In that book, Anna Freud drew a distinction between defenses directed against drive derivatives (to protect the ego against instinctual demands) and defenses against affects. The former included defenses that had long been recognized, such as repression, regression, reaction formation, introjection, projection, isolation, and undoing, as well as vicissitudes of instinct such as reversal and turning against the self which still need the intervention of the ego for their operation. To these nine mechanisms Anna Freud added a tenth: sublimation, or displacement of instinctual aims. Nonetheless, Anna Freud was well aware of the adaptive function of sublimation.

Defenses against painful affects (which may be regarded as “preliminary stages of defense”) include denial in fantasy, denial in word and deed, restriction of the ego (a defensive form of altruism), and identification with the aggressor, with which we are here concerned.

Jenny Wäelder, in a verbal communication to Anna Freud, had already given a striking picture of this mechanism in a five-year-old boy. Whenever the clinical material was about to touch on the question of masturbation or masturbatory fantasies, the normally inhibited little boy became extremely aggressive: for example, he would pretend to be a roaring lion and attack the analyst. He carried a rod about with him and pretended to be a devil, using it to attack the stairs and other parts of the room, and trying to strike his mother and grandmother. Matters came to a head when he began to brandish kitchen knives. Analysis showed that he was expecting punishment for what he regarded as forbidden activities. In his violent behavior he was both dramatizing and forestalling the attacks that he feared, and the kitchen knives pointed to his fear that his penis would be cut off.

A little boy whose Oedipus complex was at its height used this defense mechanism to try to deal with his sexual wishes towards his mother. Hitherto his relations with her had been very happy, but were now punctuated by outbursts of resentment. He would criticize her in the strongest terms for all sorts of reasons, of which the most mysterious was curiosity. This was not too difficult to explain: in his fantasies the mother knew of his sexual wishes towards her and rejected his advances with indignation. The indignation was replicated in his own outbursts of resentment, though he did not reproach her on general grounds but on those of curiosity. But the curiosity was a feature of his own instinctual life, not his mother's; he had found his scopophilic impulse the most difficult to master. Thus, defensively, he reversed the roles of parent and child.

These and other examples are described by Anna Freud. Essentially, identification with the aggressor points to a particular phase in the development of super-ego functioning, as she pointed out. For although external criticism has been introjected, the link between the fear of punishment and the offense committed has not yet been established in the patient's mind. Once the criticism is internalized, therefore, the offence is externalized—a maneuver that involves another mechanism, the projection of guilt. As Anna

Freud put it, intolerance of other people precedes severity towards oneself.

## **IDENTIFICATORY PROJECT**

The notion of the identificatory project was proposed by Piera Aulagnier to account for the I's (the perceived self's) work of identification as a function of future time. In *The Violence of Interpretation: From Pictogram to Statement* (1975), Aulagnier defined the identificatory project as "that continuous self-construction of the I by the I that is necessary if that agency is to be able to project itself into a temporal movement, a projection on which the I's very existence depends" (p. 114). The temporal dimension that is projected onto both the past of memory (in auto-historization) and the imagined future (in the identificatory project) is the basis for the I's ability to respond in its own name to the unavoidable questions that sum up the identification process: "Who am I?" and "What must the I become?"

Aulagnier's theory of identification owes a great deal to Jacques Lacan. For her, it is the mother who initially identifies the preverbal infant as the entity that demands what she gives; because of this, the infant depends upon the maternal imaginary. But at the same time, the infant self-represents itself based on the "pictographic representation" it has of its earliest experiences of pleasure. The second phase of identification, which follows this primary period, is specular identification (the mirror stage). In Lacan's theorization, this stage shapes the function of the I and establishes the imaginary register as the locus of the ego's identifications ("The Mirror State As Formative of the Function of the I As Revealed in Psychoanalytic Experience" [1949/2004]). For her part, Aulagnier emphasized that after the young child recognizes the image in the mirror as being its own, it turns toward his mother seeking approval in her gaze; this enables

the child to see in the mirror "the junction between the image and the legend" (p. 124). In these conditions, object-libido and ego-libido are joined together; the baby discovers in the image the entity whose presence brings pleasure to the mother and in turn derives pleasure from the valorization of this image that he knows to be his own. Hence the definition that Aulagnier proposed with regard to the second phase of identification: "To be like the image that others admire or to be like the image admired by those whom the I admires are the two formulations that the narcissistic wish borrows from the field of identifications" (p. 126).

With the notion of "identification with the projection" (1968/1986), which in *The Violence of Interpretation* became the "identificatory project," a fundamental change took place. The immediacy of the exchange of care, contact, and gazes was succeeded by the temporal distance of the project(ion) referring to a time in the future. However, the possibility of access to the dimension of a genuine future (one that is not merely a coming reactualization of the past) is not automatic, and it is the trial of castration that gives the subject such access.

Aulagnier likened what she calls the identificatory project to what Freud called "ego ideals." She also underscored its difficulty: "The I's task is to become capable of thinking its own temporality. To do this it must think, anticipate, and invest in a future time-space, despite the fact that lived experience will quickly reveal that in doing so, the I is investing not only in the unforeseeable, but also in a time that it might not even have to live. In other words, the I is cathecting an 'object' and a 'goal' that possess the properties that it most abhors: precariousness, unpredictability, and the possibility of inadequacy."

In the "something less" borne in the present, by comparison with the ideal-filled future, Aulagnier proposed in *The Violence of Interpretation* to see "the assumption of the castration trial in the identificatory register" (p. 116), meaning that the I will never coincide with its ideal in the present of a realization, but instead will always project it forward in time. The identificatory register can thus be seen to be indissociable from the libidinal register, because a representation of the desiring subject always figures there. Being, or rather, knowing who one is, is essentially knowing who one wants to become. This opens the way for extending these ideas into clinical practice, not only

with regard to psychosis, but in other areas ranging from geriatric depression to adolescent turmoil.

## **IDENTITY**

Identity is not a Freudian concept. Theoreticians have defined it in very different ways: as a structure that accounts for narcissism and is part of the ego; as the ability to remain the same despite changes; as a feeling of continuity; or as the sum of representations of the self.

The importance of the notion of identity in the United States is related to its use in ego-psychology, which considers the ego as a relatively autonomous and potentially conflict-free structure. Many theories of identity adapt a portion of Freud's view of the ego. Alongside the Freudian ego, which is a structure defined by its functions, another ego—or identity related to identifications—is posited (whether inside or outside ego-psychology) and conceived of as the outcome of a process of individuation.

The first mentions of the importance of the concept of identity for clinical practice and psychopathology date from the nineteen-fifties. When it first appeared

in psychoanalytic discourse, the concept of identity was associated with two approaches. The first was an attempt to extend the Freudian perspective to a general psychology that would include the ego's relationships with the surrounding world and guide research on child development. The second sought to apply psychoanalysis to pathologies, more serious than neurosis, characterized by disturbances of identity. Phyllis Greenacre evoked the internal and external faces of identity, and described their favorable and unfavorable aspects. Ralph Greenson isolated a screen-identity syndrome. Margaret Mahler viewed identity as a facet of development connected with object-relations, symbiosis, and the possibility of separation-individuation.

Two major psychoanalytical theorists have focused on identity. In 1956 Erik Erikson introduced the concept of an ego identity formed during adolescence, which served as a gauge of psychopathology. In 1961 Heinz Lichtenstein proposed giving identity the priority that the libido had for Freud. He considered it the keystone of psychopathology and eventually reframed Freudian metapsychology within a monist perspective that challenged the dualistic concept of identification.

Erikson hoped to explain human development epigenetically; the various stages of his model could not be reduced to the psychosexual level. The ego was not propelled by drives alone but must confront the challenges posed by the environment. Ego identity was the adolescent stage; it took over from various identifications and its successful establishment depended on the resolution of earlier developmental crises. Erikson's ego identity was defined by the unconscious quest for personal continuity, by the synthesis of the ego, and by group loyalties. It reflected an existential dimension of the ego. It was formed through a succession of syntheses of the ego whereby the conflicts of earlier stages were integrated. The opposite of ego identity was a diffusion of identity, a pathological syndrome in which representations of self and object are fluid and unintegrated, and oppositionalism and acting out are manifested. Otto Kernberg used this model as a diagnostic criterion for borderline states.

Lichtenstein looked upon human identity as a permanent dilemma because of the absence of any form of guarantee. The theme of an invariable identity arose from an unconscious imprint derived from the mother thanks to a process of mirror reflection. Variations on this theme constituted the feeling of identity, a creation unique to the child. Pathological developments

occurred when themes emerged that were impossible to satisfy yet necessary for the maintenance of identity. In such case a subject could be caught in a paradoxical oscillation between the search for an annihilating other and an isolating autonomy. The principle of identity was the central motivation for the human individual, who was obliged to maintain an identity under more or less continual threat. This principle replaced the reality principle in Lichtenstein's account, and the drives as well as the repetition compulsion were subservient to it. Identity was assimilated to narcissism, described as a primary thematic with secondary variants. It left room for the self, the fourth metapsychological dimension and third paradigm of psychoanalysis. Identity was part of an evolutionist view that rejected dualism of any kind.

Historically speaking, theories of identity were replaced by theories of the self and by the "self psychology" of Heinz Kohut.

These are psychological theories in which the unconscious and libido are secondary. As Freud pointed out, however, unity and synthesis are superficial concepts. Drawing on such criticism, Kohut characterized Erikson's identity as a descriptive psychosocial concept. Edith Jacobson questioned the relevance and universality of so-called disturbances of identity, which she considered exaggerated. Roy Schafer interpreted the emergence of the concept of identity as symptomatic of a subjectivity stripped of a mechanistic and reifying metapsychology and hence in need of reformulation. Merely descriptive theories of identity may be said to belong to the sphere of phenomenology. When the conceptual focus is on identity, the ego is cut off from its libidinal roots. Furthermore, the view that underpins these theories is exclusively developmental and completely rejects any causality based on deferred effects.

### **IDEOLOGY**

The word *ideology* refers to the study of ideas, a form of general or abstract discourse, immobilized thought (Piera Aulagnier, Sophie de Mijolla-Mellor), or any doctrine claiming to justify a collective activity of a political, religious, artistic, or other kind. When Antoine Destutt de Tracy in his *Mémoire sur la faculté de penser* (vol. 1, 1796–1798) and *Éléments d'idéologie* (1801) coined the word as an attempt to create a science of ideas, he remained nominally a Platonist in that he did not conceive of the term as derogatory, which it has since become. However, the Platonic "ideology" Alexandre Kojève described in his *Essai d'une histoire raisonnée de la philosophie païenne* (vol. II, *Platon et Aristote*) was not only a science of ideas but claimed to be the science of objective reality, the *Cosmos noëtos* conceived by Plato as the real, or essential world, interposed between the One and the sensible world (*Cosmos aisthètos*). Destutt de Tracy claimed to be an ideologue, as did Pierre Daunou, Constantin-François Volney, Pierre Cabanis, and Dominique Garat, but the term was used deprecatingly by Napoleon and François René de Chateaubriand.

In the work of Karl Marx, ideology assumed a critical sense that displayed the opposition between the "noble" sense given to it by Destutt de Tracy and its opposite, purely negative meaning; this opposition is itself "ideological." In the *German Ideology*, ideology is always the reflection of an alienation, an alienation obscured by the material conditions that determine the representations that constitute that alienation. Ideology, as an expression of alienation, is essentially incapable of grasping the dialectical relationships that

unite or resist those representations. By extension any non-critical system of representation is considered an ideology, for example, Catholic ideology or even Marxist ideology understood as the dogmatization of the results of Marx's critical thought (Leninism, Stalinism, etc.). Ideology would then be seen as the discourse of a class, a party, or an association that seeks to achieve or achieves cultural, political, economic, intellectual, spiritual, or other domination over society and individuals.

The essence of ideology could therefore be to weld a "collectivity" into a defensive system of representations based on an unconscious causality, material or structural, involving realities such as the Family, the Nation, the Army, the Church, the State, and so on. These can then be understood as ideological entities, just as "fixed" as individual doctrines or representations. "System," superstructure, doctrine, dogma, and so on, then become other possible synonyms for ideology.

Sigmund Freud gathered up all these meanings to express a "vision of the world" (*Weltanschauung*) whose various forms of representation philosophy elaborates in thought, which would make his research into truth the pinnacle of ideology. For philosophy is the work of sublimation while ideology, as Piera Aulagnier has shown, is an avatar of the desire for "self-alienation" (*Les Destins du plaisir*, 1979). Ideology—always and everywhere—corresponds to a "sublimated abandonment to an abstract idea" (Freud, Sigmund, 1921c). But as Sophie de Mijolla-Mellor has noted, "it isn't a question of sublimation but of intellectualization or desexualized abstraction; we do not give in to an idea but to its author, whether a group or an individual" (1992). Radical ideology might be a form of destructive madness to the extent that ideology tends to exclude conflict and sharply reduce ambivalence, thus resembling the discourse of schizophrenia.

## **ILLUSION**

Illusion is an error experienced by someone who is misled (*illudere*) by the nature of evidence or the seductive appearance of something that deceives. The deceiver may be personified (Descartes's "evil genius") or limited to a physical or physiological cause (the illusions of the senses), or even an ontological structure (the Platonic myth of the cave). However, the subject can create his own illusion by taking his desires for reality. It is this last formulation that is embodied in the Freudian approach to illusion, defined as a belief primarily motivated by the realization of a desire. To that extent the illusion has much in common with dreams and dreaming, where the philosophers of antiquity had situated it.

The concept of illusion in Freud is gradually developed, reaching its culmination in *The Future of an Illusion* (1927c). In the *Project for a Scientific Psychology* (1950c [1895]), illusion is confused with hallucination in the context of perceptual illusion. But with the *Psychopathology of Everyday Life* (1901b), the concept is further refined. In Freud's case it would be wrong to qualify the feeling of *déjà vu* or *déjà éprouvé* as illusion, because they correspond, through displacement and concealment, to an authentic unconscious daydream. Thirty-five years later in "A Disturbance of Memory on the Acropolis," Freud would refer to false recognition (*déjà vu, déjà raconté*) as a part of the "illusions in which we seek to accept something as belonging to our ego, just as in the derealizations we are anxious to keep something out of us" (1936a, p. 245).

There is a certain amount of ambiguity concerning the simple criterion that defines illusion as something that doesn't exist in reality, to the extent that the concept of reality is reconsidered in psychoanalysis as mental reality. Moreover, the single stable criterion used to define illusion in psychoanalysis is a belief motivated by the realization of desire: "[W]e will call a belief an illusion when a wish-fulfilment is a prominent factor in its motivation, and in doing so we disregard its relations to reality, just as the illusion itself sets no store by verification" (1927c, p. 31).

Freud identifies illusion as being mostly associated with religion, art, and philosophy, but he also

acknowledges the hypothesis that science itself could be an illusion, although he rejects it. In a deeper sense the greatest illusion would be the belief in the happiness and goodness of human nature. This pessimism, or realism, is first associated with the illusion that lasting sexual satisfaction is possible (“‘Civilized’ Sexual Morality and Modern Nervous Illness,” 1908d) and that social rules should be modified to procure happiness for individuals. Freud then assumes the position of a defender of a realist position, which includes negativity instead of ignoring it: “Because we destroy illusion we are accused of endangering ideals” (1910d, p. 147). In fact the only ideal he defends is that of truth. He further distinguishes two types of illusions: those that are not harmful since the illusion is obvious, and those that are dangerous because they take the place of an objective apprehension of reality (philosophy, ideology, and especially religion).

To the first category belongs art, which is said to evolve from magic and which, as an artistic illusion, produces the same affective effects as if it involved something real (1912–1913a). “Art is said to be almost always harmless and beneficent; it does not seek to be anything but an illusion.” (1933a [1932], p. 160). In what sense is art an illusion? Freud is forced to make use of the concept of reality to determine this. “The substitutive satisfactions, as offered by art, are illusions in contrast with reality, but they are none the less psychically effective, thanks to the role which phantasy has assumed in mental life” (1930a [1929], p. 75). Illusion, and especially the ability to take pleasure in it, would therefore be the result of the magical omnipotence associated with the beginnings of mental life, which led to the separation of the life of the imagination from the mental life grafted to reality, “At the time when the development of the sense of reality took place, this region [imagination] was expressly exempted from the demands of reality-testing and was set apart for the purpose of fulfilling wishes which were difficult to carry out” (1930a [1929], p. 80).

But reality-testing is difficult to manage when defining illusion. Freud emphasizes it when he distinguishes illusion from delusion: “Illusions need not necessarily be false—that is to say, unrealizable or in contradiction to reality” (1927c, p. 31). The example chosen (the illusion of a young woman of modest means of being able to marry a prince) is not convincing, because within the framework of erotomaniacal delusion, that same idea (not illusory since it is realizable, Freud says) would

indeed appear to contradict reality. We could therefore say that delusion has more to do with a difference in “temporality”—hope and expectation in one case, real certainty on the other.

The difference between the potential reality of the content of the illusion and the belief in its actual reality is what allows reality testing to be used to define the illusion. Illusion primarily involves the *Wel-tanschauung* and, in this regard, Freud emphasized religious illusion. All religious doctrines are “illusions and unsusceptible of proof. No one can be compelled to think them true, to believe in them” (1927c, p. 31). The desire they realize is that of being protected and loved by a father who is more powerful than the real father. Infantile distress is the origin of religious need, which Freud criticizes because of the weight it places on education. He also feels—and this may sound paradoxical—that it is necessary to maintain religious teaching as a basis of education and human life in common. “If you want to expel religion from our European civilization, you can only do it by means of another system of doctrines; and such a system would from the outset take over all the psychological characteristics of religion—the same sanctity, rigidity and intolerance, the same prohibition of thought—for its own defense” (p. 51). In other words even if for Freud religion is a “serious enemy” of science, it would be an illusion to believe that it is possible to renounce belief for the benefit of knowledge alone.

The philosophical illusion that believes it can deliver an image of the world that is coherent and without gaps is undermined by the progress of science; and political illusion, such as communism, is an example of a substitute for religion. The struggle against illusion is therefore a battle that will only yield incomplete results, following a process of maturation that is never realized: “Since we are prepared to renounce a good part of our infantile wishes, we can bear it if a few of our expectations turn out to be illusions” (1927c, p. 54).

In psychoanalysis the concept of illusion has, in the work of Donald Woods Winnicott, undergone a completely different development than it has in Freud. Winnicott (1953/1971) defines illusion as the necessary adaptation of the mother to the needs of the baby, which allows her to experiment with narcissistic omnipotence from the beginning. This phase corresponds to the primary creativity of the infant and is prolonged during adulthood in art and religion. Winnicott’s

ideas extended Freudian theories of the “purified pleasure ego” and the “reality test.” Winnicott postulates the existence of “intermediate state between a baby’s inability and growing ability to recognize and accept reality” (1953, p. 90). This ability is strictly dependent on what the mother allows the baby to feel. “The mother’s adaptation to the infant’s needs, when good enough, gives the infant the illusion that there is an external reality that corresponds to the infant’s own capacity to create” (p. 95).

In other words, the reality test is experienced as a frontal shock, but the reality is initially constructed by the baby who perceives it as being part of himself. During a subsequent period, it will appear to be independent, but only gradually: “The mother’s eventual task is gradually to disillusion the infant, but she has no hope of success unless at first she has been able to give sufficient opportunity for illusion” (p. 95). But illusion as a form remains and serves as a binding factor: “We can share a respect for illusory experience, and if we wish we may collect together and form a group on the basis of the similarity of our illusory experiences. This is a natural root of grouping among human beings” (p. 90).

This differs from the Freudian point of view, which remains dependent on a certain proscientific militancy, while Winnicott situates himself at a level that is both more metaphysical and more affective. “It is assumed here that the task of reality-acceptance is never completed, that no human being is free from the strain of relating inner and outer reality, and that relief from this strain is provided by an intermediate area of experience which is not challenged (arts, religion, etc.). This intermediate area is in direct continuity with the play area of the small child who is ‘lost’ in play” (p. 95).

## **IMAGINARY IDENTIFICATION/SYMBOLIC IDENTIFICATION**

Jacques Lacan differentiated between an imaginary identification, that forms the ego from a symbolic one that founds the subject. He discussed the first in his essay on the “Mirror Stage” (1936) and he examined the second primarily in his seminar on *Identification* (1961–1962).

Imaginary identification involves the image of one’s “fellow being.” Before the subject develops the proper neurological connection, he grasps the unity of his body image by identifying with the image of the other, the ideal ego. Thus the subject escapes the feeling of having a fragmented body. The mirror stage is also the source of the aggressive tension that characterizes relations with the one’s fellow being, and it is the source of desire as the other’s.

Symbolic identification, or “signifier identification,” involves an ideal signifier—an insignia of the Other or a unary trait—as the nucleus of the ego-ideal that the subject depends on.

This situation is modeled on Freud’s second form of identification, that is, an identification by adopting a single trait taken from the object. In fact, imaginary identification depends on symbolic identification. In the mirror stage, the infant looks for a sign from the maternal Other holding him up to the mirror in order to confirm that the image is his. Behind the signifier of the ego-ideal are the Name-of-the-Father and the symbolic phallus.

A subject’s sexual identity does not depend on his relation to an image, but on his position in relation to the symbolic phallus—a male subject has it, while the female subject does not have it, but is it.

In the last years of his Seminar lectures, Lacan introduced the idea of identification with a symptom

and added it to the notions of imaginary and symbolic identification.

## **IMAGINARY, THE (LACAN)**

In the work of Jacques Lacan, the real, the symbolic, and the imaginary are a central set of references. The imaginary is the field of the ego.

In his 1936 essay “Au-delà du ‘principe de réalité’” (Beyond the reality principle), Lacan noted that Freud discovered a meaning in patients’ complaints that other physicians considered imaginary and thus illusory. In his first reading of Freud’s work, Lacan emphasized the notion of the image by highlighting its function: reflecting the subject’s discrete behaviors in unified images. In the mirror stage, the subject identifies with these images and develops an ego concept in relation to another.

In his first seminar, Lacan acknowledged that such identification implies a radical alienation (1988a), but he considered this identification to be essential to the structure of the imaginary order and to the development of the human ego. At that time (1953–1954), he was interested in the ethological work of Nikolaas Tinbergen and Konrad Lorenz, which privileged the function of the image as gestalt in the development of the sexual instinct. Lacan believed that the development of the sexual drive of humans too is related to the imaginary function. This would account for the lure of images. As an example, he referred to the female stickleback, a fish whose copulatory dance is set in motion by the sight of a certain color patch on the male’s back. Yet a paper cutout bearing the same

markings can have the same effect on the female (Lacan, 1988a, pp. 122–123). What matters is that image is invested with libido. Lacan referred to libidinal investment as “what makes an object become desirable, that is to say, how it becomes confused with this more or less structured image which, in diverse ways, we carry with us” (1988a, p. 141).

But for the subject to come into being, one must find “a guide beyond the imaginary, on the level of the symbolic plane. . . . This guide governing the subject is the ego-ideal” (1988a, p. 141). The ego-ideal, according to Lacan, is the Other (caregiver) speaking. From that point on, the symbolic order (language) dominates over the imaginary order, which is reduced to being a decoy. It took Lacan twenty years to restore the imaginary to its full place alongside the real and the symbolic, which he did within the topic of the Borromean knot (a set of three interlinked rings that come apart if any one is removed).

In spite of Lacan’s focus, in 1982, on the importance of knotting the three consistencies (the real, the symbolic, and the imaginary), many Lacanians continue to neglect the imaginary. In his study of James Joyce (2001), however, Lacan showed the difficulties that follow from a failure to give proper place to the imaginary. According to Marie-Christine Laznik-Penot (1995), the treatment of autism also allows us to see the difficulties that can follow from failure to accord the imaginary order its proper place.

## IMAGO

An unconscious prototype of personae, the imago determines the way in which the subject apprehends others. It is elaborated based on the earliest real and fantasmatic intersubjective relations with family members.

The term *imago* first appeared in work of Carl Gustav Jung in 1912, and the same Latin word was adopted in various languages. The concept was borrowed from a novel of the same name by Carl Spitteler (1845–1924), published in 1906. In Jungian psychology, the term *imago* eventually replaced the term *complex*.

The imago is linked to repression, which in neurosis, through regression, provokes the return of an old relationship or form of relationship, the reanimation of a parental imago. This regression is linked to particular quality of the unconscious, that of being constructed through historical stratification. “I have intentionally given primacy to the expression *imago* over the expression *complex*, for I wish to endow the psychical fact that I mean to designate by *imago*, by choosing the technical term, with living independence in the psychic hierarchy, that is, the autonomy that multiple experiences have shown us to be the essential particularity of the complex imbued with affect, and which is cast into relief by the concept of the imago,” Jung wrote.

Jung later replaced the term *imago* with *archetype* in order to express the idea that it involves impersonal, collective motifs, but in fact this idea was already present in his earliest descriptions of imagos. In 1933 he again explained his choice of this term: “This intrapsychical image comes from two sources: the influence of the parents, on the one hand, and the child's specific

relations, on the other. It is thus an image that only reproduces its model in an extremely conventional way.” Finally, he situated the imago “between the unconscious and consciousness, in a sense, as if in *chiaroscuro*.” It is a partially autonomous complex that is not completely integrated into consciousness.

Sigmund Freud, “forgetting” that Spitteler's novel had inspired Jung, used the same title, *Imago*, for the review he created with Hanns Sachs and Otto Rank in Vienna in March 1912.

The concept of the imago, very seldom used by Freud, appeared in his writings for the first time that same year, in “The Dynamics of Transference” (1912b), where he wrote: “If the ‘father-imago,’ to use the apt term introduced by Jung . . . is the decisive factor in bringing this about, the outcome will tally with the real relations of the subject to his doctor” (p. 100). In those rare texts where he used this term, the imago refers only to an erotic fixation related to real traits of primary objects. But elsewhere, Freud had already shown the importance of the child's links with its parents and had explained that the most important thing is the way in which the child subjectively perceives its parents; these ideas are contained in the notion of the imago. He had also distinguished certain representations that had the status of the imago (the mnemonic image of the mother, or the image of the phallic mother in the work of Leonardo da Vinci). However, in “The Economic Problem of Masochism” (1924) he used the term *imago* in the Jungian sense, in relation to moral masochism and the superego. Indeed, he wrote that behind the power exerted by the first objects of the libidinal instincts (the parents) was hidden the influence of the past and traditions. In his view, the figure of Destiny, the last figure in a series that begins with the parents, can come to be integrated with the agency of the superego if it is conceived of “in an impersonal way,” but quite often, in fact, it remains directly linked to the parental imagos.

At that time the term *imago* was commonly used in the psychoanalytic community, but it was particularly developed in the work of Melanie Klein. Besides the classic imagos, she described “combined parental imagos” that provoke the most terrible states of anxiety. She linked these to the “stage of the apogee of sadism,” which in 1946 became the “schizoid-paranoid position.” The analyst's work is to bring forth the anxiety linked to these terrifying imagos, thus facilitating the passage to “genital love” (which in 1934 became the

“depressive position”) by transforming these terrifying imagos into helpful or benevolent imagos. In her view, the young child develops cruel, aggressive fantasies about the parents. The child then projects these fantasies onto the parents, and thus has a distorted, unreal, and dangerous image of people around it. The child then introjects this image, which becomes the early superego. Klein thus described the early superego more as an imago than as an agency.

Klein left it to Susan Isaacs to define what she meant by imago: an image, or imago, is what is introjected during the process of introjection. It involves a complex phenomenon that begins with the concrete external object in order to become that which has been “taken into the self” (p. 89), that is, an internal object, Isaacs explained in “The Nature and Function of Phantasy” (1948), adding: “In psycho-analytic thought, we have heard more of ‘imago’ than of image. The distinctions between an ‘imago’ and ‘image’ might be summarized as: (a) ‘imago’ refers to an unconscious image; (b) ‘imago’ usually refers to a person or part of a person, the earliest objects, whilst ‘image’ may be of any object or situation, human or otherwise; and (c) ‘imago’ includes all the somatic and emotional elements in the subject’s relation to the imaged person, the bodily links in unconscious phantasy with the id, the phantasy of incorporation which underlies the process of introjection; whereas in the ‘image’ the somatic and much of the emotional elements are largely repressed” (p. 93).

In his 1938 article entitled *Les Complexes familiaux dans la formation de l’individu* (The family complexes in the formation of the individual), Jacques Lacan drew the connection between imago and complex. It was at this time that he advanced his first theory of the Imaginary. The imago is the constitutive element of the complex; the complex makes it possible to understand the structure of a family institution, caught between the cultural dimension that determines it and the imaginary links that organize it. Lacan described three stages in it: the weaning complex, the intrusion complex (in which the mirror stage is described), and the Oedipus complex. This complex-imago structure prefigured what would become his topology of the Real, the Imaginary, and the Symbolic.

## **IMAGO PUBLISHING COMPANY**

The destruction by the Nazis of the *Verlag* (International Psychoanalytic Press) was a bitter blow to Freud, and when he arrived in London in 1938 he tried to find some way of restoring it.

Already, in May of that year, Hanns Sachs had suggested that he establish a periodical in the United States that would be devoted to non-medical applications of psychoanalysis, especially to culture, and to call it the *American Imago*. In this way Sachs hoped to continue along the path pursued by the original *Imago*, founded by himself and Otto Rank in 1912, and of which he had remained co-editor. The name “Imago” was taken from the title of a novel by a Swiss poet, Carl Spitteler, that had underlined the importance of the unconscious in its motif, a love affair. According to Ernest Jones, Freud favored the Sachs plan, for which financial backing had been guaranteed by a well-wisher, but was somewhat reluctant to agree to the title, though he quickly gave in, and *American Imago* remains successful.

Freud was deeply concerned about the loss of his own journals printed in German, as well as the *Verlag*. He found a sympathetic and gifted writer, poet, and publisher, John Rodker, who founded the Imago Publishing Company (IPC) in London. Rodker’s co-directors were Barbara Low and Martin Freud, and the headquarters of the new company were located at 6,

Fitzroy Square in London. For a short time in 1939 a combined *Zeitschrift* and *Imago* were published in London, but failed to survive the beginning of the Second World War.

Plans had already been made for the publication of a new edition of Freud's collected works, and the *Gesammelte Werke* were published by the new company and replaced the original *Gesammelte Schriften*. Its eighteen volumes were undoubtedly a publishing triumph. Individual works by Freud were also published by the IPC in German, of which *Aus den Anfängen der Psychoanalyse* (later translated as *The Origins of Psycho-Analysis* (1954) by Eric Mosbacher and James Strachey and edited by Marie Bonaparte, Anna Freud and Ernst Kris) was of cardinal importance, containing as it did the most important letters to Fliess on the subject as well as relevant drafts and notes. Other major Freud works published by the IPC in English translation were *Three Essays of the Theory of Sexuality* (1905d), *The Question of Lay Analysis* (1926e), and *On Aphasia* (1891b). The publishing house also issued important works by other authors, of which *Twins: A Study of Three Pairs of Identical Twins* (1952) by Dorothy Burlingham is exemplary. Other publishing arrangements for psychoanalytic books were well established by the time the IPC closed, shortly after its last publication in 1962.

## IMAGO. ZEITSCHRIFT FÜR DIE ANWENDUNG DER PSYCHOANALYSE AUF DIE GEISTESWISSENSCHAFTEN

Following the launch of *Jahrbuch für Psychoanalyse* and *Zentralblatt für Psychoanalyse*, Hugo Heller, the

publisher, in 1921 created *Imago*, the third psychoanalytic periodical under the editorial direction of Sigmund Freud. While the two earlier publications were primarily oriented toward clinical applications and developments, *Imago* introduced an interdisciplinary approach to journal publishing, an approach that Freud had already tested with the series "Schriften zur angewandten Seelenkunde" (Essays on applied psychology), published by Franz Deuticke. With *Imago*, the concept was enlarged and expanded in periodical form.

The original title of the journal had been *Eros and Psyche*, but that was changed to *Imago*, after the name of a novel by Carl Spitteler (1845–1924). For Freud, the name was sufficiently vague to be useful to his enterprise (letter to Ernest Jones, January 14, 1912). Directed toward other than clinical ends, the journal served as a forum to introduce an experimental dialogue with neighboring fields such as anthropology, philosophy, literature, theology, and linguistics (see Freud, 1913j).

Consistent with this approach, the first part contains a contribution from two lay analysts, the editors-in-chief of the publication, Otto Rank and Hanns Sachs. This was "Entwicklung und Ansprüche der Psychoanalyse" (Development and demands of psychoanalysis), in which the authors show that the methodology of psychoanalysis, although based on concrete methods of therapy, continued to struggle, in its theoretical paradigms, with the relation between dreams and artistic, mythological, and religious fantasies. Consequently, it was necessary to test and develop the knowledge obtained through the study of dreams, neuroses, and symptom formation as part of a general science of the mind based on the unconscious. *Imago* was not only addressed to nonmedical lay practitioners but actively courted this target group in search of authors, thereby exposing psychoanalysis to areas of expertise outside therapy.

A number of Freud's contributions to applied psychoanalysis appeared in *Imago*, ranging from excerpts from *Totem and Taboo* in 1912 to early manuscript versions of *Moses and Monotheism*, which appeared in the final volume, published in Vienna in 1937.

The periodical was the product of a flourishing publishing business. Its success was based not only on the quality of content but also the number of readers. Following its transfer to the Internationaler

Psychoanalytischer Verlag (International Psychoanalytic Press), it was the largest source of income for the publisher. After the seizure of the Internationaler Psychoanalytischer Verlag by the National Socialists in 1938, Anna Freud and other émigré analysts succeeded in continuing publication of *Imago* until 1941, when it merged with the *Internationale Zeitschrift für Psychanalyse*.

In 1939 Hanns Sachs, seeking to perpetuate the *Imago* tradition in the United States, founded *American Imago*, which still exists. After the Second World War a number of psychoanalytic periodicals followed in the tradition of an interdisciplinary psychoanalytic journal, first introduced by *Imago*.

## **IMPOSTER**

Psychoanalytic tradition considers the nature of the imposter by referring to the work of Karl Abraham originally; during the 1950s, to the work of Helene Deutsch; and later to Phyllis Greenacre.

Their work contained descriptions of clinical cases as well as a comparison of famous imposters throughout history, like James MacPherson. The imposter is someone who pretends to be someone they are not. It

is the falsification of identity that creates the imposture, the borrowed identity being that of someone else or that of an imaginary person with a different name or a different profession. The success of the imposture may depend on the complicity of others in the lie.

In truth none of the descriptions given in the literature goes much further than these relatively superficial findings. The attempt to create a composite picture of the imposter has failed because of the inaccuracy of the term itself, which is not conceptual, and the diverse personalities included under this term.

However, several characteristics have been advanced as being specific to the imposter. These include the compulsion to enact the family romance, disorders in the sense of identity (which are paradoxically relieved by the borrowed identity), and a malformed superego. Considered as a form of psychopathology, imposture has been classified among the perversions. Imposters are described as having usurped the role of the oedipal father and as identifying with the maternal phallus at an early age.

---

## **INCEST**

Characterization and definitions vary across cultures, but incest refers to sexual relations between close relatives. Prohibition may be according to custom or morality, and embodied in law. In psychoanalysis, the term

is also and especially discussed in terms of fantasy and psychological conflict.

Freud mentioned incest for the first time in his correspondence with Wilhelm Fliess (Draft N, dated May 31, 1897), in which he explained “saintliness” in terms of its impious and anti-social character (1950a). A family primordially promiscuous would be forced to give up incestuous behavior in order to avoid being socially isolated.

Incest subsequently became a central theme in Freud’s formulation of the Oedipus complex, defined as a child’s conflict between sexual desire for the parent of the opposite sex (the “positive” oedipal complex) and repression of that desire. The theory was put forth in *Three Essays on the Theory of Sexuality* (1905d) and in Freud’s discussion of the case of “Little Hans” (1909b), among other works.

From the start Freud also discussed the incest taboo in an anthropological context, in terms of its role in the evolution of society. The first chapter of *Totem and Taboo* (1912–13a) was devoted to “the horror of incest” and was based on the work of contemporary ethnologists. For Freud it was important to establish that such a taboo operated in every human society. This view gained some support in the work of later anthropologists, including Claude Lévi-Strauss, who, however, maintained reservations regarding Freud’s obligatory corollary, that the Oedipus complex was “universal.” (See André Green [1995] for a discussion of Lévi-Strauss’s views.)

Freud held that psychic energy which accumulates through repression of sexual gratification, prohibitions owed to the oedipal situation, becomes an essential force propelling the development of civilization, especially through channels of sublimation. In “‘Civilized’ Sexual Morality and Modern Nervous Illness” (1908d), Freud suggested that repression can also provoke psychological disorders through the “damming-up” of libido (the “actual” neuroses) or by substitute symptom formation (the psychoneuroses). The price of civilized morality is high when repression adversely affects too many individuals and distorts the social fabric; Freud examined these issues in *Group Psychology and the Analysis of the Ego* (1921c) and in *Civilization and Its Discontents* (1930a).

The incest theme has received little attention in contemporary psychoanalytic literature; an exception

is Paul-Claude Racamier’s interesting treatment of the “incestual” (1995).

## INCOMPLETENESS

In psychoanalysis, the state of “incompleteness” does not connote an imperfect or unfinished state, but rather implies openness and retrospective reexamination.

The notion of incompleteness in the work of Sigmund Freud presupposes two possibilities and one constraint: the integration of new ideas and the reexamination of old ideas in retrospect, provided that the whole remains coherent.

The image of the umbilical knot used by Freud in connection with dreams in *The Interpretation of Dreams* (1900a) to represent the unfathomable reaches that are endlessly saturable with meaning—the ego’s vanishing point—eventually found its homologue in the realm of reality in Heisenberg’s uncertainty principle. Some form of incompleteness can be deduced from the integration of the new, from the working of deferred action, from demands for the production of coherence; it is a relationship that can be located in psychoanalytic theory, clinical practice, and treatment.

Incompleteness in the realm of theory can be pinpointed, in terms both of Freud’s mental moves leading to theoretical creation and of the content of his theories. Several authors, such as Didier Anzieu, Jean Guillaumin, and Jean-Paul Valabrega, have established parallels between certain of Freud’s personal mental changes and his great moments of theoretical creation: “Project for a Scientific Psychology” (1950c [1895]); the writings included in the *Metapsychology* of 1915; the turning point of 1920, when dualism of the instincts was introduced into the corpus; and the years 1937–1938, when the theory of trauma from the “Project for a Scientific Psychology” was revised to make it coherent with the apparatus of the second topography, to cite only a few.

In 1895 Freud was already well advanced in his theoretical conception of neurosis, particularly hysteria. Under a certain amount of pressure from his colleagues, notably Wilhelm Fliess, who was formulating his own theory of the “periods,” Freud found himself urgently in need of a homogeneous, totalizing formulation of psychic mechanisms that would take into account the theory of the neuroses and the normal psychic apparatus—hence his haste in writing “Project for a Scientific Psychology.” This essay brings with it a paradox that attests to Freud’s felicitous inability to conceptualize a closed theoretical system: Based on the neurological metaphor, he provided a coherent and relatively finished system that he nonetheless called a “Project” in the sense of a sketch (*Entwurf*). History showed that this was indeed just a sketch, whose hypercoherence was dismantled beginning in September 1897—at the same time as Freud’s work of mourning

in connection with the death of his father—and whose elements were reworked and used in subsequent theoretical developments.

Thereafter, Freud no longer allowed himself to be dominated by the desire to devise a system that would have an answer for everything. The topography, as well as his theories of anxiety, the instincts, and the neuroses, was modified in light of his clinical work, leading to new theoretical acquisitions such as the “splitting of the ego in the process of defense,” for example.

As the foundations of the psychic apparatus, the instincts were a theoretical constant that was given even greater emphasis with the introduction of the id in the second topography. Principles and laws of psychic functioning came to modulate and use, to the benefit of ideation and meaning, the power that is inseparable from the notion of the instinct. This force can meet with two economic vicissitudes: “binding” and “discharge.” Above all, after the metapsychological complexification of the second topography, a balance between binding and discharge was imposed, even if Freud more particularly indicated the path of binding culminating in the construction of more and more representational units that can be subjectivized. After 1920, and mainly after 1923–1924, around the time of “The Ego and the Id” (1923b), the first trauma-based theories of 1895 were reworked so that the notion of trauma could be integrated and become a constituent part of the *Metapsychology*. Not only is there a traumatic kernel in neurosis, but the id, even in its normal state, is traumatic for the ego.

The relations of the instincts and the other psychic contents (ideas) are marked by incompleteness. The incompleteness of the fabric of representation and the inexhaustible nature of the quest for meaning and coherence attest to the fact that the relations between the psychic agencies and objects satisfy a complex dynamic, which Freud’s successors attempted to theorize.

Incompleteness is at the heart of psychoanalytic practice. Freud refused to reduce the scope of psychoanalysis to that of psychotherapy. To be sure, there are the symptoms and suffering of patients, but analysis opens up other horizons, as Freud unambiguously declared in the “New Introductory Lectures on Psycho-Analysis” (1933a [1932]): “I did not want to commend [psychoanalysis] to your interest as a

method of treatment but on account of the information it gives us about what concerns human beings most of all—their own nature” (pp. 156–157).

From its own unfathomability to the multiplicity of its exterior, the subject is constantly being transformed. The essential question of psychoanalysis has become that of subjectivity, which today has plunged it into a paradoxical situation. Without doubt, Freud left it to his successors to establish a theory of the subject. They have not yet managed to construct one that would be coherent with Freudian metapsychology, and most often we must content ourselves with invoking what Raymond Cahn has called the “process of subjectivation.” This places the emphasis on interpretative intent in psychoanalysis, whose essential aim is no longer simply bringing material into consciousness, but also to enable a constant reworking, through discourse, of the representations and formations of desire, identifications, and affect-fixating memories upon which the analysand writes and rewrites their history. “Where id is, there ego shall be” (1933a [1932], p. 80). Rather than seeing in this the idealistic aim of a Freud limited by a psychotherapeutic ideal, we can infer the modesty of Freud, the psychoanalyst, revealing the magnitude of the analyst’s clinical task. It is not the completion of this task, even supposing that would be possible, that would trigger the process of the end of treatment, but perhaps the ability to work through the grieving process it entails.

Whether the emphasis is placed on the subject’s coming into being or on subjectivation, this presupposes the corollary idea of maintaining that entity, which requires that it make constant adjustments in relation to the agencies, its ideals, and others. Considering the power of the drives, the state of the subject is precarious, always susceptible of dissolving into actions or symptoms, especially when it is a question of seeking out, through transference, “truths” and new insights, as analysis according to Freud proposes to do. The quest for truth and the quest for causality, moved by the power of the drives, endow the very process of subjectivation with its unstable and ever incomplete character.

The completion and incompleteness of analysis preoccupied Freud until the end of his work, as his “Analysis Terminable and Interminable” (1937c) attests. Today, the idea of a completed analysis is entirely relative, and opinion remains divided as to the criteria for ending treatment. Respect for the idea of

incompleteness bears with its full weight on the ethics of the psychoanalyst as one of the elements that protects the treatment from the alienation that would result if the analyst were to impose their own desire upon that of the analysand.

## **L'INCONSCIENT**

The periodical, *L'Inconscient*, was founded by Piera Aulagnier-Spaurani, who was the editor-in-chief, and Jean Clavreul and Conrad Stein. With the help of Renée Andrau and Lucio Covello as editorial secretaries, the first issue, published by Presses Universitaires de France, appeared in January–March 1967. At the time the psychoanalytic movement in France had been wracked by divisions and internal dissension. The Société Française de Psychanalyse (French Psychoanalytic Society) had been dissolved and rival institutions created. These included the Association Psychanalytique de France (French Psychoanalytic Association), which in 1965 became part of the International Psychoanalytic Association, and the École Freudienne de Paris (Freudian School of Paris), directed by Jacques Lacan. Two students of Lacan’s organization worked with a member of the Société Psychanalytique de Paris (Paris Psychoanalytic Society), Conrad Stein, to create a review that was open to the opposing points of view that were tearing the French psychoanalytic movement apart. It was one

of the attempts by psychoanalysts of the 1950s to establish connections with organizations other than the official psychoanalytic bodies, which pretended to ignore one another when they were not actively jockeying for position.

Appropriately, the first issue was devoted to the topic of “transgression,” and included essays by Conrad Stein, Serge Leclaire, Michel Neyraut, Guy Rosolato, and Piera Aulagnier. Other issues followed; the issue devoted to perversion contained contributions from Jean Clavreul, André Green, Jean-Paul Valabrega, and Georges Daumézon. Daumézon represented the symbolic link that united these disparate personalities: The Sainte-Anne Hospital, where many of these young psychoanalysts worked. (Most were between thirty and forty years of age at the time.)

Over the course of eight issues, there were contributions from a wide range of practitioners, including Serge Viderman, Lucien Israël, Irène Roublef, Christian David, Michel de M’Uzan, Francis Pasche, François Roustang, Jean-Luc Donnet, François Perrier, Jean Gillibert, Joyce McDougall, Dominique Geachan, Claude Robant, Robert Barande, and Cornélius Costoriadis. Unfortunately, dissension within the psychoanalytic community led to the cessation of publication after two years. The final issue, of October 1968, was devoted to the potentially explosive topic of psychoanalytic training. The founders argued among themselves, a reflection of the dissension within the Lacanian movement that had originated with Lacan’s statements concerning “*la passe*” in October of the previous year. A notice indicated that “the editors have been unable to agree on the direction most suitable for a review of psychoanalysis or on the role they felt it should play.”

Five months later Piera Aulagnier founded the Quatrième Group, Organisation Psychanalytique de Langue Française (Fourth Group: French Language Psychoanalytic Organization) with François Perrier and Jean-Paul Valabrega, and the review *Topique*. That same year, 1969, Conrad Stein founded *Études freudiennes*, which also published points of view that differed from the French psychoanalytic mainstream. It was several years, however, before the psychoanalytic ecumenicalism of *L’Inconscient* was repeated in France.

## INDIA

The founder’s meeting of the Indian Psychoanalytic Society took place in Calcutta in 1922 with Girindra-shekhar Bose, a young Bengali doctor who had read the English translations of Freud’s work, in the chair. Of the fifteen original members, nine were college teachers of psychology or philosophy and five belonged to the medical corps of the Indian Army, including two British psychiatrists. In the same year, Bose wrote to Freud in Vienna. Freud was pleased that his ideas had spread to such a far-off land and asked Bose to write Ernest Jones, then President of the International Psychoanalytic Association, for membership of that body. Bose did so and the Indian Psychoanalytic Society, with Bose as its first president (a position he was to hold till his death in 1953) became a fully-fledged member of the international psychoanalytic community.

Cut off from the debate, controversy, and ferment of the psychoanalytic centers in Europe, and dependent upon often difficult to acquire books and journals for outside intellectual sustenance, Indian psychoanalysis was nurtured through its infancy primarily by the enthusiasm and intellectual passion of its progenitor. In the informal meetings of eight to ten people held on Saturday evenings at the president’s house—which was to become the headquarters of the Indian Society after Bose’s death—Bose read most of the papers and led almost all the discussions.

Although psychoanalysis attracted some academic and intellectual interest in the 1930s and 1940s, mostly in Calcutta, the number of analysts was still small (fifteen) when in 1945 a second training center, under the leadership of an Italian expatriate, Emilio Servadio, was started in Bombay.

To judge from the record of publications of its members, the small Indian society was fairly active up through the 1940s. There was a persistent concern with the illumination of Indian cultural phenomena as well as attempts to register the “Indian” aspects of the patients’ mental life. By the early 1950s, however, the interest in comparative and cultural aspects of mental life, as well as the freshness of the papers written by the pioneering generation of Indian psychoanalysts, was lost. Thereafter, most Indian contributions, to judge from the official journal of the Indian Society, have been neither particularly distinctive nor original.

In the public arena, psychoanalysis has generally had an indifferent, if not hostile, reception. At first glance, the Indian indifference to psychoanalysis seems surprising, given the fact that there has rarely been a civilization in human history that has concerned itself so persistently over the millennia with the nature of the “self” and with seeking answers to the question, “Who am I?” As a colonized people, however, reeling under the onslaught of a conquering European civilization that proclaimed its forms of knowledge and its political and social structures as self-evidently superior, Indian intellectuals in the early twentieth century felt the need to cling doggedly to at least a few distinctive Indian forms in order to maintain intact their civilization’s identity. The Indian concern with the “self,” its psycho-philosophical schools of “self-realization,” often appearing under the label of Indian metaphysics or “spirituality,” has become one of the primary ways of salvaging self-respect, even a means of affirming a superiority over a materialistic Western civilization. Psychoanalysis was seen to be a direct challenge to the Indian intellectual’s important source of self-respect; it stepped on a turf the Indian felt was uniquely his own.

Another reason for the rejection of Freudian concepts had to do with their origins. Derived from clinical experience with patients growing up in a cultural environment very different from that of India, some of the concepts, when transposed, did not carry much conviction. The different patterns of family life and the role of multiple caretakers in India seemed to push in the direction of modifications of psychoanalytical theory. Similarly, Freudian views of religion, derived from the Judeo-Christian monotheistic tradition, with its emphasis on a father-god, had little relevance for the Indian religious tradition of polytheism where mother-goddesses often constituted the deepest substratum of Indian religiosity.

Because of its relative isolation, Indian psychoanalysis has been decisively marked by the stamp of the first Indian analyst, Girindrashekar Bose (1886–1953). Without experiencing the benefits of training analysis himself, it was Bose who “analyzed” the other members in a more or less informal manner. He developed a method of his own, similar to the active therapy and forced fantasy method of Sándor Ferenczi, which calls for a more active, didactic stance from the analyst, and which came dangerously close to what a lawyer is forbidden to do in the courtroom, namely “lead the witness,” increasing the chances of

suggestion. In hindsight, Bose’s important contribution to psychoanalysis was less his “theory of opposite wishes” and more his questioning of some presumed psychoanalytic universals, based on his clinical experience. In his letters to Freud, Bose points out differences in the castration reactions of his Indian and European patients and notes that the desire to be a female is more easily unearthed in Indian male patients than in European. Since cultural relativism was not on the psychoanalytic agenda in the 1930s when Bose communicated his observations, they received little attention.

The question of cultural relativism versus the universality of many psychoanalytic concepts and theories is very much at the heart of contemporary analyst Sudhir Kakar’s work. Based on clinical and cultural data from India, Kakar has highlighted the cultural aspects of the psyche in his many books and papers, trying to show that mental representations of the culture play a significant role in psychic life.

The Indian Psychoanalytic Society has published a journal, *Samiksa, the Journal of the Indian Psychoanalytical Society*, since 1946.

## **INDICATIONS AND CONTRAINDICATIONS FOR PSYCHOANALYSIS FOR AN ADULT**

Borrowed from traditional medicine, the notions of indications and contraindications have been very much present in the writings of Freud and his medical following from the very beginnings of psychoanalysis. Moreover, the indications and contraindications for psychoanalysis have changed in the course of theoretical and practical developments that have profoundly altered attitudes toward psychoanalytic treatment.

In *Studies on Hysteria* (1895d), Sigmund Freud and Josef Breuer listed certain conditions for applying the

cathartic method: “The procedure is not applicable at all below a certain level of intelligence. . . . The complete consent and complete attention of the patients are needed, but above all their confidence (1895d, p. 264). In “Freud’s Psycho-Analytic Procedure” (1904a [1903]), Freud specified further indications and contraindications: “Chronic cases of psychoneuroses without any very violent or dangerous symptoms are the most favourable ones for psycho-analysis: thus in the first place every species of obsessional neurosis, obsessive thinking and acting, and cases of hysteria in which phobias and abulias play the most important part; further, all somatic expressions of hysteria whenever they do not, as in anorexia, require the physician to attend promptly to the speedy removal of the symptoms. . . . The patient must be capable of a psychically normal condition; during periods of confusion or melancholic depression nothing can be accomplished even in cases of hysteria. . . . Deep-rooted malformations of character, traits of an actually degenerate constitution, show themselves during treatment as sources of a resistance that can scarcely be overcome. . . . If the patient’s age is in the neighbourhood of the fifties the conditions for psycho-analysis become unfavourable” (pp. 253–254).

Gradually, with the work of Karl Abraham, Ernst Simmel, and Wilhelm Reich, the range of cases regarded as appropriate for treatment expanded to include psychoses and borderline conditions, even perversions and drug addiction—with uneven results. As time went on, efforts were made to separate the issue of indications from medical categories and traditional diagnostic procedures, in order to create a suitable framework for understanding the metapsychological factors underlying the demand for treatment and a suitable framework allowing prediction of its results. Otto Fenichel (1945) included in his contraindications, in addition to advanced age and unfavorable life conditions, the “absence of a reasonable and cooperative ego” and the existence of significant secondary gains derived from symptoms.

In 1955 Edward Glover, discussing the “transference potential of the patient,” distinguished “accessible” cases (psychoneuroses, reactive depressions, psychosexual inhibitions, optional bisexuality) and “moderately accessible” cases (obsessional neurosis, fetishism, alcoholism and drug addiction, chronic maladaptation, psychopathic delinquency) from “rebel cases” (psychoses, grave character disorders, and sexual

disorders). The list presented by Sacha Nacht and Serge Lebovici in 1958 was fairly close to this one.

The issue of indications and contraindications has acquired another dimension with the notion of “analyzability,” especially after the Twenty-Fifth International Congress of Psychoanalysis (Copenhagen, July 1967) and René Diatkine’s 1968 article. Diatkine proposed evaluating the patient on first encounters to prognosticate the evolution of future treatment: evaluation of imaginative capacities, flexibility in object relations, screening for an “operational idea,” and so on. Subsequently, McDougall (1972) used the notion of the “anti-analysand” to characterize a patient who disassembles normalcy, sometimes as a cover for serious relational problems—a trait that poses a risk of making analysis impossible.

As a result of a growing interest in the role of the psychoanalyst’s counter-transference, whether psychoanalysis is indicated has come to mean considering the analyst’s particular capacities for empathy and tolerance for various kinds of pathologies in a candidate patient. In 1945 Otto Fenichel noted that analysis could be counterindicated with a given analyst for reasons other than the analyst’s sex or prior relationship with the candidate analysand. Robert Barande has also discussed “analyst indication.”

The expansion of the range of indications and the multiplication of approaches in psychoanalytic and related forms of psychotherapy has modified, sometimes in the direction of excessive laxity, decisions about whether analysis is appropriate. This proliferation has even been seen as a reason for the disappointment of those who expect miracles from a psychoanalytic approach to difficult cases.

Finally, it is appropriate to recall what Freud wrote to Ludwig Binswanger on May 28, 1911: “Truthfully, there is nothing that man’s organization makes him less apt for than psychoanalysis” (2003).

## INDIVIDUAL

The concept of the individual is not especially Freudian, although analysis assumes that the analysand has a degree of psychic autonomy, individuality, and even identity. The term "individual" (*Einzel*) is found in Freud, notably in *Civilization and Its Discontents* (1930a [1929]), where it stands in opposition to culture. More broadly, the concept is central to a variety of disciplines, such as ethnology, sociology, political theory, and philosophy.

Cultural historians have described the birth of individual love as an outgrowth of courtly love, the appearance of the individual feeling of finitude and death at the end of the Middle Ages, and the birth of the modern conception of childhood within the family

in the eighteenth century (Philippe Ariès). With the Enlightenment and Romanticism, the child became "the father of the man." After 1900, childhood and adolescence became distinct age categories and stages of mental development. Scholars can trace the development of the concept of the individual across the political, social, cultural, and religious landscapes from the Renaissance to the Reformation to the Enlightenment.

While having universal scope, psychoanalysis is nonetheless marked with the imprint of Western culture, in which it was born. According to Claude Lévi-Strauss, this culture "vomits up" the individual, in contrast with group societies ("holistic" societies, according to Louis Dumont), which "swallow" the individual.

Ethnopsychanalysis (Georges Devereux) examines differences in mental development according to culture. The Oedipus complex described by Freud refers to the symbolic figure of the father in Jewish and Christian cultures, and it affords the possibility of triangulation, which leads to individuation and identity construction. Other oedipal modalities are present in matrilineal societies, where the parent is differentiated from the maternal uncle, who represents the paternal function—an arrangement consistent with limited individuality and extended dependence on the social group. The history of European culture is marked by a gradual transition from a holistic society (during the Middle Ages) to a society of individuals, and accompanying this transition was the evolution of identity formation characteristic of modernity.

If a conception of the individual is a precondition for the development of psychiatry, the existence of the self, the subject, is a precondition for the creation of psychoanalysis. When the individual perceives his ego as a double and perceives the uncanny nature of his division, this perspective can be presented as a cure for the suffering that the individual experiences in the face of modernity. In *Totem and Taboo* (1912–1913a), Freud hypothesized that a "mass psychosis," a collective soul, in his text, "culture" (*Kultur*) in the sense of a collective mental formation situated above the individual, to a large extent conditions the individual's mental functioning. Freud elaborated the concepts of the ego ideal and superego, transitional formations located between culture and the individual. He also showed that the repression associated with anality in

modern culture has an impact on the modalities of identity formation during adolescence.

During the 1950s Margaret Mahler defined “individuation” as a process of separation to escape the primary union of the mother-child symbiosis. Working with the uncertainties of individuation in infantile psychosis, Mahler described a “symbiotic” stage of child development, prior to the separation and individuation that ends absolute dependence. John Bowlby, using an ethological approach to the mental development of the infant, developed the concepts of attachment and separation. José Bleger, employing the concepts of symbiosis and ambiguity, showed that traces of primitive undifferentiation persist, even among the most evolved individuals, in the form of an “agglutinated nucleus.”

Research by Alain de Mijolla (1981) and data from group psychoanalysis and family therapy have shown connections between subjectivity and the Other in culture, in the family, and across generations, that is, connections among the intrasubjective, intersubjective, and intergenerational dimensions of the psyché.

## INDIVIDUATION (ANALYTICAL PSYCHOLOGY)

Carl Gustav Jung considered individuation to be a step or process that leads to a partial disengagement from the control of the unconscious and from collective rules and norms and feelings. This process is accompanied by a development of the rapport of the ego to the self, through an ever closer recognition of the forces and figures that structure—at first without our being aware of it—our representations and behavior.

The earliest version of this notion can be found in Gérard Dorn, in the sixteenth century, then in the Goethean conception of the novel of apprenticeship (*Bildungsroman*), as well as in the works of Arthur Schopenhauer and Friedrich Nietzsche. However, in his writings of the second decade of the twentieth century, Jung gave it a whole different meaning and significance, inscribing it into his own experience, then integrating it with the successive stages of his thought on the relationship with the unconscious.

Jung mentions individuation for the first time in 1916 in his *Seven Sermons to the Dead* and in an essay entitled “Adaptation, Individuation and Collectivity.” In the first of these, the emphasis was on the imperious need for everyone to undo the obscure envelope of their origin, distinguishing and differentiating themselves from it, to learn how to live as a unique being, separate and alone (“*einzelsein*,” he wrote). In the second work he stressed the debt contracted and the price to pay by anyone who distances themselves from the common knowledge and collective norms of a group.

These works showed the impact of Jung’s own experience on his work after the break with Freud (during the period of 1912–1918). His experience led to the emergence of images that, under the influence of the emotions he was feeling, gradually took on voice and shape: individuation for him was not only a necessity and a principle, on the basis of which a human being is constituted in his singularity, it is also a work—Jung soon was to call it a process (*ein Prozess*), and even a work of long duration (the ancient alchemists, whom he studied from 1935–1936, referred to it as their *opus*)—which one can learn to accompany, support, and even provoke.

From one phase of his work to another, Jung was always very specific about the stakes and the risks (of exaltation, or inversely, of depression, or even psychotic

breakdown) of individuation, as well as its modalities, notably in the clinical conditions of analytic practice, and its effects, possible or anticipated, on the future of man and on that of the unconscious itself.

In 1918, he started working on some empirical exercises in graphics that made him experience a decentralization, which he later realized was close to that produced by the use of mandalas, as well as the destabilization of the ego produced by Taoism. His reflections on the conditions of symbolic life for us today came from these studies, and also from his later analyses of the history of Christianity and his encounters with Amerindian and African religions. This includes his conception, a rather fluid one, of the self in its relations with the ego: what is at stake presently in individuation can be all the more clearly grasped as one becomes aware of its projections in ancient systems of representation and practice.

Also, from his publication of *The Relations between the Ego and the Unconscious*, in 1928, and with the help of his analyses of alchemical literature and iconography, Jung explored the diverse stages that mark the individuation process: recognition of “the shadow” or “shadows” proper to each, the more or less upsetting or mediating effects of “the anima” or “the animus,” and especially the experience of the “Self.”

Finally it should be noted that the Jungian reflection on individuation was part of a frequenting of the unconscious that constantly assumed its compensatory capabilities and its capacity to maintain conjoined contradictory attitudes and even givens. From this perspective the quaternary model of psychic functioning that he introduced in his *Psychological Types* (1921) was deepened and enlarged in the forties and fifties to apply to the analysis of opposing movements (in the direction of incest and inversely towards differentiation) that are stirred by the transference, expanding also to include a reflection on the conditions for an integration of the feminine, and on the question of evil.

Consequently, the Jungian problematic of individuation has provided access to and perspective on certain collective issues, but its pertinence for cultures with a different history this is unknown.

### INFANS

The Latin term *infans*, derived from the Greek *phèmi* (“I speak”), means “one who does not (or rather, not yet) speak,” and refers to the baby before the acquisition of speech that marks the entry into childhood.

A number of authors (notably Melanie Klein and Donald Winnicott) used the term to describe those whose mode of communication is situated at a preverbal level. In the work of Jacques Lacan the term *infans* took on a further dimension in his discussion of language and its relation to the unconscious. Piera Aulagnier elaborated a theory of the mother-infant relation in terms of discourse (with the mother as “word-bearer”). The discussion here will be limited to the specific reference to language implied in the notion of *infans*.

In French translations of authors like Klein or Winnicott, terms such as *bébé* (baby), *nourrisson* (nursling), *petit enfant* (small/young child), or *infans* are used. A good many of Klein’s texts were originally written in German, and she used the word *infans*, which was translated in different ways in English and then in French, according to Luis E. Prado de Oliveira.

Winnicott commented on the term *infant*, commonly used in English, in “The Theory of the Parent-Infant Relationship,” originally published in the *International Journal of Psychoanalysis* in 1960. He explicitly referred to the fact that the infant does not yet have the use of verbal symbols or word-presentations. The baby’s dependence on the mother’s care is therefore more linked to maternal empathy than to any understanding the mother might have of what could be verbally expressed. In the work of Lacan, the “*infans* stage” precedes the advent of the subject through language. In “The Mirror Stage as Formative of the Function of the *I* As Revealed in Psychoanalytic Experience” (1949/2004), he wrote: “The jubilant assumption of his specular image by the kind of being—still trapped in his motor impotence and nursling dependence—the little man at the *infans* stage thus seems to me to manifest in an exemplary situation the symbolic matrix in which the *I* is precipitated in a primordial form, prior to being objectified in the dialectic of identification with the other, and before language restores to it, in the universal, its function as subject” (p. 4).

Piera Aulagnier’s theory of the *infans* stage is original in that she did not stop herself with merely noting the preverbal relationship to the mother at this stage, but also emphasizes that the mother plays the role of “word-bearer” in relation to the preverbal infant. This can be understood only in the context of the anticipation of the baby’s *I* by the mother. In *The Violence of Interpretation: From Pictogram to Statement* (1975/2001), Aulagnier writes: “The mother’s words and deeds always anticipate what the infant may know of them” (p. 10).

The idea of the mother as word-bearer draws on Lacan’s emphasis on the function of discourse. In *The Violence of Interpretation*, Aulagnier reminded us that “Every subject is born into a ‘speaking space’” and that the *I* is “an agency constituted by discourse” (p. 71). By “bearing” the word, the mother effects a twofold junction: first, between the infant’s manifestations and the outside world, by verbalizing them and giving them meaning; and second, between the world and the infant, since for the baby she serves as the representative of an external order, whose laws and demands she articulates.

Unlike the bodily needs that the newborn, because of its immaturity, cannot meet by itself, the psychic needs involving representation in its primal form (the pictogram) do not depend on intervention by a third

party. But the infant does not yet have access to the formation of ideas and naming, and it is thus in this place of lack that the mother as word-bearer is inserted. She fashions the objects that are presented to the infant by endowing them with a libidinal meaning. In Aulagnier’s words: “[F]or the senselessness of a real that could have no status in the psyche, it substitutes a reality that is human because it is cathected by the maternal libido, a reality that may be reshaped by the primal and the primary only because of that earlier work” (p. 74).

On this point, which is crucial for thinking the relationship with the world, and which marks the way in which that relationship depends on the relationship to the other—here the mother—Aulagnier simultaneously underscores her indebtedness to Lacan and her proximity to Wilfred Bion, from whom she considered herself to be fairly distant in other respects. With regard to Lacan, she notes: “The contribution of Lacan’s theory will be recognized here: indeed it might be said that the object is capable of being metabolized by the infant’s psychical activity only if, and as such, the mother’s discourse has endowed it with a meaning as evidenced by her naming of it. In this sense ‘swallowed’ with the object, Lacan was to see the primal introjection of a signifier as the inscription of a unary trait (*trait unaire*)” (p. 73).

As for Bion, she underscored her similarity to him as regarding the idea of an object that initially resided in the “maternal zone” and is then metabolized by the infant into a pure representation of its own relationship to the world. On the other hand, she diverged from both Lacan and Bion in her analysis of the consequences of this prosthetic function of the mother’s psyche in terms of “violence.” In this respect, we can assume that this notion that, a priori, seems surprising in the context of mother-child relations, came from another source—specifically, from the other violence that marks the bonds between the mother and the baby who will become psychotic, and specifically the schizophrenic.

In what sense does the mother/word-bearer inflict violence upon the *infans*? This necessary, “primary” violence is violence nonetheless, in that the infant feels the imposition of the word-bearer’s interpretations of the world. As Aulagnier explained in another work, the mother maintains a “spoken shadow” relationship with the infant, but the infant never completely coincides with this shadow that preexists it. The “violence”

is linked to the need to create and hold a subject-place (the spoken shadow) where there are as yet only potentialities. Accordingly, the future subject, the I, will come into being in a space preformed by expectations that are not its own. This is the necessary violence of maternal interpretation. But just as there is no such thing as a developmental *tabula rasa*, there can be no human subject without this pre-form. It is the discrepancy between the infant and shadow that makes it possible to situate a violence that will only really be violent (secondary violence) if the mother imposes it no longer upon the infant, but upon the I of the child.

## INFANT DEVELOPMENT

The term *infant development* refers to the processes of psychic organization and transformation that lead the preverbal infant from absolute dependency to the

earliest integrations of the ego during the first year of life.

By studying the “psychical apparatus” in its structures, functioning, and development, Sigmund Freud established facts and proposed hypotheses that are indispensable to the study of early development. Freud’s newborn is a being in a state of helplessness (*Hilflosigkeit*) whose development requires that a “mutual understanding” be established between it and its mother, as he explained in “Project for a Scientific Psychology” (1950 [1895]). The infant is active, driven by needs that give rise to the hallucination of satisfaction, which, according to *The Interpretation of Dreams* (1900a), is the prelude to fantasies and thoughts. Its oral component-instincts trigger the fundamental mechanisms of projection and introjection, as described in “Three Essays on the Theory of Sexuality” (1905d) and “Negation” (1925h). These mechanisms gradually enable the infant to form an idea of its mother as a total object; it can then bind its autoerotism to the love-object, as described in “Three Essays on the Theory of Sexuality.” The parents’ narcissistic investment in the infant, described in “On Narcissism: An Introduction” (1914d), and the quality of the primary identifications that unite the baby with its parents, described in “The Ego and the Id” (1923), are the basis for its own “life and death narcissism,” to borrow André Green’s expression.

The earliest psychoanalytic writings on the psychic life of infants came from Melanie Klein (1933), Anna Freud (1946), Donald Winnicott (1945), René Spitz (1945), and John Bowlby (1951). From the beginning, the quality of interrelations between mother-environment and the infant was universally accepted as being a vital necessity, indispensable to human psychic and somatic development. Early work in the field produced such landmark concepts as “early organizers,” “prototypes of ego-defense,” “archaic forms of communication” (Spitz); “tonic dialogues” (Julian de Ajuriaguerra); “interactional epigenesis” (Erik Erikson); and “interactive spiral” (Serge Lebovici).

Over time, Freud’s basic theories were further elaborated. Thus the conception of the oral instinct’s analysis on the alimentary function was broadened to include sensory, affective, and object forms of nourishment. The theory of an attachment instinct (John Bowlby) took into account the needs for contact that play a major role at birth and in the evolution of the separation-individuation process in the young infant

(Mary Ainsworth, Margaret Mahler). The notion of stages (Freud, Karl Abraham) was supplanted by that of “positions,” with its greater focus on the analysis of processes. Klein’s hypothesis of an ego that is active from birth, operating through projections and introjections, has been accepted and appears to be compatible with Freud’s theory of “primary identification with the parents” or fundamental narcissistic identification, set forth in “The Ego and the Id.” The infant’s access to a representation of the mother as total object and the prevalence of the depressive position over paranoid anxieties (Klein) precipitate the coming together of the ego.

Recent works on “adhesive identity,” the “psychic skin,” and the “skin-ego” (Esther Bick, Frances Tustin, Didier Anzieu) have brought new developments to these problematics. The theory of an early activation of the ego’s reflexive function has also opened a field for exploration. The advent of consciousness of self, termed the “mirror stage” by Jacques Lacan, is, in Winnicott’s view, a construction linked to “the mirror of the mother’s face and the family.” According to Winnicott, interiorization of the love-object enables the infant to find or create potential spaces for representation of the self and the outside world.

In another problematic, Daniel Stern described the evolution of different “senses of self” and explored the primitive forms of representations that result from the “interpersonal bond.” Wilfred Bion (1962) analyzed how, through the earliest projections and introjections, there immediately develops between mother and infant a process of thought, or reverie, that transforms the excitations that submerge the infant into “alpha elements.” The latter can be considered as proto-representations elaborated in the coalescence of “infant’s body” and “mother-environment” (Piera Castoriadis-Aulagnier, Monique Piñol-Douriez). They are the malleable foundations of psychic construction, and they undergo the transformations proper to the depressive position and later developments. Through maturation and interrelations, the “interactional epigenesis” leads the preverbal infant to love and to hate. At the end of the first year, the infant is ready to develop language, many of whose elements it already understands, and which it is beginning to babble.

Although Freud made joint use of “direct observation and regressive analysis” (1905d) as working methods, some psychoanalysts believe that direct observation reflects an objectifying scientism and that

because it is preverbal, the very young infant cannot be subjected to a psychoanalytic approach. Nevertheless, the theories elaborated on the basis of observation of early development can feed into psychoanalytic practice, theory, and research.

## INFANT OBSERVATION

Infant observation has long been considered an important training exercise for child psychotherapists and for psychoanalysts (Bick, 1964). This has led to certain theoretical developments commonly associated with the work of Esther Bick (1968, 1986).

Bick began this work in 1948, shortly after Melanie Klein had described the paranoid-schizoid position. In Klein's view of the paranoid-schizoid position, the ego has a primary sense of a boundary between itself and the external world. Bick described a variant of this process, in which boundary of the ego is not primary, but comes from the sensations arising from skin contact. Sufficient skin sensations are necessary to give the experience of a boundary.

One of the processes she noticed interpersonally was that the breaking of skin contact appeared to be experienced by the infant as a hole from which it could leak. She noticed the frequency with which infants become incontinent of excreta, as well as loosing tears from the eyes, and screams from the mouth. She believed she was watching just that process which Klein had described as the disintegration of the ego in the early stages after birth. The fragmentation takes the form of an experience of leaking into empty space.

Bick described various methods by which the infant seemed to operate to plug that leaky gap. It might grasp with the mouth so that literally the hole is filled. Alternatively the hands may grasp as the mouth does; or more distantly the eyes may become fixed upon a point of light or some discrete object, as if clinging like the clenched hands. In addition the infant may fix aurally upon sounds, including the sound of its own

crying. These processes of filling, grasping, fixing, and hanging on represent a method of completing a boundary. However, the mother's contact with the baby's skin remains the most potent, and perhaps natural, means of completing the boundary.

The theoretical ideas concerning the skin are related to the notion of the "skin egos" developed by Didier Anzieu (1985) and Pierre M. Turquet's "skin-my-neighbor" (1975).

Bick's view was that the boundary between ego and external world was first of all a phenomenon of the body ego, and specifically the skin. Also, it is not a given structure at the outset of life, but instead has to be achieved through the experience of the mother "giving" the infant a sense of being enveloped, through the mother's innate understanding of the baby's need for skin contact. Thus the primary object that stabilizes the ego is not Klein's good internal object internalized inside the ego boundaries, but is the ego boundary itself. The skin is thus a bodily component of the stability of the ego, and it is gained passively, at first, from the external object (mother).

Bick thought she was extending Klein's theories, by displaying a psychic level prior to and beneath Klein's paranoid-schizoid position. However, this has not been generally accepted.

## INFANT OBSERVATION (DIRECT)

The direct observation of babies is a way of learning about the developing human mind.

In “The Psychogenesis of a Case of Homosexuality in a Woman” (1920), Sigmund Freud stated that if direct observation were sufficient to provide us with information on the origins of human sexuality, he would not have bothered to write his books. Arguably, we observe nothing that we do not already know, and vision, although closely linked to the scopical instinct—the foremost tool of curiosity and inquiry—is not a productive way of investigating psychic reality. Nevertheless, his observation of Little Hans, related in “Analysis of a Phobia in a Five-Year-Old Boy” (1909), provided him with the essential elements of his theory of the libido and castration anxiety. He believed he was able to see directly in the child “these sexual impulses and these formations built by desire that we have such difficulty uncovering in the adult.” His observation of an eighteen-month-old child playing the *Fort!/Da!* game with a wooden reel, related in “Beyond the Pleasure Principle” (1920), by establishing the basis for his theory of the death instinct, played a role not only in his theorizations of narcissism, but also because it provided a paradigm for numerous currents of thought in child psychoanalysis.

Freud and Melanie Klein, working within different perspectives, encouraged their students to observe infants, but without making this a separate field of study. It was Donald Winnicott who, in “The Observation of Infants in a Set Situation” (1941), defined that field by envisioning infant observation as a “set situation” capable both of providing information about the infant carried by its mother and of establishing an authentic therapeutic relationship with the infant, working in a nonverbal mode. Winnicott proposed his own reading of Freud’s “game of *Fort!/Da!*” and helped us to see what distinguishes his interpretation from

pure behavioral observation. He analyzed the sequence of the baby’s behaviors in three stages: (a) hesitation, which he interpreted as a “sign of anxiety about something” and a symptom of a conflict between the infant’s desire and its interiorization of a threatening maternal imago; (b) then the expression of self-confidence—which is close to what he called “omnipotence.” In some cases, this phase can lead to the world of make-believe and shared play; and (c) the game of appearance/disappearance of the object, in which the infant, emerging from its depressive mood, expresses its ability to restore the object through the game.

Winnicott thus establishes a difference between the primitive processes, as they can be directly observed, and the deeper processes that are already a reconstruction and elaboration of the primitive processes, linked with experience of the environment. He made it possible to utilize direct infant observation to better understand psychic reality in the process of being constructed.

The postwar period, in which psychoanalysts were faced with the problem of early psychopathologies, renewed interest in observation. René Spitz and John Bowlby, borrowing their methods from genetic psychology and ethology respectively, proposed new developmental models focused on, respectively, the concept of organizers of the ego and attachment theory. An important research trend then developed, mainly in the United States, that interpreted the baby’s nonverbal behaviors as genuine mental acts. Her work informed by the theories both Klein and Wilfred Bion, the British investigator Esther Bick, in “Notes on Infant Observation in Psycho-Analytic Training” (1964), for her part upheld the idea that the infant’s mental life unfolds in a projective mode that must be contained by psychic structures that are sufficiently developed to support the emergence of the processes of introjection. Originally conceived as a contribution to the training of child psychotherapists and psychoanalysts, this method has been extended to other objectives: research on the beginnings of the infant’s mental and relational life, prevention and treatment techniques used in families and in various institutional settings (treatment and other centers for young children, nurseries, neonatal care services).

From an epistemological point of view, Didier Houzel (1997) underscored the difference between an ethological approach and observation that he characterized as psychoanalytical, which sticks to the

proposed framework both internally (coming as close as possible to the baby's somatopsychic experiences) and externally (type of contract established with the family, means used by the various parties to abide by or transgress the conditions, and finally the observer's capacity for empathy). Observation thus takes place in two stages: encounter with the subject, and the deferred working-over of transference and counter-transference material.

## **INFANT OBSERVATION (THERAPEUTIC)**

The method of observing the infant in its family environment, from birth to age two, using the rigor of the analytic framework, was conceived by Esther Bick. The observer visits the infant at home for one hour once each week and maintains a strict neutrality. The field of observation is the relationship that is established between the baby and its mother, within the context of the transference instituted between the mother and the observer, and between the mother and her baby. The objective is training the observer in analytic work rather than the fabrication of an instrument for research. This method, used for the training of psychoanalysts and childhood specialists, later proved to be a remarkable tool for early treatment.

In 1948, at the request of John Bowlby, Bick developed a method of infant observation in a family context. As Bick explained in “Notes on Infant Observation in Psycho-Analytic Training” (1964), the aim

was to provide an opportunity for practical experience as a part of first-year training for therapists at the Tavistock Clinic.

In 1963, Bick presented her method of observation to the British Psychoanalytical Society (BPS). A consensus was established among the various English schools that this method would be integrated into the first-year curriculum; the attentive observation of an infant's development enables the future analyst to live out a number of fundamental emotional experiences, then to think them through within the framework of the work group. It was Sigmund Freud's grandson, W. Ernest Freud—the “child playing with the spool”—who promoted this method for therapists at the Anna Freud Center, as he related in “Infant Observation: Its Relevance to Psychoanalytic Training.” (1975). Bick's method of observation is a part of analytic training within the Spanish and Belgian psychoanalytic societies. Bick herself recommended training in this method for all categories of professionals involved in children's mental health.

In France, André Green strongly opposed the use of direct observation, noting in “Entretien avec Pierre Geissmann à propos de l'observation des bébés” (1992; Interview with Pierre Geissmann on infant observation) that it carries the risk of externalizing psychic life and confusing the infantile with the actual infant, which runs contrary to the work of representation and the spirit of psychoanalysis.

Bick's method was a conceptual innovation, described as “a stroke of genius” by Martha Harris. It is a precise technique used in a fixed framework, whose goal is the training of the analyst. The observer must be able to find a space within the family that is sufficiently neutral, yet not rigid, to enable him or her to experience the emotional impact of the baby's presence, without taking action. He or she must come unburdened by theoretical preconceptions, and be receptive without interfering. After the observation, the observer writes a report that conveys his or her experiences to a work group, which keeps an eye on methodological ethics and helps to make sense of the observed material. Observing a baby presupposes an ability to identify with the different points of view of family members; this flexibility makes it a sound preparation for analytic work. Through the analysis of his or her countertransference in relation to both the mother and what he or she feels from the baby, the observer can understand the impact of the mother's

fantasies on the baby's mental space and perceive the manner in which the baby responds to this. Thus, the specific type of affective and counter-transferential opening up inherent in observation makes it an aid to the development of the future analyst's capacities for free-floating attention.

The observer's presence is a source for change. It often has beneficial effects for most families: helping the mother emerge from postpartum depression, developing the parents' attention-giving abilities, modulating the effects of repetition of the mother's past on the baby. Bick's method opened the way for new therapeutic possibilities. Infant observation in day-care facilities, hospitals, and in the home has been developed to sensitize staff, as a preventive measure against early disorders, and with a view to therapeutic intervention in cases of autistic or psychotic pathologies.

In day-care facilities, the main indicators for setting up observation are:

- Mental dysfunction in the mother. The containing effects of observation serve as a protective shield and allow for a reshaping of the imagos;
- Children who have to be entrusted to a series of foster care situations owing to inadequacies on the part of the parents can benefit from the presence of an observer who follows them from one place to the next;
- When a child has a disability that is traumatic for the parents. The observer tries to get them to recognize the child's performances and the support he or she needs;
- Early autistic or psychotic disorders. The observer serves as a support for child-raising and the parents. He or she identifies the sources of suffering, defense mechanisms, and factors that hinder the child's development, and helps to improve the family's responses in the form of caregiving and listening skills.

In hospitals, in obstetrics wards and neonatal intensive care units, attention given to the baby, especially when he or she seems to be disorganized, enables both medical providers and parents to "think" the baby, to find meaning in interactions, and to avoid functional repetition.

Observation is a remarkable tool for prevention and treatment. It is an aid to the baby, who is helpless

in the face of its intense anxieties, to the mother in need of solicitude, and to other caregivers.

## **INFANTILE AMNESIA**

Infantile amnesia results from the repression of childhood polymorphous sexuality and the oedipal complex during the latency period. It constitutes a reference point and a model for subsequent (especially hysterical) amnesias and repressions. It "hides the earliest beginnings" of our lives "up to the sixth or eighth year" even though we have "good reason to believe that there is no period at which the capacity of receiving and reproducing impressions is greater than precisely during the years of childhood" (Freud, Sigmund 1905d, p. 174–175).

The notion of amnesia is defined by Freud in his *Three Essays on the Theory of Sexuality* (1905d), when he develops his conception of infantile sexuality. Having conceived since 1895 of the notion of hysterical amnesia, he now acknowledges an amnesia bearing upon the first six to eight years of life, contrasting with the capacity of the child's memory and its ability to register impressions. The infantile impressions falling under this amnesia constitute the reference point and model for later amnesias in the adult, helped into being by the

preexistence of a repressed that attracts to itself any elements of the subject's current life that resemble it.

Freud compares infantile amnesia to the hysterical amnesia of adults and suggests that in both cases the process would consist "in a simple withholding of these impressions from consciousness, viz., in their repression" (1905d, p. 175). That withheld from consciousness (repressed) includes infantile sexuality, defined as "polymorphous perversity," which thus allows Freud to say that "neurosis is the negative of perversion." This formulation could be attributed to a belief that the lifting of amnesia (hysterical and infantile) would permit the subject to follow in a reverse direction the path that leads from a childhood that did not endure censorship to neurosis. But Freud came to distinguish between a lifting of amnesia and a true lifting of repression in "Remembering, Repeating and Working-Through" (1914g). In "Constructions in Analysis" (1937d), this belief came up against the idea of sexuality as structurally linked to anxiety through the effects of the death drive.

The sexuality of the neurotic preserves important pregenital infantile traits. The hysteric refuses the perverse dimension of these traits all the more so since the child that they once were had already refused them during the latency period. Infantile amnesia creates for everybody a kind of "enigmatic prehistory." The infantile prehistory finds the infant, who is just beginning to speak, imbued with primal fantasies that become the object of a radical amnesia, primal repression. In the *Three Essays on the Theory of Sexuality*, this is not specifically a question of the Oedipus complex; however, it much be understood that infantile amnesia bears upon the entire "polymorphously perverse infantile sexuality/Oedipus complex," the oedipal conflict in turn reinforcing the censorship of infantile sexuality.

It is notable that Freud theorizes infantile amnesia moreover starting from the observation of children outside the analytic setting rather than from adults recalling their childhoods in analysis. Infantile amnesia covers over the mnemonic traces of childhood, about which Freud says in *The Interpretation of Dreams* (1900a) that they are "outside of time" and "indestructible," which would tend to define all unconscious psychic life as infantile in its essence, on the condition that what is psychically infantile be distinguished from the real infant.

## INFANTILE NEUROSIS

A psychogenic mental disorder, infantile neurosis manifests expresses a psychic conflict that has been symbolically noted in the subject's early childhood. The term is used to designate either a disorder characterized by neurotic pathology, with variable prognostications, or a transference neurosis, constituting the prolegomenon of adult mental problems. Infantile neurosis is organized in terms of a dependency model. This results in counter-transference reactions on the part of the adult, which can be dangerous for the future development of the child, especially if the adult concerned remains oblivious to such a possibility.

"Little Hans" was treated by his father, who was in turn "supervised" by Freud. Freud himself only saw this five-year-old boy twice. Hans suffered from a phobia that prevented him from any activity, a fear that arose from having seen a horse fall on the ramp at the Vienna railroad station. When Freud saw Hans again as an adult, his parents had separated and he had drawn closer to his father. He did not recognize Freud, and he did not appear to be very healthy mentally. The son of a musician, by the end of his professional life he was director of the Geneva Opera, but his career left few traces. About all that is known about him is that he was interested in Wagner's Ring Cycle, that he staged the story of Brunhilde and Wotan, and that he was particularly taken with Siegfried's search for a mother in Brunhilde.

One might therefore agree with Jean Bergeret, who argued that this boy had a phobia linked to the his father's relations with his wife, who had been analyzed by Freud. Freud perhaps knew too much about this family's secrets. Despite the appearance of having been cured of his phobia through Freud's work of interpre-

tation, Hans suffered from a neurosis that certainly inhibited his creativity.

The cases of the “Wolf Man” and the “Rat Man” published by Freud have been the object of extensive commentary. The Wolf Man, Sergei Pankejeff, suffered from an infantile neurosis. Freud concentrated on describing the key fantasy of observing the coitus of the parents, especially in the context of the dream of wolves. In this nightmare, the patient saw immobile wolves, sitting on the branches of a tree and staring at him. Eventually the Wolf Man was declared to be psychotic. He died at the psychiatric hospital of Vienna after a number of psychotic episodes, which were treated by students of Freud. At the end of his life the Wolf Man said terrible things about Freud to a Viennese journalist. However, he had been supported by psychoanalysts, who purchased paintings in which he depicted his dream.

In fact, it was on the basis of this dream that Freud had decided to study the primal scene. He wanted to determine if the wolves that observed Pankejeff were placed in a situation opposite to the real one, when, as a child, he witnessed his parents making love. It seems probable that the coitus *a tergo* of animals had been attributed by the child to humans.

It is known that the Wolf Man had made the rounds of psychiatric services in Germany, ending up with Freud after seeing many other doctors. After he was financially ruined during the Russian Revolution, he married one of his nurses in Vienna. She was somewhat able to contain his madness. It is understandable that this man, who had paranoid tendencies, but was also persecuted in reality, would try to protect himself through various fantasies. But he needed to renounce them in order to find some peace and be able to return to a more normal life.

The Rat Man, who died during World War I, was traumatized in his childhood by his relations with the nurses who raised him and who had pathological sexual experiences with him. As an adult he suffered from an obsessional neurosis; many notes about Freud were found with him; and once in the course of a transference he attempted to transform Anna Freud into one of his nurses, insulting her constantly.

Neurotic symptoms in childhood do not necessarily lead to adult neuroses. In the adult, the existence of neurotic symptoms can mask an underlying psychotic structure. Furthermore, the study of the evolution of

certain cases of autism treated by psychoanalysis demonstrates frequent obsessional masking of psychoses, as is also the case in serious obsessional neuroses in children.

In Serge Lebovici’s report on the relation between infantile neurosis and transference neurosis presented to the Congrès des psychoanalystes de langue française des pays romans, he recalled Anna Freud’s theory that normal neurotic symptoms were a sign of good psychic health in a child during the oedipal phase: the repression of the drive is generally insufficient at that time, and thus transitory neurotic symptoms will arise. It has been demonstrated that the absence normal infantile neurosis is a sign of a predisposition to psychoses. However, subsequently Lebovici considered that his exposé should have been slightly rectified: normal infantile neurosis is also a sign of a solid narcissism, linked to a narcissistic cathexis with “His Majesty the Baby” on the part of his parents, who structure the ego of the child. The organization of intersubjectivity demonstrates the importance of family relations to the psychic life of the child. The kinship system accords a huge place to the imagined child, that is to say, to the imaginary and phantasmic child of the mother. This is contemporaneous with the child’s proto-representations. This ensemble communicates the presence of phantasmic interactions and also shows the importance of the role of the child in the psychic lives of the parents.

When this double process is satisfactory, the intergenerational transmission results in a solid and flexible ego. However, when there are “ghosts in the nursery” (Selma Fraiberg), this double process fails and the cultural constitution of filiation becomes impossible, illustrating the importance of studying the early interactive stage. But this work comes up against various obstacles that are not oedipal.

The triangulation process starts relatively early. It is preceded by a triadic arrangement, in the course of which the father and mother, in present-day society, play a specific role, allowing one to predict of the possible outcomes of triangulation. In the dull repetition of interactions, certain events are fundamental to the reconstitution of the interaction: they are “spoken backwards”—that is to say, they become truly significant events.

This perspective give understanding of the specific incidents in upbringing that demonstrate the modalities of the transmission of attachment, as

John Bowlby anticipated them. Mary Ainsworth has described this kind of attachment as the “strange situation,” transmitted according to genetic rules. The mechanisms of transmission in the adult follow the principle of a genetic transmission (Mary Main). Peter Fonagy has built on this idea, considering that children forced to deal with insecure transmission would benefit from a psychotherapeutic approach, which can modify the givens of this genetic transmission, as can be observed in thirty percent of cases. Studies on narration seem to confirm that episodic memory inscribes these givens, emphasizing the importance of the “proto-narrative envelopes” described by Daniel Stern.

## **INFANTILE OMNIPOTENCE**

The sense of omnipotence that arises in the fundamental misapprehension of reality which is central to the period of primary narcissism, during which the infant hallucinates its original love-object, persists into childhood and is found among prehistoric and preliterate

peoples who overestimate the power of wishful thinking and the real-world effect of psychic acts. Infantile omnipotence is also a feature of obsessional pathology, in which it appears as superstitious or magical thinking; in psychosis, as delusions of grandeur; and, finally and to a lesser extent, in creative people who are able to momentarily escape reality and manipulate a world of fantasy. Sigmund Freud treated the concept of omnipotent thinking at length through investigations of primitive peoples and their beliefs in telepathic and animistic thought, and also through pathologies such as obsessional neurosis and psychotic megalomania.

Although Freud did not discuss it in these terms, narcissistic regression in sleep may be viewed as putting the dreamer in a situation typical of infantile omnipotence, able to realize frustrated desires of the previous day and, on a deeper level, to fulfill repressed wishes. Dreams revive the earliest situation of the nursing infant who seeks to re-experience satisfaction through primary process thinking—that is, to use hallucination to short-circuit reality. Perceptual identity is achieved by means that are rapid, regressive, and interior to the psychic apparatus. “It was only,” wrote Freud, “the non-occurrence of the expected satisfaction, the disappointment experienced, that led to the abandonment of this attempt at satisfaction by means of hallucination” (1911b, p. 219). Omnipotence in this sense is essentially indistinguishable from the capacity of the psychic apparatus to ignore reality and has universal purchase as an archaic function of the psyche.

For the child, learning the limitations that the reality principle imposes on the pleasure principle is in effect a limitation on its sense of omnipotence. However, as Melanie Klein (1921 [1919]) noted, the child's sense of omnipotence is also tied to that which it endows its parents and with which it identifies. Reality opposes it in either case. The “decline of the omnipotence-feeling that is brought about by the impulse to diminish parental perfection (which certainly assists in establishing the limits of his own as well as of their power) in turn influences the impairment of authority, so that an interaction, a reciprocal support would exist between the impairment of authority and the weakening of the omnipotence-feeling” (p. 17). In her view, the child's experience of omnipotence as increasing or diminishing will determine whether he or she will become bold and optimistic or fearful and pessimistic. However, she added: “For the result of development

not to be boundless utopianism and phantasy but optimism, a timely correction must be administered by thought" (p. 24). A compromise thus emerges between the pleasure principle that regulates wishes and fantasies and the area in which the reality principle prevails in the sphere of thoughts and established facts.

Donald W. Winnicott showed how the young child's mental activity can transform a "good-enough" environment into perfect surroundings. This transformation is necessary for object constancy not to be disturbed. By contrast, a defective environment is harmful because faulty adaptation overwhelms the psyche-soma of the young child and prematurely forces it out of its narcissistic universe. In terms of the illusion of creating the object and what he calls "transitional objects," Winnicott (1952) wrote: "We allow the infant this madness, and only gradually ask for a clear distinguishing between the subjective and that which is capable of objective or scientific proof. We adults use the arts and religion for the off-moments which we all need in the course of reality-testing and reality-acceptance" (p. 224).

Omnipotence does not disappear as childhood ends, but it delimits itself to specific areas and coexists with the recognition that reality imposes limitations upon it. Literary fiction and especially Romanesque adventure permits safe enjoyment of omnipotence through all manner of imagined danger. "It seems to me, however," wrote Freud (1908a), "that through this revealing characteristic of invulnerability we can immediately recognize His Majesty the Ego, the hero alike of every day-dream and of every story" (1908a, p. 150). Moreover, parents transmit omnipotence to the child inasmuch as "they are inclined to suspend in the child's favour the operation of all the cultural acquisitions which their own narcissism has been forced to respect, and to renew on his behalf the claims to privileges which were long ago given up by themselves... Illness, death, renunciation of enjoyment, restrictions on his own will, shall not touch him; the laws of nature and of society shall be abrogated in his favour; he shall once more really be the centre and core of creation—'His Majesty the Baby', as we once fancied ourselves" (1914c, p. 19).

## INFANTILE PSYCHOSIS

Infantile psychosis has recently been replacing the notion of infantile schizophrenia. Infantile psychosis can be defined as precociously pathological organization that develops out of the integration of the earliest relations. Later forms of exteriorization can also be manifested in childhood. The age at the first outbreak, the greater or lesser stability of the supports of equilibrium that are constituted, and the nature of the defense mechanisms have significant repercussions on the risk and incidence of later negative developments.

The principal psychic mechanisms at work lie somewhere between the neurosis-psychosis opposition, posed by Freud, and the Kleinian theory of fantasy and the precocious Oedipus: the predominance of projection and projective identification, the fusion between real and imaginary, with infiltration of primal shattering fears, direct instinctual expression and the search for satisfaction by the shortest way, principally in the register of oral drives.

Clinical polymorphism, the absence of pathognomonic signs, and the failure of any common etiology of pathogenesis all characterize the category of the infantile psychoses in child psychiatry. Psychosis is diagnosed on the basis of the seriousness of perturbations, their atypical quality and their duration, in the context of various presenting symptoms—such as behavior problems, compromising of intellectual efficiency and functioning, retardation and/or language anomalies, expressions of great anxiety, sleep, eating, and sphincter conduit disorders; and in rare cases delirium and hallucinations. In terms of occurrence, a clear distinction has been established between schizophrenia that is declared in adolescence, without as much variety in the forms it takes, and the child schizophrenics who present more individualized particularities.

In the *Diagnostic and Statistical Manual of Mental Disorders (DSM)* of the American Psychiatric Association, psychoses are not listed as a disorder nosology, but rather placed under the rubric of “general developmental disorders” among which figures infantile autism. The overall “a-theoretical” cast of the ensemble and its descriptive corollaries suggest an organogenic and negative conception of psychosis, implying interventions that consist principally in reeducation.

Until the beginning of the twentieth century, this dominant understanding of infantile psychoses was still borrowed in large measure from that of nineteenth-century psychiatry; advocating medical pedagogical treatment (Bourneville, Seguin, Vallee), as well as psychometric approaches (Binet, Simon). Backwardness, states of idiocy and insanity, and their anatomical-clinical correlations in etiological matters were some characteristics of the dominant conception.

A threefold transformation of thought then contributed to the emergence of infantile psychoses:

- the application to ever younger children of models coming from advances in adult psychiatry and psychoanalysis;
- the rejection of these adulto-morphic models, as clinicians took account of the specificities of children;
- the gradual passing of the hypothesis of homogeneity, and the recognition of the heterogeneity of clinical tableaux and their underlying conditions.

Wilhelm Weygandt, Emil Kraepelin himself, and especially Sancte de Sanctis in 1908 with “*dementia praecox*,” described the infantile forms of early insanity. Yet all of this was merely followed the Kraepelinian model of the child. With the introduction by Eugen Bleuler of the category of schizophrenics (1911), the emphasis shifted from dementia to the dissociation of psychic functions (“*Spaltung*”). Among disorders called secondary—“responses of the sick soul”—was the hermetic isolation of “autism,” a term coined by Bleuler by subtracting “eros” from the Freudian notion of autoeroticism.

This new dynamic approach progressively influenced studies of children. From the thirties, in the United States (Charles Bradley, Howard Potter) and Europe (Georges Heuyer, Jacob Lutz, Léon Michaux), the notion of infantile schizophrenia, an autonomous endogenic illness resulting in a dramatic alteration in the developmental curve, became a familiar one. For Lutz, it was strictly opposed to organic and encephalopathic madness, or to gradually developing retardation. An overall conception of the malady was enlarged to include different clinical types and an approach to intra-familial relations. The work of Melanie Klein and her treatment of psychotic, even autistic children (cases of Dick, 1930; Erna, 1932) was especially influential, and took place well before the descriptions of precocious infantile autism by Leo Kanner (1943) and of symbiotic psychosis by Margaret Mahler (1952).

The emergence of the concept of infantile psychosis first in the United States, then in Europe, from the end of the 1940s is linked to several factors:

- the dissemination of psychoanalytic works relative to children and concerning early development: Melanie Klein, already mentioned, Anna Freud, René Spitz, Donald Winnicott;
- a progressive disengagement from any etiological presupposition;
- a challenge to the notion of dementia as an endogenous condition with ineluctable processes which had been itself a factor in negative prognoses.

Post-Kleinian authors in Great Britain attempted to make further progress in investigating the origins of thought and its disorders: Herbert Rosenfeld located the role of projective identification in the psychotic process; Wilfred Bion stressed the impact of

destructive drives against activities of liaison, perception, and attention, while describing a normal projective identification; Hanna Segal developed the notion of “symbolic equation” in schizophrenia, where the symbol is confused with the thing it symbolizes.

In France, after the early work of theorization of Serge Lebovici, René Diatkine, Conrad Stein, and Denise Kalmanson came up with a comprehensive psychological profile of infantile psychoses. The contributions of Roger Misès and Jean-Louis Lang should also be emphasized as having illuminated the rapport between psychoses and flaws in organic constitution. While the neurosis-psychosis opposition still maintains considerable heuristic value, the complexity and flexibility of the child’s systems have resulted in proposing the concepts of pre-psychosis, developmental disharmony, and para-psychosis.

The British school, through Donald Meltzer, proceeded to a synthesis of the Kleinian concepts in the very unfolding of the psychoanalytic process in the child (1948) and the observation of stages of psychic growth and of “dimensionality.” Esther Bick’s insight into a primal mode of narcissistic identification, “adhesive identification” (1968), extended the hypothesis formulated by Winnicott of premature traumatic separation and psychotic depression. Subsequently, Frances Tustin developed an original conceptualization of autistic defense mechanisms, distinguishing “shell states” (autisms) from “confusable states” (schizophrenias), where there has been access to tridimensionality. Finally, the study of the competencies of the infant, coupled with direct observation as well as the notions of interactional epigenesis and phantasmic interactions (Lebovici, 1983), posed the problem of the consistency of psychoanalysis with new models of premature dysfunctions (Didier Houzel, Bertrand Cramer). The idea that the baby creates the mother as much as she creates the baby has contributed to reflection on the access to maternity (Racamier, 1979) and on the role maternal depression plays in the psychotic process.

Leo Kanner described early infantile autism (1943), and he deduced it from the Bleulerian concept of the autism of schizophrenia. It was then applied to the “extreme autistic solitude” manifested from the start of life beginning in certain children. However, the question of whether this is a special category, in spite of Kanner’s integration of it in the general framework of infantile psychoses, remains unresolved. The especially

rigid homeostasis of their constitution locates these children in the register of the unchangeable, capable of no effect of projection, action or possession. A line can be drawn here between autism and infantile psychoses. Because the autistic system is relatively unstable, future development, once a major breakdown has been avoided, will include passage by “symbiotic” madness. Some authors, however, see in this a confirmation of the developmental continuity of various forms of child psychosis.

Described by Margaret Mahler in the child of two to four years of age, “symbiotic psychosis” is based on a primal indistinction between the psyche of the baby and that of the mother, and on a regression to this state of “symbiosis.” Psychosis involves the tentative restitution of the mania of omnipotent fusion with the mother’s image. Marked by ambivalence, its symptomatology includes a loss of functional skills and major manifestations of disturbance at the prospect of a separation from corporeal contact. Its onset is connected with maturation of the functions of the ego and the unconscious mobility of parental cathexes. A manifestly pathological “symbiotic” upsetting of equilibrium, a result of separation or sudden loss, can result in a secondary autistic condition.

Other early developmental disharmonies, psychotic in structure and composite clinical articulation, have been described. One consideration is that psychoses that are externalized later, from the age of four-to-five to puberty, can be seen as evolving adjustments to these early forms, and in continuity with them. On the other hand, without underestimating the significance of unrecognized fault lines, they surface in children who seem safe from them. Clinical configurations correspond to variable classifications of the signs of a need for help, polymorphic in nature, as has been mentioned above. Pseudo-neurotic (phobias, obsessions) and pseudo-maladjustment forms should be remarked, as well as complex motor or instrumental disorders, and some school failures, where psychosis is a factor.

The ensemble of these theories, not excluding neurobiological, environmental, and historical factors, tends to be situated outside of linear reductive causality. For René Diatkine, the understanding of psychopathology necessitates a reflection on the etiology of “normalcy.” From the time of *The Interpretation of Dreams* (1900a), the Freudian hypothesis of the hallucinatory return of the experience of satisfaction linked

normal development and psychotic functioning. Melanie Klein, in her description of the precocious Oedipus and schizoid-paranoid and depressive positions, situated “early psychotic stages” as potentialities in any human being. Infantile psychoses were the result of fixation at this early pre-psychotic phase, in which splitting, introjection, and projection dominate. They signify the failure of the depressive phase central to the second six months of life, when the child is faced with persecutory anxieties of annihilation. Projective identification, with its dimension of aggressive intrusion into the body of the mother to control her from the inside, was the key to narcissistic object relations of the schizoid-paranoid position. However, Melanie Klein has been criticized for using metaphors borrowed from psychopathology to describe the general organization of the psyche—as well as for the absence of a clear conceptual opposition between neurosis and psychosis.

Serge Lebovici and René Diatkine are of the opinion that the ensemble of psychic functioning and the economic equilibrium between different systems are what permits the differentiation of every form of psychic organization with regard to the “treatment” of projective identification. Consequently, according to Diatkine, “the optimal form of development of the pre-Oedipean organization” could be represented “as an interaction between two psychotic positions (schizoid-paranoid and depressive positions)” (1955) which is similar to some of Bion’s formulations. Psychosis would correspond to the relative primacy of the primal processes in the lowering of tensions and the reestablishment of economic equilibrium, a condition of psychic continuity. The tendency toward repetition of this primacy is what is pathognomonic. Cathexis and meaning would be established, consequently, accorded to a “primal” logic, without suppression of secondary processes. René Diatkine emphasized the crisis, decisive for psychic development, leading to the installation of the object in the second six months of life. The presence/absence opposition assumes qualitative significance, and the maternal object, lost by definition as soon as constituted, is cathected ambivalently. The working through of the ambivalence is crucial, the object of love and hate being doubly inscribed, internally and externally. Symbiotic psychosis corresponds to the impossibility of working-through, a consequence of serious perturbations in the earliest exchanges: painful representation becomes

non-representation. The environment can contribute to the stabilization of this pathological equilibrium or it can favor the constructive recapture of mental representations. Projective identification, which becomes very significant when introjection organizes desire permanently in the depressive position, allows the loved object to be spared by addressing itself to a third party. This primal triangulation is the jumping off point of the oedipean constitution, as in Kleinian formulations. For Wilfred R. Bion, projected hatred and envy become so intense, in the pathological projective identification, that the identificatory object, unable to contain and work through them, is experienced as a “superego,” crushing and destructive of the capacities of psychic development. The inversion of the alpha function necessary for the assimilation of emotional experiences results in catastrophic hallucinations and anxieties.

Donald W. Winnicott regarded failures of the early processes of illusion-disillusion, shared between the mother and the child, as the source of the psychosis centered on phases of the formation of “the continuous feeling of existence.” The lack of access to a “primal maternal preoccupation” (1965) would deprive the subject of an essential early period of illusion. For Wilfred Bion, this particular maternal phase can be considered from the point of view of a mutual projective relation of identification between the mother and the baby, reintroducing the role of the object and the environment into Kleinian theories. The containing and working-through capacities of the mother are what soothe the persecutory anxiety of the child (“capacity for maternal reverie”).

Lacanian theorization relative to infantile psychoses were developed on the basis of the concepts of the foreclosure (the “*Verwerfung*” of Freud) of the Name-of-the-Father and of the mirror stage as “formative of the function of the I.” The foreclosed signifiers, outside of symbolization, return to the heart of the Real in hallucination. The mirror phase, between six and eighteen months, marks the first version of an ego in the experience of a primal identification, anticipating a corporal unity. For Maud Mannoni, psychoses are inscribed in the maternal unconscious, with the psychotic child being unrecognized as a desiring subject, excluded from access to oedipean triangulation, and frozen as partial object subjected to maternal omnipotence. Finally, Piera Aulagnier’s notion of the “imaginary body of the child” should be mentioned. This

introduces an imaginary working through by the mother, prior to birth and anticipating the libidinal cathexis of the baby. The pictographic representation of the complementary object zone, attached to the primal process, bears witness to the disjunctive ruptures of corporal space in psychosis.

In summary, it can be affirmed that, in clinical practice, psychotic polarity is represented by projective expansion, immediate hallucinatory satisfaction and disorganization, whereas neurotic polarity is represented by the efficacy of symbolic transmission, the multiplication of liaisons, and the capacity to differentiate and work through.

A desirable early psychoanalytic treatment, extended in time, in the context of flexible institutional guidelines, should go along with a recognition of the different levels, perceptible but unpredictable, of psychic functioning of patients, as well as of related family circumstances.

## INFANTILE SCHIZOPHRENIA

The French classification of childhood and adolescent mental disorders describes two psychoses under two rubrics: childhood-onset psychoses of the schizophrenic type and adolescence-onset psychoses of the schizophrenic type.

Nineteenth-century child psychiatry, it can be assumed, followed the models proposed by adult psychiatry. Valentin Magnan applied the adult psychiatric theory of degeneration to children. In the same vein, Ernest Dupré applied the theory of constitutions to children. Later, various authors described clinical cases of children that showed obvious adult forms of schizophrenia. Thus, in 1905 Sancte de Sanctis described *dementia præcocissima* on analogy with *dementia præcox*. In 1888 Jacques-Joseph Moreau de Tours wrote the first treatise on child psychiatry, *La folie chez l'enfant* (Madness in children). A year earlier, Hermann Emminghaus demonstrated that the description of mental illness in children should be separated from descriptions of adult mental illness.

In 1908 Theodore Heller described *dementia infantilis*, a clinical group of several illnesses generally of neurological origin with various components. At the First International Congress on Child Psychiatry, held in Paris in 1937, Lutz was the first to use the notion of infantile schizophrenia, of which he made a critical study. According to him, there are very few such cases. His presentation was supported by Georges Heuyer. Already English-speaking authors had extended the concept of infantile schizophrenia to cover everything in current practice conventionally referred to as “childhood

psychoses.” In 1943 Leo Kanner proposed isolating a particular morbid illness under the term “infantile autism.” This particular psychosis does not evolve toward schizophrenia. As a matter of practice, institutions that treat children do not admit the notion of schizophrenia, while the concept of autism is very widespread.

French psychiatry has described prepsychotic and parapsychotic states that evolve toward a state of disintegration accompanied by mental retardation and that can appear analogous to certain schizophrenic states in adults. In English-speaking countries, especially in institutions following the American classification in the *Diagnostic and Statistical Manual of Mental Disorders (DSM-IV)*, the notion of psychosis has disappeared and been replaced by the concepts of autism and of pervasive developmental disorders. Some of the latter disorders may develop into schizophrenia. In German psychiatry, which long maintained its influence over the Soviet and Eastern Bloc countries, childhood autism has long been described as an initial form of schizophrenia, with development into schizophrenia more or less inevitable.

Schizophrenia that begins during adolescence will not be treated here, for it is generally at this age that symptoms of schizophrenia are first manifested. Many authors believe that schizophrenic adolescents, who are often extremely intelligent, already had bizarre behavioral problems in childhood. Most authors, however, believe that schizophrenia appears in the young adult out of the clear blue sky. In conformity with this view, the World Health Organization’s *International Classification of Diseases (ICD-10)*, “Classification of Mental and Behavioral Disorders” lists autism and childhood disintegrative disorder, but not infantile schizophrenia. Lastly, Roger Misès has described childhood borderline pathologies, within which he included states that may develop into schizophrenia. He sees this as a failure of the development of narcissism. Although it is possible to invoke some cases of infantile autism that have unquestionably evolved in the direction of schizophrenic states, the onset of schizophrenia during the latency period is altogether exceptional.

Psychiatric morbidity in children whose parents suffer from mental disorders is significant. However, these disorders are usually neuroses. When one parent is schizophrenic, the child has a 20 percent chance of being schizophrenic, whereas the rate is only 3 percent when neither parent is schizophrenic. Children adopted by parents listed on the schizophrenic register

are more likely to be psychotic than those who are apparently the children of schizophrenics. These studies, carried out in Chicago and in the Scandinavian countries, seem to be more probing than research involving identical twins.

Some serious neurotic states, especially obsessive-compulsive disorders, may be a neuroticization of certain childhood and adult psychoses. This is what Joyce McDougall and Serge Lebovici described in *Un cas de psychose infantile (A case of infantile psychosis; 1960)*. They describe the case of a child whose analysis was stopped by his parents. The parents wanted to place the boy in the care of Bruno Bettelheim. The mother of this boy said the boy was suicidal, and the boy, according to his father, became a “homosexual schizophrenic” who was among “the wealthiest Americans.” At the end of his analysis, the boy would make sure that the subway had indeed stopped in each station and would go down to check its exact position. The neuroticization of his “schizophrenia” thus led to an obsession with checking that impeded subway trains from leaving the station.

It is legitimate to wonder whether true obsessional neuroses that appear from the latency period on are not preschizophrenic. Generally, very bizarre obsessions are involved, as in the case of a boy who wanted to make certain that falling snow made no sound. These obsessional neuroses are not mild schizophrenias that have already led to a degree of defensive obsessive behavior. In adulthood, schizophrenic decompensations can emerge, as in one case of traumatic schizophrenia in a preadolescent girl who saw her sister, caught in the eddying currents of the Loire River, drown. She first blamed herself, in the manner of a delusional melancholic, then became schizophrenic.

Clearly, as these few cases show, infantile schizophrenia is rare.

## INFANTILE SEXUAL CURIOSITY

Infantile sexual curiosity must be distinguished from the “investigative drive” in that the former directly cathects sexuality. Secondarily, it can stimulate the activity of the latter, which is also directed at non-sexual objects and gives rise to theories (infantile sexual theories). For Freud, in fact, the investigative drive is “awoken” (*geweckt*) by sexual curiosity, which responds to the “selfish” interest of self-protection from the birth of younger siblings.

Sexual curiosity initially involves an interest in seeing the genital organs and sexual relations (scopophilic drive). This visual pleasure can develop into voyeurism without necessarily leading to a sublimated cathexis of the enigma surrounding sexuality and of enigmas in general. Although sexual curiosity is linked to the investigative drive and constitutes the form in which it first emerges, the quest for the sight of an object of desire nevertheless continues to play a predominant role. It may be surprising that Freud should accord this preeminent position to sexual curiosity, to the extent of regarding it as the starting point of the child’s investigative activity, whereas in fact the child displays from the earliest months an all-consuming curiosity about everything that surrounds him.

In fact, this curiosity already differs from the scopophilic drive both through its choice of an absent object, the mother’s penis (cf. Little Hans, 1909b), as a preferred object and because it is not restricted to the pleasure of seeing but immediately develops into a need for self-comparison with the object being looked at (“The ego is always the standard by which one measures the external world,” 1909b, p. 107). Unlike the scopophilic drive, which can undergo a perverse development (voyeurism) or invent the absent object by remaining fixated on it (fetishism), sexual curiosity goes beyond this register by cathecting its enigmatic dimension. In this sense, it is already undergoing a sublimatory development, even if the investigation has not yet been formulated as an independent objective. The existence of an enigma presupposes the existence of a premonitory knowledge that is not necessarily possessed. In the “Wolf Man” case (1918b [1914]), concerning the primal scene, Freud hypothesizes that the understanding of the sexual process, as well as its meaning, is conceivable even at such an early age, if it is compared with the instinctive knowledge of animals (*instinktives Wissen*). This curiosity would then be the

disposition to cathect a scene of which the meaning is intuited, giving it an enigmatic quality. However, the value of the scene in question derives only from that which is not visible, that is to say its meaning, as distinct from what is directly perceived. Sexual curiosity differs from voyeuristic pleasure in the same way, as can be stated following Freud: “An advance in intellectuality consists in deciding against direct sense-perception in favour of what are known as the higher intellectual processes—that is, memories, reflections and inferences” (1939a, [1934–38], pp. 117–118).

Sexual curiosity (epistemophilia) was extensively discussed by Melanie Klein, who emphasized that it precedes the child’s understanding of language and, because of his immaturity, contributes a great deal of frustration and a sense of ignorance that reinforce the castration complex. Melanie Klein also emphasizes the connection of this curiosity with sadism and the anal-sadistic libidinal position, which makes the child want to appropriate the contents of the body and particularly the mother’s body, which is thought to possess the penis and the babies.

Sexual curiosity does not necessarily mean that the child is asking questions about sexuality. Rather, this seems in fact to be displaced, with the child posing innumerable, often stereotypical questions to which he does not appear to expect answers because they substitute for those questions that repression prevents him from asking and in regard to which alone he could be satisfied.

Infantile sexual curiosity, in its denied form (inhibition, disgust) or its obsessional form, plays an important role in infantile symptomatology. It has important consequences for learning at school (Klein, 1923). Freud takes this viewpoint a step further by considering the failure of infantile sexual curiosity as a paralyzing factor in later life: “The impression caused by this failure in the first attempt at intellectual independence appears to be of a lasting and deeply depressing kind” (1910c, p. 79).

## INFANTILE, THE

In *Au vif de l'infantile* (At the heart of the infantile; 1996), Florence Guignard wrote: “The basic structure at the fringes of our animality, the repository and container for our drives, libidinal or hateful as well as epistemophilic, the infantile is the ‘malleable’ alloy of the instinctual and structural that makes one oneself and not some other person. Irreducible and unique, and by those very qualities universal, the infantile is thus what enables our psyche to come into being, in all the developments of its psychic bisexuality organized by the Oedipus complex.”

The concept of the infantile was born with psychoanalysis in the sense that Sigmund Freud's discovery of infantile sexuality caused the observation of psychic phenomena to move from the level of consciousness to the level of the unconscious. Both the child one sees in reality and the childhood one remembers elicit reflection about processes of secundarization, and neither constitutes the specificity of the infantile as it is revealed within the psychoanalytic setting itself. It was by thinking about the psychic causality of pathological phenomena that Freud discovered the infantile origins of the neuroses, and later the psychoses. In this way, he established a bridge between the actual structures of the mind—that of the adult analysand, but also that of the child in analysis—and the ways these structures have been informed, through deferred action during an infantile period that is reconstructed in analysis. Dreams are what give the most direct access to the infantile layers of the psyche, since the latter are so deeply hidden by the processes of primary and secondary repression.

In “L'expérience du psychanalyste chez l'enfant et chez l'adulte devant de modèle de la névrose infantile et de la névrose de transfert” (The analyst's experience

with children and adults in terms of the models of infantile neurosis and transference neurosis; 1980) Serge Lebovici specified the organizing aspects of infantile neurosis as opposed to neurosis in children. The taking over of neurotic elaboration by infantile neurosis enables the adult analysand to develop a genuine transference neurosis. In this conception the capacity to develop a transference neurosis is based in the formation of bonding processes. The infantile is thus what expresses a stratum of mental life that is as inaccessible to consciousness as the unconscious material that resides in it, yet it serves as a nodal point that makes it possible to go back and forth between past and present.

In “L'enfant, l'infantile et la causalité psychique” (The child, the infantile, and psychic causality; 1994), Bernard Brusset uncoupled the infantile from the historical, thus differentiating between causal biography (that of the infantile) and reconstructed biography (that of the child). Thus the infantile can be assimilated into the unconscious (Agnès Oppenheimer), to the extent that the infantile is not observable, or that it is observable only in the form of reconstruction or deferred action. This view thus posits the infantile as a turning point in the reworking of primal fantasies.

Making the infantile that which is unconscious and unrepresentable opens the way for a rethinking of the work of psychoanalytic observation both of the adult and of the child by the adult: To be truly psychoanalytic, any observation must involve a dimension in which the infantile within the observer responds to the infantile of the person being observed. It is this transference/countertransference echo that means that one is no longer faced with the child, but rather the approach of the infantile. This involves putting into perspective both the child and the infantile within the adult, and recognizing, in the adult's “infantile” reaction, not the child he or she once was, since that child existed only for a time, but rather the infantile playing itself out within the child.

## INFERIORITY, FEELING OF

The term “feeling(s) of inferiority” refers to a group of representations and affects that reflect an individual's self-devaluation in relation to others. In *The Interpretation of Dreams* (1900), Sigmund Freud mentioned a dream marked by both feelings of inferiority and infantile omnipotence. The thematic content of this dream is explicitly anal, which is significant, since Freud later often returned to anal issues as forces that can have a positive or negative impact on self-esteem.

Freud addressed feelings of inferiority, notably, in his analyses of the cases of the Rat Man (1909d), Schreber (1911c), and the Wolf Man (1918b). He also took up this theme in his formulations on narcissism (1914c). But above all, he examined feelings of inferiority with especially keen insight within the framework of the oedipal complex. In his paper on a child's fantasy of being beaten (1919e), he wrote that this fantasy, as well as other, analogous perverse fixations, were “precipitates of the Oedipus complex, scars, so to say, . . . just as the notorious ‘sense of inferiority’ corresponds to a narcissistic scar of the same sort” (p. 193). Within the oedipal framework, the threat of castration that weighs upon the little boy distorts his self-esteem, and the absence of a penis leads the little girl to devalue herself. In both cases, feelings of inferiority are intimately linked to the guilt inherent in the oedipal drama. The loss of love of the object and the sense of rejection accentuate this feeling.

Freud revised these views when he formulated his structural theory of ego psychology. “There is always a feeling of triumph when something in the ego coincides with the ego ideal. And the sense of guilt (as well as the sense of inferiority) can also be understood as an expression of tension between the ego and the ego ideal,” Freud wrote in *Group Psychology and the Analysis of the Ego* (1921c, p. 131).

One can thus better understand why Freud so firmly opposed Alfred Adler when Adler wanted to make feelings of inferiority the keystone of his theoretical conceptions in *The Neurotic Constitution: Outlines*

*of a Comparative Individualistic Psychology and Psychotherapy* (1912/1926). In Freud's view, feelings of inferiority were a superficial manifestation—important in clinical work, to be sure, but understandable only within the framework of a more general metapsychology.

## INFERIORITY, FEELING OF (INDIVIDUAL PSYCHOLOGY)

As early as 1907 Alfred Adler considered the state of organic inferiority as a factor in neurosis before linking it to the newborn child's state of physiological immaturity. This state of inferiority is the source of the feeling of inferiority that persists throughout life: “Being a man means having a feeling of inferiority that constantly demands compensation” (1912/2002).

The life history of Alfred Adler, who suffered from rickets as a child, goes some way to explaining his insistence on the importance of the states of organic

inferiority at the root of the feeling of inferiority. He later observed the various modulations that the family and cultural environment, as well as the child's choices, introduced into this feeling, which he saw as a stimulant to psychic life. By way of compensation the child will elaborate a directing fiction representing an ideal being who has all the qualities that the child lacks, and will project itself into the future "in the shape of the father, mother, an older brother or sister, a schoolteacher, an animal or a God" (1912/2002). The gap between the self and the directing fiction is all the greater if the child has suffered frustrations or ill treatment and encounters no obstacles in its imaginary world.

Very early on this fiction will be adapted due to the influence of social and cultural factors and will express itself in the form of a counter-fiction (1912/2002). Psychic health is characterized by harmonious relations between the fiction and the counter-fiction, whereas the neurotic will remain under the control of the fiction, making an effort "to shine while acting modestly, to conquer while remaining humble and submissive, to humiliate others with his own apparent virtues, to disarm others with his passivity, to make others suffer through his own suffering, to pursue a virile goal with feminine means, to make himself small in order to seem big."

Compensation for an exacerbated feeling of inferiority can take the form of a superiority complex, the different manifestations of which Adler described in *The Neurotic Constitution*, whereas discouragement will take the form of an inferiority complex. In this case the subject will use neurotically rich symptoms to flee all situations that threaten its prestige, hence Adler's definition of neurosis: "An attempt to maintain the appearance of value at all costs, while desiring this goal without paying the price" (1930/1927).

Cultural influence manifests itself in the elaboration of the fiction through the choice of a model representing a virile ideal that leads to a mode of apperception that is in accordance with the opposition relation: masculine/dominant/superiority, feminine/defeated/inferiority. The social influence constitutes the correcting element that determines the feeling of inferiority. These two factors make up two lines of force that are present in the formation of the child's lifestyle, which can be compared to the program of perception and behavior with which the child complies unconsciously (1929/1964).

## INHIBITION

Sigmund Freud defined inhibition as "the expression of a restriction of an ego-function. A restriction of this kind can itself have very different causes." This definition appears in the opening pages of *Inhibitions, Symptoms and Anxiety* (1926d [1925]).

Analogizing from a medical definition of the concept ("restriction of an organ function") does not perfectly express the psychopathological specificity of the notion of inhibition. Thus when Freud states that the "ego-function of an organ is impaired if its erotogenicity—its sexual significance—is increased," (1926d [1925]) this mechanism, which is borrowed from the clinical psychoanalysis of hysteria, provides no psychopathological differentiation between the inhibition and the symptom.

In the same volume he also underlines the links between inhibition and the concept of anxiety: "Some inhibitions obviously represent a relinquishment of a function because its exercise would produce anxiety." In this way Freud tries to delineate the concept by comparing it with and distinguishing it from other notions that have been described by analytic theory, as indicated fairly clearly in the title of the work. Apart from the fact that they enable us to isolate a pure form of inhibition—"The libido may simply be turned away"—these efforts lead Freud to distinguish two types of inhibition "as a measure of precaution or

brought about as a result of an impoverishment of energy.” The study of these different mechanisms enables him to define the modalities of the opposition between inhibition and symptoms: unlike inhibition, “the symptom cannot any longer be described as a process that takes place within, or acts upon, the ego.”

This opposition makes it possible to define inhibition as a simple relinquishment at the level of the ego, where the symptom accomplishes a veritable compromise between the ego and the instinctual demands of the id. Freud offers an illustration of this in relation to the horse phobia in the case of Little Hans. In this case, “the inability to go out into the streets was an inhibition, a restriction which his ego had imposed on itself so as not to arouse the anxiety-symptom.” The phobic symptom cannot be described as such except when there has been “the replacement of his father by a horse. It is this displacement, then, which has a claim to be called a symptom.”

Emphasizing the fundamentally imaginary status of inhibition, Jacques Lacan reviewed his study in the seminar devoted to anxiety by opposing it to the notion of an act. The latter appears as a response of the subject forced to adopt a position in relation to its splitting. Unlike inhibition, the act “après-coup” inaugurates a new transformed subject: “Only action engenders certitude in the subject.” By means of this opposition, inhibition appears as an attempt on the part of the subject to defer an option, a choice to be made in relation to its desire. Like Freud’s dissatisfied tone in relation to the theories developed in *Inhibitions, Symptoms and Anxiety*, Lacan’s proposed extensions confirm the difficulties of apprehending the concept of inhibition but also its heuristic value.

## INHIBITIONS, SYMPTOMS, AND ANXIETY

*Inhibitions, Symptoms, and Anxiety* was published in German in 1926, a year after Freud’s famous article “Negation” (1925h) and “An Autobiographical Study” (1925d). Ernest Jones wrote that the work was written in July 1925, corrected in December, and then published in the third week of 1926 by Fisher Verlag of Frankfurt.

Concerning this work Sigmund Freud wrote, “It contains several new and important things, takes back and corrects many former conclusions, and in general is not good” (Jones, 1953–1957, vol. 3, p. 131). There were a number of “contradictions” in the translations, and it was not until 1936 that Alix Strachey finally produced a better translation, again according to the testimony of Ernest Jones, published by Hogarth Press in the “International Psycho-Analytical Library” series. In addition to Alix Strachey, “Freud had also given the translation rights to H. A. Bunker in New York without informing either translator of the other” (Jones, 1953–1957). At the same time a thirteenth edition of this text, lacking the passage about Alfred Adler and Carl Gustav Jung, was published in the *Encyclopaedia britannica* with a different title: “Psycho-Analysis: Freudian School” (1926f).

In any event, this was obviously an extremely important essay for the evolution of Freudian thought and should be seen, in large part, as a response to the ideas of Otto Rank in *The Trauma of Birth* (1929). As a curious side note, it is worth noting that when Freud was writing *Inhibitions, Symptoms, and Anxiety*, his daughter Anna was preparing “The Psychoanalytic Treatment of Children”; that is, while the father was investigating anxiety, separation anxiety in particular, his daughter was working on the distinction between child and adult psychoanalysis.

*Inhibitions, Symptoms, and Anxiety* is divided into ten chapters (without titles) and three addenda, entitled “Modification of Earlier Views,” “Supplementary Remarks on Anxiety,” and “Anxiety, Pain, and Mourning.” Some commentators saw in the fact that Freud discussed pain in the final addendum a reflection of the theoretical difficulties he had encountered in studying the phenomenon, which he had discussed earlier in *Mourning and Melancholia* (1916–1917g [1915]).

The first chapter discusses the connections between inhibitions and symptoms. The second presents the ego as the site of anxiety (“There are good grounds for

firmly maintaining the idea that the ego is actually the site of anxiety”) and sees the role of repression from a perspective different from Freud’s earlier one, which viewed anxiety as the automatic consequence of repression. Chapter 3 takes up the relations between the ego and superego. Chapter 4 returns to the phobia of “little Hans” to show that “the motive force of the repression was fear of castration” (p. 108). Chapter 5 focuses on obsessional neurosis and the mechanism of the formation of symptoms within this context. Chapter 6 further investigates the defense mechanisms of isolation and retroactive undoing within obsessional neurosis. Chapter 7 examines the problem of phobias. Chapter 8 provides a brief interlude in which Freud analyzes the experience of unpleasure and distinguishes object loss and the fear of object loss—a distinction that provides the framework for a discussion of automatic anxiety and signal anxiety. Chapter 9 then focuses on the relations between symptom formation and the development of anxiety. Finally, the last chapter distinguishes three factors that lead to neuroses: a biological factor (“the long period of time during which the young of the human species is in a condition of helplessness and dependence” [p. 154]), a phylogenetic factor (the two-stage development of sexual life, with emphasis given to puberty), and a psychological factor (the defects of the mental apparatus lead Freud to treat libidinal drives as dangers in the face of which the ego can only restrain its own mechanisms and tolerate the formation of symptoms “in exchange for having impaired the instinct” [p. 156]).

The key points in this theoretical text are the following: Freud challenges Otto Rank’s view on the trauma of birth, which Rank regarded as the prototype of all later anxieties. For Freud:

In man and the higher animals it would seem that the act of birth, as the individual’s first experience of anxiety, has given the affect of anxiety certain characteristic forms of expression. But, while acknowledging this connection, we must not lay undue stress on it nor overlook the fact that biological necessity demands that a situation of danger should have an affective symbol, so that a symbol of this kind would have to be created in any case. Moreover, I do not think that we are justified in assuming that whenever there is an outbreak of anxiety something like a reproduction of the situation of birth goes on in the mind (pp. 93–94).

In other words, Freud wanted to retain Otto Rank’s idea that birth provides a kind of mold or expressive

content for anxiety, but insisted that the mental content of the affect of anxiety is determined by later existential experiences and subsequent psychological reworkings of the affects. He also insisted that anxiety is experienced by the ego but not produced by it. Here he returned to his theory of anxiety by making repression not the cause but the result of anxiety. Thus, what is involved is not “automatic anxiety” but “signal anxiety,” which must now be accounted for. Signal anxiety reflects the significant adaptive and maturational progress of the child to the extent that anxiety is no longer a simple reaction to object loss but an anticipation of the threat of the loss of love from the object.

Finally, the text provided Freud with an opportunity for further investigation of mental pain, which reflects a loss of a part of the self rather than a loss of the object, in the strict sense. This led Freud to recognize the importance of the more or less narcissistic valence of the lost object, which serves to demarcate mourning and melancholic depression.

## INITIAL INTERVIEW(S)

The term *initial* or *preliminary interview(s)* refers to the meeting or meetings that take place between a psychoanalyst and the person who must decide whether

or not to enter into analysis. The purpose of the initial interview or consultation is to determine the person's need for treatment.

The initial interview became standard procedure at the same time that Sigmund Freud clearly instituted the framework for the psychoanalytic situation: patient lying down, analyst hidden from the patient's view. These conditions in fact produce a radical change in a relationship that, during the preliminary interview, was fairly similar to consultation with a physician or psychologist, or indeed an interview for the purpose of soliciting advice of any type.

The issue of course is whether analysis is indicated, and this implies referring to criteria assessing "analyzability" and the degree to which such an undertaking is possible. From the beginning, however, from the phone call setting up the first meeting, the subtle mechanisms of transference and counter-transference are set in motion, shedding an entirely different light on the criteria for choices.

It is because of these intersubjective parameters that Freud advised, in "On Beginning the Treatment (Further Recommendations on Technique of Psycho-Analysis)" (1913c):

I may add . . . that I have made it my habit, when I know little about a patient, only to take him on at first provisionally, for a period of one to two weeks. . . . No other kind of preliminary examination but this procedure is at our disposal; the most lengthy discussions and questionings in ordinary consultations would offer no substitute. This preliminary experiment, however, is itself the beginning of a psycho-analysis and must conform to its rules. . . . Lengthy preliminary discussions before the beginning of the analytic treatment, previous treatment by another method and also previous acquaintance between the doctor and the patient who is to be analyzed, have special disadvantageous consequences for which one must be prepared. They result in the patient's meeting the doctor with a transference attitude which is already established and which the doctor must first slowly uncover instead of having the opportunity to observe the growth and development of the transference from the outset (pp. 123–125).

In 1930, his responses to his analysand Smiley Blanton, as revealed in the latter's *Diary of My Analysis with Freud* (1971), showed no change in this point of view. According to Blanton's entry for March 7, Freud told him: "[T]he lying down is but a matter of

convenience. But there is one point that is essential: the analysand must not see the face of the analyst. If he did, he would be influenced by the face of the analyst" (p. 50). In his entry for August 9, 1935, Blanton recalled: "In a discussion about technique, I asked Freud if he advocated talking to a patient several hours before analysis—or, rather, to begin an analysis with several hours of discussion. He replied, "With a student in training it may be permissible. With a patient who is there for treatment, no" (p. 71).

In later years, trial analysis fell out of practice, and the status of the preliminary interviews has become somewhat vague; these vary, according to different schools, in their frequency and duration, as well as in terms of whether they may be free of charge. Some practitioners limit them to one or two meetings, the latter case being intended to assess the patient's capacity for insight and working over, following the initial meeting: Was there a dream, a parapraxis, a lifting of amnesia, or an instance of acting out? Other analysts advise having several interviews to avoid the possibility of having to interrupt an analysis that, too late, turned out to be unjustified. Several authors have emphasized the importance of preliminary interviews with borderline patients, for whom, more than with other patients, possible modifications to the analytic situation may be considered.

The analyst's listening attitude, the absence of questions of a medical nature, discreet emphasis on preconscious manifestations, recognition of mental suffering and its possible modes of expression other than acting out, and assessing possible lateral transferences (if a colleague has already interviewed the patient) are among the themes evoked most frequently by authors in their discussion of preliminary interviews. Similarly, these authors have underscored the need, once the preliminary interviews have ended and if a decision has been made to undertake analysis, to establish clearly and in detail with the patient the conditions in which the treatment will take place. Such conditions include the length and frequency of sessions, scheduled times for them, method of payment, policy in case of absence from sessions, and vacation periods.

Also to be considered is certain psychoanalysts' practice of switching to a classical analytic mode of treatment after a long series of sessions of psychoanalytically inspired therapy; in their view, this move is similar to what happens after traditional preliminary

interviews. In all cases, there remains first and foremost the problem, raised by Freud, of the psychoanalytic handling of the transference and countertransference, which in the classic view is only possible within the psychoanalytic setting.

## **INNERVATION**

Freud uses the term *innervation* throughout his work, both with and without reference to hysterical conversion. We find it in its physiological and anatomical meaning as an efferent or afferent mode of action of the nervous system and/or distribution of nerves in a region of the body: “sensation of innervation,” “voluntary or involuntary innervation of the muscles,” “innervation of the brain,” “body innervation.” But we also find, more rarely: “innervation (tears),” “sensation of the innervation of the word,” “sensation of speech innervation,” “innervation of images of *movement*.”

For Freud the theory of conversion took shape within the very broad framework of these meanings: “the inhibited antithetic idea can put itself into effect by innervation of the body” (1892–93a, p. 122). As soon as the term *conversion* appeared, it was often linked to *innervation*. Two examples: “The affect that is torn [from the repressed idea] would be used for a somatic innervation. (That is, the excitation is ‘converted’.)” (1895d, p. 285), and “in the case of conversion hysteria the circuitous route led to the somatic innervation; the repressed impulse broke its way through at some point or other and produced *symptoms*” (1925d, p. 33).

The notion is not much used by psychoanalysts today. Although linked to Freud’s earliest paraneurological speculations, it has nevertheless been retained in relation to hysteria, for example, as a reaffirmation in Freud’s opinion of a correspondence or an indissoluble continuity between the psychical and the physical.

## **INSIGHT**

In psychoanalysis, insight is a process whereby one grasps a previously misunderstood aspect of one’s own mental dynamics. It refers to a specific moment, observable during the treatment, when the patient becomes aware of an inner conflict, an instinctual impulse, a defense, or the like, that was previously repressed or disavowed and that, when it emerges into consciousness, elicits surprise and a sense of discovery.

Two forms of the experience have been described. The first involves a feeling of sudden discovery or illumination—a kind of “Eureka!” moment. The second is a slower, more gradual process where the subject and usually the analyst as well experience a sensation of the

obvious: “Yes, that’s how it is. We knew this, of course, but now it’s perfectly clear.” In all cases, something other than simple intellectual comprehension is involved. Frequently, understanding at a lower level, laden with cultural references and general, abstract concepts constructed as defenses, is replaced by deeper insight that leads patients to question their entire personal histories and thinking. This happens, for example, when patients, after making defensive comments about oedipal conflicts, relive and reabsorb their own oedipal dramas. In such cases the economic and dynamic charge of such a shift and the accompanying emotions run far deeper than mere intellectual understanding.

Insight indicates a transition from the preconscious to the conscious. Attentive analysts will often anticipate a coming moment of insight, though they may feel that interpretation would be premature so long as the moment has not yet arrived. When they sense that the moment is truly imminent, they may choose to facilitate the revelation by intervening.

When assessing whether psychoanalysis is indicated during initial consultations, evaluating a patient’s capacity for insight is especially important. The capacity for insight must likewise be taken into account in gauging whether an analyst in training has yet been adequately analyzed.

## **INSTINCT**

The notion of *instinct* is usually linked to the field of ethology or the psychology of animal behavior. It corresponds to a specific program of action for a species that is genetically transmitted and theoretically independent of individual experience. Given a particular situation, this programming activates a specific set of neurophysiological and endocrine responses. Modern research in ethology tends to limit the exclusive role of heredity in the determination of instinct and focus instead on the role of epigenesis.

In Sigmund Freud’s work, and thus in psychoanalysis, the notion of instinct must be discussed on the one hand in terms of its differentiation from the notion of the drive and on the other hand in its own, animal acceptance.

Instinct falls under the category of what is inherited, that is, within the history of a species. By contrast, the drive belongs to the subject’s individual history. In fact, it is the fundamental vector of that history. In mental life, it is experienced through representatives, which in the course of psychical processes are differentiated into ideational representatives of objects and words, on the one hand, and representatives of affects on the other. Anchored in the somatic, the drive becomes psychical in its trajectory from its source to its aim. Among its characteristics, its capacity to trace a progressive course towards a real satisfaction or a regressive course towards a hallucinatory satisfaction offers the subject a flexibility of functioning that contrasts with the relative rigidity of instinct.

On several occasions, Freud hypothesized the existence in human beings of a collection of instincts analogous to those of animals. These instincts would form the kernel of the unconscious; and primal fantasies, as the inherited representative images of phylogenesis, would flow from them. For Freud, the instinct exists as a preliminary phase, before that of the drive, and during a process of psychical disturbance, the drive could revert to the level of instinct. Current studies of

psychosomatic disorders emphasize just such a “regressive” return to instinct.

### **“INSTINCTS AND THEIR VICISSITUDES”**

Written between March 15 and April 4, 1915, and immediately published, *Instincts and Their Vicissitudes* opens the “collection which I originally intended to publish in book form under the title ‘Preliminaries to a Metapsychology.’ . . . The intention of the series is to clarify and carry deeper the theoretical assumptions on which a psycho-analytic system could be founded” (Freud, 1917d, p. 222 n.).

The previous year, 1914, Freud’s introduction of narcissism and of the ego as a libidinally cathected agency altered the dynamics of the psychic conflict between sexual drives and ego drives (self-preservation), leading to “the second step in the theory of the drives” (1920g). In 1924 Freud grouped “Instincts and Their Vicissitudes” with the “Metapsychology” collection of twelve essays, five of which were published. The first translations appeared in Spanish in 1924, in English in 1925, in French in 1936, in Italian in 1972, and in Portuguese in 1974.

Freud began elaborating his metapsychology under the notion of the dynamics of the psyche. He established the drive as a concept. Prior to this he had been theorizing about one or more drives. The continuing pressure of the drive, as a “measure of the demand for work that it represents,” became the “very essence” of the drive (Freud, 1915c, p. 122). Freud then theorized

about the complex relationships among autoeroticism, the sexual drives, narcissism, and the dynamic genesis of the ego. The sexual drives, early defenses belonging to narcissistic organization, have two destinies that result in the work demanded by the drive: reversal in the opposite direction and turning against the self. The former destiny splits into another two movements: turning a drive away from activity toward passivity, which combines with turning against the self, and reversing content, the only instance of which is the transformation of love and hate. Freud’s study (1915c) then gives a new analysis of sadism/masochism, voyeurism/exhibitionism, and love/hate as pairs of opposites.

The opposition of pairs is an evolving process that starts from autoeroticism as a narcissistic formation. This opposition is subject to the active, reflective, and passive expressions of the drives, from which objects and a “new subject” emerge. The genesis of the ego thus contributes to the biological polarity of psychic life, activity/passivity, which is expressed in the ambivalence of the drive impulses.

Love and hate introduce ambivalence of feeling. Again, the opposition proves complex. Freud explained how the opposition depends on the economic polarity of pleasure/unpleasure and the real polarity of ego/external reality in the dynamics of the psyche. Loving follows from pleasure; hating from unpleasure. The initial ego/reality opposition (or internal/external reality opposition) differentiates internal and external according to a sound objective criterion—the internal being the continuing pressure of the drive, which is inescapable, and the external being subtle stimuli that can be avoided. This opposition mutates into a purified-pleasure-ego under the influence of the pleasure principle in the narcissistic position. Then ego and pleasure correspond, and external world and unpleasure correspond. “At the very beginning, it seems, the external world, objects, and what is hated are identical” (1915c, p. 136). Freud then demonstrates the role of hate as a constituent in affirming and preserving the ego, as well as the autonomy of hate in relation to love.

As a pivotal text among Freud’s works, “Instincts and Their Vicissitudes” and the essays that follow do not entirely succeed. “What has happened to my *Metapsychology*? In the first place it has not yet been written. . . . But if I still have ten years to live . . . , then I promise to make further contributions to it. A first example of

this will be found in an essay of mine entitled *Beyond the Pleasure Principle* [1920g];” Freud wrote to Lou Andreas-Salomé on April 2, 1919 (1966a/1972, p. 95). In fact, this “third step in the theory of the instincts” (1920g, p. 59) enabled Freud to elaborate various themes identified or developed in that study: the relation of the drive to biology, the problem of masochism and pain (Freud, 1924c), the polarities of sexual psychic life, the addition of the phallic/castrated opposition to the active/passive and masculine/feminine oppositions (Freud, 1923e), a more sophisticated morphodynamics of the ego (Freud, 1925h), and how hatred leads to the death drives.

“Instincts and Their Vicissitudes” was a source of inspiration for Freud and his successors. It is essential to understanding the work of Melanie Klein and Jacques Lacan, as well as André Green’s discussion of how the drives intersect in their expression, for example. It is also central to understanding the drive and the ontogenesis of the ego in psychoanalysis.

## INSTINCTUAL IMPULSE

The term *instinctual impulse* (*Triebregung*), designating the initial, productive, and local form of an instinct active within the psyche, emphasizes its intrinsic emotional dynamic. *Trieb* is the “instinct” or “drive.” *Regung* means “movement of the heart or soul, a nascent feeling, a stirring of the heart, an emotion.” Literally, *Triebregung* is the “emotional momentum of the instinct.” Etymology provides us with two versions of the verb *regen*, the origin of *Regung* (and also of *Erregung*, “excitation” or “arousal”). The first means “to place upright, to raise up, to set in motion, to stir, to arouse, to irritate, to awaken, to touch, or to affect emotionally.” *Triebregung* stems from the second meaning: “to rise, to rise up, to be in erection, to prick up.” The family of words with the root *reg-* connotes activity and movement *in action*, often in their initial stages: a desire that “pricks up” becomes *rege* in German. Sigmund Freud coined other words in an analogous way.

The term “instinctual impulse” first appeared in Freud’s work “Obsessive Actions and Religious Practices” (1907b): “A deeper insight into the mechanism of obsessional neurosis is gained if we take into account the primary fact which lies at the bottom of it. This is always the *repression of an instinctual impulse* (a component of the sexual instinct), which was present in the subject’s constitution and which was allowed to find expression for a while during his childhood but later succumbed to repression” (p. 124). In “Hysterical Phantasies and Their Relation to Bisexuality” (1908a), he wrote: “Hysterical symptoms arise as a compromise between two opposite affective and instinctual impulses, of which one is attempting to bring to

expression a component instinct or a constituent of the sexual constitution, and the other is attempting to suppress it" (p. 164). He went on to specify the meanings attached to these two transference neuroses, without giving an exhaustive definition. Until around 1914, the theory of the instincts as expounded in the "Three Essays on the Theory of Sexuality" (1905d) remained quite phenomenological. Freud thus used as near equivalents for *instinct* in its partial sense the words *impulse* or *component instinct*, as well as the terms *instinctual constituent*, *part*, or *element*. The term *impulse* appeared in 1905, described in various ways: homosexual, vengeful, or repressive impulses; sexual, hostile, libidinal, tender, or perverse impulses. In "Notes upon a Case of Obsessional Neurosis" (1909d), Freud wrote of the Rat Man: "His unconscious encompasses prematurely repressed impulses, to be described as passionate or bad." Each time the word *impulse* is used, the emphasis is on the present-time effectiveness of the instinct in question and on the emotional dimension of the psychic impulse. The impulse is located in the unconscious, with the exception of the impulse of self-preservation.

At the time of the next major development in the theory of the instincts ("Instincts and Their Vicissitudes," 1915c), the concept of the "instinct" with its "pressure" was defined, and the instinctual impulse described in more detail. The former constitutes the dynamic space underlying the psyche, and the latter actualizes it. At the end of "Instincts and Their Vicissitudes," we read: "We may sum up by saying that the essential feature in the vicissitudes undergone by instincts lies in *the subjection of the instinctual impulses to the influences of the three great polarities that dominate mental life*. Of these three polarities we might describe that of activity-passivity as the *biological*, that of ego-external world as the *real*, and finally that of pleasure-unpleasure as the *economic* polarity" (p. 140). The vicissitudes of the instincts are in fact vicissitudes of instinctual impulses. Moreover, in "Thoughts for the Times on War and Death" (1915b), Freud placed "what we call our unconscious" in apposition to "the deepest strata of our minds, made up of instinctual impulses" (p. 296), whereas in "Instincts and their Vicissitudes" he maintained that "the opposition between consciousness and the unconscious has no application for the instincts." Among the four vicissitudes of the instinctual impulses, repression makes it possible to distinguish two components: an idea or group of ideas on the one hand, and the quantitative

factor, the amount of affect in the instinctual impulses, on the other. Together, they constitute the instinctual ideation that is dissociated by repression, and they meet with different fates. Instinctual impulses are also subjected to all the defensive processes and reworked, or even worked-through, by them.

The third step in the theory of the instincts does not greatly modify the notion of instinctual impulse, except for the ideas, expressed in "New Introductory Lectures on Psychoanalysis" (1933 [1932]), that "every instinctual impulse that we can examine consists of similar fusions or alloys of the two classes of instincts [Eros and aggressiveness]" (pp. 104–105), and that their place is the id, which "originally includes all the instinctual impulses" (p. 105).

The overall understanding relating to instinctual impulses is the same as that relating to the instincts. More narrowly, the notion of affect is very close to them, as is the question of unconscious feelings. Moreover, instinctual impulses often arise in pairs of opposites. The power of instinctual impulses is necessary for the creation of dreams; unconscious fantasies are derivatives of them; and in the final analysis, any particular psychic formation is derived from them.

The notion of the instinctual impulse has been actively criticized ever since the publication of Freud's *Complete Works*: the index, at least in the case of the German and French editions, does not generally distinguish between "instinctual impulse" and "instinct." Consequently, some passages in Freud's work are ambiguous.

## INSTINCTUAL REPRESENTATIVE

In “Drives and Their Vicissitudes” (1915c), Freud defined the drive as a “concept on the frontier between the mental and the somatic, as the psychical representative of the stimuli originating from within the organism and reaching the mind” (pp. 121–122). In “Repression” (1915d), he added that this representative must be considered as made up of two components, the representative proper, or the ideational representative, and a charge of energy, the “quota of affect” (p. 152). The vicissitudes of these two components can differ markedly. Strictly speaking, only the first is submitted to repression. Psychical life is chiefly constituted by the binding and unbinding of these two components, and the psychoanalytic cure aims at reopening this process. Freud put it this way: the instinctual representative is “an idea or group of ideas which is cathected with a definite quota of psychical energy (libido or interest). . . . [B]esides the idea, some other element representing the instinct has to be taken into account. . . . [The quota of affect] corresponds to the instinct in so far as the latter has become detached from the idea and finds expression, proportionate to its quantity, in processes which are sensed as affects. From this point on, in describing a case of repression, we shall have to follow up separately what, as the result of repression, becomes of the *idea*” (p. 152). Three different vicissitudes of this “quantitative factor” can be distinguished: “[E]ither the instinct is altogether suppressed, so that no trace of it is found” (p. 153)—this first option leads to what Charcot called “*la belle indifférence des hystériques*” (p. 156). Or “it appears as an affect which is in some way or other qualitatively coloured, or it is changed into anxiety” (p. 153).

Thus there appears to be a contradiction between these two texts, in spite of the fact that they come from the same year, 1915. This contradiction was pointed out by Jean Laplanche and Jean-Bertrand Pontalis in their article on the “psychical representative” in *The Language of Psychoanalysis* (1967), and it is illustrated in the two passages quoted above. According to the first, the drive is a psychical “representative,” while according to the second, it is “represented” in the psyche by two different components, the ideational representative and the quota of affect.

It could be said that Freud is only guilty of clumsy expression or confusion of terms. In fact, it is a matter

of two different sets of difficult problems that he sought to solve in 1915. The first concerns the notion of representation, which is highly ambiguous. The second is the definition of the drive as a “frontier concept,” which has never ceased to cause problems for everyone from Freud on—to the point that its usage in psychoanalysis has been challenged (Widlöcher, 1986). Any possible path towards a solution must certainly reaffirm the character of the drive as an indispensable notion in the metapsychological edifice and acknowledge that it involves the “interface” between the somatic and the mental. Thus it is an intermediary phase in a sequence that runs from (bodily) excitation to the drive to representatives (ideational representative and quota of affect)—a sequence in which the drive is simultaneously “representing” and “represented” (Green; David).

## INSTITUT CLAPARÈDE

The Institut Claparède is a treatment and consulting center. Its objectives are “the diagnosis and treatment of mentally maladjusted children whose maladjustment is associated with neuropsychic disturbances or behavioral disturbances likely to benefit from medical therapy, medical and psychological re-education, psychotherapeutic re-education, or even specialized psychopedagogical re-education under medical control.” It is one of the Centres médico-psychopédagogique (Medical and Psychopedagogical Centers), which, since 1956, have

been monitored by the Direction d'action sanitaire et sociale (Department of Health and Social Activity) and financed by the French health care system.

A thousand families and children are treated each year. The institute has been active since 1949. In 2001 it had a team of 23 psychoanalysts, including 21 child psychiatrists, and 24 psychologists and re-educators working with 5 social workers. When the institute was created, the inclusion of child psychoanalysis added a new understanding of educational and adaptive problems in terms of the precursors of the evolution of personality. Specialized teams of psychoanalysts provide appropriate treatment to patients of all ages (up to twenty-one or older) through conventional psychoanalysis and various forms of analytic psychotherapy: psychodrama, family therapy, couples therapy, group therapy. The institute's activity provides a psychoanalytic dimension to various activities in the field of child psychiatry, education, and maternal and infant protection.

## **INSTITUT MAX-KASSOWITZ**

From 1886 to 1896 Sigmund Freud was responsible for the department of nervous diseases at the Erstes Öffentliches Kinder-Krankeninstitut in Vienna (First Public Institute for Sick Children), known as the Max-Kassowitz Institute after its founder and director. Freud saw patients there three times a week without pay. The institute was founded in 1788 to provide free

treatment to sick children of impoverished families as part of a public health program begun by Emperor Joseph II. It was the second children's clinic of its kind in Europe, the first being the Dispensary for Sick Children in London (1769).

Max Kassowitz (1842–1913), a professor of pediatrics in Vienna, took over management of the facility in 1882. A specialist in the physiology and pathology of bone formation, in 1883 he introduced a method for treating rickets using phosphorous in cod liver oil.

In 1886 the institute had only two rooms: a waiting room and a consulting office (Steindlgasse 2). That same year the institute inherited two new facilities from the Kassowitz family (Tuchlauben 8) and created two departments of internal medicine and five departments for specializations: surgery (Richard Wittelshöfer and later Ignaz Rosanes), dermatology (Eduard Schiff), nervous diseases (Sigmund Freud), ears (Josef Pollak), and nose and throat (Eduard Ronsburger). In 1889 a new department for eye diseases was created (Leopold Königstein); in 1894 the second department of internal medicine added a new doctor (Oskar Rie). All these “departments” provided care, as they would in a dispensary. Aside from the director and doctors, there were medical assistants (including Ludwig Rosenberg and Max Kahane). None of these positions was salaried. For the doctors the job had the advantage of providing access to a wide range of clinical material. In 1886 there were approximately 6000 office visits, which rose to 12,839 in 1892, and to 17,400 in 1898.

The possibility of working with children led Freud to travel to Paris and Berlin in 1885–1886. In Berlin he studied pediatrics with Professor Adolf Baginsky. In 1886, as privat-docents, Wittelshöfer, Schiff, and Freud asked the teachers college of the University of Vienna for authorization to provide lessons at the institute, an authorization that had been given to Kassowitz himself, using clinic patients for their demonstrations. Authorization was refused in order to maintain the distinction between university clinics and the institute. However, Freud gave—or at least publicized—lessons “on the nervous diseases of children with demonstrations” during the summer months of 1887, 1888 (near the institute), 1891, 1892, and 1893 (at an unknown location). Under Kassowitz's leadership the institute engaged in

considerable scientific activity and, in 1890, published a collection of articles entitled *Beiträge zur Kinderheilkunde aus dem I. öffentlichen Kinder-Krankennstitute in Wien* (Contributions to children's medicine based on research conducted at the first public institute for sick children in Vienna).

Freud's scientific activity was at the time directed exclusively at infantile cerebral palsy, with the single exception of a study on infantile enuresis. Between 1886 and 1892 he collected two-hundred seventy-five neuropathological observations on diplegia in children under ten years of age, which served as the clinical basis for nine publications during the years 1888–1900. These included three monographs, including the one he presented in 1897 to the prestigious collection "Spezielle Pathologie und Therapie," directed by Hermann Nothnagel. At the time Freud was considered to be one of the principal authorities on infantile cerebral palsy.

In 1896 Freud's position was turned over to Emil Redlich, who in 1898 in turn passed it on to Julius Zappert. In 1938 the institute celebrated its one-hundred-fiftieth anniversary with a publication that proudly stated that among its collaborators was "Sigmund Freud, a great thinker and the man who discovered psychoanalysis." The institute was dissolved that same year, following the annexation of Austria by the Third Reich.

## **INTEGRATION**

Donald Woods Winnicott distinguished three major maternal functions in his study of the role of the environment in the processes of maturation of the infant's ego: *holding*, which conditions the integration process; *handling*, which makes possible "personalization" or "psyche indwelling in the soma"; and lastly, *object-presenting*, which underlies the building of the earliest object relations.

Winnicott essentially expounded the notion of integration in two important papers: "Primitive Emotional Development" (delivered at the November 28, 1945 meeting of the British Psychoanalytical Society) and "Ego-integration in Child Development" (1962).

Integration presupposes the existence of an initial state of nonintegration, on the basis of which the individual, not yet differentiated from his or her environment, tends to become organized into a unique being by the coming together of multiple varied and fragmented experiences. In *Winnicott* (1981), Claude Geets described the process in these terms: "These early experiences are at first sensory and motor: that which will become an I is at this point only a mass of dispersed, unconnected sensations. At the end of the integration process, there is what Winnicott calls the establishing of a unitary self: the subject (from now on) has the sense of existing as an individual entity" (p. 73).

Two types of experiences intervene in the transition from primary nonintegration to successful integration: first, the care the infant receives, "whereby an infant is kept warm, handled and bathed and rocked and named" (Winnicott, 1945/1958, p. 140), and second, the acute instinctual experiences that "tend to gather the personality together from within" (p. 140). Indeed, Winnicott very strongly emphasized the effects of the encounter between the (future) subject and the object, the impact of which is central, according to him, in the constitution of the infant's self.

Nonintegration thus has a natural place in the course of the individual's development, and every individual temporarily returns to that state during moments of rest, relaxation, or dreams, provided that he or she has enough trust in the environment to yield to this regressive movement. Winnicott linked creativity and artistic experience in adults to the ability to remain in contact with this nonintegrated, primitive

self, just as the subject must be able to experience a return to a state of nonintegration in psychoanalysis.

Nonintegration is thus a positive, structuring phenomenon that must be clearly distinguished from disintegration of the personality (or fear of disintegration). The latter is to be situated within the realm of psychopathology as a modality of defense against a return to a state of nonintegration, for in Winnicott's view, madness is never a regression, but instead a last, pathetic resort against regression.

## **INTELLECTUALIZATION**

Intellectualization is the use of the intellect to defend against instinctual impulses. Obsessive neurotics use intellectualization in an effort to master obsessive representations and exhaust themselves in an intellectual activity that is as intense as it is empty, forcing themselves against their will to scrutinize and speculate as if the most important and vital personal issues were at stake. We must not confuse this sexualization of thought, which resembles indefinitely prolonged and fruitless masturbation, that one can drive from intellectual beauty.

In *Leonardo da Vinci* (1910c) Freud gave a prototype of intellectualization in its defensive function: “His affects were controlled and subjected to the

instinct for research; he did not love and hate, but asked himself about the origins and significance of what he was to love or hate” (p. 74). For Freud, this conversion of instinct into intellect had several consequences. First of all, it is by no means certain that reconversion in the reverse direction is possible, thus leaving the world of affects out of reach. In addition, “investigating has taken the place of acting and creating as well” (p. 75). These arguments are quite surprising, because Freud had earlier demonstrated in relation to “paths of reciprocal influence” (1905d) the interaction between thinking activity and sexual excitation. Freud's interpretation of da Vinci is also surprising because it contradicts what we know about Leonardo's creative power and his passion for it. However, while the example Freud chose may pose a problem, in *Leonardo* Freud was painting a picture of the passion for investigation with which he himself was not unfamiliar.

We find intellectualization more commonly in special instances of painful and incessant mental work, which can take the extreme form that psychiatrists call *intellectual rumination*. Pierre Janet describes it in the following terms: “It is a singular labor of thought that accumulates associations of ideas, interrogations, questions, innumerable research, in such a way as to form an inextricable labyrinth. The work is more or less complicated depending on the intelligence of the subject; but whether he goes round in a circle or goes off on branches, he never reaches a conclusion, he can never hold course and exhausts himself in a work that is as interminable as it is pointless” (1909). The distinctive feature of intellectualization is in fact its pointless and infinite character. Freud partly explains this through the fact that it is not the content of the thought that is pursued, but its pure mechanism. Speaking of mental rumination in relation to the Rat Man, he noted “The thought process itself becomes sexualized, for the sexual pleasure which is normally attached to the content of thought becomes shifted on to the act of thinking itself, and the satisfaction derived from reaching the conclusion of a line of thought is experienced as a sexual satisfaction” (1909d).

We may wonder whether speaking of a “conclusion of a line of thought” in such a case is not contradictory, a contradiction we already found in *Leonardo*, when Freud spoke simultaneously of the “feeling that comes from settling things in one's mind and explaining them” (1910c, p. 80), and “the fact that this

brooding never ends and that the intellectual feeling, so much desired, of having found a solution recedes more and more into the distance” (p. 80). For Freud, obsessive intellectualization is by no means a gauge of intellectual development, which is in fact redirected for the purposes of combating the instincts and very often disappears once repression has acquired the upper hand.

Intellectualization does not derive from the sublimation of an instinct, like the pleasure of thinking, but on an idealization. Freud could thus write: “The struggle which once raged in the deepest strata of the mind, and was not brought to an end by rapid sublimation and identification, is now continued in a higher region, like the Battle of the Huns in Kaulbach’s painting” (1923b).

## **INTERGENERATIONAL**

In psychoanalysis, the term *intergenerational* refers to a process allowing for the recognition of the modalities of conflict that situate a human being in relation to the generations that preceded that individual’s birth. The specifically psychoanalytic meaning of this notion has

to do with its articulation with the essential psychoanalytic concepts and methodological conditions that made possible the discovery of the unconscious. To avoid reification of this concept, it is preferable to use the word only as an adjective.

This term is a derivative of *transgenerational*, a term that came out of family systems therapy (Boszormenyi-Nagy, Ivan, 1973); it appeared in France around 1985 in connection with the notions of inheritance, transmission, and genealogy (Guyotat, Jean, and Fédida, Pierre, 1985; Eiguier, Alberto, 1987).

In the heterogeneity of its uses, this word served as a catalyst for the recognition of a problematic that numerous psychoanalysts had been working on for years: the presence of ideas coming from an “other” who from the outset participates with his or her own unconscious psyche in the constitution of the subject’s psychic apparatus.

It is not sufficient to observe empirically the involvement of three generations to speak of intergenerational phenomena from a psychoanalytic point of view. In fact, this notion involves a parental and grandparental intrapsychic agency that is distinct from the real, material parents and grandparents and that can hinder recognition of the differences between generations, sexual difference, and otherness.

By way of a precursor to this notion, let us recall Sigmund Freud’s statement, in “New Introductory Lectures on Psycho-Analysis” (1933a [1932]): “Thus a child’s super-ego is in fact constructed on the model not of its parents but of its parents’ super-ego; the contents which fill it are the same and it becomes the vehicle of tradition and of all the time-resisting judgements of value which have propagated themselves in this manner from generation to generation” (p. 67). It is precisely this parental agency that is revealed in the process of reconstruction.

To the extent that there is revealed “a third party of the other” situated in the generation of a grandparent (or an ancestor), it is possible to study the way in which the history that preceded the subject’s conception comes into play in the formation and development of the psyche. Thus, for example, René Kaës (1993) examined Freud’s work in terms of inheritance and transmission, and attributed to the group the role of mediator. Jean Guillaumin, for his part, studied the object loss in Freud’s work (1984, 1988).

This whole problematic presupposes the sequence genealogy/transmission/transference/reconstruction of unconscious ideas. This is why the term *intergenerational* is preferable to *transgenerational* (see also Alain de Mijolla, 1999, 2004). The operation that best exemplifies the link among generations is that of unconscious identification. The concept of unconscious identification is articulated together with other, complementary psychoanalytic notions and must be situated in the specific context of each author.

Among the works that are precursors to this problematic, the following can be cited: Sándor Ferenczi's work (1932) on the confusion of tongues and Jean Laplanche (1984) on the enigmatic signifier, in relation to the theme of the adult's message to the child; around the theme of the mirror, Jacques Lacan's foundational article on the mirror stage (1949), Donald Winnicott on the mother's mirroring role (1967), and André Green on the dead mother (1983); and lastly, focusing in the conditions of the appearance of psychotic thinking, Enrique Pichon-Rivière's work on internalization of the social bond and the psychotic as word-bearer of the family (1957–1962); Wilfred R. Bion's formulations on the functions of containment and transformation (1963–1965); the concept of blank psychosis (Jean-Luc Donnet and André Green, 1973); and Piera Aulagnier's work on failures in the maternal function as word-bearer and the prohibition imposed against thinking (1964, 1975, 1984).

A great many authors have approached the “intergenerational” (or “transgenerational”) from different perspectives, even though for the most part they have not used this term. The following contributions can be considered as coming out of this problematic: on the three generations of man in religious myth and genealogy (Guy Rosolato, 1967); on phantoms, the crypt, and the unavowable secret (Nicolas Abraham and Maria Torok, 1961–1975, 1978); on identification fantasies (Rimbaud and Freud) and the genealogy of fantasies (Alain de Mijolla, 1975, 1981, 1985, 2004); on confusion between birth/death and narcissistic lines of descent in psychopathology (Jean Guyotat, 1980, 1991, 1995); on alienating narcissistic unconscious identifications and the telescoping of generations (Haydée Faimberg, 1981, 1985, 1988); and on delusional inheritance (Micheline Enriques, 1984, 1986, 1987) as a consequence of the prohibition against thinking.

Continuing the line of inquiry in the work of Abraham and Torok, Serge Tisseron (1985, 1990, 1992,

1997) studied the creation of images as witnesses to family secrets, and Cl. Nachin studied the pathology of mourning (1981, 1989). Jean-José Baranès (1984, 1986, 1993) examined the possibility of formulating a “transgenerational metapsychology.” Alberto Eiguer (1987, 1997) conceptualized the “transgenerational object” in family therapy. With reference to observation of early relationships, Serge Lebovici (1980, 1995) spoke of a “transgenerational mandate.”

Other authors have studied the transmission of traumas in historical contexts: the Shoah (M. Bergman and M. Jucovy, 1982) and the assignment of names (Y. Gampel, 1982, 1986); vampire identifications (Pérel Wilgowitz, 1991); and Armenian genocide (Jeanine Altounian, 1991).

The terms *intergenerational* and *transgenerational* appeared relatively recently. The concept they cover can be applied to a variety of different theoretical domains. The psychoanalytic relevance of this concept can be put to the test through a retroactive reexamination of studies that made it possible to think the relationship among generations, even if it potentially means having to change or make more precise the term itself. It is thus possible to envision comparing it with the two Freudian models of the unconscious: the unconscious as a specific agency, or as the consequence of a primal repression in which an “other” takes part.

Analytic experience was the basis for the following definition, proposed by Faimberg in “À l'écoute du télescope des générations: pertinence psychanalytique du concept” (1988; Listening to the telescoping of generations: psychoanalytic relevance of the concept): The intergenerational relationship refers to a process of (re)construction that brings the primal into existence through deferred action, in the history of the transference. This primal, always fragmentary and hypothetical, then becomes the condition of possibility for initiating a process of historicizing the subject in relation to two or more previous generations. This process of links among generations can be mediated by means of an unconscious identification that is revealed in the same process of reconstruction.

This conceptualization of the intergenerational relationship does not aim to find out whether it is necessary to go back ever earlier in time. It is centered around the transference, the process of listening to the anachronisms of the unconscious, and (re)constructing historical truths. Accordingly, to avoid the risk of

finding only material that had already been put there, it does not aim to anticipate, based on known events, what might be brought to light through the analytic process. Further, the “intergenerational” concepts that result from the necessary work of transformation linked to the transference situation can by no means be substituted for it without becoming univocal explanatory schemes. Only by avoiding any such reification is it possible to listen to the unconscious there where it speaks: in a place where neither the analysand nor the analyst expected it.

## **INTERNAL REALITY/EXTERNAL REALITY**

An individual's internal reality corresponds to a collection of processes, representations, and affects that are essentially (but not only) unconscious, which Sigmund Freud referred to as “psychical reality.” It thus contains the representations of the world that the subject has formed, fantasies stemming from unconscious desires, and universal fantasy structures: the primal fantasies. For the analyst, it has an existence and efficiency that are comparable to physical reality.

External reality, also called material reality, subsumes the objects of our physical environment, the subject's body, and the subject's inscribed place in society.

These two concepts exist in a dialectical and sometimes paradoxical relation throughout Freud's work. They presuppose a theorization of each one taken separately and of their interconnection. In other words, what is at stake is knowing how material reality becomes internalized and how a reality that is initially completely subjective is gradually constituted as external.

In “Negation” (1925) Freud asserted, “What is bad, what is alien to the ego and what is external are, to begin with, identical” (p. 237). According to him, external reality always remains unknowable, like Immanuel Kant's *Ding an sich* (Thing-in-itself); but, like Kant, Freud did not adhere to George Berkeley's absolute idealism, which essentially holds that there exists only mental reality. Actually, such a state is only found in certain psychoses (schizophrenia, chronic delusional psychosis, etc.), in which the movements of mental reality are taken for external reality (cf. hallucination). In neurosis, these two topographical spaces remain distinct, even if “psychical reality plays a dominant role,” as Freud wrote in the *Introductory Lectures on Psychoanalysis* (1916–17b [1915–17]).

The theory of the connection between the two orders was adumbrated as early as 1891 in Freud's text “On Aphasia: A Critical Study,” where he distinguished between thing-presentations and word-presentations. The unconscious contains only *Sachvorstellungen* (thing-presentations), whereas both forms of representation are found in the preconscious and the conscious.

In elaborating the idea of mental reality Freud no doubt drew upon the teachings of the philosopher Franz von Brentano (*Psychology from an Empirical Standpoint*, 1874/1973). However, his first model can justifiably be traced back to the 1895 “Project for a Scientific Psychology,” where Freud invoked a “reality of thought [*Denkrealität*] that is autonomous although dependent upon external reality.” “Project for a Scientific Psychology,” which Jean Guillaumin has called “a wide-ranging meditation on the relationship between the Ego and the external world,” deals with material reality by introducing the concept of the “reality index,” based on the perceptual neurons capable of apprehending external reality. The actual term “psychical reality” appears for the first time in 1909 in an addendum to the second edition of *The Interpretation of Dreams*. Not until the 1919 edition was the

now-classic distinction between “psychical reality” and “material reality” finally posited.

Throughout his writings Freud attempted to specify the laws of the functioning of psychic reality and to shed light on its dialectical connection with external reality. In “Formulations on the Two Principles of Mental Functioning” (1911), he asserted that in the earliest stages of life the subject is dominated by the pleasure principle and hallucinatory satisfaction. But the failure of this as a means of attaining satisfaction forces the infant to “represent for itself the real state of the external world.” Thought, which is originally unconscious, is split: One part remains under the control of the pleasure principle and constructs fantasies; the other part, with language, becomes conscious and capable of judging whether a representation belongs to internal, psychic reality or to the external reality of the world. Thus psychic reality functions under the yoke of instinct and according to the laws of the primary processes. Unaware of time or negation, these representations and affects are displaced and condensed according to the flow of cathexis. Ever concerned with shedding light on the connections that exist between this internal reality and the external world, Freud then introduced, in “A Case of Paranoia Running Counter to the Psycho-Analytic Theory of the Disease” (1915), the idea of “primal fantasies.” These “constitute” a treasure of organizing “schemas” of all fantasies and are in a sense the hard core of psychic reality (Jean Laplanche and Jean-Bertrand Pontalis, 1985).

By postulating that the primal fantasies are phylogenetic in origin, an idea he would defend until his death, Freud re-enmeshed external reality and psychic reality. What had once been prehistoric reality later became part of psychic reality. In any case, in Freud’s view, in “An Outline of Psychoanalysis” (1940 [1938]), external reality must forever remain “unknowable,” just as a “quantity of (unconscious) processes are themselves unknowable.” He concluded this work by emphasizing the function of the internalized external world constituted by the superego that “reunites the influences of the present and the past.”

Since then, numerous psychoanalysts, inspired in particular by the writings of Melanie Klein, have developed the idea of psychic reality, most often on the basis of work on psychosis: Michael Balint, Donald Winnicott, Wilfred Bion—who emphasized the hatred the psychotic patient feels for realities—and Piera Aulagnier, with the concept of historical

reality. In France, Jacques Lacan took up this thematics with his 1953 introduction of the category of the real, as distinct from reality. In his 1975 seminar “R.S.I.,” he defined the Real as “what is impossible to subjectivize.” A stopping point for thought, it supposedly appears in psychosis and irrupts at the end of the cure.

During the same period, Serge Videman in *La Construction de l’espace analytique* (Construction of the analytical space; 1970) argued that “the reality of events is of no importance to the analyst, whose duty it is to invent it.” By stating it to the patient, the analyst in a sense brings this reality into existence. The event or its trace is argued to be at most the grain of sand around which fantasies are formed, like the pearl around an impurity. Thus Freud invented a new reality, constrained by the “epistemological necessity” of delimiting his object of study and his field of action. Although the notion of psychic reality is no longer contested today, and although all analysts recognize its heuristic value, fundamental divergences exist among the various conceptions relating to the articulation of internal and external realities.

Adherence to a physical realism has led many practitioners to invoke social and material reality from a normative perspective (Heinz Hartmann, 1956). Explaining symptoms only in terms of real events and advocating adaptation to reality are a contemporary trend in psychotherapeutic practices that retain from the analytic approach nothing but the adjective in which it is tricked out.

Another theoretical and practical current advocates the bracketing of external and historical reality (Lacan, Videman). Beyond their divergences, these theorists share the same desire to master the domain of the psyche whose purity cannot be altered by any factual opacity. Today, most analysts are in agreement on a principle of “undecidability” (Daniel Widlöcher, Jean Guillaumin, Haydée Faimberg, etc.) as to what should be attributed to material reality and what comes from psychic reality. Deeper understanding of the notion of the primal (Aulagnier) and transcultural studies show that “the infantile, culture, and the characteristic of the object,” as Maurice Dayan expressed it in *Inconscient et Réalité* (Unconscious and reality; 1985)—in other words, external reality—organize the subject’s psychic reality in their own way.

## INTERNAL OBJECT

*Internal object* refers to the mental representation that results from introjection, incorporation, or internalization of the relationship to an external object. This is reinforced by the self-representation of the representative agency engaged in that relationship, thus together giving rise to complex object relationships.

Although Freud himself never used the term “internal object,” he provided a foundation, which was then elaborated upon by Sándor Ferenczi and Karl Abraham. It was Melanie Klein, however, who proposed the original theory of an internal world with introjected objects and the ego's ambivalent relations with them. In her theoretical model (Klein 1935, 1940), the young ego split in this way experiences the threat of annihilation both from internal persecution arising from its destructive instincts and, at the same time, from reprisals by its own internal objects under attack. Ronald Fairbairn (1963), Donald W. Winnicott (1954/1958), Wilfred Bion (1962), Thomas Ogden (1987), and others subsequently offered further theoretical clarifications.

The concept of (if not the term) internal object in Freud's work originates with his paper “Mourning and Melancholia” (1916–17g). Freud suggested that during the normal mourning process, the ego introjects the loved object to maintain its close relationship with it before submitting to the reality principle and eventually acknowledging the loss. In melancholia, by contrast, investment in the loved object, which arose in the first place from a narcissistic object choice that was originally ambivalent, is withdrawn when the object is lost; but the libido, instead of being transferred to other objects, is reinvested in the ego and used to form an unconscious identification with the lost or abandoned object. Object loss becomes ego loss, and the divided ego thereafter maintains a tormented relationship with itself. Freud refers to a regression to infantile narcissism in which the subject relates to the object on an oral level; thus, identification is effected through cannibalistic incorporation accompanied by an instinctual and ambivalent struggle to detach from, or preserve, libidinal investment. Melancholia would be also associated with the superego, conceived by Freud as the internalization of parental demands upon the

ego; the superego separates itself from the ego by splitting in the course of the repression that ensues in the wake of the oedipal conflict.

After 1934, and especially with her paper “Mourning and Its Relation to Manic States” (1940), Melanie Klein took up these ideas, and introduced the notion of an internal world of introjected and internalized objects, with which the ego maintains tumultuous relations of love and destructiveness. According to Klein, the splitting of the object and the introjection of the good object are defenses of the ego when threatened with the loss of the object. This process is characteristic of the “depressive position,” during which the part-object comes to be seen by the infant as a whole object, thus susceptible to loss. In this internal world, the play of instincts will threaten the good object (the primary object, incorporated before being introjected) with destruction. But because the good object constitutes the primary core of the ego itself, the ego then fears that it will be annihilated as well. Following Freud’s model of the “purified pleasure ego” (1915c), Klein sees projection as the internal (good) object’s defense against what it experiences as bad objects, whether the feeling of unpleasure is due to frustration or resulting instinctual destructiveness.

Fairbairn’s contribution (1963) took these theories into consideration. Like Klein, he conceived of the ego as present at birth and capable of complete object relations. In case of failure of the primary object relationship, the ego splits off aspects of the self that appear undesirable to the mother, in a fixation to an unsatisfactory aspect of the object; this relation as a whole is repressed with the dual aim of mastering emotions and of creating the desired change in the object. For Fairbairn, “dynamic ego-structures” possess a certain autonomy in relation to the personality (considered as unique), and the internal object, as representative of an external object, is considered a specific agency. Thus, according to Fairbairn, the concept of the undifferentiated id is replaced by the idea of unconscious ego-object structures.

In 1954, Donald Winnicott proposed the notion of the “false self” as a defense organization developed to counter the threat of annihilation. The “false self” is a form of self-care; it energetically manages life in order to shield itself from the experience of an intense pressure to develop according to the internal logic of a primary other.

Wilfred Bion (1962) brought into play the notion of the “container” to describe the process that goes from projective identification to reintroduction. He discusses the unconscious fantasy of projecting into another the undesirable or damaged parts of the self, which can be later reintroduced after modification by this “container.” For Bion, projective identification implies a personality split and ejection of the split-off part as an internal object. The “bizarre” object is an internal object experienced by the schizophrenic patient as having a life of its own, in an ego split such that the patient at the same time recognizes the self as a thing enclosed in the object.

For Thomas Ogden, the internal object relationship necessarily implies interaction between two divisions of the personality, each an active agency (1987). He suggests conceiving of the internal object as an aspect of the split ego, projected into and identified with an object representation. As an active agency able to produce meaning, this suborganization identified with the object works as a self-representation, which corresponds to the representation of the object. The relation to the internalized object implies thenceforth a double cleavage of the ego, because another ego suborganization remains identified with the self and maintains the object relationship.

Maria Torok’s contribution, “The Illness of Mourning and the Fantasy of the Exquisite Corpse” (1968/1994), also deserves mention here. For this author, what is introjected is not the object, but the ensemble of drives and their vicissitudes for which the object serves as occasion and mediator. Here the goal here is to subjectify, to introduce into the ego unconscious, anonymous, or repressed libido. Torok distinguishes the internal object from the imago; the former represents one pole for the process of introjection while the latter represents everything that the ego appropriated through fantasies of incorporation, bringing together everything that had resisted introjection. Such an imago of fixation develops from a failed introjective relationship with an external object, and acts to prohibit sexual desire. Beyond the object, desire is lost, buried in an “endocryptic” identification.

The nature of the internal object remains an open discussion. Melanie Klein’s theoretical propositions lacked clarity, based as they are on attributing literal reality to unconscious phantasies and on postulating agencies that are capable of feeling, thinking, and perceiving. Fairbairn clarified this issue with his suggestion that the

internal object must be considered a split-off part of the ego that remains in relation with an object that is (at least partially) a dynamic structure, but he did not explain the dynamism of this structure. Bion's notion of the "bizarre object" also brought a certain clarity to the discussion by assuming a process in which a suborganization of the ego, a consequence of a split, presents itself to itself as a "thing," and has a fantasy of being included in (part of) the object.

## **INTERNATIONAL ASSOCIATION FOR THE HISTORY OF PSYCHOANALYSIS**

The International Association for the History of Psychoanalysis (Association Internationale d'Histoire de la Psychanalyse), a non-profit organization, was created on June 25, 1985, in Paris by Alain de Mijolla. The Association was created to provide as full an understanding as possible of the history of psychoanalysis and its founder. Its central concerns are the history of the discovery of psychoanalysis; the life of Sigmund Freud; his friends, disciples, and successors; the history of the psychoanalytic movement since its inception, including its international developments and internal divisions; the role of psychoanalysis in the history of the sciences and the intellectual life of the nineteenth and twentieth centuries; and its relation with general history and the political, socio-economic, and cultural characteristics of its time.

Through international meetings held every two years in Paris, Vienna, London, Brussels, and Berlin or Barcelona, the association has been able to promote renewed interest in the history of psychoanalysis. These meetings also led to the creation of other groups and associations devoted to the collection of archival documents and research concerning the historical evolution of psychoanalytic ideas and institutions as well as the contributions of the men and women who have, through their creativity, helped to disseminate Freudian theories.

Presentations, films, and the twice-yearly publication of the *Journal de l'A.I.H.P.* in French and English has given the Association a reputation for accuracy and openness in historical research, and independence from any allegiance to psychoanalytic schools or groups. The Association is open to all professionals and amateurs of history, whether or not they are psychoanalysts. In 2001 the Association received the Mary S. Sigourney award in recognition of its outstanding contribution to the field of psychoanalysis.

## **INTERNATIONAL FEDERATION OF PSYCHOANALYTIC SOCIETIES (IFPS)**

The International Federation of Psychoanalytic Societies (IFPS) was founded in Amsterdam on July 30, 1962, by four Societies: the Deutsche Psychoanalytische Gesellschaft e. V. gegründet 1910, the Sociedad Psicoanalítica Mexicana, the Wiener Arbeitskreis für Tiefenpsychologie, and the William Alanson White Psychoanalytic Society.

The main promoter of IFPS was Erich Fromm, who also was the founder of the Mexican Society, had been excommunicated in the United States, and had lost his IPA membership. As a consequence of his many disappointments, Fromm in 1956 began to wish for the creation of a non-bureaucratic psychoanalytic association of all bona fide psychoanalysts, independently from their persuasion.

He found a sympathetic listener in Werner Schwidder, who wished to overcome the post-World War II isolation of the German Psychoanalytic Society (DPG). In Germany, under the Nazi regime, the psychoanalytic terminology had been prohibited in 1938, and the Freudian Group of the Göring Institute became officially nonexistent. After the war the DPG, which had been founded in 1910, was reconstituted anew. In 1950, however, there was a schism: the DPG lost a number of members, who founded the German Psychoanalytic Association (DPV). Apparently, the reason for the psychoanalytic war was the question of loyalty to the Freudian psychoanalytic

principles: under Müller Braunschweig, the DPV accused Felix Böhm and the disciples of Schultz-Hencke in the DPG of having sold out to the Nazi ideology by rejecting integral Freudian tenets. In 1951 the DPV was admitted to the International Psychoanalytic Association (IPA), while the application of the DPG was rejected because of its deviant psychoanalytic conception (Schultz-Hencke's contributions). When Schwidder succeeded Böhm, he tried to establish international contact. Fromm encouraged him to contact the William Alanson White Society in New York, and Schwidder, hoping for an alliance supportive of analytic "freedom of speech," pointed out in a letter to the White Society that Schultz-Hencke's work had preceded the Hitler's era.

A first open international psychoanalytic meeting took place in Amsterdam in the summer of 1960, a second one in Düsseldorf in 1961, and a year later the First International Forum of Psychoanalysis was held in Amsterdam, on the subject "Present Day Trends in Psychoanalytic Theory and Practice." A number of prominent analysts had agreed to participate at the Forum, among them Franz Alexander, Herbert Binswanger, Médard Boss, Igor Caruso, Erich Fromm, Martin Grotjahn, René Laforgue, Jack Millet, Sándor Rádo, Raoul Schindler, René Spitz, Edith Weigert, and many others. On this occasion a new "Arbeitsgemeinschaft" for promoting a free discussion of psychoanalytic theory and practice, later named IFPS, was founded at a meeting between Igor Caruso, Erich Fromm, Werner Schwidder, and Gerard Chrzanowski. Sándor Rádo, representing the American Academy of Psychoanalysis and its medical psychoanalysts policy only, withdrew from participation in the organization of the federation.

According to the Statutes, "the IFPS is committed to the concept of pluralism in psychoanalytic theory and practice as well as to the interdisciplinary exchange in matters of micro- and macro- social interest." Since 1962, the Forum has been held every four years. In nearly four decades, the IFPS organized 18 international meetings (10 fora and 8 conferences), and the member societies have risen to 22, all from Europe and America, representing about 2,000 psychoanalysts. The minimum requirement for being admitted is a regular training, consisting of three years of theoretical and clinical psychoanalytic instruction (after a full course of studies in medicine or psychology), a personal analysis (three sessions per week), and supervised psychoanalytic sessions with two different supervisors. In 1992, the *International Forum of*

*Psychoanalysis*, a quarterly journal promoted and supported by the IFPS, began to be published, and in 1996 the IFPS *Archives* for the history of psychoanalysis were established.

CARLO BONOMI

## **INTERNATIONAL JOURNAL OF PSYCHOANALYSIS, THE**

*The International Journal of Psychoanalysis* began to be published in 1920 "as an English Journal or Edition of the *Zeitschrift (Die Internationale Zeitschrift für ärztliche Psychoanalyse)*, not identical of course, owned by the Vereinigung [Internationaler Psychoanalytischer Vereinigung]," to use the words of Ernest Jones who proposed the new journal to Freud in a letter dated London the 7th of December 1918.

During Jones's rather controlling editorship, which lasted till 1939, the *International Journal of Psychoanalysis* translated and published some of the most important papers of Sigmund Freud, Anna Freud, Karl Abraham, Sándor Ferenczi, Melanie Klein and others, as well as papers by British and American psychoanalysts and by psychoanalysts from other countries. From the start, *The International Journal* contained a specific section dedicated to the review of books concerned with psychoanalysis.

Originally the aim of Ernest Jones was to create a journal which could make the British Psychoanalytic Society the leading and controlling authority in this field in the English-speaking world, eliminating the competition of the Americans, whose scientific standards Jones deeply distrusted as far as the translation of Freud's papers and the diffusion of psychoanalysis were concerned.

From 1940 to 1945, the *International Journal of Psychoanalysis* was edited by James Strachey. In 1946, it was edited by Adrian Leslie Stephen and from 1947 to 1948 by Willie Hoffer, John Rickman, and W. Clifford M. Scott. It was during this period that, due to the emigration of the Viennese and other analysts from Central Europe to England and America because of Nazi persecution, the *International Journal of Psychoanalysis* became the acknowledged official organ of the International Psychoanalytical Association (IPA), publishing the Bulletins and the business meetings of

the IPA Congresses, taking the place of *Die Internationale Zeitschrift für (ärztliche) Psychoanalyse*, which had ceased publication. In 1947, it was agreed by Anna Freud and her co-workers and by the British Psychoanalytic Society that the IPA would continue to own the heading of the International Journal of Psychoanalysis but that the British Psychoanalytic Society would become the custodian of the journal, which would be edited by a British editor at least for a while. This compromise remains in force.

Willi Hoffer edited the International Journal of Psychoanalysis from 1949 till 1959; John D. Sutherland from 1960 till 1968; Joseph Sandler from 1969 till 1978; Thomas Haley from 1978 till 1988. From 1988 till 1993 Thomas Haley edited the *International Journal of Psychoanalysis* together with David Tuckett. David Tuckett then became the editor of the *International Journal of Psychoanalysis* followed by Glen O. Gabbard and Paul Williams.

During the decades after Jones retired from the editorship, the *International Journal of Psychoanalysis* has continued its policy of translating into English the best papers of psychoanalysts belonging to the various schools, although it has had to face the increasing competition of several other periodicals of psychoanalysis, not only in English, and the complexity of the increasing multiculturalism and multilingualism of the international psychoanalytic community. To try to maintain its leadership, in 1984 Thomas Haley tried to increase the democratic participation in the editorship, which until that time had been controlled only by the British editor with the help of a North American sub editor. Haley created regional boards of sub editors, including psychoanalysts from Latin America, Europe and other parts of the world. This policy is being followed by the current editor. Since 1995, the *International Journal of Psychoanalysis* has been available on CD, and since 1997 it has been accessible on its World Wide Web site.

## INTERNATIONAL PSYCHOANALYTICAL ASSOCIATION

Throughout his lifetime Sigmund Freud was concerned to maintain the unity of the theory and practice of psychoanalysis—an enterprise that he had labored so prodigiously, so single-handedly, and for so long to create. To him, psychoanalysis was not only a science and profession, but also a movement calling for dedicated and disciplined allegiance. When confronted with the enormously painful blow of Carl Gustav Jung's defection, he readily took to the idea, which Ernest Jones claimed to introduce (1955, p. 152), of creating a secret committee of seven ring holders, a group of his geographically scattered closest friends and adherents, to try to ensure the stability of his central psychoanalytic doctrines. This desire to safeguard psychoanalysis as a unified enterprise against both destructive pressures from without and human divisiveness from within also served as a principal impetus for organizing the International Psychoanalytical Association (IPA).

At the first international congress, a scientific gathering of interested colleagues organized by Jung and held at Salzburg, Germany, in 1908, Freud presented the case of the Rat Man, a presentation that took over four hours. The outstanding success of this meeting and the growing concern over the spread of substandard psychoanalytic work by uninformed outsiders, as well as antipathies and attacks emanating from the organized medical and academic worlds, led to the official founding of the IPA during the second congress at Nuremberg in 1910. Three branch societies were recognized at this congress: Vienna, Berlin, and Zurich (Limentani, 1996). This congress was more contentious than the first one in Salzburg. Sándor Ferenczi, who actively promoted this new venture, proposed, with Freud's strong backing, that the administrative center should be Zurich (not Vienna) and that Jung should be president. To mollify the disgruntled Viennese, Freud handed the presidency of the Vienna Psychoanalytic Society to Alfred Adler and designated Adler and Wilhelm Stekel as coeditors of the newly founded official journal *Zentralblatt für Psychoanalyse*.

The first IPA congresses, up through the ninth congress in Bad Homburg, Germany, in 1925, were essentially scientific conclaves of the gradually increasing cadre of psychoanalysts, mostly in the central European heartland in which analysis first grew and thrived, but with members gradually coming from a wider geographic orbit as psychoanalytic influence slowly spread throughout Europe and even across the Atlantic. In fact, at the third, Weimar, congress in 1911, a New York group was admitted as the newly formed American Psychoanalytic Association.

At the fourth congress in Munich in 1913, organizational politics erupted. Jung agreed to continue as president despite increasing opposition by many members, less reluctant than Freud, to face Jung's growing alienation from psychoanalysis. But within a few months Jung's break became final, and he resigned his IPA membership and with it the presidency. Jung's break followed Adler's earlier defection in 1911 and was contemporaneous with other significant departures, those of Eugen Bleuler and Wilhelm Stekel. This early turmoil and the rise of alternative psychologies—Adler's individual psychology and Jung's analytical psychology—prompted Jones to propose the committee of seven (Sándor Ferenczi, Otto Rank, Karl Abraham, Hanns Sachs, and Max Eitingon, in addition to Freud and himself) to watch over Freud's creation. This committee, a major result of the tensions that periodically characterized the history of the IPA, went on meeting and corresponding until 1927.

There were only four congresses, one in Austria and three in Germany, with German the dominant language in each, before the five-year hiatus caused by World War I. When the fifth congress took place in Budapest at the end of the war in 1918, only analysts from Austria, Germany, and Hungary were able to attend. At this fifth congress Ferenczi was elected President, but unfavorable circumstances in his country soon forced him to ask Ernest Jones to take over the position. Thus began a presidency by Jones that lasted from the sixth congress in the Hague in 1920 until the sixteenth congress in Zurich in 1949 (with the exception of a nine-year period, 1925 to 1934, when Abraham and Eitingon served as president). During this period between the First and Second World Wars and under Jones's presidency, a major struggle over lay analysis took place—a struggle that nearly sundered the IPA.

Wallerstein (1998) has detailed the nearly eight-decade long struggle over the question of lay analysis within the worldwide psychoanalytic movement, from its inception in 1910 to its final resolution at the thirty-fifth congress in Montreal in 1987. In 1910 there occurred two events, seemingly totally unrelated and widely separated geographically, that were fateful for the evolution of this conflict. One, in Europe, was the publication of Freud's paper " 'Wild' psycho-analysis," expressing his alarm at the proliferating practice of psychoanalysis by the analytically uninformed. The other, in America, was publication of the famed Flexner report, which exposed the shocking state of medical education in the United States and caused in short order half the existing medical schools in the country to close their doors, with the remainder moving to emulate the preeminent German model and become the approximately 100 top-notch medical schools in the nation by the 1930s. The challenge was to exorcise charlatans from therapeutic activity and to make a proper medical degree, obtained from the fully upgraded schools, the hallmark of proper training and competence in the healing arts.

From these disparate circumstances, one can trace two divergent paths, beginning in 1910, for organized psychoanalysis. One set of developments occurred in central Europe, where Freud lived and was personally influential, and the other in North America, where as early as the second decade of the century some doctors became interested in psychoanalysis, went to Europe for personal analysis and some rudiments of training, and then returned to establish the new science in North America. The European developments were, of course, heavily colored by Freud's personal career. His new doctrines were not welcomed by the established medical and academic worlds, and for the most part, psychoanalysis in Vienna and throughout Europe had to exist as a completely private activity outside of academia and organized medicine and, in its early days, in the face of medical and public opposition. When Eitingon created the first organized training institute in Berlin in 1920 to counter the threat of "wild analysis," it was as a private night school, to which Freud and his followers welcomed all who came and wanted to learn. The majority of those attracted were physicians drawn mostly from a sterile diagnostic neurology, but others came from a great array of other disciplines, including pedagogy, psychology and other social sciences, and the humanities. From the start,

psychoanalysis in Europe was open to all who could qualify, whatever their discipline of origin.

In North America, meanwhile, matters took a different course. Under the impact of the Flexner report, the Americans felt that the integrity of analysis could be safeguarded from psychoanalytic activity by the unqualified only within the increasingly respectable and scientific medical orbit. So from the start they restricted membership in the American Psychoanalytic Association, an affiliate of the IPA, to medical psychoanalysts. Thus Europe and North America, in attempting to cope with the same issues of psychoanalytic standards and competence, embarked on diametrically opposite courses, European psychoanalysis being open to all, with standards to be maintained by rigorous training in organized institutes, and American psychoanalysis excluding all but physicians, with standards to be maintained by barring those without medical qualifications.

This fundamental clash of conceptions was brought squarely into the IPA at the ninth congress, in Bad Homburg in 1925. At this congress the IPA, for the first time, undertook to become more than a scientific congress; it sought to become as well a standard-setting voice for establishing and maintaining uniform training criteria for all psychoanalysts in the growing number of geographically scattered centers of analytic activity in the world. This was done by organizing the International Training Commission (ITC), with Eitingon as its chair. The laudable intent was to establish and monitor internationally agreed-upon standards for training modeled on those of the Berlin institute, which Eitingon established five years earlier in 1920. This measure was also intended to make psychoanalytic credentials portable as analysts emigrated from their countries of origin, which at the time meant mainly from Europe to the United States.

For the Americans at Bad Homburg, this raised the specter of immigration into the United States of nonmedical analysts with credentials from European training centers, all of which accepted nonmedical applicants on the same basis as physicians. The Americans, therefore, strongly objected to the authority of the ITC and cited American laws against quackery, which required them to exclude nonphysicians from therapeutic activity. They asked to be exempted from the regulations of the ITC and to have the right to set their own criteria for admission to training in the United States and their own criteria for acceptance

to American societies, criteria that would cover their own graduates and also immigrant analysts from Europe. Thus began a major confrontation between the Europeans and the Americans that lasted up to the onset of World War II and was only “resolved” by a compromise solution at the sixteenth congress in Zurich in 1949, the first congress after the war.

Strenuous efforts were made over the six congresses between the ninth in 1925 and the fifteenth, in Paris, in 1938, to reconcile the increasingly bitter differences between the Europeans and the Americans so that a viable ITC could function across the analytic world. But each time these efforts were unsuccessful or amounted only to temporary patchworks that promptly broke down. The matter came to a head at the fifteenth congress, in 1938, when the Americans proposed a resolution declaring that the IPA is a congress for scientific purposes alone and calling for the total dismantling of the ITC and the abrogation of any training authority in the IPA over psychoanalysis in America. They backed this up with the voiced threat that if their demands were not granted, they would secede from the IPA and split the analytic world into separate American and European hegemonies. The threat was ominous because the balance in the IPA changed considerably over the immediately preceding five years subsequent to Hitler’s accession to power in 1933. Whereas the Americans were only 20 percent of the total membership at the beginning of the 1930s, by 1938 they were quickly becoming the majority, as Hitler’s march across Europe systematically depopulated the major centers of IPA activity in central Europe, sending a tide of refugees abroad, mostly to the United States.

The threat of secession was indeed portentous: the IPA would have been split asunder, with the American part much the larger and the European part, such as still existed in 1938 after the dispersal of the Berlin and Vienna institutes, under the threat of gathering war clouds. Ernest Jones, the continuing IPA president, therefore proposed deferring a definitive vote on the American motion until the next congress, scheduled for 1940, with an injunction that all affiliated societies intensively deliberate on the issues in the hope that some viable compromise might yet emerge. But two years later, in 1940, Europe was in the midst of World War II and the congress was canceled, not to reconvene until 1949, in Zurich, eleven years after the near split of 1938. In the meantime, soon after the Paris congress the Americans passed what became known as the 1938

rule, asserting full autonomy over training standards in the United States, limiting training to physicians, and barring from admission to the American Psychoanalytic Association all nonphysicians except for a grandfathered handful, all trained before 1938. During the war years the IPA was essentially dormant.

In 1949, when the first postwar congress reconvened in Zurich, a number of divisive issues came to the fore. One was the conditions under which the reconstituted German Psychoanalytic Society could be readmitted, but even more contentious for the IPA was the unresolved issue of relations between the Americans and the Europeans. As IPA president, Jones, together with colleagues from the British Psychoanalytic Society, had taken the lead in exploring this issue even prior to setting a firm date for the congress. Efforts at a solution included an intense transatlantic correspondence and a series of meetings with an American delegation that came to London to meet with the British group. In the end, an amicable gentlemen’s agreement was hammered out, and at the 1949 congress the form of the British-American agreement became clear. The ITC was defunct and would not be resurrected. The American Psychoanalytic Association was granted full control over training standards in the United States with no IPA oversight. The association could thus limit analytic training in American institutes to the medically qualified and bar all nonphysicians from admission to its ranks, except for a few individuals grandfathered under the 1938 rule. In addition, it would have an “exclusive franchise” in its geographic area, meaning that the IPA would recognize no training bodies in the United States other than those affiliated with the American Psychoanalytic Association. Also, from then on, the IPA presidency, heretofore always in Europe and for so long the preserve of Ernest Jones, would alternate between North America and Europe.

In return, the Americans made the concession that direct membership in the IPA could continue, so non-medical analysts who had immigrated to America, though barred from the American Psychoanalytic Association, could still maintain membership in the IPA without being a member of a local affiliated society. All in all, it was an agreement to proceed, in 1949, as if the American proposals of 1938, which never actually came to a vote but which the American Psychoanalytic Association had de facto made operative, had been formally adopted retroactively.

On this basis the IPA, in 1949, reached an accord that formally endured for almost another forty years until the thirty-fifth congress in Montreal in 1987. The issue of lay analysis thus receded from the center of IPA preoccupation until it was abruptly reawakened by a lawsuit against the American Psychoanalytic Association and the IPA, filed in March 1985 in New York and resolved by a negotiated settlement in October 1988, three and a half years later.

For the next several congresses the IPA occupied itself with the codification of its bylaws and procedures. In 1957 President William Gillespie, of London, created a task force headed by Secretary Pearl King to work on codification. After several congresses considered successive drafts, the twenty-third congress in Stockholm, under President Maxwell Gitelson of Chicago, adopted the final document from King's committee. These bylaws codified the special status of the American Psychoanalytic Association as the only regional society of the IPA with the two special privileges of complete autonomy in training matters and exclusive franchise within its geographic area, thus finally rendering *de jure* the rebellious American proclamation of 1938.

Succeeding administrations continued to bring innovations in organizational structure and activity, each marking an increase in IPA administrative authority beyond being merely an organizer of scientific congresses, as it had started out in 1910 and back towards which the Americans tried to consign it in 1938. In 1965, for example, Elizabeth Zetzel, as IPA secretary, was instrumental in launching, in Amsterdam, the first of the still ongoing pre-congress Conferences of Training Analysts. A compromise from the original ITC intention to manage the training activities of the IPA affiliated institutes, the new conferences constituted a forum for representatives of member institutes to discuss training problems encountered worldwide. In 1983 in Madrid the conferences were opened to any training analyst from around the world who wished to participate. Under President Pieter J. Van der Leeuw of Holland (1965–1969), the IPA began disseminating more information and committed itself to helping troubled societies and institutes by dispatching international committees for local site visits, either at the request of the local group or when clear evidence of the need for help became evident. Under President Leo Rangell (1969–1973), the IPA, housed up to that time within the British Psycho-analytical Society from the

days when Ernest Jones was the dominant figure in both organizations, established its own permanent headquarters in London. (The IPA is incorporated, however, under Swiss law.)

President Serge Lebovici of Paris (1973–1977) inaugurated the modern functioning of the IPA. Under his administration the IPA became more international, strengthened its governance, and widened participation in its governance. For example, the 1977 congress was planned for Jerusalem, the first time ever outside of Europe. From then on congresses were hosted in a wide variety of cities on other continents: New York in 1979; Montreal in 1987; Buenos Aires in 1991 (the first time in Latin America); San Francisco in 1995; Santiago, Chile, in 1999; Nice, France, in 2001; and Toronto, Canada, in 2003. Concomitantly, the number of Latin American vice presidents in the IPA Executive Council was increased to give Latin America more representation. Members of the IPA Executive Council began to be more actively involved in administration, the president often asking them to head the ever increasing number of site visits to troubled societies and institutes and to chair regular sponsoring committees for the rapidly proliferating new study groups.

Lebovici also inaugurated two other important moves. The first was to call an all-day meeting of presidents of affiliated societies on the day prior to the opening of each congress. This meeting started as a forum for exchanging information but has since evolved into a structure, the House of Delegates, representing the affiliated societies (as distinct from the Executive Council, elected by the individual members). The House of Delegates was created under President Joseph Sandler of London (1989–1993) and is currently being incorporated into the formal governing structure of the IPA in a manner not yet fully worked out. Lebovici also started a series of IPA symposia that brought together forty to fifty administrative and scientific leaders of the IPA for a week-long conference (with mornings devoted to scientific conferences and afternoons to administrative meetings). These symposia were held every two years, beginning in 1976, in the years between congresses in an isolated rural setting, usually in England but once in Portugal. There were six such symposia before economic retrenchment forced their cancellation during the presidency of Joseph Sandler (1989–1993), and they served to bring the IPA's leadership, scattered all over the world, into close collegial dialogue and friendship.

These symposia also led to the creation of an IPA publishing program. The IPA published monographs on the proceedings of its symposia (held in the years between congresses) and its Conferences of Training Analysts (held in connection with the congresses). These monographs were published in the IPA's four official languages for distribution to members and for sale to others. Two monographs were published commercially, but this plan proved untenable, since it was subject to the schedules of the publishing house and only an English-language publisher was willing to take the commercial risk. The IPA then introduced in-house desktop publishing to publish and distribute a sequence of symposia and Conferences of Training Analysts until it began publishing the *Educational Monograph Series* during the presidency of Robert Wallerstein (1985–1989), which brought this venture to a close.

The presidents after Lebovici—Edward Joseph of New York (1977–1981) and Adam Limentani of London (1981–1985)—built upon the structure put into place by Lebovici. In addition, during these two administrations the IPA involved itself, for the first time, in the turbulent events of the surrounding social and political worlds. This stand forms a stark contrast to the manner in which the IPA, during the many years of Jones's presidency, carefully refrained from political statements, even in the face of Nazi triumphs in Germany and Austria and the subsequent dismemberments of the psychoanalytic societies in Berlin and Vienna. At the thirty-first congress in New York in 1979, this activism took the form of a resolution (in keeping with the practice of other scientific and professional organizations around the world) condemning the repressive practices, disappearances, tortures, and murders being committed under the military dictatorship in Argentina, with a listing of professional colleagues and family members who were among the “disappeared.” At the 1981 congress in Helsinki, faced with a comparable situation in Brazil, the IPA moved the 1983 congress, scheduled for Rio de Janeiro, to Madrid, and shortly later drastically intervened in the analytic society in Rio de Janeiro, where there were serious allegations that a senior figure was shielding a candidate and army psychiatrist complicit in the tortures—a situation that almost totally disrupted all scientific and educational activities in that society. The IPA committee made multiple visits over a several-year period to disentangle the warring factions, marginalize

the extreme protagonists on either side, and enable a central group to restore order and functioning to the society. It should be noted, however, that such strong interventions relating to external political events are rare exceptions and not the norm in the activities of the IPA.

The major event preoccupying the presidency of Robert Wallerstein of San Francisco (1985–1989) was a lawsuit. The issue of lay analysis had not been under consideration by the IPA ever since the agreement for a regional association had given the American Psychoanalytic Association full autonomy over its admissions and training criteria. However, the issue continued as an ongoing controversy within the American Psychoanalytic Association, which, over time, took a number of limited initiatives and appointed a sequence of committees to consider various ways of accommodating the growing pressure to widen its admission criteria beyond psychiatric candidates while trying still to maintain its medical character. U.S. psychologists interested in psychoanalysis were following these years of debate within the American Psychoanalytic Association with growing impatience, and when in 1984 the American Psychoanalytic Association took up the cumulative study of many preceding years to look at the whole problem afresh, the watchful psychologists decided that their only recourse was legal action. Consequently, on March 1, 1985, four clinical psychologists, acting on behalf of a declared class of several thousand, filed a lawsuit against the American Psychoanalytic Association and two of its affiliated institutes on antitrust grounds, alleging a conspiracy in restraint of trade designed to deprive them of access to training and practice in this very prestigious and lucrative means of livelihood.

The IPA was secondarily sued for allowing its American affiliate to engage in these improper activities. The IPA administration headed by Wallerstein (with Edward Weinschel as secretary) was centrally engrossed with this divisive issue from the moment that it took office at the Hamburg congress in the summer of 1985, five months after the lawsuit was filed, until the formal settlement of the suit through a compromise solution promoted by the IPA and accepted by all the involved parties in October 1988, three and a half years after the start of the litigation.

Throughout these often tortuous legal proceedings, the IPA tried to play the role of honest broker between the American Psychoanalytic Association and the

plaintiffs, sympathetically supported by IPA affiliated societies around the world, to whom the exclusionary practices of the American association were completely repugnant. The position of the American Psychoanalytic Association was that it had a right to restrict psychoanalytic training to the medically qualified, a right accorded to it under the regional-association agreement. The American association expected the IPA to support its affiliated organizations in their rights.

Two main events facilitated settlement of the lawsuit. The membership of the American Psychoanalytic Association approved, by more than a two-thirds vote, the recommendation of a new committee studying the question of lay analysis, the Gaskill Committee. This opened the way for qualified nonmedical applicants to be admitted to full clinical psychoanalytic training within its institutes. Soon thereafter the IPA and the American association worked out an alteration of the regional-association agreement (subsequently approved at the IPA business meeting at the 1987 Montreal congress), under which the American association would retain its control over its admission and training standards but would relinquish its exclusive franchise in the United States. This, for the first time, allowed nonmedical psychoanalytic organizations that had unofficially grown up outside the aegis of the American association to qualify for IPA affiliation if they could meet IPA standards. Thus two channels for nonmedical analysts in the United States to become IPA members were opened almost simultaneously, one within the American association and one outside it. All this enabled the IPA and the American Psychoanalytic Association to push successfully for a settlement of the lawsuit, which essentially sought such alterations in training procedures, and bring to final resolution the controversial issue of lay analysis that had so divided the IPA for most of its existence, from the 1925 congress at which the International Training Commission had been established. This long history has been chronicled in Wallerstein (1998).

The Wallerstein administration undertook other important actions: (1) It made Latin America fully equal with Europe and North America by including Latin America in the rotation of the presidency (thus enabling Horacio Etchegoyen to be elected as the first Latin American president of the IPA in 1993) and by equalizing the number of vice presidents at three from each of the three regions. (2) It made IPA governance more democratic by having presidents of affiliated

societies regularly meet with IPA officers at the biannual congresses. (3) It added half-day sessions on child and adolescent analysis, on psychoanalytic research, and on applied analysis as regular components of the scientific program at IPA congresses. (4) It inaugurated the IPA *Educational Monograph Series* (replacing the earlier monographs on symposia and on Conferences of Training Analysts). In this series of teaching monographs, distinguished analysts from around the world discuss a seminal paper of Freud's, reviewing it in the light of intervening developments in analysis since Freud's time. As of 1996, four educational monographs had been published.

President Joseph Sandler of London (1989–1993) and Secretary Jacqueline Amati Mehler took office at the thirty-sixth congress in Rome in 1989. Its four years were marked by three main thrusts: (1) IPA governance became more democratic. For one, the entire worldwide membership began electing IPA officers by mail ballot. This system replaced elections at congress business meetings by those able to be present. In addition, out of the meeting of presidents of affiliated societies there evolved a new structure, the House of Delegates, whose twenty-seven members are elected by and represent affiliated IPA societies. The House of Delegates is gradually working out its role in relation to the president and Executive Council, elected by vote of individual IPA members; (2) The IPA has made psychoanalytic research part of its core mission with the inauguration of an annual Psychoanalytic Research Conference held each year at University College, London; (3) The IPA is making a greater effort to bring precept and practice together in a uniform base of training requirements so that graduating from an IPA institute has comparable meaning and represents comparable accomplishment wherever the institute is located in the world.

At the thirty-eighth congress in Amsterdam in 1993, the first Latin American administration of the IPA was inaugurated, with Horacio Etchegoyen of Buenos Aires as president and Ana Maria Andrade de Azevedo as secretary. This administration has further formalized the role of the House of Delegates (representing the affiliated societies), alongside the president and the Executive Council (representing the individual members), in the governing structure of the IPA. At the fortieth congress in Barcelona in 1997 this administration was succeeded by one from North America headed by Otto Kernberg of New York as president

and Robert Tyson as secretary. From the commitments made during the presidential campaign, it is clear that a major emphasis will be on a marked expansion in IPA support for psychoanalytic research. Kernberg also is committed to increasing regional activities in the IPA as a counterweight to the world gatherings grown increasing unwieldy as the IPA expands in numbers and geographic dispersal. By 2004 it has grown from fewer than 100 close colleagues and mostly friends who started the organization in 1910 to an organization now poised at the 10,000 mark, with over 45 societies in 30 nations on almost every continent and with four official languages. From this base of growing strength and the vitality chronicled in this brief history, it confidently faces its future.

## INTERNATIONALE ZEITSCHRIFT FÜR (ÄRZTLICHE) PSYCHOANALYSE

In the wake of conflicts concerning the *Zentralblatt für Psychoanalyse*, the directorate of the International Psychoanalytic Association passed a vote of no confidence in the editor Wilhelm Stekel on November 24, 1912. A new review, the *Internationale Zeitschrift für (ärztliche) Psychoanalyse* (International Review of [Medical] Psychoanalysis), was founded with Hugo Heller, and from 1913 it replaced the *Zentralblatt* as the official organ of the IPA. It was directed by Sigmund Freud with an editorial committee initially consisting of Sándor Ferenczi, Otto Rank, and Ernest Jones.

The creation of this review reflects the efforts of the IPA to define strict limits in relation to other psychoanalytic schools emerging at the time. Its declared aim was first of all to provide structures for scientific

communication, even outside of congresses, between the different associations interested in receiving international psychoanalytic training. Apart from clinical and theoretical contributions, the *Internationale Zeitschrift für (ärztliche) Psychoanalyse* therefore included a considerable number of reviews of contemporary literature as well as an IPA correspondence section bringing together documents concerning the activities of the different groups. It is impossible to overestimate the importance of this review, which brought together on this central stage and around psychoanalysis early scientific discussions involving all the pioneers of the day.

Faced with financial problems toward the end of World War I, Hugo Heller editions could no longer undertake to publish the review and, in 1919, the *Internationaler Psychoanalytischer Verlag* was founded mainly with a view to continuing its publication. In 1919, Karl Abraham and Eduard Hitschmann joined the editorial committee and the term "ärztliche" (medical) was dropped from the title, which thus became *Internationale Zeitschrift für Psychoanalyse*.

In 1920 Otto Rank, as director of the *Internationaler Psychoanalytischer Verlag*, became the chief editor, assisted by the members of the editorial team, who changed from year to year. Following his dispute with Freud, Rank lost all his official functions, including editorship of the review. In 1925 Max Eitingon, Sándor Radó, and Sándor Ferenczi replaced him as the new chief editors.

As soon as World War I came to an end, it became increasingly obvious that psychoanalysis was giving rise to an unexpected and growing interest in the world, particularly in Anglo-Saxon countries, so much so that a central purely German-language publication could no longer meet demands. For this reason Ernest Jones, with the support of Sigmund Freud, founded an English-language counterpart of the *Internationale Zeitschrift für (ärztliche) Psychoanalyse*, the *International Journal of Psycho-Analysis*, which published abstracts and translations of articles in reciprocal collaboration with the *Internationale Zeitschrift für (ärztliche) Psychoanalyse* and *Imago*.

The National Socialist rise to power in Austria in March, 1938, signaled the immediate suspension of the review. United with *Imago*, it appeared under the title *Internationale Zeitschrift für Psychoanalyse und Imago* from 1939 to 1941 during its exile in London.

The German Reich's policy of destruction and the events of the war made it impossible to continue to publish the review in German. The *International Journal of Psycho-Analysis*, published in London and supported by many exiles, then took its place.

## INTERNATIONALER PSYCHOANALYTISCHER VERLAG

At the end of World War I, it was uncertain whether publisher Hugo Heller could continue publishing the *Internationale Zeitschrift für (ärztliche) Psychoanalyse* and *Imago*. A project was then undertaken to establish a psychoanalytic publishing house independent of commercial interests: International Psychoanalytic Editions.

Creating the company was made possible by the generous support of Anton von Freund, a Budapest businessman and patient of Freud. In the fall of 1918, during the international psychoanalytic congress in Budapest, Freud was made aware of the existence of the grant, intended to promote scientific publication and the publication of professional journals edited by the International Psychoanalytical Association. In January 1919 Otto Rank became head of the company, now named the Internationaler Psychoanalytischer Verlag (International Psychoanalytic Press). Other participants included Sigmund Freud, Anton von Freund, and Sándor Ferenczi. The goal for the publishing company was to ensure the publication not only of journals and other publications with small circulations but above all of an “official reference” (according to Freud’s letter to the presidents of the psychoanalytic

societies, Easter 1932), to stand out from the growing literature on pseudo-psychoanalysis. Subjecting psychoanalytic literature to peer evaluation seemed necessary not only in the German-speaking world but also in the English-speaking world, where Ernest Jones was active.

In 1920 Jones, together with Rank, created an English publishing branch of the Internationaler Psychoanalytischer Verlag, the International Psychoanalytical Press. It published the *International Journal of Psycho-Analysis* and the International Psychoanalytical Library series. Along with English-language authors, this press also published authorized translations of Freud’s work by C. J. M. Hubback and James Strachey.

Working with other publishers, the Internationaler Psychoanalytischer Verlag helped produce books in Hungarian, Polish, and Italian. From its two psychoanalytic journals (*Internationale Zeitschrift für [ärztliche] Psychoanalyse* and *Imago*), the publisher produced books in the following three series: Imago-Bücher and Internationale psychoanalytische Bibliothek (Imago Books and the International Psychoanalytic Library), Neue Arbeiten zur ärztlichen Psychoanalyse (New Research on Medical Psychoanalysis), and Quellenschriften zur seelischen Entwicklung (Basic Writings on Mental Development).

The financial success of the operation was hampered by the runaway inflation after the First World War, which caused von Freund’s grant to lose a considerable portion of its value. From the early 1920s, recurring economic crises were a constant threat to the venture. Finally, in 1923, poor financial circumstances caused the liquidation of the press in Great Britain; personal dissension between Jones and Rank about the future direction of the publishing house was also a factor in its decline.

Conflicts over Rank’s revision of dream theory in his *Das Trauma der Geburt und seine Bedeutung für die Psychoanalyse* (*The Trauma of Birth*), published by Internationaler Psychoanalytischer Verlag in 1924, led to his resignation from the editorial committee. Adolf Josef Storer took over from Rank and carried out a series of ambitious editorial projects: he founded the *Psychoanalytische Bewegung* (Psychoanalytic Movement), launched the *Zeitschrift für psychoanalytische Pädagogik* (Journal of Psychoanalytic Teaching), and began publishing a psychoanalytic almanac.

Unfortunately, the publishers were unable to weather the surrounding economic crisis. After Storer's resignation, Martin Freud took his place in 1932 and attempted, with his father's help, to save the company from bankruptcy. During Easter 1932, Freud wrote an urgent letter of appeal to members of the International Psychoanalytical Association to help save the company. Through the creation of a publishing committee and with donations from members, especially from Marie Bonaparte and Abraham Arden Brill, the company narrowly escaped ruin.

But the economic crisis was replaced by a political crisis following the rise to power of the National Socialists in Germany. Freud's writings were burned in May 1933, and psychoanalytic authors were gradually forbidden to publish in Germany. In 1936 the Leipzig inventory of the *Internationaler Psychoanalytischer Verlag* was seized, and its entire publishing program for Germany had to be canceled. Under these conditions the number of books published and sold declined sharply. Shortly after the beginning of the annexation of Austria into the German Reich in 1938, the Vienna publishing house was seized by the Gestapo and liquidated by an administrator.

## **INTERPRETATION**

Interpretation seeks to bring out, within the confines of the analytic method, the latent meaning of a subject's words and behavior; its aim is to reveal unconscious desires and the defensive conflicts that are linked to them. Technically, interpretation consists in making manifest this latent meaning, in accordance with the rules dictated by the various phases of the treatment.

The first version of the theory of interpretation was delineated by Sigmund Freud in his psychoanalytic study of dreams (1900a) and is applicable to other products of the unconscious, such as parapraxes, slips of the tongue, and symptoms. For Freud, psychoanalysis was an art of interpretation, but he preferred the term "construction" as a description of the core of the psychoanalytical method, that is, the unveiling of the unconscious. This "construction" of the unconscious is entirely a matter of applying successive interpretations to the different aspects of a case. The interpretations allow an overall perspective to emerge and thus define a strategy for the treatment; however, it might also be tactically necessary at times to adjust to unforeseen developments.

Interpretation is not just a matter of what needs to be expressed and its actual utterance: it conveys its own meaning, one that disturbs that defensive arrangements meant to maintain the effectiveness of repression. Care must be taken not to provide a premature "translation" of unconscious content, as this risks discouraging the patient, reinforcing his resistance and creating a purely intellectualized understanding. Firstly, the affects associated with these defensive structures need to come to expression, and this implies a struggle of wills. While interpretation is characterized by the necessary intelligibility of its formulations—its reductiveness—as well as by its closeness to manifest representation, generalization, and theorization, it also has a darker and more complex dimension that relates to the polysemy of language, personal symbolism, or the history of the affects involved. Bringing out these affects opens up an economic dimension in which instinctual energy forces the representation into the open. This is made possible, first of all, through the workings of the transference and the counter-transference.

In "The Dynamics of Transference," Freud insisted that interpretation should not begin before the appearance of the transference, and specified that the goal in interpreting the patient's transference is "to compel him to fit these emotional impulses into the nexus of the treatment and of his life-history, to submit them to intellectual consideration and to understand them in the light of their psychical value. This struggle between the doctor and the patient, between intellect and instinctual life, between understanding and seeking to act, is played out almost exclusively in the phenomena of transference. It is on this field that victory must be won" (1912b, p. 108).

What the interpretations communicate to the patient in terms of the construction of the unconscious, and on the basis of the transference, is indissociable from the analyst's reconstruction which is based on the analysis of his own counter-transference. The analyst responds to the transference demands with only a minimum of authority, allowing him to make the counter-transference into a tool for exploring the unconscious of the patient. For Freud, the unconscious of the patient is consequently revealed through the unconscious of the analyst.

The primary goal of interpretation is the lifting of resistance: the cure is not the result of a premature recognition of whatever has been repressed, but occurs through a victory over the resistances at the source of this ignorance. Thanks to the love-transference and the psychoanalyst's patience, the analysand should be able to accept the psychoanalyst's "translation" without these revelations about their unconscious adding to their conflicts or symptoms. Freud rejected any interpretation that is isolated from the symbolic material issuing from the unconscious, and indicated that it would be a mistake to think that the interpretation of dreams is central to all analyses.

As Michel Fain wrote, "While the turning of 1920 [*Beyond the Pleasure Principle*, 1920g] shattered the metapsychology of 1915, conceptions from the first topic continued to influence Freud's conception of interpretation" (1983). It would seem useful to emphasize the necessary complementarity of the two topics, neither being able alone to account for the theoretical role of interpretation.

"The path that starts from the analyst's construction ought to end in the patient's recollection; but it does not always lead so far. . . . If the analysis is carried out correctly, we produce in him an assured conviction of the truth of the construction which achieves the same therapeutic result as a recaptured memory" (Freud, 1937d, pp. 265–66).

Interpretation has recently become one of the latest focuses in the epistemological debate over the status of psychoanalysis. The "experimental" point of view, in which interpretation is conflated with a generalizable scientific truth that results from verifiable protocols and can be duplicated within the context of multidisciplinary research, includes certain models from psychoanalytical theory, comparing them with other developmental models or conceptual tools from psychopathology.

Conversely, the "hermeneutic" point of view results in a purely relative, narrative, and pragmatic conception of truth, whereby the interpretation is only a new version of the life story that makes the patient feel better. Consequently it tends towards a language of action that valorizes the conscious dimension. Highlighting the narrative point of view obviously involves challenging the status of metapsychology (Schafer, Roy, 1983), but the "scientific" point of view ultimately leads to the same tendency.

A closely related notion, often mentioned when clinical cases are being discussed, is that of "intervention." It is often used by default, when the analyst wants to utter words that are deemed appropriate, without the elements of the construction justifying those words being clearly established. It is given that analysts do not merely proffer interpretations during the session—in addition they may request a clarification, verify an element already referred to in the treatment, encourage the patient to continue speaking, and the like.

However, because of the transference situation, it is impossible to predict the outcome of these interventions, whose inoffensive, innocent, or insignificant character cannot be affirmed *a priori*. Jean Cournut has criticized the illegitimacy of this notion, adding that, in his view, "the term 'intervention' should be eradicated from the lexicon of psychoanalysis" (1983).

## INTERPRÉTATION

The review *Interprétation* was born in 1967 of a meeting between the desire to challenge the practice and teaching of psychiatric thinking in Canada, on the part of a team of the Research and Teaching Service of the Laurentides Hospital (directed by Marcel Lemieux),—and the passion and commitment of the psychoanalyst who became its editor-in-chief, Julien Bigras.

Having taken from the very beginning the course of interdisciplinarity, for the purpose of furthering reflection through the encounter of the various human sciences, the review, independently of any school, opened itself up equally to literary and artistic milieus, making much room for foreign authors, especially French. Conrad Stein was editor for France between 1967 and 1971. The editorial committee for the first numbers of the review comprised: André Saint-Jean, Claude Lagadec, Pierre Mathieu, Carlo Serlin, Laurent Santerre, Rémi Savard, and Élizabéth Bigras. After a break of seven years, the review began publishing again, with the same editor-in-chief and a new editorial committee, including Jean-Jacques Couvrette, François Peraldi, and Josette Garon.

The review has published many articles on specifically psychoanalytical themes, such as, for example, the psychoanalytic process, fantasy life, and psychoses, or on the question of the training, education, and commitment of psychoanalysts, as well as on the theories and works of Freud and authors who have written about and after him. There have been also a

number of articles relating to anthropology, sociology, literature, pedagogy, semiology, philosophy, theology, and the theory of communication.

This review has published texts of many different forms: clinical and theoretical articles, translations, conferences, and congress reports. Exchanges have taken the form of letters, discussions, and responses; authors have also published original creative works, such as poems, stories, and theatrical scenarios. The review has organized encounters and colloquia, playing an important catalytic role in the Quebec milieu. A crossroads of the human sciences, it has kept open the question of the wealth, but also the limits of interdisciplinarity, as well as that of the limits of psychoanalysis.

## INTERPRETATION OF DREAMS (ANALYTICAL PSYCHOLOGY)

Jung considered the dream a natural and normal psychic phenomenon describing the inner situation of the dreamer, a “spontaneous self-portrayal in symbolical form of the actual situation in the unconscious” (Jung, 1947). In analytical psychology the dream is seen as neither a disguise nor a symptom but as a source of new understanding, especially of the psychic function of archetypal imagery. Jung never distinguished between manifest and latent meaning, since he based his understanding directly on dream content. Analytical psychology does not generally encourage free association per se; rather, it employs circular associations around the various images and actions in the dream to make sense of the dream in its entirety. In analytical psychology, the concepts of sign and symbol have meanings different from their meanings in psychoanalytic usage. For Jung, a sign is a token of meaning that stands for something known, whereas a symbol is an image that points to something partially known but unknowable at its core. A symbol has a subjective dynamic that powerfully attracts the individual and transforms psychological energy.

Jung first read Freud’s *Interpretation of Dreams* in 1900 as a student at the Burgholzi Psychiatric Clinic in Zurich, reviewing it for his fellow psychiatric students

(Jung, 1907). He began to develop his own ideas about the meaning of dreams shortly after his break with Freud around 1912 to 1913, and by 1928 he had outlined his mature views.

Dreams can be interpreted on three levels: objective, subjective, and transference. Any interpretation that refers the images in the dream to the subject's view of external objects is considered an interpretation on the objective level. Any interpretation that refers every part of the dream back to the dreamer is an interpretation on the subjective level. Interpretation on the objective level breaks the dream content down into memory traces referring to the external situation. Interpretation on the subjective level detaches the underlying memories from their external sources and presents the dreamer with the images as inner facts. Such experience of inner reality opens the way for psychological transformation. Transference interpretation is a mixture of the two levels, except that dream images are interpreted in relationship to the transference.

Dreams compensate for attitudes held consciously. This follows from the concept of the psyche as a self-regulating system, dreams representing an unconscious voice. Jung saw compensation as operating in two directions. One he termed the "prospectively function," by which he meant that the dream is an anticipation of future conscious achievement. This does not mean that dreams are prophetic; rather, a dream is a preliminary exercise, a combination of possibilities, roughly sketched out in advance. In their prospective function, dreams can be both integrative and synthetic. In the other direction, the reductive function, the dream operates as a retrospective compensation, bringing up repressed material. A dream can be interpreted in either or both directions at the same or different times and at different developmental stages. No interpretation is considered final.

Another important, uniquely Jungian method in dream interpretation is amplification. Here analogous material is brought into play to enlarge upon the symbols of the dream. Parallels from mythology, folklore, anthropology, comparative religion, ethnology, and current cultural patterns are presented to the analyst to elicit a richer understanding of the dream. Amplification is used less often today, as analytical psychologists have become more aware that it can be used to avoid personal issues.

Basically, analytical psychology teaches an open attitude in interpreting dreams. Jung stressed that each dream should be approached without preconceived notions. At the beginning of the twenty-first century there is a greater emphasis on transference interpretations in analytical psychology. Yet many analytical psychologists hold the view that dream images are part of the objective reality of the psyche and that dream interpretation is central to theory and practice.

## INTERPRETATION OF DREAMS, THE

Even more than the *Studies on Hysteria*, written in collaboration with Josef Breuer (1895d), or the *Project for a Scientific Psychology* (1950c [1895]), *The Interpretation of Dreams* may be considered the founding work of psychoanalysis. It was with this book that Freud sought for the first time to present an overall view of mental functioning. Most of its tenets were maintained unchanged throughout Freud's lifetime, and even today the book is considered indispensable to any possible theoretical progress in psychoanalysis.

Freud became interested in his patients' dreams early in his career, feeling that they might provide useful information about what, consciously or not, they hid from their doctor. He also came to believe that dreams and symptoms were formed in an analogous way. He went further, asserting that the mechanisms involved were not restricted to pathological processes, and that the analysis of dreams could serve as a powerful method for explaining mental functioning in general. He began to write down and analyze his own dreams, and the material generated in this way would eventually constitute the greater part of the empirical evidence on which *The Interpretation* was based.

Preparatory work went on for nearly four years, from the spring of 1896 to the end of 1899. Freud was slowed down in part by a self-imposed obligation to reviewing the whole of the existing literature on dreams, and more importantly by the fact that he had indeed embarked on the development of a general theory of the functioning of the psyche. During a burst of creative energy he produced a first outline in 1895 (the posthumously published "Project for a Scientific Psychology"). He drew inspiration from the theories of his teacher Ernest von Brücke and of Hermann von Helmholtz, who believed that all biological, and hence neurological and by extension psychological, activity could be reduced to physical and chemical processes. On this basis Freud worked out a neurobiological model that was strictly imaginary (albeit filled with extraordinary insights) and entirely based on the supposed working of neurons, which had only recently (1891) been discovered. But he was disappointed with this paper, put it aside, and set about reformulating his theory in terms of mental processes alone. Four years later, in September 1899, the manuscript of *The Interpretation of Dreams* was finished.

The work was published by Deuticke on November 4 of that year, but—prophetically enough for a book that inaugurated the "century of psychoanalysis"—it bore the publication date of 1900. The book had a rather frosty reception, however, and to begin with sales were wretchedly bad. But over the long term it enjoyed an extraordinary success: there were ten reprintings in Germany during Freud's lifetime, and innumerable translations. Over the years Freud continually modified and (especially) added to his text, so that each new edition reflected developments in his thinking.

Freud makes four fundamental claims in *The Interpretation of Dreams*:

1) He proposes a method for investigating mental processes. The content of a dream (its "material") rarely sheds direct light on the processes that shape it; the meaning has to be teased out of the interplay between chains of association in the mind of the dreamer (who is urged to express all thoughts that come to mind, excluding nothing, no matter how irrelevant it may seem) and interpretations offered by the analyst. Through their interaction, these associations and interpretations lead to a clarification of the "latent dream-thoughts" beneath the manifest content. For Freud the interpretation of dreams is the "royal road" to the unconscious—to that part of mental life which has been subjected to repression—in that the manifest content of the dream reveals the "return of the repressed."

2) He lays down a general rule: every dream represents a wish fulfilled. He sets out to show that even when the manifest content of a dream is distressing, the latent meaning always embodies a search for satisfaction. This is a direct echo of the "Project for a Scientific Psychology," according to which the neuronal apparatus tends to release large amounts of energy that circulate within it. In psychic terms, this becomes the "pleasure-unpleasure principle": the reduction of unpleasure and a corresponding access to pleasure by means of a discharge of energy. This account in terms of energy, the basis of the "economic point of view" in Freud's theory, derives directly from Helmholtz and Brücke; its generalization would later lead to the notion of the libido.

3) In order to transform the latent dream-thoughts into manifest content, the dream-work relies on four means of distortion. Freud sees these procedures as belonging to two stages: in the first, the primary processes operate by means of displacement, condensation,

and visual representation; then secondary processes (“secondary revision”) restore a consistency and surface plausibility that makes the dream content acceptable but by the same token guarantees that the dream’s latent meaning is misapprehended.

4) Freud takes pains to emphasize that he is by no means offering a new “dream book”: every dream has an individual meaning discoverable only by applying his principles of interpretation. All the same, the sources of human dreams lie in wishes of a similar kind, and give rise to analogous conflicting forms, while the latent content is submitted to the same transforming mechanisms. The result is the existence of “typical dreams” whose meaning is quasi-universal, even if the details are specific to the individual dreamer. Such typical dreams include dreams of nakedness, dreams of the death of loved ones, examination dreams, and so on.

How is such “common symbolism” related to the individual’s symbolizing processes? This is a question which preoccupied Freud continually, and indeed gave rise to most of the many revisions he made over the years to *The Interpretation of Dreams*.

## INTERSUBJECTIVE / INTRASUBJECTIVE

The intersubjective/intrasubjective dichotomy often appears in the psychoanalytic literature against the

background of another pair of opposites, interpersonal/intrapersonal. In reality, these two pairs of opposites cannot be superimposed.

Psychoanalysis is concerned primarily with the intrasubjective and the intrapsychic, and what pertains to the “subjective” (inter- or intra-) presupposes reference to a subject differentiated on both the extrapsychic and intrapsychic levels, whereas that which pertains to the “personal” presupposes only reference to individuals who are differentiated on the extrapsychic level, but may not yet be entirely differentiated on the intrapsychic level.

In his study of early childhood, Donald Winnicott made important contributions to the study of the dynamics of the intersubjective/intrasubjective dichotomy by providing a deeper understanding of the “sense of the continuity of being” and the role of the self-object environment. On the other hand, “developmental” psychoanalysis has focused primarily on the issue of interpersonal relations between the baby and its interactive partners, and has been criticized on a metapsychological level.

The work of Daniel N. Stern, a student of René Spitz, is worthy of mention in that his concept of “affect attunement” seeks to show how a mechanism at the interpersonal level helps open access to the intersubjectivity by which it is in fact determined. Another of Spitz’s students, Robert N. Emde, has also carried out important work in this vein.

Nevertheless, a purely metapsychological approach is problematic here because it is hard completely to disregard a phenomenological point of view. Moreover, the functional mechanisms and modalities that lead from the interpersonal to the intrapsychic are as yet unknown.

## **INTRODUCTORY LECTURES ON PSYCHO-ANALYSIS**

The *Introductory Lectures on Psycho-Analysis* is based on a series of two-hour talks given by Sigmund Freud at the University of Vienna between 1915 and 1917 to initiate both doctors and laypeople to the fundamental principles of psychoanalysis. Delivered with the intention of publication at a later date, the published *Introductory Lectures* had enormous success, with fifty thousand copies sold in German during Freud's lifetime. Together with the *Psychopathology of Everyday Life* (1901b), it was—and still is—Freud's best-known work.

The approach Freud used is that of the public lecture. The *Lectures* are not treatises but simplified expositions of ideas and of the results of established research. He provides a number of examples and anecdotes, and devotes a large portion of the book to the psychopathology of everyday life and dreams, subjects of immediate relevance to his audience. Yet he also strives to delineate the special nature of psychoanalysis, particularly the aspects that people find difficult to acknowledge, and that are comparable in their insult to human megalomania as the revelations of Charles Darwin and Nicolas Copernicus.

The book is divided into three parts of unequal length. The first, which is short, is on parapraxis, the second and third, which are more fully developed, are on dreams and the general theory of neuroses. There is a gradual progression in the three sections, accompanied by a notable erasure of the distinction between the normal and the pathological. Freud insists on the versatility of his method, which he claims is easier to understand by the study of dreams rather than of symptoms.

Regarding slips, Freud proposes that their relevance lies in the meaning of the symptom and not the psychophysiological determination. Along with meaning, Freud introduces two of the prime movers of mental life, sexuality and aggressivity. The theory of mental conflict is outlined: parapraxes “arise from the concurrent action of two different intentions” (1916–17a, p. 44). Dreams had been previously discussed in an

abridged presentation addressed to the general public and titled “On Dreams.” (1901a) In this essay, which provides greater details on dreams than the *Introductory Lectures*, Freud makes an attempt to identify and discuss all possible objections to his theory, as he had done in *The Interpretation of Dreams* (1900a). In this regard he discusses the number of interpretations and the complexity of the interpretative process, which he justifies by comparing it to the tortuous efforts of customs agents in trying to find contraband material. He stresses that only practice and experience can determine the actual degree of comprehensibility of the dream and that the “lay public, including the scientific lay public, are well known to enjoy making a parade of scepticism when faced by the difficulties and uncertainties of a scientific achievement” (1916–17a, p. 232).

Part three is extremely condensed, given the scope of the subjects treated, which range from the unconscious to the development of the libido, the formation of various symptoms and how they are handled during psychoanalysis. Freud discusses the differences between his point of view on the libido and that of Carl Gustav Jung. Addressing the notion of the “ego libido,” he tackles the question of treating “narcissistic neuroses,” discusses nosographic considerations in the case of paraphrenia (combining paranoia and precocious dementia under the same term), and ends with the issue of transference. Transference is compared to the intermediate layer between the tree and the bark, a layer that serves as the starting point for the formation of new tissue and an increase in trunk diameter. As a result the patient's symptoms lose their primitive meaning and acquire a new meaning in relation to the transference. The work of healing is then defined as follows by Freud: “The decisive part of the work is achieved by creating in the patient's relation to the doctor—in the ‘transference’—new editions of the old conflicts; in these the patient would like to behave in the same way as he did in the past, while we, by summoning up every available mental force [in the patient], compel him to come to a fresh decision” (1916–17a, p. 454).

In these lectures for the lay public, Freud addressed, as he had done previously in the case of dreams but on a much larger scale, the difficulties and paradoxes of university training in psychoanalysis. “As a result of receiving your instruction at second hand, as it were, you find yourselves under quite unusual conditions

for forming a judgement” (1916–17a, p. 18). Consequently, the claim that there is no objective criterion by which to judge the truth of psychoanalysis appears to eliminate it from the domain of science, where Freud maintains it belongs. The weakness of the epistemological argument leads to the pragmatic argument that we can only learn psychoanalysis through self-experimentation. Here, Freud’s talent as a dialectician is apparent, and in the remainder of the work, he gradually tries to convince his reader of his claims.

## INTROJECTION

Introjection is a fundamental process in the mental development of the infant, related to incorporation fantasies. Sándor Ferenczi emphasized the idea of identification with the aggressor in post-traumatic syndromes through introjection of the adult’s feelings of guilt.

This notion became fundamental after Ferenczi developed it. In the neurotic it entails including as much of the external world as possible within that individual’s sphere of interests; the neurotic’s ego is pathologically inflated. This mechanism is the opposite

of projection, which causes the paranoiac to project outward emotions that have become too painful; in contrast to the neurotic, the paranoiac suffers from a shrinking of the ego. The schizophrenic, meanwhile, more or less withdraws his or her interest from the outside world. In addition, from the earliest mother-child relations, introjection constitutes a primary process that organizes the psyche, as the very basis of love and thus of the transference.

Introduced by Ferenczi in “Introjection and Transference” (1909), the idea of introjection was taken up by Sigmund Freud in “Instincts and Their Vicissitudes” (1915c), and again in “Mourning and Melancholia” (1916–17 [1915]). It was then further developed by Karl Abraham in the chapter “The Process of Introjection in Melancholia: Two Stages of the Oral Phase of the Libido” in “A Short Study of the Development of the Libido, Viewed in the Light of Mental Disorders,” (1924), devoted to his research on manic-depressive psychosis. In “Instincts and Their Vicissitudes,” with regard to the instinctual mechanisms and love, Freud wrote: “Loving admits not merely of one, but of three opposites. In addition to the antithesis ‘loving—hating’, there is the other one of ‘loving—being loved’; and, in addition to these, loving and hating taken together are the opposite of the condition of unconcern or indifference. The second of these three antitheses, loving—being loved, corresponds exactly to the transformation from activity to passivity and may be traced to an underlying situation in the same way as in the case of the scopophilic instinct. This situation is that of *loving oneself*, which we regard as the characteristic feature of narcissism. . . . (p. 133). . . . [T]he ego-subject is passive in respect of external stimuli but active through its own instincts” (p. 134). The description of turning around of the instinct onto the subject, thus with the same aim but a different object, is supported with the examples of sadomasochism and voyeurism-exhibitionism.

It may be that the severe pathologies of narcissism are organized as a result of these early introjections, producing different unconscious identifications. There are three of these: primary identification, linked to a relation of cannibalistic incorporation (Karl Abraham), a primitive defense mechanism involving absorption of a part of the maternal object; projective identification, whose aim is controlling others by means of projection outside of the self of the good parts that have already been introjected, leading to

impoverishment of the ego and the psychotic consequences that are corollary to the schizoid-paranoid stage (Melanie Klein); and finally, identification with the aggressor, linked to the traumatic origins described by Ferenczi in “Confusion of Tongues between Adults and the Child: The Language of Tenderness and Passion” (1932/1949), where he emphasized the child’s “introjection of the guilt feelings of the adult” (p. 228) when there has been maltreatment or early sexual abuse, whether incestuous or not. He accounted in this way for fragmentation of the personality, turning of the instincts back onto the self (compulsive masturbation and different depressive syndromes) when there has been early abuse of this type (*Verführung* is usually translated as “seduction”). There is also a reversal into their opposites of the child’s instincts after this kind of abuse by an adult, which brings with it the child’s loss of confidence in his or her own perceptions, fragmentation of memories, recurring dreams, and a whole pathological procession that far exceeds the bounds of neurosis (often called “introjection disorder”). It involves emotional disturbance and psychopathic problems, early eating disorders, substance abuse, psychosis, or intergenerational repetition of perverse behaviors.

From a metapsychological perspective that takes into account the idea of adaptation, Ferenczi, at the end of his life, invented a neologism that combined introjection with the violent effects of parental repression and of a certain tendency in analysis. He wrote in his *Journal*: “Child analysis, education, are the ‘intropression’ of the superego by adults” (1985 [1932]). In France, this line of research was continued by Maria Torok and Nicolas Abraham, for example, in “Le crime de l’introjection” (The crime of introjection; 1963), where Abraham evoked the ego’s need, faced with the death, wickedness, or inconstancy of the external object, to put in place “a reintroduction of the corresponding Imago.” Manic-depressive psychosis is triggered not by the loss of the external object, but instead by the threat of losing the indispensable internal object. In each case, what is involved is disavowing the “crime,” which, in the final analysis, is “having introjected the object.”

## “INTROJECTION AND TRANSFERENCE”

Sándor Ferenczi met Sigmund Freud in February 1908, and the following year he wrote this successful paper, a theoretical and clinical achievement that proved his creativity and maturity. Previously he had published numerous studies on topics as varied as “love in science,” spiritualism, and the organization of a hospital ward, and had read all the psychoanalytic literature of the time before coming to Vienna. Ferenczi’s practice of hypnosis, psychiatry, and psychoanalysis provided him with a body of material that he used in

this original paper describing the distinction between the mechanism of projection characteristic of psychosis and the introjection characteristic of neurosis. “The neurotic is constantly seeking for objects with whom he can identify himself, to whom he can transfer feelings, whom he can thus draw into his circle of interest, i.e., introject” (p. 40–41), wrote Ferenczi. With regard to psychotics, he distinguished between the “dement,” who “completely detaches his interest from the outer world” (p. 40), and the paranoiac, who “would like to do the same” (p. 40) but who rejects this interest outside of his “ego” and projects his desires into the world. The psychoneurotic suffers from a widening, the paranoiac from a shrinking of his ego” (p. 41).

Some of Ferenczi’s formulations are striking. For example, “The transference born in the unconscious emerges into consciousness with an increased emotional charge, under a reversed sign,” and, later in the article: “The loved objects are introjected, taken into the ego” (p. 65). Observing that transference operates based on minute but meaningful elements, he recalled that in “Jokes and Their Relation to the Unconscious” (1905), Freud had pointed out how in these spontaneous phenomena the representation by means of details acts as a triggering factor for pleasure. “The poetical figure “pars pro toto” is thus quite current in the language of the unconscious” (36).

## INTROSPECTION

The etymology of the term *introspection* gives a clear indication of its meaning: the mental activity of a subject who is attentive to her/his own psychic processes (who *looks inside*).

Late nineteenth-century psychologists (Alfred Binet in France, the Würzburg school in Germany, Edward Bradford Tiltchener in the United States, to name but a few) considered introspection to be the sovereign method until its throne was usurped by objectivism and behaviorism.

The word has had a bad press in psychoanalysis. However, psychoanalysis was born from just such an effort at self-observation, with Freud’s self-analysis (Anzieu). Unlike introspection, however, which focuses only on conscious processes, that self-analysis opened the way for the “Freudian revolution” (Robert): Freud’s discovery, below the conscious level, of wishes and the obstacles in their way, of the roundabout processes such wishes use to achieve fulfillment—in a word, the unconscious.

Introspection should be clearly distinguished from the “capacity for insight,” the patient’s ability in the course of treatment to experience his or her own psychic dynamics in a new way—a major feature of the psychoanalytic approach (Blacker).

## INVARIANT

In the first chapter of his book *Transformations: Change from Learning to Growth* (1965), Wilfred Bion defined the idea of the invariant and elucidated the link between transformations and the invariant. He used the metaphor of a painter, a painting, and a field

of poppies to explain that the patient and the analyst have to “repaint” new realizations, starting from the primal scene, onto the canvas of the transference. In this process, a constant must be recognized for meaning to emerge. What remains unchanged between the real field of poppies and the field of poppies on the painter’s canvas, that is, between the primal scene and a transference realization, constitutes the invariant.

To develop further his ideas on the invariant, Bion turned to the notion of mathematical invariance. By way of illustration, Bion explained that the mathematical use of symbols such as ellipses, circles, dots, and lines, no matter how coherent such a use may be, must not cause us to forget that this does not involve “things in themselves,” and that a change in vertex can change the data. Thus, the eye sees two parallel lines as converging at a point that, for the mathematician, does not exist. While in algebraic projective geometry, invariance makes it possible for there to be an object common to a circular object and the elliptical representation of it, this does not apply in the case of lengths, angles, and congruence, even though these data are also a part of Euclidean geometry. Why should not the same be true of psychoanalysis? What are the invariants specific to it? How are they related to one another? According to Bion, psychoanalysis involves transformations. Through interpretations, which are themselves transformations, the analyst gains access to the analysand’s original experience and its realization.

In the work of interpretation, theories are like the painter’s tools, and they give access to meaning only if they have invariants. These theories vary in different methods of interpretation, so that a Kleinian transformation is different from a classically Freudian one. The meaning transmitted by the theory is also different, even if the material transformed is the same in the two cases. To illustrate his thinking, Bion offered a clinical example: In a first stage, the analysis seemed to reveal a patient suffering from hypochondriacal pain, but then in the second stage, external events (a family crisis, hospitalization) disrupted the mechanism and put the treatment at risk. What had changed? What had remained unchanged, invariant? In Bion’s view, the analyst must think in terms of the fate of the external and internal objects. What appeared during the second stage as external emotional objects (worried relatives, the hospital) corresponded to what remained contained, in the form of internal objects, in pains in the knee, leg, or abdomen.

What the analyst considered internal transformed into something external, but the emotional element, though disguised, had remained unchanged. Thus, the invariant provides a link that goes beyond an apparent disconnect. It ensures the continuity necessary for psychic growth and gives the interpretation its effectiveness.

## **IRMA’S INJECTION, DREAM OF**

Freud’s dream of “Irma’s injection” introduced the process of dream interpretation and, in a way, psychoanalytic technique as well. It is described in the second chapter of *The Interpretation of Dreams*, “The Method of Interpreting Dreams,” and was reinterpreted many times by Freud’s successors and biographers.

Early in the morning of July 24, 1895, Freud, then on vacation at the Hôtel Bellevue, near Vienna, had a dream about one of his patients, whom he called Irma. The manifest content of the dream can be summarized as follows:

Irma is not doing well; she has pain in her throat, stomach, and nose. Freud examines her in spite of her reluctance and is disturbed, wondering if he has made a medical error. He calls over his two friends M. and Otto, both doctors, for a consultation. This results in an absurd diagnosis that involves trimethylamine.

Later in *The Interpretation of Dreams*, Freud provided a detailed account of this dream that illustrated his approach to dream analysis. The analytical procedure suggested by Freud begins by examining “day residues,” events that occur during the days preceding the dream and which, through association, can clarify the dream episode and restore the identity of the protagonists. The interpretation is guided by the

assumption that the dream is the fulfillment of a wish, in this case, the wish to deflect responsibility for the fault onto someone else, namely M. and Otto. Freud's friend Wilhelm Fliess, an otorhinolaryngologist, who played an important part in Freud's self-analysis, appeared in the background of the dream in connection with the anomalous appearance of turbinate nasal bones in Irma's throat. In reality, Fliess had previously made a serious professional error in treating one of Freud's patients, Emma Eckstein, leaving a bandage in one of her nasal cavities after an operation, which had resulted in infection and serious hemorrhaging.

The interpretation of this dream was the beginning of Freud's self-analysis, which he conducted primarily through analysis of his own dreams. He chronicled the results of this process in *The Interpretation of Dreams* and thus introduced the practice of psychoanalysis itself.

## ISAACS-SUTHERLAND, SUSAN (1885–1948)

A British psychoanalyst and member of the British Psycho-Analytical Society, Susan Isaacs was born in Bolton, Lancashire on March 24 1885, and died on October 12, 1948 in London.

Isaacs came from a middle-class English family from the Midlands. She was educated at Bolton secondary

schools and then at Manchester and Cambridge Universities. She taught at Darlington Training College in 1913–14 and then was appointed lecturer in logic at Manchester University in 1914–15. During the First World War she was appointed tutor in Psychology at London University where she taught until 1933. She was analyzed by Flügel and then from 1922 by J. Riviere. She became an associate member of the British Psycho-Analytical Society in 1921, and a full member in 1923. She was a member of the Training Committee in 1944–45.

Isaacs's contributions to psychoanalysis were particularly important in the field of education. As early as the twenties, from 1923–1927, with the help of her husband, she directed the famous Malting House School project at Cambridge to conduct the education of a small group of children aged two to seven as a piece of scientific work and research. The theoretical framework of the project was deeply influenced by Melanie Klein's views on the importance of phantasy and play in young children. The results of this research, condensed in two volumes, *Intellectual Growth in Young Children* (1930) and *Social Development of Young Children* (1933), were immediately acknowledged as a new way of looking at the development of children and influenced even Jean Piaget.

Between 1929 and 1936, under the name of Ursula Wise, she replied to parents' questions concerning their children in *Nursery World*. She thereby exerted significant influence Britain using the psychoanalytic ideas derived mainly from Melanie Klein in changing patterns of education of generations of children in Great Britain. She effectively founded the Department of Child Development at London University in 1933. During the war she directed the Cambridge Evacuation Project; see the *Cambridge Evacuation Survey* (1941).

Isaacs's theoretical contributions played a fundamental role during the Controversial Discussions between Anna Freud and Melanie Klein (1941–45). Due to her clear theoretical mind and her academic background in general psychology, logic, and education. Klein chose her to write, read and discuss the first paper of the Discussions, "The Nature and Function of Phantasy" (1943), which, in an abridged version, was published in 1948. In this paper, which is her main theoretical contribution to psychoanalysis, Isaacs very clearly expressed Klein's views on the importance that unconscious phantasies play in the development of the

child from the beginning of its life and tried to support Klein's views, linking them where possible to general academic psychology and epistemology.

Her other clinical and theoretical contributions were collected and reprinted in a book entitled *Childhood and After* (1948).

## **ISAKOWER, OTTO (1899–1972)**

American physician, psychiatrist, and psychoanalyst, Otto Isakower was born in Vienna on June 2, 1899, and died in New York on May 10, 1972.

He studied medicine, graduating in 1923, and remained at the University of Vienna to specialize in psychiatry, working with Paul Schilder and Heinz Hartmann in Julius Wagner-Jauregg's psychiatric clinic. After analysis with Paul Federn, he became a member of the Vienna Psychoanalytic Society (WPV) in 1925, and later served as a training analyst. From 1934, he served as co-chairman with Eduard Hitschmann at the ambulatorium of the Vienna Psychoanalytic Institute. A Jew, he was forced to flee upon the arrival of the Nazis in 1938.

Isakower first emigrated to London where in June 1938 he married Salomea Gutmann, also a physician and, from 1928, a member of the WPV. They joined the British Psycho-Analytical Society and worked in

Liverpool and Manchester, and Isakower was selected to co-edit the collected edition of Freud's works (*Gesammelte Werke*) that Anna Freud carried on from London. In 1940, the couple emigrated to New York where they would spend the rest of their lives. A member of the New York Psychoanalytic Society, Isakower became essentially involved in teaching at its Institute. He served as chairman of the Educational Committee and for many years was chairman of the Curriculum and Library Committees. In February 1972, he gave up his teaching activities at the Institute due to a cardiac ailment. He died three months later.

A man of considerable learning, fascinated by history, he left only a few scientific contributions. Most notable was his classic description of self-observed hypnogogic states and body-ego regression while falling asleep, which came to known as the "Isakower phenomena." First published in German in 1936, his "Beitrag zur Pathopsychologie der Einschlafphänomene" appeared two years later in English as "A Contribution to the Pathopsychology of Phenomena Associated with Falling Asleep" (Isakower, 1938). In addition, through his teaching of the techniques of interpretation of dreams, he influenced several generations of New York psychoanalysts.

## **ISAKOWER PHENOMENON**

In 1936 Otto Isakower published an article on the psychopathology of phenomena associated with falling asleep: "Beitrag zur Pathopsychologie der Einschlafphänomene" (A contribution to the psychopathology of

phenomena associated with falling asleep). It dealt with a varied set of phenomena similar to certain hypnagogic states and capable of being observed “in a number of patients suffering from widely different types of psychological disorders and also in some normal persons” (p. 331).

After studying several clinical cases, Isakower observed:

Most striking of all is the blurring of the distinction between quite different regions of the body, e.g. between mouth and skin, and also between what is internal and what is external, the body and the outside world. We note too the amorphous character of the impressions conveyed by the sense-organs. The visual impression is that of something shadowy and indefinite, generally felt to be ‘round’, which comes nearer and nearer, swells to a gigantic size and threatens to crush the subject. It then gradually becomes smaller and shrinks up to nothing [...] The auditory impression is of a humming, rustling, babbling, murmuring, or of an unintelligible monotonous speech. The tactile sensation is of something crumpled, jagged, sandy or dry, and is experienced in the mouth and at the same time on the skin of the whole body. Or else the subject feels enveloped by it or knows that it is close at hand. Sometimes it feels as if there were a soft yielding mass in his mouth, but at the same time he knows that it is outside him (p. 333).

The reference to the breast is obvious but the description is polymorphous. It appeals to the different senses, it is based on a relative confusion of the boundaries between the outside and the inside. It implies difficulty in evaluating distances; the mouth is often the center of these phenomena, that are sometimes played out in an atmosphere of *déjà vu* and against a background attitude of self-observation in the subject.

Over and above all the neurophysiological factors that are implied in these sort of phenomena, Isakower attempts to conduct a metapsychological analysis that refers back to a set of experiences that were lived through at a very early age, that may be at the origin of the somewhat unexpected success of this description: regression, splitting of the ego, relative indifferentiation of affects—all elements that led the author to conclude “we can observe the regressive revival of ego-attitudes which from the ontogenetic standpoint are primitive” (p. 345).

Such is the Isakower phenomenon, as it opens a window on the very ancient sensory history of the child, particularly the child at the breast if not, indeed, in the uterus. Hence the conclusion of the article: “In dreams and in the phenomenon which is the subject of this paper we have the best authenticated instances of the way in which that function may be renounced in order to conjure up lost objects and submerged worlds” (p. 345). In his own way and in a literary context, Marcel Proust described somewhat comparable phenomena on the verge of sleep.

## **ISOLATION**

“Isolation” is the defense mechanism characteristic of obsessional neurosis. The links of a thought, idea, impression, or feeling with other thoughts or behaviors are broken by means of pauses, rituals, magical formulas, or other such devices.

In “The Neuro-Psychoses of Defense,” Freud conceived of defense, in hysteria as well as in phobias and obsessions, as a form of isolation: “defense against the incompatible idea [is] effected by separating it from its affect; the idea itself [remains] in consciousness, even though weakened and isolated” (1894a, p. 58).

In the case of the “Rat Man,” Freud wrote suggestively of “isolation” though still without naming it as a specific neurotic defense mechanism. He wrote that, in contradistinction to hysteria, in which amnesia attests to a successful repression, obsessional neurosis reveals that “[t]he infantile preconditions of the neurosis may be overtaken by amnesia, though this is often an incomplete one. . . . The trauma, instead of being forgotten, is deprived of its affective cathexis; so that what remains in consciousness is nothing but its ideational content, which is perfectly colourless and is judged to be unimportant” (Freud 1909d, pp. 105–106). Thus, in obsessional neurosis, “patients will

endeavour to ‘isolate’ all such protective acts from other things” (p. 243).

In *Inhibitions, Symptoms and Anxiety* (1926d), Freud returned to the analysis of isolation as a defense mechanism in obsessional neurosis—a view that Anna Freud would further develop in 1936—and he emphasized how isolation involves the “the taboo on touching” to the extent that it involves “removing the possibility of contact; it is a method of withdrawing a thing from being touched in any way. And when a neurotic isolates an impression or an activity by interpolating an interval, he is letting it be understood symbolically that he will not allow his thoughts about that impression or activity to come into associative contact with other thoughts” (pp. 121–122).

## **ISRAEL**

Reflecting the intense struggle of generations not only for survival but also for the establishment of a new social order, Israeli psychoanalysis is intertwined with modern Israeli history, the reestablishment of a nation. After the publication of the 1917 Balfur Declaration, which provided the basis for establishing a Jewish state in Palestine, the British Zionist Commission was appointed. Among its members was David Eder, the first secretary of the British Psychoanalytical Society, founded in 1913. He stayed in Palestine from 1918 to 1922, during which time he urged cooperation between Jews and Arabs and proposed extending medical and social services to all segments of the population. Together with A. Feigenbaum, who immigrated

to Palestine from Vienna in 1920, he worked with teachers and educators, applying psychoanalytic theories.

After both had left Palestine, there was little or no active psychoanalytical work in Palestine until the arrival of Max Eitingon (1881–1943) in Jerusalem in 1933, following Hitler’s rise to power. He proceeded to found the Palestine Psychoanalytic Society (later the Israeli Psychoanalytic Society) with the help of other refugees who, like himself, came to Palestine via Berlin (Moshe Wulff, Ilja Schalit, Anna Smelianski, Gershon and Gerda Barag, Vicky Ben-Tal, Ruth Jaffe, and others).

Eitingon hoped to set up the first chair of psychoanalysis at the Hebrew University in Jerusalem, where Freud had been a member of the first board of governors. But the university authorities considered the inclusion of psychoanalysis in the university setting to be premature, as a chair of psychology had yet to be established. On December 5, 1933, Freud wrote to Judah Magnes, the rector of the university, “The plan to establish a chair for psychology indicates a barely disguised rejection of psychoanalysis and the University of Jerusalem would thus have followed the example of other official teaching institutions. It is then comforting to bear in mind that Dr. Eitingon is determined to pursue the practice of psychoanalysis in Palestine also independently of the University.” Nonetheless, the attempt to introduce psychoanalysis into the university was a historic first.

Eitingon then decided to create an independent psychoanalytic institute modeled after the Berlin institute. In 1934 he founded a polyclinic and the Palestine Institute of Psychoanalysis, which became the eleventh member institute of the International Psychoanalytical Association. As in Berlin, the purpose was to offer treatment, training and supervision, and a forum for discussing psychoanalytic theory. The Israeli clinic still functions according to this model to the present (2004).

Eitingon served as president of the Israeli Psychoanalytic Society (Hachevra Hapsychoanalytit be Israel) during its first ten years. The formative years of the society and the institute were characterized by idealism, devotion, and hard work, often overshadowed by political and economic difficulties. Eitingon’s spirit continued to prevail after him, and within a few years there were twenty analysts practicing in Palestine. Three groups were formed in the three major cities,

and all three participated in the institute. Eitingon's concern and compassion for those who needed psychoanalytic treatment was maintained and handed down from one generation of analysts to the next (the first pioneer group even raised a small fund called the "Institute's Loan Fund" to offer needy patients a daily meal, as an empty stomach is not conducive to analysis). It should be noted that in the first ten years the language used at meetings was German, and for a while later as well, some analyses were carried out in a language in which either the analyst, the patient, or both were not fluent, and they sometimes even used different languages. Eitingon left a legacy of interdisciplinary and multicultural relations and interests that made the institute a vibrant intellectual and cultural center.

The second president of the Israeli Psychoanalytic Society was Moshe Wulff (1943–1953). Wulff was born in 1878 in Odessa, Russia, and later settled in Tel Aviv. He made many important contributions to psychoanalysis, one of them being "Fetishism and Object Choice in Early Childhood" (1946). On the basis of his findings, Wulff formulated a theory about the transition from infantile narcissism to the first genuine libidinal cathexis of an outside object. He also promoted the acceptance of analysis in Israel, especially in educational circles. After Wulff, the presidency of the society rotated for almost twenty years between Heinz Winnik, founder of the *Israel Annals of Psychiatry and Related Sciences* and a pioneer of psychiatric education in Israel, and Erich Gumbel, the first graduate of the institute.

In the 1950s Israeli analysts became increasingly involved in education and training. Heinz Winnik and Ruth Jaffe were the first psychoanalysts to head psychiatric hospitals. Erich Gumbel led an effort that began a three-year program in psychotherapy for non-analysts, and it still continues in 2004. Analysts began teaching at the School of Medicine in Jerusalem.

In the 1960s New Yorker Mortimer Ostow set up a group in the United States of corresponding members of the Israeli Psychoanalytic Society. These American analysts maintained a special relationship with the Israeli society through visits, symposiums, and financial assistance.

Almost as a rule, members of the Israeli Psychoanalytic Society have been continuously involved in social issues. A topic of special interest to analysts is the special conditions under which children were raised in

kibbutzim. Shmuel Golan, a leading theoretician and practitioner in the kibbutzim, based his educational and developmental theories on psychoanalysis (1959). Shmuel Nagler, another psychoanalyst involved in work with kibbutzim, wrote of his clinical observations of kibbutz children (1963).

In the Six-Day War (1967), Yom-Kippur War (1973), Lebanon War (1982), and Gulf War (1991), psychoanalysts assumed a significant role in treating and researching combat-stress reactions and the consequences of social violence (Raphael Moses, Gad Tadmor). Other societal issues of great interest to Israeli analysts were the Israeli-Arab conflict, immigration, and survivors of the Holocaust and their children (Hillel Klein, Shamai Davidson, Raphael Moses, Dan Hertz, Ilani Kogan, Shalom Robinson, Martin Wanhg, and Yolanda Gampel). The Israeli Psychoanalytic Society and the Freud Center cosponsored conferences and dialogues between Israeli and German analysts. Prominent in this dialogue was Hillel Klein, a survivor of Auschwitz. This dialogue has evolved into a working conference held under the title "Germans and Israelis: The Past and the Present."

In 1977 the International Psychoanalytical Association held its thirtieth congress in Jerusalem. This was the first IPA congress held outside Europe. At this time, after efforts by numerous analysts throughout the world, among them Martin Wanhg, Hebrew University established a chair of psychoanalysis, thus realizing Freud's dream. Joseph Sandler was the first person to hold this chair. He stayed in Jerusalem with Anne-Marie Sandler, his wife, and contributed greatly to the further development of psychoanalysis in Israel. After Sandler, a number of distinguished psychoanalysts were appointed to this chair, including Albert Solnit, who developed psychoanalytical thought in the Ben Gurion University Medical School. In the 1990s the chair was held by Shmuel Erlich, a senior psychoanalyst and academician.

Over the past twenty years, among those who made major theoretical and clinical contributions to psychoanalysis through the Israeli Psychoanalytic Society were Pinchas Noy (who contributed to psychoanalysis in the fields of art and creativity), Rivka Eiferman, Rina Moses-Hrushevski, Emanuel Berman, Ruth Stein, and Shmuel Erlich. Those who contributed to the development of child analysis in Israel include Naomi Weiss, Eliezer Ilan (who was the director of the child guidance clinic in Jerusalem), Yechezkiel Cohen

(who directed a residential treatment center where boys receive psychoanalytic treatment and education), Raanan Kulka, and Yolanda Gampel.

A theme that Israeli psychoanalysts are very involved with is the consequences of social violence. *Psychoanalysis at the political border* (Rangell and Moses-Hrushovski, 1996), presents, among other topics, the contributions of Israeli psychoanalysts to compelling issues confronting groups and nations.

In 2004 the Israeli Psychoanalytic Society has more than 100 members, and the Israeli Psychoanalytic Institute, as it is now called, has more than 70 candidates. The number of applicants has been five times higher than can be accepted. Throughout the years, analysts who completed their training in different institutes have immigrated from Argentina, France, Holland, and the United States, bringing different outlooks and perspectives from a variety of paradigms in psychoanalysis. If influence initially emanated from European, especially classical Freudian Berliner and Viennese, psychoanalysts, current major influences are Melanie Klein's model and Heinz Kohut's ideas. During the mid-1990s Donald Winnicott's and Wilfred Bion's concepts have achieved prominence in teaching and discussion in the society. The society and institute are growing and developing creatively; its members hold leading positions in psychiatry, psychology, and particularly academia.

---

## ITALY

On June 7, 1925, Professor Marco Levi Bianchini (1875–1961), director of the psychiatric hospital of Nocera Inferiore (Salerno), helped create the Societa Psicoanalitica Italiana (SPI) (Italian Psychoanalytic Society). Of its members only Dr. Edoardo Weiss (1899–1970) had been analyzed. This was an important cultural event given the climate of indifference toward psychoanalysis in the world of Italian neuropsychiatry, then dominated by Enrico Morselli (1852–1929).

In 1915, there appeared the first work of Freud translated into Italian and published by Marco Levi Bianchini for the Biblioteca Psichiatrica Internazionale under the title *Sulla psicoanalisi* (On Psychoanalysis); it included the five lectures given by Freud at Clark University in the United States. The review *Archivio Generale di Neurologia, Psichiatria e Psicoanalisi*, founded in 1920 by Levi Bianchini, became the official organ of the SPI in 1925.

On October 1, 1932, Edoardo Weiss transferred the SPI from Trieste to Rome, and Levi Bianchini became honorary president. Weiss, a Jewish physician from Trieste, had known Freud in Vienna when he was still a student and had been sent to Paul Federn for his personal analysis. He completed his training as an analyst in 1913 before obtaining, the following year, his medical diploma. After returning to Trieste he began to practice as a psychoanalyst (1919). The core of the new society consisted of Cesare Musatti (1897–1989), Nicola Perrotti (1897–1970), and Emilio Servadio (1904–1995), the last two being students of Edoardo Weiss.

Other new publications appeared, including the ephemeral *Rivista di Psicoanalisi* in 1932, which was banned by the Fascist government at the end of 1933. In 1931, Weiss's *Elementi di Psicoanalisi* was published, with a preface by Sigmund Freud. The book made an important contribution to the understanding of psychoanalysis, and in fact was the first true work of psychoanalysis published in Italy (in 1937 it was in its third edition).

But the cultural climate in Italy under Fascism was not conducive to the spread of psychoanalysis. To this must be added the hostility of official psychology, represented by the Catholic Agostino Gemelli (1878–1959, see especially the articles published between 1924 and 1925 in *Civiltà cattolica*), and mainstream philosophy, which was influenced by Benedetto Croce and Giovanni Gentile. An opportunity arose, however, through the indirect contact between Freud and Benito Mussolini. The father of a patient of Edoardo Weiss, Giovacchino Forzano, was a friend of the Fascist dictator. During a consultation in Freud's office, in the presence of Edoardo Weiss, he asked Freud to dedicate one of his books to Mussolini. Weiss was extremely embarrassed but Freud accepted with a certain ironical detachment and wrote the following dedication in the volume selected (*Warum Krieg?, Why War?*): "To Benito Mussolini, with respectful greetings from an old man who recognizes in you the hero of a culture. Vienna, April 26, 1933." Later (1952) Weiss felt obligated to explain Freud's behavior to Kurt Eissler, secretary of the Freud Archives in New York, insisting on his rejection of fascism. In a letter of June 30, 1956, to Ernest Jones, he attempted to contest the statement of his patient, the daughter of Giovacchino Forzano, according to whom Mussolini intervened with the Viennese authorities to ensure Freud's safety and enable the family to leave Vienna.

Notwithstanding Weiss's difficulties as the head of the Italian delegation, he was able to participate in the international congresses of the International Psychoanalytic Association (IPA) in Wiesbaden (1932), Lucerne (1934), and Marienbad (1936). In 1935 the IPA recognized the SPI as a member society, but the Fascist government looked askance at the affiliation of Italian psychoanalysts with a foreign association. Emilio Servadio was refused the necessary authorization from the Ministry of Foreign Affairs to affiliate with the Vienna Psychoanalytic Society and the IPA. In a report dated April 20, 1935, Carmine Senise, chief inspector of police, described the Vienna Psychoanalytic Society as a subversive movement of leftist Jews and claimed that Freud maintained relations with extremists and with Italian anarchists. This climate of hostility did not prevent Italian analysts from publishing in 1936, in the *Biblioteca Psicoanalitica Internazionale*, a series of essays entitled *Saggi in onore di Sigmund Freud* to celebrate Freud's eightieth birthday. That same year Ernest Jones, as president of the IPA, was forced to defend his Italian colleagues by writing a

letter to the consul general of Italy in London, protesting the fact that the IPA had never recognized the Italian association. In September 1938, however, the Fascist government instituted race laws, and the SPI was dissolved. Emilio Servadio emigrated to India. In January 1939, Edoardo Weiss emigrated to Chicago, where he stayed for the remainder of his life.

Psychoanalysis in Italy did not resume activities until 1945. Joachim Flescher, a Polish doctor analyzed by Edoardo Weiss, had been very active in psychoanalysis and, by publishing a number of articles, sought to propagate knowledge of the field. In 1947, the SPI was officially reconstituted with Nicola Perrotti as president and with the assistance of Alessandra Wolff Stomersee, Princess Tomasi di Lampedusa (1895–1982), who had trained at the Berlin Institute during the early twenties and had returned to Palermo, where she had a small circle of students.

The review *Psicoanalisi*, founded by Joachim Flescher, became the official mouthpiece of the SPI. Meanwhile, the first Italian Congress of Psychoanalysis was organized in Rome in 1946, followed by a second congress in 1950, also held in Rome. *Psicoanalisi* was published during the years 1945–1946, but in 1948 Nicola Perrotti founded a new review, *Psiche*, which, like its French homonym *Psyché*, created by Marie Choisy, was devoted as much to research as it was to popularization. Within the cultural debate of the time, the speech given by Pius XII on April 15, 1953, played an important part, for, overlooking the reservations of Agostino Gemelli, the Church then recognized the validity of psychotherapy and psychoanalysis. In 1955, the SPI reintroduced *Rivista di Psicoanalisi*, which has remained the official publication to this day. During the next few years some psychoanalysts trained in London by Melanie Klein and her students spread awareness of Kleinian theory in Italy. They included Adda Corti, Pierandrea Lussana, Mauro Morra, and Lina Generali Clementis. The systematic translation of the work of Melanie Klein, Wilfred Bion, Donald Winnicott, Herbert Rosenfeld, Donald Meltzer, and Hanna Segal also had considerable influence on psychoanalysis in Italy.

During the nineteen sixties, the SPI was involved in the creation of a number of local centers primarily devoted to scientific research and involvement in social policy. At the same time, differences regarding training were formalized with the establishment of three institutes—one in Milan and two in Rome—

coordinated by the Commissione Nazionale del Training.

Interest in psychoanalysis among the public at large continued to grow. By the end of the sixties, there were a number of students, doctors and psychologists, surgeons, and psychiatrists, who had begun to look to the SPI, either to begin personal analysis or to seek supervision for their own treatment of others. During the nineteen-seventies and up to the mid-eighties, upon the initiative of Dr. Piero Bellanova (1917–1987), a number of SPI members joined together to form the Società Italiana de Psicoterapie Psicoanalitica (SIPP) (Italian Society of Psychoanalytic Psychotherapy). With help from the Tavistock Clinic in London, the profound interest in the work of Melanie Klein resulted in the creation of schools of child psychoanalysis, first in Rome, then in other cities throughout Italy. In 1979 Professor Adriano Giannotti (1932–1994) created, within the department of child neuropsychiatry at the School of Medicine in Rome, a “Corso di psicoterapia psicoanalitica dell’età evolutiva” (Developmental Psychoanalytic Psychotherapy).

Also in Milan, through the efforts of Professors Cesare Musatti, Franco Fornari (1921–1985), Antonio Imbasciati, Franco Ferradini, Giovanni Carlo Zapparoli, Dr. Enzo Morpurgo, and others, psychoanalysis entered the academic world and local medical institutions by training students and clinicians in psychoanalysis. Prompted by Professor Francesco Corrao (1922–1994), the so-called “Pollaloi” group was formed in Rome in the seventies to study and practice psychoanalysis according to the principles established by Wilfred Bion. A Centro Italiano de Gruppo Analisi (CIGA), inspired by the work of S. H. Foulkes, was also created in the seventies by Alice Ricciardi von Platen. During the seventies and early eighties, seminars were organized in Italy by Wilfred Bion, Donald Meltzer, Marta Harris, and Hanna Segal, which received considerable popular attention.

At the same time the work of Jacques Lacan became known in Italy through the effort of three of Lacan’s own students—Giacomo Contri, Muriel Drazien, and Armando Verdiglione, who, in 1974, with Lacan’s agreement, formed a new association, the Cosa freudiana. The systematic translation of Lacan’s seminars and writings was begun by Giacomo Contri and continued by a student of Jacques-Alain Miller, Antonio di Ciaccia. In 1953, during the Congrès des Psychanalystes de Langues Romanes (Congress of Romance

Language Psychoanalysts), held in Rome, Jacques Lacan introduced his program: “Fonction et champ de la parole et du langage en psychanalyse.” Lacan returned several times to Italy for conferences and seminars. On October 31, 1974, a congress of the École Freudienne de Paris was held in Rome, along with the first Congress (devoted to the topic of culture), held in 1982, of the Mouvement Freudien Internationale (International Freudian Movement), founded in Milan in 1976 by Armando Verdiglione. Verdiglione was arrested in 1986 and charged with “extortion, abandonment of the disabled, and criminal association,” and condemned to four and a half years in prison.

In psychiatry the influence of psychoanalysis was evident in the new concept of mental illness and the new therapeutic methods illustrated by Professor Franco Basaglia (1924–1980). These led to Law 180/78, which profoundly transformed the organization and function of psychiatric hospitals in Italy.

In 1982, in the presence of the president of the republic Sandro Pertini, the Fiftieth Anniversary Congress of the Foundation of the SPI was held in Rome. During the eighties, the society had followed with growing interest the legislative procedure that resulted in the passage of legislation governing psychologists and psychotherapists (Law 56/89). The legislature examined the methods of intervention and engagement with the Italian state and planned to create a “Scuola di Formazione” (Training School) according to the terms of the new law.

Two IPA congresses were held in Rome, in 1969 and in 1989, and a Congress of Romance Language Psychoanalysts, was also held in Rome (1953, 1960) and in Milan (1964). The SPI as a whole and through its members has always maintained close contacts with its sister societies, especially in England and France. At the national congresses, the tenth of which was held in Rimini in 1994, foreign colleagues were always invited to attend. Throughout the eighties an attempt was made to promote interaction among members from different cities, either through seminars held every two years in Bologna or through yearly conferences organized by the center in Palermo. There were also a number of Italian-French colloquia held nearly every year, starting in November 1989.

Among the significant events of the nineteen-nineties were the revision of the bylaws and rules of

the SPI, which dated back to 1974 (1994). Under the impetus of the Site Visit Committee, presided over by Serge Lebovici, a single and unique training institute, currently established in four locations—two in Rome, one in Milan, and one in Bologna—was formed that same year. At the same time a code of professional practice was published. In 1992, a circle of members led by Emilio Servadio and Adriano Giannotti led to the creation of a study group that was recognized by the IPA in 1993 as the Associazione Italiana de Psicoanalisi (AIPsi) (Italian Association for Psychoanalysis). A series of meetings were also held concerning the relation between psychoanalysis and culture, organized annually by the commune of Lavarone under the patronage of the autonomous province of Trento and the SPI. Glauco Carloni, Michel David, Anna Maria Accerboni, and Alberto Schoen assisted in organizing the meetings. The first Italian-Spanish colloquium took place in March 1996.

The theoretical and clinical contribution of Italian psychoanalysts to psychoanalysis merits respect. Aside from the work of Outre Cesare Musatti, who began the translation of the works of Sigmund Freud (OSF, 1967–1980), other important contributions have been made by Niccola Perrotti, Emilio Servadio, Franco Fornari, Eugenio Gaddini, Francesco Corrao, and Ignacio Matte Blanco, the Chilean psychiatrist and philosopher who became a naturalized Italian citizen.

The theoretical investigations concerning the “group field” and “analytic relationship” that characterized Italian psychoanalysis in the 1980s continued into the 1990s. Initiated by analysts who defined the analytic relationship as a system, their point of extra-analytic reference was systems theory while within analysis they relied fundamentally on Freudian metapsychology. Around the same time, Francesco Corrao, a

psychoanalyst from Palermo, developed the group field model, deeply influenced by Wilfred Bion. Both trends developed clinical approaches through an extensive investigation into psychoanalytic methodology and epistemology. Several representatives of the psychoanalytic center of Milan, including Nissim Momogliano, employed not only Bion’s work but the Kleinian-based clinical theory of Willy Baranger. Other Milanese colleagues were influenced by American intersubjective theory, which has gained currency in Europe in recent years.

The Italian Psychoanalytic Society has centers located in ten major cities, each relatively autonomous. Two reviews chart the ongoing development of psychoanalysis in Italy: *Rivista di psicoanalisi*, the official publication of the IPS, and *Psiche*, a journal with broader cultural aims that reaches an audience of specialists in other disciplines.

### JACOBSON, EDITH (1897–1978)

Edith Jacobson, psychoanalyst and physician, was born September 10, 1897 in Haynau, Germany and died December 8, 1978 in Rochester, New York.

Edith Jacobson's father was a physician and her mother was a talented musician. She attended medical school at Jena, Heidelberg, and Munich, and received her medical degree from Munich in 1922. From 1922 to 1925 she was a pediatric intern at the University Hospital in Heidelberg.

Jacobson traced her interest in psychoanalysis to the period of her pediatrics internship, during which she observed instances of childhood sexuality (Milrod, 1971). In 1925 she began training at the Berlin Psychoanalytic Institute, where her analyst was Otto Fenichel. During these years she also participated in "Das Kinder Seminar," which was formed by candidates at the Berlin Institute and led by Fenichel (the name is an ironic reference to the junior status of its organizers, not to its substantive focus).

In 1934 she was named a training analyst at the Berlin Institute. During the 1930s she was imprisoned by the Nazis because she refused to divulge information about a patient (Kronold, Edward, 1979). During her imprisonment she became seriously ill with Graves disease and diabetes. While hospitalized in Leipzig she was able to escape from Germany with the help of her close friend Annie Reich, and Reich's second husband. In 1941 she emigrated to the United States of America where, as a member of the New York Psychoanalytic Society and Institute, she was a distinguished training analyst and teacher.

The investigation of ego and superego functioning, the processes of identification underlying their

development, and their role in depression were central to Jacobson's theoretical and clinical work. In her writings she sought to construct an overarching developmental perspective which would do justice to both drives and to real objects and their representations in building up of the ego and superego. Jacobson and Heinz Hartmann introduced the concept of self-representation into psychoanalytic theory, and she was particularly interested in the fate of self-representations in depressive and psychotic illness. Her collected papers, *Depression: Comparative Studies of Normal, Neurotic, and Psychotic Conditions* (1971), permit the reader to follow the development of her thinking over the years. *The Self and the Object World* (1964) is Jacobson's main theoretical text. She observes that in psychotic and borderline patients processes of regression lead to severe deterioration of object relations, ego functions, and superego structure and function. This is accompanied by dissolution of the essential identifications on which the experience of identity is founded.

Jacobson's work is "the first attempt to trace, within a strictly psychoanalytic framework, the development of the self . . . and its mental representations" (Tuttman, 1981). She is the first theorist to attempt to integrate drive theory with structural and object relations theory in a comprehensive, developmental synthesis, and her influence on subsequent work in this area has been profound.

## JAHRBUCH DER PSYCHOANALYSE

It was decided at the 1908 Salzburg congress on Freudian psychology to create a periodical that reflects the specialization and specificity of psychoanalysis. In 1909 the publisher F. Deuticke launched the *Jahrbuch für psychoanalytische und psychopathologische Forschungen* (Annals of Psychoanalytic and Psychopathological Research), a periodical specializing in psychoanalysis, the first of a series of psychoanalytic publications to appear over the following years. Eugen Bleuler and Sigmund Freud were the editors, and Carl Gustav Jung was in charge of the writing.

With the appearance of this publication, the psychoanalytic movement that had built up around the congresses and in private associations acquired an autonomous literary profile. Previously dispersed in different medical journals, psychoanalytic articles were now grouped together in a single publication and made available not only to medical circles but also to the growing lay public. The interdisciplinary interests of readers caused the *Jahrbuch* to publish many articles by pioneers of applied psychoanalysis, alongside more detailed case histories. Moreover, as Freud pointed out to Jung, because the audience was clearly defined, it did not need to be constantly reminded of either the foundations of psychoanalytic theory or the criticisms, and so more space could be devoted to new developments in analytic theory.

The first divisions to shatter the analytical world between 1911 and 1913 also translated into conflicts for

editorial control of publications. Wilhelm Stekel took over control of the *Zentralblatt für Psychanalyse*, and after the resignation of Jung and Bleuler in 1914, Freud continued as the sole director of the *Jahrbuch*, with Karl Abraham and Eduard Hitschmann as editors.

The rupture with Jung and his followers was reflected in the new title: *Jahrbuch der Psychoanalyse* (Annals of Psychoanalysis). The first issues of the new *Jahrbuch* was devoted entirely to defining the theoretical territory of psychoanalysis in relation to the positions of Carl Jung and Alfred Adler. The two works by Freud that it published—“*On the History of the Psycho-Analytic Movement*” (1914a) and “*On Narcissism*” (1914b)—defined new frontiers for psychoanalysis with polemical acuity.

In spite of this transformation of the *Jahrbuch*, it proved to be impossible to publish it on a regular basis. Because of the reduced number of subscribers caused by the war, Deuticke suspended publication after only one year.

## JALOUSIE AMOUREUSE, LA

The two volumes of this work correspond to Daniel Lagache's PhD thesis, presented in 1947. The subheading (*Descriptive Psychology and Psychoanalysis*) clearly states Lagache's intention of producing a study at the intersection of his experience and multidisciplinary training as a philosopher, psychiatrist, psychologist, and psychoanalyst.

Lagache conducted an exhaustive study of the different authors who dealt with the question of jealousy.

His work was based on fifty essentially personal clinical cases, most of them in institutions, and a few cases of analytic treatment for which he presents an ample amount of material. In the first volume he sets out to describe and classify states of jealousy; the second deals with jealousy as it is actually experienced.

“Amorous jealousy derives from a conflict between jealous (possessive) love and reality, jealous love constituting a demand for total and exclusive possession of the partner.”

But jealousy extends beyond the context of the love relationship and becomes a manner of existing (an essential part of which is devoted to passionate and instinctual life), so in fact the distinction between normal and pathological jealousy is a matter of degree and not of essence. The onset of jealousy may be exacerbated by concomitant factors creating a situation of insecurity and frustration that strikes an echo with situations of frustration in childhood, with hyperemotive and impulsive reactions that Lagache considers to be predisposing factors for jealousy. Jealousy may occupy a subordinate position in all clinical cases, but seems to have an elective affinity for the paranoid mode of psychic organization characterizing a relatively primitive level of functioning of the person and of their relations with others.

In the second volume he studies how greed, linked with covetousness in envy and possession in jealousy, can blend with the feeling of love because jealousy is distinct from envy in that we are “jealous of what we possess and envious of what others possess.” He distinguishes three types of love relations: communion-love, oblation love and captative love. Captative love implies jealousy and the desire for total, physical and moral possession of the partner, who is then compared to the ideal object and totally ignored in their otherness (sexuality, violence). Jealousy avoids the internal conflict by displacing it to a conflict with the exterior, which is experienced as a demand for atonement based on an impression of injustice. This can go as far as homicidal jealousy in which, over and above the reality of the victim, the whole of interhuman reality is denied.

## JANET, PIERRE (1859–1947)

Pierre Janet, a French physician and philosopher, was born in Paris on May 30, 1859; he died there on February 23, 1947. Janet spent his entire life in Paris, except for his years as a teacher and his travels abroad.

For fifty years (1889 to 1939) Janet was, along with Henri Bergson, the most famous French psychologist in the world, the student of two of the greatest minds in French psychopathology, Jean Martin Charcot and Théodule Ribot. Attempts were made to turn Janet into an unfortunate rival of Freud during the controversy over the discovery of hysteria.

Born into a middle-class Catholic family, he was deeply influenced by his uncle Paul Janet, a well-known spiritualist philosopher. As a philosopher and physician, Janet had the educational background of the ideal psychologist outlined by Ribot.

He entered the *École Normale Supérieure* in 1879, received his degree in philosophy in 1882, and was appointed professor of philosophy at the *Lycée du Havre* in 1883. There he began collecting material for his dissertation, and in 1889 presented the oral defense of his doctoral dissertation, “*L’automatisme psychologique, essai de psychologie expérimentale sur les formes inférieures de la vie mentale*.” It is based on experiments Janet conducted, in the department of Doctors Gibert and Powilewicz, on hypnotism, somnambulism, and suggestion with one of his most famous patients, Léonie. Janet insisted on the role of unconscious obsessions in the genesis of hysteria and the possibility of their disappearance through hypnosis and suggestion.

His work attracted the attention of Théodule Ribot, who in 1895 recommended him as his successor as professor of psychology at the *Collège de France*, which he did in 1902, and of Jean Martin Charcot, who in 1890 created for Janet a laboratory of psychology at the *Salpêtrière Hospital*. Charcot died in 1893,

immediately after Janet's defense of his medical dissertation, "L'état mental des hystériques." Although hysteria and hypnosis had been almost universally criticized, Janet, with the help of Fulgence Raymond, was able to continue working, and wrote several important works, which he cosigned with Raymond. But upon Raymond's death in 1910, Jules Déjerine fired him from the laboratory at the Salpêtrière. And in 1912 Henri Piéron was chosen, in place of Janet, as head of the Laboratory of Physiological Psychology at the Sorbonne. Janet's only institutional support at this time consisted of his courses at the Collège de France, where he taught the psychology of behavior, emphasizing genetic and social factors.

At the Seventeenth Congress of Medicine in London, in 1913, he presented a paper on "Psychoanalysis." This period, the culmination of his public dispute with Sigmund Freud, ended, as many observers concluded, with his defeat and the decline of his stature. His theories on hysteria were supposedly more rational than Freud's, and were based on the idea of mental depression that was said to be the origin of a narrowing of the field of consciousness, of "subconscious" obsessions, and the dissociation of systems of images and functions that normally constituted consciousness. With respect to etiology he also insisted on the importance of a predisposition, since dissociation was acquired, and the presence of some form of emotional trauma; sexuality did not play any special role in this. In his therapy he used suggestion under hypnosis, providing a non-traumatic substitute for the obsessions associated with events that were said to be the cause of the disease.

Although Janet modified his positions later on, Freud would never forget his criticisms and remained deeply upset by the efforts of French psychologists and psychoanalysts to give Janet priority in the essential discoveries of psychoanalysis. Marie Bonaparte and Édouard Pichon (who became Janet's son-in-law) tried to reconcile the two men, but in vain.

The founder, in 1904, along with Georges Dumas, of the *Journal de psychologie normale et pathologique*, Janet published a number of books, including *Névroses et Idées fixes* (1898) and *Les Médications psychologiques* (1919–1921). In 1926 he published his major work, *De l'angoisse à l'extase*, where he described the case of Madeleine, who suffered from mystical delusions and whom he treated for twenty years, analyzing the psychology of belief and its pathology.

Janet continued teaching until 1935 and, following his retirement, continued to write articles and even to see patients until 1942 at the Sainte-Anne Psychiatric Hospital in Paris. When he died on February 23, 1947, he was working on a paper on the psychology of belief.

## JANKÉLÉVITCH, SAMUEL (1869–1951)

Samuel Jankélévitch, a physician, was born in Odessa, Russia, on April 30, 1869, and died in Paris in 1951. He was one of the first French translators of the work of Sigmund Freud.

Affected by the discriminatory laws that affected Russian Jews in 1880, he traveled to France and studied medicine in Montpellier, then in Bordeaux. He married Anna Ryss. The couple had three children, one of whom, Vladimir, became a well-known philosopher. Jankélévitch practiced medicine in Bourges, then moved to Paris, where he remained until the Second World War. He published two books of his own: *Nature et société* (Nature and society; 1906) and *Révolution et tradition* (Revolution and tradition; 1947), together with a handful of articles in medical and applied psychology journals. His books reflect his interest in spiritualist philosophy rather than medicine. The remainder of his publishing activity consists of translations. These

were numerous and eclectic: philosophy, history, anthropology, sociology, biology, psychology, and psychoanalysis.

In the 1920s and 1930s he worked for Payot, translating not only the works of Sigmund Freud, but also those of Ernest Jones and Otto Rank. In spite of reservations concerning the difficulties for a nonanalyst in translating certain concepts or works (at the time there were no trained psychoanalysts in France), Freud allowed Payot to publish his *Introductory Lectures on Psycho-Analysis* in 1922, with Jankélévitch as translator.

In the preface of the book Jankélévitch states that he is less interested in championing the theories he is translating than in making them known to the French public to dispel common prejudices. There followed translations of *The Psychopathology Of Everyday Life* in 1922, and *Totem and Taboo* and *Group Psychology and the Analysis of the Ego* in 1924. After 1927 he stopped translating Freud, and in any case ceased to be Freud's sole translator in France: Blanche Reverchon, Hélène Legros, Ignace Meyerson, and Marie Bonaparte were also working on Freud texts. With competition from Alcan and Gallimard, Payot also lost its publishing monopoly over Freud.

Ironically, Jankélévitch died in 1951 while preparing a work on Tolstoy and death.

## **JAPAN**

The period before World War II is the first important period for psychoanalysis in Japan.

Kiyoyasu Marui went to the United States in 1919 to study with Adolf Meyer at Johns Hopkins University. Witnessing the influence of psychoanalysis on American psychiatry, he hoped to introduce psychoanalysis to the Japanese. After returning to Japan, he began teaching at the University of Tohoku in Sendai (in northeastern Japan). Psychoanalysis became the

focus of his medical school lectures on psychiatry. In 1933, Marui visited Freud in Vienna and received approval for establishing a Sendai Branch of the IPA.

Heisaku Kosawa, a student of the Tohoku School, left Japan to study at the Vienna Psychoanalytic Institute from 1932 to 1933. He received training analysis from Richard Sterba, and individual supervision on psychotherapy from Paul Federn. While in Vienna, furthermore, Kosawa visited Freud at his home at Bergasse 19 and interviewed him directly. He presented Freud with a paper explaining his theory of the Ajase complex, which he contrasted with Freud's Oedipus complex. Unfortunately, Freud does not appear to have evinced great interest in Kosawa's thesis. After returning to Japan in 1933, Heisaku Kosawa opened a private clinic in Tokyo. Here he began practicing psychoanalytic therapy as it was known in Europe and the United States.

With the outbreak of World War II in 1939, Japan became an ally of Nazi Germany, which regarded psychoanalysis as a dangerous, Jewish system of thought. Kosawa came under constant surveillance from the special police. Nevertheless, he continued to conduct a private practice throughout the war.

The end of World War II brought an influx of learning and culture from the United States, which greatly influenced all aspects of Japanese society including the field of psychiatry. It created a generation of young psychiatrists who sought to study the model of American dynamic psychiatry. They chose to receive training analysis and individual supervision from Kosawa. This group of psychiatrists who studied under him became the second generation of Japanese psychoanalysts, known as the Kosawa School. Some leading members included Takeo Doi, Masahisa Nishizono, and Keigo Okonogi.

After the death of Kiyoyasu Marui in 1953, Kosawa changed the name of the Sendai Branch to the Japan Branch which is known internationally as the Japan Psychoanalytic Society. Psychiatrists who received training analysis from Kosawa between 1950 and 1960 represent its core members.

In 1969, following the death of Heisaku Kosawa, Michio Yamamura succeeded to the presidency of the Japan Psychoanalytic Society. The period 1960–1970 also witnessed the return of several Japanese psychiatrists from clinical work abroad. Boosted by the participation of these third-generation psychiatrists,

psychoanalysis gradually gained importance in Japan, and became a major influence in the field of clinical psychiatry. From the 1950s to the 1960s, Japanese psychoanalysis was greatly influenced by psychoanalysis in the United States, especially ego psychology (Heinz Hartmann, Anna Freud, Paul Federn, Erik Erikson). In terms of clinical practice, it was during the period from 1960 to 1970 that the diagnosis and psychotherapy of borderline cases, as well as classic psychoanalytic therapy, began to attract keen attention.

During the 1980s, Japanese translations appeared for most of the essential works of object relations and Kleinian theorists. From 1980 onwards, a growing number of psychoanalysts from overseas, particularly from the United States, began to visit Japan. Leading American psychoanalysts such as Otto Kernberg and Arnold Cooper conducted the first international seminar in Tokyo, on borderline cases and narcissism. Numerous psychoanalysts from other countries followed, resulting in a dramatic increase in the number of seminars and lectures held in Japan. Leading IPA analysts, including former IPA presidents Robert Wallerstein, Serge Lebovici, and Joseph Sandler, came to Japan on various occasions to give lectures and organize seminars. As representative of IPA's Asian Committee, Ramon Ganzarain and Elizabeth Bianchedi, meanwhile, visited Japan numerous times to conduct lectures and supervisions, and Serge Lebovici, Robert Emde, Joy Osofsky, and Peter Fonagy came for the World Association for Infant Mental Health (WAIMH) Regional Meeting Tokyo.

In 1995, the Japan Psychoanalytic Society established new regulations in line with the education and training criteria set forth by the IPA. It also plans to increase the number of training analysts, and to implement training analyses in accordance with international standards. Along with the implementation of these new regulations, the Society has begun making efforts to establish a psychoanalytic institute covering all of Japan.

Japanese psychiatrists' and psychologists' study of psychoanalytic thought generated an encounter between Western and Japanese culture. Indigenous Japanese patterns of thought merged with the imported theory of psychoanalysis, paving the way for such theories as those of *amae* (Tako Doi), the Ajase complex (Heisaku Kosawa, Keigo Okonogi), and the prohibition of "Don't look" (O. Kitayama). These theories aid in understanding the mentality not only of the Japanese,

but also of people from other cultures; they furthermore promise to contribute greatly to psychoanalytical understanding itself. Japanese psychoanalysts strive to continue making significant theoretical contributions to the international community.

### **JEKELS (JEKELES), LUDWIG (1867–1954)**

Ludwig Jekels, an Austrian psychiatrist, was born on August 15, 1867, in Lemberg, Austria, now L'viv, Ukraine, and died on April 13, 1954, in New York.

Jekels (Jekeles until 1903) remained in Lemberg until the end of his secondary studies, and received his baccalaureate in 1885. He went on to study medicine in Vienna and became a doctor of medicine in 1892. In 1897, after five years of training at the Vienna University clinic, he founded an institute for hydrotherapy in Silesia. He then worked as a psychiatrist in Warsaw. In 1905 he returned to Vienna and began psychotherapy with Sigmund Freud. In 1908 he participated in the first congress of the International Psychoanalytical Association in Salzburg.

After 1909 he was often invited to attend meetings of the Vienna Psychoanalytic Society, and he became a member in 1910. Jekels attempted to introduce psychoanalysis in Poland and translated Freud into Polish. After the First World War he worked as a training analyst in Vienna. He also presented a number of lectures at the Vienna Academic Association for Medical Psychology. In 1932 he became substitute director of the admissions board of the Vienna Society for Psychoanalysis. In 1934, together with Otto Fenichel, he traveled to Stockholm to help found the Svensk-Finska Psykoanalytiska Föreningen (Swedish-Finnish Psychoanalytic Association). He returned to Vienna in 1937 but had to leave again in 1938 when Germany annexed Austria.

Passing through Australia, Jekels emigrated to the United States. He settled in New York, where he began working as a psychoanalyst. The New York

Psychoanalytic Society made him an honorary member in 1941. He died there in 1954. Jekel's *Selected Papers* were published in 1952.

### JELLIFFE, SMITH ELY (1866–1945)

Smith Jelliffe, an American psychiatrist, was born in Brooklyn, New York, on October 27, 1866, and died in Lake George, New York on September 25, 1945. His father was a school principal. He studied at Brooklyn Polytechnic Institute and graduated in 1888. He went on to study medicine at the College of Physicians and Surgeons of Columbia University and obtained his doctorate in 1889. After working at St. Mary's Hospital in Brooklyn for a while, he traveled on several occasions to Switzerland and Italy. In 1894 he married Helena Dewey Lemming; they had three daughters and two sons. After becoming a widower he remarried Bee Dobson in 1920.

Jelliffe had always been interested in the literature of the natural sciences and psychology. In the summer of 1896 he met William Alanson White at Binghamton State Hospital, and the two men became close friends. Jelliffe had a brilliant career in neurology and psychiatry, becoming Clinical Professor of Mental Diseases at Fordham University (1907–1912), president of the New York Psychiatric Society, the New York Neurological Society, and the American Psychopathological Association, co-editor, then editor-in-chief of

the *Journal of Nervous and Mental Diseases* in 1912, and corresponding member of the French and Brazilian neurological societies. He was the author of more than four hundred articles. His *The Modern Treatment of Nervous and Mental Diseases*, which he co-authored with William Alanson White, appeared in 1913 and has been a classic in the field, with many reprintings.

He met Carl Gustav Jung during the tumultuous Amsterdam congress of 1907 and became interested in Freudian theories, primarily as a way to understand the relationship between body and mind. Not incidentally, this led to his becoming one of the pioneers of psychosomatic medicine. In 1912 he invited Jung to give a series of eight lectures at Fordham University in New York. In 1913, together with William Alanson White, he founded *Psychoanalytic Review*, the first English-language publication devoted to psychoanalysis — and one that was strongly opposed by Ernest Jones. Jelliffe wrote a number of articles on psychoanalytic technique, daydreams, and transference. During one of his many trips abroad, he presided over the July 21, 1928, session of the third *Conférence des Psychanalystes de Langue Française* (Conference of French-Language Psychoanalysts) in Paris. According to Paul Roazen, it was during this period that he was analyzed by Paul Federn (Roazen, 1976).

His most important contributions were made in the field of psychosomatic medicine. These were collected in his *Sketches in Psychosomatic Medicine*. His attachment to Charles Darwin's theories led him to promote the field of "paleopsychology" to study the psychological determinants of somatic illnesses. "An organ is a structured piece of experience and a tissue of memories," he wrote in 1923.

According to Abraham Arden Brill, "Jelliffe was the father of American psychosomatic medicine, and it is pleasing to learn that Freud always credited him with this." Freud wrote to Jelliffe on October 2, 1933, concerning an offprint he had just received: "This is an additional element of the medicine of the future you are in the process of preparing." And in February 1939 he wrote: "I know that you have been one of my most sincere and loyal adherents over the years" (in Lewis, 1966).

### JOKES

A “joke” is an incongruous or tendentious verbal message, which, by discharging its psychic energy, gives the listener pleasure. Characteristically a joke is not fabricated (manufactured); rather it emerges as a spontaneous, involuntary idea (*Einfall*) and briefly returns the person to an infantile mode of cognition. Wit is, according to Freud, “the most social of activities, designed to provide pleasure through the simple and disinterested activity of the psychic apparatus” (1905c).

Freud devoted an important work, *Der Witz und seine Beziehung zum Unbewussten* (*Jokes and Their Relation to the Unconscious*, SE, 8), to jokes and their relation to the unconscious (1905c). Published five years after *The Interpretation of Dreams* (1900a), this essay confirmed the usefulness of the principal processes it described, such as the transformation of thoughts into images (metaphor), condensation, and displacement. Like *The Psychopathology of Everyday Life* (1901b), the book marks the extension of psychoanalysis beyond the field of psychopathology, without using the method of analysis, but yet offering another area where it could be rediscovered. This interest in word play is found in some of Freud’s later work (the contradictory meanings of primitive words, dreams in folklore, language, and schizophrenia), though not in respect to work on literature or the development of civilization.

The concept analysis of wit is important because it allows a description of psychic processes and thus delineates the development of pleasure from a topographical, economic, and dynamic perspective. Thought

processes in *The Project for a Scientific Psychology* (1950c [1895]) are here approached from a different angle, thus going beyond that found in *The Interpretation of Dreams*. Every successful joke indicates a victory against the inhibition that critical reason imposes on thought in the normal waking psychic state. Unlike dreams, there is no need for secondary elaboration or disguise to escape censorship. However, the joke must occur in a situation when the play of words or nonsense presents itself in a form “that is both admissible [a joke] and ingenious [wit] by virtue of the multiple meanings of words and the infinite variety of negative relations” (1905c).

Technically, the joke is related to the dream but it must take into account its audience and the listener’s ability to correct the distortions (displacements, condensations) through which sense is communicated through non-sense. The goals of dreams and jokes should not be confused. The first tends to express a desire by eliminating unpleasure, while the second is an extension of the game that seeks to obtain some additional pleasure.

Considered from the economic viewpoint, the joke is also similar to the dream (condensation) through its conciseness and, consequently, its psychic economy. This conciseness is not the result of conscious effort but the consequence of unconscious processes’ effect on preconscious thought, which is then recovered in consciousness. This development consists in letting certain elements fall by the wayside and overdetermining others that will remain, thereby obtaining much greater impact.

Freud’s work on jokes has largely been misunderstood, although it introduces new perspectives on aggression, the thought process, the production of pleasure, and infantile mental activity (see *Three Essays on the Theory of Sexuality*, 1905d). It wasn’t until Donald Winnicott that theoretical work on children’s jokes and their connection to creativity was taken up again, a prospect foreseen by Freud in these terms: “In doing so they come across pleasurable effects, which arise from a repetition of what is similar, a rediscovery of what is familiar, similarity of sound, etc., and which are to be explained as unsuspected economies in psychical expenditure” (1905c). Games with words and thoughts serve as the point of departure not only for the pleasure of jokes but the “pleasure of thinking” (Mijolla-Mellor, 1990), which includes critical reason

in its scope but escapes its inhibitory effect through the creative process that is set in motion.

## **JOKES AND THEIR RELATION TO THE UNCONSCIOUS**

Freud wrote *Jokes and Their Relation to the Unconscious* (1905) at nearly the same time as *Three Essays on the Theory of Sexuality* (1905), but here pleasure is approached from the angle of wit and its mechanisms and motives. In this work Freud further develops his principal discoveries on mental activity elaborated in *The Interpretation of Dreams* (1900), a text already containing a reference to wit in the structure of dreams.

*Jokes and Their Relation to the Unconscious* is divided into three sections: analytic, synthetic, and theoretical. As in *The Interpretation of Dreams*, Freud discusses at length the theories of philosophers (Theodor Vischer, Kuno Fischer, Theodor Lipps) and writers (Jean Paul, Heinrich Heine, Georg Lichtenberg), and gives examples from Jewish folklore in the self-analytical part of the book. This self-analysis is as essential

here as it was in Freud's *Interpretation of Dreams* and *The Psychopathology of Everyday Life* (1901).

The first part (analytic) is essentially descriptive: the mechanisms of jokes makes use of the principal elements of dream work, which Freud summarizes, providing an overview of the techniques used in telling jokes. As with dreams, these mechanisms are unconscious and can only be determined after the fact. But to these mechanisms Freud adds the element of meaning, that is, the aims of wit, the pleasurable or hostile satisfaction obtained in telling jokes. It is this meaning that makes his investigation of jokes profound.

The second part (synthetic) investigates the pleasure of jokes and its mechanisms and psychogenesis. Building on the work of Gustav Theodor Fechner, Freud developed an economic perspective based on the notion of mental economies. Here he makes use of ideas developed earlier in the *Project for a Scientific Psychology* (1950c [1895]). The distinction between jokes and the comic allowed Freud to emphasize that the former is essentially a social activity requiring the presence of a third party. The activity is further complicated by the fact that group as well as individual dynamics are at play: "Why are we driven to tell our own joke to someone else? . . . [B]ecause we are unable to laugh at it ourselves" (Freud, 1905c, p. 190).

The third part (theoretical) returns to the comparison between dreams and jokes, but from the point of view of the unconscious. Freud indicated that he hoped to convince readers of the richness of the hypotheses presented in 1900, which were often reduced to the simplistic idea of "wish fulfillment." He also related his theories to those of Theodor Lipps and noted "there is a return of the mind in dreams to an embryonic point of view" (p. 211). In the pleasure of jokes, adults rediscover the infantile as a source of the unconscious, as illustrated by play with words and thoughts. The chapter closes with an analysis of the varieties of the comic, which is more difficult to analyze because it is not a process elaborated like a dream or joke but an encounter with a situation. According to Freud, "The comic arises in the first instance as an unintended discovery derived from human social relations" (1905c, p. 234). The production of the comic (imitation, caricature) highlights a narcissistic aspect of the psyche, that is, the comparison of self and other.

The book concludes with some of Freud's subtlest and richest ideas about the subject, namely the

distinction between humor and irony. He returned to this distinction in his short article on humor in 1927.

Though this book has not always received the attention it deserves, it is definitely an important work. Lacan (1998) discussed it in his seminar on the formations of the unconscious. Theodor Reik (1935) related Freud's economic perspective on jokes to the concepts of surprise and discovery.

## JONES, ERNEST (1879–1958)

Ernest Jones, a British psychoanalyst, was born at Gowerton, Glamorgan, Wales, on January 1, 1879, and died in London on February 11, 1958. The product of a middle-class Welsh family, Jones was educated at Swansea Grammar School and University College, Cardiff, and received his medical training at University College Hospital, London. His interests at this early stage of his career included clinical medicine, surgery, neurology, pathology, and also clinical psychiatry. He qualified in 1900 for a gold medal in the London M.D. examination. He became a member of the Royal College of Physicians in 1904 and received a Diploma of Public Health (Cambridge) in 1905. After qualifying, he held various hospital appointments and published several papers on childhood and adult neurological diseases.

In 1906, with his friend Lewis Trotter, he discovered Freud's writings, and this stimulated his interest in the German language. In 1907, as a graduate student, he went to Munich, where he discovered German neurology and psychiatry.

Psychoanalysis and the new interest in the emotional life of the individual brought about a deep change in him. In April 1908 he visited Vienna with Abraham Arden Brill, met Sigmund Freud for the first time, and discussed plans on how to translate and propagate Freud's work in the Anglo-American world. In a paper written in the same year and given at the International Psychoanalytical Congress at Salzburg, Jones coined the term "rationalization," which was accepted by Freud and became part of the technical language of psychoanalysis to indicate a way of trying to make sense of unconscious motivations by rationalizing them. Partly because of a series of severe setbacks that broke the progression of his career in London, in 1909 he emigrated to Canada, where he became Associate Professor of Psychiatry at the University of Toronto.

While in Canada, Jones was in touch with neurologists and psychiatrists in the United States. He became assistant editor of Morton Prince's newly founded *Journal of Abnormal Psychology*, in which he published several papers on psychoanalysis. He also organized the American Psychoanalytic Association, intended for psychoanalysts scattered all over the United States. In the meantime, he kept in touch with Freud in Vienna and accompanied Freud when the latter visited the United States to lecture at Clark University.

After he returned to England in 1913, Jones undertook a short personal analysis with Sándor Ferenczi. During the same year he founded the London Society of Psychoanalysis, but he eventually dissolved the society because some of his important followers favored Carl Gustav Jung. During the years of the First World War, Jones continued practicing as a private analyst in London and also lecturing widely on psychoanalysis both in London and outside, contributing to the gradual diffusion of the new discipline in the medical profession, which was highly resistant, and among the larger public. Particularly important were his contributions on the subject of shell-shock neuroses.

In 1919 Jones founded the British Psycho-Analytical Society. Having lost his first wife in 1918, in 1919 he married the Viennese Katherine Jokl. Shortly

thereafter, in 1920, he established the International Psychoanalytical Press in collaboration with the Hogarth Press, founded the International Journal of Psycho-Analysis, which he edited from 1920 to 1939, and coordinated a group of translators—including James and Alix Strachey, Joan Riviere, and John Rickman—in the first systematic translation of Freud's works into English. As early as the 1920s Jones put forth the idea of a standard edition of Freud's work. To him we owe many of the English terms of Freud's technical language. Jones played a fundamental role in helping Melanie Klein to come to England in 1926.

Prior to the Second World War he effectively ruled psychoanalysis in England and had enormous influence in organizing the international psychoanalytical movement, the result being the International Psychoanalytical Association. Significant were his struggle to achieve scientific status for psychoanalysis in England, his attempts to develop the British way of looking at psychoanalysis, and his defense of Klein's views against the severe criticisms of Freud and his daughter Anna, while managing to remain a good friend and collaborator of Freud and to continue his own scientific production. Jones also became president of the International Psychoanalytical Association, a position he held for 17 years in total and finally relinquished in 1949.

In the late 1930s, when the pressure of the Nazi persecution of Jews made life impossible for his colleagues in Berlin, Vienna, and Budapest, Jones, with the help of his American colleague Brill and Marie Bonaparte, managed to get nearly fifty European psychoanalysts out of their countries first to England and then mainly to North America. Particularly important was the rescue of Freud and his family in 1938. Jones played an important role in trying to mediate between Anna Freud and Melanie Klein during the so called "controversial discussions" in the early 1940s. In 1946 he retired from the active life of the British Psycho-Analytical Society to the Plat, his beautiful cottage in Sussex. He devoted the last ten years of his life to writing Freud's biography *The Life and Work of Sigmund Freud* (1953–1957) and his autobiography *Free Associations* (1959), as well as to collecting and reediting some of his clinical papers *Papers on Psycho-Analysis* (1948), despite a cancer of the bladder, which eventually killed him.

Jones was undoubtedly the finest organizer and politician in the first generation of Freud's followers.

Without his prodigious energy and enormous work, psychoanalysis, both in the Anglo-American sphere and the world at large, would not have been able to assert itself as it did. Yet no one should forget Jones's theoretical and clinical contributions to psychoanalysis and his wide interest in applied psychoanalysis. His notion of female aphanisis (a syndrome of psychic blankness) is a significant contribution. Among his publications, particularly important are "The Theory of Symbolism" (1948c) and "The Early Development of Female Sexuality" (1948a), influenced by Melanie Klein. Jones collected his papers on applied psychoanalysis in *Essays on Applied Psychoanalysis* (1964), which shows the importance he gave to this area of research in psychoanalysis. One should also remember his work *On the Nightmare* (1910) and his classic psychoanalytic interpretation of Hamlet: *Oedipus and Hamlet* (1949). For decades his biography of Freud (1953–1957) has been considered the standard biography of Freud's life.

## JOUISSANCE (LACAN)

In his seminar of 1959–1960 *The Ethics of Psychoanalysis* (1992), Lacan developed the concept of jouissance (enjoyment) while discussing *Civilization and Its Discontents* (Freud, 1930). In that work, Freud had articulated a contradiction inherent in the concept of pleasure: “This endeavor [of striving for happiness] has two sides. . . . It aims, on the one hand, at an absence of pain and unpleasure, and, on the other, at the experiencing of strong feelings of pleasure. . . . The task of avoiding suffering pushes that of obtaining pleasure into the background” (1930, pp. 76–77).

For Lacan, these two aspects of pleasure were irreconcilable, and he argued that Freud connected the pleasure and reality principles under a no-displeasure principle. This is the very principle that blocks the path to jouissance. “Who is there who in the name of pleasure doesn’t start to weaken when the first half-serious is taken step toward jouissance?” asked Lacan (1959-1960/1992, p. 185). Even an animal, he added, “has an economy: it acts so as to produce the very least possible jouissance. That’s what we call the pleasure principle” (1969-70/1991, p. 88).

It is true that once we start down the path of jouissance, we do not know where it will lead: “It starts with

a tickle and ends up bursting into flames” (Lacan, 1991, p. 83). In *Beyond the Pleasure Principle*, Freud had already noted that “the most painful experiences . . . can yet be felt . . . as highly enjoyable” (1920, p. 17). On the basis of this text, Lacan made a connection between jouissance and repetition. He drew support for his argument from the hysterical symptom of repetition, as in the case of Elizabeth von R., and defined repetition as a trace, a kind of writing, that commemorates “an irruption of jouissance” (1991, p. 89). Jouissance (*Genuss*) is involved when the pleasure principle yields not necessarily to pain, but to unpleasure. The term was already present in Freud, but Lacan developed it as a concept. Still, he complained of never having had the time to outline its parameters, which he would have likely called “the Lacanian field” (1991, p. 93).

In *The Ethics of Psychoanalysis* (1992), Lacan emphasized that Freud posed the question of jouissance in terms of drive. The energy of the superego derives from the libido of this unsatisfied drive; the more the subject fails to feel jouissance, the more libido there is to feed the superego, and the more the superego will demand new renunciations. Lacan believed that in *Civilization and Its Discontents*, Freud was stating that “everything that is transferred from jouissance to prohibition gives rise to the increasing strengthening of prohibition” (Lacan, 1992, p. 176). Thus the guilt triggered by masturbation can be understood as an increase of libido in the superego, brought about by a short circuit in masturbation that achieves only a brief and stifled satisfaction instead of jouissance.

What is involved here is not the satisfaction of need, but of the drive. In fact, Lacan placed the two in radical opposition to one another: “And if the social bond is established by renouncing the satisfaction of the drive, it is because this satisfaction implies the enjoyment—in the juridical sense of the term—of objects that could either belong to others or deprive them of their jouissance.” This situates jouissance in another field and simultaneously introduces the question of religion, moral precepts, and the law.

In *The Ethics of Psychoanalysis* (1992), Lacan based jouissance on the law. If jouissance consists in breaking the barrier of the pleasure principle, if it can only be attained through a transgression, then only a prohibition opens the path toward it. As for the “other,” he is already implicated in Freud’s analysis of sadism: when we inflict pain on others, “we enjoy by identifying with the suffering object.” From his reading of *Civilization*

and *Its Discontents*, Lacan concluded, “Jouissance is evil . . . because it involves suffering for my neighbor” (1992, p. 184). Moreover, he noted that love of one’s neighbor seemed absurd to Freud. Each time that this Christian ideal is stated, “we see evoked the presence of that fundamental evil which dwells within this neighbor. But if that is the case, then it also dwells within me. And what is more of a neighbor to me than this heart within which is that of my jouissance and which I don’t dare go near?” (Lacan, 1992, p. 186).

In “The Subversion of the Subject and the Dialectic of Desire” (2002), Lacan inscribed jouissance in the topography of his graph of desire. At the upper level of the graph, jouissance is indicated by signifying lack in the Other,  $S(\bar{A})$ . This is phallic jouissance, which is related to castration as lack. Traditionally, the erectile organ, the phallus, represents the object of jouissance, not so much by itself, but rather as the missing portion of a desired image. Phallic jouissance is inscribed in the diagram at the level of a vector that starts out from  $S(\bar{A})$ , the Other’s lack, and goes toward  $(\S \diamond D)$ , the drive as articulated by the subject and the demand of the Other. Thus jouissance is “of the Other” and at the same time operates on the level of the drive. Recognizing the Other’s lack produces a fantasy in the subject’s unconscious. In this fantasy, the object represents what the subject imagines that the Other is deprived of.

In everyday life, the mother, as primordial Other, is prohibited from making up for her lack with her child. Thus the Other remains prohibited. In his diagram, Lacan located jouissance at the place of the barred Other,  $S(\bar{A})$  this is also where Lacan inscribed the superego that orders the subject to enjoy, “Jouis!” To this command, the subject can only respond, “Jouis!” (“I hear!”), for such jouissance is structurally prohibited. Lacan repeated that while the superego prohibits and punishes, it also requires that the subject experience jouissance. For Lacan, the requirement to enjoy is directly related to a taboo. But what is prohibited, what must remain unsatisfied, is only the subject’s jouissance. Giving the Other an experience of jouissance does not seem to be prohibited.

The Other is barred in the diagram only by being marked by the loss of object  $a$ . Thus if a subject assumes the position of the Other’s missing object and if this can make the Other whole, then “It would enjoy,” as Lacan said (2002, p. 311). He thus introduced a jouissance outside the phallic order, a mystic jouissance, which he defined as a nonphallic, feminine

jouissance (1998). For being not whole, a woman “has a supplementary jouissance compared to what the phallic function designates by way of jouissance. . . . Y]ou need but go to Rome and see the statue by [Gianlorenzo] Bernini [the Ecstasy of St. Teresa] to immediately understand that she’s coming. There’s no doubt about it” (1998, pp. 73, 76).

But what did Lacan mean when he said that a woman, for being “not whole,” was capable of a supplementary, nonphallic jouissance? With the “formulas of sexuation,” he proposed dividing subjects not according to their biological sex, but according to their relation to the phallus. On the masculine side would be those subjects who take object  $a$  as the cause of their desire and depend upon their phallic nature to attain it. Subjects on the feminine side have one eye on the phallus and one eye on the jouissance of the Other,  $S(\bar{A})$ . The male or female mystic—a designation independent of biological sex—is situated on the feminine side. Supplementary jouissance, strictly speaking, is feminine. But to attain it, the subject must stop looking both ways—toward phallic jouissance and jouissance of the Other—and become devoted only to the latter. Such an experience was attained by St. John of the Cross, for example, who was familiar with a mystical jouissance “outside sex,” and thus beyond the mark of difference and beyond lack. The moment of ecstasy arrives when the mystic, entirely desubjectified and merged with object  $a$  of the Other’s desire, becomes one with the Other, who in turn no longer lacks. The result is that to represent the Other’s jouissance, “ $\bar{A}$ ” is rewritten as unbarred,  $S(A)$ . In *Civilization and Its Discontents*, Freud referred to the “oceanic feeling” of being at one with the greater Whole. Such is the feeling of mysticism, and also of trances and ecstasy.

Whereas Freud discussed the dark relationship between mysticism and suffering with great hesitation, Lacan spoke of them more positively by remarking that on the cultural level, adoration of Christ suffering on the cross naturally sustains jouissance. If certain mystics directly experience jouissance by looking at the Other’s face—by looking at the face of God—others can attain it only by allowing the ever so broken body of Christ on Calvary to sustain it. They partake of a vicarious jouissance from Christ’s mutilated body offered up to God. Commenting on Catholicism, Lacan wrote, “That doctrine speaks only of the incarnation of God in a body, and assumes that the passion

suffered in that person constituted another person's jouissance" (1998, p. 113)

## **JOURNAL DE LA PSYCHANALYSE DE L'ENFANT**

In 1979, the initial idea that brought together several psychoanalysts from the Association psychanalytique de France—among them Pierre and Claudine Geissmann, Pierre Ferrari, Didier Houzel, and Annie Anzieu—was the need to exchange and develop ideas together. They were all convinced of the originality of practicing with children and its obvious role in psychoanalysis. A few years later, in 1986, new developments in their thinking and a desire to leave a trace of the work they had done, coupled with the absence in the French press of a specifically suitable publication, led the group to constitute an editorial committee and to create the *Journal de la psychanalyse d'enfants*

(Journal of child psychoanalysis), which has been published ever since by Bayard Presse.

The idea of the *Journal*, a sort of forum for writing that sheds light on a given theme from various different angles, leaves readers the freedom to make their own choices and to use or disregard editorial suggestions. Reading notes usually deal with the issues of the day. A network of French and foreign correspondents has been established — Robin Anderson (London), Yolanda Gampel (Tel Aviv), David Rosenfeld (Buenos Aires), Jochen Stork (Munich) — to guarantee the diversity of currents of thought and the people presenting them. In addition, contributors have included Otto Kernberg in America, Suzanne Maiello in Italy, Kleinian and post-Kleinian authors, Hanna Segal, the Tavistock Clinic, Frances Tustin, and, in France, Didier Anzieu, Serge Lebovici, and Geneviève Haag, to mention but a few.

Given the fact that it appears twice yearly, the subjects selected by the editorial committee are announced long enough in advance to enable everyone to make personal contributions and prospective authors to do the work required. Evaluation of submitted texts takes account of their formal qualities but most of all the relationship between theory and clinical practice as revealed in the vicissitudes of the transference.

As chief editor, Pierre Geissmann did most of the coordinating, liaising, and translating until November 1995. His loss is deeply felt, but his dynamism and rigor continue to be a model for the editorial committee and for Claudine Geissmann and Didier Houzel, who have replaced him.

## **JOURNAL D'UN MÉDECIN MALADE**

Faced with the worsening of his illness and thus progressive weakness that made all activity difficult, René Allendy's friends and family conceived the idea of a diary as a way of channeling his mental energies. The *Journal d'un médecin malade* describes the coming and going of indifferent visitors in the small room to which he was restricted during his illness. As Allendy, a doctor and psychoanalyst, hovered between life and death, the diary lucidly describes his attempt to make

sense of his fate and heal himself. Throughout the book he describes the various stages of illness, and provides a reassessment of his life.

## JOURNAL OF THE AMERICAN PSYCHOANALYTIC ASSOCIATION

*The Journal of the American Psychoanalytic Association*, JAPA, although not the oldest psychoanalytic journal in the United States (the *Psychoanalytic Review* dates from 1911), is the most widely read with over 6,000 subscribers in the United States and abroad. It was inaugurated in 1953, incorporating the *Bulletin of the American Psychoanalytic Association*. Its mission was articulated by Robert P. Knight, then the Association's president: "... to select the best contributions to psychoanalysis the Editor and Editorial Board can find among submitted and solicited articles."

JAPA was founded in 1953 as the official organ of the American Psychoanalytic Association, its mission to publish scholarly articles on psychoanalytic theory, clinical practice, research, and history. The Association was very much aided in the enterprise by Dr. Abraham Kagan, then president of International Universities Press, which became the publisher of the *Journal*.

The first editor was John Frosch who served for 20 years with the assistance of Nathaniel Ross, who served as book editor. He was succeeded by Harold Blum,

(editor, 1974–1983) and Theodore Shapiro (editor, 1984–1993). Arnold Richards, began his tenure in 1994 and served until 2003. The editor in 2004 was Steven J. Levy.

From its inception JAPA was the venue of choice for many of the most important contributors to the psychoanalytic literature. Issues in those early years included papers by Phyllis Greenacre, Charles Fisher, Kurt Eissler, Margaret Mahler, Bertram Lewin, Robert Waelder, Lawrence Kubie, Annie Reich, and Ralph Greenson. In the 1960s the *Journal* sponsored four monographs: *Ego Psychology and the Object World* by Edith Jacobson; *Psychoanalytic Concepts and the Structural Theory* by Jacob Arlow and Charles Brenner, and *The Id and the Regulatory Principles of Mental Functioning* by Max Schur. Special supplements issued during the terms of Harold Blum and Theodore Shapiro focused on female psychology (1976), psychoanalytic technique and theory of therapy (1979), defense and resistance (1983), books in review (1985), the concept of structure in psychoanalysis (1988), affect (1991), and psychoanalytic research (1993). A second supplement on female psychology, edited by Arnold Richards and Phyllis Tyson, was published in 1996.

The *Journal* publishes approximately 40 scholarly articles and 40 book reviews each year. JAPA has the right of refusal of all papers presented at the Fall and Midwinter meetings of the American Psychoanalytic Association and publishes summaries of each meeting's scientific panels. Several new formats have been introduced recently, including commentaries on plenary presentations and target papers. Although the majority of JAPA contributions are concerned with clinical theory and practice, the *Journal* also publishes papers on applied analysis, historical subjects, and empirical research. Papers are selected based on the quality of writing, scholarship, and research rather than on theoretical orientation. Since 1974 JAPA has awarded a prize endowed the Mark and Aiva Kanzer Fund to one or two of the best papers published during the year. In 1997, The Analytic Press succeeded International Universities Press as the distributor and marketer of the *Journal*.

New members of the editorial board of the *Journal* are nominated by the editorial board itself and elected by the Executive Council of the APsA. Board members are the "peers" of the "peer review" selection process. Although JAPA is the official journal of the American Psychoanalytic Association, members of the

editorial board need not be members of the Association, and outside reviewers are frequently called on for their expertise in specific areas. As of 2004, the book review editors were Rosemary H. Balsam and Paul Schwaber. They were preceded by Glen Gabbard, who succeeded Otto Kernberg, who in turn took over from Nathaniel Ross.

ARNOLD D. RICHARDS

## JOUVE, PIERRE JEAN (1887–1976)

Pierre Jean Jouve, a French writer and poet, was born on October 11, 1887, and died in Paris on January 8, 1976. He is important for incorporating psychoanalytic themes in his novels. His father, Alfred, was a manager in a life insurance company; his mother, Eugénie Aimée Rosé, encouraged his interest in music. A sister, Madeleine, born in 1889, married Pierre Castiau, who had considerable influence on the poet's intellectual development.

In 1902 Jouve had an appendectomy, followed by years of fatigue and depression. In 1905 he received his baccalaureate, then went on to study law at the University of Lille. At school he published a poetry review, *Les bandeaux d'or*. In 1910 he married Marie Caroline Charpentier, a history major, who monitored his uncertain health. They had a son, Olivier, in 1914.

Disqualified from active service, he served as a nurse during the First World War and struck up friendships with Romain Rolland and other pacifists. In 1921 he met Blanche Reverchon. A marital crisis ensued, followed by divorce, and in 1923 Jouve moved in with Blanche to her apartment on Rue Boissonnade in Paris. In 1933 they moved to Rue Tournon.

In 1925 Jouve published *Paulina 1880*, a novel about the author and Hélène, a composite of several women. In 1928 he published *Hécate*, and in 1931 *Vagadu*, a sequel. Together, these two works make up the *Aventures de Catherine Crachat*. In a commentary on *Vagadu*, Jouve confirmed that he had read a description of the principal steps in psychoanalytic therapy after writing *Hécate*. He then began a fictional analysis of Catherine Crachat, which became the novel *Vagadu*.

In his writing, Jouve focused on three elements of Freudian theory: there is always an unconscious; it is dominated by sexual energy and its opposite, the death impulse; the development of an unconscious sex life is accompanied by feelings of guilt and human error. Jouve created a body of work divided between the Saint Paul of the Epistle to the Romans and Freud, religious chastity and the sexual instinct, in which the soul, driven by love, contains death. The erotic writings of this period were published only after his death.

In 1933 he wrote, with Blanche, an article for the *Nouvelle revue française* titled “Moments d'une psychanalyse” (Moments of a psychoanalysis). The same year he also wrote *Sueur de sang* (Sweat of blood), a collection of poems written on the basis of unconscious values.

During the 1940s he was close to the Gaullist movement and the Resistance. He stopped writing in 1962 and died on the exact same day as Blanche two years later.

## JUDAISM AND PSYCHOANALYSIS

Judaism, a monotheistic religion, and Jewish identity, a subjective culture and experience, are part and parcel of the history of psychoanalysis. Sigmund Freud was

born on May 6, 1856, in Freiberg. His father, Jakob Freud, still mourning the death of his own father, Rabbi Schlomo, gave his son the Jewish name Schlomo and the Christian name Sigmund, later changed to Sigismund for a short time. Freud was partly reared by a catholic nanny, Monica Zadjic. He experienced his first exile at the age of three, when the family left Moravia for Vienna. Jakob taught him to read the family Bible, which he continued to read in Jewish primary school and later in the gymnasium. Freud continued to see his Hebrew teacher, Samuel Hammerschlag, until the latter's death.

Unlike the family of his wife, Martha, Freud's family neglected religious practices but respected traditions, particularly the principal holidays of Jewish life. Freud was circumcised on May 13, 1866. When he was thirty-five years old, his father gave him Philippson's bilingual illustrated Bible, with a dedication in Hebrew. Théo Pfrimmer (1982) noted more than four hundred Biblical quotations in Freud's works. Freud's Jewish identity never waned: between 1897 and 1907 he regularly attended the meetings of B'nai Brith, his first public, and remained connected to the lodge until 1926. In 1929 YIVO (Yiddisher Vissenshaftlikher Institut), an institute devoted to the Yiddish language (which his mother continued to speak throughout her life), invited him to be a member of its presidium, along with Albert Einstein and many others.

An early experience of anti-Semitism confirmed Freud's decision not to court the favor of the "compact majority" (B'nai Brith conference, May 6, 1926). The Nazis condemned his works to the fire, and in May 1933 his books were burned in Berlin. Some members of his family, including four of his five sisters, perished in extermination camps.

Like Franz Kafka, Freud was confronted with the question of his Jewish identity—an affective dimension of Freud better reflected in his correspondence than in his scientific works. Adam, Joseph, Jacob, Moses, like Grandfather Schlomo, the central figure in an "identification fantasy" (Mijolla, 1975), all had their place in the line of filiation, linking fathers and sons, that lies at the heart of the Oedipus complex he elaborated from Greek tragedy.

Caught between different cultures (Germanic, Christian, and the Greco-Roman classical humanities) and different languages (Yiddish, Hebrew, Czech, and German), Freud was confronted with the Viennese cri-

sis of modernity. This same sense of crisis can be seen in the writers of the literary group Jung-Wien, who gave expression to an identity crisis in which the Enlightenment, German Romanticism, and scientific discourse rubbed shoulders. Freud—an atheist, a "Jewish infidel" pretending not to know Hebrew and torn with regard to the Zionist ideal—rejected all notions of conversion, the "entrance ticket to Western society," as Heinrich Heine called it.

"[H]ow comes it that none of the godly ever devised psychoanalysis and that one had to wait for a godless Jew?" Freud wrote to Oskar Pfister on October 9, 1918 (quoted in Grollman, 1965, p. 115). In this question he attributed his discovery, the only one capable of promoting a "new science," to a Jew whose lack of faith contested religion and its taboos. Freud refused to affiliate psychoanalysis with Judaism, while recognizing that it was linked to a special "experience." Along with some of his students (Karl Abraham and Theodor Reik), Freud studied religious phenomena in the light of psychoanalysis, but the so-called "Jewish science" of psychoanalysis was in fact a scientific project. Freud, basing his thesis on aphasia and the *Project for a Scientific Psychology* (1950c [1895]) on neurophysiological data, was struggling to establish the scientific status of his discovery.

Until he met Carl Gustav Jung in 1907, his first disciples were Jews who more or less inherited the de-Judaization commenced by their fathers as they struggled to assimilate. Later, non-Jews joined the Wednesday Psychology Society. The introduction of Jung, son of a pastor and assistant to Professor Eugen Bleuler in Zurich, had a twofold aim: one political, to spread psychoanalysis beyond the confines of Judaism; the other scientific, to guarantee Freud a university audience. In his correspondence with Romain Rolland (1923–1936), Freud gave the "mystic element" that Jews "lack" (letter to Karl Abraham, July 20, 1908) and the "oceanic feeling" a predominant position.

In London in 1938, his twilight year and his second exile, Freud completed his work on Moses with difficulty, scruples, and pain. In *Moses and Monotheism* (1939a [1934–38]), Freud questioned the "enigmas" surrounding Moses' place and role in history and the survival of the Jewish people, the special target of centuries-old anti-Semitic hatred. When most psychoanalysts were forced by Nazi persecutions to leave Germany and Austria, Freud compared the dissolution of the psychoanalytic societies to the destruction of the

Temple by quoting Rabbi Johanan Ben Zakkai on the occasion of the opening of the Yavneh school: “The invisible temple of Judaism could not be built until the visible Temple had been destroyed.” Anna Freud spoke of the “new diaspora” in a letter to Ernest Jones dated March 8, 1934. She used the expression again in Jerusalem in 1977.

Freud rejected the Jewish religion while being faithful to his Jewish identity by recognizing its contribution to certain aspects of psychoanalysis. On May 11, 1908, Freud, for whom Judaism was part of his racial heritage, commented to Karl Abraham, “The Talmudic way of thinking cannot disappear in us just like that.” In fact, both Judaism and psychoanalysis teach the central importance of language and its effects.

Since the terror of the Holocaust, many researchers have dealt with the conflicted affinity between Judaism and psychoanalysis. Contemporary psychoanalysts Gérard Haddad, Eliane Amado Lévi-Valensi, and Jacquy Chémouni have studied the Talmudic sources of psychoanalysis (thirty years after David Bakan’s 1958 book on Jewish mysticism); equivalences between Jewish and psychoanalytic hermeneutics, particularly in relation to dreams; the ambiguous relations among Freud, Judaism, and psychoanalysis; and “secularized messianism,” going from the particular to the universal.

Historians have focused their investigations on Freud’s relationship with his father (Marthe Robert, Marianne Krull); on Freud’s creativity as it relates to his atheism (Peter Gay); and on the traces of Judaism at work in Freud’s *Moses* essays (1939) (Yosef Hayim Yerushalmi). For Yerushalmi, who refers to psychoanalysis as the “Jewish science,” psychoanalysis is the last avatar of Judaism, a “Judaism without a God.”

Showing the relations between psychoanalysis (the unconscious and its laws) and the subjective essence of Jewish culture does not preclude granting psychoanalysis a scientific, and therefore universal, status. Indeed, the teaching and transmission of psychoanalysis reveals a special tension between the particular and the universal in the field. Perhaps Judaism reveals “the hidden truth of psychoanalysis” (Jacques Ascher and Daniel Weiss).

## JUDGMENT OF CONDEMNATION

Condemning judgment is one of the possible vicissitudes of a repressed instinctual impulse. It is in fact the most highly elaborated one, since it involves neither flight nor a refusal to give access to the intruding element, but, on the contrary, since it is a judgment, acknowledging the existence of the impulse that will later be condemned.

Sigmund Freud raised the issue of condemning judgments in “Five Lectures on Psycho-Analysis” (1910a [1909], p. 53) in the context of a crucial question: If psychoanalysis makes possible the lifting of repression, what happens to the instincts that are liberated in the process? Freud’s response is nuanced and consists in emphasizing that other, more conventional

instinctual impulses may also have been liberated and can oppose the former. But above all, repression is posited as the result of the time lag between the capacities of the immature ego and its instincts. The work of analysis, in contrast, can lead to an appropriate application of these instincts. What, then, is the role of the condemning judgment? If we wish to see it not just as the conscious form of the operation of repression, we need to emphasize its adjudicatory aspect, which involves a presentation of conflicting elements and a decision—a negative one, in this case. Condemning judgments reproduce on the ethical level what judgments in general effect on the intellectual level. As Freud wrote in “Formulations on the Two Principles of Mental Functioning” (1911b): “The place of repression, which excluded from cathexis as productive of unpleasure some of the emerging ideas, was taken by an *impartial passing of judgment*, which had to decide whether a given idea was true or false—that is, whether it was in agreement with reality or not—the decision being determined by making a comparison with the memory-traces of reality” (p. 221).

In the case of reality judgments, as with condemning judgments, it is the pleasure principle that sits in the dock. It is conceivable, however, that the results of analysis may be viewed differently in the case of a child as opposed to an adult. We saw earlier that a condemning judgment was one of the possible outcomes for impulses repressed long ago. On the other hand, Freud was far more categorical in the case of “Little Hans,” related in “Analysis of a Phobia in a Five-Year-Old Boy” (1909b), precisely because the child’s maturation was not sufficient to enable him to go beyond what he must condemn. “For analysis,” wrote Freud in this essay, “does not undo the *effects* of repression. The instincts which were formerly suppressed remain suppressed; but the same effect is produced in a different way. Analysis replaces the process of repression, which is an automatic and excessive one, by a temperate and purposeful control on the part of the highest agencies of the mind” (p. 145).

It can be imagined here that condemnation by the child is closely dependent upon condemnation by the adult, in the form of upbringing. The condemning judgment liberates the condemned person in that it limits the fault by specifying its nature. Repression, by contrast, paralyzes psychic and intellectual life because it constitutes a violent action that will be opposed by another action, in the form of the return of the

repressed and symptom formation. Freud’s humanistic attitude to judgment and its liberating role, which is far from being unique, is evident here in this reference.

## **JUNG, CARL GUSTAV (1875–1961)**

A Swiss physician and psychiatrist, Carl Gustav Jung, founder of analytical psychology, was born on July 26, 1875, in a little village on the shores of Lake Constanz on the Swiss-German border. He died on June 6, 1961, in Kussnacht, Switzerland.

Jung’s father was a rural Protestant minister. When Jung was one year old, the family moved to a rural village just outside Basel, where Jung spent the remainder of his childhood. A sister was born when Jung was nine.

When Jung was three his mother became depressed and was unavailable for several months. Jung always felt much closer to his mother than to his father. He experienced his father as having lost the faith, whereas he experienced his mother as having a deeply intuitive and religious nature.

He entered the University of Basel in 1895 to study medicine, and completed his medical studies in the winter of 1900. He then began his psychiatric studies at the Burghölzli Clinic under the direction of Eugen Bleuler. His father died in 1896. His medical school thesis, *The Psychology of So-Called Occult Phenomena*, a study of spiritualistic seances of his cousin, was published in 1902. That same year, he spent several months in Paris as a student of Pierre Janet.

Jung began his scientific work with word-association experiments while at the Burghölzli Clinic. He discovered consistent patterns of expression and inhibition when select words were given to a subject who

was instructed to react with the first word that came to mind. Jung coined the term “complex” for the cluster of images and emotion revealed when he inquired closely about the subject’s experience of inhibition. He interpreted the results using Freud’s theory of repression. In 1906 Jung broadened his studies to include patients at the Burghölzli, out of which experience came his classic monograph on *The Psychology of Dementia Praecox*.

In 1903 he married Emma Rauschenbach, the daughter of a prominent family in Schaffhausen. They had five children, four daughters and one son. Jung relied on her strong character and native intelligence, and later on she became an analyst in her own right. He remained at the Burghölzli until 1909, when he opened a private practice in the village of Küssnacht just outside Zurich where he remained for the rest of his life.

The work on complexes led to a correspondence with Freud and then to a meeting in 1907. The next six years saw their intense friendship and professional collaboration. Jung became the “crown prince,” the first president of the International Psychoanalytical Association, editor of the *Jahrbuch*, and a defender of psychoanalysis. They traveled to Clark University in Massachusetts together in 1909, analyzing each other’s dreams on the long ocean voyage. But, as Jung began to delve into mythology, a divergence on the meaning of libido became a central point of conflict between the two men. Jung defined libido as meaning interest in general, and believed that all libido cannot be reduced to sexuality, other instincts such as hunger and culture having equal value. In 1911 Jung published the first half of his work *A Study of the Transformations and Symbolisms of the Libido* in the *Jahrbuch*. The second half came out in 1913. Here Jung focused on incest in terms of the mother-son pattern, and the need for the son to be delivered from the power of the maternal unconscious. By this time the relationship between Freud and Jung had become so strained that Freud urged Jung to leave the psychoanalytic fold,

From 1913 until 1918 Jung withdrew into a period of intense self-analysis, resigning his position at the University of Zurich. He called this his “confrontation with the unconscious.” All his later writings were an assimilation and understanding of his inner experiences during those years.

Jung’s first major work of his post-Freudian phase was *Psychological Types*, in which he formulated the

concepts of introversion and extroversion, along with the function types: sensation, thinking, feeling, and intuition. For Jung this work continued his struggle for identity in relationship to Freud and Adler. Also, in the appendix he defined all the concepts for which his work would become most famous; collective unconscious, archetypes, individuation, dreams, psychic energy, etc. Furthermore, during this period he explicated his notions of psychotherapy as a dialectic between therapist and patient, who are equal partners in the psychological transformation.

As his fame spread he began to receive analysands from many parts of the world. He also traveled widely, to the American Southwest, North Africa, Central Africa, and India. He received honorary doctorates from many institutions, including Harvard and Oxford Universities.

Jung’s most controversial episode occurred in 1933. He replaced Ernst Kretschmer as president of the German Society of Psychotherapy and immediately made it into an International Society, so that Jewish members could retain membership. He remained president until 1940, which meant he had to work closely with the Nazis. Some of his statements during this period have been construed as anti-Semitic, and those who have wished to discredit his work seized upon them as a pretext for their dismissal. This issue has surfaced periodically for the past fifty years, but there is no definitive evidence that Jung ever was a Nazi sympathizer.

On the other hand, we do know that he warned repeatedly against the dangers of mass movements, and that in 1936 he published *Wotan*, an uncompromising analysis of the psychological, and specifically archetypal, reasons for Nazism and of the risks it represented for the individual.

In 1944 Jung had a massive, nearly fatal heart attack. He describes his visions during the attack in *Memories, Dreams, and Reflections* (1962/1966). His recovery was complete, but he retired from practice, continuing his research into alchemical studies, and writing two important books, *The Psychology of the Transference* and *Mysterium Coniunctionis*. Jung had become interested in alchemy in 1928 when a good friend, Richard Wilhelm, introduced him to the Chinese alchemical text, *The Secret of the Golden Flower*. Noting the similarities between alchemy and the unconscious patterns he observed in his analysands, he saw alchemy as the missing link between the mythology of the pre-Christian psyche and modern dreams.

Jung valued his introversion greatly, and beginning in 1923 he built a tower in Bollingen, where he would spend solitary weeks. He died after a brief illness on June 6, 1961, in the house in which he had lived since 1908.

## **JUNG-RAUSCHENBACH, EMMA (1882–1955)**

Emma Rauschenbach was born on March 30, 1882, in Schaffhausen, Switzerland, and died on November 27,

1955, in Zurich. Analyst and wife of Carl Gustav Jung, she was the first president of the Psychology Club of Zurich (1916–1919) and vice-president of the Carl Gustav Jung Institute of Zurich (1950–1955).

Although her family came from the upper bourgeoisie and her father was a cultured patron of the arts, she did not receive a higher education. At the age of twenty-one, while visiting Berthe Rauschenbach, Jung, an old friend of Emma’s parents, noticed the adolescent Emma. He was so taken by her that he thought, “This is my wife,” as he recounted in his memoirs.

They were married on February 14, 1903, and had five children. Emma was one of the rare wives of pioneers to take an interest in her husband’s intellectual activities and to participate in his research. As was customary in family psychoanalysis at the time, Jung began to analyze her in 1910. In the six letters that Emma addressed to Freud in late 1911, she displays a subtle comprehension of the unconscious. When she intervened in the foreseeable conflict, she fearlessly and with amazing acuity interpreted Freud’s attitude to her husband: “Do we not often give much because we want to keep much?” and she recommended: “Do not think of Carl with a father’s feelings . . . but as one man to another, who like you must accomplish his own law.” She also confided in him the difficulty of being the wife of a man with whom “all women are naturally in love,” while Jung’s relationship with Sabina Spielrein was taking an amorous turn and an indestructible bond with his assistant Toni Wolf was forming. Confronted with her husband’s infidelities and in spite of the suffering they caused her, she used her intelligence and sensitivity to try to understand him; but more so, she used these traits to understand herself as a woman.

She started work as an analyst in 1930 and left a memory of great qualities as a human being. She undertook a long study of the Grail, published after her death by Marie Louise von Franz who, by integrating it into her own work, unfortunately deprived it of its originality. In 1931 she led a conference at the Psychological Club of Zurich on “The Problem of the Animus,” published by Jung in *Wirklichkeit der Seele* (Reality of the Soul) in 1934. In 1950 she wrote an essay on “The Mythical Representations of the Anima,” published in 1955 in the joint work entitled *Studien zur Analytischen Psychologie C. G. Jungs* (Studies for the Analytical Psychology of C. G. Jung). These two essays dealing with the opposing archetypes of psychic sexuation, the feminine “anima” in the

man, and the masculine “animus” in the woman, were brought together a single publication (1957).

The originality of Emma Jung’s writings lies in her woman’s approach to the female psyche, marking a break with the often sexist works of the pioneers of psychoanalysis. Moreover, her thinking always remained close to her experience as an analyst. When she died, Jung declared: “She had an immense influence of unfathomable depth on my life.”

## **JURY, PAUL (1878–1953)**

Paul Jury, a French theologian and psychoanalyst, was born on September 20, 1878, in Bergerac (Dordogne) and died in Paris on March 24, 1953. The only son of a family of six children, Jury was a boarding student at the Lycée Michelet in Vanves; to attend school he traveled from Indochina, where his father was an engineer with the railroad. At the age of thirteen he converted to Catholicism and, after receiving his baccalaureate in Pau, joined the Jesuits on November 24, 1896, in Toulouse. Because the Jesuits were unable to work in France, Jury worked in Belgium, where he was ordained a priest in 1909; he became a doctor of theology in 1910.

A man with a penchant for literature, Jury wrote for newspapers and magazines, and in 1923 left the Jesuits, reproaching them for prohibiting research. He moved to Paris and, after undergoing a spiritual crisis, became interested in psychoanalysis. He began an analysis with Charles Odier on July 30, 1932, and contributed to the work of the Paris Psychoanalytic Society. He was active in the organization’s meetings and published several articles of his own as well as translations of Freud in the recently established *Revue française de psychanalyse*.

Between 1940 and 1944 he lived in Grenoble, where a period of intense creative activity ensued. Here and in Paris he wrote several articles, which were collected into a single volume: *Le Jardin de Candide (ou De Dieu à l’homme)*, and several volumes of rationalist exegesis of the New Testament, which he published after he had left the church. Beginning in 1946, he contributed several essays to the review *Psyché*. He continued working as a translator, publishing works by Karl Abraham in the *Revue française de psychanalyse*, and a translation of Freud’s *Inhibitions, Symptoms, and Anxiety* (1926d).

He died at the age of seventy-five, nearly blind, having continued to exercise his priestly functions throughout his life. His books and manuscripts were conserved and published by his student André Michel.

## KANTIANISM AND PSYCHOANALYSIS

Both Emmanuel Kant and Arthur Schopenhauer, his disciple and interpreter, had a profound influence on psychoanalysis, although their underlying theories sometimes need to be differentiated. Just as important, however, is the fact that psychoanalysis can be considered an avatar of Kantianism, if not of metaphysics in general.

References to Kant appear in Freud's work in three different contexts:

1. Freud presents Kant's "categorical imperative" as the "inheritor of the Oedipus complex."
2. Freud contested the universal and necessary character of the categories of space and time in human sensibility. These categories undergo a process of development that depends on the relationship between consciousness and the unconscious.
3. Freud compares the unconscious and the thing-in-itself (Assoun, 1976). Although the first reference serves only to legitimate and anticipate Freudian theory, the other two references situate Freud's metapsychological reflections in terms of their differences from Kantian thought. Freud read Kant according to Schopenhauer's interpretation, which ties transcendentalism to anthropology.

Many of Freud's ideas (dreams and repression, the unconscious, sexuality, love, and death) are similar to those of Schopenhauer. Freud recognized a connection to some of his ideas, though he denied Schopenhauer's influence, which he is said to have come across late in life under the influence of Otto Rank. However, between 1830 and 1920 Schopenhauer's ideas were quite popular. The interpretation Schopenhauer gave

to Kantian thought resulted in a "marriage between a neo-Kantian philosophic orientation and the scientific work conducted under the aegis of materialist psychophysiology" (Assoun, 1976), a position held by Theodore Meynert, Johann Herbart, and others, who were well known to Freud.

Whatever the situation may have been, through his work with hysterics, Freud discovered transference, resistance, and the therapeutic framework. In spite of their shared pessimism, Freud was careful to distinguish himself from Schopenhauer in his conception of the death impulse. Also, Freud's metapsychology cannot be confused with a *weltanschauung* (worldview), which characterized Schopenhauer's work as far as Freud was concerned.

When Jacques Lacan attempted to define an ethics of psychoanalysis, he questioned Kant's conception of morality. Although he, like Kant, tried to ground ethics in something unconditioned that is distinct from the Sovereign Good, he rejected the Kantian choice between duty and the categorical imperative. Similarly, he rejects the notion that an ethics of psychoanalysis should be a morality of the superego. For Lacan, the truth of Kant's *Critique of Practical Reason* is found in the marquis de Sade's *Philosophy in the Bedroom* (1990) and, more particularly, in his long theoretical chapter "One more try for the republicans" (Lacan, 1966). The Sadean imperative of enjoyment, "You should seek enjoyment," is a fulfillment of the Kantian categorical imperative. For Lacan, enjoyment is beyond pleasure, or rather, it is the extreme of pleasure, "to the extent that this extreme consists in forcing access to the 'Thing' (*das Ding*)" (Lacan, 1986), that is, the absolute Other of the lost subject. Hence, the ethics of psychoanalysis needs to be grounded

somewhere else: in desire itself. If there is a law of desire, Lacan's associated imperative would be, "Do not give in to your desire." It remains to be determined what this desire is: pure desire, desire of castration, desire of death (Guyomard, 1992)?

For a number of philosophers who want to bring psychoanalysis within the fold of the metaphysics of subjectivity, Kant and Schopenhauer are two links in a chain that, by way of Spinoza and others, joins Freud and Lacan to Descartes (Henry, 1993; Vaysse, 1999).

## **KARDINER, ABRAM (1891–1981)**

Abram Kardiner, American physician, psychoanalyst, psychiatrist, and psychocultural theorist, was born in New York City on August 17, 1891, and died in Easton, Connecticut on July 20, 1981.

Born in New York City's Lower East Side of immigrant parents, he suffered early loss and privation, his mother dying when he was only a few years old. But given his ambition and many intellectual gifts, he acquired an excellent education, graduating first from

the City College of New York, and then from Cornell Medical School in 1917. He interned at Mount Sinai Hospital for two years and did his psychiatric residency at Manhattan State Hospital on Ward's Island. After completing his residency, at the urging of Dr. Horace Westerlake Frink, Kardiner sought analysis with Sigmund Freud and was accepted as a student-patient (1921–1922). Freud set two limitations to that analysis: that it not extend past six months, and that the fee per session should be ten American dollars. Kardiner was proud of the fact that Freud acknowledged him as a "menschen kenner" (knower of people). He did supervisory work with Frink in 1923, Abraham Arden Brill in 1923, Otto Rank in 1924, and Franz Alexander in 1927.

A member of the New York Psychoanalytic Society (founded in 1911), he was one of the founders in 1930 of the New York Psychoanalytic Institute, the first psychoanalytic institute in the United States. Kardiner was instrumental in bringing Sándor Rado from Berlin to be its Educational Director. In 1941, Kardiner left the New York Psychoanalytic Institute because of theoretical and political disputes, and in 1945, along with Rado, George Daniels, and David Levy founded the Columbia University Clinic for Psychoanalytic Training and Research, the first psychoanalytic institute that was part of a university medical school. Kardiner was its Director from 1959 to 1967, and Clinical Professor of Psychiatry at Columbia University.

In the 1950s, Kardiner explored critical questions in psychoanalysis that later become integral to psychoanalytic thinking. His first major contribution concerned the impact of culture on personality. This interest arose out of his idea that the curriculum at the New York Psychoanalytic Institute should include Freud's sociological writings. Out of seminars he conducted there, in conjunction with anthropologists, he began to theorize the impact of particular social institutions on character formation in primitive societies. He developed a psychocultural model for the relationship between specific familial patterns and modes of mother-infant bonding and the formation of the "basic personality structure" in different cultures. Published in 1939 as *The Individual and His Society*, this work (along with later publications on the same subject) had a major influence on the emergence of the "culture and personality field" in anthropology and is considered to be a precursor of the object relations theory and ego psychology in psychoanalysis. Although Kardiner had observed war neuroses

much earlier, when he was attending specialist at the U.S. Veterans Hospital (Bronx, 1923–1925), he was only able to theorize them to his satisfaction after he had written *The Individual and His Society*, which dealt with the problems of adaptation. He came to see that in the traumatic neurosis of the war the defensive maneuver to ward off the trauma sometimes destroyed the individual's adaptive capacity. Thus, the traumatic neurosis of war was the result of an adaptive failure, not a conflictual illness. So concluding, Kardiner re-introduced the concept of traumatic neurosis into psychoanalytic theory. Kardiner (with Lionel Ovesey) applied his knowledge of the impact on development of trauma and specific cultural configurations to the study of the effect on blacks of institutionalized white racism.

Kardiner was an adherent of and contributor to adaptational theory, a precursor of ego psychology generally associated with the name of Sándor Rado. Recognizing the limitations of libido theory in conceptualizing the war neurosis and cross-cultural variations, Kardiner (with Lionel Ovesey and Aaron Karush), wrote one of the first major critiques of libido theory. The libido theory, Kardiner believed, was a case of the instinctual tail wagging the adaptational dog. He emphasized that frames of reference were of value only as long as they provided rational explanations for clinical data and opened channels to research and new knowledge. In 1977, Dr. Kardiner wrote a memoir entitled *My Analysis with Freud*, which drew a portrait of the way Freud conducted an analysis and detailed some of the early history of the psychoanalytic movement in the United States, and in which Kardiner displayed, among other gifts, his great skill as a raconteur. Like Freud, Kardiner continued seeing patients until shortly before his death at age 89.

## **KATAN, MAURITS (1897–1977)**

Maurits Katan, psychoanalyst and physician, was born November 25, 1897 in Vlaardingen, South Holland, the Netherlands, the son of Jacob and Bertina Katan. He died on April 3, 1977 in Sanibel, Florida. Little is known of his early years except that he came from a large family and was the only son and youngest child.

Katan's initial medical training was as a neurologist, his initial analytic training in the Netherlands before going to Vienna in the 1930s to enter analysis ultimately with Anna Freud. In Vienna he met and married Anny Rosenberg (Angel) and they returned to the Netherlands just prior to the start of World War II. He survived the war in hiding, active in the underground, sheltered by the Dutch court portraitist, Robert Bruyn.

Katan's psychoanalytic work was very much focused on understanding psychosis, particularly schizophrenia, and his concepts of a pre-psychotic phase and the split in the schizophrenic with his non-psychotic part were integral in his thinking. He focused greatly on Daniel Paul Schreber who, in one sense, was his companion during the isolation of the war years. His clinical seminars with psychotic patients revealed an understanding tact and ability to communicate rare and unforgettable to observe.

His importance lay in coming to Cleveland, Ohio, after the war to become one of the first professors of psychoanalysis in America, with his appointment at the Case Western Reserve University School of

Medicine. His impact derived from his modest brilliance as the epitome of the analytic scholar.

While Katan focused on psychotic phenomena, his colleagues deeply respected his insights with neurotic patients, and many analysts nationwide came to Cleveland to present their work and obtain his insights. In addition his literary explorations, particularly but not exclusively of Henry James's work, were masterpieces.

## **KATAN-ROSENBERG, ANNY (1898–1992)**

Anny Katan-Rosenberg, psychoanalyst and physician, was born May 1, 1898 in Vienna, Austria, and died in Cleveland, Ohio in the U.S. on December 24, 1992.

The daughter of Mrs. Judith and Dr. Ludwig Rosenberg, she grew up in close contact with the origins of psychoanalysis as her pediatrician father and her pediatrician uncle were two of Freud's three weekly tarok card playing partners. Her uncle Oskar Rie was the Freuds' pediatrician, her cousins later spouses of Ernst Kris and Herman Nunberg. Anna Freud was a childhood acquaintance but not a particularly close companion. Ill in infancy as a failure-to-thrive baby, she was nonetheless most physically active from a young age, and was a skier, mountain climber, and horseback rider all her life.

Her analytic training was marked by a number of unusual features: prior to her analysis with Anna Freud, her first analyst became psychotic and her next two were of limited competence. For her graduation from

training she presented not one but two papers; the first was "Optimism and Denial," and the second was "The Role of Displacement in Agoraphobia," a contribution to object loss. In her adolescence, she joined the Anna Freud group of pioneering child psychoanalysts.

She played a very active role in the political storms of prewar Vienna and, after marrying fellow analyst Maurits Katan and moving to the relative safety of the Netherlands, returned many times to Vienna at extraordinary personal risk to facilitate the escape of many analysts, such as Margaret Mahler. She survived the war in the Netherlands on false papers along with her daughter, while her husband and his son (from a prior marriage) survived in hiding. With the support and encouragement of Anna Freud, she and her husband moved to Cleveland, Ohio after the war to establish a psychoanalytic community there.

In Cleveland Katan directed her attention primarily to child analysis, starting a therapeutic preschool in 1950, now the Hanna Perkins School. There she developed the new technique of treating the preschool child by way of its parents. Katan started a child therapy training program—an analytic training program for non-medical therapists, modeled on Anna Freud's Hampstead Child Therapy Course—supported by a child analytic clinic where analysis was available to children as needed on an ability to pay basis. In this setting she developed a unique child psychoanalytic research complex, still active as the Hanna Perkins Center for Child Development.

Her work was marked by the constant practical application and utilization of child analysis, never compromising on standards of training or research. Dr. Anny Katan was a fearless analyst who pursued her analytic goals undaunted by the opposition in the U.S. to lay analysis. The courage that marked her years in Vienna and in the Netherlands during the war never failed her. An astute clinician, she prided herself on being "Anny Katan, Psychoanalyst," continuing in active practice into her nineties.

### KATHARINA, CASE OF

“Katharina,” whose real name, Aurelia Öhm-Kronich, was uncovered by Peter Swales (1988), was born on January 9, 1875, in Vienna, and died on September 3, 1929, in Reichenau. Her case was the third discussed by Sigmund Freud in the *Studies on Hysteria* (1895d).

“The etiology of the neurosis pursued me wherever I went, just like the song of Marlborough the Briton while he was traveling. Recently, while on the Rax, the daughter of the innkeeper came to see me; it has been a good case for me.” Freud wrote this in a letter to Wilhelm Fliess, on Sunday, August 20, 1893, about the improvised consultation he was asked to provide during his vacation for the young daughter of the innkeeper, who complained of a suffocating feeling, accompanied by the vision of a terrifying face. “Was I to make an attempt at an analysis? I could not venture to transplant hypnosis to these altitudes, but perhaps I might succeed with a simple talk. I should have to try a lucky guess. I had found often enough that in girls anxiety was a consequence of the horror by which a virginal mind is overcome when it is faced for the first time with the world of sexuality” (1895d, p. 127).

Freud concluded:

At that time she had carried about with her two sets of experiences which she remembered but did not understand, and from which she drew no inferences. When she caught sight of the couple in intercourse, she at once established a connection between the new impression and these two sets of recollections, she began to understand them and at the same time to fend them off. There then followed a short period of working-out, of “incubation”, after which the symptoms of conversion set in, the vomiting as a substitute for moral and physical disgust. This solved

the riddle. She had not been disgusted by the sight of the two people but by the memory which that sight had stirred up in her (1895d, p. 131).

At this time Freud was greatly excited by his discovery of the sexual etiology of neurosis, but was unable to convince Josef Breuer of its validity. He also introduced the theory of the “hysterical proton pseudo,” a primal sexual scene that has been overlooked and whose memory is reawakened by a recent sensation. As Freud noted, this resembled what “Charcot liked to describe . . . as the ‘period of psychological working-out’” (p. 134), which separated the trauma from the appearance of symptoms.

Katharina's cure was akin “not so much [to] an analysed case of hysteria as a case solved by guessing” (p. 133) noted Freud, whose work as a hypnotist made him seem more like a magician than a scientist. A note added to the text in 1924 corrects the historical record with the following information: “Katharina was not the niece but the daughter of the landlady. The girl fell ill, therefore, as a result of sexual attempts on the part of her own father” (p. 134)

### KEMPER, WERNER WALTHER (1899–1975)

Werner Walther Kemper, the German physician and psychoanalyst, was born on August 6, 1899, at Hilgen in the Rhineland, and died in Berlin on September 27, 1975.

He was the second of seven children, his father being a village pastor in Westphalia and his mother coming from a family of Rhineland landowners. Having taken the special session of the baccalaureate in 1917, he was mobilized on the Western Front (the battles of the Somme, the Marne, and Champagne, escaping only after being buried alive in an explosion).

He began to study medicine in 1919, specializing in internal medicine and obstetric surgery. He was particularly interested in hypnosis and psychosomatic illness. He gave up on the university career he had initially planned in order to become medical director of a reputable clinic in Berlin-Grünewald.

He did the first part of his analytic training in the Berlin Psychoanalytic Institute in 1928 and his training analysis with Carl Müller-Braunschweig. He had supervision analysis, instituted for the first time in this institute in 1923, with Felix Boehm, Otto Fenichel, Jenö Hárník, and Ernst Simmel. At the end of his training Kemper set up in private practice as a physician and psychoanalyst. He married the graphologist and future psychoanalyst Kattrin Kemper, with whom he had three sons. Following his conference on the “Genesis of genital erogeneity and the orgasm,” he became a regular member of the German Psychoanalytic Society (DPG) in 1933, dean of the Berlin Psychoanalytic Institute in 1934, and a member of the board of directors of the DPG in 1936.

Beginning in 1941 and following the arrest and execution of John F. Rittmeister for acts of resistance, he divided his time between his private practice and the polyclinic that he managed from 1942 until the end of the war. In spring 1946, with Harald Schultz-Hencke, he created the Central Institute for Psychogenic Illness for the Berlin insurance company, which led German insurance companies to recognize analytic psychotherapy, and in 1947 he became director of the DPG’s new Institute for Psychotherapy, also established in Berlin.

To the best of our knowledge he was the only German psychoanalyst who, after twelve years of psychoanalysis under the Nazi regime, enjoyed the unreserved confidence of the International Psychoanalytic Association. In 1948, with the support of Ernest Jones, he became the first training analyst in Rio de Janeiro, where he then lived and where he founded, along with Mark Burke and Domicio A. Camara, a psychoanalytic society based on the Berlin model and which was at the origin of the stormy development of the Rio de

Janeiro psychoanalytic institute. Having worked as a training analyst for twenty years, he left his mark on several generations of Brazilian candidates.

He returned to Berlin in 1967 for health reasons and until his death in 1975 he lived apart from his German colleagues who had never emigrated. He never accepted the break between the two German analytic societies (DPG and DPV).

Under the Third Reich, Kemper published work on the psychotherapeutic indications in sexual disorders and sterility. His major work, *Die Störungen der Liebesfähigkeit beim Weibe* (Disorders in women’s capacity to love; 1942), had important repercussions and was republished several times (1943, 1967, 1972). His monograph on enuresis and its pathogenic factors, published in 1949, is the result of his experience in the polyclinic. Written for a cultivated public, his book entitled *Die Traum und seine Be-Deutung* (Dreams and their meaning; 1955) is a convincing presentation of the technique of dream interpretation and comprises a comparative study of the various theoretical schools based on his psychoanalytic experience in the 1930s and 1940s. In Brazil, Kemper criticized Melanie Klein’s position on the role of the transference in the actual analytic situation and the resulting emotional processes in the counter-transference, subjects he increasingly included in his therapeutic work. His book on group therapy, published in 1960, and his plan to publish Heinrich Racker’s contributions on the subject of transference and counter-transference were destined to familiarize German readers with Latin American psychoanalysis and its practice of group work. His other clinical works were: *Der Patient schweigt* (The silent patient; 1948), *Die Abstinenzregel in der Psychoanalyse* (The rule of abstinence in psychoanalysis; 1954–55), *Organwahl und psychosomatische Medizin* (Organ choice and psychosomatic medicine; 1954).

With remarkable skill, Kemper managed to live through the Third Reich without compromising himself too much, in spite of occupying a position of responsibility, and without undermining his identity as a Freudian psychoanalyst, so much so that, after the war, he immediately reestablished contact with international psychoanalysis and proved himself both active and fecund. In Brazil, in spite of the situation there and circumstances that were personally difficult for him, he laid the bases for the establishment and expansion of psychoanalysis by means of collegial exchanges with Adelheit Koch (São Paulo), Marie

Langer, and Heinrich Racker (Buenos Aires). In spite of his efforts to transmit his experience to German-speaking countries, he shared the same fate as almost all emigrant analysts, that of being scarcely recognized in his native Germany.

## **KESTEMBERG-HASSIN, EVELYNE (1918–1989)**

Evelyne Kestemberg-Hassin, a French psychoanalyst and a permanent member and former president of the Société psychanalytique de Paris (Paris Psychoanalytic Society), was born on May 28, 1918, in Constantinople and died on April 17, 1989, in Paris. The daughter of a French father (who was a merchant) and a Jewish Russian mother (who fled the revolution of 1917), she came to France soon after she was born. She earned a university degree in philosophy. In 1942 she left occupied France for Mexico, and in the course of her travels she met Jean Kestemberg, who soon became her husband. On her return to France in late 1945, she joined the Communist Party and remained in the party until 1956.

After undergoing analysis with Marc Schlumberger, she devoted herself to psychoanalysis. An analyst who worked with children, she practiced group therapy as inspired by Jacob Moreno at the Centre psychopédagogique Claude-Bernard (Claude Bernard Psychoanalytic Training Center) and eventually joined Serge

Lebovici and René Diatkine in their work. Together they created individual psychoanalytic psychodrama. Their assessment of ten years of psychodramatic practice with children and adolescents (Lebovici et al., 1958) showed a wide range of perspectives in their research. *Le psychodrame psychanalytique* (1987; Psychoanalytic psychodrama), written in collaboration with Philippe Jemmet, was the culmination of her long practice.

At the time of the creation of the Centre Alfred-Binet (Alfred Binet Center), founded by Philippe Paumelle in 1958 and part of the Centre de santé mentale (Mental Health Center) of Paris, Kestemberg was working closely with Diatkine and Lebovici. Her article “L’identité et l’identification chez les adolescents” (1962; Identity and identification in adolescents) was a landmark. Elected as a training analyst the following year, she was the first nonphysician woman since Marie Bonaparte to become a permanent member of the Paris Psychoanalytic Society. The report for the 1965 Congress of Psychoanalysts Working in the Romance Languages, written jointly with Jean Kestemberg, compared her authority in developmental psychoanalysis to those of the Americans Heinz Hartmann, Ernst Kris, and Rudolf Löwenstein.

As president of the Paris Psychoanalytic Society in 1971, Kestemberg actively took part in the work of the society, and in 1980 she became coeditor, with Jean Gillibert and Claude Girard, of the *Revue française de psychanalyse*. She also collaborated with Raymond de Saussure in forming the Fédération européenne de psychanalyse (European Federation of Psychoanalysis). The year 1972 saw the publication of *La faim et le corps: une étude psychanalytique de l’anorexie mentale* (Hunger and the body: a psychoanalytic study of mental anorexia), written by Kestemberg together with Simone Descobert and Jean Kestemberg. This book led to the theoretical notion of “cold,” or nondelusional, psychosis and remains an authority on its topic.

On the death of Jean Kestemberg, who, with the help of René Angelergues, had just created the Centre de psychanalyse et de psychothérapie du XIIIe (Psychoanalytic and Psychotherapeutic Center of the Thirteenth Arrondissement, Paris) for psychotic patients, Evelyne Kestemberg assumed the directorship of the center. There, from 1975 to 1988, she avidly pursued her clinical and theoretical teaching activities and took part in seminars, notably as part of a small circle that included Alain Gibault, Colette Guedeney, and Benno

Rosenberg. She developed a deeper understanding of psychosis and put in place such notions as a fetishistic relation to the object, a phobia of mental functioning, and the third-party persona. She set herself apart from Melanie Klein: her intent was to not be identified with anyone else. The center's publication, *Les cahiers du centre* (Center Notes), launched in 1980, set for itself the mission of presenting, with clinical illustrations, such notions as the splitting of the ego, negation, the delusional solution, excitation, and word presentations and thing presentations. A remarkable clinical practitioner, Kestemberg was part of a pioneering and creative generation.

## **KESTEMBERG, JEAN (1912–1975)**

Jean Kestemberg, psychiatrist, psychoanalyst, and full member of the Paris Psychoanalytic Society, was born

at Kielce in Poland on December 11, 1912 and died while traveling on August 25, 1975.

Although he was born into a religious and bourgeois Jewish family in Poland, he distanced himself from the family milieu as an adolescent and became a secret militant for the Communist Party, from which he was expelled in 1956. He went to Paris during the 1930s to study medicine, which he was forbidden to do in Poland because of the quota applied to Jews. He joined the International Brigade as a doctor in 1937 and went to work in the Spanish Civil War. As an active member of the Polish Resistance during World War II, he was forced to travel to Mexico in 1942. Evelyne Hassin, whom he met on the boat, soon became his wife.

He returned to France after the Liberation and once he had been naturalized he presented his thesis, the first thesis on occupational medicine. He became assistant to Louis Le Guiland in his psychiatric department at Villejuif while simultaneously being analyzed by Jacques Lacan. He was elected a member of the Paris Psychoanalytic Society in 1953, then went on to become a full member. His article *À propos de la relation érotomaniaque* (On the erotomaniac relation), which illustrates his interest in psychosis, won the first Maurice Bouvet prize in 1962. Working in close collaboration with his wife, Jean Kestemberg practiced the individual psychoanalytic psychodrama and with her he drafted the report to the 1965 Congress of Romance-Language Psychoanalysts, *Contribution à la perspective génétique en psychanalyse* (Contribution to the Genetic Perspective in Psychoanalysis) and co-authored *La Faim et le Corps* (Hunger and the Body) in 1972.

In order to introduce psychoanalysis to psychotic patients outside the hospital, in 1974 with the help of René Angelergues, he created the Center for Psychoanalysis and Psychotherapy within the framework of the Center for Mental Health in Paris. Following his sudden death on August 25, 1975, Evelyne Kestemberg continued the task her husband had set himself. Jean Kestemberg was a warm man who was full of humor and invention.

## KHAN, MOHAMMED MASUD RASA (1924–1989)

Masud Khan, an English psychoanalyst of Indian origin, was born in 1924 in Montgomery (Sahival) in the Indian Punjab, and died in 1989 in London. Khan's father was a wealthy landowner who raised horses. His mother, a dancer, was only nineteen when he was born. His childhood, spent "between a polygamous father and a mother who was dreamy and distant," was certainly psychologically complex. Khan wanted to be his father's favorite, although he was treated as just another of his many children. The world in which he lived, the world of colonial India, was deeply divided according to sex, a complex caste system, and the various peoples of that diverse country. When he was eight years old, Khan was entrusted to a tutor trained at Oxford, who provided him with an extremely British education. He was deeply affected by the death of a sister when he was eighteen. His love for her was perhaps greater than for any other woman in his life. Her death was almost immediately followed by that of his father, the more influential of his parents.

The grief that followed the death of his sister and father led him to seek psychotherapy. His therapist encouraged him to get involved in the British Psycho-Analytical Society. After studying literature at the University of the Punjab (in Faisalabad and Lahore), he wrote his thesis on James Joyce's *Ulysses* and left for Great Britain in 1946, ostensibly for minor surgery.

Khan was accepted as a student of psychoanalysis, analyzed successively by Ella Sharpe, John Rickman, and Donald Winnicott, and became a training analyst in 1959. His career within the International Psychoanalytical Association was brilliant, and his publishing activities intense. He was appointed editor of the International Psychoanalytical Library and the *International Journal of Psychoanalysis*, and coeditor of the *Nouvelle revue de psychanalyse*, for which he wrote twenty-seven articles between 1970 and 1987.

During his tenure with the *Nouvelle revue de psychanalyse*, he became close friends with Jean-Bertrand Pontalis, who referred to Khan as "our close foreigner." Upon Khan's death Pontalis wrote, "One day I may write about our friendship, a friendship that lasted for more than twenty years—in spite of the temporary flare-ups, it remained solid and steadfast—only because the Channel and the use of 'vous [you]' helped us maintain a certain distance. . . . Thanks to Khan, the review was opened up to people like Winnicott, Marion Milner, and Harold Searles, without being unduly swayed by them" (Bollas, Pontalis, et al., 1989).

An excellent teacher, Khan trained a number of analysts in the Independents group of the British Psycho-Analytical Society. His narrative powers were excellent, and his writings are remarkable. Typical are *The Privacy of the Self* (1974) and *Alienation in Perversions* (1979). With respect to *The Privacy of the Self*, Christopher Bollas remarked that one of Khan's favorite Persian aphorisms was, "Where am I but in the place where no news comes to me, even about myself" (Bollas et al., 1989).

Khan had to address the problems of schizoid personalities and their thought processes early in his career. He saw that they were a major problem for clinical therapy and contemporary psychoanalytic theory, and he felt that new concepts were needed to describe them. These included the concept of "cumulative trauma" (1953), a trauma that went unnoticed until its effects appeared during adolescence. He also devised new methods of listening and interpreting and, more radically, experiencing analysis. With these methods, classic notions like trauma, transference, and regression, as well as more recent ones like dependence and "false self," can then be understood when they emerge fully embodied.

During the 1970s Khan's practice was challenged within the British Psycho-Analytical Society primarily because of personality conflicts and Khan's aristocratic tastes. Complaints were lodged against him, and in 1975, after considerable hesitation, his title as a training analyst was withdrawn. At the same time he began suffering from lung cancer, which he considered a form of "outrage" (the title of one of his last articles). In his final work, *When Spring Comes* (1988), Khan was so revealing in his discussions of technique and counter-transference that he was accused of madness, anti-Semitism, and bisexuality. The affair caused a scandal, and Khan was thrown out of the British

Psycho-Analytical Society in 1988. Only in 1992 was he somewhat rehabilitated by Adam Limentani, then president of the International Psychoanalytical Association. Little light has been shed on the events that had led to his expulsion.

As Christopher Bollas wrote in “Portrait of an Extraordinary Psychoanalytic Personality” (1989), “Masud Khan was one of the most enigmatic and controversial of psychoanalysts.” Aside from the controversy, Khan remains an influential figure in the psychoanalytic movement because of his sophistication, curiosity, approach to therapy, and flexibility in solving problems within the framework of psychotherapy. Didier Anzieu, who greatly admired Khan, wrote, “His writings remain but his death has been painful to me: psychoanalysis has lost its prince” (Bollas, Pontalis, Anzieu, et al., 1989).

## **KLEIN-REIZES, MELANIE (1882–1960)**

Melanie Klein, British psychoanalyst, was born in Vienna on March 30, 1882, and died on September 20, 1960, in London.

Klein came from a traditional, though not orthodox, Jewish background in the Austro-Hungarian Empire. Her school-age ambition to become a doctor was never realized, due to her complicated relationship

with her dominant and intrusive mother, who, Klein felt, favored her brother. She therefore had no university education, but read widely and independently in subjects that interested her.

Her older sister died when Klein was four years old. She lost her brother Emmanuel when she was twenty, one year before her marriage to Arthur Klein, a chemical engineer.

Klein was close to her mother in an ambivalent relationship which caused her periods of considerable depression. Her experience of death and bereavement continued when her mother died in 1914, a few months after Klein's third child was born. These events coincided also with her husband being conscripted into the army. Klein's three children were born in 1904, 1907, and 1914.

She had become acquainted with psychoanalysis the year before, and shortly after the traumatic events of 1914, she sought analysis with Sándor Ferenczi, who worked with her until 1917. He was away from Budapest at times on military duty, and her analysis was probably interrupted. Ferenczi encouraged her to take an interest in the psychoanalytic understanding of children, as he was interested in following up Freud's “Little Hans” case. Klein began an investigation of her own children. She presented a paper in 1919 detailing these preliminary studies to the Hungarian Psycho-Analytical Society, and was made a member. However, later that year she left Hungary because of anti-Semitism and the post-war political turmoil. She traveled with her children to Berlin, while her husband worked in Sweden. They were essentially divorced from this point. In Berlin she developed her observational technique and a rigorous interpretive psychoanalysis with child patients. She went into analysis with Karl Abraham, who left an enduring mark on the development of her psychoanalytic ideas.

Klein then met Alix Strachey, who was also in analysis with Abraham. Strachey was very impressed by the presentations that Klein made to the Berlin Society (Strachey, 1986) and they became friends. Alix Strachey reported her impressions to her husband James and through this link Melanie Klein arranged to come to London to give a series of lectures in 1925. Her work was greatly appreciated in the British Psycho-Analytical Society. This was the first time her efforts had met with such acclaim; when she was invited to come permanently to London, she agreed with little hesitation. She arrived in 1926, and her children came

soon after. She was very happy in the first years. She found strong support from most of her colleagues in London before Anna Freud developed a different form of child analysis (1927) and criticized Klein's (Grosskurth, 1986).

Klein's clinical skill had a profound effect on the quality of the work of the whole Society. She was very much a teacher and innovator. Something of a backlash began however, shortly before she read her paper on the depressive position in 1935. Edward Glover, who also been analyzed by Abraham and who was at the time analyzing Klein's daughter Melitta, began controversial debate, disputing her work and her conclusions and suggesting that she was no longer practicing psychoanalysis.

When Anna Freud moved to London with her father in 1938 after Germany had annexed Austria, Klein became very worried that her own work would be jeopardized. She was resolute in standing by her ideas, and the Society arranged a series of lectures in 1943 to debate the nature and value of Melanie Klein's discoveries and ideas. The outcome of these "Controversial Discussions" was a stalemate, which allowed both Klein and Anna Freud to develop separate schools of psychoanalysis within the British Society. The majority of the British psychoanalysts formed a middle or independent group aligned to neither Freud nor Klein.

Klein's first major contribution was to create a method of child analysis which extended the tentative attempts of Hermine Hug-Hellmuth (1921). Her new technique was characterized by her astute and detailed clinical observation, and by her view that an analysis of a child demanded as rigorous an interpretative method as an adult analysis. This produced material which partly confirmed the theoretical notions that Freud had inferred in the development of children. But she described them in much greater detail and could point to significant modifications.

She found evidence to disagree with Freud on some points: firstly, she was forced to conclude that the libidinal phases were not conveniently separated in time, but instead there was much overlap; secondly, the Oedipus complex was active in a very primitive form from the earliest phases, and was colored by oral and anal impulses as well as genital ones; and thirdly, the super-ego did not supersede the Oedipus complex but probably preceded it also in a very primitive and harsh

form. These conclusions remain contentious (Hinshelwood, 1991).

Her later descriptions of the depressive position and paranoid-schizoid positions were entirely original, and have long provoked intense debate. The patterns of anxiety, defenses, and relationships which these positions represent are now quite widely accepted. And certain elements of them, notably "projective identification," is of great importance in the teaching of many institutes and schools of psychoanalysis.

Klein always gave her allegiance to Freud's theory of the death instinct, and the early observations she made of the aggression and fear that children suffer promoted the view, against Freud, that this instinct is not clinically silent. Her last major contribution, the notion of "primary envy," brought the death instinct clearly under clinical observation.

All of Melanie Klein's conclusions, as well as her technique, have been and remain hotly debated. However, her views have been increasingly discussed—and understood. There are large and growing groups of psychoanalysts in many countries who would now regard her work as standard psychoanalysis.

## **KLINISCHE STUDIE ÜBER HALBSEITIGE CEREBRALLÄHMUNG DER KINDER [CLINICAL STUDY OF INFANTILE CEREBRAL PARALYSIS]**

This work, a monograph on the group of paralytic syndromes that constitute cerebral diplegia in children, has not been reprinted or translated.

The introduction presents the history of research on this illness. (I) Thirty-five case histories (II) and their classification into different groupings (III) make it possible to show their characteristics (IV). This analysis (V) is followed by a discussion of pathological anatomical factors (VI). The illness's relationship to epilepsy and infantile poliomyelitis, the differential diagnosis, and treatment options are discussed (VII–X). The final chapter contains a bibliography with 180 references.

This study refutes previous attempts to identify the etiological, cerebral localization-related, or process-related causes of this pathology: “The clinical picture of infantile cerebral paralysis proves to be independent of these etiologies.” This diagnosis had only a descrip-

tive value until the mechanisms of the central nervous system in adults and children became known. Important points to consider are the differential diagnosis from infantile hysteria, and the significance of psychological factors in the triggering of this disease.

## **KNOT**

Jacques Lacan used a topological structure of the knot to define the relationship of the symbolic, the real, and the imaginary.

In particular, he referred to the structure of rings on the coat of arms of the Borromei family. After introducing this notion on February 9, 1972, in his seminar “... ou pire” (... or worse), he made the knot a central focus of his theory.

In mathematical terms, a knot is a simple closed curve (Jordan's curve). Lacan mainly considered two nodal structures (Figure 1):

- The Borromean Knot: three component loops joined together in such a way that when one loop is cut the other two are no longer connected;
- The clover-leaf knot: the three components have been connected together into a single continuous loop.

For Lacan, the knot symbolizes the Imaginary. As an imaginary construct, it gives consistency to the

FIGURE 1

symbolic. Taken symbolically, the knot represents the undecidability of the real or imaginary.

The knot is an object located in space. A two-dimensional representation of it is made by means of crossings over or under. The knot's structure is determined by what crosses over or under what. However, the knot's structure is not dependent on its representation. Indeed, it was to translate representation into structure that an algebraic writing system for knots was developed. This writing system was refined over the course of the twentieth century and gradually made it possible to distinguish among different types of knots. In this system, the knot's topological loops become letters (in the form of polynomials). This marks the fact that the knot originates in the lost letter.

In Lacan's spoken lectures, the knot functioned first and foremost as a piece of writing. This called into question of the relationship between speech and writing, and showed that "writeability" is essential to the formation of the unconscious (Sigmund Freud's "Letter 52" to Wilhelm Fliess). "The unconscious can only be expressed in knots of language" (Lacan).

## KNOWLEDGE OR RESEARCH, INSTINCT FOR

In a 1915 addendum to *Three Essays on the Theory of Sexuality* (1905d), Freud described the instinct for knowledge (or research) in these terms: "This instinct (*Wisstrieb* or *Forschertrieb*) cannot be counted among the elementary instinctual components, nor can it be classed as exclusively belonging to sexuality. Its activity corresponds on the one hand to a sublimated manner of obtaining mastery, while on the other hand it makes use of the energy of scopophilia (*Schaulust*)" (p. 194). This definition took into account his earlier essay "On the Sexual Theories of Children" (1908c). He thus envisioned the instinct for knowledge (or research) in terms of its instinctual composition (seeing and mastery) and in its continuation beyond childhood, when it originates.

Freud posited the instinct for knowledge as having two aspects, privileging form in one case and content or the object in the other. That an instinct for knowledge should exist seems paradoxical, since all instinct implies a movement toward its goal (discharge) but what is special about this instinct is the fact that its object is the search for knowledge—not the possession of a particular piece of knowledge, but the effort to obtain it. To the extent that this effort connotes work more than pleasure, and moreover, that this instinct is not innate, it is necessary to find its origin in another source, namely, the combination of two "component" instincts, scopophilia and the instinct for mastery. But the extension of the pleasure of seeing (*Schaulust*) to the instinct for research (*Forschertrieb*, *Wisstrieb*) requires that in this case "seeing" be understood not as contemplation but as critical scrutiny, the perception of a difference, a lack, or an absence. Similarly, the fact that the instinct for mastery (*Bemächtigungstrieb*) can enter into the composition of the instinct for knowledge, while the former stems from cruelty (*Grausamkeit*) and is expressed in destruction and in sadomasochistic reversal, means that the instinct for mastery has been diverted through sublimation. "All activities that rearrange or effect changes are to a certain extent destructive and thus redirect a portion of the instinct from its original destructive goal," Freud wrote to Marie Bonaparte on May 27, 1937 (E Jones, 1953–57, vol. 3, p. 464).

What the musculature achieves by immobilizing its object without destroying it, thought achieves by means of mastering its object through selective attention and method. In both cases, the subject itself is

also immobilized in the process. Just as sublimation is a reversible process that is never definitively achieved, obsessive rumination may flood the critical faculties (as in the attitude of the Wolf Man with regard to religious instruction), or, alternatively, inhibition in the form of doubt may condemn discursiveness to the void.

In *Three Essays on the Theory of Sexuality*, Freud asserted that what sets the instinct for knowledge into motion are practical concerns rather than theoretical interests. “The threat to the base of a child’s existence offered by the discovery or the suspicion of the arrival of a new baby and the fear that he may, as a result of it, cease to be cared for and loved, make him thoughtful and clear-sighted” (pp. 194–95). The instinct for mastery can be seen to originate in trauma, because the child believes itself to be in danger.

It was this viewpoint of the traumatic origin of thought activity that Sándor Ferenczi insisted upon; he even saw “pure intelligence” as a product of the process of the imminence of death (*Fragment*, August 7, 1931). Melanie Klein, on the other hand, because the instinct for knowledge involves investigating the contents of the maternal body, saw in it an attitude that was more predatory than defensive. Piera Aulagnier, for her part, emphasized in *Les Destins du plaisir. Aliénation, amour, passion* (The vicissitudes of pleasure: alienation, love, passion; 1979) that the I’s need to know its origins has to do with its need to effect in its own name the work of self-identification. In her view, the question “Where do children come from?” in fact refers to the subject itself, the parental desire that brought the subject into being, and the place where the subject was when not yet in the world. This question of origins is therefore inseparable from that of the possibility of no longer being in the world, and thus the death of the I (Sophie de Mijolla-Mellor, 1992).

With regard to the origins of reflection in primitive man, in “Thoughts for the Times on War and Death” (1915b) Freud indicated the value of this questioning about death especially when it affects a person who is partially loved, and thus with whom the subject can identify: “What released the spirit of enquiry in man was not the intellectual enigma, and not every death, but the conflict of feeling at the death of loved yet alien and hated persons” (p. 293). One can extend to children this origin of the thetic position of the enigma rooted both in the ambivalent feelings (characterized by Mijolla-Mellor as “the giving way of the ground of

what seems to be”) about the child’s presentiments about parental sexuality (“enigmatic signifiers,” in the words of Jean Laplanche) and, more radically, about the child’s dawning awareness, when siblings are born or in some other way, of the fact that he or she has not always existed and will not always exist.

## KOCH, ADELHEID LUCY (1896–1980)

Physician and psychoanalyst Adelheid Lucy Koch was born on October 16, 1896, in Berlin and died on July 29, 1980, in São Paulo, Brazil. German by birth and Jewish by ancestry, she became in later life a Brazilian citizen.

Koch studied medicine at the University of Berlin and joined the Berlin Psychoanalytic Society after undergoing four and a half years of analysis with Otto Fenichel.

In São Paulo, a group of physicians and non-physicians interested in psychoanalysis had gathered around Durval Marcondes in the 1920s, leading to the creation of the *Revista Brasileira de Psicanalyse* (Brazilian Review of Psychoanalysis). Although this journal did not continue beyond its first issue, the influence of psychoanalytic ideas extended both to clinical practice and to Brazilian cultural life. Brazil's social and cultural elite closely followed the evolution of European analytic movements, but there was a palpable lack of clinical experience or serious analytic training.

The well-known Berlin Polyclinic served as a model for the psychiatrist Durval Marcondes, whose insistent requests for help addressed to Ernest Jones led Jones, in 1936, to recommend Adelheid Koch, who at the time intended to emigrate there. Compelled to leave Nazi Germany, she began work as a training analyst in São Paulo in 1937. She taught the first cohort of Brazilian analysts, including Marcondes, Virginia Leone Bicudo, Ligia Amaral, Frank Philips, and Flávio Dias. In addition to didactic analyses, Koch conducted seminars and served as a control analyst.

With Koch at its head, the Brazilian group obtained official status in 1944, under the name of Psychoanalytic Group of São Paulo. In 1951, the group joined the International Psychoanalytic Association as the Brazilian Psychoanalytic Society of São Paulo.

Adelheid Koch continued to conduct didactic analyses and seminars until her death.

## **KOHUT, HEINZ (1913–1981)**

The psychoanalyst Heinz Kohut was born in Vienna on May 13, 1913, and died in Chicago on October 8, 1981. Kohut was an only child. His father, Felix Kohut, a businessman, was a soldier on the Russian front

during the First World War. Kohut was very close to his mother, Else Lampl, and his maternal grandfather. Kohut's parents were Jewish, but his mother had been baptized a Christian and had taken her first communion. Kohut's childhood was filled with sadness and solitude. The family climate was cold and distant, and his parents were often busy. He had a personal tutor for studying the classics. His teachers, especially a teacher of history and geography, often served as role models. He dedicated his book *Analyse et Guérison* (Analysis and cure) to his tutor and to his history teacher. At the age of nineteen he began studying medicine. In 1936 he spent a year in Paris and in 1938 became a doctor of medicine.

Kohut was analyzed by Walter Marseilles, then by August Aichhorn, whose openness and skill he praised. Known to offer delinquents a magnified image of their ego ideal, Aichhorn had his own ideas about narcissism. With the rise of the Nazis, Kohut was forced to go into hiding and left Vienna shortly after Sigmund Freud.

Kohut traveled to Great Britain, where he was placed in a camp for immigrants before going to live with his maternal uncle. He left for the United States and in 1940 arrived in Chicago, where his friend Sigmund Levarie was living. He began a training analysis with Ruth Eissler, became a neurologist in 1944, became a psychiatrist in 1947, and also underwent training in analysis at the Chicago Institute for Psychoanalysis, from which he received a diploma in 1948. He married Betty Meyer, a social worker at the institute who had been analyzed in Vienna before the war and had participated in a training seminar with Aichhorn. Betty later went into practice for herself as a therapist. Their only child, Thomas August, named in honor of August Aichhorn, with whom Kohut had maintained a correspondence over the years, became a psychohistorian and wrote a book on William II, taking inspiration from his father's theories.

A member of the American Psychoanalytic Association, Kohut became a full member in 1953 and president in 1964. He was vice president of the International Psychoanalytical Association from 1965 to 1973. These professional activities earned him the sobriquet "Mr. Psychoanalysis." He overhauled the Chicago Institute of Psychoanalysis, freeing it from the influence of Franz Alexander. He drew attention to the benefits of selecting different kinds of candidates, including nonphysicians, to avoid conformity and

promote creativity. He explained that his interest in narcissism originated in the observation of his own misbehavior within various psychoanalytic societies. He felt that members' attitudes went far beyond professional rivalry and aggression, and included elements of contempt and a lack of respect for others.

Kohut (1990–1991a) defined empathy as a key element of analysis, a viewpoint he maintained and extended throughout his life. “Forms and Transformations of Narcissism” (1966) and “The Psychoanalytic Treatment of Narcissistic Personality Disorders” (1990–1991b) introduced a new way of analyzing narcissism that culminated in the publication of *The Analysis of the Self* (1971) and *How Does Analysis Cure?* (published posthumously in 1984), Kohut's major works on his new psychology of the self. “The Two Analyses of Mr. Z” (1990–1991d) relates the history of an analysis by Kohut and describes his theoretical and clinical development.

Kohut's thought had considerable impact in the United States, and he has received widespread discussion in the psychoanalytic literature. His ideas have influenced not only his followers but also his adversaries. His importance can be compared to that of Jacques Lacan in France. He has had less impact internationally, however, and his influence varies from country to country. Narcissistic transference has been widely recognized, notwithstanding disagreement over the method of treating narcissism, but his new metapsychology was never widely accepted. Kohut's successors have organized annual conferences and established training institutes, but they have also distanced themselves from him to develop the insights that Kohut introduced in a more personal vein.

## **KOREA**

Since Korea was occupied by Japan during the period 1910 to 1945, it has looked to that country for its models of psychiatric thought, which, from that time, have been largely organically based descriptions. The earliest known Korean analyst was Sung Hee Kim, who trained under Kosawa Heisaku in Japan from 1940–45. He returned to Korea to become professor of psychiatry at Chonham University Medical School but did not initiate a local training program. This came later, after the Korean War, which brought American psychiatrists to Korea who taught depth psychology. That, together with the return of a few of the many Korean doctors who had gone to the United States to study psychiatry, led to the introduction of psychoanalysis as a formal system of thought.

However, prevailing systems of thought had already given rise to a set of cultural practices which have their own preventative and curative effects on individuals in times of distress (Chang and Kim, 1973). These included Shamanism and its concomitant belief that man's misfortune results from an improper relation to the spirit world. A qualified mediator or *mutang* performs the ritual of the *goot* through which relations are harmonized. Prior sufferers become qualified as shamans through their close rapport with spirits and their children are said to inherit these abilities. There is also a long tradition of folk medicine, consisting of herbal remedies, acupuncture, and *moxa*, all introduced from China and still prevalent today.

In seeking help, Korean patients are like those in other Asian countries in seeking multiple treatments for a single complaint, and they tend to somatize psychological problems (see Psychoanalysis and China, this volume). In attempting to develop a culturally relevant approach to psychotherapy the pioneering analysts devoted a good deal of their time to studying traditional cultural practices (religions, myths, folk dramas, and literature) from the viewpoint of orthodox theory.

One outcome of this endeavour was a revision of Freud's conception of the Oedipus complex, such that its resolution involves sublimation of incestuous wishes to *hyoa*, the Korean term for filial piety. This is based upon a reciprocity between generations such that respect accorded by the children is balanced by the understanding and responsibility of the parents (Kim, 1978). Another project has made use of the prevalence of Taoist beliefs about illness being due to an excess of exertion in thought or action. This has led some neo-Freudian analysts to develop a "Taoistic psychotherapy" which emphasizes an acceptance rather than a refusal of one's inner conflicts, and transcends them by training the mind towards a more positive outlook (Kim, 1996).

Not until the 1970s did Korean clinicians seek formal ties with the International Psychoanalytic Association. Cho Doo-Young, trained at Cornell and New York, organized the Korean Psychoanalytic Study Group which has since developed into the Korean Psychoanalytic Study Group. It is orthodox Freudian in orientation and has about 50 members. Two other organizations, the Korean Academy of Psychotherapy (neo-Freudian and Taoist with about 80 members) and the Korean Association of Jungian Psychology (with 30 members), are actively pursuing a culturally relevant psychoanalytic practice.

Since the 1980s, orthodox psychoanalytic interests in Korea have diminished, in line with other parts of the world, in the wake of a rising interest in biologically based explanations of psychological disturbance. A lack of Korean training has meant that those interested in being trained have had to go abroad, where the differences in language and cultural understanding have traditionally (in the West) been viewed as resistance but which might become the wellspring for future developments in cultural psychoanalytic theory (Fisher, 1996).

### **KOSAWA, HEISAKU (1897–1968)**

Heisaku Kosawa, a psychoanalyst who laid the foundation of psychoanalysis in Japan, was born on July 17, 1897, in Atsugi, Kanagawa Prefecture, and died on October 5, 1968, in Tokyo. In 1926 he graduated from the School of Medicine of Tohoku University, where he studied under Professor Kiyoyasu Marui. And he became associate professor of psychiatry there in 1931.

From 1932 to 1933 he studied at the Vienna Psychoanalytic Institute, where he received training analysis from Richard Sterba and supervision from Paul Federn. During his stay in Vienna, Kosawa visited Freud at the latter's home at Bergasse 19 and presented a paper written in German entitled "Two kinds of guilt feelings." The paper explained his theory of the Ajase complex, which he contrasted with Freud's Oedipus complex. Moreover, he attended the twelfth congress of the International Psychoanalytical Association in Wiesbaden—the first Japanese to do so. There he met Heinz Hartmann and Karl Menninger, who became

his close friends. After returning to Japan in 1934, he opened a private clinic in Tokyo. Until his death in 1968, he remained the only Japanese to practice psychoanalysis before and for a while after World War II.

While helping to publish the Japanese translation of a collection of Freud's works, Kosawa himself translated into Japanese Freud's *Neue Folge der Vorlesungen zur Einführung in die Psychoanalyse* (*New Introductory Lectures on Psycho-Analysis*) and published it in 1953. At around the same period, he began performing training analyses on Japanese psychiatrists and psychologists. In 1955 he established the Japan Psychoanalytic Society and served as its president until 1957.

Kosawa noticed that, compared with patients in Europe and America, Japanese patients tended to regress easily to the level of a mother-child relationship, and that the fundamental conflict often seen in such relationships was the child's ambivalence toward the mother. This led to his theory of the Ajase complex. Underlying this theory is Kosawa's Buddhist views of life and people.

Throughout his life Kosawa was committed to instructing his students directly through training analyses and supervisions, and he preferred not to publish papers and literary works himself. Thus, there are few works that can be regarded as his representative literary productions. However, he is credited for having trained some of Japan's leading mainstream psychoanalysts who were instrumental in promoting psychoanalysis, dynamic psychiatry, clinical psychology, and psychosomatic medicine in postwar Japan.

## **KOURETAS, DEMETRIOS (1901–1984)**

Demetrios Kouretas, Greek psychiatrist and psychoanalyst, was born on July 8, 1901, in Chrysovitsi (a small village in Arcadia) and died in Athens on May 14, 1984. Kouretas was reared in Tripoli in Peloponnisos. He

began his university studies in Athens and continued them at the École de médecine de Lyon, then in Paris at the Salpêtrière and the Val-de-Grâce hospitals. On returning to Greece he worked as a neuropsychiatrist in various military hospitals, and in 1933 he was elected associate professor in the medical faculty of the University of Athens. In 1942 he was appointed to the chair of psychiatry and neurology at Salonika University, from which he resigned six years later. In 1964 he occupied the chair of psychiatry at the University of Athens.

His analytic career began by being analyzed by Andreas Embirikos and continued with a brief analysis by Marie Bonaparte (1949–1950?). He was a member of the first Greek psychoanalytic group, organized around Bonaparte in 1947, and in 1950 he was elected a full member of the Société psychanalytique de Paris (Paris Psychoanalytic Society). After the dissolution of the first Greek psychoanalytic group in 1951, Marie Bonaparte conducted a regular correspondence with him for several years. Through his university positions, Demetrios Kouretas influenced young physicians, yet he always continued to work privately as an analyst.

Kouretas's articles and books on clinical psychoanalysis and mythology enjoyed a large audience in Greece. They dealt with the theory and practice of psychoanalysis, and also with applied psychoanalysis, such as his study of the "Io complex" in Aeschylus's *The Suppliants* and *Prometheus Bound* (1949) and "The Actual Neuroses of the Danaïdes" (1957).

## **KOVÁCS-PROSZNITZ, VILMA (1883–1940)**

Vilma Kovács-Prosznitz, the Hungarian psychoanalyst, was born at Szeged in Hungary on October 13, 1883, and died in Budapest in May 1940.

She was the third daughter of a provincial bourgeois family and her father died while she was still very young, less than six years old. The family found itself destitute, and Vilma was married at the age of fifteen and against her will to a cousin, Zsigmond Székely, who was twenty years older than she. By the age of nineteen she was the mother of three children. Alice, the eldest, later married Michael Balint. Vilma contracted tuberculosis and had to spend prolonged periods in a sanatorium. It was there that she met Frédéric Kovács, an architect, whom she married after a difficult divorce that separated her from her children for several years. The children joined Vilma and her husband shortly before World War I and were adopted by Frédéric Kovács after their father's death. A serious case of agoraphobia led Vilma into analysis with Sándor Ferenczi. He was quick to spot his patient's talents and during the 1920s he trained her as a psychoanalyst, making her one of his closest collaborators.

In 1925, Vilma Kovács became head of the training committee. A highly reputed training analyst, she organized the Hungarian Psychoanalytic Association's clinical seminars and along with Sándor Ferenczi she elaborated the Hungarian training method: the candidate's analyst supervises the candidate's first case on the couch. As patrons of psychoanalysis in Hungary, in 1931 Vilma and her husband financed the Psychoanalytic Polyclinic at 12 Mészáros Street, in a building that belonged to them.

Vilma Kovács's work related essentially to training. Practically every Hungarian analyst of her time frequented her clinical seminars at one time or another. More specifically, she analyzed Imre Hermann and Géza Róheim.

She published only five articles, but one of them, "Training Analysis and Control Analysis" (1935), is a classic of psychoanalytic literature and has been translated into several languages.

In another article, "Examples of the Active Technique," dating from 1928, she provides a remarkably clear presentation of this technique that her mentor, Sándor Ferenczi, had just introduced, illustrating it with several examples.

Through her clear-mindedness, her remarkable clinical sense, and her organizational skills, Vilma Kovács left a profound mark on the Hungarian school of psychoanalysis.

## KRAUS, KARL (1874–1936)

Karl Kraus, an Austrian writer, was born April 28, 1874, in Bohemia and died in Vienna on July 12, 1936.

He was the ninth child of the businessman and manufacturer Jakob Krauss and his wife Ernestine. The family moved to Vienna in 1877. Kraus became interested in the theater while still quite young. He studied law, philosophy, and German, and worked as a critic for several magazines; he published an essay in 1897 in which he denounced the excesses of fin-de-siècle decadence (Gustav Klimt) and attacked his friend Hugo von Hofmannsthal. In 1910 the first reading of Kraus's work was held in Berlin. This was followed by approximately seven hundred other readings in different European cities, where the work of other authors was read—William Shakespeare, Johann Nestroy, Frank Wedekind, Jacques Offenbach—some of which had been translated and adapted by Kraus.

Kraus converted to Catholicism in 1911 but abandoned the religion in 1923. In 1913 he had an affair with Sidonie Nadherny von Borutin, which was cut short by her marriage in 1920. She left the marriage six months later to join Kraus. In 1933 he wrote a text critical of Hitler that was published only after his death, but a poem of his clearly indicated his position. In 1936 he was struck by a cyclist and died on July 12.

His writing first appeared in *Die Fackel* (The Torch), which he founded and managed by himself from 1899 to 1936. Kraus examined the “small things” of everyday life, which he elevated into a general criticism of corruption and social conformity, especially that of the press, whose influence was growing. Kraus, in his criticism, was ambiguous about the question of Judaism, and in it he expressed what Otto Weininger referred to as hatred of the Jewish self. His pacifism, before and during the First World War, resulted in various forms of censorship. His “faith in language,” a language he tried to master, was a constant factor: “Language is the mother of thought, not its servant.”

Freud was one of the readers of *Die Fackel* around 1903, and mentioned it for the first time in 1905 in relation to his *Three Essays on the Theory of Sexuality*. In 1906 Kraus took part in the accusation of plagiarism launched by Wilhelm Fliess. Freud, who thought he saw an ally in Kraus, tried to meet him. The tone changed in 1910, however, after Fritz Wittels, who had been a prolific collaborator at *Die Fackel* but had left the magazine, gave a presentation before the Vienna Psychoanalytic Society entitled the “Neurosis of *Die Fackel*.” In his paper he caricatured Kraus’s aversion to the *Neue Freie Presse* as the expression of a death wish against the father. When Kraus learned of Wittel’s talk, he let loose the slings of his barbed wit against psychoanalysis itself.

## **KRIS, ERNST (1900–1957)**

Ernst Kris, an American psychoanalyst and art historian, was born on April 26, 1900, in Vienna and died on February 27, 1957, in New York. He was the son of Leopold Kris, a Jewish lawyer, and Rosa Schick. During and even before his studies at school, he became interested in art and art history. In 1918 he enrolled in the philosophy department at the University of Vienna and graduated in 1922 with a degree in art history. His dissertation was published in 1926 as *Der Stil “Rustique”* (Rustic Style). That same year he was appointed curator at the Museum of the History of Art in Vienna. His fiancé, Marianne Rie, introduced him to Freud in 1924 as an expert for his collection of antiquities. The Freud and Rie families were close friends: Oskar Rie, a pediatrician, was one of Freud’s tarok partners and also a member of the Vienna Psychoanalytic Society.

When Marianne Rie, after finishing her medical studies, began training in analysis in Berlin, Freud recommended analysis for Kris too. Kris completed his psychoanalytic training in Vienna with Helene Deutsch as his training analyst. In 1928, a year after their marriage, Ernst and Marianne Kris were made associate members of the Vienna Psychoanalytic Society.

Aside from his psychoanalytic practice, Kris worked as an art historian and published articles on art history. In 1929 he was appointed chief European expert for cameos and gems at the Metropolitan Museum of Art in New York to help catalog their new collection. As a psychoanalyst, he made important contributions to the psychology of the artist and the psychoanalytic interpretation of works of art and caricature. In the review *Imago* he published his first psychoanalytic study, “Ein geisteskranker Bildhauer” (A mentally ill sculptor) on Doctor Franz Xaver Messerschmidt. In 1932 he became coeditor of the review with Robert Waelder.

In 1933 Kris became an affiliate member of the Vienna Psychoanalytic Society, and in 1936 a delegate to the education committee. After the annexation of Austria by Germany, Kris was able to escape to London with his family. There he became a member of and training analyst with the British Psycho-Analytical Society, and he worked with the BBC on the scientific analysis of Nazi propaganda.

After 1940 he continued this propaganda work in Canada and the United States, where he settled in New York. In September 1940 he was appointed professor

at the New School for Social Research and began, with Hans Speier, a research program on totalitarian propaganda. In 1943 Kris became a member of the New York Psychoanalytic Society and began teaching at the New York Psychoanalytic Institute. In his long collaboration with Heinz Hartmann and Rudolph Loewenstein in the United States, he made essential contributions to the development of ego psychology. His longitudinal study on early infancy, done at the Child Study Center of Yale University, has remained famous. In 1945 he cofounded, and became coeditor of, the journal *The Psychoanalytic Study of the Child* and, with Anna Freud and Marie Bonaparte, edited the first edition of Freud's letters to Wilhelm Fliess.

## **KRIS-RIE, MARIANNE (1900–1980)**

Marianne Kris-Rie, the Austrian physician and psychoanalyst, was born in Vienna on May 27, 1900, and died in London on November 23, 1980.

Marianne Kris was the daughter of Oskar Rie and Melanie Bondy. Oskar Rie was a highly reputed pediatrician and a friend of Freud, with whom he published *Klinische Studie über die halbseitige Cerebrallähmung der Kinder* (Clinical Study of Cerebral Hemiplegia in Children, 1891a). Marianne's mother was Wilhelm

Fliess's sister-in-law, her older sister, Margarete, being married to Herman Nunberg.

Already a physician, Marianne Kris married Ernst Kris in 1927, and one year later they both became members of the Vienna Psychoanalytic Society. She worked in close collaboration with Anna Freud, who was also her friend. From 1925 to 1927, she did her psychoanalytic training in Berlin with Franz Alexander. She was analyzed by Freud.

Obliged to leave Vienna in 1938, after the Anschluss, she moved first in London, where she was a member of the British Psycho-Analytical Society, then to the United States, where she settled in New York in 1940, becoming a member of the New York Psychoanalytic Society in 1944. She worked mainly in child psychoanalysis and helped train child analysts. She collaborated with social workers and teachers in different social sectors and played an active role in training non-physician psychotherapists.

She became a member of the Western New England Institute for Psychoanalysis and, in 1965, she and other child analysts contributed to creating the Association for Child Psychoanalysis, becoming its first president in the same year. She established the practice of working with the family when treating children and in 1972 she delivered a paper in New York on "The Psychoanalytic Study of the Family." She was also chief editor of the review *The Psychoanalytic Study of the Child*. She worked hard to have non-physicians admitted to psychoanalytic societies. She had two sons, and lost her husband in 1957. Marianne Kris died on November 23, 1980, in Anna Freud's house, having gone to Great Britain to take part in the second International Seminar of the Hampstead Clinic.

## L AND R SCHEMAS

The L and R schemas are two of Lacan's didactic diagrams; they articulate the dual relation, between the imaginary (which is dualistic) and the symbolic, (which adds a third element).

Human beings are at first captured *in* the symbolic order before they are aware of it. They enter into it, through the parades of speech, as in the fort/da game that Freud described in *Beyond the Pleasure Principle* (1920g).

Schema L developed out of Lacan's study of Poe's story "The Purloined Letter" in his seminar of 1954–55. It depicts the "relation" of the subject with the absolute Other. As the arrows in the schema indicate, it is from the Other (i.e., the unconscious, the "treasure trove of signifiers") that a message reaches the subject in an inverted form.

**FIGURE 1**

This message makes the subject "fade" when it is received (Figure 1).

In other words, the "relation" of the unconscious subject to the Other—that is, the relation the subject has with his or her own unconscious—is precarious and uncertain. In fact, it is always mediated by the subject's ego, which, according to Lacan's theory of the mirror stage, is based on the image of another. Thus, if we ignore the direction of the arrows, communication between S and A can only follow a trajectory that moves from other people—that is, the "small other"—to the subject's ego, that is, from the specular image to one's body image. These two are trapped in a Hegelian dialectic.

In "On a Question Prior to Any Possible Treatment of Psychosis" (1959), Lacan produced schema R, which extended and completed schema L. A distortion of schema R then produced schema I, which represents psychosis. And it is schema R in the form of a diamond that gives us the formula of fantasy:  $\$ \diamond a$  (Figure 2).

This quadrangular schema represents the Oedipus complex in two different aspects, imaginary and symbolic. The square includes on the one hand the imaginary triangle mother-child-phallus, and on the other hand the symbolic triangle that structures the oedipal trio of father-mother-child.

The real is located between these two triangles. It is represented as a Moebius strip that simultaneously separates and unites the imaginary and the symbolic.

The relations of the terms on the outside of the square (M, mother; P, *père*, father; I, ego-ideal;  $\phi$ , phallus) along with those from schema L placed on the inside of the schema (S, *a*, *at*, A) are in the register of identification. This is how "The third term of

**FIGURE 2**

the imaginary ternary [mother-child-phallus]—the one where the subject is identified, on the contrary, with his living being—is nothing but the phallic image, whose unveiling in this function is not the least scandalous facet of the Freudian discovery” (Lacan, 2002, pp. 186–87).

The real in the center of the schema is in fact a Möbius strip, the edges of which are rejoined when the strip is cut out and twisted so that points *Mm* and *Ii* meet. This strip only sustains itself by extracting of object *a*: “It is thus as representation’s representative in fantasy—that is, as the originally repressed subject—that  $\$$ , the barred *S* of desire, props up the field of reality here; and this field is sustained only by the extraction of object *a*, which nevertheless gives it its frame” (Lacan, p. 213, n. 14).

In Schema I, the schema of psychosis, the phallic and paternal symbolic poles are completely distorted in favor of the imaginary relation *M-m* (Figure 3).

“[This] symbolizes . . . that the [psychotic’s] relation to the other qua relation to one’s semblable . . . [is] perfectly compatible with the skewing of the relation to the Other with a capital *O*” (Lacan, p. 204).

**LACAN, JACQUES-MARIE ÉMILE (1901–1981)**

French psychiatrist and psychoanalyst Jacques-Marie Émile Lacan was born in Paris on April 12, 1901, and died on September 9, 1981, in the suburb of Neuilly.

He was born the eldest child of a bourgeois Catholic family of wealthy vinegar merchants from Orléans. Three other children followed: a boy who died young; Madeleine, born in 1903; and Marc, born in 1907, who would later become a Benedictine monk at Hautecombe. Lacan was close to his brother, both emotionally and intellectually, and owed his theological knowledge at least in part to him. Lacan completed his secondary studies at a well-regarded Catholic school, Stanislas College, where he was taught philosophy by Jean Baruzi, a specialist in Leibniz and the history of religion, especially St. John of the Cross.

At the beginning of the 1920s, Lacan began his medical studies while also frequenting the literary

centers of the avant-garde. Along with his friends Henri Ey and Pierre Mâle, he specialized in psychiatry and interned at Sainte-Anne Hospital under Henri Clude; Gaëtan Georges de Clérambault, his “only teacher in psychiatry” (Lacan, 1966, p. 65); and Georges Heuyer. He also served a stint at the Burghölzli Clinic from August to September 1929. In 1932, he defended his thesis, *On Paranoid Psychosis in its Relation to Personality*. The centerpiece of the thesis was the case of Aimée (whose name, he would later learn, was Marguerite Anzieu), a criminal psychotic whom he observed at Sainte-Anne. When it was published, the thesis caused a bit of a sensation and was praised by René Crevel and Salvador Dalí. In December 1933, Lacan published his article, “Motives of Paranoiac Crime,” in the journal *Minitaure*. The article was about the Papin sisters, whose crimes were then in the news and of great interest to the surrealists.

He entered analysis with Rudolph Loewenstein, probably in 1933 after completing his thesis. In 1934, he married Marie-Louise Blondin, the sister of his friend from medical school, Sylvain Blondin. The couple had three children, Caroline, Thibaut, and Sibylle. In the same year, he became a candidate member of the *Société psychanalytique de Paris* (SPP the Paris Psychoanalytic Society).

In 1936, at the fourteenth congress of the I.P.A. in Marienbad, Lacan presented what he called “the first linchpin of my contributions in psychoanalytic theory,” the text of which he claimed to have “neglected to deliver” for publication in the proceedings of the congress (Lacan, 1966, p. 67). The paper was called, “The Mirror State: The Theory of a Structural and Developmental Moment in the Construction of Reality, Conceived in Relation to Psychoanalytic Experience and Teaching,” a title that is known only from Lacan’s biography, written by Anatole de Monzie, in the *Encyclopédie française*. He delivered another version of the talk at the sixteenth IPA congress in Zurich in 1949: “The Mirror Stage as Formative of the *I* Function as Revealed in Psychoanalytic Experience,” an experience that was “at odds with any philosophy directly stemming from the *cogito*” (Lacan, 2002, p. 3). The ego, from Lacan’s point of view, was not the entire subject, nor the subject of consciousness, but the primary narcissistic imago. The ego was evidence of a “mad passion—specific to man, stamping his image on reality” (Lacan, 2002, p. 23), and it “repre-

sents the center of all resistances to the treatment of symptoms” (Lacan, 2002, p. 118). Thus in Lacan’s earliest formulations, the ego, far from being formed by reality, is opposed to it. Out of this early text came the opposition between psychological reality, external reality, and the real.

In December 1938, Lacan was elected a full member of the SPP. In the same year, he wrote an article on “The Family” for volume VIII of the *Encyclopédie française*, which was edited by Henri Wallon and devoted to “mental life.” It was published the following March. The formulations in this article, which was a reworking of Freudian theory, were already quite Lacanian.

During the war, two of his daughters were born. His first wife, who finally obtained a divorce in 1941, had Sybille in 1940. And in 1941, his companion Sylvia Bataille had his daughter Judith, who would marry Jacques-Alain Miller in 1966.

With his first post-war writing in 1945, “Logical Time and the Assertion of Anticipated Certainty,” Lacan continued with the investigation of the imaginary that he had begun in 1936, now focusing on “logical time” (as opposed to Eugène Minkowski’s “experienced time,” which Lacan had recently criticized in a review). Lacan argued that logical time manifested itself at the limit of the subject’s “time for comprehending,” when the subject was assured of an anticipated certainty in a “moment of concluding,” in other words, in an act (cf. Lacan, 1945/1988, p. 10). This text foreshadowed Lacan’s manipulation of time by varying the length of analytic sessions, which would become a source of controversy within the SPP and the IPA in the 1950s.

Lacan’s post-war years were also marked by an ongoing debate with psychiatry, starting with “On Psychic Causality,” a critique of his friend Henri Ey’s organo-dynamism written in 1946 for a conference at Bonneval on the problem of the origins of neurosis and psychosis. This was followed in 1947 by a lecture on “English Psychiatry and the War,” and in 1950 by a contribution to the first world conference on psychiatry, “A Theoretical Introduction to the Functions of Psychoanalysis in Criminology,” written with Michel Cénac.

At the same time, Lacan participated actively in the post-war rejuvenation of the SPP, and in 1949, he collaborated on the “Policies and Tenets of the SPP’s Committee on Teaching.”

In 1953, during his presidency of the Society, conflicts between medical analysts (Sacha Nacht) and more

liberal academic analysts (Daniel Lagache, Juliette Favez-Boutonier) led to the resignations of Françoise Dolto, Juliette Favez-Boutonier, Daniel Lagache, and Blanche Reverchon-Louve on June 16. Lacan quickly followed, and the group founded the *Société française de psychanalyse* (SFP, French Psychoanalytic Society) on June 18. On July 8, Lacan inaugurated the new society with a lecture “The Symbolic, the Imaginary, and the Real” (SIR), which began a new phase in his thought, marked by the prevalence of language and the symbolic over the imaginary, a concept that dated back to his elaboration of the imago and the mirror stage in 1936. He launched his return to Freud with this triad, which allowed him to differentiate between (symbolic) castration, (imaginary) frustration, and (real) privation, and also the symbolic father, the imaginary father, and the real father.

Nine days later, he married Sylvia Maklès, who had divorced Georges Bataille in 1946. In August he wrote “The Function of Speech in Psychoanalytic Experience and the Relation of Language to the Psychoanalytic Field,” the original title of the lecture that he had given in Rome on September 26, 1953. Each institutional stage in Lacan’s career, each crisis, served as the occasion for a significant crystallization of his thought and a theoretical advance that apparently helped him to define the moment. After the mirror stage, the “Rome Report” marked the second stage in his work.

The lecture on “The Symbolic, the Imaginary, and the Real” showed the influence of Claude Lévi-Strauss. The “Rome Report,” with its opposition between language and speech and its attention to ahistorical speech that goes beyond the intentions of its subject, coincided with some of the conceptions of Heidegger, whose article “Logos” Lacan had just translated. From his thesis in 1932 until 1953, Lacan read Freud’s texts in a nonsystematic way, and he differed from Freud in separating the ego from the perception-consciousness system in order to situate it in the imaginary, in accordance with his original conception of the mirror stage and the new elaboration he gave it in a 1951 lecture to the British Psychoanalytic Society, “Some Reflections on the Ego” (*I.J.P.*, 1953).

In the fall of 1953, his public seminar at the Sainte-Anne Hospital began a reevaluation of Freud’s work, much of which was only available in German or English: “This kind of teaching is a refusal of any system. . . . Freud’s thought is the most perennially open to revision” (Lacan, 1953–54, p. 1). He began this

revision with Freud’s writings on technique. Already in the still unpublished lectures that he held from 1950 to 1953, Lacan had approached psychoanalytic technique from own perspective of varying session length. His public seminar began with the question of resistance, which he attributed to an “organization of the ego” (1953–54, p. 23), while for Freud, resistance had to do with remembering.

The ongoing seminar at Sainte-Anne was ended on November 20, 1963, with a single session on what was to be his topic for 1963–64, *The Names-of-the-Father*. He gave this lecture the day after his “major excommunication,” the IPA’s refusal to grant him the status of training analyst, and it testified to the subjective and intellectual crisis that this rejection provoked in him. To consider the father, Lacan turned towards “religion, and [what] I, for my part, call the Church” (Lacan, 1963, p. 84). More specifically, he turned to *De Trinitate*, by St. Augustine.

The Seminar’s relocation to the École normale supérieure (ENS) in the rue d’Ulm in January 1964 brought about a noticeable change in its style and content. The audience was larger and more intellectual, and Lacan addressed himself particularly to the “Normaliens,” the students of the ENS until June 1969, when he was forced to leave the ENS. At the ENS, Lacan abandoned the “return to Freud” in order to develop his own thought and the foundations of psychoanalysis in his seminar *The Four Fundamental Concepts of Psychoanalysis* (the unconscious, repetition, transference, and the drive). During these years he formalized his own concepts: the barred subject,  $\$$ ; object  $a$ ; and the Other, which was both the Other of language and the Other scene, the scene of the dream and of the unconscious, a term that Freud borrowed from Fechner (cf. Freud, 1900a, pp. 48, 536).

On June 20, 1964, in the aftermath of his rejection by the IPA, Lacan “alone” founded the École française de psychanalyse (EFP, the French School of Psychoanalysis), which was soon renamed the École freudienne de Paris (Freudian School of Paris). The School saw a rapid increase in membership over its fifteen years of existence, growing from about 100 to more than 600 members.

In October 1966, Lacan made his first trip to the United States to attend a conference in Baltimore on structuralism. This conference took place shortly before the publication of his *Écrits*, a voluminous book of 924 pages in which all of his essential writings were collected.

*Écrits* allowed Lacan to win over the general public just as he had the Normaliens and the philosophers.

On November 26, 1969, Lacan began his seminar entitled *The Other Side of Psychoanalysis*, which was influenced by the student protests of May 1968, by introducing his “four discourses”: the discourses of the master, of the university, of the hysteric, and of the analyst. Each one was constructed out of four terms: S1, the master signifier; S2, knowledge; *a*, surplus enjoyment; and  $\$$ , the subject. The four discourses, or the “quadripode,” anticipated the matheme that Lacan introduced in December 1971, at a series of lectures given at Sainte-Anne Hospital on the “Knowledge of the Psychoanalyst.” He returned to this matheme in 1972 in his seminar *Encore* when he developed his graph of sexuation. According to Lacan, an algebraic mode of writing allowed for the transmission of psychoanalysis and removed the incompatibility between the discourse of analysis and the discourse of the university that was apparent in the four discourses. This argument gave Lacan grounds to sanction the expansion of psychoanalysis in the university.

His final orientation maintained the equivalence of the three coordinates. In the twenty-second year of his seminar, entitled *R.S.I.* (1973–1974), the symbolic, imaginary, and real were represented topologically by the Borromean knot, three rings connected in such a way that each held the two others in a circular reciprocity.

The end of Lacan’s life was sad, marked as it was by political and theoretical conflicts within the EFP and by rivalry between the School and the Department of Psychoanalysis at Vincennes, directed by his son-in-law Jacques-Alain Miller.

During the seminar on *Topology and Time* (1978–1979), Lacan was practically mute. Finally, in a moment of lucidity, he announced the dissolution of the School that he alone had founded in a signed letter dated January 5, 1980. In February, while awaiting the legal dissolution of the EFP (which eventually took place in September), he founded the *Cause freudienne* (the Freudian Cause), and then in October, he “adopted” the EFP as the new *École de la Cause freudienne* (School of the Freudian Cause).

Following the letter of dissolution, what Lacan called his “seminar” of January 15, 1980, was actually a series of sentences addressed to the newspaper *Le Monde* on January 26. “If it should happen that I go away, tell yourselves that it is in order—to be Other at last. One can be satisfied with being Other like everyone else, after

a lifetime spent being it in spite of the Law” (Lacan, 1980, p. 135). In fact, he was hospitalized under the name of his personal physician, and died of colon cancer at the Henri-Harman Surgical Center in Neuilly on September 9, 1981. His will, dated November 13, 1980, named Judith Miller his sole heir and his son-in-law Jacques-Alain Miller as his literary executor.

Throughout the century, Lacan met and spent time with the greatest minds of his era—Joyce, Kojève, Koyré, Dalí, Picasso, Bataille, Lévi-Strauss, Jakobson, Merleau-Ponty, Heidegger, and more. He had to endure the fact that no one really understood his work. His primary endeavor throughout his career was to find a theoretical basis for the speech of the analysand that leads to the transference and thus constitutes the analyst as Other. To try to find the basis for speech in anything other than itself is certainly a Faustian project, but it indicates his passion for analysis. Mallarmé’s assessment of Rimbaud suits Lacan as well: he was “a considerable passer-by.”

## **LACK OF DIFFERENTIATION**

The question of lack of differentiation is raised mainly from a topographical viewpoint, as well as that of the

founding of the psyche in infants. Interest in this topic has recently been renewed with the emergence of what is known as developmental psychoanalysis (Daniel N. Stern) and infant psychiatry. In general, the ontogenesis of the mental apparatus is intrinsically based on a model of two processes of differentiation: extrapsychic (or interindividual) differentiation and intrapsychic (or intrasubjective) differentiation. Extrapsychic differentiation gradually produces a demarcation between the “me” and the “not me.” Intrapsychic differentiation, meanwhile, leads to the functional organization of the different intrapsychic agencies (such as the id, the ego, and the superego). Obviously, these two processes take place in tandem and cannot be separated, except from a simple theoretical or pedagogical perspective, if only because discovery of the object is necessary to enable the subject to position him- or herself as a subject, and vice versa.

Lack of extrapsychic differentiation paves the way for psychotic (for example, autistic, symbiotic, or schizophrenic) modes of functioning in which there is a profound lack of distinction between inside and outside. It is also at the core of very archaic psychopathologies and, notably, of early childhood autism.

Thinking about lack of differentiation, based mainly on retrospective material that comes out in the treatment of children or adults (which provides access, within the dynamics of transference and countertransference, to an entire series of lived experiences and extremely early psychic mechanisms), was framed somewhat differently in the 1990s, owing to considerable developments as a result of studies of the dyad, the triad, and the entire range of early interactions between the baby and its environment.

Both Frances Tustin, with her theory of a “normal autistic phase” in development (which she herself later refuted), and Margaret Mahler, by describing an autistic phase prior to the later symbiotic phase within the “process of separation-individuation,” in their own respective ways created models with an initial period characterized by a lack of psychic differentiation.

Furthermore, several psychoanalytic authors have produced classic studies that have emphasized the very intense regime of reciprocal projections that initially exists between mother and baby (for example, Donald W. Winnicott’s “primary maternal preoccupation,” Wilfred R. Bion’s “capacity for maternal reverie” and “alpha function,” André Green’s theory of detour via the other, etc.).

Finally, other investigators have stressed the topographical unit that, from a somewhat phenomenological point of view, initially comprises the psyches of the baby and its parents together as a whole (Manuel Pérez Sánchez and Nuria Abello's "primal unit," Hanna Segal's "triangular space" and "third domain," etc.). This unit serves as a matrix for the infant's future symbolization.

The real question that has since arisen is whether an early phase of nondifferentiation really does exist. Perhaps, on the contrary, the baby—equipped with the many competencies now acknowledged in infants—possesses (extra- and intra-) psychic differentiation to a substantial degree to begin with. Stern, for example, cites the baby's early competencies in perception, memorization, and mental representation as evidence that there is no early, preparatory state in which differentiation is lacking. Élisabeth Pivaz's experimental model of the "triadic game" developed in Lausanne supports the same type of hypotheses.

In light of modern research in the very earliest stages of development, what is ultimately at issue is whether or not we are justified in hypothesizing an early dyadic or triadic topography and in specifying the modalities of the still enigmatic passage from the realm of the interpersonal to that of the intrapsychic.

## **LAFORGUE, RENÉ (1894–1962)**

René Laforgue, French psychiatrist and psychoanalyst, was born on November 5, 1894, in Thann, Alsace, then under German control, and died in Paris on March 6, 1962. He was the first president of the Société psychanalytique de Paris (Paris Psychoanalytic Society).

His mother, Eugénie Heitzmann, came from a large family that lived in the Vosges. His father, Joseph, a copperplate engraver for a cloth manufacturer, was an illegitimate child. Laforgue studied at the Collège de Thann, in Forbach, and in Fribourg, then with Franz Oppenheimer, a physiologist from Berlin. In 1913, while working with Oppenheimer, he came across a copy of Sigmund Freud's *The Interpretation of Dreams*. During the First World War he was mobilized in the German army and barely escaped death in the Carpathian mountains.

In 1919 Alsace again became French and Laforgue concluded his medical studies as an intern at the Hoerdtsch Psychiatrisch Hospital, where he studied under Professor Pfsdorff. In 1922, in Strasbourg, he defended his dissertation, "Étude sur l'affectivité des schizophrènes du point de vue psychanalytique." That same year he married Paulette Erickson, whom he met at the Theosophical Society.

He arrived in Paris in 1923 and went to work at the Sorbonne with Professor Henry on the physiology of sensation. He began a short analysis with Eugénie Sokolnicka. He then worked at the Sainte-Anne Hospital as an assistant. After being put in charge of psychoanalytic consulting under Henri Claude in place of his analyst, he and Edouard Pichon wrote an article for the October 20, 1923, issue of *Progrès médical* entitled "De quelques obstacles à la diffusion des méthodes psychanalytiques en France" (Certain obstacles to the diffusion of psychoanalytic methods in France). That same month he wrote to Freud for the first time. The following year he met him in Berchtesgaden. With Freud's support he was unanimously elected a member of the Vienna Psychoanalytic Society in 1925.

He was a co-founder, and co-editor with Angélo Hesnard, of the review *L'Évolution psychiatrique*, the first issue of which appeared in April 1925. Freud discussed Laforgue's article "La Schizonoïa," a critique of Otto Rank's theory of birth trauma and his concept of scotomization, which was nearly indistinguishable from repression.

Laforgue was the first president of the Société psychanalytique de Paris (Paris Psychoanalytic Society), which he helped found in November 1926. He remained president until 1930. He edited the medical section of the *Revue française de psychanalyse* with Angélo Hesnard from its inception in 1927. Marie Bonaparte was responsible for the non-medical section. Together with René Allendy he wrote *La Psychanalyse et les Névroses* (Psychoanalysis and the neuroses), published by Payot in 1924. In 1931 he published *L'Échec de Baudelaire*, a psychoanalytic study of the poet's neurosis.

During the 1930s, Laforgue trained a number of students: Juliette Boutonier (Favez-Boutonier), Françoise Marett (Dolto) and her brother Philippe, Georges Mauco, the publisher Bernard Steele, the actor Alain Cuny, André Berge, and John Leuba, whom he supervised. These students regularly got together at Laforgue's home in the Var, where they formed the "Club des piqués," as they referred to themselves. After the war he psychoanalyzed Jacques Donnars and Mémie Grégoire.

In 1938–1939 Laforgue separated from Paulette Erickson and married Délia Clauzel. He was mobilized in 1939 as a military doctor in the French army.

In November 1940 he asked to become a member of the Berlin Institute and announced that he intended to found, in Paris, a French section of the Psychotherapy Society run by Professor Matthias Göring, with whom he corresponded until 1943. His request, which was repeated in 1941, did not materialize. His earlier membership in the International League against Anti-Semitism hardly inspired confidence among the Nazis. In 1941 he published *Psychopathologie de l'échec* (Psychopathology of failure), written around 1937, but without the chapter on Hitler. He destroyed the book during the Occupation and only one copy was given to Jean Rostand and is presumed lost. In 1942, at his home in the Midi, he provided protection for Jews and escapees from the German work camps. In 1944 he obtained authorization to publish a new edition of *Psychopathologie de l'échec*, for which he was reproached after the Liberation.

In 1945, following accusations by John Leuba, Laforgue was tried for collaboration. The case was dismissed for lack of evidence (the attempt to work with Göring was unknown at the time), but the separation between Laforgue and his colleagues at the Société psychanalytique de Paris continued to worsen.

In 1946 *Psyché*, created by Maryse Choisy, was the first psychoanalytic review to reappear after the war.

Laforgue contributed several articles and participated extensively in the preparation of the *Dictionnaire de psychanalyse et de psychotechnique*, published as a supplement to the review. His position against scientism and his spiritualist interests are confirmed here. But the idea of a form of psychopolitics based on applied psychoanalysis found little interest among his former colleagues and students. At the 1950 International Congress of Psychiatry, he claimed that in sixty percent of cases a rational technique would result in the elimination of nearly two thirds of the sessions then customary in analysis. After the 1953 split of Société psychanalytique de Paris and his resignation, Laforgue joined the Société française de psychanalyse (French Psychoanalytic Society).

He went into "exile" in Morocco, where he had traveled regularly since 1948, from December 1956 to 1959. There he founded the Institut de psychanalyse de Casablanca (Casablanca Institute for Psychoanalysis). Jean Bergeret, Jean Callier, and Monique Foissin, future members of the Société psychanalytique de Paris, began their training at the Institute.

At the end of his life, Laforgue was close to Father Bruno and his *Études carmélitaines*, and reproached psychoanalysts for the sectarianism, akin to religious fanaticism, that divided the various professional societies. The specialist of the neurosis of failure was soon forgotten by the members of the society he created when he died, March 6, 1962, following surgery.

## LAGACHE, DANIEL (1903–1972)

French physician, psychoanalyst, and professor at the Sorbonne, Daniel Lagache was born on December 3, 1903, in Paris, where he died on December 3, 1972.

An officer in the Legion of Honor, Lagache was recipient of an honorary doctorate from the University of Montreal and was a laureate of the Institut de France and Faculty of Medicine, Paris.

At age twelve, Lagache was strongly affected by the death of his father, a lawyer with the appeals court in Paris. Although deeply loved by his father, he felt that his mother preferred his youngest brother and consequently recalled his childhood as "bittersweet." With excellent grades at the Lycée Condorcet, he entered the École Normale Supérieure in 1924. Fascinating case presentations by famous psychologist Georges Dumas at Sainte-Anne's hospital motivated Lagache to pursue psychoanalysis. With fellow students Raymond Aron, Paul Nizan, and Jean-Paul Sartre, Lagache began a course in medicine, and became the only one among them to actually complete studies in medicine and philosophy. After passing his *agrégation* in philosophy in 1928, Lagache received his medical degree in 1934, worked in psychiatric hospitals for several years, and in 1937 served as chief physician in the clinic directed by Henri Claude, the eminent psychiatrist and neurologist. He was appointed professor of psychology at the

University of Strasbourg, succeeding Charles Blondel, in 1937.

From 1933 to 1936, Lagache underwent a training analysis with Rudolph Loewenstein, one of the founders of Paris Psychoanalytic Society (SPP). Lagache's perfect understanding of German allowed him to study Freud's works in the original as well as to read the German phenomenologists and psychopathologists. In 1937 his communication, "Deuil, mélancolie, manie" (Mourning, melancholia and mania) brought him full membership in the SPP. In 1938, at the Fifteenth International Psychoanalytic Congress in Paris, he offered his "Contribution à l'étude des idées d'infidélité homosexuelle dans la jalousie" (Contribution to the study of the ideas of homosexual infidelity in jealousy). During the war, expertise in forensic medicine and psychiatry led him to work in criminology. He made use of observations in cases of homicidal jealousy, and data he gathered on pathological jealousy would constitute the core of the two theses of his doctorate.

During the war, Lagache was initially an officer in the department of military health before being imprisoned; he subsequently escaped to become active in the Resistance and to rejoin the faculty of the University of Strasbourg, which had been relocated to Clermont-Ferrand, near Vichy. Receiving his doctorate in letters at the University of Paris in 1946, he obtained the chair of psychology at the Sorbonne in 1947, and in 1955, the chair of psychopathology. From 1946 to 1966 he also served as a member of the CNRS consultative assembly. In 1947 he founded and directed the collection "Bibliothèque de psychanalyse et de psychologie clinique" (Library of Psychoanalysis and Clinical Psychology, later called simply "Bibliothèque de la psychanalyse"), published by the Presses Universitaires de France. Lagache also was influential in the 1967 publication of *The Language of Psycho-Analysis* by Jean Laplanche and Jean-Bertrand Pontalis, a landmark in the history of psychoanalysis in France.

With Jacques Lacan, in 1953 Lagache founded the Société française de psychanalyse (SFP), which over the next eight years published the remarkable journal *La Psychanalyse*. After this group dissolved, in 1964 Lagache became co-founder and first president of the Association psychanalytique de France (APF), which was recognized in 1965 by the International Psychoanalytical Association (IPA). In 1968, a serious heart condition forced him to retire from official functions and to cut back his psychoanalytic practice.

Lagache's work from 1932 to 1968 includes, in addition to many books, over 170 articles and manuscripts, which were edited and published in six volumes by Eva Rosenblum. His masterpiece was *La jalousie amoureuse* (Jealousy; 1947); *Le travail du deuil* (The work of mourning; 1938) and *Le deuil pathologique* (Pathological mourning; 1956), include Freud and became outstanding titles of reference. His last manuscript, incomplete at his death, was *La folle du logis: La psychanalyse comme science exacte* (The madwoman in the attic: Psychoanalysis as an exact science; 1964). Lagache's language is limpid, concise, and simple.

Lagache's scientific authority, together with his dynamism and powers to convince, enabled him to pioneer the introduction of psychoanalysis into the French university system in 1937. His humanist orientation, scientific honesty, and unimpeachable integrity overcame the resistance of an academic world paralyzed by the fear of an upheaval in education due to Freudian ideas. As an accurate theorist of Freudian concepts, Lagache also played an influential role in promoting psychoanalysis among the general public. His contribution to the "Que sais-je?" series of brief primers, *Psychoanalyse* (1955/1963), was translated into twelve languages and is considered a masterpiece. He understood how to underpin psychoanalytic thought with reference to clinical experience, in the twenty-first century and his lectures at the Sorbonne remain relevant today. He was responsible for publishing numerous foreign works in France and established an international network of colleagues and collaborators. Selections from his collected works have been translated into English (Lagache, 1993) and Spanish. Engaged both in the creation of psychoanalytic institutions and in the organization of international congresses, Lagache was an active participant in various internequine disputes in French psychoanalysis and, more generally, played a major role in the history of the psychoanalytic movement, both in France and abroad.

## LAINÉ, TONY (1930–1992)

Tony Lainé, French psychiatrist and physician, was born in Paris on April 25, 1930, and died in Toronto on August 21, 1992. His father was an "anarcho-labor" militant worker, and his Jewish Siberian mother was an elementary school teacher and former student of Henri Wallon. He spent all his childhood in the Poitou region of France, where he was educated and studied medicine. He served as an intern in psychiatric hospitals in 1956, became a doctor of medicine in 1959, and passed the highly competitive entrance examination for hospital psychiatrists in 1960.

Influenced by the Second World War, violence, anti-Semitism, and social injustice, Lainé was first attracted to literature before taking a simultaneous interest in medicine and philosophy. He showed a sincere attachment to workers and the communist movement until the 1970s, a time of reckoning. He nevertheless remained attached to the struggle against all forms of exclusion. Out of sympathy with the Italian antipsychiatry movement, he invented particularly innovative institutional models of mental disorders.

After a personal analysis at the end of the 1970s, psychoanalysis was a constant inspiration for him. Lainé used psychoanalysis as a constant reference in his clinical practice, his theoretical reflections, and his

way of understanding institutions. He was greatly influenced by the thinking of Donald Winnicott, but he also related to theory in ways based essentially on his encounters with children and adolescents. Lainé used his talents as a storyteller to transmit the lessons he drew from his practice and make them accessible to all. He accorded great importance to the ethics of psychoanalysis: He insisted on leaving great scope for subjective evaluation, as opposed to more operational modes of practice.

Lainé took an interest in social structures and the unconscious and their reciprocal interactions. For more than thirty years he directed hospital units devoted to child and adolescent psychiatry and played a particularly active role treating child autism and psychosis, as well as adolescent problems. His contacts with film directors led him to make several television films: *La raison du plus fou* (The crazy one's reason), *La mal-vie* (Life pains), and *Le bébé est une personne* (The baby is a person). He also penned some notable popular publications: *La mort du père* (The death of Father), *Le petit donneur d'offrandes* (Little offerings), *Les violences de l'amour* (The violence of love). These films and publications contributed to making him well known.

## LAING, RONALD DAVID (1927–1989)

Ronald David Laing, a British psychiatrist, was born in Glasgow, Scotland, on October 7, 1927. He died in St. Tropez, France, on August 23, 1989.

The only child of strictly Presbyterian Scottish parents of modest means, Laing studied classics at Hutchison's Boy's Grammar School and medicine at university. To his medical peer group in Glasgow, Laing showed himself to be an extraordinarily gifted musician, scholar, and discussant. He introduced them to Freud. In a population still heavily influenced by puritan values and respectable civic expectations, his behavioral example and the range of his mind were exhilarating. As a final year student Laing opted to become an assistant on psychiatric wards. This, together with his immediate postgraduate training for six months, led to his being graded a psychiatrist throughout two years compulsory military service. At Netley Hospital he spent hours sitting with very disturbed patients and thus found himself researching psychotic states.

Returning to Glasgow, he sought and was given facilities at Garthavel Royal Mental Hospital to set up a special nursing care unit for chronic schizophrenic women. The impressive results he obtained there were published in *The Lancet* (Cameron, McGhie and Laing, 1955). In Glasgow he continued the original clinical observations which would underpin his book, *The Divided Self*. Meanwhile he read very widely in philosophy and in phenomenological and existential psychiatry. Identified by J. D. Sutherland and John Bowlby as a candidate of outstanding originality and promise, Laing was offered a full-time salaried post at the Tavistock Clinic and a training analysis in conjunction with this at no cost to himself. His analyst was Charles Rycroft, his supervisors Marion Milner and Donald Winnicott. Although his qualification as an analyst was opposed by some teachers and administrators, it was strongly supported by those training analysts just mentioned.

The publication of *The Divided Self* in 1960 marked an important turning point in British psychiatry largely because Laing was able to collate, digest, synthesize, and crystallize ideas that were already current or latent in continental Europe and North America. It gave a voice to madness. Laing's originality lay in his power to complete the task and in his capacity to present the ideas, which had by then become his, with clinical illustrations, in such a way that a very large number of people were persuaded (and continue to be persuaded) that he was right.

*The Divided Self*, subtitled *An Existential Study in Sanity and Madness*, was Laing's first book and is widely regarded as his finest. Along with *The Politics of*

*Experience* (1967), it brought him worldwide fame. In time, Laing's importance in the United States waned, and he never completely recovered from the public versus private identity crisis of his late thirties.

## **LAMPL-DE GROOT, JEANNE (1895–1987)**

Jeanne Lampl-de Groot, psychoanalyst, psychiatrist, and psychologist, was born in Schiedam, on October 16, 1895, and died in Amsterdam on April 5, 1987, both in the Netherlands.

A psychoanalyst of the first generation, Lampl-de Groot grew up as the third of four children in a Jewish family, her father a businessman, her mother the daughter of a general practitioner. She studied medicine at Leiden and Amsterdam Universities and in 1921 became a doctor.

As a student, she came across Sigmund Freud's *The Interpretation of Dreams*, which fascinated her. After finishing her studies she wrote to Freud, asking him whether she could come to him to learn psychoanalysis. In April 1922 she began her work with Freud, at the age of twenty-seven, which was unusually young in those years. With Anna Freud among others, she attended courses and seminars of the Vienna Society and also worked in the psychiatric clinic of Wagner von Juaregg. She had planned to establish an analytic practice in Holland after her training but Freud recommended that she go to Berlin to work at the Berlin Institute for one or two years. So in 1925 she moved to Berlin, where she met her future husband Dr. Hans Lampl, originally from Vienna and a family friend of the Freuds. They had two daughters together.

When Hitler came into power the family moved back to Vienna, where the Psychoanalytic Society had been rejuvenated and analysis was flourishing. Moreover, Anna Freud had developed child analytic treatment and training. Lampl-de Groot was interested in child analysis, and on the recommendation of Dr. Siegfried Bernfeld, she had been a consultant psychiatric analyst in a child guidance clinic in Berlin. She was the recipient of one of the nine rings Freud presented to colleagues.

In 1938 the family emigrated to Holland because of the threat of the Hitler regime. They settled in Amsterdam, where they resumed their analytic practice and started a training scheme for analysts. At that time the Dutch Society, founded in 1917, only counted ten practicing members. During World War II this small group held courses and seminars "underground" and after the war founded the Dutch Psychoanalytic Institute (1946). The training procedure followed the model of those of Vienna and Berlin. In the same period Lampl-de Groot developed lively international contacts among psychoanalysts. In 1950 she organized the first post-war conference of European psychoanalysts in Amsterdam. She became a member of the board of the International Psychoanalytic Association (IPA) as vice-president. In 1953 she participated in an IPA commission, including Donald Winnicott, Phyllis Greenacre, and Ruth Eissler, to inform Jacques Lacan in Paris of criticisms of his educational and treatment methods. In 1963 she was appointed to be honorary vice-president of the IPA. In 1970 she was awarded an honorary doctorate in medicine by the University of Amsterdam, and honorary membership in the Deutsche Psychoanalytische Vereinigung. In 1971, she was made an honorary member of the Dutch Society of Psychiatry and Neurology, and was in 1977 nominated as honorary member of the Dutch Society of Psychoanalysis.

In her publications Lampl-de Groot covered a range of psychoanalytic topics. Narcissism and female psychology were two topics she addressed at length. Her writings have been of essential significance to the progress of psychoanalysis as a science. Her independent approach in supplementing Freud's work was apparent from her first article in 1927. She was the first author to describe and delineate the Oedipus complex in relation to growing girls, and she elaborated on this theme in later publications (1982). Strongly influenced by the ego psychology of Anna Freud and Heinz Hartmann, she used newly-gained

insights into the functioning of the ego and the role of omnipotence in narcissism in her work. There is an obvious link between her work on narcissism and Freud's. She integrated these ideas in her articles describing defence as a function of the ego and its importance for character development. She expressed her thoughts in beautifully simple and lucid prose, keeping away from theoretical phrases and always emphasizing the enormous complexity of the psyche while never neglecting the powerful force of the drives.

Her works were collected by friends and colleagues and presented to her on the occasion of her ninetieth birthday.

## **LAMPL, HANS (1889–1958)**

Hans Lampl, an Austrian physician, was born near Vienna on October 15, 1889, and died in Amsterdam on December 1, 1958.

Hans Lampl came from a family of Jewish civil servants. As the classmate, friend, and later the travel companion for Freud's oldest son Martin, he was a regular guest of the family. He studied medicine in Vienna and qualified as a physician in 1914. He was particularly interested in pathology and anatomy, and Freud advised him to specialize in these domains.

In 1920 he was invited to attend the sixth International Congress at The Hague and a year later went to Berlin to begin his analysis with Hanns Sachs, with whom he completed his training analysis. In 1922 he worked as a physician in the Berlin psychoanalytic polyclinic and in early 1926 he became an associate member and later a full member of the German Psychoanalytic Society.

It was in Berlin that he met his future wife, the Dutch physician Jeanne de Groot, who had been analyzed by Sigmund Freud and was working in the polyclinic. After Hitler took power in 1933, they left together for Vienna

and were accepted as members of the Vienna Psychoanalytic Society. In 1934 Lampl became president of the society and in 1935 he was elected treasurer of the Ambulatorium, an outpatient clinic.

In Vienna he collaborated with Sergei Feitelberg on task resolution in experimental physiology with a view to a research project to measure the libido, conducted by Bernfeld and Feitelberg. He also worked at the University of Vienna pharmacology institute until forbidden to do so after the Anschluss.

In 1938 he emigrated with his family to the Netherlands. In Amsterdam he became a member of the Netherlands Psychoanalytic Society and worked there as a training analyst. During World War II and after the disintegration of the society, he continued to train candidates privately. After the war he devoted himself essentially to the foundation of the new Netherlands training institute, becoming president in 1946.

He was killed in a traffic accident on his way to work on December 1, 1958.

## **LANDAUER, KARL (1887–1945)**

German psychoanalyst and physician Karl Landauer was born on October 12, 1887, in Munich and died on January 27, 1945, in the Nazi concentration camp of Bergen-Belsen.

From an Orthodox Jewish family, Landauer was the youngest of three children and the only son; his father, a

banker, died after a long illness when Karl was fourteen. When he began his medical studies, he intended to become a pediatrician, but subsequently decided on psychiatry.

To complement neuropsychiatric training with Julius Wagner-Jauregg, in 1912 Landauer took the advice of psychiatrist Max Isserlin, at the Kraepelin Institute in Munich, and began a training analysis with Freud. He joined the Vienna Psychoanalytic Society in the fall of 1913. With the outbreak of war the next year, he entered the military and served as a physician on both the Eastern and Western Front. His wartime experience with poison gas made him a pacifist.

From 1919, for reasons connected with his family, Landauer continued his psychiatric training in Frankfurt. In 1923, he opened a practice, principally devoted to psychoanalysis. He thereafter worked to establish another analytic community, similar to the one developing in Berlin. He organized local and international congresses (Würzburg, 1924; Bad Homburg, 1925; Wiesbaden, 1932) and he visited Freud every year. In 1926, he founded the Southwest German Psychoanalytic Group.

In 1929, together with Heinrich Meng, Frieda Fromm-Riechmann and Erich Fromm, Landauer established the Frankfurt Psychoanalytic Institute, at the invitation of Max Horkheimer, who was one of his analysts and the founder, six years earlier, of the Frankfurt Institute of Social Research. Landauer was also mentor to psychoanalyst Sigmund Heinrich Fuchs (Foulkes).

In 1933, with the rise of National Socialism, Landauer emigrated to Amsterdam, and for the rest of the decade he was the most important analyst in the Netherlands. In 1936, in celebration of Freud's eightieth birthday, he lectured before the Vienna Psychoanalytic Society and the Netherlands Psychoanalytic Society.

Failing to take any opportunity to leave the Netherlands for the United States with the approach of World War II, with the Nazi occupation Landauer experienced the gradual loss of personal and professional freedom. In 1943, he was arrested with his wife and his oldest daughter, and transferred from the concentration camp at Westerbork, near Amsterdam, to Bergen-Belsen. There he managed to practice analysis and provide counseling to patients before dying of malnutrition.

Landauer published some nineteen articles in psychoanalysis between 1914 and 1939. Among them are: "Spontanheilung einer Katatonie" (A spontaneous cure of catatonia; 1914); "'Passive' Technik" (The "passive" technique; 1924); "Äquivalente der Trauer" (Equivalents of mourning; 1925); "Zur psychosexuellen Genese der Dummheit" (Contribution to the psychosexual genesis of mental retardation; 1929); "Die Ich-Organisation in der Pubertät" (Ego organization in puberty; 1935); and "Die Affekte und ihre Entwicklung" (Affects and their development; 1936). A posthumous collection, *Theorie der Affekte und andere Schriften zur Ich-Organisation* (Theory of affects and other writings on the organization of the ego), appeared in 1991.

Landauer also presented the first case study of narcissistic identification with the lost object, as well as original technical considerations for the treatment of narcissistic disorders—an early attempt to combine Freud's structural model with his first theory of affects—and a study on the significance of motricity. A pioneer in analytic psychotherapy for children and teenagers, Landauer's description of the psychodynamics of thought inhibition influenced the Frankfurt School's pioneering research on the character of prejudice.

## LANGER, MARIE GLASS HAUSER DE (1910–1987)

Marie Glass Hauser de Langer, a physician and psychoanalyst, was born in Vienna in 1910 and died in Buenos Aires, Argentina, on December 27, 1987.

In her youth she joined the Austrian communist party in an attempt to compensate for the dual handicaps of being Jewish and a woman. She finished her medical studies in 1935 just as Austrian fascism was getting ready to ban Jews from working in hospital services. In 1934 the Vienna Psychoanalytic Society forbade its members to belong to the Institute or to be active in clandestine parties (the communist party had been dissolved in 1933). This information was communicated to Langer by her analyst, Richard Sterba, who terminated her analysis shortly thereafter. In 1936 she decided to emigrate to Spain in order to continue her political activity. Later she left for Uruguay.

After living in Montevideo, she settled in Argentina in 1942 and Langer occupied several important posts in the Argentine Psychoanalytic Association (APA): director of seminars and publications, treasurer, secretary, member of the training Commission, president and director of the Enrique-Racker psychoanalytic clinic. She taught at the Institute and worked as a training analyst for twenty-nine years. In 1970 she left the APA in order to denounce authoritarian tendencies inside psychoanalytic institutions. She was also a founding member of the Argentinean Association for Group Psychotherapy, as well as the Buenos Aires Society of Psychosomatic Medicine. Political persecution then forced her to emigrate to Mexico in 1974.

Langer's writings indicate several lines of research, which are distinguished by her efforts to highlight the influence of the social and cultural context on the practice and theory of psychoanalysis. Among the issues she addressed were: female sexuality, sterility, eternal fantasies, rationales for war, group psychoanalysis, anti-Semitism, methodological problems related to how psychoanalysis is taught, and some technical problems raised by training analysis.

Her book *Maternidad y Sexo* (1951; *Motherhood and Sexuality*, 1992) became a reference text for those

interested in questions relating to femininity. In it she traces, as she also does in several articles (1944–45; 1945–46; 1947–48; 1951; 1953), the position of women in history. In *Fantasías Eternas* (Eternal fantasies; 1957) her leitmotif is “to recognize the power of unconscious fantasies and the creation of certain myths that reflect a traumatic social and political situation that can also become a political weapon.”

In *Ideología e Idealización* (Ideology and idealization; 1959) she rethinks psychoanalytic societies, from the point of view of the specificity of their discipline and the pressure that comes to bear on analysts in institutions at certain periods in history. Her study of a text written by a former Nazi, Dr. Roberto Ley (1947–48), shortly before he committed suicide led her to confront the question of anti-Semitism as a symptom of social conflicts and collective anxiety.

She suffered from headaches, which led her to discover certain perturbations linked to the practice of psychoanalysis. In *Dos sueños de analistas* (Two dreams of psychoanalysts; 1952) she reveals the weight of the doubling/splitting that can come to bear on psychoanalysts in the course of their practice. In a prospective article she imagined the analysis of the year 2000 (1968). Marie Langer devoted her research (1957; 1961; 1963; 1965; 1970) to psychoanalytic group psychotherapy. She was also an active figure in the scientific and political life of Nicaragua and Cuba, where her later work constituted a comprehensive review of her knowledge and experience.

Her line of approach, her quest for truth, and her interest in human beings, especially women, made her a psychoanalyst who was deeply engaged with the society of her time and capable of exploring all the aspects of the discontent of our civilization.

## LANGUAGE AND DISTURBANCES OF LANGUAGE

Language is arguably omnipresent in psychoanalysis, if for no other reason than that it is the essential tool of analytic treatment.

Apart from Freud's early work *On Aphasia* (1891b), four passages in his writings may conveniently serve as vantage points from which to consider his approach to language. These are the beginning of chapter 6 of *The Interpretation of Dreams* (1900a), chapter 5 and chapter 8 of *The Psychopathology of Everyday Life* (1901b), and the last paragraph of "The Unconscious" (1915e). These passages point up the critical importance of taking language into account in connection with interpretation and with the way words are invested with meaning.

Chapter 6 of *The Interpretation of Dreams* begins with a brief introduction where Freud asks how the relationship between the manifest content of the dream and its latent content, which he also refers to as dream-thoughts, can best be represented. He envisions four possible models, the first three of which he rejects and the last of which he emphatically accepts. This relationship may thus be assimilated to that between two descriptions of the same facts in two different languages, or in terms of the translation of a text and its original, or again as analogous to the deciphering of hieroglyphics. None of these parallels satisfies Freud, although he does not clearly state why, and he eventually decides that the relationship is identical to that of the symbols of a rebus to its deeper meaning. The word "rebus," it is worth recalling, is a short form of the expression "*scribere in rebus*," that is, "to write with [representations of] things," in contrast to "*scribere in litteris*," "to write with letters."

The rebus, however, is not a pictogram or a story in pictures, but a succession of small figures with a

meaning that can be deciphered, each figure functioning either semantically or phonetically, so that a picture of a cat, for example, can denote either the word *cat* (assuming the pertinent language is English) or the sounds of the consonants and vowel that constitute that word. There are two points to remember here: a rebus assumes a given language, and we never know whether the figure functions as meaning or as sound. So, if the rebus is the prototype of the interpretable, the interpretable presupposes a specific language and the possibility that an element can have either a phonetic or a semantic value. Interpretation, for Freud, is therefore tied in its essence to language.

The study of slips of the tongue also involves a linguistic phenomenon, but one of an entirely different nature: a word that, within the spoken sequence of words, is substituted for another that it resembles phonetically but not semantically; sometimes it may even have the opposite meaning. For example, "*Geiz*," meaning "greed," replacing "*Geist*," "cleverness" or "wit." "*Sie haben alle Geiz*" (They are all greedy) is said instead of "*Sie haben alle Geist*" (They are all witty). The speaker may correct the first sentence with the second but it is the first that truly expresses her thought (*Psychopathology of Everyday Life*, 1901b, p. 64). The slip is facilitated when a close phonetic likeness is combined with a great semantic distance, allowing a censored opinion to reveal itself in part. Sometimes a neologism is needed.

Later in the *Psychopathology*, Freud uses a parapraxis of his own to illustrate the importance of language in the interpretation of bungled actions. He relates how one evening he went to the suburbs of Vienna to examine a patient who was suffering from the inability to use her legs in order to settle a differential diagnosis as between hysteria (curable) and myelitis (incurable). He did not enjoy this type of work, because some time earlier he had made a mistake in a similar case and rebuked himself for being an ass—or, in Hebrew, *chamer*. However, when he got to his staircase landing, he realized that he had put his reflex hammer in his pocket instead of his tuning fork. He then remembered that he had recently examined an imbecile child—"an ass"—who had grabbed this tuning fork and refused to let it go. The basis of his interpretation was the phonetic proximity between the German *hammer* and *chamer*. (pp. 165–66).

The interpretation of a parapraxis therefore assumes, once again, the use of language—and not language in general, but a specific language.

In his metapsychological paper on “The Unconscious” (1915e), Freud describes quite another role played by language. He notes that while, in the most advanced forms of schizophrenia, the subject no longer cathects anything but himself, adopting a fully narcissistic posture, during the early stages he can still cathect word-presentations and so avoid thoroughgoing autism.

The above distinctions between four aspects of the metapsychological relationship to language may be slightly artificial, but they all serve to underscore the fact that language always displays both a phonetic and a semantic aspect.

## **LANGUAGE OF PSYCHOANALYSIS, THE**

*Vocabulaire de la psychanalyse (The Language of Psycho-Analysis)* is neither a dictionary nor an encyclopedia, but an inventory of the major concepts of psychoanalysis. Cursory readers might confine themselves to the brief definitions that precede the historical discussions of concepts. However, the most important work presented in this book is its analysis of the tools of psychoanalytic thinking: a methodical and thoroughgoing investigation ever ready to track down contradictions. Basing this book almost exclusively on the work of Freud, Laplanche and Pontalis set out to bring the concepts of psychoanalysis to life, showing their complexity and tracing their development through Freud’s writings. By hewing close to Freud’s texts, often retranslated into French by the authors, the *Vocabulaire* makes it possible to put these concepts to work, as it were, while steering clear of dogmatism.

The fortunate encounters and circumstances that gave birth to the *Vocabulaire* are worth recalling. The two authors became friends as soon as they arrived in Paris in 1941 to take preparatory classes in the humanities at the Lycée Henri IV. They both were candidates for the advanced teacher-qualifying examinations (*concours d’agrégation*) in philosophy, and both were successful. Thereafter Pontalis proceeded into university teaching, while Laplanche turned to medicine. Ten years later, when Pontalis was a research assistant at the Centre national de la recherche scientifique (National Center for Scientific Research) and Laplanche was an assistant professor at the Sorbonne, both found themselves under the authority of Daniel Lagache, university professor and series editor at the Presses universitaires de France. At that time Lagache, at the request of

UNESCO, was organizing a large group of researchers to produce a dictionary of terms used in the human sciences. This project came to naught, but Lagache, aware of Laplanche and Pontalis's interest in psychoanalysis, proposed that they write what became the *Vocabulaire de la psychanalyse*.

The two worked on the book from 1960 to 1967. They met several times a week to review their reading on one or more concepts. After discussion, they wrote in such close collaboration that the thinking of the two men was inextricably linked. From time to time they would show their work to Lagache, who granted them complete authorial independence. The work was published under his editorship, and he contributed a preface giving the background and history of the project.

While the book was being written, Jacques Lacan was urging a “return to Freud.” Laplanche and Pontalis accepted this proposal and, instead of simply elaborating a set of concepts, treated their task as a full-scale research project. During this period the Association psychanalytique de France (French Psychoanalytic Association) came into being (1963). Lagache, Laplanche, and Pontalis all became members, marking their distance from Lacan.

The first edition of the *Vocabulaire* appeared in 1967. Thirteen more were to follow. The book was first translated into English, under the title *The Language of Psycho-Analysis*, thanks to the collaboration and friendship between Masud Khan and Pontalis. That English-language readers should thus obtain access to a French work of this kind was considered extraordinary at the time. Subsequently the book was translated into Spanish, Italian, Portuguese, Hungarian, Russian, Rumanian, Croat, German, Japanese, Polish, Greek, Arabic, Korean, Slovakian, Swedish, and Turkish—seventeen languages in all. In 1997, thirty years after its first appearance, the *Vocabulaire* was issued in a student's edition, which gave it a much wider circulation. It is undoubtedly the most frequently cited work in the entire French psychoanalytic literature.

The authors' choice of concepts for inclusion focused on those notions that help explain Freud's theory of the mental apparatus. Almost all of the three hundred terms dealt with were taken from Freud's work. The exceptions included a few Kleinian notions (good/bad object, depressive position, paranoid position), a few Lacanian concepts (foreclosure, the symbolic, mirror phase), a Jungian one (Electra complex),

an Adlerian one (inferiority complex), Spitz's hospitalism, and Winnicott's transitional object. A three-tier system of cross-references among entries and to the bibliography encouraged readers to view topics from a succession of different angles.

Some of Laplanche and Pontalis's lengthier entries, such as “Ego” and “Death instinct” set forth their own theoretical positions. As to theoretical orientation, apart from adhering as closely as possible to Freud's work itself, they rejected ego psychology, for example, and expressed reservations about the theoretical approaches of Jacques Lacan and Melanie Klein. The *Vocabulaire* initiated the development of a number of notions not thoroughly conceptualized by Freud, among them deferred action and anaclysis, which would later constitute important milestones in the thinking of Jean Laplanche.

## LANZER, ERNST (1878–1918)

Austrian lawyer Ernst Lanzer, a patient of Freud, was born in Vienna on January 22, 1878, and died in Russia in 1914.

Dr. Ernst Lanzer is more widely known by the pseudonyms the “Rat Man” and “Dr. Lorenz”, given him by Freud and James Strachey respectively. He is the subject of Freud's case history (1909d). His parents both came from Silesia: his mother Rosa (née Herlinger) was born in 1844 and his father in 1825. (Freud and the Rat Man were alike in that at their birth, they had fathers who were old enough to be grandfathers.)

The respective names, pseudonyms, and births of the Rat Man's siblings are as follows: Hedwig (Hilde), 1870; Camilla (Katherine), 1872; Rosalie (Constanze), 1874; Robert (Hans), 1879; Olga (Julie), 1880; and Gertrud (Gerda), 1886. The deaths of Camilla (1881), his father (1899), and his aunt (1901) had variously immediate and persistent perturbing influences on the Rat Man's personal and professional life.

In 1897 Lanzer enrolled in the Law Faculty of the University of Vienna, but he could not complete his doctorate until ten years later, shortly before his analysis with Freud. Beset with similar ambivalence and procrastination, he finally made a childless marriage with his cousin Gisela Adler in November, 1908, which was not only about one and a half years after their engagement but also some ten years after he first fell in love with her.

It was during military maneuvers from August 11 to September, 1907, that Lanzer first suffered from his peculiar obsession with rats. Military records from the same year indicate owing to his father's death that he inherited 50,000 kronen, an amount starkly contrasting with the cost (3.80 kronen) of the pince-nez that he lost on maneuvers and that precipitated him into an obsessional frenzy.

Lanzer entered into an analysis with Freud on October 1, 1907. With his conflicts over work being partially resolved (he had previously worked only a little over two months), Lanzer found employment in 1908; yet he changed law offices four times before officially becoming an attorney (*Rechtsanwalt*) and finding more secure employment in 1913. In August, 1914 he was activated into military service; he was taken prisoner by the Russians on November 21, 1914 and died four days later.

## **LATENCY PERIOD**

The *latency period* is the stage of suspension of psychosexual development between the age of five and six

and puberty. During this period, sexual activity and interest tends to decrease, a consequence of repression, secondary identifications and the establishing of the superego, resulting in the resolution or the waning (*Untergang*) of the Oedipus complex. As the drives slow their pace, inhibitions surface, the product of the building of moral and aesthetic dams (shame, disgust, and modesty) through reaction formations (counter-cathexes). By the same token, with sublimation, there is a change of goal in drive discharge toward socially acceptable and valorized activities, together with the formation of an ideal, while in object relations feelings of tenderness (aim-inhibition) take precedence over oedipal eroticization.

Freud articulated this concept (1905d) based on his clinical observations, emphasizing its significance for the later normalcy of the individual subject and his insertion into the culture. The latency period is also important for the progress of civilization.

Beyond the descriptive point of view and the psychic mechanisms at work within it, the notion of a latency period seems like a logical necessity for posing certain questions. Through it infantile sexuality is approached from the perspective of future neurosis or normalcy, highlighting what Freud later called "the two-phase start" of human sexual development. In earlier writings he had already stressed the importance of sexuality in the etiology of neuroses. He had to mark the connection of neuroses with infantile experiences, the notion of deferred action and discontinuities in the evolution of sexuality. He also developed the notion of infantile amnesia through what he termed "screen memories."

Freud claimed to have borrowed the term "latency period" from Wilhelm Fliess, although nothing of the sort can be found in their known correspondence. It seems that the term *Latenzzeit* first surfaced in Fliess's work in 1909, but it meant something else in that context; also, its definition was not consistent conceptually with Krafft-Ebing's use years earlier ("*sexuelle Latenzperiode*").

Although latency appeared to be a keystone concept in his theoretical edifice, Freud did not make much of an effort to develop it. Nevertheless, in his later writings, he alluded to it frequently, although without adding anything substantial to its explanation.

However, he did make two elucidations about the latency period: In 1924 Freud affirmed that he had "no

doubt that the chronological and causal relations described here between the Oedipus complex, sexual intimidation (the threat of castration), the formation of the super-ego and the beginning of the latency period are of a typical kind" (1924d, p. 179); and in 1926 he emphasized that the struggle against the temptation of onanism is a major task, a combat ordinarily productive of symptoms like rituals or ceremonies. Subsequently he singled out the emergence of anxiety in response to the imperatives of the superego as characteristic of the latency period.

Other concepts in Freud's works can be useful in understanding latency, although he did not specifically link them to it: primary and secondary thought, the pleasure principle and the reality principle, the preconscious, fantasy, literary creation and games, daydreams and the family romance, the notions of psychic work and working through.

Throughout his work, in order to explicate this period, Freud oscillated between phylogenetic and biological formulations and formulations conditioned by the ontogenetic model and education, causal agents that he sometimes superimposed upon one another, as in the note he added in 1935 to *An Autobiographical Study*: "The period of latency is a physiological phenomenon. It can, however, only give rise to a complete interruption of sexual life in cultural organizations which have made the suppression of infantile sexuality a part of their system" (1925d [1924], p. 37).

Defined as an anodyne stage between two major periods of sexuality, the latency period has not been studied very much. Rodolfo Urribarri reformulated certain notions, insisting less on the temporal aspect than on the basis of the construction of the superego, which obliges the ego to cover itself by means of symbolization and displacement in order to allow drive discharge through the operation of various mechanisms under the control of sublimation, while utilizing diverse external resources, a process he terms the "work of latency." Urribarri also stressed modifications that occur in thought and language, the preponderant role and the functionality of the preconscious and of formations proper to it, like daydreams and the family romance. He also was able to identify sex differences in the representations of the body in games and drawing, which can be explained as a way of distinguishing functionality and genital differences. This in a way is typical of the work of latency, which precedes and conditions the masculine-feminine differentiation.

In this organization of latency, the psychic apparatus evolves while becoming more complicated by affording an outlet to the drives and expanding the subject's resources and the range of his social participation, and also extending psychosexual evolution in a disguised and subtle manner.

## LATENT

Latent dream thoughts (latent content) are the meanings psychoanalytic interpretation discovers in the manifest dream (the narrative the dreamer constructs of his dream).

Freud introduced the contrast between manifest and latent in *The Interpretation of Dreams* (1900a), and he never abandoned this distinction, as witness *An Outline of Psychoanalysis* (1940a [1938]).

Latent thoughts (also called by Freud “dream thoughts” or “latent content”) are primary; they are the motor of the dream. They are comprised of infantile memories—of “egoistic,” sexual, or incestuous contents—which because of their moral unacceptability are rejected by the censorship. They are marked by the primary processes (condensation, displacement, figurability) and undergo the “distortions” that constitute the “dream work.”

Unconscious latent thoughts—the demands of the drives and their prohibition—are the foundation of the dream and exert an attractive power over certain pre-conscious formations. Residues of the day, events of the day before, function as possible jumping-off places for associations allowing the dream to be interpreted.

Over time, accumulated clinical experience and theoretical developments nuanced Freud’s initial stark distinction between manifest and latent. In the *Introductory Lectures on Psycho-Analysis*, Freud conceded that “one manifest element can replace several latent ones or one latent element can be replaced by several manifest ones” (1916–17a [1915–17], p. 125), arguing that dream interpretation can be based either on pre-conscious content or on the unconscious. After Freud’s introduction of the second topography (1920–25), a notion even arose of “thought-transference” (1933a, p. 40) suggesting circulation of latent thought between two persons (and not only within a mental apparatus).

In 1933 and 1938 Freud returned to the notion of the latent content of the dream, emphasizing its unconscious character. In effect it was a “primitive language without any grammar,” in which “only the raw material of thought is expressed and abstract terms are taken back to the concrete ones that are at their basis” (1933a, p. 20), where temporal relations are transformed into spatial ones, and “contraries are not kept apart but treated as though they were identical” (1940a [1938], p.169). The latent is fashioned out of a “forgotten childhood,” and of an “archaic heritage, which a child brings with him into the world, before any experience of his own, influenced by the experiences of his ancestors” (p. 167). The content of dreams is said to be like that of tales and myths, and “to constitute a source of human prehistory.”

Freud reported noticing the latent functioning of psyches in treatments handled by colleagues: Helene Deutsch observed a “thought transference,” a phenomenon also recorded by Dorothy Burlingham between a mother and a son who were both undergoing psychotherapy.

In present-day theory, the “latent” may describe an unconscious psychic communication between the analyst and the analysand: the transference is intertwined with the counter-transference, the unconscious of the analyst as important to the outcome as that of the analysand, and the analyst’s interpretation may also have a “latent” aspect (Jean-Paul Valabrega). This approach takes as its starting point Freud’s remark that there is a “secret language” created “secret language” created “between two people who see a lot of each other” (1933a, p. 49).

Within the treatment, an analyst’s dream of the patient in session may represent the latent fantasy functioning of the two psyches, and perhaps the starting point of an essential working through (André Missenard). An analogous function can be served by a “chimera” (Michel de M’Uzan), or by “co-thinking” (Daniel Widlöcher). Outside the treatment, in certain group situations with analyst(s) (small groups, combined therapies, families in psychotherapy) a latent fantasy system is said to underlie a shared psychic functioning.

Manifest and latent were notions introduced by Freud in connection with theories of the dream and of the mental approaches. Like other concepts, they were the product of his self-analysis. Since 1900, the use and the meaning of the idea of the latent has greatly evolved, as witness the specific place and strict meaning accorded to it currently in the theory of psychic functioning during treatment, as well as its broader and more descriptive application in clinical thinking to latent homosexuality, latent depression, latent perversion, and so on.

**LATENT DREAM THOUGHTS**

The expression “latent dream thoughts” comes up frequently in the writings of Freud; while the term as a whole has a very definite meaning, the same cannot be said for “thoughts.”

“Latent” was opposed to “manifest” in the context of the “manifest content” of the dream and its “latent content.” Taking advantage of the weakening of the censorship during sleep, the dream fulfills wishes repressed during the waking state. This can only happen at the cost of transformations and distortions created by the dream work, which translates the latent content into manifest content (or dream narrative). The interpretation of the dream follows the same route in reverse, decoding the transformations effected by the dream work so as to bring out the latent on the basis of the manifest content. Freud illustrated this with great flair, for instance, in *The Interpretation of Dreams* (1900a), and in his case histories of Dora (1905e) and the “Wolf Man” (1918b).

This “latent content” is made up of what Freud calls “latent thoughts.” This expression, always used in the plural, was never precisely described. In fact, however, the context of its use made it quite clear that it connoted representations, affects, wishes, and conflictual patterns, all deeply marked by infantilism and fantasy. Latent thoughts also subsume whatever supplies the dream’s “raw material”: the day’s residues, somatic sensations, and excitations that directly impact instinctual impulses.

Such a use of the word *thoughts* might be questioned, thoughts usually being described as conscious. Yet Freud was very explicit in this respect: The term is

justified because it referred to psychic contents and processes, albeit preconscious or unconscious ones. Freud explained on a number of occasions after 1912 (e.g., 1912g, 1940a) that latent dream thoughts were generally preconscious; they are utilized by the dream-work because they serve as a relay point and medium for unconscious cathexes.

**LAURENT-LUCAS-CHAMPIONNIÈRE-MAUGÉ, ODETTE (1892–1964)**

Odette Laurent-Lucas-Championnière-Maugé, French physician and psychoanalyst, was born in Rosny-sous-Bois on October 18, 1892, and died in Prépatour-Vendôme in the Loir-et-Cher department of France on October 21, 1964.

She worked in the Bretonneau hospital with Françoise Murette (later Dolto). In their Paris apartment she and her husband, Henri Codet, often hosted meetings of a group for the study of the evolution of psychiatry. Marie Bonaparte analyzed her. She was appointed a contributing member of the Société psychanalytique de Paris (Paris analytic Society) on November 20, 1934, at the same time as Jacques Lacan and became a full member on June 18, 1935. During the 1930s she attended the meetings of the Soroptimist, the French branch of a U.S. union for women of all occupations. Following the death of her first husband in an automobile accident in 1939, she married the architect Laurent Lucas-Championnière.

Her article “À propos de trois cas d’anorexie mentale” (On three cases of anorexia nervosa), published in 1939 under the name of Odette Codet and republished in 1948, presents the cases of three girls between the ages of three and fifteen. In it she highlighted the fact that conflicts increase in complexity with the age

of the subject and stressed that parental attitudes have a primordial role in the genesis and treatment of such conflicts “to such a degree that we sometimes wonder . . . whether the real solution might not be to psychoanalyze the parents.”

In June 1953, during the conflict in the Paris Psychoanalytic Society against the “liberals” and Sacha Nacht’s group, Odette, backed by Marie Bonaparte, proposed the following motion: “Having remarked its profound disagreement with its president, Jacques Lacan, as noted in the session of June 2, the general assembly of the Paris Psychoanalytic Society organized in administrative session cannot testify to its faith in him and asks its vice-president to assume the role of president until the election of leaders in accordance with the statutes.” The adoption of this motion on June 16 signaled a split: Lacan resigned, and Daniel Lagache took over as president but later resigned from the Paris Psychoanalytic Society to create the French Psychoanalytic Society.

While president of the Paris Psychoanalytic Society in 1959, she began to suffer from arterial illness and had to retire. She became an honorary member in 1963.

## **LAW AND PSYCHOANALYSIS**

While psychoanalysis focuses on the individual subject, law refers to the collection of guidelines for behavior directed at all members of society. There are challenges therefore in establishing a dialogue between two disciplines whose objectives and challenges are so far apart. Yet, the necessity of psychoanalysis engaging with the human leads to its involvement with the foundations of societal values. It cannot therefore avoid taking an interest in the law, which means it must ask the same questions differently. Moreover, the discovery of a Freud who expresses himself like a lawyer justifies a new interpretation of some of his writings.

Although Freud from time to time took an interest in aspects of the legal process (1906c, 1916d, 1931d), he never tried to explain the possible interactions between law and psychoanalysis. Nonetheless, the questions of guilt and crime—primarily through the oedipal murder of the father and incest—are presented in a way that is so fundamental to his work that the confrontation of the two disciplines becomes inevitable, crime—even though perpetrated by the unconscious—leading to trial.

It was when he abandoned a legal career to turn his attention to science that Freud, in a letter to his friend Emil Fluss on May 1, 1873 (1925d), used the word *Prozess* (trial) for the first time. Rather than getting involved in real trials [*Prozesse*], he will study the “millennial cases of nature” so he can bear witness to its “eternal trials.” The use of this legal term is not an isolated occurrence in the Freudian corpus. The frequency and occurrence of its use justify seeing it as a kind of fetish word, a wink at his youthful wish to become a lawyer. He went so far as to talk about a “psychic trial” (1905d). The focus, in the Freudian corpus, on the use of a specifically legal vocabulary (conflict [*Konflikt*], defense [*Abwehr*], conviction [*Verurteilung* or *Urteilsverwerfung*], punishment [*Stafbedürfnis*]) demonstrates that the intersection of the two disciplines was not accidental.

If the psychic apparatus needs to organize a system of defense and condemnation, it is because unconscious guilt engages the subject in a continuous trial. The operation of the psyche demonstrates concrete links with that of the legal process once the question of guilt is introduced. The appearance in Freud’s work of references to a legal vocabulary, as well as to functions that are part of legal works, can be seen clearly from an examination of the multiple roles attributed by the founder of psychoanalysis to the “agency” of the superego. We find that the image he presents is that of a court that will entirely assume the burden of all legal responsibilities. The Freudian superego assumes the responsibility of legislator, judge, supreme court, attorney (for the id), public prosecutor, and even grief counselor. It also sometimes serves as a vigilante. Freud shows himself to be a skilled proceduralist by identifying the putative fatherhood referred to by lawyers (*Pater incertus est . . .*) and, when he points out the “progress of civilization” that characterizes the “transition from mother to father” (1909d, 1939a [1934–1938]), he borrows the specific vocabulary of the law

of evidence. The legal context in his work is supported by the explicit reference to Aeschylus's *Oresteia*. It appears that the reference to legal institutions to understand and attempt to resolve interior conflict does not exhaust the vision of Freud as jurist shown by his work. But it is with reference to the murder of the father that the field of interaction between law and psychoanalysis is the most fecund.

Aside from the opportunities presented by the presence of a Freudian legal vocabulary, although frequently hidden by translations that systematically “delegalize” his language, the fact that the legal functions attributed by Freud to the mental apparatus are visibly inspired by those attributed to the participants in the Last Judgment enables us to hypothesize a possible scriptural origin to his legal conception of mental agencies—especially the superego—when he evokes the “judicial activity of the moral conscience” (1933a [1932]). Another facet of Freud's work is revealed by his knowledge of Pauline thought and, more generally, of the Bible, the book in which Sigmund was taught to read by his father.

## **LAW OF THE FATHER**

In 1897 Freud remarked, on the basis of his analysis of his first patients and his self-analysis, that “The father forbids the child from realizing its unconscious wish to sleep with his mother” (letter to Fliess, October 15, 1897). This first outline of the Oedipus complex, which now appears simplistic, grew increasingly complex throughout Freud's research. In time the Law of the Father turned out to be directed both toward the mother (“You will not reintegrate your product”) as

well as her offspring swept up by desire. The law is also accompanied by an injunction against cannibalism and murder, and hold up ideals, primarily sexual ones (“Later you will enjoy, like me, a woman from another family”). Once introjected, this becomes the origin of the superego and ego ideal. The repression of drives, their suppression and sublimation, are the principal outcomes of the conflict that connects them structurally to this law.

Freud quickly recognized that the actual presence of a father is not the best guarantee of the fulfillment of this law: An absent or dead father can serve as the agent, as well as or better than the living father. This led to the creation of the myth of the primitive father (a, 1912–1913a). Jacques Lacan showed that this Law of the Father, to the extent that it serves as a principle of differentiation and separation, is in fact the law of language and a sine qua non for the existence of desire. He claimed that the subject structures himself through his unconscious response to the law and to the incestuous desires it shapes to: the repression of desire (neurosis), and the denial or foreclosure of the law (perversion and psychosis, respectively). Lacan also showed that it is important to differentiate the real Father, the imaginary Father, and the symbolic Father.

## **LAY ANALYSIS**

Lay analysis is psychoanalytic treatment carried out by someone who is not a physician. In a less common

sense, it is a treatment carried out by someone who has not received the necessary training in the practice of analysis. The term was first used by Freud in *The Question of Lay Analysis* (1926e), where he vigorously asserted that in the practice of psychoanalytic treatment, what mattered was good training, independent of diplomas obtained beforehand. He had already expressed a similar view in a preface to Eitingon's report (1923g) and in a preface to a book by Aichhorn (1925f).

On July 18, 1926, the newspaper *Neue freie Presse* published a letter from Freud correcting some inexact information regarding a lawsuit filed against Theodor Reik for the illegal practice of medicine. In it Freud reaffirmed that a nonphysician could be a psychoanalyst, citing both Reik and his daughter Anna Freud, but he added that he did not refer to such psychoanalysts cases that were serious or complicated by somatic factors. Freud had always held this position and asserted it since the beginning of the Vienna Psychoanalytic Society, to which he liberally admitted nonphysicians. In 1905 a member of the society, Max Graf, who was not a doctor, conducted, under Freud's direction, an "analysis" of his own son, "little Hans."

Thus the issue of lay analysis was raised early in the history of the psychoanalytic movement. Freud vigorously defended his position in 1926 because at that time the conflicts that developed around this issue took a serious turn. As a group Viennese psychoanalysts, among whom were a number of nonphysicians, supported Freud's position. In contrast, the Americans, under the influence of Abraham Arden Brill, wanted to bar the practice of analysis to anyone who was not a doctor. In Great Britain, Ernest Jones took a middle position, but mistrusted the nonphysicians, whom he thought must be carefully controlled. At issue in this debate were not only theoretical positions (is psychoanalysis a medical discipline, a therapy?), but also legal issues, which varied from country to country.

At the end of 1926, Ernest Jones and Max Eitingon organized a major discussion among members of the International Psychoanalytical Association so that a decision could be made on the issue at the Innsbruck congress planned for September 1927. There twenty-eight contributions (published by the two official organs of the association, the *Zeitschrift für Psychoanalyse* and the *International Journal of Psychoanalysis*)

were presented and discussed without an agreement being reached. The congress adjourned with a compromise: Each national society could follow its own policy. Jones emphasized the dangers of such a solution for the cohesion of the association, which was in fact on the verge of collapse over this issue and, some time later, over problems of training.

There were two aspects of the problem: training issues and theoretical issues. On the level of training institutes and their policies for the selection of candidates, France and other countries de facto aligned themselves with Freud's position. In contrast, the powerful American Psychoanalytic Association resolved to admit nonmedical analysts as late as 1988 only after long and costly legal battles. Weighing heavily on this question were factors of medical, psychological, and cultural history, of sociology, and of law that varied greatly from country to country.

On the level of theoretical justifications, two conceptions of psychoanalysis were opposed here. For some, psychoanalysis is a therapy that seeks to care for, and if possible cure, mental problems, even minor ones. Thus it can only be legitimately practiced by a doctor, preferably a psychiatrist, who has the necessary training to give a diagnosis and referral for analysis, and then to treat the patient with the broad-mindedness and accountability that doctors have. In France, Sacha Nacht defended this position. For others, however, analytic treatment is above all a personal experience, a liberation from the conflicts that restrict the ego and burden the mind, emotional life, and relations with others. Freedom and personal enrichment are the major aims, and any shortsighted preoccupation with a "cure" risks becoming an obstacle to good psychoanalysis. One could even argue that psychiatric training, which predisposes the physician toward diagnosis and treatment, is a handicap for the psychoanalyst. In psychoanalysis, the crucial references are cultural, even philosophical. In France, this last point of view was maintained, not exclusively but most brilliantly, by Jacques Lacan.

By 2005 the debate had largely quieted down. There seems to be general recognition that what is essential is good training in the theory and practice of analysis, especially the indispensable requirement of a personal analysis. But opinions continue to differ on what is the best preliminary training. In this respect, the debate is no longer over the question of physician versus nonphysician, but rather concerns the question of

psychiatrist or clinical psychologist. Quite possibly psychoanalysis will benefit from the confluence of these two other therapeutic traditions.

## **LEARNING FROM EXPERIENCE**

*Learning from Experience* was Wilfred Bion's first major venture into metapsychology and epistemology. In this work he set out to specify how normal and psychotic minds function. To accomplish his mission, he defines certain ideas as tools of understanding. He defines a "factor" as a mental activity that is a subset, along with other factors, of a "function." "Factors are deduced not directly but by observation of functions," he claims.

The particular function that he explicates in this work, one that he elaborates throughout his later works, is the alpha function, so named to preserve it from contamination by a penumbra of preconceptions and other associations. In the course of developing his ideas about how alpha functions work, he adds an idea borrowed from Freud (1911b) "A special function was instituted which had periodically to search the external world, in order that its data might be familiar already if an urgent internal need should arise—the function of *attention*" (p. 220). "Freud did not carry his investigation of attention far, but the term, as he uses it, has a meaning I would investigate as a factor in alpha-function."

Attention—and later notation, inquiry, and action—thus became factors in alpha-functioning. Later they became the components of the horizontal axis of his grid.

Bion frequently returns to Freud's two principles of mental functioning, the pleasure principle and the reality principle, and seems to reason that distinguishing them as primary and secondary processes is artificial in terms of the sense organ of attention that apprehends them. Consequently, he designates the alpha function as the sense organ of attention for each principle. He then introduces the factors of beta elements, the unprocessed sense impressions that require the activity of the alpha function to transform (render, metabolize) them into alpha elements suitable for mental processing into memory, dream elements, and thoughts. He came to this idea from his experiences with psychotic patients: "The attempt to evade the experience of contact with live objects by destroying alpha-function leaves the personality unable to have a relationship with any aspect of itself that does not resemble an automaton. Only beta-elements are available for whatever activity takes the place of thinking and beta-elements are suitable for evaluation only—perhaps through the agency of projective identification" (1962, p. 13).

To explain the motivation for seeking to learn from experience, Bion gives the K (knowledge) link the same, if not greater, status as the L (love) and H (hatred) links. He clearly makes a triad out of Freud's instinctual drives and Klein's epistemological instinct and transforms them from instinctual drives into subject-object linkages, with K as the leader.

Following this, he discusses the need to correlate samples from all the sense organs as one form of "common sense," in addition to the "sense organs" from both the self and the other (the analyst) as "second opinion." When these correlations are made, abstraction from them and "publication" (allowing oneself to know them and act upon them) become possible. The complementary functioning of consciousness and the unconscious as sense organs is most clear in the following passage:

The theory of consciousness is weak, not false, because by amending it to state that the conscious and unconscious thus constantly produced together to function as if they were binocular therefore capable of correlation and self-regard. . . . For these reasons and others arising from clinical experience of psychoanalysis of that

class of patient in whom the psychotic part of the personality is obtrusive, I find the theory of primary and secondary processes unsatisfactory. This theory is weak in the need to postulate two systems at the point where, in my theory of an alpha-function, an emotional experience is transformed into alpha-elements, to make dream thought, unconscious waking thinking and storage in the mind (memory) possible. I attribute the appearance of beta-elements, the closely associated bizarre objects and the serious disturbances ordinarily associated with excessive obtrusion of the psychotic elements of the personality, to the failure of alpha-function.

Bion thereupon develops the idea that the alpha function gives rise to abstraction and the progressive realizations that abstractions enable the subject to have: “The concrete statement might be: breast exists that can be depended on to satisfy his hunger for food; abstraction from this might be: there is something that can and does give him what he wants when he wants it.”

Still later Bion considers the notion of the selected fact. He states that the selected fact coheres the objects of the paranoid-schizoid outlook and thereby makes possible the onset of depression and does so by its membership in a number of deductive systems. He goes on to state, “The relationship between mother and infant described by Melanie Klein as projective identification is internalized to form an apparatus for regulation of a pre-conception with the sense data of the appropriate realization. This apparatus is represented by the model: the mating of pre-conception with sense impression to produce a conception. This model is in turn represented by ♂ ♀ . . . . The repetition of mating of pre-conception and sense data, that results in commensal abstraction, promotes growth in ♂ ♀. That is, the capacity for taking in sense impressions develops together with the capacity for awareness of sense data.”

Finally, Bion returns to the K link and, in light of his experiences with psychotic patients, contrasts it with the –K link, that which denudes the sense data of meaning to prevent realizations from developing.

## LE BON, GUSTAVE (1841–1931)

Gustave Le Bon, a French physician and philosopher, was born in 1841 in Nogent-le-Rotrou and died on December 24, 1931, in Paris. Le Bon's name has for years been associated with *The Crowd* (1895/1995), which made him one of the founders of group psychology. In spite of, or perhaps because of, the book's phenomenal success—it has been translated into several languages and was reprinted many times—Le Bon has been disparaged and misunderstood by the scientific community. He has been reproached for the summary, polemical, even reactionary nature of his analysis. A prophet and harsh critic of mass society, he ushered in the “age of the crowd,” “the most recent sovereign of the modern age.”

The son of a civil servant, this country doctor developed an early interest in anthropology, then sociology and psychology. A tireless worker, he made a living as a writer and editor. Although he was never an academic, he was well known, much more so than someone like Emile Durkheim. Government officials, writers and scientists attended his “lunches”: Théodule Ribot, Bergson, Valéry, Henri and Raymond Poincaré, Aristide Briand, and Marie Bonaparte, who introduced him to the work of Sigmund Freud and who remained Le Bon's friend until his death.

In 1902, Le Bon began editing a collection of scientific works for Flammarion, the “Bibliothèque de philosophie scientifique,” intended for the lay reader. The series had considerable success. He published the majority of his own writings as part of the collection, as well as Henri Poincaré's *La Science et l'Hypothèse* and Marie Bonaparte's *Guerres militaires et Guerres sociales*.

Taine's influence on Le Bon was considerable, but so was that of Ribot and Charcot. All of Le Bon's work bears the mark of the intellectual climate of fin-de-siècle France: an attraction to the irrational, the primacy of feeling over reason, and the role of heredity and race.

Freud read Le Bon and was directly inspired by him in writing *Group Psychology and the Analysis of the Ego*

(1921c). Like Le Bon he sought to explain the phenomena of collective life through individual psychology. But Freud eliminated the notions of heredity, mentality, and suggestion and replaced them with a model of unconscious identification. Le Bon's idea of the unconscious as an archaic heritage of the human soul was closer to Jung than to Freud. Their ideas of the social also diverged. Freud wanted to clarify the irrationality of the group in order to reduce it, while Le Bon appeared to systematically cultivate it.

## LEBOVICI, SERGE SINDEL CHARLES (1915–2000)

Serge Lebovici, a French psychiatrist and psychoanalyst, was a professor emeritus of child psychiatry and an officer of the Legion of Honor. He received the Croix de Guerre for service in 1939–1945. He was born June 10, 1915, in Paris, and died August 12, 2000, in Marvejols in the south of France.

His father was Solo Lebovici, a well-known general practitioner and specialist in dermatology. A Romanian Jew, he emigrated to France in 1904. His mother, Caroline Rosenfeld, was from a Jewish family from Alsace. Lebovici began his medical training in 1933. After being admitted as an intern at the Hôpitaux de Paris in 1938, he was forced to interrupt his studies between 1938 and 1941. After his military service he was mobilized during the “phony war,” then spent time as a prisoner of war in Nuremberg. After being

freed, along with his father, in January 1941, he completed his doctoral dissertation and in 1942 married Ruth Roos. They had two daughters, Marianne, born in 1943, and Elisabeth, born in 1953. In August 1942, his father was arrested by the Nazis after being denounced but managed to save his wife by passing her off as his part-time mistress. After spending time in the camp of Pithiviers, he was deported to Drancy on September 23 and died in Auschwitz.

Lebovici, who worked for a time with the Assistance Publique, where he was protected by professors Paul Milliez and Raoul Kourilsky, cared for his mother and two sisters, along with his wife and first daughter. He soon made contact with communist members of the Resistance, to whom he provided medical assistance. He became a member of the French Communist Party at the time of the Liberation, in 1945, when he joined the army. There he met another French Resistance member, Sacha Nacht, who was also of Romanian origin, and began psychoanalysis with him before participating in the reconstruction of the French psychoanalytic movement, which had stalled during the Occupation.

Lebovici specialized in child psychiatry. As an assistant to the department of child psychiatry with Professor Heuyer from 1946 to 1957 at the Hôpital des Enfants Malades (Hospital for sick children), then at the Salpêtrière Hospital, he helped train an entire generation of psychoanalytically oriented child psychiatrists. During the post-war period, still under the influence of communist theories, he insisted on the socio-economic origin of child disturbances and, in 1949, cosigned the antipsychoanalytic manifesto published by *La Nouvelle Critique*. It required Communist Party psychiatrists to follow the recommendations of Zhdanov throughout the Cold War. However, along with his friends Jean and Evelyne Kestenberg and Salem Shentoub, he soon renounced the manifesto and quit the French Communist Party to devote himself to psychoanalysis.

Made an associate member of the Société psychanalytique de Paris (Paris Psychoanalytic Society) (SPP) in 1946, he became a full member in 1952, the same year as René Diatkine, who remained his close friend. Lebovici and Diatkine together contributed to the creation of a number of institutions, which imparted some of Lebovici's originality to the French psychoanalytic movement. In 1948 they adapted the practices of Jacob Moreno for use in “psychoanalytic psychodrama” to treat child and adolescent psychoses. During the 1953 split, Lebovici sided with Sacha Nacht against Jacques Lacan

and the cofounders of the Société française de psychanalyse (French Psychoanalytic Society), arguing for theoretical and institutional “orthodoxy,” a position that won many friends and created many lasting enemies.

In 1961, on behalf of the Mental Health Association of the thirteenth arrondissement of Paris, formed in 1958 by Philippe Paumelle, Lebovici and Diatkine created the Centre Alfred-Binet for child and adolescent psychiatry. This pioneering institution promoted a new multidisciplinary approach to psychiatry in which psychoanalysis had a preponderant role. One offshoot of this was the review *La Psychiatrie de l'enfant*, which he began in 1958 with the help of Julian de Ajuria-guerra and René Diatkine.

Lebovici was made secretary of the Institut de psychanalyse de Paris (Paris Institute for Psychoanalysis) at the time of its creation in 1952, then director from 1962 to 1967. He made it possible for non-doctors to become accredited psychoanalysts, which Sacha Nacht, his predecessor, had opposed (enabling Evelyne Kestemberg to become a member in 1963). Along with his private practice his activities within the SPP were ongoing and varied; they included numerous conferences, colloquia, seminars, and supervisory activities. Internationally he helped train and organize psychoanalysts, and at home helped popularize the work of Anna Freud, Melanie Klein, René Spitz, and Donald Winnicott, whom he brought to Paris. Because of his work he was elected vice-president of the executive board of the International Psychoanalytic Association in 1967 and made president in 1973. He was the first person of French nationality to hold that position, but he was later reproached for not having been severe enough with a Brazilian teaching analyst whose student, a doctor, had participated in the torture of political prisoners. At the end of his term, in 1977, he was appointed associate professor at the University of Paris-North, in Bobigny. The following year he created a department of child psychiatry at the Avicenne Hospital.

Lebovici was world renowned in the field of child psychoanalysis and published a large number of books and papers (nearly five hundred bibliographic references). These include *La Connaissance de l'enfant par la psychanalyse*, published in 1975 with Michel Soulé, a friend who also contributed, along with René Diatkine, to the 1985 *Traité de psychiatrie de l'enfant et de l'adolescent*. These early publications contain a sketch of his future interest in the direct observation of infants. He was also involved in the study of autism and the use of psycho-

analysis to treat psychotic children. His work culminated in the publication, in 1960, with Joyce McDougall, of *Un cas de psychose infantile: Étude psychanalytique*.

In France he became one of the principal initiators of the direct observation of early interactions between mother and child. In this he drew from the work of John Bowlby (the theory of attachment), T. Berry Brazelton (neonatal competence of the baby), and Daniel Stern (affective tuning), authors whom he introduced to French clinicians working with young infants. In 1983 he published, together with Serge Stoléru, *Le Nourrisson, la mère et le psychanalyste: Les interactions précoces*, a book that marked the start of perinatal clinical research in France. In 1989 he edited, with Françoise Weil-Halpern, *La Psychopathologie du bébé*. In these two books the complexity of behavioral interaction—affective and fantasy—between mother, father, and infant in the development of early bonds is explored and innovative therapeutic approaches are introduced. In his work on parent-child interactions, Lebovici introduced an original approach that combined the French psychoanalytic tradition with Anglo-American developmentalism. In it he emphasized the intergenerational transmission of parental infantile conflicts and the reciprocity of inherent narcissistic transactions. Although he did not overlook the contributions of experimental psychology, ethology, or the neurosciences, he felt that an understanding of the process of parenthood required a psychological component that took into account the imaginary, fantasy, mythic, and narcissistic representations of the developing child. In his last works Lebovici developed the concept of “enaction” to describe the analyst’s emotional and physical trial in the presence of the mother and child during therapy and that of “metaphor-generating empathy” to signify his ability to verbalize and represent their affects during therapeutic sessions involving the parents and the child.

President of the International Association for Child and Adolescent Psychiatry and Allied Professions (IACAPAP) from 1966 to 1970, then of the World Association of Infant Psychiatry and Allied Disciplines (WAIPAD, now the WAIMH), Lebovici held a number of important functions in international organizations in his field. In spite of the increasing demands made on him by Parkinson’s disease, which served to isolate a man whose entire life had expressed a need for communication, until the end of his life Lebovici participated in the work of the psychoanalytic institutions he had always been involved with. He was made

honorary vice president of the International Psychoanalytic Association and honorary president of the International Association of Child and Adolescent Psychiatry.

An able manager, a humanist who loved music, a man with a curious mind who was always in search of new areas of research and activity, Lebovici played a role in the leading innovations in psychoanalysis of the second half of the twentieth century.

## **LECHAT, FERNAND (1895–1959)**

Fernand Lechat, a Belgian industrial psychologist with the Center for Applied Psychology and a psychoanalyst, was born at Mont-sur-Marchienne in 1895 and died in Brussels in 1959. He and Maurice Dugautiez

were among the first to promote psychoanalysis in Belgium. His religious, middle-class family wanted him to become a priest.

During World War I he enrolled in the air force as a volunteer. After the war he divided his energies between a prosperous insurance business and poetry. During this time he became a fervent believer in depth psychology and devised a personality test based on color selection. His first wife died. Then, following a difficult mourning period, he met a young teacher who became his second wife. She worked alongside him and encouraged him through all their years together.

After meeting with Maurice Dugautiez in 1933, he burned all his poetry and turned his back on his growing insurance business to devote himself entirely to his psychoanalytic training. In the course of his training analysis with Dr. Ernst Hoffman, a Viennese refugee in Belgium, he became a specialist on the Rorschach test and character examination in industrial psychology.

After the end of World War II he resumed his training at the Paris Psychoanalytic Institute. Having been recognized as a training analyst in 1946, he devoted himself, with his wife, to training analysis, and in 1947 he founded the Association des psychanalystes de Belgique (Association of Belgian Psychoanalysts), along with Maurice Dugautiez. He also launched the association journal, *Bulletin de l'Association des psychanalystes de Belgique*, and expanded its circulation to an international level. As president of the the association, he organized the twentieth Congress of Romance-Language Psychoanalysts in Brussels in 1958, the first congress of its kind to be held in Belgium.

An active participant at many congresses and meetings of the Société psychanalytique de Paris (Paris Psychoanalytic Society), he won many friends with his enthusiasm and jovial character. Of all his highly eclectic psychoanalytic work, he is mainly known for his report "The safety principle," presented at the seventeenth Conference of Romance-Language Psychoanalysts in November 1954.

## LECLAIRE (LIEBSCHUTZ), SERGE (1924–1994)

A French psychiatrist and psychoanalyst, Serge Leclaire (born Liebschutz) was born in Strasbourg on July 6, 1924, and died of a brain hemorrhage on August 8, 1994, in Argentière, Savoy in France.

Leclaire was born into an old Alsatian family of liberal Jews who changed their name to Leclaire and took refuge in central France during the Second World War. He studied medicine and psychiatry in Paris. In 1957, he defended his dissertation in medicine, *A Contribution to the Study of the Principles for a Psychotherapy of the Psychoses*.

From 1949 to 1953 he undertook an analysis with Jacques Lacan, and in 1953, he was involved in the protest of the trainees against the leadership of the *Société psychanalytique de Paris* (SPP; Paris Psychoanalytic Society). When that group split, he left to join the *Société française de psychanalyse* (SFP; French Psychoanalytic Society), where he was made an associate member in 1954 and served as secretary from 1957 to 1962. He became president of the society in 1963, the year of the second split of the French psychoanalytic groups. In the years leading up to that split, Leclaire, Wladimir Granoff, and François Perrier (known as the “troika”) participated in the attempt to get the SFP recognized by the International Psychoanalytic Association (IPA), but the effort ultimately failed.

With François Perrier and Françoise Dolto, he took the side of Jacques Lacan in the second split and was a member of the first board of directors of the *École Freudienne de Paris* (EFP; the Freudian school of Paris), which was founded that same year. But he also remained an independent member of the IPA until 1967. Although he was very active in the EFP at the outset, he increasingly withdrew in order to reflect on the function of the analyst in society and to produce a profoundly original body of work. While remaining faithful to Freud's text (he was a German scholar), Leclaire interrogated the Freudian clinic from a Lacanian perspective. In 1968, he published his first book, *Psychoanalyzing*, which won a wide audience thanks to

its clarity and readability, but also because it showed what the Lacanian “clinic of the signifier” could be in a detailed reading of “The Dream with the Unicorn” (1968/1975).

Maintaining his independence both from the EFP and the growing dogmatism that characterized its development, Leclaire wanted to take psychoanalysis outside of the usual institutional settings. In 1968, he founded the first university department of psychoanalysis within the framework of the experimental center at Vincennes. He resigned in 1970. Later he was at the forefront of a critique of the Freudian School and especially of Lacan's procedure of the “pass.” He also worked with feminists, notably Antoinette Fouque.

His last contribution to psychoanalysis was “A Proposal for a Regulating Institution for Psychoanalysts,” which was published in *Le Monde* on December 15, 1989, and cosigned by four friends and colleagues, Lucien Israel, Philippe Girard, Danièle Lévy, and Jacques Sédat. But the proposal was misunderstood and badly received. Still, in January 1990, Leclaire and his co-signatories founded the *Association pour une Instance Tierce des Psychanalystes* (APUI; Association for a third institution of psychoanalysts). Leclaire served as president of APUI until his death. The last project he undertook was the publication of his final book, *The Land of the Other*, in 1991.

Serge Leclaire trained numerous analysts, both as a training analyst and a supervisor. Because of his unique position and his intellectual openness, he was able to maintain friendly relations with numerous colleagues from different schools in spite of splits and divisions.

## LEEuw, PIETER JAKOB VAN DER (1909–1985)

Pieter Jakob van der Leeuw, a psychiatrist and psychoanalyst, was born in Zutphen, the Netherlands on July 9, 1909, and died in Amsterdam on November 20, 1985.

He was the first child of a family of five children and grew up in difficult circumstances since his father, an engineer, died when he was 12 and his mother had to run the family alone. He studied medicine in Utrecht and chose his specialization as a psychiatrist in the same town.

His psychoanalytic training took place in Amsterdam during World War II, with Jeanne Lampl-de Groot as his training analyst. He was chairman of the Dutch Society and of the Training Committee, and one of the founders of the Psychoanalytic Institute in Amsterdam in 1946. Internationally he made an effort after World War II to re-establish contacts between analysts in different countries. He was one of the initiators of the Arbeitstagung (Working Group) and of the European Psychoanalytical Federation of which he was vice-president for some years before being elected president of the International Psychoanalytical Association (1965–1969). Besides that he was co-founder of the Sigmund Freud Museum, Berggasse 19, in Vienna (1969). He achieved honorary membership in the Societies of Venezuela (1970), Vienna (1972), and the Netherlands (1979).

Van der Leeuw was a great scholar of Freud's writings. The development of theories by Freud had his special interest. In his publications he explained what he thought Freud meant by his concept of metapsy-

chology, and emphasized the importance of the quantitative point of view (1969). He felt very much involved, through his four-year experience as IPA president, in the sources of the conflicts between the component Societies (1968). In his article about the Freud-Jung correspondence (1977), he explains in more detail the basic problems for followers of Freud.

Van der Leeuw made contributions of his own to the clinic of psychoanalysis in his publication about the preoedipal phase of the male (1958) and the concept of defense (1971).

Van der Leeuw is remembered by his colleagues as an erudite and earnest person, self-disciplined in his profession and very much dedicated to the cause of psychoanalysis.

## LEHRINSTITUT DER WIENER PSYCHOANALYTISCHE VEREINIGUNG

On May 22, 1922, having learned from his experience of the two-year-old Berlin psychoanalytic polyclinic, Eduard Hitschmann inaugurated the Ambulatorium or psychoanalytic dispensary as director in the premises of the Vienna polyclinic, not far from Vienna's AHK General Hospital. This creation was the realization of Freud's dream of making psychoanalysis accessible to populations with modest incomes, but an administrative measure threatening to close the estab-

lishment allowed only medical doctors to practice there. Each physician in the Vienna Society had to contribute at least one free analysis.

Lectures were given periodically. Early topics included "Introduction to Psychoanalysis," by Eduard Hitschmann; and "What Every Practicing Physician Should Know about Psychoanalysis," by Felix Deutsch. Later topics included "Psychoanalysis for Beginners," from Paul Federn; "The Theory of the Libido," from Ludwig Jekels; "The Theory of Neuroses," from Hermann Nunberg; "The Sexual Perversions," from Isidor Sadger; "Clinical Psychoanalysis," from Wilhelm Reich; "Occupational Neuroses," from Robert Jokl; "Religion and Obsessional Neurosis," from Theodor Reik; and "Psychoanalysis and Psychiatry," from Paul Schilder.

In 1924 a center was set up for infantile guidance—for children and adolescents—directed by Hermine von Hug-Hellmuth. In 1932, with August Aichhorn as president, it opened its doors to Wilhelm Hoffer, Kurt R. Eissler and Editha Sterba. In 1929 Paul Schilder created a department for borderline patients and psychotics, before being replaced by Edward Bibring. When there was a sufficient number of participants, parallel English classes were organized.

In 1925, three years after the Ambulatorium, the training institute of the Vienna Society was created to provide theoretical and practical training under the direction of Helene Deutsch, Anna Freud, and Siegfried Bernfeld. The committee consisted of Paul Federn, Hermann Nunberg, Wilhelm Reich, and Eduard Hitschmann. The training program for the last winter semester before the closure of all psychoanalytic institutions (October 1, 1937 to February 28, 1938) included mandatory courses for candidates, including five or even six hours of lectures on theoretical psychoanalysis. These lectures included: "A Study of Instincts," by Otto Isakower; "A Study of Dreams," by Richard Sterba; "The Psychology of the Ego," by Heinz Hartmann; "A General Study of Neuroses," by Otto Fenichel; "A Study of the Specific Neuroses," by Eduard Hitschmann; and "Technical Problems," by Jeanne Lampl-de Groot.

Over the course of its brief existence, a number of important events occurred at the Lehrinstitut as well:

- Seminars included "Reading Freud," led by Edward Bibring and Paul Federn; "Analyzing

Children," led by Anna Freud; and "Control Analyses," led by Grete Bibring-Lehner.

- Conferences included "The Process of Ego Cathexis," led by Paul Federn; and "Dream Symbolism in Analytic Sessions," led by Maximilian Steiner.
- There were several work groups: Paul Federn and Erwin Stengel's "The Psychoanalysis of Psychoses"; Heinz Hartmann and Willi Hoffer's "Reading Freud's Writings" (for members of the Wiener Verein für medizinische Psychologie [Viennese Association for Medical Psychology]); and Edward Bibring, Heinz Hartmann, Willi Hoffer, and Ernst Kris's "The Scientific Work Group."
- Among the symposia given were "The Practice of Analyzing Abandoned Youth," by August Aichhorn; "Analyzing Children," by Berta Bornstein; "Fundamental Concepts in Psychoanalytic Theory," by Otto Fenichel; "On Dreams," by Ernst Kris; "Problems of Analysis at Puberty," by Editha Sterba; "The Theory of Therapy," by Richard Sterba; and "Interviews on Specific Analytic Situations," by Jenny Waelder.
- Specific lectures were given for teachers and teacher associations, among them, "Introduction to Pedagogical Consultation," by August Aichhorn; "Anxiety in Children," by Grete Bibring; "The Limits of Psychoanalytic Pedagogy," by Dorothy Burlingham; "Course Questions," by Edith Buxbaum; "Educating, Playing, Teaching," by Willi Hoffer; "Specific Children's Disorders," by Editha Sterba; and "On Psychoanalytic Psychology," by Richard Sterba. There were likewise seminars for professional educators, including "Seminar for Pedagogical Advisers," by August Aichhorn; and "Reading Freud's Writings," with Grete Bibring, Berta Bornstein, Hedwig Hoffer-Schaxel, Willi Hoffer, Marianne Kris, Jeanne Lampl-de Groot, and Richard Sterba.

The training institute and all other institutes of the Wiener psychoanalytische Vereinigung (WPV) were shut down in March 1938, after the annexation of Austria by the Third Reich.

## **LEHRMAN, PHILIP R. (1895–1958)**

Philip R. Lehrman was born in Plissa in Russia on October 12, 1895, and died in New York on February 4, 1958. He was the fifth of seven children in a family that emigrated to the United States in 1905. An excellent student Lehrman graduated from Fordham University Medical School in 1918. While working at the St. Lawrence State Hospital in Ogdensburg, New York, he met Abraham Arden Brill, who became a lifelong friend and mentor. He joined the New York Psychoanalytic Society in 1921 where he served for many years on the educational committee and board of directors. He was secretary of the Society from 1935 to 1944 and president in 1946. Lehrman was also a professor of clinical psychiatry and neurology at Columbia University and New York University.

In 1928 Lehrman traveled with his wife, Wanda Scheps, who was from Vienna, and their two children, Howard and Marilyn, to Vienna for a year of analytic work with Freud. He took part in the meetings of the Vienna and Berlin societies, where he met the analysts from the Tegel clinic and the Polyclinic. Lehrman was an amateur cinematographer and filmed Freud and his colleagues with a Bell and Howell camera during his year in Vienna. His films are documents of inestimable value for the history of psychoanalysis. These films were edited by his daughter, Lynne Wiener-Lehrman, in 1986 and are the subject of a forthcoming book.

Lehrman wrote about thirty articles and was the editor of Anna Freud and Dorothy Burlingham's 1943

book *War and Children* and, in 1948, also edited Brill's *Basic Principles of Psychoanalysis*.

Among his students were Louise Gordy, Ruth Loveland, and Sidney Klein.

## **LEONARDO DA VINCI AND A MEMORY OF HIS CHILDHOOD**

This monograph on Leonardo da Vinci was the first of this kind written by Freud, and he had great reservations about it. There were precedents, however: Isidor Sadger had written several histories of artists with pathologies (Conrad-Ferdinand Meyer, Nikolas Lenau, Heinrich von Kleist). For years Freud had been interested in Leonardo da Vinci (see his letter to Wilhelm Fliess of October 9, 1898) and identified with Leonardo's passion for investigation and the nature of his research, which created a scandal at the time. Leonardo da Vinci and his ilk—Francis Bacon, Nicolas Copernicus, Bernard Palissy—are heroes of scientific research, men who have “troubled the world's sleep” (Friedrich Hebbel).

The first of the book's six chapters discusses the passion for investigation, its infantile origins, and its drawbacks from the point of view of love, social relations, and other activities. Leonardo is a good example of such behavior because he allows Freud to contrast the inhibition (the slowness of execution) characteristic of his painting with his excessive investment in research. Freud defines the three outcomes of infantile sexual investigation: inhibition, obsession, sublimation. “[L]ibido evades the fate of repression by being sublimated at the very beginning into curiosity” (p. 79).

The second chapter is devoted to Leonardo's memory of his childhood. Freud interprets the memory as a fantasy and compares it with mythological information. Unfortunately, Freud's discussion is not pertinent, because a translation error leads him to talk about a vulture instead of a kite.

The third chapter provides a description, based on the fantasy of fellatio expressed in the memory, of a particular type of homosexuality. In this type of homosexuality, the subject identifies with his mother so he can experience self-love through other young men, objects of his homosexual choice. This discussion considers narcissistic choice long before Freud introduced the concept of narcissism.

In chapter 4 Freud continues his discussion of the memory of Leonardo's mother in his analysis of Mona Lisa's smile. Chapter 5 describes Leonardo's antagonism toward his father. Freud saw in this antagonism the origin of Leonardo's courage as an investigator, primarily in the face of religious authority. Chapter 6, which contains an important discussion of the role of chance, presents Freud's methodological conclusion on creativity.

Freud's essay on Leonardo is one of his best known works. Though Freud quotes several biographies of artists, he transforms the art form by investigating the obsessive investment associated with sublimated activity.

## LETTER, THE

The letter refers to the material substrate, identical to the printed character, that serves as the vehicle for spoken or written language. It represents the two sides of the signifier (metaphor and metonymy) in the creation of meaning and in the production of dreams, where the letter designates one of the terms of the rebus. As the localized structure of the signifier, the letter's nature is real, exclusive of sense or meaning. Its function is symbolic to the extent that its absence determines the automatism of repetition. The letter constitutes the unconscious to the extent that it is organized as a literal heterogeneous set.

Freud's first allusion to the letter and its function is found in his correspondence with Wilhelm Fliess on December 6, 1896 (1950a), where he describes a system of inscribing perceptions, in which the process of repression can be conceptualized as the erasure of an inscription. In the analysis of the Wolfman, Freud (1918b) returns to the letter and its workings. In 1927, in his article on fetishism (1927e), he shows how a patient's erotic life remains attached to a permutation of letters.

However Freud never really formulated a theory of the letter. Jacques Lacan in 1954–1957 (1966) provided a theoretical elaboration of the functioning of the letter to the extent that it—and it alone—constitutes the topography of the unconscious.

Several additional aspects of how the letter functions need to be distinguished: its situation within the articulation of the two essential tropes that govern language, metaphor, and metonymy (Roman Jakobson), and the function it plays in the dialectic of desire and the automatism of repetition. To explain these functions a few linguistic concepts are necessary.

Returning to the Saussurian algorithm, Lacan emphasized the impermeable nature of the bar that separates signifier and signified. Contrary to what is suggested by the illustration of the algorithm between the sound "tree" and its iconic representation, the unconscious does not acknowledge any univocal correspondence between a signifier and a signified, because the signifier only functions through its difference with other elements in the verbal chain. Because of these three factors access to meaning can only occur through metaphor or metonymy. Thus Freud discovered the processes of condensation (*Verdichtung*) and displacement (*Verschiebung*) in dreams. These two

operations take place at the cost of eliding the signifier upon which they were originally based. This first obliterated signifier is automatically repressed as part of the natural operation of the production of meaning. By extension, we recognize in this the model of symptom formation as a fact associated with language. Within the differential coupling of signifiers as they occur in a language this first signifier, the indifferent point of departure for metaphor or metonymy, can be conceptualized as precipitated in the materiality of a letter that represents it in the chain of signifiers. This letter also prefigures the trace of the lost object and the lack that causes desire, for in metonymy the trace of the loss is transferred to the object of desire. This led Lacan to designate the object-cause of desire by the letter *a*. The letter thus has a symbolic function that overdetermines the unalterable principle of the automatism of repetition to the extent that a letter will always be missing, the very letter that represents the lost object.

Moreover, the impossibility of grasping the letter in its signification, its resistance to meaning, because it lies outside the signified, shows that in its essence the letter is real: It forms a hole in unconscious knowledge. Exploration of this hole in meaning using the real of the letter remains the nub of the unconscious in the experience of analysis.

## **LEUBA, JOHN (1884–1952)**

A doctor in the natural sciences and medicine, a psychoanalyst, and a member of the Société psychanalytique de Paris (SPP; Paris Psychoanalytical Society) from 1932, John Leuba was born in Corcelles, Switzerland, near Neuchâtel, in 1884; he died there on May 11, 1952.

Leuba's father, a pharmacist in Corcelles, inspired his interest in the natural sciences. At the end of his studies he turned his focus to geology. In Neuchâtel he became assistant to Professor Schardt, whose daughter he married several years later.

After an illness of unknown origin, Leuba earned his medical degree in Geneva. During the First World War he was a volunteer in hospitals in France. In 1925 he went to Paris and worked for the publishing house Armand Colin, which published his *Introduction à la géologie* (Introduction to geology) in 1925.

During the period from 1928 to 1930, he became a doctor in the faculty of medicine in Paris. He went into analysis with Rudolph Löwenstein and worked under the supervision of René Laforgue. He was secretary of the Société psychanalytique de Paris from 1934, and served as its president from 1946 to 1948.

Leuba was an artist with a genuine talent for drawing, and he excelled in his case descriptions. Not much inclined toward theory, he devoted his best efforts to clinical observation. His articles were published in the *Revue française de psychanalyse*; “Analyse rapide d'un névrose d'angoisse à base de complexe de castration” (Summary analysis of an anxiety neurosis based on the castration complex) and “La pensée magique chez le névrosé” (Magical thinking in neurotics) exemplify his qualities as a clinician. In 1936, at the Ninth Conference of French-Speaking Psychoanalysts in Nyon, he delivered a paper entitled “La famille névrotique et les névroses familiales” (The neurotic family and family neuroses), in which he asked the question: “Are there such things as Catholic neuroses, Protestant neuroses, and Jewish neuroses?”

He was part of the “Club des piqués” gathered around Laforgue in the Midi. In a poem dedicated to Délia Laforgue, he expressed his enthusiasm for wine, wild times, and pleasures shared among true friends, “the truest of the true.”

The second volume of the *Revue française de psychanalyse* (1939) contained his article, “Batrachomyomachie: Document pour la défense et illustration du thème oedipien” (Batrachomyomachia: Document for the defense and illustration of the oedipal theme), but because of the war this issue was not released and the article appeared only in 1948. This strange article begins as follows: “For as long as I can remember, I have always felt a singular tenderness toward toads.” Childhood memories and fantasies are blended

together into a narrative without any psychoanalytic analysis.

He continued his clinical practice in Paris during the war, serving at the same time as a volunteer doctor in the emergency ward at the municipal building of the 16th arrondissement. In 1945 he accused Laforgue of having collaborated with the Nazis. His denunciation resulted in a trial, but the case was dismissed for lack of proof.

Francis Pasche, during the Occupation, and, later, Jean Favreau and Pierre Luquet did their training analyses with Leuba. At Leuba's funeral, Charles Odier described him as having lived in the physical and the human, and not in the metaphysical.

## **LEVI BIANCHINI, MARCO (1875–1961)**

Marco Levi Bianchini, an Italian psychiatrist, was born in Rovigo in 1875 and died in Nocera Inferiore in 1961. He came from a Jewish family and studied medicine in Padua. After serving as a teaching assistant at the psychiatric hospital of Nocera Inferiore (Salerno), he became a professor of psychiatry in Naples. In 1924 he became the head of the psychiatric hospital in Teramo. After publishing *L'isterismo dalle antiche alle moderne dottrine* (Hysteria from antiquity to modern doctrine), he began corresponding with Sigmund Freud and, in 1915, published a translation of "Five Lectures on Psychoanalysis" (*Cinque conferenze sulla psicoanalisi*), soon followed by *Il sognor* (The dream; 1919) and, in 1921, *Tre saggi sulla teoria sessuale* (*Three essays on the theory of sexuality*). In 1920 he founded

the Biblioteca psicoanalitica internazionale, which published works by Freud and other pioneers of psychoanalysis for the first time in Italy.

Following his encounter with Edoardo Weiss in 1921, Levi Bianchini worked to make the journal *Archivio generale di neurologia e psichiatria*, which had been recently established, the leading Italian publication on Freudian psychoanalysis. For Weiss, the collaboration with Levi Bianchini to promote psychoanalysis was more of a hindrance than a help. Because Levi Bianchini was hampered by positivist psychiatric prejudices and incomplete knowledge of psychoanalysis, his enthusiasm for Freud's ideas did little to ensure their welcome reception in Italy.

After becoming a member of the Vienna Psychoanalytic Society in 1922, Levi Bianchini surprised Weiss by deciding to found, in 1925 in Teramo, the Società psicoanalitica italiana (Italian Psychoanalytic Society), whose members were mostly local psychiatrists without any psychoanalytic training. Weiss appealed to Freud, who advised him to accept this as a fait accompli. Freud commented, "It often happens that form precedes content," and he hoped that Weiss, through his abilities and efforts, would provide the content. In 1932, when Weiss reestablished the Società psicoanalitica italiana in Rome, Levi Bianchini became honorary president for life, though rarely attending the society's meetings.

Racial laws forced Levi Bianchini to resign as head of the hospital in Nocera. After 1945 he continued to work privately as a psychiatrist and participated in meetings of the Società psicoanalitica italiana less and less. In 1956 Italian psychoanalysts asked him to preside over the hundredth anniversary of Freud's birth. In 1995 *Biolibido*, a collection of his psychoanalytic writings, was published. Although the essays are dated and have little interest for contemporary psychoanalysts, Levi Bianchini nonetheless deserves recognition as one of the first translators of Freud in Italy.

## LIBERMAN, DAVID (1920–1983)

David Liberman, an Argentinean psychiatrist and psychoanalyst, was born in Buenos Aires on October 2, 1920, and died there on October 30, 1983.

He was the second of three boys in a middle-class Jewish family. His mother died very young. Two men were to mark his life: his father Sam, a jazz musician, and the psychoanalyst Enrique Pichon-Rivière, his mentor. Liberman followed in his father's footsteps and paid for his medical studies with his earnings as a jazz musician. He married young and had two children: Diana, who became a psychoanalyst, and Alex, who turned to journalism.

Liberman took an interest in Freud when still a medical student, having heard of him from his childhood friend, Léon Grinberg. Later he worked in the psychiatric department run by Enrique Pichon-Rivière. His doctoral thesis, published in 1947, already indicated his leaning toward psychoanalysis: *Semiología Psicosomática* (Psychosomatic signs and symptoms).

Liberman was a brilliant psychoanalyst, gifted with extraordinary intuition. He showed remarkable clinical know-how with his patients and impressed the Argentine psychoanalytic milieu with his ability to tap into the unconscious of his colleagues. Although he was influenced from various different quarters, Pichon-Rivière made a major impression on him.

Liberman distinguished himself mainly by the way he integrated into psychoanalysis an approach derived from linguistics and the theory of communication. His preoccupation with external reality, particularly in analyst-patient communication when seen through the prism of what he called their “styles,” made up Liberman's own extremely original style. Throughout his life he conducted research into the theory of communication in conjunction with Argentine, French, and Soviet linguists. He remained totally independent of trends.

His output consists of more than sixty studies published between 1947 and 1984. In 1962 he published

his first book on the theory of communication, *La Comunicación en la terapia psicoanalítica* (Communication in Psychoanalytic Therapy). He developed his contributions on styles of interpretation and patient-analyst communication in a fundamental work entitled *Lingüística, Interacción comunicativa y Proceso psicoanalítico* (Linguistics, communicative interaction, and psychoanalytic process), published in three volumes in 1971–1972, followed by, among other articles and joint efforts, *Psicoanálisis y Semiótica* (Psychoanalysis and semiotics; 1975) and *Comunicación y Psicoanálisis* (Communication and psychoanalysis; 1976). His last book, *Semiotica y Psicoanálisis de niños* (Semiotics and child psychoanalysis), written in collaboration with some of his disciples, was published after his death, in 1984.

## LIBIDINAL COEXCITATION. *See* Reciprocal paths of influence

---

## LIBIDINAL DEVELOPMENT

A major contribution of psychoanalysis to human understanding is its explanation of neurotic mental disorders in terms of fixation or regression of the libido. *Libido*, a Latin term meaning desire, want, amorous desire, is defined as the instinctual sexual energy underlying all mental activity. Psychoanalysis

saw libidinal development as spanning the whole psychosexual evolution of the individual from birth to adulthood, as reconstructed in psychoanalytic treatment. Such treatment takes into account the early phases in the organization of the libido, the psychic structure that results from the individual's Oedipus complex and the modes of its resolution, the adolescent phase, and the resulting genital organization of the adult and choice of object.

Development, which involves stages, phases, and periods of organization, is a transformation from an original state to a state of completion. From a libidinal point of view, this final state is the state of adult sexuality, which Freud considered to be the end point of the infantile sexuality present in different forms in different phases. At the time, this idea of infantile sexuality provoked a strong reaction in the scientific world, which rejected psychoanalysis as being "pansexual." The affirmation of infantile sexuality may well have scandalized the world far more than other important ideas in psychoanalysis, such as the notion of dreams having a meaning and the existence of an unconscious psychic life.

The notion of the libido appears in Freud's writings as early as his letters to Wilhelm Fliess, but Freud used it in the general sense used by late-nineteenth-century authors who began to take an interest in human sexuality, particularly Albert Moll and Richard Krafft-Ebbing, who studied sexual psychopathies. In 1905, however, Freud defined the libido in *Three essays on the theory of sexuality* in reference to the theory of instincts, thus founding the psychoanalytic conception of psychic functioning. These essays invite us to follow the evolution of the sexual instinct in the individual in accordance with specific phases of psychic organization, as well as their consequences in terms of people's psychic reality and the nature and characteristics of the relations people establish with others. Psychoanalysis thus concentrates more on the dynamic character of sexuality and its role in the unconscious, rather than seeking to describe it as a succession of temporal stages.

The sexual instinct during pregenital phases is autoerotic and is linked to particular zones (the oral cavity, anus), the location of this erotic pleasure depending on the degree of maturity (sucking in infancy, the pleasure of stool retention and expulsion when acquiring sphincter control). Freud made direct observations, which he then described, such as the pleasure of the baby feeding at its mother's breast or the adolescent

masturbating. In these pregenital stages the sexual instinct consists of component instincts such as the sadistic instinct, the instinct for knowledge, the instinct for mastery, these nonerotic components being directed toward the object. (These component instincts often appear as pairs of opposites, for example, the instinct to see and be seen.) The great variety and diversity of these component instincts led Freud to declare that children were polymorphously perverse, each of these instincts being capable of continuing later in life in certain adult perversions (voyeurism and sadism, for instance). But this predisposition could also "be regarded as the source of a number of our virtues, in so far as through reaction-formation it stimulates their development" (Freud, 1905d, p. 239).

In the course of a later phase situated between the ages of three and six, the component instincts are unified and organized under the primacy of the genital zone. Then the individual discovers the anatomical difference between the sexes (for Freud, this was limited in both sexes to the presence or absence of a penis). This discovery opens the way to, and organizes, the phallic phase from the fourth year onward. The reaction to this discovery is very different in boys and girls: boys now find themselves confronted with the oedipal problem and castration anxiety. The early dual relationship of mother and son is then followed by a triangular relationship involving both parents, a situation rich in conflict. Freud called this the Oedipus complex, the resolution of which leads to a psychic structure that includes the superego, through the internalization of parental prohibitions. This "childhood neurosis" constitutes the original nucleus of all adult neuroses.

This first period of infantile sexuality is followed by a latency period that is quiet in comparison to the efflorescence of the previous period. Sexual development now comes to a halt or regresses. Previously persistent tendencies succumb to moral repression and moral reactions; shame and disgust make their appearance. During adolescence the thrust of puberty brings the oedipal conflicts to the fore all over again, and their resolution results in the adult genital organization and a definitive object choice.

In the course of development the child takes his or her own body as a love object; then the libido turns toward the parents before finally choosing some outsider as an object. This path temporarily leads to a homosexual object choice and "at the age of puberty boys and girls show clear signs, even in normal cases,

of the existence of an affection for people of their own sex” (Freud, 1905d, p. 60), before choosing a heterosexual object. The vicissitudes of this development create fixation points that become way stations in the regressive psychopathological conditions of the adult. Many authors after Freud set about describing them, particularly Karl Abraham.

Although libidinal development includes these infantile and adult oral, anal, and genital phases, it is not just a succession of temporal phases that accumulate, overlap each other, and develop concomitantly. Structuring and organization of the agencies which takes place under the effect of “après-coup.” This notion of stimulus enables us to account for the reorganizations introduced later in particular circumstances. A repressed memory, for example, can be transformed “après-coup” into a traumatism. The progressive differentiation of intrapsychic agencies—the ego from the id in early childhood, and the superego as the heir to the Oedipus complex—is one of the achievements of libidinal development and ensures psychic functioning regulated by the pleasure principle and the reality principle.

Melanie Klein offered a profound revision of the Freudian theory of libidinal development by proposing a duality in the life and death instincts. She stressed the precocious nature of the superego and the Oedipus complex. She claimed that the triangular structure of the Oedipus complex could be observed well before the beginning of the genital phase and before the child considered *total objects*, *partial objects* (breast, feces, penis) being the only objects having a role to play at this time. She also stressed the precocious modes of object relations, referring to them not as *phases* in libidinal organization, but as *positions*: the paranoid-schizoid position and the depressive position.

### **LIBIDINAL STAGE**

Each libidinal stage, or developmental phase of childhood, is characterized by a specific organization of the libido linked to a dominant, organizing erotogenic zone where excitation is centered and around which fantasies are constructed. The notion of stages does not imply any strictly chronological sequence: these are “phases” or “levels of organization” that may well overlap or coincide.

Freud’s earliest theorizations of the idea of stages already implied that each stage represented a specific organizational mode. From the outset, when he was influenced by Wilhelm Fliess’s theory of periodicity, Freud had correlated mental organization and the “choice of neurosis” with a succession of phases or periods in the child’s development. Later, he linked these different developmental phases to the dominance

or the abandonment of one or other of the erotogenic zones (mouth, anus, penis, clitoris). He also saw the process of repression as closely associated with the relinquishment of one such zone in favor of another.

The first edition of the *Three Essays on the Theory of Sexuality* (1905d) made mention only of the oral and anal erotogenic zones, as contrasted with the sexuality of puberty and adulthood, which was dominated by the genital. Subsequently Freud would flesh out the theory of the stages of the libido when, between 1913 and 1923, he introduced the oral, anal, and phallic pregenital stages which preceded the establishment of the genital stage.

In seeking to define the organizational modes of pregenital sexuality, Freud viewed matters from two standpoints. The first of these considered the successive phases of psychic organization in terms of the prevailing erotogenic zone: The one, in each case, upon which excitation focused and around which fantasies were constructed (Perron-Borelli, 1997). The second perspective stressed the libidinally-cathexed object and the temporal sequence in accordance with which the subject passed in turn through the various phases of autoerotism, narcissism, and homosexual or heterosexual object-choice. Each libidinal stage was characterized by a particular type of object-relationship, so that incorporation typified the oral stage while retention-expulsion was specific to anal eroticism (Abraham, 1924). This approach showed how the object, just as much as the erotogenic zone, played an organizing role.

The idea of libidinal stages (the terms *phase* and *level of organization* are more widely used today) has on occasion encouraged simplistic interpretations that over-emphasize the supposed dates of onset and precise order of the stages. It is impossible to overstate the fact that for psychoanalysis no strict sequencing is required: "The temporal ordering of these stages certainly implies a hypothesized priority of one phase with respect to the next, but the hypothesis in question is inferred from the analysis of adults.... In other words, all the stages survive as strata embedded in instinctual impulses and unconscious fantasies" (Perron and Perron-Borelli, 1994).

Freud himself wrote that the different phases of libidinal development could "overlap one another [or] be present alongside one another" (1940a, p. 155). In fact, the chief benefit of the theory of stages is that it helps us to construct a temporal framework in which to locate those effects of anticipation and deferred

action, which in turn allow us to understand the mechanism of repression.

## **LIBIDO**

Freud defined the term *libido* psychoanalytically in an addition, written in 1915, to *Three Essays on the Theory of Sexuality* (1905d): "We have defined the concept of libido as a quantitatively variable force which could serve as a measure of processes and transformations occurring in the field of sexual excitation" (p. 217).

In *Group Psychology and the Analysis of the Ego* (1921c), he further developed this concept: "Libido is an expression taken from the theory of the emotions. We call by that name the energy, regarded as a quantitative magnitude (though not at present actually measurable), of those instincts which have to do with all that may be comprised under the word 'love'" (p. 90).

The "libido theory" is present throughout Freud's works, beginning with the first appearance, in Manuscript E of the Fliess papers (1950a [1895]), of the notion of "psychical libido," as synonym of "psychical affect" (p. 192, 193). This draft dates from June 1894—that is to say, before the appearance of Albert Moll's book, *Untersuchung über die Libido sexualis*, from which Freud claimed to have borrowed it. The theory of the libido was constantly revised and remodeled from three main angles: the developmental, the metapsychological (then associated with the theory of

the instincts and the dynamic and economic points of view), and the psychopathological.

In the *Three Essays on the Theory of Sexuality* (1905d), Freud based the psychoanalytic notion of libido on infantile sexuality, explaining how it drew support from the major vital functions (anaclisis): “The fact of the existence of sexual needs in human beings and animals is expressed in biology by the assumption of a ‘sexual instinct,’ on the analogy of the instinct of nutrition, that is of hunger. Everyday language possesses no counterpart to the word ‘hunger,’ but science makes use of the word ‘libido’ for that purpose” (p. 135). Starting with the autoeroticism of the erogenous zones, and building on the work of Karl Abraham, he developed the idea of a series of developmental phases leading from the “pregenital libidinal organization,” through the oral, anal-sadistic, and phallic stages (1923e), to the genital stage.

At the same time, Freud contrasted libido, in his earliest versions of the instinct theory, as the energy of the sexual drives, with the energy of the “ego-instincts.” This was a subject he returned to often, so as to differentiate his ideas from the ideas of Carl G. Jung, as first outlined in Jung’s *Transformation and Symbolism of the Libido* (1913). Jung saw libido as close to the *élan vital* of Henri Bergson. Freud explained his position in a letter to Édouard Claparède of December 25, 1920: “I’ve repeated and would like to say as clearly as possible that I want to establish, for transference neuroses, the distinction between sexual drives (*Sexualtriebe*) and ego drives (*Ichtriebe*); and the libido signifies for me only the energy of the former, the sexual drives. It is Jung, not I, who conceives of the libido as the animating force of all psychic activities, consequently contesting the sexual nature of the libido. Your affirmation applies, therefore, neither to me nor to Jung totally; it rather is based on a *mélange* of the two. From me you borrow the sexual nature of the libido, from Jung its universal significance, from which is born pansexualism, something that exists only in the imagination of certain critics, so fertile when it comes to manipulating things.”

“On Narcissism: An Introduction” (1914c) marked a major theoretical turning point in Freud’s work. Ego-libido, now also called “narcissistic libido,” was viewed as a primal libidinal cathexis, a part of which was detached, and directed onto objects: “Thus we form the idea of there being an original libidinal cathexis of the ego, from which some is later given off to objects, but

which fundamentally persists and is related to the object-cathexis much as the body of an amoeba is related to the pseudopodia which it puts out” (p. 75). But if the ego was presented in this context as a reservoir of libido, with the introduction of the second topography (or structural theory), Freud revised this view: “Now that we have distinguished between the ego and the id, we must recognize the id as the great reservoir of libido. . . . The libido which flows into the ego owing to the identifications described above brings about its ‘secondary narcissism’” (1923b, p. 30n). This contradiction would be the cause of much post-Freudian discussion and theorizing. As for its object-relationships, “The libido attaches itself to the satisfaction of the great vital needs, and chooses as its first objects the people who have a share in that process” (1921c, p. 103).

Nevertheless, from *Beyond the Pleasure Principle* (1920g) on, the introduction of the death instinct announced a radical new dualism: “In this way the libido of our sexual instincts would coincide with the Eros of the poets and philosophers which holds all living things together” (p. 50), while “The opposition between the ego-instincts and the sexual instincts was transformed into one between the ego-instincts and the object-instincts, both of a libidinal nature. But in its place a fresh opposition appeared between the libidinal (ego-and-object-) instincts and others, which must be presumed to be present in the ego and which may perhaps actually be observed in the destructive instincts” (p. 61, note added 1921).

Libidinal cathexes enter the framework of Freud’s metapsychological descriptions by way of their dynamism: The libido is susceptible in the course of development to “fixations” at particular stages; even if such a fixation is bypassed later and subjected to repression, it can re-emerge when some mental obstacle, such as the fear of castration, happens to obstruct progress and precipitates a “regression.” Likewise, transformations of libidinal cathexes are possible, “in such a way that they cannot come up against frustration from the external world. In this, sublimation of the instincts lends its assistance” (1930a [1929], p. 79).

As for the “economic point of view,” it was present from Freud’s earliest descriptions of the libido as an “energy,” or a “force” (1897), right up until his very last writings, when he evokes “the total available energy of Eros, which henceforward we shall speak of as ‘libido’” (1940a [1938], p. 149). Freud studied both the process of the libido’s production and the manner of its

displacements, even invoking a certain “adhesiveness of the libido” to explain certain difficulties encountered in psychoanalytic treatments, he added that “One meets with the opposite type of person, too, in whom the libido seems particularly mobile; it enters readily upon the new cathexes suggested by analysis, abandoning its former ones in exchange for them” (1937c, p. 241).

Let us now turn to the applications of the notion of the libido in the domain of psychopathology. In a letter to Karl Abraham (1965a), Freud pointed the way: “The characteristic traits of neuropsychoses and psychoses are connected with the destiny of the libido—where it is localized relative to the ego and the object, the varieties of repression concerning this libido, as well as how this repression evolves chronologically.” It will be recalled that Freud deemed regression to pregenital stages the key to obsessional neurosis and depression. Later, “the effect of seduction, which is responsible for a premature fixation of the libido” (1922b, p. 231) was described by him as one of the causative factors of homosexuality. In an article on psychoanalysis for the *Encyclopaedia Britannica*, he wrote: “The infantile fixations of the libido are what determine the form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the development of the libido” (1926f, p. 268); and in *An Outline of Psycho-Analysis* he pointed out “that sadism is an instinctual fusion of purely libidinal and purely destructive urges, a fusion which thenceforward persists uninterruptedly” (1940a [1938], p. 154). In this connection we should mention the theory of anxiety. In *The Interpretation of Dreams* (1900a), Freud described anxiety as “a libidinal impulse which has its origin in the unconscious and is inhibited by the preconscious” (pp. 337–338); later he attributed it to a transformation of the libido under the pressure of repression, and finally offered his definitive revision of the theory of anxiety in *Inhibitions, Symptoms and Anxiety* (1926d [1925]).

In his paper on “Libidinal Types” (1931a), Freud developed a new psychoanalytical typology: “According . . . as the libido is predominantly allocated to the provinces of the mental apparatus, we can distinguish three main libidinal types. To give names to these types is not particularly easy; following the lines of our depth-psychology, I should like to call them the *erotic*, the *narcissistic* and the *obsessional* types. . . . These pure types will hardly escape the suspicion of having been deduced from the theory of the libido. But we feel ourselves on the firm ground of experience

when we turn to the mixed types, which are to be observed so much more frequently than the unmixed ones. These new types—the *erotic-obsessional*, the *erotic-narcissistic* and the *narcissistic-obsessional*—seem in fact to afford a good classification of the individual psychical structures which we have come to know through analysis. . . . We thus realize that the phenomenon of types arises precisely from the fact that, of the three main ways of employing the libido in the economy of the mind, one or two have been favoured at the expense of the others” (pp. 217–219).

Karl Abraham, Sándor Ferenczi, and the first psychoanalysts followed or developed the views of Freud, but the same cannot be said always for later generations. Critics focused on the “narcissistic libido,” rather than on those formulations of Freud’s that appeal to biology and pharmacology to account for sexual excitation—as when he wrote, for example, of the “sexual toxin which we should have to recognize as the vehicle of all the stimulant effects of the libido” (1916–17a [1915–17], pp. 388–389). While Paul Federn or Edoardo Weiss suggested calling the energy of aggressive drives “destrudo” or “mortido,” to distinguish it from the libido, some, such as Rudolph M. Lowenstein, emphasized the contradiction arising from the very notion of “narcissistic libido,” for “there cannot be two kinds of psychic energy, characterized by the simple fact that one is directed toward the object and the other towards the self” (1965). James Strachey and Heinz Hartmann have also discussed confusions arising from Freud’s successive formulations on the subject of the narcissistic libido and the role of the ego: Did these concern an “ego” or a “Self,” primary narcissism seeming to suggest “the whole person” rather than that of the Freudian “ego”? Starting in 1941, Ronald Fairbairn developed the idea that the libido is essentially searching for an object rather than pleasure, and that in psychopathology the emphasis should be on dysfunctions in object-relations. Michael Balint, basing himself on these debates, refuted the notion of “primal narcissism,” and instead worked out a theory of “fundamental lack” (1968). Heinz Kohut, for his part, wrote that “every libido that has a self-idealizing or aggrandizing quality is ‘narcissistic’” (1971).

Jacques Lacan offered a very different approach to the notion of libido at the Bonneval Colloquium (1960), returning to the theme again in *Four Fundamental Concepts in Psychoanalysis* (1964), with his “myth of the

lamella.” He stressed the subject’s search, not for a complement—as the Platonic myth (and Freud in Plato’s wake) would have it—but that part of himself that was lost with the cutting of the umbilical cord, which made of him a mortal and sexed being. The libido here is “the lamella that slides between the organism and its true limit, beyond that of the body”; it is also “something . . . that is related to what the sexed being loses in sexuality, it is like the amoeba in relation to sexed beings, immortal” (1964, p. 197). Lacan defined the libido as “an organ,” or instrument of a drive.

On his part, Freud always tied the libido to an organic substrate; he even compared libido to a toxin: “all our intoxicating liquors and stimulating alkaloids are merely a substitute for the unique, still unattained toxin of the libido that rouses the ecstasy of love” (letter to Karl Abraham of June 7, 1908, in *A Psychoanalytic Dialogue*, p. 40), or “we . . . cannot even decide whether we are to assume two sexual substances, which would then be named ‘male’ and ‘female,’ or whether we could be satisfied with one sexual toxin which we should have to recognize as the vehicle of all the stimulant effects of the libido” (1916–17a, pp. 388–389). In *Three Essays on the Theory of Sexuality* (1905d), he had even proposed a “provisional hypothesis,” rarely mentioned by psychoanalysts, on the “essential factors of sexuality”: “It may be supposed that, as a result of an appropriate stimulation of erotogenic zones . . . some substance that is disseminated generally throughout the organism becomes decomposed and the products of its decomposition give rise to a specific stimulus which acts on the reproductive organs or upon a spinal centre related to them.” He concluded: “I attach no importance to this particular hypothesis and should be ready to abandon it at once in favour of another, provided that its fundamental nature remained unchanged—that is, the emphasis which it lays upon sexual chemistry” (1905d, III, p. 216). Until the end of his life, Freud linked the theory of the libido to the body, as is still evident in the *Outline of Psychoanalysis*: “There can be no question but that the libido has somatic sources, that it streams to the ego from various organs and parts of the body. This is most clearly seen in the case of that portion of the libido, which, from its instinctual aim, is described as sexual excitation. The most prominent of the parts of the body from which this libido arises are known by the name of ‘erotogenic zones,’ though in fact the whole body is an erotogenic zone of this kind” (1940a [1938], p. 151). It is clear how very much further,

since Freud, research on neuro-hormonal links has carried these suggestions, as well as how much, in the future, psychoanalysis will benefit from these new hypotheses.

In Freudian theory, the energy-based conception of the libido was nevertheless based on an electric, or rather hydraulic metaphor, with its flows and dams, countercurrents and anchorage points, lateral pathways through replacement objects or sublimations, its viscosity or stasis: One has only to think of the oft-repeated image of a “great reservoir” of energy. Freud has been reproached for the supposedly “unscientific” nature of such propositions. His own answer to such criticism, in his *Autobiographical Study* (1925d [1924]), was at once prudent and to the point: “I have repeatedly heard it said contemptuously that it is impossible to take a science seriously whose most general concepts are as lacking in precision as those of libido and of instinct in psycho-analysis. . . . In the natural sciences, of which psychology is one, such clear-cut general concepts are superfluous and indeed impossible” (pp. 57–58).

## LIE

A lie, the dissimulation or willful deformation of the contents of a thought that the subject deems to be true, can be practiced only either vis-à-vis another person or by means of a split in the subject—in which case the subject lies “to him- or herself.” A lie implies the intent to deceive and supports self-interest. The psychoanalytic approach to lying introduces the dimension of the unconscious.

The earliest psychoanalytic consideration of lies is found in Freud’s “Project for a Scientific Psychology” (1950c [1895]), where he envisioned lies solely in the context of the psychiatric definition of hysteria as a form of simulation, although he rejected this perspective. While he acknowledged the existence of a tendency toward simulation and lying in hysterics, he attributed it to the fact that the patient “wishes to be ill,” (p. 249), itself the result of patients’ need to convince themselves and those around them of the reality of their suffering.

In “Project for a Scientific Psychology,” the *πρωτου πσευδος* (*proton-pseudos*) is usually translated as “first hysterical lie” although it in fact involves an error or mistaken connection rather than an intentional dissimulation or distortion. The well-known example of Emma shows that the “error” had to do with the fact that she related her attack of agoraphobia to the shop-assistants’ ridicule of her clothes when she was thirteen, whereas the determining event, although its felt effects were deferred, was the memory-trace of a shopkeeper’s pedophilic assault on her when she was a child. The mistaken connection resulted from the repression of a childhood memory that was not available to her at the time of the scene when she was thirteen (“Hysterics suffer mainly from reminiscences” [p. 7]).

In “Two Lies Told by Children” (1913g) Freud emphasized that lies between parents and children are “natural.” In “On the Origin of the ‘Influencing Machine’ in Schizophrenia” (1919/1991), Viktor Tausk wrote: “children learn to lie from parents and

upbringers, who by misrepresentations and unkept promises make the child obey and teach him to disguise his true purposes” (pp. 214–215 n4). The aim of Freud’s article of 1913 was thus to show the existence of unconscious motivations in certain childhood lies that “occur under the influence of excessive feelings of love” (p. 305).

Such motivations do not involve the interests of the ego but instead correspond to an instinctual impulse that cannot be admitted, not because of the strong feelings of shame or unconscious guilt that are attached to it, but because it is unconscious. In the two cases evoked by Freud, incestuous love is behind the error and, secondarily, behind the lie that covers it up. The error itself could have been admitted as a fact, and if it is not acknowledged, this is because of the unconscious content it manifests. The “impossibility” of confession opens the way for reconstitution through deferred action, based on associations produced during the analysis, of the motivations that made the error impossible to confess.

This view leads to seeing the moral fault that the lie represents as a consequence of neurosis. A strictly moral understanding of lies is thus transformed by the psychoanalytical approach into an interrogation of the desire for falsehood. Such a desire, or even need, is incompatible with psychoanalysis, which requires, of analyst and patient alike, not that they tell the truth, but that they seek it.

According to Sándor Ferenczi (1912/1968), the difference between suggestion and psychoanalysis is that the former maintains disguise and repression owing to its basis in the authority of the therapist, where the latter “combats the ‘vital lie’ wherever it is found ... its final goal [being] to let light penetrate into human consciousness as far as the most hidden wellsprings of motivations for actions.” Ferenczi, too, stigmatized the pedagogy of his time, which imposed upon children the repression of emotions and ideas. In “Psychanalyse et pédagogie” (1908; [Psychoanalysis and education, 1949]), he wrote: “The closest thing to it is lying ... current pedagogy forces the child to lie to himself, to deny what he knows and what he thinks.” Echoed here is Freud’s concern about telling children the truth about sexuality; lying, in this context, appears first and foremost as an adult form of hypocrisy, with children’s lies being a response to it.

Karl Abraham (1925/1927) studied from a psychoanalytic viewpoint the case of a captain of industry, analyzing his compulsion to deceive others as a two-phase process in which he first showed himself to be lovable because he had not been loved by his parents, then did his best to disappoint those whom he had duped in order to take revenge against them. In “Über einen Typus der Pseudoaffektivität (‘Als ob’)” (1934) Helen Deutsch introduced the important notion of the “as if” personality, which is not a utilitarian lie told on a given occasion, but rather protects the “true Self” with a “false Self” (Donald Winnicott). Mythomania can also be situated within this framework of a narcissistic pathology in which lies are addressed both to others and to the self. Moreover, in “The Antisocial Tendency” (1956/1984) Winnicott situated theft associated with lying at the heart of antisocial tendencies in children and adolescents, but also connected this to incontinence and anything that makes a mess. In this context, this would focus on ease and opportunity to the classic moral understanding of an aggressive will to deceive. Lying, like gluttony and theft, originates in frustration.

The psychoanalytic view of lying is thus very broad, because it includes both the dimension of the false, ranging from social adaptation to pathologies of identity, and that of willful deceit, for which explanations relating to frustration or repressed love can be found.

## **LIEBEAULT, AMBROISE AUGUSTE (1823–1904)**

Ambroise Auguste Liebeault, a French physician and hypnotist, was born in Favières in Meurthe-et-Moselle on September 16, 1823, and died in Nancy on February 18, 1904.

Born into a large peasant family, he received a Catholic education before studying medicine in Strasbourg, where he took an early interest in magnetism while still an intern. As a physician at Pont-Saint-Vincent near Nancy, he gave free treatment to any patients who agreed to be hypnotized. He then took a two-year sabbatical to write *Du sommeil et des états analogues considérés surtout au point de vue de l'action du moral sur le physique* (Sleep and analogous states considered mainly from the point of view of the influence of moods on physical well-being). The book was published in 1866 but went unnoticed or was considered to be outdated. In what were then the suburbs of Nancy, Liebeault set up a “clinic” (really just a sort of shed next to his house). There he used induced sleep and suggestion under hypnosis to treat working-class patients suffering from a variety of run-of-the-mill “maladies.” He was a marginal physician who had abandoned the standard practices of his profession, but a professor of medicine raised him to the dignified status of a living legend, declaring him to be the founder of a school and an unhailed pioneer. Hippolyte Bernheim was converted to his views and practices in 1882. Liebeault was suddenly famous. The clinic of the “touching old doctor” (Freud, 1925d) became a mandatory stopover for French and European visitors who, like the young Freud, were interested in hypnotism and gravitated around the Nancy school.

In his 1866 book, which was republished at the end of the century, Liebeault claimed allegiance both to the early nineteenth-century French psychological current linked to magnetism (Bertrand and Noizet) and the hypnotic current (Braid and most of all Durand de Gros), which he brought together in his own synthesis. He stressed the influence of the mind on the physical (what we now call psychic and organic). Unlike Bernheim, he refused to equate hypnosis and suggestion and remained attached to the idea of a restless sleep linked to a concentration of attention. Liebeault's therapeutic originality consisted in breaking away from traditional magnetic cures in which patients conducted their own treatment and treated themselves, and promoting positive suggestion from the therapist. According to the testimony of certain visitors, Liebeault's suggestions were sometimes more in the nature of negotiations than categorical orders.

The Freudian text where it is easiest to find traces—paradoxically anonymous because no names are mentioned—of the Nancy school is the popularizing article of 1890, “Psychical (or mental) treatment” (1905b). The main idea expressed in the title, as well as the leitmotif on the magic of words, probably came from Liebeault and Bernheim. More specifically, we find the echo of *Du sommeil et des états analogues*. The comparison of the relationship between the hypnotized person and the hypnotist with a mother feeding a child is in fact a summary of a text by Bertrand that Liebeault cites: “A mother who falls asleep beside her child's cradle, never ceases to watch over him even in her sleep; but she is watchful only for him.” Significantly, Freud then speaks in French of the “*rapport*,” a term used mainly in the vocabulary of animal magnetism to evoke the relationship between the magnetizer and the magnetized person.

### **LIFE AND WORK OF SIGMUND FREUD, THE**

Ernest Jones's biography of Freud, titled *Sigmund Freud: Life and Work*, appeared between 1953 and 1957. The biography has been translated into all the major European languages. The first volume deals with Freud's childhood, youth, complex academic and personal life, and the gradual discovery of psychoanalysis, including *The interpretation of dreams*. The second volume deals with the years of Freud's maturity: his scientific achievements, his personal and professional life in Vienna during the first two decades of this century, the foundation of the international psychoanalytic movement, his various pupils, and the so-called heretics, such as Alfred Adler and Carl Gustav Jung. The third volume deals with the last period of Freud's life: his later scientific achievements, his troubled personal life and illness, the events that led him and his family to emigrate from Vienna to London to escape Nazi persecution in 1938, and his last months in London until his death. This volume also contains an overview of Freud's work, its links to various other natural and social sciences, and the contribution of psychoanalysis to the understanding of literature and art in general and religion in particular.

In spite of Jones's declarations concerning his objectivity in writing Freud's biography, there were several mitigating factors. One must consider his declared attempt to defend Freud and psychoanalysis from the constant attacks to which they were subjected, the personality of Jones as a biographer of Freud, his complex and often ambivalent relationship toward the founder of psychoanalysis, the cultural and social context in which the biography was conceived and written, and the pressures and control exerted on him and the use

of Freud's material by Anna Freud and other Continental colleagues and friends in America and England. Furthermore, not all the documentation concerning Freud's life and work was available at that time.

In writing the biography Jones was helped by several colleagues and friends. First among them were Siegfried Bernfeld and Suzanne Cassirer-Bernfeld, without whose help many chapters of the first volume would have been impossible. Also helping were Marie Bonaparte, James Strachey, and Kurt Eissler. The biography contains numerous factual errors and has recently been criticized and attacked by many so-called independent scholars, but here one should consider Jones's advanced age and declining health. The work reflects a image of Freud as he was known, loved, and critically appreciated by the generation of analysts and friends who lived and worked with him.

### **LIFE AND WORKS OF EDGAR ALLEN POE, THE: A PSYCHOANALYTIC INTERPRETATION**

In Sigmund Freud's preface to Marie Bonaparte's book on Poe, he writes, "My friend and student Marie Bonaparte has projected the light of psychoanalysis onto

the life and work of a great writer with pathological tendencies." Two years earlier, another psychoanalyst, René Laforgue, had published *The Defeat of Baudelaire: A Psychoanalytical Study of the Neurosis of Charles Baudelaire* with the same publisher. Poe's mother died of consumption when he was three and Bonaparte's mother died of a pulmonary embolism when she was only two months old. This similarity was to play a role in the enthusiasm Marie Bonaparte put into her analysis of Poe's work. Bonaparte discovered Poe when she was eighteen through the Baudelaire translation, a gift from her father. In 1925 she reread Poe during her analysis with Freud (she was then forty-three years old) and made the following reconstruction: The fear that some of Poe's heroines had once caused her, especially the ghosts, was the fear of the return of her dead mother, whose death she had caused by her birth and who, like an "oedipal ogress," would return to take her revenge.

Bonaparte's work contains four books in two volumes. Book I is devoted to Poe's life and poems. Book II covers the stories devoted to the "mother cycles"—the dead mother-living mother, the landscape-mother, the avowal of impotence, the assassinated mother. Book III covers the "father cycle" stories—the revolt against the father, the conflict with conscience, passivity toward the father. Book IV, "Poe and the Human Soul," compares Baudelaire's genius with that of Poe.

Bonaparte questions recurrent themes found in Poe—ghosts, still waters or seas that grow motionless in the polar ice—in which she detects the fantasy of the return of the mother's body or passive submission to the father. In her comments on "The Purloined Letter," she makes the letter a symbol of the maternal penis. Jacques Lacan made use of her commentary in his seminar on "The Purloined Letter." Marie Bonaparte's book remains a classic of psychobiography.

## LIFE INSTINCT (EROS)

The *life instinct* or *Eros* was one of the two basic instincts described by Freud in *Beyond the Pleasure Principle* (1920g) when he began to construct his structural theory, in which the life instinct stands opposed to the death instinct. The life instinct subsumed uninhibited sexual instincts, instinctual impulses inhibited in respect of their aim and sublimated, and the instincts of self-preservation.

In contrast to the monism of Jung and Adler, Freud upheld a dualistic theory with respect to the instincts. Up until his discovery of narcissism (1914c), he contrasted the sexual instincts, directed toward outside objects, to the ego-instincts, which included the instincts of individual self-preservation. But then his theory needed modifying in order to respond to the discovery that the ego itself could become the sexual object (1914c). Narcissistic libido thus became a manifestation of the pressure of the sexual instincts, and the former dichotomy between ego-instincts and sexual instincts lost its force. Part of the ego-instincts, namely the self-preservative instincts, were now seen as libidinal in nature, and the main conflict became that between narcissistic and autoerotic instincts, that is, between two forms of the sexual instinct.

With the turning-point of the early 1920s, Freud introduced the hypothesis of a death instinct to account for phenomena of repetition that were independent of the pleasure principle, indeed susceptible of opposing that principle (1920g). His dualistic imperative led him to group both the sexual and the self-preservative instincts under the head of the life instincts, as opposed to the death instincts.

In *The Ego and the Id*, Freud maintained his position on the need to distinguish between the two classes

of instincts: “the task of [the death instinct] is to lead organic life back into the inanimate state; on the other hand . . . Eros, by bringing about a more and more far-reaching combination of the particles into which living substance is dispersed, aims at complicating life and at the same time, of course, at preserving it” (i.e., in the interest of evolution). “Life itself,” Freud added, “would be a conflict and compromise between these two trends” (1923b, pp. 40, 41). Deeming his “fundamental dualistic point of view” inescapable, Freud was “driven to conclude that the death instincts are by their nature mute and that the clamor of life proceeds for the most part from Eros” (p. 46).

Freud held firm to the dualistic view until the end of his life, as witness these lines from his *Outline of Psycho-Analysis*: “After long hesitations and vacillations we have decided to assume the existence of only two basic instincts, *Eros* and *the destructive instinct*.” The aim of Eros was to “establish ever greater unities,” so preserving life; but if “binding together” was thus the task of the life instincts, the aim of the death instincts was “to undo connections and so to destroy things” (1940a [1938], p. 148).

In distinguishing between life and death instincts, Freud sought to introduce a duality within the notion of instinct itself. The outcome was a dual instinct that could be described as two instincts that are so entangled, so melded, that the one can barely have meaning outside of its relationship with the other. This instinctual entanglement arises through the indispensable mediation of the object. Effective instinctual functioning requires that the life instinct serve to bind the death instinct. When the instincts become disentangled, notes Benno Rosenberg, “the subject’s cathexis of the object is so massive that he will have difficulty differentiating himself from it. So intense and unbearable is the excitation that the subject will resort to a splitting of the ego” (1991).

The beneficial contribution of the death instinct, as imbricated with the life instinct, is that it allows a tolerable distance to be maintained between subject and object, thus facilitating the working out of the subject’s wishes.

## LIFTING OF AMNESIA

The lifting of amnesia involves the return of forgotten memories, and results especially from psychotherapy with hysterics. The notion of the lifting of amnesia, more phenomenological than metapsychological, led to the thought of the lifting of repression. However, it should not be reduced to this. Lifting of amnesia negates a negation, since amnesia abolishes remembrance; lifting it allows the conscious ego to return to normal function, which had been diminished by the amnesia.

This notion surfaced in the first of Freud's works on the theory of neuroses (1894–1896), as well as those on amnesia and mnemic trace written in the same period.

The term *lifting of amnesia* is parallel to "lifting of inhibition" and "lifting of repression." Freud often utilizes the expression of the lifting of the "veil" of amnesia, representing amnesia as something that hides what should have been conscious, a screen that prevents it from being perceived. The semantic and lexicographical field is close to that of the memory-screen (*Deckerinnerung*, "memory-covering" of the "memory cover," *Gedekte Erinnerung*, buried in the amnesia). The images of veil and cover, as well as that of "lifting," emphasized the visual-perception dimension of memory and, for the early Freud, gave concrete expression

to repression, which was rediscovered after the amnesia had been lifted.

Abreaction of post-traumatic affect allows the lifting of amnesia, by "bringing clearly to light the memory of the event by which it was provoked" (1893a, p. 6). At stake here is not simply the power of recollection, but especially by "arousing its accompanying affect" (p. 6), there can be a liberating release, through symbolization. In effect, the abreaction supposes that we give the affect linked to trauma a "verbal expression" that binds it. The conception of abreaction foreshadows, in certain respects, later developments on working-through and construction in psychoanalysis.

Lifting of amnesia causes the resurgence of memories charged with affects; retroactively meaning is given to a traumatic situation, which the subject, overwhelmed and overcome by events, could not grasp at the time. Until the moment of resurfacing, "these experiences are completely absent from the patients' memory when they are in a normal psychical state, or are only present in a highly summary form. . . . [T]hese memories [then] emerge with the undiminished vividness of a recent event" (p. 9). From this point of view, the unconscious would consist of an alteration of normal memory—whence Freud's paradoxical evocation of unconscious memory (for example in 1896 in the "Aetiology of Hysteria" [1896c, p. 212]: "hysterical symptoms are derivatives of memories which are operating unconsciously").

The persistent pressure of lived experience (*Erlebnis*) seeks to lift the veil of amnesia; the strength of the impression (*Eindruck*) in itself inclines toward lifting of amnesia. The mnemic trace of either an external event resonating in the psyche of the subject, or of a purely internal psychic event, seeks repeatedly an outlet toward the perception/consciousness system. Failing to find one, it appears in dreams, screen memories, daydreams, and symptoms. An impulse to memory (*Impuls zur Erinnerung*) exists, directed toward the hallucinatory mode of satisfaction and the identification of representation with perception, sometimes to be found in what Freud called a "mnemic image": a sensory intensity, essentially visual, of the memory of sexual trauma, at the moment of the lifting of amnesia.

With amnesia we don't remember, but with the lifting of amnesia, we remember "too much" in a sense.

Lifting the amnesia confirms the correctness of the psychoanalytic interpretation, but Freud was to distinguish later between the lifting of amnesia and lifting of repression, the latter accompanied by a transformation of the economy, dynamics, and topic of the ego, and obtained more through the analysis of repetition and transference than by recollection.

Indeed, Freud discovered, in his clinical practice as an analyst, that recollection never totally lifts amnesia, in particular infantile amnesia. In 1914, in “Remembering, Repeating, and Working-through” (1914g), he said that the analysis of repetition-compulsion is the best instrument to reconstitute that part of the psychic reality that remains amnesiac: repetition is a “way of remembering” (1914g, p. 150). When “the patient does not *remember* anything of what he has forgotten and repressed, but *acts* it out,” (p. 151), then “the transference is itself only a piece of repetition” (p. 151).

Freud here abandoned a conception of the cure based on the lifting of amnesia and the abreaction of traumatic memories, in favor of the lifting of repression, that is to say the transformation of the psychic organization of the analysand. We should, consequently, treat the neurosis “not as an event of the past, but as a present-day force” (p. 151).

In 1937, in “Constructions in Analysis” (1937d), he expanded the notion of interpretation to include that of construction, proposing to the analysand a hypothetical point of view on his history and on the cause of his symptoms based on an analysis of repetitive behavior, the transference, but also of clues that have been saved from oblivion, which are the “fragments of these memories in dreams” (p. 258). The analysand’s conviction that the construction is correct has the same effect of lifting the symptom and as a full and entire recollection. Freud remained partially attached to his earlier conception of the treatment when he added that the communication to the analysand of a construction can provoke the resurgence of “lively recollections called up in them—which they themselves have described as ‘ultra-clear’” (p. 266): the lifting of amnesia as a proof of the correctness of the construction.

Lifting amnesia has a specific function in the consciousness that a subject can have of their special history and of their identity. In hysteria, the “break-through into consciousness” (1985c [1887–1904], p. 239) is expressed especially through memory, whereas

in other pathologies it may be expressed otherwise, through action or delirium, as Freud had already written to Wilhelm Fliess, on May 2, 1897.

Beyond its essentially phenomenological dimension, the notion of the lifting of amnesia leaned too heavily on a clinical conception that stressed the abreaction of trauma by remembering; Freud distanced himself from this early conception in favor of a concept based on interpretation and construction, aimed at working-through, symbolization, and transformation. Apart from the fact that the project of a total lifting of amnesia is unrealizable because new secondary repressions are still in place, the existence of an original repression would condemn such a project as illusion.

Also, in certain cases of serious trauma (Ferenczi, 1932), there is no lifting of amnesia possible. Mnemic traces exist only in the mode of scattered corporal sensations or of divided affects, which are very difficult of access. In these cases, the abreaction has to be made by means of the emergence of intense affects, which were not felt at the time of the trauma, and not by the lifting of amnesia. The analyst therefore listens for the traumatic resonance of words rather than seeking the resurgence of memories.

**LIMENTANI, ADAM (1913–1994)**

Adam Limentani, an English psychiatrist and psychoanalyst of Italian origin, was born on July 6, 1913, in Rome and died on September 9, 1994, in London after a long illness. Limentani came from a well-established Roman nonorthodox Jewish family. From an early age he showed superior abilities. He was one of only ten applicants out of three hundred to become a student intern at the Rome Teaching Medical Clinic. However, his achievement was short-lived. In July 1938, just after taking a special competitive examination to gain an appointment at the psychiatric clinic of the University of Rome, he learned from the newspapers that Italians had been declared an Aryan race. With that he lost his position as clinical assistant at the medical clinic.

In December 1938, at the age of 25, he emigrated to London. By then Limentani had developed an interest in psychotherapy, but failing to obtain a psychotherapy post, he decided to get a degree in hygiene and tropical medicine with the aim of emigrating to an underdeveloped African country to practice psychiatry. The outbreak of the Second World War prevented this move. Limentani once said that if he ever wrote an autobiography, he would call it "In adversity." To illustrate this, he could point to his not going to Africa because of the outbreak of World War II and instead returning to psychiatry.

In May 1940 his work with casualties was abruptly interrupted because Italy entered the war, whereupon Limentani became an enemy alien and was interned for six months on the Isle of Man. After his release, he eventually became a major in the Royal Army Medical Corps and was sent to the military hospital in Hertfordshire, where he worked in psychosomatic medicine. Transferred to the military mental hospital in South Wales, he worked from 1941 to 1946 with British and Allied psychiatric casualties.

When he left the army, Limentani obtained a post as government registrar at Shenley Hospital, and it proved an invaluable experience. He could practice as a psychiatrist and develop his interest in psychotherapy with the psychoanalysts in training. It was then that he decided to become a psychoanalyst. In 1962 he obtained a post at the Portman Clinic, which led him to write a number of papers on sexual deviancy and delinquency.

Limentani was elected as an analyst in 1955 and became a member of the British Psycho-Analytical

Society in 1959. After twelve years devoted to training activities, he became president of the British Psycho-Analytical Society in 1974. In 1975 the British society, under his leadership, hosted the twenty-ninth congress of the International Psychoanalytical Association. After this congress Limentani was elected as one of the vice-presidents of the International Psychoanalytical Association with a seat on its council. He was elected president of the International Psychoanalytical Association in 1981, a post he held until 1985. To maintain a link between psychoanalysis and the professional public, from 1978 he took on the role of chairman of the publications committee of the British Psycho-Analytical Society and the Institute of Psycho-Analysis for the following ten years. He took an active interest in the development of psychoanalysis in many different parts of the world. He was able to foster an atmosphere of care and concern for colleagues throughout the world who sometimes worked in isolation or in environments that were either not accepting of, or even hostile to, psychoanalysis. At the time of his death, he was honorary archivist of the International Psychoanalytical Association, and shortly before his death he was elected honorary life vice-president of the International Psychoanalytical Association. In 1966 he wrote *A Brief History of the International Psychoanalytical Association*.

He was a fellow of the Royal College of Psychiatrists and an honorary consultant to the Portman Clinic of London. Though he reached the highest positions in his profession, he never lost his humanity and his warm sense of humor, attached to a boyish mischievousness to which he would at times give quiet expression. Apart from his career, he was a devoted husband, father, and grandfather and enjoyed his family enormously.

### “LINES OF ADVANCE IN PSYCHO-ANALYTIC THERAPY”

Originally planned for Breslau, the Fifth International Psycho-Analytical Congress—the first since the outbreak of the First World War—was eventually held on September 28 and 29, 1918, in Budapest, in the great hall of the Hungarian Academy of Sciences, with Karl Abraham presiding. It was there that Freud read this paper, which was published the following year.

Freud began by comparing the work of the analyst to that of the chemist, but warning against the idea proposed by some people that the analyst’s task was somehow to create a new synthesis from the elements he successfully isolated. For “psycho-synthesis is . . . achieved during analytic treatment without our intervention, automatically and inevitably” (p. 161). The therapeutic way forward, therefore, was rather that “activity” on the part of the analyst which Ferenczi had advocated.

After recalling that “Analytic treatment should be carried through, as far as is possible, under privation—in a state of abstinence” (p. 162), Freud stressed that “we must see to it that the patient’s suffering, to a degree that is in some way or other effective, does not come to an end prematurely” (p. 163), the danger being the weakening of “the instinctual force impelling him towards recovery” (p. 163). It was thus appropriate to put up “energetic opposition” to the substitute satisfactions that patients find in their various distractions, interests, activities, love affairs, and so on. Not to mention the satisfaction to be derived from the transference: “Any analyst who out of the fullness of his heart, perhaps, and his readiness to help, extends to the patient all that one human being may hope to receive from another, commits the same economic

error as that of which our non-analytic institutions for nervous patients are guilty” (p. 164).

Likewise, and contrary to the approach promoted by the Zurich school, Freud argued that the analyst must resist the temptation to educate the patient or “to force our own ideals upon him” (p. 164)—even though, with most patients, “occasions now and then arise in which the physician is bound to take up the position of teacher and mentor” (p. 165).

As examples of “new lines of advance,” Freud cited the active encouragement of phobics to confront their fears and the suppression of the compulsion of obsessional to prolong their treatment ad infinitum.

But the broader prospect opening before psycho-analysis was the mass of patients barred from analytic treatment by reason of their lowly place in society—this despite “the vast amount of neurotic misery which there is in the world” (p. 166). The day would come, Freud felt, when society would acknowledge the importance of mental health and open free clinics “to which analytically-trained physicians will be appointed” (p. 167).

In that event, Freud speculated, “the large-scale application of our therapy will compel us to alloy the pure gold of analysis freely with the copper of direct suggestion” (p. 168)—even, as had been true in the treatment of the war neuroses, with “hypnotic influence.” All the same, concluded Freud, “whatever form this psychotherapy for the people may take, whatever the elements out of which it is compounded, its most effective and most important ingredients will assuredly remain those borrowed from strict and untendentious psycho-analysis” (p. 168).

This text was rich in consequences. For several years, with respect to psychoanalytic practice, its approach underpinned the technical innovations of Freud himself (as when he terminated the treatment of the “Wolf Man”) and above all of Sándor Ferenczi—innovations which, in conjunction with those of Otto Rank, would define deep divisions still felt in the early twenty-first century.

Indeed Ferenczi and Rank soon published a joint work, *The Development of Psychoanalysis* (1924/1925), which shook up the psychoanalytic world and instantly attracted the hostility of the Berliners, with Karl Abraham in the lead. With a view to simplifying psychoanalytic treatment and shortening its duration, Ferenczi and Rank presented, though in a more systematic form, proposals already made by Freud,

among them the use of suggestion and hypnosis, and above all the setting by the analyst of a termination date for the treatment; these considerations were incorporated into Rank's almost simultaneous revival of the sharply contested idea of the "trauma of birth" (Rank, 1924/1929).

On another plane, Freud's venture into "social" issues was to have even more significant repercussions. As early as 1919, Max Eitingon and Ernst Simmel proposed to the Berlin Psychoanalytical Society that a polyclinic be established where the sort of free treatment that Freud had recommended at the Budapest Congress would be offered; a year later such an establishment was opened. Providing treatment naturally meant training more therapists, and the training institute soon set up in Berlin to meet this demand would become, roughly speaking, the prototype for all the similar institutes that were to follow.

The two great and opposing currents that as of 2005 continue to divide the psychoanalytical world—on the one hand research, codified communication, rigor, even orthodoxy, and on the other hand practical innovation, theoretical speculation, and the risk of counter-transference—had made themselves felt well before the 1918 Congress. But clearly Freud's observations, as he rediscovered a public audience at the close of the horrific First World War, contributed greatly to their renewed vigor and to their repercussions, which psychoanalysts still have to address in their day-to-day practice.

## LINGÜÍSTICA, INTERACCIÓN COMUNICATIVA Y PROCESO PSICOANALÍTICO

David Liberman distinguishes in his book between several models of "communication theory" with a view to using them in clinical psychoanalysis. He was interested in the influence of the modes of information transmission and reception in the transference because the patient's form of linguistic expression is a communication that is just as important as the content of the utterance. Theories of communication and the real and concrete effects that pathological communication produces on the mind are illustrated by clinical examples in psychoanalytic transference. We can see the influence of Gregory Bateson (1951), Paul Watzlawick (1967), and Rudolf Carnap (1942).

The first volume of the work is devoted to providing a methodological explanation of psychoanalysis as a science, as well as the empirical models and modes of corroborating hypotheses used in this domain. The second and third volumes present clinical examples of the reception and transmission of messages in the course of a session. The author introduces the notion of style, modeled on literary styles: narrative style (obsessional), epic style (psychopathic), and lyrical or emotional style (depressive).

Liberman presents a new typology founded not on psychiatry but on the three axes of communication theory—syntactic, semantic, and pragmatic—and their respective pathological distortions. Syntactic distortion appears through parapraxes in hysteria, semantic distortion through the altered meaning that the patient gives to a sentence, and pragmatic distortion through the real and concrete effects produced on the mind of the receiver, for example the use of the imperative mode, double meanings, and paradoxes.

Another original contribution from the author is the microscopic study of sessions with the help of notes and recordings in an effort to observe the slight syntactic and paraverbal changes that take place in the course of a treatment. Patients' tangential and disqualifying responses are also studied. For example, we can observe that the analysand's recourse to responses like

“perhaps,” “I’m not sure that’s true,” “I have my doubts” are a means of discrediting the interpretation. Microscopic analysis offers a more scientific basis—especially with the help of modern linguistic theories—and helps us to understand the process of the counter-transferencecountertransference, which is apprehended as an emotion to be decoded.

This work is one of the most influential in terms of its effect on how Latin American psychoanalysts are trained.

## LINGUISTICS AND PSYCHOANALYSIS

In 1890 the “science of language” had not yet become “general linguistics,” the “fundamental science” of the humanities it would become following the work of Ferdinand de Saussure (1857–1913). Philologists studied *scripta* (written traces) and the history of languages but not their origins or that of the original language (*Ursprache*), a search that was felt to be irrelevant to the science of language, according to the first article of the bylaws of the Société linguistique de Paris, composed in 1866.

From the point of view of linguistics, Hans Sperber’s article on the “sexual origins of language” (1912)

was more an application of Freudian theory than a form of linguistic research. Émile Benveniste’s rebuttal of Carl Abel’s claims about the opposite meanings of words (“Über den Gegensinn der Urworte,” 1885) starts from the same point: The discursive use of the euphemism or antiphrasis does not justify this claim. Moreover, there is no primitive language as far as linguists are concerned. Language is a system of signs, articulated through a process of differentiation, that organizes the first representation of the world by and for the speaking subject. At the beginning of the twentieth century, the distinction “*langage/langue*”—language as spoken versus language as system—used by de Saussure in his classes and published in the *Course on General Linguistics* after his death (1916), was not widely known.

Some philologists, however, became interested in spoken language, in everyday words, in the nature of the “system” or internal structure of language (*langue*). By collecting slips of the tongue, Rudolf Meringer (1895) attempted to determine the laws of evolution and the internal operation of *Sprachorganismus* (the organism of language), comparing it to Freud’s “language apparatus” (1891b). Freud borrowed eight examples from Meringer’s corpus, including the opening and closing remarks of the president of parliament (1901b). Meringer failed to be amused (1907) by Freud’s admiration for the quoted text. Freud in return wrote an ironic comment (1910e), distancing himself from Meringer on the basis of their divergent understanding of slips of the tongue. The two men held different points of view: Meringer prefigured the Saussurian break entailing the internal synchronic description of the structure of languages (that is, at the time of spoken use). His insistence on speech (*parole*)—which revealed the underlying structure—implied an emphasis on orality, the primary characteristic of languages.

De Saussure thus gave the world approximately five thousand languages and rejected the notion of “primitive” languages, which were languages with no written tradition. According to de Saussure, a language should be considered a highly organized structure, a “system of internal relations,” whose elements were arbitrary and differential and could be analyzed along two different axes: the paradigmatic (or associative) axis, the axis of elements that were “absent”; and the syntagmatic axis, the axis of elements that were “present.” These elements were defined in negative terms: “In language there is only difference.” On the plane of

sound as well as on the plane of meaning, each element is what the others are not (this was de Saussure's concept of "value"). The axis of the spoken chain can be used to postulate the temporal linearity of the sound (or acoustic) aspect of signs, that is, the "linearity of the signifier." A language is, thus, a set of articulatory, acoustic, and representative (or symbolic) conventions that are socially imposed on the speaker, a *Weltanschauung*, a treasure deposited in the individual by the mass of speakers.

The same position is found in the work of Édouard Pichon (linguist and psychoanalyst, founding member of the Paris Psychoanalytic Society, then its president in 1938), from whom Jacques Lacan borrowed the idea of "foreclosure" (*Verwerfung*). From de Saussure's work, Lacan derived the concepts of the "treasure of signifiers," the unconscious structured as a language, and the condition of the unconscious. From Roman Jakobson (1963) he derived the concepts of metaphor (paradigmatic) and metonymy (syntagmatic), and reworked the concepts of condensation and displacement. Lacan also borrowed from de Saussure the idea of the arbitrariness of the sign and its duality: signified and signifier. The signified is the mental image, the concept; the signifier the acoustic image (or phonetic form). This relationship is reversed and hierarchized in Lacan (S/s) with an extreme (non-linguistic) expansion of the signifier.

Saussurian arbitrariness—which is what makes his work so original—does not refer to the lack of motivation between object and sign (word) (*Sache/Zeichen*) discussed in Plato's *Cratylus*, but to the absence of a one-to-one relation between elements of the system of signifieds and signifiers. The concept of "double articulation" (Martinet, 1960/1964) demonstrates this: for linguists no meaning can be attributed to a phoneme or letter, something a linguist shaped by psychoanalysis like Ivan Fonagy (1970) rejects. For Fonagy, for example, language and unconscious, language and drive, are contiguous.

The same was true for Pichon, the author, with Jacques Damourette, of a voluminous grammar text and a large number of articles. It was Pichon who created the concepts of *pensée-langage*, which reflects the separation of form and content, and *sexuisemblance*, which reflects the connection between gender and sex. His work on negation (1928) and the grammatical person (1938), criticized by Benveniste as too "psychological," serves as the premise for the concept of the "shifter" in

Jakobson's work, and research on "enunciation" for Benveniste. Among linguists, including contemporary linguists who speak of the (re)introduction of the subject into their field (through pragmatics, the analysis of meaning or discourse), the subject is always (or almost always) a controlling intentional subject. The failure to identify intentionality, moreover, is what ended the Saussurian analysis of anagrams (the search for a proper name buried—disseminated—in the poetic chain), although they can be understood as a search for an unconscious subject.

This conscious and controlling subject marks the difference between linguistics and psychoanalysis. Here, their epistemological terrain is distinct. Linguists and psychoanalysts apprehend the same words in different ways. Linguists first try to describe languages and construct a scientific theory of their workings. Their concern is one of generalized objectivity, which could be described as an Aristotelian approach. Consequently, they attempt to eliminate any subjectivity, while psychoanalysts acknowledge it as part of the process of association. The analysts' goal is not to put forth a theory of language but of the unconscious. This is why there are so many differences between the two fields in spite of the many borrowings by psychoanalysts from linguists (philologists for Freud) in the first half of the twentieth century.

Today, however, the situation is reversing itself, and some psychoanalysts consider the near "assimilation" of the mental apparatus to the language apparatus to be a failure (Green, 1984, 1989). Moreover, the number of linguists and semiologists who acknowledge the influence of psychoanalytic theory in the humanities is growing. For example, research on the contiguity between these two fields (Michel Arrivé, Jean-Claude Milner) has been conducted by linguists who have undergone analysis or who are analysts themselves; they have introduced psychoanalytic ideas into research on sign systems, writing, enunciation, modes of text analysis, meaning, and so forth. Links between the fields exist despite the fact that their founders never met. Freud may have seen de Saussure's name quoted by Meringer; de Saussure may have seen Freud's in a report on *The Interpretation of Dreams* written by one of his colleagues at the University of Geneva (Théodore Flournoy). And although Freud never read de Saussure, it is certain that he heard him referred to as the "father" and author of the *Course of General Linguistics*. For one of Freud's patients was

Raymond de Saussure, the son of Ferdinand, and Freud wrote a preface to Raymond's *The Psychoanalytic Method* (1922), where his father's book is mentioned.

## LINKING, ATTACKS ON

Wilfred Bion's notion of "attacks on linking" was first expounded in "Attacks on Linking" (1959) as part of his innovative work on psychosis. Attacks on linking are destructive attacks from the psychotic part of the personality directed against all links between objects. An internalization of an "ego-destructive super-ego," as Bion called the figure which attacks links of emotion and reason between objects, occurs when the relationship between mother and infant lacks the normal links of primary communication by projective identification. He thinks that the chief source of the failure of primary communication in such cases stems from an inborn disposition of excessive hate and envy in the infant whose situations is worsened if the mother is unreceptive, and diminished but not abolished if the mother can introject the infant's violent feelings while remaining balanced.

Bion showed the theoretical importance of the concept of "attacks on linking" for understanding some symptoms in borderline patients. Lacking a state of mind capable of making links for growth, the patient feels that his mind is an ongoing disaster which he fears is incapable of resolution. Moreover, since there is a deficiency of curiosity in his psyche, any development which depends on enquiry is impossible, and the links in his mind remain perverse, cruel, and sterile.

In clinical practice the concept of "attacks on linking" shifts the analyst's attention in an important way—from the nature of the object to the nature of the relations between objects, i.e., from structures to functions. Attacks on linking manifest themselves in the attempted destruction of the inner mental functioning of patient and analyst, and on the verbal and nonverbal communication which is the link between them. Problems in the analysis tend to become focused not on why but on what, in the sense of what the function of the analysis and the analyst are for the patient.

Bion's notion of "attacks on linking" fits Freud's description in *Civilization and its Discontents* of the

death instinct as an instinct seeking to dissolve units. It is also an elaboration of Klein's concept of splitting.

## **LISTENING**

Listening must be distinguished from audition. Audition is the function and exercise of the sense of hearing, whereas listening is much more global. Listening is simultaneously being sensitive to words, the voice that carries them, and the broader context of human communication. The relationship that links patient and psychoanalyst can be understood as listening, each listening to the other.

The psychoanalyst's relation with the patient is different from that of ordinary life. The psychoanalyst listens in silence (silence is an opening into the unconscious), listens without according priority to the content of the words, listens to the voice and the body and the affects expressed through them. The analyst's sensitivity to the effects of the voice is amplified by being in a state of free-floating attention, unaffected by the requirements of dialog, the need to respond, the interplay of ideas, and considerations of politeness. Intonation is a subtle vocal posture and expression, and tone creates a music that influences the analyst's counter-transfer and warns the analyst against repression. Analytical listening is accompanied by a benevolent, receptive attitude that abstains from all critical evaluation and judgment. Such listening affords patients a space in which, free from visual confrontation, they can deploy their imagination in free association. The psychoanalyst's listening is the patient's guarantee that the Other is present, referring the patient back to the primordial Other and all its successive representations.

By listening to what the patient says, the analyst becomes sensitive to the former child, animated by the "instinct to listen" (Bernard This, Piera Aulagnier) to the sounds of the primal scene, among other things.

For patients, the psychoanalyst's listening enables them first to hear a voice that refers them back to the benevolent voice of the first stages of life and that they can progressively introject while engaged in free-floating listening, and then to hear words enabling them to bring their histories to life by deploying their own unconscious forces. Patients have a special dialog with the analyst that requires reworking their energies in as complete and free a way as possible. Listening to the analyst's words shatters thought systems and promotes change, the analyst's reflections being brief, incomplete, and ambiguous interventions rather than explanatory interpretations. The two types of listening thus promote the elaboration of a powerful synergy.

## **LITERARY AND ARTISTIC CREATION**

Freud considered literary creations and, more generally, artistic creations enigmatic because of their ability to produce emotion in the spectator (the essence of art) and in regard to the origin of themes chosen by authors. Far from contenting himself with applying the psychoanalytic method to the analysis of works of art, Freud emphasized the heuristic value of such works for the psychoanalytic study of the human psyche. Literature and art occupy a considerable place in his work (the works of Goethe and Sophocles being among the first), as in the work of his disciples (Nunberg and Federn, 1962–1975).

In works of literature Freud identifies and confirms several clinical observations, the most perceptive being the Oedipus complex in Sophocles' *Oedipus Tyrannus* and his analysis of Hamlet in Shakespeare's *Hamlet*. Freud treats the characters of fiction, more than their authors (pathography), as true clinical cases. Freud (1907a [1906]) wrote that Wilhelm Jensen's fantasy (*Gradiva*) could be subtitled a "psychiatric study," although he simultaneously questions the value of the subtitle, because the author ignores (as does psychoanalysis itself) the split between the normal and the pathological.

It is easy to see how novelists would interest Freud, since their literary creations are based on self-analysis: "[The author of a literary work] directs his attention to the unconscious in his own mind, he listens to its possible developments and lends them artistic expression instead of suppressing them by conscious criticism. Thus he experiences from himself what we [psychoanalysts] learn from others—the laws which the activities of this unconscious must obey" (1907a [1906], p. 92). The novelist is a psychoanalyst who lacks the technique and patients but is capable of incorporating in his art his knowledge of the unconscious acquired through self-observation. To the extent that the author projects himself into his characters, this disposition justifies describing what authors do as psychoanalytic analysis. Thus in "Dostoyevsky and Parricide" (1928b [1927]), Freud simultaneously analyzes *The Brothers Karamazov* and Dostoyevsky, and he deepens our understanding of the concept of castration through his analysis of hysterical epilepsy.

The third element in the psychoanalytic study of literary creation, after the characters and the author, is the reader. In "Psychopathic Characters on the Stage" (1942a [1905–1906]) and "Creative Writers and Day-Dreaming" (1908e [1907]), Freud emphasizes what the reader gains by identifying with the hero. In addition to Aristotelian catharsis, such identification "gives people the sense, which they so much desire, of a raising of the potential of their psychical state" (1942a [1905–1906], p. 305). At first, it is surprising to see pleasure and tension identified in this way, but there is a simultaneous discharge of the tension involved, since the reader continues to enjoy the contrast between the tribulations of the hero and his own personal security. In literature there are several sources of satisfaction: pleasure in the heroic revolt against the father or his representations, masochistic pleasure in

identification with the hero, and pleasure in not being threatened in the real world.

In Freud's work, artistic creation occupies a less important place than literary creation. In *Leonardo da Vinci and a Memory of His Childhood* (1910c), Freud mainly emphasizes the conflict between artistic realization and scientific investigation. But Freud also examined the origin of the design of the painting *Mona Lisa* (the smile of Mona Lisa, said to be Anna Metterza). His examination led to an interpretation that associated a vulture with Leonardo's memory traces from childhood. The risks and limitations of such interpretations are illustrated by Freud's famous translation error, since the "vulture" was in fact a kite.

The fecundity of such study of works of art extends well beyond the question of artistic creation, for the psychoanalytic study of works of art develops new insights into homosexuality, again attesting to its heuristic value. In turn, analysis of a work of art can implicate the analytic method, as shown in "The Moses of Michelangelo" (1914b), which is carried out as if Freud were listening to a patient, incorporating details that would generally be overlooked. Here, as elsewhere, Freud compares his point of view with those of other disciplines, especially art history.

After Freud many other authors continued his work on creativity, enlarging the study to other fields (primarily music). It is worth noting that Freud did not include in his study the field he knew best, namely theoretical creativity. This oversight reflects the division he established between fantasy and critical reason, while he himself served as proof of the effectiveness of theoretical fantasies (the witch of metapsychology).

Since Freud, literary and artistic creation has also been extensively studied in its relation to psychopathology (psychosis), and this has given rise to clinical developments of unequalled value in the field of "art therapy."

## LITERATURE AND PSYCHOANALYSIS

Since the origins of psychoanalysis, the field has displayed a powerful set of connections to literature, one that might even be called a mutual fascination. Literary criticism, primarily in its academic form, has been the major mediator between the two disciplines. The three domains of psychoanalysis, literature, and literary criticism (or literary theory) intertwine and seek to use each other in distinctive ways. Psychoanalysis has occasionally sought to explain literature but far more often uses literature as a source or exemplar for psychoanalytic conceptions themselves. Literary criticism has sought to use psychoanalytic theory to explain literature, and even literature itself has sometimes sought to exploit psychoanalysis for creative purposes.

The relation of these three domains manifests particular predilections. For example, the fascination of literary critics with psychoanalytic theory from Sigmund Freud to Jacques Lacan has been far greater than the interests of historians in the same conceptions despite the fact that such theories can be as easily applied to historical phenomena as to literary ones. The field of psycho-history remains relatively marginal in American and European universities, while psychoanalytic concepts permeate most branches of literary studies. Within literature departments, interest in psychoanalytic theory eclipses attention (when there is any at all) to other systems of psychology, like behaviorism or neurological/biological approaches. Yet this does not echo the balance of forces in the same universities' psychology departments, where the situation is almost opposite.

Affinities between literature and psychoanalysis are both cultural and structural. Culturally, it is not a

coincidence that the two greatest literary dissections of the modern soul (James Joyce's *Ulysses* and Marcel Proust's *A la recherche du temps perdu*) appeared around the same time as Freud's foundational *Interpretation of Dreams*. This temporal connection is less a question of influence than of participation in a common culture. Structurally, psychoanalysis elicits and tells stories. Like most of literature, it is structured around narratives. Talk therapy is necessarily mediated by language. Psychoanalysis explores the complexities of the human soul, long a major preoccupation of literature. Already true for Freud, this structural affinity was deepened by Jung, whose system of archetypes is linked both to the creative imagination and to myths, using the universality of myths to demonstrate the collective unconscious. Lacan continues the trend with his notion that the unconscious is organized on the principles of human language (as these were conceptualized by the structural linguistics of Ferdinand de Saussure and Roman Jakobson). Language is transformed by Lacan from a mediator between the unconscious and the therapeutic realm to something that defines the unconscious itself.

Freud turned to literature both for evidence of his mappings of the unconscious and to explain what he found there. The Oedipus story, which reached Freud through the literary medium of Sophocles's tragedy to become the Oedipus complex, is the best-known example of this phenomenon. Bruno Bettelheim's classic *The Uses of Enchantment* similarly exploited the world of fairy tales to illuminate child psychology, and vice versa. More recently, in the Jungian school, Helen M. Luke in her *Dark Wood to White Rose* uses Dante's *Divine Comedy* for evidentiary, explanatory, and psycho-therapeutic purposes. Lacan himself turned his attention to Shakespeare and Edgar Allan Poe. A legion of writers from the therapeutic community has explored the psychoanalytic bases of fairy tales, popular literature, and even the texts of the Bible.

Such connections are possible because psychoanalytic theory has always seen literature and the arts generally as owing much of their appeal to their ability to express unconscious content in masked form, as well as their ability to act as vehicles of fantasy, and, in Freud's case particularly, as socially acceptable sublimations of erotic drive.

The greatest influence of psychoanalysis on literary production has probably been to add legitimacy to the already-existing trends towards greater psychological

introspection and towards more prominent and franker discussions of sexuality. Though Freud was never an exponent of sexual freedom, merely arguing that his own culture took sexual repression too far, wider circles have treated him as a liberator of sexual expression, whether to blame him or to laud him for this. (Would we have had Henry Miller without Freud?)

Between the world wars in the twentieth century, the politico-artistic school of surrealism championed psychoanalysis as an overture to new aesthetic domains. This impact has probably been clearest and longest in surrealist visual arts. But the surrealist literary school developed the practice of automatic writing as a way of tapping into the unconscious, all this under the influence of the Freudian revolution in psychology.

The closest connection between literature and psychoanalysis has always been articulated by the academic field of literary criticism or literary theory. In the United States, where the acceptance of Freud was earlier and greater than in Europe, Frederic C. Crews, Norman Holland, and Harold Bloom were among the most visible members of a large school of literary criticism that sought to apply Freudian concepts to the explication of literary texts. Crews and Holland later shifted positions. Crews to a more critical view of Freud, and Holland, more recently, to an interest in cognitive psychology and neurobiology.

Following the fashion for French theory, Jacques Lacan became increasingly prominent, contributing, for example, to a fascination with the idea of desire as fundamental to the nature of literary texts. The Slovenian Slavoj Žižek, who uses Lacan (along with Marxist theory) in his literary and cultural analyses, has become increasingly influential in Europe and America. While feminist literary critics have challenged specific conclusions of psychoanalytical schools from Freud to Lacan, they have generally done so more in an attempt to redefine and recuperate the psychoanalytic universe than to set it aside.

Perhaps most typical of the affinities between literature, literary criticism, and psychoanalysis has been the fact that some figures have been able to master all three. The protean writer Julia Kristeva, for example, is at once a trained psychoanalyst, a well-known literary critic (whose writings use both literature and psychoanalysis to deepen the understanding of each), and a successful author of imaginative fiction. Thus, while in the mass media interest is increasingly turning to drug

therapies and neurobiological explanations of behavior, elite culture manifests a continuing interpenetration of the worlds of psychoanalysis and literature. The case of Norman Holland, though it may portend future trends, remains atypical.

## **LITTLE ARPÅD, THE BOY PECKED BY A COCK**

“Ein kleiner Hahnemann” (a little cock-boy) is the fictitious name Sándor Ferenczi, in 1913, gave to little Arpåd, a previously well-balanced five-year-old boy who suddenly decompensated, the pathology comprising a set of perversions and regressions associated with modifications in language and behavior. The case is an example of an on-going psychotic phase after trauma: “A chicken or a capon with yellow feathers (sometimes he said brown) bit his penis and Ilona, the chamber maid, dressed the wound. Then they cut the cock's throat and it ‘dropped dead’” (Ferenczi, 1927).

Little Arpåd's pathology became manifest after a latency period of one year without any apparent disorder except perhaps a compulsion to masturbate. (This compulsion called for an investigation into any threats made to little Arpåd.) During his consultation with Ferenczi, little Arpåd was hypomaniac, with sadistic fantasies about the cruel punishments he imposed on himself, religious ruminations, and megalomaniac plans to marry all the women around him, like a

veritable “village cock” (identification with the aggressor). In *Totem and Taboo* (1912–1913a), Freud takes this description as an example of “positive totemism,” comparable to the case of “little Hans,” where we find displaced manifestations of ambivalent affect and identification with the totemic animal.

This story, a clinical illustration of genital trauma experienced prior to puberty, is paradigmatic in Ferenczi’s work. But alongside the sexual wound acting as a trigger (“We think of fruit that becomes too quickly ripe and sweet when injured by the beak of a bird, and the precocious maturity of a worm-eaten fruit,” as Ferenczi was to later write in 1949), there is a threat of castration coming from the family environment prior to the trauma.

### **LOEWENSTEIN, RUDOLPH M. (1898–1976)**

A physician and training analyst, Rudolph M. Loewenstein was born in Lodz, Poland, on January 17, 1898, and died in New York on April 14, 1976.

Born into a Jewish family, Loewenstein attended secondary school in Zurich, then pursued studies in medicine and neurology in Berlin, where he trained at the Psychoanalytic Institute (1923–1925). He was analyzed by Hanns Sachs, and probably worked under the supervision of Max Eitingon. He was admitted as a

member of the German Psychoanalytic Society (DPG) and in 1925 became an assistant at the outpatient clinic, where he gained recognition as a young and brilliant training analyst.

Eitingon then recommended Loewenstein to René Laforgue to train other analysts. A polyglot, capable of expressing himself with equal fluency in Polish, German, English, and French, he had no difficulty practicing analysis in the various countries in which he was to live. He settled in Paris as a training analyst in 1925 and trained the first generation of analyzed analysts. In 1926 he participated, along with Laforgue, Eugénie Sokolnicka, Marie Bonaparte, and others, in the creation of the Société psychanalytique de Paris (SPP, Paris Psychoanalytic Society) and became the society’s secretary. He also contributed, in 1927, to the creation of the *Revue française de la psychanalyse*, financed by Bonaparte, through whom he met Sigmund Freud several times. He became a naturalized French citizen in 1930 and resumed his studies, earning baccalaureate and doctorate degrees in medicine; the defense of his thesis, “La conception psychanalytique des troubles de la puissance génitale chez l’homme” (The psychoanalytic conception of male sexual impotency), in 1935, was presided over by Professor Claude Henri. He was director of a psychoanalytic seminar at the SPP until 1939; that year he was mobilized as a doctor in the French army, where he was decorated with the Croix de Guerre. After the armistice of 1940 he took refuge in Marseilles, where he practiced and taught psychoanalysis up until his departure for the United States in 1942.

Forced into exile, he settled in New York in 1943, maintaining his institutional and personal connections with French psychoanalysis, for which he was the New York correspondent. Rapidly recognized as a training analyst, he was soon enlisted to fill all the major institutional functions: president of the New York Psychoanalytic Institute (1950–1952), secretary and then president of the New York Psychoanalytic Society (1959–1961), president of the American Psychoanalytic Association from 1957 to 1958, and finally vice president of the International Psychoanalytic Association (IPA) from 1965 to 1967.

In 1952 Loewenstein published *Christians and Jews: A Psychoanalytical Study* (published in French under the title *Psychanalyse de l’antisémitisme*), but in terms of theory, he is mainly known as the cofounder of the new American psychoanalytic school of the

1950s, and for his work in ego psychology; his name remains associated with those of Ernst Kris and Heinz Hartmann, his collaborators in research. Taking up a point that was indicated in Freud's work, but that he developed into a theory, ego psychology, he gave privileged status to the unconscious ego over the instinctual drives and moved it towards the center of the psychic system.

This theory has been called a psychology of adaptation, which Loewenstein was to expound and defend in "Rapport sur la psychologie psychanalytique de H. Hartmann, E. Kris et R. Loewenstein" (Report on the psychoanalytic psychology of H. Hartmann, E. Kris, and R. Loewenstein), presented to the Twenty-sixth Congress of French-speaking Psychoanalysts, held in Paris in 1965. Unanimously criticized in Europe, ego psychology is certainly historically linked to the issue of immigration.

At the end of his life Loewenstein was working with Milton Horowitz on the theory of psychoanalytic technique, trying to conceptualize his five years of practice as a training analyst.

Loewenstein played an important institutional role within the psychoanalytic community, not only in the three countries where he practiced, but also on an international level (IPA). Jacques Lacan underwent an analysis with him—terminated too soon, against the advice of his training analyst. He was also the training analyst for Sacha Nacht, Daniel Lagache, Michel Cénac, Pierre Mâle, Georges Parchemeney, John Leuba, and others. Supervisor and later a friend of Marie Bonaparte, he helped her with her 1935 translation of Freud's *Five Lectures on Psycho-Analysis*.

## LOGIC(S)

*Logic* refers to the formal structures determining a coherent order in a sequence of ideas. With its notion of the primal, psychoanalysis has extended the question of logic beyond conscious rational thought and developed hypotheses on the primitive modalities (modes) of representation.

According to Freud in the "Formulations on the Two Principles of Mental Functioning" (1911b), "It is probable that thinking was originally unconscious in so far as it went beyond mere ideational presentations and was directed to the relations between impressions of objects, and that it did not acquire further qualities, perceptible to consciousness, until it became connected with verbal residues" (p. 221). The earliest psychoanalytic view of logic is thus limited to connections, if not among objects themselves, at least among the subjective impressions they leave on the observer, which then unite with memories of other analogous perceptions.

With *The Interpretation of Dreams* (1900a), Freud demonstrated the logical functioning of unconscious thought by elucidating the opposition between "primary process" and "secondary process." Thus causality, the basis for reasoning in conscious thought, is expressed in dreams by means of simple succession, where the main clause is represented by the most developed part of the dream and the dependent clause is represented by the briefest part: "'Because I am of such low descent, the course of my life has been so and so'" (p. 315).

In this essay, Freud asked: "What representations do dreams provide for 'if', 'because', 'just as', 'although', 'either/or', and all the other conjunctions without which we cannot understand sentences or speeches?" He concluded that "dreams have no means at their disposal for

representing these logical relations between the dream-thoughts. For the most part dreams disregard all these conjunctions, and it is only the substantive content of the dream-thoughts that they take over and manipulate. The restoration of the connections which the dream-work has destroyed is a task which has to be performed by the interpretative process" (p. 312).

Freud's thinking suggested, if not a plurality of logics, at least diversity in their modes of representation, and this idea was extended by other authors. Melanie Klein and Wilfred Bion showed how the logic of the infant's fantasies corresponds to relational categories other than that of causality (for example, destructive desire in response to frustration or projective identification). Piera Aulagnier, described categories of the primal (pictogram), the primary (fantasy), and the secondary (idea)—representational modalities impelled by specific logics: the postulate of self-procreation, the all-powerfulness of the desire of the other, and causality, respectively.

In *Les Logiques de l'inconscient* (Logics of the unconscious; 1978), Michel Neyraut reexamined and analyzed the issue of the plurality of logics (primitive, primary, and secondary), thus reinitiating reflection on the opposition between the rational and the irrational.

## **LOOK/GAZE**

"The look," also translated as "the gaze," refers to the activity of intentionally directing one's vision toward

something. It implies the anticipation of an image and a narrowing of the visual field.

With his prior experience with the gaze in hypnosis and with his invention of the analytic couch, Freud showed that he was acutely aware of the important axis that ran from the eye of the analyst to the look of the analysand and of the perceptual asymmetry that resulted from it. He openly declared that he could not bear to spend his entire working day being stared at by the patients he was treating. Contrary to Jean Martin Charcot, he dispensed with the omnipotent look in treatment and even came to consider it a kind of mistake. By characterizing the look as an element of the scopic drive, he opened the way to a series of reflections preserved in his metapsychology, most notably, his study of the voyeur/exhibitionist opposition.

Referring to the "split" between the look and vision, Jacques Lacan, following up on his work with the optical schema of the inverted bouquet as reflected in a mirror, made the look the object of the scopic drive, developing a theory that "most completely eludes the term castration" (Lacan, p. 78). In neurosis, the other's look is most often experienced by the subject with an "uncanny" feeling. In psychosis, the look can amount to persecution leading to a breakdown if it comes to be confused with its source, the eye. And finally, the look, focused on sex, plays an essential role in the genealogy of perversions.

What does "the look" look for? And what is looked at? For Lacan, the phallus is what is looked for, and castration is what is found. The phallic reaction, in the form of erection or a petrified look, is a response to fear of castration. For the subject, the scopic drive is expressed by the appearance or disappearance of the look. From that point on, the subject will use what is supposedly the other's look to construct the fantasy of castration and to make that fantasy seem possible: "I see from only one point," Lacan said, "but in my existence I am looked at from all sides" (1978, p. 72). The myth of Medusa shows that individuals use protective images to try to defend themselves against erection or petrification by the other's look.

Donald Winnicott, in his reflections on why the baby's look turns toward the mother's face, and Françoise Dolto, by insisting that the look plays an important role in symbolizing the difference between boys and girls, both emphasized the structuring role of visual activity. At the beginning of the twenty-first century, psychoanalytic research attempts to draw a

distinction between the drives of seeing and looking. In the treatment of perversions, the field of the look is considered in its relation to speech. The look thus constitutes an organizational schema for the person, as is shown by its overdetermination in various cultures in ways that cut across the fields of the visible and the invisible, such as the “evil eye,” a voracious invidious look.

## **LORAND, SÁNDOR (1893–1987)**

Sándor Lorand, a physician, psychoanalyst, and professor of psychiatry, was born on December 2, 1893, in Kassa, Hungary, and died on July 29, 1987, on Long Island, New York.

Born into an Orthodox Jewish family that had been farmers for two generations, Lorand first studied theology, then philosophy (earning a PhD), and finally medicine at the University of Pressburg (now Bratislava), where he earned his medical degree in 1920. The 1918 Budapest psychoanalytic congress impressed him “so much that [he decided] to become a psychoanalyst” (Lorand, 1963). He discovered the writings of Sándor Ferenczi, took the initiative of writing to him to discuss the latter’s theory of hypnotic suggestion, and attended Ferenczi lectures in the medical faculties. While working as a physician attached to the hospital

at Kosice in Czechoslovakia, Lorand arranged in 1921 for Ferenczi to present a paper on “Psychoanalysis for the General Practitioner” to his colleagues. During 1923–24, Lorand was analyzed by Ferenczi and did training work with Paul Federn and Vilma Kovach.

That same year Lorand return to the hospital at Kosice and, following Friedlander in the Netherlands, experimented with a technique for painless childbirth that utilized hypnosis. Despite Ferenczi’s wish that Lorand remain in Czechoslovakia to disseminate psychoanalysis, he decided to emigrate because of the unstable political situation. He settled in New York in 1925 and, with the encouragement of Professor Kirby and Abraham A. Brill, became an American citizen and retook his medical exams. He established a private practice in psychoanalysis and also worked at the Mental Health Clinic of Mount Sinai Hospital. In 1926 he arranged for Ferenczi to lecture at the American Association for Psychoanalysis and at the New School in New York.

Lorand was a training and supervising analyst at the New York Psychoanalytic Institute, where he taught analytical theory and technique to several generations of candidates. He wrote numerous papers, among others on fetishism, nudism, the character of inventors, depressive states, perversions and fairy tales, and liliputian dreams. The range of his writings bears witness to his anthropological and clinical focus, in the tradition of Ferenczi and Géza Róheim. Lorand dedicated *Clinical Studies in Psychoanalysis* (1950) to Ferenczi and edited *Psychoanalysis and Culture* (1951) in honor of Géza Róheim.

## LOS ANGELES PSYCHOANALYTIC SOCIETY AND INSTITUTE

Psychoanalysis in Los Angeles enjoyed considerable success after World War II. A fairly large contingent of working analysts, frequently with university and hospital affiliations, had busy practices and widely enjoyed intellectual prestige. On an institutional level, however, West Coast analysis was notable for conflicts that, though largely healed by the 1990s, included splits, internal tensions, and damaging personal rivalries.

The beginnings of psychoanalysis in Los Angeles date to an informal study group in the late 1920s. By the mid-1930s a more formal group had been organized under the aegis of the Chicago Institute for Psychoanalysis, with Ernst Simmel, originally of Vienna, as the first of a number of highly-regarded European analysts who, once in the United States, migrated to California. The arrival of Otto Fenichel, the eminent analyst and prolific author formerly of Berlin, was another key addition; others included May Romm, Frances Deri, and Hannah Heilborn, whom Fenichel eventually married.

The Los Angeles Institute was founded in 1946. Although financial resources were at first strained, with some classes for analysts-in-training held in a nursery school, the institute eventually established itself in Beverly Hills as the profession itself became a highly regarded specialty, with its practitioners much in demand.

From the beginning, however, tensions among members caused strife at the institute, which led to a factional crisis and split in 1950. The reasons for the split seem to have been both personal and ideological, with nonmedical analysts as a major issue. Some of the institute's founding members, including Otto Fenichel, were not against lay analysis, which Freud himself had supported, but others, Martin Grotjahn and May Romm among them, were strongly opposed. This issue, which arose even before the institute was founded, was particularly difficult to resolve, in part because newly arrived European analysts, even if physicians, were compelled, whether by state law or

evolving custom, to retrain in the United States if they wished to be considered doctors. Indeed, Fenichel was undergoing a medical internship when he died unexpectedly in 1946, perhaps from the rigors of hospital work.

The Institute for Psychoanalytic Medicine of Southern California emerged as the breakaway group of medical analysts in the 1950 split, while the Los Angeles Institute retained its name, and both groups affiliated with the American Psychoanalytic Association. The Los Angeles Institute did not programmatically eschew nonmedical analysis and so retained its European-trained contingent. The preponderance of its members were especially insistent on orthodox Freudian theory and technique. By way of contrast, the medical group was strongly influenced by novel ideas in analysis, such as the practice of short-term therapy and "corrective emotional experience," originally promoted by Franz Alexander.

During the 1950s both institutes flourished in the heyday of psychoanalysis in the United States. By the early 1960s, however, the Los Angeles Institute was again riven with internecine strife. A good deal of the tension revolved around the rivalry of two of the institute's most prestigious members, Ralph Greenson and Leo Rangell, each in his way a charismatic figure. Greenson became (like his training analyst Fenichel) the author of a key textbook on psychoanalytic technique; Rangell was also prolific and twice served as president of the American Psychoanalytic Association. Their rivalry was said to have negatively affected the institute's training program.

By the time reorganization of the training program reduced these problems to manageable proportions, the Los Angeles Psychoanalytic Society and Institute, as it was called from 1967, was embroiled in conflicts over the controversial introduction of Kleinian thought into American psychoanalysis. For its part, the American Psychoanalytic Association eschewed the views of Melanie Klein and long ignored the significance of her intellectual successors, such as W. Ronald D. Fairbairn and Donald W. Winnicott, who fruitfully developed object-relations theory. Los Angeles, far from the East Coast centers of psychoanalysis, became for a time a key destination for visits by British Kleinians and object-relations theorists, including Wilfred Bion and Herbert Rosenfield.

Growing enthusiasm for British theorists, particularly at the Los Angeles Psychoanalytic Society and

Institute, led the Kleinians to engage in a bitter fight for acceptance from that organization, amid attacks from within and without. A report by a committee from the American Psychoanalytic Association after a site visit in 1973 accused the institute training program of a variety of faults, an accusation that many viewed as connected to the credibility that some of the analysts at the institute accorded Kleinian thought. In the tumultuous period that followed, a new split threatened, with the Kleinians at one point prepared to go to court. However, issues of both training and theoretical orientation were resolved by the late 1970s and the institute remained unified.

In the 1980s, when psychoanalysis began to lose intellectual ground to biological psychiatry and analysts began competing for patients with practitioners of a welter of new therapies, both institutions adapted to the changing times in a variety of ways. Continued intellectual strife was not absent, but there was also dialogue, tolerance, and movement toward pluralism. The advent of Heinz Kohut's self psychology may have played a role in this process, both by creating conflict and by enabling resolution without the same magnitude of acrimony as in earlier crises.

In contrast with the turbulence at the Los Angeles Psychoanalytic Society and Institute, the Southern California Psychoanalytic Society and Institute, as the breakaway progeny of the 1950 split eventually became called, remained relatively calm for several decades until the influence of self psychology led to strife within the organization in the late 1980s. The Southern California body gave up its insistence on psychoanalysis as a medical specialty, and it actively developed and cultivated a psychoanalytic training program for academics in a variety of fields. In addition, it welcomed Franz Alexander, who moved from Chicago to end his career in California, and was the home organization of Judd Marmor, who served as president of the American Psychiatric Association and, during the 1970s, was influential in deleting homosexuality as a mental disorder in the third edition of the *Diagnostic and Statistical Manual of Mental Disorders (DSM-III)*.

Over the course of several decades, new institutions broadened the base of psychoanalysis in Los Angeles. The Los Angeles Institute and Society for Psychoanalytic Studies, an organization of psychologists and educators, was founded in 1970 and eventually became affiliated with the International Psychoanalytical Association. It offers a training program for mental-health

professionals from a variety of backgrounds. Kleinian analysts, who remained influential in both the Los Angeles Psychoanalytic Society and Institute and the Southern California Psychoanalytic Society and Institute, went on to form the Psychoanalytic Center of California, which joined the International Psychoanalytical Association in 1989. Analysts devoted to self psychology formed the Institute of Contemporary Psychoanalysis in 1990.

As a sign of convergence among analysts on the West Coast, though not without some turmoil and resignations, soon after the turn of the twenty-first century negotiations were begun for a merger between the Los Angeles Psychoanalytic Society and Institute and the Southern California Psychoanalytic Society and Institute. Both institutes are located in the mainstream of psychoanalytic thought, and each is similarly engaged in training psychiatrists as well as postgraduates in the fields of medicine, psychology, social work, marriage and family counseling, law, and the humanities.

## LOST OBJECT

According to Sigmund Freud, the loss of the object is a two-step process whereby the subject is constituted. First, the earliest partial object, the breast, is lost. Then the primary love object, the mother, is likewise lost.

The earliest sexual object is the breast, and the earliest source of satisfaction for the sexual instinct is the encounter between two partial objects, the infant's mouth and the mother's breast. In *Three Essays on the Theory of Sexuality* (1905d), Freud explained that the breast becomes a lost object "just at the time, perhaps, when the child is able to form a total idea of the person to whom the organ that is giving him satisfaction belongs" (p. 222). Loss of the object of the oral instinct is thus a precondition of access to the total person as a

possible love object. At the same time, however, this loss opens the door to autoeroticism for the infant as the infant assumes a complete body image. The infant, though in a passive position, is active with regard to a part of its own body, and this enables the infant to find a source of satisfaction that is the first substitute for the breast.

Later the lost object becomes the “whole person” in the context of the “Fort!/Da!” game described by Freud in *Beyond the Pleasure Principle* (1920g). Here separation from the object is addressed in two ways: either the child expresses an impulse to master the object by breaking it, casting it aside, or incorporating it in fantasy (and so working it over in the psyche), or the child bypasses the need for the object by regarding it as a lost object beyond the reach of the self. With the recognition of the absence of the object, therefore, the child makes a transition, as a result of working over in the psyche, to a capacity to do without the object.

When the subject does not recognize the object as lost, as in melancholia, the object is incorporated in fantasy, where it maintains a silent existence within the subject. Freud described this process in “Mourning and Melancholia” (1916–1917g [1915]). Object loss can also provoke anxiety, mourning, or pain, as Freud outlined in *Inhibitions, Symptoms, and Anxiety* (1926d [1925]).

After Freud, a number of psychoanalysts took up the lost object and developed it in their theories. Melanie Klein described internal objects in “Mourning and Its Relation to Manic-Depressive States” (1935). Jacques Lacan theorized that object *a* is substituted for the lost object. And Nicolas Abraham and Maria Torok related mourning and melancholia to the lost object.

## **LOVE**

From a psychoanalytic point of view, love is the investment in, and ability to be loved by, another without experiencing this love as a subjective threat, such as that represented by the Thing (*das Ding*) which Freud described in the Project of 1895. For psychoanalysis the genesis of the love investment must be taken into consideration and the very different modalities through which it manifests itself must be identified.

It is important to differentiate love from infatuation or being in love (*Verliebtheit*), which is associated with a pathological feeling (*Leidenschaft*): “That the state of being in love (*Verliebtheit*) manifests itself abnormally can be explained by the fact that other amorous states outside the analytic cure resemble abnormal rather than normal psychic phenomena” (1915a). Being in love is essentially marked by an overestimation of the love object and a devaluation of the self that resembles the condition of melancholia (1921c).

The genesis of love begins with the oral relation of the infant’s mouth and the mother’s breast: “The picture of the child at the mother’s breast has become the model of all sexual relations” (1905d). Also, in choosing an object later in life, the child will attempt “to reestablish this lost happiness” (1905d). But this happiness, even if it is marked by this choice of a primary infantile object, must later reunite and conjoin two libidinal currents, the tender current arising from infantile cathexis and the sensual current that appears during puberty, “The man will leave his mother and father—as the Bible indicates—and will follow his wife—tenderness and sensuality are therefore reunited” (1912d). This can only occur through the loss of the infantile object choice: “The individual human must devote himself to the difficult task of

separating from his parents,” as Freud indicated in the twenty-first of the *Introductory Lectures on Psychoanalysis* (1916–1917a [1915–16]). Yet, in “On the Universal Tendency to Debasement in the Sphere of Love” (1912d), Freud recalls the difficulty of loving and the numerous splits that remain: “When they love, they do not desire, and when they desire, they cannot love.”

In “Instincts and their Vicissitudes” (1915c), he examines the different splits and oppositions in which love plays a role; these are: loving/hating, loving/being loved, and loving and hating together in opposition to the state of indifference. The pair loving/hating is related to the pleasure/unpleasure polarity; the ego interjects pleasure and expels unpleasure, which is transformed into the opposition ego-pleasure/exterior world-unpleasure. Thus, hatred and the rejection of the exterior world emanate from the narcissistic ego. The pair loving/being loved originates in the reversal of an impulse into its opposite, of activity into passivity, and corresponds to the narcissism of self-love. The pair love/indifference is associated with the polarity ego/exterior world. We love the “object that dispenses pleasure” and we repeat “the original flight before the exterior world” (1926d) in the face of an object that does not dispense pleasure. In this way the intellectual economy of love is profoundly affected by these different forms of ambivalence.

## LOVE-HATE-KNOWLEDGE (L/H/K LINKS)

In the 1960s and 1970s Wilfred Ruprecht Bion developed the concept of the link, through three works that appeared in this period: *Learning from Experience* (1962); *Elements of Psycho-Analysis* (1963); and *Transformations* (1965). In these books he described three kinds of links: links of love (L), links of hate (H), and links of knowledge (K)—a model that therefore went beyond the Freudian model of the sexual drives of love (with their uniting function) and the sexual drives of hate (with their dividing function).

These concepts were particularly developed in chapters 14 and 27 of *Learning from Experience* and chapter 6 of *Transformations*.

“The feelings we know by the names ‘love’ and ‘hate’ would seem to be obvious choices if the criterion is basic emotion. Envy and Gratitude, Depression, Guilt, Anxiety, all occupy a dominant place in psychoanalytic theory and would seem with Sex to be choices to place with love and hate. In fact I prefer three factors I regard as intrinsic to the link between objects considered to be in relationship with each other. An emotional experience cannot be conceived of in isolation from a relationship. The basic relationships that I postulate are (1) X loves Y; (2) X hates Y; and (3) X knows Y” (1962, pp. 42–43) In reality, according to Cléopâtre Athanassiou: “W. R. Bion not only opposes the formation of links to whatever breaks them apart; he opposes them with another kind of union, the agglomeration, group formation par excellence.” She adds: “The basic elements of a person can be transformed through the intervention of another person. This encounter leads to a modification in the way the (psychic) elements are linked together: instead of forming agglomerations, they will form veritable bonds of such a sort that the rigid screen presently secretes a more supple matter, to take its place, capable

of allowing passage from one side of the (contact) barrier to the other” (1997).

In other words, the links are formed dynamically at the very heart of the primitive interrelationship. On that basis, Wilfred Bion describes the three links of love, hatred, and knowledge and he makes of these links working tools allowing the easy understanding of the content of a session: “Meaning is a function of self-love, self-hate or self-knowledge” (1965, p. 73).

It is on the basis therefore of a search for the “key” to a session, and of a reflection on the theory of interpretation, that Bion clarifies and deepens the nature of these three types of links. He remains insistent on the fact, fundamental in his eyes, that there is no knowledge of the object that is not, first of all, deeply rooted in emotional ties. The discovery of the object proceeds fundamentally by feeling, which, in itself, is already a kind of encounter with and knowledge of the object—an idea which Donald Meltzer developed later, through his concept of “aesthetic conflict.” For Bion, in effect, all emotional experience is a link, because it puts a Self and object in the presence of each other.

The L, H, and K links are proper to life and indissoluble from the mechanism of projective identification. Recall that for Melanie Klein the object of projection is not only matter for an expulsion of whatever has become undesirable in oneself, but enters in fact into a veritable relation with oneself on the basis of only the external expression of an internal link. The object finds itself thereby invested by a link of love, hatred, or knowledge, in direct rapport with the kind of link the subject entertains with its internal objects.

Ultimately, Bion describes equal, but negative ties for each of the three links: –L, –H, and –K, specifying that –L is not the equivalent of H (“not to love” is not “to hate”), –H does not equal L (“not to hate” is not “to love”) and that –K, or an aptitude for misunderstanding, is sometimes superior to understanding. “The relationship of K to –K can be epitomized by saying that in K particularization and concretization of the abstract and general is possible, but in –K it is not because the abstract and general, in so far as they exist, are felt to become things-in-themselves” (1962, p. 98). It is considered that the links K and –K testify in their manner to the Kantian influence in Bion on the concept of the thing-in-itself.

## LOW, BARBARA (1877–1955)

Barbara Low, a British psychoanalyst, was born in 1877 in London, where she died on December 25, 1955. She was the youngest daughter of eleven children in an Anglo-Jewish family with Austrian and Hungarian parents. Several members of the family distinguished themselves in various walks of life. After attending a pioneering girls' school in London, she gained her degree at University College before training as a teacher. She taught for several years at girls' schools, and during the First World War taught at Hackney Downs School for boys. For some years she lectured on education, history, and literature at the London County Council Training College for Teachers at Fulham. She joined the Labour Party and worked actively on its behalf. She was also active in the Fabian Society, joining soon after its formation with Herbert G. Wells, Bernard Shaw, and D. H. Lawrence, the last

of whom she had a warm correspondence with, reflecting her wide culture.

Low was introduced to psychoanalysis by Dr. David Eder, who had married her sister Florence (to whom she was closely attached). She gave up her career as a teacher to study psychoanalysis and went to Berlin for analysis with Hans Sachs (as did Sylvia Payne and Ella Sharpe). She was impressed by the polyclinic in Berlin and urged setting up a similar organization in London.

While maintaining her wide interests, Low devoted the rest of her life to psychoanalysis. In 1919 she was a founding member of the British Psycho-Analytical Society, and until the arrival of Melanie Klein, she and Eder were the only Jewish members. She brought her lively mind, clarity of thought, and didactic skills to bear on her new profession. In 1920 she wrote *Psycho-Analysis: A Brief Account of the Freudian Theory*, a book that ran to several editions. She wrote a number of important papers, including a number that dealt with unconscious factors in education, and she conceived the Nirvana Principle, which Freud approved of and acknowledged in his writings. She was an active member of the Institute for the Study and Treatment of Delinquency, which she served both as lecturer and therapist.

Low was an active discussant in international meetings and contributed to the intellectual and scientific life of the British Psycho-Analytical Society. She served as its librarian and as a member of the Public Lectures Committee. She also served as director of Imago Publishing Company on its foundation. She always fought vigorously for her beliefs, as was particularly evident in the controversial discussions between Anna Freud and Melanie Klein between 1941 and 1945 (King & Steiner, 1991). She was a staunch supporter of Edward Glover and Anna Freud in these debates, putting forward several proposals for discussion and attending all of the meetings until Glover's resignation from the society in 1944.

Though her health was good during her last two years, she was forced into semiretirement. Dr. Eder predeceased her, and she shared a home with her sister. There she died peacefully in her sleep at the age of seventy-eight on Christmas morning, 1955.

## **LUCY R., CASE OF**

“Miss Lucy R.” is the second case study presented by Freud in *Studies on Hysteria* (1895d). Lucy was a British governess whom he treated for nine weeks, beginning in December 1882.

Thirty years old, she was being treated by a colleague of Freud's for chronically recurrent suppurative rhinitis. This young English woman of delicate constitution was a governess for the managing director of a factory in the Vienna suburbs. She had recently lost the ability to smell and suffered from depression accompanied by olfactory hallucinations of the smell of “burnt pudding,” which Freud immediately identified as the origin of her hysteria.

“I therefore decided to make the smell of burnt pudding the starting point of the analysis,” Freud wrote (1895d, p. 107). But the treatment, which should have been short, turned out to be more difficult than expected because the patient, who was working, was unable to see him outside his consulting hours. As a result, he could only devote a few moments of time to her, unlike those patients who were able to make appointments in advance. “We used therefore to break our conversation off short and take up the thread at the same place next time. Miss Lucy R. did not fall into a state of somnambulism when I tried to hypnotize her. I therefore did

without somnambulism and conducted her whole analysis while she was in a state which may in fact have differed very little from her normal one” (p. 107).

In his description of Lucy’s case, Freud, for the first time, provides a detailed explanation of his new procedure. “When, therefore, my first attempt did not lead either to somnambulism or to a degree of hypnosis involving marked physical changes, I ostensibly dropped hypnosis, and asked only for ‘concentration’; and I ordered the patient to lie down and deliberately shut her eyes as a means of achieving this ‘concentration.’ . . . I decided to start from the assumption that my patients knew everything that was of any pathogenic significance and that it was only a question of obliging them to communicate it” (pp. 109–10). To force this response, “I placed my hand on the patient’s forehead or took her head between my hands and said, ‘You will think of it under the pressure of my hand. At the moment at which I relax my pressure you will see something in front of you or something will come into your head. Catch hold of it. It will be what we are looking for.—Well, what have you seen or what has occurred to you?’” (p. 110). This procedure, he added, “has scarcely ever left me in the lurch” (p. 111), and all Freud had to do was to tell his patients that it was impossible to fail to extract information from them.

Freud helped Lucy realize that she was in love with the widower whose children she cared for. After his prescribed hydrotherapy treatments failed to have an effect, he was astonished to see her return after the Christmas holidays without any real improvement. Moreover, the smell of burned pudding associated with her hidden love for her employer had been replaced by the smell of cigar smoke.

Freud again applied pressure to her forehead with his hands. Another scene materialized where her

employer had scolded her violently for having allowed a female visitor to kiss his children. This scene indicated that she realized he did not love her, and was associated with another scene, this time of the conclusion of a meal and the presence of cigar smoke. This realization resulted in her complete recovery, probably near the end of January 1893.

Freud saw Lucy again in June 1893, when she was in perfect health. He never questioned himself about the cigar smoke. Cigar smoke came up again during Freud’s treatment of Dora, for none of his patients was likely to overlook his passion for cigars. Nothing like a transference neurosis can be found in Freud’s descriptions of these early treatments, which have little in common with later psychoanalytic therapy. Nonetheless, they are important, aside from the interest in Freud’s activity as a therapist, for what they teach us about his theoretical development. With Miss Lucy R., Freud abandoned hypnosis and became certain that his patients possessed an intimate but repressed knowledge of their symptoms. He thus recognized the importance of the means used to overcome patients’ resistance to remembering.

JÄHRLICH 6 HEFTE BEI 40 BOGEN STARK M 18.— = K 21.60

Die „Internationale Zeitschrift für ärztliche Psychoanalyse“ stellt sich die Aufgabe, dem Anfänger durch didaktische Aufsätze eine Einführung in das Wesen und die Übung der Psychoanalyse zu geben, den Vorgesrittenen Gelegenheit zum Austausch ihrer Erfahrungen zu bieten und sie durch Kritiken und Referate fortlaufend von der Entwicklung dieser jungen Wissenschaft zu unterrichten.

Die Zeitschrift bringt Originalarbeiten zum Abdruck, von denen eine Erweiterung unserer psychoanalytischen Erkenntnisse zu erwarten ist, und Mitteilungen, durch welche die bekannten Lehren erläutert und bestätigt werden sollen.

Es erscheinen jährlich sechs Hefte der Zeitschrift, jeden zweiten Monat abwechselnd mit „Imago“, im Gesamumfang von ca. 36—40 Druckbogen zum Jahrespreis von M 18.— = K 21.60.

Auch wird ein gemeinsames Abonnement auf die beiden psychoanalytischen Zeitschriften zum ermäßigten Gesamtjahrespreis von M 30.— = K 36.— eröffnet.

Das rege Interesse, das insbesondere Amerika und England an der Entwicklung und Ausbreitung der psychoanalytischen Lehren nehmen, läßt einen engeren Kontakt mit den Forschern und Ärzten dieser Länder wünschenswert erscheinen. Die Zeitschrift wird von nun an diesem Zwecke der psychoanalytischen Literatur besondere Aufmerksamkeit widmen und hat sich zur Förderung dieses Zweckes die redaktionelle Mitwirkung ihres geschätzten Mitarbeiters Dr. Ernest Jones in London, Professors der Psychiatrie an der Universität in Toronto, gesichert.

12

Für die Redaktion bestimmte Zuschriften und Sendungen an:

Dr. S. Ferenczi, Budapest, VII. Elisabethring 54.

All American and English communications and contributions should be sent (typewritten) to Dr. Ernest Jones, 69 Portland Court, London W.

Alle Manuskripte sind vollkommen druckfertig einzusenden.

Sämtliche Beiträge werden mit dem einheitlichen Satz von K 50.— pro Druckbogen honoriert.

Von den „Originalarbeiten“ und „Mitteilungen“ erhalten die Mitarbeiter je 50 Separatabzüge gratis geliefert.

## MAEDER, ALPHONSE E. (1882–1971)

Alphonse Maeder, a physician specializing in psychiatry and psychotherapy, was born in La Chaux-de-Fonds, Switzerland on September 11, 1882, and died in Zürich on January 27, 1971.

The bilingual son of a Swiss German watchmaker, he began to study medicine at Berne in 1901 and continued his studies in Zürich and Berlin. In 1903 he made the acquaintance of the zoologist and philosopher Hans Driesch, who had already integrated Aristotelian entelechy into his neo-vitalist philosophy.

From 1906 to 1910 Maeder worked in Zürich as assistant physician to Eugen Bleuler and Carl Gustav Jung, who introduced him to psychoanalysis. He attended the 1910 Nuremberg congress.

From 1911 to 1918 he worked as a therapist in Dr. Bircher-Benner's sanatorium before opening a private practice as a psychotherapist in Zürich, where he worked almost until his death.

Beginning in 1906, he published psychoanalytic works in German: *Die Sexualität der Epileptiker* (The sexuality of epileptics; 1909), *Psychologie der Schizophrenen* (The psychology of schizophrenics; 1910), as well as articles on the symbolism of dreams, whose origin he linked to projection: *Zur Entstehung der Symbolik im Traum* (On the formation of symbols in dreams; 1910–1911) and the function of dreams: *Funktion des Traumes* (The function of dreams, 1912). He stressed the “prospective capacity of the soul” in the sense of Hans Driesch's entelechy.

Freud had great respect for Maeder and put him in charge of relations with French-speaking colleagues.

However, when Maeder formulated an hypothesis in 1912 concerning the prospective capacity of dreams, Freud severely criticized him (much to Maeder's surprise) and warned him against mystical tendencies.

Following that episode, Maeder broke with Freud at the same time as Jung and henceforth continued to seek his own path. His approach gave priority to the self-regulating and self-healing capacities of the soul, the “personal association” between the physician and the patient, and the role of the physician as “healer,” as “the one who reconstitutes globality.” This idea of “synthesis” led him to Martin Buber's circle and, in 1932, to collaborating with Frank Buchmann's Oxford Group. In 1957 he published a text on his spiritual development and his memories of Freud.

## MAGICAL THINKING

Magic is the technique associated with an animist conception of the world. It seeks to impose on objects in the external world laws that are part of mental life and, more generally, to subject natural phenomena to human will. The magical practices of primitive peoples are compared by Freud to children's play, art, and neurosis.

In chapter three of *Totem and Taboo* (1912–1913a), Freud develops his ideas about magic and a modality of thought—“magical thought”—that he compares to the omnipotence of ideas. His remarks are taken directly from his reading of sociologists and anthropologists like Marcel Mauss, Salomon Reinach, Sir Edward Tylor, and Sir James Frazer. They reflect not only the utility of such ideas for psychoanalysis and psychopathology (obsessional neurosis, paranoia) but also the modifications that the psychoanalytic approach can provide to our understanding of the concept of magic. Returning to an idea already introduced concerning the epistemophilic drive in children, Freud stresses the fact that the practical need to subjugate the world together with simple speculative curiosity pushed humans to create their first cosmic systems.

Freud identifies sorcery as a tool to influence “spirits” by treating them as one would human beings, that is by appeasing and subjugating them through magic. Magic, which is more primitive, corresponds to a preanimist phase when nature is alive and spiritualization has not yet been concentrated in “spirits.” Referring to Frazer, Freud distinguishes between imitative, or homeopathic, magic, which produces the desired phenomenon by carrying out a similar action with symbolic value, and “contagious” magic, whose efficacy is not tied to any similarity but temporal contiguity. However, regardless of the form magic assumes, it always satisfies the same need—human desire—and expresses mankind's overconfidence in the omnipotence of his desires and his ideas. Narcissism (1912–1913a) is the cause of this excessive confidence that the primitive and the neurotic attribute to mental activities, which is the foundation of magical practices and neurotic symptoms that simultaneously strive to counteract and to grant the bad wish, which is in fact the desire for death.

According to Freud, magic is situated within a preanimist system: “Whereas magic still reserves omnipotence solely for thoughts, animism hands some of it over to spirits and so prepares the way for the construction of a religion” (p. 95). The distinction between these two systems is associated with the affective conflict that death leaves with the survivors, leading them to create spirits through projection. In this sense magic can be seen to belong to a narcissistic system, while animism implies, with the recognition of the inevitability of death, the initial recognition of *ananke*.

Géza Róheim (1950) created a body of work based on the use of psychoanalysis as an explanatory instrument in anthropology, in contrast to the customary procedure of limiting anthropological explanation to a single culture, or even a single tribe. His research has provided considerable insight into magical thought in this field, as has the work of Georges Devereux.

## MAHLER, GUSTAV (MEETING WITH SIGMUND FREUD)

During the summer of 1910, when Freud was vacationing with his family on the North Sea in the Netherlands, Gustav Mahler, in a state of deep depression, decided to consult him. The neurologist Richard Nepallek, a relative of Alma Mahler, was the go-between. The composer's “maddening doubt” led him to put off the meeting on three successive occasions. August 26 was the last day it was possible to meet Freud, since he was getting ready to travel to Sicily together with Sándor Ferenczi.

The meeting took place in a restaurant in Leyden. For four hours there took place a “psychoanalytic session,” along the canals of the city where the two men walked. That summer of 1910 Mahler had experienced a personal drama: He feared his wife would leave him and became aware that his life had become that of a neurotic.

In a letter to Theodor Reik, written in 1934, Freud noted Mahler’s “brilliant faculty of comprehension.” This unique psychoanalytic session allowed him to discover the musician’s Marian complex (mother fixation), but “no light was shed on the symptomatic façade of his obsessive neurosis.” Freud continued, “If I can believe what I have heard, I have done good work.” Mahler, for his part, wrote in a telegram he sent to Alma the day after the meeting, “I’m filled with joy. Interesting conversation. . . .” He died May 18, 1911, nine months later.

## **MAHLER-SCHÖNBERGER, MARGARET (1897–1985)**

The psychoanalyst Margaret Schönberger Mahler was born in the old Hungarian city of Sopron on May 10, 1897. She died in New York on October 2, 1985.

The Schönbergers were a wealthy and intellectual Jewish family. Mahler’s father, Gustav, was a general practitioner to whom she was close; but her relationship with her mother, Eugenia, was distant and conflicted. While still attending the gymnasium, she first encountered psychoanalysis when she met Sándor

Ferenczi, who greatly impressed her. She entered medical school at the University of Budapest in 1917, moved to Germany two years later, studied pediatrics and graduated magna cum laude from the University of Jena in 1922. She settled in Vienna where, because she had opted for Austrian citizenship in the wake of World War I, she could practice medicine.

Mahler’s interest in psychiatry and psychoanalysis developed as she turned away from the unempathic, sterile practice of pediatrics then common in the Austrian clinic where she worked. She met August Aichhorn and Karl Abraham, attended Anna Freud’s child analysis seminar, and in 1926 applied to the Vienna Psychoanalytic Institute and underwent a training analysis (Stepansky, 1988). Her first analysis, with Helene Deutsch, disappointed her; she subsequently was analyzed by Aichhorn, with whom she had a love affair; her final analysis with Willi Hoffer, from 1930 to 1935, was more successful. She was finally certified as an analyst, after various difficulties, in 1933. In 1936 she married Paul Mahler, Ph.D., a chemist.

With the approach of the Second World War—her mother would die in a concentration camp—Mahler moved briefly to Britain before emigrating to the United States in 1938. The next year, settled in New York, she set up private practice as an analyst and became a member of the New York Psychoanalytic Society. In 1945 she once more entered analysis, with Edith Jacobson.

Mahler assumed various responsibilities at the New York State Psychiatric Institute, affiliated with Columbia University, before becoming professor of psychiatry at the Albert Einstein College of Medicine in 1950. She also became chair of the child analysis training program at the Philadelphia Psychoanalytic Institute and, importantly for her observational studies, she directed research at the Master’s Children Center in New York.

Mahler’s early publications, dating to the late 1940s, concerned tic disorders. Her work with severely ill young children led to prognostic considerations in cases of child psychosis, then a controversial diagnosis. In 1952 she suggested a “symbiotic” syndrome, to be distinguished from autistic psychosis on the basis of “a fixation at, or regression to, a more differentiated stage of personality development” (Mahler, 1968, p. 71). Mahler viewed these disorders as emerging at certain key developmental landmarks—when the child

faces separation from the mother, for example, or when triggered by a specific event. Subsequently there developed a “dramatic disorganization along with loss of functions, such as deterioration of speech, often associated with or ascribed to such events. . . . By the third and fourth year of life, reorganization took place, with a range of psychotic symptoms in the foreground. These include: loss of boundaries of the self. . . , extreme reaction to any failure; magic gestures. . . , echolalia and echopraxia, psychotic preoccupations with an inanimate object. . . .” (p. 78). Unlike other psychoanalysts at the time, Mahler did not share the popular view that inadequate mothering was responsible for autism.

Mahler’s more influential work emerged from her research with normal children that began in the 1960s, when she created a program for directly studying young children in a setting that favored observation of mother-child interaction. Her theory of separation-individuation, which emerged directly from this research, distinguished clearly between psychological and biological birth. “The biological birth of the human infant and the psychological birth of the individual,” she wrote, “are not coincident in time. The former is a dramatic, observable, and well-circumscribed event; the latter a slowly unfolding intrapsychic process” (Mahler, Pine, and Bergman, p. 3).

*The Psychological Birth of the Human Infant*, published in 1975, was a mature statement of her theory. Mahler described the separation-individuation process as unfolding from the age of four to five months to thirty-six months of age and beyond. The earliest weeks of infancy constitute a period of psychic gestation that, in turn, is comprised of two stages: the normal autistic phase, during which the baby is centered on proprioceptive and enteroceptive sensation that represents a “model of a closed monadic system, self-sufficient in its hallucinatory wish fulfillment” (Pine, and Bergman, p. 41). It is followed by the symbiotic phase during which infant and mother form a “dual unity within one common boundary” (p. 44).

The separation-individuation process proper, Mahler suggested, begins at about four to five months of age and may be divided into four subphases. Differentiation, from about five months, Mahler viewed as a period of “hatching” of a primitive self from the earlier symbiotic attachment to the mother. In the practicing subphase (ten to twelve until sixteen to eighteen months), the infant becomes a “toddler” with growing

motor and cognitive skills who enjoys a “love affair with the world”; during rapprochement (sixteen to eighteen until twenty-four to thirty months) the toddler experiences both separateness and associated crises of dependency. A final, open-ended subphase that Mahler characterized as Toward Object Constancy, occurs as the child achieves an individual and variable measure of autonomy and emotional balance associated with a relatively stable, permanent, and differentiated intrapsychic representation of the mother.

Although recent research in infant and child development tends to emphasize the importance of innate capacities of newborn infants, not only in terms of perception and cognition but also in terms of attachment, Mahler’s theory remains an influential touchstone. The overall significance and influence of her work, most notably her concept of separation-individuation in normal psychological development, has been considerable and long-lasting.

## MAIN, THOMAS FORREST (1911–1990)

Thomas Forrest Main, a British physician, psychiatrist, and psychoanalyst, was born on February 25, 1911, in Johannesburg and died on May 25, 1990, in London. He graduated in medicine at Newcastle on Tyne in 1932 and was proud of his Geordie (Newcastle) background. He qualified for the MD in 1932, received the MD in 1934, then turned to psychiatry (DPM, 1936), and at a very young age became a consultant psychiatrist.

Main, one of the new generation of psychiatrists selected by John R. Rees, had a brilliant war career. To understand the stresses of war, he made parachute drops and went to the front line in France. In the training of soldiers, he condemned artificial attempts to stimulate hatred of the enemy, and he investigated the maintenance and loss of morale. He worked in the Eighth Army in the desert and in the twenty-first army group before the invasion of France. It was said that he and Field Marshal Montgomery could not get along with each other.

As a lieutenant colonel, Main was a senior figure at the Northfield Military Hospital, where he was a colleague of Siegmund H. Foulkes and Harold Bridger. This was at the time of the second Northfield experiment, the first having been that of Wilfred R. Bion and John Rickman. Main's famous paper ("The Ailment," 1957) stated that the hospital as an institution should study its own processes, thereby enhancing its therapeutic powers and recognizing its antitherapeutic aspects.

After the war Main became director of the Cassel Hospital for Functional Nervous Disorders and was responsible for moving the hospital close to London. He had two motives for doing this: First, patients should not be isolated from family and society, and second, staff should be close to London to avail themselves of psychoanalytic training. He himself had analysis with Michael Balint, and his supervisors were the grandes dames of British psychoanalysis, Anna Freud and Melanie Klein.

The hospital treated a wide range of neuroses and personality disorders and, under Main, began to treat mothers who had become psychologically ill after childbirth. Main pioneered admission to the hospital of

mothers with their babies, later with their older children, and eventually with husbands and the whole family.

Famous for his concept of the therapeutic community, a term that he originated, Main was especially skilled to hospital dynamics and psychosocial medicine. "The Ailment," reflected his observations on patients who engendered splitting and projective identification in the staff. Main was also a fine teacher and supervisor. Following Michael Balint's example, he led many Balint groups for family doctors and later developed Balint-group techniques for professionals treating sexual disorders. He founded and became the first president of the Institute for Psycho-Social Medicine.

A member of the British Psycho-Analytical Society, Main always maintained a psychoanalytic practice. Though he was not drawn to group-analytic psychotherapy, he appreciated the work of both Siegmund Foulkes and Wilfred Bion and wrote a classic paper on large-group dynamics. Another field that he explored was short-term psychotherapy, again collaborating with Michael Balint in a study eventually described by David Malan (1963).

Main, an important link between psychoanalysis and psychiatry, was active in the Royal College of Psychiatrists, of which he became vice-president. He was disappointed, however, that he did not become president, as he somewhat overoptimistically hoped and believed that he could help develop a psychodynamic psychiatry in Britain.

Fortunately, before his death his daughter Jennifer, herself a psychoanalyst, collected his papers in a book (1989). Main died from a carcinoma of the colon on May 25, 1990. His wife Molly, also a psychoanalyst and child psychiatrist, died in London in 1999. Two of their four children followed them into the field of psychiatry.

## MÂLE, PIERRE (1900–1976)

French psychiatrist and psychoanalyst Pierre Mâle was born in Charolles, France, on October 11, 1900, and died in Paris on July 20, 1976.

The son of Émile Mâle, an eminent art historian and member of the French Academy, he performed brilliantly in his secondary school studies at the Lycée Henri IV. He studied medicine in Paris and in 1920 worked as an extern in the department of Henri Claude, the first professor to agree to supervise psychoanalysts. The 1920s were the years of Surrealism and the first translations of the works of Sigmund Freud. In 1926 Mâle was an intern in the staffroom at the Hôpital Sainte-Anne alongside Henry Ey and Jacques Lacan; he was among the first to undertake training analysis, initially with Rudolph Löwenstein, then resuming with Marie Bonaparte after World War I.

In 1926 the Société psychanalytique de Paris (SPP; Paris Psychoanalytical Society) was founded; Mâle was elected a member on June 21, 1932. Elected to permanent membership on April 20, 1948, he became the society's president after the schism of 1953, and in 1954 he inaugurated the Institut de psychanalyse de Paris (Paris Institute of Psychoanalysis), the leadership of which was entrusted to Sacha Nacht. In the face of the choices necessitated by the successive crises within French psychoanalysis, without discounting the importance of individuals' problems, his decisions were always based on the therapeutic vocation of psychoanalysis, in line with Freud's approach mandating a certain rigor in practice and training.

Beginning in the 1930s he participated in the emergence of child and juvenile psychiatry, under the influence of Georges Heuyer. In 1948, at the Hôpital Henri-Rouselle (part of Sainte-Anne), he created Guidance Infantile (Children's Guidance Center), where, initially seconded by Jean Favreau, his clinical practice and work became widely known. In this setting he taught a form of total clinical work in which psychoanalysis, the centerpiece, was in the service of a veritable anthropology, based on the comparative weight of conflicts, "equipment," and history, oriented toward a

multidisciplinary approach to the child and taking the family into account. Mâle was director of Guidance Infantile from 1948 to 1976.

From 1932, faithful to the contributions of Pierre Janet and Henri Wallon but inspired by Freud's *Three Essays on the Theory of Sexuality* (1905d), Mâle studied children's character and perverse behaviors in a new light, taking into account structures, but also events and instincts. If his preferred focus was adolescence, it was because that period seemed to him like a second birth in which buried material could come to the surface and be within reach of his activity in the operative field of the transference, a productive moment for intervention where it was possible to take up individual finality anew. The various forms of his therapies—in particular, short-term and non-ritualized versions—are elaborated in *Psychothérapie de l'adolescent* (Psychotherapy for adolescents, 1964) and relate to "the crisis of youth" and the "disharmonies of puberty," but also to criminality and "preschizophrenias," which topics he addressed, respectively, in 1951 with Serge Lebovici, and in 1958 with André Green.

At the beginning of the 1960s, Mâle began to focus on two adolescent states: "failure neurosis," expressed in terms of school performance, "pathology of error" and "refusal to succeed" (for which he proposed a combination of psychotherapy and an original curative pedagogy, developed with Thérèse Tremblais-Dupré), and "apathy," a phenomenon of modern society characterized by an absence of investment and intolerance of daily life, and heralding behaviors such as running away from home, delinquency, drug use, and suicide, which are most common among adolescents whose early home life was disturbed. Here, his observation of particular resistance to therapy pointed him, in the 1970s, toward research using a "vertical" approach to disturbed mother-child relations, together with Alice Doumic-Girard. Finally, with his friend René Held, Mâle contributed to the status of psychoanalytically inspired psychotherapy for adults.

Described by Philippe Gutton as leader of the French school of adolescent psychiatry (*Adolescence*, No. 1, 1983), Mâle continued to the end to expand the extraordinary possibilities of applying psychoanalysis in all areas and for patients of all ages. Pierre Bourdier and Ilse Barande, who succeeded Mâle as directors of the facility that was renamed Guidance infanto-juvenile Pierre Mâle (Pierre Mâle Children's and Youth

Guidance Center), worked alongside Simone Daymas to ensure the transmission of Mâle's life work.

## **MALINOWSKI, BRONISLAW KASPAR (1884–1942)**

Bronislaw Kaspar Malinowski, a British anthropologist, was born on April 7, 1884, in Krakow, Poland, and died on May 16, 1942, in New Haven, Connecticut. The only son of a Slavic professor of philology, Malinowski completed a doctorate in the philosophy of science at the University of Krakow in 1908. After reading the work of James G. Frazer, he turned to anthropology. In 1910 he settled in Great Britain, where he studied with Charles G. Seligman and Edvard Westermarck at the London School of Economics.

During the First World War, although the Australian authorities considered him an enemy alien, he was still allowed to conduct ethnographic research and worked for a period of twenty months in the Trobriand Islands (Melanesia, to the east of New Guinea). At Seligman's request, he studied the Oedipus complex and other manifestations of the unconscious in a community based on maternal law.

In a series of articles, some of which appeared in *Sex and Repression in Savage Society* (1951) and *The Sexual Life of Savages in Northwestern Melanesia* (1962), he claimed that for the Trobriand people, "sex, in and of itself, was not subject to any form of restriction." There was no period of what Freud referred to as

pregenital or anal-erotic interest. "Any idea of consanguinity or paternal parenthood, conceived as a physical relation between father and child, is completely foreign to the indigenous mind." "The desire is to marry the sister and kill the maternal uncle." On the basis of these findings, Malinowski contested the universal validity of Freudian claims and denounced "the failure, even the explicit aversion, of psychoanalysts to seriously consider social organization."

As Ernest Jones and Géza Róheim were quick to point out, Malinowski's claims were not supported by a close examination of his own ethnographic data: A number of taboos, especially that of speech, influenced the sexuality of the Trobriand Islanders. Several convergent indices led to the conclusion that they understood physiological parenthood. A conventional Oedipal triangle seemed to be present: the son was the first to be suspected of killing the father through witchcraft. Malinowski himself acknowledged that he was unfamiliar with the psychoanalysis he relativized and criticized. He was unaware of the distinction between the latent and the manifest, and directly questioned the native population about the incestuous content of their dreams. Moreover, his writing can be questioned in terms of his peculiar mental equations, which the posthumous publication of his *Diary in the strict sense of the term* (1967) allows us partially to reconstruct.

The head of the so-called functionalist school, Malinowski benefited from his considerable fame: He held the first chair of anthropology at the University of London, which was created for him in 1927. Even in the early twenty-first century, his Trobriand Island work is presented by anthropologists as a key moment in intensive ethnography (prolonged residence, knowledge of the language). His theoretical perspectives have largely been abandoned, but a number of anthropologists continue to refer to his work to refute the universality of the Oedipus complex and the ability of psychoanalysis to account for the workings of the psyche in variable social contexts.

## MANIA

Mania is a state of psychomotor excitation. Its onset most often comes through inversion of a melancholic mood, either spontaneously or owing to treatment for depression.

The manic mood is euphoric, changeable, and accompanied by emotional hyperesthesia. The subject exhibits pathological optimism with an overestimation of the self and unrealistic plans that sometimes lead to delusions along megalomaniacal lines (grandeur, omnipotence, messianism). The expansiveness of mania is associated with agitation, expressed in hyperactivity and hypermimia. It is also accompanied by tachypsychia (“rushing thoughts”), an acceleration of the thought processes externally manifested in logorrhea, graphorrhea, hypermnesia, and distractibility. Hypersyntony, a immediate and increased receptivity to stimuli from the outside world and a loss of the ability to discriminate between important facts and details, gives the impression that the subject is closely emotionally attuned with his or her surroundings. Reduction in the duration of sleep, sometimes to the point of total insomnia, is a constant clinical sign.

In “Mourning and Melancholia” (1916–17g [1915]), based on his impressions as an analyst, Sigmund Freud observed that melancholic and manic patients were “wrestling with the same ‘complex’” (p. 254)—a complex to which the melancholic ego succumbs and over which the manic ego triumphs. From nonpathological states of jubilation, triumph, and joy, he extrapolated the economic precondition of mania: It corresponded to a fresh availability of the psychic energy expended in the unconscious work of

melancholia, which in mania again becomes “available for numerous applications and possibilities of discharge” (p. 254). At the point where melancholia turns into mania, the subject’s ego is liberated from the object of its suffering; it surmounts its loss and triumphs over the object, and consequently the psychic energy that has been counter-catheted and bound to mental pain is suddenly available. In mourning there is no liberation of this type, for detachment from the object is more gradual, although Karl Abraham (1924/1927) viewed the increase in libidinous desires in some bereaved persons as comparable to mania.

From a topographical viewpoint, Freud showed in “Group Psychology and Analysis of the Ego” (1921c), that whereas a severe ego ideal crushes the melancholic’s ego with its rigorous control, during mania it is suddenly absorbed or merged into the ego. The ego and the ego ideal of the manic subject become one, thus freeing the subject from all hindrances and all criticism, procuring for the subject a feeling of triumph and boundless satisfaction.

For Abraham, “the manic patient has thrown off the yoke of his super-ego, which now no longer takes up a critical attitude towards the ego, but has become merged in it” (1924/1927, p. 471). Abraham compared mania to a cannibalistic orgy. The manic subject, he argued, manifests an “increase in . . . oral desires” (p. 472) a veritable object-bulimia. This accelerated incorporation of the object is immediately followed by an “equally pleasurable act of ejecting [introjected objects] almost as soon as they have been received” (p. 472). The subject’s “psychosexual metabolism” (p. 472) thus appears to be significantly accelerated.

## MANIC DEFENSES

The notion of *manic defenses* was introduced by Melanie Klein as an extension of Freud's thoughts on mania. By adopting a triumphantly scornful attitude toward psychic reality, the patient uses this kind of defense to avoid the depression associated with the conviction of having destroyed an internal object.

In "Mourning and Melancholia" (1916–17g [1915]), Freud wrote: "In mania, the ego must have got over the loss of the object (or its mourning over the loss, or perhaps the object itself)... [T]he manic subject plainly demonstrates his liberation from the object which was the cause of his suffering" (p. 255). Karl Abraham elaborated on Freud's view by attributing manic triumphalism to a liberation from the sway of the ego ideal or of an incorporated object.

In the context of her theories on the depressive position, Melanie Klein (1940) emphasized the importance of manic defenses for mental life. She enriched the Freudian conception of mania by adding the idea of the subject's feelings of guilt concerning the disappearance and destruction of the object. The manic subject tends to downplay the power of the object, to disdain it, while at the same time maintaining maximum control over objects. Manic defenses are typified by three feelings, namely control, triumph, contempt.

In clinical practice, the notion of manic defenses has suffered from the rise of a psychiatric approach that tends to sideline any consideration of psychic conflict.

## MANIFEST

Manifest content is the narrative that the dreamer tells about his or her dream. In contemporary usage, the criterion *manifest* is also applied to other types of verbal production and to behaviors. Sigmund Freud contrasted manifest content to the latent dream thoughts brought out by psychoanalytic interpretation.

The Freudian theory of dreams "is not based on a consideration of the manifest content of dreams but refers to the thoughts which are shown by the work of interpretation to lie behind dreams" wrote Freud in *The Interpretation of Dreams* (1900a, p. 135).

Manifest and latent are notions by the "dream work." During sleep, wishes linked to childhood events, normally repressed, are actualized owing to the relaxation of censorship. Dreaming requires, however, that "selfish," sexual, sadistic, or incestuous wishes be transformed. The dream fulfills these wishes ("latent thoughts," "latent contents," "dream thoughts"); only if they are modified, distorted, and/or transformed in their expression, which is the manifest dream. But the manifest dream is also a product of the effects of certain events of the previous day (day's residues) or of bodily sensations on the unconscious. The manifest dream results from a combination of the day's residues, bodily sensations, and latent dream-thoughts. The regression to archaic forms of thought provoked by sleep entails the repression and transformation of the latent thoughts. A secondary revision, which gives the dream a certain coherence, then succeeds to these transformations. What is manifest may therefore function as a "façade" or "trompe-l'oeil."

Interpretation of the manifest dream entails following the path of the dream work in reverse and, by tracking associations and uncovering the latent thoughts, although Freud stressed that there were limits to the interpretation of dreams (see his discussion of the "dream's navel," 1900a, p. 525).

Over time, the opposition between manifest and latent posited by Freud in his earliest works was reconsidered. However, he continued to refer to it even as late as his "Outline of Psycho-Analysis" (1940a [1938]), as a means of understanding and working out dreams.

The exigencies of the second topography (or structural model), with its complex picture of the mental agencies (the ego being deeply rooted in the id) made the opposition between manifest and latent more difficult in relation to dreams. The dream became one form of material among others, caught up in the movements of transference and resistance. The analyst's goal was no longer conceived as the revelation of what was unconscious or rather as latent through the interpretation of dreams, but rather as development of the psychoanalytic process. Manifest and latent were seen as interpenetrating instead of radical opposites. The manifest could therefore be treated, much like the latent, in the work of the session.

The initial importance assigned in the theory of dreams to the manifest, making it as important, in fact, as the latent, was reduced: Analytical treatment came to focus on the dynamics of the latent psychic functioning of the analyst and the analysand. Dreams were also considered in their totality, as a space of projection/protection, and as a mode of expression for the dreamer in their very nonsense (Jean-Claude Lavie)—simply another mode for apprehension of the manifest.

In the treatment, behaviors (attitude, gestures, somatization) are manifest forms of a latent mode of psychic functioning in the patient. But because they are outside the patient's consciousness and verbalization, they elude the process of working over. They can be related to early modes of psychic functioning, when the dynamics of the one remained indistinctly linked to the primal other. The mechanisms involved are thus splitting, repetition, and reversal into the opposite.

The nonverbal manifest and the latent it conceals can be discovered by the patient, notably in situations where bonds of identification and transference are developed by means other than those used in treatment, and where expressiveness through the body, actions, and attitudes emerges in situations such as analytic role-playing and/or small-group situations with analysts.

## MANN, THOMAS (1875–1955)

German writer Thomas Mann was born in Lübeck, Germany, in 1875 and died in Kilchberg, near Zurich, Switzerland, in 1955. He settled in Munich with his family after the death of his father, remaining until 1936; he then went into exile in the United States. His life and work were dominated by two major questions: Germany and German identity; the status of the artist and art in society.

Concerning the question of German identity, Mann began by holding conservative, monarchist, and militarist beliefs until the rise of Nazism. He opposed a Germanic ideal that accepted values held by the rest of Europe. In this he distanced himself from the position of his brother Heinrich Mann, a republican, cosmopolitan, and critic of the Empire. During this time, Mann's literary output began with a lengthy autobiographical novel, *Buddenbrooks* (1901), in which he describes the decline of four generations of a rich Hanseatic family. The fate of this fictional family can be compared with his own experience of the loss of his father while he was still very young. After dabbling briefly with Nazi ideology, Mann underwent a fundamental change of opinion in the thirties. It was in his novel *The Magic Mountain* (1924) that he developed his new attitudes toward all the most important areas of thought and action, including psychoanalysis.

Mann contrasted the mediocrity of an average, bourgeois existence with the unconscious drives of the sensitive intellectual enamored of knowledge and beauty. He continued to articulate, throughout the course of his work, series of paired opposites: art and morality, art and civilization, culture and society, the genius of disease and the stupidity of health. He contrasted the North, cold and puritan, where his family

had come from, with the South, Bavaria, where he lived. This was the carnal South of Tonio Kröger (1903), the mephitic Venice of Gustav Aschenbach (1910), the voluptuous Egypt of Joseph (1933–1934), the magic mountain of Hans Castorp—all of them fantasies of the experience of forbidden desire, places of love and death, of disease, of castration.

He contrasted liberating psychoanalysis with an alienating hypnosis. In *Mario and the Magician* (1929), Mann created a portrait of a disturbing illusionist who evokes Hitler. And in 1938, after the Anschluss, Mann contrasted Freud with Hitler: “How that man must hate analysis! I secretly suspect that the furor with which he marched against a certain capital was at bottom directed against the old analyst living there, his real enemy, the philosopher who unmasked neurosis, the great disillusionist, the man who knows so much about belief and genius.”

Mann praised Freud directly on several occasions. From his “My Relationship with Psychoanalysis” of 1926, where he exposes his ambivalence toward Freudian theories, to the two texts written for the seventy-fifth and eightieth birthdays of Sigmund Freud, where he is compared, using an allegory from a Dürer painting, to the knight between death and the devil, Mann saw Freud as the “pioneer of a humanism of the future.”

## MANNONI, DOMINIQUE-OCTAVE (1899–1989)

French philosopher and psychoanalyst Dominique-Octave Mannoni was born on August 29, 1899, in Lamotte-Beuvron (Loir-et-Cher), a small town in the Loire Valley, and died in Paris on July 30, 1989.

The son of a Corsican director of a disciplinary institution, Mannoni studied philosophy in Strasbourg, where his professor of psychology, the influential Charles Blondel, was positively hostile to psychoanalysis. In 1926, after completing his studies, he was appointed to the Lycée Gallieni in Tananarive. He would remain in Madagascar until 1945, when he was sent back to France for having supported the island's independence movement. During this period he published numerous literary and ethnographic articles.

In Paris, Mannoni began analysis with Jacques Lacan in 1946 and wrote *Psychologie de la colonisation*, published in 1950, which was to appear in English as *Prospero and Caliban: The Psychology of Colonization* (1956), and which became the subject of critiques by both Aimé Césaire and Frantz Fanon. After the famous split with the International Psychoanalytical Association in 1953, Mannoni joined the Société Française Psychanalytique (SFP); but ten years later, due to his close relationship with Lacan, he was not elected a full member; as one consequence, he lost interest in the administrative and political side of psychoanalysis.

Beginning with his return to Paris, Mannoni wrote regularly for Maryse Choisy's review *Psyché*, serving among other duties as film critic; his articles also appeared in *Esprit* and, still more prominently, in *Les temps modernes*, for which he continued to write until his death. He became a member of the École freudienne de Paris (EFP) and was appointed analyst of the school (AE), a position he retained until the EFP closed in 1980. In 1982, with Patrick Guyomard he co-founded the Psychoanalytic Training and Research Center (CFRP), which was established on the initiative on his wife, Maud Mannoni.

Cultivated and independent, open to various avenues of thought in philosophy, anthropology, ethnology, and French and English literature, Mannoni remained aloof from the institutions to which he belonged. He avoided both administrative duties and fealty to either persons or theories. His work, of considerable importance, includes collections of articles on psychoanalysis and evaluations of literary figures. In his *Lettres personnelles à monsieur le Directeur* (1951), he undertook to “decolonize himself,” a result of his analysis with Lacan. In 1968, he published a remarkable essay, *Freud*, which was widely translated. The lecture he composed after his failure to be appointed a full member of the SFP was published as

“Je sais bien mais quand même” (I understand but still ...; 1963). His famous article on Freud’s relationship with Fliess, “L’analyse originelle” (The first analysis), appeared in 1967. “In 1907,” Mannoni explained in that essay, “Freud was finally able to repeat with another the experience he had first undergone himself; and by making it repeatable, his experience became the first.”

## **MANNONI-VAN DER SPOEL, MAUD (MAGDALENA) (1923–1998)**

French psychoanalyst Maud (Magdalena) Mannoni née Van der Spoel (was born on October 22, 1923), in the Belgian city of Courtrai and died in Paris on March 15, 1998.

With her mother, who was Belgian, and her father, a Dutch diplomat, she spent her early childhood in Colombo, Ceylon (present-day Sri Lanka); her first languages were Hindustani and English, both later forgotten after she returned to Belgium at age six. She studied criminology at the University of Brussels and began a training analysis with Maurice Dugautiez, one of first Belgian psychoanalysts. She would remain until her death a full member of the Belgian Psychoanalytic Society, an affiliate of the International Psychoanalytical Association (IPA).

Moving to France in 1949, she settled in Paris, met Françoise Dolto, married Octave Mannoni, and had both analysis and training analysis with Jacques Lacan,

whom she supported during the 1953 split in the French psychoanalytic movement. Mannoni worked with retarded children at several institutions and her *L’enfant arriéré et sa mère* (1964) was the first title to appear in “Le champ freudien,” a series under the editorial direction of Lacan published by Le Seuil. She went on to write numerous books for an analytic audience on childhood psychopathology. Her view of the child as “spokesperson” for the dysfunctional family helped render obsolete the concept of “retardation” (*débilité*) then widely used in medico-social discourse in France. The child who appeared “retarded” was in fact waiting to be heard.

Mannoni’s work in child psychology led her in 1969 to found the residential community known as École expérimentale de Bonneuil, which she directed until her death. The institution, which operated beyond traditional boundaries and used a variety of therapeutic strategies, with workshops and internships within and outside the school environment, became internationally renowned. Upon dissolution of the L’École freudienne in 1980, Mannoni appealed for the creation of training institute for young analysts and, with her husband and Patrick Guyomard, she established the Centre de formation et de recherches psychanalytiques (Center for psychoanalytical training and research; CFRP). Subsequently, internecine quarrels led to a crisis that went so far as to entail legal action against Mannoni herself. After the plaintiff’s suit was dismissed, she called for dissolution of the CFRP, which was duly voted on January 30, 1995. Several months earlier on October 16, 1994, at the end of a contentious general assembly of the CFRP, she had founded the “Espace analytique.” She remained its president until her sudden death from heart disease.

At the end of her life, Mannoni wrote of the practice of analysis that its lively dynamisms were “akin to the energy of the poets or of those who work face to face with poverty.” These words epitomize both her unflagging engagement with writing and her attentiveness to those areas where psychoanalysis confronts life’s hardships.

**MARCINOWSKI, JOHANNES (JAROSLAW) (1868–1935)**

Johannes (Jaroslaw) Marcinowski, a German neurologist, was born in Breslau, Poland, on November 13, 1868, and died in Tübingen-Waldhausen, Germany, on February 13, 1935.

He was the son of Johanna and Johann Gottlieb Marcinowski; his father was an administrative councilor. He attended a cadet training college and graduated as an officer. He was wounded in the course of his military career and subsequently devoted himself to medical studies, graduating from the University of Breslau as a doctor of medicine in 1894. From 1901 onward he worked as a neurologist in different treatment centers and in 1907 he founded his own center (Haus Sielbeck bei Eutin, in the province of Holstein).

Carl Gustav Jung drew Freud's attention to one of his papers. Freud responded: "Today I received a charming letter from Marcinowski, in which he declares himself to be our staunch supporter and comrade in struggle. He tells me that three further papers are being published in various places. He is trying to make contact with our group and is asking for addresses" (Freud and Jung, 1974a [1906–1913], p. 231).

Freud mentions Marcinowski's rest home in *On the History of the Psycho-Analytic Movement* (1914d) as the first German institution to open its doors to psychoanalysis. At the second psychoanalytic Congress, held in

Nuremberg in 1910, Marcinowski gave a conference on *Sejunktive Prozesse als Grundlage der Psychoneurosen* (Sejunctive processes as the foundation of the psychoneuroses). In the fall of 1911 he was appointed a permanent collaborator of the *Zentralblatt für Psychoanalyse* as well as the *Internationale Zeitschrift für (ärztliche) Psychoanalyse* from 1913 to 1919. He was a member of the regional Berlin group affiliated to the International Psychoanalytical Association from 1912, and remained a member until he was admitted to the Vienna Psychoanalytic Society in 1919.

After World War I he acquired a farm at Heilbrunn bei Bad-Tölz in Upper Bavaria and transformed it into a clinic, which he directed until 1928. In 1919 he became a member of the Leonhard Seif's society: *Gesellschaft für angewandte Seelenkunde* (Society for applied psychology) in Munich. He resigned one year later along with psychoanalysts Hans von Hattingberg and Viktor von Gebattel because Seif, who was already close to Adler and then Jung, was moving too far away from Freudian concepts.

Marcinowski developed his own form of psychotherapy and from the mid-1920s he can no longer be classified in any given sector. He gave conferences on psychoanalysis in the context of the *Arbeitsgemeinschaft für medizinische Psychologie* (Study group for medical psychology) founded by Carl Gustav Heyer at the University of Munich in 1925. He published in Hans von Hattingberg's collection *Der nervöse Mensch* (The nervous man), collaborated in the *Zeitschrift für Menschenkunde* (Review of anthropology) founded by Hattingberg in 1925, in Wilhelm Stekel's publications, and in other medical and psychotherapeutic reviews. He died on February 13, 1935, in Tübingen-Waldhausen, where he had lived with his family since 1928 and where he had opened another rest home, which his wife continued to run after his death.

## MARCONDES, DURVAL BELLEGARDE (1899–1981)

Durval Bellegarde Marcondes was born in São Paulo on November 27, 1899, and died there on September 27, 1981. He was one of the leading promoters of psychoanalysis in Brazil.

In 1919, while still a medical student in São Paulo, he learned of the existence of Freud's work through the efforts of his professor, Franco da Rocha. In 1925, having completed his medical training, he opened consultation rooms where he received patients suffering from neuroses and treated them using the psychoanalytic technique. Moreover, he was the only early practitioner of psychoanalysis in Brazil to later submit to orthodox training and to practice throughout his life, thus becoming a "pioneer," according to Marialzir Perestrello's classification in *Primeiros Encontros com a Psicanálise no Brasil* (1899–1937).

In 1927 Marcondes conceived of and founded the first *Sociedade Brasileira de Psicanálise* (Brazilian psychoanalytic society). The stated goal of this institution was "to bring together people who are interested in studying Freudian theory and spreading these ideas." Juliano Moreira also founded an affiliate psychoanalytic society in Rio de Janeiro. The *Revista brasileira de psicanálise* (Brazilian review of psychoanalysis) was launched in 1928. A copy of the first issue was sent to Freud, who responded to Marcondes with this letter on June 27, 1928: "Dear Colleague. The content of the new *Revista brasileira de psicanálise* gave me great pleasure. May it have a fruitful future! As a result of this dispatch, I bought a small Portuguese grammar book and a German-Portuguese dictionary. I am curious to see whether I can manage to read the review for myself dur-

ing these holidays. Greetings and many thanks, yours Freud." In another letter to Marcondes in 1928, Freud asked the members of the newly founded society to request to be affiliated to the International Psychoanalytical Association (IPA). Volumes 10 (p. 515, 1929) and 12 (p. 510, 1931) of the *International Journal of Psychoanalysis* record that the group did respond to Freud's suggestion, with an informal request that was favorably received by Max Eitingon, then president of the IPA.

In 1930 Marcondes received a publication from Eitingon, celebrating the tenth birthday of the Berlin Psychoanalytic Institute (BPI). The publication contained a description of the system of psychoanalytic training developed and perfected by the institute, based on training analysis, supervisions, and theoretical/technical studies. Marcondes was immediately convinced of the necessity of establishing the same training system in Brazil and the need to invite a training analyst to help. René Spitz was the first choice but the political situation prevented the project from coming to fruition: the constitutionalist uprising of 1932 brought São Paulo into military opposition with the rest of country and caused the federal government to impose a blockade on communications in the state of São Paulo. Another occasion to invite an IPA-approved psychoanalyst did not present itself until November, 1936, when Dr. Adelheid Koch arrived in São Paulo. Marcondes was among the first six people to be analyzed by the Berlin analyst.

Marcondes played an active part in the life of psychoanalytic institutions. He was president of the São Paulo branch of the *Sociedade Brasileira de Psicanálise*, a mandate he received twice. He helped found the *Associação Brasileira de Psicanálise* in May 1967 and became its first president.

In 1938 he created the mental hygiene section of the school health service in São Paulo and became its first director. In it he developed a program of infantile mental hygiene on psychoanalytic bases, thus creating a hitherto unknown occupational category in Brazil: mental health workers and psychiatric advisors that visited homes, the precursors of psychologists. Some of these mental health professionals went on to become psychoanalysts. Marcondes made the profession accessible to non-physicians, this being a distinctive feature of the São Paulo section of the *Sociedade Brasileira de Psicanálise*. Marcondes taught in the School of Political Sociology, in the Public Health Faculty, in the Psychology Institute, in the University of São Paulo, and in the Catholic Pontifical University of São Paulo.

He wrote many articles on psychoanalysis and art criticism, and in 1951 he published a book, *A Medicina e a Psicologia* (Medicine and psychology).

## MARCUSE, HERBERT (1898–1979)

Herbert Marcuse, an American philosopher of German origin, was born in Berlin in 1898 into an assimilated Jewish family and died in 1979 in Starnberg, Germany, where he had returned after World War II. He studied philosophy in Berlin and Fribourg, and his doctoral dissertation, *Hegel's Ontology and the Theory of Historicity* (1987), was sponsored by Martin Heidegger. He militated against social democracy, defended a critical Marxism, and participated, along with Max Horkheimer and Theodor Adorno, in the creation of the Institute for Social Research in Frankfurt. When Hitler came to power in 1933, Marcuse left Germany for the United States and taught at different universities: New York, Columbia, Harvard, Brandeis, and the University of California at San Diego.

He had a Marxist training and in 1958 published *Soviet Marxism: A Critical Analysis*. He also harbored a passionate yet critical interest in psychoanalysis. These

two facets of Marcuse contributed to his writing, where one can discern individual libidinal structures and economic, political, and social realities characterized by domination and alienation continuously coming into conflict. His best-known works were widely read by students in the United States and Europe in the 1960s. In *Eros and Civilization: A Philosophical Inquiry into Freud* (1955) and *One Dimensional Man* (1964), he denounced “repressive sublimation” in consumer society, where society caters to the individual's drives only to better control the individual. Ever the rebel, Marcuse also published *Reason and Revolution* (1941), *An Essay on Liberation* (1968), and *Counterrevolution and Revolt* (1973).

## MARTINIQUE

Psychoanalysis is a relatively recent activity in Martinique. West Indian intellectuals studying in Paris in

the 1930s nevertheless showed an early interest in it. Martinican students could thus declare, in the review *Légitime défense* (Legitimate defense): “As for Freud, we are ready to use the immense machine for dissolving the bourgeois family that he set in motion.”

The poetic works of Aimé Césaire began to be published in 1939 and were hailed by André Breton as “The greatest lyrical monument of our time [...] a general abdication of the mind.” There is a definite influence of a Surrealist version of psychoanalysis on a poetic project that set as one of its major goals the exploration of the depths of the black psyche.

Frantz Fanon, the Martinican psychiatrist, criticized psychoanalysis in 1952. He claimed that Freud, Jung, and Adler had not thought of blacks in their research. Similarly, he saw the Oedipus complex as being impossible in West Indian families. For more than twenty years the complex conflicts surrounding decolonialization in the West Indies were to make Fanon’s critique the breeding ground for resistance to psychoanalysis in the name of a cultural determinism with uncertain principles. The few people who took any interest in psychoanalysis had no more than a bookish knowledge of it.

The first psychoanalytically-informed work in Martinique began in 1973: interpreting children’s drawings, a seminar directed by the French child psychiatrist Bernard Bousquet. But the true beginning of psychoanalysis in Martinique dates from 1974. It derived from the presence of a Swiss couple, Pierre and Lucette Stittelmans, two non-physician psychoanalysts. Shipwrecked on their way to the Trobriand Islands (Papua New Guinea), they had to land on the island. Their stay was extended until 1980. The Stittelmans had been trained by and were members of the Swiss Psychoanalytic Society (affiliated with the International Psychoanalytical Association [IPA]). They thus provided analysis, training and supervision for all who wished to become psychoanalysts.

In October 1975 the first psychoanalytic group came into being: the Groupe antillais de recherche, d’étude et de formation psychanalytique (GAREFP; The West Indian Group for Psychoanalytic Research, Study and Training), the founding members being Héliane Bourgeois and Luce Descoueyte, along with Mrs. Marcel Manquant and Mrs. Raymond Saint-Louis Augustin. From 1975 to 1980 this group worked to secure theoretical training of its members with analysts from the Paris Psychoanalytic Society,

affiliated to the IPA. Among the members were Florence Guignard, Jean Bégoïn, René Diatkine, and Michel Neyraut. There was also an initial collaboration with Roberto Fontaine of Venezuela for transactional analysis. Dr Mauriello, a Martinican psychoanalyst living in Quebec, also contributed to the effort.

Following the trauma occasioned by the departure of the Stittelmans in 1980, the GAREFP developed a Lacanian orientation that increased with time, some of the founding members having decided to withdraw from the group.

December 1990, saw the birth of another association, the Forum, the founding members being Benedetta Jumpertz, Marcel Manquant, and Guillaume Suréna. It organized the first Martinican symposium on psychoanalysis in March 1991. It organizes training for its own members and is not affiliated with any external psychoanalytic associations. Its members come from various different backgrounds but it sees Freud’s work as its cornerstone. In this sense it could be said to identify with the IPA orientation, although it is not a member.

The absence of West Indian doctors and academics is easily noticeable. Twenty-five years after the introduction of psychoanalysis, there were only two Martinican psychiatrists practicing psychoanalysis there and the two existing associations had been founded by non-physicians. Psychoanalysis has no direct influence on either the medical or the academic world. The paramedical and in the psycho-educational sectors have displayed a certain amount of interest.

As of 2005, psychoanalysis does not yet play any significant role in West Indian culture. It is not present in questions of national identity, literary debates, or political aspirations. Martinican psychoanalysis has not yet created distribution networks. A very small number of individuals have written clinical and theoretical papers but there has been no substantial contribution to psychoanalytic theory.

This psychoanalysis is evolving in isolation in relation to the Caribbean, like Martinique itself. There are a few practitioners in Guadeloupe, but no organized movement. Our ignorance of what is happening in English-speaking and Spanish-speaking countries is proportionate to the divisions established by five centuries of European rivalry in the Caribbean.

In conclusion, we can say that psychoanalysis exists in Martinique in spite of all. Changes coming from the

inside will probably ensure the development of fecund psychoanalytic thinking.

GUILLAUME SURÉNA

## MARTINS, CYRO (1908–1995)

Cyro Martins, a Brazilian psychoanalyst and full member and training analyst of the Psychoanalytic Society of Pôrto Alegre, was born on August 5, 1908, and died in Pôrto Alegre on December 15, 1995. He spent his childhood in Quaraí, where life was dedicated to farming. In 1920 at age eleven, he went to Pôrto Alegre to attend school and prepare for medical school, which he entered in 1928. Besides having an interest in medicine, from very early on Cyro proved to be a writer. When he was fifteen, he published his first short stories dealing with life in the country. “Influenced by friends and rural life, I wrote because of a personal feeling of disquiet,” he said, recalling his childhood and adolescence.

During his last year at medical school, Martins became interested in studying psychiatry. After medical school he returned to Quaraí, where he worked for three years, and in 1937 he went to Rio de Janeiro to study neurology and psychiatry. The following year he moved to Pôrto Alegre, where he began to work as a psychiatrist. From 1946 to 1948 he was an assistant instructor in neurology at the Pôrto Alegre Medical School.

In 1951 he and his friend Mário Martins went to Buenos Aires, where, at the Argentine Psychoanalytic Society, he concluded his psychoanalytic training. He was analysed by Arnaldo Rascowski, and his teachers included Angel Garma, Leon Grinberg, Enrique Pichon-Riviere, Arminda Aberastury, and Heinrich Racker. He was supervised by Pichon-Riviere and by Dr. Alvarez Toledo. In 1956 he returned to Pôrto Alegre and, together with Mário Martins, José Lemmertz, and Celestino Prunes, founded the Pôrto Alegre Center for Psychoanalytic Studies, the nucleus of the study group acknowledged by the International Psychoanalytical Association in 1961. In 1963 the center became the Psychoanalytic Society of Pôrto Alegre. Martins was president of the society from 1965 to 1969. He was also president of the first Brazilian Congress of Psychoanalysis, organized by the society. He represented

the society at various Brazilian congresses and was the official reporter on creativity at the Brazilian psychoanalytic congress held in Rio de Janeiro. Martins was a founding member of the Psychiatric Society of Pôrto Alegre and president for two successive terms. He was also a founder of the Society of Psychosomatic Medicine of Pôrto Alegre. As a consultant, he remained active and dedicated to the interests of the Psychoanalytic Society of Pôrto Alegre.

Martins wrote and published many papers, especially in the *Revista brasileira de psicanálise*. In 1964 he published the first book on psychoanalysis in Pôrto Alegre, *Do mito à verdade científica: Estudos psicanalíticos* (From myth to scientific truth: Psychoanalytic studies), a collection of his lectures and scientific papers presented at congresses.

A kind person who inspired respect and admiration, Martins died on December 15, 1995, in Pôrto Alegre.

## MARTY, PIERRE (1918–1993)

Pierre Marty, a psychiatrist, psychoanalyst, member, and former president of the Société psychanalytique de Paris [Paris Psychoanalytic Society], was born on

March 11, 1918, in Saint-Céré, France, and died in Paris on June 14, 1993. He was considered the leading representative of the *École psychosomatique de Paris* (Paris School of Psychosomatics), whose work attracted a large international audience after the 1962 appearance of *La Pensée opératoire*, which he wrote with Michel de M'Uzan.

Marty spent his entire student life in a northern suburb of Paris, where his father was a teacher. During childhood and adolescence, the sickness of those closest to him caused him considerable distress. He claims that this was the origin of his interest in psychosomatics. After the lycée he began studying medicine, then psychiatry, and underwent personal analysis in 1947 with Marc Schlumberger. He married Simone Fain, the sister of Michael Fain, and the couple had one daughter, Catherine. Marty became a widower in 1963 and never remarried.

Marty quickly rose in the ranks of the SPP. Elected an associate member on June 20, 1950, he became a full member on May 20, 1952, and on January 20, 1953, Jacques Lacan, then president of the SPP, chose him as his secretary (a position he held until 1961). In this way Marty was able to directly follow the events that led to the split in the SPP, following the departure of Lacan and the founders of the *Société française de psychanalyse* (French Society for Psychoanalysis). Marty was an integral part of these events but he never wavered in his decision to remain within the SPP. He established solid ties to Sacha Nacht, Francis Pasche, Maurice Bouvet, and many others. Even at this time he had developed an interest in psychosomatics.

Secretary of the fifteenth *Congrès des psychanalystes de langues romanes*, held in November 1952, he closely followed these conferences, which enabled him to remain in contact with Spanish colleagues with whom he had shared his ideas and developed close friendships over the years. During the twenty-first *Congrès des psychanalystes de langues romanes*, held in Rome, he presented the paper “Dépersonnalisation et relation d’objet,” which Maurice Bouvet, who was then dying, was unable to present. Faithful to his friend, Marty was one of the founders and the “administrator” of the Maurice Bouvet Prize, created in 1962. Made vice president of the SPP in 1961, he became president of the organization in 1969. Throughout his tenure and through his activity, an “administrative board” was created by a vote on June 16, 1970, the first step toward in-depth reform of the bylaws and

structure of the SPP. This led to the direct participation of membership categories that had previously been excluded. Two years later, in 1972, Marty and Michel Fain created the *Institut de psychosomatique* (IPSO, Institute of psychosomatics), in Paris, where he continued to see patients. At IPSO there was a *Centre d’enseignement et de recherches en psychosomatique* (Center for Psychosomatic Teaching and Research), which over the years was to become a world-renowned center for training, research, and treatment.

Marty became interested in psychosomatics early in his career. On May 9, 1950, he presented, before the SPP, a paper, “Aspect psychodynamique de l’étude clinique de quelques cas de céphalalgie,” and he wrote the chapter “Clinique et pratique psychosomatiques” in *La Psychanalyse d’aujourd’hui*, a collection of essays edited by Sacha Nacht. With his description of “operative thinking,” followed by the publication of *L’Investigation psychosomatique* (1963), written with Michel de M'Uzan and Christian David, Marty discovered a new approach to clinical work: that of “operative” patients in whom there are only two possible outlets for non-mentalized excitation—behavior or the somatic path. But it was in his two most important books, *Les Mouvements individuels de vie et de mort* (1976) and *L’Ordre psychosomatique* (1980) that he best described his architectural and psychosomatic conception of human beings.

Starting from classical psychoanalytic theory and especially Freudian metapsychology, which remains the fundamental principle of mental organization, he expanded its theoretical-clinical model to the psychosomatic economy of subjects. Evolutionary and counter-evolutionary movements determine points of attachment on the central evolutionary chain, as well as on lateral and parallel chains. This led to the development of a new system of psychosomatic nosography, which placed, between neurotic structures and ongoing psychotic structures that are symptomatologically organized, fully conscious neuroses, inadequately mentalized or poorly mentalized neuroses, and behavioral neuroses. Diagnostic distinctions are made during the psychosomatic investigation through an understanding of the patient’s preconscious system. This new system of classification entailed an improved form of psychotherapy for patients whose “mentalization” seemed deficient. The “maternal function” of the analyst was then used in an attempt to “reactivate the relationship,” something at which Marty, a remarkable clinician, excelled.

The experience he acquired at the Poterne-des-Peupliers Hospital, now the Pierre Marty Hospital, where he was senior physician at the time of its creation in 1978, enabled him to establish the validity of his theoretical and clinical model. It appeared that mental work protected the body against somatic disorganization, regardless of its nature or form, and if this was already in place, it promoted reorganization through modifications of the psychosomatic economy that accompany engagement in a regular psychotherapeutic relationship. Originally conceived with adult patients in mind, this psychosomatic approach to human behavior was extended to adolescents, children, and infants. A children's unit has been in place at the Pierre Marty Hospital since its inception.

Marty's work has experienced, and continues to experience, widespread recognition in France and abroad. There are several Pierre Marty centers around the world.

## **MARXISM AND PSYCHOANALYSIS**

A priori, there seems to be nothing that would provide common ground between a theory of unconscious psychic processes, such as psychoanalysis, and a social theory such as Marxism. Nothing, that is, but that which derives as much from social processes as from psychic processes: the intellectual activity and beliefs of human beings. In *New Introductory Lectures on Psycho-Analysis* (1933), Sigmund Freud explicitly referred to Marxism. He did not dispute the fundamental validity of the theory, he merely considered it incomplete. If there are social conditions for the production of the intellectual, moral, and artistic activities of human beings, there are also psychological conditions that are independent of the former.

In the second generation of psychoanalysts, some authors, positioning themselves on the Left (within the social-democrat or communist movements), sought to constitute a social psychology by bringing Freudian analysis of psychic processes into articulation with Marxist analysis of social processes. This line of thinking has been called “Freudian Marxism,” despite its heterogeneity. Particularly productive during the 1920s and 1930s, this approach was notably illustrated by Wilhelm Reich, Siegfried Bernfeld, Erich Fromm, and Paul Federn.

In *The Dogma of Christ and Other Essays on Religion, Psychology, and Culture* (1930), Fromm sought to establish the factors that shaped the development of ideas about the relationship between God the Father and Jesus Christ up until the Nicene Council. The basis for the articulation is as follows: Marxist class theory provides the tools for analyzing the life conditions of the different social groups; on the basis of these conditions and the science of the unconscious, which sheds light on the frustrations and expectations of the believers, it becomes possible to describe the “psychic surface” of the persons involved in various events.

In “Dialectical Materialism and Psychoanalysis” (1929), Reich argued that if the instincts are biologically conditioned, they are also susceptible to change under the influence of environment and social reality. Social psychology studies the psychological characteristics shared by members of a group and the group's instinctual structure as a function of its “destiny”—that is, its economic and social situation. Reich wrote

*The Mass Psychology of Fascism* (1933/1946) in this same spirit. He again argued that the sexual poverty of human beings is mainly the result of their alienation by economic and social modes of production. *The Sexual Revolution, toward a Self-Governing Character Structure* (1936/1962) denounced the role of the family as “a factory for authoritarian ideologies and conservative structures” (p. 72), and in this work Reich denounced, as Fromm had done, the “patriarchal” system that prevails in our societies.

Work of this type was poorly received on the side of both psychoanalysis and Marxism. Nevertheless, Freudian Marxist research continued after World War II in Germany, with Alexander Mitscherlich (author of *The Inability to Mourn* and *Society without the Father: A Contribution to Social Psychology*) and the journal *Psyche*. During the same period, the Marxist-oriented philosophers of the Frankfurt Institute of Social Research became interested in psychoanalysis and tried their hand at bringing the two theories together with regard to ideology. Works such as *The Authoritarian Personality* (1950) by Theodor Adorno and collaborators marked this convergence.

In the United States, Herbert Marcuse, a former member of the Frankfurt School, published *Eros and Civilization: A Philosophical Inquiry into Freud* (1955). In this work he openly posed the question of happiness. He rejected Freud’s theory that civilization requires that the individual’s libido be sacrificed. Must happiness and the values of culture be antithetical? No, argued Marcuse. He attempted to show that libidinal repression does not take the same form in all cultures. He forged the concept of *surplus repression* to refer to that part of repression which is specific to a given culture and is not indispensable for group life.

During the 1970s there was renewed interest in the idea of bringing together Marxism and psychoanalysis, but on different bases. Jacques Lacan’s rereading of Freud, on the one hand, and Louis Althusser’s rereading of Marx, on the other, were relevant to this trend, not necessarily through direct influence, but by calling into question old stereotypes. Much of the work is being done in the early twenty-first century on belief systems, social representations, the ideal, or the *habitus* originated in this cultural ferment and bears its imprint, although it is more accurate to speak in terms of multireferentiality rather than of “synthesis.”

## MASCULINE PROTEST (INDIVIDUAL PSYCHOLOGY)

Masculine protest is a concept described by Alfred Adler. In women it gives expression to a rejection of their feminine condition, the consequence of a devalorization of girls in their family or cultural milieu and the choice of a masculine ideal in the formation of their guiding fiction. In men it expresses itself as a superiority complex.

In *Social Interest: A Challenge to Mankind* (1933/1938), Alfred Adler wrote: “When a girl imagines that she can change into a boy, it is because the feminine role has not been presented to her as the equal of the masculine role. She revolts against what she believes to be a permanent perspective of inferiority for her. The Freudians have interpreted this fact as what they call the ‘castration complex.’” This rejection of the feminine role is also the consequence of the mother’s preference for her son or sons, which constitutes a paradox. Writing about one of his patients, Adler said: “Her mother, a fact that is unfortunately very frequent, had more affection for her sons than for her daughter, which confirms that she also accorded greater value to the male principle without, however, giving her husband the advantage that is inherent in this mode of

appreciation” (Adler, 1912/1926). This decathexis of the father facilitates father-daughter alliances. This patient had become the absolute mistress of the house. Speaking of another patient, he commented: “In her childhood antecedents we find a powerful feeling of inferiority, maintained in a constant state of tension by the fact that her mother preferred her younger brother and that he was more intelligent than she was. This patient’s most ardent conscious desire was always to be tall, very intelligent, to be a man.”

A conflictual relationship with the mother exacerbates the need to compensate against the inferiority complex through the elaboration of an ideal virile model and leads to a hostile attitude to women. Sexual and aggressive instincts then come together either in masculine behavior that rivals with men or in homosexual behavior where a dominant role is assumed. When the woman becomes a mother herself, she can transpose these problems to her relations with her children, as described by Adler in the following case: “Her attitude of rivalry with regard to her daughter was completely unconscious and might be said to act as a cover for an infantile attitude: the desire to surpass a sister that her parents had spoilt to the point of excess. But this latter attitude proved in turn to be equivalent to the fundamental attitude, namely her desire to acquire greater importance, to occupy her brother’s position” (Adler, 1912/1926).

For Adler the organization of the Self is indissociable from the history of the subject and the subject’s culture. As he wrote in *Understanding Human Nature*: “In civilization every woman wants to be a man” (1927/1992). The choice of a son to express this masculine protest could encourage delinquent or transsexual behavior. Social feeling plays an essential role in the socialization of such behaviors, or indeed their sublimation. In men, masculine protest becomes manifest in the cult of the superman, wherein human feelings are considered to be a sign of feminine weakness.

## **MASCULINITY/FEMININITY**

The feeling of belonging to a gender, masculine or feminine, has different meanings: first, a biological meaning that refers to primary and secondary sexual characteristics; second, a sociological meaning that has to do with the real and symbolic roles that society attributes to men and women; and finally, a psychological meaning that considers the ensemble of traits belonging to either gender.

As early as 1897, in his correspondence with Wilhelm Fliess, Sigmund Freud showed interest in the masculine/feminine dichotomy from two different, complementary perspectives: that of bisexuality and that of psychosexual development. He continued his study in “Three Essays on the Theory of Sexuality” (1905d), and then further refined his thinking in an article, “Feminine Sexuality” (1931b) and in lecture 33, “Femininity,” in his “New Introductory Lectures on Psycho-Analysis” (1933a [1932]).

Freud upheld the notion of a bisexuality that involves, in every human being, a more or less harmonious and more or less accepted synthesis of masculine and feminine traits. In developing his hypotheses, he was unable to relinquish the idea of biological bisexuality, even though he attributed a dominant role to the interplay of oedipal and preoedipal identifications.

In Freud’s view, the opposition between masculinity and femininity is preceded by other pairs of opposites—active/passive, phallic/castrated—that pave the way for it. Furthermore, in his view femininity does not appear until after the reorganization of the psyche that occurs at puberty. This conception of masculinity and femininity comes from the fact that Freud based his theory of sexuality on the prevalence of the phallus for both sexes. The opposition between masculinity

and femininity thus tends to become blurred, since both sexes are united in the same repudiation of a femininity that is equated with being deprived of the penis. Only masculinity is identifiable; femininity can only be understood in terms of the negative. Its development remains vulnerable to disturbances resulting from the after-effects of the earlier masculine period—that is, the regressions and fixations of the preoedipal stage. Freud thus envisioned the masculine/feminine dichotomy as an alternation of periods in which one or the other of the elements has the upper hand, including the libido, which pursues masculine or feminine aims in sexual life.

Freud himself acknowledged that he was not entirely at ease in his approach to the questions of feminine sexuality and bisexuality. He has often been criticized in this area, notably with regard to his equation of femininity with passivity. Currently, psychoanalytical studies of gender identity and early parent-child interactions have made possible a better understanding of the relationships between masculinity and femininity and their origins.

Masculinity and femininity are rooted in the intimacy of the earliest interactive bonds between parents and the child. The processes of “psychobisexualization,” a term introduced by Christian David, are established very early on, based on the child’s instinctual oppositions, which are modulated by the adaptive capacities of the mother and father. Each parent presents to the child his or her own opposition between masculine and feminine, in a manner that differs according to the baby’s sex. This abundance of interactive material further informs the oppositions already active within the infant (presence/absence, active/passive, phallic/castrated, good/bad), paving the way for the masculine/feminine opposition, which only appears, as such, in the oedipal stage.

Other authors have considered the question from the more archaic perspective of psychic envelopes, which also contain a dichotomy capable of grounding the opposition between masculine and feminine.

In any case, it is the baby that solicits the parents in one register or another, and not necessarily the father in his masculine aspects or the mother in her feminine aspects. The father and the mother, through regressive identifications, enter into communication with the child, incorporating varying amounts of their own masculine and feminine components. The child discovers the difference between the sexes within these

interrelationships and internalizes, in variable proportions, the ensemble of both masculine and feminine components, to establish the basic framework of his or her own psychic bisexuality.

Masculinity and femininity are situated at the crossroads of, on the one hand, interactions in the here and now, and on the other, maternal and paternal transgenerational filiations.

## **MASOCHISM**

Masochism is a form of pleasure obtained through suffering. The term was initially defined by Kraft-Ebbing in his book on sexual perversion, and is derived from the name of the author of *Venus in Furs*, Leopold von Sacher-Masoch. Initially considered by Freud as one of the infantile polymorphous perversions present in all human beings, masochism was associated with its opposite, sadism, with which it is generally paired. Although Freud originally saw masochism as deriving from sadism, he reversed this conception with the introduction of the second theory of drives: masochism became primary, the initial fusion of the death

instinct with the life instinct, protecting the human being from the self-destruction toward which the death instinct drove it.

In *The Interpretation of Dreams* (1900a), Freud, referring to a bunch of violets present in a dream, identified, through association with the English term *violation*, a masochistic character trait in the dreamer. In a 1909 note he refers to unpleasant dreams as satisfying masochistic functions. In *The Psychopathology of Everyday Life* (1901b), Freud for the first time makes a parallel between the hysterical fantasies of sexual cruelty, delusions of persecution (of which Judge Schreber was an illustration), and the deviant behavior perverts engaged in to satisfy their desires.

In his *Three Essays on the Theory of Sexuality* (1905d), Freud remarked (in a note added in 1910) that the masochistic component of sexual instinct allowed the subject to form an unconscious fixation on the figure of the hypnotist, which accounts for the hypnosis. He then described sadism and masochism, the latter always being derived from the first through a process of reversal—the subject becomes object. Masochism is associated with passivity and sadism with activity. An essential characteristic of the perversions is that the active and passive forms are found in the same individual. Since neurosis is the “negative of perversion,” this holds true for every human being. It is the anal-sadistic pregenital phase that clearly reveals the opposition between active and passive, a precursor of the later opposition between masculine and feminine. “The skin functions as an erotogenic zone in the component sexual instincts,” and one of the infantile erogenous sources of masochism is the “painful stimulation of the skin of the buttocks” (1905d, p. 193), a phenomenon that has been well known since the *Confessions* of Jean-Jacques Rousseau. In the *Three Essays* Freud describes libidinal coexcitation, prefiguring what would become erotogenic masochism in 1924.

“Instincts and Their Vicissitudes” (1915c) provides the first full Freudian description of masochism, which is derived from sadism turning back upon itself. First it turns back on the individual—the subject takes the place of the object—then activity turns into passivity. The pair of opposites that is formed is compared to another pair—voyeurism and exhibitionism. Freud, however, must address the following difficulty: although the child’s first aggressive acts are directed only at inflicting pain and are associated with self-preservation, he is logically led to consider that it is

only when the subject has become capable of reversing his masochism that he can become truly sadistic. Once this component of sexual excitation has been confirmed, the “pains inflicted on other people [can be] enjoyed masochistically by the subject through his identification of himself with the suffering object” (p. 129). There is an even greater satisfaction: The sadist can enjoy the sexual excitation associated with pain without experiencing pain himself. Freud resolves this contradiction with a temporal paradox where two originals are postulated, entailing a strange process of deferral: “The enjoyment of pain would thus be an aim which was originally masochistic, but which can only become an instinctual aim in someone who was originally sadistic” (p. 129).

In “A Child is Being Beaten” (1919e), Freud discusses the “genesis of masochism”. This appears to be based on clinical material drawn in part from Freud’s analysis of his daughter Anna. Freud maintains there is an initial period of sadism, with a growing tendency toward masochism. Masochism is described as participating in fantasy and autoeroticism, in the repression of oedipal jealousy. Expanding a child’s fantasy of punishment, Freud reveals the presence of an oedipal jealousy satisfied through sadism that leads, during a second stage, to a masochistic reversal, which remains unconscious under the influence of guilt: to be beaten by the father. The third stage—that of fantasy—whose protagonists have become anonymous, is sadistic only in appearance; the pleasure is in fact masochistic.

In *Beyond the Pleasure Principle* (1920g) Freud notes (in a passage added in 1921) that a traumatic dream could reveal “the mysterious masochistic trends of the ego” (p. 14). For the first time he sees that “there *might* be such a thing as primary masochism could also be primary” (p. 55). He then connects the negative therapeutic reaction to the feeling of unconscious guilt and its satisfaction through experiencing suffering as punishment.

It is in “The Economic Problem of Masochism” (1924c) that Freud describes his second theory of masochism, now adjusted to accommodate the second topographical subsystem and the new duality of drives that accompanies it: the death and life instincts. Masochism is broken down into erogenous masochism (pleasure in pain), feminine masochism (the expression of the female component in both sexes), and moral masochism (behavior associated with the

unconscious feeling of guilt)—the latter two expressions being based on the former.

Original erogenous masochism, or primary masochism, enables the libido's initial control of the death instinct within the individual, thus protecting him from destruction. One part of the death instinct is diverted outward by the libido, giving birth to destructive drives, drives of control, and sadistic drives, by putting it at the service of the sexual function. The other part, which remains within the organism, is bound through libidinal coexcitation; this is the original erogenous masochism. While masochism can, like a "drug" of self-preservation, lead the human being toward death, it is also a means for the libido to bind and thereby contain the death instinct and protect it from self-destruction.

Freud would maintain this model throughout his work and in "Analysis, Terminable and Interminable" (1937c) insisted on the role of masochism in the need for punishment, in the unconscious feeling of guilt in the resistance to treatment, and in the negative therapeutic reaction, thus providing a foothold for modern theorizations of these fundamental problems.

The evolution of Freud's theory of masochism is an integral part of his need to conceptualize a second theory of instincts, "beyond the pleasure principle," and recenter masochism as the foundation of the human psyche.

Benno Rosenberg has insisted on masochism's role as a "guardian of life," promoting survival under extreme external conditions, and as an internal organizer of the psyche. This conception makes masochism a primary kernel of the ego. By emphasizing the "internal" capacity of the psyche to fuse the life and death instincts, and thus organize itself, it contradicts theorizations that promote an external genesis for drives, whether this is reflected in the structuralism promoted by Jacques Lacan, the generalized seduction of Jean Laplanche, or the claims of "object relations" theory. Lacan was not unaware of erogenous masochism, which he referred to as "jouissance." Similarly, in the case of female femininity and maternity, female masochism served as a powerful impetus for the ego.

Karl Abraham and Melanie Klein made extensive use of the concept of sadism in their treatment of sado-masochism. For Klein, who agreed with Freud's formulation of the second theory of drives, sadism soon came to embody the destructiveness of the death

drive, which can be compared to the prevalence and precocity of projection in her theorization.

Edmund Bergler provided an original contribution to the theory of masochism, which he felt played an early, and significant, role in the development of libidinal stages. His theory of what he termed *basic neurosis* was based on oral masochism, the underlying structure for all other mental structures.

## MASS PSYCHOLOGY OF FASCISM, THE

As Wilhelm Reich notes, his *The Mass Psychology of Fascism* "was thought out during the German crisis years, 1930–33. It was written in 1933; the first edition

appeared in September of 1933 and the second edition in April of 1934, in Denmark” (1970b, p. xvii). A genuinely burning question lay at the heart of the book: How did Hitler succeed in imposing himself? More specifically, how could a people of seventy million cultivated, hardworking individuals let themselves be seduced by a manifest psychopath? Even beyond the period when it was formulated, which culminated in horror, this question is surely still fundamental to any serious political thinking.

As a militant well versed in Marxism and the author of “Dialektischer Materialismus und Psychoanalyse” (Dialectical materialism and psychoanalysis; 1970a), Reich set out to analyze “the economic and ideological structure of German society between 1928 and 1933.” He wanted to illuminate the state of mind of the middle classes and the petite bourgeoisie. Their frustrations, resentments, fears, envies, and hatreds together formed what Reich called an “emotional plague,” which found release and gratification in the themes and imagery pounded out by Nazi propaganda and ideology.

Reich denounced the authoritarian family (which he described as “antosexual,” as a “central, reactionary cell”); strict, repressive education (which oppressed and subjugated the individual); nationalistic feelings; and religious indoctrination—all fertile ground, he argued, for sanctifying a charismatic leader brandishing obscure myths of blood, race, and soil in mystical defiance of human reason.

In Reich’s view, the symbolism of the swastika, evoking the fantasy of the primal scene (and reproduced hundreds of thousands of times), showed in spectacular fashion how Nazism systematically manipulated the unconscious. A repressive family, a baneful religion, a sadistic educational system, the terrorism of the party, and economic violence all operated in and through individuals’ unconscious psychology of emotions, traumatic experiences, fantasies, libidinal economies, and so on, and Nazi political ideology and practice exacerbated and exploited these tendencies. This unconscious mental dimension was still beyond the ken of traditional politicians, whether liberal or communist, and this ignorance led them to failure and disaster.

For Reich, fighting fascism meant first of all studying it scientifically, which was to say, using the methods of psychoanalysis. Reason, alone able to check the forces of irrationality and loosen the grip of mysticism, is also

capable of playing its own part in developing original modes of political action, building on a deep respect for life, and promoting a harmonious channeling of libido and orgasmic potency. Reich proposed “work democracy,” a self-managing form of social organization that would preserve the individual’s freedom, independence, and responsibility and base itself on them.

## MASTERY

The term *mastery* has several meanings in psychoanalysis. The first relates to the anal stage in infantile sexual development, as Sigmund Freud described it in *Three Essays on the Theory of Sexuality* (1905d). During this period in the structuring of the personality, the child is becoming better able to exercise muscular control over fecal contents and finds pleasure in the actions of retention and defecation. In “‘Civilized’ Sexual Morality and Modern Nervous Illness” (1908d) Freud described three characteristics of the anal stage: order, economy, and obstinacy. All three are marked by mastery, and they result from the sublimation of anal erotism.

It must be noted that anal erotism and mastery of its concomitant excitation are articulated with the loss of an object that is an integral part of the body. The

function of mastery thus has to do with the excitation produced in the anal zone at the very moment of defecation and the possible perception of a part of the body that becomes detached from the whole. Anal erotism is commonly associated with sadism and aggressivity: Mastery over an object can be understood as the psychic correspondent to control of the sphincter. Some types of depression can be linked to feelings of powerlessness resulting from an inability to exercise complete control over the inevitable separation from the object. The symbolic equivalency between feces, gifts, and money demonstrated by Freud makes it possible to see, throughout this chain, the importance of phenomena of mastery in gifts, indebtedness, and exchanges.

On the level of fantasy, an expression of mastery is found in fantasmatic scenarios constructed around beating or being beaten, typified by “A Child Is Being Beaten: A Contribution to the Study of the Origin of Sexual Perversions” (1919e). The analysis of this fantasy proposed by Freud reveals an unconscious wish to be beaten by the father and refers to the satisfaction—initially masochistic and secondarily sadistic—of this fantasmatic constellation. The fantasy suggests an appeal to a cruel superego that ensures mastery over the ego yet simultaneously procures enjoyment (*jouissance*) for it. The terms *master* and *mistress* in the erotic tradition foregrounded by Leopold von Sacher-Masoch represent mastery’s perverse dimension.

It is worthwhile to establish a conceptual distinction between *mastery* and *dominance*. Mastery is more specifically aimed at excitation, whereas in Freudian theory, dominance has the status of an instinct that specifically involves an object or part-object.

Following Roger Dorey in “La relation d’emprise” (1981; The dominance relationship), it can be said that mastery involves and presupposes a relative recognition of alterity as well as a certain renunciation of the object. But this notional differentiation, while essential, is not easy to establish in clinical practice, since fantasies of seduction and beatings express in paradoxical ways the effects of both dominance and mastery. It is thus appropriate to consider the specific allocation, for each individual, of the processes of dominance aimed at conservation of the object and the processes of mastery of excitation that make it possible to maintain new cathexes and identifications. And indeed, it is the perennial nature of the identificatory project that attests to the efficacy of mastery: It is

constitutive of the nature of identification, which is always being reshaped into new formations while maintaining the narcissistic quest for domination, although this quest is hidden.

The assurance of mastery involves the ego itself in its relation to the world: Integrating the requirements of the ego ideal, it makes the ego’s identificatory project a process that is simultaneously continuous and differentiated. The ego ideal serves as a relay between the subject and his or her community, which serves as a symbolic model in terms of the taboos against murder and incest. The community exerts a mastery to which the subject is submitted, and which the subject must appropriate to signify their membership in the human community.

Finally, it is appropriate to situate the notion of mastery at the very heart of analytic technique. The rules of free association and free-floating attention are fundamental and paradoxical from the point of view of mastery. They indicate a pathway that, at first view, entails letting go of conscious mastery in order to make possible the resurgence of the primary processes that enable unconscious formations to pass into the preconscious. They are also rules of a type of mastery that is specific to the psychoanalytic process, on the part of both analyst and analysand, allowing unconscious representations and affects to be elicited. The issue of mastery in relation to the analyst’s countertransference is essential here in order to limit countertransference projection, seduction, or even abuse, so that the analysand can be heard in their authentic relationship to their own unconscious truth.

## MASTERY, INSTINCT FOR

The expression *instinct for mastery* refers to an instinct whose aim is the appropriation of the object. For Sigmund Freud, this is a nonsexual form of instinct that can be blended with the sexual instincts. The introduction of this concept within the evolution of Freudian theory is representative of an early stage of the concept of the dualism of the instincts.

The instinct for mastery first appears in Freud's *Three Essays on the Theory of Sexuality* (1905d), where it is initially included in the evocation of a *Bemächtigungsapparat*, or apparatus for mastery, and later under its direct name of *Bemächtigungstreib*. There are seventeen occurrences in Freud's work from 1905 to 1933.

This instinct has a central place in the “Three Essays on the Theory of Sexuality” in that Freud places it in the service of the satisfaction of hunger and sexual needs and posits that sadism derives from it. The elements of the apparatus for mastery must be deduced from Freud's text; these include the sense of touch, the muscular apparatus, and the sensory organs in general. “The activity is put into operation by the instinct for mastery through the agency of the somatic musculature” (p. 198), he writes. The muscles of the body thus appear as the agent of mastery; the hand, whose movements involve the sense of touch and the musculature working in tandem, is thus an essential organ of the apparatus for mastery.

Freud clearly indicates the role of the instinct for mastery as it serves the sexual needs: “A certain amount of touching is indispensable (at all events among human beings) before the normal sexual aim can be attained” (p. 156). Moreover, in connection with masturbation: “The preference for the hand which is shown by boys is already evidence of the important contribution which the instinct for mastery is destined to make to masculine sexual activity” (p. 188).

He links the instinct for mastery and its derivatives—cruelty, the pleasure of looking, and the pleasure of showing—to bodily functions “that appear in a

sense independently of erotogenic zones” (p. 192) or even in the case of cruelty “independently of the sexual activities that are attached to erotogenic zones” (p. 193). He further links the instinct for mastery to the “instinct for knowledge,” which “cannot be counted among the elementary instinctual components, nor can it be classed as belonging exclusively to sexuality. Its activity corresponds on the one hand to a sublimated manner of obtaining mastery, while on the other hand it makes use of the energy of scopophilia” (p. 194).

The link between the instinct for mastery and cruelty is explained in a way that prefigures the notion of instinctual blends: “The sexuality of most male human beings contains an element of aggressiveness—a drive to subjugate; the biological significance of it seems to lie in the need for overcoming the resistance of the sexual object by means other than the process of wooing. Thus sadism would correspond to an aggressive component which has become independent and exaggerated and, by displacement, has usurped the leading position” (pp. 157–158).

The instinct for mastery thus begins to change in its status in Freud's work; it starts to appear more as an intermediary concept between the sexual and the nonsexual than as a conceptual pole that can be opposed to the sexual. In his subsequent search for a dualism that is more clearly grounded in biology, Freud relegates the instinct for mastery to the background, preferring to focus instead on the notion of self-preservation instincts as the polar opposite of the sexual instincts (“Notes Upon a Case of Obsessional Neurosis” [1909d]). The instinct for mastery nevertheless retains a place in “Instincts and Their Vicissitudes” (1915c), but finally, from about 1920, in the dualism that pits the life instincts against the death instincts, the instinct for mastery is viewed as merely a derivative of the latter.

Long neglected by theorists, the instinct for mastery returned to prominence in psychoanalytic thought only with the publication of Jean Laplanche and Jean-Bertrand Pontalis's article on it in their *Vocabulaire de la psychanalyse* (1967). Roger Dorey (1981) discusses it in the context of the “mastery relationship”; Jean Bergeret uses the Freudian concept of the instinct for mastery as his point of departure in his development of the notion of “fundamental violence”; Jean Gillibert (1982) describes it as the “drive's drive” behind destruction, the result of “madness for mastery”; and

Paul Denis (1992) proposes to reconsider the theory of the drives beginning with the hypothesis that the drives themselves, in their constituent organization, bring together a “formative component of mastery” and a “formative component of satisfaction,” whose economic weight can vary and whose dissociation can be observed.

## **MASTURBATION**

Masturbation is the act of obtaining pleasure from manipulation of the genital organs.

Before Sigmund Freud shed light on infantile sexuality, masturbation was exclusively viewed from the extremely negative perspective of religion and morality, rather than being seen as a social and medical problem. This is attested by Dr. Samuel Auguste David Tissot’s *L’onanisme: Dissertation sur les maladies produites par la masturbation* (Onanism: Dissertation on the illnesses produced by masturbation; 1778), which for more than a century and a half remained the standard reference on the issue. In 1576 Michel de Montaigne, in his *Essays* (II, 12), was the first to introduce the term *masturbation* into the French language; its

etymological origins are controversial. In 1835 the word appeared in the sixth edition of the dictionary of the French Academy, where *onanism* was given as a synonym.

In his *Three Essays on the Theory of Sexuality* (1905d), Freud defined masturbation as an infantile sexual activity, an autoerotic practice whose erotogenic zone is the genital region. During the child’s development, most of the other erotogenic zones lose their importance and are subordinated to the genital zone. Within psychoanalytic theory, Freud gave a central place to masturbation, specifying in a note added to the same text in 1920 that “masturbation represents the executive agency to the whole of infantile sexuality and is, therefore, able to take over the sense of guilt attaching to it” (1905d, p. 189, n. 1). He placed the three phases of infantile masturbation at the period when the infant is nursing, at four years of age, and at puberty.

René Spitz held that autoerotic activity in the form of playing with the genitals during the first eighteen months of life is a good indicator of appropriate object relations, just as appropriate sexual activity is in the adult. Melanie Klein always placed great importance on masturbatory fantasies, arguing that these indirectly feed into most activities of the normal child, such as play and schoolwork.

The reactions of caregivers to the child’s masturbatory behaviors play a part in structuring the child’s personality. In the case of the “Wolf Man,” presented in “From the History of an Infantile Neurosis” (1918b [1914]), Freud explained that within the childhood nodal complex, in the realm of sexual relations the father takes on the role of the enemy: the person who interferes with autoerotic sexual activity. Spitz showed that this restriction of sexuality, masturbation in particular, allows for social and civilized attainments such as the superego in humans.

Freud insisted on the infantile aspect of masturbation, and this topic became controversial at a 1910 meeting of the founders of the Vienna Psychoanalytic Society to discuss “the harmful effects of masturbation” (Nunberg and Federn, 1962–1975). From this it was wrongly extrapolated that masturbation in adults is regressive and should be viewed as psychopathological. It should be stressed that masturbation in adults, within the framework of an object relation, is a normal expression of adult sexuality. Hence, it is to be distinguished from infantile autoerotism, which, if it persists

into adulthood, is considered a sign of neurosis or perversion.

## **MATERNAL**

*Maternal* refers to the physical and psychological care given to another person on the model of a needy

infant. For Freud ever since the *Project for a Scientific Psychology* (1950c [1895]), the ambiguity of the maternal for the infant was inherent in its ambiguous nature: breast-object or person-mother, total/partial, satisfying needs (mixed with the quality of care dispensed and the sensations procured), internal/external, protective shield/seduction.

Freud isolated an essential component in these dualities: the care associated with the protective shield and intended to satisfy needs also awakens partial sexual drives in the erotogenic zones. Supported by the self-preservation drives, they manifest themselves in autoeroticism. The infant stimulates the erotogenic zone freed from need, creating a second erotogenic zone. This is accompanied by fantasy activity, which then replaces this self-production of pleasure. The ego thus develops and becomes autonomous through the internalization of maternal functions (1905d).

The maternal object is at the origin of desire, but is sensorially initially known with certainty by the pleasure ego. In the infant's first memories, perception of this object is associated with cessation of unpleasure, sensations of nursing or contact, and the pleasure of elimination. The infant is vitally dependent on this perception, since it compensates for its original powerlessness. The numerous memory traces left behind serve various functions. The ego makes use of memories of the shared origin of pleasure and memories of the maternal object to maintain the two modes of mental operation. Internally, the ego begins to conceive of the continuity of the internal object through hallucinated reinvestment of the memory traces. Between inside and outside, ego responses, combined with the emotive and muscular expressions of tension, gives meaning: It establishes mutual understanding and provides a basis for gratitude. Externally, the maternal object, although essential, is lost, sought for (1926d [1925]), and possibly rediscovered. The mother's absence and the loss of the object (initially unthinkable other than as a malefic occurrence) are prototypes of danger. The desire for the mother unaccompanied by her presence triggers anxiety and mobilizes thought.

“For the infant the psychic maternal object replaces the fetal biological situation” (1926d [1925]). The breast epitomizes that sensory object, which has become mental. A part of the ego-other, susceptible of being lost outside yet preserved inside, the sensory object thus forms the core around which narcissistic unity is organized. The infant's consciousness of no longer being the

breast triggers a constructive depressive crisis during weaning in subjects introduced to the oedipal drama. The maternal fusion is then repressed to promote a bond with the mother. Yet unconscious ideals continue the infant's primary identification with the original infant-mother unity.

Whenever an aspect of the repressed primary maternal fusion becomes conscious, a feeling of the uncanny overcomes the subject, while regression promotes the subject's nightly hallucinatory return to the maternal breast in dream thoughts (Braunschweig and Fain, 1975). The child—seduced by the care he has incorporated with repressed sexual aspects of the mother, and subject to continued excitation of this internal sensory object whose signifiers are enigmatic—attempts to control the experience by repeating it autoerotically.

The subject's imago, an imaginary schema, arises from the libido-charged imprint resulting from the attentions of the mother and attached to the subject's inner core. It provides a focus for regression, orients the choice of a man's sexual object later in life, and definitively marks the secondary nature of the relationship of a daughter to her father and to men. For the mother, a girl who has become a woman, maternal love prolongs sublimated sexuality as an alloy of narcissism and object love. Unbounded solicitous affection gives rise to a "shared illusion" of unity between mother and child: the child constructs itself in unity with the maternal, in a space for a two, seeking reciprocity, which is then individualized.

The mother then leaves the phase of "primary maternal preoccupation" to address her womanly desire for a lover and her sexuality. This introduces the child to its limitations (Aulagnier, 1975/2001). Maternal affection is a reaction formation, a compromise between sexual and aggressive drives.

Melanie Klein presents the bisexual maternal as the foundation of the psychic world, which contains both good and bad objects. For Donald Winnicott, only satisfaction of initial psychic and somatic needs frees the subject from the illusion of omnipotence and establishes the pleasure of thinking. For Wilfred Bion, maternal reverie initiates thought. And for Didier Anzieu (1989), perceived maternal affects form part of the skin-ego. Freud thus initiated a series of developments in thinking on mother-child attachment and interaction that has continued to this day.

## **MATERNAL CARE**

Maternal care covers all aspects of the mother's care-taking activity from her child's birth until it reaches the age of twelve to fifteen months, or, in the view of some authors, such as John Bowlby, the age of three years. Primarily, it is the quality of the relationship established by the mother with her infant and main-

tained throughout this period. While “the mother” usually means the woman who has carried the child to term and looks after it after birth, in the present context it may also denote any person who fulfills the maternal role in a continuous fashion from birth on (mother substitute).

The concept of maternal care is essentially post-Freudian. Freud assigned the mother no primary structuring role in the mental development of the child, nor did he view the loss of the mother as a traumatic event of particular import when it occurred in the child’s earliest years. He did, however, make mention of maternal care in a footnote on the “autistic” fiction of a shell in his paper on the “Two Principles of Mental Functioning” (1911b, pp. 219–220n). And towards the end of his life, he intuited the importance of the mother-infant relationship, describing it as “unique,” and as “the prototype of all later love-relations” (1940a [1938], p. 188), and suggesting the existence of an early sexualized relationship centered in particular on the oral satisfactions the infant obtains from feeding.

The idea of maternal care was developed during the 1950s, starting from two different, if overlapping, areas. The first was a concern with the fact that the mother’s extended absence—the effective loss of the mother—could lead to a depressive response on the part of the child (Spitz, 1946), to anxiety reactions, or to developmental delays. The term was used in the same sense but in a somewhat more official way in John Bowlby’s report to the World Health Organization (1951), which provided a critical review of clinical studies and research on the harmful results of deficiencies in maternal care. Bowlby’s monograph precipitated major changes in the practices of institutions and childcare centers in many countries.

In the second place, the pediatrician and psychoanalyst Donald Winnicott contributed much to the establishment of the idea of maternal care by describing a particular state that he called “primary maternal preoccupation” (1956/1958): a hyperacute state that allowed the mother to respond with sensitivity and delicacy to the very first demands of her infant. Winnicott also placed great stress on the need to recognize and describe what he called the “good-enough mother,” who by virtue of her constant presence was able to meet the child’s basic needs, present the world to it in acceptable doses, and protect it from stimuli, whether of internal or of external provenance, that

were too intense. And lastly he underscored the reciprocal nature of mother-infant interaction.

Before long, since a “lack” or “deprivation” of maternal care came to connote a great variety of situations, it was necessary to distinguish between inadequate of interaction with the mother (and the specific shortcomings of such interaction), and discontinuities within the mother-child relationship caused by frequent or permanent separations (Ainsworth, 1962).

This early work addressed both the failures of maternal care and the importance of high-quality mother-infant interaction. Subsequent research increasingly focused on the systematic observation of day-to-day relations between mother and infant. The outcome was a characterization of various well-defined phases. Thus the first three months of life were said to see the development of a synchronicity between mother and child founded upon waking and sleeping patterns, while the period between three and six months of age witnessed the emergence of reciprocal exchanges pleasurable to both parties, and the six-to-nine-month stage was marked by much more initiative by the child in its interaction with the mother (Sander, 1964).

Following the path opened up by Bowlby’s theory of attachment (1969), numerous studies were made of various behaviors indicating the child’s attachment to the maternal figure: smiling, vocalization, tears at moments of separation, the tendency to follow the mother no matter how little she moved, and so on. Little by little, the notion of maternal care was defined more precisely in terms of the availability of the mother figure, her accessibility to the expressed needs of the child, and her degree of sensitivity to, and comprehension of, those needs (Ainsworth et al, 1978). Daniel Stern (1985) has employed the word *attunement* to describe the bond made between mother and child in the first months. Regularity, continuity, and consistency seem to be the qualities essential to the satisfactory unfolding of mother—infant interaction.

It has become clear that a close correlation exists between the quality of the maternal care received in the first year of life and the quality of the attachment manifested by the child on reaching the age of one. A young child is “secure” when the mother has managed to be sensitive to its needs and respond to them in an adequate and consistent manner, “insecure-resistant” when the mother has generally responded erratically to its needs and signals, and “insecure-avoiding” when

its care has been mediocre or where it has been simply rejected. (Ainsworth et al., 1978).

Several studies have observed that, as the child becomes more sociable, mother and infant react a great deal to each other's affective states. Because mother-child interaction seems so emotional, studies emphasize the major role played by positive and negative affects in the child's overall development.

Research since the 1990s (Fonagy et al., 1993) seems to show quite clearly that the quality of maternal care throughout the first year of life is largely determined by the quality of the mother's attachment to her own mother.

## MATERNAL REVERIE, CAPACITY FOR

Wilfred R. Bion developed the concept of the capacity for maternal reverie in his three books written during the 1960s: *Learning from Experience* (1962), *Elements of Psycho-Analysis* (1963), and *Transformations: Change from Learning to Growth* (1965).

Although he was an adult analyst and was primarily interested in group dynamics and the workings of psychosis, the concepts that he proposed (based on study of the analytic relationship in these two areas) in fact also proved to be very dynamic and very productive in connection with study of the foundations of the psychic apparatus—that is, the ontogenesis of the psyche.

In Bion's view, this ontogenesis of the psyche can be related to a digestive model of the workings of the "thought-thinking apparatus." At the beginning of its life, the baby does not have access to a thought-thinking apparatus that is mature enough to metabolize—that is, to use and integrate its very first mental or proto-mental materials. Bion thus described the beta (b) elements, which correspond to extremely archaic bodily feelings, to emotional states linked to the infant's very earliest sensory and relational experiences, which it cannot utilize as such. There is thus a need, for the baby—that is, for its mental growth and maturation—for a detour through the Other.

The infant projects these beta elements into the psyche of its mother (or other adult caregiver); this adult effectively lends the child their own "thought-thinking apparatus" to reshape, detoxify, and transform the beta elements into alpha (a) elements, which can then be assimilated by the infant and integrated into its

own mental functioning. This transformation is due to the “alpha function” of the mother’s psyche, or “capacity for maternal reverie,” which thus fulfills what could be described as a “desaturating” function with regard to the beta elements produced and felt by the infant (or by the patient).

From vantage point of the history of ideas, the emergence of this concept is situated at the confluence of Bion’s ideas on the functioning of groups, which also have a containing and transformative function (containers), and his analytic practice with adult psychotics: “If the patient cannot transform his emotional experience into alpha elements, he cannot dream,” he wrote in *Elements of Psycho-Analysis*.

This model is indissociable from the grid that Bion proposed to categorize the different types of mental materials (horizontal rows) and the various ways these can be used in communication (vertical columns). The beta and alpha elements correspond to the first two horizontal rows (A and B) of the grid, the last row of which is the “algebraic calculus” (H).

The extrapolation of this model to early psychic development was effected more by later theorists of child analysis than by Bion himself. In France, René Diatkine published *L’Enfant dans l’adulte ou l’éternelle capacité de rêverie* (1994; The child in the adult; or, the eternal capacity for reverie), in an implicit homage to all that this concept has contributed to the work of child analysts. In Diatkine’s view, the concept of the maternal reverie must be understood along with Jean Laplanche’s work on psychic translation in the context of his theory of generalized seduction.

## MATHÈME

In Greek, *mathêma* means “that which is taught.” Following the same path that led Freud to the discovery of slips and jokes, Lacan forged connections between the fields of spoken discourse and logical inscription. In 1955, he introduced what could be called his first matheme, schema L.

The main Lacanian mathemes in order of their appearance are:

1. *Schema L* (1955), which identifies four points in the signifying chain: first, the unconscious, or the discourse of the Other (A), and then the subject (S), which in turn results from the relation between the ego (*a*) to the other (*a'*).
2. *The formula of the signifier* (1957), *S/s*, links the laws of the unconscious discovered by Freud to the laws of language (metaphor and metonymy).
3. *The “big graph”* (1957) represented two different stages of the signifying chain. Lacan situated jouissance, castration, the signifier, and the voice at the various points of intersection on this graph.
4. *The four discourses* (1969) were used to link the discourses of the master, the university, the hysteric, and the analyst. Four terms—*S1*, the master signifier; *S2*, knowledge;  $\$$ , the subject; and *a*, surplus enjoyment—turn in a circular motion to take up four successive positions defined by the discourse of the master: the agent, the other, the production of the discourse, and truth.
5. *The formulas of sexualization* (1972) present sexual difference as a logical inscription. Using the signs  $\exists x$ ,  $\Phi x$ , and  $\forall x$  outside of the field of mathematics where they originated, Lacan inscribed a masculine psychical structure on one side and a feminine psychical structure on the other.

The Lacanian matheme is characterized by being both open and asymmetrical. It does not tend towards closing discourse, and in spite of its character as a statement, it is primarily an enunciation. And there lies the paradoxical aspect of the enterprise—to found a science of the subject. Even though Lacan finally

concluded (at the 1978 Congress of the *École freudienne de Paris*) that there can be no transmission of psychoanalysis, he always situated psychoanalysis within knowledge: access to the unconscious is legible and transmissible. Mathemes advance and illustrate the theses that in relation to speech and writing, another structure besides that of grammar or syntax organizes speech, namely the structure of the signifier.

The Lacanian *matheme* proceeds neither by faith nor by pure mathematics. Lacan situates religion on the side of making real, or “realizing,” the symbolic of the imaginary, or RSI (Seminar 21, session of November 13, 1973). On the other hand, Lacan defined mathematics as imagining the real of the symbolic, or IRS. If such were the case with the *matheme*, then it could become a model of the real. In fact, it is no such thing. Lacan never used mathematics as a demonstration, but as an exercise necessary for a better reading of the unconscious. Thus the *mathemes* should be read with a shift that allows for them to be situated as a symbolizing of the imaginary of the real, or SIR .

## **MATHILDE, CASE OF**

The Mathilde case involves a patient of Freud's whose death, from a medical overdose, is discussed in his commentary on the “dream of Irma's injection.” Mathilde S., a twenty-seven-year-old woman, came to see Freud at the beginning of 1889 for treatment. She presented the signs of inhibition, self-reproach, and delusional melancholia. The trigger turned out to be a broken promise of marriage that had been made to her. After a significant improvement with hypnotic treatment, the patient decompensated while Freud was away, with polymorphous symptoms, and had to be

hospitalized in October 1889 in a private psychiatric clinic in Vienna.

At the clinic it became obvious that the patient was developing erotomania, whose object was initially Freud, then a physician at the institution. The circumstances supported the diagnosis of a transference psychosis. It appears that the patient's eroticized transference reinforced the ideas that Freud's former teacher, the psychiatrist Theodor Meynert, was defending at the time, specifically with respect to hypnosis.

While the patient was hospitalized, use was made of the entire range of medications available at the time: morphine, chloral hydrate, valerian, bromide, digitalin, opium, scopolamine, and sulfonal, a sedative that had recently been discovered. Unwanted and extremely severe side-effects resulting from the chloral hydrate endangered the patient's life. But she recovered and left the clinic in May 1890, still suffering from melancholia.

Freud resumed treatment, prescribing alternating high doses of chloral hydrate and sulfonal, but apparently did not hypnotize her further. In the autumn she displayed a heightened pattern of vomiting, abdominal pains, and retention of urine, which was red in color. At the end of September the patient died. Shortly afterwards, a warning was issued against this kind of medication, and Mathilde's clinical symptoms were recognized as the expression of the presence of a severe hepatic porphyria resulting from the medication. In a report that was succinct and clear, Freud assumed responsibility for the fatal consequences of his treatment.

Five years later, as part of his associations with the dream of Irma's injection, Freud recalled this case, and his feelings of guilt were plainly apparent when he made the connection between his fear for the life of his daughter Mathilde, who was suffering from diphtheria—Behring had just introduced the serum therapy that was to save so many lives—and this case with its dramatic outcome: “This Mathilde for the other Mathilde, an eye for an eye, a tooth for a tooth.” In the dream and its interpretations, feelings of guilt reappear concerning the failure to take medical precautions, and the secondary effects of the medication and the hypnosis; but along with these there is also present the fantasy of becoming a kind of “Behring of neuroses.”

### MATTE-BLANCO, IGNACIO (1908–1995)

Chilean physician, Ignacio Matte-Blanco was born at Santiago de Chile on October 3, 1908, and died on January 11, 1995, in Rome. The scion of an old Chilean family, he was educated at the German Gymnasium at Santiago and graduated as physician-surgeon at the University of Chile in 1930.

Before leaving Chile for London, Matte-Blanco was in analysis with Fernando Allende Navarro, Latin America's first qualified psychoanalyst. He trained at the Maudsley Hospital and in psychoanalysis at the London Institute, where he supervised with Anna Freud and James Strachey, becoming a member of the British Society in 1938. Then he worked in New York with mathematician Courand, who encouraged his seminal paper on the relationship of set theory and psychoanalysis. Returning to Chile in 1943, he became the founder and guiding soul to the Chilean Society and a noted professor of psychiatry at the University of Chile from 1949 until his departure for Rome in 1966. He was a professor of psychiatry at the University of Chile Medical School, 1949–1966, and at Catholic University of the Sacred Heart, Rome, 1970–1974. He remained a teacher and a center of innovative discussion up to his death.

Matte-Blanco's pioneering paper, presented at the First Latin American Psychoanalytic Congress in Buenos Aires in 1956, “Expression in Symbolic Logic of the Characteristics of the System Ucs., or the Logic of the system Ucs.,” appeared in the *International Journal of Psycho-Analysis* in 1958. His two main books, *The Unconscious as Infinite Sets* (1975) and *Thinking, Feeling and Being* (1988), were published in London. Relevant papers published in Italian are not widely known.

In the idea that much of the wealth of our clinical practice is simply not seen because it does not fit with the theories we use, Matte-Blanco redresses in terms of modern logic Freud's fundamental distinction of primary and

secondary processes in *The Interpretation of Dreams* (1900a) and later, in “The Unconscious” (1915e). Absence of contradiction between the representations of diverse impulses and the ensuing absence of negation; displacement; condensation; atemporality; and substitution of external by psychic reality, that is, the qualities ruling in the unconscious, differ drastically from those secondary processes, this is, of Aristotelian, symbolic or scientific logic. Building upon von Domarus's “logic of the attribute” found in schizophrenic thought, Matte-Blanco holds that the characteristics of the unconscious derive from two principles: 1) The principle of Generalization: Unconscious logic does not take account individuals as such, it deals with them only as members of classes, and of classes of classes. 2) The principle of Symmetry: The Unconscious can treat the converse of any relation as identical to it; that is, it deals with relationships as symmetrical. The Freudian qualities of the unconscious result from the principle of Symmetry, or from both principles operating together. Thus, atemporality derives from symmetry, which precludes order in a temporal series, and displacement treats two individuals as members of the same class. Later on Matte-Blanco restates this saying, after Frege, that the unconscious operates in terms of propositional functions.

### MATURATION

Maturation, in the broad sense, means all of the processes in the course of the development of an organism

that lead it to a mature state. In a more precise sense, it can be taken to mean the set of preprogrammed mechanisms that set in motion and coordinate the functions necessary for the life of the organism, before they come into operation, and for which biological maturation creates the means and conditions.

The term has made only marginal appearances in psychoanalytic literature. It would seem that Freud never used it in his writings, as evidenced by its absence in James Strachey's detailed index to the Standard Edition.

However, Donald W. Winnicott called one of his books *The Maturational Processes and the Facilitating Environment*, but, as the title itself indicates, the term is used with the broad understanding that most of the work on mental development could be considered to be studies of maturation. With explicit references to embryogenesis, René Spitz (1979) attempted to describe the *organizers* that preside over the succession of maturative stages of the mind (the first smile, walking, language)—these organizers themselves being preprogrammed.

From a totally different angle, the adjective *maturing* is sometimes used to characterize some of an analyst's interpretations in the course of the treatment, in a sense similar to what led James Strachey in 1969 to refer to *mutative* interventions. Here the term is used to designate interpretations that favor the process of maturation in the treatment through a reorganization of the psychic apparatus.

## **MAUCO, GEORGES (1899–1988)**

Georges Mauco, housemaster in the Seine school for elementary school teachers, educationist, demographer, and psychoanalyst, was born in Paris on April 16, 1899, and died there on May 18, 1988. The son of a waiter who later became a landowner, he was reared in the country by an agricultural laborer. He was mobilized in the *Armée de l'Orient* in 1918 and left the army in 1920 as *maréchal des logis* (the approximate equivalent of a sergeant). He graduated with a bachelor's degree in history and commenced analysis with René Laforgue.

His thesis, *Les étrangers en France: Leur rôle dans la vie économique* (Foreigners in France: Their role in economic life) was published in 1932. Although he argued in favor of integration, he claimed that Asians, Africans, and Levantines were unassimilable. In 1937 he wrote a paper recommending that the Israelites be sent to the countryside. This project was rejected even though it was proposed to the government while he was a member of the committee for the French population in Léon Blum's cabinet.

He was demobilized in 1940 and collaborated on the journal *Ethnie française* (The French ethnic group), run by Georges Montandon, a well-known anti-Semite. While under oath in the Supreme Court (during the Riom trial), he affirmed that foreign Jews in France were one of the major causes of defeat in 1940.

He escaped the purges after the war. With the support of General Charles de Gaulle, who appointed him secretary of the High Commission for the Population and the Family, he created the first psychoeducational consultancy in the Lycée Claude-Bernard in Paris. Many psychoanalysts worked there as consultants and analysts.

A believer in the right to be different, after 1946 he devoted considerable energy to defending children against adults, psychologists against doctors, the youth of 1968 against the bourgeoisie, and women's liberation. He defended Margaret Clark-Williams, a colleague of Claude-Bernard, when she was attacked by the Medical Association. In 1953, along with Didier Anzieu, he founded the Union of Psychoanalysts and Psychologists.

He recovered from leukemia in 1956 after a stay at high altitudes. He wrote an article in *L'Express* recounting this experience and denouncing the high

priests of medical knowledge. His last book, published in 1977, was devoted to the question of foreigners. It studied racism and the unconscious responsibility of victims of racism.

## **MEAD, MARGARET (1901–1978)**

Margaret Mead, an American anthropologist, was born on December 16, 1901, in Philadelphia and died on November 17, 1978, in New York City. She spent her entire career as a curator of the American Museum of Natural History and was an associate professor at Columbia University. After studying psychology and anthropology at Columbia, where she was influenced by the work of Franz Boas and Ruth Benedict, Mead first did fieldwork in eastern Samoa. In the published result, *Coming of Age in Samoa* (1928), she wrote, “[A]dolescence represented no period of crisis or stress, but was instead an orderly developing of a set of slowly maturing interests” (p. 109). She also noted, within “a larger family community, in which there are several adult men and women, seems to ensure the [Samoan] child against the development of the crippling attitudes which have been labelled Oedipus complexes [and] the Electra complexes” (p. 147).

She made several trips to New Guinea and reported her findings in *Growing Up in New Guinea* (1930) and *Sex and Temperament in Three Primitive Societies* (1935). Through these writings, Mead established herself as the leading proponent of the so-called “culture

and personality” school of anthropology. Her work emphasizes the diversity of cultures and the plasticity of human nature, the preponderant influence of cultural models in the development of personality, and the cultural determination of sexual roles (1949). Influenced by the work of Erik H. Erikson and Gregory Bateson (her third husband), Mead saw trauma specific to individual cultures as leading to particular types of development in those culture. Relying mostly on photographs, she attempted to describe the infantile experiences that determine the formation of character (Bateson and Mead, 1942).

Although she sometimes used psychoanalytic concepts (identification, erotogenic zone, narcissism), she was primarily engaged in a relativist critique of psychoanalysis. For example, she reproached Freud for confining himself to an examination of the “specific ambivalence of attitudes institutionalized in our own culture.” She believed she had refuted Lucien Lévy-Bruhl, Jean Piaget, and Freud by showing that primitive children “displayed no tendency for spontaneous animist thought.”

Mead’s work, unable to escape the doubts of relativism, has been contested both ethnographically and theoretically (Freeman, 1983). Her principal merit is that she drew anthropologists’ attention to the importance of early infancy, education, diet, and sexuality. Her criticisms of psychoanalysis, however, were based on considerable misunderstandings of the field, as she herself later recognized. “Instead of making the laborious and often painful effort of understanding psychoanalysis, we have been content to use some of its products, especially projection tests,” she wrote. As a result, Mead’s observations relate only to manifest behavior and not to intrapsychic conflicts or the unconscious.

## MEGALOMANIA

Megalomania is commonly understood as a mental behavior characterized by an excessive desire for power and glory and by illusory feelings of omnipotence. The latter can be expressed in the psychopathological form of delusions of grandeur.

Megalomania can be understood as exacerbated narcissism in relation to the ideal ego. In his account of the Schreber case in “Psycho-Analytic Notes on an Autobiographical Account of a Case of Paranoia (Dementia Paranoides)” (1911c [1910])—a case that presented its share of delusions of grandeur—Sigmund Freud envisaged narcissism as a stage in psychosexual development situated between autoeroticism and object relations. Narcissism can certainly be placed not just within a linear perspective, but also as a structural point in the psyche, with megalomania at its zenith. Indeed, if we postulate a primal intersection formed by the interaction between primary narcissism and primal masochism, conceptualized as the earliest fusion of the life and death instincts, we are led to envision a sort of primal, archaic damming-up that is self-constituted (and therefore without an object) in the psyche. Megalomania could then be considered as an expression of reactualization and regression to this primal position, which is characterized by an image of an ego ideal that is all-powerful and self-sufficient, having no object-directed needs or desires in order to survive. This type of mental functioning would also involve a systematic denial of otherness and an infantile theory of sexuality involving self-procreation.

These structural elements, present in every psyche, and especially in every formation of the ego, are expressed in the various modes of psychic representation—pictographic, fantasmatic, and ideational. Omnipotence and denial of the other’s reality are the organizing framework.

The “ideal ego” is posited as being the intrapsychic formation that engenders megalomania. Different from the “ego ideal,” it is the psychic agency that inherits infantile primary narcissism; it maintains the possibility of recourse to an ideal of omnipotence and, by that very fact, to an attitude that negates the existence of the object and otherness. As the guardian of imaginary omnipotence, in the realm of identifications the megalomaniacal ideal ego opposes taking into account the separating and symbol-generating elements of gender and generational differences. It is the organizer of defense mechanisms such as the denial of reality, and accordingly, the disavowal of castration.

To be sure, in paranoid and melancholic types of psychopathological organizations one can find the effects of the megalomaniac’s colorful frames of reference. In paranoia, persecution is the mechanism that continually justifies the omnipotence of the ego, which is attacked only to better demonstrate the megalomania’s validity. Finally, the ultimate persecutor is only a jealous god on the verge of being supplanted by the new god that is the ego. In melancholia, megalomania is also linked to the process of narcissistic identification with the object. This confusion of identities makes mourning and separation impossible. Megalomania as an extreme form of manic defense can be one outcome of the process of melancholia. If we recall that another possible outcome is suicide, megalomania can be considered an attempt to deny death and a defense against the anxiety resulting from separation from the object.

In addition to its pathological forms, megalomania is a mental behavior that can be used by any individual as a way of coping with distress linked to frustration, abandonment, loss, or disappearance of the object. The megalomaniacal fantasy is then a desperate attempt to repair an ego that has been damaged by object-loss experienced as an amputation or mutilation, which are the prototypes of castration. Getting beyond this psychic position marked by omnipotence requires the presence of another person in the role of “word-bearer” (Aulagnier, 1975/2001), someone who can endow object-loss and the attendant feelings of

anxiety with a representation and a meaning. Thus there is a need for the exercise of a word-bearing function, generally allotted to the mother, which will be re-created in the context of analysis.

The calling into question of infantile megalomania involves the psychic work of de-idealizing the omnipotent ideal ego of the *infans* period and a reorganization of the psyche to take into account the desire of the other in his or her difference. This redefinition of the ideal requires appropriation of an ego ideal that is external to the subject and which preexists him or her in the symbolic realm that governs exchanges in accordance with the taboos against incest and murder. As a form of disavowal, megalomania is thus a tendency to remain unconsciously within a realm of barbarous images in which desires for murder and incest can be satisfied and prohibitions against them transgressed. Megalomania reflects a transgression of the fundamental taboos as a way of avoiding sublimation, which is a socialization of the instinctual.

## **MELANCHOLIA**

In the traditional language of psychiatry, *melancholia* denotes a type of depressive state characterized by its intensity and its responsiveness to biological antidepressant agents. The experience of the melancholic individual, often called “mental suffering,” is characterized by profound sadness and lack of interest in the

outside world. Melancholia brings about a form of pessimism that sees the future as blocked and unchangeable. Such pessimism is accompanied by ideas of guilt and unworthiness, which find expression through self-accusation and can even give rise to delusion. Hypochondriacal ideas are also frequent. In addition, the subject complains of emotional numbness and the painful sentiment of being unable to love. Mental suffering engenders a continual desire for death. Hence, the subject runs the risk of suicide. Melancholia is accompanied by a marked slowdown in psychomotor activity, sometimes leading to stupor. Classic signs of the illness are anorexia and weight loss, insomnia and disturbed sleep patterns, and an improvement in clinical symptoms in the evening.

An episode of melancholic depression can be unique or recurrent, in which case it becomes part of the framework of a manic-depressive illness that is unipolar (recurring melancholic episodes) or bipolar (recurring melancholic and manic episodes). The bipolar situation reveals a fundamental characteristic of melancholia: it can reverse itself spontaneously or under the effect of drug treatments, into a state of manic excitation.

Karl Abraham (1927b) noted the relationship between mourning and depression, and he distinguished melancholia from neurotic depression, which results from the failure to satisfy drives because of repressed unconscious factors. For Abraham, the structure of melancholia is closer to that of obsessive neurosis on account of the intense hostility toward the outside world. In both illnesses, hostility considerably reduces the ability to love, and this reduction is responsible for the onset of the illness. But in melancholia, the projection of hostile drives is combined with their repression. Abraham proposed a psychopathological model of psychotic depression, based on the Freudian model of paranoia, in which libidinal hatred, projected onto the outside world, reverts back onto the subject in the form of depressed feelings of being detested and of guilt (the source of masochistic pleasure).

In “Mourning and Melancholia” (1916–1917g [1915]), Freud based his thinking on how melancholia and mourning converge. They are both triggered by the same phenomenon, namely loss. They differ in that although mourning occurs after the death of a loved one, in melancholia the lost object is an object of love and therefore is not truly dead. Melancholic

individuals may, in some cases, know that they have lost something, but they never know what they have lost, for the loss is inaccessible to consciousness. The clinical signs of melancholia and mourning are identical, except that melancholia is accompanied by a loss of self-esteem. Unlike people in mourning, melancholic individuals suffer from a loss involving the ego, which they describe as poor and without value. They reproach themselves but do not experience shame, for their reproaches are really directed not at themselves but at lost objects. Their egos are split: one part, the critical faculty, takes as its object another part, which is identified as the lost object by means of a narcissistic mechanism. This process implies that the object choice is narcissistic and characterized by a strong fixation on the object but a weak cathexis of it, with cathectic energy always readily withdrawn into the ego.

For melancholia to occur, the object relationship must be ambivalent: hate and love must be in contention. Once love for the object has taken refuge in narcissistic identification, hatred can function against the part of the ego identified with that object. There it obtains sadistic satisfaction, as reflected in the melancholic individual's suicidal desires. Such desires result in hatred of the object being redirected back upon the self. The ambivalence, constitutional or associated with the circumstance of loss, leads to love and hate doing battle against one another in various parts of the unconscious psyche until love escapes into the ego to preserve itself and melancholia finds expression in the typical form we are familiar with. This confrontation always ends in exhaustion, whether the unrelenting struggle with the lost object stops on its own or the object is abandoned because it is without value.

In "Melancholia and Obsessional Neurosis" (1927a) Abraham investigated the relation between manic-depressive states and the pregenital stages of libidinal organization. After clarifying the connection between sadism and anal eroticism, he divided the anal-sadistic phase into two periods. In the earliest period, the drives obtain satisfaction by rejecting and destroying the object. During this first period the libido of the melancholic individual begins to regress. The libidinal regression does not end with the first period, however, but continues through the oral-cannibalistic stage by introjecting the lost object. This is accompanied by a refusal to eat, a key indicator of melancholic depression. Abraham concluded by listing five factors whose "interaction causes the specific clinical manifestations

of melancholia." These are the constitutional reinforcement of oral eroticism in melancholics, the fixation of the libido on the oral phase of its development, the injury to infantile narcissism caused by disappointment in love from the maternal object, the overcoming of this injury prior to the control of oedipal desires, and the repetition of this primary disappointment later in the life of the subject.

## **MELANCHOLIC DEPRESSION**

Melancholic depression is a severe mood disorder that is psychotic in nature. In psychoanalysis, it is understood to arise from incorporation of the lost object (experienced as a bad, "abandoning" part-object) into the ego, which identifies with it. This object is then attacked by another part of the ego, the superego. The ego is thus the recipient of the reproaches (self-reproaches) and attacks targeting the object with which it has identified ("[T]he shadow of the object fell upon the ego," as Freud wrote in "Mourning and Melancholia" [p. 249]).

The above definition follows Freud's account almost to the letter. Freud used the term *melancholia*

to refer to depressive states in general. However, while this dynamic as described helps explain the various depressive states, it more precisely describes melancholic depression of the psychotic type. As early as 1911, Karl Abraham discussed the problems of depressive patients and thereafter continued to develop the characteristics of such personalities. He also gave a detailed account of the melancholic introjection of the lost object at once into the ego and into the superego. Sándor Rádo (1928) underscored the melancholia's purgative effects—the “processes of expiation and reparation” set in motion by the internal struggle between the superego and the ego. In Abraham's view, this struggle made possible the destruction and anal expulsion of the bad object. In this way the ego once more became worthy of entering into contact with good or idealized objects; and, ultimately, the route to mania was opened to it.

From the Kleinian perspective, Hanna Segal (1964) describes melancholia as the result of manic-schizoid defense mobilized against the depressive position. The melancholic's identification with the lost object tends to be of the projective kind—an archaic psychotic defense mechanism. This explains the almost perfect match between the ego and the part-object with which it becomes confused.

The defensive functioning is thus diametrically opposed to that of schizoid-paranoid mechanisms, where the ego identifies—most often projectively—with a more or less idealized object (Palacio Espasa, 1977). Indeed, as a counterpart to the variety of manic defenses seen across the whole range of mental operations, psychoanalytic experience shows different types of melancholic defenses designed to counter depressive anxiety; there are also paranoid defenses, or, on the contrary, neurotic anxiety. When the melancholic defenses are used against persecution anxiety, the persecuting-destructive aspects of the object with which the ego identifies are more visible, whereas in the face of depressive anxiety, the object's damaged/destroyed aspects come to the fore. The various psychic tendencies often called “masochistic” (based on expiation, appeasement, submission, propitiation through seduction, and so on) may be viewed as the range of essentially neurotic melancholic defenses.

## MEMOIRS OF THE FUTURE

The concept of “memoirs of the future” or “inherent preconceptions” reveals Wilfred Bion's indebtedness to the ideas of Plato and Kant. The very wording of the concept was so appealing to Bion that he employed it as the overarching title for his psychoanalytic autobiography.

The paradox in the wording of the concept, “memoirs of the future,” designates the platonic idea of Ideal Forms, preconceptions which inherently accompany us from birth—and long before! They are older than the thinkers that think them and can anticipate their rendezvous with their future, external counterparts. Thus, the infant, “hard-wired” with the pre-conception of the idea of the breast, can anticipate and then locate that breast, when found, and thereby confer “conception” upon it as the reward for its success in finding what its pre-conception had already anticipated.

“Memoirs of the future” poetically implies that we are born with an atavistic “memory” of the history of the species, to which the specific pre-conception is a subset. Perhaps a concrete example would help. The human infant is born with a number of immune bodies in its immunological armamentarium which have already been “programmed” to anticipate future antibodies who are, as in the phenomenon of déjà vu, “strangely familiar.”

In his triadic autobiography (*A Memoir of the Future*, 1975, 1977, 1979), Bion proffered a highly original aspect of dialogics in the spirit of Bakhtin. He wrote, for instance, of different, split-off, personified

aspects of fetal mental life which appeared to be independent of one another and yet could communicate as if they were separate selves from different time zones of maturation—speaking to another, one from the future and other from the past.

## **MEMORIES**

For psychoanalysis, memories are conscious representations of the past suspected of being, at least in part, illusory. The fact is that conscious memories or recollections may conceal unconscious ones, even if the ego accepts them at face value and finds comfort therein. In his early work Freud spoke of “unconscious memories,” but he later replaced this term with “memory traces.

In Freud’s initial work on the theory of neuroses (1894–96), “memories were pathogenic reminiscences of traumatic seduction; subsequently the memories of childhood were included in the category.

Freud contrasted the obsessive “memory image,” or “mnemonic image,” with the supposedly genuine memory adequate to the affect experienced. Memories could be false, however, from their inception (*Erinnerungsfälschung*): one has only to think of the “first lie” of the hysterical proton-pseudos of Freud’s “Project for a Scientific Psychology” (1950c [1895]), or of “screen memories” (1899a), behind which authentic memories lie.

Freud’s notion of memories, even when he uses it in the context of the psychology of consciousness in normal states, is always related to his first theory of the neuroses caused by traumatic seduction. It is not by

accident that Freud used two very similar words to designate two conceptually opposed concepts—conscious memory (*Erinnerung*) and the unconscious memory-trace (*Erinerungsspur*)—and the paradoxical expression “unconscious memory” can often be found in his writings. In the theory of the traumatic origins of hysteria, he constructs the notion of memory traces from that of unconscious memories: the conscious memory of the trauma has been refused, rejected, repressed, or split. It is no longer accessible to consciousness, at least not directly, and is now represented in altered form in the symptom, notably in the mnemonic symbol. The unconscious memory strives to become conscious once more, for ontically it is conscious. The notion of unconscious memories prefigures that of the unconscious, as distinct from the idea of a provisional pathological repression, which is still tainted by the psychology of consciousness; likewise, unconscious memory traces or mnemonic images are so intense and sensorially alive that they overflow into consciousness in a quasi-hallucinatory form nonetheless distinct from hallucination.

Memories are par excellence the memories of affects, “the persistent effect of an emotion experienced in the past” (1896a) in the “memory chain.” In Freud’s work there is much that belongs to the associative theory of memory. Memories, like the mnemonic symbols, screen memories, and fantasies, form “memory chains.” It was from this conception of memory that Freud developed the technique of free association, whence in turn he derived the notion of primary processes.

The archaeological metaphor accompanied the notion of memory throughout Freud’s work, from 1896 (“The Aetiology of Hysteria”), where he writes of the explorer, whose “interest is aroused by an expanse of ruins” and who “may start upon the ruins, clear away the rubbish, and, beginning from the visible remains, uncover what is buried.... If his work is crowned with success ... [it may] yield undreamd-of information about the events of the remote past, to commemorate which the monuments were built” (p. 192), to *Civilization and its Discontents* (1930a [1929]), where he introduces a visitor who discovers beneath the city of Rome not an ancient Roman city but the ruins of reconstruction performed at the end of the ancient era on the site of primitive buildings that have disappeared, attempting to picture to himself what might produce the simultaneity of

memories, here visual, of intertwined monuments from different eras.

What distinguishes between “true” and “false” memories is the affect, which is “always right” (1900a), and which can lead to the rediscovery, on the basis of the mnemonic symbol of the original idea. In the Emma case (1950c [1895]), the phobic symptom and the belief that an ordinary event from adolescence could be its cause concealed what should have been a memory but had become a memory trace, namely the scene of childhood seduction. The transition from conscious memory to unconscious memory trace follows the topography of a psychic internalization of the event requiring a certain amount of time. Every memory is more or less a screen, always suspected by Freud of not faithfully conveying the impressions of the actual experiences of childhood.

In *Leonardo da Vinci and a Memory of His Childhood* (1910c), Freud states that memories include both historically constituted memory-traces of perceptions in childhood and pure fantasy elements. In Leonardo’s memory a vulture opens the mouth of the child Leonardo with its tail, which Freud analyzes as the desire to have been engendered by a phallic mother. A memory then, appears to be a fantasy, but in fact the fantasy harbors real memories: the memory of having been passionately kissed by his mother during childhood, the memory of breastfeeding, the father’s absence—all essential elements described by Freud as “real nothings,” out of which Leonardo created his fantasy. Finally, what Leonardo remembers is not any specific event from childhood but elements from the psyche of the child he was, which constitutes the background of his adult psyche. Without realizing it Leonardo discovers on the lips of the Mona Lisa his mother’s smile, of which he has no memory.

In psychoanalysis the concept of memory is part of the paradigm of the lost object. In “Mourning and Melancholia” (1916–17g [1915]), Freud demonstrates how, in melancholia, the pathological memory fixes and fetishizes the idealized object, hated as much as loved, and how, in the work of mourning, all memories about the object are illuminated in their smallest detail, so that remembering may facilitate abreaction, followed by a withdrawal of cathexis.

Freud envisages a drive to remember (*Impuls zur Erinnerung*) whose motor is a wish for a kind of representation close to hallucination: where the “mnemonic

image,” the sensory intensity of the “unconscious memory” becomes conscious in a hypnoid mode by virtue of the lifting of amnesia. This drive also strives to rediscover the strength of the impressions (*Eindruck*) imparted by previous experience (*Erlebnis*).

In Freud’s original approach to therapy, centered on abreaction and remembering, memories were meant to confirm the accuracy of the interpretation. In “Remembering, Repeating and Working-Through” (1914g), Freud noted “the patient does not *remember* anything of what he has forgotten and repressed, but *acts* it out” (p. 150). “[T]he patient repeats instead of remembering” (p. 151). This leads to the possibility of a clinical approach based on working-through rather than remembering and abreaction, or, otherwise stated, a conception of remembering centered on constructions rather than memory. From this point of view a childhood memory is always a memory about childhood. The concept of memories belongs to the psychology of consciousness more than to the metapsychology of the unconscious, despite the obvious kinship between *Erinnerung* (memory) and *Erinnerungsspur* (unconscious mnemonic trace) in Freud’s work. An illusion of consciousness, memories support the defenses and idealizations of the ego.

No memory is exempt from the influence of fantasy, and no fantasy can do without ideational elements borrowed from a perceived reality. The notion of memory employed by Freud differed from that found in psychology and philosophy. Although in “Heredity and the Aetiology of the Neuroses” (1896a) he tried to establish the ages of memories because it was the oldest events that were the most pathogenic, he wrote to Fliess on May 2, 1897 that it was not, strictly speaking, memories that the hysteric repressed but instinctual impulses associated with stimulating fragments of memories. What he refers to as memories derive from multiple sources and are the object of constant reworking. In discussing the memories and the childhood dreams of the “Wolf Man,” Freud concluded that what was involved was a complex mixture of memories, fantasies, and day’s residues (1918b [1914]). Psychoanalytic interpretation rediscovers—but more often reconstructs—childhood memories with the help of screen memories, fantasies, and dreams, whose day’s residues, in combination with memory traces, give rise to visual representations that appear as memories. What is thus disinterred is the child’s psyche. The frequently debated question is whether analysis

constructs the mind as fiction or reconstructs the past facts to take into account the complexity and paradoxical nature of memories at once historical and subjectively constructed. The continuous rewriting of every subject's history by the subject himself defines memory as a temporary current version only. Freud played down the contrasts between memory and screen memory and memory and construction, emphasizing instead the complexity of psychic working-through, which mixes different types of mnemonic representations as well as non-mnemonic ones—including libidinal representations and unconscious and conscious thoughts. A memory is something other than a memory-trace, but there are points of contact between the two. Freud refuted the idealist psychology of consciousness but he also avoided falling prey to a metaphysics of an unconscious with no relationship to reality, perception, or memories.

## **MEMORY**

If one views memory as the ability to retain and recall past states of consciousness, then psychoanalysis has played a considerable role in its delineation. But in terms of memory theory considered more broadly, its significance is much more modest. Freud approached memory from three perspectives. In terms of

neurology, his contributions were original but limited. From the standpoint of psychology, he added to the pre-existing framework. Finally, in creating the psychoanalytic perspective, Freud essentially reworked views that had been extensively discussed in philosophy, literature, and scientific research.

In 1891 Freud's *On Aphasia: A Critical Study* (1891b) proposed a solution to the problem of memory retrieval and disorders of memory, which was much discussed at the end of the nineteenth century following the discoveries of Paul Broca. Freud did not take sides in the dispute between Broca, who localized language function to a specific cerebral area, and Carl Wernicke, who developed the functional concept of conduction aphasia. Freud's solution, which resembled the one that Henri Bergson adopted five years later in *Matter and Memory*, could serve as the basis for a dialogue between neurology and philosophy. But the 1891 text is a pre-psychoanalytic work.

Freud's second, psychological perspective finds him apparently subscribing to the theory of memory traces. Already expressed in its major outlines in Plato's *Theaetetus*, this theory was commonplace in the nineteenth century, when the vogue for scientific materialism made it seem self-evident (although spiritualists also accepted it). In this sense Freud is close to his contemporary, Théodule Ribot, but for Freud the theory of memory traces assumed a specific form intended to account for the role the unconscious plays in remembering. This led to Freud's *Project for a Scientific Psychology* of 1895 (1950c [1895]) and the best expression of the doctrine, in chapter 7 of *The Interpretation of Dreams* (1900a). The “Mystic Writing Pad” (1925a) represents an attempt to provide the theory of memory traces and process of memory retrieval with a metaphor suitable for psychoanalysis. But in these texts, Freud was concerned to place facts revealed by psychoanalysis within the framework of conventional psychological theory; he made no effort to create a new “theory of memory.”

Much more familiar (and often wrongly considered as the specific psychoanalytic contribution to problems of memory) is the third perspective, involving the alleviation of pathological symptoms by recalling forgotten traumata. Freud himself did a great deal to promote this point of view through the significance he attached in numerous of his writings to Josef Breuer's treatment of Anna O. Too common is the impression that the famous formula “hysterics suffer mainly from reminiscences”

(*Studies on Hysteria*, 1895d, p. 7) expresses the most fundamental idea in psychoanalysis.

There is no question that the idea of recollection constitutes an essential part of psychoanalytic therapy, and to think otherwise is to betray Freud in a fundamental way. Serge Viderman's claim in *La Construction de l'espace analytique* (1970) that the search for lost memories is one of Freud's youthful illusions to be replaced, in analysis, with co-constructions of subjectivity, is simply an attempt to employ non-analytic therapy, proposed in the past by such authors as Karen Horney. Until the end of his life Freud remained attached to this model: trauma / repression / forgetting / symptom / remembering / healing. In 1937, in "Analysis Terminable and Interminable," he went so far as to say that, like hysterics, psychotics also suffer from reminiscences, implying that certain delusional representations were, in fact, the reappearance in consciousness of past experiences unrecognized as such. Between Anna O. and this late text, Freud's entire body of work is sprinkled with thoughts along these lines. In "Remembering, Repeating and Working-Through" (1914g), for example, he resolved the conflict between impossible access to memory and the sterility of repetition through the introduction of what he called "working through" (*Durcharbeitung*). Further proof is found in his "A Disturbance of Memory on the Acropolis" (1936a), in which Freud displaces the memory trauma (thinking the Acropolis did not exist) onto another type of fact (fear of surpassing the father). The "search for lost time," the attempt to alleviate repression that has produced a failure of memory and the associated symptom, is one of the major themes of Freudian psychoanalysis. However, reservations are in order regarding its originality and theoretical scope.

Even though Freud often felt that the cure for hysterical symptoms through recollection of repressed traumatic memories could be presented as a revolutionary discovery, such figures as Janet and other late nineteenth-century psychotherapists viewed the idea and even the method as commonplace. The idea can even be traced back much further. For example, in a letter to Pierre Chanut, dated June 6, 1647, René Descartes recounts that his penchant for girls with a squint came to an end with his recollection of a childhood memory. Descartes's interest in such women may not have been a true hysterical symptom, but the link

between current behavior and its origin in the past is indicated along with all the characteristics (forgetting, unconsciousness, healing through remembrance) that Freud would later employ. Much earlier, Plato, in the *Phaedrus*, interpreted the process of falling in love in a similar manner. In short, there is no end to the number of literary, philosophical, and clinical sources for what is often considered the most significant psychoanalytic contribution to the theory of memory.

More plausibly, psychoanalysis lent to a certain type of amnesia and memory retrieval an unanticipated practical (therapeutic) scope. Its importance was practical. Although it constitutes an original theoretical point, it does not amount to a global theory such as those developed by philosophers and psychologists. However, it has a good fit with such theories. It works, for example, within the framework that Henri Bergson described and interpreted in *Matter and Memory*.

**MEMORY TRACE.** See Mnemic trace**MENG, HEINRICH (1887–1972)**

Heinrich Meng, the German physician, professor, and psychoanalyst was born in Hohenhurst, Germany, on July 9, 1887, and died in Basel, Switzerland on August 10, 1972.

When he was two years old he contracted poliomyelitis and very nearly died from it. Throughout his life he manifested a disposition to be useful to others; while still a student he took an interest in nutrition and physiology. He was vegetarian and joined youth movements to promote temperance, popular education, social and mental hygiene, socialism, and pacifism.

When he finished his medical studies (1907–1911) he practiced in Stuttgart. During World War I he came into contact with Karl Landauer, a psychoanalyst from Frankfurt. In 1921 he went into analysis with Paul Federn in Vienna, followed in 1922 by a second analysis with Hanns Sachs in Berlin. In 1923, thanks to the influence of Clara Zetkin, he was summoned along with other physicians to Lenin's bedside in the Kremlin. From 1929 to 1933 he and Landauer managed the Frankfurt Psychoanalytic Institute (FPI) in association with the Institute for Social Research, which they co-founded. In 1933 he emigrated to Switzerland and in 1937 he acquired the first university chair of "mental hygiene" in Europe. He occupied the chair until his retirement in 1956.

In collaboration with Federn, Meng edited the *Psychoanalytisches Volksbuch* (1926, a popular manual of psychoanalysis) and co-edited the *Zeitschrift für Psychoanalytische Pädagogik* (Magazine of psychoanalytic pedagogy; 1926–1937). He manifested his interest in psychoanalytically-informed mental hygiene through many publications, also editing the *Praxis der seelischen Hygiene* (The practice of mental hygiene; 1943) and *Psychohygienische Vorlesungen* (Conferences on mental hygiene; 1958). He published his major work on psychosomatic questions with Louis R. Grote: *Über interne und psychotherapeutische Behandlung der endogenen Magersucht* (Contribution to the internal and psychotherapeutic treatment of endogenous anorexia; 1934) and developed the concept of *Organpsychose* (organic psychosis). His autobiography, *Leben als*

*Begegnung* (Life as encounter; 1971) played an important role in the history of psychoanalysis in Germany.

Meng's many publications contributed greatly to popularizing psychoanalysis in Germany. By means of subtle influences he managed to have the city of Frankfurt attribute the Goethe prize to Sigmund Freud in 1930 (Plänklers, 1996). In Switzerland he was the pioneer of psychoanalytically-informed mental health praxis.

**MENNINGER CLINIC**

The Menninger Clinic is an international facility for mental-health treatment, education, research, and prevention. It was started in 1925 by Dr. Charles Frederick, Karl A. Menninger, and his two sons, Karl and Will Menninger out of a small farm house on the outskirts of Topeka, Kansas. In the 1930s a small group of highly dedicated clinicians began to develop methods of applying psychoanalytic ideas to hospital

treatment. By 1942 the Topeka Institute for Psychoanalysis was founded as part of the Menninger Clinic.

After World War II the psychiatric residency program at the Menninger Clinic greatly expanded, with the result that the center became a major training site for American psychiatry. More than 2,000 mental-health professionals have graduated from Menninger training programs. As the Clinic developed, research became a high priority. The Menninger Psychotherapy Research Project, for example, was a seminal investigation of the outcome of psychoanalysis and psychoanalytic psychotherapy.

As Menninger clinicians became increasingly sophisticated at applying psychoanalytic principles to hospital treatment, the clinic became internationally known as a tertiary-care referral center for treatment-refractory patients. Patients came from all over the world for extended hospital treatment with an intensive psychoanalytic focus.

The Menninger Clinic continues to be rated as one of the best two or three psychiatric hospitals in the United States. While a psychoanalytic perspective is still at the core of its treatment philosophy, clinicians have integrated modern psychopharmacologic approaches into their psychotherapeutic efforts. Largely because of the influence of the managed-care movement within the United States, patients who come to the Menninger Clinic stay in the hospital for much shorter periods. As inpatient services have contracted, the clinic's partial-hospitalization and outpatient services have expanded.

The Topeka Institute for Psychoanalysis continues to thrive as part of the Menninger Clinic. Training programs for psychiatry residents, postdoctoral psychology fellows, and post-master's social-work fellows are a central part of the facility. Also flourishing at the clinic are psychoanalytically oriented research programs on the psychotherapy process and outcomes and on child development.

The Menninger Clinic provides comprehensive evaluations for patients from all parts of the United States and abroad. The clinic also has specialized treatment programs for trauma survivors, impaired professionals, substance-abuse patients, eating-disorder patients, and chronic psychotics.

## MENNINGER, KARL A. (1893–1990)

American psychiatrist and psychoanalyst, Karl A. Menninger was born in Topeka, Kansas, on July 22, 1893, and died there on July 18, 1990.

Raised in Topeka, the son of a general practitioner, he was educated at Harvard University Medical School before returning to Topeka to work with his brother and father in the establishment of a psychiatric clinic and a major psychiatric residency training program there, the present-day Karl Menninger School of Psychiatry. He brought many European analysts to the Menninger Clinic to escape Nazi oppression, among them Otto Fenichel, Martin Grotjahn, and Ernst Simmel. He went on to become a leader in psychoanalysis, serving as president of the American Psychoanalytic Association from 1942 to 1943. He founded the Topeka Institute for Psychoanalysis in 1942.

Menninger was a prolific writer. Among his books were *The Human Mind* (1930), which brought psychoanalytic understanding to the lay public, *Man Against Himself* (1938), in which he explored self-destructiveness (and made a compelling case for the validity of Freud's death instinct), *Love Against Hate* (1992), which examined the human capacity to overcome self-destructiveness, and his magnum opus, *The Vital Balance* (1963). He was also intensely interested in the penal system, and in his book *The Crime of Punishment*, he suggested that many convicted criminals needed treatment rather than punishment (1968). His volume, *Theory of Psychoanalytic Technique*, was one of the few books to examine the theoretical underpinnings for the analyst's interventions.

Menninger spent his life as a champion of the underdog. He was a crusader for a variety of causes, including the American Indian, nuclear nonproliferation, neglected and abused children, and penal reform. In 1981 he received the Medal of Freedom, the United States's highest civilian honor, from President Jimmy Carter.

## MENTALIZATION

The term *mentalization* is a neologism created to meet the needs of research into psychosomatic phenomena. Used by Édouard Claparède as early as 1928, the term was adopted by Pierre Marty around 1970. Marty has acknowledged that this concept, which has become an established part of psychoanalytic terminology, was born of the need to establish a psychosomatic classification.

The notion was defined on the basis of a hypothetical impoverishment of the mental functions within the framework of the psychosomatic economy. In both theory and practice, it relates to the representational system, including affective ideation. It covers the quantity and quality of the individual's mental representations, the quality of their articulations, bonds, and networks. Mentalization supports fantasies and dream elements, and facilitates associations and the conversion of internal excitations into thoughts.

In terms of the psychosomatic economy, Marty spoke of inadequacy in acquired ideas, of a lack of availability owing to avoidance or repression, and of mental disorganization; three possible origins, then, all associated with a decreased vigor in mental reality. The first is based on violent or unpleasurable affects linked to perceptual memory traces from a very early time that have not been subjected to the mechanisms of repression; the focus here is on unsymbolizable early traumas, offering a possible structural hypothesis for the process of somatization. The second origin involves conflicts that pit ideas with a heavy instinctual charge against early psychic formations. Their nature being modified by censorship, these ideas are in theory stripped of their original affective value. The third origin is mental disorganization, a crucial concept in Marty's approach.

Mentalization is thus closely bound up with the key elements of the deficiency-oriented paradigm reflected in the notions of *operative* and *essential* depression, as well as with the hypothesis of disorganization.

The notion of mentalization has been used to construct a nosological framework, whence such characterizations as "good mentalization," "poor mentalization," and "uncertain mentalization," as well as that "irregularity in mental function" said to play a role in the so-called character neuroses.

## MERLEAU-PONTY, MAURICE (1908–1961)

Maurice Merleau-Ponty, a French philosopher, was born on March 14, 1908, in Rochefort-sur-Mer and died on May 3, 1961, in Paris. A graduate of the École Normale Supérieure, he held a degree in philosophy and a PhD in literature. He taught in the literature department of the University of Lyon, then at the Sorbonne, and he succeeded Louis Lavelle at the Collège de France in 1952. Introduced to existentialism by Gabriel Marcel, familiar with the work of Edmund Husserl, gestalt theory, and the work of Max Weber, he published several important works of philosophy: *The Structure of Behavior* (1963), *The Phenomenology of Perception* (1962), and *Adventures of the Dialectic* (1973), a critique of a certain conception of Marxism. He also left behind the unfinished manuscript *The Visible and the Invisible* (1968), which pointed to a fundamental reorientation in his thinking. Merleau-Ponty occasionally attended Jacques Lacan's seminar and was present at the Journées de Bonneval conference on the unconscious in 1960.

Merleau-Ponty's work touches on psychoanalysis in three different ways. In his early work he was part of a tradition that viewed phenomenology as an integral part of a comprehensive conception of the world and knowledge, as it was represented in experimental psychology by Wolfgang Köhler and Kurt Koffka, in neurology by Kurt Goldstein, and in philosophy by Max Scheler and Georges Pollitzer. Freud's work also played a role, in that it seemed to Merleau-Ponty to be a search for the concrete and a counterbalance to reductionism, which made behavior and experience the sum of discrete elements, arranged *partes extra partes*, within an unacceptable empirical system.

More specifically, in the chapter of the *Phenomenology of Perception* titled "The Body in its Sexual Being," Merleau-Ponty proposes that we conceive of sexuality not as a mixture of representations and reflexes but as a purposeful way of being in the world and an unalterable drama. The sexual history of a person provides the key to that person's life because it expresses synthetically that person's way of being with respect to time and other people. Merleau-Ponty then considers two aspects of Freud's work. One aspect of Freud's work, his theoretical work, Merleau-Ponty felt, was tinged with nineteenth-century scientism and hence made obsolete by a holistic and dialectical conception of being in the world that challenges the causal approach to studying this order of phenomena. Merleau-Ponty finds value in the other aspect of Freud's work, concrete individual research, where symptoms have several meanings, where everything is overdetermined, and where a person's singular history is ultimately incomparable to any other. It is this second aspect that Merleau-Ponty emphasizes.

What Merleau-Ponty frequently referred to as "existential psychoanalysis" represents less a theory and practice based on the work of Ludwig Binswanger than a holistic conception of humans. Here, sexual life retains its specificity while being part of a dialectical relationship with being in the world, a dialectical relationship that binds the body to sexual activity without making sexual activity a supplemental and possibly dissociable part. Such a conception could result in a form of therapeutic practice.

## METAPHOR

Metaphor is a figure of speech that involves designating one thing with the name of another, a process that is carried out essentially by substituting one term for another.

Metaphor is a fundamental notion that Jacques Lacan introduced in relation to his thesis that "the unconscious is structured like a language." He justified its legitimacy principally by analogy with the Freudian mechanism of "condensation," and more generally in relation to the structure of the formations of the unconscious and the metaphorical process of the Name-of-the-Father.

Lacan proposed the following symbolic formula for metaphor (2002, p. 190):

$$\frac{S}{S'} \bullet \frac{S'}{x} \rightarrow S \left( \frac{1}{S} \right)$$

The Lacanian use of metaphor is founded on the principle of a signifying substitution that promotes the authority of the signifier over that of the signified. In language, metaphorical substitution most often occurs between two terms on the basis of semantic similarity. At the level of unconscious processes, this similarity is not always immediately apparent, and only a series of associations can bring it to light.

Thus Freudian condensation plays a role in the different unconscious formations, such as dreams and symptoms, for example. Just as the unconscious material in dreams, telescoped by condensations, reappears in a meaningless form in the manifest dream content, so the symptom expresses, in reality, something completely different from what it appears to mean.

The metaphor of the Name-of-the-Father, as it was called by Lacan, is based on the same principle—that of the substitution of signifiers. In this case, the signifier of the Name-of-the-Father substitutes for the signifier of the mother’s desire, which thus becomes the object of repression and becomes unconscious.

The “fort/da game” that Freud described (1920g) directly attests to the process of metaphorization and the repression that is linked to it. A relation of signifying substitution is established by the child as soon as they “name” the signifying reference to the father as the cause of the mother’s absences. In addition to the paternal metaphor, which makes it possible, the fort/da game is also inscribed in a double metaphorical process. In itself, the reel is already a metaphor for the mother, and the game of its presence and absence is another metaphor since it symbolizes her departure and return.

## **“METAPSYCHOLOGICAL SUPPLEMENT TO THE THEORY OF DREAMS, A”**

Freud seems to have composed this text, as well as “Mourning and Melancholia,” between April and May of 1915, according to James Strachey (*SE* 14), but neither was published until he was done “putting my final touches” on them (letter to Karl Abraham of 11 November, 1917). In the article he had fewer new things to say on the subject of the dream, than on its role as the guardian of sleep, and on how to integrate

it into his most recent theoretical positions. He planned to set out a synthetic view of these positions subsequently, in twelve metapsychological essays.

Freud suggests that the wish to sleep conducts the libido through a “temporal regression” to a selfish state close to primal narcissism, and the ego to the stage of the hallucinatory realization of wish. In this way he returned to the question he had raised from 1895 in *Project for a Scientific Psychology* (1950a): how to differentiate fantasy, delirium, and external reality? The feeling of conviction afforded by the dream prompts a hallucinatory psychosis: “The process, begun in the *Pcs.* and reinforced by the *Ucs.* pursues a backward course, through the *Ucs.* to perception, which is pressing upon consciousness,” (1916–1917f [1915], p. 227) realizing consequently a “formal regression.” However the dream is differentiated from states like the amentia of Meyner or the hallucinatory phase of schizophrenia, whose mechanisms are close to it, since “reality-testing,” one of “the major institutions of the ego,” (1916–1917f [1915], p. 233), persists in the dreamer.

This text, which is still linked to the formulations of the first topic, pursues the discussion begun in “Formulations on the Two Principles of Mental Functioning” (1911b) on the rapport between the psyche and external reality—which Freud continued to elaborate on in “Neurosis and Psychosis” (1924b) and “Fetishism” (1927e). His growing interest in the functions of the ego can be perceived in the differential explication he gave: Psychotic hallucinations do not occur until the “disintegrated” ego has become incapable of exercising its function of reality-testing, so they can, on no account, be interpreted as early symptoms.

Freud concluded his article by emphasizing the importance of the topic of repression for understanding psychic disorders: “In dreams the withdrawal of cathexis (libido or interest) affects all systems equally; in the transference neuroses, the *Pcs.* cathexis is withdrawn; in schizophrenia, the cathexis of the *Ucs.*; in amentia, that of the *Cs.* (1916–1917f [1915], p. 235).

## METAPSYCHOLOGY

The concept of metapsychology was created by Freud to refer to the most theoretical and abstract elements of psychoanalysis. It consists of a set of laws, principles, and fundamental concepts used to represent and describe the operation of the mental apparatus in three fundamental structural aspects: dynamic, topographical, and economic.

The term itself appeared early in Freud's work and is found in a letter to Wilhelm Fliess. It was most likely coined by analogy with the philosophical term "metaphysics," which Freud proposed to "transform . . . into a metapsychology" (1901b, p. 259). The meaning of the concept was gradually refined, and in 1915 Freud attempted to provide a systematic metapsychological description of his current model of psychic structure. The "witch," as he liked to call this metapsychological description, consisted of a set of principles (like the pleasure-unpleasure principle) and hypotheses (such as hypotheses about repression and the unconscious) that presented the functioning of the mind and the processes responsible for its organization as a coherent and intelligible whole.

Freud suggested "that when we have succeeded in describing a psychical process in its dynamic, topographical and economic aspects, we should speak of it as a *metapsychological* presentation" (1915e, p. 181). The economic viewpoint considers the psychic apparatus as crisscrossed by forces that tend toward resolution. The dynamic viewpoint examines how those forces are constructed and how they negotiate mutual conflicts. The topographical viewpoint assumes that we can

describe the psychic apparatus as a space where different areas can be delimited (conscious, preconscious, unconscious), these being governed by laws and intersected by specific processes (unconscious primary processes and preconscious secondary processes). These three viewpoints in combination can present these processes in light of how they are cathected, the role they play in mental organization, and the effect they have on the course of psychic events.

Freud also suggested adding a fourth viewpoint, the genetic, to the first three, which are structural. Freud's proposal, admittedly never fully developed in his work, was given little consideration in French psychoanalysis. But especially in America, writers such as Ernst Kris, Rudolph M. Loewenstein, and Heinz Hartmann have incorporated the notion into ego Psychology. Other authors feel that the three structural viewpoints should be contrasted with a historical viewpoint, which, though not "genetic" in the strict sense, comprises the notion that the psychic processes undergo historical development and organization.

The overall organization of Freud's metapsychology underwent a change of direction in 1920 with the movement "beyond the pleasure principle" to a compulsion to repeat. This turning-point of 1920 led to a "second topography." This new system, also known as the "structural model," does not overlap with the earlier arrangement of conscious, preconscious, and unconscious point by point. Instead, it divides the psychic apparatus into ego, superego, and id. This topographical change entailed a theoretical reorganization so broad that it may be considered a "second metapsychology." Some authors maintain that the introduction in 1937 of the process of splitting introduced a "third metapsychology."

A dialectic existed in Freud's work between metapsychology and clinical practice: the identification of new clinical facts would bring about a corresponding evolution in metapsychology, and this in turn had an affect on theoretical-clinical description. Although the foundations of metapsychology are well established, there is no reason to believe that it is incapable of change and enrichment from advances in clinical knowledge, just as it may evolve through metapsychological research papers.

Metapsychology is the most fundamental component of psychoanalytic theory, the component that consolidates the most essential elements of a psychoanalytic conception of mental functioning. This is

what makes it a metapsychology, that is, a second-level psychology with direct bearing on the processes that govern individual psychologies, a theory that enables us to account for specific clinical variations, using general and universal principles and processes. By abstractly describing processes of ordering, classification, displacement, and condensation (the transformations of psychic reality), metapsychology overcomes the paradox of a theory applied to itself. It defines a process of theorization that, in its movement and mutations, successfully averts the risk of self-validation that its reflexivity might bring about.

Early twenty-first century debates with detractors who refuse to grant metapsychology the status of a rigorous theory and with some psychoanalysts who claim to be able to do without “the witch” and her claims in their daily clinical work center around this fundamental theoretical status. But to reject the status of metapsychology within psychoanalysis amounts to eliminating the most fundamental element of its contribution to depth psychology.

## **METONYMY**

Metonymy is a figure of speech that involves transferring a name from one thing to another on the basis of certain typical kinds of relations: designating the effect with the cause, the whole with a part, the contents with its container. An example would be “a sail on the horizon” for “a ship on the horizon.”

Metonymy is a fundamental notion supporting Lacan's thesis that “the unconscious is structured like a language.” It is analogous with the Freudian concept of “displacement” and refers to the problematic of desire and demand.

Lacan (2002, p. 155) proposed the following symbolic formula for metonymy:

$$f(S \dots S') S \equiv S(-) s.$$

This formula represents the fact that any new signifier ( $S'$ ) intervenes because it is contiguous with a prior signifier ( $S$ ). Metonymy is best illustrated by the kind of displacement that takes place in dreams.

The Freudian concept of displacement emphasizes the shift of value and of meaning. What usually happens is that words and feelings, in a distorted and disguised form, are transferred to nearby material. Lacan insisted that metonymy resists being meaningful by always producing apparent nonsense, as is usually the case with the manifest content of a dream.

Primal repression and the metaphor of the name of the Father impose the mediation of a signifier upon desire. The signifier of the name of the Father initiates the alienation of desire in language. Desire can no longer operate directly. Insofar as it takes the form of speech and is expressed as demand, desire becomes nothing more than a reflection of itself. Increasingly lost in the chain of signifiers, desire refers to an indeterminate series of objects, one after another, that are substitutes for the lost object (*das Ding*), and thus it refers to an indeterminate series of signifiers that symbolize these substitutive objects.

Desire always refers to something fundamentally other than the objects it aims for or the signifiers that symbolize them. Thus desire inevitably follows the

path of metonymy. Because desire is expressed by a symbolizing demand, it always designates a desire for the whole (the lost object) by expressing a desire for a part (the substitute object), just as the metonymic figure “a sail on the horizon” designates the whole (a ship) by a part (a sail).

## MEXICO

During the XX International Psychoanalytical Association (IPA) Congress in Paris in 1957, the Asociación psicoanalítica mexicana (APM; Mexican Psychoanalytic Association) became the first official Mexican affiliate of the IPA. Since that time, the Mexican Psychoanalytic Association has played a substantial role in the IPA: three IPA vice presidents have been from the Mexican Psychoanalytic Association, as have several members serving on nominating committees and on sponsoring committees within the IPA. The Mexican association has also had three members serve as president of the Federación psicoanalítica de América latina (FePAL; Psychoanalytic Federation of Latin America).

In the past, inadequate local training conditions in Mexico had sent many psychiatrists to Argentina, and also to the United States and France, countries that benefited when analysts fleeing from the Nazis enriched existing psychoanalytic training programs. The return of these now-trained analysts to Mexico produced transitory tensions with psychiatrists who had remained in Mexico. Their circumstantial encounter with Erich

Fromm, who had come to Mexico only for his wife's health, diminished tension, as he helped to fulfill their needs for training, founding the Mexican Institute of Psychoanalysis.

The founding group of the Mexican Psychoanalytic Association included Santiago Ramirez, Ramón Parres, José Remus, Avelino González, José Luis González, and Rafael Barajas all of whom were training analysts. Victor Aíza, Fernando Cesarman, Luis Féder, Estela Galván Remus, and Francisco González Pineda were initially included as candidates, were later incorporated into the founding group of members. Carlos Corona and Alfredo Namun eventually joined the Association. Santiago Ramirez and Parres pioneered psychoanalytical training in México City; Rafael Barajas in Monterrey. Successive generations and study groups included other important researchers in theoretical and applied fields.

Initially all doors and roads seemed closed. Though the Hospital General was blocked as a project for psychiatric training, eventually the Hospital Central Militar, Hospital Infantil, Universidad Nacional Autónoma de México Psychology faculty, and the Instituto Nacional de Pediatría, among others, opened their institutions to psychoanalytic training. After one year, the Mexican Psychoanalytic Association's influence spread to other medical and psychological spheres and to all disciplines, covering most socioeconomic and cultural levels within Mexico. The flow of patients with careers in the arts and sciences was remarkable. Mexican authors produced close to 3,000 articles in the Mexican Psychoanalytic Association's *Cuadernos de Psicoanálisis* (begun in 1965), in books, and in other national and international psychoanalytical journals.

The unexpectedly high demand for treatment oversaturated the available capacity, spawning large populations of self-appointed psychoanalysts and psychotherapists. From 37 groups studied that called themselves psychoanalytic, few had earned the name, a consequence of the continuing lack of international, regional or even national regulation of psychoanalysis as a career and title.

An anti-establishment psychoanalytic left “*Plataforma*” emerged during the turbulent mid-1960s. The Viennese-Argentine Marie Langer led a fight from Mexico, which spread throughout Latin America, against “ultra-rightist” Institutes. But the *Plataforma* soon disappeared. Some present Lacanian psychoanalysts are former *plataforma* members.

“L’Asociacion Regiomontana de Psicoanalisis”, (ARPAC), is another psychoanalytic society, equivalent to the Mexican Psychoanalytic Association. It was founded in 1979 to serve the northern part of the country by a group of Monterrey Mexican Psychoanalytic Association members, including Diego Rodriguez, Roger Garcia, Alfonso Moreno Robles, Ruben Hinojosa and Ruben Tames. The founding members were later joined by Ricardo Diaz Conti, Cesar Garza and Hernan Solis. In 1993, the IPA recognized ARPAC as an independent affiliate.

As of 2005, the Association had 130 members and 22 candidates. Mexico City also suffers a consumer’s crisis; patients who once averaged 3 to 4 visits a week only average 2 sessions as of the early 2000s. Peripheral groups are developing including Jungians, local and foreign Lacanians. The Mexican Psychoanalytic Association began to provide distance education and new projects for fellowships for each state were being considered. Josefina Mendoza was president of the Mexican Psychoanalytic Association in 2005. The Institute of the Asociación Psicoanalitica Mexicana has had over 20 graduating classes. Its post-graduate programs include training analysis and child psychoanalysis. Its post-graduate center also trains psychoanalytically-oriented psychotherapists. The Mexican Psychoanalytic Association has a full extension program and participates in applied psychoanalytic activities along with study groups, research, publishing, and two yearly congresses (one open, one closed).

The Association inspired and developed groups all over the country. Some of the groups in Mexico City include AMPAG—Analytic Group Therapy Association (founded by L. Feder, J. L. Gonzalez, G. Quevedo, F. Zmudt. Graduates: first generation, A. Palacios, H. Prado); IMPPA (Armando Barriguete); and Asociacion Mexicana de Psychoanalytic Psychotherapy, founded by Santiago Ramirez, Dolores Sandoval, and others. In Guadalajara, there are two groups: GGPP (Varela and Gramajo) and APJ (Torres and Manuel Fernandez V.). There are nearly 10 other groups in other parts of Mexico. There are individuals practicing in Yucatan, Chiapas, Guadalajara, Cuernavaca, Aguascalientes, and Vera Cruz. Specialized psychoanalytic institutions and hospital services include IFAC (Family Therapy Institute), which provides family therapy, merging psychoanalytical and Frommian orientations; CPPO, bringing distinguished lecturers; and IMANTI, which provides special education.

Some of the contributions to psychoanalytical thought include the following: psychology of the Mexican (Santiago Ramirez); aggression and destructivity of the Mexican (González Pineda); studies on transference-countertransference (José Remus, Luis Féder); mammoth group psychotherapy (José Luis González); separation anxiety (Avelino González); child analysis (Victor Aiza, M. I. López; M. Salles, child psychiatry); ecocide and non-human objects relations (Fernando Cesarman); and the “unwanted child” developed into preconceptology theory and psychogenoma project (L. Féder team of J. Islas, R. Balderas, S. Weinstein). Significant training contributions have been made by Eduardo Dallal, M. A. Dupont, Jaime Ayala and José Camacho. Recent awards suggest that Mexico’s creative and pioneering fervor continues into the twenty-first century.

### **MEYER, ADOLF F. (1866–1950)**

Adolf Meyer was born on September 3, 1866, in Niederweningen, a small village near Zurich, Switzerland, and died on March 17, 1950, in Baltimore, Maryland. An early, influential psychiatrist, Meyer was one of the founders of the New York Psychoanalytic Society and of the American Psychoanalytic Association.

Son of a Zwinglian minister, Meyer studied medicine in Zurich, where he was student of Auguste Forel at the Burghölzli Mental Hospital. He also studied in England with Hughlings Jackson and in Paris with Jean Martin Charcot.

In 1892 Meyer emigrated to the United States. He worked at the Illinois Eastern Hospital for the Insane, then at the Worcester Lunatic Hospital, in Massachusetts. From 1902 he practiced at the New York State Pathological Institute of Manhattan. There he joined early informal meetings about psychoanalysis. From 1904 to 1909 Meyer served as professor of psychiatry

at Cornell Medical School. He began teaching his original views concerning dementia praecox (schizophrenia), taking a broader view of its etiology and prognosis than was common at the time. (The Emil Kraepelin tradition of psychiatry viewed dementia praecox as an organic disease without possibility of cure.) In 1909 Meyer lectured on the dynamics of this disease at Clark University's twentieth anniversary jubilee, in which Freud also took part. In 1910 he became the first psychiatrist appointed to a chair at Johns Hopkins University, where he taught until 1941. And in 1913 he was named director of the university's new Henry Phipps Psychiatric Clinic.

At a time when knowledge about the brain was highly limited, Meyer deemphasized organic factors in such severe mental disorders as schizophrenia, in favor of a functional typology. His *Psychobiology: A Science of Man*, published posthumously in 1957, represents in part the influence of Hughlings Jackson's biological approach to neurology; Meyer had studied Jackson's institute in London in 1891. (In Meyer's usage, *psychobiology* adumbrates but is far short of the contemporary discipline of the same name.) Downplaying efforts to link behavior to brain lesions or neurological abnormalities, Meyer attempted to relate specific disease states to conscious emotions, linking even severe disorders to a patient's experience and habitual reactions. Meyer did not view schizophrenia, for example, as an untreatable illness with a fatal prognosis, as was common in Kraepelinian psychiatry. He suggested instead that dynamic factors could lead to debilitating mental disease, and he advocated treating individual patients in private practice. This viewpoint, because it saw psychotherapy as offering optimistic prognoses, helped introduce psychoanalytic thinking into psychiatry and extend its influence in the field from the mid-twentieth century.

Meyer was also a key figure in the mental-health movement in the United States. Psychiatrists and neurologists were formerly largely limited to practicing in mental institutions. Meyer advocated employing psychiatrists in schools, prisons, and a variety of community and workplace settings. He thus was instrumental in vastly expanding the role of psychiatrists.

### **MEYERSON, IGNACE (1888–1983)**

Ignace Meyerson, a French physician and psychologist, was born in Poland on February 27, 1888, and died in Paris on November 17, 1983.

Having been active in the Russian-Polish insurrection of 1905, he arrived in Paris in 1906 and met up with his uncle, Émile Meyerson, a philosopher and historian of science. From 1907 to 1920 he studied medicine, the natural sciences, philosophy, and sociology. During World War I he replaced Henri Wallon, who was serving at the front, under Chaslin and Nageotte at the Salpêtrière. He got to know Pierre Janet and Georges Dumas and became Dumas's assistant in the psychology laboratory of the Saint Anne asylum.

At the request of Dumas and publisher, Félix Alcan he started to translate the *Traumdeutung* (Freud, 1900a, *The Interpretation of Dreams*) in 1922. As odd as it is that Freud allowed his book of dreams to be translated by someone totally unknown, and a student of the man whom he considered to be his most formidable enemy in France, the attraction of being published by Alcan, the most prestigious publisher of academic works, must have had a determining influence.

In spite of his lack of enthusiasm (he never admired psychoanalysis), Meyerson accepted the difficult task, which nevertheless ensured him a comfortable retirement as a result of the gilt-edged contract he negotiated with Alcan (ten percent of the rights). *La Science des rêves* (*The Science of Dreams*) appeared in 1926. It was not republished until 1953, and 1967 saw a new translation published by the Presses Universitaires de

France, revised by Denise Berger and entitled *L'Interprétation des rêves* (The interpretation of dreams).

In 1947 Meyerson presented his PhD thesis, his main written work: *Les Fonctions psychologiques et les œuvres* (Psychological functions and works). In it he presents the bases of his historical psychology as applied to the individual. He then applied for the Sorbonne chair of general psychology, left vacant by Paul Guillaume, but Daniel Lagache was appointed and thus gave a much more clinical orientation to French psychology.

Meyerson died at the age of ninety-five, having abandoned his teaching post in section six of the *École des hautes études en sciences sociales* (EHESS, College of Advanced Studies in the Social Sciences) only a few months earlier. Although he is not credited with having had much influence, Meyerson did have a long-lasting and profound effect on French psychology. For thirty years he was the editor of Janet's and Dumas's *Journal de psychologie normale et pathologique* (Journal of Normal and Pathological Psychology), making it one of the great forums of intellectual expression between the two world wars. He also founded comparative historical psychology in the *École Pratique des Hautes Études* (Practical College of Higher Studies).

## **MEYNERT, THEODOR (1833–1892)**

Theodor Meynert, an Austrian psychiatrist, was born in Dresden in 1833 and died at Klosterneuburg, near Vienna, in 1892.

His father was a writer and his mother a singer at the court opera. Meynert, a "curious mixture of artist and naturalist," became a doctor of medicine in 1861 and in 1865 he presented a thesis that authorized him to teach in third level education: *Bau und Leistungen des Gehirns und Rückenmarks mit Beziehung zu deren Erkrankungen* (Structure and activity of the brain and spinal cord in relation to their pathology). In 1868 his authorization was extended to include psychiatry. An experienced dissector, he was appointed director of a psychiatric hospital in Lower Austria in 1870. By 1873 he occupied a chair of psychiatry and in 1875 he became the director of the psychiatric clinic attached to the University of Vienna.

Meynert's scientific contributions are related to his work on the pathology of the brain, such as mapping the topography of the sensory and motor pathways and identifying the nerve endings in the cerebral motor cortex and the linking pathways of the cerebellum, as well as functional antagonisms that are important for the history of the evolution between the cerebral cortex and the rest of the brain. Meynert is recognized as the founder of the cytoarchitectonics of the cerebral cortex. He devoted himself to establishing psychiatry as an exact science based on anatomy. He formulated the antagonism between the cortex and the sub-cortical zones as being the key to the abnormal function of cerebral mechanisms in mental illness. He left his mark on theories concerning the causal links between cerebral pathologies and psychoses as a result of deficits in cerebral nutrition related to vasomotricity. His article "Amentia" (1890/1983) describes and demonstrates the interaction between organic and psychological factors.

In July 1882, when he entered the general hospital of Vienna as an intern, Freud had already abandoned his career as a researcher with Brücke for financial reasons. Having worked as an assistant physician in Meynert's clinic from May 1 to September 31, 1883, he continued his laboratory research into the anatomy of the brain for another eighteen months. However, his initial high esteem for Meynert was transformed into a critical distance with regard to the "idol Meynert enthroned in the heavens." Meynert later distanced himself from Freud because of the latter's interest and experience with Charcot's ideas in Paris and his therapeutic involvement with hypnotism.

## MIDLIFE CRISIS

As a major evolutionary stage in middle adulthood, the midlife crisis corresponds to a change, a transition, or an existential turning point that is not necessarily pathological and takes place somewhere between the ages of thirty-five and fifty.

Based on a more or less deep questioning of oneself it may contribute to the possible emergence of psychopathological disturbances that in all probability stem from the personal history and constitution of each person (depressive reactions, suicide or attempted suicide, manic or hypomanic defenses, and psychotic outbursts). Somatic complaints may also often come to the fore.

From a psychopathological point of view, the midlife crisis has its roots in a complex interweaving of different biological, psychological, and social factors. Some Anglo-Saxon authors (among them Elliott Jaques and Daniel J. Levinson) have studied the factors that may contribute to the fragility of the mind; in particular reduced physical performance, the approach of

menopause in women, or a painful awareness of the time that has already passed.

From a psychodynamic point of view a role may be attributed to the reverse parental identification with the children, who are approximately going through adolescence when their parents are having their midlife crisis. These reverse identifications run an implicit risk of causing depressive moods by virtue of the fact that they are based on an existential impasse.

In relation to the midlife crisis it is worth referring to Carl Gustav Jung's already quite old writings, particularly the article titled *The Stages of Life*. Having described the "archetypes" that constitute the collective unconscious (the true substrate of the psyche, an immutable structure, a sort of symbolic heritage that is proper to all humanity), Jung then went on to complete this view of the psyche with the notion of "psychological types." Here he described individual characters that are organized around the introversion/extroversion dialectic and are centered by a process of individuation that leads the human being toward a unification of the personality through a series of metamorphoses or stages, among which the midlife crisis occupies a relatively important position.

The concept of crisis has lost some of its importance in modern psychopathological writing both in relation to adolescence and to this midlife period that is sometimes called *maturescence* and then considered to be a sort of second adolescence or a third phase in the separation-individuation process. Nowadays we tend to lay more stress on the processes of psychic mutation or transformation with reference to the concept of "catastrophic change" (René Thom), but without the harmful aspect that is often associated with the term *crisis*.

## MINKOWSKA-BROKMAN, FRANÇOISE (1882–1950)

Françoise Minkowska-Brokman, a physician and psychiatrist, was born on January 22, 1882, and died in Paris on September 15, 1950.

From a Polish Jewish family, she was prevented by the czarist régime from studying medicine within the Russian empire, as was her future husband, Eugène Minkowski. She studied under Eugen Bleuler in the Burghözli asylum in Zürich, and then she went to Kazan in 1909 to acquire a diploma that would allow her to work in Russia at the same time as Eugène Minkowski, whom she married on her return.

In Zürich she also met Hermann Rorschach, another of Bleuler's students, who also considered moving to Russia because of his marriage to Olga Stempelin. Minkowska was therefore familiar with the ideas of the inventor of the famous Rorschach test well before the publication of his *Psychodiagnostics* in 1921.

Although she had lived in France for several years, after World War I her family responsibilities prevented her from resuming her studies in order to practice medicine there. Her research work in Paris was therefore conducted independently of any official organization. In 1925 she contributed to the collective publication *L'Évolution psychiatrique* with *Les troubles essentiels de la schizophrénie dans leurs rapports avec les données de psychologie et de la biologie moderne* (The relationship between essential schizophrenic disorders and modern psychology and biology), and again in 1927 with *Le problème de la constitution examinée à la lumière des recherches généalogiques et son rôle théorique et pratique* (The problem of the constitution examined in the light of genealogical research and its theoretical and practical role). She was referring to

Kretschmer's morphopsychological distinction (in *Körperbau und Charakter*, [Physique and character; 1921]) between schizoid and cycloid. In the same vein, she described a third type of constitution or personality structure as epileptoid or, to be more precise, *glischroid*, a term chosen by Édouard Pichon. Having read Jaspers's study of Van Gogh, she took an interest in the painter's life and work and came to the conclusion that glischroid epilepsy was the psychopathological register that best corresponded to the painter's psychiatric experiences.

Minkowska's untimely death prevented her from completing a study of the Rorschach test, but a collection of her papers was published posthumously in 1956. Seven of them had been published between 1940 and 1950 in *Annales médico-psychologiques*, *L'Évolution psychiatrique* and *Le Journal de psychiatrie infantile*. Study number 2, dating from 1943, was banned in France but made its way clandestinely to be published in *Rorschachiana* in 1945. The remaining two studies have never been published. They were: *Le Rorschach en tant que "Formdeutungsversuch"* (The Rorschach as an attempt to interpret form; Françoise Minkowska preferred this expression to "test"), presented on the occasion of the First International Rorschach conference in Zürich in 1949, and a particularly moving text: the paper she gave on March 20, 1950, written in reaction to a posthumous article by Rorschach reviewing a paper given to the Swiss Society for Psychoanalysis in March, 1922. Her own death on September 15, 1950, did not allow her to review it for publication.

The funeral oration in honor of Minkowska was delivered in the name of *L'Évolution psychiatrique* by Jacques Lacan.

## MINKOWSKI, EUGÈNE (1885–1972)

Eugène Minkowski, a psychiatrist and philosopher, was born on April 17, 1885, in Saint Petersburg and died on September 15, 1972, in Paris.

Born into a Jewish family from Lithuania, he began his medical studies in Warsaw but, because of political repression from the czarist government, was forced to complete his education in Munich, where he obtained his degree in 1909. To practice in Russia, he sat for another degree in Kazan, where he met Françoise Brokman, whom he married when he returned to Western Europe. Upon his return to Munich, this time to study philosophy, he found himself caught up in the First World War. He initially sought refuge in Zurich, and worked with Eugen Bleuler at the Burghölzli Asylum. He then joined the French army, where he served as a military doctor on the battlefield.

As a result of volunteering for service, Minkowski was made a French national and settled in Paris after the war, where he spent the greater part of his life. He worked as a consultant at the Rothschild Hospital and the Henri-Rousselle Pavilion at Sainte-Anne's Hospital.

In 1926 Minkowski defended his dissertation, "La notion de perte de contact avec la réalité et ses applications en psychopathologie," based on the concept of *élan vital* introduced by Bergson in *Creative Evolution* (1907). He associated this loss of *élan vital* with autism, as Bleuler referred to autoeroticism, a fundamental symptom of the schizophrenic psychoses (1911). It was through Bergson's vision that French psychiatrists approached Bleuler's work, using the new tools of psychoanalysis to revise the concept of dementia praecox constructed by Emil Kraepelin at the end of the nineteenth century.

In 1923 Minkowski published an article that clearly indicated his interest in phenomenology, "Étude psychologique et analyse phénoménologique d'un cas de mélancolie schizophrénique." He also contributed articles to the two collections published as *L'Évolution psychiatrique*: "La genèse de la notion de schizophrénie et ses caractères essentiels" (1925) and "De la rêverie morbide au délire d'influence" (1927). In 1925 Minkowski, together with the analysts who went on to create the Société psychanalytique de Paris (Paris Psychoanalytic Society) the following year, helped found the organization L'Évolution psychiatrique. Minkowski was secretary general of the organization until the Second World War, when the society interrupted its activities. During this period Minkowski made *L'Évolution psychiatrique* a place where French psychiatrists would have access to new information from philosophy and science that contributed to the evolution

of their discipline. Minkowski himself barely escaped deportation during the Occupation.

Minkowski, together with Ludwig Binswanger, is considered the creator of phenomenological psychiatry. *Le Temps vécu, études phénoménologiques et psychopathologiques* (1933) describes the spatialization of being, which compensates for the feeling of time that is no longer experienced in schizophrenia. In April 1938, Minkowski published, in the *Annales médico-psychologiques*, "À propos de l'hygiène mentale: Quelques réflexions," where he protested against the law requiring the sterilization of mentally ill patients with hereditary diseases that was promulgated in Nazi Germany as a form of mental hygiene.

In 1956, *L'Évolution psychiatrique* published a volume dedicated to Eugène Minkowski, with contributions from more than forty authors. Minkowski devoted the end of his life to writing *Traité de psychopathologie* (1966/1999), an important synthesis of his life's work.

## **MINUTES OF THE VIENNA PSYCHOANALYTIC SOCIETY**

Otto Rank, hired as appointed secretary at the age of twenty-two, began drafting the *Minutes of the Vienna Psychoanalytic Society*, along with two small volumes containing papers presented and attendance lists, on October 16, 1906. Until April 27, 1910, he wrote these by hand; the acquisition of a typewriter made it possible

to produce multiple copies thereafter. Rank was mobilized in 1915 and Theodor Reik took over secretarial functions for the society. However, he recorded only paper titles and attendance lists. The next minutes were not produced until November 19, 1918; they recorded a lecture given by Siegfried Bernfeld, the last in the series.

Sigmund Freud kept these minutes, though their existence was for the most part forgotten. Before leaving for London in 1938, Freud entrusted them to Paul Federn. Since 1924, Federn had been Freud's personal representative as well as administrator and vice president of the Vienna Psychoanalytic Society. He took the minutes to the United States and published one set of them in 1947, in volume one of *Samiksa*, the review of the Indian Psychoanalytic Society. His attempts to publish the minutes in their entirety remained fruitless due to lack of money. At the execution of his will in 1950, he bequeathed the publication rights to Hermann Nunberg and his son Ernst Federn.

Editing of the minutes began in 1951, with the help of a five-thousand-dollar loan. The first volume in English, translated from the German by Margarete Nunberg, was published by International Universities Press in 1962; the fourth and final volume appeared in 1975. In German, the first volume was published by S. Fischer Verlag in 1976; the fourth volume, with an afterword by Harald Leupold-Löwenstein, came out in 1981. The English-language edition ends with the 250th set of minutes; the German edition stops in 1918. Both editions include the minutes of Bernfeld's lecture on November 19, 1918, and those of the society's last session on March 20, 1938. The first volume of the French edition, translated by Nina Schan-Bakman, was published in 1976 by Gallimard; the fourth volume appeared in 1983. A first volume, 1906–1908, was published in Italian and in Spanish. The manuscripts were returned to the Vienna Psychoanalytic Society by Ernst Federn, in accordance with Paul Federn's wishes as expressed in one of his letters.

The publication of the Vienna minutes is of the utmost importance for the history of psychoanalysis. There are several areas that the minutes cast in a new light:

- From 1903 on, Freud was by no means as isolated in his research as Ernest Jones described in his autobiography. The men and women who accompanied him at this time belonged to Vienna's intellectual and medical elite; among them were two eminent musicologists, David Back and

Max Graf. Other renowned personalities emerged within the circle of guests.

- The process that led to the split with Alfred Adler in 1911–1913 is clearer.
- Psychoanalytic knowledge was elaborated over the course of many years of clinical work with a whole series of collaborators. Freud sometimes waited ten years before publishing his observations, which, like the theories based on them, were always debated within the circle.

The minutes show why Freud referred to psychoanalysis as “an eminently social affair.” They are an important presentation of an experimental group led by Freud and also help re-create the general intellectual and social climate of Vienna before the First World War.

## MIRROR STAGE

The mirror stage, occurs when an infant, beginning at six months, discovers its own reflection in a mirror. The baby then turns toward the adult who is holding it and entreats that adult to confirm with his or her expression what it perceives in the mirror, namely the image of a mastery not yet achieved.

It was an observation of Henri Wallon's (1931) in the context of his work on the development of the child's conception of its “own body” that inspired the adoption of the term *mirror stage* and its elaboration by Lacan in particular. Confronted by its own image in a mirror, a six-month-old human will grow excited, fascinated, whereas a chimpanzee of the same age will lose interest as soon as it realizes that the reflection is illusory.

Lacan gave special importance to this moment where the Other confirms that the mirror image is one's own, for at this moment, the infant supposedly

becomes conscious of its body as a totality even before successfully integrating the motor functions and achieving real mastery of that body.

The concept of the mirror stage was Lacan's first formal contribution to psychoanalytic theory, presented at the Fourteenth International Psychoanalytic Congress in Marienbad in 1936. The text of his presentation was not published at the time, but he revisited the issue in a paper published in 1949.

Calling it a "stage" stressed the important place this moment was assigned in mental development. When Lacan said that it occurred between six and eighteen months, this was one of the very rare occasions when he referred to developmental chronology. That said, he also said that the mirror "serves as a prototype that reveals other relations between the subject and his image as the latter is the ego's" (1954).

Between 1936 and 1962, Lacan's concept of the mirror stage underwent a significant reorientation. Early on, Lacan was influenced by Gestalt psychology, and what interested him, as it did a number of ethologists, was the power of the image itself as a finished form, pregnant with meaning, capable of sustaining the baby's identity. Basically, he wanted to trace the effects of the imaginary on the formation of the ego and the body, and the relationship with the counterpart.

When Lacan introduced the concept of the "Other," however, the mirror stage came to indicate how the founding role of the Other's gaze works to form the subject's mental apparatus. Thenceforward the very possibility of the mirror stage presupposed a symbolic operation. Were such operations lacking, the mirror stage would not occur, as happens with the autistic child, in whom there is no relationship in the Imaginary either to a body image or to any kind of counterpart. Beginning with his seminar on the transference (1991 [1960–61]), Lacan took the mirror as a metaphor for the Other's gaze.

Winnicott (1967) extended the Lacanian notion of the mirror stage by emphasizing the part played by the face, and especially the gaze of the mother, as a mirror for the child.

## **MIRROR TRANSFERENCE**

Mirror transference is the remobilization of the grandiose self. Its expression is: "I am perfect and I need you in order to confirm it." When it is very archaic, mirror transference can easily result in feelings of boredom, tension, and impatience in the analyst, whose otherness is not recognized. Counter-transference is thus a sign of it.

The notion, which first appeared in Heinz Kohut's work in "The Psychoanalytic Treatment of Narcissistic Personality Disorders" (1968), was further elaborated in his *Analysis of the Self* (1971). Mirror transference can take three forms, depending on the degree of regression and the nature of the point of fixation. Fusion transference is the most archaic form and refers to a primary identity relationship in which the Other is completely part of the self. It shows itself when the analyst is taken to be omnipotent and tyrannical and is

experienced as an extension of the self. In twinship or alter ego transference, the other is experienced as being like the self. Lastly, in mirror transference properly speaking, the analyst is experienced as a function in service of the patient's needs. If the patient feels recognized, he experiences a sense of well-being linked to the restoration of his narcissism.

Mirror transference can be primary, the reaction to a broken idealizing transference, or secondary to one of these. In *The Restoration of the Self* (1977), Kohut distinguished it from alter ego transference.

Some authors have refused to consider this transference as being a result of the evolution of narcissism; they have seen it as a defense.

## **MITSCHERLICH, ALEXANDER (1908–1982)**

The German physician and psychoanalyst Alexander Mitscherlich was born in Munich on September 20, 1908, and died in Frankfurt on June 26, 1982.

He grew up in Hof, a district in northern Bavaria, the only child of Harbord Mitscherlich, an industrialist, and his wife, Clara. As a youth, Alexander was raised under his father's severe and authoritarian discipline, common in Germany at the time. Graduating from high school in 1928, he first studied history, art history, and philosophy in Munich and Prague. After failing to obtain his doctorate, he went to work in a Berlin bookstore. He developed left-wing political contacts with writer Ernst Jünger and the "National Bolshevik"

Ernst Niekish. (National Bolsheviks favored Germany's rapprochement with the Soviet Union against the rest of Europe.) In 1932, he entered medical school.

Opposed to National Socialism, Mitscherlich was arrested by the Gestapo in 1937 and spent eight months in prison awaiting trial. Afterwards, he was able to continue his medical studies in Heidelberg under physician and philosopher Viktor von Weizsäcker, and successfully defended his doctoral thesis in 1941. Until the end of the war, he worked mainly in the area of psychosomatic medicine at the Ludolf Krehl Clinic in Heidelberg.

Thanks to his clear opposition to the Nazis, Mitscherlich was among a minority of German physicians whom the victorious Allies considered politically trustworthy. As a consequence, he briefly served as minister in the post-war government. He also enjoyed a measure of moral authority among psychoanalysts, many of them Jewish, who, after the rise of National Socialism, had fled to England and the United States. The esteem in which he was held by colleagues abroad, including Anna Freud, proved a great advantage for psychoanalysis in Germany.

Beginning in the 1950s, Mitscherlich succeeded in bringing representatives of the psychoanalytic community to Germany, including Franz Alexander, René A. Spitz, William G. Niederland, Peter Blos, Willi Hoffer, Jeanne Lampl-de Groot, Piet Kuiper, Michael Balint, John Klauber, Paula Heimann, Fritz Morgenthaler, and Paul Parin. He was able to create new credibility for German psychoanalysis, which since the Nazi era was widely thought to be politically retrograde and scientifically discredited. It was principally due to Mitscherlich's prestige that the German Psychoanalytic Association (Deutsche Psychoanalytische Vereinigung), founded in 1950, was recognized by the International Psychoanalytic Association (IPA); he was one of the organization's directors from its inception. Mitscherlich himself had a training analysis with Paula Heimann in London.

Mitscherlich's relationships with German medicine remained problematic, however. In 1947 he published *Doctors of Infamy: The Story of the Nazi Medical Crimes*, written in collaboration with Fred Mielke; it was the fruit of his work as head of the German Medical Commission, which reported to the American Military Tribunal. Mitscherlich effectively transgressed an institutional taboo by reporting on experiments that German physicians conducted on concentration

camp prisoners in a unique document that finally won attention in Germany when it was republished in 1948 under the title *Medizin ohne Menschlichkeit* (Medicine without humanity). Mitscherlich also founded, with Hans Kunz and Felix Schottlaender in 1948, the review *Psyche*, which as of 2005 remains the most important psychoanalytic publication in Germany. As director of the series “Literatur der Psychoanalyse” Mitscherlich helped to raise professional standards of psychoanalysis in Germany to a par with those in other countries.

The high point of Mitscherlich’s institutional work was his helping to found, in Frankfurt in 1960, the Sigmund Freud Institute, where physicians, non-physicians, psychoanalysts, and social scientists could conduct interdisciplinary research on individual and social issues related to psychological disorders. He remained the institute’s director until 1976, and from 1973 to 1976 was on the faculty of philosophy at Johann Wolfgang Goethe University in Frankfurt. As an author, Mitscherlich’s reputation and influence extended well beyond psychoanalytic and philosophical circles. His psychosociological works include *Society without the Father: A Contribution to Social Psychology*, published in 1963 and translated into English six years later. His *Die Unwirtlichkeit unserer Städte* (The inhospitality of the modern city) appeared in 1965. In 1967 he and his wife, Margarete, published *The Inability to Mourn: Principles of Collective Behavior*; translated into several languages, the theme of this controversial work was the failure of Germans to acknowledge the crimes committed in the name of National Socialism.

Mitscherlich was one of the rare scholars and writers—not just in Germany but around the world—who was constantly taking a stance on social and political issues. Philosopher Jürgen Habermas called him “the people’s pedagogue.” To the extent that psychoanalysis was able to revive and ultimately to thrive in post–World War II Germany, is due in great measure to Mitscherlich.

## MNEMIC SYMBOL

The idea of the *mnemic symbol* (*Erinnerungssymbol*) occurs in Freud’s early writings as the equivalent of the notion of the hysterical symptom. A mnemic symbol appears as a hysterical thought with an unaccounted for intense affect, or it manifests itself through compulsion, for example, a hysterical attack in which the patient’s movements represent a seduction scene. The term *mnemic symbol* appears prominently in “A Project for a Scientific Psychology” (1950c [1895]) and *Studies on Hysteria* (1895d), but also in “The Neuro-psychoses of Defence” (1894a) and “The Aetiology of Hysteria” (1896c). In “The Aetiology of Hysteria,” Freud reiterated the explanation given by Josef Breuer in *Studies on Hysteria* (1895d): “The symptoms of hysteria (apart from the stigmata) are determined by certain experiences of the patient’s which have operated in a traumatic fashion and which are being reproduced in his psychical life in the form of mnemic symbols” (pp. 192–193).

The mnemic symbol, a psychic stigma resulting from a traumatic event, is a *mnemic trace*—although not all mnemic traces necessarily correspond to a seduction and a trauma—that displaces the affect associated with the trauma onto an isolated adjacent representation in such a way that the person does not understand the intense cathexis of this representation.

The mnemic symbol is characteristic of a hysterical symptom, but no doubt is also characteristic of all symbols. This notion belongs to the first theory of the neuroses, the theory that trauma causes hysteria, from before 1900, and it is not often encountered in Freud's later writings. A mnemic symbol results from a displacement, as Freud explained in "A Project for a Scientific Psychology": "B stands in a particular relation to A. For there has been an occurrence which consisted of B + A. A was an incidental circumstance; B was appropriate for producing the lasting effect. The reproduction of this event in memory has now taken a form of such a kind that it is as though A had stepped into B's place. A has become a substitute, a *symbol* for B" (p. 349). Condensation and metaphor are also at work here. When A is substituted for B, there is total amnesia of B. B is repressed but remains "a mnemic image like any other; it is not extinguished" (p. 351); that is, it remains as an unconscious memory trace. This explains hysterical compulsion. In hysterical repression, "A is compulsive" (p. 350), and "instead of B, A always becomes conscious—that is, is cathected. Thus it is symbol-formation of this stable kind which is the function that goes beyond normal defence" (p. 352).

The mnemic symbol not only repeats what was experienced at the time of the trauma; it also reinforces it. Affect and libidinal excitation are more intense in the symptom than in the event it commemorates, according to Freud in "The Aetiology of Hysteria." This sheds light on the paradox, recounted in "A Project for a Scientific Psychology," of Emma's childhood seduction, whose attendant affects she did not feel until puberty. The mnemic trace of this traumatic seduction must indeed have been registered when it occurred in childhood, but this trace was only intensified through deferred action, when it was transformed into a mnemic symbol. Emma's fear of entering shops and her conviction that her symptoms came from an episode during puberty where she felt seduced by a young shop assistant were in effect the mnemic symbol, A, of the repressed childhood scene actually at issue, B. The mnemic symbol is the clothing through which Emma was sexually molested as a child. In the episode from her adolescence, Emma thinks that people are making fun of her because her clothes are ridiculous, while she also feels attracted to the young shop assistant. In this case, the mnemic symbol almost takes on the value of a fetish.

The notion of the mnemic symbol, encompassing the notions of mnemic trace, hysterical symptom, and

symbol, may seem overly general, but its definition limits its usage to a very specific field of psychopathology.

## **MNEMIC TRACE/MEMORY TRACE**

The mnemic trace, the notion of unconscious memory that is essential in Freudian theory, results from the inscription upon the psychic apparatus of a perception that is strong enough to cross the barrier of the protective shield. This perception is totally unconscious, whereas the memory of it is conscious. Sigmund Freud envisaged the psychic apparatus as a system of multiple and complex facilitations of mnemic traces. The mnemic trace, usually sensory, can also be the trace of a thought, especially when it is verbal.

Used throughout Freud's works, this notion appeared in his first theories of the neuroses before 1900, mostly in the "Project for a Scientific Psychology" (1950c [1895]); it was then reformulated in *The Interpretation of Dreams* (1900).

The mnemic trace, a metapsychological construct, originated in neurophysiology. In "Project for a Scientific Psychology," Freud saw in it both the complex reality of "facilitations" in the neurons, which present-day neurobiology would call "neural networks," but also a differential system of inscription of perceptual impressions. The postulate of incompatibility between, on the one hand, consciousness and perception, and, on the other hand, the unconscious and the lasting quality of mnemic traces expressed in 1895 and reiterated in 1900, remained intact throughout the developments of his later work.

In a letter to Wilhelm Fliess dated December 6, 1896, Freud posited that memory consists of multiple strata corresponding to different points in time, and that these are always being rearranged because they are constantly being transformed into different “signs”: In the mnemonic trace, the sensory perception becomes a sign of perception. The German *Erinnerungspur* literally means “trace of a memory.” In Freud’s text the same linguistic root is used for two notions that are contradictory in other languages: the “mnemonic trace,” which is unconscious, and a memory (*Erinnerung*), which is conscious. The semantic slippage between the two terms in Freud’s work reflects the fact that he elaborated the notion of the mnemonic trace based on his theory of seduction and trauma in hysteria, in which the trace of the trauma is conceived as being a more or less forgotten and more or less unconscious memory, resulting in the paradox of an “unconscious memory.”

Freud discovered the existence of the mnemonic trace based on the insistent character of the deformation produced by the trauma—that is, the persistent intensity of the symptom, which he envisioned as a state of charge in the neurons that would evacuate a quantity, producing what he described in *The Interpretation of Dreams* (1900) as “permanent modifications” (p. 538) in the nervous tissues. Mnemonic traces tend to “re-find” their perceptual and conscious origins in a hallucinatory mode. The mnemonic trace is the trace par excellence of the object of desire associated with the scheme of action leading to the satisfaction of the instinct. Essentially a visual trace—although the mnemonic trace can be olfactory, tactile, or verbal—it is sometimes called a “mnemonic image.” In hysteria and in the neuroses more generally, the imprint of mnemonic images and obsessive memories is linked to the pregnancy of the affects. The mnemonic trace corresponds to the impression produced by a perception, not to the perception as such: It is a representation of an absent object, accompanied by affects. In the unconscious, the instinct hallucinatorily cathects the mnemonic trace of this absent object, which can be theorized as an “internal object.”

In 1895 Freud underscored the question of the coincidence between the unconscious representation and the external object of perception, to the extent that the ability to evaluate their identity or their difference defines the ego as a stable agency situated at the boundary between inside and outside. In “Project for a Scientific Psychology” he explained how the ego

inhibits the hallucinatory mode of internal representations and provides the means by which “traces of thought-processes are distinguished from those of reality” (p. 335). His arguments in this essay presume, beyond the difference between mnemonic trace and perception, a difference between traces mediated by thought, which exerts a secondary influence on them, and mnemonic traces strictly speaking, which come from perception.

It is by means of language that traces originating in thought become mnemonic traces, because language is registered at the level of the senses: that is, through hearing speech or reading something written. Verbal mnemonic traces are posited as having the power to bring into consciousness all the other mnemonic traces that they name. But the secondary processes can never totally inhibit the tendency toward immediate discharge in the coalescence between representation and perception, as Freud concluded in “Project for a Scientific Psychology.”

This conception was further elaborated in 1900 in *The Interpretation of Dreams*, where the dream-work is envisioned as the metabolization of a combination of memories, unconscious mnemonic traces, instinctual representatives, and complex thoughts. In chapter 7 Freud proposed a comparison between the mental apparatus and a compound microscope or camera, and wrote: “On that basis, psychical locality will correspond to a point inside the apparatus at which one of the preliminary stages of an image comes into being” (p. 536). He stressed the different types of mnemonic traces, based on, but also beyond, the assumptions that there may be several traces corresponding to a single perception, and that memory traces are grouped according to resemblance or simultaneity. Here, the notion of mnemonic trace is inseparable from that of the unconscious wish seeking identity between representation and perception. Mnemonic traces are “paths which can always be traversed . . . indestructible” (p. 577); when a memory trace “is touched, it springs into life again and shows itself cathected with excitation” (p. 578). The mnemonic trace is thus endowed with the capacity to radiate outward that is characteristic of desire.

In “A Note upon the ‘Mystic Writing Pad’” (1925a), the dominance of the mnemonic trace over consciousness—of which it is ostensibly the necessary prior stage—is attributed to consciousness being switched on and off in alternation within perception, openings

and closings of the psychic apparatus at the interface between the *Pcs.*-*Cs.* and *Ucs.* The sense of the passage of time is posited as being the effect of these openings and closings; the screen between inside and outside, a veil that covers unconscious memory, the protective shield, is above all a receptive surface for impressions destined to become mnemonic traces.

Alongside this metapsychological conception, Freud's work also reflects a historian's approach, with the mnemonic trace attesting to the historical reality of a psyche that develops based on the past. In the case of Emma (reported in "Project for a Scientific Psychology"), the phobic young woman believed that her symptom had originated in an episode during her adolescence in which she had felt seduced by a young man; Freud interpreted this as a screen and displacement of a childhood episode in which she had been sexually molested by an adult. According to Freud, it had to be the case, even if Emma believed she had felt nothing during the childhood incident, and even if the disturbance and the affect of a seduction were only apparent in deferred form during the episode in her adolescence, that at the time of the childhood incident a tension had been established and inscribed as a mnemonic trace that could later be reactivated at the time of her sexual maturation at puberty. The mnemonic trace of the childhood trauma repeated a deformation, a lasting modification, in Emma. Here the trace took a different form, an associative linking as much as a quantitative libidinal charge. It sought in external reality forms that were equivalent to what the early impression aroused, both to expunge its unpleasurable character and to replicate the exciting aspect of seduction.

As early as 1895 in Freud's work, the notion of what will come to be called *repetition compulsion* is based on the idea that the unconscious mnemonic trace is far more evident in repetition—and therefore in what would later be theorized as the transference—than in memories of past events. In a memory there is always a discrepancy between the perception as it was at the time and the current representation of it, whereas in repetition, through "refindings" of situations and substitute objects, the mnemonic trace remains extremely close to the mode of hallucinatory wish fulfillment. In *Studies on Hysteria* (1895d) and "The Aetiology of Hysteria" (1896c), Freud brought out the notion of the mnemonic trace based on the phenomenon of the "excessively intense idea" in the hysteric—that is, as close as possible to the state of hallucinatory wish fulfillment without actually falling into it.

The postulate of an incompatibility between perception and consciousness, on the one hand, and the mnemonic trace, on the other, in some respects comes out of an ontological dualism. Freud held that mnemonic traces are indestructible, but what happens in the case of severe traumas or in certain psychotic states? Are we to take literally Freud's hypothesis, advanced in *Moses and Monotheism: Three Essays* (1939a), of a hereditary phylogenetic transmission of transgenerational mnemonic traces? The notion of the mnemonic trace raises epistemological questions. The paradox of deferred action in the case of Emma's seduction defines the mnemonic trace as both the mirror of an elementary reality and a hypercomplex construction, midway between a materialist ontology and a formalism within a perspective of constant transformation. In the "Project for a Scientific Psychology" Freud compared the charge of the mnemonic trace to the notion of the "moving quantity" from quantum physics, bringing together traditional materialism and a more modern point of view on self-organization and complexity.

Similarities (correspondences) exist between the Freudian notion of the mnemonic trace and some contemporary research in neurobiology and the cognitive sciences, even though the psychoanalytic approach distinguishes itself radically from the latter with its specification of the psychic dimension of a subject governed by the pleasure/unpleasure principle in object relations. The mnemonic trace is not a cognitive representation of the external world; it results from a singular historical construction in which representations are stabilized into thoughts, but also into fantasies and affects. However, the question of the degree of coincidence between mnemonic trace and object of perception, which Freud emphasized, in some respects falls within the purview of the "mentalism" characteristic of cognitive psychology—against a background of Darwinism, because for Freud the search for identity between mnemonic trace and object of perception is what makes possible efficacious action adapted to the environment.

The fiction of the "Mystic Writing Pad" is as much a neurobiological model of memory as it is a metaphor of the mind. There are mnemonic traces that come out of internal psychical productions, rather than from perceptions: The question of the coincidence between mnemonic trace and object of perception must be included in a conception in which it is the subject who constructs his or her "psychology" in a unitary way. As

if to protect himself from any form of spiritualism, Freud wrote in chapter 7 of *The Interpretation of Dreams* that consciousness is “only . . . a sense organ for the perception of psychical quantities” (p. 615)—in other words, that it is constituted only of mnemonic traces of a particular kind. He linked psychology and metapsychology when he used *Erinnerung* for “memory” and *Erinnerungsspur* for “mnemonic trace,” in a conception where it is the conscious ego that remembers the impression (*Eindruck*) of lived experience (*Erlebnis*), but it is unconscious mnemonic traces, independently of consciousness, that contain memory. Alongside *Erinnerungsspur*, the notion of *Gedächtnisspur*, or “trace memory,” is found in Freud’s work.

## **MODERN CONFLICT THEORY**

The body of psychoanalytic theory about the mind and its functioning has the sobriquet *modern conflict theory* for two reasons. First, they indicate its relation to Freud’s so-called structural theory and his so-called topographic theory, both of which attribute psychoneurotic symptom formation to conflict among or between mental systems or structures. In the case of the earlier, topographic theory the systems or structures are called Unconscious, Preconscious, and Conscious. They are abbreviated as Ucs., Pcs., and Cs. In the case of the later, structural theory, they are called id, ego, and superego. The later theory was an extension and modification of the earlier one. Modern conflict theory is an extension and modification of the

later, so-called structural theory. Second, these words distinguish it from the many other psychoanalytic theories of psychopathology, such as Kleinian theory, Bionian theory, relational theory, subjectivist theory, and so on.

The brain—in particular, the forebrain—is the organ of the mind. Mental functioning is one aspect of cerebral functioning. The functional capacity of the brain changes dramatically during the course of the first several years after birth; with respect to its functioning, the brain is a different organ at birth from what it is later on. By the age of three to four years, on average, the brain is capable of acquiring language and of having thoughts that require language to frame them. Among the thoughts that begin to be identifiable at that time are pleasure-seeking wishes of a sexual and aggressive nature. Children yearn for the attention of other persons, particularly their parents (and parent substitutes) and for the stimulating pleasure of physical contact with them. They are jealous of any rival. They intensely resent any evidence of infidelity, lack of interest, or neglect on the part of the persons they yearn for. They desire revenge, whether against a successful rival, the faithless loved one, or both. Being ignorant, they are curious about what adult sexual partners do to each other and with each other and which to do the same themselves. Being relatively small, weak, ignorant, and unintelligent, they feel inferior and humiliated and, in turn, miserable, desperate, and enraged at feeling so. They intensely desire to be grown-up, sexual men and women who are as clever, wise, and sexually successful as the adults around them seem to them to be. In brief, as Freud pointed out, with respect to his psychological side, a child’s sexual life is in full flower by the time a child is four or five years old, long before it reaches puberty and the beginning of physical sexual maturity.

However, young children ages three to six years are not independent creatures. They are dependent on their caregivers—usually parents—not only physically, but emotionally as well. Parental love, physical contact, approval, admiration, protection, and all that go with them are of the utmost importance as sources of pleasure before, during, and after that time of life. Contrariwise, anything that—in a child’s mind—forfeits or threatens to forfeit parental love and approval, anything that a child believes will turn one or both parents against it, or has already done so, becomes a source of intense unpleasure. High on the list of such sources of

intense unpleasure are a child's own sexual and aggressive wishes, being that many of these are directed toward his parents, against his parents, or both. In other words, the sexual and aggressive wishes that were briefly outlined are longed for and shunned at the same time, a situation labeled as one of mental or psychic conflict.

In general, the mind functions so as to achieve pleasure in thought and action and to avoid unpleasure. In a situation of mental conflict, an individual's thoughts and actions are such as to achieve the maximum of pleasure with a minimum of unpleasure. Such thoughts and actions are labeled compromise formations. Every child, by the very nature of things, finds itself wishing for things that are intensely pleasurable in fact or fantasy and that are also associated with intense unpleasure. Its sexual and aggressive wishes become associated with intensely unpleasurable ideas of disapproval, rejection, abandonment, retribution, and punishment by its parents. That association, that concatenation of pleasure and unpleasure which is the essence of mental conflict, is an inevitable feature of the mental life of every child.

The compromise formations resulting from conflicts over the sexual and aggressive wishes characteristic of ages three to six years can persist into later childhood and into adult life and give rise to psychoneurotic symptoms and neurotic character traits, as Freud discovered as early as 1985. What modern conflict theory adds is that they always persist into adult life, that they are ubiquitous in mental life from the time they first appear. Every thought and every action is a compromise formation that is the result, however disguised and distorted, of conflicts over childhood sexual and aggressive wishes. Such compromise formations are not occasional and abnormal. They are ubiquitous. The difference between "normal" and "pathological" in mental life is not the presence or absence of conflict and compromise formation. The difference is a quantitative, not a qualitative, one. If a compromise formation allows for adequate pleasure from the satisfaction of sexual and aggressive wishes of childhood origin, if it does not involve too much unpleasure in the form of anxiety and depressive affect, if its defensive aspect does not result in too much inhibition of function and too much by way of self-punitive and self-destructive trends, it deserves to be called normal. If the reverse is the case, it is properly labeled pathological.

The calamities, real and fantasied, that give rise to unpleasure can be categorized, as Freud did, into abandonment or object loss, loss of love, and genital injury. The last name is usually referred to, inexactly, as castration. Common to all is, usually, the idea that the child's parents did or will cause them. The nature of the unpleasure can be classified as anxiety or depressive affect. The former, if the thought is that the calamity will happen in the near or distant future, and the latter if the thought is that the calamity has already happened, that it is a fact of life.

Changing to the structural theory from the topographic theory substantially altered psychoanalytic practice by introducing the concept that when an analyst is engaged in analyzing a pathological compromise formation, the analysis of the defensive aspect of the compromise formation is an important part of the analytic work, more specifically, that defenses are to be analyzed, not dealt with in some other way. The change to modern conflict theory from the structural theory makes explicit the idea that every thought and action is potential grist for the analytic mill, rather than just the ones judged to be pathological.

Both the topographic and the structural theory include the conclusion that the mind is best understood as composed of separable symptoms, agencies or structures, each of which is defined according to its functions. As this conclusion appears in the structural theory, the ego is the part of the mind that is attached to and deals with external reality while the id is equally attached to pleasure-seeking sexual and aggressive wishes. Among analysts who accept modern conflict theory as valid there are some who accept the validity of the idea that the mind is composed of separable, functionally different agencies, and some who consider that idea is invalid and should be discarded.

## MODESTY

Modesty is a feeling or a behavior that is motivated by shame, in that it essentially bears upon the sexualized body, the genital organs, the anal zone, or any part of the body that, culturally or individually, is endowed with an erotic investment. In a secondary sense, it is a mode of being that limits all motor or linguistic expression of subjectivity.

In the German language, and thus in Sigmund Freud's writings, it is not possible to distinguish that which is motivated by modesty from that which is motivated by shame, whereas in French, English, and some other languages, two different concepts exist, with modesty in a sense constituting the positive aspect of shame, when the feeling of guilt is transformed into adherence to a socially sanctioned ideal.

The issue of modesty comes up several times in Freud's work, as distinct from the issue of shame. First, it appears as an aspect of the transference and the counter-transference, from the earliest analyses described in "Studies in Hysteria" (1895d). Indeed, "confidence" is why psychoanalysis "invariably leads to the disclosure of the most intimate and secret psychical events" (p. 265), and the lifting of verbal modesty, sometimes accompanied by the gesture of touching the forehead, is the paramount condition for the patient's unreserved speech that is required by the fundamental rule. Second, the origin of modesty is associated with the anal stage, which cannot be reduced to its instinctual localization but instead, as Françoise Dolto underscored, involves, as a whole, motivity and the ethic of the relation to self, others, and the external world. It is in this sense that modesty generates a whole series of instinct-avoidance behaviors, through obsessional-type rituals. Third, it is doubly associated with the phallus and genitality: On the one hand, it lends consistency to the veil of the phallus inasmuch as it is not reducible to the genital organs and is only given up in the experience of symbolic castration; on the other, it valorizes, by keeping it from being seen, genitality and sexual difference, essentially on the feminine side. For both sexes, the hysterical logic of "hiding/showing" is present here.

It is essentially with regard to children, and then adolescents, that the notion of modesty has been examined by psychoanalysts and can be dissociated from shame. In children modesty is not pathological except in its excessive, hysterical, or obsessional forms, which are associated with severe shyness or an inhibition that affects several registers. Otherwise, it corresponds to the child's way of managing the superego and its ego ideals, limiting polymorphous and ordinary perversion. Dolto clearly showed how parents' failure to respect the rules of family life, in the form of slipping into voyeuristic or exhibitionistic behaviors, is by contrast conducive to perversion.

Apart from the issue of the difference in metapsychological and psychogenetic status between shame and modesty, a question raised by the notion of modesty is that of how the anal instinct, the phallic signifier, and genitality are articulated together, whereas orality is governed by a different moral code; this is aptly shown in Luis Buñuel's film *The Phantom of Liberty* (1974), where the characters gather in a circle to defecate together and hide in the lavatory ("au petit coin") to eat.

One can wonder whether the force of modesty is not directly linked, individually or culturally, to the importance of infantile sexual theories about the anus, which might persist and become more pronounced, not only for obsessional personalities, in the access to genitality.

## MOM, JORGE MARIO (1922–1997)

Jorge Mario Mom, an Argentinean psychiatrist and psychoanalyst, was born in Cañada de Gómez in the province of Santa Fe in 1922 and died in Buenos Aires in 1997.

Having left his native province with his brothers, Jorge Mom studied medicine in the university of Córdoba. He married María Teresa Muñoz whose father, a farmer and owner of a textile factory, was a veritable patron for the Argentine Psychoanalytic Association (APA).

As a training analyst and president of the APA, he made a name for himself among the second and third generation of Argentinean psychoanalysts. He was a great expert on the works of Freud and Melanie Klein and for many years he expounded on the history of Freudian ideas with a personal vision that left an indelible impression on his students.

In his approach to psychopathology Mom took a keen interest in the concept of anxiety, to which he devoted a large number of theoretical and technical studies. When Willy and Madeleine Baranger arrived in Argentina, Mom established bonds of friendship and exchange with them, which translated into work being presented at various congresses and which constituted an important milestone for the Argentinean school. Prominent among these papers are “Proceso y no proceso en el trabajo analítico” (1982; “Process and Non-Process in Analytical Work,” 1983) and “The Infantile Psychic Trauma from Us to Freud: Pure Trauma, Retroactivity and Reconstruction” (1988). Mom’s primordial goal was to always have an increasingly better understanding of anxiety, anxiety as an alarm signal, and phobias, in Freudian terms, although he was far from disdaining Melanie Klein’s contributions (1956, 1957, 1960). He disseminated his psychoanalytic thinking enthusiastically: He traveled around the country giving lectures and conferences and offering to act as a supervisor. His most important written work is the collection of fifteen studies around the concept of anxiety, as evidenced by his presentation at the thirty-second International Congress of the International Psychoanalytic Association in Helsinki in 1981: *Angustia y falta de angustia en las fobias* (Anxiety and lack of anxiety in phobias).

Jorge Mom was a likeable man, noble, sensitive, and typically Argentine, gifted with a very characteristic sense of humor that enabled him to get out of embarrassing situations.

## MONEY AND PSYCHOANALYTIC TREATMENT

The role of money in the analytic setting is an essential aspect of the arrangements that institute treatment and underpin it as it proceeds. Freud realized early on that subjective attitudes toward money are sure to create difficulties, for they inevitably are affected by outside reality, that is to say social and economic factors, and affect psychic reality, especially in its sexual dimension. Payment, as customarily required in the contract between analyst and patient, is a necessary if not always sufficient condition—the needed symbolic mediation—that frees the analysand from the danger of the analyst’s repeating the kind of abuse to which the analysand has already been subjected in life. It is a mechanism, in other words, that saves the patient, in the transference, from acting out and paying in pounds of flesh and with the coin of suffering. It is also a means of protecting the analytic process from an excess of unanalyzable resistances. The analyst is thus helped in interpreting the transference. And, last but not least, the analyst’s material needs are taken into account.

In two technical papers, “Recommendations to Physicians Practicing Psycho-Analysis” (1912e) and “On Beginning the Treatment” (1913c), Freud addressed the function of payment in the dynamics of therapy and its implications for the transference and counter-transference.

In “On Transformations of Instinct as Exemplified in Anal Erotism” (1916–1917e), Freud discussed the metapsychological ramifications of money in the analytic situation and the equivalence, for the unconscious, of the concept of excrement (and its derivative notions of money and gifts) with the concepts of the infant and the penis. Finally, in 1918, with the publication of *From the History of an Infantile Neurosis* (1918b [1914]), the “Wolf Man” provided the opportunity for considering a variation in the framework of analysis that took the form of money collected to support the patient. In the same year, at the International Psychoanalytic Congress in Budapest, Freud drew attention to the neurotic suffering of segments of the population who for economic reasons were unable to benefit from psychoanalysis, and for the first time he broached the idea of an institute where analysis would be free.

Under the direction of Karl Abraham, the Berlin Psychoanalytic Polyclinic began its activities in 1920. Ernst Simmel, in his report to the Berlin Psychoanalytic Institute in 1930, emphasized the role of the new social institution of “health insurance” in assuming financial responsibility for treatment. From the 1980s this question became the subject of intense debate, though one rarely discussed in the literature, to judge by the scarcity of work on it (Dupeu; Frécourt; Levy; Viderman). Meanwhile, a growing number of analytic practices make use of third-party payment systems (such as health insurance) within a private or institutional context. Thus, there is considerable risk that such systems will strengthen the medical approach to psychoanalysis already strongly developed in many countries.

## **MONEY-KYRLE, ROGER EARLE (1898–1980)**

Roger Money-Kyrle, a British psychoanalyst and member of the British Psycho-Analytical Society, was born on January 31, 1898, in Hertfordshire and died on July 29, 1980, in London. He was educated at Eton and fought in the First World War and was wounded in France. After the war he went to Cambridge to study mathematics and physics but graduated with a degree in philosophy. In 1919 he started an analysis with Ernest Jones, married, and then spent four years in Vienna to earn a PhD under Moritz Schlick, but also to be analyzed by Freud. Back in London, he decided to study anthropology and earned another PhD, under J. C. Flugel at London University. His thesis was published in 1930 with the title *The Meaning of Sacrifice*.

Money-Kyrle became an associate member of the British Psycho-Analytical Society in 1928, a full member in 1945, and a training analyst in 1949. At the beginning of his psychoanalytic career, he did not take an active part in the scientific life of the society. In the 1930s he began a training analysis with Melanie Klein. Immediately after the Second World War, he spent six months in Germany as part of the German Personnel Research Branch, which sought to find people who had not been involved with the Nazi regime and who could help build up a new administrative and political life in Germany.

His contributions to psychoanalysis can be divided into two parts: works written during the 1930s under the influence of his classical analysis with Freud and later works written under the influence of Klein. From the late 1940s to the 1960s he also commented

on and developed the ideas of Wilfred R. Bion, Hanna Segal, and others.

Money-Kyrle used his broad cultural background in all his work, where philosophy and particularly the British empirical tradition blended with the neopositivistic approach to philosophy of the Viennese school of Moritz Schlick. These interests played an important part in his work, as did his interest in anthropology and the social sciences in general.

Particularly important is his research on the psychoanalytic interpretation of the causes of war: "A Psychological Analysis of the Causes Of War" (1978b) and "The Development of War" (1937). In these papers he foresaw the danger of the Nazi regime and its propaganda, leading to the Second World War. Under the influence of Klein, he became increasingly interested in problems related to the psychoanalytic interpretation of ethics and politics. One result of this interest was *Psychoanalysis and Politics* (1951). Later Money-Kyrle also became interested in clinical issues and problems related to the theory of psychic development. He discussed the problem of inborn misconceptions of the primal scene (adults engaged in sex) and the early Oedipal complex as described by Klein (Money-Kyrle, 1961, 1978). His views have influenced many aspects of neo-Kleinian interpretations of the Oedipus complex.

## **MONISM**

Introduced into philosophy by Christian Wolff (1679–1754), the notion of *monism* refers to ontologies maintaining that all things lead back to mind or to matter. More generally, monism describes a system in which the totality of things is reducible to a single type of entity, be it substantial, logical, physical, or moral. Variations in usage and the competing expression "philosophy of the One" mean that the term should be used judiciously. People speak of the monisms of Parmenides (515 BCE), Georg Wilhelm Friedrich Hegel (1770–1831), Ernst Haeckel (1834–1919), and Wilhelm Ostwald (1853–1932); of the monism of psychophysical parallelism; and even of the monism of the bridge relation that characterizes dualism.

Freud, who deliberately kept away from philosophy, never used the noun *monism* and seldom used the adjective *monist*. Yet his dualistic theory of the instincts implicitly challenges the idea of instinctual monism. Freud's treatment of this issue began with his early notion of narcissism in "Psycho-Analytic Notes on an Autobiographical Account of a Case of Paranoia (*Dementia Paranoides*)" (1911c [1910]) and culminated in his positing the life and death instincts in *Beyond the Pleasure Principle* (1920g). General discussion of these issues included polemics between Alfred Adler and Carl Gustav Jung, and numerous authors have addressed the topic after 1920. According to Freud, instinctual dualism underlies psychic conflicts and forms the foundation for the psychic structures that result from them.

Narcissism, and thus the libido's cathexis of the ego (the locus of the instincts of self-preservation, according to the first topography) threatened to lead to an instinctual monism and left Freud stymied: "These are problems which we are still quite helpless and incompetent to solve" (p. 74), he wrote in "Psycho-Analytic Notes on an Autobiographical Case of Paranoia (*Dementia Paranoides*)." Moreover, Freud introduced major, complex, irreducible constructs, such as the ego and narcissism, within a theory whose objects he had

been at pains to reduce, in the manner of traditional science. This development posed unprecedented epistemological problems for trying to understand these theoretical entities and brought with it another threat, structural monism. The opposition between object-libido and ego-libido and the idea that the instincts exert continual and constant pressure explained the dynamics of the newly described agencies of the psyche (Freud, 1915c). Freud described additional forms—primary and secondary narcissism, ideal ego and ego ideal—but maintained, as he wrote in “On Narcissism,” that “a unity comparable to the ego cannot exist in the individual from the start; the ego has to be developed . . . , so there must be something added to auto-erotism—a new psychical action—in order to bring about narcissism” (p. 77). Freud spent three years developing the theory presented in “On Narcissism: An Introduction” (1914c). Freud thus reduced the threat of monism by positing of the life and death instincts (1920g) and developing the second topography, set forth in *The Ego and the Id* (1923b).

Freud’s delayed introduction of narcissism and the ego was in part responsible for Adler’s and Jung’s monist dissents. Later, Jacques Lacan’s theories on the signifier (the phallus) would suggest another form of monism, a correlate of his static structuralism.

## **MORAL MASOCHISM**

Moral masochism is seeking unpleasure without being aware of the masochistic sexual satisfaction thus obtained because of unconscious feelings of guilt.

Freud used the term *moral* in *The Ego and the Id* (1923b), where he linked negative therapeutic reactions to a “what may be called a moral factor” (p. 49), an unconscious sense of guilt and its satisfaction by means of punishment and suffering.

In “The Economic Problem of Masochism” (1924c), Freud described moral masochism as the third form of masochism, alongside feminine masochism and erotogenic masochism. In moral masochism the connection to an external object comes undone: “The suffering itself is what matters; whether it is decreed by someone who is loved or by someone who is indifferent is of no importance. It may even be caused by impersonal powers or circumstances; the true masochist always turns his cheek whenever he has a chance of receiving a blow” (p. 165).

Unconscious guilt feelings are thus assuaged. This is at once one of the greatest benefits of neurotic suffering and the source of negative reactions to therapy. Freud made the valuable observation that the notion of a need for punishment applies only to patients whose sense of guilt remains unconscious. The ego’s masochism in fact stems from the cruel superego, which, at its formation, assumed the mantle of the introjected parents. “The dark power of Destiny” (p. 168) is the final figure in this series of authorities that begins with the parents, and it remains their unconscious representative. Whereas self-punishment by the cruel superego is consciously perceived, this is not the case with masochism of the ego.

This shift from self-punishment by the sadistic superego to masochism of the ego is fraught with destructive consequences. It ruins moral consciousness, which is now used to obtain internal, essentially oedipal satisfaction. Indeed, the subject’s relationship to the parents is resexualized by an eroticization of the ego’s relationship to the superego. The analysis of moral masochism thus reveals a feminine masochism and, in the final analysis, an erotogenic masochism. The subject must suffer endless self-punishment, because all punishment is subverted to masochistic gratification. In this context Freud, in “Dostoevsky and Parricide” (1928b [1927]), evoked certain Russian

character types. Arising from instinctual fusion and libidinal satisfaction, moral masochism comes from a death drive that has not been diverted outward, and for this reason is dangerous.

It is worth noting that in its incestuous internal regression, which is all the more effective because any impersonal life circumstance can mask its nature, masochism of the ego in fact denies all authority and subverts the impersonal nature of the superego (which Francis Pasche as a prerequisite of its effective functioning). This circumstance makes ego masochism into an instrument of transgression even more apt to conceal the incestuous relation to internal objects. The self-destructive aspect of ego masochism also comes from a relative de-objectification of external objects in their otherness. The moral masochist loses the strong sadomasochistic pregenital bond with the object that is found in sexual perversion.

## **MORENO, JACOB LEVY (1889–1974)**

Jacob Levy Moreno, a Romanian physician and the creator of the psychodrama technique and sociometry, was born in Bucharest in 1889 and died in Beacon, New York in the United States in 1974.

Opinions vary concerning his exact date of birth: 1889 or 1892? It would seem that when he arrived in the United States he declared himself to be three

years younger than he actually was. He was the son of Moreno Levy, who came from an old Sephardic Jewish family of Bulgarian origin (though Turkish by nationality), and his mother was Romanian. Failing business (his father sold funerary objects) forced the family to move repeatedly; they lived in Romania, Germany, Austria, and Hungary during his youth.

Moreno settled in Vienna where he began to study medicine and philosophy. He qualified as a physician in 1917 under the psychiatrist Otto Petzel. His double training, combined with his interest in theatre, very quickly led him to take an interest in the possibilities for expression offered by dramatic art and to seek a new therapeutic method using the cathartic efficacy of improvisation. Starting from this base he created an "experimental theatre" in Vienna in the 1920s, inviting the participants to propose and play scenes in which they would play different roles in turn. The purpose of these "role plays" was to sensitize each person to the different aspects of their own personality and those of their partners, to open the way for creative spontaneity and the expression of their emotional capacities.

He emigrated to the United States in 1925 and settled in Beacon, on the banks of the Hudson. While actively continuing his experiments with psychodrama (particularly family psychodrama), Moreno was increasingly drawn to study interpersonal relations and group dynamics. He particularly tried to introduce group therapy into psychiatry and into prisons (Sing Sing, for example). Research in this area formed the basis of sociometry, which he developed in a book entitled *Who Shall Survive?* published in 1934. Sociometric techniques aimed to provide an objective description of the interactions operating within groups, and to theorize about the different aspects of group interaction. Anxious to maintain the originality of his research, Moreno adopted a critical attitude to psychoanalysis, without denying its usefulness.

In 1950 he created the International Committee for Group Psychotherapy in Paris, and organized the first World Conference on Psychodrama there in 1964. This opened the way for new exchanges between psychodramatists, psychoanalysts, and specialists in corporal medicine. After that his methods met with increasing success in the United States and in Europe. Child psychoanalysts in France remodeled his psychodrama technique and transformed it into a veritable analytical treatment, which progressively spread to adults also.

## MORGENSTERN-KABATSCHNIK, SOPHIE (1875–1940)

Sophie Morgenstern-Kabatschnik, a Polish psychiatrist and psychoanalyst, was born on April 1, 1875. She committed suicide in Paris on June 16, 1940.

Coming from a Polish Jewish family, she began to study medicine in Zurich in 1906. In 1915 she was working as an assistant physician in the Burghölzli asylum under Eugen Bleuler. She moved to France sometime in 1924. It was around this time that she began her analysis with Eugénie Sokolnicka, who is considered to have introduced psychoanalysis to France. Beginning in 1925, Morgenstern became a volunteer worker in the auxiliary clinic for infantile neuropsychiatry directed by Georges Heuyer, who always spoke highly of her even after he dissociated himself from the psychoanalytic movement. The date of her marriage to Abraham Morgenstern is unknown, as is the date of his death. Her only daughter, Laure, unanimously recognized as being extremely intelligent and having a brilliant future, died during an operation, probably in 1937.

Morgenstern killed herself when German troops entered Paris in 1940. All who knew her at the time stressed the unfathomable suffering caused by her daughter's death; few made any mention of her status as a Jewish émigré.

Between 1927 and 1939 Morgenstern published fifteen articles and one book. Her work was entirely based on an in-depth reading of Sigmund Freud. In the

conflict between Anna Freud and Melanie Klein, she firmly allied herself with Anna Freud's position. She believed that child neurosis shared the same structure and the same origins as adult neurosis, but the greater malleability of the infantile superego facilitated the resolution of conflicts. She stressed the importance of caution in the formulation of interpretations and considered, unlike Melanie Klein, that they should not anticipate the sexual curiosity of the young patient.

With the 1927 publication of "Un cas de mutisme psychogène" (A case of psychogenic mutism), she described her technique for treating children—drawing—which was to remain the primary focus of her research throughout her practice. She also used games, modeling, and, of course, dreams and free association with older children.

Morgenstern was without doubt one of the pioneering figures in child psychoanalysis in France, particularly with regard to the use of drawing in treatment. Her contributions to the *Revue française de psychanalyse* and *L'Évolution psychiatrique* reflects the fact that her peers recognized the importance of her work. Françoise Dolto was her most illustrious student. All who take an interest in her work must ask why she has slipped into unjustified oblivion. Her book, *Psychanalyse infantile Symbolisme et valeur clinique des créations imaginatives chez l'enfant* (Child psychoanalysis, symbolism, and the clinical value of children's imaginative creations; 1937), like her articles "A Case of Psychogenic Mutism" (1927) and "Quelques aperçus sur l'expression du sentiment de culpabilité dans les rêves des enfants" (Some insights into the expression of guilt in children's dreams; 1933) deserve to be reread in the light of recent research inspired by her original work in child psychoanalysis.

## MORGENTHALER, FRITZ (1919–1984)

Fritz Morgenthaler, a Swiss physician specializing in neurology and a member of the Swiss Psychoanalytic Society, was born at Oberhofen on July 19, 1919 and died on October 26, 1984, while visiting Addis Ababa.

The son of a famous painter (Ernst Morgenthaler) and doll designer Sacha Morgenthaler-von Sinner, he was also a painter and a professional juggler. He was educated in Zurich and Paris, studied medicine in Zurich and then worked as a physician in war-torn Bosnia for one year. This was the beginning of his friendship, then scientific collaboration and, beginning in 1952, joint practice with Paul Parin and Goldy Parin-Matthèy. In 1947 he commenced his analysis with Rudolf Brun. Between 1954 and 1971, Morgenthaler accompanied the Parins on six voyages of ethno-psychoanalytic research in West Africa (Parin, et al., 1963, 1971).

Most of Morgenthaler's remarkable influence was due to his charm and the intellectual sparkle of his personality as a lecturer, seminar director, and supervisor. Starting from a case history or a dream, he had an exceptional gift for communicating the psychic functioning of the patient, the unconscious emotional relations between the analyst and the analysand, and for discovering new and unexpected aspects therein. His original approach to Freud's dream in 1986: *Ein Traum als Beweismittel* (An evidential dream) is a good example of this: although he may not have opened up new theoretical pathways, he used Freudian concepts pertinently and effectively.

His often playfully dialectic mode of thinking earned him divided opinions with regard to the scientific value of his work. When his admirers praised him for making great progress and outstripping Freud in therapeutic technique (1978), in the theory of sexuality (1984), and in analyzing dreams (1988), more detached observers ranked him in classic psychoanalytic thinking somewhere between Freud and Kohut. In his later work he did, however, try to work politico-social (Marxist-inspired) concepts into the theory of psychic functioning, but without much success: the "sexual" as an

indeterminate motion, without orientation of the primary process (1988, p. 106–107), is considered as an "emotionality" (p. 107) that alone enables us to "appear alive," (p. 107) and this "sexual" runs up against the "dictatorship of sexuality" (1988, p. 110), which is "established by the instinctual and ego developments by means of the events in the secondary process in order to absorb the motion of the primary process, guide it into certain controllable channels, and restrict it by means of conditions" (p. 110).

## MORICHAU-BEAUCHANT, PIERRE ERNEST RENÉ (1873–1952)

Pierre Morichau-Beauchant, a French physician and professor at the Poitiers school of medicine, was born in Vivonne, France on November 1, 1873, and died in Poitiers in 1952. He was the first Frenchman to join the Freudian movement, in 1910.

His father, Joseph Eugène Beauchant, was a notary in Vivonne and his mother, née Berthe Brillouin, the only child of an apothecary in the Vendée. As a result of bad business deals his father moved to Paris. Pierre was a gifted child and had excellent academic results in the Collège Stanislas (winner of the *Concours Général* for French lycées) and later in the medical faculty. He took the Paris internship examination in 1899, being

forced by necessity to also give Latin and Greek lessons. On completing his military service in 1902, he joined *Le Sillon* (The Furrow), a Christian Democratic movement, founded that year and managed by Marc Sangnier (1873–1950).

In 1903, he was appointed assistant commissioner for hospitals and assistant professor in the Poitiers medical school. In 1904, he married Édith Rambaud, a pharmacist's daughter and a pharmacy intern in Paris. They had five children and their three sons also became doctors and professors of medicine. He was mobilized during the First World War, and was made a Knight of the Legion of Honor in 1918. He was appointed professor of clinical medicine in 1919 but kept his private practice and, upon retiring in 1941, he continued as an honorary consulting professor of geriatric medicine in the Dalesmes hospital until 1951.

As a highly cultured man, a good German scholar, and free of prejudice, he read *The Interpretation of Dreams* (1900a), *Three Essays on the Theory of Sexuality* (1905d), and soon began to read the Viennese analytic reviews. He tested the Freudian method and wrote to Freud in 1910, introducing himself as a disciple: "This letter will show you that you also have disciples in France who follow your work with passion." In the same year he wrote the first psychoanalytic article to be published in France: *L'Inconscient et la défense de l'individu* (The unconscious and the individual's defense), published in the social review *L'Effort* (The effort), founded by the writer Jean-Richard Bloch, who put him in charge of the Psychology and Psychiatry section. Two further articles appeared under his name in this review, *La défense de l'espèce dans l'hérédité* (The defense of the species in heredity) and *Le déterminisme héréditaire et la liberté humaine* (Hereditary determinism and human freedom), to be followed by the better known *Le rapport affectif dans la cure des psycho-névroses* (The affective relationship in curing psycho-neuroses), published in 1911 in the *Gazette des hôpitaux* (The hospital gazette).

Freud noted his importance, seeing "Mr Beauchant, the intelligent Frenchman" as "a good sign" and "solid support" for acceptance of his method in France. He sent Angélo Hesnard to him, requesting help and clarification with his thesis. Ernest Jones recognized that he had "a good grasp" of Freud's theories.

In 1912, he was elected a member of the Zurich Psychoanalytic Association and became an occasional

collaborator in the *Zentralblatt für Psychoanalyse* and the *Jahrbuch*. But he played no part in the birth of the French psychoanalytic movement, nor in any of its events. He no doubt moved away from Freud and psychoanalysis on the occasion of the break with Jung. His name does not appear in psychoanalytic literature or correspondence after 1914, when Freud mentioned him in "On the History of the Psycho-Analytic Movement" (1914d).

We are particularly indebted to him for his analytical observations of children, as in *L'instinct sexuel avant la puberté* (The sexual instinct before puberty), one of the first works on the nostalgia of soldiers, work on infectious pathology, and especially gastroenterology in which he discusses the hypothesis of psychic causality and recommends psychotherapeutic treatment.

### MORSELLI, ENRICO (1852–1929)

Enrico Morselli, an Italian psychiatrist, academic, and active promoter of the Italian positivist school of neuropsychiatry, was born in Modena on July 17, 1852, and died in Genoa on February 18, 1929.

A famous clinician and president of the Italian Society for Neurology and Psychiatry, he was director of various psychiatric hospitals and took an interest in many disciplines, ranging from anthropology to philosophy and biology to psychiatry. As an influential personage in Italian cultural circles at the beginning of the twentieth century, this Lombrosian organicist never missed an opportunity to vaunt the superiority of the “Italian Lombroso” over the “Austrian Freud.”

His writings deal with a great variety of subjects: He discussed euthanasia and suicide, pathological psychology and animal psychology, psychiatry, traumatic neuroses, semiotics and anthropology, magnetism, spiritualism, forensic medicine, and blood transfusions.

He is also known as the author of a large two-volume work titled *La Psicanalisi* (Psychoanalysis), published in Milan by Boca in 1926. Reprinted many times and widely promoted in university circles, it would be impossible to underestimate its disastrous influence on psychoanalysis in Italy. An apparently well-documented work, it is a magnificent example of resistance to psychoanalysis, of incomprehension and the impossibility of comprehending. Just after it was published, Sigmund Freud wrote a letter to the author on February 18, 1926, in which he spoke of Morselli’s “important” work while regretting that he could not give his “approval to our young science: what is referred to as psychoanalysis—esteemed colleague—is not psychoanalysis!” (1960a).

Marked by Lombrosian thinking and paternalistic concepts, Morselli criticized all of Freud’s theories from sex to religious questions. Horrified by homosexuality and so-called perversions of any kind, he adopted a moralistic attitude and delighted in the use of exasperating mockery. He repeatedly accused Freud of plagiarism, and tried at length to prove that all the foundations of Freudian research already existed in the work of the Italian positivist school. Freud’s letter in response to *La Psicanalisi* is an interesting example of Freud’s tact and tactical sense; making an effort to speak positively about Morselli’s work, he nevertheless uses this foil to advance the cause of psychoanalysis.

## **MOSER-VON SULZER-WART, FANNY LOUISE (1848–1925)**

Fanny Louise Moser, née von Sulzer-Wart, was born in Switzerland on July 29, 1848, and died in Au, near Zürich, on April 2, 1925. She was the patient described in Freud’s *Studies on Hysteria* (1895d) under the pseudonym of Emmy von N. Ola Andersson discovered her identity in 1965 and Henri F. Ellenberger completed her biography in 1977.

She was the thirteenth of fourteen children born to a rich aristocratic family. Reared by a mother who is described as severe and austere, she caused a scandal in her milieu on December 28, 1870, when she married Heinrich Moser, a rich industrialist forty-two years her senior. They had two daughters, Fanny, born on May 27, 1872, and Mentona (named after the town Menton in the south of France) on October 19, 1873.

Following her husband’s sudden death in 1874, his son from a previous marriage contested the will that made Fanny an extremely wealthy widow, and rumors began to spread to the effect that she had poisoned her husband. She demanded an autopsy, which proved to be negative, but the suspicions remained.

From 1875 to 1877 she traveled from one spa town to another but finally settled in a sumptuous residence she acquired near Zürich, where she could lead the sophisticated social life she desired. She is said to have had numerous lovers and her visitor’s book bears witness to the social standing of her guests. It also records visits by Auguste Forel and Eugen Bleuler, among other physicians. Freud figures there on July 18, 1889.

She commenced the cure described in the first case study in *Studies on Hysteria* on the first of May preceding Freud’s visit. The treatment ended in June but Freud visited her in the course of a journey to meet Hippolyte Bernheim in Nancy.

We know that he treated her for another eight weeks in 1890 and saw her again in the spring of 1891. On that occasion he stayed in her residence for a few days because she was having difficulties with her older daughter. He also resumed her treatment briefly. Relations between them did not end on a good note, as evidenced by the slip of paper masking his signature in her visitor's book, the usual sign that someone had fallen from grace in her eyes.

In a note added to her case history in 1924 Freud recounts that some years after that last visit he met a doctor with whom she had behaved as she had with him: docile and easy to hypnotize in the beginning, then irritable and subject to relapses. "It was a genuine instance of the compulsion to repeat." We know that toward the end of her life she fell passionately in love with a younger man who persuaded her to part with some of her fortune. The letter Freud received in about 1920 from her older daughter probably corresponded to this situation. The daughter asked him for a certificate because she wanted to make a legal case against the "cruel despot" who had estranged Moser's two children.

She died on April 2, 1925, and was buried in the Kilchberg cemetery near Zürich.

## **MOSES AND MONOTHEISM**

Begun in 1934, and rewritten in 1936, Freud's *Moses and Monotheism* appeared in an abridged form in the review *Imago* (the first two essays), and the final version was published in 1939. It also appeared in the *Standard Edition* edited by James Strachey (1964).

Upon first examination the work seems somewhat disordered, and contains repetitions and inconsistencies. The writing appears to reflect the movement of

Freud's thought, his doubts and hesitation, his concern regarding the scientific nature of the information he provides, and his fears concerning the way the text might be received among Viennese Catholics and by the Jewish community.

The work contains three essays of unequal length, "Moses an Egyptian," "If Moses Was an Egyptian," and "Moses, His People, and Monotheistic Religion." The last essay includes prefatory notes written at different times, one in Vienna before Freud's departure for Great Britain, the other in London, which partly contradicts the first. Finally, part two of the third essay is preceded by a "Summary" in which he reevaluates much of the information in the first essays.

*Moses and Monotheism* can be approached in several different ways. First, it is a biography of Moses, the "historical novel" whose scientific nature Freud wanted to establish. Freud claims that Moses was not Jewish but Egyptian and bases this claim on the fact that the name "Moses" was Egyptian, as well as on certain considerations about the family origin of heroes, based on Otto Rank's *Myth of the Birth of the Hero* (1909).

In the second essay Freud tries to understand the reasons that would have led Moses to assume the leadership of the minority people who were to become Jews and impose a new religion upon them. He then comes up with the idea that what would become Mosaic religion originated in the cult of Aton practiced by the pharaoh Amenotep IV. Moses, as a devoted believer, is said to have adopted the new religion as his own. After the revolt that followed the death of the pharaoh, Moses chose exile and the creation of a people upon whom he was able to impose his religious beliefs, together with the (Egyptian) practice of circumcision. These are the people he led out of slavery. The cult of Aton and following Mosaic faith brought to religion, for the first time in history, the monotheistic notion of a unique and universal god. Because of his tyrannical and domineering character, and his desire to impose a monotheistic religion upon all Jews, Moses is said to have been assassinated during a revolt of the Jews against his authority.

Freud meets the criticism that situates the exodus one or two centuries after the reign of Akhenaton by advancing the idea that Moses did not draw his religious beliefs directly from the pharaoh but from priests who had been devotees of the cult of Aton. He

also responds to certain historical conclusions that situated the origin of the Jewish religion in the cult of a volcano god, Yahweh, defeated by a Moses who was of Midian origin, by postulating the fusion of two religions: Aton's religion of truth and justice, which was temporarily repressed by the religion of Yahweh, which was focused more on conquest. While reconstituting the history of the Jewish people, Freud rediscovers the dualist system that was so important to him: the fusion of two Moses in a single character, of two new religions into a single monotheistic religion, of two peoples into a single nation.

Freud's work is thus an explanation of the formation of monotheistic religion on the basis of parricide (that of Moses), the collective repression of this murder, its passage from memory, but also its survival in the unconscious and its reappearance in religious phenomena. This theme is similar to one developed in *Totem and Taboo*: parricide as the origin of civilization and monotheistic religion. According to Freud, this explanation holds for both the Jewish religion, where parricide is not recognized as such but reappears in the feeling of guilt, and Christianity, where guilt (original sin) and parricide are recognized and assumed. Paul of Tarsus (the true founder, for Freud, of the Christian religion) is supposed to have recognized the murder. The expiation of parricide could only be carried out by the sacrifice of an expiatory victim: the son of God himself. The euphoria of being the chosen people in the Jewish religion is replaced in Christian religion by the sentiment of compensatory liberation through the sacrifice of the son. Original sin and atonement through sacrifice are the pillars of the new religion founded by Paul. In Freud's approach, Moses is desecralized, reduced to his human nature (as in "The Moses of Michelangelo," [1914b]), and God is reduced to a strictly human origin arising from projections of the individual unconscious.

Freud's *Moses and Monotheism* represents an application of the data of individual metapsychology to collective psychology. For Freud there is an "analogy" between the collective phenomena upon which religions are based and the process of repression at work in individual development according to the following schema: infantile trauma—defense—latency—onset of neurotic illness and partial return of the repressed. As Marie Moscovici noted, Freud's work on Moses is also a consideration of the status of the father, whose function escapes any sensory appreciation or direct

perception, and who can only be recognized as father through the mental activities of the son who designates him as father. *Moses and Monotheism* is also a reflection on Jewish identity, the character traits on which it is based and which ensure its longevity, the hatred it arouses in anti-Semitism and which Freud explains as the price to be paid for the denial of parricide and the refusal to acknowledge this.

As in all of Freud's work, one possible reading of Moses can refer to the individual history of the founder of psychoanalysis. The book was written immediately before his death. It constitutes what is almost his final text at a time when he feared that psychoanalysis, because of the rise of Nazism and the internal struggles among his own followers, was threatened with extinction. The idea that some might desire the death of the founder of psychoanalysis, just as the Jewish people would have desired the death of Moses, was probably not far removed from his contemplation of parricide.

### “MOSES OF MICHELANGELO, THE”

“The Moses of Michelangelo” is a short essay on Michelangelo’s masterpiece adorning the tomb of Pope Julius II in the church of San Pietro in Vincoli in Rome. Freud provides a reading of this enigmatic work that has given rise to a number of contradictory interpretations. The essay was first published anonymously in volume 3 of *Imago* in April 1914, then acknowledged by Freud in 1924 during the publication of volume ten of his collected works in German. In 1927 he added an afterword reaffirming his 1914 interpretation.

Freud saw the *Moses* for the first time in 1901. The idea for writing the essay came to him during a trip to Rome with Ferenczi in September 1912. On his return to Vienna he pored over texts about the statue, then had photographs sent to him of the various details. But doubts concerning the accuracy of his interpretation continued to torment him. He returned to Rome in September 1913 and visited the tomb several times. He wrote his essay in a few days at the end of 1913.

Freud’s approach in this essay is unique and radically unlike his work on Leonardo da Vinci and his interpretation of Saint Anne. His reading of the *Moses* is not based on a construction of Michelangelo’s unconscious libidinal past or even on the concepts or theoretical developments arising from psychoanalysis. It makes use of a procedure developed by Ivan Lermolieff, which was used to distinguish original paintings from copies on the basis of details that had been neglected by the copyists.

So, it was the details of the statue that had been neglected or distorted in descriptions, the “rubbish heap, as it were of our observations” (1914b, p. 222), that Freud focused on: the position of the right hand of Moses and the twists of his beard that it holds, the position of the Tablets of the Ten Commandments.

After a minute description of these details, he reconstructs and illustrates, in a series of drawings, the changes in position he assumes they have undergone to clarify their role in the sculpture. The sacrilegious implications of the statue then become obvious—on the verge of rising and allowing his anger to break out, Moses restrains himself to save the Ten Commandments.

The essay has elicited a number of commentaries and articles primarily bearing on Freud’s interpretation of the statue. But the singularities of the text and Freud’s approach (treating the unnoticed details of observations as letters whose displacement reveals their hidden meaning) have supplied analysts with a number of opportunities that remain largely unexplored.

### MOTHER GODDESS

The expression *mother goddess* or *maternal divinity* designates a historic or prehistoric female figure that was the object of a cult. The oldest examples are found in Paleolithic Europe; these are the Venuses found in grottoes that served as sanctuaries. The exaggerated breasts and buttocks and the clear demarcation of the pubis relate them to fertility cults. Similar statuettes from different geological periods have been found in other regions.

The beginning of the Neolithic period, with the introduction of agriculture and large-scale breeding, coincided with a multiplication of these fertility symbols, especially in the Middle East. The great goddesses of love, such as Aphrodite and Venus, partially absorbed the functions of the earlier mother goddesses, even though their form evokes female seduction more than maternity.

The concept of maternal divinity was addressed by Sigmund Freud in 1911 in an article on the Diana of the Ephesians (1911f) and in 1913 in an article on patterns on caskets (1913f).

Starting from a work of French archeology, Felix Sartiaux's *Villes mortes d'Asie Mineure*, Freud established a parallel between the cult of Artemis, the great goddess of Ephesus, and the cult of the Virgin Mary, who, according to tradition, is said to have ended her earthly existence at Ephesus alongside the apostle John. The cult of Artemis, often assimilated with Diana, is said to have served as the model for that of Mary as a maternal divinity. Freud reminds us of the extraordinary popularity of this "pagan" goddess, whose worship provided a livelihood for a guild of goldsmiths, who started a riot when a prediction by Saint Paul led to competition. Also, in his article on the patterns on caskets (a theme taken from Shakespeare's *Merchant of Venice*), he notes that Artemis, like all the maternal divinities of Asian peoples, is a goddess of both life and death, of generative and destructive principles.

The theme of maternal divinity does not play a central role in the work of Freud, who was much more interested in male figures like the father of the horde (see *Totem and Taboo* [1912-13a]) or Moses. The same is true of Jacques Lacan who emphasizes the paternal phallus as the primordial signifier, in the same way as the linga ("sign" in Sanskrit) of the god Shiva is the structuring element of Indian religion. Carl Gustav Jung and Jungian psychoanalysts in general have considered these maternal divinities to be of considerable importance, representing an archetype of the universal Great Mother, a figure that is both maternal and sovereign, filled with pity and compassion (1933). The work of Jung's followers has found considerable support in American feminist circles. Archeological digs conducted during the last few decades across the five continents have revealed an abundance of female statuettes, often corresponding to the oldest layers of the civilization being studied. The main problem remains the interpretation of this material given our frequent uncertainty concerning the role of women in prehistoric or protohistoric societies and the state of their knowledge about human reproduction. The omnipresence of these female figures could be associated with ignorance about the fecundating role played by sperm. These mother goddesses, the most recent example of which would be the Virgin Mary, might thus symbolize a kind of parthenogenesis.

### MOURNING

The "work of mourning" is a set of mental processes, conscious and unconscious, initiated by the loss of an emotionally and instinctually cathected object. Once this work is complete, the subject is gradually able, within a period of time that cannot be shortened, to separate from the lost object.

Extreme pain, denial of reality, hallucination of the presence of the object, and awareness of the loss of the object are experienced in sequence. Eventually the mental changes occur that allow attachment to new objects to develop.

The notion of the work of mourning was introduced by Freud in "Mourning and Melancholia" (1916–17g [1915]). He seems to have been particularly concerned with death and mourning at the time—the middle of the First World War, when everyone in Europe was dealing with such losses—for these issues are also mentioned in "Thoughts for the Times on War and Death" (1915b) and "On Transience" (1916a [1915]).

Having lost his father in 1896, Freud had himself experienced grief and mourning; his father's death is

mentioned in *The Interpretation of Dreams* (1900a). The long hiatus between that death and Freud's conceptualization of the work of mourning underlines the cardinal role of the passage of time in this context: Freud's own mourning preceded by far the greater part of his written work, a fact that reminds us not to confuse the psychic work of mourning with any kind of intellectual work. Talking, reflecting, or writing about a bereavement does not amount to a work of mourning. Intellectual mastery or the power of discernment are not of much help when it comes to reassembling everything associated with the lost object. Finding words to express the pain, the unimaginable distress caused by the loss, is usually an insurmountable task as much for those who seek to console as for the bereaved. On the other hand, particular words may sometimes indeed evoke the lost object or a recognizable link to that object, but the forms of such speech cannot be predicted or laid down in advance.

"What is painful may none the less be true," wrote Freud in "On Transience" (1916a [1915], p. 305). This remark, made a few months after he composed "Mourning and Melancholia," encapsulates an essential part of his thinking on mourning. Accepting the truth of the object's disappearance involves suffering. The work of mourning is not unlike the work—the "labor"—of childbirth. Any birth takes time, and, like truth, is the outcome of a creative process. The truth of a loss acknowledged is no exception to this rule.

For Freud the pain of mourning was an enigma. What to the ordinary mortal seems obvious and inevitable posed an insoluble problem for the inventor of psychoanalysis. Viewing the cruelest of patent facts as a question to be answered exemplifies the heuristic approach of psychoanalysis, for which the patent is not the true—indeed, it may even hide the truth. Anyone agreeing to accompany the mourner during this depressive process will be obliged to experience it in himself, and for himself.

The main point of "Mourning and Melancholia" is to show how these two states have certain depressive traits in common. In addition to a highly contagious feeling of sadness, the two share three characteristics: loss of interest in the outside world, loss of the capacity to love, and the inhibition of all activity. The suspension of interest in the outside world is indicated by the disappearance, from one day to the next, of all attention directed toward the environment, close or distant. What was of the highest importance yesterday ceases

utterly to exist today. The only other state displaying such a marked narcissistic withdrawal is sleep. In that case, being cut off from the outside world facilitates access to the intimacy of the inner world, of unconscious wishes, by way of another kind of psychic work, namely the dream-work. Could it be that, as in dreams, withdrawal into mourning makes it possible to organize the world not on the basis of external perceptions, but on the basis of a subjectivity turned completely inward? Inasmuch as sleep is a prerequisite of mental recuperation, a chance to start again relying on one's inner resources, it would seem reasonable to conclude that a kind of psychic restoration likewise occurs through mourning, with its deferment of all outside stimuli; that the loss of a cathected object requires a psychic reorganization so absorbing that it means confining all cathexis to the internal world. There are in fact few tasks more engrossing than taking stock of what will never again exist.

This withdrawal of object-libido, and the dismantling of all the bonds that have hitherto united subject and object, is bound to result in the second abovementioned common feature of mourning and melancholia, namely loss of the capacity to love. Exaggerated concentration on oneself prevents any consideration of others and blocks any expression of affection. For the time being, the cathexes available to the ego cannot be directed onto objects. Freud did not confine himself to this economic view, however, in his interpretation of the disappearance of all loving impulses toward objects. He speculated that any potential attachment to another object could imply the lost object's replacement. By taking care not to become attached to a new object, the subject was in effect defending himself against the charge of lethal intentions with respect to the lost one. But to imagine, as a defense, that one might have an impact on the outside world—be the cause, in the event, of the object's disappearance—is itself a way of refusing reality. For the object's finite nature exists in that outside world, irrespective of the subject's wishes; it is, precisely, what is at stake in the subject's relationship with reality.

Meanwhile, cutting oneself off from external reality paradoxically implies the necessity to acknowledge it. The psychic working out of the loss on the plane of subjectivity and object relationships leads to the subject's detachment from other aspects of reality also. From this derives the third corollary of mourning, the inhibition of *all* activity. Inaction and indifference to

outside reality do not arise exclusively, however, from absorption in the work of mourning. Such indifference indeed includes attempts to deny the reality of object-loss by denying all reality. Oscillation between the recognition of reality and its denial accounts for the contradictory and circular tendencies often observed in this context.

The experience of mourning is paradoxical. Overcoming the loss of an object means an exaggerated presence of that object in the psychic activity of the bereaved. The work of mourning may thus be defined as an excessive attention paid to an object in order to come to terms with its definitive demise.

## **“MOURNING AND MELANCHOLIA”**

The manuscript of “Mourning and Melancholia” dates from 1915, but the paper was not published until two years later. In this short, rich article, Freud described the essence of melancholia by comparing it to the normal affect of mourning. He distanced himself from the psychiatric perspective he had once adopted in “Draft G” of the Fliess papers (1950a [1895]), while emphasizing that the concept of melancholia had many aspects (especially somatic ones) that he would not examine. Methodologically speaking, here as so often we encounter Freud’s continual effort to clarify the psychopathological by reference to the normal (as for example with dreams, jokes, or parapraxes).

This essay is a direct pendant to Freud’s “On Narcissism: An Introduction” (1914c), a context that helped him characterize melancholic regression (see

Otto Rank, as cited by Freud in relation to the narcissistic basis of object choice.). Freud also made use of the ideas of Karl Abraham (to whom he submitted the first draft of the paper for comment) concerning cannibalistic orality and the ambivalence of the bond that lies at the origin of melancholia. He also developed the concept of identification (“incorporation” for Abraham) and advanced the notion of the work of (normal) mourning (*Trauerarbeit*) on the model of the dream work (binding). The period during which he developed his ideas on mourning, that of the First World War, was particularly significant for Freud.

Freud’s definition of mourning is very broad, comprising, aside from the reaction to the loss of a loved one, reactions to any substituted abstraction (fatherland, freedom, ideal). This conception, which is connected with that of abandonment being sublimated as an abstract idea, is not developed further, but it does introduce sociopolitical perspectives of considerable importance.

Freud stressed an economic definition of mourning (loss of interest in the outside world) and the work of grieving as it acts on the binding of painful memories, an ego activity quite unrelated to the attenuation stemming from the forgetfulness associated with the passage of time. He immediately discusses the similarities with, and above all the differences from, melancholia, which is characterized by an apparently unjustified loss of self-esteem. “In mourning the world has become impoverished and empty, during melancholia, it is the ego itself” (p. 246). However, melancholic self-depreciation is actually directed at the love object itself. For this was the cause of disappointment for the subject, who, instead of withdrawing cathexis, unconsciously identifies with the now-hated object to which he remains ever more firmly attached. This pathological development stems on the one hand from the narcissistic nature of the initial object choice, which by its nature promotes narcissistic regression, and on the other hand from the ambivalence of the choice and the predominance in it of the sadistic impulse, which here assumes masochistic form, while directly tormenting the patient’s entourage. This helps explain suicide as a redirection toward the self of a murderous impulse originally directed at others. Reversion to mania is likewise explained, in economic terms, as a sudden release from the psychic charge maintained by melancholia.

But in melancholia as in mourning, it is essentially the work consisting in finishing with the object (by

degrading it or declaring it dead) that will “strike dead” the dead and release the subject. This theory of melancholia is clinically important in considering the different forms of depression. It has also been confirmed by a number of anthropologists and embodies some of the ideas Freud set forth in *Totem and Taboo* (1912–1913a). The notion of identification was further developed in *Group Psychology and the Analysis of the Ego* (1921c). Thus “Mourning and Melancholia” occupies a central position for both individual and group psychology.

## MOURNING, DREAM OF

The dream of mourning is a “typical” dream in which someone close to the dreamer is dead or in which their death is evoked.

In *The Interpretation of Dreams* (1900a), Freud returned several times to this type of dream, which he included among those “typical dreams” whose form and content are similar for everyone.

He discussed the objection that the painful nature of such dreams seemed to run counter to his main thesis that all dreams are fulfillments of wishes. One had to accept, he said, that despite their sad subject matter these dreams did, in fact, express a secret wish for the death of the person concerned; the dreamer’s brother or sister (rivals to be eliminated), or father or mother (in the oedipal context, often first articulated in such dreams). There is often relatively little affect in these dreams, a fact that astonishes the dreamer when she or he recalls the dream upon awakening. This lack of feeling, explained Freud, was because the dream fulfilled

childhood wishes, a legacy of the time when death was conceived simply as the disappearance of the person in question. Later, in “Fragment of an Analysis of a Case of Hysteria” (1905), he would analyze Dora’s dream of her father’s death in detail.

Freud never perceptibly changed his views on this type of dream; his theory of dreams as the fulfillment of wishes continued to prevail, even after *Beyond the Pleasure Principle* (1920g).

## MOUVEMENT LACANIEF FRANÇAIS (FRENCH LACANIAN MOVEMENT)

More than twenty associations emerged from the 1980 dissolution of the École freudienne de Paris (EFP, the Freudian School of Paris) and the demise of La Cause freudienne (The Freudian Cause) in January 1981. A new school, the École de la cause freudienne (The School of the Freudian Cause) was immediately formed as a substitute for them. What follows is a chronological listing of the principle groups.

On the February 1, 1981, Claude Dumézil and André Rondepierre founded the Cartels Constituants (Constituent Cartels), an association that was later weakened by the death of Rondepierre and numerous defections that formed the basis of two other groups.

On March 7, 1981, Jean Clavreul, Solange Faladé, and Charles Melman founded the Centre d’études et de recherches freudiennes (CERF, Center for Freudian Study and Research), which collapsed just a short while later and was the origin of three other groups.

In June 1982, Charles Melman founded the Association freudienne (Freudian Association), which has since become the Association freudienne internationale (AFI, International Freudian Association), the most important of a number of Lacanian associations. This group publishes *Discours psychanalytique*, *Le Journal de la psychanalyse de l'enfant*, *Le Trimestre psychanalytique*, *Le Journal français de psychiatrie*, and since 1999, *La Célibataire*. The AFI, which reintroduced the question of the pass in June 1994, has a large number of members in both Belgium and Argentina.

On June 28, 1982, Maud Mannoni put forth a call for an institution that could ensure the training of young analysts. She subsequently founded the Centre de formation et de recherches psychanalytique (CFRP, the Center for Psychoanalytic Training and Research) with Octave Mannoni and Patrick Guyomard. This group developed rapidly and numbered 550 members at the time of its dissolution in 1995. It also published *Esquisses Psychanalytiques* and an important series on psychoanalysis with the publisher Denoël.

The École lacanienne de psychanalyse (ELP, the Lacanian School of Psychoanalysis) was founded in 1983, by former members of the Constituent Cartels, Jean Allouch, Guy Le Gaufay, Philippe Julien, Erik Porge, and Christian Simatos. This group maintained the ritual of the “pass,” but did not nominate the passer. It is very intellectually active and publishes numerous journals, including *Littoral* (forty-four volumes published) and *L'Unebvue* (twelve issues published as of 1999). The ELP is very active in Latin America and includes many Argentines and Brazilians.

Analyse Freudienne (Freudian Analysis) was founded by Claude Dumézil after the breakup of the Constituent Cartels. It publishes *Analyse freudienne* (seventeen issues in 1999), which became *Analyse freudienne presse* in 2000.

Two numerically important associations arose out of the dissolution of the CFRP. One was L'Espace Analytique (Analytic Space), founded by Maud Mannoni on October 16, 1994; it publishes *Figures de la psychanalyse*. The other was the Société de psychanalyse freudienne (Society for Freudian Psychoanalysis) founded in February 1995 by Patrick Guyomard. This group publishes the *Lettres de la société de psychanalyse freudienne*. Like the CFRP, both of these groups reject the pass and emphasize teaching and the training of analysts. Analysts become members upon the approval of an authorizing jury, which takes into account the

course of the candidates' careers and their analytic practice.

Other important groups include the École freudienne (Freudian School), founded in 1983 by Solange Faladé, the Cercle Freudien (The Freudian Circle), and the Mouvement du coût freudien (Freudian Cost Movement).

On the international level, many Lacanians exist within a flexible organization, Convergence. And the Interassociatif européen de psychanalyse (European Coalition for Psychoanalysis) gathers together many of the organizations listed above as well as several others in France, Denmark, Spain, Italy, and Luxembourg.

Finally there is the Association pour une instance tierce de la psychanalyse (APUI, Association for a Third Era in Psychoanalysis) which was founded by Serge Leclair in January 1990. This group reflects upon the position of psychoanalysis in European culture, holds biannual seminars, elaborates on the place of psychoanalysis and psychoanalysts in society, and opposes state and medical constraints on psychoanalysis.

## MÜLLER-BRAUNSCHWEIG, CARL (1881–1958)

Carl Müller-Braunschweig, a German psychiatrist, philosopher, psychoanalyst, an founder and president of the German Psychoanalytic Association (DPV), was born in Braunschweig on April 8, 1881, and died in Berlin from arteriosclerosis on October 12, 1958, after a long illness.

His father, Heinrich Müller, owned joinery works in Braunschweig. Müller-Braunschweig studied philosophy

with Jonas Cohn, Heinrich Rickert, Cay von Brockdorff, Paul Menzer, Carl Stumpf, Georg Lasson and, most importantly, Alois Riehl. His studies also included physics, biology, history, and political economy. Beginning in the winter of 1901–1902, he spent time studying in Heidelberg, Freiburg, Braunschweig, and Halle. In 1905 he settled with Riehl in Berlin and concluded his Kantian studies with a PhD in 1909.

After finishing his medical studies, particularly in psychiatry, with Karl Bonhoeffer (1912–1914), he completed his training by undergoing analysis with Karl Abraham, and then Hanns Sachs. He was a member of the Berlin Psychoanalytic Association (BPV) from 1919, in charge of training at the Berlin Psychoanalytic Institute (BPI), and became a member of the Executive Committee of the International Psychoanalytical Association (IPA) in 1925.

After a first marriage to child analyst Dr. Josine Müller, née Ebsen (1884–1930), which ended in divorced in 1925, he married the Jungian analyst Ada Schott (his analysand in training), with whom he had two children (Hans in 1926 and Elke in 1927).

Following the Nazi rise to power in 1933 he was appointed provisional president of the “Aryanized” committee of the German Psychoanalytic Society (DPG). In this capacity he worked as editor, treasurer, training analyst, and president of the candidates’s commission, and broadly concentrated on adapting the institute ideologically to the National Socialist regime.

In 1938 Matthias H. Göring appointed him administrator in charge of the Vienna Psychoanalytic Society, the Berlin polyclinic and psychoanalytic publications, but he failed in this last mission because the National Socialists questioned his loyalty. He was then prohibited from conducting personal and training analysis, as well as from teaching in the Göring Institute, a prohibition he later invoked when claiming to be a “victim” of the Nazis.

On October 16, 1945, he was commissioned to reconstruct the DPG and appointed president of the society. In spite of his Jungian affinities (he had undergone some analysis with the Jungian Gertrud Weller), he found himself viewed as the representative of orthodox psychoanalysis. His intense personal and theoretical disputes with Harald Schultz-Hencke, the medical founder of neoanalysis who had succeeded in winning government recognition for the profession (psychoanalysis and psychotherapies were financed by social security in the Zentralinstitut für psychogene Erkrankungen

[Central Institute for Psychogenic Diseases]), found their epilogue in an official confrontation at the first post-war congress of the IPA, held in Zurich in 1949. This led to the creation of the German Psychoanalytic Association (DPV) on June 10, 1950, which then began to offer classic training in the Berlin Psychoanalytic Institute. Members who had stayed in the DPG were angry with their president for secretly forming a new association. Only the DPV was admitted to the 1951 IPA congress in Amsterdam.

While continuing to practice as an analyst, Müller-Braunschweig taught psychoanalysis at the Berlin Free University. He was particularly interested in the intersection between anthropology and psychoanalysis. From 1920 until the Nazis took power he regularly wrote in the *Internationale Zeitschrift für Psychoanalyse*, in the *Zeitschrift für Sexualwissenschaften*, and in *Imago*. After the war he concentrated essentially on a detailed exegesis of Freud’s work.

## **MULTILINGUALISM AND PSYCHOANALYSIS**

Multilingualism is the ability to understand and speak several languages. The general term covers

plurilingualism (learning to speak several languages simultaneously) as well as polyglottism (learning other languages after one acquires one's mother tongue). It can be used as a generic term whenever there is no need to differentiate between the two situations. Its initial appearance in the psychoanalytic vocabulary is difficult to date.

The term was redefined in *The Babel of the Unconscious* (Amati Mehler et al., 1990). Prior to this there was little interest in the analytical significance of multilingualism, which is surprising given that the history of the psychoanalytic movement is itself crisscrossed by the migration and transmutation of languages since Freud's first patients came to see him in Vienna.

For a number of those patients (the "Wolf Man", Miss Lucy, even some analysts, like Princess Marie Bonaparte), German was not their mother tongue. Freud even analyzed some of his English-speaking patients in English, which at the end of his life became the language he used most frequently in his work. So, during the first years of the psychoanalytic movement, it was rare that the analyst and his patient shared a native language.

The multilingualism of the patient, just as the plurilingualism of the analyst, presented difficult questions about the analytic framework and analytic technique, as well as challenges to the conceptual apparatus of psychoanalysis. And although it may not be necessary to attribute a specific form of mental operation to multilingual individuals, the unique pathways multilingualism adds to the flow of the unconscious deserve further study.

Ever since *On Aphasia* (1891b), the question of the transition from one language to another had caught Freud's attention. He noted "the loss, through damage to the speech apparatus, of new languages acquired as super-associations, while the mother tongue is preserved" (p. 87). He observed the differences between word representations and thing representations, which later enabled him to define the factors that made the unconscious different from the preconscious-conscious system (1915e). The relation between word representation and thing representation defines a crucial substrate of the multilingual context.

Assuming that the multilingual speaker enriches the fabric of his preconscious with other word representations, what happens to their links with thing representations? Do both systems always refer to the same

thing representation or does the thing representation also change? Answers differ. Some believe that thing representations remain the same, while others have introduced a deviation that refers to two distinct thing representations. According to the latter hypothesis, thing representations would still be part of the same associative complex, deviating because of a particular cathexis of the thing representation by the affective representative of the drive—most important according to Freud. For Erwin Stengel (1939), a new language establishes a new libidinal relationship with the word and the thing to which it refers.

The second language can come to the aid of a vacillating system of repression, be a sign of splitting or isolation, or even produce new symbolic richness. It is the subject's personal vicissitudes that will determine if the other language is used for resistance or allows for greater intrapsychic plasticity in the act of working-through.

Finally, multilingualism should not obscure the fact that the subject must perform an act of translation in every act of communication with others, as well as between his or her intrapsychic agencies.

**MURDER OF THE FATHER.** See Parricide

## MURRAY, HENRY A. (1893–1988)

American psychologist and psychoanalyst Henry A. Murray was born in New York City on May 13, 1893, and died in Boston on June 23, 1988. He was one of the most important pioneers who introduced psychoanalysis into American academic psychology.

Originally trained as a physician, he was analyzed by both Carl G. Jung and Franz Alexander, and became one of the founding members of the Boston Psychoanalytic Society. Not only was Murray a leader in the field of personality theory, but Murray (with the help of Christiana Morgan) created the Thematic Apperception Test (TAT). He also took a leading role in making psychological profiles for the American government's Office of Strategic Services during World War II. For years Murray headed the Harvard Psychological Clinic, originally founded by Morton Prince, and he also worked on the writings of Herman Melville for almost half of his long life. Although Murray took a wholly independent path apart from both Freudian and Jungian organizations, his contact with both men has to be considered historically memorable.

Although Murray was self-taught as a psychologist, he felt proud to be in the humanistic tradition of a philosopher like William James. He remains notable for having inspired generations of graduate students. His TAT test was a means of drawing forth from people by means of words and stories important aspects of personality that an individual could or would not volunteer. The TAT test was designed to be both a diagnostic tool and a research tool. His most famous single book, which was the outcome of collaborating with others at his Psychological Clinic, was *Explorations in Personality* (1938). He also co-edited, with the Harvard anthropologist Clyde Kluckhohn, an influential book of readings, *Personality in Nature, Culture, and Society* (1948).

Murray, along with Kluckhohn and the sociological theorist Talcott Parsons, helped create the famous, but short-lived, interdisciplinary Department of Social Relations at Harvard. And he was illustrious enough to have been asked to testify as an expert witness in behalf of Alger Hiss in the second trial that ended in Hiss's being convicted of perjury. (Murray's social standing was so secure, one of his forbearers having been the last Tory governor of Virginia, that J. Edgar Hoover's FBI conducted only the most cursory report on him.) Dean Acheson, secretary of state under President Harry Truman, was a classmate of Murray's

at Groton, and reported in 1970 that Murray had been the "outstanding" member of their class "in the sense of originality of mind, curiosity about everything, sympathetic personality, catholicity of taste, cultural breadth." Murray felt blocked as a writer, not just in connection with his Melville project but in explaining his whole orientation toward human nature. Yet he remains memorable not just for his emphasis on turning from the abnormal to the normal, and from failure to success, but because he fought against dogmatism in psychoanalysis as unscientific, and insisted on distrusting any truth that became a sect.

## MUSATTI, CESARE (1897–1989)

Cesare Musatti, an Italian psychoanalyst and psychologist, was born in Dolo (Venice) on September 21, 1897, and died in Milan on March 20, 1989. He was a leading figure for the first generation of Italian psychoanalysts.

He spent his childhood and adolescence in Venice, his family's hometown. His mother was an elementary school teacher and his father, a Jewish idealist and revolutionary, was a socialist deputy.

In 1915 he began to study mathematics in the university of Padua before moving on to the faculty of philosophy. He studied under Vittorio Benussi before becoming his assistant. Benussi was conducting research into the use of suggestion and hypnotic techniques. Musatti later took over from him as lecturer and succeeded him as director of the Padua University Institute of Psychology.

In 1934 he established contact with Edoardo Weiss, who was then training a group of students associated with the *Rivista italiana di psicoanalisi* in Rome. Musatti immediately joined the Società psicoanalitica italiana, which Weiss was actively forming at the time. Although race laws forced him to abandon teaching, an enlightened industrialist, Adriano Olivetti, invited him to Ivrea in 1943 to create a laboratory devoted to industrial psychology, the first of its kind in Italy.

Musatti entered a period of intense activity after the war. His *Trattato di psicoanalisi* (Treatise on psychoanalysis), published in 1949 and soon nicknamed *il freudino* (the little Freud) by students, continues to be one of his most famous and most successful books. He collaborated with the publishers of psychoanalytic texts and was a leading protagonist in introducing psychoanalysis into Italian culture.

Musatti's main contribution may be the fact that he directed the translation, along with publishers Borin ghieri, of the complete works of Sigmund Freud into Italian. In his preface in 1966 to Michel David's *La Psicoanalisi nella cultura italiana* (Psychoanalysis in Italian Culture), the same Musatti observed, not without regret, that the small number of analysts and the absence of kindred spirits had prevented him from undertaking any considerable research and forced him to focus essentially on facile vulgarization that was devoid of any real originality.

As a lay analyst, Musatti contributed to propagating and developing psychoanalysis in Italy, finding the means to enable it to enter cultural debates—ranging from psychology to art and jurisprudence to literature—and introducing Freudian thought with skill and talent into domains where resistance was great. All of this he accomplished without perhaps realizing the importance of *Laienanalyse* (lay analysis) for psychoanalysis. As it happened, in the *Complete Works* published under Musatti's editorship, Freud's essay (1926e) was mistranslated as *Analisi dei non medici* (Analysis of non-physicians).

A keen observer and frequently ironic, even with himself, he was the author of several books that were also intended for the general public, among them: *Curar nevrotici con la propria autoanalisi* (Treating neuroses with the appropriate self-analysis; 1987) and *Chi ha paura del lupo cattivo?* (Who's afraid of the big bad wolf?; 1987). In his last work, *Psicoanalisti e pazienti a teatro, a teatro!* (Psychoanalysts and patients

to the theatre, to the theatre!; 1988), Musatti concentrated particularly on discovering the links between psychoanalysis and theatre in order to introduce the common ground between these two fields into the "internal theatre" of each human being.

## MUSIC AND PSYCHOANALYSIS

Sigmund Freud's attitude toward music was very ambivalent. He described himself as being *ganz unmusikalisches* ("totally unmusical"), despite his familiarity with certain operas, such as *Don Giovanni* and *The Marriage of Figaro*. In his view, the danger with music was that of losing the rational mastery that he had fixed as his objective.

Historically, the confrontation between these two realms first appeared in the work of Theodor Reik (1888–1969), notably in *The Haunting Melody: Psychoanalytic Experiences in Life and Music* (1953), where Reik took up the theme of the "haunting melody" in Freud's *Introductory Lectures on Psychoanalysis* (1916–17 [1915–17]) to demonstrate, by contrast to Freud, who was interested only in text, that musical structure can represent feelings. In Reik's view, melody can convey emotion far better than words.

There is doubtless a specific mode for mentally registering music that belongs to the preverbal period: Music has been posited as the representation of affect.

From contemporary data on intrauterine and postnatal life, it is known that vocal sounds that are emitted or heard are accompanied by various affects, many of which have no equivalent in language but remain registered in the body's memory. Longing for a sense of oneness refers to the attunement of the mother's voice to that of the infant prior to the establishing of a transitional space. Thus, in the earliest part of life the mother's voice is indissociably linked both to harmonious, reassuring feelings and to deathly anxieties of being swallowed up. For Daniel Stern, the changing and discontinuous feelings that make up the fabric of the infant's mental life can be conceived in terms of musical metaphors: Musical tempo is what best captures the mental rhythms of this period of life.

Music is a code of signifiers—a coherent whole subject to certain laws—that structures time. It thus has a therapeutic value. Music therapy, which as of the early twenty-first century is still not sufficiently well defined or systematized, uses listening to and producing music to treat various disorders, ranging from psychosis to neurotic issues, in either individual or group therapy. In psychoanalysis proper, moreover, some analysts are growing more interested in that which is vocal and yet nonverbal: that which is linked, in the analyst, to his or her maternal role and, in the patient, to the movement of his or her affects.

## **MUTATIVE INTERPRETATION**

The notion of *mutative interpretation* was advanced by James Strachey in a lecture delivered to the British Psycho-Analytical Society in 1933. With remarkable clinical acumen, he described a privileged interpretative lever whose goal is to encourage, within the framework of the transference process itself, recognition of the archaic nature of certain instinctual impulses, especially aggressive ones, thus bringing about in-depth change in the patient's neurotic organization.

Through at least a slight degree of submission to the analyst's superego-like aspect, the patient necessarily becomes aware of the instinctual contents that motivate him or her, because the analyst, owing to the transference, is the object of the patient's unconscious instincts. If all goes well, the patient becomes aware of the gap between the aggressive nature of his or her feelings and the analyst's attitude; the patient will thus recognize that there is a difference between his or her original fantasmatic object and the real, external object.

The key point in Strachey's conception revolves around the "breach" thus created within the "neurotic vicious circle": realizing that the external object is not actually endowed with the aggressiveness attributed to it, the patient will reduce his or her own aggressiveness toward the object, enabling him or her to introject a less aggressive object. In consequence, his or her superego will become less aggressive, and the patient will gain increased access to his or her infantile material.

Of course, the analyst is a part of this movement. Strachey emphasized that the three classic phases of

the interpretative dynamics—becoming aware of a state of tension within the ego, showing the means of repression, then uncovering the unconscious instinct responsible for the pressure from the superego—must in practice be carried out in conjunction, little by little, in order for the effects of “mutative interpretation” to develop in these three directions. In his view, mutative interpretation underscores the idea that change occurs on a “small scale”: only small quantities of instinctual energy are displaced.

In contrast to the more recent hypotheses of the advocates of “self-exposure,” Strachey emphasized another corollary: It is essential that the analyst’s attitude remain based on analysis of the countertransference and that it not veer off course and become a direct emotional response, even one that is positive. He reiterated that the ongoing risk of the analytic situation is that it will “degenerate” into a real-life situation; having become, without realizing it, a real object, the analyst would then become more difficult for the patient to distinguish from the seductive or persecutory object, thus hindering the interpretation’s effectiveness in bringing about change.

## **MUTUAL ANALYSIS**

Sándor Ferenczi viewed mutual analysis, a late notion in his work, as an active form of counter-transference that attempted to resolve the blockages encountered by classical technique in cases of particularly difficult patients. It was admittedly an unsuccessful innovation, but it remains useful as a limit case for any approach to the psychoses.

Ferenczi developed this technique in his *Clinical Journal* of 1932 (1988) and supported it with many detailed examples. It aims at allowing a patient in an intense regressive state not to be blocked by the treatment itself. In this active counter-transference, an illusory sense of reciprocity and a temporary symmetry need to be established so that with the trust thereby

offered, the patient can gain access to the analyst’s unconscious. This paradoxical attitude shows intuition taken to an excessive degree, since the perverse side effects of the technique are soon seen to be worse than the original difficulties encountered. So that he could struggle against “mutual co-subordination,” Ferenczi doubled the very double bind that he was attempting to lift—a process that he described very clearly: “The exaggerated emphasis on the analytic situation against the patient’s emotional convictions, makes him feel as if he has been coerced into a difficult position by means of suggestion” (1988, p. 96).

Ferenczi himself went on to establish the limits of his technique, since he detected a risk of paranoia in it. He concluded that it was a “last resort, rendered necessary by the insufficiently deep analysis of analysts.” The classical technique had become, in his view, too pedagogical because of Freud’s repugnance toward psychotics and pervers. In spite of his critique, Ferenczi acknowledged his own theoretical dependence on Freud and maintained that “the best analyst is a cured patient.”

These thoughts on the handling of the counter-transference have given rise to several innovations among therapists treating the psychoses. Harold Searles developed the notion of the child as therapist of the adult and the patient as therapist of the analyst, as well as the notion of the “attempt to drive the other mad.” Donald Winnicott, noting the “hatred in the counter-transference,” pointed out that “technical purity is only an idealization in the Freudian sense, and abets repression.” Finally, Michael Balint emphasizes that in the area of the basic fault, “words are not quite reliable” (p. 166).

## MYSTICISM

Mysticism is a set of beliefs and practices evoking an intimate union of man and the principle of being (god or divinity). The term *mystic* (*mystisch*) appears in *The Interpretation of Dreams* (1900a). In its March 20, 1907, session, the Vienna Psychoanalytic Society listened to a talk by Adolf Häutler on “Mysticism and the Comprehension of Nature,” with critical comments by Adler, Rank, and Freud.

Mysticism was understood at that time in a pantheistic sense, as a union of man and nature and of nature with God. In a related sense, Freud “reserved for mysticism a consciousness of the inanimate,” that is of matter and the mineral world (1915e).

The discussions between Freud and Romain Rolland on the “oceanic feeling” and “Universal river” partook of the same pantheistic atmosphere that the French writer was fond of attributing to the “Germanic soul,” and that he had borrowed from Indian thought. The feeling for nature and the idea of God were combined in a communion that drew equally on art and religion. For his part, however, Freud wrote to Rolland, on July 20, 1929, “I have as little appreciation for mysticism as I do for music.”

Unlike Carl Jung, Freud was distinctly reticent about mysticism, which he felt had more to do with nature than with culture, more to do with intuition (if not drives) than with reason. Near the very end of his life, on August 22, 1938, he wrote in his notes: “Mysticism, the obscure self-perception of a kingdom outside the ego, or id.” This obscurity, according to Freud, is not unrelated to the “dark continent” of the female psyche.

But although he seemed to reject mysticism, Freud acknowledged an irrational element in himself: the residue of his self-analysis, which he called “the specifically Jewish nature of [his] mysticism.” Moreover, he loved mystery and wrote to Fliess (June 12, 1900) that he had dreamt of a marble plaque on his house that read:

In this house,  
on July 24, 1895,  
the mystery of the dream was revealed  
to Dr. Sigmund Freud.

## MYTH OF ORIGINS

Freudian thought on origins translates an effort to think the extraindividual, in order to anchor the subject within the ancestral lineage and the history of the species as well as within biology. Several modalities can be discerned: the myth of origins; the genetic myth—the foundational role of the drives as a substrate of the psyche; and primal fantasies and/or fantasies of origins.

Neither maternal nor natural, the myth of origins in the work of Sigmund Freud from the outset placed the history of humanity at the horizon of the paternal function: The original myth is held to be that of the murder of the father. This Freudian theory posited the murder of the primitive father as the starting point for humanity and society. The hypothesis must be understood not as historical truth but as a working myth that expresses the posited requirement that each human being, in the words of Freud, be “an offshoot of Oedipus.” Put forward by Freud in *Totem and Taboo* (1912–1913) and taken up again in *A Phylogenetic Fantasy: Overview of the Transference Neuroses* (1985a [1915]), this myth retraces the history of the primitive horde ruled by a tyrannical father who requires total submission of his sons and exclusive ownership of all the females. However, the brothers form a coalition to kill the father, and devour him in a cannibalistic

celebration. They then erect a totem representing the father and impose a prohibition against incest. This symbolic pact and the rules that result from it constitute the beginnings of society.

Freud elaborated this myth of origins in light of his readings in ethnology and anthropology, analyzing the meanings of totems and taboos in so-called primitive societies. This enabled him to observe that totemic activity coincided with exogamy, that is, the neutralization of the practice of incest. Freud asserted in *Totem and Taboo*: “The violent primal father had doubtless been the feared and envied model of each one of the company of brothers: and in the act of devouring him they accomplished their identification with him, and each one of them acquired a portion of his strength. The totem meal, which is perhaps mankind’s earliest festival, would thus be a repetition and a commemoration of this memorable and criminal deed, which was the beginning of so many things—of social organization, of moral restrictions and of religion” (p. 142). Elsewhere, he pointed out that in the Christian myth, the original sin was the result of an offense against God the Father. By sacrificing his own life to free men from this sin, Christ tends to reconcile humankind with God the Father. Through his sacrifice, the son himself becomes God in place of the father. The religion of the son replaced the religion of the father. To mark this substitution, the old totemic meal was revived: The communion was instituted, in which the gathered brethren eat and drink the flesh and blood of the son, rather than the father, to sanctify themselves and identify with him. At the same time, noted Freud in “Totem and Taboo,” a “sense of guilt for an action has persisted for many thousands of years and has remained operative in generations which can have had no knowledge of that action” (p. 158).

In this regard, Jacques Lacan believed that Freud had implicitly assumed that “a forgotten drama traverses the ages in the unconscious,” as he wrote in *Écrits* (1966/2002); he deduced from this that the true father, “the symbolic Father, insofar as he signifies this Law, is truly the dead Father” (p. 189). More specifically, according to Lacan, “it is thanks to the Name-of-the-Father that aggression against the Father is at the principle of the Law and that the Law is in service to the desire it institutes by the prohibition against incest.”

What we find to be of primordial importance in the reading of this myth is that the murder of the father is repeated by the sons during the religious ritual in the

form of sacrifice; this constitutes the symbolic pact among the brothers, who thus celebrate the restoration of authority, in which they participate from that point on. It is this precise moment that we consider to be the cornerstone of hominization and of culture (Kristeva, 1996). In Freud’s view, on the individual level we are all, unbeknownst to ourselves, repositories of this myth of origins, which each of us reactualizes through the realization of his or her Oedipus complex; he considered the latter, as he wrote in “Totem and Taboo,” to constitute “the beginnings of religion, morals, society and art” (p. 156) and also “the nucleus of all neuroses” (p. 157). He was later led to reintegrate into his inquiries into origins the maternal function, seemingly evacuated from this myth, by discovering an early link between mother and daughter that he compared to Minoan-Mycenaean culture, long hidden by Athenian culture.

By extension, thinking about origins appears in the form of an anchoring of the psyche in the *archè* of biology, expounded initially in Freud’s correspondence with Wilhelm Fliess between 1887 and 1902 (*Extracts from the Fliess Papers* [1950]) and later in “A Metapsychological Supplement to the Theory of Dreams” (1915), “Negation” (1925), and “An Outline of Psychoanalysis” (1940). For the father of psychoanalysis, there could be no doubt that psychic life originated in the organism and that it could thus be conceived of as an evolved form of biological life. This bracketing together of the two is conceptualized in terms of analysis, with self-preservation serving as a support to the libido. Also resulting from this is the essential place of the drives as a borderline concept between the somatic and the psychic. In this spirit, in his “metapsychological” essays Freud advanced the hypothesis of an innate “unconscious kernel,” around which agglomerates all that the individual represses in the course of development. This explains how the unconscious can be organized in the same way in all individuals and how it can be made intelligible in and through psychoanalysis. To attach the psychic apparatus to this biological reservoir, Freud proposed the models of his two topologies (*Ucs./Pcs./Cs.*; *id/ego/superego*). He was at pains in “Negation” to establish the steps and modalities of this transformation of the drive into meaning and, to this end, he emphasized the role of language, which provides an alternative trajectory for pulsional negativity by demarcating the pathway of thought and the symbolic. In analysis, the coming to awareness of the primal repressed is often manifested by means of the

symbol of negation, in which thought is freed from the limitations of repression.

The primal fantasies that are fantasies of origins (observation of the parents' sexual relations, seduction, castration) make up the third panel in the triptych of Freudian thinking on origins. On the one hand, these fantasies have an object that allows infantile sexual curiosity inevitably to confront the question of "where babies come from." On the other, hereditary mnemonic traces are organized into scenes developed by narrative scenarios, with these foundations encompassing conceptual forms or "schemes whose fundamental property is their polarizing, organizing, and classifying role," as André Green put it in "Penser l'originaire" (1991; Thinking the primal). Fantasies of origins are anterior to any individual experience; present in the form of phylogenetic mnemonic traces, they thus belong not to the historical part of the psyche, but to a transmissible heritage. These schemes, which require a phylogenetic explanation, are justified according to Freud by reality as a missing link in individual psychic experience and are related through it to humanity's archaic past, during which, for example, castration was presumably actually practiced by the father on his sons, as he conjectured in *A Phylogenetic Fantasy*.

It could be submitted, in conclusion, that the Freudian "ur" transcends the limits of the individual to move toward the history of the species (in a Darwinian perspective) and toward being (in a phenomenological perspective), with the subject appearing, in Lacan's formulation, as a "parlêtre" (being-through-speaking).

## **MYTH OF THE BIRTH OF THE HERO, THE**

In Otto Rank's view, this book was the first to attempt a psychoanalytical interpretation of myths: In it he declared that psychological reality is responsible for organizing what is narrated by the myth or the story. This work, a "cornerstone" of the psychoanalytical study of mythology (Theodor Reik), and written at Freud's request, did indeed open up original perspectives in the methodological approach to the problem of the formation and function of myths.

Breaking away from the naturalist analysis of mythology, Rank founded his study on the parallel between dream and myth and on the concept proposed by Freud of the "family romance of neurotics." Rank also composed a *Legend of Lohengrin* (1911) in which he tested out his hypotheses and convincingly demonstrated their plausibility.

*The Myth of the Birth of the Hero* is in three parts. In the first, Rank establishes the universality of the myth of the hero; then he sets out his central hypothesis by bringing out the role played by unconscious psychosexual life in myth formation. When it comes to the myth of Oedipus, Rank emphasizes the resistance aroused by the psychoanalytical hypothesis, opposed as it is to the naturalist interpretation, which sees in myth nothing more than personified natural processes. In the second part, Rank surveys a wide range of myths, eighteen in all, garnered from different cultures: Babylonian, Hebrew, Greek, Germanic, Celtic, and Latin. Then he isolates their recurrent themes so as to bring out the structure of what he calls a "typical legend." The myths of Gilgamesh, Cyrus, Moses, Jesus, Oedipus, Tristan, Romulus, Siegfried, and Lohengrin are all analyzed in this way. The survey is completed in part three by references to research on Melanesian, Mexican, North American, African, and other corpuses.

The third part of the work centers on uncovering the typical legend from characteristic elements encountered in the survey, which Rank summarizes in these terms: the hero is the child of parents from a high stratum of society, often of divine or royal origin; his birth is preceded by difficulties in his conception (chastity, sterility, clandestine intercourse). During pregnancy, a presage warns of this birth and announces that the child's father is in danger; as a result, the child is condemned to death by exposure, usually on the initiative of the father or a substitute figure, and more often than not he is set adrift in a casket; the child is then saved and suckled by an animal or by a woman of humble condition; once he has grown up, he undergoes many adventures during which he finds his noble parents and takes revenge on his father; he is recognized and attains glory and renown.

Rank leaves to the process of interpretation the task of bringing out the meaning of the typical legend: this is a rigorous and relatively modern position, that draws support from divergences or variants between myths in order to establish or question the hypotheses proposed. The overall pattern of his interpretation can be seen in the way typical dreams shed light on the analysis of different elements of the myth. His analysis is thus conducted like that of a dream: a myth is the realization of an unconscious desire, and myth is constructed by the same processes as dream—displacement, condensation, considerations of representation, and symbolization.

Rank provides a precise analysis of certain of the myth's elements, starting out from typical dreams: thus the hidden meaning of the "mytheme" of exposure is elucidated by the analysis of dreams of birth, which leads him to suppose that "the same symbolic expression dominates the language of dream and that of myth simultaneously." The desire expressed by the myth of the hero is the oedipal desire for triumph over the father, and the theme of rebellion against the father, which dominates in the theme of exposure, also illuminates the theme of the father's secondary elevation to the rank of king and the theme of rescue. The concept of the "family romance of neurotics" allows Rank to specify how, in the imagination of pre-pubertal daydreams as well as in myth narratives, we find represented both the desire to get rid of parents for whom one feels little esteem and replace them by others who are nobler and more prestigious, and at the same time questions about the knowledge of sexual processes,

procreation, birth, and the mother's body. This parallel between the tendency to family romance and the tendency to evoke the myth of the hero means that Rank can establish an analogy between the ego of the child and the hero. Rank notes that in literary creation the hero represents the poet himself, an idea that Freud took up at the end of *Group Psychology and the Analysis of the Ego* (1921c).

The work ends with two important considerations: the one concerns the genesis and function of the myth of the hero in social life and in individual and collective processes of identification; the other concerns the pathological role of the hero and the relations between myth and delirious fantasies of descent.

The wealth of themes dealt with in this book, and the originality of its approach, meant that it became extremely influential: It inspired major works by Géza Róheim and Carl G. Jung, among others.

## MYTH OF THE HERO

The concept of the *hero* is consubstantial with that of *myth*: they evolved together through the ages. Myths relate the exploits of a man, most frequently the son of a god and a mortal, or of a goddess and a mortal, endowed with extraordinary value and destined to carry out glorious exploits, especially an act of protection or rescue. From a psychoanalytic perspective, the heroic myth has its roots in the fantasy of the family

romance. It expresses and sustains the identification of the ego with an idealized imago, especially during adolescence. It is an essential aspect of training for groups and institutions.

It is difficult to assign a date to the origin of myth. Several authors consider the epic of Gilgamesh to be one of its first expressions. The structure of the myth of the hero has gradually been deduced from the analysis of classical works (Assyrian epic poems, biblical tales, Greek and Latin mythologies), and it can be confirmed in the chansons de geste and epic theater, as well as the modern novel. In spite of the diversity of forms, in the end it remains anthropologically invariant.

Several disciplines have contributed to determining the structure, content, and functions of the myth of the hero: literary criticism, the history of religion, mythology, and with the important work of Otto Rank (*The Myth of the Birth of the Hero*, 1909/2004), psychoanalysis. Rank emphasized the family romance as the organizational schema for the myth of the hero and heroic identification. The structure common to representations of the myth establishes the characteristic elements of the development of the hero:

- conception from illustrious parents, either divine or representatives of the divinity; amazing deeds, oracles, miracles, or prophecies that generally threaten the father prior to the birth of the infant;
- the birth of the hero: the threatening prophecies justify the abandonment and exposure of the child hero at the time of birth in a hostile universe once the secret of his origin has been established;
- obscurity: the hero leads a secret life and will have to undergo an apparent death, from which he will be saved before having to confront terrible challenges;
- the ordeal and epiphany of the hero: critical confrontations (the monstrous) force the hero to confront persecution and depressive anxieties and transform him into a recognizable hero;
- the recognition of his triumph, of his glory, and brilliance (solarity): his apotheosis as an immortal alters him. He can then be used as a model for imitation by mere mortals.

## **MYTHOLOGY AND PSYCHOANALYSIS**

The closest psychoanalytic definition of the term *mythology*, found in dictionaries, is a “set of beliefs and ideas about a single concept imposed on the members of a group.” Professor Jean Rudhart of the University of Geneva notes that a myth is a story that “signifies differently than conceptual speech and contains a deep meaning that is distinct from its surface meaning” (1981).

We can assume that, for Sigmund Freud, myth, “signifying differently” and distinct from the apparent meaning of conceptual speech, represented “with the introduction of the reality principle one species of thought-activity [that] was split off; it was kept free from reality-testing and remained subordinated to the pleasure principle alone” (1911b, p. 222). We can easily recognize the creation of fantasies described in Freud’s “Formulations on the Two Principles of Mental Functioning” (1911b). In the same sense the role of myth, collective or individual, would correspond to the religious and cultural fantasies that influence, introduce, or modify ego ideals and the pre-oedipal and post-oedipal superego; they also promote various identifications and sublimations. Additionally, mythology, being a part of the cultural heritage of the collectivity, and transmitted “phylogenetically” or diachronically through oral traditions, contributes to the

formation of primal fantasies, the family romance, and “cultural romances” (Nicolaidis, 1988).

A distinction between myth (the production of desire through fantasy) and history (an event-driven narrative corresponding to the reality principle) could be made through the use of the concepts of conjunction and structure. In this sense history would be a “conjunction” having an event-driven continuity and a fantasy-driven discontinuity, while mythology (myths) would be a “structure” having a fantasy-driven continuity and an event-driven discontinuity. However, myth structures the desire of a group of individuals. This distinction brings us back to Freud’s abandonment of his *neurotica*, of the actual seduction (letter to Fliess, October 15, 1897), which until then had been the etiology of the neuroses (event-driven history). To ground his new theory, he made use of the Oedipus myth and the history of Hamlet, as dramatized by Shakespeare.

In this way the Oedipus complex was born as humanity’s universal core. Later on, the myth of Narcissus (1914) became the link between the first and second topographical subsystems. We know that throughout his work Freud made reference to mythic characters and contexts as metaphors for the evolution of psychic reality. He clearly expressed the closeness between myths and fantasies, the products or creations of drives, when he wrote, “The theory of instincts is so to say our mythology. Instincts are mythical entities, magnificent in their indefiniteness” (1933a, p. 95). The fact that the role of myth in psychoanalytic theory is obvious presents the following questions: Why was Freud’s thinking, influenced by the neopositivism of his time, oriented toward myths? Why did he emphasize some myths and ignore others?

At the beginning of his career, Freud constructed a “psychic apparatus” that he tried to connect with the neuroses (*Project for a Scientific Psychology*, 1950c [1895]), but he repudiated the essay for the remainder of his life. He did so following the introduction of psychic reality, although the concept forced him to contradict the scientific and cultural climate of his age and his own tradition as a neurologist. For, to some extent, he separated the psyche from its biological substrate. But by claiming to be an atheist, and certainly an agnostic, there was no question for Freud of attaching the psyche (the soul) to religion, or a mystical or metaphysical concept. On the other hand, because he acknowledged that the illusion he criticized played an

important role in the shared life of mankind, he sought this illusion (of the imagination) in myth. Because fantasy fell halfway between the real and the imaginary, myths, at least some of them, fell somewhere between the mysticism of religion and the reality of desire. Thus the mythologies closest to the mental apparatus and psychosexual evolution reinforce and are mirrored in his conception of “psychic reality”.

Reading the index to the *Standard Edition*, we find that *Faust* and *Hamlet* are the most frequently cited texts. With respect to mythic texts strictly speaking, Greco-Roman mythology is the most prevalent. Germanic-Scandinavian mythology is absent in Freud’s writings. The mythology and art of Egypt are of interest to Freud and he writes often of Amenophis IV–Akhenation (with respect to monotheism) and he mentions Isis and Osiris. He is familiar with the Brihad-Aranyaka Upanishad of India, where the genesis of the world is described on the basis of the *Aturan* (the self or ego); he quotes Ramakrishna and Vivekananda but never the *Veda* or the revelations of Brahma. The Buddhist concept of nirvana serves as a metaphor of instinctual economy. He also cites the epic of Gilgamesh. The Bible is found throughout his work but as a religious reference rather than a mythic context. He does comment on the dilemma of Abraham and Isaac, and the dream of Solomon, but for Freud the mythical hero of the Bible is Moses, because of his strength and spirituality. Fascinated by Roman statuary, especially Michelangelo’s *Moses*, Freud devoted his last book to the legend of Moses. *Moses and Monotheism* (1939a [1934–1938]) is an anthropological construct, where the eternal Freudian quest for the origin of mankind and the evolution of civilizations unfolds, especially in the transition from the matriarchy to the patriarchy, which is presented as a victory of spirituality over sensuality. Concerning this, Freud writes, “An echo of this revolution seems still to be audible in the *Oresteia* of Aeschylus” (p. 114).

But it is *Totem and Taboo* (1912–13a) that unquestionably remains Freud’s laboratory on the question of origins, primal fantasies, and the origin of fantasy, even the origin of myth and its role in structuring “psychic reality”. In the first part of the book, Freud generalizes his thinking, quoting several historians of primitive peoples, but without reference to a specific mythology. In evoking the guilt arising from the totemic meal, or “tragic fault,” he writes, “In particular, I have supposed that the sense of guilt for an

action has persisted for many thousands of years and has remained operative in generations which can have had no knowledge of that action” (pp. 157–158). The first two-thirds of the book refers to the fear of incest, to taboo, and the ambivalence of the feelings associated with animism, magic, and the omnipotence of ideas. Throughout the work Freud attempts, using analogies from mythology, to structure this primitive-instinctual inconsistency, sometimes expressed by legends dominated by magical or animist thought, with a kind of anthropological coherence. The omnipotence of ideas provides him with an opportunity to quote Hamlet and create a connection between animist thought and obsessive representations, but it is chapter IV, “The Return of Totemism in Childhood,” that marks a turning point toward “Occidental” psychopathology and the mythology that masks it.

Freud gradually abandoned pre-Hellenic “mythology,” which had been necessary until then to identify primitive thought. In analyzing totemism and the totem meal, he notes that their content coincides (1912–13a, p. 132). He begins with the sacrifice, “the sacred act par excellence,” quoting often from *The Religion of the Semites* (1889) of W. Robertson Smith: “The primitive animal sacrifice was already intended to replace a human sacrifice, the solemn killing of the father.” Freud remarks that, analogically, Christ, in sacrificing his own life, freed all other men from original sin. However, the doctrine of original sin for Freud is of Orphic origin. To support his hypothesis he introduced the pre-Olympian myths (Orphism), the Titans, who killed and cut into pieces the young Dionysus-Zagreus. Using this information, Freud again returns to Greco-Roman mythology to house the fantasies and psychopathology of his psychoanalytic theory. By insisting on the importance of the “tragic fault,” he writes that “the beginnings of religion, morals, society and art converge in the Oedipus complex. This is in complete agreement with the psychoanalytic finding that the same complex constitutes the nucleus of all neuroses, so far as our present knowledge goes” (1912–13a, p. 156). He shows that the “modernity” of this myth conforms to the actuality of the neuroses of the modern world.

Freud, in “Why War?” (1933b [1932]), wrote to Albert Einstein, “It may perhaps seem to you as though our theories are a kind of mythology and, in the present case, not even an agreeable one. . . . Our mythological theory of instincts makes it easy for us to find a formula

for *indirect* methods of combating war. If willingness to engage in war is an effect of the destructive instinct, the most obvious plan will be to bring Eros, its antagonist, into play against it” (p. 212).

In *Beyond the Pleasure Principle* (1920g), he situated this antagonism: “If . . . we are not to abandon the hypothesis of death instincts, we must suppose them to be associated from the very first with life instincts. But it must be admitted that in that case we shall be working upon an equation with two unknown quantities” (p. 57). Here, Freud acknowledges his scientific dissatisfaction and refers to a myth, an “instinct to restore an earlier state.” This is the myth of Aristophanes in the *Symposium* of Plato, where there is a question of the primal physical bisexuality of human beings. He mentions this myth again in “Why War?”

Greco-Roman mythology fascinated the inventor of psychoanalysis not only because of its consistency in terms of fantasy (Didier Anzieu, 1970; André Green, 1969/1979; Graziella Nicolaïdis, Nicos Nicolaïdis, 1994), but also because of the role of Eros and sexuality in this mythology-religion, where carnal pleasure was not considered a sin but as a right that God or nature had given to man. This mythology alleviated Freud’s guilt, so to speak, by legitimizing infantile sexuality and adult sexuality, the fruits of his own discovery.

To conclude, it can be said that mythology and some myths or “mythemes,” condensing and displacing the representations of drives, have served as metaphorical models for several fundamental fantasies in the theory of psychoanalysis.

## MYTHOMANIA

The concept of mythomania appeared in the academic psychiatric literature at the beginning of the twentieth century. It was introduced by Ernest Dupré (b. 1905), a specialist in “constitutions,” in *Pathologie de l’imagination et de l’émotivité* (Pathology of the imagination and emotions; 1925) to refer, precisely, to the supposedly constitutional tendency of certain subjects to confabulate on the mental level and to simulate on the somatic level.

In his *Manuel alphabétique de psychiatrie* (Alphabetical manual of psychiatry; 1952), Antoine Porot devoted a relatively long article to this topic. He studied mythomania in children as distinct from mythomania in adults, recalling the three main types identified by Dupré—vanity-based mythomania, malignant mythomania, and perverse mythomania—and adding to these the particular form of errant mythomania, potentially associated with fugue states (“fables in action”).

In children, Dupré described a sort of gradient ranging from quasi-physiological mythmaking activity to true mythomania, by way of lies, pretending, and fabrication. In adults, vanity-based mythomania was posited as being the most benign clinical form, the prototype of which is illustrated by Alphonse Daudet’s

*Tartarin de Tarascon*. However, according to Dupré this type of mythomania could also be observed in cases of debility, whereas the more serious, malignant, and perverse forms were described as occasionally going as far as delusional imaginings. In this author’s view, whether mythomania was episodic or permanent, it was linked to a so-called primitive mentality, even though he believed that this disorder was more common among women and sometimes transmitted in a hereditary pattern that could affect several successive generations. According to him, mythomania was based on emotivity, exaltation of the imaginative faculties, and suggestibility, whereas Eugène Minkowski linked mythomania to the idea of “inconsistency” introduced by Pierre Janet.

The classical psychiatry of that era took an incidental interest in the connections among mythomania, simulation, and hysteria, but the climate of the times was more inclined toward the isolation of descriptive entities than toward structural reasoning. This perspective is obviously not that of psychoanalysis, which, accordingly, took relatively little interest in mythomania per se.

Michel Neyraut must be credited for taking a metapsychological approach to this disorder in “À propos de la mythomania” (On mythomania; 1960). This study enabled him to show that a symptom can register within a variety of psychic functions, and that only an in-depth study of a subject’s psychopathology from a threefold economic, topographical, and dynamic perspective can reveal the meaning and function of a symptom that seems relatively identical from one individual to another based solely on a surface behavioral description.

In addition, Neyraut’s study retraced the history of this concept with regard to the development of psychoanalytic discovery itself, with its well-known central focus on the question of hysteria.

## MYTHS

Myths are tales of unknown origin handed down by tradition, sometimes orally and sometimes by written word. The stories are set in a primordial period during which the order of the present world is established. They tell the story of the origin of the world, of human beings and animal species, of death, and of the relationship between man and supernatural beings.

Until the fifth century BCE, the Greek word *mythos* was a synonym for *logos* (word). With Pindar and Herodotus, it came to mean words of illusion; rumor; the speech of others; irrational, barbarous, even scandalous speech (Détienne, 1979). For better or worse, Western mythology inherited this opposition between rational thought and mythical thought.

When ethnologists realized that the social organizations of the peoples they studied were significantly related to their mythologies, they helped move the study of myths from the impasse that nineteenth-century authors had become stuck in. Claude Lévi-Strauss saw myths as books without authors, their messages “coming, properly speaking, from nowhere” (1969–1981). Studying native American myths in their own terms, he demonstrated that they are transformations of each other and that their different codes express an underlying logical structure. In fact, myths are not only speculations about social organization but also, and above all, they reflect the structure of the human mind (Lévi-Strauss, 1969–1981). Georges Dumézil (1968–1973) laid bare the underlying principles of social organization in ancient Indo-European mythologies, particularly regarding the functions of sovereignty, war, and fecundity.

Freud related psychoanalytic theory to mythology in the broad sense of the term (myths, tales, sayings, jokes): “It is extremely probable that myths, for instance, are distorted vestiges of the wishful fantasies of whole nations, the secular dreams of youthful humanity,” Freud wrote in 1908 (p. 152). In 1909 Karl Abraham developed this idea in *Dreams and myths* (1913) by showing that myths use the same mechanisms as dreams (figuration, condensation, displacement, and secondary revision), and that they are the

realization of desires. They can therefore be interpreted in the same way as dreams (see Otto Rank, 1952, 1975).

While Abraham used the Greek myth of Prometheus for his demonstration, Géza Róheim, a psychoanalyst and field anthropologist, directly studied Australian aborigines. For them, mythical time, the time of the primordial ancestors, is “dream time.” These aborigines’ notion of “eternal dream beings” enabled him to show “how the typical mechanism of all dream construction operates at the heart of mythology and aboriginal rituals” (Róheim, 1952).

Jean-Paul Valabrega (1967, 1992, 2001) devotes considerable attention to the epistemological question of the relation between myths and the unconscious, between myths and fantasy. For Valabrega, myths, which are neither individual nor collective, tend to metamorphose (as shown by the many different versions available) yet remain eternal and perpetually regenerate, in both respects like the unconscious. Moreover, myths are related to fantasies in that they both represent. Myths are made from the stuff of fantasies, and fantasies are made from the stuff of myths: there is a circular relationship between them in which neither is primary. “Psychoanalysis was practically born entirely out of a myth—Oedipus— . . . that Freud rediscovered by analyzing the dreams and fantasies of his first patients, as well as by analyzing his own dreams and fantasies” (Valabrega, 1994). There is also his use of mythical figures like Narcissus, Eros, and Thanatos.

The loose use of the term *myth*, encouraged if not created by Roland Barthes’s work (1970), is more a matter of ideology. This usage, Valabrega (1994) claims, preserves the “function of myths” and the “structure of symptoms.” In this usage, words without an author, productions that borrow the anonymity of myths and a few contemporary elements of content, bear witness to the persistence of a discourse that is both intimate and foreign to the self.

## NACHT, SACHA EMANOEL (1901–1977)

Sacha Nacht, French physician, neuropsychiatrist, and psychoanalyst, was born at Racacini in the department of Bacau, Romania, on September 23, 1901, and died in Paris on August 25, 1977.

The son of Samuel Nacht, who was ruined financially by a fire in his sawmill, and of Cécilia Bril, Sacha Nacht completed his secondary education and first year medical studies, then emigrated to France in 1920 in order to continue his studies there, because of a *numerus clausus* limiting Jewish enrollment in Romania. The influence of Charles Foix stimulated his interest in neurology and he presented his graduate thesis in 1926: *Contribution à l'étude de l'anatomie pathologique des myélites syphilitiques en général et de leurs formes progressives en particulier* (Contribution to the study of pathological anatomy in syphilitic myelitis in general and its progressive forms in particular).

In 1926 his success (as a foreigner) in the *Internat des Asiles* (a competitive examination for trainee physicians wishing to work in psychiatric asylums) nevertheless directed him into psychiatry. Legend has it that psychoanalysis was revealed to him while he was watching Henri-René Lenormand's play, *Le Mangeur de rêve*, which triumphed in Paris in 1922, but this underestimates the importance of psychoanalysis and the first French psychoanalysts working under Professor Henri Claude in the Sainte-Anne hospital where he was soon to work.

He was analyzed for two and half years by Rudolph Loewenstein before going to Vienna where Freud received him on the recommendation of Marie Bonaparte. Being unable to understand his German, Freud

considered that it was impossible to continue the analysis and recommended that he continue his treatment with Heinz Hartmann in Vienna, a treatment they later continued in Paris when Hartmann emigrated there.

Nacht was invited to attend a conference on schizophrenia in 1927 and was elected a member of the Société Psychanalytique de Paris (SPP, Paris Psychoanalytic Society) on January 17, 1928, becoming a full member on October 21, 1929. In December 1931 he was appointed head of the psychotherapy and psychoanalysis laboratory under Henri Claude and in 1933 passed the Concours des Médecins des Asiles (a competitive examination for asylum physicians), though he never occupied a position as head of a hospital department. In 1935 Alcan published his first book, *Psychanalyse des psychonévroses et des troubles de la sexualité* (Psychoanalysis of the Psychoneuroses and Sexual Disorders), but he mainly made a name for himself at the tenth Conference of French-speaking Psychoanalysts in February 1938 with his report on *Le masochisme, étude historique, clinique, psychogénétique, prophylactique et thérapeutique* (Masochism, an historical, clinical, psychogenetic, prophylactic and therapeutic study). Challenging the notion of a death instinct, he stressed the aggressive instinct, one of its manifestations being fear, masochism representing an eroticized turning of this against the self. In 1935 he married Louise Lydie Farman and their son Marc was born the following year. They divorced in 1950 and in 1952 he married Edmée Tedesco-Chemla. Their witnesses, one year before the split in the SPP, were Jacques Lacan and Sylvia Bataille.

During World War II he joined the Resistance as “agent P1” in the Brick network of the Fighting French Forces from November 1, 1942 to September 30, 1944. He was arrested in 1943 while trying to make his way to London. He narrowly escaped deportation thanks to his wife, who used a false baptism certificate to conceal his activities and his origins from the Germans. He was continually harassed by the Militia and went into hiding at Gassin (in the Var department). After the Liberation he resumed his activities as a captain and psychiatrist before being demobilized.

It was at this time that he began to do training analyses with such figures as Serge Lebovici and Salem Shentoub. He also inaugurated the shortening of sessions to forty-five minutes. In 1947 he succeeded John Leuba as president of the SPP and proved to be particularly active in this role. Along with his friend Jacques Lacan he was one of the two reporters at the eleventh Conference of French-speaking Psychoanalysts, held in Brussels in May 1947, where he presented a paper on *Les manifestations cliniques de l'agressivité et leur rôle dans le traitement psychanalytique* (Clinical Manifestations of Aggression and their Role in Psychoanalytic Treatment). In 1956 he presented, along with Serge Lebovici, *Les indications et contre-indications de cure psychanalytique* (Indications and Counter Indications of the Psychoanalytic Cure); in 1955, with René Diatkine and Jean Favreau *Le Moi dans la relation perverse* (The Ego in Perverse Relations) and; in 1958, with Paul-Claude Racamier, *La théorie psychanalytique des délires* (The Psychoanalytic Theory of Delusions). At the first Congress of Psychosomatic Medicine in 1960 he demonstrated his constant interest in psychosomatic medicine in a report written with René Held: *Maladies ou malade psychosomatique?* (Psychosomatic Illness or Patient?).

His staunch support for the training criteria laid down by the International Psychoanalytic Association—he was vice-president of the Association from 1957 to 1969—led him, on the occasion of the foundation of the Paris Institute of Psychoanalysis, to adopt a radical position in favor of a more rigorous, medical-style teaching. In this he found himself opposed to Daniel Lagache and Jacques Lacan. This opposition resulted in a definitive break in relations when the split took place on June 16, 1953. In 1951 he was appointed director of the institute, which was inaugurated on June 1, 1954, and ruled it with an iron fist until the revolt of the full members resulted in Serge Lebovici

being elected to his position in 1962. There is no doubt that the serious riding accident that plunged him into a coma in 1956 and left him with an embarrassing diplopia also modified his character and limited his activity. During his directorship he nevertheless created the Diagnostics and Treatment Center in 1954 and the Advanced Training Seminar in 1958.

It was essentially at these annual Seminars that Sacha Nacht continued his teaching activity and his activities within the SPP, refusing all other positions from this point onward. As a testimony to his services he was awarded as a parting gift the title of “director-founder in charge of relations with psychoanalysts in the provinces and abroad.” His influence over the general public began to wane before the rising star of the man who became his main adversary, Jacques Lacan.

We can see the beginning of his decline in the relative failure of the collection “*La psychanalyse d'aujourd'hui*” (Psychoanalysis Today)—the eponymous volume, published in 1957, which gave a fairly exhaustive outline of the conception of psychoanalysis that was behind it, followed by the equal relative failure of the *Traité de psychanalyse* (Treatise on Psychoanalysis), which was a personal project that he had earlier discussed with Ernest Jones (in a letter dated April 24, 1938, in which Nacht insisted “above all [on] the ‘didactic’ character I would like to see it have”). Only the first volume of *Traité* appeared in 1964. Although suffering from cancer, he nevertheless continued until the end in the considerable practice that his therapeutic reputation had won him.

In addition to his institutional work, and the mark it left on the French psychoanalytic movement for several decades, it is important to stress the no less negligible influence of his theoretical stances. For nearly thirty years they were a fairly constant if not a mandatory reference for the leading members of the SPP, almost all of whom had spent some length of time on his couch.

He was nevertheless a clinician rather than a theorist, his influence being manifested in the sphere of psychoanalytic practice, as he commented on it to his listeners at his famous Technical Seminar. He also outlined it in the books that documented his many, religiously attended contributions at the SPP symposia, among them *La Présence du psychanalyste* (The Presence of the Psychoanalyst; 1963), *Guérir avec Freud* (Healing with Freud; 1971). His comments on “non-verbal communication” were in response to

Lacan's assertions, as was his assertion that the psychoanalyst acts more "through what he is than through what he says." Nacht also stressed the distinction to be made between "transference reactions" and "transference neurosis," just as he stressed, in relation to the counter-transference, the necessary "goodness" of the psychoanalyst, as manifested in his/her "presence," ideas that are quite close to Sándor Ferenczi's position on tact. He even went so far as to advocate silence as a factor of vital integration, maintaining that words separate just as much as they lift the repression.

Little by little, although he had stressed the Freudian notion of "conflict" and the "cycle of frustration-aggression-fear" as opposed to the "autonomous Ego," repeating that "the energy sources of the Ego always derive from the aggressive and sexual instincts," toward the end of his life he nevertheless drew closer to the Ego-Psychology of his former analysts, declaring this publicly on the occasion of Rudolph Loewenstein's last visit to France in 1967.

Though not devoid of a sense of humor, Sacha Nacht affected a brusque manner and was often criticized for his authoritarianism, which earned him the nickname "satrap." And although his work is not much read today, he nevertheless remains an important figure for psychoanalysis in France, both for the institutional role he played and for the influence that his theoretical and technical conceptions exercised over the psychoanalysts of the Paris Psychoanalytic Society for some thirty years.

## **NAKEDNESS, DREAM OF**

Considered a "typical dream" by Freud, the dream of nakedness fulfills an exhibitionistic wish.

In a letter to Wilhelm Fliess dated May 31, 1897, Freud related one of his dreams: Wearing very few clothes, he was going up a staircase; upon encountering a woman, he felt "glued to the spot . . . paralyzed" (Letter 64, p. 254). He returned to this dream and analyzed it in *The Interpretation of Dreams* (1900a), in the paragraph he devoted to "typical dreams," that is, dreams that are more or less identical in everyone.

Freud emphasized three characteristics of the dream of nakedness: shame at being naked, indifference on the part of the spectators (usually numerous), and the sense of being paralyzed. He interpreted it as an oneiric fulfillment of an exhibitionistic wish dating back to the happy period of early childhood, when such a wish could legitimately be satisfied. Sándor Ferenczi, with the same interpretation, related several dreams of nakedness that enabled the dreamer to express their "undying longing for the return of the paradise of childhood" (1909/1952, p.106); elsewhere, however, he mentioned the dream of a woman who, after some hesitation, bathes nude in the presence of her son and uses it as a "means of inspiring terror" (1919, p. 329).

Dreams of nakedness, always linked to an erotic or exhibitionistic theme, are universal, and accordingly should be considered "typical dreams," as Freud proposed. Despite their commonality, however, they have not yet led to a specific theorization.

## **NAME-OF-THE-FATHER**

Jacques Lacan introduced the notion of the “Name-of-the-Father.” By it he meant that every signifier, by its connection, not to an object, but rather to another signifier (Ferdinand de Saussure), symbolizes the lack that it introduces into being. As the particular symbolizer produces this effect while at the same time transforming it, the Name-of-the-Father enables human beings to tolerate and maintain desire. Without it, lack is experienced as a devouring force (cf. the case of Little Hans, Freud, 1909b) or a sucking force, the representation of a wound in the maternal body that is the source of a debt that can never be repaid.

The child discovers this name as a metaphor for the enigmatic object desired by the mother in the body of the child’s father. Thus, the child can find his way to one of two ways of assuming for this phallus; he can either have it like the father, or be it, in order to be desired.

The Oedipus complex makes the father the agent of the prohibition that makes it the impossible to access the object-cause-of-desire. Lacan’s structural analysis shows that the father is not himself the guarantor of the symbolic law, but is the one who authorizes desire. “[T]he true function of the Father . . . is fundamentally to unite (and not to oppose) a desire to the Law,” he wrote in “Subversion of the Subject and Dialectic of Desire” (Lacan, p. 309).

In the Other, the phallus thus no longer symbolizes a devouring agency, but instead one that rejoices if the subject experiences sexual enjoyment (*jouissance*) and procreates. Only one father can take on such a function, to the point of identifying with the phallus as symbolized by the dead Father.

It is understandable that some religions hold non-procreative sexual enjoyment (*jouissance*) to be sacrilegious, thus defrauding the phallic symbol by defying or abusing the dead Father. Religion’s traditional function is to affirm the primacy of sexual enjoyment against the destructive, abnormal forms of enjoyment that are in fashion.

## **NARCISSISM**

The term *narcissism*, in keeping with the Greek myth of Narcissus, refers to self-love. The concept was introduced in Freud’s work shortly before the publication of “On Narcissism: An Introduction” (1914c). This paper was a response to four related issues: the difficulties encountered in psychoanalysis in working with

neurotics; the controversy with Jung, who defended the idea of the unity of psychic energy; the debate with Adler over the role of “masculine protest” in symptom-formation; and above all Freud’s growing interest in the psychoses, which opened his way to the study of the ego (1923a).

By proposing the notion of narcissism, Freud (1914c) meant to show how four different phenomena were related: narcissism as sexual perversion; narcissism as a stage in development; narcissism as libidinal cathexis of the ego; and narcissism as object-choice. He also described an ego-ideal as the heir of infantile narcissism and as a psychic agency of self-observation. These last two concepts would be elaborated on later by Freud.

The term was borrowed from Paul Näcke, who in 1899 described a form of behavior, resembling a perversion, whereby an individual treated his own body as one might treat the body of a sexual partner. In 1910 the word appeared in Freud’s writing for the first time in a long note added to the third edition of *Three Essays on the Theory of Sexuality* (1905c, p. 145n). He used it again in *Leonardo da Vinci and a Memory of his Childhood* (1910c), then offered a more complete account in his discussion of the case of Schreber: “There comes a time in the development of the individual at which he unifies his sexual instincts (which have hitherto been engaged in autoerotic activities) in order to obtain a love-object; and he begins by taking himself, his own body as his love-object” (1911c, p. 60). In the third chapter of *Totem and Taboo*, “Animism, Magic and the Omnipotence of Thoughts,” Freud defined narcissism in much the same way (1912–13a, p. 89).

At this time he formed the hypothesis of a narcissistic stage of development occurring between the autoerotic stage and the stage of object-love. In “Instincts and their Vicissitudes” (1915c), Freud described “a primal psychical situation”: “Originally, at the very beginning of mental life, the ego is cathected with instincts and is to some extent capable of satisfying them on itself. We call this condition ‘narcissism’ and this way of obtaining satisfaction ‘auto-erotic’” (p. 134). On its face, this account would seem to conflict with the one set forth in “On Narcissism” (1914c). But it becomes easier to see how narcissism can be viewed as a phase between autoeroticism and object love, and autoeroticism as a mode of satisfaction, if we bear in mind that the significance of autoeroticism changes

during development, as the identificatory processes described by Karl Abraham (incorporation) and by Sándor Ferenczi (introjection) come into play. Freud described the relationship between narcissistic identification and hysterical identification in the twenty-sixth of his *Introductory Lectures* (1916–1917a [1915–1916], pp. 427–428).

Freud postulated an original cathexis of the ego, a primary narcissism, in the infant; later some part of this libidinal cathexis would be redirected onto objects, creating an opposition between ego-libido and object-libido. Narcissism was thus seen as the libidinal complement to the egoism of the self-preservative instinct. It therefore played a part in the structural definition of the ego, for the ego retained a permanent narcissistic cathexis that no instinctual vicissitude could exhaust (1917a). In 1915 Freud had added a section on “The Libido Theory” to part 3 of the *Three Essays* (1905d), in which narcissistic libido was described as “the great reservoir from which object-cathexes are sent out and into which they are withdrawn once more” (1905d, p. 218). This metaphor recurred almost every time Freud discussed narcissism thereafter: in *Beyond the Pleasure Principle* (1920g), in the encyclopedia article “The Libido Theory” (1923a), and in *The Ego and the Id* (1923b). The narcissistic phase of libido fixation was also illustrated by the metaphor of an amoeba capable of putting forth extensions or pseudopodia that can in due course be withdrawn once more, this primitive distribution of the libido being reestablished during sleep. This analogy, first used by Freud in “On Narcissism” (1914c, p. 75), was repeated frequently between *Beyond the Pleasure Principle* (1920g) and *An Outline of Psychoanalysis* (1940a [1938]). The editors of the *Standard Edition* review Freud’s use of these two metaphors in an appendix to *The Ego and the Id* (1923b, pp. 63–66).

Freud contrasted the paths leading to object-choice of the narcissistic type with object-choice of the anaclitic or attachment type. In the case of narcissistic object-choice, a person loved “(a) what he himself is (i.e., himself), (b) what he himself was, (c) what he himself would like to be, (d) someone who was once part of himself.” In anaclitic object-choice, a person loved “the woman who feeds” or “the man who protects” (1914c, p. 90).

Freud presented an instance of narcissistic object-choice in his “Wolf Man” case history. There he inter-

preted a shift of object-choice by little Sergei (the future “Wolf Man”) from his nurse, or “Nanya,” to his father (1918b [1914], p. 27). This shift was precipitated by what he felt was a rejection by the nurse, which thus offered him the opportunity to “renew his first and most primitive object-choice”—that of his father—“which, in conformity with a small child’s narcissism, had taken place along the path of identification” (p. 27). Freud revisited this mode of identification in *The Ego and the Id*, where he distinguished it from the initial object-cathexis of the mother’s breast (1923b, p. 31).

In his paper on “The ‘Uncanny,’” Freud argued that “the double,” as studied by Otto Rank, had its origins in the period of primary narcissism, when it was invented on the basis of “unbounded self-love” as “an assurance of immortality”; only later would it become a “harbinger of death” (1919h, p. 235).

In the adult, infantile narcissism was replaced in Freud’s view by the ego-ideal. It was in “On Narcissism” (1914c, pp. 94–95) that he first discussed a specific psychic agency responsible for measuring the actual ego against an *ideal ego* or *ego ideal* (Freud himself never clearly distinguished between the two terms). This “critically observing agency” was involved, according to Freud, in so-called normal consciousness, in dream censorship, and in delusions of being watched (1914c, pp. 95–98). In “Mourning and Melancholia,” Freud assigned it a leading role in the onset of pathological states of mourning, pointing out that the ego ideal splits off from the rest of the ego (1916–17g [1915], pp. 247–48). He reiterated the idea of a splitting-off of the ego ideal in *Group Psychology and the Analysis of the Ego* (1921c). When the superego made its first appearance in Freud’s work (1923b, p. 28), it was an alternative name for the ego ideal; later, it would operate principally as an agency of guarding and prohibiting. In his later work Freud referred to the ego ideal only intermittently, using it in a quasi-technical way. In the *New Introductory Lectures on Psycho-Analysis*, the superego was described as “the vehicle of the ego ideal by which the ego measures itself” (1933a [1932], pp. 64–65 and n.).

Freud’s contemporaries clarified the change in his thinking represented by the introduction of narcissism. Sándor Ferenczi remarked in “Introjection and Transference” (1909) that the newborn experienced everything in a monistic way. The desire to rid itself of unpleasant affects led the child to exclude objects from

the mass of its perceptions. The infant invented the outside world and then opposed its ego to it by means of a primitive projection that thus established dualism—a point of view that Melanie Klein did not take into account later when she posited the existence of a dualism from the beginning. Ferenczi first used the term *narcissism* in 1913.

The earliest contributions of Karl Abraham, between 1913 and 1920, show that it was the difficulties he encountered in the treatment of neurotics that prompted him to consider the role of narcissism. In “A Short Study of the Development of the Libido, Viewed in the Light of Mental Disorders” (1924), however, he based himself on the study of the psychoses, and especially of melancholia, to connect narcissism with the specific quality of thought needed to transform a fantasy into a delusional idea. The symptomatology of melancholia further led him to consider overestimation and underestimation as expressions, respectively, of positive and negative narcissism related to self-love and self-hatred.

In his article “On the Origin of the ‘Influencing Machine’ in Schizophrenia” (1919), Victor Tausk argued that the libido, at the beginnings of mental life, corresponded to an “objectless” period (p. 47). The formation of the ego was thus associated with the discovery of the object and corresponded to the development of the sense of reality. Tausk posited the existence of a psychic narcissism that renewed itself “with each new acquisition of the ego,” contrasting it with an “organic narcissism that guarantees in the unconscious the unity and functioning of the organism” (p. 56). Lou Andreas-Salomé, for her part, identified narcissism with pregenital sexuality, as distinct from object-love, which implied a partner. She looked upon narcissism as a borderline concept with a twofold orientation, referring on the one hand to a reservoir for all the manifestations of the psyche and on the other to the location of all tendencies to regression to pathological childhood fixations. For Andreas-Salomé, narcissism defined physical being, unifying internal and external processes.

Several later authors contributed significantly to the discussion of narcissism. Although there was no place in Melanie Klein’s theory for autoeroticism or narcissism, her descriptions of infantile omnipotence and megalomania provided important insights for the clinical understanding of narcissistic states. In 1963, writing on the psychopathology of narcissism, Herbert

Rosenfeld (1965) was especially concerned to arrive at a better definition of object-relationships and their attendant defense mechanisms in narcissism. The study of therapeutic factors led him later to analyze the influence of narcissism on the work of the psychoanalyst. He drew attention to the existence, alongside the libidinal aspect of narcissism, of a destructive narcissism related to the death instinct.

Heinz Kohut offered his own reformulation of narcissism, describing it as the cathexis of self-representations (and not of the ego); he defined it as an agency of the personality responsible for issues of relationship. His clinical study “The Two Analyses of Mr. Z” (1979) reflected the transition from ego-psychology to the self-psychology that he developed out of it. These ideas were outlined in Kohut’s *The Analysis of the Self* (1971). Kohut might be criticized for presenting his very rich contribution to the field as an alternative to classical analysis, but his observations show the benefits of a way of listening, clearly within the Freudian tradition, that combines attention to narcissism with attention to object-cathexes.

D. W. Winnicott made no direct reference to narcissism. His account of the self differed greatly from Kohut’s. The articles published in *Collected Papers: Through Paediatrics to Psychoanalysis* (1958) and in *The Maturational Processes and the Facilitating Environment* (1965) contain everything he wrote on the subject. His brilliant observations of the mother-child couple nevertheless throw considerable light on primary narcissism, which in the young child can be viewed as the extension of the mother’s narcissism. In contrast to the metaphor of the mirror in which Narcissus recognized himself and was lost, Winnicott offered his own vision of a child destined to find itself and live, the mirror in this case being the mother’s face: “What does the baby see when he or she looks at the mother’s face? I am suggesting that, ordinarily, what the baby sees is himself or herself. In other words the mother is looking at the baby and *what she looks like is related to what she sees there*” (1967, p. 131). It is worth pointing out the importance in this view of the environment and of emotional experience.

Since Freud, in France, there has been a particularly lively interest in the question of narcissism. The mirror stage, as described by Jacques Lacan, originated in the work of the psychologist Henri Wallon. Unlike Winnicott, for whom the child’s environment was supportive, Lacan (1949) saw it rather in terms of

“constraints,” and contrasted it sharply with the eighteen-month-old’s “jubilant assumption of his specular image.” According to Lacan, “It suffices to understand the mirror stage... *as an identification*” (2002, p. 4). The knowledge of the ego that Lacan proposed here amounted to the suggestion that we consider rather the “misrecognition” characteristic of the ego.

Harking back to Lou Andreas-Salomé, Béla Grunberger drew attention to a double orientation of narcissism—as both a need for self-affirmation and a tendency to restore permanent dependency. The active presence of narcissism throughout life led Grunberger to suggest treating it as an autonomous factor (1971). He even mooted the idea of promoting it to the status of a psychic agency.

Under the evocative title *Life Narcissism, Death Narcissism* (1983), André Green clarified the conflict surrounding the object of narcissism (whether a fantasy object or a real object) in its relationship to the ego. For Green, it was because narcissism affords the ego a certain degree of independence by transferring the desire of the Other to the desire of the One that a lethal kind of narcissism must be considered, for the object is destroyed at the beginning of this process. Rather than unpleasure, it is the “neutral” that replaces pleasure in Green’s account. In this connection Freud had proposed the metaphor of the return to the inanimate. By analogy with Freud’s analysis of masochism, which distinguished between erogenous masochism, female masochism, and moral masochism, Green evokes physical narcissism, intellectual narcissism, and moral narcissism, without suggesting any analogy between these terms.

A broad range of studies exists on Freud’s “On Narcissism,” as may be seen from the inventory in a monograph published under the auspices of the International Psychoanalytical Association (Sandler et al., 1991).

## NARCISSISM OF MINOR DIFFERENCES

In his article on “The Taboo of Virginity” (1918a) and on the subject of man’s “narcissistic rejection” of woman because of his castration complex, Freud isolated for the first time a particular reaction that he later saw as the driving force behind racism. He wrote “the practice of taboos we have described testifies to the existence of a force which opposes love by rejecting women as strange and hostile. Crawley, in language which differs only slightly from the current terminology of psychoanalysis, declares that each individual is separated from the others by a ‘taboo of personal isolation,’ and that it is precisely the minor differences in people who are otherwise alike that form the basis of feelings of strangeness and hostility between them. It would be tempting to pursue this idea and to derive from this ‘narcissism of minor differences’ the hostility which in every human relation we see fighting successfully against feelings of fellowship and overpowering the commandment that all men should love one another” (p. 199).

He returned to this idea without naming it in *Group Psychology and the Analysis of the Ego* (1921c) when discussing hostile sentiments with regard to whatever is strange: “In the undisguised antipathies and aversions which people feel towards strangers with whom they have to do we may recognize the expression of self-love—of narcissism. This self-love works for the preservation of the individual, and behaves as though the occurrence of any divergence from his own particular lines of development involved a criticism of them and a demand for their alteration. We do not know why such sensitiveness should have been directed to just these details of differentiation” (p. 102).

Not until *Civilization and its Discontents* did Freud give the notion the full meaning that it has today: “It is always possible to bind together a considerable number of people in love, so long as there are other people left over to receive the manifestations of their aggres-

siveness. I once discussed the phenomenon that it is precisely communities with adjoining territories, and related to each other in other ways as well, who are engaged in constant feuds and in ridiculing each other—Germans and South Germans, the English and the Scotch, and so on. I gave this phenomenon the name of ‘the narcissism of minor differences,’ a name which does not do much to explain it. We can now see that it is a convenient and relatively harmless satisfaction of the inclination to aggression, by means of which cohesion between the members of the community is made easier. In this respect the Jewish people, scattered everywhere, have rendered most useful services to the civilizations of the countries that have been their hosts” (1930a [1929], p. 114).

After Freud the notion entered psychoanalytic discourse without much further study. Otto Fenichel described it as a stumbling block in identification with the other that is destined to surpass hostile sentiments (1934). The idea is mentioned in other papers to illustrate incomprehension between adults and adolescents or disagreements between psychoanalysts despite their belonging to the same group. Glen O. Gabbard in *On Hate in Love Relationships: The Narcissism of Minor Differences Revisited* presented the most thorough study of it. Gabbard stresses the experience of disappointment when, in spite of the aspiration for similarity, we find differences in the loved object, and he links this disappointment to preoedipal and oedipal experiences that punctuate the processes of separation and autonomy.

With the exception of this last work, the notion has been used essentially to explain the hate relations that develop between humans or groups of humans that, by all appearances, have much in common.

## NARCISSISM, PRIMARY

Primary narcissism corresponds to the original libidinal cathexis of the ego. Later, part of that cathexis will be redirected onto objects, giving rise to the opposition between ego-libido and object-libido.

It is worth noting that Freud often spoke as often of “original narcissism” as of “primary narcissism”—the sense is the same.

In the second part of “On Narcissism: An Introduction” (1914c), Freud offered an ex post facto explanation of the nature of narcissism based on the tender attitude of parents towards their children, an attitude that embodies a “revival and reproduction of their own narcissism, which they have long since abandoned” (p. 91). As a result parents attribute every conceivable perfection to their young children.

The disturbances to which primary narcissism is prone are what allow its existence to be inferred. Among them are the effects of the castration complex, described by Freud at the beginning of the third part of “On Narcissism” as anxiety in boys about the penis and envy of the penis in the case of girls (p. 92). In opposition to Adler’s theory of masculine protest, Freud defended a psychology of repression, arguing that a precondition of repression was the establishment of an ideal, and that such an ideal was instituted during the development of the ego. As it evolved, the ego distanced itself from primary narcissism, formed an ego-ideal, and proceeded to cathect objects.

Primary narcissism is the narcissism of the suckling. Serge Lebovici (1997) points up the coextensive nature of primary narcissism and the individual’s sense of his or her own continuity. Failures of primary narcissism are responsible, in Lebovici’s view, for

precipitating the fantasy of the primal scene, and hence for feelings of being the third party. The state of primary narcissism is clearly compatible with the infant’s absence of any sense of its need for help, so well described by Freud in a note added in 1912 to his paper “Formulations on the Two Principles of Mental Functioning” (1911b). This theorization is particularly useful in understanding depression brought on by de-idealization.

## NARCISSISM, SECONDARY

Secondary narcissism corresponds to the return to the ego of the libido, withdrawn from objects. Freud described this for the first time (1914c) in relation to a state he called “paraphrenia,” which corresponded to the precocious dementia of Kraepelin or to the schizophrenia of Bleuler. Withdrawal of the libidinal investment in objects, followed by a re-investment in the ego, was considered responsible for two characteristic manifestations: lack of interest in the external world and delusions of grandeur.

Another approach to narcissism was indicated in the last section of “On Narcissism: An Introduction,” on the basis of original narcissism. The construction of an ego ideal played a central role in the psychology of

repression, conceived as a result of the conflict between instinctive drives and cultural representations. This is the narcissistic aspect of a structure of surveillance, of which Freud would complete the description in 1923, with *The Ego and the Id* (1923b). Freud in 1914 had moreover attributed the critical voices of the delusion of being watched, of paranoia, rising out of regression, to this surveillance mechanism.

Finally, the interpretation of Leonardo da Vinci's homosexuality (1910c) constituted the descriptive model of a process of identification by replacement of an object investment (the mother), and by the introjection of the qualities of this object (identification). This identification process was taken up again in "Mourning and Melancholia" (1917e), where Freud discussed narcissistic identification. He returned to it again in *Group Psychology and the Analysis of the Ego* (1921c) and finally in *The Ego and the Id* (1923b).

## **NARCISSISTIC DEFENSES**

Narcissistic defenses are psychic procedures utilized by the ego, in the case where the latter is understood as the only (or almost only) object of investment by the libido. Their function is to protect the integrity and the psychic endurance of the ego.

Precise indications of specifically narcissistic defenses are not to be found in the works of Freud. However, the concept appeared in relation to a number of topics: infantile omnipotence, idealization of the love object, paranoid projection, counter invest-

ment in the external world, the depressed person's "narcissistic" identification, the hypochondriac's overinvestment in the organs of the body, regression in treatment, and regression in dreams.

Several authors, among them Viktor Tausk (1919/1933), Michael Balint (1935/1965), Paul Federn (1928), Francis Pasche (1965), Béla Grunberger (1975), and André Green (1983), have contributed to the study of narcissism. However, it has been particularly the analysis of the pathologies of narcissism, either by the members of the Kleinian school, or by representatives of the American schools (Otto Kernberg, Heinz Kohut), which have allowed a better delineation of narcissistic defensive processes, based on an analysis of the mechanisms of denial, separation, projective identification, and pathological idealization.

In discussing narcissistic defenses, both the Freudian distinction between primary and secondary narcissism, as well as that between the normal and the pathological, must be maintained. In effect, primary narcissism is first conceived by Freud as a state situated between autoeroticism and object love; following his second theory of the psychic apparatus, it is understood as an primal state wherein the child takes itself as a love object, even before the constitution of the first objective links, raising the question of whether a state of such psychic immaturity could raise "defenses" other than of a sensory-motor sort. Besides, as Freud demonstrated, the continuum between the normal and pathological has allowed the subject to be considered to be, in a certain measure, narcissistic.

## NARCISSISTIC ELATION

The term *narcissistic elation* was coined by Béla Grunberger (1971/1979) to describe the state of prenatal beatitude, which according to him characterizes the life of the fetus: a state of megalomaniacal happiness amounting to a perfect homeostasis, devoid of needs or desires. The ideal here is bliss experienced in absolute withdrawal from the object and from the outside world. Narcissistic elation is at once the memory of this unique and privileged state of elation; a sense of well-being of completeness and omnipotence linked to that memory, and pride in having experienced this state, pride in its (illusory) oneness.

Narcissistic elation is characteristic of an object relationship that is played out, in its negative version, as a state of splendid isolation, and, in its positive version, as a desperate quest for fusion with the other, for a mirror-image relationship. It involves a return to paradise lost and all that is attached to this idea: fusion, self-love, megalomania, omnipotence, immortality, and invulnerability.

After birth, the infant continues to enjoy the proto-narcissistic existence as before, and this is reinforced by the fact that people around it, in particular the mother, meet all its needs and wishes. This state of illusion is soon compromised, however, as inevitable frustrations begin to occur. The traces of this state of elation and megalomania, based on the notions of harmony and omnipotence, nevertheless provide a source of psychic energy that will remain active

throughout life. The child, and later the adult, will seek to preserve and return to this narcissistic mode of being, notably through music, passionate love, or mystical ecstasy. Perhaps, after all, what fascinated Narcissus was the sight—beyond his own reflection—of the amniotic water, and the deep, regressive promise of happiness that it held out.

Following an initial period of elation known as the “honeymoon,” psychoanalytic treatment must succeed in bringing together the narcissistic elements of the self by integrating them into interpretations of reality: ego-libido and object-libido must arrive at a satisfactory compromise.

## NARCISSISTIC INJURY

The concept of narcissistic injury does not appear as such in Freud. Since Freud, the theoretical elaboration of narcissism and the development of new entities of psychopathology (narcissistic personalities, borderline states) has led to the creation of this concept to describe the consequences, on the narcissistic level, of a trauma to the psychic apparatus arising from internal or external factors.

It should be remarked, however, that the introduction of the concept of narcissism (Freud, 1914c) prepared the way in metapsychology for the notion of narcissistic injury, if one also takes into account the Freudian propositions concerning the development of the ego in relation to the exigencies of the reality principle (Freud, 1911b), and his ideas about infantile helplessness (*Hilflosigkeit*). On the one hand, conflicting drives, and, on the other, the object and its vicissitudes inflict a series of traumas on narcissism, whereby the anguish linked to loss and/or separation becomes structural. Thereby, birth, weaning, anality, the castration complex, and the fear of death are all prototypical phenomena that give rise to narcissistic injuries.

Further reflection on narcissism, and the post-Freudian clinic, have led to theories in which the notion of narcissistic injury occupies a central place, as well as to developments and modifications in psychoanalytic technique. In the United States, the “Self Psychology” of Heinz Kohut and the description of borderline states and narcissistic personalities by Otto Kernberg have made this category central, allowing the evaluation of psychic organization and serving as transference-countertransference guide in the course of the analysis. Heinz Kohut particularly has stressed the significance of “narcissistic rage” as a reaction to narcissistic injury: faced with the failure of the self-object, narcissistic rage would be the aggressive result of shame.

In France, Béla Grunberger considered that narcissistic injury, inflicted on the ego by the vicissitudes of a disappointed ego-ideal, is an integral part of narcissism; accordingly, this theory made narcissistic injury a pivotal notion, since the impotence inherent in the human condition constitutes, in itself and from the outset, a narcissistic injury, one that is preponderant subsequently in the dialectic between narcissism and the drives, as well as being the source of ethics and civilization. André Green, stressing the role of the object, speaks of object trauma, whose very existence is the cause of injury, calling for never-completed reparation.

The notion of narcissistic injury is useful in accounting for the rapports between narcissism, the drives, and the object. However, as critics of Kohut point out, its excessively univocal development risks de-emphasizing sexuality.

## **NARCISSISTIC NEUROSIS**

Freud proposed the term *narcissistic neurosis* as a designation for manic-depressive psychosis insofar as it was characterized by the withdrawal of libido onto the ego. German psychiatric nosology subscribed to a clinical distinction between psychoses and neuroses, but at the end of the nineteenth century only the psychoses were clearly defined, while the neuroses were still a rather disparate category.

Little by little, in the drafts Freud included with his letters to Wilhelm Fliess (1950a) and in a series of articles (1894a, 1895b, 1895c, 1896a, 1896b) contemporary with the *Studies on Hysteria* (1895d), Freud adopted a distinction between the “actual neuroses,” related to somatic conditions, and the “psycho-neuroses” (or “neuro-psychoses”), related to mental conflicts. The Schreber case (1911c), in which homosexuality played an essential part, led him to point up the role of narcissism (1914c) in the etiology of illnesses like Schreber’s. The symptoms in such cases indicated a withdrawal of libido from objects in the outside world. This libido was then redirected onto the ego, causing delusions of grandeur.

Thereafter, Freud divided the psychoneuroses into transference psychoneuroses and narcissistic psychoneuroses, the latter corresponding to the psychoses. Only later, after the major theoretical revision occasioned by the introduction of the death instinct (1920g), and of a more radical description of the mental personality, now seen as made up of the id, the ego, and the superego (1923b), did it become possible for Freud to sum up the difference between neurosis and psychosis in a much simpler way: neurosis meant conflict between the ego and the id, while psychosis resulted from an analogous difficulty in the relationship between the ego and the external world.

While acknowledging that much remained unknown concerning the origin and role of the superego, his theory of repression led Freud to examine conflict between ego and id. Meanwhile he defined narcissistic neurosis as the outcome of a struggle between the ego and the superego. He stressed that melancholia was a

prime example. All pathologies arising from conflict between the ego and the superego were to be categorized as “narcissistic psychoneuroses.” The identification of this group of illnesses lying at the frontier between neuroses and psychoses cleared the way for much later discussions of borderline states, drug addiction, and for the sort of approach to psychosomatic illness promoted by the so-called Paris school.

Melancholia qualified as narcissistic psychoneurosis par excellence: a state where a “pure culture of the death instinct” supports a superego at war with the ego. “Complete and unrestricted cannibalism” is fueled by “unrestricted narcissism” (Abraham, 1924, p. 488): the melancholic is unaffected by the interests of the object, and the destruction of the incorporated object is pursued with no scruple. Such are the terms used by Karl Abraham, and there can be no doubt that Melanie Klein had them in mind later. At the same time Abraham evoked the useful idea of a more restrained narcissism, an impulse to partial incorporation that shows a degree of respect for the object—a picture demonstrating how variously having and being can be melded.

Francis Pasche (1965) sought to clarify the issue of depression by opposing an antinarcissism to narcissism, and grounding this polarity in the dualism of the life and death instincts. He called antinarcissism a “tendency whereby the subject renounces a part of himself” The idea suggested itself to him on the basis of a feeling reported by patients, for whom “the object is not formidable only because it is felt to be destructive and destructible element, but also because it can be experienced, by virtue of its very presence in the subject’s emotional world, as a thief of vital forces and a drainer of energy.”

Narcissism and antinarcissism, Pasche argued, were derivatives both of Eros and Thanatos. Clinical experience with psychoses invariably showed that psychotic alienation was experienced subjectively in terms of submission to an external will. Reconstruction of early mother-child relationships supported the conclusion that “the first cathexes would imply not only fusion and interpenetration, but also distinction and separation, with the resulting emergence, alongside the wish to reject and the wish to be absorbed, of a wish to confirm the object in some sense in its rightful place.” Hence, the infant who drinks the mother in with its eyes, or sets her on a pedestal and invests her with the authority that is her due.

Narcissism and antinarcissism constitute a dynamic structure, a permanent combination in which the instincts are deeply rooted.

## **NARCISSISTIC RAGE**

A reaction to narcissistic injury in the context of narcissistic pathologies, narcissistic rage is to narcissism as aggression is to Oedipal desire.

As a descriptive term, *narcissistic rage* was first employed by Heinz Kohut and became a significant concept in psychoanalysis about 1972, with publication of his *The Analysis of the Self*. Derived from analyses of narcissistic personalities, the term also reflected Kohut's broader interests in literature, culture, and civilization.

Narcissistic rage can include phenomena as different as slight annoyance, paranoid rancor, and catatonic fury. Linked to loss of control, it signals the existence of some unresolved psychic injury of an archaic, narcissistic character. Such rage aims to repair an injustice, a narcissistic wound unrelieved so long as shame persists and the witness to it is not destroyed. Thus, the need for revenge in the face of ridicule, disdain or contempt, represents an expression of narcissistic rage. Destructiveness is linked to this kind of narcissistic defect, not a reaction to a primary instinct.

Aggression toward another person (or mental representation of one) should be distinguished from narcissistic rage directed at a *self-object*, Kohut's term for an archaic object that must not be experienced as a disappointing or failing. Although aggressivity ceases when the obstacle is lifted, narcissistic rage cannot be quelled.

As a descriptive term, the concept of narcissistic rage gained considerable acceptance in psychoanalysis. Kohut's broader view of narcissism as a separate line of development, however, though much discussed, won less support.

## **NARCISSISTIC TRANSFERENCE**

*Narcissistic transference* is a post-Freudian term introduced by Heinz Kohut, in the context of his theory of narcissism, to refer to a group of clinical phenomena observed during analytic treatment.

For Freud himself, transference concerned the transposition of object relationships; transference and narcissism were such contrary ideas for him that the expression *narcissistic transference* would have been meaningless in his eyes: "Observation shows that sufferers from narcissistic neuroses have no capacity for transference or only insufficient residues of it" (1916–17a [1915–17], p. 447).

One of the first authors to take narcissism into account in the evolution of the treatment was Béla Grunberger, in 1956. Grunberger deemed narcissism one of the motors of the analytic cure, and this even among neurotics. Out of fidelity to Freud's thinking, he nevertheless refrained from using the term "narcissistic transference," and spoke only of a "narcissistic analytic relationship." In this context he described certain ploys on the part of the patient, as for example "using the analyst to create a double [or mirror] image of himself" or projecting his ideal ego onto the analyst, which would later be evoked by Heinz Kohut.

Kohut brought narcissism into relation not with the ego but with a broader and less limited entity, the self. At the same time he introduced the idea of a line of development of narcissism paralleling the development of object-cathexes and interacting with it. Narcissism and object-love were thus no longer in contradiction with each other, but complementary, and it became possible to speak meaningfully of narcissistic transferences.

In *The Analysis of the Self* (1971), Kohut describes several aspects of such transferences. "Mirror transferences" correspond to a remobilization of the idealized "grandiose self" and imply the following demand with respect to the other person: "I am perfect and need you to confirm it." A mirror transference easily gives rise to a feeling of boredom or impatience in the analyst, whose otherness it does not acknowledge. Such transferences are of three types (pp. 114–16). The most archaic is "merger transference," in which the patient strives for an omnipotent and tyrannical control over the analyst, who is experienced as an extension of the self. In an "alter-ego transference," the other is experienced as very similar

to the grandiose self. Lastly, in the case of mirror transference “in the narrower sense,” the analyst is experienced as a function serving the patient’s needs. If the patient feels recognized, he will experience sensations of well-being associated with the restoration of his narcissism. An “idealizing transference” is defined by Kohut as the mobilization of an idealized and all-powerful parent imago (p. 37), and it is encapsulated in the sentence “You are perfect, but I am part of you”; it is correlated with a struggle against feelings of emptiness and powerlessness. Kohut’s notion that certain people are cathected as parts of the self, integrated into the mental functioning of the patient himself, led him to speak of “self-objects” and to describe narcissistic transference as based on an idealized self-object.

Kohut’s approach has been criticized on the grounds that it first relegated the instincts and the Oedipus complex to the background and then eliminated them completely.

## **NARCISSISTIC WITHDRAWAL**

The term *narcissistic withdrawal* is used to describe the turning back of the individual’s libido from the object onto themselves. Narcissistic withdrawal is what occurs in the hallucinatory regression of dreams. This term is also used in pathology, where narcissistic withdrawal is differentiated from regression in the dream-work and must be studied in relation to the ego. Finally, in the context of psychoanalytic treatment, following Donald Winnicott (1954), regression, as a process of change, can be differentiated from withdrawal, a state that is not very productive. Thus narcissism, inseparable from the notion of regression, can be considered as a movement, with a libidinal trajectory from subject to object followed by a return of the object-cathexes to the subject.

Sigmund Freud had referred to narcissism several times before devoting a whole study to it in 1914: “On Narcissism: An Introduction.” Here he broached the notion of withdrawal: “The condition of sleep, too, resembles illness in implying a narcissistic withdrawal of the positions of the libido onto the subject’s own self, or, more precisely onto the single wish to sleep. . . . In both states we have . . . examples of changes in the distribution of libido that are consequent upon a change in the ego” (p. 83)—the ego that is manifested in the dream appearance. This withdrawal is also found in illness or pain, where libidinal cathexes are withdrawn from the object to the ego. Freud returned to this notion of regression in “A Metapsychological Supplement to the Theory of Dreams” (1916–17 [1915], where he wrote: “We distinguish two regressions—one affecting the development of the ego and the other that of the libido. In the state of sleep, the latter is carried to the point of restoring primitive narcissism, while the former goes back to the stage of hallucinatory satisfaction of wishes” (pp. 222–223). In “Mourning and Melancholia” (1916–17g [1915]), written the same year, he took up the study of the object, showing that following a disappointment linked to the object the latter is decathected of its libidinal charge, which flows back onto the ego in a movement of narcissistic regression.

In “La tendance convergente de la regression narcissique” (The tendency towards convergence in narcissistic regression; 1996), César and Sara Botella insist on “the unifying instinctual quality of narcissistic regression, for which the model is the dream-work.”

Alongside this positive approach towards narcissistic regression, we can consider the case in which the subject appeals to narcissistic withdrawal as a defensive solution. In *Life Narcissism, Death Narcissism* (1983/2001), André Green viewed narcissistic withdrawal as “yet another lure. Freud showed he was aware of this in his description of ‘Libidinal Types’ (1931). The narcissistic character type is more independent, but also more vulnerable” (p. 101). And indeed, Freud believed that evolution towards psychosis was possible in this type of personality. Green added: “The disinvestment of the object and narcissistic withdrawal expose the subject’s ego to a very threatening type of anxiety: narcissistic anxiety” (p. 101). He viewed this withdrawal as a precarious refuge that comes into being as a defense against a disappointing or untrustworthy object. This is found in studies of narcissistic personalities or borderline pathologies by authors such as Heinz Kohut or Otto Kernberg.

In conclusion, it can be said that although Freud uses the notion of withdrawal as the equivalent of narcissistic regression, in the contemporary literature the term *narcissistic withdrawal* is instead reserved for an ego defense in pathological personalities.

## **NARCO-ANALYSIS**

The term *narco-analysis* is derived from the Greek word *narkē* (meaning “anesthesia” or “torpor”) and is used to describe a diagnostic and psychotherapeutic technique that uses psychotropic drugs, particularly barbiturates, to induce a stupor in which mental elements with strong associated affects come to the surface, where they can be exploited by the therapist.

Narco-analysis appeared in the mid-1930s as a result of the discovery of quickly acting barbiturates with a short-term effects. The term *analysis* is used in Pierre Janet’s sense of a process that, by means of a partial dissolution of consciousness, undoes the complex syntheses of waking mental life and accesses mental content that is more automatic. Other terms have also been used, such as “narco-synthesis,” “chemical psychoanalysis” and “psychosomatic narco-analysis.”

The procedure was mainly intended for neurotic and psychosomatic patients, and it met with a certain success in treating traumatic pathologies and conditions charged with strong emotions. Applications of the technique in forensic medicine have been questioned. Narco-analysis has been used mainly in Anglo-Saxon countries.

Similar to narco-analysis is the use of other substances, such as amphetamines or psychodysleptics, with a view to creating a shock (amphetamine shock) that lifts inhibitions and reticence and promotes the emergence of major transference phenomena. In France these procedures have been used by Jean Delay at Sainte-Anne Hospital, and the good results reported related mainly to cases of hysterical conversion pathologies, hypochondria, and alcoholism. The psychoanalysts working with his department presented and commented on the effects of this treatment (Green, 1961).

**NATIONAL PSYCHOLOGICAL ASSOCIATION FOR PSYCHOANALYSIS**

The National Psychological Association for Psychoanalysis (NPAP) was first organized in 1948 by Theodor Reik and a small group of student analysts. In 1950 it was incorporated as a educational membership association, under the laws of the State of New York. It is comprised of a training institute and a membership organization. NPAP is committed to training individuals from within the tri-disciplines of medicine, psychology and social work as well as other qualified persons who possess a master's degree in the humanities.

Theodor Reik immigrated to the United States in June of 1938 and settled in New York City. Because he possessed a PhD in psychology, rather than a degree in medicine, he was denied full membership in the New York Psychoanalytic Society. When Freud (1926e) wrote *The Question of Lay Analysis*, in defense of Theodor Reik, he defined the philosophy to which NPAP has been committed since its inception. That is, not merely that a medical degree was not necessary for the practice of psychoanalysis but that restricting training exclusively to those who had such a degree evidenced a misunderstanding of what psychoanalysis was and could become.

Reik was most known for his many publications, and particularly for *Listening with the Third Ear* (1956). His small group of students, from outside the medical field, has grown to number, as of 2000, more than 350 members and more than 175 enrolled students. During its history, NPAP has significantly influenced psychoanalytic training, particularly in New York City. A majority of the founding members of such organizations as The Institute for Psychoanalytic Training and Research (IPTAR), The New York Freudian Society, and the New York Center for Psychoanalytic Training, were trained by NPAP. Many organizations outside New York City also trace their origins to NPAP.

By supporting groups and organizations dedicated to keeping psychoanalytic training open to qualified individuals, NPAP has been a leading force in the Uni-

ted States for the training and recognition of non-medical psychoanalysts. Although committed to its Freudian tradition, NPAP also encompasses object relations theorists as well as self-psychology theorists. Its institutional structure is democratic, as evidenced by its allowing student-candidates to choose their own analyst and control analysts from among the entire membership list. Training analysts are not permitted to report back to the institute. The training requirements are: (1) the completion of twenty-six courses, (2) a minimum of a thrice-weekly analysis for four hundred and fifty sessions, (3) one hundred and fifty sessions of control-analysis supervision and (4) case presentation, before a board of five members. Upon graduation all members are approved as training analysts and control analysts.

Since the 1960s NPAP has sponsored a referral service, The Theodor Reik Clinical Center for Psychotherapy, offering low-cost psychoanalysis and psychoanalytic psychotherapy to qualified persons. The Association publishes *The Psychoanalytic Review* as well as the in-house journal *News and Reviews*. It has an extensive psychoanalytic library and holds monthly scientific meetings.

NPAP is a member of the World Federation for Mental Health and a founding member of The Council of Psychoanalytic Psychotherapists and The International Federation for Psychoanalytic Education.

**NEED FOR CAUSALITY**

According to Freud, no innate need for causality exists in the human mental apparatus, rather, such a need is

itself the result of a practical interest (*praktisches Interesse*).

Regarding the awakening in the infant of the impulse to investigate (1905d), he emphasizes that the interest that impels the infant to research is not theoretical (*nicht theoretisch*). This means that it is has no relation of the drive for knowledge—where it is precisely a matter of establishing origins—but rather that it is practical and is related in this instance to egoistic drives (*eigensüchtige Triebe*), that is, to the ego-drives. These drives, in fact, claim the entire love of the parents and, in order to guard against the danger of the appearance of younger siblings, will force the activity of thought in the direction of investigation. Likewise, in reference to primitive peoples, Freud thought that “What released the spirit of enquiry in man was not the intellectual enigma [of death], and not every death, but the conflict of feeling at the death of loved yet alien and hated persons” (1915b, p. 293).

Freud did not deny that causality could at a given moment create the object of a need, but he based it on other more primitive needs or gave it an origin, in the above case the conflict of ambivalence. The enigma, as Freud saw it, was a product of the urgency of life (*Lebensnot*), which emphasizes both its restrictive character and the fact that it does not depend on a desire to know, but rather on the necessity of knowing as a means of self-preservation.

Once this origin was established, Freud emphasized the need for causality, but more often it took the form of illusion insofar as its only object could be a unique exhaustive explanation. “It is enough for our need to discover causes (which, to be sure, is imperative) if each event has *one* demonstrable cause” (1939a [1934–1938], p. 107). This unitary fantasy is the root of every *Weltanschauung*, defined as an “intellectual construction which solves all the problems uniformly on the basis of one overriding hypothesis, which, accordingly, leaves no question unanswered and in which everything that interests us finds its fixed place. It will easily be understood that the possession of a *Weltanschauung* of this kind is among the ideal wishes of human beings” (1933a [1932], p. 158).

He had, regarding the dynamics of the transference (1912b), noted that “in contrast to what ordinarily holds good for the real world, people prefer to be satisfied with a single causative factor” (p. 99n) and already in 1909, in *Five Lectures*, he spoke of fact that “what

seems to be our innate craving for causality declares itself satisfied with a single psychological cause” (p. 38). The question of a need for causality is, for Freud, mired in the necessity to defend intellectualist idealization. The need for causality that motivated, at each step, his own research was linked together with and humbled by the resistance of reality and, in his case, clinical experience.

The position of Piera Aulagnier on the question of causality is different from Freud’s because she starts with the experience of a dispossession of the search for causes and a negation of this need in psychotics. The need for causality, a notion that this author attributes to Ernst Cassirer, is merged in her work with a need for identification. The questioning of the child does not inquire so much about the threat of the birth of younger sibling, but rather the desire of the parents who were able to cause the child’s own birth. Far from being abstract or superfluous, causality bears upon desire: the wish to know what causes the mother’s desire (once the child stopped trying to be its unique object) and to know what causes the world to be as it is, necessitates a “contriving from what seems true (which does not necessarily mean what is true), from meaning, even while there is a risk of the irruption of the non-meaning and the not-known of desire” (1967). Making sense seems to be the work of the I, and also what makes it emerge as such, and in such a way that “the causal explication becomes, for thought, part of necessity” (1979).

Aulagnier found that in psychosis, before the delusional reconstruction, it is precisely the need for causality that is confronted with “the collapse of the function of signification” (1979). The delusion, in turn, has the function of creating a “reasonable interpretation of the violence suffered.”

In this understanding, the creation of meaning by the I implies in effect that it is capable of thinking of itself as a being that is not just the reduplication of what preceded it, that has had a history of its own and is going to know a future full of changes. The need for causality, for from being reducible to a single cause, encompasses the multiplicity of all the causal events of the past. Conversely, in psychosis, causality is self-created, a pure repetition of what has already been. Aulagnier writes, “The fantasy of self creation that we see in certain forms of psychosis is most often able to be decoded, when it is looked at closely, as a fantasy that attributes to the subject the power to engender

not only its own past, but all of the past, not only its own origin, but the origin of everything” (1984). In this case, the need for causality does not disappear, but is limited to a unique cause that is the subject itself.

## **NEED FOR PUNISHMENT**

The need for punishment is an internal need of some individuals to seek out painful or humiliating situations and to take pleasure in them. For Laplanche and Pontalis (1973), basic to such behavior is a link to the death drive.

Freud referred to the need for punishment for the first time in *The Interpretation of Dreams* (1900a) in discussing “punishment dreams.” Such dreams are the fulfillment of an unconscious desire to be punished for a suppressed or forbidden impulse.

The need for punishment directs the sadism found in all libidinal urges toward the ego. Feelings of guilt can develop only when the subject, in an ambivalent

state in which love and hate both subsist, attempts to find an equilibrium. When repression leads to neurosis, the libidinal tendencies are transformed into symptoms, and aggression becomes a feeling of guilt.

It is always possible to distinguish the feeling of guilt as such from the need to atone. The first expresses a yearning to refind the (annihilated) lost object, while the second expresses a need for punishment after the subject repeats the act. The feeling of guilt is therefore in the service of an unsatisfied object-libido; the need to atone is related to eroticized destructive drives and is directed against the ego. The need for punishment is a consequence of the feeling of guilt, even though they seem closely linked and have common phylogenetic roots.

Suffering and inclinations toward self-punishment are expressions of a tendency toward self-annihilation. This tendency reaches its culmination in the suicide of a melancholic, whom the need for punishment comes to dominate to such an extent that he could commit a real crime solely to justify his torment and obtain relief by atonement.

Many authors do not clearly distinguish between the need for punishment and other notions such as moral masochism and negative therapeutic reaction, which they consider to be part of the need for punishment.

## NEGATION

The term *negation* (*Verneinung*) denotes a mental process in which the subject formulates the content of an unconscious wish in a negative form. The content of the wish finds expression in consciousness, yet the subject continues to disown it.

This concept first appeared in Freud's work in connection with the analysis of the "Rat Man" when the patient produced an association having to do with the death of his father but immediately "rejects the idea with energy" (1909d, p. 178). Yet Freud's main discussion of the topic appears in "Negation" (1925h), where he sets forth a theory of negation that is close to being a theory of forms of language or a theory of judgment.

Freud posits two distinct processes of negation: one involves the rejection of a thought, the other the acknowledgment of a disappointed expectation. The first kind of negation, involving rejection, is the kind encountered in the "Rat Man" case. Another example is when a patient refuses to believe that the woman he has just dreamed about is his mother: "You're going to think it was my mother," he will say to the analyst, "but it wasn't my mother." This negation may be interpreted to mean, "I reject the idea that this person could be my mother because I dislike that idea." Negation is a rejection of an unpleasant idea by means of the pleasure principle alone. The process of projection is already at work in the utterance "You're going to think it was my mother," for in this way the patient projects into the mind of the analyst a thought that is in fact the patient's.

Negation as a defense mechanism is more supple than repression in that it preserves the thought content that repression would render unconscious. The defensive aspect of the mechanism is confined to the distancing achieved by means of the negation, which allows the patient to avoid shouldering the disagreeable implications of a thought that has successfully formed.

In addition to this first kind of negation, Freud describes a second type, namely a judgment by a psyche that fails to encounter in the outside world a satisfying mental representation of what it desires. The psyche is then obliged to arrive at the negative conclusion that what it has been seeking in external reality is indeed not present. This type of negation thus amounts to an assertion of absence. In making this assertion, the psyche recognizes the independent existence of the outside world and, thus achieving effective reality-testing.

The idea of negation lies at the center of a very dense conceptual nexus within the Freudian model. Several other terms are closely linked to *Verneinung* (negation) and overlap with it in meaning to a greater or lesser extent. Occasionally Freud used the Latinate German term *die Negation* to refer to a basic trait of the "system Ucs.," in which there is "no negation" (1915e, p. 186). This enabled him to define the system of the unconscious as prior to intellectual judgment. By contrast, the Germanic word *Verneinung*, embracing as it does both negation as a mental process and negation as a grammatical form, presupposes a psychic agency capable of making judgments.

In Freud's usage there is a wider difference in meaning between *Verneinung* and *Verleugnen*, which is translated into English as either "denial" or (following the preference of the editors of the *Standard Edition*) "disavowal." In the process of disavowal, the subject refuses to embrace the psychic consequences of something perceived. Thus the "Wolf Man" (1918b [1914]) said, in effect, "I see that a woman does not have a penis, but I deny any force to this observation, and what is more, I shall continue to believe that she has a penis." In disavowal, a reality judgment produces a conclusion ("A woman does not have a penis"), but this conclusion is a dead letter having no impact on the psyche. Thus the recognition of a reality ("[I see that] a woman does not have a penis") is juxtaposed to a wish ("[I want] a woman to have a penis") without being integrated together. In both disavowal and negation, the subject avoids responsibility for a disagreeable thought. The two differ, however, in that disavowal is rejection of a disagreeable perception, whereas negation is the acceptance of a wish.

Lastly, the term *foreclosure* (French *forclusion*) was introduced by Jacques Lacan to render Freud's use of the term *Verwerfung* in connection with the psychotic

mechanism of “expulsion of a fundamental ‘signifier’” (Laplanche and Pontalis, 1973, p. 166).

The theory of negation is no doubt an area where the psychoanalytic theorization of mental processes comes very close to linguistic concerns, especially to the study of utterances. From a linguistic standpoint, one might say that negation in the sense of rejection is equivalent to a polemical negation (as in, for example, “For me, this woman in my dream is not my mother”), whereas the recognition of absence—a negation that can be expressed as a reality judgment—is equivalent to a “simple” negative report, much like a statement such as “I have not had a dream for a long time.”

Clear boundaries need to be drawn between negation, absence, and the idea or representation of absence. These distinctions, in broad outline, are as follows. In all cases, negation is directed at an ideational content. This content, in the context of the theory of the hallucinatory satisfaction of a wish, emerges as a consequence of the absence of the wished-for object. This absence obliges the subject to hallucinate, to represent, the missing object. Absence is thus a precondition of the emergence of the representation. In this regard, absence is distinct from negation, which is an operation affecting an ideational content. As for the representation of absence, it arises only after the capacity for judging reality has been established, when the subject is able to articulate the gap between what he wants and what he sees.

## “NEGATION”

Written by Freud after “A Note upon the ‘Mystic Writing-Pad’” (1925a), this article was first published in the review *Imago*.

Seen in its clinical context, negation dramatizes a situation of interpretative conflict. The patient first produces the interpretation, which he imputes to the psychoanalyst, claiming that it is false. Negation is thus related to a dialogical situation: “Now you’ll think I mean . . . but really I’ve no such intention.” (1925h, p. 235).

Returning to a distinction he had established in the analysis of the “Rat Man” (“Notes upon a Case of Obsessional Neurosis,” 1909) between the pure “ideational content” (“Notes,” p. 176) and the positive or negative judgment in which it is incorporated, Freud says that the contribution of the unconscious to knowledge consists in the access it grants us to the repressed content. This knowledge of the repressed content does not require a lifting of repression. The dichotomy is thus displaced, and the pair of opposites affirmation/negation is eclipsed by the opposition between the affective and the intellectual. “[I]ntellectual acceptance of the repressed” (1925h, p. 236) leaves the process of repression intact, since this latter consists in a process of separation. But isn’t the phrase “intellectual acceptance” a contradiction in terms? The

compromise in which negation consists thus seems to make it possible, if not to lift the repression, at least to uncover the repressed content.

Over and above registering the content, the function of judgment is, Freud states, to produce “decisions” (*Entscheidungen*). Taking up the philosophical distinction between judgments of attribution and judgments of existence, Freud describes two levels of psychic working-through. The first level consists in attributing a good or bad quality to something, and is linked to the instinctual impulses that drive the original pleasure-ego, which “wants to introject into itself everything that is good and to eject from itself everything that is bad” (p. 237). The decision of judgment thus plays the decisive role in operations determined by instinctual factors, swallowing and spitting—operations that establish the first distinction between inside and outside. Freud’s insistence here on the instinctual dimension of negation met with a certain reservation on the part of Jean Hyppolite: “There is not yet any judgment in this moment of emergence; there is the first myth of inside and outside.” So we might think in terms of a first evaluation that, when it is positive, leads the object to disappear within an enriched pleasure-ego, rather than an operation of judgment bearing on an external object.

In order for the second level of judgment to intervene and decide whether the object actually exists or not, a certain mediation is necessary—that of representation, attesting to the reality of the represented. The definition of the judgment of existence thus ties in with the notion of reality-testing and rests on the occurrence of a cut that is linked with the loss of the primal objects. However, the judgment of existence cannot be defined as a mere process of thought, because it is related to a motor process that “puts an end to the postponement due to thought . . . and leads over from thinking to acting” (p. 238).

In counter-distinction to the theme put forward in “Moses and Monotheism: Three Essays” (1939 [1934–38]), with its emphasis on the cut between the sensory and the intellectual domains, the study of negation invites us to see the processes at work in sense-perception as lying at the very heart of intellectual operations: tactile exploration (*tasten*) and the fact of tasting (*verkosten*) small perceptual samples, which endows the processes of thought with a two-phase temporality, made up of advances and retreats. Should this participation of two aims be understood in terms of rhythm,

or related to the opposition between Eros, which upholds affirmation, and Thanatos, which upholds negation?

The last section of Freud’s text returns to the topographical question: Negation, unknown at the level of the unconscious, needs to be situated on a secondary level, and we can gain access to it only by way of the symbol. The study of the interrelation of oral instinctual motions and the establishment of negative and affirmative behavior has been further investigated in the works of René Spitz.

## NEGATIVE CAPABILITY

Wilfred Bion, having discovered the importance of the mother’s (and by association, the analyst’s) capacity to tolerate the infant’s (and patient’s) projective identifications, sought a source for this tolerance. He reasoned that in analysis, the analyst must possess the capacity for patience and be able to have faith that in time he will be able to find the “selected fact” (Henri

Poincaré) which unites the apparent randomness of the analysand's associations. *Negative capability* is the capacity to tolerate frustration because of the faith that meaning can ultimately be found.

Bion associates it with the capacity of the "Man of Achievement," following a passage in Keats which Bion often cited: "I had not a dispute but a disquisition with John Dilke on various subjects; several things dove-tailed in my mind, and at once it struck me what quality went to form a Man of Achievement, especially in Literature, and which Shakespeare possessed so enormously. I mean Negative Capability, that is, when a man is capable of being in uncertainties, mysteries, doubts, without any irritable reaching after fact and reason" (Bion, 1970).

Negative capability and the man of achievement were concepts that prefigured Bion's later idea of transformations in "O," by which he meant a domain that is beyond sensing, imagining, or knowing. One just becomes "O." In order to achieve a resonance with this unknowable domain either within oneself and/or in relationship to the other as subject, one must have patience that clarity will ultimately arrive with the destined selected fact and that coherence will emerge.

Bion was thus suggesting, in his anticipation of post-modern non-determinism, that the analytic field bears more resemblance to chaos, beta elements, "thoughts without a thinker," "things-in-themselves," noumena, than they do to deterministic concepts such as drives, or instincts, or the like. Consequently, the analyst who is to become an "analyst of achievement" must be able forswear knowing or having to know, so that he can be free to intuit and ultimately to realize.

Bion later seemed to link negative capability with reverie, which means the acceptance of and surrender to a state of ultimate timeless receptiveness without desire, memory (preconceptions), or the need to understand—just to be there with the analysand. This state of mind and of the receptivity associated with it allows the analyst to be all the more open to his own psychic reality (internal world), where his intuition about the analysand's experiences with him and of him are directly felt.

## **NEGATIVE HALLUCINATION**

Negative hallucination is the active erasure of a perception; it produces a gap in reality, or a vague impression of unreality.

The term first appeared in "Psychical (or Mental) Treatment" (Freud, 1890), an article relating to hypnosis. Freud wrote that it was possible to suggest to a hypnotized subject that he or she not see a person or thing that would be present to the subject upon awakening; in such cases the object appears to be "thin air" (p. 297). Freud borrowed this notion from Hippolyte Bernheim, with whom he studied to perfect his hypnotic technique.

Reading Freud's first references to hypnosis and hysteria, or *The Psychopathology of Everyday Life* (1901), one might be inclined to link negative hallucination to repression involving not thought, but perception. Indeed, early in his work Freud did not theorize the more archaic mechanisms; for lack of these, he spoke in terms of massive forms of repression (rejection of reality, primary repression, etc.). Thus, according to Freud in "Delusions and Dreams in Jensen's 'Gradiva,'" (1907 [1906]), Norbert Hanold, the hero of Wilhelm Jensen's story, having repressed the totality of his love life, suffers from a propensity to negative hallucination that paves the way for hysterical delusions. Freud also evoked a form of hysteria, hysterical terror that is induced by major traumas that erase lived impressions and can produce "gaps in the psyche" as the origin of a psychosis.

Present in outline here is a more specific conception of negative hallucination, later formulated in "A Metapsychological Supplement to the Theory of Dreams" (1916–1917 [1915]); it posits that negative hallucination has a sort of logical anteriority relative to positive hallucination. Freud pursued this idea in 1924 in relation to hallucinatory confusion, speculating that when an unbearable reality cannot be perceived, a delusion appears to close the perceptual breach.

Among Freud's successors, Sándor Ferenczi (1929) was most active in developing the idea that psychosis is constituted in two phases. In his view, the first phase

of negative hallucination is a narcissistic protection against the traumatic influx of excitations, while the second phase is the compensatory production of positive hallucinations or delusions. More recent authors (Margaret Mahler, Frances Tustin) have instead focused on the massive forms of negative hallucination of the external world in the severe psychoses.

From 1977 to 1994, André Green reexamined negative hallucination and gave it an important place in theory and clinical practice. In his view, the mother's negative hallucination is a necessary condition for the child's ideational abilities. It is the blank screen (a theme borrowed from Bertram Lewin), the canvas on which representations are registered. In the child's representational process, the mother's negative hallucination is registered as a border, or frame for the process. Green used the example of the famous hallucination of the "Wolf Man"; the hallucination of the severed finger thus forming the connection between this process and the borderline states between neurosis and psychosis. In recent work, Green proposed a mechanism for negative hallucination in response to objections that had been raised about the scope of the concept; negative hallucination occurs when there is a convergence of quantities of excitation coming from the interior and the exterior, between a traumatic trace and an actual perception that reactivates it.

Following Green's lead, other authors have returned to this notion. In "Nouveaux développements sur l'hallucination négative et la représentation" (1992; New developments on negative hallucination and representation), François Duparc examined Freud's references to it, arguing that beyond hysterical repression or the early signs of psychosis, a close connection between negative hallucination and denial can be grasped from many of Freud's texts. For instance, in "Some Psychological Consequences of the Anatomical Distinction between the Sexes" (1925), Freud wrote: "[W]hen a little boy first catches sight of a girl's genital region, he begins by showing irresolution and lack of interest; he sees nothing or disavows what he has seen, he softens it down or looks about for expedients for bringing it into line with his expectations" (p. 252). Denial is posited as a means of attenuating perception, a defense that is less costly, in terms of counter-cathetic energy, than the urgent, transitory suppression involved in negative hallucination, a more primitive mechanism that attacks the subject's connection with reality. In order to avoid the return of what has been

refused, structures that transform reality into denial of reality—the origin of all sorts of pathologies. Duparc thus linked negative hallucination to the lateral cathexis of fetishism, to motor escape in manic defenses and allergies, and to chemical escape in substance abusers. He described different modes of negative hallucination that depend on the primal motor forms used to construct white noise, the screen that makes it possible to negate perception.

## NEGATIVE THERAPEUTIC REACTION

The expression "negative therapeutic reaction" is used to describe a situation in clinical practice wherein there is an exacerbation of the patient's symptoms following a correct series of interpretations. According to Sigmund Freud, this phenomenon was caused by unconscious feelings of guilt, as seen in primary masochism, which he ultimately linked to the death drive. The negative therapeutic reaction has also come to be regarded as an essential key to understanding the limits of ego functioning.

Freud described the negative therapeutic reaction in *The Ego and the Id* (1923b) as an "inverted" reaction,

the patient preferring to suffer than be cured: “The need for illness has got the upper hand in them over the desire for recovery” (p. 49). For Freud this was the expression of a feeling of guilt that found its satisfaction in the state of illness and sought punishment through suffering. This feeling of guilt is difficult to bring to light, because it remains “silent” for the patient, who does not feel guilty, but rather ill. It manifests itself in a resistance to being treated and Freud regarded it as very difficult to overcome.

In “The Economic Problem of Masochism” (1924c), Freud emphasized the fact that the way the unconscious feeling of guilt is satisfied is directly related to the subjective benefit brought by the illness: “The suffering entailed by neuroses is precisely the factor that makes them valuable to the masochistic trend” (p. 166). He thus contrasts the sadism of the superego, which is usually conscious, with the masochism of the ego, which generally remains unconscious. He proposes replacing the expression “unconscious feeling of guilt” with that of “need for punishment.”

In “Analysis Terminable and Interminable” (1937c), Freud linked the negative therapeutic reaction, ultimately, to the workings of the death drive, as the phenomenon of resistance to the cure could not be explained as a mere function of the pleasure principle.

Thus, after the second topic, whenever Freud described the negative therapeutic reaction, he emphasized the need for self-punishment, the severity of the superego and the masochism of the ego. All the self-hatred inside these subjects, driven as they are by a logic of despair, reflects a compromise between an unquenchable desire for vengeance and the need to protect the object from the hostile desires directed against it. The conflict between love and hatred is here predominant, and “if love is always uncertain, hatred is always sure” (Green, 1990), with the result that these subjects do everything to ensure that the form of sado-masochistic relation that they have chosen can be perpetuated for as long as possible.

Thus, the new theorization of the unconscious feeling of guilt that the second topic makes possible offers a logical explanation for the status of suffering: displeasure for one system (the ego), and pleasure for another (the superego); ipso facto, it provides us with a precise economic definition of the negative therapeutic reaction. If the death drive essentially works in

silence and is observable only in a form interwoven with the life instinct, the negative therapeutic reaction, through the notion of a cruel and severe superego, and especially through the idea of primary and secondary masochism, offered Freud the possibility of giving a precise clinical form to this speculation. It is, indeed, observable in the process of treatment and thus can in certain conditions be analyzed.

Psychoanalysts have often used the expression negative therapeutic reaction descriptively, to designate the forms of resistance to change that are particularly difficult to overcome in treatment. Jean-Bertrand Pontalis (1981), following several other authors, has criticized the attitude that too easily attributed the reasons for the failure of treatment to the psychic structure of the patient, thereby over-hastily freeing the analyst from their own therapeutic responsibilities. The struggle must not be abandoned in the face of the silent work of the death drive, that “force which is defending itself by every possible means against recovery and which is absolutely resolved to hold on to illness and suffering” (Freud, 1937c, p. 242).

Pontalis has emphasized how often the negative therapeutic reaction has been invoked by analysts to justify their sense of discouragement and how much it needs, in such cases, to be understood as “[their] reaction to those who cause their method to fail merely by saying no.” The analyses considered as failures should in fact be understood in relation to the particularities of the transference and counter-transference.

Some authors have attempted to reply to these questions. For Joan Rivière, it is by means of a sort of “self-sacrifice” that these patients refuse to be cured until they have cured their primary internal objects. Harold Searles sees it as the expression of an unconscious tendency to look after the analyst, which is to say the mother. These studies do indeed underline how at the heart of the negative therapeutic reaction there is clearly “the crazy passion to cure the crazy mother inside the Self (Pontalis, 1981).

René Roussillon (1991) has shown that the main clinical phenomenon is constituted by the pair of opposites “paradoxical improvement/worsening.” Influenced by the studies of Donald Winnicott, he stresses the role of unintegrated and unsymbolized traumatic experiences that remain split off within the psyche and lead to a permanent disorganization in the subject. For him, Freud applied the name “negative

therapeutic reaction” to those moments in the treatment when the patient is overwhelmed by disorganizing experiences, traces of “primal agonies,” moments of “psychic death” undergone long ago. The therapeutic process leads the subject to relive those unsymbolized and unintegrated traumatic states. Didier Anzieu has also given the name “paradoxical transference” to this type of situation, one form of which is an intense emotional transference.

Thus, when it can be combined with the analytical work of co-construction, the negative therapeutic reaction no longer appears merely as a troublesome disruption in the analysis, but as an essential way of tackling and working through the functions of the ego that treatment can reveal only in this form. Thus it is the sign that a traumatic kernel is about to be actualized in the analytical space, thereby opening the way for its transference and working-through.

## **NEGATIVE TRANSFERENCE**

The term *negative transference* refers to the aspects of the transference that counter the progress of psycho-

analytic treatment. It is thus not a matter simply of the patient’s expressing hostile feelings towards the analyst—which may in fact be helpful to the treatment—but rather negative feelings toward the person of the analyst that strengthen resistances and may bring analytic work to a halt whether or not the sessions are actually broken off.

Freud evoked these difficulties as early as the *Studies on Hysteria* (1895d): “If, now, this relation of the patient to the physician is disturbed, her cooperativeness fails, too; when the physician tries to investigate the next pathological idea, the patient is held up by an intervening consciousness of the complaints against the physician that have been accumulating in her.” Freud described three main types of cases in which this occurred: cases where “the patient feels she has been neglected, has been too little appreciated or has been insulted”; cases where “the patient is seized by a dread of becoming too much accustomed to the physician personally, of losing her independence in relation to him, and even of perhaps becoming sexually dependent on him”; and, lastly, cases where the patient is afraid of “finding that she is transferring on to the figure of the physician the distressing ideas which arise from the content of the analysis” (pp. 301–302).

The actual expression “negative transference” made its first appearance in Freud’s “The Dynamics of Transference” (1912b): “We must make up our minds to distinguish a ‘positive’ transference from a ‘negative’ one, the transference of affectionate feelings from that of hostile ones, and to treat the two sorts of transference to the doctor separately.” The transference onto the person of the analyst “is suitable for resistance to the treatment only in so far as it is a negative transference or a positive transference of repressed erotic wishes” (p. 105).

After 1920, Freud linked negative transference to the repetition compulsion and the death instinct. In his wake, the Kleinians would lay justifiable stress on the analysis of negative transference. Thus Melanie Klein rebuked Anna Freud for not analyzing it in children, and, in “Some Theoretical Conclusions Regarding the Emotional Life of the Infant,” recommended that the reinforcement of the positive transference not be systematically pursued, but rather that the analyst should at times allow himself to “stand for frightening figures, [for] only in this way can the infantile persecu-

tory anxieties be fully experienced, worked through and diminished” (1975 [1952], p. 90, n. 2).

The two aspects of the transference always coexist, but they do not always appear simultaneously. Hostile feelings towards the analyst does not inevitably mean a negative transference; it may indicate reaction formations, which can augur well for the progress of the treatment, since they are in fact defenses against a positive transference. Conversely, negative transference may have an indirect role only, in the background to a manifest positive transference, yet effectively undermine all therapeutic progress. The absence of forward motion in an analysis may indeed be the only sign of negative transference. Freud himself pointed out that “Bitterness against men is as a rule easy to gratify upon the physician; it need not evoke any violent emotional manifestations, it simply expresses itself by rendering futile all his endeavours and by clinging to the illness” (1920a, p. 164). The negative transference thus means that “the ego treats recovery itself as a new danger” (1937c, p. 238). It may also have a retroactive impact: “If the negative transference gains the upper hand,” the successes of the therapy “are blown away like chaff before the wind” (1940a [1938], p. 176).

It is essential to underline that in Freud’s eyes negative transference was an aspect of the transference in the fullest sense: it represented a repetition of a relationship in the patient’s childhood and had to be interpreted accordingly. Thus the analyst should offer very little gratification to the patient, as this complaisance might hinder the externalization of the patient’s hostile feelings and deprive the analyst of opportunities to tackle them.

Most authors concur that inadequate analysis of negative transference or of hate in the transference are at the root of psychoanalytic failures. As Freud observed, “Under the influence of the unpleasurable impulses which [the patient] feels as a result of the fresh activation of his defensive conflicts, negative transferences may now gain the upper hand and completely annul the analytic situation” (1937c, p. 239). When Sándor Ferenczi reproached Freud for not having analyzed the negative aspects of his transference onto him, Freud’s response included the following: “A certain man, who had himself practised analysis with great success, came to the conclusion that his relations both to men and women . . . were nevertheless not free from neurotic impediments; and he therefore made himself the subject of an analysis by someone else whom he regarded as superior to himself. This critical

illumination of his own self had a completely successful result. . . . But then . . . trouble arose. The man who had been analysed became antagonistic to the analyst and reproached him for having failed to give him a complete analysis. The analyst, he said, ought to have . . . given his attention to the possibilities of a negative transference. The analyst defended himself by saying that, at the time of the analysis, there was no sign of a negative transference” (p. 221).

The notion of negative transference must be distinguished from that of “negative therapeutic reaction,” which refers to a paradoxical aggravation of symptoms after an interpretation to alleviate them. Even though the upshot of a negative transference may be a negative therapeutic reaction, the appearance of such a reaction does not necessarily imply negative transference, and the analyst may in fact contribute to this by his counter-transference or by the timing, form, or tone of his interpretations.

## NEGATIVE, WORK OF THE

Contemporary psychoanalytic theory generally uses the term *negative* in its adjectival form (“negative transference,” “negative therapeutic reaction”). Here it is conceptually treated as a substantive. The “work of the negative” is an expression drawn from Georg Wilhelm Friedrich Hegel (1770–1831), but its application in psychoanalysis is only remotely connected with Hegelian philosophy, except through the work of Jacques Lacan, who quickly dissociated himself from such a connection.

Freud, in his metapsychology, makes implicit use of the negative. The unconscious, for example, does not simply describe what is not conscious, but designates an organization of the psychic apparatus. Later Freud abandoned the unconscious as an agency and replaced it with the id to emphasize that everything we might know of this agency was defined only negatively in relation to the ego. However, the negative is more directly perceptible in what concerns object loss and the work of mourning. In the early stages of Freudian theory, it was just such a structural relation that defined neurosis as the “negative of perversion.” More generally, the idea of representation can also be understood from this viewpoint, in comparison with perception. Representation implies the absence of an object from immediate perception; the object was once perceived but no longer needs to be present to the senses in order to be once again accessible to the mind. Moreover, repression, which keeps consciousness at a distance, can only reinforce the repercussions of the psychic reality while making them ineffable. Even the concept of identification, when contrasted with desire, can be included among the meanings of the negative. These remarks should suffice to weaken the idea of the negative as limited to the pathological and to show that very general concepts of mental life, normal and pathological, can be productively interpreted from the negative viewpoint.

The role played by the destructive drives in Freud’s final theory of the drives is no less productive a site for exploring the work of the negative, particularly when it is framed in terms of how the psyche is undermined by the repetition compulsion, the maintenance of

infantile conflicts, or the nonresolution of the transference neurosis. The last development takes the form of a “relation of non-relation,” and all these developments play their parts in the negative therapeutic reaction. This negative tendency in Freud’s thought is accentuated by his adherence to the concept of the death drive and by his references to masochism as the origin of other psychopathologies.

It is significant that Freud’s article “Negation” (1925h) begins with the use of language in the clinical setting, goes on to argue that negation operates as an intellectual substitute for the repressed, and ends with reference to the oldest instinctual impulses, of which the prototypes, swallowing and spitting, are considered the roots of affirmation and negation. Freud then closes his discussion by evoking the negativism displayed in some cases of psychosis.

André Green has proposed bringing together some of the defense mechanisms discussed by Freud: the prototypical defense of repression, which yet has its own character (Freud designated it first and foremost as having the function of preventing the appearance of displeasure, and so gave it a privileged position with regard to affect, although it is more readily recognizable with respect to representation); splitting or disavowal, which, according to Freud, bears more specifically on perception; foreclosure, which radically rejects the expression of the drives to the point where it is difficult to discern the different modes of representation; and finally, negation, which is essentially involved in the structuring of language and thus is not limited to the pathological but extends as well to the cultural. Green argued for combining these different forms of defense and understanding them as fundamental indices of the work of the negative. They all carry with them the obligation of a yes-or-no decision. Eventually, other defenses might be added to this list, for instance Melanie Klein’s projective identification, but this grouping permits one to grasp their coherence, to see the common ground in the clinical treatment of the neuroses and nonneurotic psychic structures, and to examine the modalities of their articulation.

The structural organization of splitting, disavowal, and foreclosure have been most frequently accounted for by conceiving destructiveness as echoing those difficult-to-discern vicissitudes of libido. In this vein, the negative has contributed to a reinterpretation of the controversial death drive. In this theoretical work, narcissism is a key concept. Green proposed reconsi-

dering narcissism as “negative narcissism,” where the psyche aspires toward its own destruction after the failure of other solutions. Negative narcissism is a process that tends not toward the One, as narcissism does in its Freudian version, but toward nothing. The negative must be understood here not as the inverse of the positive, but as a return to nothing. This interpretation allows a better understanding of certain aspects of contemporary clinical practice: empty states and deactivation; futility and nonengagement; Pierre Marty’s “essential depression”; the impairment of basic drives in eating disorders, suicidal behaviors, and addictions—phenomena that are poorly illuminated by existing theories. While these states are offered here as examples of the concepts presented, the field of the negative is far from limited to them. In corresponding fashion, this approach of deploying the negative might also permit better articulation between the theory of the drives and the theory of object relations.

A fundamental function of psychic life consists in the transformation of drive into object. In other words, object relations cannot be limited to transformations of existing internal and external objects, but must also involve the capacity of the psyche to create objects from the drives and thus contribute to the complexity of psychic investment. This is what Green has called “the objectifying function.” Conversely, the activity of the destructive drives does not limit itself to patent destructiveness, but also operates to deobjectify, or undo prior objectification. When the destructive drive deobjectifies a given object, it seeks to renounce whatever is unique or irreplaceable about that object for the subject.

The application of these ideas has permitted a reconsideration of how narcissism obscures alterity (or alienation) and in this way plays a part in primary masochism and negative reactions to therapy. They have also revealed how splitting has privileged application in the negative states of disengagement and indifference frequently found in borderline cases.

The negative has particularly important application with respect to hallucination. Hallucination is at the base of a primary hypothesis on psychic functioning: the hallucinatory realization of desire that connects dreams and hallucination. Negative hallucination, which was so often found in the early texts of psychoanalysis but subsequently disappeared from Freud’s writing, reveals itself to be a heuristically rich concept for comprehending certain regressive functioning

involving a hallucinatory mode, rather than hallucination itself.

Green’s is not the only work in contemporary psychoanalytic theory to attend to the negative. One can find an intuition of the negative in Winnicott’s late work on objects and transitional phenomena. In another way and from a different inspiration, a similar intuition can be said to shape Bion’s distinction between the “no-thing” and the nothing. These refer to representation and absence, respectively, while the reference to nothingness, or inexistence, could be understood as the result of a projective identification.

## **NEOPSYCHOANALYSIS**

In stages, Harald Schultz-Hencke developed a psychological theory that in 1945 became known as *neops psychoanalysis*. His idea was to create a successful, more scientific amalgamation of the three “historical trends” in research (Sigmund Freud, Alfred Adler, and Carl Gustav Jung).

In *Einführung in die Psychoanalyse* (Introduction to psychoanalysis; 1927) Schultz-Hencke posited that psychoanalysis could be conceived in terms of descriptive psychology. Between 1928 and 1931 he attempted, in accordance with his empirical positions, to dissociate the supposed “facts” of psychoanalytic discovery from the “theoretical scaffolding,” in order to reject the most important theoretical concepts one by one (in particular, metapsychology, libidinal theory, the Oedipus complex, and the unconscious). In addition, beginning in 1929 he tried to integrate into his “amalgamation” those empirical elements of the theories of Adler, Jung, and Freud that seemed certain to him. In this he was influenced by the then-dominant currents within the

Allgemeine Ärztliche Gesellschaft für Psychotherapie (General society of psychotherapeutic medicine): “eclectic psychoanalysis” (Wilhelm Stekel, Walter Schindler) and by attempts to establish a unified medical psychoanalysis (cf. Johannes Heinrich-Schultz).

In *Der gehemmte Mensch* (Inhibited man; 1940) he conceptualized his theory of the neuroses as *Desmolyse* (from *desmos*, meaning “chain”), in accordance with his belief that the inhibition of expansivity constituted the essence of all neurotic development. In 1945 he named his conception *Neopsychoanalyse*, and from that year until 1952 he made various attempts to present it as “modern psychoanalysis,” “psychosomatics” (Franz Alexander), or as a specialty within psychiatry.

The psychoanalytic theory of the instincts was replaced, in Schultz-Hencke’s model, by a more conventional doctrine of psychological impulses (*Antrieblehre*), in which independent impulses are distinguished: autochthonous; intentional lived impulses, such as the grasping (oral), retentive (anal), aggressive, self-esteem, and urethral impulses; and finally, the lived impulse of love (sexual impulse). The nodal process of the formation of neuroses is similar to inhibition; neurotic symptomatology does not result from an old intrapsychic conflict, but instead functions like an embedded “piece of shrapnel” from a former integral life experience, and the corresponding etiological factors stem from an upbringing that has been either overly rigorous or overly lax. In this regard the implicit theoretical model of neopsychoanalysis is similar to behaviorist theory, making it superior, in the view of some of Schultz-Hencke’s followers, to classical psychoanalysis.

In terms of technique, the goal is to stress amnesia (recollection), leading to different treatment indications depending on the depth of the neurosis: Short-term therapy may be recommended. Emphasis is placed on current reality: evaluating the work of therapy, skepticism with regard to interpretations, and giving up the transference and countertransference. In many respects it is a conventional medical model that involves applying a treatment method according to prescribed rules with the aim of curing an illness. Schultz-Hencke’s essentially descriptive theory of the neuroses was propagated and vulgarized by Fritz Riemann in *Grundformen der Angst* (Primitive forms of anxiety; 1966). Neopsychoanalytic treatment technique was developed by Annemarie Dührssen and Helmut Bach, among others. Werner Schwidder used and further developed Schultz-Hencke’s psychosomatic theory.

In 1960 German neopsychoanalysts (of the Deutsche Psychoanalytische Gesellschaft [DPG, German Psychoanalytic Society]) became affiliated with the International Federation of Psychoanalytic Societies; founding members of this international forum included Walter Schindler, René Laforgue, Erick Fromm, Karen Horney, and Franz Alexander. Setting aside internal theoretical divergences, this movement was originally intended to be a “progressive” alternative to the International Psychoanalytical Association and aimed to take positions distinct from those of “orthodox” psychoanalysis. But international intellectual exchanges, above all in the area of ego psychology, produced a shift that ended up making Schultz-Hencke’s neopsychoanalysis superfluous, because within the spectrum of internationally recognized trends, a number of elements of neopsychoanalysis gradually emerged and were reworked, without needing to be identified with Schultz-Hencke’s name to lend them weight.

## NERVOUS ANXIETY STATES AND THEIR TREATMENT

This book, for which Sigmund Freud wrote a foreword, was a compromise between Wilhelm Stekel’s

view, that all neuroses were rooted in a psychological conflict, and the position of Freud, that anxiety states were caused by the toxic effect of supposed sexual missteps. The contents were discussed by Stekel with Freud in a series of weekly meetings during 1907–1908; Stekel persuaded his mentor that at least some anxiety states had a psychological etiology and for such cases Freud proposed the term “anxiety hysteria.”

The first part of the book, on anxiety neuroses, presents a large amount of case material indicating the successful treatment of a number of anxiety equivalents through the removal of the sexual mispractice. The second part, which deals in a similar way with different forms of anxiety hysteria, has an introductory section by Freud himself (acknowledged only in the third and fourth editions). A third part includes chapters on the diagnosis and therapy of anxiety states, and on the technique of psychotherapy. There it is revealed that Stekel has given up using the couch, and is sitting beside his patients at a desk.

The second and subsequent editions of the book, which appeared in 1912, 1921, and 1924, formed the first of a ten-volume work, *Störungen des Trieb- und Affektlebens*. Over the course of these volumes, Stekel increasingly distanced himself from Freud. The latter's rather lukewarm foreword was dropped in later editions.

The main characteristic of this book is its abundance of fascinating case material. Unlike Freud, who was inclined to theorize on the basis of paradigm cases, Stekel presented as much material as possible and was inclined to avoid “sterile theoretical considerations.” (Stekel, 1908, p. 180) The book includes much medial detail, particularly in the chapter on therapy where the use of opium and bromide are discussed. Both Eugen Bleuler and Carl Gustav Jung reviewed the book favorably. The fact that Arthur Schnitzler read it is some pointer to its impact.

## NETHERLANDS

Interest in psychoanalysis within Holland developed from 1905 onward and came from three different sources. The first source consisted of psychiatrists who were struck by Freud's studies on dreams. August Stärcke corresponded with Freud and J. van Emden had an analysis with him during a holiday in Karlsbad in 1911. Both became members of the Viennese Society in 1911. The second source came from psychiatrists who went to Jung in Zürich for analysis between 1911 and 1913. The third source was Leiden University. Jelgersma's rectorial address in 1914 at Leiden University was the first official recognition of psychoanalytic science in Europe. Thirteen representatives of these three groups, Freudians, Jungians and theoretical university analysts, founded the Dutch Society of Psychoanalysis on March 24, 1917. It was the seventh branch society of the International Psychoanalytical Association (IPA), formed with the goal of supporting the development of psychoanalysis according to Sigmund Freud. The Sixth IPA Congress took place in The Hague in 1920, chosen (because of Dutch neutrality during World War I) to facilitate the reunion of analysts who had been territorial enemies.

After that, however, there followed a period of quarreling and lessened productivity, which was partly due to the diversity of the members. The main points of controversy were the question of lay analysis—until 1938 only medical doctors were admitted—and the introduction of the tripartite training system, especially the obligation of personal analysis, introduced by Max Eitingon and Hanns Sachs in 1925 for all IPA

branch societies. The conflict was mainly between the Society's president, Van Ophuijsen, who defended both lay analysis and the tripartite training model (he was treasurer and later vice-president of the IPA), and the theoretically-oriented psychiatrists of the university and Van Ophuijsen's former analysts Westerman Holstijn. The conflicts escalated and led to a split when in 1933 four Jewish analysts emigrated from Germany to Holland: Karl Landauer, Theodor Reik, Levy-Sühl and Watermann. The poorly-trained Dutch analysts, with lesser income from analytic practice, felt threatened by the arrival of four more competent analysts. A few expressed their panic in open anti-Semitism. Most were not anti-Semitic but refused to accept the refugees as members of the Society. Van Ophuijsen, however, saw a possibility to improve the quality of psychoanalysis in Holland with the help of the refugees and arranged Landauer's participation in his psychoanalytic institute (founded in 1930 in The Hague). In the resulting uproar by the members Van Ophuijsen resigned as president and member and founded, with Van Emden, Maurits Katan and a few others, a new society, the Society of Psychoanalysts in the Netherlands, of which the German immigrants became members. In the years to come the diplomatic analyst Westerman Holstijn put much energy in the reconciliation of the two societies, which succeeded in 1937. However, he himself resigned as a member, badly hurt by the lack of appreciation of his colleagues.

In 1938, after the Anschluss of Austria, Jeanne Lampl-de Groot and Hans Lampl came from Vienna to Amsterdam. Jeanne de Groot, a Dutch psychiatrist, had gone to Vienna in 1923 for analytic training with Freud and in 1925, after her marriage with Hans Lampl, to Berlin. In 1933 they had returned to Vienna. In Holland they started to reform the training program according to Viennese standards in cooperation with the members Le Coultre and Maurits Katan. Both the tripartite training model and lay analysis were accepted.

In May 1940 Holland was occupied by the Germans. When in November 1940 Jews had to resign as society members by German law, the non-Jewish psychoanalysts resigned as well in an act of solidarity and the Society virtually ceased to exist. Psychoanalytic training was organized underground with only two analysts functioning: Jeanne Lampl-deGroot and Le Coultre. In November 1945 the Society was refounded.

In 1946 some members founded the Psychoanalytical Institute (PAI), an ambulatorium where patients could come for psychoanalytic treatment at limited cost by candidates who earned a small fee. The house of the PAI became and as of 2005, still is the center of training, where, among other things, seminars are held and scientific meetings organized.

In 1947 Westerman Holstijn and Van der Hoop, who both had left the Society in discontent, founded with others the Dutch Psychoanalytical Association. Initially, the Association was meant to be a forum where one could discuss psychoanalysis in a free atmosphere without the stress of training. Soon, however, a training program was organized, though with much milder requirements than those of the Society. Training analyses were performed at low frequency and for a short period. During the first twenty-five or thirty years of its existence, the relationship between Society and Association varied from non-existent to very bad. Three successive presidents of the Association; Jan Groen, Poslavsky, and Stufkens, managed to raise the quality of training gradually to IPA level, coinciding with a much more friendly cooperation with the Society. The societies share an increasing number of mutual members. In 1983 the Association founded its own institute in Utrecht, the PIU. The psychoanalytic institutes of Society and Association fused into the Dutch Psychoanalytic Institute (NPI) in 1995, which serves the candidates of both societies. It is expected that the Association will be a component society of the IPA in the near future.

From 1945 until roughly 1970 psychoanalysis blossomed in Holland. The number of candidates steadily increased; there were more patients for analysis than could be treated; there was an active scientific life. Three IPA congresses were organized in Amsterdam, in 1951, 1965 and 1993. Van der Leeuw became vice-president of the IPA in 1963 and president from 1965–1969. Montessori was secretary from 1965–1969 and vice-president after that until 1975. Lampl-deGroot was honorary vice-president from 1963 until her death in 1987. Several Dutch held an office in the European Psychoanalytical Federation: Thiel and Dalewijk as vice-president, Mekking as treasurer, and Groen-Prakken as president.

In 1966 a child-analytic training was organized within the Society by Teuns, with great support of especially Frijling-Schreuder through many years to come. Teachers from the Hampstead clinic came to

Leiden or Amsterdam for theoretical and technical seminars and supervision. Also in 1966 the government decided to subsidize psychoanalytical treatments as far as the patient could not afford the treatment himself. In 1980 therapies at the Institutes for mental health, including the analytic Institutes, became virtually free from payment. The important chairs in psychiatry, child psychiatry and clinical psychology at the universities were mainly occupied by psychoanalysts.

Over the course of the 1980s there was a decline in interest in psychoanalysis, as in most western communities. In Holland, the growing grip of the authorities on psychoanalytic practice, the near-disappearance of private practice, and the replacement of psychoanalytically-oriented university teachers by biologically oriented ones were important factors. The same period, however, saw a mounting interest in the application of psychoanalysis to other fields. In 1979 the analytic societies founded together the Dutch Society for Psychoanalytic Psychotherapy and in 1989 the Foundation for Psychoanalysis and Culture was established, by the analysts Baneke and De Jong and the scientists in literature Schönau and Hillenaar, to connect psychoanalytical with general cultural experience. The annual workshops, organized by the Association, to introduce modern analytic views to a wide audience of psychotherapists are always overbooked.

Traditionally, the Dutch have been tradesmen for many centuries. They played an active role also in the export of psychoanalytic knowledge to Germany in the first period after the war, and in the late twentieth century to some former Soviet satellite countries: Prague first, and from 1994 onward, to Romania and Lithuania, where regular seminars are organized.

Four main scientific threads have developed, mostly after 1945. From the predominantly ego-psychological orientation after 1938 a continuous trend emerged to integrate drive- and ego- psychology with observations on narcissistic development and pathology (Lampl-de Groot, Le Coultre, Van der Leeuw, Spanjaard, Treurniet). Many analysts from before the war already came from Child Guidance Clinics. The direct observation and treatment of neurotic and psychotic children has led to a mutual influence of adult and child psychoanalysis and to the use of psychoanalytical approaches in prevention of childhood disorders (Frijling-Schreuder, Kamp, Van Waning). The Dutch training

programs are founded upon integrated child and adult theoretical seminars. In the third place there was and is a vivid exchange between psychoanalysis and the adult psychiatric clinic (Kuiper, De Blécourt, Van Tilburg). The fourth mainstream is centered around the aftermath of war in the first, second, and the contemporary generation (Keilson, De Wind, Jacques Tas, Louis Tas, De Levita, Bruggeman). Among the solitary theoreticians in the widened scope of psychoanalysis, De Jonghe, Ladan, Stufkens, and Bögels should be mentioned.

Regularly, textbooks and analytic books on a specific topic are published in Dutch. In 1978 Keilson published his long-term investigation on Jewish war orphans in Germany, *Sequentielle Traumatisierung bei Kindern* (now translated into English). In 1985 the collected papers by Lampl-de Groot were published in English titled *Man and Mind*. In 1991 Halberstadt-Freud published *Freud, Proust, Perversion and Love*. In 1993, at the thirty-eighth IPA congress in Amsterdam, *Dutch Art and Character, a Psychoanalytic View* was edited by Baneke and others. In 1993 and 1995 two volumes of the *Dutch Annual of Psychoanalysis* appeared, edited by Ladan, Groen-Prakken, and Stufkens, and in 1996, on the occasion of a celebration of Treurniet, *Psychoanalysis in a Post-Classical Context* was published, edited by Groen-Prakken and featuring Treurniet's article "On an Ethic of Psychoanalytic Technique," alongside papers by foreign and Dutch friends.

## NEURASTHENIA

The term *neurasthenia* was coined in English by the American psychiatrist George Beard (1839–1883) to describe an illness characterized by its etiology and its clinical manifestations; it appeared in Beard’s *Neurasthenia As a Cause of Inebriety* (1879) and *Sexual Neurasthenia (Nervous Exhaustion), Its Hygiene, Causes, Symptoms and Treatment* (1884). Sigmund Freud retained the word, although he gave it a more limited meaning, and included it among the defense neuroses, alongside anxiety neurosis and, later, hypochondria.

In Beard’s work, neurasthenia is characterized by the appearance, in subjects who had no family or personal history suggesting mental degeneration, and who, men and women alike, had previously lived the active life of “managers” peculiar to the feverish lifestyle of the New World, of a chronic symptomatology that was both somatic and mental. Somatic symptoms included fatigue that is not alleviated by rest, cephalgias with constriction, back pains, dyspepsia, flatulence, constipation, and dysurea; mental symptoms included insomnia, sadness, lack of interest, anhedonia, impoverishment of sexual activity that had previously been satisfying, and morosity. He attributed this neurasthenia to an excess of activity by those who, in the brutal world of business, must expend an excessive daily energy, and he thus contrasted it to the spleen and melancholia of idlers. As early as 1879, Beard stigmatized alcohol use as a fallacious remedy to this condition, and one that could lead to a secondary pathology.

In Freud’s view, expressed in “On the Grounds for Detaching a Particular Syndrome from Neurasthenia under the Description ‘Anxiety Neurosis,’” Beard’s clinical description was too general and the etiology was imprecise, but it was appropriate to keep the term in medical terminology, on the condition that its semiology be restricted and its origins specified. He retained physical fatigue, somatic disorders, and the impoverishment of sexual life (in particular masturbation that fails to resolve libidinal tension) as neurasthenic symptoms, but he excluded chronic states of anxious expectation and acute anxiety attacks (sometimes with a substantial somatic component), which he held to be typical of “anxiety neurosis.” From an etiological point of view, neurasthenia is a defense neurosis whose symptomatology is not a symbolic and

overdetermined expression, and whose etiology must be sought not in childhood conflicts, but rather in a present frustration.

## “NEURASTHENIA AND ‘ANXIETY NEUROSIS’ ”

Written around June 1894 and published on January 15, 1895, after it had been read by Josef Breuer, the article “On the Grounds for Detaching a Particular Syndrome from Neurasthenia under the Description ‘Anxiety Neurosis’ ” earned Freud considerable recognition, for the syndrome that he isolated in it was discussed at length at neuropsychiatric congresses in the early twentieth century.

Freud’s correspondence with Wilhelm Fliess reveals the extent to which the problem of neurasthenia preoccupied the two men: They had decided to undertake a major joint study of this topic, though it was never published. As early as 1892, Freud wrote in Manuscript A, “No neurasthenia or analogous neurosis exists without a disturbance of the sexual function” (1950a [1887–1902], p. 178). In fact, what separated anxiety neurosis (*Angstneurose*) from George Beard’s broad, all-purpose category of neurasthenia was essentially the thesis of a sexual etiology (very common, according to Freud), which he presented in the 1895 article.

Freud began his article with a description of the syndrome itself: a general susceptibility to stimuli (especially auditory ones), chronic states of anxious expectation, excessive moral scruples, and the well-known somatic problems associated with anxiety attacks (such as dizziness, night terrors, animal phobias, and agoraphobia). It did not, however, involve repressed ideas. Freud also distinguished anxiety neurosis from a simple anxiety attack, which he still conceptualized on a biological model that he abandoned only later.

In the next part of the article, Freud examined the etiology and occurrence of anxiety neurosis. Its onset, Freud noted, comes in the form of virginal anxiety (he referred to it in connection with Katharina in *Studies in Hysteria*, published that same year), or in newlyweds or in those practicing abstinence or coitus interruptus. It results from an accumulation and a “deflection of somatic sexual excitation,” together with a deficiency in mental participation, which would normally discharge in “adequate action” (1895b [1894], p. 108).

In the third section, titled “First Steps towards a Theory of Anxiety Neurosis,” Freud explains that the mind experiences anxiety when it is unable to face an external danger, and anxiety neurosis when the source of sexual excitation is internal.

In the fourth and concluding section, titled “Relationship to Other Neuroses,” Freud hypothesized that anxiety neurosis is the “somatic counterpart to hysteria” (1895b [1894], p. 115), which is provoked by psychic conflict. While anxiety neurosis and neurasthenia have a common somatic origin, they are different in that neurasthenia comes from an impoverishment of excitation, whereas anxiety neurosis is linked to its accumulation.

Although the birth and development of these ideas can be traced over the course of Freud’s correspondence with Fliess, the 1895 article on anxiety neurosis, published a few months before *Studies on Hysteria* (1895d), was their first public expression.

Following publication of the paper, Freud was very upset by the criticism of a Munich psychiatrist, Leopold Löwenfeld, whom he held in esteem. “What I must contest,” wrote Löwenfeld, “is only the regularity and specificity of the sexual etiology posited by Freud in ‘acquired’ anxiety states.” This immediately occasioned one of Freud’s rare polemical responses,

“A Reply to Criticisms of My Paper on Anxiety Neurosis” (1895f), in which he specified that “anxiety neurosis is caused by everything that keeps somatic sexual tension away from the psychical sphere, which interferes with its being worked over psychically” (p. 124), adding that “the neuroses are overdetermined” (p. 131). He also noted the distinctions that needed to be established among the conditions of a syndrome (here, heredity), its specific causes (here, sexual etiology), its auxiliary causes, and its triggers.

“I am pretty well alone here in tackling the neuroses. They regard me rather as a monomaniac, while I have the distinct feeling that I have touched on one of the great secrets of nature,” Freud wrote to Fliess on May 21, 1894 (1954, p. 83). Indeed, most commentators in the decades to come accepted Freud’s isolation of anxiety neurosis, but its sexual etiology, which Freud consistently made a condition, continued to be challenged.

Meanwhile, the idea of anxiety neurosis continued to circulate and drew support from an 1897 study by Felix Gattel involving about a hundred cases observed in Richard vonKrafft-Ebing’s psychiatric clinic in Vienna. Several French authors, alerted by a review of Freud’s article published in the *Revue neurologique* (vol. 3) in 1895, discussed anxiety neurosis, and their views were included by Paul Hartenberg in *La névrose d’angoisse* (Anxiety neurosis; 1902). Hartenberg concluded, “The ideas of Freud and some other authors on the sexual origin of the neuroses are far from being accepted by the majority of doctors, especially in France. And no doubt many practitioners would refuse to accept an etiology that is so exclusive. Thus, by introducing these restrictions, it seems to me that I have fostered the success of anxiety neurosis. By recognizing that it has a more general etiology, which includes overwork and exhaustion of the organic [that is, the biological], I am presenting it under a more easily acceptable physiognomy.” Charles Féré, Joseph Capgras, Gilbert Ballet, A. Cullère, and numerous other authors followed this same route.

In April 1907 Wilhelm Stekel (who in 1908 would publish *Nervöse Angstzustände und ihre Behandlung* [*Conditions of Nervous Anxiety and Their Treatment*; 1923]) delivered a lecture entitled “Psychology and Pathology of Anxiety Neurosis” to the Vienna Psychoanalytic Society. In it Stekel said that contrary to the opinion of Freud, according to whom “anxiety neurosis is provoked by coitus interruptus” and who saw

“the source of anxiety in the fact that somatic sexual excitation is diverted from the psyche,” he (Stekel) “remains convinced that in anxiety neurosis—as in all neuroses—psychic conflict is essential” (Nunberg and Federn, 1962–1975). Alfred Adler, for his part, then suggested that anxiety neuroses are found in anyone manifesting psychic weaknesses.

In his response of February 16, 1908, to a question from Karl Abraham, Freud distanced himself somewhat from what he had written thirteen years earlier: “As for the reducibility of the anxiety in anxiety neurosis, you will find full information in Stekel’s book on anxiety hysteria (expected in April). I myself still regard the old position as theoretically unassailable, but I see that pure cases of anxiety neurosis are great rarities and perhaps once again only abstractions, and that the not actually typical phobias permit and call for psycho-analytic resolution. I ‘fancy’ there is nearly always an element of hysteria in them. In practice what happens is that actual therapy is first attempted, and resort is then had to psycho-analytic therapy to deal with what turns out to be resistant” (Freud and Abraham, 1965, p. 26).

Discussion increasingly shifted toward hysterical anxiety, and this shift went hand in hand with diminished interest in the notion of “actual [anxiety] neurosis,” except by Sándor Ferenczi and Freud, who continued to focus on it. According to Paul Federn’s (1933) memories of Ferenczi, Freud confided to Ferenczi his belief that hypochondria was a narcissistic actual neurosis with an excessive libidinal cathexis of the affected organ. This opinion was later taken up by Otto Fenichel (1945). In addition, several American authors (Grete Bibring, Abram Blau, Leo Rangell, Angela Richards, and Elizabeth Zetzel, among others) found correlations between anxiety neurosis and some sexual conditions reported in Masters and Johnson (Fink, 1970). Investigators of psychosomatic disorders (Pierre Marty, Joyce MacDougall) also made sure to refer to anxiety neurosis.

In *A Phylogenetic Fantasy* (1985 [1915]), according to Peter Gay’s account in *Freud: A Life for Our Time* (1988), Freud speculated, “Anxiety hysteria might prove to be a legacy from the ice age, when early mankind, threatened by the great freeze, had converted libido into anxiety. This state of terror must have generated the thought that in such a chilling environment, biological reproduction is the enemy of self-

preservation, and primitive efforts at birth control must in turn have produced hysteria” (1988, p. 368).

Freud elaborated several theories of “anxiety,” properly speaking, the last of these in *Inhibitions, Symptoms, and Anxiety* (1926).

## NEURO-PSYCHOSIS OF DEFENSE

The “neuro-psychosis of defense,” a nosological category identified by Freud in 1894, covers neurotic and psychotic disorders characterized by conflict between affects and ideas: hysteria, obsessions, phobias, and hallucinatory psychoses. Two years later, the notion of the defenses became more central in Freud’s theories (1896b).

In “The Neuro-Psychoses of Defence” (1894a), Freud reported on his “detailed study of a number of nervous patients suffering from phobias and obsessions” (p. 45). He viewed this study as a contribution to “the theory of hysteria, or rather a change in it, which appears to take into account an important characteristic that is common both to hysteria and to the neuroses I have just mentioned” (p. 45). He isolated the defense that is characteristic of hysteria and established possible connections between it and phobias and obsessions. Above all, the article was one of Freud’s earliest discussions of the conflict between affects and ideas and of the consequences such conflict could have in the functioning of the ego.

In “Further Remarks on the Neuro-Psychoses of Defence” (1896b), Freud returned to his discussion of the different forms of neurosis, emphasizing that his observations in the last two years had reinforced his view of “defence as the nuclear point in the psychical mechanism of the neuroses in question” (p. 162)—a view he maintained in his subsequent writings.

At the time Freud wrote these articles, he had not yet entirely worked out his first theory of repression, so his discussion seem essentially descriptive.

## NEUROSIS

For psychoanalysts, neuroses are mental disorders that have no discernible underlying anatomical causes and whose symptomatology arises from intrapsychic conflict between unconscious fantasies bound up with the Oedipus complex and the defenses that these fantasies arouse. Neuroses may be defined in several ways. From a topographical standpoint, they may be defined in terms of a specific differentiation of the ego. From a dynamic standpoint, they may be defined by the ego’s embrace (under the influence of the superego) of the reality principle, to the detriment of the pleasure principle and the id’s instinctual demands, and this leads to the emergence of castration anxiety. From an economic standpoint, they may be defined by a prevalent but partly ineffective mobilization of the mechanisms of repression against the id’s instinctual demands. Finally, from a developmental (or genetic) standpoint, they may be defined by the achievement of a symbolization of intrapsychic conflicts in accord with the oedipal model. This basic neurotic structure is variously associated, in the adult as in the child, with different sets of symptoms (hysterical, phobic, or obsessional).

Nineteenth-century medicine used the terms *neurosis* and *psychasthenia* interchangeably to denote nervous conditions of “functional” origin. It was accepted that the impact of such conditions on the various bodily systems (digestive, cardiopulmonary, urogenital, etc.) was unrelated to any underlying clinical or anatomical factors, and furthermore that there was no major degradation of the subject’s relation to reality. This kind of exclusive diagnosis, purely behavioral and “pre-psychoanalytical,” was revived in the 1990s by some present-day nosologies, among them the fourth edition of the *Diagnostic and Statistical Manual of Mental Disorders (DSM-IV)* and the tenth edition of the World Health Organization’s *International Classification of Diseases (ICD-10)*.

As early as 1894 Freud drew a distinction between two classes of psychopathological phenomena: on the

one hand, the so-called “actual” neuroses, which, in accordance with classical medical theories, he related to a sexual dysfunction contemporaneous with the mental condition (frustration in the case of “anxiety neurosis,” masturbation in the case of “neurasthenia”), and on the other hand, the psychoneuroses of defense, whose cause, he set out to show, was to be found in an intrapsychic conflict of infantile origin.

Only the psychoneuroses, which for a time Freud called “transference neuroses,” correspond to genuine neuroses as Freud definitively described them in 1924: anxiety hysteria (or phobic neurosis), conversion hysteria, and compulsive (or obsessive) neurosis. This clear distinction between the two types of neuroses, though Freud acknowledged that it was sometimes arbitrary, remained essential to his theory. The hypothesis that the origin of the psychoneuroses lies in intrapsychic childhood conflict constitutes, along with dream theory, the theoretical bedrock of psychoanalysis.

The topographical, dynamic, and economic viewpoints, as presented briefly above, have not undergone any serious revision since Freud’s work of 1924. A handful of details aside, all psychoanalytic authors would probably concur with the following formulation from “Neurosis and psychosis”: “The ego has come into conflict with the id in the service of the super-ego and of reality; and this is the state of affairs in every transference neurosis” (1924b [1923], p. 150). In contrast, the “genetic” or developmental standpoint still continues into the twenty-first century to spark endless controversy.

In his rereading of Freud’s case of the “Wolf Man” (1918b [1914]), Jacques Lacan (1988) drew a clear distinction between what he called “foreclosure” (*Verwerfung*) and the concept of repression (*Verdrängung*). Evoking the feminine position assumed by the subject in the oedipal scenario (a position that prohibits the subject, under the threat of castration, from accepting genital reality), Lacan noted, “The *Verwerfung* thus cuts off short any manifestation of the symbolic order” (1988, p. 38). For Lacan, this inability to access the symbolic order differentiates psychosis from neurosis, where there is access to the symbolic order. In his terms, neurotics seek, in a more or less elaborate way, “to introduce into the demand whatever the object of their desire is” and, symmetrically, “to satisfy the demand of the Other by conforming their desire to it.” Because the “Wolf Man” could not place himself

within this oedipal interplay by means of a “deferred” interpretation of the initial scene of seduction, visited upon him at a very early age by his elder sister, he was partially barred from the “chain of signifiers.” In contrast, the phobia of “little Hans” (Freud, 1909b) gave him access to the symbolic order and allowed him to structure his infantile neurosis.

From a quite different perspective, Melanie Klein (beginning in 1930) took up Freud’s metapsychological hypothesis concerning the death instinct. Theorizing that infantile anxiety was directed not against the libido but against the destructive instincts, she developed the notions of the schizophrenic and depressive positions, which created a need to revise the theory of the neuroses. For Klein (1975), the possibility of arriving at the depressive position by acknowledging the presence of the destructive instincts within the personality enabled the subject to access the triangular relations of the Oedipus complex and hence to neurotically organize a personality capable of tolerating loneliness. Working in the same Kleinian theoretical tradition, Hanna Segal (1957) described the transition from symbolic equation (an inability to distinguish between symbols and the objects symbolized) to authentic symbolization. Later Segal (1991) extended the theory still further by considering the conditions of artistic creation and revisiting Freud’s thoughts on sublimation.

Freud proposed the term “narcissistic neurosis” as a designation for manic-depressive psychosis. This suggestion was not adopted by others, but it draws attention to the need to distinguish between manic-depressive psychosis and the other psychoses, in which the nature of the intrapsychic conflict is clearly very different. Jean Bergeret has described as “false neuroses” a number of clinical conditions mentioned by a variety of authors (“failure neurosis,” “abandonment neurosis,” “character neurosis,” “organ neurosis,” and so on) and has proposed a more neutral nomenclature (“failure-prone behavior,” “anaclitic relationship,” and so on). It is true that, in contrast to hysterical neurosis and obsessional-compulsive neurosis, such conditions are not clearly related to the concept of a neurotic structure. Among such false neuroses, the “traumatic” or “war neuroses” occupy a special place in Freud’s metapsychology, for they serve as a point of departure in his development of the hypothesis of a death instinct lying “beyond the ‘pleasure principle’” (1920g). Finally, it should be noted that the classification

*transference neurosis* has come to have a different meaning from what Freud originally assigned to it; it refers to certain phenomena manifesting themselves in the analysand's relationship with the analyst (*transference psychosis* is also used in this way).

The notion of neurosis is also related, of course, to the ideas of *neuroticization* and *infantile neurosis* as mental processes that give access to symbolization. It is in fact such a powerful organizing concept that it has sometimes been taken for an "overall vision of the human being." However, we would do well to remind ourselves of Freud's consistent and deeply negative attitude toward all such overarching visions and the mysticism that invariably accompanies them.

## NEUROSIS AND HUMAN GROWTH

According to Karen Horney in *Neurosis and Human Growth*, people defend themselves against feeling unsafe, unloved, and unvalued by developing interpersonal and intrapsychic strategies of defense. The interpersonal strategies involve adopting a self-effacing, expansive, or resigned solution. Each of these solutions entails a constellation of personality traits, behaviors, and beliefs, and a bargain with fate in which obedience to the dictates of that solution is supposed to be rewarded. Because people tend to employ more than one solution, they are beset by inner conflicts.

In the self-effacing solution, people try to gain safety, love, and esteem through dependency, humility, and self-sacrificing "goodness." Their bargain is that if they are helpful, submissive people who do not seek their own gain or glory, they will be treated well by fate and by other people.

There are three expansive solutions: the narcissistic, the perfectionistic, and the arrogant-vindictive. Narcissists are full of self-admiration, have an unquestioned belief in their own greatness, and often display unusual charm and buoyancy. Their bargain is that if they can hold onto their exaggerated claims for themselves, life is required to give them what they want. Perfectionists take great pride in their rectitude. They have a legalistic bargain in which correctness of conduct ensures fair treatment by fate and fellow humans. Arrogant-vindictive people have a need to retaliate for childhood injuries and to achieve mastery by manipulating others. They do not count on life to give them anything but are convinced that they can reach their ambitious goals if they remain true to their vision of the world as a jungle and do not allow themselves to be influenced by their softer feelings or the traditional morality.

Resigned people worship freedom, peace, and self-sufficiency. Their bargain is that if they ask nothing of others, they will not be bothered; that if they try for nothing, they will not fail; and that if they expect little of life, they will not be disappointed.

The intrapsychic strategies are linked to the interpersonal. To compensate for feelings of weakness, inadequacy, and low self-esteem, people develop an idealized image of themselves that they seek to actualize by embarking on a search for glory. The idealized image generates neurotic pride, neurotic claims, and tyrannical shoulds. People take pride in the imaginary attributes of their idealized selves, demand that the world treat them in accordance with their grandiose conception of themselves, and drive themselves to live up to the dictates of their solution. This tends to intensify self-hate, since any failure to live up to one's shoulds or of the world to honor one's claims leads to feelings of worthlessness. The content of the idealized image is most strongly determined by the predominant interpersonal strategy, but because the subordinate strategies are also at work, the idealized image is full of inner divisions. As a result, people are often caught in a crossfire of conflicting shoulds.

The object of therapy for Horney is to help people relinquish these self-defeating defenses and actualize their real selves. This book is a major contribution to psychoanalytic theory and has influenced the study of literature, biography, gender, and culture.

## NEUROTIC DEFENSES

Neurotic defenses are procedures developed by the ego which can be considered damaging to mental life. Their function is avoiding the anxiety and guilt caused by inhibitions connected with sexual desires and aggressive tendencies. They reveal the complexity and vicissitudes of the links between affect and representation.

In 1896, Freud demonstrated that defense is the “core” of the neurotic psychic mechanism. This conclusion followed his analysis of the neuro-psychoses of defense (1894a). In this text he linked repression to hysteria, and designated conversion as a defense. Conversion was later placed in the category of symptoms. In his early writings on hysteria, Freud spoke of “abreaction,” a kind of hallucinatory reproduction of memories or of emotional release as a means for dissolving conversion symptoms. Later, repression (the “model” of the defenses) came to be considered the essential first line of defense of the obsessive (or phobic) subject.

It was not until 1926 that “isolation” replaced repression as the major mechanism of obsessional neurosis. Freud saw in the obsessional neurosis a separation of representation (image, thought, memory) from the drive and its affect, while this affect, through “displacement” or “transposition,” established a link with another representation that pushes

the earlier representation, with which it is irreconcilable, into the unconscious, making it inaccessible to memory.

In *The Interpretation of Dreams* (1900a), Freud presented regression as a type of defense, to the extent that he considered it as “an effect of a resistance opposing the progress of a thought into consciousness along the normal path” (p. 546), adding that “regression plays a no less important part in the theory of the formation of neurotic symptoms than it does in that of dreams” (p. 548).

In “Repression” (1915d), he resumed his minute analyses of neurotic defenses in connection with the “return of the repressed,” whose similarity with the mechanisms of dream work was evident. He focused on the linking of affect and representation through the processes at work in anxiety or (phobic) hysteria, whose proximity with conversion hysteria and obsessional neurosis he emphasized. “Displacement” is the major defense of the phobic neurotic, while for the obsessional neurotic there is “a substitute by displacement, often a displacement on to something small or insignificant” (p. 157). Finally, with conversion hysteria, there is the “*belle indifférence*” (p. 156, [sic]): at the same time as a factor of regression, one also of “condensation.” This is because a portion of the repressed representation of the drive has attracted to itself, by condensation, the totality of the cathexis, as well as a tendency for identification.

Other defenses were considered by Freud: projection, a very basic type of defense Freud alluded to throughout his work; delusional jealousy (1922b), which is a defense against homosexuality; the distinction between internal and external, which is a means for the ego to defend itself against that which is experienced as disagreeable (*Civilization and Its Discontents*, 1930a).

The analysis of defenses has been refined and extended in the work of Helene Deutsch (1926), Otto Fenichel (1932), and Maurice Bouvet (1967–68), among others. For the phobic neurotic, “avoidance” of anxiety, “canceling” and “reaction formation” were added. Sublimation (Freud, 1905, 1910) was finally considered as a separate kind of defense (Hartmann, 1955), since it is the only one that implies a change of the kind of energy.

This refinement of the analysis of defenses has allowed the consideration of neurosis as other than an

essentially pathological system. Currently, these defenses are also described in the context of what is called normal-neurotic psychic activity. On the other hand, the study of traumatic neuroses since Freud, including mechanisms of repetition, splitting, and denial, as well as the study of psychic functioning in what have been called borderline processes, have probably contributed to a certain vulgarization of these defensive manifestations, which, nevertheless, remain essential for an understanding of Freudian metapsychology.

## **NEUROTICA**

Freud created the neologism *neurotica* to refer to his first approach to the etiology of the neuroses. The word appears only once in Freud's writing, in a letter to Fliess dated September 21, 1897. In an earlier letter, dated January 24, 1897, Freud had introduced a similar neologism: “The majority of my assumptions on the *neuroticis* were subsequently confirmed.” The September 21 letter, however, is more pessimistic: “And now I must immediately reveal to you the great secret that, during these past months, has slowly begun to become clear. I no longer believe in my *neurotica*.”

According to Freud's *neurotica*, the etiology of the neuroses unfolds in three stages:

1. Some form of sexual abuse was committed by someone close to the person, possibly a parent.

Freud placed the abuse in adolescence and then traced backward in time to place it in childhood and even early infancy.

2. The scene involving the abuse is repressed.
3. The repressed traumatic scene has a tendency to reappear in the form of anxiety or symbolic acts. This leads to the well-known formulation that “hysterics suffer from reminiscences.” It is the father’s perversion that is responsible for the neurosis of the child: “Hysteria is the negative of perversion.”

It is this conception of the traumatic etiology of the neurotica that Freud questioned in his September 21 letter to Fliess. The generalization about the perversion of fathers now seemed unlikely to Freud, who claimed, “There are no indications of reality in the unconscious, so that one cannot distinguish between truth and fiction that has been cathected with affect. (Accordingly, there would remain the solution that the sexual fantasy invariably seizes upon the theme of the parents.)” This led Freud to a new conception of the etiology of neurosis, a conception based on fantasy rather than trauma.

No sooner had Freud finished his letter to Fliess questioning his neurotica theory than he hastened to Berlin to meet Fliess and clarify his position. Freud returned to Vienna in a state of great intellectual agitation, filled with dreams, reminiscences, and parapraxes associated with conversations between himself and his mother about his childhood. An intense two-week period of mental scrutiny resulted in Freud’s discovery of the Oedipus complex. The question of what is prominent is the origin of the neurosis, actual real events or psychic reality, combined to preoccupy Freud throughout his scientific life (see the “Wolf Man” case, 1918b [1914]).

Freud’s abandoning his neurotica later gave rise to a number of comments, critiques, and developments. Marie Balmory and Marianne Krüll have investigated, from a psychoanalytic point of view, what drove Freud to abandon the seduction theory. They explained his abandonment not in terms of scientific motives but rather in terms of Freud’s relationship with his father, and they saw his abandoning the theory as an attempt to protect his father. In a more polemical vein, Jeffrey M. Masson has reproached Freud for abandoning this theory out of cowardice before his Viennese colleagues and denying the reality of the sexual abuse whose victims were girls and women. Jean Laplanche addressed

the problem from the opposite point of view and provided an original interpretation that ranges from limited to generalized seduction. He saw the seduction as coming not from the father but from the mother and considers the seduction to be “a fundamental situation, where the adult proposes to the child non-verbal and verbal, even behavioral, signifiers impregnated with unconscious sexual meanings.”

## **NEUTRALITY/BENEVOLENT NEUTRALITY**

The terms *neutrality* and *benevolent neutrality* characterize the counter-transference attitude that the psychoanalyst is supposed to adopt throughout the psychoanalytic treatment. Though Freud did not use these particular terms, he did, however, stress the climate of “abstinence” in which the treatment should take place. The introduction of the word neutrality is attributed to James Strachey, who used it in 1924 to

translate the word *Indifferenz* in Freud's "Observations on Transference Love."

We know from the testimonies of patients like Smiley Blanton and Joseph Wortis how far Freud himself was from remaining "neutral" in the way he conducted his sessions. On October 26, 1934, he even announced to Wortis that "The psychoanalytic relation is not a chivalrous relation between two equals" (Wortis, 1954). However, though Anna Freud did not use the term either, she nevertheless lent substance to the notion of neutrality: When summarizing Freud's description of the analyst as "opaque like a mirror," she defined the analyst's position as "at a point that is equidistant from the id, the ego and the superego" (Freud, 1936/1937). Alex Hoffer later suggested adding "external reality" to that list (Hoffer, 1985).

Edmund Bergler coined the expression *benevolent neutrality* at the Symposium on the Theory of the Therapeutic Results of Psycho-Analysis in 1937, and the term met with much success after World War II. Most American psychoanalysts naturally followed his example, but some French analysts, like Daniel Lagache (1950) and Sacha Nacht (1954), did as well. Nacht stressed that the analyst must not abandon "benevolence" all through the treatment and even introduced the notion of "goodness."

Over time, "neutrality" was interpreted in two very divergent ways. Some analysts adopted an excessively cold and indifferent, even amoral, attitude to the things that are said in the course of a session. This spurred Otto Kernberg to suggest the term "technical neutrality" in order to distinguish between a "lack of spontaneity and natural warmth" and an "authentic concern for the patients [...] that protects their autonomy, independence and capacity to accomplish their work on their own" (Kernberg, 1976).

In opposition to that, particularly after Otto Rank and Sándor Ferenczi stressed the importance of the primary relation with the mother and its repetition in the transference, as well as the idea of comprehensive receptivity that can rightly or wrongly be associated with notions of repairing, of *holding* and *handling*, other analysts stressed benevolence and adopted increasingly maternal and gratifying attitudes in treating difficult patients.

Moreover, the ideas of authors like Heinz Hartmann, Ernst Kris, and Rudolph Loewenstein with regard to the latest theory of instincts have brought the

concept of an "aconflictual sector" to the fore, which may account for the special success of the notion of neutrality in Anglo-Saxon literature.

## **NEW INTRODUCTORY LECTURES ON PSYCHO-ANALYSIS**

In 1932 the financial situation of the world, shaken by the aftermath of World War I and the economic crisis

that had struck the United States, threatened the existence of the Internationaler Psychoanalytischer Verlag (International Psychoanalytical Publishers). Measures were taken, including an appeal to psychoanalytic societies and the creation of an international management committee, at the Twelfth International Psychoanalytic Congress held in Wiesbaden in September 1932.

Beginning in the spring of that year, however, Freud was occupied with writing a follow-up to the volume that, of all his works, remains the most popular worldwide: his *Introductory Lectures on Psycho-Analysis* (1916–17 [1915–17]). This follow-up was the *New Introductory Lectures on Psychoanalysis*, completed at the end of August and released on December 6, 1932, despite the 1933 copyright date.

In his preface, Freud explained that illness prevented him from teaching courses as he had done in 1915, but that he had used “an artifice of the imagination” (p. 5) to write these lectures, which, he said, were only “continuations and supplements” (p. 5) of the earlier lectures—hence their numbering. In reality, these texts represented a major synthesis and updating of theories that had been considerably modified since 1923. They were no longer intended for a neophyte public, but for informed readers who were to find in them theoretical and practical advice and refinements.

The twenty-ninth lecture is titled “Revision of the Theory of Dreams.” It contains few new elements, except for the assertion that not all dreams can be interpreted, and the attenuation of the former understanding of dreams as “wish-fulfillment” by taking into account repetition in traumatic neuroses or the reproduction of painful childhood events.

The thirtieth lecture, “Dreams and Occultism,” takes on a universally contested subject. Although Freud set forth all the arguments that cause the scientific mind to doubt the existence of telepathic transmission, he also gave some examples of observations that had perplexed him, including that of Vorsicht/Forsyth, and he wrote, “I must encourage you to have kindlier thoughts on the objective possibility of thought-transference and at the same time of telepathy as well” (p. 54).

The thirty-first lecture, “Dissection of the Psychical Personality,” emphasizes subjects that had characterized theoretical research in psychoanalysis since the establishing of the second topography (structural

theory): stress upon the ego, the importance of the superego, the abandonment of the agency of the unconscious in favor of recognizing an “unconscious” character in other sectors of the personality, and its replacement by the agency of the id. The lecture concludes with the well-known propositions concerning “the therapeutic efforts of psychoanalysis. . . . Its intention is, indeed, to strengthen the ego, to make it more independent of the super-ego, to widen its field of perception and enlarge its organization, so that it can appropriate fresh portions of the id. Where id was, there ego shall be [*Wo Es war, soll Ich Werden*]. It is a work of culture, not unlike the draining of the Zuider Zee” (p. 80).

The thirty-second lecture, “Anxiety and Instinctual Life,” describes the new theory already put forth in “Inhibitions, Symptoms and Anxiety” (1926), which holds that repression is not what creates anxiety; rather, anxiety, residing in the ego alone, is what creates repression. Moreover, “the instinctual situation which is feared goes back ultimately to an external situation of danger” (p. 89): the danger of the state of powerless to help oneself (*Hilflosigkeit*) in the earliest period of life, the danger of castration in the phallic stage, anxiety in the face of the superego during the latency period. The lecture ends with a presentation of the “theory of the instincts” which “is so to say our mythology” (p. 95). The return to a description of the instincts and their vicissitudes leads, above all, to a new picture of the opposition and blending of the sexual instincts, Eros, and the aggressive instincts, “the expression of a ‘death instinct’ which cannot fail to be present in every vital process” (p. 107).

The thirty-third lecture, “Femininity,” has caused a good deal of controversy. The “riddle of femininity” (p. 116) is not explained, and rather than trying to describe “what a woman is” (p. 116) Freud tried to understand “how she comes into being” (p. 116). He emphasized the girl’s preoedipal attachment to her mother and the frequency of its transformation into hate at the time of the organization of “penis envy.” Henceforth, he would view this early bond of love and the needs that accompany it as the source of fantasies of seduction. However, faced with “the riddle of femininity,” he concluded: “If you want to know more about femininity, enquire from your own experiences of life, or turn to the poets, or wait until science can give you deeper and more coherent information” (p. 135).

The thirty-fourth lecture, titled “Explanations, Applications and Orientations,” returns to the points of dissent that had marked the history of psychoanalysis and comments on them. In the section on applications there is a plea in favor of teaching—with Freud commenting, “I am glad that I am at least able to say that my daughter, Anna Freud, has made this study her life-work” (p. 147)—and thus in favor of the use of analytic therapy for children. “[E]ducation must find its way between the Scylla of non-interference and the Charybdis of frustration” (p. 149), Freud reminded readers, before giving his concluding considerations on psychoanalysis as therapy: “You are perhaps aware that I have never been a therapeutic enthusiast” (p. 151), but nevertheless, “[c]ompared with the other psychotherapeutic procedures psycho-analysis is beyond any doubt the most powerful” (p. 153). However, in cases such as psychoses where a constitutional factor comes into play, the weight of the family environment for children, and the rigidity of some adults shows the limits of possible action. Further, the analytic work requires a long period of treatment, despite attempts that had been made (Otto Rank) to shorten cures.

The final lecture, “On a Weltanschauung,” was actually written first, and it refuses psychoanalysis the pretension of offering a new world view. Its scope is limited to the scientific, and in this it differs from religion and philosophy, as well as from political ideologies such as bolshevism.

Freud concluded with a paean to science, to which psychoanalysis must link itself. “A Weltanschauung erected upon science has, apart from its emphasis on the real external world, mainly negative traits, such as submission to the truth and rejection of illusions. Any of our fellow-men who is dissatisfied with this state of things, who calls for more than this for his momentary consolation, may look for it where he can find it” (p. 182).

## NEW YORK FREUDIAN SOCIETY

The New York Freudian Society was founded in 1959 as the New York Society of Freudian Psychologists. (Its name was changed to comply with the New York State Psychology Certification Law.) As of 2004, with more than 200 members, it is the largest independent society within the International Psychoanalytical Association (IPA). Gisela S. Barinbaum, born in Vienna, founded the Freudian Society with a small group of analysts, many of whom were her patients or supervisees. Like the Institute for Psychoanalytic Training and Research (founded in 1958), also an IPA society, and several other New York training institutes, the society was formed by members who split from the National Psychological Association for Psychoanalysis (NPAP), founded by Theodor Reik in 1948. The apparent reasons for the split were theoretical differences, but the underlying reasons were probably personal. The national association was considered not sufficiently Freudian in spite of Reik’s connection to Freud, and Reik, uninterested in psychoanalytic politics, made no effort to keep members from leaving.

The society grew slowly, having only a small number of members until the mid-1960s, when another younger group of disaffected NPAP members joined the organization and supplanted the original group that had coalesced around Barinbaum. Membership and the body of candidates grew steadily with the addition of analysts from the National Psychological Association for Psychoanalysis, the New York University Postdoctoral Program in Psychoanalysis and Psychotherapy, and analysts who had “bootleg” training, often by members of the New York Psychoanalytic Society. Barinbaum died in 1981, but her influence by that time had become insignificant.

A lawsuit seeking to restrict the mental-therapy trade, brought by members of the American Psychological Association against the American Psychoanalytic Association and the International Psychoanalytical Association, proved beneficial to the New York Freudian Society. The settlement of the lawsuit permitted societies to apply to the International Psychoanalytical Association. Site visits by the association followed

from 1987 to 1989, and the New York Freudian Society became a provisional member of the association in Rome in 1989 and a component society of the association in Amsterdam in 1993. The Confederation of Independent Psychoanalytic Societies, as of 2004, includes four independent American IPA societies.

The society's program of instruction and requirements for graduation follow a model used by the National Psychological Association for Psychoanalysis (which in turn is based on a model of the Berlin Institute for Psychoanalysis, probably originated by Reik, who taught there). Its four years of course work are best characterized as contemporary Freudian in content. It has a program of instruction in Washington, D.C., and a program in child and adolescent analysis in New York and Washington. Its programs have 100 analysts in training as a result of a less formerly restrictive approach toward who is eligible to become a training analyst—a carryover from the National Psychological Association for Psychoanalysis. A board of directors governs the society and its attached Psychoanalytic Training Institute. About half its members are psychologists, 40 percent social workers, and 10 percent physicians. The training institute has 100 candidates in various stages of training.

The society sponsors numerous scientific programs, an annual conference, and many study groups and presentations. Its members publish widely and make important contributions to the broader psychoanalytic community. In 2004 almost half of the members of the Freudian Society were graduates of the Psychoanalytic Training Institute.

## NEW YORK PSYCHOANALYTIC INSTITUTE

The New York Psychoanalytic Institute is an educational institution whose purpose is the training of psychoanalysts in the Freudian tradition.

Its origins derive from an organization, the New York Psychoanalytic Society, founded by Abraham Arden Brill and others in 1911 for the study of psychoanalysis, the first such organization in the United

States. Brill had previously translated Freud into English, published in a widely-distributed Modern Library edition.

After World War I a small group of psychiatrists from New York went to Vienna for personal analysis with Freud with a view to obtaining a psychoanalytic education. Their number increased in the 1920s with the addition of Americans who had been formally trained in the institutes of Berlin, Budapest, and Vienna. In response to a growing demand for formal instruction the New York Psychoanalytic Society organized its first series of lecture courses in the fall of 1922, and in 1923 appointed its first educational committee to organize and improve the teaching functions of the society. Enrollment was limited to physicians with an MD degree to conform to the recent standardization of medical education in the United States. The basic structural elements of the tripartite model was already in place: personal analysis, seminars, and the supervision of cases in analysis.

On September 24, 1931, the New York Psychoanalytic Society established the New York Psychoanalytic Institute, patterned after the Berlin Psychoanalytic Institute from which Sandor Rado was recruited to become the first educational director. The institute has been educationally autonomous and financially self-supporting from its inception. The graduates of the New York Psychoanalytic Institute become members of the New York Psychoanalytic Society. Dues, tuition, and income from an endowment created by the members provide the funds. Then as now, the society sponsors the presentation and discussion of scientific papers and interdisciplinary seminars. The institute, responsible for the training of candidates, selects teachers and training analysts, at first by the Educational Committee itself, later by the faculty electing an ad hoc committee which has come to include the intensive evaluation of current psychoanalytic work.

In the 1930s, psychoanalysis was an important part of the intellectual ferment of the times so that prominent intellectuals as well as many others sought personal analysis. Eminent psychoanalytic writers who contributed to the expansion of psychoanalytic knowledge at that time included Bertram Lewin, Paul Schilder, Sandor Rado, and Sandor Lorand.

During World War II, the successful application of psychoanalytic principles to the treatment of war neuroses, the only set of ideas that explained these condi-

tions, influenced many American doctors to seek psychiatric training so that they could qualify for psychoanalytic training. Applications to the institute exceeded 60 in those years, and classes of 30 were not unusual, compared to the early twenty-first century's average number of applications of six to eight and classes of four or five.

Hitler's persecution resulted in the immigration of large numbers of eminent European psychoanalysts who became intellectual leaders and senior teachers. In New York these included Heinz Hartmann, Ernst Kris, Rudolph Loewenstein, Edith Jacobson, Robert Bak, Kurt Eissler, and many others. In cooperation with Anna Freud, they established contemporary ego psychology. In the area of child analysis leadership was supplied by Berta Bornstein, Marianne Kris, and Margaret Mahler.

Hartmann introduced the adaptational point of view as part of his effort to make psychoanalysis a general psychology. These ideas as well as the earlier contributions by psychoanalytic thinkers in the 1940s, 1950s, and 1960s greatly influenced the fields of social science, mental hygiene and child care. The New York Institute in that period served as a model for institutes throughout the United States.

With the passing of the European psychoanalysts in the 1970s and 1980s, the mantle of leadership fell chiefly to Jacob Arlow and Charles Brenner, who also clarified and codified Freud's contributions in 1923 and 1926, and outlined a modern, contemporary psychoanalysis based on human psychology viewed as the outcome of intrapsychic conflict.

There have been many profound teachers who published very little, but influenced large numbers of candidates at the institute. One such individual was Otto Isakower, who revised the curriculum in the late 1950s from a chronological reading of Freud's works to a topic-dominated collection of courses covering the literature from Freud's earliest works to contemporary contributors and critics within the Freudian tradition. In recent years many of the proliferation of divergent ideas in psychoanalysis have been added to the curriculum.

The administrative structure of the New York Institute and Society is a representative democracy. Every graduate of the Institute becomes a member of the Society and automatically a member of the Institute, with the right to vote and hold office in both. The Society is concerned with the scientific program and

the relationship to other societies of the American Psychoanalytic Association; the Institute with psychoanalytic training. The governing body of the Institute is the Educational Committee. The training analyst members of the faculty select a committee that nominates training analysts who are eligible for membership on the Educational Committee. The electorate consists of the entire membership of the Institute/Society.

In recent years there has been a vast expansion of the Institute's and Society's activities beyond the training of candidates. There is a large Extension School for psychiatric residents, psychology interns, and social work doctoral candidates which teaches psychoanalytic principles, psychotherapy, child development, and various special subjects such as dreams, and the treatment of severe character disorders. The Institute also provides an externship for graduate students in psychology which includes supervision of psychotherapy, and a fellowship program for selected potential candidates which has come to include psychiatric residents and PhD students in psychology and social work. This program offers seminars in theory and case supervision. A psychotherapy training program is in the planning stage. With the decline of psychoanalysis as a profession in the United States, and its fragmentation as a discipline, the New York Institute is attempting to teach what is considered fundamental to the Freudian tradition, but does not neglect the multiplicity of ideas and technical innovations that have emerged and have contributed to enlarging our psychoanalytic understanding. The Institute has also expanded its interaction with training programs of potential candidates, and with the community at large, to attempt to educate larger numbers about psychoanalysis and its value.

## NIGHT TERRORS

Night terrors are pathological phenomena that begin around three or four years of age. The child suddenly wakes up at the beginning of the night; he or she is terrified, screams in bed, and seems to be in the grip of hallucinations. When the worried parents arrive, the child does not recognize them and they are unable to calm the child. This state persists for a few minutes, at most, and brings with it neurovegetative manifestations (sweating, tachycardia, and polypnea). Once he or she has calmed down, the child goes back to sleep. The next day the child has no memory of the episode. Night terrors can be recurrent, but in general they disappear around the age of five or six.

There is no reference to night terrors in the works of Sigmund Freud. The phenomenon is difficult to apprehend from a psychoanalytic point of view; because of the amnesia that follows them, night terrors are not accessible, as dreams are, to any secondary revision. This sleep disorder probably reflects a failure in the dreaming function—a weakness in figuration and the binding of affects with mental representations.

We can refer to the work of Didier Houzel, who used electrophysiological observations as the starting point for a physiological explanation for night terrors. They occur during the phases of slow wave sleep (phase IV), outside of the phases of paradoxical sleep in which dreams occur. Phase IV sleep includes physiological aspects that herald the paradoxical sleep phase. Slow wave sleep is a reparatory phase of dream activity; night terrors suggest a blocking of the dream, which cannot begin during this slow sleep phase and, therefore, cannot proceed with the work of psychically binding instinctual energy.

As for the etiology of night terrors, which coincide with the arrival of oedipal conflict, different factors have been identified: libidinal conflicts proper to this period of emotional life, traumatic events, and, finally, disturbances in the child's affective relationships with people close to him or her. The persistence of night terrors beyond the oedipal period is a sign that the child is incapable of elaborating better psychic defenses. They can mark a return to preoedipal positions.

## NIGHTMARE

Nightmares are dreams whose contents are unpleasant or anxiety provoking and which, depending on their intensity, can awaken the sleeper. Also known as anxiety dreams, nightmares attracted the interest of Sigmund Freud, who refers to them for the first time in *The Interpretation of Dreams*. There, he shows how nightmares are not an exception to dream theory and, more specifically, that they are consistent with the theory that dreams are the fulfillment of a wish. The anxiety experienced during the nightmare can only be apparently explained by its content. Although intrinsically linked to its accompanying representations, the anxiety arises from a different source. In this sense the anxiety of the dream is identical to the anxiety experienced during neurosis.

Based on this analogy, Freud claims that nightmares are dreams with a sexual content whose libido is transformed into anxiety. The content is generally exempt from any form of distortion and represents the unveiled realization of a repressed desire that has shown itself to be stronger than censorship. The anxiety that accompanies the dream then takes the place of the censorship.

Nightmares can awaken the dreamer, and sleep can be interrupted before the dream's repressed desire has, faced with the censorship, reached its complete realization. In this case there is a failure to form the compromise that constitutes the dream, which then fails to fulfill its function as the guardian of sleep.

Although Freud did not change his dream theory, he updated it in *Beyond the Pleasure Principle* (1920). The repetitive anxiety dreams observed in people suffering from traumatic neuroses cannot be explained by the fulfillment of a repressed desire. In these nightmares a profoundly unpleasant and anxiety provoking event is repeated. To explain this, Freud introduces the hypothesis that the dream serves to bind the instinc-

tual excitation to avoid overwhelming the psychic apparatus with traumatic material. In traumatic neurosis this binding function is disturbed.

Ernest Jones, in his book *On the Nightmare*, interpreted anxiety dreams as the fulfillment of a repressed wish associated with infantile sexuality. More recently, French authors, relying on experimental findings that reveal that through the different paradoxical sleep cycles the same dream matter becomes increasingly less comfortable as dreaming progresses, have hypothesized that this phenomenon may be the reflection of the dream's work of organization, integration, or binding. This would result in the gradual development of the most archaic signifiers, increasing their complexity, combining them, and dramatizing them in primary fantasies that have been relegated to secondary importance. According to this assumption, nightmares are the reflection of the failure of these binding processes, whereby anxiety occurs through the inability to repress archaic signifiers.

## **NIN, ANAÏS (1903–1977)**

Anaïs Nin, a diarist, writer, and lay analyst, was born on February 21, 1903, in Neuilly, near Paris. She died on January 16, 1977 in Los Angeles.

She was the daughter of Joaquin J. Nin y Castellanos (1879–1949), Cuban-born Spanish pianist and composer, and Rosa Culmell (1871–1954), Danish-French soprano. Nin lived in France, Belgium, Germany, and Spain until 1914, when her mother took her and two younger brothers to America. Her father, a compulsive Don Juan, had deserted his family for a young student. In New York Nin soon quit school, educated herself, and worked as a model for artists and clothing manufacturers.

In 1923 she married Boston-born Hugh Parker Guiler (1898–1985), a Columbia University graduate. From 1924 until 1939 the Guilers lived in Paris, where "Hugo" became an officer of an America bank, and Nin pursued her writing. They returned to New York in 1940, due to the war, and Nin, in 1948, began a "trapeze" life between her husband in New York and a lover in California, which she secretly pursued for almost thirty years. She died of cancer in Los Angeles in January 1977.

Lastingly traumatized by the enforced separation from her beloved father, on her journey into lifelong "exile," the eleven-year-old Catholic girl began a deeply confessional diary, from which edited selections first appeared in 1966. A record of an unending effort to realize and reconcile multiple potentials of an essentially fluid self, to find absolution in art, and to express an unrestrained female sexuality—see, for instance, the erotic stories in *Delta of Venus* (1977) and *Little Birds* (1979)—Nin's *Diary* stands as a unique, massive, psychological document of a woman's life in the 20th century.

Nin read and defended D. H. Lawrence in her first book, *An Unprofessional Study* (1932), and had an incestuous reunion with her father in 1933. Confused by her eruptive sexual awakening, and after discovering psychoanalysis, Nin initially became a patient of René Allendy, who failed to understand her creative needs. Her next treatment was with Otto Rank, who fell in love with her. In 1934 she followed Rank to New York. She briefly served as his assistant and conducted result-oriented therapy sessions with a number of patients in 1935 and 1936, but eventually returned to Paris and her writing. See, for instance, the story "The Voice" in *Winter of Artifice* (1939).

## NIRVANA

The term “Nirvana,” first suggested by Barbara Low and acknowledged and used by Freud, is intimately connected with the development of the concepts of the pleasure/unpleasure principle. The concept has a long history, and contributed to Freud’s understanding of the infantile wish-fulfilling character of dreams.

In Chapter Seven of *The Interpretation of Dreams* (1900a), in which Freud conceptualized the mental apparatus, he suggested that, to begin with, the apparatus is directed towards keeping itself as free from stimuli as possible in accordance with the “Principle of Constancy.” This principle was already a basic assumption, and had appeared as such in many of Freud’s earlier writings—for example in a letter to Josef Breuer (June 29, [1892] 1960a) and in various sections of Part One of the *Project for a Scientific Psychology* (1950c [1895]), through in quasi-neurological terms. But as Freud indicated in a footnote added in 1914 to the dream book, the concept is explored more fully in his paper on “The Two Principles of Mental Functioning” (1911b).

The Lust/Unlust–pleasure/pain principle is described there as the governing purpose of the primary process. There is a continued striving towards gaining pleasure, and a retreat from anything that might arouse unpleasurable affect. It is precisely the latter that dreams seek to avoid: when the state of rest is disturbed by internal needs, an attempt is made to achieve satisfaction in a hallucinatory manner.

With the emergence of the secondary process, reality is at least recognized, even when disagreeable; and the individual now must seek pleasure in accordance

with what is possible in the circumstances in which they find themselves. To put the matter in energetic terms: unpleasure was associated with a rise in excitation; pleasure with its reduction and discharge, and, with the acquisition of the reality principle, this discharge of excitation, once sought as a peremptory demand under the influence of the pleasure principle, now has to wait until reality presents the necessary conditions or until those conditions can be brought about. (Pleasure can, of course, always be expressed in fantasy and day dreams, whatever the circumstances.) The search for pleasure, it will be observed, is related to, but not identical with, the “Principle of Constancy” referred to above.

Already, especially in the paper *Instincts and their Vicissitudes* (1915c), Freud had stated that the relation existing between pleasure and unpleasure on the one hand, and the rise and the “fluctuations of the amounts of stimuli affecting mental life,” on the other, was no simple matter, and that the relations were many, various, and in need of elucidation.

In *Beyond the Pleasure Principle* (1920g) Freud reformulated his two classes of instincts and opposed the one, Eros or the Life Instinct, with the destructive or Death Instinct. The aim of the Death Instinct was to get rid of life through the running down of the organism, and therefore of the tensions within it. This “dominating tendency of mental life”—“to reduce, to keep constant or to remove internal tensions due to stimuli”—was called the “Nirvana principle,” a term suggested by Barbara Low and here adopted by Freud.

The difficulties and anomalies inherent in these formulations were reconsidered by Freud in *The Economic Problem of Masochism* (1924c). Re-affirming his adoption of the Nirvana principle, he pointed out that, if the pleasure principle were identical with it, that principle would be “in the service of the death instincts” and would act as a warning against the demands of the life instincts that threatened to disturb the intended course of life. But that view, said Freud, could not be correct. Furthermore, in the series of tensions and their increase and decrease, there were pleasurable tensions (for example, sexual excitation) and unpleasurable relaxations of tensions. Pleasure and unpleasure could not depend on some quantitative factor alone, but on some qualitative characteristics. It might be “the rhythm, the temporal sequence of changes, rises and falls in the quantity of stimulus.” Freud added: “We do not know.” Whatever the truth

of the matter, the Nirvana principle had undergone a modification in living organisms through which it had become the pleasure principle. “Henceforward,” he continued, “we shall avoid regarding the two principles as one.” And he concluded by saying that the Nirvana principle expressed the trend of the death instinct; the pleasure principle represented the demands of the libido; and the modification of the latter principle, the reality principle, represented the influence of the external world.

It may be worth adding that an optimum level of tension normally gives life its sense of vividness and alertness. Reduction of tension to zero, unless transient, is often pathological, and found, for example, in states of depression, some kinds of depersonalization, and in the anergic forms of schizophrenia.

### **NODET, CHARLES-HENRI (1907–1982)**

Charles-Henri Nodet, a French psychoanalyst and psychiatrist, was born July 5, 1907, and died on March 20, 1982, in Bourg-en-Bresse.

On both his mother’s and father’s side, Nodet came from five generations of doctors. His mother was the daughter of the sculptor Cabuchet, who had a reputation locally. Heir to a lengthy Catholic bourgeois tradition, Nodet attempted to gain some distance from his background.

He was a brilliant student at school in Bourg-en-Bresse and later in the department of medicine in Lyon. He was first academically among his fellow medical clerks and, in 1932, obtained first place in the internship competition for the Asiles de la Seine, where his teachers were G. de Clérambault, P. Guiraud, and H. Claude, and his fellow students Henri Ey, Sacha Nacht, Daniel Lagache, Julien Rouart, and Jacques Lacan. Among the patients was Antonin Artaud, about whom Nodet wrote in a memo of April 1938: “His literary pretensions may be justified to the extent that the delusion may serve as an inspiration.” His medical dissertation, completed in 1936, was on “chronic hallucinatory psychoses.” He attended the philosophy courses given by Jacques Maritain. He received his license to practice psychiatry in 1937, again in first place. He married Isabelle Blanquet du Chayla at the end of 1943; they had three children.

When he returned to Bourg-en-Bresse in 1939 as a psychiatrist, he knew little about psychoanalysis. What changed his mind was a transference episode that was almost a caricature of the concept. While treating a hysterical paraplegic patient who was his mother’s age, he claims he was amazed to find that, after the third interview, the patient was able to move her limbs, while stating to him, “You’re a genius. I’m healed, but, I don’t know how to say this, I’m in love with you!” From 1947 on Nodet began to undergo treatment with Charles Odier, Raymond de Saussure, and Michel Gressot, and in 1964 became the first—and the only one at the time—provincial member of the Société psychanalytique de Paris (Paris Psychoanalytic Society). He practiced psychoanalysis from 1951 until 1982, the year of his death.

Nodet was a prolific author, some of whose articles were “pedagogical” in nature, designed to introduce psychoanalysis to members of the Catholic Church. His only book, published posthumously, is an anthology of his published essays together with some unpublished writing.

One of Nodet’s major contributions was that, while the unconscious is always an integral part of every

human activity, even the most apparently rational, analytic theory cannot be conceptualized “without reference to an implicit ideological presumption and a teleology of truth and ethics” (Oudot, R., 1982).

Nodet, more a clinician and practitioner than an innovative theorist, deserves a place in the history of French psychoanalysis for a number of reasons. Being the only provincial exemplar for years, he attracted a number of future analysts—some of whom are fairly well known—to his practice. In 1958 he co-founded the Groupe Lyonnais de Psychanalyse (Lyon Group for Psychoanalysis). He conducted clinical and theoretical seminars and provided technical supervision to individuals and groups.

It has also been said that Nodet had “demonized” psychoanalysis among the hierarchy of the Catholic Church. But he remained true to his profession, and did so without making any concessions, without obscuring the theoretical content of the discipline.

## **NONVERBAL COMMUNICATION**

The question of nonverbal communication involves two distinct areas of epistemology whose theoretical and clinical characteristics have, as of 2005, yet to be articulated: a developmental and linguistic field and a psychoanalytic field. In terms of developmental issues, Frédéric François notes that the body has been largely

overlooked by theoreticians of meaning, language, and communication. Understanding facts often begins with an understanding of the final state of their ontogenesis and it is only afterwards that we can retroactively investigate the roots, foundations, and precursors of the object of study. According to François, “It may be the descriptions of the final state that enable us to begin with well-formed utterances, with syntax, and then go on to examine their semantics, whatever it is those utterances may want to say and, ultimately, of the pragmatics, of the reasons for saying, of what it is that urges us to speak and what we are doing when we speak. And although it is true that linguistics has followed this sequence in its development, it is just as true that the child follows the opposite sequence.” In other words, it is the result of a natural process in the history of understanding that structural linguistics has developed (Ferdinand de Saussure) before what is currently known as subjectal or dynamic linguistics, which makes greater use of preverbal levels of communication.

Today it is obvious that work on the development of language in children essentially involves an investigation of its corporeal roots, whether these are found in the work of pragmatists (John Austin, Jerome Bruner), cognitivists (C. Trevarthen), or those interested in suprasegmental elements of the speech chain (Ivan Fonagy). All of them attach great importance to deepening our understanding of the preverbal communication that precedes the development of verbal communication, but which accompanies it, shadowlike, throughout life.

For neurophysiology, verbal communication, often referred to as encoded or digital communication, serves an analytical function and is primarily supported by the major hemisphere (involving the integration of the “twofold articulation” of language into phonemes and monemes described by André Martinet), while preverbal communication, known as suprasegmental or analogical, is said to serve a more global and holistic function, and is principally supported by the minor hemisphere (integration of behavioral communication and the music of language: prosody, rate of speech, rhythm, timbre, intensity, and so on, all of which are elements that constitute the nonverbal component of verbal speech).

In terms of psychoanalysis, the history of research on nonverbal communication is superimposed on the history of the concept of counter-transference to the

extent that the latter is essentially grounded in a more or less archaic level of emotional communication. From this point of view so-called preverbal communication refers as much to bodily communication, mimicry and behavior, as it does to the unencoded element of language.

It was primarily Melanie Klein who exposed this field of study by her introduction of the concept of projective identification. The importance that the post-Kleinian movement accorded to the process of counter-transference is well known. For rather than being considered an obstacle to therapy, counter-transference was treated as a fundamental tool for working with the patient, regardless of his or her age. Wilfred Bion, through concepts like the “mother’s capacity for reverie” and the “alpha function,” did much to improve our understanding of these primitive levels of communication, which come into play in group dynamics and in the minds of psychotic subjects. Bion’s model was then used for investigating the development of the mental life of the infant.

Julia Kristeva studied the suprasegmental elements of the language of depressive patients. Guy Rosolato, through his concept of “metaphoric-metonymic oscillation,” tried to take into account the modalities of the transition between representations of things and representations of words, or, ultimately, between unconscious systems and preconscious-conscious systems, modalities that would clarify the different levels, analog and digital, of communication. Gradually, and in parallel with this work, affect began to assume the function of “representance” (André Green), which acts directly as a medium for nonverbal communication.

At present it is in the investigation of analytic therapies for very young children or patients presenting archaic pathologies that the work of developmental psychologists (Daniel N. Stern) and psychoanalysts finds common ground. Nonetheless, research on nonverbal communication has become a central part of therapy for all patients, even adult and neurotic patients.

## **NORTH AFRICAN COUNTRIES**

Psychoanalysis is practiced in some North African countries, particularly Morocco and Tunisia. In Algeria it can be found in rare institutions. It seems never to have made an appearance in the remaining two North African countries (Libya and Mauritania). The presence of psychoanalysis is due to several factors: a French colonial past, cultural openness, multilingualism, the proximity of Europe, and the existence of several different trends in clinical psychiatry. However, psychoanalysis remains relatively undeveloped in spite of a genuine need to help a generation that suffered the effects of social violence and upheaval in the 1990s.

Morocco was the only North African country exposed to psychoanalysis during the colonial period. It was introduced by René Laforgue in 1948 when he went into exile with a group of friends and analysands, who were then joined by practitioners already practicing in the country (Jean Bergeret, Maurice Igert, Monique Foissin, and Louis Clément). Laforgue postulated the existence of radical structural differences among different peoples, ethnic groups, religions, and races. These nationalistic theories were far removed from North African preoccupations and were rejected by North African practitioners. Some of his students occupied positions of responsibility in hospitals (Igert, Clément, and Rolland) and contributed to introducing psychopathology to Morocco.

Because of the existence of a structured school of psychiatry under the patronage of Antoine Porot and the absence of psychoanalysts working in institutions, Algeria remained untouched by psychoanalysis during the colonial period. Nonetheless, three analysts set up practice there during the 1950s.

Though Angélo Hesnard was mobilized and stationed at Bizerte, Tunisia, in 1940, his stay there did not contribute to introducing psychoanalysis to the country. Institutional psychotherapy was introduced by Frantz Fanon, a politically committed psychiatrist who worked in Algeria in 1953 and Tunisia in 1956. Psychoanalysis began to take root in Tunisia in the 1960s as a result of the work of Lydia Torasi, an Italian psychologist-psychoanalyst.

After Morocco gained its independence in 1956, Laforgue and the other members of his group progressively returned to France. Some, like Clément and Legrand, delayed longer than others. During this period the first Moroccan psychoanalyst, Leila Cherkaoui, commenced work in 1969, followed by Smiljka Sif and Mohamed Abed. In the 1980s a new wave of French-trained psychiatrists and psychologists reintroduced psychoanalysis in the public and private sectors. Of special note are Jalil Bennani, Monique Kasbaoui, Ghita El Khayat, and Mohammed Fouad Benchekroun.

When Algeria became independent in 1962, most French psychiatrists left the country and local talent such as Khaled Benmiloud and Mahfoud Boucebcı began to develop psychiatry. The latter helped open up treatment centers to psychoanalysis. Although not a psychoanalyst, Boucebcı used some psychoanalytic concepts in his writings. Prominent psychoanalysts during the 1980s were Boubker Gouttali and Lotfi Benhabib, the latter of whom created the first psychoanalytic institution for children.

The same period in Tunisia saw the appearance of Tunisian practitioners (Samia Attia, Saïda Douki, Fakhredinne Haffani, Essedik Jeddi, Taoufik Skhiri, Khalifa Harzallah) and the integration of psychoanalysis in training centers and institutions. Although these therapists do not all practice as psychoanalysts, an element of psychoanalysis is present in their writings and practices.

As of 2004, North Africa had no developed psychoanalytic institutions similar to those in Europe and North America. Nonetheless, work groups and individuals

practicing in the public and private sectors contribute to transmitting and developing psychoanalysis in North Africa; psychoanalytic thought exists as a frame of reference for many clinical psychiatrists and psychologists; and practitioners affiliate themselves with different psychoanalytic trends. Not all the work of these practitioners has been published, so an inventory of current research cannot be exhaustive.

In Morocco, Jalil Bennani, a psychiatrist and psychoanalyst, was the driving force behind the creation of the association *Le texte freudien* (The Freudian Text) in 1985 and the *Association marocaine de psychothérapie* (Moroccan Association for Psychotherapy) in 1992. For three years the first of these organizations brought together all who were interested in psychoanalytic texts, whether practitioners or not. The second consisted of several commissions, including one devoted to psychoanalysis. Studies published during the 1980s and later deal with a variety of questions, such as circumcision (Mohammed Fouad Benchekroun), bilingualism (Jalil Bennani), the role of the father (Dachmi), and cultural resistance (Ghita El Khayat).

In Algeria, Loufti Benhabib and Abdelhag Benounich created the *Association de formation continue en santé mentale* (Association for Ongoing Mental Health Training) in 1988 and organized psychoanalytic training seminars and symposia, to which practitioners from abroad were invited to attend. In 1994 the association had to suspend its work because of the political situation. In 1989 clinical psychologists Mohand A. Aït Sidhoum, Fatima Arar, and Djamilia Haddadi founded the *Société algérienne de recherches en psychologie* (Algerian Society for Psychological Research). This society launched the journal *Psychologie* (Psychology) and the book series “Sémailles” (Seeds) with a view to disseminating psychoanalytic thought, and in the 1990s it was studying how to establish psychoanalytic training complying with the requirements of the International Psychoanalytical Association. Earlier publications worthy of attention are Mahfoud Boucebcı’s work on individual and family psychopathology and on children in traditional environments.

In Tunisia, the *Société d’études et de recherches en psychanalyse* (Society for Psychoanalytic Study and Research) formed in 1990 around Mohamed Halayem, the child psychiatrist and psychoanalyst. It uses seminars and supervised groups to introduce young psychiatrists and psychologists to psychoanalytic theory

and practice. Among available studies, Mohamed Ghorbal's work on the oral nature of communication in North African society is of particular interest. Also worthy of note are Saïda Douki's research on depression and suicide, Essedik Jeddi's studies of the family and psychosis, and Mohamed Halayem's study of semantics. But this society had only a brief existence.

In 1998 another Tunisian, Riadh Ben Rejeb, founded the *Unité de Recherche en Psychopathologie Clinique* (URPC) [Unit for Clinical Research in Psychopathology] and began to organize annual international meetings around various themes. Training in psychoanalytic psychotherapy, in individual psychoanalytic psychodrama, and analysis is organized through conferences, seminars, and psychoanalytic treatment. Neither a training institute nor a society per se, the range of its courses and activities remains restricted, creating an intellectual climate informed by psychoanalysis but not a culture of analytic learning. Psychoanalysis has had a salutary effect on the training of Tunisian physicians with respect to infant and adolescent psychopathology, but the country is still without a psychoanalytic institution.

Psychoanalysis is thus established in North Africa, and institutions in the region are studying how to open up new orientations and promote new initiatives in analyst training.

Also worth mentioning is the work of researchers outside North Africa whose writings have contributed to a greater awareness of psychopathology and psychoanalysis in North Africa. Of note is Fethi Benslama's work on Islam and psychoanalysis and on the role of the father, the individual, and sacrifice. Malek Chebel continues to research the Arabo-Muslim imagination, the body, love, and seduction. Daniel Sibony has studied how fundamental texts structure mentalities, but his interpretations concerning the community of believers in Islam have received much criticism. Many authors, whether North African (such as Zhor Benchemsi, Mohand Chabane, Okba Natahi, and Abdesselem Yahyaoui) or non-North African (for example, Jacques Hassoun, René Kaës, Olivier Douville, and Jean-Michel Hirt), have studied exile and migration. Research that focuses on North Africa is characterized by fruitful and sometimes contradictory debates and ongoing questioning reflecting the unique character of North Africa, its relationship with foreign languages (which are sometimes rejected and sometimes reap-

propriated), and questions of identity specific to each North African country.

## **NORWAY**

Psychoanalysis has throughout its history in Norway had strong connections with both the psychiatric health-care system and with academic psychiatry and psychology.

In 1905, Ragnar Vogt, who was to become the first professor of psychiatry in Norway, referred to the “psychocathartic” method of Freud in his psychiatric textbook, *Psykiatriens grundtrek* (An outline of psychiatry). Freud (1914d) referred to this as the first textbook of psychiatry to refer to psychoanalysis. It was not until the 1920s, however, that psychoanalysis was practiced in Norway, first and foremost under the leadership of Harald Schjelderup, who was from 1928 professor in psychology at the University of Oslo.

Schjelderup and several others went to central Europe for training, and psychoanalysis was established as a clinical discipline over the course of the 1930s, although there were intense debates and at times heavy opposition from the medical and clerical establishments. In the cultural field psychoanalysis was discussed both theoretically (the Freud-Marx debate) and on the practical and political level in the struggle for a healthier attitude toward sexuality. The latter was spear-headed by the journal *Sexual Information*, published by Karl Evang, later the surgeon general in Norway.

On August 22, 1931, a group of Scandinavian psychoanalysts gathered in Stockholm to establish a study-circle of psychoanalysts, with the aim of seeking an affiliation with the International Psychoanalytical Association (IPA). In 1933 a Nordic psychoanalytic society was formed with Alfhild Tamm from Sweden as president and Schjelderup as vice-president. At the Luzern congress in 1934, it was decided to establish a Danish-Norwegian and a Finnish-Swedish society, following a heated debate on the subject of unscientific analysis. This debate stemmed in part from the fact that Wilhelm Reich came to Oslo in 1934 at the invitation of Harald Schjelderup. Ernest Jones, the president of IPA, set the condition that Wilhelm Reich was not to be member of the Danish-Norwegian society. This was unacceptable as a condition, but Reich was nevertheless rejected for membership by society vote. The Danish-Norwegian society (soon altered to Norwegian-Danish because of the limited participation from Denmark) was then established, with Harald Schjelderup as president and Otto Fenichel as secretary. Fenichel had arrived in Oslo in 1933 and stayed until 1935. The first years of organized psychoanalysis in Norway were then marked by the struggle between the forceful personalities of Fenichel and Reich. This created a split in the milieu. The battle, which also engaged the medical establishment and the public, was centered on Reich's development of character-analysis, "vegetotherapy," and his quasi-scientific discoveries of the energy of life. Reich was ordered to leave Norway in 1939. His work on character-analysis has, however influenced psychoanalysis and psychiatry, and especially child-psychiatry through the work of Nic Waal.

When Germany occupied Norway, it was decided to temporarily dissolve the psychoanalytic society, to avoid being seen in Germany as interfering with the Nazi regime. Most of the members of the society participated in the resistance movement or in other defensive activities. Harald Schjelderup, as leader of the resistance at the university, was sent to the Grini concentration camp, near Oslo, and several others were forced to flee. Landmark died in violence in northern Norway, and P. Bernstein died in a concentration camp in Germany.

The temporary dissolution during wartime was not intended as a resignation from the IPA, but was treated as such by IPA authorities. The pioneers Schjelderup, Braatøy, and Simonsen re-established the Norwegian-Danish society in 1947, and it continued until 1953

when the Danes started their own organization. They were accepted as a component society in 1957 but it was not until 1975 that the Norwegian society received this status. The reason for the exclusion after wartime has not been established, and there is no official documentation that such an exclusion occurred. It was, however, obvious that the shadow of Wilhelm Reich's influence was a disadvantage for membership. An application made at the XVIII congress in London in 1953 was turned down with the argument that there were some members of the group who did not practice psychoanalysis, obviously referring to people seen as followers of Reich. The Norwegians argued that it was impossible to break with colleagues with whom one had resisted during the war. There followed a long struggle for recognition, with applications made at different congresses. One problem was the limited practice of Schjelderup, who maintained few sessions a week in training analysis, with the express purpose of increasing the educational capacity (he also claimed good results). In 1971 the Norwegian society was given status as a study group, and it finally regained status as component society in 1975 (Alnæs, 1994).

The Norwegian Psychoanalytic Institute had already been established in 1967 under the leadership of Peter Andreas Holter and the formal recognition by IPA gave impetus to an expansion of its activities, with a responsibility for psychoanalytic education being at the center. In later years other activities have seen increased focus, including research, teaching, and lecturing. The institute publishes the *Scandinavian Psychoanalytic Review* in collaboration with the other Scandinavian societies.

The modern Society has more than fifty members and still more candidates. There is an active child-analytic group and a group working with psychoanalytic research. The main trend is a broad object-relational approach with emphasis on analysis of character, along with some inspiration from ego-psychology.

The most significant figures in Norwegian psychoanalysis have contributed in a variety of capacities. Harald Krabbe Schjelderup (1895–1974) was the main pioneer of psychoanalysis in Norway. His numerous publications on psychoanalysis include, *Neurosis and the Neurotic Character* (1940) and "Lasting Effects of Psychoanalytic Treatment" (1957). Trygve Braatøy (1904–53) trained in Berlin. He worked at the Menninger clinic, 1949–1951, and was clinical director of a psychiatric hospital in Oslo. His publications include

*Foundation of Psychoanalytic Technique* (1954). Hjørdis Simonsen (1899–1980), perhaps the most important figure in the 1930s and after the war, was trained in Berlin, and later worked as a training analyst. Nic Waal (1905–1960), trained in Berlin and became a child psychiatrist. Finn Hansen (b. 1918), trained in Berlin and worked as training analyst. Peter Andreas Holter (b. 1927), a training analyst, was the first leader of the institute.

## **NOSTALGIA**

Nostalgia (*Sehnsucht*) refers to the moral pain of the expatriate when he is overcome with the obsession of return. The self-absorption, morosity, and feeling that there is nothing more to say about the situation are the first clinical manifestations of a secret torment that is likely to become aggravated. A state of desolation and physical malaise is soon established, which is fertile ground for infection and functional disorders, as if the subject's vitality had been sapped. In eighteenth- and nineteenth-century medical practice, this feared diagnosis went hand-in-hand with a grim prognosis.

The word is a neologism that appears for the first time in a medical dissertation written in Latin in Basel on June 22, 1688. It records, in academic language, what was then commonly referred to as “homesickness,” or *Heimweh*. Johannes Hofer's thesis is based on two clinical histories: a student from Bern who wasted away in Basel, and a servant who, after an accident, wasted away in the hospital far from her family. In both cases the patient was in agony and the return to

the family home resulted in a nearly miraculous cure. He proposed an interpretation based on the movement of animal spirits to account for the pathological phenomena.

Hofer described a new disease, unknown to Hippocrates and Galen, one that had become the subject of debate in departments of medicine throughout Europe. There was concern that the illness may have been unique to the Swiss, associated with the geographical isolation of mountain life or the physiological effects of migration to low-altitude regions. There had been cases of nostalgia among the Swiss regiments serving the king of France, and among foreign soldiers. There was, for example, a grenadier from Westphalia who had been consumed by *Heimweh*, which negated the idea that the illness was confined to mountain dwellers.

Although nostalgia was a medical discovery, it also held the interest of philosophers. Haller wrote an article on the subject for Diderot's *Encyclopaedia*. Rousseau, in his *Dictionnaire de la musique*, described a certain melody, the “Ranz des Vaches,” that had the power to trigger an epidemic of nostalgia and desertion among the Swiss garrison at Versailles. Kant believed that nostalgia was not a disease of exile but of poverty, and that territorial ties could be overcome through social success and wealth. Later, Jaspers, in his medical dissertation showed how *Heimweh* could turn young adolescents who left home too early into criminals or delinquents.

A century after the Basel dissertation, circumstances contributed to a new clinical understanding of nostalgia. Between 1789 and 1815, the number of cases multiplied, especially among emigrants and soldiers away from home. Military doctors developed clinical experience and therapeutic skills, as shown in the writings of Percy, Des Genettes, and Larrey. They learned how to recognize the feverish language and false sense of shame of the true nostalgic, and developed a form of psychotherapeutic treatment that pushed the patient to recall the “pleasant memories” of home, in his own language if possible. “The treatment of essential nostalgia,” wrote Baron Percy, “should be moral rather than pharmaceutical. It has been shown by experience that the administration of medicines does more to aggravate the symptoms than to relieve them.”

After 1830 the triumph of the anatomical-clinical method would gradually discredit the diagnosis of

nostalgia. Medical progress was based on the examination of lesions of organs and the identification of infectious germs, but autopsies and microscopes revealed nothing about the obsession with a return to one's home. Within a period of fifty years the word nostalgia disappeared from the medical lexicon. At the same time it made its appearance in literature, where it then referred to a romantic emotion and not a disease: the sadness of being born too late, the sense of exaltation occasioned by the setting sun when there was no hope of a tomorrow.

Rousseau's comments concerning the strange power of a melody that wiped away the bravura of the Swiss soldiers introduced nostalgia to the stage of history. Did the “Ranz des Vaches” have any special musical properties? No, Rousseau answers, but it is a “sign of remembrance.” There is nothing special other than a symbolic value for a native of the Swiss mountains. It suddenly restored to the abandoned and much regretted countryside a sonorous and impalpable presence, the mysterious presence of absence.

Several observations have confirmed the role of sound (a melody, a sound, a voice) in homesickness, either as a pathogenic agent that increases the pain of absence, or as a therapeutic factor that can instantly bring about remembrance. The subtleties of this intimate and subjective logic have been repressed by the progress of scientific medicine and its apology for the visible, from Bichat to Charcot.

The historian can approach the rise and fall of the diagnosis of nostalgia in the evolution of medical thought as a precursor to psychoanalysis. Within this tradition (about which Freud says nothing), it is interesting to note the points of divergence: the nostalgic individual suffered from remembrance, the hysterical patient from reminiscence. Attention has been shifted from conscious expressions of memory, involving a return home, to a veiled mnemonic utterance, often truncated or falsified, which infiltrates all speech and constitutes the first model of the unconscious.

However, psychoanalytic research on object loss has paid scant attention to attachment to the spaces and places of childhood, as if confirming Kant's arguments, which gave nostalgia a dimension that was more temporal than spatial: not a lost country but a lost time; the nostalgic individual would never rediscover his youth.

The paradox remains, however, that at a time when “displaced persons” are so numerous and when the findings of medicine and psychiatry have revealed a number of pathological phenomena related to the illnesses of migrants, the concept of nostalgia has been erased, except to sometimes refer to a miniscule and captivating territory, the maternal breast.

### “NOTE UPON THE ‘MYSTIC WRITING PAD’, A”

In this “note” written in the fall of 1924 and published in 1925, Freud justified a hypothesis he had made “long had about the method by which the perceptual apparatus of our mind functions” (p. 231), but that had remained unformulated until then. He hypothesizes that “cathectic innervations are sent out and withdrawn in rapid periodic impulses from within into the completely pervious system Pcpt.-Cs. So long as that system is cathected in this manner, it receives perceptions (which are accompanied by consciousness) and passes the excitation on to the unconscious mnemonic systems; but as soon as the cathexis is withdrawn, consciousness is extinguished and the functioning of the system comes to a standstill” (p. 231).

The operations of the memory apparatus are here the center of Freud's proposition. Human memory expresses or reveals the dual “magical” capacity of our mental apparatus for unlimited receptivity and the preservation of durable traces, though deformed or altered. While the writing instruments available at the

time (sheets of paper or slate) had shown themselves incapable of representing these functions, the “mystic writing pad,” which was marketed in the 1920s, could be used to illustrate the contradictory operation.

The pad was made of a piece of resin or wax, covered with a transparent sheet attached to its top edge, containing two layers that could be separated except along their top and bottom edges. The upper layer was a transparent sheet of celluloid and the bottom layer was made of thin, waxed paper. Whatever was written on the pad could be erased by separating the wax pad and the cover sheet without losing the initial writing. The analogy between this device and the mnemonic apparatus can be then be understood: celluloid/stimulus shield of the mental perceptual apparatus, waxed paper/Pcpt.-Cs., wax pad/unconscious, memory traces that cannot be reactivated except with “appropriate illumination.” The mystic writing pad satisfies the impossibility of combining two opposite functions. The sheet of paper will never be a slate, but the mystic writing pad is both, while it is never only one or only the other, but something quite different. By temporally combining what is spatially separate and by separating through spatial distribution what is temporally bound, the mystic writing pad offers the example of a paradoxical technique of writing. The psychic system—better than the mystic writing pad, which is unable to reproduce from within the writing that has been erased—does so, according to Freud, “as if the unconscious, by means of the Pcpt.-Cs. system, extended in the direction of the outside world antennas that, after they have sampled the excitations, are quickly withdrawn.” The discontinuous work of the Pcpt. Cs. system, cathexis and de-excitation, would explain the appearance of time.

In his “note” Freud confirms that there is no reason to have confidence in our memory. Not because it is supposedly a limited method for recording experiences (the content of the Pcpt-Cs system) as a momentary and continuous recording involving a continuous spatial dislocation, or, in contrast, as a durable but limited recording, which it is not. Rather, it is because it procures durable traces at the same time as it receives new imprints, and that it is imperfect whenever it is no longer limited.

The Freudian defiance of memory is contrasted with an attitude of denigration that legitimates forgetting and ignorance and would, conversely, require a strengthening of his position. This attitude is not

established on the basis of the functional imperfection of memory, assumed to be lasting if it is compared to the durable imprints provided by paper or the renewable imprints afforded by slate. To overcome the challenge, the functionality of the mnemonic apparatus must be accurately represented. The “mystic writing pad” helps illuminate its operation.

The value of this note implicitly touches upon the goal for psychoanalysis that Freud had indicated as being like “draining the Zuider Zee”: bringing to light the ego rather than the id (see “The Decomposition of the Psychic Personality” in 1933a [1932]) and working through the unconscious repressed. The mystic writing pad offers the example of a dualistic and opposed mnemotechnical function that is carried out without disturbance, allowing the metapsychological representation of the mnemonic psychic apparatus and illustrating its operation.

Since Freud, the suggested connection between the history of representation and theoretical models, and the future of technique would, according to some authors, relativize the relevance of Freudian topological subsystems. The computer and the virtual image have come to require us to present a different model, for our referent is no longer the “mystic writing pad.” This has led Jacques Derrida to claim that the Freudian topographical subsystems of the psychic apparatus were part of a model that is no longer relevant. Freud, however, did not see his topographical representation as a model that was subordinate to technology.

### “NOTES UPON A CASE OF OBSESSIONAL NEUROSIS” (RAT MAN)

Dr. Ernst Lanzer, alias the “Rat Man,” consulted Freud on October 1, 1907, and began an analysis that allegedly lasted a little more than eleven months and ended

in a complete cure. The patient's presenting symptoms were florid: Obsessions lasting from childhood had intensified most dramatically in the previous four years. In the recent past Lanzer's obsessional ideation involved lethal injury dealt to his girlfriend or even to his dead father. Lanzer also complained about compulsive impulses, such as cutting his own throat with a razor; he also described his personal prohibitions, which sometimes concerned quite trivial matters. As a result, procrastination affected both his personal and professional life, including the efforts to finish his legal education, to work, and to marry.

The importance which Freud attributed to the case of the “Rat Man” is revealed by these facts: During its duration, he gave four “progress reports” to the Vienna Psychoanalytic Society; he made it the subject of his lecture at the First International Congress of Psychoanalysis in Salzburg; and it was the only case for which he retained day-to-day process notes. In sum, since Dr. Lanzer had previously consulted Wagner-Jauregg, Vienna's most famous psychiatrist, Freud was moved to make the case a psychoanalytic showpiece, much as he was later to do with the “Wolf Man,” who had previously seen the leading psychiatrist in all Europe, Emil Kraepelin. During his second hour on the couch Lanzer recounted an incident that was the origin of his famous pseudonym.

While on maneuvers the previous summer, he lost his pince-nez; subsequently on the same day he heard a “cruel captain” describe an Asian torture in which a heated pot containing live rats is applied to the buttocks of the intended victim. Upon hearing the sadistic story, the Rat Man imagined that the torture was being applied simultaneously to both his ladyfriend and to his father. To prevent the fulfillment of that fantasy, the Rat Man resorted to the defensive formula “But whatever you are thinking of,” accompanied by a gesture of repudiation. An immediate derivative of the rat story was Lanzer's crazed compulsions about reimbursing his military comrade who paid for his new pair of pince-nez, sent by post. Subsequently in Lanzer's mind, the rat, symbolically thriving in a colony of good and bad objects and their identifying features, could signify, among other things: the Rat Man himself, his mother, his girlfriend, babies, anuses, genitalia, money, the acts of gambling, marrying, devouring, penetrating, containing.

Freud's claim about completely restoring his patient's health is a notable exaggeration. However,

although carrying out conspicuous indoctrination, neglecting immediate transference reactions (especially of the negative kind), and diminishing the role of women in the Rat Man's analysis, Freud was able to achieve a measure of therapeutic success by focusing on and clarifying his patient's oedipal relationship to his father. In addition, Freud repeatedly demonstrated to his patient that his obsessional compulsions could be dynamically understood when their original wording was recovered. In sum, Freud was able to some degree to allay his patient's panic and render him more functional, both personally and professionally.

Although a classic psychoanalytic study of the obsessional-compulsive personality, the case has its own share of historical fictionalization. Lecturing before the Vienna Society Psychoanalytic on November 20, 1907, Freud boasted that the name of Lanzer's ladyfriend could be inferred from his anagrammatic, magically defensive prayers even though her name was not yet disclosed; Freud's process notes reveal that he learned it by October 27. Freud went on to discuss the case at the First International Psychoanalytic Congress in 1908; according to Jones's erroneous although generally accredited account, Freud lectured for an incredible five hours on the clinical material. On a more serious score, a minute comparison of Freud's process notes and their write-up in the case history shows that in critical places he lied, constantly giving the effect that the treatment lasted longer than it actually did.

There is also considerable confusion in Freud's write-up of his case history, which manifests a remarkable imbalance between its first and second parts. Anal eroticism and the reverberations of the rat story dominate the first, practical half of Freud's text; but in its second half there are but two incidental references to anality and one passing reference to the rat story. Freud had to wait four more years before gathering the insight into the etiological link between anal eroticism and obsessional neurosis. Thus, in his second section, Freud can only clarify such issues as the phenomenology and structure of obsessional ideas, the psychological significance of obsessional thinking, characteristic attitudes to superstition and death, and a non-phasic consideration of compulsion and doubt as originating in the drives.

In his private correspondence Freud recurrently called attention to the disconnectedness of his case, a textual feature mimetic of the disconnected nature of

his patient's perceptions and obsessions. Thus, Freud's expression, through counter-transference, was infected by its contents: obsessional neurosis, which, by severing causal connections (through defensive isolation), is a pathology that affects both the contiguity of psychic material and its expression. Accordingly, the very symptomatic nature of Freud's writing in his case history reveals several problems. He confused precipitating causes; he elaborated little on the links among heterosexual object choices in the patient's oedipal and preoedipal life; he did not harmonize his clinical and theoretical considerations; he did not integrate his explanatory principles of anality, ambivalence and economic theory; and finally, he omitted to neatly tie together his patient's child and adult symptomatology.

## NOUVELLE REVUE DE PSYCHANALYSE

The *Nouvelle revue de psychanalyse* (New review of psychoanalysis), founded and headed by Jean-Bertrand Pontalis, was published in Paris by Éditions Gallimard from Spring 1970 to Autumn 1994. By 2004, over fifty collectively-authored volumes were published at the rate of two per year.

Despite the discreet indication found under the title, "published with the collaboration of the Association psychanalytique de France (APF; French Psychoanalytical Association)," the journal was not the official organ of any analytical institution and was not reserved, as a closed field, to analysts alone. The pluralistic composition of the editorial board explicitly manifests this: it was made up of Didier Anzieu, Guy Rosolato, and Victor Smirnoff, all analysts from the APF; André Green, an analyst from the Société psychanalytique de Paris (SPP; Paris Psychoanalytic Society); Masud Khan, a London-based analyst; Jean Pouillon, a scholar of philosophy and ethnology; and Jean Starobinski, a literary critic and scholar of intellectual history.

In the first issue (*Incidences de la psychanalyse* [Incidents of psychoanalysis]), Pontalis's opening article, "La question de la psychanalyse" (The question of psychoanalysis), announced the journal's guiding principles: Psychoanalysis, as a question, asks questions and allows questions to be asked of it; it questions itself, not within the closed "inside" circle of analysts, but in an open terrain of exchanges and confrontations with the other scientific disciplines. The journal did not erect uncrossable borders between analysts and nonanalysts: By being open to others, it opened up first to itself, to explore its own confines and limits (*Aux limites de l'analysable* [At the limits of the analyzable] was the title of the tenth issue).

Each issue focused on a theme, but these themes effected a kind of displacement in relation to the established repertory of psychoanalytic notions: for example, *The L'Espace du rêve* (The dream space) rather than "Le rêve" (Dreams), or *L'Amour de la haine* (The love of hate) rather than "Amour et haine" (Love and hate) or "Ambivalence." Each theme proposed an idea and its inherent instability, eliciting both reflection and perturbations in thinking. *L'Attente* (Expectation), *Dire* (Say), *Excitations*, *La Plainte* (Complaint), *Liens* (Connections) are commonplace words or expressions that, within the space of a collectively written volume,

become an open questioning of both theory and practice, on the part of both analysts and the “guests” from outside the field of analytic treatment proper who participated in producing almost all of the issues.

The *NRP*, as it came to be commonly known, always sought to remain open to the “strange” or foreign, not only by welcoming the work of authors who were foreign by virtue of their country, discipline, or institutional affiliation, but also by its resolve, in each issue, to effect the “test of strangeness,” an approximation of the alien dimension that inhabits the very thing of analysis as much as it does the desire of the subject who comes face to face with it. *L’Intime et l’Étranger* (The intimate and the strange), the title of one issue, refers to the horizons of its writing: what is proper to the psychoanalytic experience, in terms of both treatment and thinking, always being that which dispossesses us and transfers us to what does not belong to us. The choice of this theme was an occasion for confrontation and exchanges, a time to bring forth or invent perspectives that were new and disconcerting for the thinking of everyone, hosts and guests alike, all of them becoming hosts to the strangeness of the unconscious. The *NRP* was attentive to the international psychoanalytic scene, especially in English-speaking countries, as attested by its publication of the work of Masud Khan, Harold Searles, Robert Stoller, and Donald Woods Winnicott.

For many young analysts or analysts in training, this journal was a sort of workshop, a laboratory for psychoanalytic writing and thinking. The “argument,” elaborated by the editorial team made of up François Gantheret, Michel Gribinski, and Laurence Kahn (with Michel Schneider also a member from 1981 to 1988), was circulated among a group of authors, to provide an opening point for questioning and a stimulating deployment of the proposed theme. From 1983, the *Varia* or miscellany section, collected and edited by Gribinski, provided an open forum for ideas that were coming or waning, light or occasional pieces—in the manner of a log book for the working analyst indulging in reverie.

The success of this publication was broad-based and sustained, both in France and abroad, throughout its run. The *NRP* was able to claim and maintain an eminent place in the French psychoanalytic landscape, by means of the quality and depth of its theoretical and clinical reflection, and by the independence and originality of its thinking. In his preface to the “Cata-

logue 1970–1994,” Pontalis wrote: “Free of any institutional or university affiliation, and of allegiance to the word of any Master, the *Nouvelle revue de psychanalyse* has obeyed only one exigency: to make sensible, without erasing it, the life of the unconscious, to make its work intelligible without pretending to master it. It would like its past and future readers to be able to recognize in the movements of its thinking a bit of the approach of the Gradiva, who, supple and decisive, moves forward between the power of dreams and the attraction of life.” At the decision of its director, publication of the *NRP* ceased with the issue titled *Inachèvement* (Incompletion). The fifty volumes that constituted its written body were one of the places where the Freudian heritage was able to remain alive and, at the same time, be renewed. The *NRP*, with its successful creation and embodiment of a style, marked psychoanalytic thinking and practice in a decisive and lasting way.

## NUCLEAR COMPLEX

The expression “nuclear complex” was first used by Sigmund Freud to designate what he would later call the “Oedipus complex.” While still signifying from a genetic or structural point of view the universal Oedipus complex, the notion of the nuclear complex came to be used in the narrower perspective of psychopathology: this complex was described as the characteristic core of neuroses, and contrasted to pre-oedipal pathologies.

The term first surfaced in the text that Freud devoted in 1908 to the sexual theories of children. The child who, with mixed feelings, sees a little brother or sister arrive, “now comes to be occupied with the first, grand problem of life and asks himself the question: ‘Where do babies come from?’” (1908c, p. 212). Not very satisfied with the fallacious responses they get from adults, “children . . . have a suspicion of there being something forbidden which is being withheld from them . . . they consequently hide their further researches under a cloak of secrecy. . . . The nuclear complex of a neurosis is in this way brought into being” (pp. 213–214). The term *nuclear complex* in this text was very broadly described, suggesting an idea present since the beginnings of psychoanalysis, that of intrapsychic conflict.

From this moment forward, the definition became much more precise. Freud illustrated what he meant through the case of “little Hans,” who was the subject of an extended discussion the following year. In this case the Oedipus complex was very much in evidence, as well as its correlate, castration anxiety (1909b). That same year, Freud again used the expression “nuclear complex of the neurosis” in the case of the “Rat Man” (1909d), in which he said that it “comprises the child’s earliest impulses, alike tender and hostile, towards its parents. . . . It is entirely characteristic of the nuclear complex of infancy that the child’s father should be assigned the part of a sexual opponent” (p. 208n). Also in 1909, in the fourth of the *Five Lectures on Psycho-Analysis*, he tied it in specifically with the Oedipus myth. The term Oedipus complex, which was introduced in 1910, prevailed subsequently, with rare exceptions.

When the term *nuclear complex* appears in contemporary psychoanalytic literature, it is in reference to an early phase of Freud’s thought, and marks the central role of the Oedipus complex in neurotic pathology.

## **NUMINOUS (ANALYTICAL PSYCHOLOGY)**

The term *numinous*, based on the Latin *numen* (“will, the active power of the divine”) was coined by Rudolf Otto (1917/1926) to define a “category for the interpretation and evaluation” of nonrational manifestations of the sacred. According to Otto, the numinous is characterized by a “sense of one’s creature state” (p. 10), mystical awe (*tremendum*), a presentiment of divine power (*majestas*), amazement in the face of the “completely other” (*mysterium*), demoniacal energy, and paradox.

Otto’s phenomenological method and the importance he granted to experience are congruent with the empirical approach of Carl Gustav Jung, who as a matter of course integrated this notion into his own field of research beginning in the 1930s (Jung, 1937–40). He had previously used the term *numen* to describe the autonomy of psychic energy, conceived in its most primitive sense, in relation to *mana* (spiritual power) (Jung, 1928b [1948], p. 233).

For psychology and psychotherapy, the numinous is a borderline concept that names and circumscribes certain dynamic and constraining psychic events through which the subject becomes linked to an object that is “completely other” and cannot be understood intellectually. Indeed, conscious will has no hold over the numinous object, which is experienced as indescribable and which “puts the subject into a state of amazement [being dumbstruck], or passive submission” (Jung, 1928b [1948], p. 186). The state of consciousness is altered, the mental level “lowered.” The numerous warnings from therapists about this effect are commensurate with the risks entailed: schizophrenic dissociation, inflation of the ego, fascination, or possession; as well as the broader social consequences of fanaticism and the “terrifying suggestibility that lies behind all mass movements” (Jung, 1942 [1948], p. 184).

However, based on his own experience of the collective unconscious during his self-analysis from 1913 to 1918 and on the dreams and visions of his patients, Jung believed that the numinous effect

could be therapeutic. Indeed, it signals the emergence of an archetype with specific energy or emotional charge, which can effectively compensate for the overly unilateral attitude of consciousness. For example, the numinosity of the archetype of the self “incites” man to realize the paradoxical totality of his being, conscious and unconscious, by means of the symbols of the quaternity that appear in dreams. In this case, the attitude of the ego is the determining factor. Jung described it as “religious,” in that sense that for him, religion (from the Latin *relegere*, or “send forth,” and not *religare*—“restrain”) was “a careful and scrupulous observation of ... the *numinosum*” (Jung, 1937–40, p. 7).

## **NUNBERG, HERMANN (1884–1970)**

Hermann Nunberg, a physician and psychoanalyst, was born on January 23, 1884, in Bedzin, Poland, and died on May 20, 1970, in New York City. As a child, he was tutored at home until, after his mother’s death in 1896, he attended the college-preparatory school in Krakow, Poland. There he studied medicine for two years before continuing his studies in Zurich, where he obtained his medical degree in 1910.

While a student, Nunberg had met Eugen Bleuler and Carl Gustav Jung at the Burghölzli Psychiatric Clinic of the University of Zurich, and he worked on the latter’s word-association test. Nunberg began practicing psychiatry in Schaffhouse and Berne, Switzerland, and continued practicing at the university clinic when he returned to Krakow in 1912. In Switzerland he had belonged to the Zurich psychoanalytic group, and back in Poland he began teaching psychoanalysis at the Krakow psychiatric society in 1912.

In 1914, after moving to Vienna, Nunberg underwent a training analysis with Paul Federn. He worked at the university psychiatric clinic under Julius Wagner-Jauregg and joined the Vienna Psychoanalytic Society in 1915. At the fifth congress of the International Psychoanalytical Association, held in Budapest in 1918, Nunberg, with Freud’s consent, called for training analyses to be required for psychoanalysts in training. Viktor Tausk and Otto Bank strongly opposed this idea. After the training institute of the Vienna Psychoanalytic Society was created in 1925, Nunberg taught general neurology there for several years, publishing his lectures in 1932, which were later translated as *Principles of Psychoanalysis* (1955). Freud, in his preface to the book, wrote that it “contains the most complete and conscientious presentation of a psycho-analytic theory of the neurotic processes which we at present possess” (1932b, p. 258). He emphasized that Nunberg did not content himself with simplification or mere description of complex issues.

In 1932 Nunberg emigrated to United States, staying awhile in Philadelphia and finally settling in New York. He remained a member of the Vienna Psychoanalytic Society until its dissolution in 1938. In 1940 he joined the New York Psychoanalytic Society and served as its president from 1950 to 1952. In collaboration with Ernst Federn, Nunberg compiled the minutes of the Vienna Psychoanalytic Society (1906–1918), published between 1962 and 1975.

## **OBERHOLZER, EMIL (1883–1958)**

Emil Oberholzer, a Swiss doctor who specialized in psychiatry and psychoanalysis, was born December 24, 1883, in Zweibrücken, and died May 4, 1958, in New York. He studied medicine and received his training in psychiatry from Eugen Bleuler in Zürich, beginning May 6, 1908. From February 1, 1911, to October 1, 1916, he was an assistant physician at the psychiatric clinic at Breitenau-Schaffhouse, then a physician at Dr. Brunner's sanatorium (Küsnacht, in the canton of Zürich). In 1919 he began working as a private practitioner in Zürich.

Oberholzer became friends with Hermann Rorschach and helped in developing the shape interpretation test; he continued work on the test and was considered one of its best interpreters. Most of his writing was devoted to the Rorschach test and its interpretation. As a member of the Zürich group, which was part of the International Psychoanalytical Association (IPA), he gave a presentation on November 3, 1911, on dream analysis.

After an initial analysis with Oskar Pfister, he began analysis with Freud in June 1913 and remained faithful to Freud following Carl G. Jung's defection. With his wife, Mira Ginzburg (1887–1949), a physician who was also analyzed by Freud, and Oskar Pfister, he created the Swiss Society for Psychoanalysis on March 21, 1919, and became its first president, a position he held until 1928.

He is important because he was the first person in Zürich, in fact the first person in German-speaking Switzerland, to be analyzed in the Freudian manner, with several weekly sessions over a period of several

years. He published relatively little on psychoanalysis, aside from two case studies of children (1922).

At the end of 1927 Oberholzer tried to resolve the conflict that had been developing within the Swiss Society for Psychoanalysis "because of analyses that had been enthusiastically shortened" (letter from Freud to Pfister, February 17, 1928) by Oskar Pfister. Because there was some confusion between Pfister's specific problem and the more general problem of "lay analysis," the Schweizerische Ärztgesellschaft für Psychoanalyse (Swiss Medical Society for Psychoanalysis), which he created in 1928, was not accepted into the IPA and was dissolved after a few years.

On March 25, 1938, Oberholzer emigrated to the United States, and escaped the threat of Nazi Germany, primarily out of concern for his Jewish wife and his son. The couple practiced psychoanalysis in New York (they were not licensed to practice there as physicians). After his wife's death in 1949, Oberholzer became increasingly isolated and died in 1958 after suffering for many years from diabetes.

## OBJECT

The concept of the object in psychoanalysis proves to be an enigmatic one, because of its mobile and polysemic aspect and constantly changing character; there always remains an unknown zone that nurtures the object-cathexis and is therefore necessary for its continuation. The object in psychoanalysis is constituted of fluctuating impulses of unconscious, preconscious, and conscious cathexes, that are exchanged on a reciprocal basis. The object is neither a thing or a person, nor the fantasmatic content or a bodily zone of that person, although it relates to these throughout the analytic work. The concept of the object is a tool of understanding for the analyst and a notion that would become meaningless if it were studied as an independently existing entity. It is the unconscious element that lends some continuity to the cathexis of the various kinds of representations that are evoked by the patients' words, provided that the analyst constructs this continuity through the bi-vocal melody to which he is listening. The term *object* can be used only from the moment when analytic work is possible, however early this may be (Diatkine, 1989).

There is a polysemy to the term *object*, as it flows into the part-object; the total, narcissistic, internal, and external objects; the self-object; the object relationship; object choice; and others. This semantic richness reflects the complexity of the connections to other people in the psyche; it also can lead to confusion.

In his study of the drives ("Instincts and Their Vicissitudes," 1915c), Sigmund Freud explores a connection between the object and the drive: the drive excitation comes from inside the organism (pressure) and it corresponds to a need that is assuaged by the satisfaction (aim of the drive). The object is therefore the means by which the drive can attain this aim. Freud already emphasizes, however, that the object is the most valuable element of the drive and also that is

it not intrinsically connected with it; the link is therefore something that has to be constructed. He adds that the object is not necessarily an unfamiliar object; it can be anything that is susceptible to cathexis, including therefore the subject's own body through the forms of auto-erotism (object-cathexis, narcissistic cathexis).

Between 1905 and 1924, Freud described a series of pregenital stages that are to be understood less in genetic terms than as something defined by partial (or component) drives; the satisfaction of each is linked with an erogenous zone (oral, anal, phallic), and thus also by their corresponding oral, anal or phallic object relationship. The concept of "part object" was introduced by Melanie Klein, but the concept of the "part" already exists in Freud within the "partial drive" concept. The object choice that unifies the sexual life under the aegis of genitality and orientates it definitively towards others does not therefore occur until puberty.

Freud went to on distinguish between two types of object: an object that relates specifically to the drive (a person, part of a person, a part-object, a fantasmatic object) and a total object, an object of love or hatred. At the very beginning of psychic life, the external world, the object, and what is hated are identical (the object emerges in hatred). When, following the purely narcissistic stage, the object is recognized as a source of pleasure, it can become an object of love, being loved and incorporated into the ego. In "Instincts and Their Vicissitudes," Freud writes that the terms "love" and "hatred" should not be used for the relation of drives to their objects but reserved for the relations of the total ego with the objects. The concept of "object choice" (object choice or narcissistic object choice) thus refers to the object of love or hatred and not to the object of the drive.

When Freud refers to the libido of the ego as opposed to the libido of the object, the object in this expression is understood in the restricted sense of an external object that does not include the ego; furthermore, it nevertheless clearly transpires that Freud generally focuses on psychic reality and the intrapsychic in his metapsychological theory. His theory of anaclysis required nothing more from the object than its necessity for ensuring self-preservation; here it was the child who was "responsible," based on the satisfaction of their bodily needs, for developing auto-erotisms in order to prepare for their existing and future sexuality.

However, Freud was evidently well aware “that there is no such thing as a baby without a mother” (as Donald Winnicott was later to say) when he wrote in *The Ego and the Id*, albeit in a footnote: “The effects of the first identifications made in earliest childhood will be general and lasting. This leads us back to the origin of the ego ideal; for behind it there lies hidden an individual’s first and most important identification, his identification with the father in his own personal prehistory (Perhaps it would be safer to say ‘with the parents’; for before a child has arrived at definite knowledge of the difference between the sexes, the lack of a penis, it does not distinguish in value between its father and its mother). This is apparently not in the first instance the consequence or outcome of an object-cathexis; it is a direct and immediate identification and takes place earlier than any object-cathexis” (1923b, p. 31).

How then should we understand the relation between the parents, or those who perform this function, as people, as against the father or mother as “objects” used in the psychoanalytic work? The psyches of mother and father clearly play an essential role in the creation of the human being’s representational system from the very beginning of life. By conferring a meaning on the very young child’s activity, the capacity for “maternal reverie” (Wilfred Bion) does not introduce this meaning into their psyche, but rather harmoniously or discordantly modulates stimulations and “calming” attitudes or temporary abandonments that are constructed by the child. The meaning given by the mother produces another meaning in the subject, each of which becomes interconnected in a process that is as complex as the process that gives rise to the bi-vocal melody in the analytic treatment.

Following on from Freud and Karl Abraham, Melanie Klein, in her study of archaic states of functioning, attributes to the psyche from the outset a primitive ego (self), an external-internal boundary, a (part) object and the capacity for splitting and projecting; like Freud, she uses footnotes to take account of external objects. With reference to Sándor Ferenczi, she notes that it may be that complex mechanisms (living organisms) cannot continue as stable entities independently of the influence of external conditions. When these conditions become unfavorable, the organism disintegrates. “Integration and adaptation to reality depend essentially on the infant’s experience of the mother’s love and care.”

Donald Winnicott, a contemporary of Klein and a highly innovative author who theorized the bond between object and subject, attributes prime importance to the object’s response in the creation of this vital illusion to be shared between mother and child, namely the transitional space, of which the transitional object is only one of the signs. The “use of the object” is at the heart of this author’s concerns and he gives precedence to the access to subjectivation, “*first being*,” over the economy of drives. For him, this hallucination occurs in response to the increase in tension, always independently of the reality of the object; the problem of primary binding (that is, the object’s binding of the hallucination or the drive excitation) arises as follows: if the object is absent, the drive excitation and the hallucination are dealt with either by evacuative discharge or by a mode of binding and fusion *in statu nascendi*, primary masochistic binding. It is essential that the object’s absence or separation (creating the excitation) should not continue for a period that exceeds the subject’s capacities to re-establish through the hallucination the psychic continuity that is necessary to the sense of continuity of being. If, on the contrary, the object is present and if its response is “granted” to this hallucinatory process, it instigates the “created-found” aspect of the object and the transformation of the hallucination into an illusion. The threat that will inevitably be posed to the primary illusion (the lover’s censure, decrease in primary maternal concern) then triggers an upsurge of destructivity connected with distress and rage at the object’s lack of attunement. It is here that Winnicott introduces a further element into the theory: whereas classically the object was discovered in hatred as a result of frustrations, Winnicott accords a primordial position to the object’s response in the child’s symbolization process. To be discovered, the object has to “survive” the destructive activity and has to allow itself to be “used.” Winnicott refers here to three fundamental characteristics of object response: an absence of withdrawal, a lack of reprisals or retaliation, and a capacity to be manifestly creative and vital.

It is the object’s response to the destructivity, through the gap that it creates against the background of its primary adaptation to the subject’s needs and thus through a support that is introduced, that opens up the field of experience through which the complex process of symbolization will begin. The concept of the “good enough mother” is thus defined in its connection with the object’s pre-symbolizing function.

More recently, with reference to Winnicott, René Roussillon (1997) has sought to explore in more depth what he refers to as the object relationship that can allow representational activity and symbolization. He established symbolizing objects of the “malleable medium type” as a term by describing the qualitative characteristics of the relationship of primary attunement, and formulated a preliminary outline of the future attributes of the symbolization apparatus (hardness/malleability, indestructibility, tangibility, transformability, sensitivity, availability, reversibility, loyalty, and constancy).

Melanie Klein’s successors developed in new directions and reassessed her premises, including in the field of object relations and of projective identification as a primary mode of exchange. Esther Bick introduced the concept of adhesive identification and “psychic skin,” but it was principally Wilfred R. Bion who created new models for the relationship between two psyches. He defined the relationship between container and contained, and then analyzed this relationship using a complex mathematical system. During the maternal reverie, the alpha function psychically processes the beta elements, drives, and drive-derivatives that the child is unable to assimilate individually, in order to enable them to process these psychically, and then to introject this function itself. This is very much a theory of psychic transmission.

In France, Maurice Bouvet made Freud’s concept of the object relationship the main focus of his work, exploring it in more depth between 1948 and 1960 and developing it into a true concept. He and his students studied the object relationship in clinical practice (addressing hysteria, phobia, obsessional neurosis, and depersonalization) and went on to address the subject-subject relationship: the dual and reciprocal object relationship existing between ego-subjects. Addressing psychopathology in terms of the psychic object provides some ways of gaining a new perspective on the structural approach and produces a better understanding of difficult cases.

French psychoanalysts have preferred to address the successive description of the two psyches to account for the way in which the mother’s psyche contributes to the child’s psychic constitution. Denise Braunschweig and Michel Fain theorize “the lover’s censure” (1975), in which the mother’s experiences during pregnancy, her experience of childbirth, and the experiences relating to

the almost total erotism with the newborn give way retroactively to the fantasmatic elaboration of an incestuous erotic fulfillment in which the unconscious oedipal bedrock is evident. This conflict leads her to convey a censure to the child in a prelude to the fantasmatic life of the human being, in order to protect the child from the desire of and for the father, a two-fold desire that incorporates both the desire for her as a woman and the desire for the father’s penis in the child’s unconscious. The confused perception of these psychic realities then imposes on the mother the necessity of duping the child.

Jacques Lacan holds a distinctly opposing view, with his structural theory of the contribution of the symbolic register and of language as an organizer of the psychic; for him, there can be no discussion of drives that does not establish a “circuit of the drive” passing through the other; using a different term from that of the object, this big Other/little other demonstrates the theoretical shift from the intrapsychic to the intersychic. Following on from Lacan, Piera Aulagnier, with the “violence of interpretation” refers to the foundational violence that the “word-bearer” exerts over the infant and reintroduces temporality and a subject, the *I*, which is re-evaluated with reference to Lacan’s emphasis on the subject of the unconscious to the detriment of the ego. With his theory of the child’s “seduction” by the mother’s “enigmatic signifiers” as the origin of psychic life, Jean Laplanche does not restrict the object’s contribution to language but extends his theory to the object’s drives. In a different way, Didier Anzieu returns, through his metaphor of the “skin ego,” to a theory of a psychic formation based on the mother’s care and cathexis that is close to Esther Bick’s theory of “psychic skin.”

With his concept of “fantasmatic interactions,” Serge Lebovici, who took a particular interest in early mother-infant relations, provides an analytic version of the concept of interaction, which is too often influenced by objective reality. This is where Daniel Stern diverges from psychoanalysis: Although we may accept his concept of “emotional attunement,” his convictions regarding a neurophysiological evidence of perception lack the subtlety of Winnicott’s “created-found” and the importance of cathexis and hallucination for access to perception in Freudian theory. Let us further mention the originality of Christopher Bollas with his concept of the “transformational object”: the object is identified based on what the child feels is

modifying his experience of the self. Rather than being perceived as an object, the mother is experienced as a process of transformation.

For several authors, the need for the object to be inaccessible is a central focus of concern. For Jean Guillaumin, the object in psychoanalysis is postulated and targeted through the insistence of the drive but never actually given: We apprehend it as such only through our sense of that aspect of it which remains concealed to us. The rhythm of the mother's absence-presence and Winnicott's *holding* and *handling* can allow the experience of the hallucinatory satisfaction of desire theorized by Freud as an experience that establishes the drive orientation towards an object. However, the concept of the object corresponds to the experience of non-fulfillment because when it is found, attained, and mastered, it ceases to have any clinically observable psychic existence. This evident fact is irksome because it constitutes a paradox for logical thought; the nature of the total object can be described as something that necessarily includes a component of otherness that eludes the subject's control. This point is explored in more depth by Klein, who makes it the main focus of her essential reflections on the depressive position.

According to André Green, the concept of the object inevitably creates some philosophical difficulties, namely the impossibility of defining an object other than for a subject that constitutes it as an object and is constituted by it. This paradox is insurmountable. Subject and object are reciprocal terms: eliminating the object always means eliminating the libidinal subject and sexuality. According to Green, who therefore maintains the Freudian model, the object is primarily an object for the drive. However, there is an essential and constituent asymmetry between the pole of the subject (Green refers to the "ego-subject" because object and drive lead to the concept of the ego rather than of the subject) and the pole of the object in any consideration of the relationship with the other that introduces the third or "the other of the object." As concerns the link between the external object and the internal object: Whatever its indisputable reality (objective, objectal), the external object remains unknowable and it is only ever possible to work with its representatives. Psychoanalysis has nothing to say about this, unless it is by including a displacement in terms of function; if the object is described in these terms, it becomes possible to consider every process as an object.

André Green introduced the concept of the "objectalizing function": if the ego is characterized by certain appropriations of the object (incorporation, introjection, and beyond this, every form of internalization and identification), it transforms the status of the object with which it enters into a relationship, but above all it creates objects itself based on drive activity. What corresponds to the objectalizing function, an expression of the sexual drive, is its opposite and its negative: a disobjectalizing function, an expression of the death drive. Symbolization is placed here in the service of destructivity as the dramatization is transformed into an actualization. The disobjectalizing function operates to withdraw from the object the cathexes that are attached to it or even to move the object cathexes towards the narcissistic cathexes, narrowing the field of otherness.

In the United States, Otto Kernberg draws extensively on object-relations theory, which he regards as a supplement to ego-psychology and drive theory. He subscribes to Heinz Hartmann's theory that the ego defines the attitudes and intellectual processes that allow secondary-type mental activity, but there are many points of convergence between the views of this theorist, who has focused particularly on narcissistic disorders, and the European currents of psychoanalytic thought. For Kernberg, object relations are not a style of interaction with others but a mode of fantasmatic organization and a form of imaginary relationship with an object that is sustained to a greater or lesser degree by the perception of others. To the extent that every fantasmatic object relationship involves an imaginary relation between a self-representation and an object-representation, Kernberg argues that these object-relations become constituent of the personality and contribute to the person's individual development. Thus narcissism can no longer be considered simply as the return of the drive to the subject but as an internalization of a set of self-representations and representations of others that comprise intrapersonal relational systems. The general self-representation results from these partial representations; Kernberg takes up the description of the "grandiose self," a term introduced by Heinz Kohut (1974), which is concealed behind apparent signs of depression and inferiority feelings. However, whereas Kohut conceived the narcissistic organization of these patients as the result of a fixation at an archaic developmental stage of narcissism, Kernberg regards it as the result of a poor differentiation of the

psychic agencies, in which the grandiose self is a cluster of idealized and internalized object-relations, poorly differentiated self-representations, and pathological representations of the ego ideal. It thus certainly entails a combined pathology of the id, ego, and superego, that is mainly due to the excessive burden of the archaic aggressive drives. In this respect, Kernberg is closer to Melanie Klein than to Kohut; he has less confidence in the reparative value of psychotherapy than in the interpretation of archaic conflicts of ambivalence.

According to Jean Guillaumin (1997), a substantial, if not interminable, amount of work remains to be done on the question of the subject and the object. The anxiety surrounding experiencing oneself as a subject and being considered as a subject, which are preconditions for subject-object differentiation, is so intense in early experiences that it can only be checked by an auto-erotism of anxiety that can very naturally develop into a form of masochism, which thus becomes a matter for sharing and communicating with others on a minimal basis of a joint denial of difference. The sharing of the subject's anxiety with two or several individuals creates silences, attacks, and complicities in lack that seem to be the most authentic form of relationship between human beings (Angélo Hesnard).

## OBJECT A

Object *a* is the object that causes desire. Here, as is common in logic, a letter is used so as to avoid the confusion of meaning that could arise from the use of a more specific term.

At first, Jacques Lacan intended that *a* would designate the small other (*autre*)—that is, the fellow being—as an erotic object (Seminar 5, *Formations of the Unconscious*, 1957–58). Later, after having shown that lack is what makes the erotic object, Lacan used *a* to designate both what symbolizes this lack and also the lack itself.

In *Desire and Its Interpretation*, his seminar of 1958–59, Lacan used *a* to designate that part of the body given up in symbolic sacrifice. Its relationship of conjunction and disjunction with the barred subject is what constitutes the fantasy, as expressed in the formula,  $\$ \diamond a$ . It is disjoined from the subject, it is not the object that desire aims at, but rather it organizes the imaginary scenario of the fantasy which orders desire: *a* is thus the cause of desire (Seminar 10, *Anxiety*, 1962–63). Should object *a* become conjoined with the subject, this cannot be considered a recovery. It

also does not imply that the subject has some knowledge of the object. It is rather the transitory abolition of subject (aphanisis) in the face of the object, where the object is not the subject's complement, but its substitute.

Lacan believed that the original subject was sustained, prior to the loss of the object and the constitution of the fantasy, by what Donald W. Winnicott described as the transitional object. And referring to a later stage in the infant's life, he saw the reel in the *fort/da* game as a symbol of the part of the body that was being detached (and not as a symbol for the mother; to Lacan, separation was not about an infant separating from a mother, but rather about each of them separating from the object *a*).

Lacan differentiated four objects *a*, which he called "fragments of the body" (1975, p. 189): the breast, feces, the look, and the voice, each of which related to a bodily orifice and corresponded to a partial drive. These objects are not placed in developmental order. They are all designated by the same letter because they all have the same function, to symbolize castration. Object *a* is a partial object, but there is no corresponding whole object because *a*, insofar as it is lacking, creates an obstacle to any kind of totality.

The lost object could certainly be grasped in the imaginary register (as the breast from which the infant is separated or the feces that the infant rejects, for example), but that should not obscure the fact that Lacan used *a* to designate the real insofar as it is inexpressible by speech (thus the breast, as object *a*, is the inexpressible remainder of the oral demand). Object *a* is also outside of the phenomenal field, neither perceptible in the image of the body, nor in objects in the world.

This is why *a* is "the object that does not correspond to any idea," that is, "representation" (1975, p. 183). It is an object that can only be approached or delimited in logical or topological ways. Very early on, Lacan designated that which discourse made ungraspable as the "metonymic object," that is, the object that slides under the signifying chain. Later, he formalized *a* as the hole that hollows out the repetition of the demand (as in the model of the torus), like the disk that separates the cut from the signifier (as in the model of a cross-cap, a topological figure without edges that Lacan used to define the relations of the subject with the object as cause of desire). Then he defined *a* as the loss produced by the articulation of S1 and S2. This loss, which results from a subtraction of

*jouissance* by discourse, is what Lacan called "surplus *jouissance*," and it is homologous with Marx's "surplus value." The equivocal nature of this term, which in French can mean both "more enjoyment" and "no more enjoyment," indicates that something of this *jouissance* is regained in the functioning of the drive, which "gets around" (*fait le tour*) object *a*, in the sense that it both "circles" it and "evades" it. Starting in 1975, with the introduction of the Borromean knot, *a* became the point at which the three consistencies R, S, and I (Real, Symbolic, and Imaginary) are joined together, a kind of entry point for all *jouissance*.

Lacan considered his elaboration of object *a* as an extension of the discoveries of Karl Abraham and Winnicott and as opposed to object relations theory, which for him was confined to the register of the imaginary. This elaboration referred to Freud's distinction between narcissistic libido and object libido and refuses to consider the latter simply as a portion of the former that had somehow "overflowed," but instead wanted to show their structural difference. Lacan attempted to specify the mechanisms of object *a*'s diverse manifestations (anxiety is related to the emergence of *a*, and thus to the look in anxiety) and to establish clinical distinctions in relation to object *a* (the neurotic seeks to obtain object *a* by demand; the pervert makes object *a* the absolute condition of desire; and the psychotic keeps his objects *a* "in his pocket"). Lacan's work on object *a* has clinical implications because it directs the treatment toward a separation between the identification with the ego ideal and identification with the object *a*. This approach allows the analyst at the end of treatment to know the object of his or her fantasy.

## OBJECT, CHANGE OF/CHOICE OF

The expressions *change of object* or *choice of object* refer to the notion of a love-object. The theme of a change of object refers back to the earliest sources of object relations. In his “Three Essays on the Theory of Sexuality” (1905d) Sigmund Freud described object-choice as being “diphasic, that is, it occurs in two waves” (p. 200). The first wave occurs in the oedipal period and the second at puberty, when the definitive form that sexual life will take is determined. The sexual instinct that until then had been essentially autoerotic discovers the sexual object. The adolescent can choose a new object only after renouncing the objects of his or her childhood: “The finding of an object is in fact a refinding of it” (p. 222). Psychoanalytic authors have concurred in thinking that in both sexes, the primary object is the mother.

While, for Freud, the oedipal stage was lived out between two and five years of age, some post-Freudian authors consider an earlier Oedipus complex. Melanie Klein described a fantasy of both parents combined that is present very early in the infant’s psychic life. André Green also noted, in *Les Chaînes d’Éros* (1997);

The chains of Eros), that the father exists in the mother’s mind; she is the guardian of the father’s place, of the paternal function—“its metaphor,” in the words of Jacques Lacan. Denise Braunschweig and Michel Fain also introduced the father at an early stage, describing “censoring the lover in her” as a constituent element in the infant’s development. The introduction of the father into the primary bond with the infant very early on allows for early triangulation, the basis for the introduction of a third party into the relationship. But it is certain that from the outset, the mother’s relationship with her baby, whether a girl or a boy, entails a fantasmatic and interactive specificity owing to sexual difference: homosexual in the one case, heterosexual in the other. The fate of the primary object differs according to sex. The boy will return to it by displacement at the time of oedipal object-choice, while the girl must renounce it to proceed to a change of object.

This evolution is crucial in the course of development. For the girl, this is time when she libidinally invests her father and turns away from the maternal object. For the boy, this movement appears to be simpler. At puberty, under the influence of the superego, he turns away from the mother and can invest other objects. According to Freud, from the time of the phallic stage the girl develops an intense hatred for the mother (reflecting an ambivalent feeling of love-hate), which will foster a change in her object-choice. This explains the emergence of penis envy, which causes the girl to detach herself from her mother and take refuge in the oedipal situation. For her, Freud posited that object-change is of three orders: a change of love-object, a change of erotogenic zone (the clitoris is replaced by the vagina), and a change from an active to a passive position. During the preoedipal period, the little girl is both active and aggressive toward her mother, of whom she would like to have exclusive possession, and she feels her father to be a rival. At the time of the Oedipus complex, the girl turns from the mother toward the father, initially in a manner that is active, possessive, and sadistic. Love is directed toward the father and hatred toward the mother (through the castration complex). Catherine Parat theorized that these active sadistic impulses produce a masochistic shift in normal cases, which is accepted by the ego, and that this movement colors the development of femininity in a particular way. The taking up of the feminine, masochistic position entails a series of identifica-

tions with the mother, although without complete cessation of a degree of identification with the father. During and by means of the movement of object-change, the girl no longer lays claim to the penis; she has just traversed the pathway that leads from the desire to take the father's penis away from him, to the desire to receive a child from him. By means of feelings of tenderness and non-conflictual identifications with the mother, the girl can then (and this is an essential moment in her history) develop feelings of oedipal love for her father (and thus for men in general), an object different from herself. Through cathexis of her real gender, she has acquired the possibility of realizing her love in complementarity with the other. Heterosexuality is thus acquired, and the genital mode attained.

The integration of bisexuality is a fundamental element in heterosexual life. Feminine bisexuality causes some women to remain fixated on the mother, to make a homosexual object-choice, or to display alternating masculinity and femininity. Freud believed that in normal loving behavior, the currents of tenderness and sensuality come together. Tenderness is the older of these two currents. It comes from the first years of childhood and corresponds to the primary infantile object-choice. Then, with the advent of puberty, the powerful "sensual" current is added and will run up against the barrier of incest. This is when the tendency to find another, outside object with which to lead a real sexual life is manifested. Infantile object-choice paves the way for object-choice at puberty. In "On Narcissism: An Introduction" (1914c) Freud proposed that there are two fundamental types in the choice of the love-object: narcissistic object-choice and anaclitic object-choice. They are not necessarily opposed to one another, Freud thought, but may be subject to alternation or combination in each of us. In the first case, the choice of love-object relates to the subject himself; in the second case, anaclitic object-choice, the love-object is chosen based on the model of the parent figures. These two currents are present and complementary from the oedipal period.

Freud's writings on female sexuality have inspired heated controversies, and the feminine is a point on which he faltered. If the Oedipus complex is characteristic of both sexes, according to his theory a "sexual

monism" should exist until puberty in both sexes, the model of which would be the masculine one. The difficulty in Freud's work arises from anticipating a symmetry between what happens in boys and what happens in girls. Freud himself repeatedly underscored his uncertainty and the insufficient, trial-and-error nature of his inquiries into this "dark continent," as he called it, thus acknowledging the incompleteness of his explorations.

## **OBJECT RELATIONS THEORY**

Psychoanalytic object relations theories may be defined as those that place the internalization, structuralization and clinical reactivation (in the transference and counter-transference) of the earliest dyadic object relations at the center of their motivational (structural, clinical, and genetic and developmental) formulations.

Internalization of object relations refers to the concept that, in all interactions of the infant and child with the significant parental figures, what the infant internalizes is not an image or representation of the other ("the object"), but the relationship between the self and the other, in the form of a self image or self representation interacting with an object image or

object representation. This internal structure replicates in the intrapsychic world both real and fantasized relationships with significant others.

Several major issues separate object relations theories, the most important of which is the extent to which the theory is perceived as harmonious with or in opposition to Freud's traditional drive theory: that is, whether object relations are seen as replacing drives as the motivational system for human behavior. From this perspective, Melanie Klein as well as Margaret Mahler and Edith Jacobson occupy one pole, in that they combine Freud's dual drive theory with an object relations theory approach. For Ronald Fairbairn and Harry S. Sullivan, on the other hand, object relations themselves replace Freud's drives as the major motivational system. Contemporary interpersonal psychoanalysis, as represented by Joanne R. Greenberg and Stephen Mitchell—based upon an integration of principally Fairbairnian and Sullivanian concepts—asserts the essential incompatibility between drive-based and object relations-based models of psychic motivational systems. Donald Winnicott, Hans Loewald, and Joseph Sandler (each for different reasons) maintain an intermediate posture; they perceive the affective frame of the infant-mother relationship as a crucial determinant in shaping the development of drives. While adhering to Freud's dual drive theory, Otto Kernberg considers drives supraordinate motivational systems, while affects are their constituent components.

A related controversy has to do with the origin and role of aggression as motivator of behavior. Those theoreticians who reject the idea of inborn drives (Sullivan), or equate libido with the search for object relations (Fairbairn), conceptualize aggression as secondary to the frustration of libidinal needs, particularly traumatic experiences in the early mother-infant dyad. Theoreticians who adhere to Freud's dual drive theory, in contrast, believe aggression is inborn and plays an important part in shaping early interactions: This group includes Klein in particular and to some extent Winnicott, and the ego psychology object relations theoreticians such as Kernberg.

Finally, contrast may be made between object relations theories and French approaches, both Lacanian and mainstream psychoanalysis. The latter has maintained close links with traditional psychoanalysis, including the British object relations theories, insofar as Lacan conceptualizes the unconscious as a natural

language and focuses on the cognitive aspects of unconscious development, he underemphasizes affect—a dominant element of object relations theories. At the same time, however, in postulating a very early oedipal structuralization of all infant-mother interactions, Lacan emphasizes archaic oedipal developments, which implicitly links his formulations with those of Klein. French mainstream analysis also focuses on archaic aspects of oedipal developments, but places a much more traditional emphasis on Freud's dual drive theory and on the affective nature of the early ego-id. As neither mainstream nor Lacanian psychoanalysis spells out specific structural consequences of dyadic internalized object relations, however, neither would fit the definition that frames the field of object relations theory as proposed in this essay.

All object relations theories focus heavily on the enactment of internalized object relations in the transference and on the analysis of counter-transference in the development of interpretive strategies. They are particularly concerned with severe psychopathologies, including those psychotic patients still approachable with psychoanalytic techniques, borderline conditions and severe narcissistic character pathology, and the perversions. Object relations theories explore primitive defensive operations and object relations both in cases of severe psychopathology and at points of severe regression with all patients.

The contemporary re-evaluation of Freud's dual drive theory that has occurred mostly in France is relevant to the relationship between object relations theory and drive theory. Perhaps particularly the work of Jean Laplanche and André Green has emphasized the central importance of unconscious destructive and self-destructive drive manifestations in the form of attacks on object relations, and the central role of unconscious erotization in the mother-infant relationship in libidinal development, all of which tends to link drive theory and object relations theory in intimate ways.

Another important development within psychoanalytic theory has been the growing emphasis on affects as primary motivators, and the centrality of the communicative functions of affects in early development, particularly the infant/mother relationship. This emphasis has linked affect theory and object relations theory quite closely, despite the persistent controversy between those who see affect, particularly peak affect states, as essential representatives of the drives, and

those who stress the psychophysiological nature of the affective response, and attempt to replace drive theory with an affect theory.

The basic units (self representation, object representation) of internalized object relations thus include the constituent affective components of the drives. One might say that the affect of sexual excitement is the central affect of libido in the same way as the affect of primitive hatred constitutes the central affect of the death drive. The id is conceptualized in this model as the sum total of repressed, desired, and feared primitive object relations. The gradual integration of successive layers of persecutory and idealized, prohibitive and demanding, internalized object relations forms part of the primitive superego, while internalized object relations activated in the service of defense consolidate as an integrated self structure within the ego, surrounded by integrated representations of significant others. In short, the Id or dynamic Unconscious, the Superego, and the Ego are constituted by different constellations of internalized object relations, so that the development of the drives and the development of the psychic apparatus—the tripartite structure—occur hand in hand.

Perhaps the most important practical implication of object relations theory is the conception of identification as a series of internalization processes ranging from earliest introjection to identification *per se*, to the development of complex identity formation. Each step includes the internalizing of both self and object representations and their affective interactions under the conditions of different developmental levels.

In the transference of healthier patients, with a well-consolidated ego identity, the diverse self representations are relatively stable in their coherent mutual linkage. This fosters the relatively consistent projection onto the analyst of the object representation aspect of the enacted object relationship. In contrast, patients with severe identity diffusion lack such linkage of self representations into an integrated self. They tend to alternate rapidly between projection of self and object representations in the transference, so that the analytic situation seems chaotic. Systematic interpretation of how the same internalized object relation is enacted again and again with rapid role reversals makes it possible to clarify the nature of the unconscious object relation, and the double splitting of (a) self representation from object representation

and (b) idealized from persecutory object relations. This process promotes integration of the split representations which characterize the object relations of severe psychopathology.

## **OBSESSION**

The term *obsession* refers to images, ideas, or words that force themselves into the subject's consciousness against their will, and which momentarily deprive them of the ability to think and sometimes even to act. The term is derived from the Latin *obsidere*, which means "to sit before," "to lay siege to," and figuratively "to control an audience." From this is derived the noun *obsidio*, which means "detention," or "captivity," and figuratively "a pressing danger."

Classical psychiatrists had described the experience of a person whose consciousness was besieged by an

intrusive thought and who, although lucid and in possession of his faculties, was incapable of stopping it. Philippe Pinel (mania without delusion), Jean-Étienne Esquirol (affective monomania), and Jules Baillarger (madness accompanied by conscious awareness) all distinguished this pathology from mental alienation in the strict sense. But it was Bénédict-Augustin Morel (emotional delusion) and Jean-Pierre Falret (the madness of doubt and the delusion of touch) who described a clinical picture that was closest to what would later be referred to as obsessional neurosis.

It was Sigmund Freud, however, in his description of obsessional neurosis in “Heredity and Aetiology of the Neuroses” (1896a), who considered obsession to be a symptom that is part of a larger clinical picture, a symptom that serves as a compromise and has an economic function. “Obsessive ideas ... are nothing but reproaches addressed by the subject to himself because of anticipated sexual pleasure, but these reproaches are disfigured by an unconscious psychic process of transformation and substitution.”

For Freud the notion of *Zwang* (compulsion) assumed a much broader and more fundamental meaning than that which he gave it in the clinical picture of obsessional neurosis. It reflects what is most radical in the drive: “In the mental unconscious, we can recognize the supremacy of a repetition compulsion arising from libidinal emotions that are most likely dependent on the most intimate nature of drives that are sufficiently powerful to place themselves above the pleasure principle, lending certain aspects of psychic life their demoniacal character” (1919h).

In his article on the case of the “Rat Man” (1909d) Freud writes, “The definition I gave in 1896 of compulsive ideas, namely that they are ‘reproaches that have been repressed but now return transformed, always related to a sexual act from childhood that brought pleasure when carried out,’ seems to me today to be arguable in formal terms. ... In fact it is more correct to speak of ‘compulsive thinking’ and to emphasize the fact that compulsive structures may be equivalent to the most diverse psychic actions. These may be defined as wishes, temptations, impulses, reflections, doubts, commands and prohibitions.”

Obsessions must be distinguished from phobias. A *phobia* is the fear of an object in the outside world whose absence or avoidance is sufficient, in principle, to avoid anxiety, while an *obsession* involves a

mental representation that the subject cannot escape. Although the distinction had little meaning for Pierre Janet when he described “psychasthenia,” it was essential for Freud. Phobias are associated with the qualities of objects, whereas obsessions are concerned with the characteristics of mental representations. Obsessions must also be distinguished from *idées fixes* and *prevalent ideas*: “The latter are integrated in the subject’s personality and are not recognized as unhealthy. A claimant can be constantly preoccupied with the idea of an injustice suffered; he suffers from it, tries to obtain satisfaction by any means, but never thinks that the object of his preoccupations is absurd or without grounds” (Guiraud, 1956). As for the impulsive act, it lacks the hesitation and internal struggle typical of obsession, which, even resolved, always entails a period of uneasiness and indecision.

There would be little point in making a list of obsessions by type. They can be religious, metaphysical or moral; they might concern purity or physical protection, or protection against external dangers; or follow questions of precision and completeness, order and symmetry, or the flow of time (Green, 1965).

It would almost be possible to retrace the evolution of psychiatry from the classical period to the present-day by following the status of obsessions within the clinical groupings provided by various authors. We have seen how Freud, by giving obsession its status as a symptom, something that is both a compromise and has an economic function, enabled dynamic psychiatry to become thoroughly modern. The description of obsessional neurosis served as a model for all psychoanalytic theory. This is why Freud, throughout his work, constantly returned to the economic, topographical, and metapsychological problems presented by this concept.

Innovations in the United States (DSM III and IV—*Diagnostic and Statistical Manual of Mental Disorders*) have expanded the framework of clinical concepts and brought about the near disappearance of the science of psychopathology. As a result, new groups of symptoms have been introduced, based on a statistical approach, and new entities created, such as the compulsive obsessional disturbances. These revisions have expanded the clinical spectrum by including somatic obsessions (hypochondria, dysmorphophobia), physical obsessions (eating disorders like anorexia and bulimia), sexual obsessions (paraphilia), and pathological jealousy. In this way we have come full circle, back to a

prepsychoanalytic era, back to the origins of classical psychiatry itself.

## **OBSESSIONAL NEUROSIS**

The term *obsessional neurosis* (or *compulsive neurosis*) denotes a condition in which the patient’s mind is intruded upon (against his or her will) by images, ideas, or words. The patient’s consciousness nevertheless remains lucid and his or her power to reason remains intact. These uncontrollable obsessions are experienced as morbid inasmuch as they temporarily deprive the individual of freedom of thought and action. Sometimes the defenses can eliminate the anxiety and the symptoms, but at the price of displacing

characteristics of primitive obsession (uncontrollability, compulsions) onto the defense mechanisms.

Sigmund Freud’s view of obsessional neurosis appeared as early as 1894. In “The Neuro-Psychoses of Defence” (1894a) he broke with the conceptions of classical psychiatry and stipulated that the cause of obsessional neurosis lies in the existence of an intrapsychic conflict of sexual origin that mobilizes and blocks all flows of energy. He thus opposed the classical theory of degeneration and the idea of innate weakness of the ego that Pierre Janet used as the basis for his description of psychasthenia. Freud proposed a traumatic etiology for obsessional neurosis. An early sexual event occurs before puberty; however, in contrast to what happens in hysteria, this event is a source of pleasure to the child. The individual experiences strong feelings of guilt and is overcome by self-reproach. These feelings are repressed and then replaced by a primary system of symptoms and traits: scrupulousness, shame, mistrust of self. The success of these defenses allows the individual to go through an apparently healthy period. But eventually these defenses are exhausted and there is a return of the repressed memories with the outbreak of the illness and its attendant symptoms.

In “The Disposition to Obsessional Neurosis: A Contribution to the Problem of Choice of Neurosis” (1913i), Freud defended the idea that the choice of this neurosis is linked to developmental inhibitions, and he stressed the role of fixation and regression to the anal-sadistic stage. He suggested “the possibility that a chronological outstripping of libidinal development by ego development should be included in the disposition to obsessional neurosis. A precocity of this kind would necessitate the choice of an object under the influence of the ego-instincts, at a time when the sexual instincts had not yet assumed their final shape, and a fixation at the stage of the pregenital sexual organization would thus be left” (p. 325). Thus, in the object relation, hate will precede love and “obsessional neurotics have to develop a supermorality in order to protect their object-love from the hostility lurking behind it” (p. 325). This opposition between love and hate for the object was underscored by Freud in the case of the “Rat Man,” related in “Notes upon a Case of Obsessional Neurosis” (1909d). He saw it as the source of the doubt, compulsions, and ambivalence that are characteristic of obsessional functioning.

In “Inhibitions, Symptoms and Anxiety,” Freud described the two main defense mechanisms in obsessional neurosis that replace repression: undoing what has been done and isolation. The first of these, undoing (*Ungeschehenmachen*), means making something that has already happened “unhappen” by means of a symbolic motor action; it is also found in magical practices, folk customs, and religious rituals. The second, isolation, involves the motor sphere and consists in the fact that after an unpleasurable event there is a pause during which nothing further can happen, no perception is possible, and no action can take place. Motor isolation functions to guarantee a break in the connection of thoughts.

In the same way that the obsessional patient enacts the taboo against touching (because he fears that contact with the object will force him to face his unbound ambivalence between love and hate), the isolation of an impression or an activity, by means of a break in the chain of thoughts, symbolically indicates that he does not want to allow thoughts relating to it to “contaminate” other thoughts. This mechanism is present in normal people in their everyday mental activities involving concentration.

The fundamental rule of free association involves asking the ego to give up this defense. The patient suffering from obsessional neurosis finds it particularly difficult to follow this rule. This is why, paradoxically, psychoanalysis is both the most indicated treatment for these patients and at the same time the most difficult to implement.

Like Freud, the psychoanalysts who came after him always placed the accent on the obsessional structure rather than on symptoms. This poses problems of terminology. The term *obsessional neurosis* is not the exact equivalent of the German *Zwangsneurose*: *Zwang* refers not just to compulsive thought or obsessions (*Zwangsvorstellungen*), but also to compulsive acts (*Zwangshandlungen*) and compulsive affects (*Zwangsaffecte*). Certain French authors therefore prefer to use the term *névrose de contrainte*, and some American authors prefer the term *compulsive neurosis*. *Obsessional functioning* is the preferred term for the group of processes and defense mechanisms that characterize obsessional neurosis, but which are also present, to a lesser degree, in other patients, in the form of obsessive personality traits or a system of defenses put up as an alternative to a costlier mode of psychic functioning, psychotic functioning.

In this regard, let us note that because organized obsessional neuroses are sometimes extremely debilitating, the categorization of this pathology has been questioned and it has been compared with the psychoses. Several factors present in the former are lacking in the latter: self-recrimination by the ego, adherence to insistent preoccupations, and the deployment of elaborate defenses. In the obsessional patient, affective isolation allows the ego to cut itself off from desire, whereas in psychosis the ego is cut off from reality.

## OCCULTISM

Occultism is the belief in secret doctrines and practices that are recognized neither by science nor religion and require some form of initiation. Related, but distinct, is telepathy, mental communication at a distance with

the dead or the living. Such beliefs appeared in nineteenth-century Europe with the weakening of Christian churches, which had traditionally fought these phenomena, and as a form of resistance to rationalism, which claimed to be able to explain everything by means of logical reasoning. Occultism and telepathy are also related to an interest in mystery and the mysterious: Sir Arthur Conan Doyle, the creator of Sherlock Holmes, devoted much his later life to the study of occultism, and a number of successful authors have taken an interest in paranormal phenomena.

Psychology and psychiatry in the late nineteenth century were strongly influenced by spiritualism and magnetism. Belief in a “celestial fluid” was not wholly unrelated to the growing use of an invisible energy (electricity), or a new device for communicating at a distance, known as the telephone. Freud referred specifically to this last invention to characterize the relationship between conscious and unconscious, between doctor and patient (“Recommendations to Physicians Practising Psycho-Analysis,” 1912e). The word *telepathy* was created in 1882 by the English psychologist Frederick Myers (1843–1901), who was the first British author to discuss Freud’s work.

Parapsychology was referred to by Freud during his conversations and correspondence with several of his followers, primarily Theodor Reik and Sándor Ferenczi. With his daughter Anna and Ferenczi, he performed thought transmission and table-turning experiments. In his articles “Psychoanalysis and Telepathy” (1941d [1921]) and “Dreams and Telepathy” (1922a), he clarified his position with respect to paranormal phenomena as being a combination of “repugnance and ambivalence.”

Freud’s thoughts on occultism and telepathy involve an element of ambiguity as well as tactical maneuvering. Freud, the founder of psychoanalysis, was unable to ignore the support the fragile new movement received from parapsychology, while also having to confront the criticisms of rationalist science. However, based on the advice of Ernest Jones and Max Eitingon, he did not wish to compromise the scientific nature of psychoanalysis with irrational theories. Faced with the “black sea of occultism,” Freud maintained a prudent sense of reserve, although this did not hamper his considerable interest in techniques of communication between minds, which presented analogies with transference.

## OCEANIC FEELING

After reading *The Future of an Illusion* (1927c), in a letter dated December 5, 1927, Romain Rolland wrote to Freud: “By religious feeling, what I mean—altogether independently of any dogma, any Credo, any organization of the Church, any Holy Scripture, any hope for personal salvation, etc.—the simple and direct fact of a feeling of ‘the eternal’ (which may very well not be eternal, but simply without perceptible limits, and as if oceanic). This feeling is in truth subjective in nature. It is a contact.” (Vermorel and Vermorel, 1993, p. 304)

The notion of an *oceanic feeling* derives on the one hand from the writings of Baruch Spinoza, who criticized religion but, with his “third degree of knowledge,” retained “the intellectual love of God,” and on the other hand from Rolland’s studies on Indian mysticism: *The Life of Ramakrishna* (1929/1931) and *The Life of Vivekananda and the Universal Gospel* (1930/1947). He sent these works to Freud, providing him with a name for a concept hitherto latent in his thinking.

In the first chapter of *Civilization and Its Discontents* (1930a [1929]) Freud located the oceanic feeling within the primitive ego—more precisely, within primary narcissism and the ego ideal—which is later reduced to a “shrunk residue” (p. 68) under the influence of reality. Freud compared that ego to the vestiges of ancient Rome lying beneath the constructions of later centuries; and Rolland, perhaps unsurprisingly for a man whose writings are so immersed in the universal Mother that the role of the father in the Oedipus complex is circumvented, sensed that Freud’s

reference to the Eternal City, to Rome and the Romans, betokened a primal maternal transference.

Upon receiving Rolland's letter, Freud experienced a mixture of excitement ("your letter has left me without any rest") and, it would seem, paralyzing shock, for it took him two years to write a response to Rolland's letter and another two years to send it—which might be interpreted as a transference reliving of the trauma of the premature death of his baby brother Julius when he himself was two years old. There was an unconscious complicity between Freud and Rolland, who had also been wounded by grief in childhood: Rolland's *Journey Within* (1942/1947), begun immediately after his visit to Freud, started with this event and was mirrored by Freud's "A Disturbance of Memory on the Acropolis (An Open Letter to Romain Rolland on the Occasion of His Seventieth Birthday)," addressed to Rolland in 1936, which was the ultimate self-analysis of his relations with his father and also with the "dead mother."

Freud later acknowledged that he had not done justice to religion and its "historical truth." In response to Rolland, "one of the twelve men upon whom rests the destiny of the world," he gave free rein to his fantasy of being the Moses of psychoanalysis; in retrospect, his trajectory can be considered as an approach, within the individual unconscious, to the sacred, where he had taken refuge after the "death of God."

## ODIER, CHARLES (1886–1954)

Charles Odier, a Swiss psychoanalyst, was born in Geneva in 1886 and died in Lausanne in 1954.

Born into a family of shopkeepers and musicians, Odier completed his secondary education in Geneva before going on to study medicine, and training as a neurologist and psychiatrist in Geneva, Vienna, and Paris. In 1920 he set up in Geneva as a general practitioner. He devoted himself increasingly to psychoanalysis until 1929, when he left for Paris.

As early as 1914 Odier took an interest in Freud's ideas, and in 1923 he went into analysis with Van Ophuijsen in the Netherlands before going on to work for one semester in the Berlin polyclinic with Franz Alexander (to which he returned for a second period in 1927). He joined the Swiss Psychoanalytic Society (founded in 1919) and in 1920 he was among the founding members of the short-lived Geneva Psychoanalytic Society with Édouard Claparède as its president.

Between 1920 and 1929 Odier worked on developing Freud's ideas, not only in French-speaking Switzerland but also in Paris where, along with Raymond de Saussure, he was one of the founding members of the Paris Psychoanalytic Society. We also find him among the initiators of the Conference for French-Speaking Psychoanalysts, which met for the first time in Geneva in 1926. The following year, in 1927, he played an active role in the creation of the *Revue française de psychanalyse*, being a member of the directing committee from 1927 until 1938. In 1929 Odier settled in Paris where he practiced psychoanalysis until 1939. He returned to Switzerland when war broke out and worked in Lausanne as a psychoanalyst until his death in 1954.

His "Contribution à l'étude du Surmoi et du phénomène moral" (Contribution to the study of the superego and the moral phenomenon) was a congress

report that was destined to present Freud's recently-elaborated (1927) notions of the ego, superego, and id to French-speaking psychoanalysts. In his essay *Les Deux Sources consciente et inconsciente de la vie morale* (The twin sources, conscious and unconscious, of moral life; 1943) he sought to shed light on the connections between conscious moral judgments and the unconscious relations between the ego and the super-ego. *L'Angoisse et la pensée magique* (Anxiety and magical thought; 1948) and *L'Homme esclave de son infériorité* (Man as slave of his own inferiority; 1950) are an effort to conceptualize the ego's problems of insecurity and anxiety both in terms of psychoanalysis and Jean Piaget's psychogenetics. He published some sixty papers, more than forty of them being devoted to psychoanalysis.

## OEDIPUS COMPLEX

The term *Oedipus complex* designates a network embracing the wishes and hostile impulses of which the mother and the father are the objects, along with the defenses that are set up to counter these feelings. Freud called this complex “the nucleus of the neuroses,” and, beyond that, it may be considered the central structure in the functioning of the human mind.

This skeletal definition needs refining in a number of ways:

- Although very direct expressions of the Oedipus complex can be observed in young children, for the most part it manifests itself through unconscious formations identifiable only through their transposition onto other objects and their impact on other kinds of conflict.
- The term itself suggests the complexity of this network; most modern-day authors assign it a structuring role in the development of the psyche, of which it will later become an essential functional feature.
- It is important to distinguish between two *aspects* of the Oedipus complex, depending on whether the little boy's desire is directed at his mother and his hostility at his father (the *positive* version), or vice versa (the *negative* or *inverted* complex).
- In both of these instances, the conflict is between wish and prohibition, a fact which signals that the cultural context of the establishment of the conflict in the child must not be overlooked.
- By extension, it should be borne in mind that, although the objects in question in any society founded on the triangular or nuclear family are the father and mother, this may not be so in other cultures.
- Lastly, because the Oedipus complex concerns not only the difference between generations but also that between the sexes, a distinction must perforce be drawn between the case of the girl and that of the boy.

The term *Oedipus complex* itself did not appear in Freud's published work until his paper “A Special Type of Object-Choice Made by Men” (1910h, p. 171). At that time, with some reluctance, he borrowed the word *complex* from Carl Jung. Freud's reference to the myth of Oedipus, however, originates much earlier. In a letter dated October 15, 1897, to his friend Wilhelm Fliess, he wrote: “I have found, in my own case too, falling in love with the mother and jealousy of the father, and I now regard it as a universal event of early childhood. . . . If that is so, we can understand the riveting power of *Oedipus Rex*” (1954 [1887–1902]). Indeed the notion is to be found in *Studies on Hysteria*, where Freud, in quest of the etiology of hysteria, stressed the traumatic role of sexual

*seductions*, experienced by the child and for which the father was responsible (1895d).

The notion took on growing significance for Freud over the next few years, as witnessed by the following remarks from *The Interpretation of Dreams*: “It is as though—to put it bluntly—a sexual preference were making itself felt at an early age: as though boys regarded their fathers and girls their mothers as rivals in love, whose elimination could not fail to be to their advantage” (Freud, 1900a, p. 256), and “it is the fate of all of us, perhaps, to direct our first sexual impulse towards our mother and our first hatred and our first murderous wish against our father. Our dreams convince us that this is so. King Oedipus, who slew his father Laius and married his mother Jocasta, merely shows us the fulfillment of our own childhood wishes” (p. 262). The theme was also central to Freud’s analysis of “Dora” (1905e [1901]). It is noteworthy, however, that the Oedipus complex made no explicit appearance in *Three Essays on the Theory of Sexuality* (1905d), though Freud took an important step forward in that work by fully acknowledging for the first time the idea of a childhood sexuality prior to puberty. The implications of this were very clear in the case of “Little Hans,” published four years later, where Freud focused his explanation of the horse phobia of this “lively little boy” on oedipal impulses: desire for the mother founded on a very active infantile sexuality, along with fear of the father’s retribution (1909b). In another case history published in the same year, that of the “Rat Man” (1909d), the role of the Oedipus complex, though evident, was veiled. By contrast, in his narrative of the “Wolf Man” case, effectively completed by the fall of 1914, Freud assigned the complex a major role, correlating it with the theme of the primal scene (the perception, whether real or fantasized, of sexual intercourse between the parents) (1918b [1914]).

Throughout this whole period, therefore, the Oedipus complex was pivotal to Freud’s clinical thinking. One problem continued to bother him, however. He considered that the complex was universal, a defining characteristic of the human race. But how was this universality to be explained? He offered one possible answer in *Totem and Taboo* (1912–13a), where he hypothesized as follows: In very ancient times humans were organized in *primal hordes*, each dominated by a strong, despotic male who monopolized the women and banned their access to the young men under the

ultimate threat of castration. But a day came when the sons rose up, killed the father and thus gained access to the women. Thenceforward, however, guilt for this primal crime dogged them. Passed down from generation to generation, the conflict between wish and prohibition, still dominated by guilt regarding the murder of the father, is reborn in each individual: Such is the origin of the Oedipus complex. This mythical story (which aroused opposition even among prehistorians) is typical of Freud’s tendency to revisit history and model the past of the individual on the past of humanity as a whole: Psychogenesis was based on what he called *phylogenesis*. Two years after *Totem and Taboo*, Freud carried this line of inquiry even further in *A Phylogenetic Fantasy: Overview of the Transference Neuroses*, a text so speculative that he himself refrained from publishing it.

As omnipresent as the notion is in his works, it is striking that, aside from these two contributions concerned with the conjectured history of humanity, Freud never devoted a theoretical text to the specific issue of the Oedipus complex; in the great metapsychological papers of 1915 the oedipal theme is evoked only indirectly. There are, however, two papers, from 1923 and 1924 respectively, which clarify Freud’s thinking on the issue in two major respects.

In “The Infantile Genital Organization” (1923e), Freud described for the first time what would thereafter be considered a major turning-point in mental development, namely a complete reorganization, occurring roughly between the ages of three and five, centered on the primacy of the penis as erotogenic zone and, with respect to object-relations, on the oedipal drama. In this way Freud rounded out his developmental theory, which identified a series of *stages* or *phases*, also referred to as *organizations*), each characterized by the primacy of a particular erotogenic zone and by a specific object-relational mode. Thus, the oral phase was followed by the anal, the phallic (or oedipal), and then, after a “period of latency,” adult genital organization. The phallic phase constituted the high point of the oedipal scenario: During this time sexual desires directed toward the parent of the opposite sex, as well as castration anxiety aroused by the child’s fear of retribution from the rival parent, were at their most intense. Later this conflict would wane, as repression did its work (in this case welcome work), and the child would enter latency. Puberty and the intense psychic work it initiated would reactivate the

earlier conflict in new guises, but after this stormy episode equilibrium would be achieved thanks to the onset of adult genital organization and the changes of object it made possible: the shift of desire to a woman other than the mother, or a man other than the father.

May we then conclude that the Oedipus complex fades away? Freud's paper titled, precisely, "The Dissolution of the Oedipus Complex" might be thought to suggest as much. In this text, Freud spoke of the complex being destroyed, or collapsing "because the time has come for its disintegration, just as the milk-teeth fall out when the permanent ones begin to grow" (1924d, p. 173). It is impossible to believe, however, that Freud intended to abandon his major thesis according to which the Oedipus complex was the very framework of the human psyche. What disappears, in fact, is oedipal conflict in its infantile form—not the form of organization that results from it.

There are two points that need emphasizing here. In the first place, oedipal conflict in its most acute phase constitutes an essential motor of the play of identifications through which the individual person is constructed; the little boy, after wishing to *be* his father, and thus replace him in his mother's bed, eventually wishes instead to be *like* his father with respect to other women. Secondly, the reference to the boy cannot be allowed to obscure the problem of the Oedipus complex in the girl. This issue constituted a major theoretical stumbling block for Freud, and it has been a continual source of difficulty for Freud's successors.

To begin with, Freud simply described the Oedipus complex in boys and added that, *mutatis mutandis*, the same applied to girls. The problem lay in the *mutatis mutandis*. As long as only the "positive" aspect of the complex was considered, it was enough to say that the little girl directed her incestuous desires toward her father, from whom she wished to obtain a child; indeed, this represented the realization in fantasy of the penis envy that, according to Freud, she harbored since finding out that, unlike boys, she had no penis (1925j). Later on, after the "resolution" of her Oedipus complex, she would obtain that child from a man other than her father.

But this account appeared too simple, even to Freud himself, once it became clear that the Oedipus complex had to be viewed in its *complete* form, composed of both positive and negative aspects. How did the boy and the girl, respectively, enter the oedipal

crisis that confronts these two aspects, and how did they emerge from it? And how, in each case, did the play of identifications become established?

Freud's own answer to this question focused on castration anxiety. He asserted that, for the girl as for the boy, there was at first only one sexual organ, the male one. According to this *infantile sexual theory*, everyone had a penis, even if it was not obvious; it sufficed to say, with "Little Hans," that it was "quite small," but "it'll get bigger all right" (Freud, 1909b, p. 11). The child's discovery of the anatomical difference between the sexes was greeted at first by incredulity. In the boy, this was soon replaced by anxiety: if the little girl did not have one, it must be that she *no longer* had one; he believed that she used to have one, like everyone else, but had been deprived of it. In other words, the little boy understood girls to be, in effect, boys castrated as punishment for their masturbation and incestuous wishes. Thenceforward, castration anxiety, in the case of the boy, would be the chief motor of renunciation of such wishes and behavior, and the factor that would get him out of the acute oedipal crisis of the phallic phase. In contrast, Freud described castration anxiety in the case of the girl as stemming from a castration that had already taken place, and for which she sought reparation from her father, was what caused her to "enter" the oedipal crisis. She would emerge from it, like the boy, by means of a change of object, by directing her desire toward a man other than her father, just as the boy directed his toward a woman other than his mother.

The term *change of object* needs clarifying, for it might seem ambiguous. The child's first object, for both the boy and the girl, is said to be the mother; this was Freud's view, and all psychoanalytic thinking since Freud has confirmed it. The boy effects change in a fairly simple way, shifting his desire to another person of the same sex as his mother; the girl, for her part, must transfer her desire onto someone of the opposite sex. Things remain straightforward, however, only as long as we focus exclusively on the positive complex; things become much more complicated as soon as we consider the complete form, and this theoretical step has sparked a good deal of controversy. Indeed, debate surrounding the theory of the Oedipus complex has remained intense in post-Freudian psychoanalytic discourse.

- a) Freud's original *phallic monism* aroused vigorous protest during his own lifetime, notably

among women psychoanalysts such as Ruth Mack Brunswick, Helene Deutsch, Karen Horney, and Melanie Klein. It is important to bear in mind that Freud's ideas on the primacy of the phallus, penis envy, and castration do not apply to biological or sociological realities but rather to an imaginary register inscribed in culture as well as in the unconscious of each individual. Beyond that, problems of female sexuality, and of femininity itself, remain important areas for psychoanalytic investigation.

- b) As mentioned above, Freud saw the phallic, or oedipal phase as preceded in turn by two other major modes of organization, dominated by the oral and anal erotogenic zones respectively, each having its specific type of object-relationship. Since Freud's time, ever greater attention has been paid to these so-called *pregenital* phases, such as the earliest object-relationships, the *primary narcissism* in which the subject is forged, and lastly to autoerotism, the basis of this whole process of development. Their deep theoretical divergences notwithstanding, Anna Freud and Melanie Klein, the founders of child analysis, have played an essential part in this avenue of research; other contributors include pediatricians, notably Donald W. Winnicott, and, more typically, child psychiatrists such as Margaret Mahler, Donald Meltzer, Frances Tustin, Serge Lebovici, and René Diatkine. The field in which most of this work was done was childhood psychopathology, though it has been rounded out by studies of the earliest mother-child relationship conducted within psychoanalysis (Serge Lebovici) or on its fringes (Daniel N. Stern).
- c) Beyond the consideration of the origins of the Oedipus complex, this whole line of advance has given rise to the suggestion that the complex itself might be primal in character. Thus Melanie Klein, in certain of her writings, went so far as to say that, like the object, the oedipal structure was present from birth or even earlier; this thesis has been widely rejected, however, by many psychoanalysts. More acceptably, Claude Le Guen (1974) has described a *primal Oedipus complex* said to embody an initial triangular situation involving the nascent subject, the mother, and a third party who provokes *eight-month anxiety*,

characterized by René Spitz as a response to the perception of a stranger whose presence suffices to reveal the absence of the mother and cause the child to recreate her intrapsychically to mitigate this loss (Spitz and Cobliner, p. 155). Similarly, André Green (1990) has evoked the relations between the self, the object, and the *Other's object*.

- d) The claim that the Oedipus complex is universal has occasioned lively polemic. Some authors, such as Géza Róheim, set out to demonstrate the correctness of Freud's view by mustering the ethnographical evidence. This approach was contested by anthropologists and sociologists who emphasized the diversity of family and social structures from one culture to another, and based on those grounds argued that such a complex could only exist within a modern Western society—or even only in the *fin-de-siècle* Vienna of Freud's day. A whole *culturalist* current (Bronislaw Malinowski, Ruth Benedict, Margaret Mead, and others) sought a middle way. Many years after Freud's time, these controversies seem somewhat dated. Claude Lévi-Strauss (1949/1969) crystallized an important idea in this connection by asserting that, whatever the differences in human social and familial forms, the prohibition against incest was both fundamental and universal.
- e) Finally, it has long been evident that non-oedipal forms of mental organization, or those just lightly marked by the Oedipus complex, are widely found; this truly vast field, extending from perverse structures to autism and infantile and adult psychoses, has seen very significant developments over the last two or three decades.

In conclusion, let it be said that the Oedipus complex and its correlate, the castration complex, are at the very heart of psychoanalysis. These ideas underwent a long maturation within Freud's work, and the theoretical tendencies that have developed since Freud have brought out the great complexity that attends them. The fact remains that in clinical practice these two notions are indispensable to the analyst and invoked on a daily basis; from a theoretical point of view, even if a synthesis is still elusive (there are as many attempts as there are major authors), there is a good measure of agreement on a few essential points.

The assumption that the Oedipus complex is universal remains axiomatic to the architecture of the theory; after all, it is felt to be the basis of the specificity of the human race. It is generally acknowledged, further, that a primary conflict between desire and its prohibition first arises in relation to two parental figures who incarnate its future operation. To which it should be added, in accordance with the contribution of Melanie Klein, that each of these two figures, just like the subject, present two aspects, as “good” and “bad” objects of love and hate. This is the context in which the complete Oedipus complex, and the play of identifications that springs from it, need to be apprehended.

## **OEDIPUS COMPLEX, EARLY**

Underlying the Oedipus complex as Freud described it, there is an earlier layer of more primitive relationships with the oedipal couple. These precede the classical Oedipus complex that arises in the third year of life and subsides with the development of the superego. This notion first appears in a Melanie Klein publication (1927a and b).

In describing the Oedipus complex in a letter to Wilhelm Fliess dated October 15, 1897, Freud (1985c) founded psychoanalysis upon a theory of fantasies. The core of childhood development is the fantasies about the oedipal couple. He sought to verify these theories with evidence from children (1909a). A number of people produced children's fantasies that confirmed the Oedipus complex, among them Sándor Ferenczi (1913/1927).

Klein developed a rigorous technique for working with children, through which she demonstrated that disturbing oedipal fantasies intrude into all the activities of childhood. She found areas of development in the infant that were too distant to reach with adult analysis. The Oedipus complex was active, in some form, from a period much earlier than the third year of life. The evidence was of two kinds: Firstly, the analysis of symptoms which had started in the first year of life indicated fantasies, anxieties, and defenses that operated then, when the symptoms started. Secondly, much of the fantasy life involved pregenital impulses suggesting the presence of the three-person constellation of exclusion, rivalry, and murder, right back to the oral phase. She also concluded that the violence of the Oedipus complex can be seen to arouse guilt in children, and therefore posited the presence of a super-ego at the earliest stages of the Oedipus complex. That finding reversed the theory of the development of the super-ego out of the Oedipus complex (Klein, 1928, 1933).

It was not only children's play, but the developmental task of learning that could be obstructed, according to Klein (1930, 1931). The development of the primal scene into the terrifying images of the early Oedipus complex could lead to severe distortions of intellectual development.

These early fantasies had a remarkably different character from those of the later "mature" Oedipus complex. In these early phases the oedipal objects were experienced in primitive form, archaically "good" or "bad," and engaged in an immense variety of forms of intercourse between themselves. So different was this conception of the oedipal couple that Klein coined the term "combined parent figure" for it. In 1935 Melanie Klein described the depressive position, which arises from a major developmental step. At that point good and bad versions of the object can be recognized for the first time to be the same figure in reality (1935,

1940). Much of the distortion of the oedipal couple at the early stage is connected with the combining of the good and bad objects. The capacity to enter the depressive position marks the transition from the early Oedipus complex to the mature stage and results in an increasing respect for the reality of external objects. And with the emergence into the depressive position, feelings of protectiveness and repair gather, as the determining characteristics of the mature Oedipus complex (1945).

When Klein described the paranoid-schizoid position (1946) her interest in the Oedipus complex fell away, and the world of primitive defense mechanisms at the earliest moments in life absorbed the energy of Kleinian research. It was not until the 1980s that Kleinians returned to a serious study of the Oedipus complex (Britton, et al., 1989).

The Oedipus complex has come to be seen less in terms of innate impulses of love and hate. Instead the primal scene, which the oedipal parents inhabit, is a stage upon which enquiry, learning, and creativity are founded. The child has the opportunity to attain the third position, the observer of (and enquirer into) parental intercourse. Achieving this position emotionally is the primitive foundation of thought, knowledge, and intellectual life.

Otto Fenichel (1931) postulated a connected notion, that of "precursors of the Oedipus complex."

Early fantasies are regarded by many analysts as immature and unformed attempts at creating mental representations of the external reality, and not necessarily as having a central role in development. These early experiences are claimed by some to be mere precursors of the mature Oedipus complex; present, but essentially inactive components.

## OMNIPOTENCE OF THOUGHTS

The belief that ideas are all-powerful is inherent in animistic thought and belief systems but also common in obsessional neurosis, where the same kind of magical thinking occurs as a symptom. It consists in the belief that one can transform or influence the external world through one's thoughts alone.

In *Totem and Taboo* (1912–13a), Freud emphasized that he owed the expression “omnipotence of thoughts” to “a highly intelligent man who suffered from obsessional ideas,” (p. 85)—in fact, the “Rat Man” (1909d). That it was a question of something symptomatic in nature and not part of a system of thought was clear from the fact that the patient acted on the basis of superstitious ideas that ran counter to his own convictions. At the same time, according to Freud, omnipotence of thoughts underscores a general trait characteristic of every neurosis. “Neurotics . . . are only affected by what is thought with intensity and pictured with emotion, whereas agreement with external reality is a matter of no importance” (1912–13a, p. 86).

Omnipotence relates, in fact, only to thoughts that express or are derived from a repressed wish. Unconscious aims create or modify reality. As such, omnipotent thinking suggests the way an infant may employ hallucination to overcome a perceived lack of some object of gratification. In the adult, it is the attempt to ward off unconscious hostile wishes that leads to animistic thinking and obsessional neurosis.

The concept of omnipotence of thoughts can not be dissociated from narcissistic thinking or narcissism more generally conceived. In “On Narcissism: An Introduction” (1914c), Freud employed the notion of omnipotence of thoughts and desires—in infants, primitive peoples, and schizophrenics—as a means to establish the concept of narcissism theretofore evoked only in *Totem and Taboo*. That libidinal energy is invested first of all in the ego and, later on, partly in objects suggests how the outside world can be subjected to the power of thoughts. This kind of narcissistic investment will subsequently be found in adult self-esteem, leading to repression of all that fails to conform to the ego ideal; similarly, however, “every remnant of the primitive feeling of omnipotence which . . . experience has confirmed, helps to increase . . . self-regard” (1914c, section 2), which is the very expression of the ego's grandiosity.

To the extent that it originates in primary narcissism, omnipotence of thoughts is a notion susceptible to various elaborations that touch on the earliest modalities of an infant's representation of, and relation to, the external world. Sándor Ferenczi (1916) discussed the development of the sense of reality and emphasized that the child remains attached to omnipotence even after acknowledging that reality must be taken into account. In her discussion of the sense of reality in a four-year-old, Melanie Klein (1923) also underscored the child's belief in omnipotence of thoughts. D. W. Winnicott (1970) showed how maternal care lavished on infants promotes the feeling of omnipotence necessary to evoke the object, who though already present is recognized only through the illusion of creating it.

It is difficult to restrict or impose limits on the concept of omnipotence of thoughts inasmuch as, whether located in magical practices and animistic thinking or in neurotic symptoms, it is coextensive with the boundary-less character of primary narcissism.

## **“ON DREAMS”**

Freud’s major work, *The Interpretation of Dreams* (*Die Traumdeutung*, 1900a), was published in November of 1899, and he was disappointed that the book initially met with little success. His friend Wilhelm Fliess suggested that he publish a more easily-accessible, abridged version, but Freud resisted the idea, as he was already working on *The Psychopathology of Everyday Life* (1901b). However, he soon got to work on the project, which he considered to be strictly utilitarian drudgery. The essay appeared in 1901.

By its very nature, the book is a summary that adds nothing to *The Interpretation of Dreams*, but in thirteen short, untitled chapters, Freud did lay out the essentials of his theory of dreams:

- The analysis of dreams, the “royal road” to the elucidation of unconscious processes, aims at extracting the latent meaning from the manifest text of the dream (the dream narrative).
- Every dream represents the fulfillment of a wish.
- The dream work proceeds in two stages, the first being that of primary processes (condensations, displacements, representation by images) and the second being that of secondary processes that set up the “façade” of the dream; the satisfaction that is aimed at in a dream is thus possible because of the disguise of its latent content.

- Dreams involve symbolic processes that must be deciphered on a case-by-case basis; but there are also “typical dreams” that are in some sense universal, and the meaning of these can be taken as immediately apparent.

In this short work, Freud added the narrative and analysis of six new dreams, of which the best known is that of the “company at table d’hôte” (pp. 636–640). He also completed the analysis of the dream of “Goethe’s attack on Herr M.” (pp. 662–63), in which he revealed his aggressive feelings toward Wilhelm Fliess, whose friendship with Freud was soon to come to an end.

## **“ON NARCISSISM: AN INTRODUCTION”**

In a letter written to Karl Abraham on September 21, 1913, while he was vacationing in Rome, Sigmund Freud announced he had begun “the sketch of an article on narcissism” (Freud and Abraham, 1965a [1907–26, p. 148]). The term was borrowed from a German psychiatrist, Paul Näcke, and the notion that the self “is a frequent placement of the libido (narcissism)” had already been circulating for almost three years in psychoanalytic discussions (Nunberg and Federn, session of 18 May 1910, p. 541) and in writings by analysts such as Isidar Sadger. At an evening gathering of the Vienna Psychoanalytic Society on October 12, 1910, Freud commented, “A prolonged remaining at the transitory stage of narcissism definitely predisposes to homosexuality and to dementia (Bleuler’s ‘autism’)” (Nunberg and Federn, p. 13). Freud had evoked this notion himself in *Leonardo da Vinci and a Memory of His Childhood* (1910c) and in his thinking on homosexuality, and in 1911 Otto

Rank had published "A Contribution to Narcissism" in the *Jahrbuch*.

However, Freud's essay had, and would continue to have, repercussions on a far greater scale. Carl Gustav Jung's criticisms of the libido theory, and his remark that it failed to account for dementia praecox, led Freud, in this period of rupture with his former "heir apparent," to sketch out a theoretical text that he would return to several months later, and would complete shortly after he finished the more polemical "On the History of the Psycho-Analytic Movement" (1914). "I am short because again engaged in writing. Narcissism has to be finished," he wrote to Ernest Jones on February 25, 1914 (Freud and Jones, p. 265). On March 16, he wrote to Abraham: "Tomorrow I am sending you the 'Narcissism,' which was a difficult birth and bears all the marks of it. Of course I do not like it particularly, but it is the best I can do at the moment. It is still very much in need of retouching" (Freud and Abraham, 1965a [1907–26], p. 167); and, on March 25: "Since finishing the 'Narcissism' I have not been having a good time. A great deal of headache, intestinal trouble, and already a new idea for work, which is an added difficulty for the summer" (p. 168). On April 6, in response to Abraham's congratulations, he wrote: "Your acceptance of my 'Narcissism' affected me deeply and binds us still more closely together. I have a strong feeling of its serious inadequacy. I shall incorporate the comment you would like on the by-passing of sublimation in the Zürich therapy" (pp. 170–71).

"On Narcissism" is divided into three parts. In the first, Freud seeks to show that the libido theory is applicable to "paraphrenia" if one is willing to accept that "the libido that has been withdrawn from the external world has been directed to the ego" (p. 75). Thus, it is possible to distinguish between "ego-libido" and "object-libido," and "the more the one is employed, the more the other becomes depleted" (p. 76). At which point, "in the total absence of any theory of the instincts" (p. 78; such a theory would be elaborated only six years later, in *Beyond the Pleasure Principle*), a debate began over the hypothetical distinction between "sexual instincts" and "ego instincts."

In the second part of Freud's paper, the study of narcissism is approached by way of the study of "organic disease, hypochondria, and the erotic life of the sexes" (p. 82). The last of these gives Freud a

chance to discuss the conditions under which object-choice occurs. The "anaclitic" type is already known ("the woman who feeds [the individual]," "the man who protects him" [p. 90]), but to this must be added loving "according to the narcissistic type: (a) what he himself is (i.e. himself), (b) what he himself was, (c) what he himself would like to be, (d) someone who was once part of himself" (p. 90). Object-love of the anaclitic type is said to be "characteristic of the male" (p. 88), in contrast to women, whose narcissism, like that of children (onto whom parents project their own narcissism), cats, beasts of prey, humorists, or master criminals, acts as a powerful attraction.

The third and last section proposes a theoretical improvement that prefigures the changes of the second topography of 1923. By attributing repression to "the self-respect of the ego" (*Selbstachtung*) (p. 93), Freud defined an "ideal" against which each individual measures his or her actual ego. "This ideal ego [*Idealich*] is now the target of the self-love which was enjoyed in childhood by the actual ego" (p. 94). Narcissism is displaced onto it or onto the object chosen to represent it, a process that is different from the desexualization of the object in sublimation. A psychic agency must perform the task of "seeing that narcissistic satisfaction from the ego ideal is ensured and which, with this end in view, constantly watches the actual ego and measures it by that ideal" (p. 95)—an observing agency that Freud linked to moral "conscience" (p. 95) and in which the earliest administration of the superego may be discerned.

Numerous clinical considerations on delusions of grandeur, the paranoiac's feeling of being observed, passionate love, narcissism in homosexuality, or group psychology have illustrated or further enriched the major new lines of theoretical inquiry introduced in this short paper, which has become one of the touchstones of psychoanalytic theory and an essential moment in its development.

## **“ON THE HISTORY OF THE PSYCHOANALYTIC MOVEMENT”**

On January 12, 1914, Sigmund Freud wrote to Karl Abraham: “I am writing the history of the psychoanalytic movement. The text will be very energetic and direct.” On February 15 he wrote, “I have just finished, no more than an hour ago, the manuscript for ‘On the History of the Psychoanalytic Movement.’” The text turned out to be a polemic he had “worked on in a rage” (January 12 letter to Sándor Ferenczi) and which Freud intended to use against Jung and the Zurich group. On several occasions he uses the term ‘bomb,’ reflecting the jittery state of Europe’s nerves and the popular myth of the mad bomber anarchist on the eve of World War I. Moreover, Jung had given up his position as president of the International Psychoanalytical Association (IPA) on April 20 and the Zurich Group withdrew from the IPA in July, after Freud’s text appeared in print.

Under the epigraph “*Fluctuat nec mergitur*,” the text is divided into three chapters. In the first Freud explains the subjective nature of his contribution to the history of the psychoanalytic movement: “For psychoanalysis is my creation; for ten years I was the only one occupied with it. . . . Even today, when I am no longer the only psychoanalyst, I feel myself justified in assuming that none can know better than myself what psychoanalysis is.” According to the method he again advocated in 1923, he began by relating the history of his discovery, especially that of the sexual etiology associated with infantile sexuality, an emphasis that was intended to counteract Alfred Adler and Carl Gustav Jung’s rejection of this aspect of his theory.

Chapter 2 describes the birth and development of the psychoanalytic movement but, to defend himself from accusations of intolerance, Freud emphasizes that “the self-reliance of intellectual workers, their early independence of their teacher, is always gratifying from a psychological point of view.” He exposed the differences that existed between “experiments with association” and “free association,” for a number of commentators, especially in France, confused the two. He also attempted, although in vain, to stifle interest in the theory of “complexes” by showing that it did not have “the value attributed to it by people outside psychoanalysis . . . it cannot be inserted naturally and logically into the existing group of psychoanalytic theories.”

The geographic map of the movement’s conquests followed: Northern Europe, America, India. But, “among European countries France has hitherto shown itself the least disposed to welcome psychoanalysis.” Freud also provides a fairly complete picture of the relationship between psychoanalysis and the other branches of knowledge without, however, repeating the arguments he made in “Claims of Psycho-Analysis to Scientific Interest” (1913j), which had appeared the previous year.

The third chapter is the most directly political and polemic. Based on the advice of his first readers, Freud softened some of his comments, but he is addressing the crowd of followers who are still hesitating between Freud, Adler, Stekel, and, especially, Jung. The future of the movement depends on their decision. After reviewing the foundation of the IPA in 1910, Freud provides the background to the dissension that followed, specifying that while he is constrained to “make use of analysis,” he will reduce its use to the minimum since “analysis is not suited, however, for polemical use; it presupposes the consent of the person who is being analyzed and a situation in which there is a superior and a subordinate.”

Adler is the first to be discussed, for his theory constitutes a “system” and, although it makes a contribution to the psychology of the ego, it ignores unconscious motivations, especially sexuality. The “will to power” and “masculine protest” weaken repressed tendencies or the fears aroused by the threat of castration. But if Adler’s claims are based on a theory of instincts, including aggressivity, the same cannot be said of Jung. Jung’s ideas are confused, and dominated by desexualization and moralizing, which

have denatured the discoveries of psychoanalysis to create an ethical-religious system. “The sexual libido was replaced by an abstract idea,” the “Oedipus complex has been given a ‘symbolic’ sense,” the only recognized conflict being that of the “life task” and “psychic inertia,” and so on. “The truth is that these people have picked out a few cultural overtones from the symphony of life and have once more failed to hear the mighty and primordial melody of the instincts.” This reflects the disastrous consequences of these transformations on a form of therapeutic practice that no longer recognizes either the past or the transference. And Freud concludes, “that the new teaching which aims at replacing psycho-analysis signifies an abandonment of analysis and a secession from it.”

On February 8, 1914, Freud announced to Ernest Jones, “I have done with the first rogue today and hope I may finish the other next Sunday.” On February 11 he wrote to Ferenczi, “I am writing very assiduously on the history of the  $\Psi$ -a movement, and I hope to have worked on Jung, and with that have finished it by Sunday.”

Jones drew from this the conclusion that Freud should never be allowed to abandon “the fields of pure science in the positive sense. My desire has been to create around you a circle of men who will take care of the opposition while you continue your work; the perspective of an ideal situation of this type appears very promising” (letter of May 25, 1914). This was to be the birth of the secret committee.

## “ON THE ORIGIN OF THE ‘INFLUENCING MACHINE’ IN SCHIZOPHRENIA”

Viktor Tausk completed his medical studies in 1919 and went on to work as a psychiatrist with an interest in the psychoses. After three consultations with Tausk, a Miss Natalija A. consented to describe for him the

*influencing machine* which she felt was being operated in an obscure fashion by a rejected suitor of hers who had previously sought to influence her, to make her agree to marry him. Though in Tausk’s view this case was unique, the machine described was analogous, if atypically, to a number of such machines alluded to but not interpreted in the psychiatric manuals. In “On the Origin of the ‘Influencing Machine’ in Schizophrenia”, Tausk developed several psychoanalytical hypotheses.

Influencing machines were of a “mystical nature,” described by patients at once in would-be technical terms and allusively with respect to their persecutory effects, namely images, thoughts, feelings, motor phenomena, sensations, and various bodily manifestations. Such a machine would make its appearance late in the evolution of schizophrenia, arguably as the unstable product of feelings of estrangement, of influence, of inner change, or of transformation that for their part tended to emerge early on, and in a most striking way. A machine would be constructed in an attempt at identification with the persecutor and projection into the outside world. After the fashion of the complicated machines in dreams, the influencing machine was an outwardly projected representation of a patient’s genital organs conflated with his or her own body. Tausk noted how attempts would be made to eliminate parts of the body (sexual organs, arms, and so on), and how the head (in the case of Natalija A.) might be replaced by a “lid” (as of a coffin).

Interpreting this description in the light of another symptom of schizophrenia, the loss of ego boundaries, Tausk set forth hypotheses concerning the combined and conflictual development of narcissism and ego-formation. Whereas an “innate” narcissism fixed the libido at the level of the organs and their functions during an early, objectless stage, the search for the object indispensable to the formation of the ego led to a finding of it in the subject’s own body, still experienced as external. This process preceded the encounter with the object proper in the outside world, which would, in a second stage, inaugurate an “acquired” psychic narcissism, nourished and regenerated by the earlier basic narcissism and locked in a complex struggle with the ego.

This kind of very early functioning, at the start of extrauterine development, affected not only the relationship to the subject’s own body but also the relationship to thought (still, however, within the context of the distinction between inner and outer worlds),

and Tausk was led into a whole discussion of the mechanism of hallucinatory representation. In the last reckoning, the important polarity for him was not that between the sexes but that between object-libido and narcissistic libido, as revealed by the regressions characteristic of schizophrenia, which also showed sites of libidinal stasis in the “physiological” sense.

At the very early infantile stage following a first renunciation—that of the mother’s protection—the whole body was experienced as a genital organ, and the male subject wished to “creep back” into the genital from which he had emerged. The image of the genital organ—as the representative of sexuality—had been preserved in the form of a figurative representation, in the form of language. The machine aspect taken on by the influencing apparatus argued strongly for the idea that it was a projection of the body considered in its entirety as a genital organ, threatened in its narcissistic posture, independent of the intentions of the ego, and hence subject to an external will.

Although it was reasonable to speak of “somatic paranoia” with respect to the construction of the machine, the fact remained that, in contrast to paranoia, it was the persecuted in this case, not the persecutors, who were organized in a kind of systematic passive plot: The subject’s dear ones or love objects were subordinated to a narcissistic object-choice by identification, while the exigent persecutor was eliminated by a paranoid mechanism.

Tausk concluded his paper by evoking the astonishment of the young boy when he becomes aware for the first time of his erection, which he experiences as independent of the ego, as imperfectly controlled, and as part of the external world. Curiously, Tausk never returned in his study to his initial report that his patient Nataliya A. had been completely deaf for several years as the result of a recurrent middle-ear infection that obliged her to communicate with those around her by means of the written word.

This article is considered the main legacy of Tausk, whose brilliant career was cut short by his suicide in the year of its publication (1919). It is rife with more or less well-worked-out ideas, including, for instance, the casual mention of the notion of an ego “the chief weapon of which is the intellect” (p. 48). One may readily imagine the multifarious responses it elicited and the many rereadings of it that developments in psychoanalysis would later make possible; one has merely to consider how many

ideas it addressed: hallucination, the psychic, the somatic, the psychosomatic, the “ego,” narcissism, the object, and—unnamed but clearly present—seduction. Tausk deployed all of these after his own fashion, often distinct from Freud’s approach. But, in his text as in the footnotes, he emphasized time and again (perhaps even too often?) how great an inspiration Freud had been for him, and how the relationship of the two men was comprised of enigmatic encounters, and how this reflected the difficulty of their relationship.

## “ON THE SEXUAL THEORIES OF CHILDREN”

Freud’s article “On the Sexual Theories of Children” was first published in the same periodical as “‘Civilized’ Sexual Morality and Modern Nervous Illness” (1908d). In fact it is part of a whole set of writings, beginning with the *Three Essays* (1905d), in which Freud developed the themes of childhood sexuality and of the role, not just of childhood sexuality but of sexuality in general, in the face of the demands of civilization. These issues are illustrated by the case of “Little Hans”

(1909b), and further explored in *Leonardo da Vinci and a Memory of His Childhood* (1910c) and in the “Rat Man” case history (1918b [1914]).

In connection with the sexual theories of childhood Freud here evokes various repressed primal ideas (among them ideas of a woman with a penis, castration, and the sexual use of mouth or anus) that are to be met with as readily in dreams and folklore as in neurotic symptoms and perversions. He bases his understanding on both the direct observation of children and on the unconscious memories of neurotics, isolating a number of juvenile theories that he considers typical.

The child’s curiosity about origins (“Where do babies come from?”) arises, according to Freud, from a “vital exigency” (*Lebensnot*), namely the need to guard against the birth of younger siblings with whom parental love must be shared. This question is the point of departure of an “instinct for research” which will continue to operate independently.

The theories that the child conceives are directly related to its own sexuality, which means that they are true, albeit in a distorted way. Freud identifies three typical theories. The first consists in the attribution to all human beings, including females, of a penis—whence the belief in a castration that accounts for the actual configuration of the woman’s genitalia. A second theory concerns birth. This is the cloacal theory, according to which the baby is evacuated like a stool from the mother’s body. The third deals with parental coitus, picturing it as a struggle in which the father is attacking the mother.

These theories are all products of a curiosity that deconsecrates the parents by portraying them as engaged in dirty or forbidden activities (fantasy of the primal scene). The wish to know (*Wissbegierde*) is a sexual wish, and in Freud’s view the source of our intellectual interest in riddles.

### “ON TRANSIENCE”

“On Transience” was written by Freud in November, 1915, at the invitation of the Goethe Society of Berlin for a commemorative volume scheduled to appear the following year, *Das Land Goethes 1914–1916*. According to H. Lehmann (Schur, 1972), the characters referred to, that is the taciturn friend and the young poet, are respectively Lou Andreas-Salomé and Rainer Maria Rilke. This has not been confirmed, although Rilke visited Freud one month after the preparation of the text, in December, 1915 (letter to Sándor Ferenczi, December 24, 1915).

This short essay, over which hover the background of war and death that were prevalent at the time, was written the same year as Freud’s “Thoughts for the Times on War and Death” (1915b) and *Mourning and Melancholia* (1917a [1915]). These three essays constitute a whole focused on the notion of mourning. The theme of the relationship between mourning and melancholia had already been broached in Manuscript G (1950a, January 7, 1895): “melancholia consists in mourning over loss of libido” (p. 201). In “On Transience” the approach is one of a moral philosophical defense of the love of life when confronted with a depressive pseudo-wisdom, but it also contains some of Freud’s thoughts on culture and time.

In the essay Freud describes a conversation that takes place one summer day between a taciturn friend and a young poet who suffers from an inability to enjoy the beauty of nature because it will disappear during the coming winter. For Freud the waning of beauty leads to two different mental concepts: a painful disgust, related to the devaluation of the object, which can no longer keep the promise of pleasure, and

a revolt against the reality of facts, that is, the denial of time, which essentially corrupts. Freud begins by rejecting the second concept as being an illusion resulting from desire (“what is painful can also be true”). He then reverses this concept, providing several justifications for his argument: the objects are often less transient than we are and therefore we have no reason to deplore their loss, their transience confers upon them a supplementary charm, the value of things is independent of their duration.

As in the story of the cauldron, these arguments cancel each other out and are hardly convincing. There is no point in the poet torturing himself further for his own transience. Market logic (“what is rare is expensive”) implies either a position of omnipotence with respect to the object and the rivals that want to hold of it, or a romantic, or even masochistic, identification with the object’s transience, the presentiment of death adding to the worth of the object, as if mourning were taking place during the object’s lifetime.

Freud’s most interesting argument comes later and can be summarized as the affirmation that transience does not alter the object’s value, which is independent of time. This dissociation implies that value doesn’t disappear, even when there is no one to cathect to it as such. This paradoxical argument is combined with another that states that, unless the concept of value is isolated, there will be nothing left to cathect to because everything is transient. The atemporal nature of value connects the poet’s complaint about transience to its subjective and narcissistic dimensions when he complains that the object is not isomorphous to him in its duration. This short, penetrating essay is driven by the notion of mourning and the possibility of expressing and overcoming it.

In “On Transience” Freud introduced an original aspect of mourning, the “anticipatory mourning” of the object, which consists in the rejection of its cathexis to avoid suffering from its loss. Anticipatory mourning is a mechanism of narcissistic defense that denies the libidinal attachment as it is being developed. By debasing any possible relationship, the subject also debases a part of himself in the hope that the remainder will be preserved from suffering. This withdrawal of libido in the face of anything that is liable to be transient is a form of protection against the depressive catastrophe that mourning would entail for certain subjects. This exclusion of the object differs from

the work of mourning and the hate-filled attachment of the melancholic individual to an object.

**ONTOGENESIS**

Ontogenesis is a theory of the development and structuring of the individual that takes into account the individual’s origins and the conditions of his or her development. Sigmund Freud always associated the ontogenesis of the human subject with phylogenesis, adopting a biogenetic perspective.

Ontogenesis comprises the developmental processes and acquisitions specific to the individual, in contrast to phylogenesis, which involves the processes of evolution and acquisition particular to a species. Ontogenesis and phylogenesis are not independent from one another: Individual acquisitions are only possible within the fixed limits of the species.

Defining ontogenesis, or the development of the individual, requires examination of what constitutes the mind and what the primary conditions of its organization are. What is called for is nothing less than a clear understanding of the origins, developmental stages, and earlier states of an individual’s history.

At the end of the nineteenth century, psychology found fertile soil in Darwin’s overarching theory of the evolution of animal species. It was believed at the time that the level of functioning of an earlier species was retained in a virtual state in later species. As Ernst Haeckel famously put it: “Ontogeny recapitulates phylogeny.” Haeckel and other nineteenth-century

evolutionist thinkers held that in human beings, the development of the fetus to adulthood (ontogeny) paralleled, in brief, the entire history of the species (phylogeny).

Meanwhile, the British neurologist John Hughlings Jackson hypothesized a hierarchical organization of the central nervous system, showing that the suspension of control from the higher centers freed up archaic automatic responses in the lower centers that correspond to earlier phases in development. Freud drew inspiration from this model with the notion of “regression.” In France, Henri Ey based his theory of organodynamism on Jackson’s “dissolutions.”

At the time, the prevailing idea was that some functions with adaptive value for lower animal species persisted in a virtual state and could be reactualized by pathology: failure of control at a higher level liberated lower levels in the hierarchy. The idea that pathology liberated a less differentiated, more “automatic” level of functioning, dating from an earlier stage in individual or species development, influenced many authors, including Freud and Pierre Janet.

Thus Freud, from his earliest writings, implicitly adopted a biogenetic conception of human sexual development. Along with Wilhelm Stekel, Wilhelm Bölsche, Granville Stanley Hall, and many others, he applied Haeckel’s “fundamental biogenetic law” to the question of sexual development.

If the child, in its growth, recapitulates the history of the species, Freud concluded that it must, by extension, recapitulate the sexual history of the species. In other words, the prepubescent human being must have the innate capacity to experience all the archaic forms of sexual pleasure that characterized the adult stages of our distant ancestors. In “Some Thoughts on Development and Regression—Aetiology,” the twenty-second of his *Introductory Lectures* (1916–1917a), Freud wrote of the development of the ego and libido that “both of them are at bottom heritages, abbreviated recapitulations of the development which all mankind has passed through from its primaeval days over a long period of time” (p. 354).

This biogenetic logic not only subtended Freud’s thoughts on the “polymorphously perverse” nature of infantile sexuality, but also later buttressed other developments in his theory. The concepts of “fixation” (arrested or inhibited development), “regression” (linked to Jackson’s general notion of “dissolution”),

and “perseveration of early impressions” (after Wilhelm Roux’s model of embryological experiments) all emerged from a developmental perspective to account for the organization of the neuroses.

Freud pursued the logic of recapitulation in a footnote added in 1915 to his *Three Essays on the Theory of Sexuality* (1905d), where he insisted that each major “pregenital” stage in infantile sexual development preserved a specific inheritance from this phylogenetic influence. From the same perspective, mental pathology was considered a return of past stages of ontogenetic and phylogenetic development that are integrated, and at the same time rediscovered. For Freud, symptom formation actualized the past, and psychoanalytic treatment was itself a therapeutic form of remembering.

Seeking the origins of Oedipal conflict, Freud detailed a series of three primal fantasies—seduction, castration, and the primal scene—that he considered to be a given from the outset and at the source of all mental organization, beyond the traumatic events of the individual’s history. The presumed universality of the Oedipus complex led him to believe that in each individual there was an embryonic version of these fantasies that are found in all cultures, as the phylogenetically transmitted trace of the murder of the father by the primitive horde.

The neo-Lamarckian perspective of Freud and his phylogenetic theories have received a good deal of criticism, despite Frank J. Sulloway’s study, *Freud—Biologist of the Mind* (1979), which presented the full scope of Freud’s constructions. The fact is that in early twenty-first century cultural and linguistic transmission, along with communication in one way or another, from the parental or grandparental unconscious, are far more readily invoked to define the way in which the psyche’s earliest constitutive fantasies originate than a hypothetical inscription in the genetic material of the species. Research on transgenerational effects (Kaës, 1993) takes this direction, as does Jean Laplanche’s “general theory of seduction” which argues that the maternal unconscious transmits sexualized messages, or “enigmatic signifiers,” to the child.

Present day research is concerned less with discovering the ultimate origins of the formation of the individual than with accounting for the conditions under which it comes about. As of 2005, the ontogenetic approach—that is, research into the development of the individual or into the genesis of the

Oedipus complex—concentrates on two main lines of inquiry. The first is libidinal development, taking into consideration the successive phases of mental organization, with a focus on the predominant erotogenic zone around which psychic excitation is centered and fantasies organized. The second focuses on the development of object relations in their relationship with the development of the ego.

## **OPERATIONAL THINKING**

The expression *operational thinking* was introduced by Michel de M'Uzan and Pierre Marty in 1962 at the Barcelona psychoanalytic congress, based on a so-called psychosomatic approach. It is conceived as a deficient form of thought that is quasi-conscious, without organic links to dreaming, fantasy, or symbolization. It is almost instrumental in nature, and suggests the idea of deementalization. Like “basic depression,” operational thinking is said to function as a defensive system and possibly as a structural, antitraumatic factor; in this role, however, it would be liable to introduce an element of disorganization that could lead to somatic disorders. Early on, operational thinking was cast in a metapsychological light within the framework of Freud's first topography; later, it played a role in the second topography (or structural model) and in the second theory of the drives.

This type of thinking repeats and illustrates action, preceding or following it within a limited temporal span. It does not work according to an associative system and elements in it are treated as pieces of the present; it is ostensibly without symbolic scope or trophic sublimatory value. It is thus subjected to reality without signifying it, causing a reduction in the libidinal value of the elements of this reality. These criteria cause it to be conceived as a psychopathological type of thought.

Operative thinking is also linked in this view to deficiencies in the play of identification as well as in all emotional involvement; it renders all relationships “blank” inasmuch as others are considered to be identical to the subject, evoking “projective duplication.” Operational thinking reflects behavior that, while socialized, appears as if it is imposed by purely adaptational requirements. By placing emphasis on the economic dimension, it can be described as an archaic breakdown of the evolution of the primary process with libidinal degradation; the processes of investment thus remain at the archaic level, favoring the instrumental functions of life—to the detriment of adequate secundarization—with pseudo-mastery standing in for a sound integration of reality.

This notion has become a clinical construct in psychosomatic disorders and has been theoretically and clinically fleshed out, highlighting the traits that are dynamic in dimension, notably on the relational level, in *L'investigation psychosomatique* (Psychosomatic research; 1985). This book dealing with operational thinking and served as the rallying point for the group of psychoanalysts dubbed the École psychosomatique de Paris (Psychosomatic School of Paris).

Marty has extended the notion of “operational” to other aspects of mental life besides thinking, and these together, in his view, made up “operational life.” Combining this with the notion of basic depression in the first volume of *Les mouvements individuels de vie et de mort* (The individual movements of life and death; 1976), he defined the framework of a quasi-structural approach that is both a defensive system against trauma and a participating element in what he called “progressive disorganization.”

The original theorists of operative thinking privileged the role of the first Freudian topography and—Marty in particular—the flawed category of the preconscious. It should be noted that in the context of Marty's model of progressive disorganization, the

death instinct is not the same thing as the death drive in Freudian theory. Present-day authors tend to place operational thought in the context of the second Freudian topography and the death drive, including self-destructiveness.

## **OPERE (WRITINGS OF SIGMUND FREUD)**

The Italian edition of the *Opere* (Writings of Sigmund Freud) in twelve volumes was begun in 1966 under the direction of Cesare Musatti and was completed in 1980. The essays that were not published in the *Opere* were collected into a volume of *Complementi* in 1993, with a critical apparatus by Angela Richards and Ilse Grubrich-Simitis.

Each of the twelve volumes is accompanied by an introduction by Musatti and a historical essay that describes the context in which Freud's writings can be placed. Each text is also accompanied by an editor's preface, which includes a list of publications and translations. Volume twelve is an index and includes keywords, together with bibliographical references, lists of publications, and a concordance with the complete

works in English (*Standard Edition*) and German (*Gesammelte Werke*).

The Italian edition duplicates the unrevised *Standard Edition* prepared by James Strachey (1953–1974) and refers to it; consequently it does not include the so-called preanalytic works or the fragments of analytic works revised by Freud, the letters, or minutes of the Vienna Psychoanalytic Society. Like the English, German, and French editions, the Italian edition is not a critical history because it does not discuss Freudian politics in terms of the circular letters, nor does it enable the reader to grasp Freud's process of development through his writing.

The Italian edition was directed by Paolo Boringhieri, who, with Cesare Musatti, turned over the corrected edition to Renata Colorni and various translators. There were few psychoanalysts in this group other than Giacomo Contri and Elvio Fachinelli. Many translators were unfamiliar with psychoanalysis, while Freud himself wanted to have his work translated only by those trained in psychoanalysis.

Every translation is linguistically situated in the period in which it is undertaken and the Italian edition is no exception. It reflects the psychoanalytic culture of the 1960s, the language that corresponds to the period, and a concept of psychoanalysis as understood by practitioners like Edoardo Weiss. Because it promoted genuine interest in psychoanalysis, the *Opere* represents the most important psychoanalytic creation yet produced in Italy.

## OPHUIJSEN, JOHAN H. W. VAN (1882–1950)

A physician, psychiatrist, and psychoanalyst, Johan H. W. van Ophuijsen was born on November 12, 1882, in Sumatra, Dutch East Indies, and died on May 31, 1950, in Detroit, Michigan. He was sent to Holland for secondary schooling at age thirteen. He graduated with an MD from Leiden University in 1909 and went for four years to Zürich to the clinic of Eugen Bleuler. He had analysis with Jung and analyzed some English-speaking patients. He was secretary of the Züricher Psychoanalytic Society and as such present at the meeting of Freud and Jung about the escalation of their conflicts in November 1912 in Munich, together with Karl Abraham and Ernest Jones.

Back in Holland in 1913 he worked at the psychiatric clinic of Jelgersma in Leiden and participated in meetings with some colleagues who were also interested in psychoanalysis, partly analyzed by Jung. Together they founded the Dutch Psychoanalytical Society in 1917. Van Ophuijsen was the link between Dutch and international psychoanalysis, through his reports in the *Internationale psychoanalytische Zeitschrift* and the Dutch Medical Journal. In 1922 he went for a few years to Berlin for further analysis with Abraham, cooperating with Max Eitingon and Hanns Sachs, who were developing the tripartite training model at the Berlin Institute. After his return again to Holland he settled in the Hague and became president of the Dutch Psychoanalytical Society, fervently defending the desirability of lay analysis and the tripartite training model against the opposition of most of the other members.

From 1927–1934 he was treasurer, and from 1936–1938 vice-president of the International Psychoanalytical Association (IPA). His international involvement caused much resentment among the Dutch. In 1932 he was on the committee to save the *Internationaler Psychoanalytischer Verlag* in Vienna from financial distress. His appeal to the Dutch analysts for a financial contribution raised opposition in the Society, where earnings from analytic practice were poor. The opposition rose to an uproar when in 1933 four German Jewish refugees came to Holland, with the active cooperation of van Ophuijsen, who hoped that they would play an important role in Dutch analytic training. In fact, he had asked Karl Landauer to join him in the

Psychoanalytic Institute, which he had founded a few years earlier. The Dutch analysts feared that they would be overshadowed and lose the limited earnings they had, and refused to accept the immigrants as society members. In a stormy meeting, van Ophuijsen resigned as president of the society and one week later also as a member, followed by five others. He founded a new society, the Society of Psychoanalysts in the Netherlands, which was open to the German immigrants. However, in 1937 van Ophuijsen emigrated himself to Johannesburg (South Africa) together with his analyst Fritz Perls (also a German immigrant and later the founder of Gestalt therapy) and one year later to the United States, where he joined the psychiatric staff of some New York hospitals and became a teacher at the New York Psychoanalytical Institute. Later he settled in Detroit as an analyst and teacher. He continued his psychoanalytic practice until the day of his death.

### OPTICAL SCHEMA

Lacan borrowed his optical schema from physics. He used it to illustrate the role of the real Other in constructing both the body and the specular image as the model for the ego.

Lacan introduced this schema in his seminar of 1953–1954, on *Freud's Papers on Technique*. He took his cue from Freud's reference to an optical schema in

FIGURE 1

*The Interpretation of Dreams* (Freud, 1900a, p. 536; Lacan, 1953–54, 74–76). Lacan first used the schema to illustrate the reciprocal play of the real, the imaginary, and the symbolic in Melanie Klein’s case of “Little Dick.”

Because of the optical properties of concave mirrors, a bouquet of flowers that is hidden from the visual field of the viewer emerges above the vase. And if the eye of the viewer is properly placed, an image of flowers in the vase is produced as a whole or a unity (Figure 1).

The illusory presence of the flowers in the vase represented a baby’s relation to his body, but this is something the baby cannot see. To create a “substitute for the mirror-stage” (1953–54, p. 74), Lacan introduced a plane mirror (Figure 2).

In the virtual space beyond the mirror, a specular image is created,  $i'(a)$ , and this is where the baby as

FIGURE 2

FIGURE 3

subject recognizes the image as its ego. This represents the dimension of radical alienation in ego formation as it occurs in relation to the image of a fellow being—a process that is specific to secondary narcissism and the ideal ego.

Lacan returned to the optical schema in his seminar on *Transference* (1960–61), but then the plane mirror shows the effect that the parental Other’s look has on the baby’s organism. This look allows the baby to sense its own body, modeled on its specular image. Lacan even gave the Other a role in the formation of primary narcissism. This schema allows for an approach to the treatment of early psychopathologies prior to the mirror stage (Laznik-Penot, 1993).

In his seminar on *Anxiety* (1962–63), Lacan redesigned the schema in response to a question asked by André Green regarding the relations between the real, the imaginary, and the symbolic (Figure 3).

This version of the schema presented two principle modifications:

1. The flowers, a metaphor for libidinal investment, were no longer the reflection of a bouquet hidden under the table, but rather the effect of a lack, which Lacan wrote as  $-\varphi$ .
2. The inscription of lack,  $-\varphi$ , also appeared behind the plane mirror, in the imaginary field. Thus the new version of the schema emphasized the constitutive role of lack in any mental functioning.

Lacan used the plane mirror in two different ways. Sometimes it referred to the mirror of the mirror stage, still very much centered on the structuring character of the image itself. And sometimes it

referred to a mirror without a reflection, that is, a representation of the Other's gaze. Indeed, our understanding of this schema has been modified retroactively by the introduction of the concept of the big Other; nevertheless, it is still most often understood in its strictly intrapsychic dimension.

## **ORALITY**

*Orality* is a major component of the organization of the libido during the first, pregenital phase of its development; it is thus an essential aspect of psychosexuality.

Freud gave his first overall description of the phases of the libido in his *Three Essays on the Theory of Sexuality* (1905d). Sucking, initially autoerotic, is the earliest expression of the instincts. It is anaclitically supported by a function necessary to the preservation of life, the absorption of nourishment. Pleasure is therefore linked to an erotogenic zone, the mouth, and more specifically to the mucous membranes of the lips and mouth. This pleasure will later be found again in kissing, in the pleasure of eating, drinking, or smoking, and so forth, and it can become the basis for perverse practices. This excitability may persist throughout life, linked—to some degree—to genitality. Due to the very fact of this link, oral pleasure may be repressed and eating disorders may appear.

In a note added to the *Three Essays*, in 1915 Freud specified that during the oral phase, “the sexual aim consists in the incorporation of the object—the prototype of a process which, in the form of identification, is later to play such an important psychological part” (1905d, p. 198). Orality is thus also a mode of relationship to the object. Freud elaborated on this idea in connection with the psychopathology of instances of the ego's loss of the objects it has cathected. “The ego wants to incorporate this object into itself, and . . . it wants to do so by devouring it,” he wrote in “Mourning and Melancholia” (1916–1917 [1915], p. 250). At the stage of the oral organization of the libido, love of the object still coincides with the destruction of the object, according to Freud in *Beyond the Pleasure Principle* (1920g).

Freud's perspectives were slightly modified with his introduction of the second topography (or structural theory). During the oral phrase, he then argued, because the three agencies were not yet differentiated, object-cathexis was still based on identification. “Later on object-cathexes proceed from the id, which feels erotic trends as needs,” he wrote in *The Ego and the Id* (1923b, p. 29).

Since erotogenic masochism is a part of all phases of libidinal development, Freud held (1924c) that the fear of being devoured by the totem animal (the father) emanated from the primitive oral organization.

In his important article “The Influence of Oral Eroticism on Character Formation,” (1924) Karl Abraham associated envy and jealousy with oral erotism. Adopting Abraham's thesis, Freud in his *New Introductory Lectures on Psycho-Analysis* (1933) distinguished two substages of the oral phase: The first is preambivalent (conflict-free); the second, linked to the development of dentition, is marked by ambivalence owing to conflict between the desire to bite the breast and inhibition of that desire, and is thus described as “oral-sadistic.”

Abraham's and Freud's views were the basis for Melanie Klein's theory that premature activation of the oral-sadistic tendencies is the cause of hypertrophied sadism and strongly ambivalent object-relations. More generally, it was with reference to the oral stage of libidinal development that she elaborated her notion of a close bond between destructive and libidinal impulses. She contended that anxiety stems essentially from the instinctual dangers of the destructive tendencies and

their repression. This is the source of what later in her theoretical work would become the love/hate opposition marking the earliest relations to the breast, and its fundamental split into good breast and bad breast.

## **ORAL-SADISTIC STAGE**

The oral-sadistic phase of infantile libidinal organization is the second part of the oral stage, as described by Karl Abraham; it is also known as the cannibalistic phase. During this period incorporation means the destruction of the object, so the relationship to the object is said to be ambivalent.

It was in a passage added in 1915 to his *Three Essays on the Theory of Sexuality* that Freud introduced the notion of an “oral” organization that he also described as “cannibalistic”: “the sexual aim consists in the incorporation of the object—the prototype of a pro-

cess which, in the form of identification, is later to play such an important psychological part” (1905a, p. 198). The evocation of “cannibalism” served to underscore certain features of the oral object-relationship: the incorporation of the object and its characteristics, identification with it, and, at the same time, greed and destructiveness.

Abraham (1927 [1924]) subdivided the oral stage into two parts: first, an early oral phase dominated by the pleasure of sucking and described as “preambivalent,” because the breast is not yet conceived as at once good and bad, both frustrating and gratifying; and secondly, an oral-sadistic or “cannibalistic” stage, occurring later, during the second six months of life, and contemporaneous with teething, which sees the emergence of the wish to bite and to incorporate the object, destroying it in the process. Instinctual ambivalence makes its appearance during this second phase, as incorporation becomes destructive. The oral-sadistic phase is thus characterized by the advent of aggressiveness, by ambivalence, and by the anxiety associated with the destruction of the loved object and the fear of being devoured in turn by that object. Elsewhere, in the context of a discussion of interaction, attention has been drawn to the way in which the child’s cannibalistic instincts can revive those of the mother (Golse, 1992).

Freud used the model of cannibalistic devouring and the intrapsychic effects of ambivalence in his study of melancholia (1917e, pp. 249–50). In mourning, he argued, the lost object was assimilated into the ego, incorporated as in the totem meal. Once magically incorporated in this way, it was conflated with the ego, which could either draw strength and power from this (as in identification or the totem meal), or, alternatively, fall victim to attacks from within from this ambivalently cathected object (as in melancholic self-reproach).

Melanie Klein radicalized Abraham’s account of a destructiveness linked to orality and to object-love, going so far as to say that libidinal development as a whole is completed only once the innate destructive instincts have been integrated into it. In her view the whole of the oral stage was oral-sadistic in nature, indeed it was the high point of infantile sadism. The libidinal wish to suck and incorporate was combined with the destructive aim of scooping out and emptying the object. In her *Envy and Gratitude* (1957/1975, pp. 180–81), Klein defined envy of the breast as bound up with oral greed, in which the destructive component

instincts predominated: the desire to attack and destroy the object was not tempered by the gratitude generated by good experiences with the mother. This primal wish precipitated the split between the good breast to be retained and the bad breast to be expelled. Klein thus returns via this account of primal oral desire to the idea of a differentiation between ego and non-ego that is secondary to that between good and bad, as organized by the mechanisms of introjection and projection specific to the Freudian model.

## **ORAL STAGE**

The oral stage is the initial mode of organization of libidinal cathexes, establishing the buccopharyngeal area and the lips as the predominant erotogenic zone—and hence as the source of the instinct operating in conjunction with the instinctual aim (incorporation) and the instinctual object (the breast).

The act of taking nourishment tends to symbolize the mother's breast and the primal link that the infant establishes with its mother. Sucking at the breast, governed by biologically programmed behavior, procures an experience of pleasure for the infant which vouchsafes the mouth its role as the first erotogenic zone.

At the same time, however, the concept of anaclysis highlights the foundational role played by the mother's ministrations and the taking of nourishment, making it possible to see how, at this first moment in development, there is an interaction between the vital sphere of need and the mental sphere of sexuality and fantasy.

Jean Laplanche has described both the dual movement of sexuality, as it first props itself upon (“anaclysis”) and then disengages itself from the realm of physiological need, and the dual shift—metaphorically, from ingestion to incorporation, and metonymically, from milk to breast (or bottle). This model underscores the importance of maternal care for the constitution of the psyche. For Laplanche, “primal seduction,” linked to the mother's sexuality, is at the root of the child's autoerotism and sexuality. Similarly, on the basis of the idea of a retroactive effect of the object of the drive upon its source, Laplanche evokes a “source-object” as the first form of internal object, constituted by autoerotism and constituting the origin of fantasy. Thus the representation of the mother's breast supplies the prototype of incorporable objects and precipitates the development of the first object-relationship.

René Spitz introduced the idea that the earliest oral experience of nursing gives rise to the representation of a “primal cavity” which orders the structuring relations between inside and outside. This “bridge from inner reception to external perception” (Spitz, 1965, pp. 61–62) may be looked upon as the matrix of the mechanisms of introjection and projection.

Oral experience thus initiates “the language of the oldest—the oral—instinctual impulses,” evoked by Freud to account for the primal rejection of the bad and incorporation of the good in the establishment of the first boundary between the self and the outside world (1925h, p. 237).

It was Karl Abraham, in 1924, who subdivided the oral stage into two parts: an early oral phase covering the first six months of life, dominated by the pleasure of sucking and described as “pre-ambivalent” because the breast is not yet conceived as at once good and bad; and a later phase, covering the second six months, known as the oral-sadistic or “cannibalistic” stage, contemporaneous with teething, which sees the emergence of the wish to bite and the fear of destroying the loved object (and of being devoured in turn by that object). Ambivalence makes its appearance during this

second phase, incorporation having become destructive. The child's cannibalistic instincts have been described as reactivating those of the mother (Golse, 1992).

Melanie Klein radicalized Abraham's account of a destructiveness linked to orality and to object-love, going so far as to say that libidinal development as a whole is completed only once the destructive instincts have been integrated into it. She maintained that sadism is at its height during the first six months of life.

The organization specific to the early, "passive" oral stage was characterized by Klein as the "swallow/be swallowed" object-relationship, by anxieties about being emptied or annihilated. The oral-sadistic stage was marked by the "devour/be devoured" object-relationship, by fear of dismemberment, and by projective identification. Fixation at the oral stage was reflected in a character type marked by greed, passivity, and dependency.

The experience of satisfaction obtained from feeding is not confined to oral pleasure, for it may involve the entirety of bodily feelings. This last consideration has been judged essential in the genesis of the feeling of identity, that is, of the self, and the first underpinnings of narcissism.

Oral introjection is also considered to underlie such other corporeal functions as cutaneous absorption, sight, hearing, respiration, and manual prehension. Contemporary work on autism has underlined the importance, in the first organizing experience of the psyche, of mouth-nipple and tongue-nipple contact, thought to convey the contrast between the elemental sensations of hard and soft (Donald Meltzer, Frances Tustin, Geneviève Haag, 1991).

## **ORGAN PLEASURE**

Organ pleasure is erotic satisfaction linked to any part of the body that becomes an erogenous zone, including internal organs. It rises from the earliest phase of development of infantile sexuality and is marked by independent, autoerotic partial drives in search of sexual satisfaction.

The notion of organ pleasure is part of the framework of infantile sexuality and is intimately linked to the notion of erogenous zones. This notion appeared late in Freud's work, rising out of his theoretical extrapolations on narcissism. In "On Narcissism" (1914c), Freud studied a number of cases of pathology, as well as of normal psychology, to analyze the narcissistic functioning of the ego. In addition to psychosis and physical illness in love life, he took up the subject of hypochondria. In this connection he was led to reconsider the notion of corporeal erotogenicity, which he defined as an activity of a part of the body giving rise to sensations that excite the psychic apparatus sexually. Freud then extended erotogenicity to the level of a general property of all the organs. Thus the notion of organ pleasure was born. At the core of the libidinal economy, modifications of organic erotogenicity lead to corresponding modifications in the ego's libidinal investment.

The notion of organ pleasure is in reality a resumption of the notion of an erogenous zone, which Freud theoretically developed in *Three Essays on the Theory of*

*Sexuality* (1905d). In the chapter on infantile sexuality, Freud defined an erogenous zone as “a part of the skin or the mucous membrane in which stimuli of a certain sort evoke a feeling of pleasure possessing a particular quality” (p. 183). In infantile sexuality, the sexual goal of all partial drives remains the satisfaction of erogenous zones. This domination of the erogenous zone is tempered only by the first stirrings of pregenital organizations in the development of infantile sexuality. The notion of organ pleasure thus extends the erogenous zone beyond the skin and mucous membranes to all the internal organs, which, from the point of view of the subject’s sexuality, are conceived as having the same characteristics.

The notion of organ pleasure reappeared in Freud’s “Instincts and their Vicissitudes” (1915c) and in the *Introductory Lectures on Psychoanalysis*, on the development of the libido and the sexual systems (1916–17a [1915–17]).

The notion of organ pleasure results principally from two series of clinical observations. First, it has been linked to infantile sexual activity, such as sucking and anal activity. Second, it has been inferred by interpretation in the course of psychoanalytic treatment of neuroses, particularly hysteria. These psychoanalytic observations have shown that an organ or system of organs can substitute for the genital organs in the search for sexual satisfaction. This led Freud to connect the erogenous zones to the hysteria-generating zones. Later research on hypochondria has confirmed this point of view.

## **ORGANIC PSYCHOSES**

In traditional psychiatric language, *organic psychoses* are psychotic states—whether acute (like *delirium tremens*) or chronic (like the senile dementias)—having a known, identified biological substrate (histological, toxic, and so on) that is directly related to the pathology. They are opposed to the *functional psychoses* (acute, like delusional fits, or chronic, like schizophrenia).

From the beginning of the nineteenth century, the term *psychosis* has been used to describe all pathologies, whatever their pathogenesis, that combine a loss of reality (deficiency in the reality-apprehension functions) with the creation of an alternative reality (hallucinations and delusional ideas). Initially, the term *organic* referred to “organ” and designated those psychoses where the symptoms are due to organ damage (the language apparatus in the dementias, for example), as opposed to functional psychoses—for example, in schizophrenia, also called *dementia praecox*, disorders of language are not caused by an organ being affected, but by a problem of function. Gradually, the term organic came to be used for all pathologies with a biological substrate, and was thus opposed to psychogenic. As of 2005, the opposition between organic psychoses and functional psychoses has fallen into disuse.

Freud never adopted this terminology, doubtless owing to the originality of his approach, which established concepts (such as the instincts, the libido, the economic theory) that make it possible to conceive of the biological and the mental in conjunction. Thus, he did not hesitate to speak of “toxic” etiology with regard to certain types of melancholia and hallucinatory psychoses, which in his view referred to anomalies in the level and/or the distribution of the libido, and which was in no way in opposition to the demonstration of psychological mechanisms.

## **ORGANIC REPRESSION**

The theory of organic repression was elaborated throughout Freud’s work in order to propose a synthetic, “psychobiological” solution to the problem of pathological repression and the choice of neurosis. Civilization was considered to be built on the model of

an “organic” repression of abandoned libidinal zones, for example the abandonment of olfactory satisfactions as hominids evolved into standing upright. Throughout his life Freud tried to find a “psychobiological” solution to the question posed by the psychic organization, notably those of the choice of neurosis and pathological repression (Sulloway, 1979). The same Lamarckian and biogenetic model of human development inspired the earliest, as well as the latest Freudian discoveries, giving rise to an underlying model of psychosexual evolution meant to interpret human behavior. Many of the phylogenetic points of view that Freud promulgated after *Totem and Taboo* (1912–13a) had been adopted by him as early as the 1890s, as his correspondence with Fliess shows.

A few phases of the evolution of Freudian thought concerning the problem of repression can be distinguished, in the course of which Freud perfected complementary theories, one psychological and the other organo-phylogenetic. The instincts rooted in phylogenesis never stopped haunting his thought (Laplanche, 1993).

After abandoning the seduction theory in 1897, Freud replaced the notion of defense against real traumatic seductions linked to the environment with an organic olfactory theory of repression. He explained the propensity of man toward sexual neurosis by an excessive repression of the affects of pleasure, which were associated with certain infantile erogenous zones, such as the mouth, the nose, throat, and anus (letter to Fliess of November, 14, 1897). He took up this point of view again, in particular, in “The case of the Rat Man” (1909d), who had been a “sniffer” in his childhood, identifying people through their particular odor. In this case study he wonders whether “the atrophy of the sense of smell (which was an inevitable result of man’s assumption of an erect posture) and the consequent organic repression of his pleasure in smell may not have had a considerable share in the origin of his susceptibility to the disease” (p. 248). In later writings, *Totem and Taboo*, in 1912, then *Civilization and its Discontents* (1930a [1929]), Freud will renew this evolutionist hypothesis of a relation between sexuality, neurosis, and the erect posture of man.

However, even before abandoning his theory of seduction in the autumn of 1897, he had developed his psychological theory of repression, appealing to the notion of “organic” reversal of affect (disgust, shame),

associated with certain infantile sexual experiences. In the same “organic” perspective, he connected the acquisition of disgust and shame, in *Three Essays on the Theory of Sexuality* (1905d), to “a development that is organically determined and fixed by heredity, and can occasionally occur without any help at all from education” (p. 178–179).

For a long time, he had been considering the reaction of disgust at excrement as a phylogenetic consequence of the vertical position. He had already discussed this point of view with Fliess, referring to “abandoned erogenous zones”: “I have often had a suspicion,” he wrote him on November 14, 1897, “that something organic plays a part in repression; I was able once before to tell you that it was a question of the abandonment of former sexual zones.... The extinction of these initial sexual zones would have a counterpart in the atrophy of certain internal organs in the course of development” (*Complete Letters to Fliess*, p. 279).

On November 17, 1909, in the course of a debate at the Psychoanalytical Society of Vienna, Freud explained “that there is no repression that does not have an organic core; this organic repression consists of the substitutions of unpleasurable sensations for pleasurable ones. Probably man’s detachment from the soil is one of the basic conditions for [the formation of] a neurosis; the olfactory sense is prone, as a consequence of this detachment, toward repression, since it has become useless... the bigger the child gets to be, the further it rises away from ground” (Nunberg, p. 323). This distinction between the organic repression of childhood and the more psychological repressions of the adult corresponds to the later Freudian dichotomy distinguishing between primal repressions and secondary ones (1915d).

Subsequently, the logic of *Totem and Taboo* amplified the organic theory of repression proposed as first of all linked to odor. Along with the myth of the primitive murder of the father, “the ontogenetic acquisition of remorse, guilt and moral sense now became conceivable to Freud as a phylogenetic precipitate from the primal father complex of early man” (Sulloway, p. 373). At the time of the 1915 edition of the *Three Essays*, Freud added the following passage: “The barrier against incest is probably among the historical acquisitions of mankind, and, like other moral taboos, has no doubt already become established in many persons by organic inheritance” (p. 225n).

With *Civilization and its Discontents*, he summed up thirty years of reflection on the question of the sexual etiology of neuroses, suggesting that the propensity of civilized man towards pathological repression should be imputed to prehistory in the following manner. Man was first an animal on four legs, responding to olfactory stimuli. When he adopted the vertical posture, visual stimuli came to replace olfactory stimuli. This giant step towards hominization led to feelings of shame (visible sexual organs), as well as disgust, linked to organic repression of the odors of excrement and of the genitals. Olfactive repression opened the way then to the evolution of civilization toward cleanliness and the first displacements, repressions, or sublimations, leading to the “organic” rejection of strong odors.

Freud completed the biogenetic scenario of the repression founding civilization with the hypothesis of the parricide that founded the human family, already advanced in *Totem and Taboo*. He linked this phylogenetic point of view to the diphasic development characteristic of human sexuality.

In 1930 Freud wrote one of the most comprehensive versions of his theory, expressing his conviction of the tight ties between sexuality, culture, and neurosis. Ontogenetically, neurosis was conceived as a particular malady, linked to a specific stage of libidinal fixation, to which the libido had to have regressed. The “hereditary” predisposition constituted a basic “scheme” for ontogenetic development, “provoking the fantastic rewriting of many infantile experiences, in conformity to the universal grill of phylogenesis” (1930a).

## ORGANIZATION

The concept of *organization* belongs in several different scientific fields. It is used just as frequently in biological discourse as in sociology or psychology. The notion of organization is usually associated with that of development. Neurobiology thus describes the nervous organization of human beings going from the simplest to the most complex structures, each integrated in the other.

Freud used the notion of organization and associated it with the development of the libido. He proposed that the sexual life of human beings does not develop in one phase but gradually, through a series of successive phases or organizations. He wrote in Lecture 21 of *Introductory Lectures on Psycho-Analysis* (1916–17a [1915–17]): “Normal sexuality has emerged out of something that was in existence before it, by weeding out certain features of that material as unserviceable and collecting together the rest in order to subordinate them to a new aim, that of reproduction” (p. 322). In the beginning infantile sexuality is characterized by relative anarchy and the absence of any real organization, with each of the component instincts striving independently of the others for satisfaction. The features of sexual organization take shape progressively, leading to a relatively stable libidinal structure, which is then replaced in the course of development with what we call normal adult sexuality. Particularly in *Three Essays on the Theory of Sexuality* (1905d), “The Disposition to Obsessional Neurosis” (1913i), and “The Infantile Genital Organization” (1923e), Freud described pregenital organizations and an adult genital organization. The first of the pregenital organizations leave it in the sadistic-anal organization, in which it is not the component genital tendencies that come to the fore but rather the sadistic and anal tendencies. From the point of view of psychopathology, obsessional neurosis represents a regressive form of this. On a more primitive level, and following Abraham’s work, Freud described another pregenital organization in which the erogenous zone of the mouth plays the main role, an organization that is

illustrated psychopathologically in the form of melancholy. In opposition to these infantile sexual organizations, genital organization is characterized by the fact that it is definitively constituted after puberty and all the component instincts are subordinated to the primacy of the genital organs and the goal of procreation.

Another line of development other than the erogenous zone must be taken into account in the constitution of libidinal organization: that of the relationship to the object. Freud did in fact describe this second line of development leading the little human being from an autoerotic phase (or organization) to a narcissistic phase and then to a phase of object discovery. Although they refer specifically to the psychoses in order to postulate the existence of a narcissistic organization, modern psychoanalytic studies, particularly those dealing with borderline and psychosomatic states, further enrich this notion by highlighting the defects in the constitution of primary narcissism and its object relations.

## ORGASM

Orgasm is the pleasure obtained at the culmination (end pleasure) of sexual activity; it differs from the preliminary pleasure of foreplay in that it corresponds to a relaxation rather than a rise in excitation. Freud takes up the commonly referred to link between orgasm and death (*petite mort*) by analogy with the separation between the soma and the germen and, in some of the lower animal species, the death of the male. From a metapsychological viewpoint the momentary short-circuiting of Eros through the satisfaction obtained ensures Thanatos a degree of supremacy.

The question of female orgasm and its dissimulation for reasons of cultural propriety is discussed by Freud in the first manuscripts addressed to Fliess (1950a [1897–1902]) and in the *Studies on Hysteria* (1895d), where he notes that, during orgasm, thought disappears almost completely and this restriction of consciousness is very similar to the hypnoid state, or even a hysterical crisis. Some years later, in the *Three Essays* (1905d), referring to the observations of the pediatrician Lindner, he notes that the sensations of the satiated infant can lead to a motor reaction similar to orgasm if it does not lead to sleep. He also acknowledges that the orgasm associated with genital emission is inaccessible to the infant, whose masturbatory activity is incomplete, a perspective he associates with the infant's endless quest for sexual knowledge (1910c). It is interesting that among Freud's last works this same idea reappears:

“The ultimate ground of all intellectual inhibitions and all inhibitions of work seems to be the inhibition of masturbation in childhood. But perhaps it goes deeper; perhaps it is not its inhibition by external influences but its unsatisfying nature in itself. There is always something lacking for complete discharge and satisfaction—*en attendant toujours quelque chose qui ne venait point* [always waiting for something which never came]—and this missing part, the reaction of orgasm, manifests itself in equivalents in other spheres, in absences, outbreaks of laughing, weeping [...], and perhaps other ways.—Once again infantile sexuality has fixed a model in this.” (1941f [1938], p. 300).

Freud didn't actually define orgasm as a psychic or affective phenomenon associated with, but somewhat

**ORGANOGENESIS.** *See* Psychogenesis/Organogenesis

distinct from, a somatic process, although he drew attention to its absence in discussions of the symptom of frigidity. Sándor Ferenczi (2000/1931), in describing masochistic orgasm, attempted to define normal orgasm as the “meeting of two tendencies to action. The love relationship apparently does not arise from subject A or from subject B but between the two of them.” This definition of a hypothetical “normality” does not go as far as his description of masochistic orgasm during female rape: “The reaction,” Ferenczi writes, “is primarily a shock, accompanied by the anxiety of death and disintegration, and only secondarily a plastic identification with the emotion of the sadist, a hallucinatory masculine identification” (p. 248).

The function of the orgasm played a central role in the work of Wilhelm Reich (1940/1968), illustrating that it is necessary to incorporate an “actual” neurosis into any psychoneurosis. Reich took up Freud’s propositions concerning libidinal stasis and its conversion into anxiety. He defined “orgiastic power” as “the aptitude to achieve satisfaction matching the libidinal stasis of the moment.” Moreover, according to Reich, while inhibition prevents the transference of sexual excitation to the sensorimotor system and the genital apparatus, the excitation remains compressed within the vasovagal system and produces the phenomena of vasomotor neurosis. Reich believed, however, that civilization and monogamous marriage do not allow orgasm to develop and fulfill its function. There is not only a biological perspective in Reich’s work (bioenergy, orgone), but a moral and political vision as well: “The patient, previously moralistic in his ideology and perverse, lascivious and neurotic in reality, becomes free of this contradiction in himself; with his moralism he also loses his sexual anti-sociality and acquires a natural morality in the sex-economic sense” (1933/1946, p. 156).

## ORGONE

The term *orgone energy* was coined by Wilhelm Reich to designate what he hypothesized to be the fundamental energy of a biological nature omnipresent in the cosmos. In addition to sounding scientific, the term *orgone* derived from Reich’s views concerning orgasm, a pivotal concept in his theory of “sex economy.” In the summer of 1939, while performing “bioelectrical” experiments, Reich believed that he isolated energy-filled microscopic vesicles that he called *bions*. He went on to formulate a specific hypothesis that “organismic orgone energy” is a vital, irreducible form of energy that manifests itself with special intensity in sexual activity. Reich came to believe that orgone energy is also present in etheric form in the atmosphere and active in certain kinds of precipitation such as storms and tornadoes; he believed it exists throughout the cosmos and played a role in formation of the universe. Reich’s later writings are entirely taken up with aspects of *orgonomy*, as he called his theory and teachings. Clinically, he invented *orgone therapy*; he called the research institute that he established in Maine (the present day Wilhelm Reich Museum) the *Orgonon*. Reich also defined an egglike geometric form as the *orgonome*, which he viewed as a basic biological shape. To capture atmospheric orgone and put it to clinical use, Reich built box-like devices he called *orgone accumulators*. His therapeutic claims for these led to an injunction by the Food and Drug

Administration (FDA) in 1954. This resulted in a contempt citation that brought about Reich's imprisonment in Lewisburg Federal Penitentiary, where he died three years later. In a famous act of censorship, the FDA ordered certain of Reich's pamphlets and publications concerning orgone energy to be banned and destroyed.

### **ORNICAR?**

The journal *Ornicar?* was founded in January 1975 by Jacques-Alain Miller, Jacques Lacan's son-in-law. Subtitled *Bulletin périodique du champ Freudien* (Journal of the Freudian field), *Ornicar?* "was both the home and the organ of the Young Turks" (Miller, 1984). Lacan supported it against the opposition of the elder members of the École Freudienne de Paris (Freudian School of Paris). *Ornicar?* is also the journal of the Department of the Freudian Field at the University of Vincennes, which was founded by Serge Leclair in 1968 and was led and directed by Lacan and Miller from 1970.

From the start, Miller, who was entrusted with the transcription of Lacan's seminar, used *Ornicar?* as a venue for publishing seminar sessions. Published seminars include *R.S.I.* (The real, the symbolic, and the imaginary; 1974–1975) in nos. 2–5; *Le Sinthome* (The symptom; 1975–1976) in nos. 6–11; *L'une-bévue* (A blunder; 1976–1977) in nos. 12–18; and the final seminar, *Dissolution* (1980) in nos. 20–23. With the publication in no. 9 of a talk that Lacan delivered on January 5, 1977, "The Inauguration of the Clinical Program," *Ornicar?* became a

vehicle for elaborating Lacan's clinical technique, which was developed and taught outside of the École Freudienne at Vincennes.

From January 1975 to June 1989, twenty-eight issues of *Ornicar?* were published under Miller's editorship. Simultaneously, sixty-three issues of *Analytica*, a research journal for Freudian studies, were also published. These issues included reprints of psychiatric classics and essays on contemporary clinical practice.

After Lacan's death in 1981, Miller began to publish some of Lacan's unpublished writings in *Ornicar?* (nos. 24–25), starting with the seven lectures on *Hamlet* from seminar 6, *Le désir et son interprétation* (Desire and its interpretation).

Laurence Bataille, the daughter of Sylvia Lacan and Georges Bataille and the stepdaughter of Lacan, acted as director of the publication from 1976 to 1978 and helped to edit the journal before eventually withdrawing.

In 1998, starting with no. 49, the journal got a new lease on life under the direction of Miller.

### **OSSIPOV, NIKOLAI LEGRAFOVITCH (1877–1934)**

Nikolai Ossipov, a Russian physician and dean of Moscow University and Charles University of Prague, was born on October 12, 1877, in Moscow and died in Prague on February 19, 1934.

The only son of a respected physician, he was brought up in a very cultured family. In 1897 he graduated summa cum laude from the best lycée in Moscow and immediately enrolled in the medical faculty of Moscow University. In 1899 he was suspected of taking part in a student brawl, imprisoned, and expelled from university. He then went abroad to continue his studies in Germany and Switzerland. He presented his doctoral thesis in histology before Kaufmann in Basel and graduated as a physician on November 16, 1904.

That same year he returned to Moscow and worked in the university histology department, as well as in the municipal psychiatric hospital (*Preobechensk*). In 1906 he followed Vladimir Serbski to the Moscow University psychiatric clinic and definitively abandoned histology.

In 1907 Ossipov began to study Freud's work and spent some time with Jung. In his *Mémoires* he describes himself as the first to popularize Freud in Russia and he was the founder of Russian psychoanalytic terminology. His first work in the discipline (1908) consisted of inventories of Freud's previously published works. His first personal publication dates from 1910, the year when he visited Freud in Vienna and founded the collection "The Psychotherapeutic Library." He was also the cofounder of a psychotherapeutic outpatient unit in the University Clinic in which psychoanalytic techniques were applied without restriction. In 1911 he was elected president of the Moscow Psychoanalytic Society. In the same year Ossipov, Serbski, and most of their colleagues left the university in protest against restrictions on autonomy decreed by Kasso, the Minister for Education. Ossipov then set up in private practice. In 1912, a psychoanalytically-informed seminar was organized under the name of "little Fridays," with Serbski as president and Ossipov acting as secretary during the sessions.

After the Bolshevik Revolution of 1917 he fled his beloved Moscow, lived in Southern Russia and, in 1921, continued his flight via Istanbul to Prague. His scientific and teaching skills were recognized in Czechoslovakia. In 1922 he was offered a post as professor of psychiatry in Masaryk University at Brno. The ever-conscientious and modest Ossipov declined to accept the position, claiming an insufficient knowledge of the language and socio-cultural conditions of the country. He did, however, accept a position as director of the psychiatric outpatient clinic at Charles University and lectured there on psychoanalysis.

He privately built up a stable work group consisting of émigré Russian students and physicians whom he trained in psychiatry and psychoanalysis. Ossipov always maintained good relations with the Prague psychoanalytic group and in 1931 he and Emmanuel Windholz took the initiative of placing a commemorative plaque, in honor of Freud's seventy-fifth birthday, on the house where he was born in Píbor (Freiberg). For reasons of ill health neither Ossipov nor Freud could personally attend the inauguration, which took

place on October 25, 1931. Ossipov was suffering from myocarditis, from which he died in 1934. He was given a solemn burial in the Russian cemetery in Prague.

The author of articles on "Tolstoy's Childhood Memories" (1923) and "Revolution and Dreams" (1931), in the course of his exile Ossipov was published in the *Internationale Zeitschrift für Psychoanalyse* and other journals. He corresponded with Freud until his death. As a central figure in the development of psychoanalysis in Russia, he played an active role in having Freud's work published there. Through his actions he also had an influence on the development of the psychoanalytic movement in Czechoslovakia, where his student, Theodor Dosuzkov, managed to keep psychoanalysis alive under both the Nazi and the Communist régimes.

## OTHER, THE

The notion of "the Other" was developed by Jacques Lacan in particular (*Écrits*, pp. 9, 16, 55–56, 379, 431, 575, 690, 751, 807, 852).

Yet, properly speaking, the Other is not a Freudian concept, even if it seems central to the experience of treatment.

Situating the dream and the unconscious in "another scene" was as far as Freud went in conceptualizing this place. The Topographical theory (conscious—preconscious—unconscious) like the structural theory (id—ego—superego) does not allow for the radical otherness of the unconscious, because it

situates its terms on the same level. But the unconscious is what forces us to think three-dimensionally despite the dualities that define the imaginary.

The Lacanian Other does not have a philosophical origin either. Platonic otherness (cf. *Timaeus*) is reserved for what temporarily disrupts sameness, considered as ideal. Of course, the difference between the sexes is in all likelihood the imaginary basis for Plato's thought. But homosexual influence, which generally underlies his thought, continues to treat woman as a degraded man, that is, identical except for a single detail, but at the price of investing this detail narcissistically.

The Other dimension introduced by Freud and conceptualized by Lacan is all the same an essential contribution to the conduct of treatment, as well as to the cultural field.

How can a reader grasp a category that, without being magical or supernatural, cannot be touched or seen? Perhaps by appealing to the shared experience of speech, insofar as it always supposes an interlocutor—it is said that a child learns not so much to speak as to respond, in such a way that the original address remains the force behind his words. Dialogue both unites and divides speaker and listener through what they are unaware of and what motivates them, the unconscious. This reciprocal opening is just what is needed if each is going to seek in the other the object, the unknown cause of his own desire, without which each one sings his or her own song, and no harmony results.

This other place, which is circumscribed by the opening proper to the "speaking-being," (who engages the lost object, the great sustainer of desire, through the operation that Freud called castration) and which overlaps with that of the partner, is the gap, covered or sutured, that shelters the unconscious.

The Other as a concept refers to the heterogeneity of this place, as that from which a speaker's own speech comes back to him or her; when that happens, the speaker discovers that he is a subject. But it is also the place to which the speaker talks back, since it conceals the object that concerns him or her most intimately. Our two interlocutors, assumed to exist in the same space, are thus revealed as radically heterogeneous. No longer does any supposed detail differentiate them. Rather the place that they occupy, the one coming to the locus of the Other to represent the lost object (object *a*, according to Lacan) ignites desire.

Coming thus from the Other, the address made to the subject comes to him by the intermediary of the little other that supports desire. But just because it is reduced to being represented by either the gap or the eclipse (Lacan writes that the all of Euclidian space is supported by the gap that it veils), the Other place is not for all that a dark continent. It comes to the infant by his mother's speech. Later the infant will have to abstract from that speech the laws of language. This necessary ordering—shown by Ferdinand de Saussure to be organized by signifiers that each refer to another signifier rather than to some object—introduces the child to the dimension of loss.

This loss becomes evident when the speaker receives from this place a message that expresses a desire. When a slip of the tongue makes it too explicit, he feels shame. Neurosis is the I's refusal to adapt to, or endorse, this desire coming from the Other, which the subject might experience as pathological or foreign (in obsession) or intrusive (in hysteria).

This Other place, as an unimpeachable third party, is the only thing that makes it possible for two speakers to avoid a fatal, mirror-image confrontation, in which it is the word of one against the other. Not only the place of lack, the Other is also the place of truth insofar as it allows our ideas, however vain, the dignity of representing the truth.

We live in a time when the remarkable progress of science tends to foreclose any such otherness, its defining importance for human experience notwithstanding. The unmediated duality that science promotes is discernible even in the success of economic liberalism, even in the elevation of the idea of direct democracy. The very face of power is obliged to display itself as a mirror image, familiar and without mystery; while powerful popular tendencies push for the homogenization of human groups. It will be the better for us if analysis can prevent us from underestimating the risks.

## OTHERNESS

Otherness (alterity) is a logical and metaphysical concept of considerable generality that would not ordinarily be included in a dictionary of psychoanalysis if, together with the concepts of the Big Other and the small other, Jacques Lacan had not taken Freud's ideas as far as he did and if contemporary French psychoanalysis had not been so enamored of the philosophical and moral system proposed by Emmanuel Levinas. In Plato's *Sophist*, the "other" is one of the first five kinds (along with existence, rest, motion, and sameness). For Hegel, to the extent that the first moment of every being-there contains its own negation, alterity can be considered as the engine of dialectical movement. In a different register, the Christian tradition, reformulated by Kant, conceives the categorical imperative of morality as the commandment that requires us to treat others not simply as means but as ends. We can also consider the concept of alterity as one of the foundations of ethics. But there is little sign of Freud in this, and we would be assigning psychoanalysis a task of considerable ambition if we were to look within it for the solution to these philosophical and moral problems.

Nonetheless, the concept is not completely foreign to either Freud or psychoanalysis, and there are certainly signs of its presence there, although indirect. Although Freud's work supplies no formula for moral relations with the other, the question of the essence of human relationship is treated explicitly in *Group Psychology and the Analysis of the Ego* (1921). Here, Freud discusses the theories of Gustave Le Bon and, more generally, the notion of this relationship as the result of a kind of "sympathy." For him all relations among humans involve the image of the father. Humankind,

Freud says, is not a gregarious animal (*Herdentier*) but a horde animal (*Hordentier*). He therefore transposes into the real world the schema found in *Totem and Taboo*, according to which the (Darwinian) primitive horde is a society in which the only bonds consist of a shared dependence on the primitive father. Thus Freud rediscovers, probably without realizing it, Leibniz's vision of monads that can only communicate with one another through God. Prime examples of this would be, according to Freud, the Church and the Army, to the extent that their unity lies in the relation of each of their members to a leader (Christ, the general). But we find the same thing in more banal situations (for example, the collective body of all the young girls in love with the same singer), where the interhuman bond is not sympathy but a more or less sublimated form of jealousy. However, this is a psychosociological theory of interhuman relations and not a moral conception of the relation to the other.

That being said, there is a great temptation among authors inspired by Freud to try to develop from his work a "psychoanalytic" theory of the "true" relationship to the other and to assume that the psychoanalyst will lead the patient toward a genuine recognition of the other, for example, by overcoming his narcissism. Obviously, this exceeds the content and claims and to some extent even the spirit of Freud's work. Whenever Freud appears to move in this direction, he always manages to qualify his position. For example, in *Three Essays on the Theory of Sexuality* (1905d), he states that during puberty, when the sexual drive is subordinated to the reproductive function and the adolescent begins to love another human being, this drive "becomes, so to say, altruistic" (p. 207). But the expression "so to say" (*sozusagen*) clearly indicates that he is not referring to any kind of moral altruism.

Naturally, the concept of the "other" being extremely common, some, relatively obscure, Freudian texts have managed to give rise to farfetched speculation, although there is no shortage of interest in them. For example, there is an enigmatic passage in *The Ego and the Id* (1923b) in which Freud, criticizing the notion of "unconscious sensation," evokes "a quantitative and qualitative 'something' in the course of mental events" (p. 22) and emphasizes the originality of the notion of the "id" that he is in the process of borrowing from Groddeck.

Somewhat more picturesque is the role accorded by Freud to a play by the Austrian dramatist Hermann

Bahr, presented for the first time in Vienna on November 25, 1905, and whose title is *The Other* (the title is feminine in German, *Die Andere*). Freud’s comment appears in an article entitled “Psychopathic Characters on the Stage” (1942a [1905–06]). After describing the conditions needed to make a neurotic or psychotic the hero of a drama, Freud states, rather curiously, that these conditions are fulfilled in *Hamlet* but not in the play by Bahr, where the young violinist Lida Lind goes mad between the first and fifth acts. Yet, independently of this peremptory judgment on the heroine’s choice, we are struck by a kind of “play of alterity.” For we may suspect—and the author invites the spectator to believe this—that Lida’s madness arises from her dependence on her first lover, Amschl, who would then be the seducing other (*der Andere*, which is masculine). But it gradually becomes clear that she is the victim of the fact that she herself was, in the past, in love with a personality from whom she was unable to detach herself, the feminine other. Of course, in his remarks, Freud does not comment on this aspect of the play. But one wonders if he did not initiate a train of thought that might have led him to develop certain aspects of alterity that would have become, although not explicitly, a genuine psychoanalytic concept.

### **“OUTLINE OF PSYCHOANALYSIS, AN”**

“An Outline of Psychoanalysis” was never completed. Freud, returning to an earlier project of providing an

overview of psychoanalysis, began writing it in Vienna in 1938 as he was waiting to leave for London. By September 1938 he had written three-quarters of the book, which was published in 1940, a year after his death.

Composed of three sections, the “Outline” opens with a description of the psychic apparatus, including its spatial organization and differentiation into agencies. The ego, which develops through contact with the outside world, attempts to reconcile the needs of the id, the superego, and reality. The id represents the hereditary past, the superego, tradition. Drives, which are basically conservative and located in the id, represent somatic needs for the psyche. Eros and the destruction, or death, impulse, whether antagonists or combined in biological functions, are the two fundamental impulses.

The libido is the energy of Eros. The libido of the ego is characterized by its narcissistic mobility toward objects. The sexual function, whose somatic sources are the erogenous zones, undergoes a two-phase development process, including a latency phase. The infantile period, which is later forgotten (infantile amnesia), is characterized by the succession of the oral, sadistic-anal, and phallic phases in both sexes. A genital phase of instinctual integration completes sexual organization at puberty. The realization of normality depends on quantitative factors.

Psychic processes can have three qualities: conscious, preconscious, or unconscious. The first two are related to the ego, the last to the id. The ego receives perceptions whose origins—external or internal—it distinguishes by testing them against reality. The id is formed of primitive and repressed contents. The difference in psychic qualities is primarily a function of the laws of energy that govern the processes: primary, with free energy in the case of the id, secondary, with bound energy in the case of the ego. A sleep impulse drives the ego to return to the life of the womb, with a weakening of the anti-cathexis of the ego; studying dreams can help us understand the laws of the primary process.

Analysis assumes an alliance between the “fundamental rule” of the analysand and knowledge and discretion on the part of the analyst. Transfer, the true driving force behind analysis, can help in a “post-educational” process. The strengthening of the ego is combined with the difficult work of removing various forms of resistance, with those arising from the defusion of impulses being the most difficult to resolve.

Neurosis, which has no specific causes, is associated with the traumatic effects of early infancy and education on an ego that is not fully formed, the two-phase nature of human sexuality, and partially repressed impulses. The first object is the mother, the “first seductress,” the prototype of all subsequent love relationships. The Oedipus complex and the castration complex are organized differently depending on sex, with fantasies helping to perpetuate bisexual conflicts and identification (psychic bisexuality). Unlike the id, the ego, in contact with the outside world, understands the reality principle and self-preservation by signaling our anxiety. The child with an immature ego represses its sexuality and the Oedipal complex out of fear of losing the love of its parents, who provide its security. Even during psychosis, a part of the psychic apparatus can maintain a normal relationship with reality, reflecting a split in the ego. This split, which arises from a denial of perception, is observed in the fetishist or during development when the growing child is faced with the requirements of reality.

In neurosis, the habitual conflict is distinct, from a topographical point of view, pitting the ego and the id against one another. After the age of five, we see the emergence of the superego, the heir to the Oedipus complex, resulting from the child’s identification with the parents. An intermediary between the ego and id, the superego represents the past of the child’s civilization, an exterior world that is converted into an internalized past.

For Freud the “Outline” introduced no new insights, an opinion shared by Ernest Jones. The text illustrates Freud’s constant reference to an economic point of view, with an emphasis on quantitative factors. It focuses on an examination of the ego and deepens his understanding of splitting. Eros, the agent of union, reunites sexuality and love, and the object is here given a predominant place.

## OVERDETERMINATION

The idea of overdetermination refers to the organization of multiple determinants combining to define a psychic formation. The notion may be represented metaphorically as multiple nodes anchoring a web whose linking strands are lines of associated thoughts. The content of psychic formations understood in this way is determined by the points of intersection of the lines of association, along which psychic energy flows as part of a process of displacement.

Another Freudian conceptualization of overdetermination, lateral and etiopathogenic, views psychic formations as the outcome of a cumulation of causes whose combination is the necessary condition of their coming into being.

Freud introduced the concept of overdetermination very early on: it is sketched out in the *Studies on Hysteria* (1895d), though more in the etiopathogenic sense of a constitution of the subject rendering him vulnerable to a traumatic accumulation of factors than in the sense of chains of association. The latter sense emerged more clearly, indeed in its definitive form, in *The Interpretation of Dreams* (1900a), where the elements of the dream-content, viewed as nodes, are described as overdetermined in that they are represented many times over in the dream-thoughts, which crystallize at these points. Overdetermination thus came to be seen as the basis of dream-formation, and Freud focused the remainder of his study on the mechanisms that facilitated it. Thus in analyzing the dream of “Irma’s injection,” he isolated the mechanism of condensation, and in particular developed the idea of “collective figures.” And since overdetermination suggested a procedure for selecting the components of the dream-content, he proposed the notion of the displacement of psychical intensity along associative chains and ramifications. Displacement and condensation, he argued, were the foundation of dream-formation.

Overdetermination was seen by Freud as affecting the symptom as well as the dream; in the wake of

Jacques Lacan it is applied more broadly to all formations of the unconscious. It should not be taken, however, as a principle of very wide extension, but simply as the basis of that fluctuation of associations which makes different interpretations of the same psychic formation possible.

## **OVER-INTERPRETATION**

*Over-interpretation* is the possibility, envisaged by Freud (1900a), that the psychoanalyst may encounter an increase in material and produce a new interpretation very close to the patient's unconscious fantasy. Over-interpretation can result from the patient's freely associating on the basis of his dream, thereby increasing the material subject to interpretation. More generally, over-interpretation involves giving an interpretation that is not limited to clarification but comes close to the unconscious fantasies that structure the material. Fantasies not only occur in dreams, to be extracted by interpretation; they predetermine how dreams are interpreted. Over-interpretation allows these fantasies to be dynamically revived.

In chapter 7 of *The Interpretation of Dreams* (1900a), where *over-interpretation* appeared for the first time, Freud employed it as a way of warning the novice analyst that his work is not finished when he arrived at what he believes to be a complete and coherent interpretation of the dream: "For the same dream may perhaps have another interpretation as well, an 'over-interpretation,' which has escaped him. It is, indeed, not easy to form any conception of the abundance of the unconscious trains of thought, all striving to find expression, which are active in our minds. Nor is it easy to credit the skill shown by the dream-work

in always hitting upon forms of expression that can bear several meanings—like the little tailor in the fairy story who hits seven flies at a blow" (p. 523).

The possibility of over-interpretation is thus directly linked to the overdetermination of unconscious formations and the interdependence of mental contents, which this overdetermination presupposes. Unconscious formations do, of course, result from different causes (such as symptoms and fantasies), but in each case they are connected to multiple unconscious elements. In this sense, over-interpretation is the repeated attempt to stay as close as possible to sexual and infantile contents. Yet over-interpretation also points directly toward what Freud designated as the main stumbling-block for interpretive work on dreams, the umbilical navel of the dream: "There is often a passage in even the most thoroughly interpreted dream which has to be left obscure; this is because we become aware during the work of interpretation that at this point there is a tangle of dream-thoughts which cannot be unravelled and which moreover adds nothing to our knowledge of the content of the dream. This is the dream's navel, the spot where it reaches down into the unknown" (1900a, p. 525).

The notion of over-interpretation thus allowed Freud to show that there is no such thing as a true or false interpretation that could be related to a realist conception of meaning. On this subject Pierre-Henri Castel has remarked, "It is thus never one single meaning that is really present to the mind, and can be given a true or false interpretation: rather, it is always a partially realized set of meanings that can be given a true or false interpretation only if this interpretation takes into account their potential interrelations" (1998).

More generally, the notion of over-interpretation, by making an open, dynamic conception of interpretation possible, raises the question of origins. Fantasies of origin create and determine the formations of the unconscious in general and of the dream in particular.

## PAIN

The term “pain” refers to a physical sensation or a distress linked to instinctual tension, which the psychic apparatus then seeks to discharge by work according to the principle of pleasure/unpleasure.

Jean-Bertrand Pontalis (1981) noted that the outline for an original theory of pain can be found in Freud’s work from “A Project for a Scientific Psychology” (1950c [1895]) onward. Taken up again in *Inhibitions, Symptoms, and Anxiety* (1926d [1925]), this theory covers the basic reference points of analytic theory: the theory of narcissism, the question of trauma, the definition of primary masochism, and the presentation of the death instinct. Finally, with the concept of negative therapeutic reaction in place, Freud, in *The Ego and the Id* (1923b), described how pain drives resistance to analysis, indeed, how pain is the final refuge from renouncing the lost object, as the resistance implies.

By 1895 Freud had postulated bipolarity as the principle of psychic functioning, and, anticipating his later theory of instinctual dualism, he opposed the experience of pain to the experience of satisfaction. In qualitative terms, pain is different from unpleasure in that pain is situated outside the economic apparatus of pleasure/unpleasure. In dynamic terms, “[p]ain is . . . characterized as an irruption of excessively large Qs [quantities] into N [neurones that don’t retain quantities of energy] and R [neurones that do retain energy and are capable of retaining memory]” (1950c, p. 307). Then the body discharges the accumulated excitation. Pain can cause the subject to break out of preestablished paths only because there are boundaries (bodily boundaries, ego boundaries); however, its internal discharge has an implosive effect. Like a physical or psychic hole

(to be distinguished from a possible lacuna or a lack), the excess of excitation caused by pain obstructs all binding activity. Pontalis (1981) has stressed that this theory of pain breaching is a departure from the economic apparatus where the theory of anxiety is more generally situated.

In 1926, in addendum C to *Inhibitions, Symptoms and Anxiety*, Freud again tried to differentiate pain from anxiety, though not without difficulty or contradiction. Pain is primarily a reaction to the loss of the object, whereas anxiety is a reaction to the danger that loss entails. Pain is the consequence of a breaching of the protective shield, and by acting as a constant instinctual excitation (some authors have proposed the idea of a pseudo-instinct here), it prevents the subject from escaping from it. Nonetheless, pain has a locus: it emanates from the periphery of the body or the organs. If anxiety has already led the subject to regard the loss of the object metaphorically, the unmediated reality of pain ensures that the subject can survive without the loss of the object or the nostalgia of that loss. In a third stage of his exposition in addendum C, Freud returns to the difference between mental pain and physical pain, arguing that the former is much more closely related to the mechanism of anxiety. “The transition from physical pain to mental pain corresponds to a change from narcissistic cathexis to object-cathexis. An object-presentation which is highly cathected by instinctual need plays the same role as a part of the body which is cathected by an increase of stimulus” (1926d, pp. 171–172).

Freud thus uses the same model to describe both physical pain and psychic pain. As Pontalis has made clear, pain is not a case of metaphor but rather a case of analogy—a direct exchange between one level and

another, as if with pain the body mutates into psyche and the psyche into body. But while anxiety can be communicated, pain cannot. Despite a scream of pain, the cry does nothing to ease it. The experience of pain takes place within a bodily ego. Both physical pain and mental pain partake of the content-container relationship (Enriquez, 1980; McDougall, 1978). The subject in pain finds it impossible to recover the object by means of representation: "Where there is pain, it is the lost, absent object that is present; the real, present object that is absent." The distinctive feature of pain is its blurring of boundaries. Thus, for example, certain types of physical suffering serve to alleviate mental pain. Recent clinical work on somatization and borderline states is often faced with this inchoate nature of pain: absolute, naked pain.

## **PAIRS OF OPPOSITES**

Freud uses the term "pairs of opposites" to designate the pairing of two apparently contradictory terms and, beyond this, the two psychic phenomena to which

these terms refer. Freud refers to the idea in his correspondence with Wilhelm Fliess, to whom he writes on March 2, 1899, "I can hardly wait for Easter to show you in detail a principal part of the story of wish fulfillment and of the coupling of opposites" (1985c [1887–1904]). Curiously, despite Freud's alleged impatience, there is no further sign of this elaboration, at least in the published correspondence, where Freud restricts himself to setting out the uncertainties and contradictions that he is experiencing in relation to his work.

Freud thus restricts himself, inadvertently perhaps, to working out the essence of what he understands by the pairing of opposites, as he clearly states in *Three Essays on the Theory of Sexuality* (1905d): "Certain among the impulses to perversion occur regularly as pairs of opposites" (p. 160). He then refers to the pairs sadism/masochism and masculine/feminine, also mentioning activity/passivity in an addition in 1915. In the same text he emphasizes, "An especially prominent part is played . . . by the component instincts, which emerge for the most part as pairs of opposites: . . . the scopophilic instinct [the gaze] and exhibitionism and the active and passive forms of the instinct for cruelty" (p. 166).

The vagaries of the transference highlight these oppositions. Often the negative transference is found "side by side with the affectionate transference, often directed simultaneously towards the same person. Bleuler has coined the excellent term 'ambivalence' to describe this phenomenon" (Freud, 1912b, p. 106).

Freud returned to the sadism/masochism pair in a note added in 1924 to the text of *Three Essays on the Theory of Sexuality*. There he wrote that his recent observation, as outlined in "The Economic Problem of Masochism" (1924c), led him "to assign a peculiar position, based upon the origin of the instincts, to the pair of opposites constituted by sadism and masochism" (1905d, p. 159n). This derives directly from the structure of the second theory of drives, in which the life instinct and death instinct form a pair of opposites that directs all the other drives.

The concept of pairs of opposites, which might seem narrowly descriptive, in fact involves some fundamental aspects of metapsychology. Specifically, this concept relates to the conflict at the core of the processes of the psyche, with its drives and ambivalences.

The dualistic nature of Freud's thought, which he adduced to explain and pair apparently contradictory

terms and concepts, has often been emphasized. Yet this Freudian dialectic has nothing to do with the dialectic of classical Aristotelian logic or of modern Hegelian philosophy. When Freud indicates a contradiction, he seeks to demonstrate the underlying conflict generating it. The contradiction itself is but a secondary transposition at the level of conscious thought. Hence, Freud's solution to contradiction is not Hegelian transcendence, but a dynamic and economic process of psychic transcendence.

## **PANKEJEFF, SERGEI (1887–1979)**

Dr. Serguei Pankejeff, alias the "Wolf Man," is the subject of Freud's longest case history (1918).

According to our current Gregorian calendar, this remarkable patient was born on January 6, 1887, but according to the Julian calendar used at the time in Russia (and crucial to understanding his famous dream) he was born into a fabulously wealthy family on Christmas Eve, 1886. Marked psychopathology existed in the family on his father's side. His father himself was born in 1859; suffering from prolonged manic-depressive illness, he took a fatal overdose of veronal, in 1908; his mother was born in 1864 and died naturally in 1953. Serge's only sibling, Anna, who was two and a half years older than he, lethally poisoned herself in 1906.

Anna's suicide increased her brother's depression, and in 1908 he consulted some of the most eminent psychiatrists in Europe: Bechterev in Petersburg, Ziehen in Berlin, and Kraepelin in Munich. Serge spent a long time in German sanatoria, but it was in Kraepelin's that he met his future wife, Teresa Keller (she committed suicide in 1938). The Wolf Man's first analysis with Freud lasted from February, 1910, to July 14, 1914; subsequent to his dramatic impoverishment caused by the First World War, the Wolf Man went back into analysis with Freud from the fall of 1919 to Easter, 1920. For the next six years, Freud collected money for the sustenance and an occasional holiday for the Wolf Man and his wife. He eventually found employment in an insurance company and dealt with legal aspects of social security matters.

News of Freud's cancer contributed to the Wolf Man's subsequent psychotic decline. As a result, he went back into analysis with Ruth Mack Brunswick for a four-month period spanning 1926–1927. Starting in 1929, he resumed an irregular analysis with Brunswick for several years. Every summer from the mid 1950s to 1979, Kurt Eissler engaged the Wolf Man in "analytically directed conversations" and prescribed medication. He was also having irregular analytic treatment in Vienna during that time.

The Wolf Man's misery dramatically mounted over the last two decades of his life. Lonely and approaching senility, he was embroiled in a maddening relationship with a harmless psychopathic woman named Louise. Muriel Gardiner and Kurt Eissler monetarily supported them. He died in Vienna in 1979 at age 92. In sum, a fundamental feature of the Wolf Man's identity was his patienthood—he became a ward of psychoanalysis.

## PANKOW, GISELA (1914–1998)

A French psychiatrist and psychoanalyst, Gisela Pankow was born in Düsseldorf, Germany, on February 25, 1914, and died in Berlin on August 14, 1998. She came from a Christian democrat family that paid heavily for its active opposition to the Nazi regime. After obtaining degrees in mathematics, physics, geography, and philosophy at the University of Berlin, Pankow began studying medicine in Tübingen, where she became an assistant to Professor Ernst Kretschmer. She helped with his research in morpho-endocrinology and began to publish articles in the field.

Having arrived in Paris in 1950 with a grant to conduct research, she worked as an intern at the hospital of La Pitié under the direction of Jacques Decourt. She published articles in German and French. In February 1953 she obtained a doctorate in science from the University of Paris with a dissertation entitled “Les rapports métriques entre la base du crâne et la partie supérieure de la face.”

While following her medical and scientific studies, she began training in psychoanalysis in 1944, first in Germany with Luisa Weizsäcker (later Käte Weizsäcker-Hoss), then with members of the German Institute for Psychological and Psychotherapeutic Research (DIPF), and finally with Ernst Blum, a member of the Swiss Psychoanalytic Society, in Berne. In France she became a member of the Société Française de Psychanalyse (SFP) (French Society for Psychoanalysis) in 1953. For a while she attended Jacques Lacan's seminars at Sainte-Anne Hospital and conducted a number of supervised analyses with Lacan, Françoise Dolto, and Daniel Lagache.

In 1956 she published, in French, her first book (an abridged version of the German edition that appeared the following year): *Structuration dynamique dans la schizophrénie—Contribution à une psychothérapie analytique de l'expérience psychotique du monde*. With a preface by Juliette Favez-Boutonier, the book established the foundations of her research on the psychoanalytic approach to psychoses. After giving a series of conferences in Australia, in 1956 Pankow left for the United States to work as a research assistant at the psychiatry institute of the

University of Baltimore. She taught at John Rosen's Institute for Direct Analysis, met Gregory Bateson, Helen Flanders Dunbar, and most importantly, Frieda Fromm-Reichmann, who strongly encouraged her to continue her work.

She returned to France in late 1957, where she settled permanently. There, she introduced a private seminar in March 1958 and broke with the SFP in 1960, although she remained a member of the International Psychoanalytic Association. In 1960 she began teaching in the school of medicine of the University of Bonn. She also taught in Paris, at the Sainte-Antoine school of medicine (University of Paris VI), beginning in 1971. She participated in a number of international congresses and gave talks in several European countries, in Tunisia, the United States, Canada, and Australia.

Gisela Pankow was decorated with the cross of the Legion of Honor. She left behind a substantial body of writing—books and articles, in French, English, and German. Her work has been translated into Spanish, Italian, and Japanese. A remarkable clinician, she influenced several generations of psychotherapists in France and abroad through her insights and work on psychosis. In her practice she introduced an original technique involving modeling clay as a mediating element in transference dynamics. Deeply faithful to Freud, her work, enlivened by her extensive philosophical—primarily phenomenological—and scientific learning, is remarkably rigorous. Her theories, derived from clinical research, are based on the conception of an “image of the body,” which, according to Pankow, serves two functions. The first involves the recognition of spatial and formal structure, incorporating a dialectic of inside and outside, and part and whole; the second involves the content and meaning of that structure. The use of modeling enabled her to reveal the structural destructiveness of psychoses, the most serious of which affect the first function (*Kernpsychosen* or Kretschmer's “nuclear psychoses,” which are distinguished from *Randpsychosen*, or “marginal psychoses,” which affect only the second function). Her conceptual apparatus led the way to an understanding of psychotic experience and initiated, through a reintroduction of the symbolization process, a therapeutic strategy whose productivity proved itself in practice. “Transference graft” and “structuring fantasies” are two terms in Pankow's theory that qualify the essential moments of a therapeutic process that attempts to encourage the

psychotic patient to “build, inhabit, and think” the concreteness of his being.

## **PAPPENHEIM, BERTHA (1859–1936)**

Bertha Pappenheim was born in Vienna on February 27, 1859, and died in Frankfurt on May 28, 1936. Pseudonymously known as Anna O, she was the patient whose case Joseph Breuer presented in *Studies on Hysteria* (Freud and Breuer, 1895d).

People who knew Pappenheim and admired her as a pioneer social worker were shocked when Ernest Jones, in the first volume of his biography of Freud, revealed Anna O's real identity.

Bertha's father, Siegmund Pappenheim, was a wealthy Viennese merchant, descended from an old Jewish family from Germany; her mother, Recha Goldschmidt, gave birth to four children but only two, Bertha and Wilhelm, survived. Born in 1860, Wilhelm would become a famous attorney. Raised in a bourgeois household, Bertha learned English as a child and used it exclusively for a time during her illness; she also read French and Italian.

Reconstructions of Pappenheim's illness and the treatment she received, by such historians as Henri F.

Ellenberger (1972) and Albrecht Hirschmüller (1978), reveal many disparities in Breuer's account. When Breuer, a well-known specialist in Vienna, was first consulted in December 1880, Bertha was suffering from facial neuralgia and muscular contractions. These disorders were partly linked to the illness of her father, whom she nursed and to whom she was passionately attached. In a waking dream, her vision of a black snake preparing to kill her father was one of her first symptoms; a cough that Breuer qualified as “hysterical” followed soon after, in November 1880, when he began to see her regularly. The seriousness of her father's disease was concealed from her and Bertha was no longer allowed to visit with or care for him; after learning of his death, at age fifty-seven on April 5, 1881, she suffered a severe and newly debilitating set of hysterical symptoms, including an episode of “negative” hallucinations from which only Breuer was spared. Her family brought her to a country home outside Vienna. Breuer was seeing her regularly by the autumn of 1881, and during evening sessions, while in a state of self-hypnosis, she began recounting stories that she referred to as the “talking cure.” Breuer subsequently noticed that her “obstinate whims” disappeared when the fantastic thoughts that originated them could be evoked by this verbal “chimney sweeping,” as she called it.

During the summer of 1881, probably in mid-August (although Ellenberger dates it to early 1882), an incident occurred of considerable importance for the future of psychoanalysis. One of Bertha's symptoms was a refusal to drink water. While in an hypnotic state, she revealed that she had been disgusted to see her lady-companion's dog lapping water from a drinking glass; then, awakening from her hypnosis, she asked for a glass of water. From this incident emerged a new treatment aim in the discovery of etiological factors through what became known as the “cathartic method.” Breuer attempted to guide her to uncover the memories of events that would elucidate each of her multiple symptoms but which had apparently been forgotten.

Back in Vienna in November 1881, Bertha's condition worsened. She experienced a recrudescence of symptoms that caused her to reexperience events of the previous year. Employing the “cathartic method,” Breuer wrote that “[e]ach symptom with such care to detail that she linked each individual symptom in this complicated case was taken separately in hand; all the

occasions on which it had appeared were described in reverse order. ... When this had been described the symptom was permanently removed” (p. 35). Success was such that the date of termination for this treatment can be fixed to the end of June 1882. According to Breuer, “After this she left Vienna and traveled for a while; but it was a considerable time before she regained her mental balance entirely” (pp. 40–41). Indeed, Ernest Jones revealed Breuer’s shock when he was called the very evening of his departure from his patient, to be informed that she was showing signs of hysterical childbirth.

Various and contradictory accounts of Anna O’s termination of treatment persisted until research by historians revealed her hospitalization from July 12 to October 29, 1882, at the Kreuzlingen Clinic, under the direction of Robert Binswanger. Bertha was then suffering from severe trigeminal neuralgia, which Breuer had been treating for several months with chloral hydrate and morphine, the dosages of which had to be reduced during her hospitalization.

Relatively little is known about the rest of the story. Bertha and her mother, with whom she had a difficult relationship, settled in Frankfurt. Her health appears to have gradually improved, as Breuer noted. She served as headmistress of an orphanage for a dozen years. Under the pen name Paul Berthold (her initials reversed just as her pseudonym “Anna O” [A.O] was formed from the letters preceding her real initials [B.P]), Pappenheim wrote children’s short stories and even plays. She also translated the Memoirs of Gluckel von Hameln, a seventeenth-century maternal ancestor who had saved Jews from persecution. Breuer had correctly gauged the quality of Pappenheim’s intelligence.

In addition, Pappenheim became a prominent activist and social worker. After founding the Care for Women Society (*Weibliche Fuersorge*) to help young women after leaving orphanages, in 1904 she established the *Juedischer Frauenbund*, and served as its first president. With close ties to the German feminist movement, Pappenheim also fought for decades against the “white slave trade” that preyed on young women, who were often sold into servitude by their parents. She discovered the magnitude of white slavery during a journey to Galicia.

In 1905, upon the death of her mother, Pappenheim was free to travel. She first established a shelter for runaway girls and illegitimate babies near Frankfurt; a

year later, she left to visit America. She went to London in 1910, and spent 1911–1912 in Turkey, Jerusalem, Egypt, and Eastern Europe. Pappenheim continued to pursue social work during World War I and its aftermath and wrote numerous articles concerning Jewish women and criminality.

When Hitler came to power, Pappenheim found herself opposed to Zionist organizations that advocated relocation of Jewish children to Palestine without their parents. Suffering from intestinal cancer that forced her to cut down on her social and humanitarian activities, she died on May 28, 1936. That November, Nazis looted her home and destroyed her furniture and belongings. Most of her social worker colleagues died in concentration camps.

In 1945, Germany issued a stamp in a series titled “Helpers of Humanity” to honor her. Her relatives assembled elements for a biography; an initial version by Dora Edinger in 1963 was followed in 1972 by a version of her life, part fiction and part analytical, by Lucy Freeman.

In spite of critics of psychoanalysis, such as Mikkel Borch-Jacobsen, it is a simplification to attempt to falsify the story told in *Studies in Hysteria* with information subsequently discovered by historians. One should beware of edifying biographies of Pappenheim or of charging Josef Breuer with mystification. Symptoms alone offer insufficient data to a psychoanalyst and questions arise concerning the long-term effects of “mothering” that Bertha experienced in the context of a “fatherly” transference of which no one at the time had the slightest grasp or understanding. Clearly, symptomatic improvement in Pappenheim’s case was not immediate; however, her thorough personality transformation after the “talking cure” could be related to her treatment. Nothing is known of Pappenheim’s subsequent emotional and sexual life, and none of her friends or relations seemed to be aware of her youthful psychological problems prior to Ernest Jones’s disclosures in 1953.

## PARADE OF SIGNIFIERS

The concept of the parade of signifiers was formulated by Jacques Lacan in relation to his thesis that “the unconscious is structured like a language” and more specifically to his conception of unconscious desire. The speaking subject constantly expresses something of his or her desire by way of demand. Thus the parade of signifiers is structurally linked to the flow of speech. Since a single signifier never signifies anything as such, it is necessarily linked to others that form a chain of signifiers and, in fact, discourse, or a march of signifiers.

The series of signifiers that parades through speech has its source in the necessity of demand, which is always fundamentally a demand for the lost object (*das Ding*). This demand is repeated as a demand for the object of desire, object *a*, the object that remains forever lacking. In this sense, since desire is always inscribed between need and demand, it can have no other outcome than to make itself heard in the indeterminate series of signifiers that march through the signifying chain.

Through the intervention of the signifiers of the Name-of-the-Father, the structuring character of the paternal metaphor imposes a regulated order on this signifying parade. The absence of such regulation, which results from the foreclosure of the signifiers of the Name-of-the-Father, causes the chain of signifiers to disintegrate, as psychotic pathologies clearly show.

## PARADOX

A paradox is defined, according to Paul-Claude Racamier, as a “mental formation that indissolubly binds two propositions or directives that are irreconcilable and yet not contradictory.”

This character of non-contradiction is essential. According to transactionalists, it is associated with the fact that irreconcilable prohibitions are not part of the same logical class, or, more simply, are not part of the same class (gesture and verb or affect and speech, for example). However, these irreconcilable directives can sometimes belong to the same class. In all cases the paradox results in infinite oscillations between two utterances of opposite meaning that are not contradictory but antagonistic—which is what accounts for its remarkable indeterminacy. The implicit conclusion of a paradox is that  $A = \text{not-}A$ . In 1952 Gregory Bateson and his colleagues began investigating the paradoxes of communication in men and animals.

We distinguish two kinds of paradox: logical paradox and pragmatic paradox. The most famous example of logical paradox, first formulated in antiquity by the Greek sophists, is attributed to Epimenides: “Epimenides the Cretan claims that all Cretans are liars. But Epimenides is a Cretan. Therefore he is lying when he says that Cretans are liars. But if Cretans are not liars, Epimenides is telling the truth.” Pragmatic paradoxes are practical paradoxes. We distinguish paradoxical forecasts from paradoxical prohibitions. The “double bind” is a sophisticated version of the paradoxical prohibition.

The introduction of the concept of paradox into psychoanalytic theory and clinical practice occurred

during the 1970s, from several different sources simultaneously. In France it is largely the result of Didier Anzieu's article "Transfert paradoxal" (Paradoxical transference; 1975) and Paul-Claude Racamier's "Humour et la folie" (Humor and insanity; 1973) and "Paradoxes des schizophrènes" (Paradoxes of schizophrenics); 1976, 1978, 1980). Anzieu insisted on the fact that paradoxical transference assumes, in individual or group psychotherapy, two forms: the paradoxical prohibition and disqualification, both of which are uttered by an individual or group in order to force psychoanalysts to contradict themselves and prevent the work of psychoanalysis from being accomplished. Paradoxical transference is thus one of the manifestations of the work of the negative. Paradoxical transference is accompanied by paradoxical resistance and paradoxical counter-transference.

Racamier extended the class of paradox to a type of mental and rational defensive organization—"paradoxicality"—which is found in schizophrenics, in whom it is both generalized and eroticized in particular ways. René Rousillon has investigated the formal nature of the paradox while contrasting it with the transitional class. Jean-Pierre Caillot used the concept of paradoxicality, applying it to interactive behavior and the psychoanalytic treatment of families engaged in psychotic transactions (1982). He described the paradoxical narcissistic position, where defense, through the oscillation of narcissistic and anti-narcissistic cathexes (Francis Pasche), against catastrophic, claustrophobic, and agoraphobic sensations or anxieties, characterizes the paradoxical narcissistic object relation. This position is comprised by the paranoid-schizoid position elaborated by Melanie Klein, where defense entails splitting and idealization. Caillot has defined paradoxical transference, whether individual, group, or familial, as a transference act or fantasy that indissolubly binds, self-referentially, two aspects of transference with opposite meanings, irreconcilable and yet non-contradictory. For example, Didier Anzieu has described the transference dream of a patient, in which he is simultaneously forced to remain at home and enjoined not to do so. This patient cannot remain in the analyst's office, nor can he leave it. Caillot and Gérard Decherf (1982) have described a paradoxical family transference where "living together kills and living apart is fatal."

According to Racamier, paradoxical behavior is obviously part of the general possibilities of the ego

and the avatars of human relations. But its prevalence as a clinically close-knit system is associated with an overwhelming defensive organization designed to fend off intrapsychic and group conflict, the risks of individuation and separation, the internal or collective movements of fantasies of desire and death, as well as dream images and feelings of mourning or disillusionment. It is used to foster feelings of omnipotence and is active in the denial of desire, of mourning, and of the difference between the sexes and generations.

## **PARANOIA**

Paranoia has individual and institutional, social and cultural forms and determinants. There is probably at least a germ of paranoia in everyone which may be activated in regressive states with increased vulnerability. Clinically, paranoia may be found in mild transient forms, paranoid states of varying degree and duration, fixed paranoid traits and paranoid character, and bor-

derline schizophrenia. The range of paranoid conditions doubtless depends upon constitutional, characterological, and experiential variables.

Unlike other types of psychosis, a paranoid psychosis is usually well-defined, and more or less circumscribed in a delusional part of the personality. The disturbance may remain encapsulated or systematized without generalized tendencies toward deterioration of the overall personality.

The paranoid personality is characterized by a number of common traits: basic distrust; suspiciousness; readiness to feel slighted, injured or persecuted; a tendency to collect grievances and grudges; and vindictiveness. The paranoid personality either anticipates or fears being exploited and abused; is irrationally suspicious of hidden dangers or threats; and expects or believes in the infidelity of a spouse, the disloyalty of friends, and notions of hostile conspiracy. Betrayals are anticipated or assumed, so that for the paranoid friend may immediately become foe, and seeming affection may be replaced by an implacable animosity. Self-esteem issues are also apparent—connected with both the extraordinary sensitivity to narcissistic injury and humiliation, and concomitant grandiosity which may extend to megalomania.

The psychoanalytic understanding of paranoia was initiated by Freud (1911c) who, prior to the Schreber case, had already linked the defense mechanism of projection to the paranoia personality. Via projection, the paranoid defends against unacceptable impulses, especially hate and aggression, which are also related to paranoid defiance. The importance of regression to narcissism, with attendant hypersensitivity to narcissistic mortification and grandiosity associated with infantile omnipotence, was highlighted in the Schreber case. Grandiosity could also be a compensatory reaction to unconscious feelings of inadequacy and inferiority. However, Freud shifted the dynamic understanding of paranoia at the same time to a core oedipal conflict. The paranoid defense constellation warded off unconscious homosexual wishes. In the paranoid male the unconscious proposition: “I, a man, love him, a man,” is contradicted in the following ways: (1) delusions of jealousy: “It is not I who love the man; it is she,” (2) delusions of persecution: “I do not love him, I hate him. Because of this he hates and persecutes me,” (3) erotomania: “I do not love him. I love her, and she loves me,” (4) megalomaniac disavowal: “I do not love anyone else, but only myself.”

It should be noted that Freud’s formulations in the Schreber case were based upon the utilization of the libido theory and an attempt to understand paranoia in terms of psychosexual disturbance, which reversed his earlier formulation of repressed hostility. Subsequent contributions have confirmed the importance of malignant narcissism and the defense of projection, but also of hatred, aggression, and splitting of the ego and of self and object representations.

This defensive splitting off (Klein, Melanie, 1932) is also recognizable in group processes, as in the tendency to idealize one’s own group and to distrust and project evil and hostility to those outside the group, especially against defenseless minorities unable to counterattack. Paranoid processes may be discerned in various sects and ideologies, where there is devaluation and persecution of those who are seen as opposed to the sect or group’s narcissistically-invested belief system. In such dynamics, those who diverge may be scapegoated, and those who deviate or depart may be persecuted as heretics. Individuals with paranoid proclivities are far more readily attracted and susceptible to paranoid demagogues and groups. Paranoid leaders may foment and foster group paranoid reactions among vulnerable individuals. On the other hand, paranoid tendencies may contribute to individuals being vigilant guardians of civil liberty, ever-ready to detect a base of power and threats of exploitation. Feelings of being watched and scrutinized, so commonly seen with paranoid superego regression and externalization, may also have adaptive functions.

Contemporary understanding of the paranoid personality sometimes relates to circumstances in which a traumatic reality is embedded in fantasy, and historical truth in delusion (Freud, 1937d; Blum, 1994). There is often a history of childhood paranoia, so that pronounced narcissistic and paranoid features are already present in childhood. Feelings of mistrust, suspicion, and susceptibility to feelings of insult and injury may have been lifelong. The nightmares of paranoid patients may leave a hangover effect, so that the paranoid nightmare and terror of attack invades reality.

Traumatic experience with the terror of helplessness and inevitable narcissistic mortification may also be associated with severe and enduring vulnerability to narcissistic hurt and humiliation. Some cases involve selective identifications with paranoid parents.

Paranoid dispositions may be anchored in familial styles of paranoid suspicion and scapegoating, or blaming and vengeful familial attitudes.

Furthermore, the paranoid often not only detects the latent envy and hostility of others, but tends to activate and evoke hostile reactions as well. The paranoid's expectation of social slights and hurts becomes a self-fulfilling prophecy as their own suspiciousness and hostility arouses similar mistrusts and hostility in others. Freud (1922b) observed the tendency of the paranoid personality to recognize but exaggerate the imagined infidelity present in both partners. Since blame and guilt are projected, the paranoid remains indignant about innocent victimization and may become litigious. Narcissistic rage over feelings of injury and compensatory aggrandizement serve to undo and reverse traumatic helplessness and avenge prior narcissistic hurts and humiliations (Kohut, 1972). The paranoid's own urge toward betrayal becomes a means of vengeance, vindication, and mastery. A preemptive strike may be related to the paranoid's expectation of attack, betrayal, and the rationalization of a defensive counterattack. Any narcissistic frustration, disappointment, or traumatic disturbance may regressively activate a paranoid persecutory system. All levels of personality development may contribute to the paranoid persecutory system.

Current explanations of paranoia involve recognition of diffuse developmental disturbance without a single point of developmental fixation or deficit, appreciating the possibility of complex overdetermination. In paranoia, murderous hostility is now considered far more important than repressed homosexual love. There is a stress on preoedipal roots, leading to failure of oedipal resolution, and to the patient's vulnerability to malignant narcissistic regression (Kernberg, 1975).

Freud's proposition of the delusional reconstruction of the lost object world is still accepted by many analysts, while others have proposed different views concerning impaired reality testing and paranoid object relations. Reality testing, cognition, and affect regulation may be constitutionally fragile and further impaired by projection, traumatic injury, and ego regression. The paranoid personality may have many areas of intact ego, but it has been proposed (Blum, 1981; 1994) that the persecutor is a narcissistic object or a part object (Klein, 1932), incompletely differentiated from the self representation. In addition to the splitting

of representations, there is a regressive failure of object constancy with incomplete separation-individuation (Mahler, Margaret, 1971), and a desperate effort to reestablish object constancy within a constant persecutory relationship. The persecutory narcissistic object is sought, followed, or is imagined to be following the paranoid patient. The split-off dangerous object is the lesser evil when compared to objectless disorganization and fragmentation. Extreme ambivalence prevails, with the dominance of hate over love and with predominant projection of destructive rage, hatred, and self-hatred. Fear of being attacked by an invading or engulfing object is readily fused and confused because of unstable self-object differentiation, intrapsychic representation, and ego integration. Masochistic wishes to be attacked are less unpalatable to the paranoiac than the potentially malignant narcissism.

In national and social paranoia, concern with ego boundaries and narcissistic injury is reflected in concerns about national boundaries and enemy betrayal. The nation's integrity, and its boundaries, must then be defended because of fear of destructive invasion and engulfment.

The paranoid personality, depending upon the degree and fixity of the underlying disturbance, may be variably amenable to psychoanalytic treatment. Mistrust and lack of confidence in the analyst or therapist, fear of humiliation and abuse, coupled with an entrenched and entitled narcissism make the paranoid patient a major therapeutic challenge. For those patients amenable to psychoanalysis, consistent interpretation of paranoid transference manifestations, management of paranoid regression, and awareness of the patient's ego fragility and extreme ambivalence are of critical importance.

## PARANOIA (FREUDIAN FORMULAS OF)

“Paranoia” is one of the oldest concepts in the history of the description of mental states. It initially appears in Greek tragedy, on two occasions; first to describe the passionate love of Oedipus and Jocasta and then to refer to Orestes’ state following his murder of his mother, Clytemnestra.

For most of the 19th century, the term paranoia occupied a position of the same importance as the term “schizophrenia” today. It was then understood as a mental state that was characterized by feelings of persecution on all sides. Freud’s approach to paranoia, as to psychopathology in general, brought to it a perspective that is simultaneously dynamic, topographical, genetic, and economic. It is dynamic in that Freud regards paranoia as deriving from a form of psychic activity, namely projection; topographical because this projection, initially connected with incestuous fantasies and later with homosexuality, is based on uncon-

scious impulses; and genetic because the seduction experiences that stimulate these incestuous or homosexual impulses occur at an early stage. Finally, this perspective is also economic in that paranoia, like every other symptom, is an “attempt at reconstruction” directed at protecting the subject from more acute problems.

Freud took an interest in paranoia from the outset of his work, comparing it with other forms of psychopathology. His analysis (Freud, 1911c [1910]) of Daniel Paul Schreber’s *Memoirs of My Nervous Illness*, which contains the essence of his theories on the subject, nevertheless poses a few problems.

The connection between paranoia and homosexuality emerged late in Freud’s work. Initially, if homosexual elements were present at all, they were overlooked and it was incestuous relationships or fantasies that were emphasized. In fact, the connection between homosexuality and paranoia seems to have resulted from some collaborative work by Freud, Carl Gustav Jung, and Sándor Ferenczi. Furthermore, the analysis of homosexuality based on the *Memoirs* differs from the analysis based on Leonardo da Vinci’s childhood memory. Whereas the former involves a romantic fixation on someone of a different sex from the subject, the latter is entirely focused on his relations with someone of the same sex.

What Schreber reveals of the progress of his “nervous illness” demonstrates few of the characteristics of paranoia, or even paraphrenia or paranoid dementia. In fact, he describes the natural and spontaneous development of a psychosis, throughout its progression and in all its forms, without any substantial medical intervention. Instigated by a moment of hypochondria that rapidly turns into a catatonic breakdown, this progression leads him into a paraphrenic phase that gives way to paranoia before concluding in a transvestite perversion with strong hysterical components, which is followed by a rather successful professional reintegration.

Freud incorporates within paranoia the classic forms of delusions of persecution, erotomania, jealous delusions, and megalomania, but he overlooks querulousness and discursive mania. The formulas that Freud puts forward for understanding repression and the return of the repressed in paranoia are problematic in spite of their value. He suggests that a single formula—“*I (a man) I love him*” is denied in four ways:

- a. "I do not *love* him—I *hate* him," which is transformed by projection into, "*He hates* (persecutes) *me*" (1911c, p. 63), giving rise to delusions of persecution;
- b. "I do not love *him*—I love *her*." As a result of projection, this becomes: "I observe that *she* loves me" (p. 63), which leads to erotomania;
- c. "It is not *I* who love the man [or woman]—*she* [or he] loves him [or her]" (p. 64), which characterizes jealous delusions;
- d. "*I do not love at all*—*I do not love any one*" (p. 65), which becomes "I love only myself."

Karl Abraham made some variations to these formulae to deal with manic-depressive psychoses. He grafted the essence of formula (a), that is, the inversion of the affect combined with projection, on to formula (d). The formula "*I do not love anyone*" that Freud proposes is only one of the possible consequences of "*I do not love at all*"; the other obvious consequence is "*I do not love at all—I hate*," or even "*I hate the whole world*," a fantasy that can appear in conjunction with "*I love only myself*." Schreber's delusion of grandeur in fact portrays a world that has been completely destroyed. Freud explains this fantasy purely in terms of libidinal decathexis but the need for libido to be cathected does not necessarily mean that this concerns the ego. The libido can disperse, with "*I hate the whole world*" being extended into "*including myself*." Schreber attempted suicide and asked to be killed.

Finally, formula (d) can also appear in another form in delusions of grandeur: "*I do not love anyone—I love the whole world*," which is expressed in the delusions of mystics concerning the salvation of humanity and the transformation of the world, which also appear in the *Memoirs*.

There is a further equation of this: "*I love the whole world, but the world hates me*," which is expressed in paranoid masochism, when hatred presents itself as the guarantee of a supreme love.

The application of the formula for delusions of persecution (a) to the formula for jealous delusions (c) concerns the subject's feeling of persecution by the couple of whom he is jealous. The complete formula here is: "It is not *I* who love the man *and* the woman—it is *they* who love *each other*. *I hate them*"; and, by projection, "*it is they who hate me*," who despise me and so on.

The formula (b) applied to formula (c) produces "It is not *I* who love the man *and* the woman—it is *they* who love *me*," a fantasy that is not unusual in erotic delusions, particularly in the form that leads to the "ménage à trois," whether preceding or following the jealousy, the pleasurable aspect of which barely conceals the anxiety. Daniel Lagache pioneered the study of the connection between erotomania and jealousy, as well as the study of ideas of homosexual infidelity in jealousy.

There is also the application of formula (a) to formula (b) and vice versa, as elaborated by Luiz Eduardo Prado de Oliveira. In the first case, the formula for homosexual erotomaniac delusion appears as: "I (a man) love him (a man)" and by projection: "I do not love him—he loves me," a fantasy that emerges clearly in Schreber's *Memoirs* and in clinical practice. In the second case, there is a close connection both between jealousy and erotomania and between erotic delusions and feelings of persecution. If these formulae are then applied to each other: "I love her (a woman). No, I hate her," and by projection, "I observe that she hates me," the woman appears as the man's persecutor, just as the man can appear as the woman's persecutor. These observations, entirely based on the wide range of phenomena in clinical practice, are an extension of the foundation constituted by Freud's work.

These developments as a whole illustrate the heuristic innovativeness of Freud's and they encompass a much broader spectrum of possibilities in the clinical field. Freud's for understanding paranoia also gave rise to the concept of foreclosure, developed by Lacan as a result of an error in the early French translations and initially accepted as an adequate basis alone for understanding the psychoses.

At very early stage, Freud drew a distinction between three variations of repression: repression concerning affect alone; repression concerning mental representation alone; or, finally, in the most extreme case, concerning both affect and mental representations, in which all the processes occur outside the ego. In his early studies on paranoia, each of these forms of repression found an outlet in projection. In his Schreber study, Freud uses the term *Verwerfung* (foreclosure or repudiation) to characterize the third form of repression. Freud's first translators into French had simply—and incorrectly—retained the term "projection" Lacan, seeing this as a flagrant mistranslation and connecting it with his work on the symbolic law,

introduced the term “foreclosure” (*forclusion*) in its place. In an everyday linguistic system such as Freud used, the term would have been better translated into French by the concept of “rejet” or “refus” (“rejection” or “refusal”), which is more closely reflected in the alternative English term repudiation. The correction of this translation error at the origin of the concept of foreclosure has certainly indicated a difficulty concerning the formation of psychoses and today this term is as widely accepted as the term “projective identification” which originates from Tausk’s writings.

## PARANOID POSITION

Young children are frequently afflicted by paroxysms of anger and fear. Underlying these panics and night terrors is a vicious circle, an unconscious fantasy, involving fear of, and attacks upon, a malign “bad” object.

The term is first used in Melanie Klein (1932), however the descriptions of aggression and paranoia go back to her earliest writings, but notably Klein (1927b, 1928, 1929a and b).

Klein found that children’s symptoms were often based in an extreme anxiety about the child’s own desired aggression towards important and loved people. This conflict represents the infant’s version of the

super-ego conflict described by Freud. As the symptoms that Klein analyzed had arisen in infancy—before the age of one—she assumed the super-ego arose at that early age.

Klein described these “anxiety-situations” as she called them, following Freud (1926), and found that she could analyze them with her “technique of early analysis.” It appeared that the aggression the child exhibited towards the object that frustrated it, gave rise to a belief that the object would retaliate, with equal violence towards the child (Klein, 1927b, 1929a, 1930, 1932). This fear arising from the child’s own aggression often resulted in even greater attacks, in fantasy, on the feared object in order to finally dispose of it. That increase in aggression then led to an increased fear that the now dead object would rise from the dead, and retaliate with even greater force. These crescendos of aggression led to children having paroxysms of fear, such as *pavor nocturnus*, panic attacks, or other symptoms.

At first Klein called this state of aggression and retaliation the “paranoid position.” However, the term did not survive her introduction of the depressive position (Klein, 1935). Later, the nature of this kind of experience became clearer as she described the paranoid-schizoid position (Klein, 1946).

Freud’s view of paranoia was that it hid an underlying homosexuality, such that an underlying love turned to hate (Freud, 1911). This contrasts with the Kleinian “anxiety-situation” that hate overwhelms love. In Rosenfeld’s view, homosexuality covers an underlying unconscious paranoia (Rosenfeld, Herbert, 1949).

With the introduction of the theory of the depressive position, it was understood that the crises of terror in children (Isaacs, Susan, 1939) and adults (Heimann, Paula, 1942) were about internal objects. Later, descriptions of the paranoid-schizoid position presented these internal states of persecution in more thorough detail.

## PARANOID PSYCHOSIS

In the sixth edition (1899) of his *Lehrbuch der Psychiatrie*, Emil Kraepelin, spoke of dementia praecox as an autonomous illness, describing three major forms: hebephrenia, catatonia, and paranoid dementia.

In its conception, the paranoid forms of dementia praecox are opposed to the systematized delusions of paranoia. The paranoid grouping of dementia praecox is characterized by its disintegration, apparent incoherence, a progressive cutoff from the world and growing insanity, all notions that Eugen Bleuler will reduce to the fundamental process of dissociation (“*Spaltung*”) in schizophrenia, substituting this term (1911) for that of “dementia praecox.” On the other hand the polarity represented by the paranoid’s delusion distinguishes itself by the systematization of the delusions in the form of unshakeable convictions, developed in an orderly manner and clearly, and in the absence of any tendency of deterioration. A third group with chronic delusions corresponds to the observations of Kraepelin, and designated by him with the term “paraphrenia,” had two characteristics: they had constructions that were more or less chaotic, based on fantastic themes and hallucinatory mechanisms, but maintained their intel-

lectual integrity, and their adaptation to the exigencies of reality.
