pathological behavior is the manifestation of this split vertical sector.

## **SQUIGGLE**

The squiggle was Donald Winnicott's technique of communicating with children through drawing, in psychotherapeutic consultation. First he would make a “squiggle,” a twisted or wiggly line spontaneously drawn on a piece of paper. The child then adds elements to the drawing, and the analyst and child comment on its meaning. The analyst then transforms the child's drawing, and the analyst and child further comment on the drawing. This interview diagnostic is based on the idea of testing a therapeutic response.

Winnicott described the game first in 1958 and later more fully, with a series of case studies, in 1971. During his career as both pediatrician and psychoanalyst, Winnicott developed techniques in his work with children that were at once diagnostic and frequently therapeutic, based on his view that creative communication and play both occur in the “third area” or “area of experiencing”—the space between persons where contributions from each overlap.

Winnicott's concept of the “third area,” “transitional area,” or “area of experiencing” derives from his thinking about the infant's development from the

early illusory stage of omnipotence to the stage of recognizing objective reality, and is linked to his ideas about transitional objects and phenomena. An earlier example of communicating with and observing an infant is given in his description of the “spatula game” (Winnicott, 1941).

In both games, Winnicott observed the responses of all parties in the interaction: in the spatula game, the responses of mother, baby, himself, and any observer; in the squiggle game, his own and the child’s spontaneous actions and comments.

His description of the squiggle game is exquisitely detailed: how he met the child and introduced the game, how he took pains to diminish possible anxiety, and how he allowed the child, if the child wished, to decline this invitation to play.

Winnicott discovered that this technique, in the setting provided by him, provided reference to current emotional difficulties and also to their roots in developmental and structural reality. The clinical descriptions given in his writings are detailed and give an insight into the mind and work of this unique psychoanalyst and pediatrician. Winnicott’s widow, Clare, described Winnicott’s own enjoyment of his private squiggles, which he would draw after work each day. A collection of them is held in the Archives of the British Psychoanalytical Society.

Winnicott’s description of his technique has inspired other analysts, who have found it useful, although some analysts have leveled the criticism that his spontaneity and his own particular facility for communicating with children were idiosyncratic and are difficult to reproduce.

Melanie Klein also made use of play as a technique, though she used her technique in ongoing psychoanalysis rather than in diagnostic or therapeutic consultations. Anna Freud as well made use of play with children.

## **STAGE (OR PHASE)**

The term “stage” is used to designate a developmental phase that, for Freud, is characterized by a specific organization of the libido, linked to a particular erotogenic zone, and dominated by a particular modality of object relations. Some authors prefer to speak of “phases” or “positions” rather than stages, because these alternatives emphasize the fact that what are referred to here are moments in psychosexual development that partake of the dialectic of the Oedipus complex, rather than a precisely stable stage in the evolution of the libido. Each phase of sexual development corresponds in effect to a distinct type of organization.

Thus the psychoanalytic notion of stage does not refer to the structural study of the genesis of cognitive processes, nor does it impinge on the field of developmental psychology (for instance, the theory of Jean Piaget). The Freudian approach concerns itself exclusively with the child’s developing psychosexuality constructed in “stages,” “phases,” or “organizing moments” as the child proceeds through various steps in its maturation.

This perspective attempts to account for the constitutive effects, during childhood, of bodily and mental experiences of pleasure and unpleasure, and hence for the role played by the erotogenic zones at two levels: object relationships and narcissism, or love and hate—the basic modes of mental life, which the successive versions of Freud’s theory of the instincts sought to explicate. From this standpoint, the scheme of libidinal stages provides a set of reference points, a grid against which the specific traits of an individual’s mental organization can be plotted and clearly profiled (Brusset, 1992).

Both psychopathology and the psychology of the ego have used a scheme of stages as a main axis of reference. In psychopathology, this general model

makes it possible to relate pathological structures (character types, disease entities) to various fixations or regressions of the libido. One of the most remarkable demonstrations of the consistency of the model is the association between obsessional neurosis and the anal character type. The essential role that anal eroticism plays in obsessional neurosis led Freud to define the anal-sadistic stage as a major moment in the organization of the psyche. This account served as his initial model for a general conception of “stages of organization of the libido.” On the basis of his analysis of the “Rat Man” (1909d), Freud was able to define the dynamic organization and structure of obsessional neurosis by drawing out the close connections between sadomasochism and anal eroticism. Similarly, Freud’s analysis of the autobiography of Daniel Paul Schreber (1911c [1910]) served as the basis for Freud to relate paranoia to a fixation at the narcissistic stage of development and to relate dementia praecox (schizophrenia) to a fixation at the autoerotic stage.

In the psychology of the ego (Anna Freud, René Spitz, Otto Fenichel) and ego psychology (Ernst Kris, Heinz Hartmann, and Rudolph Loewenstein), sets of problems are tackled in terms of developmental stages—a development that brings the notions of regression and fixation into their own. These two ideas stand in contrast with those of evolution, process, and change. From the genetic point of view, fixation, as a factor in invariable and repetitious behavior, is a constraint imposed by the instinctual unconscious. Regression may be pathological (as when it becomes fixated, for example), but it may also be purely functional and part of normal development, notably when it occasions narcissistic reinforcement as preparation for resuming the dynamic process of object cathexis (Golse, 1992).

When Freud abandoned his theory of seduction, he inevitably gave new weight to fantasy and emphasized psychic over material reality. Fantasies, it should be remembered, are scenarios of action first constructed in an autoerotic period and tending to actualize mnemonic traces of the experience of satisfaction. This theoretical step called for a metapsychology, rather than a simple psychology of the lower, normal, and rational forms of human mental activity that confines its scope to conscious phenomena alone. Thus the system of stages could remain a valid theory only if it was integrated into a properly psychoanalytic framework, one that took account, in particular, of the notions of the unconscious and of repression. Early experience

includes the body, but also the unconscious sexuality of the mother (Perron-Borelli, 1997).

The object is both a constitutive element of the instinct and a pole of cathexis within external reality. The notion of object relations has tended to enhance the general impact of the model of stages. In particular, it has opened this model up to the diversity and complexity of parent-child interaction, lessening the former emphasis on pressure and source (that is, on the erotogenic zones) and stressing instead the two other defining aspects that make the libidinal instinct into a complete structure, namely the aim and the object (Brusset, 1992).

Psychoanalytically speaking, the genetic dimension is necessarily related in a dialectical manner to the structural dimension, that is, the oedipal organization and its different triangulations. Jean Laplanche and Jean-Bertrand Pontalis (1973) have pointed out that the use of the terms “phase” or “position” instead of “stage” underscores the fact that we are concerned here with intersubjective moments within the oedipal dialectic, rather than mere stages of libidinal development. The concept of deferred action (*après coup*) also runs counter to a purely linear view of mental development in which each stage is understood as unfolding in simple opposition to the preceding one. For example, deferred action, operating in conjunction with the diphasic nature of human sexuality, results in a period of latency.

In an even more radical sense, the fundamental Freudian ideas of the timeless unconscious and of a compulsion to repeat serve to explain how a past of which the subject has no memory can return in the shape of “a perpetual recurrence of the same thing” (1920g, p. 22).

The Freudian model of libidinal development has been vulnerable to simplifying uses that threaten, in particular, to dissolve metapsychology into a naively realistic psychology or else into a psychology of the ego and of development that retains nothing of psychoanalysis. All the same, quite apart from the explanatory value of structural approaches, the practice of psychoanalytic interpretation, founded on a reconstruction of the past, continues to derive inspiration from a genetic point of view: “The task is certainly to account for structures in terms of the processes that have constituted them, and for processes in terms of the stages that make them intelligible” (Brusset, 1992).

A model based on stages, if it is to remain pertinent, must therefore remain subordinate to the metapsychology of mental processes, and by extension, it must remain dialectically consonant with the structural perspective.

## **STAMMERING**

Stammering is a disorder in the rate of speech delivery. It appears in the communication patterns of children aged between two and five and is characterized by repetitions or blockages that lead to ruptures in the

rhythm and melody of speech. Three out of four children are destined to overcome it before adolescence. Stammering is a universal complaint and has been documented in the most ancient cultures.

Sigmund Freud associated this type of disorder with hysteria, but classified it separately as a fixation neurosis (on an organ [of speech]). Otto Fenichel located this functional speech disorder in the group of pregenital conversion neuroses. The patient's mental structure was the same as that of an obsessive, whereas the symptomatology was of the conversion type. Speech had acquired an unconscious significance related either to its verbal content or to the general meaning of the function of “speaking” itself, as in severe cases of stammering in which the speech act represents a reprehensible drive.

Bernard Barrau draws attention to the frequent presence of situations of oral violence in these cases, and fantasies of “forcible introduction,” whether in relation to forced food or its metaphorical equivalents (the voice and speech of the mother). Ivan Fonagy stresses the fact that speech is capable of absorbing narcissistic, oral, anal, or genital libido, and reports observations of parallel strategies in the anal and glottal sphincter (stammering when establishing sphincter control), and upward transfers of anal libidinal cathexis (one of Charlotte Balkany's patients identified resonant air with air emitted by the anal sphincter). René Diatkine points to the absence of a psychic structure specific to stammering subjects, whose symptom, as a disorder in verbal communication, modifies their relational system, particularly the balance between narcissistic- and object-cathexes.

Annie Anzieu traces the elements in the neurotic dynamics of stammering subjects. An anal-sadistic relation is often established between the (grasping and abusive) mother and the child, with the child fixating on a dual, merging relation with the mother, excluding all connections to a third object, unless it takes part in the mother-child whole. Stammerers thus have difficulty in engaging oedipal problems. Supervisions must be redoubled in order to integrate oedipal prohibitions into the ego, because what enters the body or comes out of it assumes a new erotic meaning. The speech act permanently alludes to castration anxiety. This relational mode leads to the persistence of what Melanie Klein calls the paranoid-schizoid position. Indeed the stammerer is persecuted by a particularly demanding father and mother. All

verbal emissions are problematic. Like feces, words are experienced as aggressive objects whose true intentions may be to wound or kill. They become the concrete symbols of interiorized aggressive objects. These paranoid characteristics entail a considerable obsessional element as well. Stammerers exhaust their discourse to the point of fragmentation; they remain haunted by the specific words they should be saying. Obsessional cathexis of discourse can be understood in the process of neurotic construction as a superegoic symptom in relation to the hysterical symptom stammering constitutes. The phonetic dysfunction and suffering caused by verbal emission are a form of hysterical conversion, a conversion that lends genital significance to an originally anal-sadistic symptom. The stammerer expresses the conflict he has always experienced through his symptom; the subject hides behind it. The act of speaking conceals what is said. The psychotherapy or psychoanalysis of stammerers always evinces these hysterical, obsessional, and paranoid contents in a more or less typical fashion depending on the moment in treatment and patient in question. For Nicole Fabre, stammering is an archaic difficulty shot through with oral aggressivity and anal sadism, from which the subject has not yet been able to break free in order to fully accede to oedipal triangulation.

Although psychoanalytic treatment is rarely indicated initially, especially with children, this approach does provide an understanding of the disorder that does not exclude its meaning from the outset.

The etiology of stammering is unknown. Constitutional factors interact with environmental ones in addition to factors linked to the personal dynamics of the child in varying proportions depending on the subject in question, thus illustrating the uniqueness of the trouble each stammerer faces.

## **STANDARD EDITION OF THE COMPLETE PSYCHOLOGICAL WORKS OF SIGMUND FREUD**

This was the title given by James Strachey in 1948, and adopted by the British Psycho-Analytical Society Memorial Appeal, to the English translation of all of Freud's psychoanalytic works. In accordance with Freud's wishes, the *Standard Edition* does not include Freud's prepsychoanalytic work as a neurologist.

The *Standard Edition*, which consists of twenty-four volumes published between 1943 and 1974, was prepared by James Strachey and his wife, Alix, with the collaboration and supervision of Anna Freud and the help of Alan Tyson. The twenty-fourth volume of the *Standard Edition*, which includes the "General indexes" and the "Addenda and corrections," was edited and published in 1974 by Angela Richards, a collaborator of the late James Strachey. In addition to the English translation, the *Standard Edition* also contains "Notes on some technical terms whose translation calls for comment," edited by Strachey, who made use of the old *Glossary of Psychoanalytical Terms*, published in 1924 and edited by Ernest Jones, and of Alix Strachey's *New German-English Psychoanalytical Vocabulary*, published in 1943. Furthermore, the *Standard Edition* has a considerable editorial apparatus: the introduction to each work of Freud's establishes its various dates of publication in German, English, or other languages; the context in which the text has to be read, in terms of the progression of Freud's work; the links that can be made with Freud's earlier and later work; and all the additions or deletions Freud made if a specific text, such as *The Interpretation of Dreams*, had more than one edition in German. In some instances, Strachey and his coworkers tried to check the various German editions of each text, and Strachey also added explanatory and informative notes at the

end of each of the texts that he and his colleagues translated.

One of the main organizational problems of the *Standard Edition* concerned the rights of translation into English, which Freud had given to his nephew Edward Bernays and to Abraham Arden Brill in America. For decades this made Strachey's task of a systematic translation of Freud's work impossible. For instance, only as late as 1949 was Strachey able to retranslate *The Interpretation of Dreams*.

Ernest Jones first conceived of the project of preparing a standard edition of Freud's work in English in the early 1920s (Steiner, 1989). Together with Abraham A. Brill, he had already translated many of Freud's technical terms into English when he was in America at the beginning of the twentieth century (Steiner, 1987). He sent James Strachey and his wife and then Joan Riviere and John Rickman to Vienna to be analyzed by Freud, with the added intention of creating a team of translators who could then systematically translate Freud into English and take over the leadership of Freud's translations from Abraham Brill. The result of those first systematic attempts were the first four volumes of Freud's *Collected Papers*, which were translated by the Stracheys, Joan Riviere, and others, often under the supervision of Jones, and were published in the 1920s and 1930s in London. It is important to remember this, since there is a clear line of continuity between the translations done by Jones and his group of translators in the 1920s and 1930s and the *Standard Edition*. Strachey did not make many changes to the *Glossary of Psychoanalytical Terms*, published in 1924 for translators and edited by Ernest Jones, which already contained translations for the most famous and questionable technical terms: "ego" for "Ich," "superego" for "Über-Ich," "instinct" for "Trieb," and so on. To Strachey in particular are attributed the translations of "cathexis" for "Besetzung" (a term, incidentally, also accepted by Freud) and "anaclitic" for "Anlehnung." All four volumes of the *Collected Papers* were republished in the *Standard Edition*, with corrections and improvements; apart from the papers on metapsychology, which had been badly translated, Strachey did not make many alterations to the translations done in the 1920s.

The *Standard Edition* reflects not only the personal idiosyncrasies of the Stracheys but also Jones's project to create in English a scientific Freud acceptable to

the medical and scientific psychiatric establishment. Although Jones and the Stracheys in the 1920s disagreed on many aspects of how to translate Freud (Meizel, 1986) Jones and James Strachey consulted each other constantly on technical and interpretative matters even during the 1950s, when they were working on the biography of Freud and on the *Standard Edition*. The supervision of the translation was also important, particularly by Anna Freud. Like any other translation, the *Standard Edition* bears the marks of the cultural context in which it was conceived; the complex political, institutional, and financial pressures that surrounded this colossal enterprise; and the personalities and ageing of the translators, James and Alix Strachey. Among the shortcomings of the *Standard Edition* were that Freud's polysemous, elegant, and expressive literary vocabulary and style were at times excessively stifled and rendered scientific, and that its editorial apparatus was inevitably restricted by the information, documents, personal letters, and notes of Freud's life and work available at that time. Yet there is no doubt that the *Standard Edition* constitutes a unique and irreplaceable instrument for the study of Freud. Perhaps one of the most amazing achievements of the *Standard Edition* is that other translations and editions of Freud's work depended on the *Standard Edition* rather than on the original German texts.

## STATE OF BEING IN LOVE

The concept of “being in love” was investigated by Christian David in *L'État amoureux*, published in 1971, at a time when his ideas about psychosomatics were changing. David continued to believe in the importance of questioning the fluctuations to which mental processes were exposed, but he now stressed those generated through the encounter with the other rather than those implied by a physical presence.

Overall, his study attempts to point out the internal behavior of the subject confronted, through this encounter, with the state of “being in love.” For David this state is characterized by a form of subjectification that has two components: the subjectification of the drive in the face of the specific trauma caused by love, and the ability to integrate the narcissistic release implied by the encounter with the loved one. With respect to the subjectification of the love trauma, Sigmund Freud, who is quoted by David, sees it as similar to the work of mourning or dreaming. The analogy enables him to emphasize the singular quality of this type of activity, where the drive is immobilized at the crossroads of destiny and constantly re-released through the encounter with the other. Through this encounter the subject is constantly forced to confront the necessary death of the ego. “Where love is awakened, ego, that somber despot dies,” writes David, repeating Freud's quote of Jalal el Din (1911c).

One of the basic premises of David's book is to explain love as a narcissistic disturbance. The con-

comitant risk of forcing the subject to confront the most primitive dimensions of the drive is one that may restore the condition of narcissism. These aspects are at work in the tragedy of *Penthesilea* by Heinrich von Kleist, a text for which David provides a psychoanalytic reading. In the myth Penthesilea, queen of the Amazons, is in love with Achilles and loved by him. In the end she kills her lover and devours him with the help of her dogs. However, the violence of the drama underscores the necessity of a two-sided abandonment: abandonment of proximity to the being onto whom the subject projects his ideal, and abandonment of preserving intact the contours and limits of the ego. While the work of mourning flattens the contours of experience, the mental work required by the love trauma restores to it the variety and truth of its nuances. But to do this requires subjectification. At the extreme, this subjectification can assume the aspect of an “affective perversion,” like that expressed by Nathaniel in Gide's *The Fruits of the Earth*, when he exclaims, “My desires have given me more than the possession of the object of those desires.” In a sense the work implied by being in love, including “affective perversion,” mirrors the effort therapy demands of the patient caught up in transference love.

## STEKEL, WILHELM (1868–1940)

An Austrian physician and psychoanalyst, Wilhelm Stekel was born on March 18, 1868, at Boyan, Buko-

vina. He died on June 25, 1940, in London. After matriculating from a German secondary school in Czernowitz, Stekel studied medicine in Vienna. He worked in Richard von Krafft-Ebing's clinic for a while before defending his thesis in 1893.

A certain mystery surrounds the date of Stekel's first meeting with Freud, as well as that of the analysis (or analyses) that he undertook with him. In his paper "The Aetiology of Hysteria" (1896c), Freud cites Stekel's "Über Coitus im Kindesalter" (On infantile sexuality; 1895), and in another article written in 1896 but published in the following year, Stekel mentioned Freud's report on Paul Julius Möbius's book on migraine. It was probably Freud who, in 1901, recommended Stekel for a position as medical journalist at the well-known newspaper *Neues Wiener Tagblatt*, in whose pages, in January 1902, Stekel published a complimentary article on Freud's *Interpretation of Dreams* (1900a).

In October 1902, Stekel initiated setting up the Wednesday Psychological Society, which in 1908 transformed itself into the Vienna Psychoanalytic Society. Judging by the minutes (Nunberg and Federn), Stekel was its most active member during the first ten years. Stekel strongly challenged Freud on such subjects as the harmfulness of masturbation and the existence of the actual neuroses. In 1910 Stekel proposed setting up *Zentralblatt für Psychoanalyse*, of which he was soon sole editor. A dispute about his rights in this office led to Stekel's resignation from the Vienna Psychoanalytic Society in 1912. The underlying reason, however, was almost certainly Stekel's refusal to accept Freud's ideas on the actual neuroses. After World War I, Stekel set up his own school of "active analysis" and founded the Organisation of Independent Medically Qualified Analysts. He also launched and edited a number of psychotherapeutic journals.

Stekel was a prolific writer, producing fifty books (many of them for a general readership), hundreds of newspaper articles, and numerous scientific papers. The most important part of Stekel's psychoanalytical work is contained in his ten-volume *Störungen des Trieb- und Affektlebens* (Disturbances of the impulses and the emotions). The first volume was *Conditions of Nervous Anxiety and Their Treatment* (1923). It was followed by volumes on masturbation and homosexuality, frigidity in women, impotence in men, psychosexual infantilism, peculiarities of behavior, fetishism,

sadism and masochism, and finally two volumes on compulsion and doubt. Other academic books of his deserving special mention are *Die Sprache des Traumes* (The language of dreams; 1911), *Die Träume der Dichter* (The Dreams of Poets; 1912), *The Interpretation of Dreams* (1943), and *Technique of Analytical Psychotherapy* (1939). The most well-known of his popular books was his *Primer for Mothers* (1931).

Stekel was a popularizer of psychoanalytic ideas, both through his journalistic output and through his books, yet he was also an innovator in technique and theory. He devised a form of short-term therapy called active analysis, which has much in common with some modern forms of counseling and therapy. He argued strongly for the view that all neuroses are psychoneuroses.

## STERBA-RADANOWICZ-HARTMANN, EDITHA (1895–1986)

Psychoanalyst Editha Sterba was born on May 8, 1895, in Budapest, and died December 2, 1986, in Detroit, Michigan.

From a Catholic family, Editha was the daughter of Colonel Heinrich von Radanowicz-Hartmann, a commander in the Austrian army. After secondary education at a humanistic gymnasium ordinarily restricted to boys, she attended the University of Vienna, where she initially studied German language and literature and classical philology before turning, in 1916, to musicology. She graduated in 1921 with a thesis on “Viennese Song from 1789 to 1915.”

As secretary to Otto Rank at the Internationaler Psychoanalytischer Verlag (the official psychoanalytic publishing house) and secretary at the training institute, she became familiar with analysis, and by the end of 1925 she was an associate member of the Vienna Psychoanalytic Society. A year later, divorced from her first husband, she married the Viennese physician and analyst, Richard Sterba. In June 1927, she gave a lecture “Blasphemy and the Punishment of Heaven” and in 1930 she became a full member of the Vienna Society.

Editha Sterba’s major focus was the emerging field of child psychoanalysis. In 1928, she was placed in charge of the educational services center of the Vienna Psychoanalytic Society and, in 1932, of a larger center with August Aichhorn, Anna Freud, and Willi Hoffer. With Aichhorn she also served as an adviser and consultant to educational institutions in Vienna and, in October 1934, she directed the introductory seminar on child psychoanalysis. From 1927, she regularly published her works in *Zeitschrift für psychoanalytische Pädagogik*.

The Sterbas left Vienna in 1938, first for Switzerland. On Ernest Jones’s advice, they applied for a visa for South Africa with the intention of helping to found a psychoanalytic society there. However, they failed to obtain the necessary visas and instead emigrated to the United States in 1939. Editha became a member of the Detroit Psychoanalytic Society, the American Psychoanalytic Association, the Association for Child Psycho-

analysis and, in 1955, of the Michigan Association for Psychoanalysis. In 1953, she was asked to join the newly opened department of psychiatry at Wayne State University. Her study *Beethoven and His Nephew*, written in collaboration with her husband, appeared in 1954. With Alexander Grinstein she wrote *Understanding Your Family*, published in 1957.

Editha Sterba played a variety of roles in organizational and research projects over the course of three decades in the United States. She worked at the Children’s Service of the McGregor Center at Wayne State University and the Northeast Guidance Clinic; she also helped found the Roeper City and Country School, a training institution for nurses. She was associated with the University of Michigan, practiced at the Children’s Hospital of Michigan, and for the Jewish Family Service she developed methods for treating young survivors of the Holocaust.

## STERBA, RICHARD F. (1898–1989)

Richard Sterba, physician and psychoanalyst, was born in Vienna on May 6, 1898, and died on October 24, 1989, in Grosse Pointe, Michigan. His father, Josef Sterba, taught mathematics and physics at the high school level. Conscripted shortly before graduating

from the gymnasium in 1916, Richard entered the army and was eventually promoted to lieutenant. While in the military, he became interested in psychoanalysis and, after the war, began medical studies at the University of Vienna, graduating in 1923. The next year he started a training analysis with Eduard Hitschmann; without sufficient funds, he paid no fee, on the understanding that in the future he too would analyze some patients for free. His first supervising analyst was the neurologist Robert Hans Jokl, and he began treating patients after six months of analysis.

In 1926 Sterba married Editha von Radanowicz–Hartmann, and the couple were among the first students to attend the training institute of the Vienna Psychoanalytic Society, which opened at the end of 1924. Sterba became an associate member of the society in 1925 and a full member in 1928 (Sterba, 1982, p. 43). Shortly after presenting his 1926 paper, “Über latent, negative Übertragung” (On latent negative transference), Wilhelm Reich offered him a residency at a psychoanalytic outpatient clinic (Sterba, 1982, p. 40). Leaving his hospital position, he worked at the clinic with Grete Bibring and Eduard Kronengold. By 1929 Sterba was a training analyst, and in 1931 Adolf Josef Storfer, director of a psychoanalytic publishing house, suggested that he compile a psychoanalytic dictionary. Five fascicles of the lexicon were published (1936) before the coming of the Second World War put an end to the project.

Sterba was still in Austria in 1938, when the Nazi takeover of the country immediately disrupted psychoanalysis there. As a member of the board of directors of the Vienna Psychoanalytic Society, Sterba announced his intention to leave the country, to the relief of Freud and his daughter Anna, who themselves would soon migrate to England. As an “Aryan,” Sterba was welcomed by the Nazis, but he declined a post at the neuropsychiatric clinic of the University of Vienna and also rejected an offer to head the Vienna Psychoanalytic Society under fascist auspices.

The Sterbas left Austria on March 16, 1938, first for Switzerland then, in 1939, for the United States. Ernest Jones and Anna Freud suggested that they immigrate to Johannesburg and help found a psychoanalytic society there, but the South African government thwarted these plans by denying them visas. They settled in Detroit, where Richard Sterba founded the Detroit Psychoanalytic Society in 1940 and served as its president from 1946 to 1952. He was appointed

Professor of Psychiatry at the medical college of Wayne State University in Detroit in 1945.

Sterba specialized in psychoanalytic profiles of artists and published a study of Michelangelo and, in collaboration with his wife, a biography of Beethoven. In clinical matters, his hypothesis of “a therapeutic split of the ego” was controversial (Sterba, 1982, p. 91). In 1931 he published in German a treatise on the theory of the libido based on a course he taught at the Vienna Psychoanalytic Institute. In 1942 an English translation appeared under the title *Introduction to the Psychoanalytic Theory of the Libido*. In 1982 he published his memoir, *Reminiscences of a Viennese Psychoanalyst*. He was the author of about one hundred articles, a number of which appear in *Richard Sterba: The Collected Papers* (1987).

### STOLLER, ROBERT J. (1925–1991)

American psychoanalyst, professor of psychiatry, UCLA Medical School, was born December 15, 1925, in Crestwood, New York and died on September 6, 1991, in Los Angeles.

He was born and raised in suburban New York to Russian-Jewish immigrant parents, attended Columbia University and Stanford Medical School, was married for 43 years, and had four sons. Stoller underwent

psychoanalytic training at the Los Angeles Psychoanalytic Society and Institute from 1953 to 1961 with analysis by Hanna Fenichel. He was the author of nine books, co-author of three others, and publisher of over one hundred and fifteen articles. Stoller's writing is unique in its clarity and accessibility as well as its critical perspective on psychoanalytic methodology.

Stoller is known for his theories and research concerning the development of gender and the dynamics of sexual excitement. In *Sex and Gender* (1968), Stoller articulates a challenge to Freud's belief in biological bisexuality. Drawing on his extensive research with transsexuals at UCLA's Gender Identity Clinic and new advances in the science of sex, Stoller, in "Primary Femininity," advances his belief in the initial orientation of both biological tissue and psychological identification toward feminine development. This early, non-conflictual phase contributes to a feminine core gender identity in both boys and girls unless a masculine force is present to interrupt the symbiotic relationship with mother. Stoller identifies three components in the formation of core gender identity, an innate and immutable sense of maleness or femaleness, usually consolidated by the second year of life: 1) Biological and hormonal influences; 2) Sex assignment at birth; and 3) Environmental and psychological influences with effects similar to imprinting. Stoller asserts that threats to core gender identity are like threats to the sense of self and result in the defenses known as perversions.

In his most notable contribution, *Perversion* (1975), Stoller attempts to illuminate the dynamics of sexual perversion which he fights valiantly to normalize. Stoller suggests that perversion inevitably entails an expression of unconscious aggression in the form of revenge against a person who, in early years, made some form of threat to the child's core gender identity, either in the form of overt trauma or through the frustrations of the oedipal conflict.

In *Sexual Excitement* (1979), Stoller finds the same perverse dynamics at work in all sexual excitement on a continuum from overt aggression to subtle fantasy. In focusing on the unconscious fantasy, and not the behavior, Stoller provides a way of analyzing the mental dynamics of sexuality, which he terms "erotics," while simultaneously de-emphasizing the pathology of any particular form of behavior. Stoller does not consider homosexuality as a monolithic behavior but rather as a range of sexual styles as diverse as heterosexuality.

Less well known is Stoller's contribution toward making psychoanalysis a legitimate research tool through the publication of the analyst's data—verbatim notes and transcripts of interviews. Stoller melds the work of the ethnographer and the analyst as a means of producing scientifically valid psychological data. Many of Stoller's books, like *Splitting* (1973), are devoted to the documentation of the interviews on which he based his research.

## **STONE, LEO (1904–1997)**

Leo Stone, American psychoanalyst and teacher, was born on August 11, 1904, in Brooklyn, New York, where he died on July 27, 1997. He was the third of four children born to Ruben and Marcia Stone. His father, a man "with a good heart," was an avid reader and owned a large library, through which Leo read systematically. His mother was a kind woman with a fine singing voice—a factor in Leo's love of music. During his childhood the family moved to a farm north of New York City. Seven years later they moved back to Brooklyn. Later in life, Leo purchased from Brooklyn College a tract of land across the state line in New Jersey, an act reflecting his early attachment to nature. He was married twice and was the father of three daughters.

Leo Stone graduated from Erasmus High School in Brooklyn in 1916, from Dartmouth College in 1924, and from Michigan University Medical School in 1928. After a year on call, he studied pathology in Vienna and Berlin in 1930 and then completed a residency in neurology at Montefiore Hospital. He trained in psychiatry at the Menninger Clinic until 1936, after which he started a private practice in New York City, which he continued until his death.

He graduated from the New York Psychoanalytic Institute in 1941, having been analyzed by Clara Thompson, an analysand of Sándor Ferenczi. Then he joined the faculty of the institute and was active for many years until late in his life. He was Brill Memorial lecturer and received many honors and awards. He served as president of the New York Psychoanalytic Institute and as president of the New York Psychoanalytic Society. From 1951 to 1957, he also served as medical director of the New York Psychoanalytic Society.

Stone first achieved prominence after Anna Freud approvingly discussed his paper “The widening scope of indications for psychoanalysis” (1954), a plea for humanely expanding the use of psychoanalysis to treat a broad range of illnesses. This paper became the basis of his best known book, *The Psychoanalytic Situation: An Examination of Its Development and Essential Nature* (1961). He also published *The Therapeutic Experience and Its Setting: A Clinical Dialogue with Robert Langs* (1980) and *Transference and Its Context: Selected Papers in Psychoanalysis* (1984).

A key participant in the historic 1971 International Psychoanalytic Congress in Vienna, where he spoke on aggression as a reaction to frustrating reality rather than an inborn drive—a view with which Anna Freud concurred. He was an early proponent of a flexible approach. His view was that an analyst who remained too rigid risked damaging his patient and undoing any treatment—a view that was radical at a time when analysts favored giving the silent treatment or acting as a reflecting mirror.

Stone was widely respected in the United States for being gentlemanly and courteous, kind and modest, and lucid and thorough in presenting psychoanalytic ideas and concepts.

### STORFER, ADOLF JOSEF (1888–1944)

Adolf Josef Storfer, journalist and publisher, was born in Botoschani, Siebenbürgen (now in Romania) on January 11, 1888, and died in Melbourne, Australia, on December 2, 1944.

He was of Jewish origin and his father was a well-to-do wood merchant. He grew up at Klausenburg (Cluj), where he completed his secondary education and began to study law and political science. In 1908 he went to Zurich to continue his studies and became a journalist for the *Frankfurter Zeitung* and other publications.

In 1910 he contacted Sigmund Freud and sent him his manuscript “Zur Sonderstellung des Vatermordes” (“On the Primordial Role of Father Murder”), which Freud published that same year in *Schriften zur angewandten Seelenkunde* (“Writings of Applied Psychology”). In 1913 Storfer settled in Vienna and attended the meetings of the Wednesday Society.

He was mobilized during World War I and in 1919 became a member of the Hungarian Psychoanalytic Society, before moving back to Vienna. From 1921 onward he collaborated with the Internationaler Psychoanalytischer Verlag, becoming director in 1925. Until 1932 Storfer left his print on the content and editorial policy of this powerful instrument for the dissemination of psychoanalysis. His solid humanistic

education and his vast general culture particularly suited him to this task, as did his experience as a journalist.

The Internationaler Psychoanalytischer Verlag had its most productive period between 1925 and 1932: three new periodicals were founded and the publication of Freud's *Gesammelte Schriften* was completed under Storfer's directorship, along with his personal contributions to the content.

His contacts with the members of the Vienna Psychoanalytic Society were somewhat half-hearted, as he never practiced psychoanalysis. His role was essentially to be the intellectual indicator of Sigmund Freud's editorial policy. As editor of publications and as a result of internal financial crises, Storfer often had to deal with the competing interests of the psychoanalysts, as well as the consequences of the economic crisis.

As a leftist liberal intellectual, he frequented one of the most fashionable cafes in Vienna, the Café Herrenhof. In 1932 he left the Verlag after bitter disputes, thereafter working as a self-employed journalist, and publishing two works on etymology: *Wörter und ihre Schicksale* ("Words and their Destiny") and *Im Dickicht der Sprache* ("In the Thicket of Language").

In 1938 he succeeded in fleeing to Shanghai at the last minute and worked there as an editor for the last time. From 1939 to 1941 he published one of the best German-language newspapers for exiles, the *Gelbe Post*. As the Japanese advanced, in 1941, he managed to flee to Australia with the help of the British intelligence services. As a result of pneumonia he died in Melbourne in 1944 in extreme poverty.

## **STRACHEY, JAMES BEAUMONT (1887–1967)**

James Strachey, British psychoanalyst, was born in London on September 26, 1887, and died there on July 3, 1967. He belonged to a very distinguished upper-middle-class family. He studied at St. Paul's School in London, achieving good academic results, and in 1904 went to Trinity College, Cambridge, to study classics. Owing to personal difficulties, he ended up not with a degree in classics but with an unclassified degree in moral sciences (1909). Like many other pioneers of the British Psycho-Analytical Society at Cambridge, Strachey discovered the Society for Psychical Research, where he read Freud's paper "A Note on the Unconscious in Psycho-Analysis," published in the society's journal in 1912. It was this paper that stimulated Strachey's interest in psychoanalysis.

He had a brief career as a journalist working in London for *The Spectator* and *The Athenaeum*, during which time he also became part of the Bloomsbury Group, led by his brother Lytton. In 1919 he approached Ernest Jones about becoming a psychoanalyst. He married Alix in 1920. In the same year Jones, having perceived Strachey's literary talents and wanting to use him to begin the systematic translation of Freud's work into English, sent him to Vienna to be analyzed by Freud. While in analysis with Freud, who chose him officially as his translator, James, together with Alix, began to translate several of Freud's works, such as "A Child is Being Beaten" (1919e) and "Group Psychology and the Analysis of the Ego" (1921c). This was done under Freud's supervision and with the help of Anna Freud, who then became his collaborator and counselor in translating Freud's works.

Strachey returned to London in 1922 and, while practicing as a psychoanalyst, nevertheless dedicated most of his time to translating Freud's work. Particularly important was the Stracheys' translation of five of Freud's case histories, published in 1925 as the third volume of Freud's *Collected Papers*. James became an associate member of the British Psycho-Analytical Society in 1922, a full member in 1922, and a training analyst in 1928.

As a training analyst, Strachey took an active part in the life of the British Psycho-Analytical Society, then under the rule of Ernest Jones, who as early as the 1920s had already planned what was to become, after the Second World War, the *Standard Edition of the*

*Complete Psychological Works of Sigmund Freud.* Strachey helped Melanie Klein to come to London and played an important mediating role in the controversial discussions between Anna Freud and Melanie Klein in the 1940s. In 1948 Strachey became the general editor of the *Standard Edition* translation of all the psychological works of Freud into English, and after retiring to the country at Marlow with his wife, he dedicated the rest of his life to accomplishing this task, using and revising the translations made in the 1920s by him, Joan Riviere, and others that had appeared in the first four volumes of Freud's *Collected Papers* and retranslating other works such as *The Interpretation of Dreams* and the metapsychological papers. One of the greatest contributions of his work was the editorial apparatus that he added to the translations of the *Standard Edition*, which has become invaluable in understanding and contextualizing Freud's work.

Strachey was well aware that his translations and editorial apparatus were not definitive and that they would need further revisions and corrections. Particularly important was the glossary of psychoanalytic terms, which he prepared reusing old material and most of the terminology already established in the 1920s and published in 1924 in *The Glossary of Psychoanalytical Terms*, edited by Ernest Jones. To Strachey we owe, among other translations, the terms "cathexis" to translate the German "Besetzung" and "anacletic" to translate "Anlehnung." Both terms were derived from ancient Greek. Indicating the importance of its translations and editorial apparatus is the fact that the *Standard Edition* has become the text used by the International Psychoanalytical Association and that it is also the point of reference for other translations of Freud's works into such major languages as German, Italian, Spanish, Portuguese, and French. In 1967 Strachey was awarded the Tieck Prize for his translation of the *Standard Edition*.

Strachey also significantly contributed to clinical psychoanalysis on his own. One paper particularly deserving to be remembered is "The Nature of the Therapeutic Action of Psycho-Analysis" (1934). This paper is considered a landmark for its discussion of problems related to the interpretation and mutative effects of transference.

### **STRACHEY-SARGENT, ALIX (1892–1973)**

Alix Strachey, British psychoanalyst was born on June 4, 1892, in Nutley, New Jersey, and died in London on April 28, 1973.

She came from a rather complex but highly intellectual family background and her childhood was quite erratic due to family problems. Educated at Bedales School and then at the Slade School of Art in London, she went up to Cambridge in 1911, where she graduated with a degree in modern languages in 1914. Through her brother Philip and other friends she met at Cambridge, Alix took part in the life of the Bloomsbury Group where she met James Strachey, whom she married in 1920. She became an associate member of the British Psycho-Analytical Society in 1922 and a full member in 1923.

She had a personal analysis in Vienna with Freud for two years from 1920 to 1922, as did her husband. It was during this period that she began helping her husband to translate Freud's work into English. She then went to Berlin for further analysis with Karl Abraham in 1924. In Berlin, she continued her translation work and met Melanie Klein. Alix was instrumental in arranging Klein's first visit to London in 1925 and translated some of her papers into English. Together with her husband, she published the translation of Freud's *Five Case Histories*, which were assembled in the third volume of his *Collected Papers* (1925). She finally returned to England after Abraham's death in December 1925.

She undertook other personal analyses: with Edward Glover in 1926 and later with Sylvia Payne. She took part in the administrative life of the British Psycho-Analytical Society but her main contributions were in the field of translation, helping to translate Freud's and others' papers into English. For instance, in collaboration with Douglas Bryan, she translated *The Selected Papers of Karl Abraham* (1927) and Klein's *Psychoanalyse der Kindes—The Psychoanalysis of Children* in 1932. She also translated Freud's *Inhibitions, Symptoms and Anxiety* in 1936. In 1943 she published *A New German-English Psychoanalytical Vocabulary*, a complete index of psychoanalytic terms in English which was instrumental for the *Standard Edition*. The rest of her time, from the late forties until the late sixties, she was dedicated to helping James publish the *Standard Edition*. It is sometimes difficult to evaluate Alix's contribution, which has, nevertheless, been invaluable as far as the *Standard Edition* is concerned. When the *Standard Edition* was well advanced, Alix was able to dedicate herself to some more personal work, going back to the interests of her youth: social issues, war, and pacifism. She published *The Unconscious Motives of War* in 1957 and *The Psychology of Nationhood* in 1960.

## **STRANGER**

Fear of strangers (or stranger anxiety) is a normal emotional response that occurs in the second half of the first year of life; the concept was introduced and developed by René Spitz, who called it "eight-month anxiety."

This construction was the result of direct observation from a developmental psychoanalytic perspective. The fear of strangers reaction signals a point where development has encountered a difficulty or even gone off track. According to Spitz's conceptual framework, as outlined in "Anxiety and Infancy" (1950), eight-month anxiety marks a decisive phase in object relations: the infant's mental accession to object permanence. This is in contrast to the social smiling of the preceding period, which is addressed indifferently to both unknown and familiar faces, and comes after archaic pre-objectal fears and anxieties. It is referred to as the "first genuine manifestation of anxiety" (Spitz and Cobliner, 1965; Spitz 1968), and thus figures in interpretations and differences of opinion relating to separation anxiety and theories of anxiety in general.

Spitz's principle of "organizers" of mental life places eight-month anxiety as the second organizer. However the embryological metaphor implied by the term "organizer" has been contradicted by demonstrations of early interactive capacities in babies, while fear of strangers has been marginalized within metapsychology by attachment theory, which has attracted many adherents. John Bowlby argues that intrusions upon the primary need for attachment cause the infant to reject the traumatizing face. Serge Lebovici developed the concept of eight-month anxiety into a primary phobia with the proposed name "Stranger's-Face Phobia." This is a proto-phobia that unfolds via displacement onto the stranger of the infant's aggressive impulses against the mother. Thus it both protects her imago and appeals to her return. From the viewpoint of current psychosomatic theories of mental development in France (Pierre Marty), stranger anxiety evinces the emergence of various psychic functions. The absence of stranger anxiety is a symptom of mental deficiencies and is a remarkable indicator of the silence of the mechanisms of inter-relational and

intra-psychical defense, which may be discerned from six to twelve months in disorders such as eczema (already observed by Spitz), asthma, anorexia nervosa, and the severe disorders caused by deficiencies in maternal care which are categorized under the name “empty behavior syndrome” (Léon Kreisler).

The distinction between separation anxiety and stranger anxiety has been clinically proven by the fact that they appear independently of one another. When it is not experiencing acute sensitivity to separation, the separated child (*le petit allergique*) is all smiles to whomever it sees, stranger and familiar alike, like the baby described in the first of Spitz’s organizers. As pure affect deprived of representation that repeats the baby’s distress at being separated from the mother, anxiety separation affords a view onto the future development of eight-month anxiety, which is itself a prototype of object-anxieties, and hence the original prototype for mental development itself.

## **STRATA/STRATIFICATION**

In psychoanalysis, the term “stratification” refers to the layers of ideation constructed by the psyche. In *Studies on Hysteria* (1895d), Freud noted, “Thus it came about that in this, the first full-length analysis of a hysteria undertaken by me, I arrived at a procedure which I later developed into a regular method and employed deliberately. This procedure was one of clearing away the pathogenic psychical material layer by layer, and we liked to compare it with the technique of excavating a buried city” (p. 139).

Exploring the theme in greater detail in the chapter entitled “The Psychotherapy of Hysteria,” he stated that his aim was a “dynamics of ideation” (p. 287). “The psychical material,” he explained, “presents itself as a structure in several dimensions which is stratified in at least three different ways” (p. 288). First is a reverse linear chronology, “as though we were examining a dossier that had been kept in good order” (p. 288). Second is a concentric stratification around

the pathogenic nucleus, where resistance increases as one gets closer to the nucleus. Here the strata represent zones of “an equal degree of modification of consciousness” (p. 289). Finally, there is dynamic stratification, which follows thought contents. Dynamic stratification is revealed by trajectories that zigzag from the surface down into the deep strata and back up again, passing through all levels and convergent nexuses of communication. The overdetermination of symptoms results from this type of stratification.

The problem of the stratification of the psyche, and thus of a “dynamics of ideation,” remained a constant preoccupation for Freud from then on. Indeed, psychoanalysis itself can be characterized as a psychology of depths. To explore these depths of the psyche, Freud developed topographies in writings spanning from *The Interpretation of Dreams* (1900a) through “Splitting of the Ego in the Process of Defence” (1940e [1938]). But the topographies were not enough. Freud also posited different temporalities within the psyche, such as the atemporality of the unconscious. Also playing a part in Freud’s elaboration of the structure of the psyche were phylogenetic traces of an archaic heritage, fixation, regression, and the life and death instincts. Described in “The Ego and the Id” (1923b) as the “precipitate of abandoned object cathexes” (p. 29), the ego too exhibits considerable stratification. What happens at the boundaries between the various strata and among the agencies of the mind can also be characterized as strata dynamics.

In mathematics, a stratified set is made by stitching together varieties of different dimensions. Catastrophe theory sheds light on the dynamics capable of generating these stratifications and on modes of passage from one stratum to another. This could be an outstanding tool for linking together the questions raised by Freud.

## STRUCTURAL THEORIES

A *structural* theory may be defined as one which tends to organize a set of propositions—and, in the realm of the natural sciences, a set of observations to which they refer—as a whole made up of interdependent parts. A *structure* may be defined as a functional whole presiding over a system of transformations and governed by self-regulating mechanisms.

Such a definition applies equally well to inanimate material systems (self-regulating machines), to constructions of the mind (logico-mathematical wholes, as for instance set theory), to living organisms, or to subsystems of living organisms. This last category would include the psychical apparatus in Freud's sense, and that apparatus can thus be deemed the object of a structural theory in psychoanalysis.

From its earliest formulations, Freudian metapsychology may indeed be looked upon as a structural theory according to the above definition, for it was meant to describe the functioning of a system made up of interdependent elements, namely the psychical apparatus as a whole. This was clear in Freud's work as early as the “Project for a Scientific Psychology” (1950c [1895]) and his reformulation of the ideas of the “Project” five years later in *The Interpretation of Dreams* (1900a). During this first period in the development of psychoanalysis, Freud was already specifying local aspects of an overall functioning. After describing how ideas are linked together, for instance, he observed that their concatenations crossed at “nodal points” which it was the task of analysis to locate: “The logical chain corresponds not only to a zigzag, twisted line, but rather to a ramifying system of lines and more particularly to a converging one. It

contains nodal points at which two or more threads meet” (1895d, p. 290). Sometimes, even, several interconnected nodes were observable, like those constituting what Freud called a “pathogenic organization.”

The whole of Freud's subsequent work strove for an ever more refined and better articulated description of the operation of the psychical apparatus as a structure, and this at a number of levels. It is thus possible to distinguish those writings in which Freud described partial, local aspects of that operation in terms of a network—as, for example, the breast-feces-penis-money interplay of symbolic equivalents—and indeed the term *complex* itself denotes such a local organization; those writings concerned with modalities of overall mental functioning characteristic of particular groups of individuals (for example, the obsessional structure); and those writings whose subject was the general laws of mental functioning. Two major stages in Freud's approach to these laws were represented by the metapsychological papers of 1915 and by his introduction in the 1920–1923 period of a second topography and a second theory of the instincts.

The structural view was always paralleled in Freud by a developmental approach to the same issues. If one accepts the idea that any structure may be apprehended in terms of its genesis (the successive stages of its establishment), and that any genetic process presents its own diachronic structure, it would seem that the two perspectives must be inextricably linked. The structural and the developmental have nevertheless often been opposed to each other by psychoanalysts, who have privileged one to the detriment of the other.

This separation has been spurred by two currents of thought. The first, within psychoanalysis itself, accompanied the advent of child psychoanalysis and of theoretical options that stressed development. The chief figures here were Anna Freud, Melanie Klein, and their more or less direct heirs, among them Margaret Mahler, Frances Tustin, Donald Meltzer, Donald W. Winnicott, and Serge Lebovici. In the wider general cultural framework, a second contributing factor was the “structure-versus-history” debate that stirred up so many disciplines during the nineteen-seventies (Green, 1963). The origins of that debate may be traced back to linguistics, to the moment around 1910 when Ferdinand de Saussure introduced an avenue of research which treated language as a system of signs each of which derived its meaning from its

relationship with the others: in other words, a structural approach to language sharply opposed to the hitherto dominant diachronic one. This orientation was further refined later by many linguists, notably by Roman Jakobson, who inspired Jacques Lacan. In another area, Claude Lévi-Strauss revolutionized traditional cultural anthropology by asserting that the kinship relationships observable in any given society were structures, and added that in all societies the taboo on incest was “the rule of rules.”

It is important to note that two major schools of thought, though radically at odds with one another, considered themselves, or were considered by others, to be “structural” psychoanalysis. The first was “ego psychology,” developed above all in the United States under the influence of Heinz Hartmann. The qualifier “structural” refers in this instance to ego psychology’s embrace of the second Freudian topography, in which the id-ego-superego system—a set of polarities and complementarities—unquestionably implies a structural conception of psychoanalysis, as envisaged in the latter part of Freud’s work. Inasmuch, however, as the developmental axis was dominant for the ego psychologists, French-speaking authors have tended to characterize their doctrine as “genetic psychoanalysis,” and in many cases expressed strong reservations about what they deemed an “objectivist realism” which by overvaluing “direct observation” of children’s behavior was liable to water psychoanalysis down into a mere developmental psychology.

In any event, Jacques Lacan is thought to stand in diametrical opposition to ego psychology, referring directly as it does to Saussure, Jakobson, and Lévi-Strauss. For Lacan language constituted the paradigmatic structure of the psyche, and more especially of the unconscious, which he therefore described as “structured like a language.” Language was a system of signs none of which signified anything in itself, for meaning arose solely from the place and function of a given sign within the system as whole. In his later work, however, Lacan distanced himself somewhat from this linguistic orientation and called upon logico-mathematical models borrowed from topology, notably metaphorical uses of the Möbius strip and the Borromean chain. He was led eventually to distinguish three main types of structures in the sense of modalities of the functioning of a whole: the structures of neurosis, marked by repression, the structures of per-

version, characterized by disavowal, and the structures of psychosis, produced by foreclosure.

## STRUCTURALISM AND PSYCHOANALYSIS

Structuralism, a major current of thought in the second half of the twentieth century, developed in France from the 1960s onward in reaction to existentialism and humanism. From a methodological point of view, in the analysis and understanding of “objects” (especially those in the social sciences), it tended to see “structures” as pre-eminent and to see the given and its directly observable features as mere “effects.” [Ed: Quotes indicate jargon terms in structuralism.]

Arising from the linguistics of Ferdinand de Saussure and in particular from the Prague and Moscow schools, structuralism counts many representatives in various fields. There are the linguist Roman Jakobson, the socioethnologist Claude Lévi-Strauss, the philosopher and archeologist of knowledge Michel Foucault, the reinterpreter of Marxism Louis Althusser, the writers for the periodical *Tel Quel*, the literary critic Roland Barthes, and the psychoanalyst Jacques Lacan.

Gilles Deleuze, in his article “À quoi reconnaît-on le structuralisme?” (How to recognize structuralism; 1973), tried to enumerate “formal criteria” for recognizing what is structuralist, in particular, as they apply to the field of psychoanalysis. The criteria are the following:

- d) The symbolic, which proceeds from a rejection of the mere interplay of opposition and complementarity between the real and the imaginary (Lacan, 1974–1975). In Deleuze’s view, Freud can be interpreted on the basis of two principles: “the reality principle, with its force of disappointment, and the pleasure principle, with its power of hallucinatory satisfaction,” he writes. Carl Gustav Jung and Gaston Bachelard take the perspective of the “transcendent unity and borderline tension” of the two principles. The symbolic, a structure that has nothing to do with perceptible forms (gestalts and figures of the imagination) or with any intelligible essence, must be understood in Louis Althusser’s fashion, “as the production of an original and specific theoretical object.”
- e) Localization and positioning. Any element of a structure has neither extrinsic designation nor intrinsic meaning, and thus has only one sort of meaning, positional meaning (with no real extent nor imaginary extension). Thus, in genetic biology, “genes are part of a structure insofar as they are inseparable from ‘loci,’ places capable of changing their relations within the chromosome.” The real subjects or objects are thus not what “occupy the places,” since they are determined in a topological and relational way. In his *Écrits* (1966), Jacques Lacan defines intersubjectivity as a symbolic structural space, that of the signifier.
- f) The differential and the singular, which bring into play the positional units that are the symbolic elements of a structure. The phoneme shows this in an exemplary fashion, since it is a relationship that is neither a thing nor an imaginary, but a component of an elementary differentiation of two words with different meanings (“robbing” and “bobbing” differ by the phonemic relation of “r” and “b”). Singularities are assigned by the differential and produce structural particularities (as do names and attitudes for Lévi-Strauss). Lévi-Strauss uncovered “parentemes,” positional units that do not exist outside differential relations (brother/sister, husband/wife, father/mother, maternal uncle/sister’s son). Serge Leclair showed in “Counting with Psychoanalysis” that the “libidinal movements” of the body are linked to symbolic elements of the unconscious, “incarnating the singularities of structure in this place or that.”
- g) The differentiating element, the act of differentiation. “The structure is not actualized unless it differentiates itself in time and space,” and it does so by its actualization. “The two notions of multiple internal temporality and static ordinal genesis are, in this sense, inseparable from the interplay of structures,” Deleuze wrote.
- h) The serial, in other words, the necessary organization of symbolic elements in their differential relations by means of which a structure arranges itself into different developments that play on and through one another. For instance, a social structure is organized into series: economic, political, juridical, etc. An operative structure has at least two series; for instance, phonemes require the

second series of morphemes. In Lacan (1966), the unconscious “implies a development in two [variable] series,” as his commentaries on Edgar Allan Poe’s “The Purloined Letter” or Freud’s case of the Rat Man (1955a [1907–1908]) show.

- i) Finally, the empty square, which is the paradoxical element of structure. It can never be filled without being disabled. This singular object  $x$  “is the point of convergence of the divergent series as such.” It is the “handkerchief” referred to by André Green (an associate of Lacan) in his essay “Othello” (1969), which runs through all the series in the play. The empty square is the guarantor and representative of the third party, “which intervenes essentially in the symbolic system.” The object is always displaced in relation to itself, “missing from its own place” according to Lacan, without being distinguished from that place, adds Deleuze.

From Deleuze’s article, it is thus clear that structuralism claims that the determinants of reality and those of the imaginary are essentially unconscious structures, because they are in every place and at every time “covered over by their products and their effects.” From this viewpoint, one can regard the second Freudian topography of the psychic apparatus as already a structuralist representation of the psyche, since even consciousness, on the plane of the ego, is an effect of the interplay of different agencies: the id, the ego itself in its different characters, and the super-ego. By way of contrast, Jean Piaget, in his article “La psychologie” (Psychology; 1972), characterizes psychoanalysis as a “complete reductionism” insofar as it seeks, in his view, to reach mental processes by means of “the direct study of the contents of representations and affects” and does not recognize any autonomy of the ego (Heinz Hartmann) “free of sexual conflicts.”

It was Jacques Lacan who radically located psychoanalysis within the domain of structuralism. At the beginning of the twenty-first century we are witnessing a return of the subject, which existentialism, for one, refused to abandon. But because it is difficult to see how an autonomous subject, independent of structure, can again be affirmed without returning to ego psychology or existential psychoanalysis (the most traditional rationalism), there does not seem as yet to be any alternative to structuralism.

## STUDIENAUSGABE

The *Studienausgabe*, a critical edition of Freud’s work comprised of ten numbered volumes and a supplementary volume (*Ergänzungsband*), is the sole German-language edition offering a broad selection of the writings accompanied by an impressive scholarly apparatus.

Edited by Alexander Mitscherlich, Angela Richards, and James Strachey, Volumes 1–10 were published by S. Fischer Verlag between 1969 and 1975. The supplement (*Schriften zur Behandlungstechnik*), co-edited by Ilse Grubrich-Simitis, which added Freud’s writings on psychoanalytic technique, appeared in 1975. On the fiftieth anniversary of Freud’s death, in 1989, the *Studienausgabe* were reissued in an updated and revised version. Simultaneously, the *Sigmund Freud—Konkordanz und Gesamtbibliographie*, originally compiled by Ingeborg Meyer-Palmedo and already associated with the

*Studienausgabe* in 1975, was radically reworked, with the assistance of Gerhard Fichtner, and published under the title *Freud-Bibliographie mit Werkkonkordanz* as a companion to the revised *Studienausgabe*. (A new, corrected edition of the *Freud-Bibliographie* appeared in 1999.)

The ten volumes of the *Studienausgabe* are arranged thematically. Some contain a single work, as in the case of Volume 1, the *Introductory Lectures on Psycho-Analysis*, or Volume 2, *The Interpretation of Dreams*, while those which collect several texts on a single subject are arranged chronologically. The editorial commentary consists essentially, with a few additions, of a translation of James Strachey's critical apparatus for the *Standard Edition*. Strachey, who had participated actively in the planning of the *Studienausgabe*, died in 1967, so it fell to his collaborator Angela Richards to undertake the better part of the editing, with constant assistance from Ilse Grubrich-Simitis and Ingeborg Meyer-Palmedo.

All volumes of the *Studienausgabe* are supplied with substantial bibliographies and detailed indexes to help researchers, teachers, and students. Freud's numerous revisions in successive editions of his writings, especially in such major works as *The Interpretation of Dreams* or the *Three Essays on the Theory of Sexuality*, are clearly identified and dated. More than two-thirds of the Freudian texts assembled in the *Standard Edition* are to be found in the *Studienausgabe*.

When Freud went into exile in London in 1938, his projects with respect to publishing his work went with him. James Strachey and his group of collaborators then proceeded to build up an editorial culture around their projected *Standard Edition* which had no equivalent in Austria or in the Federal Republic of Germany of the 1960s. The paradoxical result is that the first, and up to now the only critical edition of Freud's work in German relies for the most part on the work of English-speaking editors.

In conclusion, it may be fairly said that after the brutal stop put by the Nazis to the influence of Freud's work in the German-speaking countries, the *Studienausgabe* have effectively promoted it, not only among specialists but also among general readers.

## STUDIES ON HYSTERIA

Beginning in 1892, Sigmund Freud gradually abandoned the technique of hypnosis and began using the "method of cathartic abreaction" that had been described to him by his older colleague, Josef Breuer, ten years earlier. He became increasingly convinced of the sexual origin of neurotic disturbances in his patients and, uneasy over the work Pierre Janet had begun to publish (*L'État mental des hystériques*, 1892–1894), convinced Breuer to join him in writing a book that, by situating the origin of their research in 1881, would assure them of priority in the world of scientific research.

A letter to Wilhelm Fliess on June 28, 1892, referred to Breuer's agreement. The two authors were going to contribute jointly to the volume. In the autumn of that year Freud began testing his new techniques of concentration on the symptom and placement of his hands on the forehead in an attempt to draw out Elisabeth von R.'s forgotten pathogenic memories, and by December he and Breuer had signed a "Preliminary Communication" that appeared in January 1893 (1893a). They attributed the cause of hysterical symptoms to the forgotten memory of a trigger incident that had not been "abreacted" and acted on the psyche as if it were a foreign body. The symptoms disappeared whenever the memory and its affect were awakened by providing them with a verbal outlet, which led to the famous maxim that "hysterics suffer primarily from reminiscences" (1895d, p. 7). For his part, Breuer insisted on the "tendency to a dissociation of consciousness" (1892–93a, p. 122) caused by daydreams. The "Preliminary Communication" aroused considerable interest in the international scientific community, as shown by a reference from Frederick W. H. Myers in Great Britain, only three months after its appearance.

However, the theory of sexual etiology began to appear increasingly convincing to Freud, which

created a rift with the reticent Breuer. An 1894 article on the “Psychoneuroses of Defense” (1894a) enabled Freud to distinguish his theory from that of Pierre Janet and describe the concept of “conversion.” At the same time he began to take an interest in dreams and, having written down his observations, in the spring of 1895 he wrote the preface and final chapter of *Studies on Hysteria*—during a period when he was still experiencing the disastrous consequences of Wilhelm Fliess’s operation on Emma Eckstein.

The book appeared in May. The first chapter incorporated the “Preliminary Communication.” The second was devoted to the case studies: Anna O., who was Breuer’s patient, followed by “observations that read like novels and do not bear the stamp of seriousness typical of scientific writings.” These were written by Freud and described his treatment of Emmy von N., Lucy R., Katharina, and Elisabeth von R. (and Frau Cäcilie M., to whom reference is made throughout the book).

A third chapter by Breuer is devoted to theoretical issues. Here he describes the ideogenous nature of hysterical disturbances, the “unconscious or subconscious representations” of a primitive trauma that is primarily associated with sexual matters, and the recognition of mental hyperactivity in hysterics—the same individuals in whom Janet had found a “weakness,” if not a constitutional mental inadequacy. He insisted on the presence of “hypnoidia” and the constancy of hypnoid states.

Freud wrote the last chapter, “The Psychotherapy of Hysteria.” In it he describes the overdetermination of symptoms and the value of the cathartic method. The preliminary structure of what will become psychoanalysis is laid out: the patient on the couch, free association, the consideration of “false connections,” and the disjunction *mésalliance*, which is the transference to the doctor of “the distressing ideas which arise from the content of the analysis” (1895d, p. 302). For Freud the psychic materials of hysteria appear to be arranged in strata, starting from a kernel of traumatic memories. This arrangement can be chronological—in which case, Freud writes, “it [is] as though we were examining a dossier that had been kept in good order” (p. 288)—or thematic, such themes being “stratified concentrically round the pathogenic nucleus” (p. 289). The goal of the analysis is to “penetrate . . . to the nucleus of the pathogenic organization” (p. 295), an operation that requires considerable effort on the part

of the therapist, who must overcome the patient’s resistance in order to unearth the buried memory that is the source of the problem. The means used to overcome this were still rudimentary, gentle, physical pressure applied to the points of the forehead, and an increasing barrage of questions intended to “extort” a patient’s secrets. Even though the method was claimed to be successful, Freud concluded, “No doubt fate would find it easier than I do to relieve you of your illness. But you will be able to convince yourself that much will be gained if we succeed in transforming your hysterical misery into common unhappiness. With a mental life that has been restored to health you will be better armed against that unhappiness” (p. 305).

By the following October, Freud would publicly abandon Breuer’s theory of hypnoid states and affirm that hysteria arises from seduction early in life, a “pre-sexual sexual fright” (letter to Fliess, October 15, 1895).

But the book went out into the world and Freud, already known for his neurological work, became recognized as a “psychologist.” Although Adolf Trümpell sharply criticized the book (letter to Fliess, February 6, 1896), an event that deeply affected Breuer, Havelock Ellis praised it, as did Théodore Flournoy and a number of French authors. Eugen Bleuler himself wrote, in 1896, that it was “one of the most important recent additions to the field of normal and pathological psychology.” The success of the *Studies on Hysteria* did come at a price, however. For a number of years the book was considered, by those who did not have access to Freud’s later writings, to contain the essence of his theory and practice. Even Pierre Janet, in his critiques of psychoanalysis in 1907 and 1913, did not appear to look any deeper for an understanding of Freudian theory.

Although Sándor Ferenczi, in a letter to Freud on March 2, 1909, described it as the “germ of everything we now know,” Freud had mixed feelings about the book and struggled against the ongoing references to theories he believed to be outdated. As early as 1901 he wrote, “Ever since we wrote the *Studies*, psychoanalytic technique has undergone a fundamental transformation. The work had symptoms as its point of departure and their successive resolution as its goal. Since then I have abandoned this technique, for I found it unsuited to the delicate structure of the neurosis.” Freud even minimized his contribution to the book in his *On the*

*History of the Psycho-Analytic Movement* (1914d) and especially in *An Autobiographical Study*: “As regards the theory put forward in the book, I was partly responsible, but to an extent which it is to-day no longer possible to determine. That theory was in any case unpretentious and hardly went beyond the direct description of the observations. It did not seek to establish the nature of hysteria but merely to throw light upon the origin of its symptoms. . . . The theory of catharsis had not much to say on the subject of sexuality. In the case histories which I contributed to the *Studies* sexual factors played a certain part, but scarcely more attention was paid to them than to other emotional excitations. . . . It would have been difficult to guess from the *Studies on Hysteria* what an importance sexuality has in the aetiology of the neuroses” (1925d, p. 22). Freud did not include the book in the first edition of his collected works, the *Gesammelte Schriften*.

In 1925 Freud added, “The practical results of the cathartic procedure were excellent. Its defects, which became evident later, were those of all forms of hypnotic treatment. There are still a number of psychotherapists who have not gone beyond catharsis as Breuer understood it and who still speak in its favor” (p. 22).

At a time when psychoanalytic practice, for reasons of pseudo-efficiency, risks incorporating psychotherapeutic techniques dating from before the *Studies on Hysteria*, the study of this key work is more relevant than ever. This is undeniably important, if only to situate its ideas as a historical step, simple but important, in the trajectory that would lead Freud, over the next ten years, to modify his theory and practice, thereby defining the framework of psychoanalytic therapy as it has come to be known.

## SUBCONSCIOUS

A term that appears rather frequently in the psychological literature of the late 19th century, especially in France, the “subconscious” was used to designate a mental state that is subliminal, diminished, or weak and obscure; in terms of conscious thought it implied a difference a degree not of kind. “Judgment and reasoning, whether conscious, subconscious, or unconscious, remain the same, except for a difference in the degree of clarity of the representation,” wrote Théodule Ribot in *La Logique des sentiments* (1905, p. 80).

The subconscious was most clearly delineated in the work of Pierre Janet. In *Automatisme psychologique* (1889), he posited two contrasting forms of mental activity, automatism and synthesis. The former corresponded to the primal and archaic; the latter, to creativity and higher levels of consciousness. On the basis of experimental work with hysterics, Janet demonstrated that in morbid states, due to a diminished field of consciousness, automatism took precedence over the activity of synthesis.

Janet essentially identified the subconscious with psychic automatism and, in hysteria, he hypothesized profound dissociation and splitting of the personality. He was influenced by the work of Frederick Myers, the British psychical researcher, and the work of American physician Morton Prince on dual and multiple personalities; he also took into account earlier investigations by Jean-Jacques Moreau de Tours on hashish intoxication.

In his early writings, including *Studies on Hysteria* (1895d), Sigmund Freud used “subconscious” as more

or less equivalent to “unconscious” but he soon abandoned the former and disapproved of usage that conflated the two terms. He characterized the unconscious as actively associated with intrapsychic conflict while viewing Janet’s subconscious as passive and associated with psychological and physiological weakness. To Janet’s “dissociation” he opposed the concept of repression and the psychological duality of separate domains of conscious and unconscious mental functioning.
