Although we find the same fundamental themes of incest and murder in the counter-Oedipus of the mother, they are envisioned differently. In the mother's relationship with a daughter, primary homosexuality, long-term alienating bonds, and mother-daughter rivalry become important. In the mother's relationship with a son, the incestuous dimension of the child's penis comes to the fore. Additionally, whether the child be a boy or a girl, murder fantasies cause the mother to be anxious during pregnancy.

The notion of the counter-Oedipus thus brings together an extremely varied set of clinical facts and theoretical elements. Though it is a convenient term current in France, it still awaits full theoretical development. A task for the future is to relate the counter-Oedipus to transgenerational phenomena.

## **COUNTERPHOBIC**

We speak of *counterphobic* objects or phenomena when the person seeks out one or more external objects or phenomena, whether consciously or unconsciously, to escape from the manifestations of anxiety linked to his or her phobias.

The specificity of the counterphobic phenomenon appears to be linked not to the nature of the object

used, but rather to the function that object assumes within the person's psychic economy. In the phobic situation, anxiety is focused on an "external object" (which may be an object, a person, or a situation). In these conditions, the counterphobic object is that object whose link or relationship to the phobic object is sufficiently well established within the person's psychic economy that its presence can neutralize the anxiety associated with the phobic object.

Given the extreme heterogeneity of phobic phenomena, this perspective means that we need not attempt to make a clear distinction between the counterphobic object and the various types of objects described in other contexts that enable the person to escape from manifestations of anxiety (psychotic object, transitional object, fetish object, etc.).

## **COUNTER-TRANSFERENCE**

Counter-transference refers to the analyst's unconscious reactions to the transference of the patient, including the feelings projected onto the analyst by the patient.

Sigmund Freud introduced the concept at the Nuremberg congress of the International Association of

Psychoanalysis in 1910: “We have become aware of the ‘counter-transference’, which arises in [the analyst] as a result of the patient’s influence on his unconscious feelings, and we are almost inclined to insist that he shall recognize this counter-transference in himself and overcome it” (Freud, 1910d, p. 144–145).

He spoke of it again in a letter to Ludwig Binswanger dated February 20, 1913: “The problem of counter-transference . . . is—technically—among the most intricate in psychoanalysis. Theoretically I believe it is much easier to solve. What we give to the patient should, however, be a spontaneous affect, but measured out consciously at all times, to a greater or lesser extent according to need. In certain circumstances a great deal, but never one’s own unconscious. I would look upon that as the formula. One must, therefore, always recognise one’s counter-transference and overcome it, for not till then is one free oneself” (letter 86f, p.112). He made reference to it again in “Observations on Transference-Love” (1915a [1914]): “For the doctor the phenomenon [the patient’s falling in love with successive analysts] signifies a valuable piece of enlightenment and a useful warning against any tendency to a counter-transference which may be present in his own mind” (p. 160).

In spite of these references, the notion of counter-transference remains ambiguous in Freud’s work. What are the analyst’s unconscious feelings? Can the analyst merely master the counter-transference or must he or she overcome it, which would imply a working-through? These three texts sowed the seeds of a theoretical and technical debate that developed after Freud’s death.

The conceptual tools needed for a theorization and explication of the counter-transference were introduced by Melanie Klein (1946) with her discovery of projective identification. This made it possible to understand how the patient could act upon the analyst’s psyche by projecting a part of his or her own psyche onto the analyst. Thus the counter-transference no longer appeared to be just the sum of the analyst’s blind spots, but instead became a way of perceiving certain aspects of the patient’s communication—primitive communication in particular. Melanie Klein did not use the term counter-transference very often, thought it could be said that her entire technique is founded on the concept.

It was her student Paula Heimann who, at the 1949 International Psychoanalytical Association conference

in Zurich, first made counter-transference a genuine tool for perceiving certain aspects of the patient’s communication: “My thesis is that the analyst’s emotional response to his patient within the analytic situation represents one of the most important tools for his work. The analyst’s counter-transference is an instrument of research into the patient’s unconscious” (1950, p. 81). From this point on, the concept became an object of increasing interest, most notably in relation to developing research in the fields of child analysis and the psychoses.

The definition of counter-transference remains controversial insofar as it is understood either strictly as a response to the unconscious processes that the patient’s transference produces in the analyst or more globally as the part played within the framework of the treatment by the analyst’s personality. In analytic work, this concept is used in two different ways: on the one hand, as a defensive position on the part of the analyst, who must take care to remain as much as possible a projective surface, a mirror, for the patient’s transference, and on the other, as a position in which the personality of the analyst, most notably his or her emotions, is engaged in the transference/counter-transference dynamic on the basis of a more three-dimensional conception of the transference. For the analyst, then, it is a matter of working through the counter-transference experience in order to distinguish between the patient’s projections and his or her own internal objects and see the common elements that might serve to guide the interpretation.

This concept carries two potential pitfalls. On the one hand there is a possibility of psychologizing the analytic relation to the extent that it could be considered more in terms of personal interaction than in terms of a transference repetition of unconscious scenarios (Fédida, 1986). On the other is the possibility of forgetting that while counter-transference can be a guide for understanding and the most faithful of servants, it can also be the harshest of masters (Segal, 1981).

## **“CREATIVE WRITERS AND DAY-DREAMING”**

In 1908 Sigmund Freud presented a talk entitled “Creative Writers and Day-Dreaming” at the publisher Hugo Heller’s offices. This was an important article in which Freud responded to the questions introduced in “Psychopathic Characters on the Stage” (1942a [1905]). It is contemporary with the “Gradiva” essay (1907) and was to be continued in numerous texts that discussed artistic creation, such as “The Uncanny” (1919h) and “Dostoyevsky and Parricide (1928b [1927]). The condensed and theoretical nature of Freud’s statements here summarize ideas he was to present elsewhere in his work.

He begins with an idea that Donald Winnicott would later take up concerning the link between childhood games and creation—in this case, literary creation. The game is defined as a “daydream” and extends into adolescence in “fantasies.” Both belong to the more general category of fantasy activity, which is itself the result of unsatisfied desires. The link with literary creation takes place through popular literature, whose heroes are always victorious after they have undergone various trials. The pleasure of reading is defined as essentially narcissistic. The hero is always His Majesty the Ego and the “psychological” novel differs from the adventure novel only in that the ego is split into “partial egos” that are represented by the various heroes in conflict. The social novel, however, makes the ego an outside observer.

The novelist’s literary capacity is supported through the echoes that real events or folkloric sources awaken in his or her childhood memory. The creator allows the reader to participate in his fantasy world through the formal techniques he exercises, which provide a source of pleasure. This frees a deeper source, enabling the reader to “enjoy his fantasies without scruple and without shame.” Even though, as Freud himself acknowledges, the origin of this creative ability remains mysterious, this dense text introduces several new paths for discovery and reminds us of popular literature’s importance in understanding the pleasure of reading.

**CREATIVITY**

The term “creativity” is not used by Sigmund Freud but the concept is Freudian if we understand it to mean the creative imagination embodied in fantasies or daydreams. These may or may not receive further elaboration and be transformed into a work of art, regardless of its specific nature. However, it is primarily Melanie Klein and Donald Winnicott who are responsible for establishing the concept as an active attitude of the ego with respect to its objects.

As early as the *Studies on Hysteria* (1895d), Freud realized that the world of fantasy (Anna O’s private theater) can take the place of the real world, and this includes the researcher captivated by his subject. In discussing humor (1905c), Freud also emphasized the freedom of the intellect in the face of highly constrained situations. Literary creation (1908e [1907]) appeared to Freud as an extension of children’s daydreams, situations in which the fantasy is affirmed in the face of the empire of reality, without, however, leading the subject to misinterpret it as happens in delusional states. It is precisely this ability, whose origin remains mysterious, to turn fantasies into a reality inscribed in a work of art and therefore something that can be shared with others, that constitutes creativity, regardless of the field of endeavor. Freud was especially interested in literary (Dostoyevsky, Hoffmann, Jensen) and artistic creation (Leonardo da Vinci, Michelangelo).

Melanie Klein (1929) had a very different outlook on creativity, which she saw as an impulse experienced by the infant to repair the object that had been initially split into good and bad and attacked during the paranoid phase. The creative function is therefore initially curative but goes hand in hand with the representation of a unified object. In this sense the creative function constitutes a reconstitution of the ego and the object, which having been simultaneously destroyed, subsist in an empty or mutilated state.

Donald Winnicott (1971) gave the fullest extension to the concept of creativity by emphasizing its function as an attitude in the face of outside reality and not necessarily successful or recognized creative work. He

contrasted creativity and submission to the outside world but, unlike Freud, emphasized the fact that fantasy life could diverge from the creative attitude. Fantasizing is not living but can, on the contrary, as Freud noted with respect to hysterics, isolate the individual from life; it will never serve as an object of communication.

For Winnicott, while creativity is related to dreaming and living, it is not really a part of our fantasy life. The experience of self can only be achieved through that physical and mental creative activity whose model is game playing. Creativity is not the creative capacity but something universal, inherent in the very fact of living. In the case where the individual submits to outside reality to the point of losing himself in it (false self), his creativity disappears and remains hidden without however being destroyed. It is in this way deprived of contact with the experience of life. “The creative impulse,” Winnicott writes, “is present as much in the moment-by-moment living of a backward child who is enjoying breathing as it is in the inspiration of an architect who suddenly knows what it is that he wishes to construct” (1982, p. 69).

The concept of creativity is much closer to the question of activity than to the production of a work of art. This aspect is only sketched out by Freud but was theorized by Winnicott for whom the concept is associated with considerations of the ego and non-ego and the transitional space that serves as an “outlet” for primary narcissism.

**CRIMINOLOGY AND PSYCHOANALYSIS**

Criminology is the “scientific” study of criminal behavior. Part of its mandate is to look for the causes of criminality. A distinction is made between general criminology, which coordinates and compares results from different criminological “sciences,” and clinical criminology, which is an interdisciplinary approach to the individual criminal (Pinatel, 1975). Criminalistics is the set of methods and scientific means used by law enforcement to search for criminals and establish their guilt.

It is customary to trace the origins of criminology to Cesare Lombroso (1836–1909), trained in medicine at Pavia and Padua, a volunteer in the Piedmontese army for seven years. A physician of Jewish origin, Lombroso became famous with the publication of *L’Uomo Delinquente* (Criminal man) in 1876. His countryman Enrico Ferri, a professor of law and sociology, was the author of *Criminal Sociology* (1917) and Raffaele Garofalo wrote *Criminologia* (1881), from which the term derives. Lombroso is notorious for his theory of “the born criminal,” based on the search for an “atavistic” factor in criminality (in fact part of a larger naturalistic quest for the origins of crime that ranged from the occipital lobe to a supposed “criminal chromosome”). It is too often forgotten, however, that he founded the comparative approach to large numbers and introduced the study of criminals’ writings. Historians of criminology put the true beginnings of the discipline almost a century before Lombroso. His genius lay in his ability to combine phrenology, anthropology, legal medicine and proto-psychiatry under the aegis of Darwinism (Mucchielli and Lantéri-Laura, 1994).

Sigmund Freud, who made no secret of his aversion to criminals, was silent about the work of his contemporaries in that area and singularly cautious when it came to applying psychoanalysis to criminology. In June 1906 he was invited to give a talk to Professor

Löffler’s students on the possible application of psychoanalysis to the “establishment of facts in legal proceedings” (1906c, p. 103). He directed his comments to future judges and lawyers, providing advice about the “interest in a new method of investigation, the aim of which is to compel the accused person himself to establish his own guilt or innocence by objective signs” (1906c, p. 103). This text has given rise to considerable misunderstandings, which have been discussed by François Sauvagnat (1992). Freud cautioned his audience about a considerable obstacle: the judge was likely to be misled by neurotics, who were liable to behave as if they were guilty. He gave free rein to his skepticism, taking but a few sentences to discuss the psychoanalytic method as having no practical application in legal matters given the risk of error entailed.

In “Criminals from a Sense of Guilt” (in 1916d, pp. 332–33), Freud goes a step further, based on his experience in treating subjects who had committed some minor offense during therapy: “He was suffering from an oppressive feeling of guilt, of which he did not know the origin, and after he had committed a misdeed this oppression was mitigated. His sense of guilt was at least attached to something” (p. 332). The origin of this obscure feeling of guilt was the Oedipus complex, with its implications of criminal intent: “killing the father and having sexual relations with the mother” (p. 333). Freud hypothesized that this could clarify our understanding of some criminals but he was careful to exclude those who did not have such feelings, those who were without moral inhibitions, and those who rationalized their struggle against society.

It would have been easy to make use of the Oedipus complex to account for criminal acts, especially patricide. In 1931, Freud was asked by Joseph Hupka, a professor of law at the University of Vienna, to provide testimony during a review of the trial of Philipp Halsmann, accused of having killed his father. In examining both possibilities, guilt or innocence, Freud steered a careful course between a defense of psychoanalysis and his ethical reservations concerning its use; he again exercised considerable caution, writing, “because it is always present, the Oedipus complex is not suited to provide a decision on the question of guilt” (1931d, p. 252).

Apropos of his rare allusions to the relationship between psychoanalysis and criminology, it must be said that Freud’s prudence has proved salutary. It was

subsequently evident that an overly hasty application of psychoanalysis can mechanically alter the role of fantasy, or generalize unconscious feelings of guilt, or even sustain the illusion that psychoanalysis might one day conquer the world of law.

Sándor Ferenczi must be mentioned here, not only for his hope of contributing to the development of a psychoanalysis of crime, but also for the richness of his theoretical and clinical ideas, which served as the foundations of a psychoanalytic understanding of victimhood, especially in his accounts of identification with the aggressor and introjection of the aggressor, who “disappears as external reality and becomes intrapsychic.”

## **CRUELTY**

Cruelty is a multi-faceted concept in Freud's work. It can relate to actions and motivations but also to agencies, events, or destiny. When Dora (1905e [1901]) abruptly terminated her analysis, Freud mentioned the young girl's "cruel impulses and revengeful motives" (p. 120), which, through Freud in the transference, were directed at Herr K. and through him at her father. This text, written in 1901, contains an implicit question as to whether these impulses originate from the drives or the ego, but also as to the type of person associated with these impulses: in fleeing the transference, did Dora intend to be cruel towards Freud?

An "instinct of cruelty" appears in the *Three Essays on the Theory of Sexuality* (1905d). In this work, Freud relates it to male sexuality: the man has a tendency to subjugate in order to overcome "the resistance of the sexual object" (p. 158) and satisfy his sexual urges. Freud states: "There is an intimate connection between cruelty and the sexual instinct" (p. 159). Along with scopophilia and exhibitionism, cruelty is classified as a partial or component drive. Whether active or passive, it also stems from the drive for mastery. Whereas this drive is exerted through the "apparatus for obtaining mastery" (p. 159), connected with the musculature, it is the skin, as the "erotogenic zone *par excellence*" (p. 169) that constitutes "one of the erotogenic roots of the passive instinct of cruelty" (p. 193). Freud also refers to Jean-Jacques Rousseau's memories of being beaten, which he goes on to discuss further in "A Child is Being Beaten" (1919e).

Like mastery, cruelty involves the use of the object simply as a means of satisfaction. In this sense, it differs from the “sadism proper” (1924c, p. 163) that results from the binding of the drive for cruelty with the sexual drive towards the object. Whereas the drive for cruelty, like the drive for mastery, is characterized by indifference on the part of the subject to the feelings experienced by the object of satisfaction, considered as a part-object, sadism involves a pleasure derived from the object’s suffering.

Describing sadism in *Instincts and their Vicissitudes* (1915c) as “the exercise of violence or power upon some other person as object” (p. 127), having also described the drive for cruelty in this way ten years earlier, Freud added: “the sadistic child takes no notice of whether or not it inflicts pain, nor is it part of its purpose to do so” (1915c, p. 128). Thus, strictly speaking, the small child is cruel but not sadistic. This becomes possible only after he has discovered the total object and his ambivalence towards it.

In the same year (1915b), Freud specifically related cruelty to egotism. Intrinsically neither good nor bad, the drives acquire these qualities with regard to the necessary process of civilization. But the child is able to renounce drive gratification because of his need to be loved by his libidinal object. However, the object still remains an unloved and sometimes hated stranger as a direct result of its otherness. Egoistic and cruel impulses resurface and are directed at the object, particularly if the object is generally designated as an enemy. Wounded by these attacks, the object becomes even more frightening.

After the introduction of the death drive in 1920, the drive for cruelty gave way to the “destructive drive,” understood as an external deflection of the death drive (1923b) and described as aggressive when directed at objects. If it is taken up by the ego, the ego itself becomes cruel or sadistic. The ego then risks not only losing the object’s love but also being subjected to the reprimands of the superego. This agency, which equates with moral conscience, can demonstrate an extreme cruelty, according to the need for aggression aroused by present and past frustrations. Rebellious by nature towards what is nevertheless the necessary process of civilization, the human being is always able to display a “cruel aggressiveness” (1930a, p. 111) if circumstances lend themselves to this.

Melanie Klein substantially developed this concept of cruelty on the part of the superego. In the context of

the controversy that pitted her against Anna Freud, she drew attention to the extreme severity of the infantile (or early) superego, even where the parents are conciliatory (1927). The harshness of the agency is proportional to the aggression felt by the child as a result of the frustrations experienced during weaning and toilet training. Thus a cruel superego, “something which bites, devours and cuts” (1928, p. 187) is the outcome of the oral-sadistic and anal-sadistic drives. Taking up Freud’s hypothesis concerning the necessary external projection of the death drive, to which the effects of pre-oedipal frustrations are added, Melanie Klein described an extremely cruel child who “attacks its mother’s breast” (1933, p. 253), “thinks of sucking out and eating up the inside of its mother’s body” (p. 254) and attacks its object with excrements that are “regarded as burning and corroding substances” (p. 253). This intense hostility both from the object and toward it is the product of the deflection of the death drive and past frustrations but also of fears of reprisal for the hostility towards the hated object, ultimately of the influence of the early superego. Thus, “the small child becomes dominated by the fear of suffering unimaginable cruel attacks, both from its real objects and from its super-ego” (p. 251). Although the oedipal phase is influenced by the earlier stages, these destructive rages are tempered with pity and some reparative impulses emerge.

Donald Winnicott (1955/1975) has clearly demonstrated the process of transition from a “pre-ruth era” in which the little child can inadvertently or unintentionally display aggression, since “if destruction be part of the aim in the id impulse, then destruction is only incidental to id satisfaction” (p. 210), to a subsequent stage when the child is concerned about his object. He then has worries about it and is able to feel compassion or potentially creative reparative wishes, which prevents him from remaining cruel toward his object.

Of course, these drives are primitive and potentially cruel toward the object. Throughout his life, the subject will have to find compromises between the claims of the narcissistic pole of his drives and the intensity of his love for the object. However, the object’s tolerance of the subject’s drive-based egoism varies. In fact, some parents and spouses are better able than others to tolerate narcissistic egocentrism in their child or partner and are accordingly less vulnerable to their “cruelty”.

## CRYPTOMNESIA

Cryptomnesia is a memory that has been forgotten and then returns without being recognized as such by the subject, who believes it is something new and original. In general, the memory returns in the form of an idea or intuition, but reappearances in the form of actions have also been included.

The word was first used by the Geneva-based psychiatrist Théodore Flournoy in *From India to the Planet Mars: A Case of Multiple Personality with Imaginary Languages* (1901/1994), his book about the case of the spiritualist medium Catherine-Élise Müller, who used the name Hélène Smith. It thus comes out of an attempt at a rational approach to spiritualist phenomena that showed a delusional character: “In the communications or messages provided by mediums, the first (but not the only) question that arises is always whether, where spiritualists see the influence of disembodied spirits or some other supranormal cause, one is not simply dealing with cryptomnesia, with latent memories on the part of the medium that come out, sometimes greatly disfigured by a subliminal work of imagination or reasoning, as so often happens in our ordinary dreams.”

In his thesis, “On the Psychology and Pathology of So-Called Occult Phenomena” (1902), and an article, “Cryptomnesia” (1905), Carl Gustav Jung expressed his belief that he had isolated this phenomenon in Nietzsche’s *Zarathustra*. Cryptomnesia was the object of a few studies or mentions until around 1920 (Géza Dukes, Sándor Ferenczi, Wilhelm Stekel). Thereafter, it was seldom mentioned in the psychoanalytic literature and was even rarer in the psychological and psychiatric literature.

The notion’s interest remains marked by the particular use Sigmund Freud made of it, from 1919, by linking it to the issue of the originality of his inventions. Entering into the category of forgetting, cryptomnesia indexes it with a univocal meaning, that of tempering a claim to the originality of an idea. In an article signed “F.” and titled “Note on the Prehistory of the Technique of Analysis” (1920), Freud acknowledged that a text by Ludwig Börne, *Die Kunst in drei Tagen ein Original-Schriftsteller zu werden* (How to become an original writer in three days; 1823), had served as a precursor to the technique of free association. Freud also mentioned his cryptomnesia with regard to Josef Popper-Lynkeus, Empedocles, and Wilhelm Fliess, and interpreted Georg Groddeck’s statements along these lines. It is known that he was sometimes reluctant to refer to himself as the inventor of psychoanalysis, invoking the contributions of Josef Breuer, and that in addition, in *The Psychopathology of Everyday Life* (1901), he made himself vulnerable to a claim of priority on the part of his friend Fliess by accusing himself of harboring the unconscious wish to

steal the idea of bisexuality from him. No doubt we should see in this problematic, to which Freud linked the meaning of cryptomnesia, the characteristic difficulty the man of science has in taking personal responsibility for a discovery that shakes the foundations of the very rationality he identifies himself with. Invoking cryptomnesia in this context arguably means maintaining the fiction of a subject-supposed-to-know guaranteeing that the knowledge was already there before the creator invented it.

**CULTURAL HEREDITY.** *See* Cultural transmission

---

### **CULTURAL TRANSMISSION**

The term “cultural transmission” does not appear in Sigmund Freud’s work, but the idea is implicit in such notions as *cultural heritage* and *phylogenetic inheritance*. Freud believed that the (since abandoned)

biological precept, according to which “ontogenesis recapitulates phylogenesis,” could be applied to human psychic development. The notion of cultural transmission refers to the possibility that the acquisitions of an individual or of a culture can be transmitted to descendents and form the basis of cultural development.

Freud addressed the topic for the first time in *Totem and Taboo* (1912–13a), where he advanced the hypothesis that the feeling of guilt over the murder of the primal father had persisted over the centuries and still affected generations that could know nothing directly about it.

In Freud’s later works, the main mechanism of transmission was said to be identification, which ensconced the lost object in the ego, as described in “Mourning and Melancholia” (1916–17g [1915]), and finally produced an alteration in the ego that gave rise to the superego, as described in *The Ego and the Id* (1923b). In the *New Introductory Lectures* (1933 [1932]) Freud observed that the superego could be viewed as the outcome of successful identification with the parental agency, and as the natural and legitimate heir to the Oedipus complex. As the bearer of tradition, the superego was a true agent of cultural transmission from one generation to the next. In *Moses and Monotheism* (1939a [1934–38]) Freud returned to the idea of an archaic heritage and compared such inherited acquired characteristics to instincts in animals—an inheritance on par with symbolism.

After Freud, the idea of phylogenetic transmission was seemingly relegated to the background, as an explanation of last resort, and the emphasis shifted toward a detailed and expanded study of identifications. The point of departure for this was Freud’s remark in the *New Introductory Lectures*, in which he observed that the child’s superego was not formed in the image of the real or imaginary parents, but instead modeled on the parents’ superego. The main focus soon moved beyond direct parental and intergenerational identifications to more distant identifications, such as those with grandparents, ancestors, or mythical characters in family history, who re-emerge amid the descendents as a kind of actualization of family prehistory. The theme of the intergenerational (or transgenerational) appears in psychotherapeutic work with families, children, and adolescents, and sometimes gives the impression that this sphere of

observation is being invaded by the study of archaic identifications. The other area where this theme comes to the fore is work with survivors or descendents of survivors of the Holocaust or other genocides, such as those committed by Latin American dictatorships. In these two areas, the importance of secrets, the unspoken, or ancestral crimes that the family has decided to bury, is much in evidence. In the case of the survivors of genocide, there is an attempt to make the traumatic situation disappear by denying it representation. But the buried material reappears two or three generations later, as a ghost that occupies the place where the concealment of important aspects of the ancestor's life has produced a "blank" in the descendant's psyche. In such cases, we speak of "alienating identifications." A particular aspect of this type of intergenerational transmission was studied by Nicolas Abraham and Maria Torok (1972/1978), in relation to the problem of grief.

We thus see that a number of ideas are related: in Freud's work we encountered identification, phylogenetic heritage, and intergenerational process; in other authors, the notions of transgenerational transmission, "fantasies of identification" (de Mijolla, 1986), and "alienating identifications."

In summary, we may say that the concept of phylogenetic heritage has gradually been reconsidered, to the benefit of more detailed study of the mechanisms of possible transmission, notably identification, the core of the issue. The uncovering of alienating factors in the subject's prehistory, factors that can go back several generations, has come to the fore, replacing the ideas of "family romance" and "mythical descent," so well known to us since Freud. But emphasis on the intergenerational may push analytic work in the direction of applied psychoanalysis, so distancing it from a deeper understanding of the configurations and processes of the analytic situation, which is the prime locus of psychoanalytic discovery. This danger may even be exploited by the ever-renewed faces of resistance to psychoanalysis.

## **CURE**

Freud clearly stated that "the aim of the treatment will never be anything else but the *practical* recovery of the patient" (1904a, p. 253). He also declared that "Psycho-analysis was born out of medical necessity. It sprang from the need for bringing help to neurotic patients, who had found no relief through rest-cures, through the arts of hydropathy or through electricity" (1919g, p. 259).

Many of the arguments that divide psychoanalysts on the problem of the "cure" arise from their different conceptions they have of the term's meaning. The medical model leads to the idea that the cure is a matter of the disappearance of symptoms or lesions, or even of a *restitutio ad integrum* (restoration of health) that would actually be impossible in the mental field. Hypnosis and suggestion made disorders disappear as if by magic, but only temporarily, which is why Freud abandoned these techniques. He was more concerned with deeper causes and, from the time of *Studies on Hysteria*, he limited his own influence: "[Y]ou will be able too convince yourself that much will be gained if we succeed in transforming your hysterical misery into common unhappiness. With a mental life that has

been restored to health, you will be better armed against that unhappiness" (1895d, p. 305).

In the analysis of "Little Hans," he insisted that "a psychoanalysis is not an impartial scientific investigation, but a therapeutic measure. Its essence is not to prove anything, but merely to alter something" (1909b, p. 104). Thus the objective is "change," giving the patient a capacity to mobilize his defenses differently and more effectively to manage both the external and internal conflicts that the cure cannot prevent from returning. In a note to *The Ego and the Id*, Freud wrote that "analysis does not set out to make pathological reactions impossible, but to give the patient's ego freedom to decide one way or the other" (1923b, p. 50n).

It is necessary to remove all obstacles to the attainment of this goal, and that is the work of the treatment: the unconscious must "convey itself into the preconscious" (1900a, p. 610); treatment involves "overcoming the internal resistances" (1905a, p. 267); analysis "replaces repression by condemnation" (1909b, p. 145); the patient must "make the advance from the pleasure principle to the reality principle" (1919b, p. 312); and "the aim of the treatment is to remove the patient's resistances and to pass his repressions in review and thus to bring about the most far reaching unification and strengthening of his ego, to enable him to save the mental energy which he is expending upon internal conflicts, to make the best of him that his inherited capacities will allow and so to make him as efficient and as capable of enjoyment as possible" (1923a, p. 251). From this perspective, "partial or complete sublimation" represents, as Freud wrote to James Jackson Putnam in a letter of May 14, 1911, "the goal of [psychoanalytic] therapy and the way in which it serves every form of higher development" (1971a, p. 121).

Freud never concealed the pedagogic aspect of such a program. He insisted on several occasions that psychoanalysis was a kind of "after-education" (1916–17a, p. 451; 1940a, p. 175), even though he also maintained that the psychoanalyst must not fall into the role of an educator. Similarly, he often spoke out, right up to the end of his life, against the idea that a "schematic normality" could define the end of the treatment, adding that "The business of analysis is to secure the best possible psychological conditions for the functions of the ego; with that it has discharged its task" (1937a, p. 250).

A growing awareness of the death drive and the repetition compulsion led Freud to reconsider the

secondary gain from illness as an obstacle to the cure and to reexamine the role of the "negative therapeutic reaction." The latter, which satisfies unconscious guilt feelings and the need for punishment in the neurotic (through masochism), represents one of the most important obstacles to the satisfactory progress of a psychoanalytic treatment.

Freud's continuing efforts to describe and analyze the negative therapeutic reaction shows that he persisted in looking for this, in the sense of "change," despite his later pessimistic remarks. Other analysts broadened the concept of cure, even if certain remarks by Jacques Lacan seemed to devalue it. On February 5, 1957, after a lecture by Georges Favez on "The Encounter with the Analyst," Lacan expressed with the utmost clarity an idea that has since been greatly distorted by both his adversaries and partisans. He began by arguing against the idea that "if the measure of a therapeutic analysis is defined by its achieving the aim of producing a cure, that would mean that a therapeutic analysis is always something rather limited. All the same," he went on, "cure always seems to be a happy side effect—as I have said, to the scandal of certain ears—but the aim of analysis is not cure. Freud said the same thing himself, namely, that making cure the aim of analysis—making it nothing more than a means towards a specific end—leads to something like a short circuit that could only falsify the analysis. Thus analysis has another aim" (1958, p. 309).

Lacan made these remarks were within the context of an argument that pitted him against the idea of "therapeutic analysis" and against the aim of "cure"—defined by Sacha Nacht as the "disappearance of fear and the possibility of loving and being loved" (1960)—as extolled by the Psychoanalytic Institute of Paris. His remarks aimed at a "pure psychoanalysis" that Lacan associated with training analysis.

In any case, Lacan's remarks can be compared to a formulation of Freud's that is similar only if we neglect the fact that it involves the question of symptomatic suffering and not "cure." However, as stated at the outset, everything depends on how one understands the term: "The removal of the symptoms of the illness is not specifically aimed at, but is achieved, as it were, as a by-product if the analysis is properly carried through" (1923a, p. 251).

## CZECH REPUBLIC

The first pioneer of psychoanalysis in the Czech lands was Jaroslav Stuchlik (1890–1967), the Czech psychiatrist. He studied medicine in Switzerland, where he met with Eugen Bleuler and Carl Gustav Jung. At the end of the First World War, he was the first Czech to visit Freud's seminars in Vienna. He surrounded himself with a group of young physicians in Slovakia (Kaschau) in the 1920s.

Another group, consisting of Russian physicians, originated in Prague around the Russian emigré Nikolaj I. Osipov (1877–1934, who lived in Prague from 1921 until his death and founded the Russian Psychoanalytical Association with Drosnez, Tryto, and Viroubov. Osipov lectured in psychoanalytic psychiatry at Charles University in Prague.

Nicolaj Osipov and Jaroslav Stuchlik, along with Eugen Windholz, formerly of the group in Kaschau, initiated the idea of the commemorative plaque that was installed on Freud's home in Freiberg on October 25, 1931. Anna Freud took part in the celebration and Sigmund Freud, at that time 75 years old, sent a letter of greeting to participants. In connection with this event the first *Czech Yearbook of Psychoanalysis* (1932) appeared, edited by Windholz. Windholz (1903–1986), a Slovak Jew, was the first in the Czechoslovakian history to receive a proper psychoanalytical training. He started his analysis with Dr. Wolfe in the Berlin Psychoanalytical Institute where he spent few weeks in 1930. Then he continued his training in Prague with Frances Deri, a German analyst, who was the first émigré from Germany, followed by Heinrich and Yela Loewenfeld, Steff Bornstein. Hanna Heilborn, Annie Reich, and Elisabeth Gero-Heymann.

The Prague Psychoanalytical Study Group was established in 1933, led by Frances Deri until 1935, when she moved to Los Angeles and, after that, by Otto Fenichel, who trained and taught in Prague until 1938 as an emissary of the Viennese Psychoanalytical Society which was affiliated with the Prague Group officially at the Lucerne Congress in 1934. Among the

analysts from Vienna who traveled to Prague on weekends to present lectures were E. Bibring, R. Waelder, R. Spitz, P. Federn, E. Kris, and A. Aichhorn. Among the pupils were Emmanuel Windholz, Jan Frank, a Slovak psychiatrist and neurologist, Richard Karpe, a Czech pediatrician, Theodor N. Dosuzkov, a Russian émigré, neurologist and psychiatrist, and Otta Brief and Theresa Bondy. The Czech Study Group was officially recognized by the 14th IPA Congress in Marienbad in 1936. The Munich treaty in 1938 had disastrous consequences for the psychoanalytic movement: Czechoslovakia was occupied by Hitler in March 1939.

During the years 1938–1939, a majority of the Czech Study Group emigrated to the United States (Windholz to San Francisco, Frank to New York, Karpe to Hartford, Connecticut), some died in concentration camps, and the only member to survive the German occupation was Theodor Dosuzkov (1899–1982). He had been trained by Annie Reich and Fenichel supervised him. During the war he went on with his psychoanalytic work illegally, surrounding himself with a small group that played a significant role in the postwar development of psychoanalysis in Czechoslovakia.

The Society for the Study of Psychoanalysis was reestablished in Prague in 1946. It had to be dissolved officially at the beginning of the 1950s, after the Communist putsch, but it continued illegally a further 40 years (1950–1989). The training in psychoanalysis went on secretly. Theodor Dosuzkov and his pupils Otakar Kuera, Ladislav Haas (emigrated in 1965 to London), and M. Benová were direct members of the IPA, and had some private contacts with analysts

abroad. In the 1960s the younger generation of analysts started to train candidates: P. Tautermann, A. Sizková.

In the early 1980s, descendants of Dosuzkov and others established the new group and the Psychoanalytic Institute. Since 1987, the Czech Group has been visited by several important European and American psychoanalysts. An important step was made at the 26th IPA Congress in Rome in 1969: V. Fischelová, Jiri Kocourek, Vaclav Mikota, M. Šebek, and B. Vacková were recognized as the direct and associate members of the IPA. The Czech Group became a Study Group of the IPA at the 38th Congress in Amsterdam in 1983. The official journal of the Czech Study Group, *Psychoanalytický sborník*, has been published since 1989.

## DALBIEZ, ROLAND (1893–1976)

Roland Dalbiez, a French philosopher, was born in Paris on June 23, 1893, and died in Rennes on March 14, 1976. He is best known for his *Psychoanalytic Method and the Doctrine of Freud*, a philosophical critique of psychoanalysis published in 1936. Dalbiez was born into an aristocratic Christian family (his father was a general in the army and his mother a Churchill) and entered the French naval academy in 1911. He was a naval officer during the First World War. After contracting pleurisy he was forced to abandon the military and turned to philosophy, graduating in 1921 and receiving his doctorate in 1936. He spent his entire career as a professor in the literature department of the University of Rennes.

His research involved the boundaries between biology and metaphysics. Together with Professor Rémy Collin of the University of Nancy, he founded *Cahiers de philosophie de la nature* (The philosophy of nature), and published several studies on the theory of evolution.

In the early 1930s he was part of the circle of people around Jacques Maritain, the neo-Thomist philosopher, where he met Emmanuel Mounier and Maurice Merleau-Ponty. It was Maritain who encouraged Dalbiez to write about Freud. His research was so extensive that it turned into a dissertation. He defended his dissertation at the Sorbonne and it was published the same year by Desclée de Brouwer, as *La Méthode Psychanalytique et la Doctrine Freudienne* (Psychoanalytic method and Freudian theory). There were two volumes: The first included an account of Freud's ideas and the second a discussion. There was a preface by Henri Claude. Claude introduced Dalbiez as a student who had become personally acquainted

with the psychoanalytic method through his study, together with several psychiatrists, of various cases over a period of years.

Dalbiez insists on the fact that his judgment is not only based on what he has read but also on what he has seen. "On a number of points, books leave us with a feeling of uncertainty, but the facts are convincing." (p. 8) The main thrust of his dissertation is that while Freudianism is wrong for many reasons—exaggeration, eccentricity, dogmatism—the method is excellent and fruitful. Dalbiez essentially reproaches Freud for lacking philosophic rigor and behaving "as if he were unaware of the idea of proof." His principal merit is to have emphasized the primacy of the unconscious in mental life.

Dalbiez's friend Édouard Pichon provided a detailed review of the book in the *Revue Française de Psychanalyse* in 1936. He presents the work as "a milestone in psychoanalysis in France" and feels that the philosopher from Rennes will "convince even the most reluctant of philosophers that the psychoanalytic method represents a definite advance, something real and durable in the field of psychology." He fully accepted the distinction made by Dalbiez between Freudian doctrine, "about which we are free to accept what we wish," and method. Moreover, he claims to be the origin of this idea. At the beginning of the Second World War, Henri Ey also published an article entitled "Réflexions sur la Valeur Scientifique et Morale de la Psychanalyse (à propos de la Thèse de Roland Dalbiez)," which represented his first important statement about psychoanalysis.

The impact of Dalbiez's work on philosophy was less significant than it was in the analytic community.

There was no mention of the book in philosophical reviews of the time and, as Dalbiez himself notes, the book aroused considerable hostility at the Sorbonne. It was only gradually that it became an important work on the application of philosophy to psychoanalysis, primarily through the efforts of Paul Ricoeur, who was a student of Dalbiez. His book, especially the distinction he made between theory and method, was the source of considerable misunderstanding.

## **DANGER**

As with many concepts a tentative definition of danger is based on its use in ordinary language: it signifies either a situation or set of circumstances that compromise the security or existence of a person or thing. Aside from the past or present, it can include future situations, that is, threats or risks having a high probability of realization. This definition likewise concerns threats to the operation of the mind.

The term “danger” appeared for the first time in Freud’s writings in an article entitled “On the Grounds for Detaching a Particular Syndrome from Neurasthenia under the Description ‘Anxiety Neurosis’” (1895b [1894]). Freud used it to define an external situation likely to provoke emotional and structural reactions. The danger forces the psychic apparatus to ensure the stability of its organization by implementing defensive measures intended to avoid a catastrophic disturbance (psychic trauma).

There are two dimensions to the concept: (1) In terms of clinical treatment and theory, it implies the

existence of two spaces, an external space with its own reality and an internal space that is part of what Freud named psychic reality (related to the later concept of reality-testing). (2) It entails the need to consider temporal differences, quantitative aspects, and specific effects. “Danger” refers to a situation that may have been accidental or contingent, consciously experienced, or unconscious.

This picture was later refined in Freud’s work, but it retained its initial features. Situations involving danger came to be viewed as more internalized and more specific: the dangers of separation and object-loss, of castration, of uncontrollable drives, of threats from an internal object. With the development of the second theory of anxiety, the concept of danger became more ambiguous, almost completely identified with the anxiety that signaled its presence. However, it is essential to distinguish clearly between the affects of anxiety (*Angst*), fright (*Schreck*), and fear (*Furcht*), each of which reflects a specific relationship to danger.

The notion of danger still has to be used with caution, especially in view of the inevitable and necessary evolution of psychoanalytic language, which now emphasizes psychic envelopes, the therapeutic setting, or a topography of “interfaces” rather than the older metapsychological models. There is also a risk of confusion with concepts from cognitive psychology and neurobiology (such as the concept of “stress,” for example).

CLAUDE BARROIS

## DARK CONTINENT

In *The Question of Lay Analysis* (1926e), Freud wrote, “We know less about the sexual life of little girls than of boys. But we need not feel ashamed of this distinction; after all, the sexual life of adult women is a ‘dark continent’ for psychology” (p. 212). The evocative phrase *dark continent* connotes a geographic space that is murky and deep, one that defies understanding. Freud borrowed the expression from the African explorer John Rowlands Stanley’s description of the exploration of a dark forest—virgin, hostile, impenetrable. By using this phrase and comparing the adult woman’s sexual life to an unknown continent, Freud indicates both his embarrassment as well as his explorer’s curiosity. He also emphasizes the obscure and incomplete nature of the clinical material on the sexual life of girls and women for the psychoanalyst. His metaphor for the female sex turns it into an unrepresentable enigma, expressing the castration anxiety of the man who approaches it. For although he insists on the central idea constituting his theory of female sexuality—namely, the primitive masculinity of the little girl, who is a little man before she changes objects and wishes to acquire a child from her father—Freud does have doubts about his theory.

If we consider his statements about female sexuality, a theory that was never really explained in a comprehensive manner, we see that Freud is close to being his most severe critic. In 1923, the year his most specific statements about female sexuality appeared, he presented, in “Infantile Genital Organization,” his thesis of the primacy of the phallus: “For both sexes, only one genital, namely the male one comes into account. What is present, therefore, is not a primacy of the genitals, but a primacy of the *phallus*.” He immediately adds, “Unfortunately we can describe this state of things only as it affects the male child; the corresponding processes in the little girl are not known to us” (1923e, p. 142).

However, Freud himself attempts to illuminate the darkness of the continent. For he discovers that for the little girl, the mother, who first provides care for the child, is the object of an especially intense and long-lasting cathexis. This archaic bond between mother and daughter, which psychoanalytic theory would later describe as one of primary homosexuality, is compared by Freud to Minoan-Mycenaean civilization, which had been hidden for so long by Athenian

civilization. Freud also insists on the function of the phallus for the woman. The phallus—not to be confused with the penis—is understood to represent the paternal function and the capacity for symbolization in all human beings. These ideas were further developed by Jacques Lacan and his school.

In Freud’s writing on femininity, a rigorous, sometimes even dogmatic, conceptualization always shares space with a sense of perplexity. But the invisibility of the female sex, its internal nature, a multiplicity of theories have been offered. Research by Freud’s disciples, such as Ernest Jones and Karen Horney, exposed new fields of exploration that are rich and heteroclit. Female psychoanalysts deepened the investigation of the female Oedipus and the young girl’s relationship to the phallic phase (Janine Chasseguet-Smirgel). Following Lacan, important work was done (Michèle Montrelay) on the “other” *jouissance*, which functions centrifugally in women, unlike the centripetal *jouissance* found in men. Influenced by the philosopher Jacques Derrida, there has also been important work on the feminine and the unrepresentable (Luce Irigaray). Finally, analysis of the female Oedipus resumed and was seen to consist of two phases (maternal object and paternal object, sensoriality and language) that constitute the basis of female bisexuality (Julia Kristeva).

## DARWIN, DARWINISM, AND PSYCHOANALYSIS

In 1859, when Charles Darwin published *The Origin of Species*, Sigmund Freud was three years old. As a young student and later, during his early years as a dedicated scientific researcher, Freud greatly admired Darwin, who had gained considerable popularity throughout Europe. In his *Autobiographical Study*, Freud would recall that “Darwin’s doctrine, then in vogue, was a powerful attraction, since it promised to provide an extraordinary thrust to understanding the universe” (1925d). From then on Darwin joined Hannibal in Freud’s personal pantheon and he dreamed of becoming his equal. In “A Difficulty in the Path of Psycho-Analysis,” he described the three wounds inflicted on humanity’s pride: when Copernicus established that the earth was not the center of the universe, when Darwin proved that mankind developed in an unbroken line from other animal species, and when he, Freud, showed that man did not have control over the most important aspects of his own mental processes (1917a).

Freud cites Darwin at least twenty times in his published writings. It is possible, however, to identify three “Darwins” in Freud’s work:

The first Darwin is the Darwin of *The Expression of the Emotions in Man and Animals* (1872), referred to by Freud in the *Studies on Hysteria* (1895d), where Darwin is cited in connection with Emmy von N. and Elisabeth von R. Freud writes that Emmy von N.’s symptoms remind him “of one of the principles laid claim to by Darwin to explain the expression of the emotions—the principle of the overflow of excitation.” In describing Elisabeth von R., Freud emphasizes the symbolic meaning of her symptoms, which, he writes, “are part of the ‘expression of the emotional movements,’ as Darwin has taught.” Consisting “originally of acts that are well-motivated and appropriate,”

civilization has reduced and symbolically transposed the expressions into language.

This sort of reference occurs several times, especially in *Inhibitions, Symptoms, and Anxiety* (1926d), where the affects are “reproductions of earlier events of vital importance, possibly preindividual.” Adaptation is involved since “anxiety must fulfill the biologically essential function of reacting to a state of danger.” We can, therefore, consider the theory of anxiety presented in this work to be of Darwinian origin. Emotion (anxiety) is adaptive in two ways, for it prepares the animal for danger not just by mobilizing energy but also by aiding adjustment based on the nature of the threat (signal anxiety). However—and this too is taken from Darwin—under certain conditions the excess excitation can become disorganizing and non-adaptive.

The second Darwin is the Darwin of *The Origin of Species* (1859). This is the influence that is most often noted. It is used to support Freud’s views when he postulates a correspondence between phylogenesis (humanity’s evolution since its origins) and ontogenesis (the individual development of the child of today). Freud refers to Ernest Haeckel’s hypothesis according to which ontogenesis repeats phylogenesis. Freud writes, “Important biological analogies have enabled us to acknowledge that individual psychic evolution repeats, in abbreviated form, the evolution of humanity” (1910c). In “From the History of an Infantile Neurosis” (1918b), he writes, “The phylogenetic schemas that the child possesses at birth . . . are the precipitates of the history of human civilization . . . this instinctive heritage would constitute the core of the unconscious.”

This idea is central to *Totem and Taboo* (1912–13a), where it is used to establish the universality of primal fantasies, the Oedipus complex, and more generally the processes of development and human mentation. It occurs again in “A Phylogenetic Fantasy: Overview of the Transference Neuroses” (1985 [1915]), where the “prehistoric fantasy” (the expression is Freud’s) is used to establish a correspondence between three kinds of time: the time of the assumed succession of psychopathologies, that of phylogenesis, and that of ontogenesis.

Freud’s views were sharply criticized, even within psychoanalysis, for a variety of reasons, among them the questionable nature of the anthropological data on

which they were based and the impossibility of accepting Haeckel's hypothesis.

It is worth noting that in these texts (especially in the "Overview") Freud is more Lamarckian than Darwinian: it is essential to his theory that individual traits be transmissible by incorporation into the genetic heritage. Freud never abandoned this postulate in spite of the discredit that befell Lamarck's ideas.

The third and final Darwin is the Darwin of *The Descent of Man* (1871), a work that postulated a process of continuous evolution from animal to man and distinguished stages within human evolution, that is, a temporal sequence that was also a form of progress, a hierarchy ranging from the most primitive forms to the most noble: lower animals, higher animals, the "savage," civilized man. Darwin distinguished between "inferior" human races and "superior" races, even superior nations (such as Great Britain). Like many others at the time, Freud accepted these ideas and used them to support his views on the progress of civilization through the difficult, but necessary, repression of instinctual drives, a repression that made necessary the phenomenon of sublimation, which directed these energies to more "noble" ends.

This notion of the evolution of civilizations remains a source of continued interest. However, we can obviously no longer adhere to the idea of a hierarchy of values among human "races" that would "naturally" follow from the process of evolution as described by Darwin. And we know only too well what excesses and crimes "social Darwinism" can lead to. Nor is it any longer possible to postulate, as Freud once did, an equivalence between prehistoric humanity, or "primitive peoples" of today, and the child.

## **DAY'S RESIDUES**

According to Freud's theory of dreams, day's residues are memory traces left by the events and psychic processes of the waking state; they are used as raw material by the dream-work that serves the wishes of the dreamer.

This idea is much in evidence in Freud's *The Interpretation of Dreams* (1900), and is consonant with his basic thesis that all dreams are wish-fulfillments. With the help of the relaxation of the defenses that sleep allows, unsatisfied wishes of waking life work their way to a fulfillment that is described as "hallucinatory," because though invested with an illusory reality, it is cut off from both perception and motricity.

This permeability of the censorship permits explicit daytime wishes to be represented in dreams. It may still oppose their expression in an overly crude form. However, the distorting mechanisms characteristic of the primary processes then come into play: condensation, displacement, and putting into images, or "representability." The mechanism of displacement lets the dream-work use the day's residues for the purpose of wish-fulfillment by producing innocent-seeming representations: whence the dreamer's impression, upon awakening, of details that are trivial, if not meaningless. An acceptable meaning may emerge, however, when secondary revision comes into play, giving the dream an intelligible "facade" and thus in fact perfecting the distortion.

The day's residues, perhaps in combination with sensory impressions occurring during sleep, constitute the "raw material" that will be reworked by the dream. Here Freud used the metaphor of work performed in the construction industry: daytime thoughts and the work to which they were subjected played the role of the contractor, while the unconscious wish was

comparable to the capitalist who finances the operation (furnishing its plan and the power for it).

Freud extended and rounded out this account in “A Metaphysical Supplement to the Theory of Dreams” (1916–1917f [1915]), notably from a topographical angle. He argued that the day’s residues are part of the preconscious, but receive the full cathexis necessary for the dream-work from the unconscious. He returned to this group of hypotheses in the *Introductory Lectures on Psychoanalysis* (1916–1917 [1915–1917]).

Thereafter, the question of day’s residues was paid scant attention by Freud, but inasmuch as the notion has a bearing on perception, memory, reality testing, hallucination, and other issues, it remains central. Meanwhile, psychoanalytic technique and practice continue to make use of it on a daily basis.

## **DEAD MOTHER COMPLEX**

The complex of the dead mother was described by André Green in 1980. Evidence of it emerges during the transference, so it is often not identifiable when analysis is first requested. It is manifested especially by a “transference depression,” a repetition of an infantile

depression that is often not capable of being recalled. The essential characteristic of this depression is that it occurs in the presence of an object that itself is absorbed in mourning. The causes of this mourning can be many, and are not admitted by the maternal object. They are therefore, for the most part, hypothetically deduced through the analysis, with more or less certainty.

The main observable consequence on the level of the counter-transference is insight into a cold, hard, unfeeling kernel at the heart of the transference. This is the result of a brutal maternal decathexis that the child is unable to understand and that turns his psychic world upside down. After vain attempts at reparation, feelings of impotence became dominant. Complex defenses are then set up which associate a mirror-representation of the disinvestment in the maternal object with an unconscious identification with the dead mother. The result of this is the psychic murder of the object, which takes place without any hatred. The maternal affliction prohibits any aggressive expression, which would risk augmenting the maternal detachment. On the one hand, the pattern of object relations is punctured, while on the other, peripheral cathexes are clung to at the edge of this hole. Silent destructiveness does not allow the subject to reestablish an object relation capable of overcoming the conflict and opening the way to connections that would strengthen it, or else definitive adjustments serve only as a shield that prevents access to the kernel of the conflict. The only thing that endures is a dull psychic pain, characterized especially by an incapacity to cathect closely with any object having anything to do with affects. Hatred is as impossible as love, and it is impossible to receive without feeling obliged to give back, so as not to owe anything, even masochistic pleasure. The dead mother is omnipresent, but without being represented, and seems to have seized the subject, making him captive of his mourning for her.

This clinical picture develops against the background of the child’s inability to grasp the reasons for it. Important measures of infantile depression are the loss of meaning, and the feeling of inability to repair the mourned object, to awaken the lost desire. Sometimes significant rationalizations displace the source of the conflict onto the external world, the mother’s desire becoming inaccessible compared to what the child believes he has observed. The child then blames a failure of subjective omnipotence in relationships,

leading, by compensation, to a reinforcement of omnipotence in areas less directly connected with the primary object.

An oedipal analysis of pregenital fixations and unconscious guilt is of no use in finding a way to move past this situation, insofar as analysis is not centered on the configuration of the complex of the dead mother. For the mother is not directly identifiable in the discourse of the patient. She only appears to the extent that the analytic situation succeeds in drawing out evidence of her silent presence without being able to find her in this absence where even indirect signs of her existence are missing.

Repression has erased the memory trace of her touch, of contact with her, and of the child's cathexis with her before the occurrence of his mourning for her, which put a sudden end to this forgotten relation. This is a repression that returns to bury her alive, even demolishing everything, including a tomb, that would mark her past existence. Winnicottian holding has collapsed in this situation, because the object has been encysted, with no trace of it left. The identification has been with the vacuum left behind by the disinvestment. The absence of all meaningful reference points cannot be too strongly emphasized. Since the modification of the maternal attitude seemed to be inexplicable, it led in turn to all sorts of questions which arouse a feeling of guilt, and these in turn are aggravated by secondary defenses and displaced onto elements that have been annexed for that purpose.

In effect, attempts to block problems not governed by repression of this untenable situation prompt some significant reactions. Their purposes are: (1) To keep the ego alive through secondary hatred of the object, by the frenetic, but unquenchable, search for pleasures, or through the headlong search for a possible meaning to the displacements that have been made; (2) To reanimate the dead mother, interest her, distract her, seduce her, give her back the taste for life, breathing into her by any means possible, including the most artificial, a joy of being alive; and (3) To compete with the object of mourning in a precocious triangulation.

The dead mother complex, as a powerful and intense element, naturally draws to it other components of psychic life, and is closely tied to its most important systems. Consequently the fantasy of the primal scene attempts to make intelligible the competitive relations with the hypothetical object of sudden mourning, and to reawaken the pain of being de-

cathected, by highlighting whatever recalls the primal scene, and often in an apocalyptic way, through projective identification. The catastrophe thus envelops and retaliates against the maternal object, which shifts between indifference and terror. It is frequently the case that the father is the object of a precocious investment in an Oedipus complex that is rushed into for this very occasion, but lacking in its normal attributes. This variant complex brings with it not so much castration anxiety, but a feeling of impotent rage and paralysis, helpless against the violence that follows action against a supposed rival. The result is often an intensified feeling of emptiness, repeating and amplifying the most deleterious effects at the heart of the conflict.

On the bases of these clinical observations, André Green hypothesized a destiny of the primary object as a framing structure for the ego, hiding the negative hallucination of the mother. The dead mother complex demonstrates the failure of this process, forcing its representations into a painful vacuity, and obstructing their capacity to bind together in any preconscious thought pattern. The dead mother complex opposes a "hot" castration anxiety, linked to the vicissitudes of object relations, which can be threatened with corporal mutilation, to a "cold" anxiety, which is linked with losses suffered on the narcissistic level (negative hallucination, flat psychosis, dull mourning), resulting in the clinical treatment of negativity.

## **DEATH AND PSYCHOANALYSIS**

Our own death cannot be represented, which is obvious since it would require a self-observing consciousness that disappears with death and therefore cannot perceive the death. Any anticipation of our own death as nothingness is therefore impossible. For

Freud, this philosophical evidence was reflected in his remarks that “our unconscious . . . does not believe in its own death; it behaves as if it were immortal” (1915b, p. 296) and “it is indeed impossible to imagine our own death; and whenever we attempt to do so we can perceive that we are in fact still present as spectators” (1915b, p. 289). These two propositions should not be confused. The second is a logical statement, since in the absence of existence there is no consciousness, while the first refers to the make-up of the unconscious system and especially the fact that it ignores time and its passage, and more radically, negation.

The inability to represent one’s own death does not imply that we fail to suffer about the certainty of death. Anxiety about death occupies a central place in our lives, and ultimately it is this that superego anxiety and castration anxiety refer to. Moreover, death is represented in dreams and symbols. Departures and muteness, or the ability to hide from others are oneiric representations of death. Among the typical dream types Freud mentions in *The Interpretation of Dreams* (1900a) is the dream of the death of loved ones.

Perception about the death of the other is a central element in obsessive neurotics. Freud wrote, “these neurotics need the help of the possibility of death chiefly in order that it may act as a solution of conflicts they have left unsolved” (1909d, p. 236). By suppressing an element of indecision, death would allow resolution, but death, and the possibility of escaping it through superstitious magical activities, is associated with their unconscious hatred in the conflict of ambivalence. The idea of death offers a solution in obsessive neurosis, but it is also, for everyone, a value that, by establishing a contrast, exalts the value of life. Freud demonstrates this in relation to transience (1916a [1915]), but he also emphasizes it in relation to the risk of death: “Life is impoverished, it loses in interest, when the highest stake in the game of living, life itself, may not be risked” (1915b, p. 290).

Beyond the impossible representation of one’s own demise, there is the question of death as enigma, similar to birth, as the end mirrors the beginning. Freud questions primitive man’s attitude to death (1912–1913a) by distinguishing between the triumph before the corpse of the enemy and the pain experienced in the loss of a loved one. Certainly, in these cases identification could lead primitive man to also consider his own death. But Freud introduced an additional idea,

that of the ambivalence that would lead to suffering and relief, and considered it to be the root not of the representation of death but of the fact that the disturbance caused by it might have led men to think: “What released the spirit of enquiry in man was not the intellectual enigma, and not every death, but the conflict of feeling at the death of loved yet alien and hated persons” (1915b, 293).

As for children, Freud also felt that the origin of the activity, if not of thought, at least of research, was found in the desire for affection (preserving the love of one’s parents without sharing it with younger siblings). In contrast he does not appear to have considered that for children the representation of death and, in particular, their own death, might have constituted an enigma and encouragement for reflection. “Children”, he wrote, “know nothing of the horrors of corruption, of freezing in the ice-cold grave, of the terrors of eternal nothingness—ideas which grown-up people find it so hard to tolerate, as is proved by all the myths of a future life” (1900a, p. 254). On the contrary, we can consider that the theories, or myths, that the child creates to explain the origin of life also treat its end, and that both preoccupations are inseparable.

These theories raise the question of the causality of death. We know that the adult, rather than seeing death as an inevitable destiny, will consider the immediate causes, or even look for those responsible (1915b). The child, in a similar position, does not hesitate to make death the result of murder. For here the relationship to death retains its original form, that is, the impulse to kill repressed by an important moral injunction, “Thou shalt not kill.” However, there is one area where this impulse can be given free rein: literary fiction, which provides the pleasure of remaining alive and the certainty that we have not killed anyone. “In the realm of fiction we find the plurality of lives which we need” (1915b, p. 291). The fact that so-called “crime” writing has always enjoyed such success attests, as surely as the existence of a moral imperative, to the existence and persistence of this impulse to murder and the enigma contained in this return to death, here couched in playful terms (Mijolla-Mellor, 1995).

**DEATH DRIVE.** See *Death instinct (Thanatos)*

---

## **DEATH INSTINCT (THANATOS)**

The death instinct or death drive is the force that makes living creatures strive for an inorganic state. It does not appear in isolation; its effect becomes apparent, in particular through the repetition compulsions, when a part of it is connected with Eros. Its tendency to return living creatures to the earlier inorganic state is a component of all the drives. In this combined form, its main impetus is toward dissolution, unbinding, and dissociation. In its pure form, silent within the psychic apparatus, it is subjugated by the libido to some extent and thus deflected to the outside world through the musculature in the drive for destruction and mastery or the will to power: this is sadism proper; the part that remains “inside” is primary erogenous masochism.

Having put forward, particularly in “Instincts and Their Vicissitudes” (1915c), a dualism in which the sexual drives conflict with the ego drives, in *Beyond the Pleasure Principle* (1920g), Freud introduced the concept of the death drive as a negative term in opposition

to the life drive: “The opposition between the ego or death instincts and the sexual or life instincts would then cease to hold and the compulsion to repeat would no longer possess the importance we have ascribed to it” (p. 44).

The death instinct was Freud’s attempt to explain this repetition compulsion that overrides the pleasure principle, whether in post-traumatic dreams, certain compulsive children’s games (such as the “fort-da” game), or indeed in analysts’ resistances to the treatment (the transference). He observed that “*the aim of all life is death*,” “*inanimate things existed before living ones*” and that “*everything living dies for internal reasons*” (p. 38). Drawing on August Weismann’s differentiation of soma from germ-plasma, Freud went on to draw “a sharp distinction between ego-instincts, which we equated with death instincts, and sexual instincts, which we equated with life instincts” (pp. 52–53). He thus continued to adhere to the dualistic concept of the drives: “even more definitely dualistic than before—now that we describe the opposition as being not between ego instincts and sexual instincts but between life instincts and death instincts” (p. 53).

Freud found support for his arguments in Fechner’s stability principle: “The dominating tendency of mental life . . . is the effort to reduce, to keep constant or to remove internal tension due to stimuli . . . a tendency which finds expression in the pleasure principle; and our recognition of this fact is one of our strongest reasons for believing in the existence of death instincts” (p. 55–56).

In 1924, Freud drew a clear distinction between three principles: “The Nirvana principle [Barbara Low’s term], belonging as it does to the death instinct, has undergone a modification in living organisms through which it has become the pleasure principle . . . the *pleasure* principle represents the demands of the libido; and the modification of the latter principle, the *reality* principle, represents the influence of the external world” (1924c, p. 160). Although Freud recognized the speculative nature of his final drive theory, he continued to adhere to it throughout the rest of his work.

The source of the death drive lies in the cathexis of bodily zones that can generate afferent excitations for the psyche then; this certainly involves tension in the musculature determined by a biological urge. Its locus is in the id, then later under the influence of

the ego, as well as in the superego, where it functions to restrict libidization. In melancholia, “a pure culture of the death instinct” (1923b, p. 53) governs the superego, such that the ego can impel the subject towards death.

The energy of this urge is fairly resistant to shaping, diversion, or displacement and it manifests in subtle but powerful ways. The operation of this almost invisible energy has been described as a “work of the negative” (André Green). Its object is the implementing organ—the musculature—that enables the aim to be fulfilled. Paradoxically, the libido, subject to restraint by the *destrudo* (Edoardo Weiss’s term), and leading to primary masochism and sadism, is the object of the death drive here. According to Freud’s descriptions, its goal is dissociation, regression, or even dissolution. While leading organic life back to an inorganic state is the final stage, “the purpose of the death drive is to fulfil as far as is possible a *disobjectalising function* by means of unbinding” (Green, p. 85). It is therefore an entropic process in the strict sense.

After explaining the notion of the death instinct in *Beyond the Pleasure Principle*, Freud returned to it a number of times in his later works. He mentioned it in *Group Psychology and the Analysis of the Ego* (1921c) as the source of aggression and hostility between people and in “The Libido Theory” (1923a), and then developed the theory in *The Ego and the Id* (1923b), especially in the chapters on “the two classes of instincts” and “the dependent relationships of the ego.” In this work, he connected his new drive theory with the structural theory that he had just expounded.

Then, following a dispute with Fritz Wittels, who jumped to a hasty conclusion concerning a connection between the death of Freud’s daughter Sophie (January 1920) and the emergence of the concept of the death drive (a claim that is still being debated today—cf. Grubrich-Simitis), Freud returned to this concept in “The Economic Problem of Masochism” (1924c), in which he posited primary masochism both as evidence and as a vestige of the conjunction between the death drive and Eros. He thus elucidated the negative therapeutic reaction and the concept of unconscious guilt and indicated that “moral masochism becomes a classical piece of evidence for the existence of fusion of instinct. Its danger lies in the fact that it originates from the death instinct and corresponds to the part of

that instinct which has escaped being turned outwards as an instinct of destruction” (p. 170).

In his short article on “Negation” (1925h), Freud explained: “Affirmation—as a substitute for uniting—belongs to Eros; negation—the successor to expulsion—belongs to the instinct of destruction” (p. 239). He returned to this subject in *Civilization and Its Discontents* (1930a [1929]), in his letter to Albert Einstein (1933b [1932]) and finally in the thirty-second of the *New Introductory Lectures* (1933a [1932]), in which he discussed anxiety in connection with the life of the drives.

For Melanie Klein, a firm advocate of the existence of the death drive, psychic conflict is never a conflict between the ego and the drives but always between the life drive and the death drive. Anxiety is the immediate response to the endopsychic perception of the death drive. For Jacques Lacan, the death drive as something beyond the pleasure principle forms the best starting-point for introducing his concept of the “Real,” in connection with the Imaginary and the Symbolic. He links to this the lethal dimension inherent in desire and *jouissance* and makes the death drive “the necessary condition for the natural phenomenon of the instinct in entropy to be taken up at the level of the person, so that it may take on the value of an oriented instinct and is significant for the system insofar as the latter as a whole is situated in an ethical dimension” (1959–1960/1992, p. 204).

Toward the end of his life, Freud recognized that “the dualistic theory according to which an instinct of death or of destruction or aggression claims equal rights as a partner with Eros as manifested in the libido, has found little sympathy and has not really been accepted even among psychoanalysts” (1937, p. 244). Its detractors include authors such as Michel Fain (1971), who regard the concept of the death drive as the result of Freud’s speculations on matters that could for the most part be explained without it—for example by the mechanism of “reversal into its opposite” (1915c, p. 126). Others have objected to the theory of the death drive either because this would mean that psychic conflict, the cornerstone of psychoanalysis, could no longer be the expression of lived experience alone, since the death drive is “evidently innate, intrapsychic from the outset, and not secondarily internalized” (Nacht), or because “this drive restricts the field in which conflicts can be elaborated both internally and externally; it introduces a fatalism into

the gradual progression of the treatment and brings out the negative therapeutic reaction instead of a relational problem between analyst and analysand” (Nicolaidis). Yet others have taken more interest in Freud’s methodology and are surprised at the “quality of a foreign body—within psychoanalytic theory—that characterizes the conflict between Eros and the death drive [which] emerges here from the use of dialectical procedures in which Freud is not well versed” (Denis).

By contrast, other authors, such as Melanie Klein, Jacques Lacan, and André Green, consider this concept of the death drive as further evidence of Freud’s scientific rigor, as he demonstrates his willingness to rework his previous drive theory to take account of clinical facts and hypotheses that do not accord with it. Furthermore, studies based on the treatment of psychotic subjects, particularly by post-Kleinians, seem to have reinforced the theory of the prevalence of the death drive in the psychic apparatus of these patients, as something that constantly tears at the fabric of their representations and undermines their attempts to establish an apparatus for thinking thoughts (Wilfred Bion).

## DECATHEXIS

Decathexis describes both the action and the result of withdrawing psychic energy—usually libido—away

from where it had been attached to a psychic formation, a bodily phenomenon, or an object.

The idea of decathexis, or withdrawal of cathexis, is linked to the notion of psychic energy and occurs very early on in Freud's work, although the term itself or its equivalents are not explicitly used. As early as "The Neuro-Psychoses of Defence" (1894a), Freud outlines certain mechanisms for repressing representations when he writes that we have "an approximate fulfillment of the task if the ego succeeds in *turning this powerful idea into a weak one*, in robbing it of the affect—the sum of excitation—with which it is loaded" (1894a, p. 48). In fact the notion of decathexis first appears as a means of repression in his work on the paranoia of Justice Schreber: "It is quite possible that a detachment of the libido is the essential and regular mechanism of every repression" (1911c [1910], p. 71). But the important role eventually attributed to energy in the very constitution of the psyche would make decathexis a central notion, independent of the mechanism of repression. The nature of decathected mental structures or objects, the more or less massive modalities of the decathexis, and the fate of the withdrawn energy, all would have serious consequences. As Freud writes: "the liberated libido will be kept in suspension within his mind, and will there give rise to tensions and color his mood" (1911c [1910], p. 72), until it finds another attachment. In the case of paranoia it will hypercathect the ego. In "Mourning and Melancholia" (1916–17f [1915]), Freud studied the progressive withdrawal of cathexis from the lost object, this being necessary for the reality of loss to be finally acceptable.

## **DEFENSE**

The term "defense" refers to all the techniques deployed by the ego in conflicts that have the potential to lead to neurosis. In the sense in which Freud first used the term, defenses are unconscious because they stem from a conflict between the drive and the ego or between a perception or representation (memory, fantasy, etc.) and moral imperatives. The function of the defenses is thus to support and maintain a state of psychic stability by avoiding anxiety and unpleasure. The concept of defense was broadened somewhat when Freud attributed an important role to the reality principle and to the superego. Melanie Klein then formed the more radical view that the defenses exist within an archaic ego.

In his letter to Wilhelm Fliess dated May 21, 1894, and concerning his interpretation of the neuroses, Freud introduced the concept of defense in connection with the notion of psychic conflict: "What is warded off is always sexuality" (1985c [1887–1904], p. 75). In reference to the emergence of anxiety, he argued that sexual tension turned into anxiety when it was not psychically elaborated and thereby transformed into affect. Freud attributed this phenomenon to, among other things, a repression of psychic sexuality, that is, to a defense. In his letter to Fliess dated May 30, 1896, he linked repression with defense by emphasizing, "Surplus of sexuality alone is not enough to cause repression; the cooperation of *defense* is necessary" (p. 188).

In "Further Remarks on the Neuro-psychoses of Defence" (1896b), Freud deepened his analysis of defense as arising from the conflict between the drive and the ego, the conscious agent of repression. Freud considered the defense as the "nuclear point" (p. 162) in the psychic mechanism of the neuroses. With regard to how symptoms arise, he detailed more clearly how

the unconscious psychic mechanism of defense resulted from the conflict of a representation with moral imperatives.

In “Repression” (1915d), Freud emphasized that the mechanism of defense “cannot arise until a sharp cleavage has occurred between conscious and unconscious mental activity—that *the essence of repression lies simply in turning something away, and keeping it at a distance, from the conscious*” (p. 147).

Much later (1926d), Freud observed that after he had abandoned the term “defensive process” for thirty years and replaced it with the term “repression” (without clearly explaining the possible connection between these two concepts) (p. 163), there were “good enough grounds for re-introducing the old concept of *defence*” (p. 164). In fact, Freud had never entirely abandoned the term, since he discussed the denial of castration (albeit initially without using the term “denial” [*Verleugnung*]) in relation to children’s theories of sexuality (1908c) and little Hans (1909b). Freud discussed denial more explicitly with regard to fetishism (1927e), a concept that plays a pivotal role in his work, and in his paper on negation (1925h), which he defined as representing “a kind of intellectual acceptance of the repressed, while at the same time what is essential to the repression persists” (p. 236). Thus, “the content of a repressed image or idea can make its way into consciousness, on condition that it is *negated*” (p. 235). Freud also discussed sublimation, a concept that was already present in “Leonardo da Vinci and a memory of his childhood” (1910c) and that reappeared in *The Ego and the Id* (1923b) in connection with the ego energy, which Freud stipulated as involving “a desexualisation—a kind of sublimation” (p. 30).

These distinctions, which predate *Inhibitions, Symptoms, and Anxiety* (1926d), were later probably instrumental in Freud’s ascribing a more important function to this “old concept of *defence*” and restricting the role of repression, to the extent that he suggested making defense “a general designation for all the techniques which the ego makes use of in conflicts which may lead to a neurosis, while we retain the word ‘repression’ for the special method of defence which the line of approach taken by our investigations made us better acquainted with in the first instance” (p. 163).

In furthering her father’s work, Anna Freud sought to develop a theory that would demonstrate how the

three agencies of the structural theory functioned. In particular, she described how the ego becomes “suspicious” in the face of the onslaught of the drives and “proceeds to counter-attack and to invade the territory of the id. Its purpose is to put the instincts permanently out of action by means of appropriate defensive measures, designed to secure its own boundaries” (1936, p. 8). Thus, Anna Freud’s account of psychic functioning attributes some force to the adaptive functions of the ego.

Her works were often quoted by the ego-psychology movement that formed in the 1950s in the United States. Within the ego-psychology movement, Heinz Hartmann developed his theory of the ego in connection with the problem of adaptation, which he described in terms of the development of a “conflict-free ego sphere” (1958, p. 3) or autonomous ego. In this movement, psychic functioning in general is considered in terms of defense and its quest for equilibrium.

Along similar lines, René Spitz, who located the first defense in the emergence of the second organizer (the so-called eight-month or stranger anxiety), explained that these defenses initially “serve primarily adaptation rather than defense in the strict sense of the term” (p. 164). It is when the object is established and ideation starts that their function changes. With the fusion of the aggressive and libidinal drives, some defense mechanisms, in particular identification, “acquire the function that they will serve in the adult” (p. 164).

When Anna Freud was publishing her first psychoanalytic works, Melanie Klein, while breaking with Freudian orthodoxy by asserting that the agencies of the psyche begin functioning much earlier, introduced a perspective that restored to anxiety and psychic conflict a fundamental role in psychic functioning. Drawing on Freud’s second theory of the drives, she attributed a central role to the death drive and the conflicts between love and hatred. She thus developed her ideas on early defense mechanisms that were already present, in her view, in the earliest months of life during the paranoid-schizoid position.

The concept of defense, as it has developed and been used since Freud, has become somewhat common in both clinical psychology and psychoanalysis. There it refers either to a relatively conscious behavior that rejects psychic reality (a definition that makes the

concept more akin to the concept of resistance) or to a psychic impulse that seeks to avoid anxiety and unpleasure in the quest to adapt and achieve a state of equilibrium. As a result, the function of defense as a mechanism necessary for psychic growth is often overlooked.

## DEFENSE MECHANISMS

Defense mechanisms are psychic processes that are generally attributed to the organized ego. They organize and maintain optimal psychic conditions in a way that helps the subject's ego both to confront and avoid anxiety and psychic disturbance. They are therefore among the attempts to work through psychic conflict but if they are deployed in an excessive or inappropriate way they can compromise psychic growth.

There is no clear distinction in Sigmund Freud's work between a defense and a defense mechanism, (the latter referring to the unconscious processes by which the defense operates). The concept of defense first appeared in his article “The Neuro-Psychoses of Defence” (1894a) and was next discussed in “Further Remarks on the Neuro-Psychoses of Defence” (1896b) and “The Aetiology of Hysteria” (1896c). Finally, in the text entitled “Instincts and their Vicissitudes” (1915c), turning against the self and reversal into the opposite were identified as defense mechanisms, in addition to repression and sublimation.

For Freud, the concept of defense refers to the ego's attempts at psychic transformation in response to representations and affects that are painful, intolerable, or unacceptable.

He abandoned the concept of defense for a period in favor of the concept of repression. He then reintroduced it in “Neurotic Mechanisms in Jealousy, Paranoia and Homosexuality” (1922b [1921]). Freud

ascribed a defensive significance to introjection (or identification) and projection by terming them all “neurotic mechanisms.” Then in an addendum to *Inhibitions, Symptoms and Anxiety* (1926d [1925]), he reconsidered this concept in relation to that of repression, suggesting that: “It will be an undoubted advantage, I think, to revert to the old concept of ‘defence,’ provided we employ it explicitly as a general designation for all the techniques which the ego makes use of in conflicts which may lead to a neurosis, while we retain the word ‘repression’ for the special method of defense which the line of approach taken by our investigations made us better acquainted with in the first instance” (p. 163). Freud added that: “further investigations may show that there is an intimate connection between special forms of defense and particular illnesses, as, for instance, between repression and hysteria” (p. 164). By this he meant, more specifically, that the ego protects itself against the tendency towards conflict by means of a counter-cathexis. It was this counter-cathexis that came to represent the supreme essence of the defense mechanisms.

This idea was taken up by Heinz Hartmann (1950) in the context of his theory of the autonomous functions of the ego. He argued that once the energy of the counter-cathexis had been withdrawn from the tendency that caused the conflict, it was neutralized. For him, the autonomous processes (organization, cathexis, delay) can be the precursors of defense mechanisms. In general, neurotic defense mechanisms constitute an exaggeration or a distortion of regulating and adaptive mechanisms.

With strong support from the ego-psychology movement in her studies on ego functions, Anna Freud listed and described the ego’s defense mechanisms. For her, “every vicissitude to which the instincts are liable has its origin in some ego-activity. Were it not for the intervention of the ego or of those external forces which the ego represents, every instinct would know only one fate—that of gratification” (1937, p. 47). To the nine defense mechanisms that she identified: “regression, repression, reaction-formation, isolation, undoing, projection, introjection, turning against the self and reversal,” she suggested that, “we must add a tenth, which pertains rather to the study of the normal than to that of neurosis: sublimation, or displacement of instinctual aims” (p. 47).

Finally, for adherents of the Kleinian school, the defense mechanisms take a different form in a struc-

tured ego from the one they assume in a primitive, unstructured ego (or an undifferentiated id-ego). The defenses become modes of mental functioning. For Susan Isaacs (1948), all mental mechanisms are linked to fantasies, such as devouring, absorbing, or rejecting. Melanie Klein herself (1952, 1958) principally identified the following primitive defenses: splitting, idealization, projective identification and manic defenses.

The terms “defense” and “defense mechanism” are still used interchangeably today, which suggests a degree of confusion between a descriptive approach to the concept of defense and an approach based on the analysis of psychic adaptations from an economic viewpoint.

## **DEFERRED ACTION**

This notion is important to any understanding of the psychoanalytic conception of time. It implies a complex and reciprocal relationship between a significant

event and its later reinvestment with meaning, a reinvestment that lends it a new psychic efficacy.

It was the French reading and translation of Freud that brought out the import of “*nachträglich*” and “*Nachträglichkeit*,” terms which had not hitherto been consistently translated into either French or English.

The index of Freud’s *Gesammelte Werke* has no entry for either *nachträglich* or *Nachträglichkeit*, and perusal of the indexes of the works of Freud’s chief successors garners similarly negative results. It was Jacques Lacan who first drew attention to this notion, defining it in a precise if narrow way (1953, p. 48). Lacan did not consider the broader implications of the concept of *Nachträglichkeit* in Freud’s work, concerning himself solely with its occurrence in connection with the “Wolf Man” case (1918b [1914]) and ignoring its use in the 1895–1900 period. It fell to Jean-Bertrand Pontalis and Jean Laplanche to point up the overall importance of the concept, first in “Fantasy and the Origins of Sexuality” (1964) and then in *The Language of Psycho-Analysis* (1967).

First let us consider Freud’s view. He used the terms “*nachträglich*” and “*Nachträglichkeit*” over a good part of his working life—from the period, in fact, of his correspondence with Wilhelm Fliess, through *The Interpretation of Dreams* (1900a), “Little Hans” (1909b), the “Wolf Man” case, and even well beyond. It is thus possible to trace the development of this idea in the general context of his work. It never achieved sufficient conceptual substance, however, for Freud to dedicate an entire paper to it.

The earliest development of the notion may be seen in Freud’s letters to Fliess. The adjective “*nachträglich*,” part of German common usage, is employed by Freud in several ways. In the first place, it has the simple meaning of “additional” or “secondary”; and hence, in a temporal sense, of “later.” A second use implies movement from past time in the direction of the future, while a third implies the opposite, a movement from the future towards the past. The second use, meaning movement from past to future, is very much bound up with the seduction theory: it implies that something is deposited in the individual that will be reactivated later, thus becoming active only at a “second moment.” It is in this regard that the notion of *Nachträglichkeit* is closely correlated with another constant of Freudian thought, the idea that there are always two moments in the constitution of a psychic

trauma: that of the event which leaves its trace and that of the event’s later revival by an internal factor. It is thus easy to understand how the idea of afterwardsness emerged in parallel with the seduction theory, even if it survived the abandonment of that theory. It should be pointed out that for Freud the seduction theory did not contradict a determinism according to which the past governs the present.

Freud never thought that the temporal direction could be reversed. The analogy of a time-bomb serves well here: the initial memory is like a time-bomb set off by a delayed-action mechanism; there is no suggestion of retroactivity. On the other hand, there are a number of passages in Freud where the inverse process occurs, where things are perceived on the first occasion, then understood retroactively. Such passages are relatively few, however.

The fact is that whenever Freud had a choice between a deterministic account proceeding from the past towards the future and a retrospective or hermeneutic conception proceeding from the present in the direction of the past, he almost invariably opted for the former. Thus in his letter to Fliess of October 3, 1897, after recounting an episode in his self-analysis, he makes the following comment: “A severe critic might say of all this that it was retrogressively phantasied and not progressively determined. *Experimenta cruce*s would have to decide against him” (SE 3, p. 263).

So things are not simple. As much as we might wish to find in Freud a dual—perhaps even a contradictory—application of the concept of *Nachträglichkeit*, what we actually find is a highly deterministic one.

Much the same goes for Freud’s theoretical confrontation with Carl Jung: in defending his view of the reality of the “real” primal scene, Freud made a number of concessions but never wavered in his conviction that what comes before determines what comes after. The Freudian idea of *Nachträglichkeit* may by no means be conflated with the Jungian notion of *Zurückphantasieren* (retrospective fantasizing).

To what extent can the concept of afterwardsness enable us to transcend the alternative between, on the one hand, a determinist view that places the entire burden of psychic causality on events of the remotest past, and, on the other hand, a so-called hermeneutic, or even narrativist, approach that reverses the arrow of time, so to speak, and focuses on “resignifications,” or reinvestments with meaning, effected afterwards,

whether in life or during psychoanalytic treatment? When things are framed in this way, it seems impossible to resolve the polarity between childhood events, events pure and simple, and the moment when they are retrieved as meaning, within a history. Yet a way out of this cul-de-sac presents itself if we consider that the childhood event is itself pregnant with meaning—not on the psychophysiological level, but on the level of the interhuman relationship. Even if all our attention is focused on the retroactive temporal direction, it cannot be overlooked that when someone reinterprets their past, that past can never be strictly factual, cannot be a concrete, untransformed “given.” On the contrary, it must contain in immanent fashion something earlier still: a message from the other. A purely hermeneutic approach, meaning that each person interprets their past on the basis of their present, is therefore untenable, for, already deposited in the past, is something that cries out to be deciphered, namely a message from the other person.

Instead of considering only the bipolar temporal vector connecting the child with the adult that the child has become, we need to add a third term, external to the subject, which is the message emanating from the other adult, a message which is imposed on the child and which the child must translate. Indeed it is the idea of “translation” so understood that may be expected to cast a new light on the Freudian concept of *Nachträglichkeit*.

## **DEFERRED ACTION AND TRAUMA**

Freud called upon the notions of deferred action and of trauma to account for how time and causality are organized in a mental life that he conceived of as permeated by sexuality. He argued that an impression inconsequential on its face but unintegrated into the flow of life by reason of its sexual character left mnemonic traces that could be reactivated by later events in the history of the individual. Only then, retroactively, would it acquire a meaning capable of affecting psychic organization.

In his earliest thinking, Freud observed that certain childhood experiences left mnemonic traces of an active albeit unconscious nature. These operated like internal “foreign bodies,” and getting rid of them required that they be made conscious and “abreacted” (discharged by being revealed to the analyst). Such traces were always related to a seduction in early childhood that had not been fully comprehended at the time.

Freud quickly abandoned this theory and replaced it with that of “deferred action” (*Nachträglichkeit*), according to which the child first receives impressions that have an exciting effect, but not a traumatic one, for the child is still sexually undeveloped. When a particular experience occurring after puberty recalls

the earlier one by virtue of some resemblance, the individual reinterprets the early event, which thus acquires a force that it never had initially.

Before long, however, Freud discovered infantile sexuality and could then no longer ground deferred action in a sexual life that developed in two phases. He therefore stipulated that all childhood experiences left a residue, a mnemonic trace, which cried out to be reinterpreted and would be reinterpreted at a later time. This residue or trace always had a sexual character. Freud developed this theory in his account of the “wolf man” case (1918b [1914]). As a two-year-old child, the patient had witnessed his parents engaged in sex without experiencing anything more than an impression of strangeness; only at the age of four did he construct his primal-scene fantasy as a way of accounting for the original perception.

The theory of deferred action is one of the keys to Freud’s metapsychological system. It effectively addresses both the sexual nature of repressed memories and the manner in which time and memory work within the psyche. In Freud’s view, our past—our whole past from birth on—is responsible for what we later become, but there is a sense, too, in which what we become alters what we once were: the present transforms, translates, remolds a past that is still present in us. The individual has contact with the past at every instant of life, but is unable to apprehend that past, which is forever emerging only to be retranslated instantly into other terms.

The notion of deferred action must not, however, be confused with a cognitivist view of how memories are transformed. The cognitivist view sees memories as being reorganized and simplified in natural ways, like material objects moving away from an observer, for example. For psychoanalysis, each moment lived by an individual, if it has a sexual aspect, is experienced as enigmatic, as bearing a residue that poses a question. Such a moment may resonate with a past event with nothing special about it, save for an ever so slightly unsatisfactory and unexplained dimension, which the psyche now remobilizes as desire.

Like the unconscious, and like desire, deferred action is capable of utterly disrupting an individual’s spontaneously created idea of himself in relation to the outside world and to other people. For one, it explodes the notion of causality: not only is the indi-

vidual unable to relate his actions in life to his conscious will, not only is he always disappointed when he obtains what he thought he wanted, because his desire is never satisfied thereby, but also he can never succeed in explaining the present in terms of the past. What went before is never past: it is always present, always ungraspable, always needing to be worked through.

Deferred action is usually associated with trauma. The sight of cruelty can thus be traumatic if it reactivates an infantile sadistic occurrence dating from an early time when cruelty was not disturbing. Likewise, a rape may be traumatic if it revives an infantile sexual wish that was left pending and never erased. Deferred action is also closely tied to repression. If certain later experiences and wishes need to be repressed, it is because at the moment of their occurrence they acquire a strength out of proportion to the circumstances, for they are reinforced by the power of hitherto unassimilated past experiences. The representation of the object of desire then has to be repressed, because, between the first and the second experience, regulatory and prohibitory superstructures have been set up.

Psychoanalysts are divided on how much importance to give to the idea of deferred action. For some, this mechanism comes into play only during a second phase. They believe that some early infantile experiences are traumatizing in themselves and require the deployment of mechanisms more radical than repression, such as splitting or foreclosure. Analysts with this view strive to elicit the memory of such experiences by means of the regression that the analytic situation allows. Pioneers of this approach include Sándor Ferenczi, Wilfred R. Bion, and Donald W. Winnicott.

In contrast, some consider this orientation a simplification of psychoanalysis. In this school of thought, psychical trauma of any kind should not be treated as a quasi-physical event of external origin, imposed by reality. In their eyes, such a trauma is inseparable from deferred action, which they place at the center of a mental life shot through with and determined by sexuality. What the young child seeks, but cannot obtain, is the mother, and later the father—not in respect of what they give, but in respect of what they withhold, what they hide, namely their unconscious wishes. The disparity in sexual maturity between the child and the adult means that whatever the child receives (nourish-

ment, caresses, rebukes) is received in a way that is enigmatic, and hence disturbing, to some degree. The fact is that for the adult, the child is not just a child but also the object whereby the adult gratifies his or her desire. Hence the enigmatic quality to what is given to the child.

It was Jacques Lacan who first reasserted the importance of Freud's concept of deferred action, and Jean Laplanche made it a key concept in his theoretical work.

## **DÉJÀ VU**

*Déjà vu* refers to a state wherein a person feels certain (cognitive judgment) that he or she has previously seen or experienced something that is actually being encountered for the first time. Sigmund Freud believed

the feeling corresponded to the memory of an unconscious daydream.

The term first appeared in a French translation of the *Psychopathology of Everyday Life* (1901b) as part of the discussion of the superstition that can be associated with this mysterious feeling. Freud quotes certain “psychologists,” without specifying who they are. The concept falls squarely within the framework of the paramnesia extensively described by psychiatrists in France, primarily Wigan (1844) and Valentin Magnan (1893), who described systematic delirium accompanied by the illusion of doppelgängers, J. Capgras (1923), who described the illusion of doppelgängers, and Pierre Janet (1905), who described cases of false recognition.

Freud discusses the concept in terms of the psychopathology of everyday life (errors, slips) by removing it from the context of psychosis and by supporting it with his own self-analysis (“rapid sensations of déjà vu that I myself experienced”). He returned to it again, but within the context of therapy, in his “Fausse reconnaissance (*déjà raconté*) in Psycho-Analytic Treatment” (1914a), referring to a central example of the analysis of the Wolf Man. He then provided a partial summary of authors who had discussed the issue, separating them into “believers” (who thought that déjà vu was proof of a previous existence), among whom he includes Pythagoras, and “nonbelievers,” who regard such events as false memories (Wigan, 1860). Freud himself assumes a different position (which he acknowledges sharing with Joseph Grasset, 1904) by believing in the reality of the representative content, but associating this with the reactivation of an older unconscious impression. He returned to the question again in terms of self-analysis at the end of his life in “A Disturbance of Memory on the Acropolis” (1936a).

Déjà vu is one of the “uncanny feelings” that, for Freud, play the role of hallucinations, which become more frequent and systematic during certain mental disturbances. This is the most convincing example of breaching the boundary between the normal and the pathological addressed by Freud. It involves a dissociative type of change experienced by the subject in his or her perception of things or himself. Reality appears distant, like a dream or a shadow, and it is at this point that false recognition occurs. Along with this displacement of the perceived object from the present into the past, there is a confused feeling of expectation

or foreknowledge, whereby the subject is simultaneously projected into the future. For Freud this involves the replacement of some part of reality by a repressed desire (1901b). In the example cited here, a young girl replaces the perception of her wish to have seen her brother die with the sensation of having already experienced the situation (a trip to the countryside to visit some young girls whose brother is seriously ill). The topographic displacement (unconscious/conscious) is also spatio-temporal, for the memory involves the house and the girls' dresses but not the brother's illness. In "A Disturbance of Memory on the Acropolis," the same phenomenon is reversed since the reality of the Acropolis dissolves within the feeling of disbelief Freud experiences. Here, doubt replaces certainty; doubt is awakened by the reality of the perception but contaminates perception at the same time.

The concept of *déjà vu* must be compared with other analogous terms in analysis, such as *déjà vécu* (already experienced) and *déjà raconté* (already communicated). According to Freud, this paramnesia can be explained as a confusion between the intention to communicate and its realization. As with the doubt in his dream, these forms of paramnesia refer to specifically significant facts, such as the hallucination of the severed finger that the Wolf Man is convinced he has already told Freud about, when, in fact, he had only mentioned the existence of the small knife carried by his uncle. Generally speaking, paramnesia leads to a reflection on the process of remembering during therapy and on the patient's illusion of having "always known" the repressed content revealed by interpretation ("Remembering, Repeating, Working-through"). "It is by this means," Freud writes, "that the problem of analysis is resolved" (1914g).

*Déjà vu* touches on the whole question of forgetting as a dissociation of memory, as well as on the question of true and false from the psychoanalytic point of view. The false recognition of Norbert Harnold ("Is it a 'real' ghost?") is the true recognition of the originally invested object displaced within the context of archeology in *Delusions and Dreams in Jensen's "Gradiva"* (1907a [1906j]).

### **DELAY, JEAN (1907–1987)**

Jean Delay was a psychiatrist and writer, a professor of medicine in Paris, and a member of the Académie française and the Académie de médecine. He was born on November 14, 1907, in Bayonne and died on May 29, 1987, in Paris. He was the only son of Maurice Delay, a surgeon who went to Bayonne to practice and ultimately became mayor, and Berthe Mihura, a musician, mystic, and cultured woman from an old Basque family. Delay obtained his baccalaureate degree when he was only fourteen and a half, and had to obtain permission from Léon Bérard, minister of education, to attend medical school. He was less than sixteen when he left for Paris to study medicine, and he remained a precocious student throughout his life. He excelled as an extern at the hospital but soon discovered that he had little interest in surgery and enrolled in the university's literature department. Georges Dumas, who held the chair of psychopathology at the Sorbonne, introduced Delay to psychiatry.

In 1928 Delay was an intern, the youngest doctor in the Paris hospital system, and in 1939 he joined the staff of the Sainte-Anne Hospital, where he worked with Henri Claude and Maxime Laignel-Lavastine. After the Germans deported Joseph Lévy-Valensi, Delay became head of the psychiatry department. He served as an expert adviser at the Nuremberg trials, where he examined Rudolf Hess and Julius Streicher. In 1946, when he was only 38 years old, Delay was appointed to the chair of mental illness and brain diseases and later held the Charcot chair until 1970, when he retired.

After defending his doctoral dissertation in literature, entitled “Dissolutions de la mémoire” (1942), which was influenced by the work of Pierre Janet, he became part of the great tradition of French psychopathology through such publications as *Les dérèglements de l’humeur* (1946) and *Études de psychologie médicale* (1953). Upon the departure of Henri Piéron, he became director of the Institut de Psychologie at the University of Paris.

Delay was chair of the first International Congress in Psychiatry held in Paris in 1950 and was elected member of the Académie de médecine in 1955. His neurological training is reflected in his dissertation on tactile agnosia and other work published in this area. He coined the term “neuroleptic” and introduced the use of reserpine into psychiatry. His interests extended to the use of antidepressants, and he completed his research on mescaline by studying LSD and psilocybin, which he referred to as “oneirogenics.” He was also involved in the discovery of Lergactil, used in psychopharmacology. In 1960 he chaired the first Congrès de médecine psychosomatique (Congress of Psychosomatic Medicine).

Édouard Pichon introduced him to psychoanalysis before the Second World War during a brief training analysis. Delay retained a nuanced, non-doctrinaire attitude toward Sigmund Freud’s work. During the Occupation, the psychoanalysts John Leuba, Georges Parcheminey, Jacques Lacan, and Marc Schlumberger worked in his department; after the war Jacques Lacan and André Green had a psychoanalytic practice there. His department also hosted Jacques Lacan’s Wednesday seminars (from November 18, 1953, to November 20, 1963) and Friday seminars, until it was decided that they were no longer appropriate. He remained suspicious of the “quacks of the unconscious” and what he considered poorly managed psychoanalysis. Delay was elected to the Académie française in 1959.

Throughout his life Delay maintained a literary career, his work initially being published under the pseudonym Jean Faurel (*La cité grise* [1946], *Les reposantes* [1947], *Les Hommes sans nom* [1948]). His two-volume work on André Gide, *The Youth of André Gide* (originally published in 1956–1957), soon became famous. Jacques Lacan, in “Jeunesse de Gide, ou la lettre et le désir” (1966), wrote, “Jean Delay extends this ambiguity by locating the effect within the soul, at the very place where the message is formed.” He also worked on a historical reconstruction of his mother’s

family in the four volumes of *Avant-mémoire* (1979–1986).

In a final homage to Delay at the Académie française, Jean Dutourd wrote, “In the case of Jean Delay, who knew everything, who had explored medicine’s most hidden pathways, the philosophy of the past, and even madness, we do not have the feeling we are talking with a contemporary but with one of those immense gluttons for knowledge who made the Quattrocento and the sixteenth century so amazing. Nor was he contemporary in his behavior. In his courtesy, his refinement, and his kindness, he was the kind of gentleman one might have found in Balthazar Castiglione, and an ‘honest man’ as well.”

## DELBOEUF, JOSEPH RÉMI LÉOPOLD (1831–1896)

Joseph Delboeuf was a Belgian psychologist and hypnotherapist. He was born in Liège on September 30, 1831, and died in Bonn on August 13, 1896. He was a professor at the University of Ghent from 1863 to 1866 (philosophy), and after 1866 taught at the University of Liège (Latin, Greek, and psychology). Signs of Delboeuf’s influence can be found in many places in Sigmund Freud’s work, at least until 1900. The most significant include:

1. Delboeuf treated a woman traumatized by the death of her son. He eliminated her symptoms, which resembled the terrible conditions of his death, by having her relive those experiences several times. Delboeuf explained “how the magnetizer assists in the healing process. He places the subject in a state where the evil has manifested itself and through speech combats that same, recurring evil.” Freud discussed this hypothesis extensively in “On the Psychological Mechanism of Hysterical Phenomena” (1893a) and in the *Studies on Hysteria* (1895d).
2. Looking back on his therapy with Emmy von N., Freud doubted for the first time the value of claims by Bernheim and the “perspicacious” Delboeuf. He questioned whether Bernheim was correct in continuing to claim that “suggestion is everything,” and Delboeuf for having claimed that “that being so, there is no such thing as hypnotism.” Unable to resolve these issues, he abandoned theory and turned to practice, finally showing preference for the analytic and genetic method, which was in fact that of Delboeuf.
3. Delboeuf’s *Le Sommeil et les Rêves* [Sleep and Dreams] (1885) and Freud’s *Interpretation of Dreams* (1900a) have several traits in common. Delboeuf’s work opens with the famous dream of the lizards and the *Asplenium*, an intriguing dream from several points of view and one that led the psychologist to articulate his conception of memory and remembrance, whose meaning he attempted to grasp through the randomness of free association. In the *Interpretation of Dreams* two of Delboeuf’s concepts are treated favorably: “forced rapprochement” (to account for the tendency of dreams to merge) and “cliché” to explain the presence of verbal expressions in certain dreams. Having decided to use his own dreams for hermeneutic purposes, Freud acknowledges that he had to overcome [conquer] his initial reticence. He remarks that he overcame his resistance by subjecting it to a process expressed by Delboeuf, whom he quotes: “every psychologist must acknowledge even his weaknesses if he feels he can shed light on a problem by doing so” (Freud, 1900a; Delboeuf, 1885, p. 30).

## DELGADO, HONORIO (1892–1969)

A Peruvian psychiatrist and philosopher, Honorio Delgado was born in Arequipa on September 26, 1892, and died in Lima on November 20, 1969. Delgado studied natural science at the University of San Agustín in Arequipa before becoming a surgeon (1918) and a doctor of medicine (1920) at the University of San Marcos in Lima. A self-taught psychiatrist (formal training then being unavailable), Delgado was a precocious and enthusiastic proselytizer for psychoanalysis in Peru and Latin America between 1915 and 1927. His first publication on psychoanalysis appeared in 1915 when he was only twenty-three years old. Published in *El Comercio*, it was a commentary on Sigmund Freud’s “The Claims of Psycho-analysis to Scientific Interest,” which appeared in 1913 in *Scientia*, which Delgado read on a regular basis.

In 1922 he traveled to Europe to attend the Berlin congress but his ship was delayed and he missed the presentations. In 1927 he traveled to Innsbruck for the annual congress. He published the first work in Spanish on psychoanalysis, entitled *La Psychanalyse* (1919). Between 1919 and 1934 he corresponded with Freud, whom he met in Weimar in 1922 and visited in Semmering in 1927. In 1918, together with Hermilio Valdizán, he founded *Revista de psiquiatría y disciplinas conexas* (Review of Psychiatry and Related Disciplines), which adopted a favorable position regarding psychoanalysis. In 1921 he

published “Der Liebesreiz der Augen” (The Amorous Attraction of the Eyes) in *Imago*. In 1926, with the collaboration of several eminent Peruvian intellectuals, he edited a special issue of *Mercurio Peruano* devoted to Freud. That same year he also published a biography of Freud, which Freud annotated extensively throughout their correspondence. Freud took an active interest in Delgado’s publications, and the way he responded to his eclectic approach to psychoanalysis, which was in several respects related to the ideas of Alfred Adler and Carl Gustav Jung, should not come as a surprise.

After 1930 Delgado held the country’s only chair in psychiatry and became a fierce adversary of psychoanalysis, paradoxically citing in his support the references to him made by Freud in a 1923 note added to “On the History of the Psychoanalytic Movement” (1914d) and in an article written in English in 1924, “A Short Account of Psycho-analysis” (1924f [1923]).

While still a young man Delgado had identified with Freud’s initial period of isolation. There exists a letter, collectively written by Ernest Jones, Hanns Sachs, and Oskar Pfister, congratulating Delgado for his *Pionierarbeit*. His later rejection of psychoanalysis appears to have arisen from his growing popularity and a refusal—which he never concealed—to accept some of the fundamental premises of psychoanalysis, coupled with his increasingly strong attachment to Catholicism. In spite of his productivity as a writer, his lack of clinical experience is obvious (he had no personal experience of psychoanalysis aside from his own self-analysis). His early work contains little of lasting value and there is an obvious difference in quality with his later work in psychiatry, influenced by the phenomenology of Karl Jaspers.

His correspondence, however, contains numerous insights into Freud’s ideas about creating an institutional structure as well as Freud’s tendency to pardon some of Delgado’s theoretical errors, for which he would certainly have been less indulgent in other circumstances. His letters contain no more than mild rebukes to Delgado for his sympathy toward Adler (with whom he corresponded) and Jung.

## DELUSION

The first essential feature that defines a delusion is that it concerns something that appears to be external to the subject. It is thereby distinguished from obsessive ideas and *idéés fixes*. More precisely, we can say that in a delusion, an internal experience appears in the perceptual field. Delusion therefore concerns reality as a whole, which distinguishes it from phobia, where the distortion of reality is more circumscribed, because projection manages to localize conflict, and keep the rest of the subject’s mental life intact. In delusion, conversely, the whole of reality is affected, and indeed the delusion, for the subject, is the whole of reality.

In this sense, delusion represents a critical risk. Sigmund Freud speaks accordingly of a necessary restoration of the object (1924e), whether it is a matter of the high level of libidinal or narcissistic tension evident in extreme cases, or a fundamental questioning of identity and relations with others that is at stake.

Delusion is therefore something other than error. Being delusional remains compatible with an accurate apprehension of reality. We can even consider the delusional individual as deprived of the freedom to establish a flexible relationship between reality and truth, as Paul-Claude Racamier has said.

From this general perspective, we can differentiate the two main modalities for the expression of delusions. In one, this involves a disturbance of consciousness, whose heightened character can have different

causes: a consciousness that is captive and agonized; or a *delirium tremens*, which externalizes metabolic disturbances in the form of images; or the dream-like upheaval of acute psychotic delusions; or the psychedelic intoxication of hallucinogens. In the other mode, the same reversal of reality can express the refusal that occurs during hallucinatory confusions that seek to isolate a repressed complex, and keep it in a shadowy, hysterical state.

There are occasions, however, when acute delirious moments are experienced in isolation, as in the "primordial delusional fact" described by Jacques Moreau de Tours, or the "primary delusional experience" described by Karl Jaspers, where the strange and uncanny appears, sometimes in the form of illuminating moments in which a perception takes on a revelatory quality, or a moment of questioning emerges without yielding any sense. These seem to be direct confrontations between unconscious fantasy and reality, like a topographical short-circuit that requires a return of the preconscious from the exterior world, within the delusion of interpretation.

In yet another dynamic of delusion, less sharp in its temporal unfolding, the dominant issue concerns the limit between inside and outside. During moments of mental automatism, thought grows heavy with the weight of words that have lost their meaning. The schizophrenic seeks in hallucination to exteriorize an internal life that is invasive and does not seem to belong to him. Chronic delusions, in the French systems of classification, or in Kraepelin's paraphrenias, are more likely to create delusions that are simultaneously persecutory and protective, sometimes to the point of allowing a reconstruction of the entire world (Schreber, 1903).

Passion also, with its affective power to dominate, can provide material for delusions, along other lines. The paranoiac projection of homosexual impulses can turn into delusions of persecution, jealousy, or erotomania, depending on whether it is the subject or the object of the fantasized investment that is affected by the delusional force. However, emphasis should be placed on the narcissistic demand, the lack of an object, and the shortcoming, within the primary homosexual relation, that eroticization compromises and which the delusion of persecution maintains as both present and distant (Jenneau, 1990). In other cases it is the superego that returns in the "delusion of reference," where the shame and guilt of voyeurism blend together in projection (Kretschmer, 1927).

One sees in this brief description that delusion cannot be explained simply in terms of a certain way of treating instinctual life at the expense of reality. One also has to take into account the patient's need to express conflict, in a single-minded way, within this reality. It is the causality of delusion that remains the foremost question, even within radically different accounts.

## **DELUSIONS AND DREAMS IN JENSEN'S "GRADIVA"**

Freud wrote this essay in the summer of 1906, seemingly to please Carl Gustav Jung, who had called to his attention a short story by the German writer

Wilhelm Jensen that was of interest because a dream served as its point of departure.

In his essay Freud first minimally summarized and commented on the story. It is the story of Norbert Hanold, a young archeologist obsessed with his work for whom women do not exist. Visiting a museum, he is struck by the beauty of a bas-relief of young Roman woman, very light on her feet, whom he baptized “Gradiva” (she who walks). He purchases a reproduction, which he hangs on the wall of his workroom. Gradually his mind is invaded by the enigma of this young woman. One night he dreams that he is in Pompeii in August 79 c.e., just before the eruption of Mt. Vesuvius. There he meets Gradiva and wants to warn her of the terrible danger that is about to occur, but he is powerless to rescue her. After waking, he is overcome by the desire to meet Gradiva. He leaves for Pompeii, where he meets a young woman, very much alive, whom he takes for Gradiva. In the course of the meetings that follow, he organizes his mania, stalking and interpreting signs (Gradiva appears at noon, the ghost hour, and the like). “Gradiva” seeks to cure him by gradually revealing her identity to him. Through this adventure, Norbert finally sees “Gradiva” for who she really is: his neighbor and childhood friend Zoe Bertgang (“Bertgang” is the German equivalent of “Gradiva”), who also traveled to Pompeii. For years he had not seen her and had no desire to see her, but, in love without knowing it, he had displaced his love on the young woman of the bas-relief, Gradiva. Happily, the mania yields to reality, and Norbert is cured.

Frequently citing his *Interpretation of Dreams* (1900), Freud suggested in his comments that dreams “invented” by a writer can be analyzed by the same method as real ones. He meticulously analyzed the two dreams figuring in Jensen’s story, linking them to residues of daytime occurrences. He thus demonstrated that dreams were substitute wish fulfillments and established that they constitute a return of the repressed. The source of Norbert Hanold’s mania is his repression of his sexuality, which caused him to forget Zoe Bertgang, so as to keep him from recognizing her (anticipating his later views, Freud called such phenomena “negative hallucinations”).

The dream and the mania that makes the dream real function by condensation and displacement, by way of images. The correct proposition—I, Norbert, am living in the same time and place as Zoe—is removed to Pompeii in the year 79. Zoe treats Norbert in the manner of a

good psychoanalyst, cautiously bringing to consciousness what Norbert forgot through repression.

Freud’s essay was published in May 1907. Four months later, in September, in the course of a trip to Rome, he went to see the bas-relief representing “Gradiva” at the museum of the Vatican, the same bas-relief that had inspired Jensen’s tale. Just like Norbert, Freud bought a copy of it and hung it in his office, at the foot of the divan. He left it there until he left Vienna, and took it with him to London in 1938.

## DEMAND

The concept of demand is not Freudian. It was developed by Jacques Lacan, who linked it with need and desire (Lacan, 1966, 1991). Demand is identifiable by the five clinical traits that constitute it, by the status that it gives the object, by its function in relation to the Other, and finally by its topological register.

Regarding demand, we can say that 1) it arises only from speech; 2) it is addressed to someone; 3) it is nevertheless only implicit; 4) it is related to a need for love, but also to desire; 5) it does not need to be sustained by any real object.

The object of demand is what is lacking in the unconscious Other, and thus it is only a fantasmic object. Its function is to satisfy the drive and to make the demand of the subject and the demand of the Other coincide. Although it is tied to both the symbolic and the real, the register of demand is primarily imaginary, and thus most closely related to the body.

Before outlining more recent perspectives on demand, we must return to what Lacan said about it in relation to oral, anal, and genital regions of the body that serve as the sources of demand.

The oral demand calls for an inverse response, such that the other's answer to the imperative "feed me" is "let yourself be fed." This inversion becomes a source of discord or even of destructive urges. To whom is the demand addressed? To the Other, and not the mother. It is addressed to the Other that separates the demand from a desire. And that desire, in turn, deprives the demand of its satisfaction. Thus the demand becomes a non-demand. The dream of the "beautiful butcher's wife," as reported by Freud, is a perfect example of this. What is the object of her desire to define? It is a cannibalistic object. This desire is directed towards the nourishing body, an organic unconscious object through which the demand's relation to the Other can be sexualized. This libidization, "which is nothing but surplus," deprives the need of its gratification. The function of desire, which sustains all demand, is in turn maintained in it and thus preserved. Desire can be recognized in the field of speech by the negation with which it originates: this, and not that!

The original oral relation between the mother and her child is constantly fed by a kind of hostility in which each one is convinced, at the imaginary level, of being "bawled out" by the other. Donald Winnicott (1974) emphasizes moreover that the object is so good, so exciting—that it bites. Consultations with mothers and children always show this.

At the anal stage, need reigns supreme; but while demand sets out to restrain need, desire wants to expel it. The one is entrusted with satisfying it, while the other is determined to control it. In the end, this control is legitimated only by turning need into a gift expected by an other, who is always primordially the mother. The oblation of this exonerating gift is metonymic. In order to evacuate the gift of symbolic desire, the one who gives it (child, student, or citizen, for example) could well adopt the slogan "everything for

the other" in reference to the one who expects it (the mother, the teacher, or an authority figure)—this is true enough in the voting booth, at any rate. Such a gift is not produced by the one who gives it: someone else is the producer, someone who is able to wait for it only as long as the giver is suffering. It is not that the gift is necessarily painful in itself; the reaction of the one who receives it is the determining factor in that respect. So that her expectations will not be in vain, the mother eroticizes her relation with the child. She makes the child a sexual partner, involved in a fantasy in which he becomes the imaginary phallic object. In the end, the child will have been forced to do the only thing it was able to do. This was how the sadomasochistic economy was described by Freud, who took the symbolic equivalence of penis, feces, and child as his starting point.

How do we recognize an obsessional neurosis? By a declared conflict between demand and desire, satisfaction and discipline, need and legitimacy, gift and exoneration. The outcome of this conflict can only be a resignation to suffering. The characteristic "it could have been worse" attitude alludes to the masochistic *jouissance* that the obsessional derives from it, while "You had that coming" sums up the sadistic expectation of the other, who is without doubt the father—when it comes to need, he's always too much.

At the genital stage, demand seeks out a real partner. A repressed demand returns in the field of sexuality, and it will be satisfied only by a real engagement—one the subject wants to wait for, since he or she intends to bring it about. Thus the demand is based on the primacy of a sexual desire that is certainly sustained by a need, but that emphasizes a real lack in the other. Far from realizing desire, this lack constantly renews it. "The subject does not know what he desires most," either from the other or in terms of his own lack. From then on, the "something else" that originates from this lack of knowledge is related to a desire that is deceived. It is deceived if it believes itself to be lacking only the other, the missing half that is but a shadow from the past.

Taking the concept of transitivity as their point of departure, Gabriel Balbo and Jean Bergès (1996) have reconceptualized the analysis of demand. For them, demand cannot be conceived independently of the infant's identification with the discourse that the mother expresses in response to the baby's cries, smiles, gurgling, and gestures. There is a double division at work here. The mother's own discourse, which she puts in the mouth of her child, divides the mother into

a bodily, experienced real demand in contrast to what she expresses. The child is also divided from its own real demand by identifying with whatever part of that demand the mother expresses. This double division, with its consequent double repression, has an organizing influence on the ego, the status of the object, body image, the infant's jubilation at its own specular image, and the I. All processes of identification must be rethought in these terms, while at the same time demand and identification are also the origin of no less a dualism than that of life and death.

Such an analysis allows one to rethink the demand for an analysis, the preliminary interviews, the analytic contract, the direction and conduct of the treatment, and ultimately the transference. This reconceptualization reaches the very core of the discursive framework, and the analysis of dreams as well as the patient's speech is determined by it.

## DEMENTIA

Dementia has been defined in two very different ways. The first definition, which came into use in the nineteenth century with the establishment of a nosographic framework for the psychoses, culminated in the concept of dementia praecox in the work of Emil Kraepelin. The second definition concerns altered states in memory and ideation following injury to the brain.

The word *dementia*, which first appeared in a psychiatric sense in Philippe Pinel's work contrasting

mania and dementia, underwent changes in meaning during the nineteenth century. In 1911 Eugen Bleuler, in his discussion of the concept of schizophrenia, centered around dissociation or splitting (*Spaltung*), proposed bringing together the old notion of "vesanic dementia" (the culmination of psychotic development) and Kraepelin's three forms of dementia praecox: hebephrenic, catatonic, and paranoid.

Sigmund Freud approved of Kraepelin's approach but he criticized the term *dementia praecox*, as well as the term *schizophrenia*. This despite the fact that he felt it important to distinguish between the two, writing, in "Psycho-Analytical Notes on an Autobiographical Account of a Case of Paranoia (Dementia Paranoides)" (1911 c[1910]): "... we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations" (p. 62). In reality, he continued to use both terms indiscriminately. He focused his study of the psychoses on paranoia in the essay cited above. After "On Narcissism: An Introduction," (1914) he proposed to distinguish among the neuroses, the psychoses, and the perversions. In Freudian theory, dementia praecox consists of a withdrawal of object libido onto the ego through regression and fixation. Freud later went on to specify its linguistic characteristics (words are subjected to the primary process) and its functioning (reality testing is no longer operant; verbal delusions are an attempt at healing), but essentially it was Freud's successors who developed a psychoanalytic theory of the psychoses.

In current usage, the term *dementia* refers to erosion of the intelligence caused by many different kinds of damage to the brain: degenerative dementias (dominated by Alzheimer's disease), vascular diseases, infectious diseases, toxic conditions, or metabolic disorders. Clinical treatment of dementia from a psychoanalytic perspective runs up against problems of theoretical elaboration. Psychoanalysis has limited applications for these conditions and is used mainly in the early stages of illness. The goal is to limit the breakdown of identity for a certain time. The gradual erosion of the capacity for symbolization and the work of representation owing to memory loss, the weakening of repression and the breaking through of the protective shield, and the instinctual flooding that ensues, has led to reliance on a therapeutic approach focusing

on the reconstitutive function of the affects as the basis for mental activity, since, as Michèle Grosclaude suggested in *Le Statut de l'affect dans la psychothérapie des démences* (The status of the affects in the psychotherapy of dementia; 1997), verbal therapies are among the first to be affected by the degenerative process. Denial, projective delusions, and heightened anxiety are all typical of these conditions.

## **DENMARK**

After World War I, psychoanalysis was diffused among artists and pedagogues, but the discipline was condescendingly dismissed by the leading university professors in philosophy, psychology, and psychiatry.

After hearing a speech by Ernest Jones in 1926, though, the psychologist Sigurd Næsgaard became the first Dane to undertake a serious study of Freud. In February 1933, Wilhelm Reich gave a speech in Copenhagen and the IPA was requested to allow him to come to Denmark as a training analyst; the answer, however, was negative. Instead the Danes were offered Jenö Hárnik from the Institute of Psychoanalysis in

Berlin. Unfortunately he turned out to be psychically ill, and all that survives of his brief stay in Denmark are the reports of the scandal caused by his behavior. Reich was to come to Denmark anyway in May 1933, but as a political refugee. He was only granted six months' asylum, which was not extended, as he was suspected of practicing psychoanalysis without the requisite work permit.

Reich nonetheless remained in touch with a circle of disciples in Denmark during his ensuing stays in Sweden and Norway. Another influence came from Oskar Pfister, who enjoyed a certain popularity among prominent theologians and teachers. He gave a series of much-attended talks in Copenhagen in 1936.

From 1930 on, a series of more or less short-lived psychoanalytic societies were founded in Denmark, all marked by their respective founders and leaders. The most important was the group that surrounded Sigurd Næsgaard, who in the public eye was largely identified with Danish psychoanalysis. Another group was led by P. C. Petersen, who had a background in dairy production, and it represented especially the inspiration of Pfister. A third group arose around Reich's Danish pupils, led by the physicians J. H. Leunbach and T. Philipson; these were known in particular for their work in the movement for sexual reform.

The person with the greatest influence on the establishment of psychoanalysis in Denmark was Sigurd Næsgaard (1883–1956). He started as a teacher and then completed a university degree in philosophy and psychology. He had strong roots in the Danish high school movement, and considered general education, education reform, and sexual freedom his most important goals. As a psychoanalyst he was self-taught. His large authorship is characterized by a popularizing tendency and a predilection for pat and quick-witted interpretations. He is known for his analyses of a number of the important cultural figures of his time, among others the painter Asger Jorn. Some of the leading Danish IPA analysts after World War II also started their analytic careers on his couch.

The Danish-Norwegian Psychoanalytic Society that was founded at the IPA congress in 1934 had only one member with a Danish address, the Hungarian Georg Gerö, a pupil of Reich who had been educated at the Institute of Psychoanalysis in Berlin. Under pressure

from the IPA, Gerö broke with Reich around 1937. The only known work of his in Denmark today is his training analysis of the psychiatrist Poul Færgeman. Gerö emigrated to the United States at the beginning of World War II.

Færgeman (1912–67) left for the United States in 1946 to terminate the training analysis he had started with Gerö in Denmark. He later became a member of the New York Psychoanalytic Society, but returned to Denmark in 1960 and joined the Danish society. He is best known for his work with psychogenic psychoses (Færgeman, 1963). Because of his premature death he was not to have the influence on Danish psychoanalysis to which he seemed entitled.

After the war, Næsgaard and Petersen each established new societies. Both sought admission to the IPA, but since neither had had IPA-accredited training, they were unsuccessful. Instead, the initiative slid to another group. The Swedish analyst Nils Nielsen, member of the IPA, came to Denmark in 1949 with a view towards starting a number of training analyses and founding a psychoanalytic society. The Danish psychiatrists Thorkil Vanggaard and Erik Bjerg Hansen, who had received accredited psychoanalytic training in New York and Vienna, respectively, later joined Nielsen. Their Danish Psychoanalytic Society attained status as a study group under the IPA in 1953 and obtained full IPA membership in 1957. The society hosted the international IPA congresses in 1959 and 1967. The accession of members was low, as was the level of activity throughout the 1960s and 1970s.

Thorkil Vanggaard (1910–1998) was the strong leader of the Danish Psychoanalytic Society in the years following World War II. He received his psychoanalytic training in New York with Robert Bak as his training analyst. His psychoanalytic authorship is not prolific, but a fairly original theory of the phallus as a meditating symbol in connection with the transfer of authority from master to pupil merits mention (Vanggaard, 1972). He was vice president of the IPA from 1967 to 1969, but then began to move away from psychoanalysis and left the psychoanalytic society in 1984. He is known to the Danish public rather for his highly controversial position on gender roles and incest than as a psychoanalyst.

Not till 1980 was the increasing general interest in psychoanalysis reflected in the number of members. Among the Danish public, psychoanalysis has mainly

been represented by psychologists, researchers and writers with no analytical training (e.g., Andkjær Olsen and Køppe, 1988).

In the 1990s the Danish Psychoanalytic Society had around 30 full members, of whom more than one third are from the southern part of Sweden, having chosen to belong to the Danish society due to the fact that Copenhagen is closer than Stockholm. There is no institute, and the society depends greatly on its collaboration with the other Scandinavian societies, who among other things have cooperated since 1978 on the publication of the *Scandinavian Psychoanalytic Review* (in English).

Among the societies that do not belong to the IPA are the Group Analytic Institute (established with the support of the British group analysts Colin James and Malcolm Pines) and the Psychoanalytic Circle (Lacanian).

## DEPENDENCE

The term “dependence” is part of contemporary language; it is frequently used in the field of psychopathology but more for descriptive convenience than to specify a precise relational modality concerning the subjection of a subject to an object. Sigmund Freud used the term infrequently but made reference to it in his discussion of the pleasure principle: “It will be rightly objected that an organization which was a slave

to the pleasure principle and neglected the reality of the external world could not maintain itself alive for the shortest time, so that it could not have come into existence at all. The employment of a fiction like this is, however, justified when one considers that the infant—provided one includes with it the care it receives from its mother—does almost realize a psychical system of this kind” (1911b). Serge Lebovici (1991) remarked that the human being’s original state of dependence is a fundamental postulate of Freudian theory; it is the baby’s *Hilflosigkeit*, or helplessness (*détresse* or *désaide* in French).

As Michael Balint (1968) remarked, the notion of “oral dependence” appeared in the work of Otto Fenichel in 1945. Fenichel describes oral character traits, especially a disguised dependent need, created by reaction-formation, manifest in attitudes and behaviors of independence and rebellion. Franz Alexander used this idea to describe ulcerous subjects who indicate their condition by the conflict between the desire to maintain a state of infantile dependence and the affirmation of independence of the adult ego.

Melanie Klein showed no interest in the concept, but her students Paula Heimann and Joan Riviere, in *Developments in Psychoanalysis*, refer to the infant’s total dependence on the mother at the beginning of life. The concept becomes central in the thought of Donald Winnicott (1963), who emphasizes that the baby, who is dependent on the care of those around him, is subject to a “dual dependency,” which will become simple dependency as soon as he or she becomes aware of it.

This is part of a normal process for every human being, so that not every state of dependence later found to exist can be reduced to it. Yet this inaugural kernel, which is characterized by a sense of powerlessness (as well as the narcissistic omnipotence associated with it), is the basis of subsequently-observed states of mental dependence and defects in the separation-individuation process. Adolescence especially is a period of reactualization and the heightened revival of feelings of dependence and infantile helplessness. Philippe Jeammet (1989), who considers dependence to be characteristic of this period, has developed the concept within a metapsychological perspective that cannot be easily summarized. According to this conception, the adolescent shows himself to be clinically dependent whenever he feels that his object needs threaten his autonomy and narcissistic equilibrium.

Some authors have examined dependence in the treatment of borderline states, following Winnicott, who emphasized the danger of underestimating the transference dependence in this type of case as part of the counter-transference risks of his interpretation. He, like Balint, cautions against an overly systematic interpretation of transference dependence, introducing the risk of reinforcing the dependence—especially oral dependence—of the patient on the analyst, and the latter’s omnipotence. Otto Kernberg, working with narcissistic patients, describes their inability to depend on the analyst from the beginning of therapy, which can be compared to the fear of “giving in to dependence” described by Masud Khan.

In contemporary psychiatric clinics there has been a recategorization and clinical reassessment of dependence. The term is no longer only applied to drug addiction, alcohol or tobacco dependence, and so on, but tends to define a biological-psychological-behavioral syndrome that is very broad and includes those states as well as pharmacodependence. The concept of “addiction,” which is very similar to that of dependence, is an indication of this broadening. Thus the pathological behaviors in which an act of incorporation (often but not exclusively through use of a toxic object) allows the subject to relieve the internal tension by short-circuiting a threatening mental condition are grouped under the term “addiction.” These include alcoholic and drug-related behavior, bulimia (and anorexia), as well as addictions that do not involve the ingestion of a product (games of chance, shopping sprees, sexual addiction), and even relational dependence.

## DEPERSONALIZATION

The term “depersonalization” refers to the appearance of subjective impressions of change affecting the person or the surrounding world. Their intensity varies, ranging from a simple feeling of dizziness to painful feelings of physical transformation, from the fleeting feeling of estrangement to the impression that the world has become unrecognizable, dead, or uninhabited. Moments of depersonalization can occur during the customary development of any individual or within overtly pathological clinical settings.

The concept of depersonalization is not directly present in the work of Sigmund Freud. In “Psychoanalytic notes on an autobiographical account of a case of paranoia (dementia paranoides)” (1911c [1910]), the elements of depersonalization perceptible in the subject’s memory—themes of physical transformation, nerves of voluptuousness, the “hastily improvised men”—are not treated as such by Freud. Similarly the themes of depersonalization found in the Wolf Man—the “veil” that is torn during successive washings—are not referred to as such even though they are analyzed in depth (1918b [1914]). It is possible that it was only after the development of his concept of narcissism and the reorganization of the concept of the ego it contained that Freud became aware of depersonalization, in “The Uncanny” (1919h) and later in “A Disturbance of Memory on the Acropolis” (1936a). In both cases it is through feelings affecting the perception of the outside world that the topic is addressed, that is through the question of “derealization,” which can be considered the result of a type of depersonalization.

Paul Schilder was one of the first authors to take an interest in depersonalization. He saw it as a function of the libido’s withdrawal of cathexis from the image of the body. Paul Federn believed it corresponded to an alteration of the distribution of narcissistic libido throughout the body and its boundaries. Hermann Nunberg associated it with the loss of a significant object. Clarence Oberdorf emphasized the polymorphism of the clinical situations in which it could be observed and Andrew Peto investigated the role of the precocious loss of introjection. Maurice Bouvet, in an important study entitled “Dépersonnalisation et relation d’objet,” demonstrated the similarity of structure between states of depersonalization in their various clinical forms and treated “depersonalization as a state of weakened ego structure.” He insisted on the importance of a “rapprochement” with the object, that is a decrease in the creation of psychic distance to the object, whereby the object returns to the position it held in the subject’s unconscious fantasies. He also pointed out the character of the object relation that made it a narcissistic object since “the maintenance of the ego structure . . . depends on its unconditional and absolute possession.” Bouvet also noted the importance of the conflict between the need to introject the object and the fear of this introjection.

**DEPRESSION**

Depression is a mood disorder, understood from the psychoanalytical viewpoint as resulting from an intrapsychic conflict that stems from the ego's difficulties in integrating aggressive drives that are experienced as too dangerous for the preservation of libidinally cathected objects. These aggressive drives turn against the subject via the superego, which becomes too strict and demanding. Depressive manifestations are frequent in other clinical entities where the conflicts are essentially intrapsychic, such as the psychoneuroses.

Karl Abraham (1912/1989) was one of the first psychoanalytical authors to concern himself with depressed patients and to describe the extent of the ambivalence of their drives. Narcissism is another characteristic of the depressive personality, which that Freud emphasized in "Mourning and Melancholia" (1916–17g [1915]). Subsequently, Abraham (1924/1927) described the pregenital underpinning of this ambivalence, given the importance of oral fixations in these patients.

Freud compared the psychological mechanisms of melancholia with those of mourning, which constitutes a depressive state in the normal person. The essential difference is the narcissism of the melancholic, whose intolerance of experiences of loss lead him to the oral incorporation of the lost object into the ego, where it is attacked by the superego. Conversely, the person in mourning finds himself faced with the painful difficulty of detaching the libido cathected onto the lost object so as to recathect it onto objects in the external world. However, the major problem raised by Freud's descriptions of the dynamics of melancholia is that he does not specify the variations in the psychological mechanisms corresponding to the different degrees of depressive states.

Melanie Klein (1940) developed the comparison with mourning in her description of the depressive

position. For her, the capacity to work through one's mourning will depend on the possibility of resolving the reactivation of the conflict proper to the depressive position that the conflict causes, i.e., the feeling of losing good internal objects. Klein, like Freud, is imprecise when it comes to the different problematics of depression. However, clinical analysis shows a whole series of levels of severity in this problematic between the working through of the mourning process (or during the integration of the depressive position) and the peak of this process, which Klein described as "a melancholia *in statu nascendi*" (Palacio Espasa). These depressive forms of conflict can be defined by reference to the predominant form of the fantasies expressing the experiences of the loss of the object of libidinal cathexis, and by the quality of the types of anxiety experienced by the ego.

When fantasies of the catastrophic and irreparable destruction of the object predominate, given that the subject has very little confidence in his libidinal capacities, feelings of guilt become intolerable and feelings of sadness are massively denied. The ego can only resort to archaic mechanisms of defense: splitting, denial, projective identification, idealization, etc.—the mechanisms proper to schizo-paranoid functioning or to the dynamics of extreme melancholia, with confusion between the ego and the object attacked (the "parapsychotic" depressive conflict proper to borderline or psychotic structures).

When fantasies of severe and barely reparable damage or death of the objects take the upper hand, the ego will be confronted with intense feelings of guilt and sadness. The significant repression of the aggressive drives towards the object (an aggressiveness that reinforces the severity of the superego) will make it possible for the negative affects to be partially denied. The ego will succeed in keeping the conflict interiorized but at the cost of diverse inhibitions in the functions of the ego. Thus, the symbolic possibilities of the individual are limited, but are not qualitatively affected. This very narrow form of repression is often insufficient, and the ego also has to resort to maniacal defenses or to defenses of a melancholic type, which then determine the clinical manifestations of mood disturbances.

When feelings of abandonment and rejection prevail—i.e., when the experiences of loss are above all fantasies such as the loss of the object's love—depressive conflict will take a "paraneurotic form."

The feelings of sadness are often conscious, for guilt is less intense and can equally easily become conscious. The ego's greater confidence in its libidinal capacities gives these subjects a profusion of fantasies of reparation that will counteract the damage done to the object, damage that is fantasized as resulting from their own aggressiveness. These fantasies underlie many of the neurotic mechanisms of defense, especially those of an obsessional kind, for example retroactive cancelling, reaction formation, etc. Under their influence, repression authorizes a greater possibility of symbolic expression, which distinguishes neurotic repression from the massive repression of the depressive type. Such a libidinal predominance changes the nature of what is repressed, for the counter-cathexis does not operate on aggressiveness alone, but also on the libidinal fantasies of an incestuous nature. This contributes to the sexual differentiation of parental objects, bringing into operation the conflict occasioned by triangulation and the Oedipus complex.

## **DEPRESSIVE POSITION**

A developmental stage in the first year allows the infant to begin to integrate his objects, which become mixed and take on both good and bad aspects. Particularly when the objects that attract ambivalent emotions are internalized, it creates a deeply troubling internal world, dominated by various forms of guilt feelings, sadness and reparative attempts to deal with them. (Melanie Klein, 1935).

Melanie Klein derived her notion of internal objects from the work that Abraham and Freud had done on the internalization of objects through oral incorporation in melancholia (Freud, 1917 [1915], Abraham, 1924). Abraham described symptoms which vividly expressed the movement of "loved objects" into and out of the body.

Klein (1935, 1940) viewed aggression from the earliest stages as producing a particularly problematic internal object. Freud described the internalization of the loved one as a response to its loss, when there was a particular heightened degree of ambivalence towards that person. In other words when a loved object, towards whom a lot of aggression is felt, is then lost, a persisting depression rather than normal mourning occurs. Klein discovered that this process also occurred with an *internal* object that was damaged (by the aggression) or, indeed, a dead internal object. It is this internal sense of damage and death which is the core experience of clinical depression, and was Klein's addition to Freud and Abraham's work on depression.

However, the depressive position (in contrast to depression) is a normal enough process. In this case, aggression, while internalizing loved objects, leads to restorative efforts towards the object internally, or in a symbolized and sublimated (and externalized) form. In turn, fears about the state of the internal object are always aroused by the loss of, or harm to, loved external objects.

Because of the love for a damaged or dead internal object the experience is extremely painful, and this anxiety of the depressive position has an internal reference point, known as guilt. During development the harshness of guilt is at first very severe, and is felt to be the retaliation of the damaged object inside—a phantasy that is in line with Freud's description of guilt arising from the superego. As a result the developing infant may have great difficulty in accepting these

feelings, and therefore hesitates to enter the depressive position. Crucially, the infant is anxious that its own badness and aggression will overwhelm its capacity for love. In this sense it is an intensely “moral” position, and indeed presupposes the struggle between love and hate as an inherent morality.

Klein and her followers found themselves in possession of the difficult notion of “internal objects.” This term refers to phantasies about the contents of the self, and especially the concrete contents of the body. This idea developed Abraham’s work on introjection and projection of objects which he found were phantasies of incorporation or expulsion of physical objects from the body (food and excreta). In Klein’s theory these objects are animate, and are motivated with good or bad intentions towards the ego, as if quite real homunculi were resident inside the person.

The developmental step—crucially the recognition that the loved person is also hated and attacked (at least in phantasy)—may be avoided for the time being by various specific defenses. Firstly, the infant may revert to more paranoid-schizoid states—the paranoid defense. Then the confluence of love and hate are prevented by continued splitting of good from bad objects.

Manic defenses are characteristic in the depressive position. Then, the importance of the loved object (and therefore its condition) is denied. As a result no serious guilt or dependence on the object is felt if it has been rendered so unimportant.

Alternatively if, and when, the guilt can be tolerated the ego is driven to seek methods of reparation for the damage done in phantasy or reality. In this case the harshness of the guilt, and the superego-like quality of the internal object becomes softened, and elements of forgiveness can develop.

The coming together of good and bad objects, and of the impulses of love and hate, mark the onset of a new respect for the reality of external people. Crucially, absence can begin to be tolerated without it being marked by a “bad object.” But the beginning of a transformation in many aspects of mental life and development are ushered in (Hinshelwood, 1994). No final solution to the depressive position problem is found, and the attempt to deal with aggression against objects that are also loved and depended upon is a slowly evolving thread all through life.

In many respects this developmental voyage based on object-relations supplants the progress through Freud’s libidinal phases. The achievement of reality testing (secondary process) is a comparable moment in development to that of the depressive position. Guilt is conceptualized in a slightly different way by Freud, as deriving from the strict superego (the only internal object that Freud attends to—Freud, 1923), and this contrasts with guilt from a damaged internal object in the theory of the depressive position.

For classical psychoanalysts, the notion of the depressive position and its place in the development of the infant, disregards the classical descriptions of the libidinal phases. In addition the early onset—in the first six months of life—is argued to be improbably early, for such a sophisticated set of emotional reactions. The integration that Melanie Klein described is then attributed to an age of two or three years when the mature Oedipus complex arrives.

However, for many non-Kleinian analysts a developmental scheme based on object-relations is compatible and complementary to the libidinal phases.

## DEPRIVATION

Psychoanalytically, deprivation is the reduced fulfillment of a desire or need that is felt to be essential. Sigmund Freud (1927c) considered deprivation the result of the frustration of a drive that could not be satisfied because of a prohibition, and he was particularly interested in sexual deprivation. Later, psychoanalysis focused on the maternal deprivation caused either by the final or temporary absence of the mother or by her difficulty in providing primary care for the infant—a deprivation likely to have irreversible effects on the child's development.

For the infant, deprivation, as the result of an intrapsychic process related to needs or desires, assumes various forms. It is modulated by the reaction of the primary object, the mother, as well as the moment when the deprivation is produced, its duration, or even the attitude of mother substitutes.

The importance given to reality and its traumas compared to the reality of the representational world forms the basis of the differences among psychoanalytic theories. For example, psychoanalysts have studied the effects of “quantitative deprivation,” when the infant must confront the physical absence of the primary maternal object from birth, a condition known as hospitalism (Spitz, 1945), or after the establishment of a bond, a condition known as anaclitic depression (Spitz, 1946), which includes the phases of fright, despair, and separation. During these three phases, the infant is primarily searching for the lost anaclitic object, then, overcome with despair, enters into a situation of more or less pronounced denial, depending on the level of structuration of the internal object and the duration of separation. This process involves directing diffuse but unbearable aggressive impulses against the self, hatred of the incorporated internal object, and deprivation of the maternal breast accompanied by deprivation of the (oral) apparatus that would enable the infant to use it. Sometimes there is also a deprivation of all creative ability and the dissolution of the integrative process together with the inhibition or dissociation of impulses (Winnicott, 1984).

“Qualitative deprivation” has also been described, and occurs when the infant is presented with an object that prevents him from experiencing his impulses in an acceptable form because they are uncontrolled. This object does not assume the contradictory role of ensuring the satisfaction of the infant's needs and

pushing him toward autonomy and does not understand his signals or his thoughts. Operating behaviors and idealizing systems dominate this form of mother-child relationship (Kreiser, 1992) to prevent transient personal difficulties, struggles, and traumas from becoming mental pathologies, especially depressive and schizophrenic.

Forms of “mixed deprivation” are also known, where the interruption of maternal care and inadequate support are the basis of narcissistic collapse and weakness during the process of separation-individuation.

The effects of affective deprivation (Bowlby, 1951) have been studied among infants placed in institutions, hospitals, or foster homes (Winnicott, 1984), and in the context of family life. This has led to observation of depression and borderline and antisocial pathologies such as psychosis. Françoise Dolto has described the sudden and long-lasting dissociation found to exist following early hospitalization or repeated changes of care providers—without any possible reparation of the image of the body or the subject. The infant can regress to a state in which his vital needs are satisfied in a context where subtle, verbal, mimetic, or motor exchanges no longer take place. Having become autistic, the child's impulses no longer have an outlet and result in teratological symbolization through hallucination.

Léon Kreiser has studied depression (blank and empty) during periods of qualitative deprivation, especially their development on the psychosomatic level. Other authors have ascribed important narcissistic pathologies (feelings of emptiness, captive self-image, lack of confidence), along with the intolerance to frustration that provokes the transition to action, which is manifested during adolescence. Donald Winnicott has studied the dynamics of the antisocial act and the accompanying feeling of hopeful suffering. “In fact,” he writes, “deprivation does not deform the organization of the ego as in psychosis but pushes the infant to force the context to recognize the deprivation and ... the antisocial act manifests itself when the infant begins to create an object relationship and invest a person.”

## **DESEXUALIZATION**

“Desexualization” may be most easily understood through a discussion of its antonym, “sexualization” (Freud, 1905d). From an analytic point of view, sexualization is a response on the one hand to the endogenous imperatives of the sexual instinct and on the other to the exogenous imperatives of the encounter with the object and its otherness. The sex drive comes into play at the boundary of the biological body and the psyche, tracing signs of its libidinal energy on the body. The body then becomes “erogenous,” and bears the stamp of pleasure and unpleasure it experiences from encounters between a bodily source and a complementary object, the prime example of which is the encounter of mouth and breast.

The object, which is partial but complementary to the instinctual source, is present-absent as soon as mental life begins. Through its presence it participates in the experience of pleasure; its frustrating absence

will push the mental subject toward the initial hallucinatory experience, which, interacting with perception, will constitute the basic of ideation. Sexualization and objectification are coexistent and coalescent. Sexualization is both a manifestation and an effect of the sexual impulse that libidinally cathects the object in a way that is both quantitative and qualitative, as reflected in the strength and the emotional form of the object-cathexis.

In Freud’s first theory of the instincts, sexualization is subservient to and anaclitically dependent on the self-preservation that governs biological and mental life. Because of the paths taken by the object-libido, sexualization operates not only with respect to the object, but also with respect to the ego in the shape of the withdrawal of narcissistic libido. We may thus assume the existence of a desexualization of the object that goes hand in hand with the sexualization of the ego, and conversely.

If, for Freud, the sexual and the infantile are constitutive of the unconscious, it is strictly because of repression that they are preserved on this underlying level and separated from the conscious one. On the conscious level, the sexualizing activity of the psyche is not systematically apparent; signs of anticathexis and reaction formation may be discerned in manifest psychic contents that are desexualized while their latent inscriptions in the unconscious remain sexual. The gamut of psychic formations, including not only symptoms, be they hysterical, obsessive, or phobic, but also dreams, parapraxes, and slips, may appear to be “desexualized” yet betray, as compromise formations, latent sexual aspects that are accessible through free association. Childhood phobias are a case in point. The fear of a wild or domestic animal appears in the conscious mind as the repercussion of a traumatic event, associated with a concrete experience, but in fact it may be the transposed expression of, say, a guilty unconscious wish to have sexual relations with one’s mother. In that case it will also express a fear of castration by the father, which is experienced as the prohibition of that wish.

Desexualization can thus be viewed as a conscious mental process that leaves repressed sexualization intact in the unconscious. Whence the importance of the preconscious as a meeting ground, a place where desexualization—characterized by the repression of sexual impulses—and resexualization—arising from the return of repressed ideas attached to infantile sex-

ual activities and aroused during analysis by free association—can come together.

The Freudian concept of sublimation can help us understand the process of desexualization. It indicates a change of aim and object, which become social rather than sexual, and a shift from the pleasure principle to the reality principle. The sublimation of sexual impulses is associated with their plasticity; desexualization is in a way the precondition of access to socialization. Another psychic process, idealization, accounts for the transformation of the object, which, brought to perfection thanks to narcissistic projection, then becomes a model for identification.

The second theory of the instincts, and the second topography of the psychic apparatus that resulted from it, round out our understanding of the phenomena of desexualization. What is often called the great turning point of 1920 led Freud to rethink his instinct theory, taking into account a realm “beyond the pleasure principle” which he described in terms precisely consistent with the Nirvana principle, one of the basic tendencies of the psyche underpinning the compulsion to repeat and the push for a return to the inert and inanimate. Alongside the sexual instincts, therefore, and indeed pre-dating them, another category of instincts, the death instincts, now needed to be considered. This meant that a tendency to non-sexualization and to deobjectification was present from the beginning of the development of the mind, a tendency that could serve as a focal point for desexualization now conceived as a return to the inert and the inanimate, as a kind of paradoxical desire for non-desire. The Freudian conception of primal masochism proposes a fundamental psychic structure involving the coalescence of sexual and death instincts. Masochism is fundamentally the organizer of autoerotism as it is of narcissism, and it is at once the motor and consequence of instinctual fusion. As a sexualizing factor it may be a “guardian of life,” but it can also be lethal, fostering desexualization and leaving the field open, as it were, to the death instinct. The work of melancholy that is present, more or less, in every depressive situation, includes the effects of desexualization and deobjectification: the tendency to suicide represents the most extreme form of the desire for non-desire and the victory of the death forces characteristic of this ultimate form of desexualization.

The notions of sublimation and idealization were also changed and refined by Freud’s new conceptualization of instinctual dualism and of the functioning of

the mind. Processes of identification, and more specifically primary identification, now presupposed a desexualization that can facilitate the transmutation of object-cathexes into the new instinctual vicissitudes implied by sublimation and idealization.

Although in the analytic literature the term “desexualization” later received more systematic treatment by Heinz Hartmann in the context of the “desexualized ego,” as applied to adaptation to the social environment, it still seems important to distinguish clearly between a neurotic kind of desexualization characterized by repression of the sexual impulses, or by their sublimation and the idealization of the object, from a psychotic process engendered by the leveling effects of the death instinct on the sexual instincts.

In sum, as a result of the stimulation they represent relative to instinctual defusion, the psychic phenomena of desexualization are most clearly bound up, specifically, with the processes of unbinding, decathexis, and deobjectification; they also have a dialectical relationship with processes of identification.

## **DESOILLE, ROBERT (1890–1966)**

Robert Desoille, a French engineer, psychotherapist, and creator of the concept of the “directed daydream,” was born on May 29, 1890, in Besançon, France, and

died on October 10, 1966, in Paris. Born into a family of military officers, Desoille studied engineering as a young man. In 1923 E. Caslant initiated him into an experimental technique of mental imaging, which he felt had psychoanalytic applications. He worked out his theory over the course of seven volumes.

In *Exploration de l'Affectivité Subconsciente par la Méthode du Rêve-éveillé* [Exploration of subconscious emotions using directed daydreams] (1938), he studied the relationship between symbolism, invention, and memory, demonstrating the advantages of his method for exploring sublimation. He built on the work of Pierre Janet, Sigmund Freud, Carl Gustav Jung, and Roland Dalbiez.

In *Le Rêve-éveillé en Psychothérapie* (The directed daydream in psychotherapy; 1945), he made reference to Jung's collective unconscious. For him, the psyche consists of two poles: the Freudian id and the self, which consists of the limit of what sublimation can obtain. The conscious ego shifts between the id and the self as a possible representation. In the directed daydream, transference is expressed and resolved.

In *Théorie et Pratique du Rêve-éveillé Dirigé* (Theory and practice of the directed daydream; 1961), Desoille moved toward a "rational psychotherapy" and developed a Pavlovian conception of neurosis. Through the directed daydream, he held, poorly adapted reflexes are dissolved and new dynamic stereotypes are formed, initially in the imagination.

Upon its appearance a number of authors—including Charles Baudouin, Gaston Bachelard, Juliette Favez-Boutonier, Françoise Dolto, and Daniel Lagache—took an interest in Desoille's work. Moreover, it has continued to generate commentary and further analysis since its introduction.

## DESTRUDO

The Freudian concept of "destrudo" is one of a group of concepts that appeared fleetingly in Sigmund Freud's work and subsequently disappeared, although it is not always easy to identify the reasons for their disappearance. In the present case the situation is clearer since from an energy perspective Freud has always refused to postulate a "destrudo," that is, an energy specifically associated with the death drive, even though the term makes its appearance in *The Ego and the Id* (1923b).

Freud did not want to associate the duality of the drives with a duality of energies, since for him there was no energy dualism, but with a kind of energy monism, that of the libido. He subsequently abandoned use of the term "destrudo," which would have risked implying the existence of an energy dualism.

On several occasions Jean Laplanche has returned to this problem of terminology (1970, 1986). Destrudo does not appear in Jean Laplanche and Jean-Bertrand Pontalis's *The Language of Psychoanalysis*.

## DETERMINISM

The most general meaning of "determinism," one applicable in most contexts, is the condition of being

determined. If we understand determinateness to be a qualification of an object, determinism sees this determinateness initially as identification of the object (by several processes) and then as a causal response to a request for an explanation of why. All scientific or theoretical research thus necessarily presupposes determinism, but not in the sense of merely naming or the other operations of contemporary language, since the conditions for the initial application of language are not determinant. The meaning customarily given to determinism is determination, through the principle of causality, of the objective conditions for a phenomenon to occur.

Initially, the concept of determinism (*Determinismus*) arose within German theological and moral thinking, where it served narrow requirements related to predestination and was used to provide dogmatic answers; it did not have an objective theoretical meaning as such. Then in nineteenth-century scientific positivism, the “condition of determination” became associated with an empirical or descriptive principle of causality based on the primacy of observation, and not on explanation in the strict sense. Subsequently, for experimental science, determinism came to be considered a condition for the conduct of science itself, that is, as the epistemological principle of scientific knowledge. In this way determinism became normative. For example, physiological determinism claims to decide between the normal and the pathological in medicine, as shown by Georges Canguilhem.

Determinism, without being explicitly referred to, has been the ideal of mechanics since the seventeenth century. Projected onto objects made to satisfy the demand for causality, determinism ended up requiring that all phenomena satisfy the principle of ontological objectivity assumed in nature. Quantum physics, however, led to a retrenchment of this principle of establishing the conditions of determination, at least on the microphysical scale. Chaos theory has accentuated this point of view. In the sphere of the psyche, when Sigmund Freud attempted to explain dreams by psychoanalysis, he assumed a notion of psychic determinism in his theory of intentionality. He thus shifted the doctrine of causality in the direction of a theory of intentionality that assumed the existence of a subjective causality beyond or alongside objective causality, as shown by Pierre-Henri Castel in his introduction to Freud's *Interpretation of Dreams*.

Determinism essentially informs all theoretical or scientific research. So how can we explain the fact that

modern philosophical thought, at least since Kant and Fichte, is so strongly opposed to it? Natural determinism, after serving as the principle of Spinoza's immanent metaphysics, has come to dominate science. This domination reveals that the term has undergone both a confinement and an unwarranted extension in twentieth-century thinking. The confinement of the term to natural science constrains philosophers of freedom from examining the conditions that determine what they say. In the nonclassical sciences, confinement of the term to well-behaved natural sciences subjects intellectuals to indeterminacy complexes that seriously inhibit their theoretical inventiveness and subjects them to denigration. Freudian psychoanalysis, for example, is denigrated by positivist psychology and the various forms of psychological, organicist, and physicalist reductionism. As a result, Freudian psychoanalysis continues to search for an epistemological legitimacy based on theoretical models of the natural sciences, as was shown by Paul-Laurent Assoun. In physics, Max Planck and Werner Heisenberg created a quantum physics that was indeterminate from the point of view of classical determinism (as formulated by Pierre Simon Laplace). Because they were under the ideological spell of the old determinism, they could not completely accept their own discoveries as good science. There were two reasons for this situation: first, the concept of determinism arose not in the minimalist causal sense given above but in a theological sense, and second, ever since classical mechanics, the degree of determination that scientific objectivism has achieved has delimited the meaning and norm of determinism. Because they exclude identity and assume the differential nature of the symbolic, the status of the psyche and, even more so, the structuralist approach to the subject as taken by Jacques Lacan show that objective legality and causality could not serve as paradigms for everything we talk about. This is especially so for the unconscious, which, although “structured like a language,” is not structured as a determining cause.

A robust determinism must renounce naturalist metaphysics, which has continued to control its principles. A new philosophy of “determined” freedom can be developed without indeterminism. Freud's determined freedom led Jean-Paul Sartre, probably wrongly, to reject the Freudian unconscious and to confront a “natural determinism”. All of Freud's efforts, contrary to Jung's, clearly attempted to establish a paradoxical materialism that went beyond

philosophical idealism and the old materialisms, dialectic or otherwise.

## **DETSKI DOM**

The Detski Dom (Children's Home, also known as the Solidarity International Experimental Home) was a kind of boarding school and experimental laboratory designed to help model the future "new man," the builder of communism. It opened in August 1921 in the center of Moscow and shared with the Psychoanalytic Institute the magnificent former home of Stepan Ryabushinsky. Though Ivan Ermakov, president of the Psychoanalytic Society and Institute, was officially responsible for the home, Vera Schmidt ran day-to-day operations. During a period filled with revolutionary ideas, in the broadest sense of the term, an attempt was made to merge Freudianism and Marxism. For many of Ermakov's friends this involved using psychoanalysis, "a powerful method of liberating man from his old reductive shackles," to create individuals who conformed to the ideals of the new society. At this time the new discipline of "pedology" was established.

Vera Schmidt ran the home on a theoretical, as well as practical, level. For Schmidt, an adept of Freud, early childhood was a critical period in the formation and evolution of the future adult. Accordingly,

children were admitted to the home between two and four years of age. Initially, the twenty-four residents were cared for by fifty-one staff members. The children lived there permanently, parents visiting only periodically. The residents came from various social backgrounds. They included Schmidt's son Volik (mistakenly referred to in some publications as Alik). After 1925 residents included many children of party bureaucrats, government officials, the Komintern, and even the youngest of Stalin's two sons, Vassili.

High-ranking visitors and inspectors found the environment pleasant; the staff calm, attentive, and considerate; the children clean and properly dressed; the rapport with teachers good; and the physical and psychological state of the children healthy. Moreover, in spite of external unrest, the home was well financed. Contributors included the State Department of Finance, the Union of Manual and Intellectual Workers of Germany (from which the name Solidarity International was derived), and some of the children's families. Otto Schmidt, Vera's husband and publisher of *The Library of Psychology and Psychoanalysis*, allocated a portion of the profits from the publishing house to the home.

Vera Schmidt organized periodic meetings of the teachers, who kept daily logs with detailed observations and prepared personal reports, diagrams, and graphs detailing the evolution of each child. Staff organized wake-up activities: drawing, découpage, modeling with clay, educational games. One of the purposes of the study was to examine infantile sexuality as well as various forms of impulse display.

Professional psychotherapists, including Sabina Spielrein, treated the children. Though Vera Schmidt did not have any psychoanalytic training, her publications on the experiment and the methods used at the home (which she herself translated into German) attracted high regard even from Anna Freud in Vienna, according to some sources. In early 1923 the Schmidts went to Vienna, where they met Sigmund Freud, Otto Rank, Karl Abraham, and other analysts.

Although the trip was successful (the Russian Psychoanalytic Society became a member of the International Psychoanalytic Association), back in Moscow the situation deteriorated for the home. The staff, with Vera Schmidt at its head, continued to request psychoanalytic training. United until then, the staff began to argue among themselves. In mid-1923 the number of

residents fell from twenty-four to twelve, and the staff was reduced to no more than eighteen members. The Solidarity International Experimental Home had to confront serious financial problems (exacerbated by the fact that assistance from Germany ceased). Moreover, the institution began receiving unfavorable publicity in the local press. In late 1923 and early 1924 a struggle broke out about the future of the Home. Several committees were dissolved and wild rumors circulated, most of which were based on an incorrect understanding of childhood sexuality. Aron Zalkind, the father of pedology and a Marxist-Freudian defector, wrote in 1926, “The sexual must be subjected to the class principle.”

Ideological resistance grew, and the home became its first victim, followed by psychoanalysis and pedology. Having become a nursery school, the institution had assumed an elitist character. On August 14, 1925, the Narkompros (Ministry of Public Education) ordered the experimental home closed. Later, during the 1930s, the house on Malaya-Nikitskaya Street became the personal residence of Maxime Gorky. Today the magnificent building houses the Gorky museum.

## DEUTICKE, FRANZ (1850–1919)

Franz Deuticke, a Viennese publisher, was born on September 9, 1850, and died on July 2, 1919. In 1878 he and Stanislaw Töplitz took over the Viennese bookstore of Karl Czermak, together with the modest publishing house that was part of it. After Töplitz's departure in 1886, he became the sole owner of the Franz Deuticke Company. Using the funds from the bookstore, the company devoted its first years mostly to publishing books on medicine and the natural

sciences. Among the authors published were several professors from Sigmund Freud's university, including Theodore Meynert, Salomon Stricker, Max Kassowitz, and Heinrich Obersteiner. After having published a series of manuals and monographs in medicine and the natural sciences, Deuticke expanded his list between 1880 and 1890 to include scientific reviews and periodicals such as *Zentralblatt für Physiologie*, *Jahrbücher für Psychiatrie*, and *Monatsschrift für Kinderheilkunde*. Around this time he also became interested in the young science of economics.

After the turn of the century, Deuticke further broadened his publishing list to include scholarly books, law books, and psychoanalytic works. Freud's first contacts with Deuticke took place within the context of his own translation projects: the translation of Jean Martin Charcot's *Nouvelles conférences sur les maladies du système nerveux (Neue Vorlesungen über die Krankheiten des Nervensystems [1886])*, which appeared in 1886 and was included in volume one of the translation of the *Conférences polycliniques (Poliklinischen Vorträgen [1894])*, the translation of Hippolyte Bernheim's *La suggestion et son effet thérapeutique (Die Suggestion und ihre Heilwirkung [1888])* and Bernheim's *Nouvelles études sur l'hypnotisme, la suggestion et la psychothérapie (Neue Studien über Hypnotismus, Suggestion und Psychotherapie [1892])*. In 1891 Freud also entrusted the young and enterprising publishing house with his first monograph, *Zur Auffassung der Aphasien (On Aphasia: A Critical Study, 1891)*.

Until the outbreak of the First World War, Deuticke was, with rare exceptions, Freud's most important publisher, and his company can rightly be considered the first publisher of psychoanalysis. In 1895 Deuticke also published *Studien über Hysterie (Studies on Hysteria, 1895)*, written in collaboration with Josef Breuer, and in 1900, *Die Traumdeutung (The Interpretation of Dreams)*. On Freud's recommendation Deuticke also published some of Freud's scientist friends, such as Wilhelm Fliess, and later a number of psychoanalytic authors, such as Carl Gustav Jung. The company even took the risk of publishing the first psychoanalytic periodical: *Jahrbuch für psychoanalytische und psychopathologische Forschungen (1904–1914)*. To promote the new science, Freud became editor of the first series of works on psychoanalysis: *Schriften zur angewandten Seelenkunde (Writings on applied psychology)*.

At the start of the First World War, Hugo Heller positioned himself to be a publisher devoted to Freudian psychoanalysis, while Franz Deuticke Company, then run by Franz's son Hans, increasingly became a forum for publications by dissident psychoanalysts. After the war Deuticke published both Jung and, after his break with Freud, Otto Rank.

## **DEUTSCH, FELIX (1884–1964)**

Felix Deutsch, psychoanalyst and physician, was born in 1884 in Vienna, and died on 1964 in Cambridge, Massachusetts.

Deutsch was educated at the University of Vienna. His family was Jewish and he developed firm Zionist convictions. In 1908 he became a doctor; internal medicine was always his specialty. Felix Deutsch met his future wife Helene, also a psychoanalyst, in Munich in 1911. Within a year they were married, and they remained married fifty-two years.

Deutsch had an artistic personality; he painted and composed, and was an excellent piano player. His musicality played a role in a contribution to psychotherapy that he made in America. He found he learned a lot about patients by provoking associations through repeating words, since tone had such meaning for him. As a therapist he learned to use his natural directness, and childlike inquisitiveness, to become an excellent interviewer.

Helene and their son moved to Boston in September 1935, and Felix joined them in early 1936. Between the fall of 1939 and the spring of 1941 Felix accepted an invitation to be the first professor of psychosomatic medicine at Washington University in St. Louis.

Felix grew increasingly confident within analysis, and back in Boston he attracted a number of devoted disciples. He also taught at the Smith College of Social Work. He was attracted by clinical possibilities other than strict analysis, and he hoped to be able to make a science of technique.

He published articles on psychosomatic medicine, and *Applied Psychoanalysis*, on the objectives of psychotherapy. Deutsch was one of the creators of psychosomatic medicine, and a leader in exploring new techniques of psychotherapy. He was also, for the period in 1923 when Freud first contracted cancer of the jaw, his personal physician.

## **DEUTSCH-ROSENBACH, HELENE (1884–1982)**

Helene Deutsch, psychoanalyst and physician, was born October 9, 1884 in Przemysl, Poland, and died March 29, 1982 in Cambridge, Massachusetts.

Helene was the daughter of Jewish parents, but she grew up a Polish nationalist. Although formal schooling was impossible in Poland for a woman, private tutoring enabled her to enroll at the University of Vienna in 1907. From the outset she was interested in a psychiatric career. She received her medical degree from the University of Vienna in 1913.

As early as 1898 she was involved with a much older man who was a Social Democratic leader, Herman Lieberman. He was married, however, and a divorce in those days was politically out of the question.

While spending a year in Munich in 1910–11, studying with Emil Kraepelin, Helene finally broke off with Lieberman, who since 1907 had been a deputy from Poland in the Parliament at Vienna. In Munich she had met her future husband Felix Deutsch, and they were married in 1912. Women could not then hold clinical psychiatric appointments at the University of Vienna, but Professor Julius Wagner Ritter von Jauregg had

made a great impression on her. Once World War One broke out physicians were needed by the Austrian military, and Helene found new and welcome responsibilities thrust upon her. She functioned as one of Wagner-Jauregg's assistants, a post to which as a woman she could not formally be appointed. In the fall of 1918 Deutsch left Wagner-Jauregg's clinic in order to undertake a personal analysis with Freud, which lasted about a year. While for some, particularly Freud's exceptionally talented male pupils, he could be a burden to their independent development, Deutsch found that Freud released her most creative talents. She could write as Freud's adherent and at the same time fulfill her own needs for self-expression. She was not a mere imitator of Freud's, but within his system of thought she was able to express her own individual outlook.

The 1920s proved to be Deutsch's most creative period; she emerged as one of the most successful teachers in the history of psychoanalysis. In 1924 she became the first to head the new Vienna Psychoanalytic Training Institute, which meant that between 1924 and 1935 (when she left for Boston, MA) she had to assess all who came to Vienna for instruction in analysis. She was much sought after both as a training analyst and a supervisor; her seminars were remarkable experiences for students, and her classes were remembered as spectacles.

In Vienna Deutsch's case load became two-thirds American, and in 1930 she visited the United States to attend the First International Congress of Mental Hygiene. She was already looking around for a new position. One problem was the future possibilities of her husband Felix, an internist who had also been Freud's personal physician when he first contracted cancer in 1923. It turned out that Boston was the best place for the family, because a new psychoanalytic training institute was being founded there, and at the same time Dr. Stanley Cobb was creating a psychiatric department at the Massachusetts General Hospital. Cobb was interested in psychosomatic medicine, Felix's special field, so Cobb was eager to attract them both. Helene came over in the fall of 1935 with their son, and Felix arrived in Boston in early 1936.

Helene's stylishness, combined with the force of her personality, allowed her to attain a unique status in Boston. Many of the analysts involved in setting up the Boston institute had been her students abroad at a time when she was already one of Freud's favorites.

In 1925 Helene Deutsch became the first analyst to publish a book on the psychology of women. The

interest that she and Karen Horney showed in this subject prompted Freud, who did not like being left behind, to write a number of articles on women himself. Deutsch's insistence on the importance of maternity made her a pioneer.

At the end of World War II, she published her two-volume *Psychology of Women* (1944–45). She was especially interested in the conflict between maternal and erotic feelings in women, and she was acutely aware of how much she herself had missed in both realms. She felt that, in human terms, she had paid dearly for her professional commitment. Deutsch placed much emphasis, meanwhile, on the real conflicts of young women. Her works are heavy with the kind of cases one might expect never to see dealt with by a psychoanalyst. It was her view that in order to understand pathological behavior one must first have a clear idea of what normal behavior was like. For Deutsch, the fact that women had a more intense inner life meant that they were a unique source of human potential. Her best-known clinical concept was that of the "as-if" personality, a notion that allowed her to spotlight the origin of women's particular ability to identify with others. Her theories also helped her better understand her own ties to Freud and Lieberman.

In Deutsch's view, the crucial danger created by female masochism was that of victimhood, though the threat was potentially offset by the countervailing force of a healthy self-esteem. Horney criticized Deutsch's view of women, charging that she had fallen prey to biological reductionism through her neglect of social factors. Deutsch felt secure enough, however, to reply only in the most elliptical way. After all, she had held the fort in Vienna in the wartime, and her students had included the most notable among those of Freud's students who had remained loyal.

In 1973 Helene Deutsch published a set of memoirs, *Confrontations with Myself*, which constitutes an important testimonial to the history of Vienna and of the beginnings of psychoanalysis.

## DEUTSCHES INSTITUT FÜR PSYCHOLOGISCHE FORSCHUNG UND PSYCHOTHERAPIE (GÖRING INSTITUTE)

The Deutsches Institut für Psychologische Forschung und Psychotherapie (German Institute for Psychological Research and Psychotherapy) in Berlin was the first independent institution for training in, research on, and practice in psychotherapy. It represented a significant realization of the aims of medical and nonmedical psychotherapists in Germany, an ethical capitulation to the threats and opportunities presented by the Nazi regime, and a controversial continuity of professional development into the postwar period.

The institute was founded in 1936 as a registered association under the supervision of the Ministry of the Interior. Its founding came about as a result of the desire of a number of psychotherapists in the German General Medical Society for Psychotherapy under Matthias Heinrich Göring to functionally unite the various schools of psychotherapy in an organization independent of the control of university psychiatrists and Nazi health activists, as well as the aim of the Nazi party and government to destroy the “Jewish” German Psychoanalytic Society without disposing of the practical benefits of psychoanalysis. Although officially dedicated to the creation of a *Neue Deutsche Seelenheilkunde* (New German Psychotherapy) in line with Nazi ideals and Germanic tradition, the so-called Göring Institute functioned more significantly as a locus for the development and application of generally short-term psychotherapeutic techniques in service to state, society, military, and business in Nazi Germany.

The institute was initially funded by the psychotherapists themselves, but in 1939 the German Labor Front assumed formal supervision over the institute and poured a great deal of money into its operations. This support was increasingly supplemen-

ted by money from the Luftwaffe (German Air Force) and from German industry and business. Individual psychotherapists and psychoanalysts also worked under the aegis of the SS (Schutzstaffel) and the Wehrmacht (German Army). In 1942 the institute became a member of the Reich Research Council, which, under the leadership of Herman Göring, was to mobilize science for the war effort. In 1944 followed the creation of the Reichinstitut für Psychologische Forschung und Psychotherapie im Reichsforschungsrat (Reich Institute for Psychological Research and Psychotherapy in the Reich Research Council), the final organizational manifestation of the Göring Institute. The institute came to an end in May 1945 with the end of the Second World War.

Psychoanalysts at the institute were prominent in the outpatient clinic inherited from the German Psychoanalytic Society. In teaching, training, and practice, the Jungians, Adlerians, and Freudians maintained a degree independence from each other. Most of the Freudians, out of a combination of preference and position at the institute, adopted a neo-Freudian emphasis on social adjustment and short-term therapy. Gerhard Scheunert was Göring’s first choice to head the clinic because of his expertise in short-term methods. The “neo-analysis” of Harald Schultz-Hencke was also influential. Many German analysts of the postwar period practiced and/or trained at the Göring Institute. Some, like Harald Schultz-Hencke, Felix Boehm, and Carl Müller-Braunschweig, were heavily criticized after the war for their involvement with a Nazi-sponsored entity.

Of all the groups at the institute, the psychoanalysts had the most political difficulty under Nazism because of their identification with Freud, a Jew. In 1938, as a protective measure in the wake of the November pogrom, their group was designated simply as “Work Group A.” With the arrest of outpatient director John Rittmeister in 1942, this group was formally dissolved and the psychoanalysts’ activities at the institute were further camouflaged.

### DEVELOPMENT OF PSYCHO-ANALYSIS, THE

In this book, conceived in 1922 and published in 1924, Sándor Ferenczi and Otto Rank were reacting against the practical fallout (transference and resistances in psychoanalytic treatment) from Freud's ideas on repetition compulsion and analysis of the ego.

According to the authors, the psychoanalytic movement gave in to a desire to claim to "know too much" and thus was diverted from its earliest "active" orientations. Psychoanalysts had developed incorrect technical precepts and were clinging to rigid or obsolete rules with regard to the transference.

The authors argued that the psychoanalyst's role is to "condition the unity of the process," to act as a catalyst for the transference, and to encourage repetition by partly playing the role of the parental imago. In this way, unconscious memory traces can finally be felt by the patient, transformed into "actual memories" (remembering/remembrance/recollection), and interpreted upon dissolution of the transference. It is *lived experience* that carries conviction, the true source of knowledge and the guarantee of therapeutic "effectiveness."

However, the analyst's "desire to learn and to teach," they held, led to errors in technique such as "fanaticism of interpretation" or seeking to confirm knowledge. By situating resistance on the side of the transference and the patient's narcissism, analysts increase the patient's unconscious guilt, masking their own difficulties in integrating negative transference and their narcissistic countertransference.

The future of the discipline, the authors said, depended on the "elimination of intellectual resistances." "Training analysis is in no way different from therapeutic analysis" and should not be reserved for medical doctors. Family physicians could be given special training (including hypnosis, provided it was better understood) that would contribute to mass

prophylaxis for psychiatric conditions. The authors emphasized therapeutic use of repetition in the transference, whereas Freud saw it above all as an obstacle to the process, since for him interpretation was the privileged therapeutic tool. This marked the beginnings of a schism.

Rank broke with the Committee. Ferenczi replaced his "active" method—based on an increase in tensions—with a principle of "laissez-faire" or "relaxation," which Freud opposed after 1930.

This book introduced ideas and controversies that were taken up by later authors (Michael Balint, Donald W. Winnicott, Harold F. Searles, Jacques Lacan): the therapeutic use of object relations and regression; the analyst's "discretion" (caution in interpretation); the analyst's resistances and the role of countertransference; interest in training for physicians; and the risks inherent in "training" analysis.

**DEVELOPMENT PROCESSES.** *See* Processes of development

## DEVELOPMENTAL DISORDERS

The term “developmental disorders” describes alterations in the normal process of development and any functional structures resulting from those alterations.

As early as *Studies on Hysteria* (1895d), Freud conceived of psychoneuroses as functional structures that had been altered by factors having a premature effect on the normal processes of psychogenesis. He thus developed a theory of the etiology of hysteria whereby psychic trauma (a sexual aggression) occurred at an early age but did not take full effect until puberty (1894a and 1896b). He also attributed a similar etiology to obsessional neurosis (1895c). After 1897 he admitted that the causative moment of a neurosis could equally well derive from fantasies or from real events, and he maintained throughout his work that the pathological structure thus constituted was explicable in terms of fixations and regressions. Three major clinical texts illustrate this thesis: Little Hans (1919b), The Rat Man (1919d), and The Wolf Man (1918b [1914]). Beginning in about 1908, he extended this system to the psychoses—which he considered to be narcissistic neuroses—despite certain theoretical difficulties, as witnessed by his conversations with Jung.

After Freud, psychoanalytical thinking spread particularly to the field of psychiatry and especially to infant and child psychiatry, which it contributed to creating. It would take a major comprehensive study to review the developmental disorders that psychoanalysis can envisage treating with one or another of its specific modes of action (whether a classic analysis, face-to-face psychotherapy, or psychoanalytic psychodrama), or with other modes of action (psychiatric, educational) guided by a psychoanalytical approach to the disorder. A classification of these developmental disorders is presented in *Traité de psychiatrie de l'enfant et de l'adolescent* (Treatise on child and adolescent psychiatry), edited by Serge Lebovici, René Diatkine, and Michel Soulé (1995), and the following is based on its main sections:

- Disorders resulting from disturbances in the early mother-child relationship: these disorders (particularly in cases of infantile autism or psychosis) from the pre-oedipal period affect the very foundations of personal identity and the development of a distinct, autonomous, and permanent Self.

- Symptomatic disorders of early childhood (disorders relating to sleeping, eating, and psychosomatic disorders such as infantile asthma): without excluding possible organic etiologies, these disorders should always be considered as the causes and effects of dysfunctions in the family structure and can, in serious cases, jeopardize the life of the baby.
- Disorders in psychological development resulting from dysfunctions of the motor or sensory systems that may be congenital or may have developed prematurely (epilepsy, cardiopathies, cerebral motor infirmities, blindness or amblyopia, deafness, etc.).
- Disorders with a neurotic structure (hysterical or obsessional functioning, states of anxiety): here we must distinguish between the “normal” infantile neurosis, resulting from the oedipal drama, and childhood neuroses that call for specific interventions. Many cases present a more localized symptomatology, to be considered in the context of neurotic organization: persistent bed-wetting, eating disorders, language problems and problems with fine motor skills, intellectual inhibitions (which can be mistaken for mild or moderate mental handicaps), academic phobias or failure, etc.
- Borderline states and psychopathic structures (Misès, 1990). Perverse structures are rare in children; in adolescents and adults they indicate serious disorders in the processes of identification and must be understood in the light of the subject's history.
- Finally, many disorders in children can be understood in terms of deprivation or serious alterations in the environment, primarily in the family (premature separation from the mother, alcoholism and/or sexual aggression by the father, maltreatment); even in the absence of a pathological condition in the parents, problems relating to adoption or medically assisted procreation may justify the intervention of a psychoanalyst. In all these cases, even more than those previously mentioned, it is the whole family, over and above the individual subject, that needs to receive care.

In this entire field, but no doubt more so in cases that strike us by their severity (infantile autism, for instance), there are controversies and polemics that

oppose psychoanalysts (and those who speak in their name, sometimes making outrageous claims) and organicists intent on ignoring the specifically psychic and relational dimensions of the issue in question.

Reconstructing the subject's past remains one of the major pathways in the psychoanalytic approach to disorders. Dysfunctions in the present structure of a given person are analyzed with reference to the developmental stages of that structure and by referring to a model of normal development.

The practice of analyzing children has greatly contributed to defining such developmental models. It is worth noting in this regard that some authors (André Green) criticize the use in certain developmental models of an ad hoc "fictitious baby" and stress structure (synchronic organization) rather than history (diachronic).

## **DEVEREUX, GEORGES (1908–1985)**

Georges Devereux, an ethnopsychanalyst, was born György Dobo on September 13, 1908, in Transylvania, Hungary, and died in Paris in 1985. His ashes were

dispersed according to Mohave funeral rites in Parker, Arizona. Dobo assumed the name Georges Devereux in 1932, the same year he converted to Catholicism. He spent his childhood and adolescence in Lugos (Transylvania), his birthplace, which was annexed by Romania in 1919. He was the youngest of three children; the eldest committed suicide during adolescence. Devereux's family was well off and cultivated, polyglot, and riven with conflicts. His pro-German mother systematically objected to the pro-French sentiments of the rest of the family.

Devereux displayed considerable musical talent as a child, both as a pianist and composer, and he wrote poetry. He left Bavaria for Paris in 1926, frequented Parisian literary circles, and formed friendships with a number of famous individuals among them, including Klaus Mann. In 1927 he published poems and essays, written in German, in French avant-garde journals like Eugène Ionesco's *Transitions*. He oscillated between lifestyles and professions: bookseller, writer, physicist, chemist, mathematician, sociologist, ethnologist. In Paris during the early thirties, he studied with Marcel Mauss and Lucien Lévy-Bruhl, and then with Alfred Kroeber at the University of California, Berkeley. From there he left on his first expedition to live among the Mohave Indians, to whom he remained emotionally and scientifically attached. The following year he traveled to the high plateaus of Indochina to study the Sedang Moi (1933–1935).

His experiences in the field led him to psychoanalysis and transcultural psychiatry in 1938. Ethnopsychanalysis and ethnopsychiatry developed in response to the cultural relativism of the time. Devereux was in Paris at the end of the Second World War, where he served in the U.S. navy, and began his own psychoanalysis with Marc Schlumberger. After returning to the United States, he worked with Karl Menninger at the Menninger Clinic at the University of Kansas at Topeka, from 1946 to 1953. Indian veterans suffering from traumatic neuroses were his patients. He practiced psychoanalysis and became a member, in 1952, of the International Psychoanalytic Association (IPA) and the Philadelphia and New York Psychoanalytic Societies. He taught at Temple University in Philadelphia.

Devereux returned to Paris in 1963. He became a member of the Société Psychanalytique de Paris in 1964, and taught ethnopsychiatry and psychoanalysis

at the École des Hautes Études en Sciences Sociales and, occasionally, at Oxford University.

Devereux's published works comprise more than four hundred contributions. His articles, reports, and monographs range from a detailed descriptive approach to the psychopathology and therapeutic practices of the Mohave and Sedang peoples, to the psychoanalytic interpretation of Greek mythology, to considerations of the mental disturbances of Western societies, and the methodological difficulties in the social sciences. He was in contact with American anthropologists, including Margaret Mead and Ralph Linton, but never abandoned his analytic approach. He introduced methodological concepts such as "complementarity" and "transculturalism" and opened new fields of investigation by integrating psychoanalytic, psychiatric, ethnological, and mythological explanations.

## DIATKINE, RENÉ (1918–1997)

René Diatkine, a French psychiatrist and psychoanalyst, was born on April 6, 1918, in Paris, where he died on November 2, 1997. He was born into a Russian Jewish family (from the region of Vitebsk) that emigrated to France during the early part of the twentieth century. He began studying medicine in 1939 and continued through World War II, during which he was

mobilized twice. When not on active duty, he lived in Marseille, where he established his first significant professional contacts, most notably with Rudolph Loewenstein.

In 1946, as soon as the war was over, Diatkine became a physician and trained in psychiatry and psychoanalysis in Paris, where he settled permanently. He worked as an intern, then as a senior psychiatrist at the children's hospital Hôpital Necker des enfants malades in Professor Georges Heuyer's department. During this period he met Julian de Ajuriaguerra, with whom he opened a practice to treat language and motor disturbances. He and Ajuriaguerra also worked together to open a center for observing children, where they collaborated with language educators and psychomotor and language trainers. At the same time, Diatkine began his analytic training, undergoing analysis with Jacques Lacan. He became an associate member of the Société psychanalytique de Paris (Paris Psychoanalytic Society) on June 26, 1951, and a full member on July 1, 1952, after having resumed analysis with Sacha Nacht. He participated in the critical dialogue that expanded the field of French psychiatry, which until then had been restricted to asylums. It was at this time that Diatkine established what were to become the key interests of an extremely active career.

In 1958, together with Serge Lebovici and Rosine Crémieux, he established the journal *La psychiatrie de l'enfant* (Psychiatry of the child). That same year, with Serge Lebovici, Philippe Paumelle, and others, he founded the Association de santé mentale (Mental Health Association) in Paris. There in 1963 he helped establish the Centre Alfred-Binet, a psychoanalytic institution for children.

In 1972 Diatkine, together with Julian de Ajuriaguerra and Serge Lebovici, founded a children's line as part of the series *Le fil rouge*, published by Presses universitaires de France.

In Geneva and Paris, Diatkine helped develop a system of adult care for schizophrenic patients. In Geneva he was appointed associate professor in 1972, then part-time professor, and finally honorary professor in 1991. He continued to lead seminars until 1995.

In addition to his institutional commitments, Diatkine was active in the Paris Psychoanalytic Society. In 1953 he became director of the Centre de consultations et de traitements psychanalytiques (Center for

Psychoanalytic Consultation and Treatment) of the new Institut de Psychanalyse in Paris. That same year he participated in supervisory committees of the International Psychoanalytical Association, working to spread the use of psychoanalysis in Spain and Portugal. In 1964, under the auspices of the Paris Psychoanalytic Society, he instituted the annual Deauville Colloquium, known after his death as the René Diatkine Colloquium. In 1968 he was president of the Paris Psychoanalytic Society and remained active in its teaching committees and candidate training programs.

In 1982, with Marie Bonnafé, he founded Actions culturelles contre les exclusions et les ségrégations (Cultural Activities to Counter Exclusion and Segregation), a unique organization providing access to books to children and parents living in marginalized or poor communities. That same year Diatkine created *Les cahiers du Centre Alfred-Binet* (Journal of the Alfred Binet Center).

Diatkine wrote extensively: his list of publications includes more than four hundred titles. From the 1950s he progressively developed his ideas. Since then his approach was recognized as highly different, even though his work was still influenced by contemporary neuropsychology, especially the research of Julian de Ajuriaguerra. His work helped establish foundations for a new form of child psychoanalysis. His book *La psychanalyse précoce* (Precocious psychoanalysis; 1972), written in collaboration with Janine Simon, remains an important text on child psychoanalysis. In it he developed his notion of the role of primal fantasies. Several of his studies were significant for the evolution of French psychoanalytic thought after World War II: “Étude des fantasmes chez l’enfant” (Fantasies in children), in collaboration with Serge Lebovici (1954), “Aggressivité et fantasmes d’agression” (Aggression and aggression fantasies; 1964), “Rêve, illusion et connaissance” (Dreams: illusion and understanding; 1974), “Introduction à une discussion sur le concept d’objet en psychanalyse” (Introduction to a discussion of the object in psychoanalysis; 1989).

While maintaining his individual practice, Diatkine developed original techniques for expanding the application of psychoanalysis: individual psychodrama, collaboration with teams of multidisciplinary caregivers, techniques of language reeducation, field work, coordinated programs involving teachers and librarians. He explained how links between the nor-

mal and the pathological could be used to escape overly rigid classifications, questioned the “ravages of fate,” and worked to reestablish the historical continuity that dissolves during a difficult adolescence. Emphasizing latent mental potential, he insisted on the possibility of psychic reorganization, and transmitting, rather than teaching, the richness and discipline of psychoanalytic thought; he fought against reductionism.

## DIPSOMANIA

The term “dipsomania” was used in clinical psychiatry. It is not a psychoanalytic term but was used on occasion by Sigmund Freud and other psychoanalysts. The classic definition of “dipsomania” is that of Valentin Magnan (1893): Preceded by a vague feeling of malaise and a burning sensation in the throat, dipsomania is a sudden need to drink that is irresistible, despite a short and intense struggle. The crisis lasts from one day to two weeks and consists of a rapid and massive ingestion of alcohol or whatever other strong, excitatory liquid happens to be at hand, whether or not it is fit for consumption. It involves solitary alcohol abuse, with loss of all other interests. These crises recur at indeterminate intervals, separated by periods when the subject is generally sober and may even manifest repugnance for alcohol and intense remorse over his or her conduct. These recurring attacks may be associated with wandering tendencies (dromomania) or suicidal impulses. Although “dipsomania” means compulsive thirst, the use of the term is reserved for the compulsive intake of alcoholic beverages.

The term was introduced by Dr. C. W. Hufeland in 1819 in his preface to *Trunksucht* (Dipsomania), a study of the phenomenon by C. von Bruhl–Cramer. Even as early as 1817 the Italian physician Salvatori had identified a “furor to drink.” All of these authors contrast dipsomania and chronic alcoholism.

Freud alluded to dipsomania in his correspondence with Wilhelm Fliess (Freud to Fliess, January 11, 1897, and “Draft K”) and in his “Further Remarks on the Neuro-Psychoses of Defence” (1896b). He saw dipsomania as a secondary symptom of a defense against an obsessive thought that forms when the compulsion is displaced from that thought onto the motor impulses directed against the thought. In more exact terms, the compulsion, emanating from the ego, is mobilized against the affects linked to the obsession, as a measure of protection against and desensitization to suffering induced by these affects and as a means of obtaining pleasure. This need for alcohol is a substitute for an associated repressed sexual activity of an autoerotic kind, namely masturbation, which Freud, in a letter to Fliess dated December 22, 1897, calls “the one major habit, the ‘primal addiction’ ” (1950a [1887–1902], p. 272). The drunken stupor represents both a desensitization of the ego to painful affects and the pleasure of active mastery of experiences of passivity. Motor

acts (drinking, whether or not associated with dromomania) are central to the obsession.

In a letter of January 11, 1897, Freud cited the case of “a man of genius” who “had attacks of the severest dipsomania from his fiftieth year onwards” and who was “a pervert and consequently healthy” until that point (1950a [1887–1902], p. 240). The man’s crises were heralded by catarrh, hoarseness, and diarrhea (“the oral sexual system”), all of which represented bodily “reproduction of his own passive experiences” and brought together desensitization, repetition, and mastery. Freud compared this substitution of compulsive drinking for the sexual instinct to the substitution that culminates in the passion for gambling. In this letter to Fliess, Freud outlined an intergenerational psychopathology. During the same period he published, in succession, “Heredity and the aetiology of the neuroses” (1896a) and “Sexuality in the aetiology of the neuroses” (1898a).

There is little elaboration of this notion in Freud’s subsequent writings. However, in considering epileptic fits and pathological gambling as they relate to (autoerotic) sexuality and death in “Dostoevsky and Parricide” (1928b), Freud provided, without designating them as such, insights into the alcoholic’s crises: “He never rested until he had lost everything” (p. 191). “The irresistible nature of the temptation, the solemn resolutions, which are nevertheless invariably broken, never to do it again, the stupefying pleasure and the bad conscience which tells the subject that he is ruining himself (committing suicide)—all these elements remain unaltered in the process of substitution” (p. 193).

In this essay Freud proposes the hypothesis of an abnormal mechanism of discharge of the instincts, posited organically, that operates both in histolytic or toxic brain disease and in cases of inadequate control over the psychic economy when energy levels reach a certain threshold. This mechanism is closely related to the sexual processes, understood as “fundamentally of toxic origin” (p. 180), and enables the ego to “get rid by somatic means of amounts of excitation which it cannot deal with psychically” (p. 181). The meaning and intentionality of such crises (drunkenness, coma, or deep sleep) are well known: Such “deathlike” (p. 182) states express an identification with a dead person, in either reality or fantasy, the latter being more significant (boys, in their fantasies, usually wish for the death of the father). The dipsomania crisis,

preceded by an aura of supreme happiness, liberation, and triumph, has a punitive value: the subject is dead, like the person the subject wished dead. This is similar to the situation of the brothers of the primitive horde and relates to totemic ritual.

In the view of Otto Juliusburger (1913), dipsomaniacs who seek out the company of “lower-class” drunks in this way demonstrate their subjection to sadomasochistic instincts. Edward Glover (1932) compared dipsomania to an obsessive ceremonial (less obvious in solitary drinkers) and saw it as an “artificial” manic-depressive syndrome (with more direct sadism and a less severe oral fixation). Similarly, Otto Fenichel (1945) saw a link between pathologically impulsive characters and “the ego’s morbid syntonic impulses,” expressed on the economic and dynamic levels as manic-depressive disorders characterized by alternating acts and remorse. These impulses are seen as (futile) attempts to master old experiences through repetition and active dramatization, to master guilt, depression, and anxiety. John W. Higgins (1953) and William J. Browne (1965) emphasize the passage from thought to motor action, a return to the mother, an incorporation of the mother’s breast, and denial of passivity. For Charles Melman (1976), aversion therapies that seek to create new boundaries are actually aggravating factors in dipsomania. In an observation based on just two interviews, Jean-Paul Descombey (1992) relates the case of a young dipsomaniac who engages in a repetitive ritual of a “tournament of grand dukes” with his various brothers and sisters, begun from when he discovered the body of his dead mother; autoerotism and the death instinct are condensed in the subject’s comment “I must finish myself off.”

The notions of somalcoholosis (P. Fouquet, 1955) and alcoholism (Edmund Jellinek) are synonymous with dipsomania. Alcoholepsy, or alcoholic seizures (P. Fouquet, 1970) is a critical episode in a chronic alcoholic; associated forms of dromo-dipsomania have been described. Bulimic behaviors, which are comparable to dipsomania, are sometimes associated with it. Alimentary orgasm (Sándor Radó, 1933), which has a euphoric pharmacogenic effect, is provoked by the ego, which thus rediscovers its broadest narcissistic dimension.

The relative dearth of studies of dipsomania is explained by the fact that dipsomaniacs are often approached only in single interviews in hospital

emergency rooms, where they tend to end up; there is rarely any follow-up. Nevertheless, as a particular form of alcohol abuse, dipsomania is of interest in that it involves a kind of epitome and condensation of various aspects of alcoholism: a compulsion for repetition; a short-circuiting of psychical working through by acting out an undeclared depressive state; the problematic interplay of desensitization and attempted mastery; and autoerotism and self-destructive, potentially lethal actions. There are two possible dangers here: overdistinguishing dipsomania from other forms of alcoholism and, alternatively, failing to perceive its specificity. The same is true for transitory alcohol abuse and drunkenness in “normal” subjects, which are insufficient in and of themselves to account for alcohol addiction, whether or not dipsomania is present. A dynamic approach must go beyond organicist views, which attempt to link dipsomania to manic-depressive psychosis or epilepsy, and take into account the connections suggested in clinical practice. Finally, Freud, in “Dostoevsky and parricide” (1928b), though he does not explicitly cite alcoholism (from which Dostoyevski himself was not immune), nevertheless proposes a toxicity-based theory of sexuality and the neuropsychoses (Descombey, 1994).

## DIRECT ANALYSIS

Direct analysis is a therapeutic technique developed by John Rosen for the treatment of schizophrenics. Rosen began from the basic postulate that serious pathologies have their origins in inadequate or poor maternal care. As the result of such care, the patient is psychically a baby and must be treated as such, with unconditional love from a caregiver. This led Rosen in some cases to assume the nearly continuous care of a single patient for several weeks, and sometimes several months, while actively trying to shake up or pierce the patient's defensive shell through so-called "direct" interventions (including violent physical contact).

Rosen's position was appealing because of its optimistic slant (its assumption that if the therapist does not know where he is going, the patient's unconscious would), because of the courage and sacrifice required of the therapist (whose personal life was thereby relegated to the background), and without doubt because of the generous but obviously simplistic nature of the etiological theory involved. At its most extreme, Rosen's technique is not so very different from that proposed by Sándor Ferenczi before Freud convinced him to abandon it. Yet on a theoretical level, Rosen's theory obviously misinterprets the central role of conflict in psychic pathology, and on a practical level, his technique ignores the obvious risks of uncontrolled counter-transference.

## DIRECTED DAYDREAM (R. DESOILLE)

The notion of the directed daydream refers to a product of the imagination, an expression of a waking oneiric state, used in the 1930s by Robert Desoille for therapeutic purposes; he later gave it the name *directed daydream* (or *directed waking dream*).

The directed daydream is an active mobilization of the imagination in a relaxed setting by means of suggestions of climbing and descending, for the purpose of exploring "subconscious affectivity" and gaining access to the "superior part of the mind that is not exclusively colored by instinct." Imaginary space appears in this context as a metaphor for mental space. The approach's theoretical development extends from Freudian sublimation (1938) to a Pavlovian conception of the search for new, dynamic stereotypes (1961), by way of a Jungian mobilization of archetypes (1945).

At the beginning of the 1970s, practitioners of the directed daydream technique in the Groupe International du Rêve Eveillé en Psychanalyse (GIREP; International group of the directed daydream in psychoanalysis) integrated the Freudian unconscious into their practice and theory. This gave rise to an analytical practice known as the "directed daydream in psychoanalysis." This involved allowing images to form as spontaneously as possible, creating an imaginary space based on the idea of moving or traveling, describing to the analyst the scenes that unfold, and having the patient describe his associated feelings. Treatment comprised two inseparable and interactive elements: producing the directed daydream and putting it into words, and the associative work of exploring its meaning in relation to memories, nocturnal dreams, and fantasies; constructions and interpretations operated on a metaphorical level. Psychoanalytic in its reference to the unconscious and to various Freudian and post-Freudian concepts, this treatment is distinctive in terms of its procedures and its view of the therapeutic relationship, according to which the dynamics of the directed dream treatment imply analysis of the transference. Among the approach's main theoretical orientations are the following:

- Nicole Fabre, for whom the space of the directed daydream, a joint creation, facilitates the expression of old problem areas and partakes of sublimation in the Freudian sense.

- Roger Dufour, who emphasizes the specular function of the directed daydream: the patient works on the relationship between speech, the body, and the Imaginary—a relationship that is basic to mental dynamics.
- Gilbert Maurey, who locates the directed daydream at the metaphorical boundary between the Imaginary and the Symbolic as a mediator for access to the unconscious, the treatment being worked out in terms of the Real-Symbolic-Imaginary triad.
- Jacques Launay, who emphasizes the role of movement in the imaginary space and its ability to invigorate the primary process.
- Jean Guilhot and Marie-Aimée Guilhot, who describe the directed daydream as an instrument for change through the visualization of reparative or innovative experiences within an analytic and transpersonal perspective.

## DISAVOWAL

The term “disavowal” (*Verleugnung*), often translated as “denial,” denotes a mental act that consists in rejecting the reality of a perception on account of its potentially traumatic associations. The notion of disavowal made its appearance rather late in Freud’s work. For years he was content to describe the little boy’s refusal to recognize the absence of a penis in a little girl, as observed in clinical practice, without employing a

specific term. Thus, in his “On the Sexual Theories of Children” (1908c) and in the case history of “Little Hans” (1909b), he noted the phenomenon and described it in terms of a rejection of perceptual evidence. Little boys, he argued, do not doubt “that a genital like [their] own is to be attributed to everyone [they] know. . . . This conviction is energetically maintained by boys, is obstinately defended against the contradictions which soon result from observation, and is only abandoned after severe internal struggles (the castration complex).” The period concerned, lasting approximately from three to five years of age, Freud dubs the “phallic stage” in view of the narcissistic hypercathexis of the idea of the penis by which it is usually characterized—especially in the little boy, who finds it unthinkable that anyone worthy of respect should be without a penis, least of all his mother.

The little girl cannot similarly reject the perception of her own lack of a penis. However, in certain young girls, Freud notes “the hope of some day obtaining a penis in spite of everything and so becoming like a man may persist to an incredibly late age and may become a motive for strange and otherwise unaccountable actions.”

Freud’s first reference to the term was in the “Wolf Man” case history (1918b [1914]; see also 1914a), where he conceived of disavowal as operating between at least two regions of the ego which invalidated one another. Thus one region might accept the symbolic character of castration and sexual difference while the other embraced the all-or-nothing logic of the phallic structure, and everything proceeded as though the two spheres had no influence upon each other at all.

Beginning with the *Introductory Lectures on Psychoanalysis* (1916–17a), Freud began systematically using the verb *verleugnen* to refer to the mental act of rejecting a perception as inconceivable—which James Strachey translated as “to disavow.” The noun form—*die Verleugnung* (disavowal)—was not used to designate the metapsychological concept until a little later (1925h). It was mainly in his late work, in “A Short Account of Psychoanalysis” (1940a [1938]) and “The Splitting of the Ego in the Process of Defense” (1940e [1938]), that Freud sought to anchor the specificity of disavowal by situating it within the particular topography of the split ego.

In “The Infantile Genital Organization” (1923e), Freud reasserted that only the male organ played a

significant role in the mind of the child of either sex around three years of age. The child could understand the absence of a penis only as the result of castration. It was therefore the manner in which the initial disavowal was overcome that determined the castration complex to which the individual would become subject. Returning to this crucial question in “Psychical Consequences of the Anatomical Distinction between the Sexes” (1925j), Freud presented castration as a result of a “deferred action,” the threatening nature of the possible absence of the penis assuming its full mental force only after a more or less extended period of disavowal.

Freud also noted that the persistence of such disavowal beyond the phallic period, into adolescence and adulthood, could lead to a form of mental illness: “The process I would like to describe as denial [*Verleugnung*] . . . appears to be neither rare nor very dangerous for the mental life of the child, but in adults it could lead to psychosis.”

Moreover, Freud had published two observations of young men in whom denial of the lack of a penis appeared to determine the outbreak of psychotic symptoms (1914a). The first was the famous “Wolf Man,” whom Freud claimed had “dismissed” [*verwarf*—see “Foreclosure”] the “reality [sic] of castration,” that he “refused to know anything about it, in the sense of repressing it. He did not actually pass judgment as to whether it existed or not, [castration] but effectively it did not.” This rejection, as inconceivable, of the possible absence of the penis was what triggered the patient’s returning hallucination of a severed little finger. For Freud, then, the psychotic ego disavowed perceptual reality in a way somewhat akin to the way a neurotic repressed certain instinctual demands.

But Freud subsequently went on to broaden his clinical work on disavowal well beyond the realm of psychosis. In “Fetishism” (1927e) he reported a case of two young men each of whom denied the death of his father. However, Freud notes, neither of them developed a psychosis, even though a “a piece of reality which was undoubtedly important has been disavowed [*verleugnet*], just as the unwelcome fact of women’s castration is disavowed in fetishists.”

He then returned to the notion of the splitting of the ego (already discussed in the Wolf Man case history), presenting it as the topographical corollary of

the mechanism of disavowal: the possible juxtaposition in the psyche of at least two incompatible mental attitudes that appeared to have no influence on one another. It was no longer a question, therefore, of treating disavowal as the disavowal “of” something but rather as a mutual disavowal, a disjunction “between” two discrete realms of the split ego. Similar disavowals were common, Freud noted, and not merely among fetishists. In his later works Freud maintained that disavowal was present to varying degrees in psychosis, perversion, and very possibly too in all normal subjects. He offered an instance from his personal experience in a public letter to Romain Rolland (“A Disturbance of Memory on the Acropolis,” 1936a, p. 245).

It was also in his paper on “Fetishism” that Freud showed that disavowal, unlike repression, did not erase the idea or perception in question but only its meaning; this was why he rejected the term “scotomization” proposed by René Laforgue (1927e, pp. 153–54). Disavowal was in fact a suspension of the function of judgment, of that same attributing judgment he felt was decisive in the formation of the ego. As a consequence of his methodological concern more clearly to distinguish disavowal and repression, he ended by suggesting that repression treated the affect as disavowal treated the idea, which may be taken to mean that repression no more eliminates the affect (it is only displaced) than disavowal erases the idea (whose meaning alone remains obscure).

This having been said, it is important to recognize that all the clinical illustrations of disavowal supplied by Freud over a thirty-year period are based on two canonical illustrations: the disavowal of women’s lack of a penis and the disavowal of the death of the father. Disavowal is thus always a disavowal of absence, which is why it is so important in the process of symbolization. In fact, Freud specifies as a prerequisite of symbolization the ability to represent the object to oneself as something that can be absent: an object, he says, can only be symbolized in absentia. The disavowal (of absence) therefore constitutes a fundamental obstacle to the very process of constructing psychic reality, and in this it is quite distinct from negation, which operates as the starting point of the (preconscious) mental recognition of something: disavowal and negation are radically different in their logical functions.

Disavowal, as opposed to negation, is a narcissistic expedient whereby the individual seeks to avoid

acknowledging absences or shortcomings of key parental figures (castration of the mother, death of the father). In practice, however, it transpires that persistent disavowal hardly allows the subject to overcome the traumatic burden of the representations in question; indeed the potential latent virulence of these representations appears rather to be made permanent by the invalidation of possible symbolic links. Moreover, whatever suffering disavowal and splitting may spare the subject's consciousness is generally proportionately visited upon those around him.

In the treatment of patients afflicted by enduring disavowal, everything suggests that they want to leave the responsibility of thinking what is for them unthinkable, of integrating what they cannot integrate, up to the "other" member in the therapeutic relationship. This occurs primarily through the mechanism of projective identification, which requires considerable psychic expenditure on the part of that other person, often within a very painful experiential realm. This kind of detour through the mental economy of the therapist is seemingly a necessary but not sufficient condition for the subject's successful integration of such elements into a symbolic interplay thanks to which the pleasure principle can again become effective.

Jacques Lacan in his seminar on "Object Relations" (1956–1957), talks about disavowal (he uses the French "*démenti*") as a fundamental mechanism of the so-called perverse structure, with its characteristic manner of treating castration: simultaneously rejecting and accepting it. He employs the term "foreclosure" to refer to the mechanism of symbolic denial, which he feels is a key factor in psychosis.

## **DISCHARGE**

An economic term borrowed from a physicalist epistemological model, "discharge" was used by Sigmund Freud in his theorization of how the psychic apparatus deals with excitation. The notion of discharge thus refers to an outward release of the energy produced in the psychic apparatus by excitations, whether these are external or internal in origin.

By virtue of its economic orientation, this notion is part of the metapsychological approach and speaks to the quantitative dimension in Freud's model. Freud discussed discharge when he described the pleasure/unpleasure principle: the pleasure of discharge, the unpleasure of retention. We should recall that according to Freud, the source of the instinct is a state of excitation in the body and its *aim* is to eliminate this excitation. Obviously, the concept of discharge implies as a corollary the notion of tension, or charge. Pleasure and unpleasure probably depend less upon an exact level of tension than upon the rhythm of variation in tension. The principle of pleasure/unpleasure is thus considered a particular case of Gustav Fechner's "tendency toward stability," that "tendency" becoming in this instance the "principle of consistency."

Consistency is said to be achieved by means of the discharge of the energy already present, but also by the avoidance of factors that might increase the quantity of excitation. The principle of consistency is indeed basic to Freud's economic theory and is closely linked with the pleasure principle. The psychic apparatus, in this view, also tends to cancel out excitations or reduce them to a minimum, and Freud, following Barbara Low, called this the "Nirvana principle," which works in tandem with the principle of inertia. It is in this realm that the forces of Thanatos lurk; moreover, it was in *Beyond the Pleasure Principle* (1920g), where the death instinct is introduced, that Freud explicitly formulated the principle of consistency and related it to the Nirvana principle.

Discharge can be total or partial; it can be appropriate or it can contribute to psychopathological, even psychodramatic disorders. The notion thus appears in Freud's discussions of "abreaction" or "acting-out," when there is insufficient regulation of excitation by the psychic apparatus. Another possibility is discharge into the body, which suggests the mysterious leap from the psychic to the somatic, the notion of somatic compliance, and the phenomenon of conversion. Freud also mentioned the pathogenic role of defective discharge in considering the model of actual neurosis, and in presenting the hypothesis of the damming up of the libido to explain the phenomenon of hypochondria. Still in the context of discharge, the soma as an internal safety-valve has been viewed as a way of handling tensions that cannot be worked through or that are too massive—in short, a kind of somatic "acting-in."

## **DISINTEGRATION, FEELINGS OF (ANXIETIES)**

The expressions *feelings of disintegration* and *disintegration anxieties* refer to a feeling of extreme anxiety that the personality is "falling to pieces" or disintegrating into elements that are no longer connected together. This serious form of depersonalization has been described in the psychoses, particularly schizophrenia. It has been mainly evoked, however, with regard to the earliest stages of the infant's development and their consequences.

Following Melanie Klein's description of the schizoid-paranoid position in "Notes on Some Schizoid Mechanisms" (1946), the notion of fragmentation appeared in theoretical descriptions and psychoanalytic clinical practice to characterize the anxieties inherent in that position. Under the influence of the death drive, and introjected in the form of the persecutory breast or penis, archaic defenses produce a major splitting of the self considered in terms of bad internal objects. This defensive mechanism is accompanied by feelings of destruction, annihilation, or fragmentation of the ego that have been interpreted by some as a precursor to castration anxiety. Linked to deprivation, privation, and frustration, only the introjection of a good object can restore the cohesion of such a fragmented self, by creating a path toward the depressive position.

These psychopathological notions have been taken up by Kleinian authors such as Donald Winnicott, although in his case greater importance is granted to the environment, particularly the mother. Esther Bick returned to the notion of fragmentation through her observations of infants, and Wilfred R. Bion makes it a constant, to varying degrees, of the psychotic part of all personalities, with the ever-active threat of "catastrophic change."

Pierre Marty describes another form of fragmentation in his work on "essential depression," and Heinz Kohut views it as one of the main elements in the pathologies of the self. Jacques Lacan, meanwhile, reverses the Kleinian positions by viewing the archaic anxieties of the "fragmented body" as the consequence of castration, which is by definition inscribed within the real from the beginning.

## DISINTEGRATION PRODUCTS

A psychoanalytical theory founded on the development of the Self postulates a stage of development at which its integration is achieved. This stage is characterized by a subjective feeling of continuity in time and space, and simultaneously by an ease of communication between body and mind. Before one reaches this stage, there is the psychological equivalent of separate zones of operation, characterized by distinct zones of pleasure and activity. A return to this previous stage of disparate activity amounts to a form of disintegration: any integration already achieved is undone. This disintegration is manifested by the emergence of isolated activities that are non-communicative and unlinked and involve isolated parts of the body, pleasure felt in one isolated zone, and an isolated ideational preoccupation. This can take various forms: hallucinatory thoughts, repetitive motor activity and/or hypochondriacal ruminations. This phenomenon can assume alarming dimensions, but it can easily be overcome by means of a rapid reintegration brought about by a connection, described as a Self-object relation, which serves to restore this temporarily lost state of cohesion.

From this point of view, the appearance and disappearance of psychotic symptomatology can be explained by the shift from an integrated Self to the emergence of products of disintegration. The particular cause of this regressive movement is some form of narcissistic wound: in other words, it stems from wounds to the Self that are serious enough to produce a downward spiral involving fragmentation. The appearance of products of disintegration in the course of psychological treatment is considered to be the result of the loss of a Self-object, which is the equivalent of a break in the Self/Self-object relation—a break which is in turn experienced as a narcissistic wound.

## DISMANTLING

The term *dismantling*, introduced by Donald Meltzer, refers to a very primitive defense mechanism involving

dissociation of the perceptual apparatus “by a passive process that allows the various senses, specific and general, internal and external, to attach to whatever object is most stimulating at the moment” (Meltzer, 1975/1991)—for example, a light, a sound, or an odor.

Meltzer used this term for the first time in a paper delivered at a meeting of the British Psychoanalytical Society in June 1969, “The Origins of the Fetishistic Plaything of Sexual Perversions” later published in his second book, *Sexual States of Mind* (1973, pp. 107–113). He took the idea of the dismantled object from the psychoanalytic treatment of children who had suffered from early infantile autism. He defines dismantling as “the most primitive working of obsessional mechanisms” (p. 108). Unlike the splitting processes described by Melanie Klein, which make use of the sadistic drives, dismantling, which is reversible at any time, instead relies on a relaxation of the attention function.

The author invented this term with reference to the notion of “consensual validation” defined by Harry Stack Sullivan, which is very close to Wilfred R. Bion’s idea of the “common sense.” Meltzer’s proposed idea involves a dissolution of such constructions, leading to the creation of a multitude of unisensory objects. He emphasizes that the implementation of such a defense mechanism suppresses genuine relational experiences and thus their introjection. In the first publication, he hypothesizes that dismantling is also seen in sexual perversions where the exciting objects (fetishes) are “dismantled objects” used in their purely sensorial aspect.

The notion of dismantling is then taken up in greater detail in Meltzer’s 1975 book *Explorations in Autism*, where he shows the massive use of this defense mechanism in autism proper, explaining the stereotypes of sensory autostimulation under the influence of the repetition compulsion. He demonstrates a more complex use of this phenomenon in postautistic obsessiveness and in obsessional states in general. Meltzer argues that dismantling, which is beyond consensuality or within its dissolution, does not belong to the spectrum of projective identification but rather belongs within the notion of “adhesive identity” positing a two-dimensional space, proposed by Esther Bick (1975).

Some French authors (J. Bégoïn, 1994; D. Ribas, 1994; D. Maldavsky, 1995) have compared dismantling to decahexis in the Freudian sense, and it is indeed possible to do so: The former can be considered as a very primitive form of the latter. Dismantling also

seems to be at work in the self-soothing behaviors described by Claude Smadja (1993) and Gérard Szweç (1993). These authors compare this mechanism with the abnormal, destructive primary masochism that Benno Rosenberg (1991) describes as “centered around excitement in and of itself . . . and the gradual abandonment of the object.” Frances Tustin also shares this view in *Autistic States in Children* (1981), in which is described an autosensuality, differentiated from autoerotism, in autistic maneuvers and its exacerbation into self-directed sadism in certain cases.

## **DISORGANIZATION**

The concept of disorganization is not specifically Freudian. It is part of a semantic field that constitutes one of the contemporary currents of psychoanalysis, namely the psychosomatic economy of Pierre Marty. It refers to a set of mental transformations, which at each step cause the psychic apparatus to lose its structures of meaning and reduce its capacity for impulse expression.

We find similar concepts in Freud, primarily in his work on actual and traumatic neurosis. In 1894, in Manuscript E on anxiety (1950a), and in 1895, in his article, “Detaching a Syndrome of Anxiety Neurosis from Neurasthenia” (1895b), he created a new classificatory entity, anxiety neurosis, for which he provided a clinical description and formulated a psychological hypothesis. His hypothesis involves a breakdown in the connection between somatic sexual excitation and “thing representations” in the unconscious. The first anxiety theory postulates the accumulation of somatic sexual excitation. Among the psychic obstacles to somatopsychic communication, Freud gives three possible mechanisms: repression, the difference between somatic sexuality and psychic sexuality, and degradation (of the libido). This last mechanism can be compared to the concept of disorganization. In 1920, in his essay, *Beyond the Pleasure Principle* (1920g), Freud developed his economic hypotheses concerning traumatic neurosis. He states that, faced with the traumatic irruption, “Cathectic energy is summoned from all sides to provide sufficiently high cathexes of energy in the environs of the breach. An ‘anticathexis’ on a grand scale is set up, for whose benefit all the other psychical systems are impoverished, so that the remaining psychical functions are extensively paralysed or reduced” (p. 30).

Since Freud we have come to understand actual neurosis as one of the modalities of traumatic neurosis, and its psychoanalytic study is a major component of the analysis of psychosomatic behavior.

In 1967, in an article titled “Régression et instinct de mort: Hypothèses à propos de l'observation psychosomatique,” Marty systematically described for the first time the two major processes of somatization: the path of regression and the path of progressive disorganization. While the process of somatization through regression culminates in reversible “crises,” the process of somatization through progressive disorganization

leads to progressive illnesses that can result in death. This last process is supported, according to Marty, by the action of the death instinct and is generally accompanied by depression and an externalized mode of existence.

In *Les mouvements individuels de vie et de mort* in 1976 and in *L'ordre psychosomatique* in 1980, Marty situated the concept of disorganization within the general framework of his theory of individual evolution, which refers to the counter-evolutionary movement caused by the precedence of the death drive over the life drive. This apparent precedence is generated by a traumatic context that has an impact on what is generally the psychic organization of character. The process of disorganization is generally made possible by the lack of points of fixation capable of serving as psychic and somatic obstacles. Consequently, the concept of disorganization is distinct from that of regression, with its points of fixation, or attachment.

## DISPLACEMENT

For Freud, displacement (a primary process) means the transference of physical intensities (1900a, p. 306) along an "associative path," so that strongly cathected ideas have their charge displaced onto other, less

strongly cathected ones. This process is active in the formation of hysterical or obsessional symptoms, in the dream work, in the production of jokes, and in the transference.

Between 1887 and 1902 the concept of displacement appeared several times in Freud's writings (in Drafts K and M in his correspondence with Wilhelm Fliess, in the "Project for a Scientific Psychology" [1950c (1895)], and in *The Interpretation of Dreams* [1900a]). It was introduced in connection with his clinical work, apropos of the analysis of neurotic symptoms and paranoia. In Draft M (1950a), Freud described the types of displacement that result in compromise-formations. He distinguished "Displacement by association: hysteria.; Displacement by (conceptual) similarity: obsessional neurosis (characteristic of the place at which the defence occurs, and perhaps also of the time).; Causal displacement: paranoia" (p. 252).

In addition, in his search for a model of psychic functioning still informed by the scientific thinking and medical research of the time, Freud noted: "Hysterical repression evidently takes place with the help of symbol-formation, of displacements on to other neurones. We might think, then, that the riddle resides only in the mechanism of this displacement, and that there is nothing to be explained about repression itself" (1950c [1895], p. 352). Displacement, at work to a pathological degree in hysteria, "is thus probably a primary process, since it can easily be demonstrated in dreams" (Ibid., p. 353).

It was in fact Freud's analysis of the dream work that led him to discover the importance of displacement. He noted in *The Interpretation of Dreams* that: a) "The consequence of the displacement is that the dream-content no longer resembles the core of the dream-thoughts and . . . the dream gives no more than a distortion of the dream-wish which exists in the unconscious" (p. 308); b) Dream distortion can be "traced . . . back to the censorship which is exercised by one psychical agency in the mind over another. . . . dream-displacement comes about through the influence of the same censorship" (p. 308); and c) "[A] transference and displacement of psychical intensities occurs in the process of dream-formation" (pp. 307–308).

The notion of displacement did not see much further development. In his various revisions to his theories on dreams, Freud focused more on the

separation of images from the affects that had been attached to them, on the vicissitudes of these affects (displacement, conservation, metamorphosis), and on the fate of images (stripped of affect) in relation to the “sensory intensity of the image presented” (1900a, p. 306, n. 1). But it was above all in the process of refining the analysis of the transference during treatment and its different manifestations—lateral, indirect, and direct transference (Freud, 1915a; Sandór Ferenczi, 1909/1994; Michel Neyraut, 1974)—that the notion of displacement was expanded. It was further explored, too, by such authors as Jacques Lacan (1957/2002; 1958/2002) and Guy Rosolato (1969) who took as their starting point the work of linguists (Ullmann, 1952; Jakobson and Halle, 1956) on the relationship between signifier and signified, and on metonymy (displacement by contiguity) and metaphor (displacement by substitution).

Displacement is often linked to substitution. Not infrequently, this link is made without an adequate distinction being drawn in temporal terms between substitution where there is an immediate exchange based on the disavowal of one of the two poles involved (perceptual, hallucinatory, or conceptual substitutions), and substitution where deferred action comes into play.

## **DISPLACEMENT OF THE TRANSFERENCE**

Displacement of the transference, also called lateral transference, is a defense in which transference is directed away from the analyst to a third party or an activity that both conceals and represents undesirable aspects of the transference. The idea of displacement of the transference originated in Freud’s technical writings. In “On beginning the treatment” (1913), Freud cautioned analysts about sessions that were too infrequent, which allowed the analysis to wander down side paths, and about patients who discussed their treatment with close friends every day, which would cause a “leak” in the analysis and the transference. In “Remembering, repeating, and working-through” (1914), he also said that the patient’s transference is revealed “not only in his personal attitude to his doctor but also in every other activity and relationship which may occupy his life at the time” (p. 151).

Later, other authors (for example, Daniel Lagache and Michel Neyraut) mentioned displacement of the

transference when discussing transference, usually speaking of it as resistance of a sort. Not until the work of Alain Gibeault and Evelyne Kestemberg (1981) was a positive role attributed to it. For these authors, the displacement of the transference prevents only the awareness of the transference, not the analysand's unconscious cathexis in the analysis and with the analyst. In the analysand, the external object nevertheless maintains a symbolic link with the analyst and really represents the internal-object relation resulting from the repetition of an infantile experience. These authors nevertheless recognize that the displacement of the transference, even if it is sometimes useful (notably in cases of character neurosis, where it moderates the direct confrontation with an archaic imago that is too threatening), may also interrupt the analytic process if it becomes too fixed and impervious to interpretations.

In the work of François Duparc, the displacement of the transference has been linked to analysands' difficulties in representing traumatic experiences in their histories and in connecting the affects mobilized by treatment to sufficiently elaborated representations. Thus the displacement of the transference could be considered as a less apparent aspect of negative transference, that is, of the invisible transference that Freud complains about in "Analysis terminable and interminable" (1937) in connection with his analysis of Sándor Ferenczi. Lateralization of the transference would be a primary defense and counter-cathexis of a nonrepresentable or not yet represented experience. By means of a displacement of the transference, the patient might be trying to protect the analyst from a violent discharge in the transference, which the analyst could not bear without a traumatizing counter-transferential reaction.

One can describe a range of transferences, according to their greater or lesser lateral aim: the direct transference, which in the case of traumatic material induces disturbing and strange counter-transferential experiences; transference on a model, which is more protective because the model is the inert part of the transference that limits the involvement of nonrepresentable experiences; and finally displacement of the transference, which aims at protecting both the patient and the analyst from a traumatic outbreak.

### DISQUE VERT, LE

In 1924 *Le Disque vert*, a Belgian review founded and directed by the poet and writer Frédéric Van Ermenegen, known as Franz Hellens (1881–1972), published a special issue devoted to "Freud et la psychanalyse," confirming Sigmund Freud's belief that "interest in psychoanalysis has spread to writers in France." (1925d) It is significant that at this time very few of Freud's writings were accessible in French.

A message from Freud, dated February 26, 1924, introduced the issue: "Of the many lessons lavished upon me in the past (1885–1886) by the great Charcot at the Salpêtrière [1885–1888], two left me with a deep impression: that one should never tire of considering the same phenomena again and again (or of submitting to their effects), and that one should not mind meeting with contradiction on every side provided one has worked sincerely."

There were approximately forty-five contributors to the special issue, all with different opinions, positive and negative, about psychoanalysis, providing an important overview of the attitudes toward psychoanalysis in France. Among the contributors were writers (M. Arland, R. Fernandez, V. Larbaud, H. R. Lenormand, J. Rivière, Philippe Soupault, René Crevel, Henri Michaux), psychoanalysts (Angélo Hesnard, René Laforgue, René Allendy), psychiatrists and psychologists (E. Claparède, L. Lapicque, Y. Le Lay).

According to Edmond Jaloux, many writers were hostile to Freud's theories because "they saw in them an attack on the classical conception of human

personality.” For Jacques de Lacretelle, although some subscribed to the new field, many could not, “because its ideas take place in a field that is almost new to them, one they are only beginning to make use of: the unconscious.”

Louis Lapicque, who then held the chair of general psychology at the Sorbonne, had no hesitations: “I have to admit that the ideas of the Viennese professor, although they were sufficiently amusing for me to acquaint myself with them superficially, did not seem to be scientific material and I do not feel capable of discussing them seriously.” Étienne Rabaud, professor of biology at the Sorbonne, had a similar opinion: “Within being unaware of Freudianism, I haven’t taken the time to make a serious study of it; my limited examination has not left me with a desire to continue.” Georges Dwelshauvers, director of the laboratory of experimental psychology in Catalonia, suspected fraud: “He has been inspired by the clinics of Charcot and his school, and the work, so rich in written material, of doctors Raymond and Pierre Janet. He is their student and continues their tradition. And do we know who the real author of psychoanalysis was? It was J. Delboeuf, the psychologist from Liege.”

The partisans remained undecided. Professor Henri Claude, head physician at the Clinique des Maladies Mentales at the Sainte-Anne Hospital, the first and only hospital that employed psychoanalysts, wrote, “It is mostly psychologists and writers who have been discussing Freud’s work and that of his followers, faithful or dissident, and who, leaving the primitive framework of medicine, have decided to criticize the extension of the doctrine, especially the theory of pansexual symbolism, to all manifestations of intellectual activity. In place of these glosses, we would have preferred reliable personal research, free of prejudice, imbued with the spirit of scientific observation.” He added, and René Allendy was in agreement, “I feel, like Adler and Stekel, that we should not lead those unfamiliar with psychoanalysis to believe that Freudian pansexualism is all there is to the field.” “Pansexualism” and “symbolism” were signs of Freudianism’s disgrace, even though, as Edmond Jaloux so reassuringly remarked, “there are few repressed individuals in France.”

Angélo Hesnard indicated the prevailing pessimism of the time: “Current French opinion about Freud remains inconclusive ... It will never be

favorable to him for, whatever he may think—and in spite of his work with Charcot—the Master of Vienna has remained, in his work, quite remote from French attitudes. And in the extreme and naïve way it confuses facts and theory, doctrine and method, psychoanalysis will never convince anyone except those who have the courage and scientific probity to experiment with it themselves and adapt it to the French mind.”

Along with Édouard Claparède, Albert Thibaudet, a writer, who had already written a positive article in April 1921 in the *Nouvelle Revue française*, was more optimistic. He wrote, “I only want to say that I see Freud as a man who has entered a long corridor, filled with disorder, with poorly catalogued, poorly lit, poorly interpreted objects, but which holds treasures for the museums of the future and for the literature of today.”

André Gide, on June 19, 1924, wrote, after closing the copy of *Le Disque vert* he had been reading in the train that carried him to Cuverville, “Oh, how annoying Freud is; it seems to me that we managed quite well without him in discovering his America! ... What he adds, most of all, is his audacity, or, more exactly, he relieves us of a certain false and tiresome modesty. But there is so much that is absurd in this imbecile of genius!”

## “DISTURBANCE OF MEMORY ON THE ACROPOLIS, A”

Sigmund Freud had begun corresponding with Romain Rolland in 1923, and this open letter is the

acme (and indeed the end) of their exchange. In it, Freud relates a personal experience dating from his first visit to Athens, in 1904. He had climbed the Acropolis in company with his brother Alexander, who was ten years his younger—the same age, in fact, as Rolland—and in front of the Parthenon he was overtaken by a feeling of strangeness, of a sense that “this is too good to be true.”

In 1904 Freud was bringing his relationship with Wilhelm Fliess to a close in an atmosphere of conflict. A transference to Fliess had provided him with the support needed for his original self-analysis, and it was not until 1936, relying now on a transference to Rolland, that he was able to analyze this episode. The few pages of the letter here under consideration are a self-analytical summary of an entire lifetime, and they retrace the path followed by Freud’s whole work, with two Frenchmen standing for the beginning and end points respectively: at the beginning, Charcot (suggested by Freud’s use of several French psychiatric terms of the period); and, at the end, Romain Rolland.

The letter resembles an analytic session, with Freud addressing an alter ego to whom he seems to have lent his pen, thus handing off the role of analyst (Kanzer, Mark, 1969). Oedipal themes are in evidence: guilt about having surpassed the father and conquered the mother (Athens, after Paris and Rome) by producing a work of whose value Freud was well aware. The feeling of strangeness (or “derealization”) might stem from the emergence of unconscious material (or “sensations”) split off as a result of the trauma experienced by Freud at the age of two, when his young brother Julius died. Here Freud’s letter mirrors Rolland’s evocation—in his *Voyage Within*, which he began writing right after his visit to Freud in 1924—of the death of his sister Madeleine when he was five, and the long mourning of his mother that followed. Freud’s letter is also a response (itself deferred) to his French friend concerning the inner reality of that oceanic feeling whose existence in himself Freud had at first denied (in *Civilization and Its Discontents* [1930a], p. 65); here he stresses the feeling’s traumatic aspect—perceived only when there is no longer a split between the two levels of mental functioning involved.

Feelings of strangeness also arise from the gulf separating Freud’s integration into German culture (the Acropolis being associated with the cult of antiquity of the Goethe years) and the *sotto voce* reference to the destroyed temple in Jerusalem, a foundation of

Freud’s Jewishness; the first title given this letter, namely “Unglaube [disbelief or incredulity] auf der Akropolis,” is certainly evocative of Freud’s identity as an atheist Jew, and suggests a kind of Spinozist collusion with his churchless Christian correspondent.

But if the hallowed nature of the site (see Freud, 1927c) harks back to religion—the chief topic of the Freud-Rolland correspondence—in a more secular sense it summons up the origins of sublimation as a latent theme of the dialogue between these two great creators. The *Erlebnis*, Freud’s experience of the Acropolis, bespoke the rush of emotion that assailed him on this high place as his life’s work was just getting under way; by 1936 Freud could look back in tranquility on the road behind him.

To his correspondent, likewise well on in years and nearing the end, Freud sends a message that is also a meditation on death—and on immortality. Embedded within it is the fantasy that he might climb up to the Acropolis accompanied by a winner of the Nobel Prize—a distinction which Freud, discreetly, had not abandoned hope of attaining himself. The resolution of Freud’s transference to Romain Rolland would free up a vital energy sufficient to inspire a cluster of last writings developing many of the themes touched upon in this open letter.

## DOCUMENTS ET DÉBATS

The Association psychanalytique de France (APF), or French Psychoanalytic Association, has, since it was formed in 1964, published a *Bulletin intérieur*; this name was retained until 1970, when it became *Documents et Débats* (Documents and Debates). Originally its purpose was to publish reports of internal discussions and the annual general meeting. Editorial responsibilities initially belonged to a committee presided over by Jean Laplanche, who entrusted Jean-Louis Lang, vice president, with the role of editor.

Looking through past issues of the review provides an illuminating survey of the world of publishing; the quality of the paper, print, and typography make for pleasant reading. The cover design has changed over the years—from Bordeaux red to dark green, from carmine red to light gray, the color of the present volume, which is devoted to *Gradiva*. In 1991, with Raoul Moury as president, *Documents et Débats* underwent its latest design overhaul.

Organization of the magazine is unique. The editor changes whenever a new board is elected. The editor accepts but does not suggest material for publication. Distribution is restricted exclusively to members and analysts undergoing training. The review serves a unifying role in a profession that tends to isolate analysts: the text is edited in Lyon and printed in Paris; editors have come from Bordeaux, Lyon, Nantes, and Paris.

Issues appear on a regular basis and mark the progress of the association. Every year an issue is devoted to the publication of official documents, reports of the annual meeting, national and international reunions at which association members have participated ex officio. A second issue publishes the texts of papers given throughout the year as part of the biannual meetings and scientific get-togethers.

There have also been special issues devoted to the work of individual colleagues at the time of their death. There have been homages to Daniel Lagache (1975), Angelo Bejarano (1981), Georges Favez (1982), and Victor Smirnoff (1995). Occasionally,

special issues have been proposed on particular topics—“La psychanalyse en société” (Psychoanalysis in Society) (1985), “APF and IPA” (1987), “A.P.F. au passé-présent” (The A.P.F. in the Past and in the Present) (1988), “La formation” (Training) (1990)—introducing discussion within the association. However, in spite of the number of requests, it appears that this method of exchange is not necessarily the most appropriate or the most popular.

Psychoanalysts in the APF have often helped found psychoanalytic journals. The list of their editorial contributions is long and includes *Nouvelle Revue de psychanalyse* (New Review of Psychoanalysis), *Psychanalyse à l’université* (Psychoanalysis in the University), *L’Écrit du temps* (The Writing of Time), *La Revue internationale de psychopathologie* (International Review of Psychopathology), *L’Inactuel*, *Le Journal de la psychanalyse de l’enfant* (The Journal of Child Psychoanalysis), *Le Fait de l’analyse* (The Fact of Analysis), and *Libres Cahiers pour la psychanalyse* (Psychoanalytic Notebooks). These publications have created forms of discussion and research outside the APF that have strengthened the identity of *Documents et Débats*.

The bulletin remains the vehicle for disseminating information about the association and promotes the circulation of texts among members to solicit and support scientific research. In this way *Documents et Débats* contributes to maintaining a serious dialogue that any association worthy of the name must have.

## DOLTO-MARETTE, FRANÇOISE (1908–1988)

Françoise Dolto-Marette, a French psychoanalyst, was born in Paris on November 6, 1908, and she died there on August 28, 1988. Dolto’s *Enfances* (Childhoods; 1986) and *Autoportrait d’une psychanalyste* (Self-portrait of a woman psychoanalyst; 1989) tell the story of how a little girl born into a middle-class family at the turn of the twentieth century became a doctor and psychoanalyst. The two books recount the traumatic loss of a beloved nanny when she was a few months old; the death at the front on July 10, 1916, of her

uncle Pierre, who was her godfather and whom she thought of as her “fiancé”; and the death of her older sister, Jacqueline, when she was eleven. At her first communion, her mother asked her to pray to save her sister, who contracted bone cancer at the age of eighteen. “I would never have become a psychoanalyst,” she wrote, “were it not for this grief that upset the whole family. I think I would have become a doctor in any case, because I had wanted to since I was eight, but I would not have become an analyst if my sister had not died and if I had not experienced my mother’s pathological mourning, my father’s suffering and bewilderment, and the pain of my brother Pierre, the oldest of the boys.” René Laforgue, her analyst, noted a “family neurosis” extending across the generations in her family. Part of this family neurosis was a “myth of the savior”: Dolto’s paternal grandfather died while rescuing five women in a railway fire, and her maternal grandfather, a prisoner in 1870, was “saved by his sister disguised as a peasant girl.”

Dolto began her analysis with Laforgue in 1931, and he subsequently encouraged her to get involved in child analysis, at which she was very gifted, according to Sophie Morgenstern. Her supervisors were Heinz Hartmann, Angel Garma, Rudolph Löwenstein, René Spitz, John Leuba, and Morgenstern. She was elected to membership in the Société psychanalytique de Paris (Paris Psychoanalytic Society) on June 20, 1939, about the time of the publication of her thesis in medicine, *Psychoanalyse et pédiatrie* (Psychoanalysis and pediatrics; 1971b).

At the Hôpital Trousseau, Dolto worked for a short time in Jenny Aubry’s pediatric ward. Then after Édouard Pichon’s death, she took over and ran his consultancy from 1940 to 1978. She ran the consultancy in innovative ways and independently of the psychiatry ward, and she opened it to analysts wishing to train in child analysis. Numerous participants can attest to the quality of her input and to what they learned by watching her work with children and their parents. She was the first analyst to modify the therapeutic setting by bringing in “witnesses” who rarely contributed, one of them taking notes and the others playing a role analogous to that of a Greek chorus. Here she began accepting infant patients, which was most unusual at the time. At offices in Paris she engaged in the same sort of practice with children from the Antony nursery and state foster homes.

In tandem with these activities, she started a Tuesday-evening study seminar on children’s drawings and, on two Thursdays per month, a seminar in child analysis for psychoanalysts and therapists. She led the seminar for nearly fifteen years. During its last years, the seminar brought together as many as several hundred participants.

At the time of the first split in the French psychoanalytic movement, Dolto—along with Jacques Lacan, Daniel Lagache, and Juliette Favez-Boutonier—founded the Société française de psychanalyse (French Society of Psychoanalysis) in 1953. For the 1960 congress on female sexuality in Amsterdam, she wrote “La libido génitale et son destin féminin” (Genital libido and its vicissitudes in women; 1996b). From 1947 she published numerous articles in the socialist journal *La revue de l’union des femmes françaises*, and later in *Les études carmélitaines*, *Psyché*, and the journal of the École des parents (Parents’ school). She worked at the Centre Étienne-Marcel from its inception and published in *Le coq-héron*, and in 1971 published *Dominique: the analysis of an adolescent*, a case history of the treatment of a “retarded” patient.

In 1964 she was a follower of Jacques Lacan during the creation of the École freudienne de Paris. At that time the International Psychoanalytical Association excommunicated the Lacanians, forbidding them to teach and train analysts. On August 2, 1962, Serge Lebovici, addressing the executive committee of the International Psychoanalytical Association in Edinburgh, demanded that they separate “the wheat from the chaff” and accused Dolto of being what she was, neither a Kleinian nor a follower of Anna Freud. In Dolto’s case, the reasons for the excommunication still have not been clearly explained. One can only conclude that a great injustice was committed.

Her radio programs, beginning in 1976 and listened to by parents all over France, established her as an analyst in touch with society and actively engaged in the cause of children. The list of her contributions is extensive: her work with the deaf, her active support of the Neuville schools, her long preface to Maud Mannoni’s book, *Le Premier rendez-vous avec le psychanalyste*, her decisive influence in the training of educators and childcare workers, her contributions in support of children’s rights. She also actively participated in numerous colloquia and meetings: *Naître et ensuite* (Birth and Afterwards), within the framework of the Groupe de recherche et d’étude du nouveau-né

(Group for the Research and Study of Newborns), and the Bordeaux conference *Enfants et souffrance* (Children and suffering). These many innovative experiments have given her an original and incontrovertible place in the history of relations between psychoanalysis and society. Her concepts of the “unconscious body image,” female libido, and “symbolic castration,” debated by the psychoanalytic community, were, for her students, “valuable tools that were indispensable in the clinical treatment of very young children or patients in great distress.” They were the fruit of a life devoted to “hearing” the needs of infants when they are still incapable of speech but can express themselves in their own ways.

The creation of a welcome facility for little ones accompanied by their parents (founded in January 1978), later the *Maison verte de Paris* (which opened in January 1979), attests to the efforts of Dolto and her collaborators at the Centre Étienne-Marcel—Pierre Benoît, Colette Langignon, and Bernard This—to promote, together with Marie-Noëlle Rebois, Marie-Hélène Malandrin, Nelba Nasio, Claude This, and all those who came later, the prevention of early childhood emotional disturbances. This innovation by a group of analysts and educators, recognized by the Fondation de France (Foundation of France), led to many other welcome facilities in France and other countries.

A three-volume collection of Dolto’s radio programs, *Lorsque l’enfant paraît* (When the child appears; 1990), first appeared in 1977, 1978, and 1979. Her other publications include *The Jesus of psychoanalysis: a Freudian interpretation of the Gospel* (1979); in 1981, *La difficulté de vivre* (The difficulty of living; 1995), *Au jeu du désir* (The play of desire), and *Les évangiles et la foi au risque de la psychanalyse* (The Gospel and faith in the light of psychoanalysis; 1996a); in 1982, *Séminaire de psychanalyse d’enfants* (Seminar on child analysis); in 1984, *L’image inconsciente du corps* (The unconscious body image); in 1985, *La cause des enfants* (The cause of children) and *Solitude* (1987b); in 1987, *Tout est langage* (Everything is language; 2002), *L’enfant du miroir* (The child of the mirror), and *Dialogues québécois* (Quebec dialogues); and in 1992, *Inconscient et destin* (The unconscious and fate) and *Quand les parents se séparent* (When parents separate). Many aspects of Dolto’s career show that this clinician and internationally renowned psychoanalyst sought to make her ideas accessible to all. After her death on August 25, 1988,

many of her contributions were published, and the Association archives et documentation Françoise Dolto was established in Paris in 1990.

## DON JUAN AND THE DOUBLE

In 1914 and 1922, Otto Rank published two essays in German in *Imago: The Double* and *Don Juan*. Rank was inspired to write *The Double* after seeing a film by H. H. Ewer, *The Student of Prague*, and a presentation of Mozart's Don Giovanni led him to write *Don Juan*. As the author himself noted, "In both texts, there is a question of problems going back to the most remote origins of mankind, which continue to have a profound influence on art." These problems are "the relationship between individuals and their own ego and the threat of its complete destruction by death."

Rank was a particularly prolific writer with an extensive knowledge of literature and anthropology, as shown by these two essays and alluded to in his belief that "the creative artist is, from the psychological point of view, the extension of the hero of prehistoric humanity." In *The Double* he explores the theme of the double in literature as a kind of shadow, reflection, portrait, twin, or even duplication of mental life resulting from amnesia or manipulation (as in Robert Louis Stevenson's *Dr. Jekyll and Mr. Hyde*). Rank examines various possibilities, including the terrible consequences if the shadow is lost and the independent double persecutes the ego.

Sigmund Freud in his essay "The Uncanny" (1919h) noted that Rank had succeeded in explaining the surprising evolution of the theme of the double. "For the 'double' was originally an insurance against the destruction of the ego, an 'energetic denial of the power of death,' " but, Freud adds, "such ideas have sprung from the soil of unbounded self-love, from the primary narcissism which dominates the mind of the child and of primitive man. But when this stage has been surmounted, the 'double' reverses its aspect. From having been an assurance of immortality, it becomes the uncanny [unheimlich] harbinger of death" (1919h, p. 235).

Referring to the myth of Narcissus and to the narcissistic hero Dorian Gray in Oscar Wilde's *The Picture*

of *Dorian Gray*, Rank notes that the hero's misfortune follows from his disposition to narcissism, which turns him into the prisoner of his double. The double then becomes a rival in sexual love or appears in superstitious belief as a terrifying messenger of death, a devil, or an anti-ego, destroying rather than replacing the ego.

The essay on Don Juan (1922/1975) is also related to the theme of the double. Rank asserts that it is impossible to consider the legend of Don Juan solely in Freud's sense and explain it by the father complex (p. 86). Rank shows that the division of the personality into the master Don Juan and the valet Leporello is a "necessary part of the artistic presentation of the hero himself" (p. 50), for "[b]y inhibiting the will of his master, whose thirst for action he continually keeps in check with uncanny irony, he is characterized as the critical-ironic part of the ego" (p. 59). Starting from the idea of "avenging death" Rank also develops interesting perspectives on cannibalism.

## DOOLITTLE-ALDINGTON, HILDA (H.D.), (1886–1961)

The American poet Hilda Doolittle was born on September 10, 1886, in Bethlehem, Pennsylvania, and died in Zurich in September 1961. From her analysis with Freud during 1933–1934 she left a diary, a written homage to Freud: *Tribute to Freud*, (1944), which represents a precious account of their warm and positive analytic relationship.

The only daughter of four children, her father was Charles Leander Doolittle, a professor of astronomy who, in 1897, began teaching at the University of Pennsylvania. There Hilda discovered her calling as a poet, encouraged by her relationship with Ezra Pound, who at age 20, just a year older than she, had just been appointed instructor. Although her father forbade her to carry on a relationship with Pound, who would soon be expelled for immorality, Hilda kept up a correspondence with him that in 1911 brought her to Europe, where she would spend the rest of her life. She went initially to England with Frances Gregg, with whom she had a homosexual liaison, and soon met Richard Aldington, a poet six years younger than herself.

H.D. published her first poems in 1913, and married Aldington the same year. The couple lost their first daughter in 1915, but a second daughter, named Perdita in memory of the first, was born on March 31, 1919. Hilda's favorite brother, Gilbert, was killed in France in 1918, and her father, seriously affected by the news, died a year later. In 1919, H.D.'s marriage ended, as did her brief but intense friendship with D. H. Lawrence.

When H.D. had suffered post-partum depression after the birth of her daughter, she owed her recovery to Bryher (Winifred Ellerman), an energetic novelist and poet who became her companion and took her and Perdita to live in Greece. While living in Corfu, H.D. suffered an episode of depersonalization, an experience that held no particular interest for Havelock Ellis, who was in some measure attracted to her. She also had a hallucinatory vision of "writing on the wall" that Freud characterized as a "dangerous symptom" when she told him about it. This vision may explain the mild and tender positive countertransference behavior that Freud adopted toward her.

Bryher, who had been analyzed by Hanns Sachs, acquainted H.D. with psychoanalysis. An initial effort at analysis with Mary Chadwick in the spring in 1931 was a failure, but it led H.D. to begin treatment in Berlin with Sachs, who subsequently introduced her to Freud. By then well-known for her imagist verse, H.D. sought analysis to remedy a sense of sterility in her writing.

Freud had read some of her work, including *Palimpseste*, before their first meeting on Wednesday, March 1, 1933. In the diary she kept of her analysis (in

spite of his disapproval—he viewed it as resistance), she described him as "like a curator in a museum . . . ; he is like D. H. Lawrence, grown old but matured and with astute perception. His hands are sensitive and frail" (1974, p. 116). From the beginning of treatment Freud brought her to see his collection of antiquities and showed her a small statue of Athena: "This is my favorite," he remarked (p. 118). "You are the only person to have ever entered this room and looked at the objects before looking at me."

This first session set the tone of an analysis in which Freud quickly interpreted that "not only did I want to be a boy but I wanted to be a hero" (p. 120). His interventions made him into "the grandfather godfather, god-the-father" (p. 120). He told her at one point, "I was thinking about what you said, about its not being worthwhile to love an old man of seventy-seven," and H.D. wrote, "I had said no such thing and told him so. He smiled his ironical crooked smile. I said, 'I did not say it was not worthwhile. I said I was afraid.' But he confused me. He said, 'In analysis, the person is dead after the analysis is over—as dead as your father'" (p. 141).

Freud also confided in her that "I do not like being the mother in transference—it always surprises and shocks me a little. I feel so very masculine" (pp. 146–147). H.D.'s mother had traveled with her and Aldington when they were lovers, and later lived with her in Europe for long periods in the 1920s before her death in 1927; Freud viewed her as the root cause of H.D.'s confusion and homosexuality.

After three months of analysis, H.D. left Vienna on June 15, 1933. When she returned at the end of October, to remain until December 1, she was concerned about the rise of Nazism; she immediately perceived the danger that it posed for "the Professor." Once again, describing in unparalleled fashion during the next five weeks of exceptional sessions, she sketched a poetical and moving portrait. She did so without concessions; attracted by the strange and bizarre, by astrology and belief in paranormal phenomena, she sometimes confronted the convictions of an old man. For his part, Freud hoped to introduce into her mental universe the father figure and finally succeeded. "We have gone into deep matters," he told her after one session (p. 177); after another, he said, "Today we have tunneled very deep." (p. 18).

H.D. had further sessions in 1936 and 1937, rather more as psychotherapy, with Walter Schmideberg.

Until his death she never failed to send Freud gardenias for his birthday. In 1944 she wrote her memoir, first entitled *Writing on the Wall*, which appeared in 1956 as *Tribute to the World*. Soon after World War II, H.D. turned toward spirituality and underwent a severe mental breakdown and deep depression.

Moving to Switzerland in the late 1940s, H.D. enjoyed a productive and successful career in the last years of her life, publishing several books of poems, memoirs, and short stories that brought her considerable attention in literary circles in the United States. A hip fracture in 1960 left her handicapped until her death on September 27, 1961.

## “DOSTOYEVSKY AND PARRICIDE”

Freud distinguished Dostoyevsky the writer, Dostoyevsky the neurotic, Dostoyevsky the moralist, and Dostoyevsky the sinner. Freud regarded Dostoyevsky the writer as unassailable, placing his work alongside Sophocles’ *Oedipus Rex* and Shakespeare’s *Hamlet*. The moralist Freud dismissed, for Dostoyevsky confined himself to being the sinner, subject to the czar and God, even while he oscillated between faith

and atheism. Sadistic toward the outside world where small things were concerned, and toward himself where large things were concerned, Dostoyevsky finally appeared to be a masochist, “that is to say the mildest, kindest, most helpful person possible” (p. 179). But for Freud there is more: Dostoyevsky’s projections into his characters—violent, egocentric, criminal—bear witness to his identification with them. The sexual attack on the young girl as related to Strakov, would support this view, as would Dostoyevsky’s passion for gambling.

Dostoyevsky’s impulsive character interfered with his neurosis, and as a result, his ego lost its unity, a condition that expressed itself in his so-called epilepsy. This condition was, however, no more than a symptom of his neurosis, hystero-epilepsy, a serious form of hysteria. Freud pointed out the memory difficulties associated with such epilepsy and the limited understanding of the disease at the time. Dostoyevsky’s affliction appears to have been a case of the ancient *morbus sacer* (sacred illness) or a clinical variant. Its link with psychic life does not interfere with “complete mental development and, if anything, an excessive and as a rule insufficiently controlled emotional life” (p. 180), characteristic of Dostoyevsky’s mental functioning. The mechanism of his abnormal instinctual discharge, organically preconditioned, was made available to his neurosis, and through somatic means, it eliminated any excitation not psychically contained.

For Freud, Dostoyevsky’s first, slight attacks harked back to childhood and did not assume a true epileptic form until after the traumatic event of the murder of his father by Russian peasants. Psychoanalysis showed that this was the keystone of Dostoyevsky’s neurosis, and the parricide of the Karamazovs reflects this. Dostoyevsky’s anxieties about death, which he experienced in his youth, together with his states of lethargic sleep, would indicate that Dostoyevsky identified with the dead or with someone whose death he desired, and may have triggered a mechanism of self-punishment.

Freud then returns to his hypothesis about the murder of the father in the primitive horde, humanity’s primal crime, which is reproduced in fantasy in every individual: the little boy, in his ambivalent relationship to his father (fear of castration or tenderness), must renounce his desire to possess the mother and eliminate the father, but a sense of unconscious guilt

remains. In Dostoyevsky, a strong bisexual disposition conditioned and reinforced his neurosis, intensifying his defense against a “remarkably harsh” father. Thus the relationship between Dostoyevsky and the paternal object was transformed into a relationship between the ego and the superego. Once the murder of his father had given a sense of reality to such repressed desires, epilepsy followed.

The atmosphere indicates the liberation experienced, whereas the punitive dimension is confirmed in jail, where Dostoyevsky’s crises do not disappear but at least no longer weaken him, in spite of the injustice of the punishment: the czar has replaced the father. Dostoyevsky took this one step farther: the epileptic is the parricide—the culmination of his identification with common, political, and religious criminals—but the gambling debt, satisfying the need for self-punishment, enables him to write and succeed as a novelist.

Curiously, at the end of this article on Dostoyevsky, Freud also analyzed Stefan Zweig’s short story “Twenty-four Hours in the Life of a Woman.” Freud sees this short story as the fantasy of a young man (also a gambler), in which his mother initiates him into sexual life to protect him from masturbation, a compulsion Freud assumed to be present in Dostoyevsky.

Freud spent two years (1926–1928) reluctantly writing this article on “the cursed Russian,” whom he claimed not to have liked. His work led to discussions with Theodor Reik and Stefan Zweig. The article did not cause much of a stir when it was published, and the question of epilepsy failed to generate interest. Freud’s ambivalence toward the writer’s “pathological nature” attests to a certain rivalry with Dostoyevsky over the latter’s exploration of the unconscious, but may also indicate Freud’s parricidal wishes toward Jean Martin Charcot, the father of hystero-epilepsy, wishes quite different from Dostoyevsky’s epilepsy. Freud’s interpretation of the onset of Dostoyevsky’s crisis remains questionable, as does his interpretation of the father’s “murder.” At the time (1928), Dostoyevsky’s past was still largely unknown.

## DOSUZKOV, THEODOR (1899–1982)

Theodor Dosuzkov, a physician and practicing psychoanalyst, was born on January 25, 1899, in Baku, then Russia, and died in Prague, Czechoslovakia, on January 19, 1982. He was the only child of a jurist aristocrat father and a Jewish mother.

The October 1917 revolution surprised the family in Saint Petersburg. They fled before the Red Army and finally arrived at Novorossiisk in 1919. There Theodor Dosuzkov took his baccalaureate and met his future wife, with whom he left the country in 1920 bound for Prague via Constantinople. The Prague government was offering grants to Russian students. He studied medicine from 1921 to 1927 and then worked in the university neurology clinic, specializing in neurology and psychiatry.

Through a circle of Russian intellectuals he met Nicolai Ossipov, who awakened his lifelong interest in psychoanalysis. When Ossipov died in 1934, Dosuzkov inherited his library and his correspondence with Freud. Internal intrigues prevented Dosuzkov from winning a university appointment. Disappointed, he left the university clinic and opened his own clinic in 1934 and practiced as a neurologist and psychoanalyst. He finished his psychoanalytic training in Prague with Annie Reich and then with Otto Fenichel.

Dosuzkov survived the German occupation of Czechoslovakia from 1939 to 1945, during which he continued to teach and practice psychoanalysis in secret as the only properly trained psychoanalyst in all of Czechoslovakia. Subsequently, he received the professional and moral support of his students in 1946. He then reestablished the Society for the Study of Psychoanalysis, resumed contact with colleagues in other countries, and was appointed training analyst by the International Psychoanalytic Association. From 1946 to 1948 Dosuzkov and his students engaged in intense scientific and therapeutic activity. In 1947 and 1948 Dosuzkov published articles in the *Annales de psychanalyse* (Annals of psychoanalysis), but the 1949 volume never appeared because of the putsch in 1948. Dosuzkov had to go underground again. In 1968, during the Prague Spring, he was finally able to work openly for a short time.

Dosuzkov's interests and scientific activity are important in the study of neuroses and in applied psychoanalysis. Dosuzkov forged the notion of *scoptophobia* as a fourth psychoneurosis and worked on other phobias, which he interpreted in relation to urethral erotism. He also wrote works popularizing psychoanalysis. His work had an immense influence on the introduction of psychoanalysis in Czechoslovakia. He was an indefatigable proponent of psychoanalysis among specialists and to the general public. He was recognized as a representative of the discipline, defending its viewpoints with fervor, even during politically disturbed periods. He was also important for his scientific contributions. As a student of Fenichel, Dosuzkov took an interest in the psychology of the instincts. Owing to his work, psychoanalysis has survived in Czechoslovakia to the present day.

He died in an accident in a railway yard closed to traffic. The circumstances surrounding his death have never been explained.

## DOUBLE BIND

Gregory Bateson coined the term *double bind* in 1956. In trying to understand the characteristic effects of communication in schizophrenics' families, Bateson and his collaborators identified a specific constraining interaction, the paradoxical injunction that they called the *double bind*.

The double bind fits into one of the three types of paradox, the pragmatic paradox. The effects of the paradox in human interactions were first described by Gregory Bateson, Don D. Jackson, Jay Haley, and John H. Weakland in a document entitled *Toward a Theory of Schizophrenia*, published in 1956. Bateson and his collaborators were looking for sequences of interpersonal experience that could lead to a type of behavior that would justify the diagnosis of schizophrenia.

This is one of the typical cases constructed by Paul Watzlawick from real clinical facts: A mother buys two neckties for her little boy, one green and one blue. The next day the child is in a hurry to sport the green necktie. The mother: "So you don't like the blue tie I gave you?" The next day the boy puts on the blue tie and draws the symmetrical response: "So you don't like the green tie I gave you?" So, on the third day, the child tries to find a compromise solution in order to satisfy his mother's two demands: he puts on the two ties together. And his mother comments: "You poor boy, you're out of your mind. You're going to drive me crazy." This paradoxical injunction, where the double bind mechanism is particularly obvious, clearly shows the annihilating effects on the person at the receiving end.

Antonio J. Ferreira (1960) described one particular form of double bind, the split double bind, observed in the families of young delinquents. The expression "prescribe the symptom" was first introduced in Bateson's group's work on family therapy in schizophrenia. The group showed the paradoxical nature of this technique: the therapeutic double constraint. From a structural point of view, a therapeutic double constraint is the mirror image of a pathogenic double con-

straint. The therapist formulates an injunction of such a structure that it reinforces the behavior that the patient expects to see disappear. A patient presenting persistent headaches (in-depth medical examinations revealed nothing) transmitted the following message through her symptoms and her earlier relations with doctors: “Help me but I won’t let you help me.” The therapist understood that given the history of physicians’ “failures,” any allusion to the help that psychotherapy could provide would predestine the treatment to fail. The patient therefore had to face the fact that her state was incurable. All that the therapist could do was help her learn to live with her pains.

In the nineteen-seventies the notion of paradox was introduced into clinical and theoretical psychoanalysis from several different directions, largely due to Didier Anzieu’s article on *Transfert paradoxal* (Paradoxical transfer) (1975) and Paul-Claude Racamier’s work on humor and madness (1973), and later on schizophrenics’ paradoxes (Congress of Romance-Language Psychoanalysts, 1978).

## **DOUBLE, THE**

The double refers to a representation of the ego that can assume various forms (shadow, reflection, portrait, double, twin) that is found in primitive animism as a narcissistic extension and guarantee of immortality, but which, with the withdrawal of narcissism,

becomes a foreshadowing of death, a source of criticism and persecution.

The figure of the double dates back to primitive civilizations, as shown in legend, but it is also found throughout literature. It was Otto Rank who in his essay on the double (1914) was the first to develop this idea in psychoanalysis, and Sigmund Freud quotes him at length in “The Uncanny” (1919). However, the idea of the doubling of consciousness is present in his first texts on hysteria (1893, 1895), and the unconscious itself is introduced by Freud as a second consciousness capable of producing dreams, parapraxes, and so on. The theme of the double is taken up by Freud and integrated in his concept of the uncanny. “The ‘uncanny’ is that form of terror that leads back to something long known to us, once very familiar” (1919), but has become terrifying because it corresponds to something repressed that has returned. “The double,” Freud wrote citing Heinrich Heine, “has become an image of terror, just as, after the collapse of their religion, the gods turned into demons.” (1910).

Rank’s study of the double has two aspects: anthropological and psychopathological, the latter being approached through literature and the personality of authors. For anthropology, the double is omnipresent as a representation of the soul and therefore a guarantor of survival. It also helps us understand the nature of sacrifice, such as the cannibalistic incorporation of the son by the father (Chronos) because the son has drawn to himself the father’s image or shadow. The double is similarly the origin of certain taboos, and Rank notes the evolution between the narcissistic claim of immortality and the acceptance of the genetic continuity of parents through their children, which is at the origin of totemism. “It is no longer the double itself (the shadow) that continues to live but the spirit of a dead elder who is reborn in the embryo” (Rank, 1914).

In literature (E.T.A. Hoffmann, Edgar Allen Poe, Guy de Maupassant, Alfred de Musset, Fyodor Dostoevsky), Rank points out the description of a paranoid state revolving around the persecution of the ego by its double and compares these imaginary creations to their authors’ symptoms, through which the theme of the double reveals a psychopathological dimension (epilepsy, splitting of the personality). Similarly, Freud noted that an older form of narcissism that has been overcome can continue to have an effect by changing into a “moral conscience” susceptible of being split off

from the ego, as seen, for example, in delusions of being watched.

The double is also found, although on a different plane, in real or imagined twins and, more generally, in twin brothers. The paradox of identity versus alterity arises here together with—in the case of the doubles of myth who are not brothers (Achilles and Patroclus, Orestes and Pylades)—the narcissistic foundations of friendship. This can be contrasted with the tragic destiny of Narcissus, who drowned while looking at his own reflection. The theme of the double appears, therefore, to be susceptible to very broad interpretation, similar to the primal narcissism from which it originated.

## **DOUBT**

The distinction between doubt as an instrument of rational thought and pathological doubt was known to philosophers (Descartes, Spinoza) long before Freud, and had long been studied as a symptom or syndrome in psychiatry. Théodule Ribot defined doubt as “a conflict between two tendencies in thought, incompatible and antagonistic, without any possible reconciliation, into a succession of positive and negative judgments about the same subject that does not culminate in a conclusion” (1925). In his study on obsessional neurosis, Freud noted that “[a]nother mental need . . . obsessional neurotics . . . is the need for uncertainty in their life, or for doubt” (1909d, p. 232).

Freud first discussed doubt in his work on dreams where he saw it as a mark of resistance and an indication to the analyst of the significance of the repressed element to which it related. But for the most part Freud considered doubt in the context of obsessional neurosis, where it applied to events that had already occurred, and could be seen above all as an expression

of ambivalence, a repudiation of the instinct for mastery as sublimated into an instinct for knowledge (1913i, p. 324).

The etiology of doubt as a symptom is analyzed at length in the case history of the “Rat Man” (1909d). Freud summarized it in a letter of April 21, 1918, to Lou Andreas-Salomé: “The tendency to doubt arises not from any occasion for doubt, but is the continuation of the powerful ambivalent tendencies in the pre-genital phase, which from then on become attached to every pair of opposites that present themselves” (1966/1972, p. 77).

Obsessional thought, however, to characterize it more accurately, has three somewhat different aspects: uncertainty, hesitation, and doubt. Uncertainty can be viewed as that voluntary blurring of references, which underpins the aversion for watches, for example. Doubt, for its part, is an internal perception of indecision, which just like hesitation is associated with the volitional sphere, whereas uncertainty belongs to the cognitive and doubt to the affective. These three aspects do not necessarily function simultaneously, as witness the fact that we can be certain yet unable to decide on action; at the same time, action can overcome hesitation in the absence of the slightest certainty about the reasonableness of that decision. The essence of wisdom would be to achieve certainty before abandoning hesitation—the precise attribute obsessionals find it so hard to adopt (Mijolla-Mellor, 1992).

Apropos of the Rat Man, Freud mentions the “predilection for uncertainty” of obsessional neurotics who turn their thoughts to “those subjects upon which all mankind are uncertain and upon which our knowledge and judgments must necessarily remain open to doubt” (1909d, p. 232–33). This tendency extends to easily accessible knowledge, seemingly as a form of protection against the risk of knowing. In fact the obsessive neutralizes any idea, any decision, by evoking its opposite. Thus hesitation and the predilection for uncertainty constitute the cognitive aspect of the impossibility of choosing, an attitude that serves to delay action indefinitely. The obsessive is paralyzed by ambivalence, immobilized by two instinctual impulses directed at the same object.

What is the source of this ambivalence? Since it is too general a concept to determine the “choice of neurosis,” Freud offered a hypothesis based on constitutional factors: “The sadistic components of love have,

from constitutional causes, been exceptionally strongly developed." And in terms of individual history, these "have consequently undergone a premature and all too thorough suppression" (1909d, p. 240).

Serge Leclaire (1971) has made significant contributions to our understanding of the nature of doubt in the obsessive individual, which he sums up rather laconically as "He doubts because he knows."

## **DREAM**

The dream, guardian of sleep, provides disguised satisfaction for wishes that are repressed while we are awake; dream interpretation is the "royal road that leads to knowledge of the unconscious in psychic life." Such, in highly condensed form, is Freud's theory as set forth in the founding work of psychoanalysis, *The Interpretation of Dreams* (1900a). As Freud himself pointed out, this was a revolutionary thesis.

The only scientists interested in dreams during the late nineteenth century were psychologists looking for "elements" of mental activity or psychiatrists interested in hysteria and hypnosis. All of them saw dreams as nothing more than degraded products of a weak and thus dissociated psyche. Freud's approach was a

radical departure for he claimed that hysterical symptoms were the expression of "conflicts," and that dreams were the product of a "dream work." In both cases there was no weakening of psychic activity but quite the opposite, an intense activity driven by the opposition between wishes and psychic defense mechanisms. The radical nature of Freud's position was illuminated by his divergence from Josef Breuer, who saw hysteria as the product of "hypnotic states" brought on by a weakening of organizing mental activity and a concomitant decrease in what Pierre Janet called "mental tension" (Freud and Breuer, 1895d).

Freud conceived his theory of dreams very early. His exposure to the work of Charcot and later to that of Bernheim was undoubtedly a contributing factor. In 1892 he noted that many dreams "spin out further associations which have been rejected or broken off during the day. I have based on this fact the theory of 'hysterical counter-will' which embraces a good number of hysterical symptoms" (1892-94a, p. 138). ("Counter-will," meaning an opposition to the satisfaction of desire for moral reasons, was a conceptual forerunner of repression.) The "Project for a Scientific Psychology" (1950c [1895]) introduced a number of ideas about dreams that were later expanded and refined.

Between 1897 and 1900 Freud, with moral support from his correspondent Wilhelm Fliess, conducted the self-analysis that gave birth to psychoanalysis. For the most part, that self-analysis drew on Freud's own dreams (Anzieu, 1975/1984), and in due course those same dreams supplied a large portion of the material of *The Interpretation of Dreams*.

Freud's dream theory may be summarized as follows:

1. The dream expresses a wish unsatisfied during the waking state, whether because of a conscious objection or, more frequently, because of repression, in which case the wish is unrecognized. During sleep, the psychic apparatus finds its natural tendency, which is to reduce tension, that is, to experience pleasure. The dream, like hysterical symptoms, slips, parapraxes, and so on, is a sign of the return of the repressed. Freud went further still, claiming that every dream was the fulfillment of a wish, which obviously invites an objection about unpleasurable dreams and anxiety dreams. On several occasions Freud rebutted this objection, continuing to analyze such dreams

until he isolated a wish behind distress or anxiety, which he claimed were merely expressions of resistance and conflict. Truth to tell, his argument was not always persuasive. On the basis of necessarily fragmentary material, it sometimes gave an impression of the ad hoc. Freud was able to overcome this difficulty only much later, when he introduced the repetition compulsion that lay “beyond the pleasure principle” (1920g).

2. Two circumstances favor this return of the repressed. The first is the inhibition of perception and motricity during sleep, protecting the dreamer against the dangers of actual satisfaction. This results in a “topographical regression,” that is, the excitation flows back unto the psyche and reinforces the dream-work. The second circumstance is that sleep weakens the censorship.
3. A measure of censorship remains, however, and often allows satisfaction of a disguised kind only. This is the function of the “dream-work.” This work employs the mechanisms of condensation and displacement (primary processes) before proceeding to generate images (representability). Then, by means of secondary revision, the “dream façade” is improved to provide a plausible meaning; i.e., the manifest content of the dream, which is quite different from the underlying meaning, that of the “latent dream-thoughts.” The dream work is a form of thinking, but its rules are very different from those that prevail in the logical thought of the waking state: dreams know nothing of contradiction.
4. The dream thus provides an outlet for libidinal pressure. It is the “guardian of sleep” since, without its intervention, the pressure would awaken the dreamer.
5. The dream’s raw materials are “day’s residues” (events, thoughts, or affects from the recent past) and physical sensations that occur during sleep. But its “real” content is reactivated infantile memories, especially those of an oedipal kind: the dream is a regression to an infantile state.

These tenets underpin dream interpretation, whose aim is to render meaningful elements in the dream’s manifest content (to restore their latent meaning), on the basis of the dreamer’s associations. Freud insisted that any “key to dreams,” that is, any list of symbolic

equivalents of supposedly general value, be excluded. He did, however, recognize some universal “symbols,” transmitted by culture, and some “typical dreams” to be met with in many dreamers (dreams of nudity, for example).

## DREAM INTERPRETATION

The procedure of dream interpretation is based on the theory of the dream’s functions and of the dreamwork outlined in Freud’s great work *The Interpretation of Dreams* (1900a). This book was based in large part on Freud’s own self-analysis of 1896–1897, in which dream interpretation played a leading role (Anzieu, 1975).

For Freud, dream interpretation is based on several basic principles:

- Every dream represents a wish as fulfilled. Thanks to a relative relaxation of censorship in sleep, a dream expresses repressed desires whose satisfaction is forbidden during the waking state. The conflicts involved may be expressed in unpleasant or anxiety-provoking dreams, however.

- The driving force of the dream, unconscious wishes, are rooted in childhood, notably in oedipal conflicts.
- The “dream material” is supplied by “day’s residues”—usually recent events of waking life.
- The dream work transforms this material by means of the primary processes of condensation, displacement, and visual representation, followed on occasion by a secondary elaboration that perfects the “dream façade.”
- Having once transformed into the “manifest content of the dream,” the “latent dream-thoughts,” now unrecognizable, are able to cross the barrier of censorship.
- The scenes thus created have, for the dreamer, all the characteristics of reality; they are hallucinatory in nature.
- The logic governing the dreamwork is very different from that of waking life, and the dream’s manifest content is often incoherent, filled with bizarre or absurd elements.

Interpretation relies on these principles, but it also needs the dreamer’s associations. He or she is therefore asked to associate as freely as possible, to elicit details of the day’s residues used in the dreamwork, to explicate the displacements and condensations, and to understand the choice of the visual images that make up the manifest content. In this way the thoughts latent beneath that manifest contest, the wishes and conflicts underlying the dream, can be unearthed. Special attention should be paid to bizarre or absurd details, for these indicate points where the dream’s work of distortion has been less effective. At the same time, however, Freud cautioned against concentrating on the latent and ignoring the manifest content (1916–17f).

For Freud, the interpretation of dreams was the “*via regia*,” the royal road leading to the unconscious. On several occasions in *The Interpretation of Dreams*, he noted that the procedure should be carried to the extreme, yet the examples he provided could hardly be said to adhere to this recommendation—presumably because these are for the most part his own dreams, and he may have been reluctant to expose the most intimate aspects of his personal life. It is in any case doubtful that such an exhaustion of meaning is conceivable or even desirable. Dream interpretation may well be the royal road to the unconscious,

but the unconscious is inexhaustible. Nor is it desirable for either patient or analyst to claim that the moment has arrived when there is nothing more to be said.

Finally, there are two points that need underscoring:

- Waking interpretation never deals directly with the dream but rather with a dream narrative, that is, a verbal summary of mainly visual images produced in the waking state. The result is often an over-elaboration of the “material” offered for interpretation (Diatkine, 1974).
- During an analysis, some dreams are responses to and echoes of an earlier session or a preparation for a future session. Every such dream bears the stamp of the transference, and this must not be overlooked.

## **DREAM-LIKE MEMORY**

Psychic reality is the subject of psychoanalysis. It is important to distinguish psychic from external reality, which we perceive through our senses. Wilfred R. Bion refers to psychic reality as *O*. In his 1970 work *Attention and Interpretation* he focused attention on the necessity for analysts to actively disengage from anything that might saturate their minds with sense data or elements rooted in sensorial data, in order to free the mind for psychic reality as much as possible. However, this psychic reality has no sensorial qualities as such, even though it must use sensorial forms to represent itself: anxiety has no color, no taste, no smell. He therefore suggested that analysts be “without memory or desire” because memory and desire are linked to sensorial elements and if analyst’s minds remain attached to these elements they are no longer available to receive the unknown, the mystery, that is, to be in contact with *O*.

Bion distinguished, however, between two forms of memory: “recalled memory” which corresponds to the usual conception of memory, what we know in advance, what we can remember consciously about an event or a person, about the patient who comes for the session, for example; and the “dream-like memory” that springs into the analyst’s mind in the course of the session, without any conscious effort at recollection. This second type of memory is the form that psychic reality takes in order to be representable in the here and now of the session. It has nothing to do with remembering events from the past: “Recalled memory saturates the psychoanalyst’s preconceptions and obscures the goals to the single point where clarity of judgment coincides with the field where it is exercised: the ongoing session [...]. Dream-like memory is the memory of psychic reality and is the stuff of analysis” (Bion, Wilfred R., 1970, p. 70).

Wilfred R. Bion went a step further when he declared that the aim of analysis is not only a knowledge of *O* but “becoming *O*,” insofar as psychic reality cannot be known but only “be been.” He therefore asks analysts not only to be without desire, without memory, but also without knowledge, in order to promote in so far as possible this “becoming *O*” that he calls “evolution.”

### **“DREAM OF THE WISE BABY, THE”**

“The Dream of the Wise Baby” is a one-page text that Ferenczi wrote in 1923. It is a description of a typical adult dream, not a fantasy or a myth, regardless of any analogy with the episode of Jesus teaching the doctors of the Law. It recounts a very young child, a neonate, a baby with glasses, who is teaching adults. Although Freud makes no mention of it in the final edition of *The Interpretation of Dreams* in 1926, he does write: “Dreams are so closely related to linguistic expression that Ferenczi has truly remarked that every tongue has its own dream-language. It is impossible as a rule to translate a dream into a foreign language and this is equally true, I fancy, of a book such as the present one.”

A footnote to Ferenczi’s text introduces the notion of children’s “effective knowledge” [*tatsächliches Wissen*] of adult sexuality. If the dream is repeated often it illustrates what Ferenczi was later to call the “traumatolytic function of the dream” more than a sensual reminiscence that the infant may have enjoyed when at the breast. This knowledge poses a question: Is it a knowledge that is linked to a visual or auditory perception, to an autoerotic excitation, or to an intuition in relation with a primal fantasy? The answer was clear for Ferenczi: It is a knowledge that is linked to facts and to prematuration consequent to trauma, thus to an experience of suffering. In “Confusion of Tongues” (1933/1955) he wrote: “The fear of the uninhibited,

almost mad adult changes the child, so to speak, into a psychiatrist [...]. It is unbelievable how much we can still learn from our ‘wise children,’ the neurotics.”

## **DREAM SCREEN**

It was Bertram D. Lewin, in his article “Sleep, the Mouth and the Dream Screen,” who proposed calling upon “an old familiar conception of Freud’s—the oral libido—to elucidate certain manifestations associated with sleep” (1946, p. 419).

“The dream screen, as I define it,” wrote Lewin, “is the surface on which a dream appears to be projected. It is the blank background, present in the dream though not necessarily seen, and the visually perceived action of ordinary manifest dream contents takes place on it or before it. Theoretically it may be part of the latent or the manifest content, but this distinction is academic. The dream screen is not often noted or mentioned by the analytic patient, and in the practical business of dream interpretation, the analyst is not concerned with it” (p. 420).

In developing his argument Lewin referred to the Isakower phenomenon, recalling that psychoanalyst Otto “Isakower interprets the large masses, that approach beginning sleepers, as breasts” (p. 421). Lewin expanded on this insight as follows: “When one falls asleep, the breast is taken into one’s perceptual world: it flattens out or approaches flatness, and when one wakes up it disappears, reversing the events of its

entrance. A dream appears to be projected on this flattened breast—the dream screen—provided, that is, that the dream is visual; for if there is no visual content the dream screen would be blank, and the manifest content would consist solely of impressions from other fields of perception” (p. 421). At the end of his article, Lewin offered this summary: “The baby’s first sleep is without visual dream content. It follows oral satiety. Later hypnagogic events preceding sleep represent an incorporation of the breast (Isakower), those that follow occasionally may show the breast departing. The breast is represented in sleep by the dream screen. The dream screen also represents the fulfillment of the wish to sleep” (p. 433).

Today, over and above the attempt to link sleep and oral libido, the notion of the dream screen should no doubt be viewed in conjunction with the idea of the introjection of “containers,” and with Didier Anzieu’s discussion of the “skin ego,” with his concepts of the skin as a “projective” or “writing surface” (1985, p. 40), and even with his view of the dream’s function as a film or pellicle.

At all events, the dream screen is an aspect of the dream-work which operates as a “non-process,” and which as such calls for no specific interpretation.

## **DREAM SYMBOLISM**

In the context of psychoanalysis, the idea of symbolism in dreams should be understood in three ways: (1) as pertaining to relatively constant and universal correspondences between the symbol and what it symbolizes within a given culture (and in the view of some, no doubt, within all cultures); (2) as pertaining to symbol/symbolized correspondences specific to a given dreamer and a given dream; and (3) as pertaining to the

processes of symbolization that give rise to the aforementioned correspondences.

In Chapter 6 of his *Interpretation of Dreams* (1900a), Freud devoted a section to “Representation by Symbols in Dreams.” Anyone who read only this section, however, would have a completely mistaken view of the Freudian approach to the interpretation of dreams. For what Freud dealt with here, in essence, were correspondences of the first kind defined above, that is to say representations (to be met with especially in “typical dreams”) whose meanings seemed so invariable from one dreamer to the next that they could be taken as read, even without reference to the subject’s associations. For example, any long or pointed object, any weapon (but also a hat) stood for the penis, and hollow objects for the vagina or, more generally, a woman’s body; similarly, going up a staircase or flying represented sexual excitement, erection or coitus, coming out of a tunnel meant birth, a tooth being pulled related to masturbation, and so on. Nor were these equivalences exclusive to dreams, for they occurred widely too in stories, myths, and folklore, a fact tending to confirm their universal validity. Verbal connections were very common in this context. In the case of masturbation, for instance, vulgar locutions in German embodied a similar symbolism: “*Sich einen ausreissen*,” literally “to pull oneself out,” meant to masturbate (pp. 348n, 388), and so on.

The sheer profusion of examples given by Freud in this section might suggest to an incautious reader that *The Interpretation of Dreams* is nothing but another “dream-book”; in reality, of course, the entire work is a protest against the “decoding” approach to dream interpretation. Indeed Freud repeatedly stresses that, even if an initial interpretation may be based on a sort of a-priori table of correspondences, a symbol is always modulated by the mental activity of the particular dreamer. For symbols “frequently have more than one or even several meanings, and, as with Chinese script, the correct interpretation can only be arrived at on each occasion from the context.” (p. 353). Beyond the very first or “symbolic” reading, therefore, it was essential, in Freud’s view, to draw out the dreamer’s associations.

The dream work is the task of inserting into each dream the wish which lies at its origin, without offending the conscious mind. Representations in dreams are constructed in the two phases of this transformation: the primary-process phase (condensation, displacement, considerations of representability) and the phase of the

secondary revision which completes the transformation by giving consistency and an acceptable meaning to the manifest text of the dream. The meaning of a given representation can therefore as a general rule be established solely by working in reverse, by de-condensation, so to speak, by re-placing what has been displaced, and so on, on the basis of the associations of the dreamer and the intervention of the analyst.

Processes of symbolization organize the dream-work. Consequently, the whole of *The Interpretation of Dreams*, indeed all Freud's writings on dreams, may be considered to have them as their subject; beyond that, these processes constitute the very core of Freud's metapsychology (Gibeault, 1989).

Works on dreams since Freud have been extremely numerous, dealing notably with the issue of the articulation between "general symbols" and "individual symbols." Ernest Jones (1916/1920) was one of the first to take up this discussion.

## **DREAM WORK**

Freud introduced the notion of "dream work" to clearly emphasize that the dream is not the result, as was generally thought to be the case, of a weakened state of mental activity producing incoherent fragments, but, on the contrary, the outcome of very complex psychic work.

This was the notion that was articulated in *The Interpretation of Dreams* (1900a), based on a fundamental hypothesis: the dream represents a fulfillment

of desires that are repressed in waking life, but this realization is typically disguised so as to pass through censorship during sleep. The "dream work" is responsible for this disguise.

The "materials" used in this process are essentially of two types: residues of the day, that is to say "mnemonic traces" of events, thoughts, affects, etc., of waking life (usually recent), and bodily sensations during sleep (hunger, thirst, pain, etc., but particularly erotic excitation). The source of the dream, however, is to be found in conflicts and wishes of childhood—oedipal conflicts prominent among them.

The dream work proceeds in two phases. The first phase is that of the primary processes: "condensation," resulting in compressing into a single image disparate, even contradictory material (events, personages, representations, affects, etc.); "displacement," whereby an affectively neutral representation is substituted for another, and finally visual imagery is primarily the mode of representation for thoughts, affects, and sensation. There is the passage into images itself, or "representability": the dream is made up of essentially visual sensorial images. Condensation and displacement use a stock of easily available images, which are residues of the day.

The first phase of the dream produces the manifest content, which is the unrecognizable translation of the "latent thoughts" that can be made conscious through analysis. However, the manifest content has to be subjected to a secondary revision upon awakening in order to create a superficial coherence in the remembered and repeated dream.

It is significant that while Freud described these primary and secondary processes as the two phases of the dream work, he also considered them as the two processes governing mental activity: the "primary processes," characterized by the free flowing of an unbound energy; and "secondary processes," dominated by rational intellectual activity and bound energy. Consequently, there is a wide chasm between the primary and secondary processes that can be revealed by dissection of the dream work (Neyraut, 1978, 1997).

### "DREAMS AND MYTHS"

This essay is an exercise in applied psychoanalysis: reference can be made to introduction to the "Essays in Applied Psychoanalysis" written by Sigmund Freud in the first edition of *Delusions and Dreams in Jensen's "Gradiva"* (1907a [1906]), as well as to Freud's essay "Creative Writers and Day-dreaming" (1908e [1907]). Abraham's essay can be compared to Franz Riklin's "Réalisation de désir et de symbolisme dans le conte" (Desire and symbolism in tales; 1908).

Abraham compared collective myths with dreams and located the following similarities: both make use of symbolic imagery; both are the products of human fantasy aimed at the fulfillment of wishes; both are subject to censorship and the same defense mechanisms: "Myths are what survives of the psychic life of peoples; dreams are individual myths," he wrote. This same theme was subsequently discussed by Otto Rank, Theodor Reik, and Géza Róheim before interest in it faded.

### DREAM'S NAVEL

In *The Interpretation of Dreams* (1900a), Freud wrote, "There is often a passage in even the most thoroughly

interpreted dream which has to be left obscure; this is because we become aware during the work of interpretation that at that point there is a tangle of dream-thoughts which cannot be unraveled and which moreover adds nothing to our knowledge of the content of the dream. This is the dream's navel, the spot where it reaches down into the unknown" (p. 525).

This careful formulation seems to contradict Freud's whole approach to analyzing dreams, which is to take the analysis as far as possible. As he later wrote when discussing the Wolf Man's dream, "It is always a strict law of dream interpretation that an explanation must be found for every detail" (1918b, p. 42n).

It is therefore unsurprising that Freud, rather than accept "the unknown" as a barrier, should wonder whether a given patient's resistance indicated failure stemming from the inadequacy of the analyst or of the analytic method themselves. In "Notes on Dream Interpretation" (1925i) he returned to the issue, pondering "the limits to the possibility of interpretation of the interpretable" (p. 127). There he stressed, "Those dreams best fulfil their function [to satisfy a wish in spite of the ego] about which one knows nothing after waking" (p. 128) or that are quite simply forgotten. They therefore appear to be uninterpretable. All the same, "it sometimes happens, too, that after months or years of analytic labour, one returns to a dream which at the beginning of the treatment seemed meaningless and incomprehensible but which is now, in the light of knowledge obtained in the meantime, completely elucidated" (p. 129).

## DRIVE/INSTINCT

“The whole flux of our mental life and everything that finds expression in our thoughts are derivations and representatives of the multifarious instincts [drives] that are innate in our physical constitution” (Freud, 1932c, p. 221).

“[T]he “instinct [drive]” appears to us as a concept on the frontier between the mental and the somatic, as the psychical representative of the stimuli originating from within the organism and reaching the mind, as a measure of the demand made upon the mind for work in consequence of its connection with the body” (Freud, 1915c, pp. 121–122).

The German verb *Treiben* generally means “to set into motion”; its earliest meaning was “to drive cattle.” The verb was also used to refer to getting plants to grow, to stamp metal, to drill a mineshaft, to practice languages, to do business, to spend money, to act up—German uses *Treiben* for each of these. Likewise to propel someone into flight, to push someone to the limit, or to feel pressured to do this or that.

The noun *Trieb* shows the same range of force and diversity. Sprout, shoot, or offshoot, for plants; impulse, tendency, penchant, inclination, and instinct for animals and humans—these are all described by the word *Trieb*, which also becomes pejorative when someone gives in to his or her appetites. *Triebleben* means “instinctual life,” and *Triebhaft* means “instinctive.” In physics, *Trieb* means “motor force,” and it appears in a number of compounds such as *Triebfeder*, “mainspring,” *Triebkraft*, “driving force.” *Triebstoff*, literally “driving stuff,” means “fuel.”

Although James Strachey chose to translate *Trieb* by “instinct,” the English word “drive,” like its German counterpart, is in everyday use. It involves the inherent principle of change and activity in living beings. From a dynamic point of view, it is very similar to the ancient Greek concept of *physis*. In 1780, Schiller wrote about *Trieb* in an essay that was well known to Freud and included the passage, “The animal drives awaken and expand the intellectual drives.” Freud often quoted Schiller’s poem “Die Weltweisen” when referring to “the influence of the two most powerful motive forces—hunger and love” (1899a, p. 316).

Freud coined more than forty-five expressions based on the word *Trieb*, such as *Triebkonflikt*, Strachey’s “instinctual conflict.” Further, he qualified drives in

myriad ways, including the sexual drives, the ego-drives, the drive for self-preservation, the aggressive drives, the drive for power, the drive for mastery, the destructive drive, the life-drive, the death-drive, the drive for knowledge, and the social drive. This list does not even include the classification of the partial drives. Nor does it refer to the theory of the drives, Freud’s *Trieblehre*. Finally, *Trieb* designates either the dynamics underlying a specific mental dynamic, in which case Freud spoke of a *drive* or *drives* manifested in “instinctual impulses” (1915c, p. 124); or, alternatively, it designates an overarching dynamic, in which case he referred to the drive or to the *life-drive* and the *death-drive*.

Language provides us with a constant aspect of the meaning of “drive”: the motor principle inherent in living organisms that underlies, in the last instance, all their actions. A drive is activity.

As soon as the concept of libido was introduced, in 1894, as psychical sexual excitation, a rough sketch of the sexual drive became necessary so that the “concept of the mechanism of anxiety neurosis can be made clearer” (Freud, 1895b [1894], p. 108). At first, the sexual drive belonged to the conceptual level. It signified a relatively continuous change of phase and location that transformed the energy of the organic sexual processes into psychical sexual energy, or libido. The sexual drive refers to this transition and its dynamic; it is the conceptual referent of the libido.

Three constants soon appeared. Drive and theory: “drive” is a fundamental concept, necessary for the dynamic understanding of psychical processes. It is inferred from its effects, just like magnetic or gravitational fields in physics. Drive and biology: the theory of the drive is the part of psychoanalytic theory that, since it is founded on somatic processes, borders on biology (Brown-Séquard’s experiments of 1899 were not unknown to Freud). Drive, sexuality, and libido: Freud’s entire work is concerned with the sexual drive. Regardless of the structural oppositions into which it is introduced, it remains the preeminent dynamic referent of human mental life, and as such, is expressed as libido.

Though Freud was later to sharpen and to elaborate it, the concept of the drive was transgressive as early as 1894, and in at least three different senses:

1. It highlighted the importance of sexuality in human mental life.
2. It subverted the body/mind dualism.

3. And by so doing, it reestablished, in the manner of Aristotle and contemporary mathematicians and physicists, the primacy of the dynamic factor in the realization of stable and individualized forms.

Freud distinguished three successive “steps” in the theory of the drives: an “extension of the concept of sexuality,” “the hypothesis of narcissism,” and the “assertion of the regressive character of [drives]” (1920g, p. 59). We can trace these steps in his major works: first, *Three Essays on the Theory of Sexuality* (1905d); next, “On Narcissism: An Introduction” (1914c) and the metapsychological papers of 1915, published in 1924; and finally, *Beyond the Pleasure Principle* (1920g). The first step dissected the sexual drive into component partial drives and emphasized the importance of infantile sexuality. The second step generated new psychic formations of larger dimensions, beyond the basic level, such as the ego and narcissism. At this stage, a difficulty developed regarding the drive’s dualism; nevertheless, the drive, its pressure, and its psychical representatives were clearly defined. The third step established the life-drive and the death-drive, a dualism of vast proportions under which all of mental life and all matter was now subsumed. At each step, Freud expanded the drive’s domain without abandoning previous knowledge or more limited perspectives.

Freud’s “thorough study of the . . . essential characters of the sexual [drive] and . . . the course of its development” (1905d, p. 173), took him far beyond both language and tradition, and on the basis of this research he founded the dynamics of psychoanalysis. The theory of the drives was so crucial that Freud—in contrast to his practice with his other fundamental works—continually revised the *Three Essays* as the theory evolved, until the edition of 1924, which introduced such concepts as the phallic stage and primary masochism. Nevertheless, the elements constituting the theory of psychoanalysis could have been taken as established as early as 1905, if we can rely on Freud’s recollection in 1924: “They are: emphasis on instinctual life (affectivity), on mental dynamics, on the fact that even the apparently most obscure and arbitrary mental phenomena invariably have a meaning and a causation, the theory of psychical conflict and of the pathogenic nature of repression, the view that symptoms are substitutive satisfactions, the recognition of the etiological importance of sexual life, and in particular of the beginnings of infantile sexuality” (1924f, p. 198).

These factors depend on the theory elaborated in the *Three Essays*, as the order of their enumeration indicates. The sexual drive was first dissociated from its “natural” object, an adult of the opposite sex, and then broken down into partial drives that appear in infancy, the oral drive, the anal-sadistic drive, and so on. They are defined by their source, which is a bodily erogenous zone; their aim, which is the cessation of their excitation through discharge; and their object, which is the most variable factor. The possible paths that they can take are diverse: foreplay in adult sexual activity; repression and symptomatic expression in the neuroses; fixation and exclusivity in the perversions; and finally all the defensive formations—reaction-formation, inhibition as to their aim, sublimation, and so on. Thus the diversity of adult sexuality is clarified by its “polymorphously perverse” infantile development—and the opposition between the normal and the pathological is eliminated. The two stages in the constitution of human sexuality, first early childhood and then puberty, explain the “damming up” of the drive’s energy and the psychical development of the individual by the establishment of defenses at the expense of the sexual drives. “The simplest and likeliest assumption as to the nature of the instincts would seem to be that in itself an instinct is without quality, and, so far as mental life is concerned, is only to be regarded as a measure of the demand made upon the mind for work” (1905d, p. 168). The variability and plasticity of the drive’s dynamics are essential to this work, since it views the development of the person and of culture on the course of drive development.

Regarding the enlargement of the concept of sexuality, Freud wrote: “These facts could be met by drawing a contrast between the sexual instincts [drives] and ego instincts [drives] (*instincts [drives] of self-preservation*) which was in line with the popular saying that hunger and love make the world go round: libido was the manifestation of the force of love in the same sense as was hunger of the self-preservative [drive]. The nature of the ego instincts remained for the time being undefined and, like all the other characteristics of the ego, inaccessible to analysis” (1923a [1922], p. 255). As one component of psychic conflict, the drives of the ego were therefore indispensable.

Proceeding with the investigation of the drives in 1911 with the Schreber case, Freud at first saw himself as “defenseless,” because the concept of libidinal investment in the ego seemed to undo the dualism of

the drive. “Thus the instincts [drives] of self-preservation were also of a libidinal nature: they were sexual instincts [drives] which, instead of external objects, had taken the subject’s own ego as an object. . . . The libido of the self-preservative instincts was now described as *narcissistic libido* and it was recognized that a high degree of this self-love constituted the primary and normal state of things. The earlier formula laid down for the transference neuroses consequently required to be modified, though not corrected. It was better, instead of speaking of a conflict between sexual instincts and ego instincts, to speak of a conflict between object-libido and ego-libido, or, since the nature of these instincts [drives] was the same, between the object cathexes and the ego” (1923a [1922], p. 257).

From 1914 to 1920, there is no longer a dualism of the drive. The continuous and constant pressure of the drive—along with the pleasure principle—was sufficient to generate the psychic dynamics as well as the diversity of psychical formations (by means of anti-cathexis and primal repression). “By the pressure [*Drang*] of an instinct [drive] we understand its motor factor, the amount of force or the measure of the demand for work which it represents. The character of exercising pressure is common to all instincts [drives]; it is in fact their very essence” (1915c, p. 122). In universalizing the *drive* as a potential state underlying the psyche, Freud also accounted for the way in which *drives* manifest themselves: They are the workings of the drive in the unconscious, and the twofold determination of its representatives revealed by repression: ideas and quota of affect.

Dissatisfied with this situation, which is monist at the dynamic level and dualist in the effects it brings about (though such a dualism is common in any qualitative dynamics), Freud hypothesized: “On the ground of far-reaching consideration of the processes which go to make up life and which lead to death, it becomes probable that we should recognize the existence of two classes of [drives], corresponding to the contrary processes of construction and dissolution in the organism” (1923a, p. 258). In *Beyond the Pleasure Principle* (1920g), he constructed a space in which the substrate is inert matter plus living substance, on which the two types of dynamics act. One refers to pure stability: the death-drives. The other refers to a continuity and to a flexible stability in living beings that continue to exist: the life-drives, or Eros. This space accommodated a

psychical apparatus that was enlarged to include the id, ego, and superego, in which the fundamental drives appeared as libido, as destructiveness and masochism; or even, as Freud put it: “For the opposition between the two classes of instincts we may put the polarity of love and hate” (1923b, p. 42).

From that point on, this model of the dynamics and space of the drive was sufficient. But the theory of the life-drives and death-drives still included propositions too diverse to fit within this model. Several factors remained to be accommodated: the necessity of constructing a space of sufficient dimensions to accommodate all the psychical processes; the fundamental idea of the plurality of the dynamics of psychical work; and finally the necessity of introducing, at the dynamic level, the stability, and even the stabilization, that constitutes, via the “fixation” of a drive, the essence of symptoms and the constraint of repetition. Thus the death-drive includes, among other things, the “instinctual” aspect of the drive. Even though this distinction between drive and instinct is obscured in English by Strachey’s translation, the death-drive integrates the “conservative” and “regressive” nature of instinct. Moreover, this model emphasizes the essential role of the repression of destructive drives in cultural development; it explains the process of the internalization of aggression in the superego; and it explains the origin and the dangers of guilt feelings.

The prevailing qualitative dynamics recognizes what could be called, borrowing a term from the mathematician Seifert, the “fiber spaces” in drives. These include the dynamics out of which the actual forms of the drive develop. From this point of view, it is obvious that any psychoanalytic concept depends, in the final instance, on the theory of the drives. Thus it is consistent that the first ontogenesis of the purified ego appeared in “Instincts and Their Vicissitudes.” Moreover, it was necessary that this paper opened the metapsychology and preceded the essays on repression, the unconscious, dreams, and mourning and melancholia. Likewise, it was necessary to propose the theory of life-drives and death-drives in order to construct the second topography. The pleasure principle itself depends on the death-drive. The constant updating of the *Three Essays* makes it obvious that the theory of the drive is at the basis of the entire theoretical edifice.

What is missing in the theory of the drives is a dimension that would accommodate all of psychical dynamics and economics—for example, reality, to

which Freud conceded an economic and dynamic status that he continually returned to during the years 1923–1925. He reevaluated its role in the constitution of the neuroses and psychoses, and then he reworked the theory of anxiety, and described a realistic anxiety (*Realangst*).

The transgressive features of the drive, listed above, indicate the ways in which it has been critiqued. The accusation of pansexualism is easy to refute: “. . . it is a mistake to accuse psycho-analysis of ‘pan-sexualism’ and to allege that it drives all mental occurrences from sexuality and traces them all back to it. On the contrary, psycho-analysis has from the very first distinguished the sexual instincts [drives] from others which it has provisionally termed ‘ego-instincts [drives]’ . . . and even the neuroses it has traced back not to sexuality alone but to the conflict between the sexual impulses and the ego” (1923a, pp. 251–252).

In the field of psychoanalysis, it is far more common to reproach Freud for his “biologism,” his supposed emphasis on biology as opposed to the unconscious or language. And thus idealism and the mind/body dualism are reintroduced.

The primacy of dynamics, which places psychoanalysis within the larger tradition of scientific modernism (along with thermodynamics, theories of dynamic systems, and qualitative dynamics), has run into several difficulties. First of all, *Treib* does not have an etymological correspondent except “drive” where the pressure disappears after fixed discharge. Instinct has the same problem, as was demonstrated by Agnès Oppenheimer in her studies of the British “object-relations school.” Without an adequate term, the concept of *das Dynamische* is not communicated. Another obstacle was noted by Freud in 1910: “The most striking distinction between the erotic life of antiquity and our own no doubt lies in the fact that the ancients laid the stress upon the [drive] itself, whereas we emphasize its object. The ancients glorified the [drive] and were prepared on its account to honour even an inferior object; while we despise the activity [of the drive] in itself and find excuses for it only in the merits of the object” (1905d, p. 149). Language, culture, and the various dominant epistemologies (for example pragmatism, empiricism, positivism, and structuralism), by privileging object relations, mask the dynamic point of view.

Conversely, Ferenczi delved into the dynamics of the drive audaciously in his *Thalassa* (1924). Having the term *pulsion* at their disposal as a translation for *Treib* from 1910 on, French-speaking analysts—such

as Jean Laplanche, Jean-Bertrand Pontalis, and André Green—were able to preserve the meaning of the concept and to develop it.

Freud admitted his difficulties with the theory of the drives. In fact, dynamic science remains to this day *extremely* difficult, and the theory of the drives is a work in progress. According to Freud, even the sexual drives, which are the most well known, are still obscure, thanks to their interchangeability. Sublimation remained a difficult concept after Freud (S. de Mijolla-Mellor, 1992), and research on this topic today is still centered on the themes that he discovered.

However much we may accept the Freudian point of view, there is still the death-drive. “A queer [drive] indeed, directed to the destruction of its own organic home!” (1933a [1932], pp. 105–106) If all the demands included in the life-drives and death-drives are admissible (Porte, 1994), a theory of the drives exploiting the facts of qualitative dynamics would distribute them differently. Nothing obliges us to restrict the number of dynamics, and we could suppose the existence of “fast” and “slow” dynamics (Kubie, 1960). Fear would count among the basic affects, along with love and hate, for “It is like a prolongation in the mental sphere of the dilemma of ‘eat or be eaten’ which dominates the organic animate world” (1933a [1932], p. 111).

Elaborating for Einstein “a portion of the theory of the [drives],” Freud noted, “It may perhaps seem to you as though our theories are a kind of mythology and, in the present case, not even an agreeable one. But does not every science come in the end to a kind of mythology like this? Cannot the same be said to-day of your own Physics?” (1933b [1932], p. 211). Thus it is in the sense that every science worthy of the name constructs a mythology, and then controls its expansion, that Freud can speak of “Our mythological theory of [drives]” (p. 212).

## **DUALISM**

In the history of religion, dualism refers to the eighteenth-century doctrines that see God and the devil as

two first principles, irreducible and coeternal. Christian Wolff (1734/1968) classified dogmatic philosophies into dualistic systems, which separated the soul from the body as distinct substances, and monistic systems, both groups being distinct from skepticism. In anthropology, epistemology, and ethics, a theory is dualistic when two irreducible principles can serve as a foundation for the theory.

From “A case of successful treatment by hypnotism” (1892–1893) to his last works, Sigmund Freud envisioned mental processes as resulting from underlying conflicts, fed by opposing forces: “Psychoanalysis early became aware that all mental occurrences must be regarded as built on the basis of an interplay of the forces of the elementary instincts” (1923a). In the first topographic subsystem, these forces arise from the sexual instincts in conflict with the ego, or self-preservation, instincts. Later Freud (1914c) said that they arise from the object libido in conflict with the ego libido, as well as from the pressure of the drives. In the second topographic subsystem (after 1920), they arise from the life and death drives. These forces structure the form and dynamics of the mental processes.

Although Freud emphasized the existence of two types of drives in his dualistic approach, he avoids the word “dualism.” Originating in the body, effecting the association of body and mind, and causing physical changes (conversion) or other types of modifications (other defenses), the drives create a dualistic dynamic, though this is not sufficient for saying that psychoanalytic theory is dualistic.

As Freud's research evolved, the essential polarities and the role of instinctual dualism changed as well. When studying the transference neuroses, Freud postulated an “opposition between the ‘sexual impulses’ directed toward the object and other impulses that we can only identify imperfectly and temporarily designate with the name ‘ego instincts’ ” Freud noted the concordance with the opposition between hunger and love. He added, “In the forefront of these instincts, we must recognize the instincts that serve for the preservation of the individual” (1920g). In the first topographic subsystem, these forces arising from instincts were like vectors applied to quasi points (unconscious representations). In this way they resembled the structures of classical physics (Freud, 1899a).

Freud's introduction, between 1911 and 1915, of narcissism, of the ego as agency, of transference (rather than phenomenological transfer), and of a series of correlative

terms of considerable scope shows his dissatisfaction with the former dynamic system. Freud then insisted that antagonistic forces account for morphogenesis, stabilization, and the evolution (in modern terms, structural stability) of large irreducible structures such as the ego, the ego ideal, and certain identifications.

After a period of confusion when Freud replaced the dynamics of conflict with the opposition between object libido and ego, together with the pressure of the drive, Freud proposed the dualism of the life and death drives. A chiasma was introduced, since the sex drive, a disturbing toxic force in the first topographic subsystem, was now integrated in the life drive (*germen*), while the ego instincts (*soma*) were partially integrated in the death drive. The difficulty that this chiasma creates can be resolved by assuming that the new dualism, which is more comprehensive, resolves conflicts between tendencies with different degrees of stability. The ego affects its own immediate stability by conflicting with the expression of sexuality, which forces the ego to change. The sexual drive is directed, in the last instance, at the long-term structural stability of the species.

Drive dualism correlates with a number of conflicts. These include the polarities of mental life: the economic polarity of pleasure and unpleasure, the reality polarities of the ego and the outside world, the biological polarities of activity and passivity. This last pair introduces the polarities around which the contrasts between the sexes develop: active/passive, phallic/nonphallic, masculine/feminine. In ambivalence there is movement between love and hate, and ultimately between the life and death drives; or between the pleasure principle and the reality (formerly constancy) principle, and ultimately between the life and death drives.

The dualism of the life and death drives has often been rejected or poorly understood. It has been interpreted in an exclusively realist sense (Melanie Klein and the Paris school of psychosomatics) even though there was also a theoretical component. The repetition compulsion and death drive have been unilaterally interpreted as nondynamic structural formalisms. Freud's requirements for drive theory involve dynamically accounting for the simple stability that repetition implies (for example, in symptoms) while taking into account the structural stability (always deviating in the same way) that the majority of mental structures implement. "But," according to Freud (1920g), "in no region of psychology were we groping more in the dark [than in the case of the drives]." Only Gustav

Fechner and his hypotheses of stability were of use to Freud. Contemporary dynamicists provide more refined instruments for plumbing the depths of Freudian drive dualism while respecting its preconditions.

## **DUBAL, GEORGE (1909–1993)**

George Dubal, Swiss psychoanalyst and doctor of theology, was born in Geneva on September 18, 1909, and died there on March 9, 1993.

He received a Protestant education. Upon finishing secondary school, he commenced university studies at Eugène Pittard's laboratory, then successively attended the universities of Strasbourg, Geneva, and Paris. He took part in the new-schools movement in French-speaking Switzerland and took a very early interest in psychoanalytic thinking. At the age of sixteen he experimented with the Jungian method of free association. "This method," he wrote in his memoirs, "enabled me to save a comrade from suicide."

He discovered the psychoanalytic experience from one of the first Swiss psychoanalysts, Dr. Gustave Richard of Neuchâtel. He joined Richard, Marguerite Bosseret, and William Perret in creating "new schools" to forward educational reform. Dr. Richard entrusted one of his sons to him for psychotherapy. During this

period Dubal met Charles Baudouin, one of the pioneers of psychoanalysis in Geneva. He went on to become his friend and collaborator. A course of several months spent working in Préfargier Hospital introduced him to the treatment of psychotics. He then encountered Charles Odier, with whom he undertook psychoanalysis. In 1933 he corresponded with Freud on the subject of the libido. He wrote, “In accordance with the concept of general relativity, Freud responded to me that he had no major objection to making a distinction between a general libido and a particular libido.”

In 1935 he married a psychoanalysis buff who wrote various works under the name of Rosette Dubal, among them *La psychanalyse du diable* (Psychoanalyzing the devil) in 1953. Dubal and his wife were both committed to social change and collaborated closely in integrating into social change a psychoanalytic point of view. His psychoanalytic work within the framework of the cure and preventive work outside this context were of equal importance to George Dubal. In fact, like Sándor Ferenczi or Wilhelm Reich, he struggled for the inclusion of psychoanalytic considerations in education and cultural policy.

Before World War II, if we can trust his memories, he was the only practicing psychoanalyst in Lyons, where he became the friend and collaborator of Dr. A. Réquet, head of the Vinatier Clinic. He claims to have introduced psychoanalytic thought to members of the Esprit Group under Frutiger, the president. He also gathered around him friends from the Philosophical Society to discuss the influence of psychoanalysis on philosophical thought. His pedagogical need to reach the general public spurred him on to write a hundred or so pamphlets on psychoanalysis, some of which were published.

In 1953 he made the acquaintance of Marie Bonaparte and John Leuba, who invited him to attend the 15th Conference of French-Speaking Psychoanalysts in Paris and to react to the theory of the instincts propounded by Maurice Bénéssy. Two years earlier he had published in the *Revue française de psychanalyse* (French review of psychoanalysis) a much-appreciated paper titled “La psychanalyse existentielle de Sartre (Sartre’s existential psychoanalysis). As early as 1947 in his book *Psychanalyse et connaissance* (Psychoanalysis and Knowledge) he had analyzed the limits of a phenomenological approach and criticized the finalism of a theory of the instincts as reflected in psychoanalytic practice.

During the events of May 1968, when protests by students at the Sorbonne became violent and led to protests at universities across France and strikes by

French workers, George Dubal defended the students and called into question the relationship between knowledge and power, sparing neither psychoanalysts nor the societies that shelter them. Like some of his Zurich colleagues, he did not share the ideology of those who, as he wrote in his memoirs, “try to put their patients in the party line with respect to power,” to the detriment of respect for the individual.

In the French-speaking Swiss psychoanalytic community, in his practice, as a committed author writing in the journal *Construire* (Building) and the review *Vivre* (Living), and in his conferences at the Artimon, George Dubal was a creative individual who defied all forms of man’s indoctrination and stultification of man.

## **DUGAUTIEZ, MAURICE (1893–1960)**

Maurice Dugautiez, a Belgian civil engineer and psychoanalyst, was born near Tournay in 1893 and died in Brussels in 1960. He was born and reared in a middle-class, provincial environment where nothing predisposed him to be a pioneer of psychoanalysis in Belgium except perhaps a passionate curiosity about psychic life. He was an autodidact and initially very enthusiastic about hypnotism and suggestion. He gave many lectures in a socialist politico-cultural forum, which were later printed in the review *Le pédagogue* (The teacher).

During this period, in 1933, he met Fernand Lechat in the course of one of these seminars. The two men became progressively aware of their common interest in psychoanalysis and contacted Édouard Pichon, then president of the Paris Psychoanalytic Society, who encouraged them to do a training analysis with Dr. Ernst Hoffman, a Viennese refugee in Belgium. After the silence of World War II, contact was reestablished with Paris in 1945. Dugautiez and Lechat were invited

as special students to attend the courses of the Paris Psychoanalytic Institute, and by 1946 Dugautiez was a full member of the Paris Psychoanalytic Society.

In 1947 Dugautiez and Lechat founded the Belgian Association of Psychoanalysts, where they began to train and supervise candidate psychoanalysts. As the result of intense gassing in World War I, Dugautiez's health was fragile and forced him to take a less active role. The responsibility of directing seminars and editing the *Bulletin de l'Association des psychanalystes de Belgique* (Bulletin of the Belgian Association of Psychoanalysts) thus fell to Lechat. Dugautiez, who was more of a clinician than a theorist, continued to train Belgian psychoanalysts until the end of his life.

## **DYNAMIC POINT OF VIEW**

Alongside the topographical and economic points of view, the dynamic point of view is one of the three major axes of metapsychology. It studies the way in which the forces that run through the mental apparatus come into conflict, combine, and influence each other.

The model for mental dynamics was present in Freud's thought from the beginning: it is a direct extrapolation from the dynamic theory of physics in the nineteenth century. It is based on the idea that the mind, with different forces running through it, is the seat of conflict between them. In order to decrease or eliminate the displeasure occasioned by these conflicts, the mental apparatus uses different mechanisms, repression being the prototype. By means of repression the mental apparatus changes the topographical location of the ideational representatives of the instincts. It thus protects itself from the painful or displeasing aspects of its conflicting desires by making some of them or some of their aspects unconscious. The analysis of the dynamics of how mental conflicts are processed is thus an essential component in the practice of psychoanalysis and in metapsychology, which attempts to describe them.

Freud later put forward the idea that, in addition to the defenses that work against but within the conflict, the psyche can implement defense processes that no longer aim at organizing the means to process the conflict but at preventing the conflict itself from appearing. Thus, in addition to repression, which nevertheless retained a generic value in his mind, Freud and many of his successors described forms of projection, denial, even splitting and foreclosure, that attack the very possibility of the existence of a mental conflict by trying to expel from the psyche the existence of one of the components of the conflict.

However, it is also one of the fundamental characteristics of Freud's thinking, as well as that of his principal successors, to simultaneously affirm that in spite of the intensity of the expelling forces that can come to bear on conflicts and their mental representatives, the psyche keeps a trace of what it has tried to expel from itself in this way. That which is expelled tends to come back, in one form or another, often in negative form. Therefore the analysis of mental dynamics must also focus on the measures implemented in order to face up to the internal or external return of what it has sought to remove from representation.

## EARLY INTERACTIONS

The notion of early interactions between the child and its environment first appeared during the 1970s and has since become widely accepted. The further development of the concept corresponds very closely with the spread of knowledge concerning what is now referred to as the psychology, psychopathology, and psychiatry of the baby (or nursing infant).

The concept was put forward by developmental psychologists and is generally contested by psychoanalysts insofar as it refers more to the field of interpersonal relations than to intrapsychic problems in the strict sense of the term. Psychoanalysts prefer to speak of “interrelations,” a term they use in reference to the constitution of the child’s imagos and the progressive establishment of its mental representations (of self, object, and object relations).

However, the term *early interactions* is now very widely used. It is based on a new vision of the nursing infant, a vision that first appeared toward the end of World War II. Although before that time babies were very largely considered by professionals to be eminently passive beings engaged almost exclusively in oral and digestive functions, they slowly came to be described as being much more active in the relationship and already having an intensely social orientation. They were recognized as having many skills, particularly the personal capacity to engage a relationship with its caregiving adult or, on the contrary, to withdraw from this relationship. Infants use some of these skills spontaneously in their daily lives while others, on the contrary, remain potential, as if in abeyance or on reserve, being manifest only in experimental situations (free motricity, early imitation).

It is this notion of active skills and relational reciprocity (in spite of the indisputable dissymmetry between the psychic organization of very young infants and adults) that gave rise to the concept of an interaction. From being seen as a passive consumer, the baby increasingly came to be considered as an evolving human being. This shift in focus can probably be linked on the one hand to adult guilt feelings with regard to children at the end of the last world war and, on the other, to intensified research into the earliest stages of psychic development as a result of the exacerbating urgency of our quest for origins.

In reality the concept of early interactions covers different levels of facts. Five different levels are classically distinguished in a baby’s interactive system: biological interactions, ethological interactions, whether instinctual or behavioral, affective or emotional interactions, fantasy interactions and, lastly, the so-called symbolic interactions. Early interactions really only related to the first four levels, the last one being more concerned with children who have already acquired the use of language.

Biological interactions come into play very largely during intra-uterine life and are generally referred to as “feto-maternal interactions.” They continue to a lesser degree after birth, particularly in the form of breast-feeding.

Behavioral interactions facilitate the various postural adjustments (in his own day Henri Wallon spoke about the “stimulating dialogue” between the mother and child), as well as the attunement of a certain number of biological rhythms (for example, regulating the contractions of the muscle cells in the mother’s mammary glands with the rhythms of the baby’s crying). They require no humoral mediators.

Affective and emotional interactions enable both the mother (or, indeed, the father for that matter) and the child to harmonize their emotional state with that of the other. The main mechanism coming into play seems to be the process of affective attunement described by Daniel N. Stern.

The level of fantasy interactions has been the subject of the liveliest debates with psychoanalysts insofar as they contest the very idea of the action of fantasies and stress the fundamental dissymmetry in the organization of psychic processes in the adult and the child. The process of affective attunement also appears here as the best current candidate for the role of messenger in these fantasy interactions, a study of which is obviously essential with regard to inter- and trans-generational transmission. In fact this level of fantasy interactions poses the whole question of its role in relation to the complex mechanisms of identification and projective identification.

In Anglo-Saxon countries the study of early interactions continues to be very largely the domain of developmental psychologists (T. B. Brazelton, A. J. Sameroff, R. N. Emde), whereas in other countries, particularly in France, a whole research trend came into being in the wake of Serge Lebovici's (1983) work, mainly in an effort to integrate this concept of early interactions into the data of classic psychoanalytic metapsychology.

The following are the main questions currently raised by the concept of early interactions: Can the different types of interactions between the baby and its environment be considered as first forms or precursors of future object relations? How is the change effected from the interpersonal level to the intrapsychic level? What is the role of these interactions in the child's relation to intersubjectivity? Is there not a danger that the question of interactions will lead to a sort of metapsychology of presence to the detriment of the role of absence and the excluded middle?

## **ECKSTEIN, EMMA (1865–1924)**

Between 1892 and 1893 Emma Eckstein was one Sigmund Freud's most important patients and, for a short period of time around 1897, became a psychoanalyst herself. She was born on January 28, 1865, in Vienna and died on July 30, 1924. Eckstein belonged to a family that the Freuds were friendly with. One of her brothers, Frederick, was a Sanskrit specialist; another, Gustav, was a leading member of Karl Kautsky's Austrian socialist party. Aside from some cryptic passages concerning her (1937c), Freud never published her case history. In his *Project for a Scientific Psychology* (1895), Freud presented her phobia of stores in the chapter "Hysterical Proton Pseudos," but the manuscript was never published during Freud's lifetime.

In early 1895, finding that analysis could not eliminate Eckstein's compulsion for masturbation, which resulted in dysmenorrhea and stomach pains, Freud turned to Wilhelm Fliess for help. Fliess, basing his thinking on his theory of a "nasal reflex neurosis," operated on her nasal concha but left fifty centimeters of gauze inside her nose. The error was repaired by Professor Rozanes in Vienna, but Fliess felt he had been wronged because Freud had called in another physician to attend to Eckstein's problem. Freud attributed the accident to Eckstein's hysteria (1985, letter 56 et seq.), but she remained disfigured. Freud resumed his analysis of her and provided some improvement, and this motivated her to become a psychoanalyst in 1897. In December Eckstein confirmed that she had been seduced by her father (1985, letter 150), which Freud had doubted as late as September of that year.

Freud continued his relationship with Eckstein. He was furious to learn that Eckstein, during an operation for a myoma, had undergone a hysterectomy. He refused to resume analysis in November 1905. Meanwhile, Eckstein had published a small book on the sexual education of children (1904), in which she does not mention Freud. She seems to return to a theory of ancillary seduction, and she viewed infantile sexuality from a constitutional point of view: sucking and masturbation. From this time on a relapse forced her to take to her bed, where she remained until her death nineteen years later.

## **ÉCOLE DE LA CAUSE FREUDIENNE**

After the failure of the negotiations between the Société française de psychanalyse (French Society for Psychoanalysis) and the International Psychoanalytical Association over whether to recognize Jacques Lacan as a training analyst, two groups were founded. One was the Association psychanalytique de France

(French Psychoanalytic Association), which was founded on May 26, 1964, and became a member of the International Psychoanalytical Association even though it included a number of Lacanians. The other was the École française de psychanalyse (French School of Psychoanalysis), founded by Jacques Lacan on June 21, 1964. The school was renamed the École freudienne de Paris (Freudian School of Paris) when its bylaws were filed with the police on September 24 of the same year. Lacan dissolved this school by a letter dated January 5, 1980, though its legal dissolution was not voted on until September 27, 1980.

Then on February 21, 1980, with his “letter to the thousand,” which was a call to follow him, Lacan founded the Freudian cause, which he entrusted to Solange Faladé, Charles Melman, and Jacques-Alain Miller to direct. Following much discord and many departures, including the resignations of Faladé and Melman, Lacan established, as his base, the École de la Cause freudienne (ECF, School of the Freudian Cause). Its statutes were modified on September 24, 1993.

The ECF is the largest and most important Lacanian association in France. It has international connections with a number of other schools through the Association mondiale de la psychanalyse (World Association of Psychoanalysis), founded in Paris in 1992. The ECF is represented by Jacques-Alain Miller, Lacan's son-in-law and literary executor, and is led by a directorate of five members (who serve terms of two years and are responsible for its administration) and a council (which guides its orientation). The school has two levels of membership: member analyst of the school, a permanent title, and analyst of the school, a temporary title. These titles are holdovers from the old École Freudienne de Paris. Also, a practicing analyst can declare his or her practice within the school without the school certifying it.

The Association de la Cause freudienne (Association of the Freudian Cause) was founded on November 1, 1992, to gather the fifteen regional associations of the ECF, most of which publish a journal or bulletin. Through the Association mondiale de la psychanalyse and the Association de la fondation du champ freudienne (Association for the Foundation of the Freudian Field), founded by Lacan in 1979 and directed by his daughter Judith Miller, the Lacanian movement has an official presence in twenty-six foreign countries (and an especially important presence in

Latin America). Two organizations have split off from the ECF: the École de psychanalyse Sigmund Freud (The Sigmund Freud School of Psychoanalysis), which was founded in May 1994 and which revived the experiment of the pass (See Daniel Lagache, “On the Experiment of the Pass” [1973]), and the Forums du champ lacanien (Forums of the Lacanian Field), which was founded in May 1999 by three former presidents of the ECF.

The ECF publishes a semiannual journal, *Cause freudienne*, and a monthly newsletter.

## ÉCOLE EXPÉRIMENTALE DE BONNEUIL

The École expérimentale de Bonneuil (Experimental school of Bonneuil) was founded on September 12, 1969 under the leadership of Maud Mannoni.

In his seminar, Jacques Lacan had asked analysts to take a somewhat closer interest in what went on in hospitals, in the belief that analytic discourse could be used to subvert the workings of these structures. In this context, Maud Mannoni began an institutional experiment at the Institut médico-pédagogique (Medical training institute) in Thiais, France. This experiment enabled her to produce *Le Psychiatre, son “fou” et la psychanalyse* (The psychiatrist, his “madman” and psychoanalysis; 1970), exposing the ways in which psychoanalysis betrays its vocation by participating in the institutional order. Her earlier works were *The Backward Child and His Mother: A Psychoanalytic Study* (1964/1972), in which she showed that in seeking to treat the symptom the patient’s needs were denied, and *The Child, His “Illness,” and the Others* (1967/1970), where she showed that the vision of the “sick person” is warped by one’s preconceptions.

Mannoni’s encounter with the anti-psychiatrists confirmed her ideas: They, too, were rebelling against any ideology based on “managing” madness, and were returning to Sigmund Freud’s suggestion that for the patient, delusions are an attempt at reconstruction. This break with medical thinking occasioned a focus on the idea of segregation that was operative in the

traditional psychoanalytic institution and entailed grouping patients into broad categories in psychiatric clinical work.

This principle of nonsegregation that presided over the opening of the Bonneuil facility was made concrete in its ideal mode of operation: One third of the children were autistic or psychotic children, one third were mentally deficient or emotionally disturbed, and one third were suffering from neuroses of varying degrees of severity. This mode of operation made it possible to maintain a mix of symptomatology that opened up dynamic perspectives, underscoring by this very fact the negative consequences of segregation for the subject, even when segregation was given a new guise and sanctioned by medicine under the name “mental illness.” That term implies as an alternative a hypothetical “mental health,” which has no place in a psychoanalytic perspective. The fundamental notion of “breaking out” is situated within this ethos of nonsegregation.

A place that is open to the outside rather than a self-enclosed institution cut off from the world (an organism created by normative forces acting against the emergence of foreclosed alternatives, to whose detriment this normativity has been maintained), the École expérimentale de Bonneuil was accredited as an outpatient hospital with nighttime intake facilities on March 17, 1975, with a capacity of twenty-six children, ages six to eighteen. Daily practice at Bonneuil is based on a psychoanalytic approach. Theory allows for the work of retrospective interpretation that examines individual pathways and institutional avatars. This constant back-and-forth movement between theory and praxis—in particular in the numerous work groups—characterizes the analyst’s place in the institution. That place is thus a paradoxical one: Practice is not what establishes analysts in their role, but it is what determines their specific place in this setting and the journey they will make with these troubled children. Cooking, running errands, working alongside artisans or farmers, completing schoolwork, and taking workshops—these activities are seen as so many mediations that make it possible to escape from an imaginary situation in which relations between adult and child are built without reference to any third party. The other possibility created is that the children can become the agents in a story that at some point converges with their own. What makes this legible is the putting into place of a framework, not in the sense of institutional rules, but rather a structure that

provides a sense of bearings and facilitates questioning, to guarantee that work will be ongoing. On March 12, 1980, an experimental family placement service was established for patients from eighteen to twenty-five years old. Since September 1, 1995, family placement has existed for patients older than twenty-five.

## **ÉCOLE FREUDIENNE DE PARIS (FREUDIAN SCHOOL OF PARIS)**

On June 21, 1964, Jacques Lacan founded the *École française de psychanalyse* (EFP, French School of Psychoanalysis), which, without changing its initials, was quickly renamed the *École freudienne de Paris* (Freudian School of Paris). The meeting to found the new school was held in the home of François Perrier, the same place where the Quatrième Groupe (the Fourth Group, an offshoot of the EFP) would be founded in 1969. The gathering was attended by about fifty members of the *Société française de psychanalyse* (SFP, French Psychoanalytic Society), which would not formally be dissolved until January 1965. Lacan chose the word “school” in reference to the ancient schools of philosophy: “certain places of refuge, indeed bases of operation against what might already be called the discontents of civilization” (Lacan, 1964/1990, p. 104). The School’s “Founding Act” was completely different from that of any other psychoanalytic institution. Lacan announced the School’s project in a solemn tone: Its task would be “a labor which, in the field opened up by Freud, restores the cutting edge of his discovery” (p. 97). In order to do this, he made new distinctions in the field of psychoanalysis by creating three divisions, the direction of which he personally

undertook: the division for “pure psychoanalysis . . . which is and is nothing but . . . the training analysis” (p. 98), the division for “applied psychoanalysis, which means therapeutic and clinical medicine” (p. 99), and the division for “taking inventory of the Freudian field,” which would “undertake to publish those principles from which analytic practice is to receive its [scientific status]” (p. 99). Such a distinction between pure and didactic psychoanalysis on the one hand and the therapeutic field on the other could logically only lead to a recourse to science in order to legitimize psychoanalysis. Thus in the “Founding Act” the idealization of science that would later lead to the *mathème* was already on the horizon. It had already led Lacan in 1955 to imagine the “recognition of psychoanalysis, as either a profession or a science” on the basis of a “principle” (Lacan, 1966, p. 325).

The School recognized three categories of members, which did not in any way correspond to the traditional forms of membership in a psychoanalytic society. The rank of Analyst of the School (AE) was initially held by those who had been full members of the SFP, their task was the “doctrinal elaboration of training analysis.” To become an AE, one had to make a request to the “jury of approval.” The Analyst Member of the School (AME) were directly named, without a personal solicitation, by a “jury of reception” that guaranteed their “professional ability” based on the “approval of their training analyst, the advice of their supervisor or supervisors, and accounts of the candidate’s practice.” It was specified that, “in regard to the psychoanalytic treatments undertaken under his or her direction, the analyst is only authorized by him- or herself” (*Annuaire EFP* 1977). This sentence contributed to serious misunderstandings when its second half was taken to be a formula by which one could become an analyst, while in context it is clear that it is only a matter of being authorized in the session. The third category is that of the practicing analyst (A.P.), who declared their practice to the EFP without being sanctioned by it. Finally, it was also possible to be a member of the School without being an analyst by participating in its work and research.

The first board of directors that led the EFP was made up of Piera Aulagnier, Jean Clavreul, Jacques Lacan, Serge Leclair, François Perrier, Guy Rosolato, and Jean-Paul Valabrega. Each of them left the board successively, and some of them left the School altogether, with the exception of Jean Clavreul, who was a

member of the last board of directors to be formed (1967), and Lacan, president of the 1967 board, with Solage Faladé as vice-president, Éric Laurent as secretary and administrator of cartels, Jacques-Alain Miller as administrator of cartels, Charles Melman and Christian Simatos—longtime secretary of the School—as administrators of teaching, Claude Conté and Irène Roublef as administrators of publication, and René Bailly as assistant treasurer.

The EFP was officially established as a non-profit organization when its first set of bylaws, which were very concise, were filed on September 24, 1964. The members of the corporate board were lay people, friends of Lacan's. In 1969, in an effort to have the School recognized as a state-approved agency, more detailed bylaws were filed by Solange Faladé, but in 1970, the Council of State turned down the School's application.

During its fifteen years of existence, the EFP went through a series of institutional crises over policies and theoretical issues. On December 1, 1965, François Perrier resigned from the board of directors over the question of training, and on March 31, 1967, he proposed the formation of a "college of analysts" focused on the clinic. Jacques Lacan responded with his "Proposition of October 9, 1967, on the Psychoanalyst of the School" in which he suggested his procedure of "the pass." This proposal led to the 1968 departure of Guy Rosolato, who rejoined the Psychoanalytic Association of France (AFP). The first split within the Lacanian movement itself soon followed, with the departures of Piera Aulagnier, François Perrier, and Jean-Paul Valabrega during discussions on the pass at the Lutetia Assizes during January 1969. They took with them about twenty members of the School.

The departures of such eminent members caused disruptions within the School. Bit by bit, a rift developed between the EFP and the Department of the Freudian Field at Vincennes, which was founded by Serge Leclair in 1968 and taken over by Jacques Lacan and Jacques-Alain Miller at the end of 1970. This rift led to an implied division between the EFP's clinical analysts and the young analysts at Vincennes, whose academic training in psychoanalysis set them apart. This younger group became the vehicle for the logical orientation of Lacan's later career, especially after the founding of the journal *Ornicar?* by Jacques-Alain Miller in 1975. The Deauville Assizes on the experiment of the pass, held in January 1978, gave ample evidence of the failure of what Lacan had hoped would be

the primary institutional procedure of the School. It was also at this time that Lacan began to suffer from serious neurological problems (progressive aphasia).

In the end, the EFP collapsed on legal grounds. An extraordinary general assembly convened on September 30, 1979, to expand the corporate board from seventeen to twenty-five members and to elect a new board. But on January 5, 1980, in a letter addressed to the members of the School and read at his seminar, Lacan announced the dissolution of the School. This letter prompted Michèle Montrelay and twenty-seven other members to file a lawsuit claiming irregularities in the September meeting. A provisional administrator was named by the Paris municipal court on January 25, 1980. In 1980, three extraordinary general assemblies met without attaining a statutory majority until finally, on September 27, the dissolution of the EFP was passed.

When it was founded in June 1964, the EFP included about 100 members. In January 1980, membership stood at more than 600, a number that testifies to the vitality of French Lacanianism in that era.

## ECONOMIC POINT OF VIEW

Along with the topographical and dynamic points of view, the economic point of view is one of the three main axes of metapsychology. It deals with psychic

events in terms of the intensity of the forces that run through them and animate them.

This concept was present in Freud's early thinking and appears in his first metapsychological formulations. It then assumed increasing importance during the evolution of his theoretical thinking and his conception of psychopathology. It is based on the hypothesis, much criticized in recent times, that the mental apparatus is invested with forces that are specific to it (instincts) and which can vary in intensity, either "constitutionally", or as a result of reinforcements linked to the vicissitudes of development (particularly trauma). These primary forces can oppose each other, combine together, and form complex amalgamations and alliances with each other. The economic point of view is an attempt to describe this interplay of forces and the resulting intensities.

After 1920, the economic approach assumed increasing importance in Freud's thinking because of the clinical difficulties encountered in non-neurotic cases. The metapsychological notions that Freud then developed attributed a centrally determinant role to the economic point of view in the genesis and maintenance of pathological conditions and their different structures.

In the same way that the concept of instincts is criticized by certain psychoanalysts who prefer more contemporary concepts that focus on information, representation, or signifiers (Widlöcher, D., 1997), the economic point of view has also elicited certain theoretical reservations. However, it is difficult to see how to modify this aspect of metapsychology, which is directly linked to the question of instincts, without seriously jeopardizing the whole of the corpus. Moreover, clinical work makes us sensitive to variations in instinctual intensity and investment which would be difficult to explain without recourse to the economic point of view and the binding and unbinding of instincts.

## ÉCRITS

Until the publication of his *Écrits* (Writings), Jacques Lacan's only published book was his doctoral thesis in medicine, *De la psychose paranoïaque dans ses rapports avec la personnalité* (*On paranoid psychosis in its relations with personality*; 1932), written from a psychiatric, rather than psychoanalytic, perspective.

In the 1960s Lacan was asked by several of his students and by his friend François Wahl, of the publishing house Seuil, to collect his writings in a single volume. The considerable success of *De l'interprétation, essai sur Freud* (*Freud and Philosophy: An Essay on Interpretation*), by Paul Ricœur, in 1965 and then that of *Les mots et les choses* (*The Order of Things*), by Michel Foucault, in 1966 prompted him to prepare a collection of his articles.

He omitted all his work from before the war, notably his article "La vie mentale" (Mental life; 1938) from volume eight of the *Encyclopédie française* (the alternate title of which, "The Family Complexes in the Formation of the Individual," only appeared on the cover of an off-print). He did, however, make an exception for a text written in 1936 for Marienbad, where he delivered his lost lecture on the mirror stage to the congress of the International Psychoanalytic Association.

In the collection, he slightly modified his articles, often without any indication of the changes. He introduced the book with a recollection of his medical and psychiatric origins, “De nos antécédents” (On my antecedents), and preceded “Discours de Rome” (Rome discourse) of 1953 with a brief text that indicated the consequences of this discourse for the psychoanalysis of the future, “Du sujet enfin en question” (On the subject who is finally in question).

*Écrits* was published in the third trimester of 1966 by Seuil. The book very quickly achieved critical acclaim and was widely reviewed and debated in the press. It included a “Classified Index of the Major Concepts” by Jacques-Alain Miller. This index introduced a logical dimension to Lacanism that was emphasized from 1975 on. In the introduction to the index Miller wrote, “According to my conception of these *Écrits*, it is to our benefit to study them as forming a system. . . . For my own part, not needing to concern myself with the efficacy of the theory in [the clinic], I will encourage the reader by proposing that there is no outer limit to the expansion of formalization in the field of discourse” (pp. 358–359).

A measure of the influence of *Écrits* is that it has been translated in to numerous languages. Moreover, it was followed by a sequel, *Autres Écrits*, published in June 2001. In that volume Jacques-Alain Miller collected nearly all of Lacan’s articles from before 1939, such as “Les complexes familiaux dans la vie de l’individu” (Family complexes in the formation of the individual; 1938). Also included are the version of the “Discours de Rome” (Rome discourse) circulated in the proceedings of the IPA congress (1953) and all the texts that appeared after the publication of *Écrits* up to that of “L’étourdit” (Stunned; 1972), Lacan’s last published article.

### EDER, DAVID MONTAGUE (1866–1936)

David Montague Eder, an English psychoanalyst, was born in August 1866 in London, where he died on March 30, 1936. He studied medicine in London, opened a practice as a general practitioner and, with Clara Grant, started the first school clinic as a result of his interest in education. He met Ernest Jones in 1904, but it was his enthusiasm that stemmed from his reading “Little Hans” in 1909 that led him to psychoanalysis. In 1911 he gave the first psychoanalytic conference in Great Britain, which scandalized members of the British Medical Association. After becoming an analyst in 1912, he met Jung and translated two of his works into English: *Diagnostische Assoziationsstudien* (Diagnostic Association Studies) and *Versuch einer Darstellung der psychoanalytischen Theorie* (The Theory of Psychoanalysis). In 1913 he traveled to Vienna to be analyzed by Freud, who sent him to Viktor Tausk. Eder was successively analyzed by Tausk, by Jones, and, after an attempt with Karl Abraham, by Sándor Ferenczi, with whom he shared the illusion of the “perfectly analyzed analyst.” Eder also introduced the work of Alfred Binet and Théodore Simon in Great Britain.

Eder was involved in a number of political and social issues. He argued against the unfairness of the Mental Deficiency Bill. Associated with Zionist literary and political circles through his Jewish family (he was a cousin of the writer Israel Zangwill and a friend of D. H. Lawrence; his wife, Edith, was the sister of the analyst Barbara Low), he embraced the Zionist cause.

In 1915 Eder joined the army as a doctor and was stationed in Malta, then at a neurological clinic in London. He published a book about his experiences entitled *War-shock* (1917), which focused on wartime neuroses

and their treatment. In 1920, while living in Palestine, he worked with Chaim Weizmann, Israel's first president, and led seminars in analysis (with Dorian Faigenbaum). This represented the first appearance of analysis in Israel prior to the arrival of Max Eitingon. He later became an elected representative of the Zionist Executive in Palestine and served from 1921 to 1927.

Eder distanced himself from Jung's ideas. In 1923 he joined the British Psychoanalytic Society, where he held numerous positions: first as secretary, then as director of the Institute of Psychoanalysis and director of the London Clinic of Psychoanalysis. In 1932 he was elected president of the medical section of the British Psychological Society.

He was the first to use psychoanalysis to treat a case of stuttering, which is described in "Das Stottern eine Psychoneurose und seine Behandlung durch die Psychoanalyse" (Stuttering: a psychoneurosis and its treatment through psychoanalysis; 1913). His theoretical works comprise some thirty articles, covering subjects that include dreams and resistance (1930), the psychological problems of eugenics and birth control, the economy and future of the superego (1929), the father's animosity toward the son, and Jewish rituals (1933).

This "political pugilist" and "liberator by vocation" (as Edward Glover described him) was also a passionate advocate of psychoanalysis, which he introduced into schools and prisons. Sigmund Freud confided to Barbara Low that he represented "a rare blend of intrepid courage and an absolute love of truth, together with tolerance and a great capacity to love."

## EGO

The notion of *das Ich* (literally "the I") was present in Freud's thought from the earliest days of psychoanalysis, but over the years it underwent serious theoretical modifications, often connected to advances in clinical practice. The term had long designated the self-conscious person as a whole, but in 1923 Freud assigned it the role of an agency of the mental apparatus with a mediating and regulatory function vis-à-vis the id, the superego, and external reality. He would always, however, allow a measure of ambiguity to persist with respect to the two meanings, and it was only after his death that they were disentangled and promoted separately in contradistinction to one another. With the stress placed by the proponents of ego psychology on the ego's adaptative functions, the notion tended to be upstaged by the "self," the "I," or the "subject."

To begin with, then, Freud tended to employ "*das Ich*" in a sense akin to that of the philosophers, that is to say as a synonym for "conscious person." Only later did he reserve the term for a portion of the mental personality, in accordance with his constant concern to distinguish analysis from synthesis. But the German word remained ambiguous, along with its use in Freud's writing, and its translation into other languages inevitably occasioned problems and debates. The choice of "ego" by the translators of the *Standard Edition* has been challenged, by Bruno Bettelheim among others: "To mistranslate *Ich* as 'ego' is to transform it into jargon that no longer conveys the personal commitment we make when we say 'I' or 'me'" (Bettelheim, p. 53). As for the early French psychoanalysts, they hesitated between "ego" and "*le Moi*" before plumping for this last term in preference to either "ego" or "*Je*."

Very early on in his thinking, contemporary research on "split personality," that is to say, on the dissociation of consciousness, along with his own use of hypnosis, led Freud to place the ego qua consciousness in the position of an active judge in the conflicts underlying psychopathological symptoms. In his article on "The Neuro-Psychoses of Defence" (1894a), he

emphasized the “task which the ego, in its defensive attitude, sets itself of treating the incompatible idea as ‘*non arrivée*’” (p. 48). The following year, he described the ego at length in biological terms, in the “Project for a Scientific Psychology,” (1950a [1895]), as a group of neurones designed to control primary processes and avoid unpleasure: “the ego is to be defined as the totality of the psi cathexes at the given time” (p. 323). As thus characterized, the ego was no longer synonymous with the whole person: Its future role as a psychical agency was foreshadowed, and it was already responsible for regulating energy flows, a task that would fall to it more and more clearly in the psychological context.

Freud’s “first topography,” founded on the distinctions between the Conscious, the Preconscious, and the Unconscious, made no essential appeal to the ego, which makes its appearance in *The Interpretation of Dreams* mainly as the bearer of the wish for sleep or else as a key actor at the center of the masquerade in which, as censor, it itself cloaks unconscious wishes: “Dreams are completely egoistic. Whenever my own ego does not appear in the content of the dream, but only some extraneous person, I may safely assume that my own ego lies concealed, by identification, behind this other person; I can insert my ego into the context. On other occasions, when my ego does appear in the dream, the situation in which it occurs may teach me that some other person lies concealed, by identification, behind my ego. In that case, the dream should warn me to transfer on to myself, when I am interpreting the dream, the concealed common element attached to this other person. There are also dreams in which my ego appears along with other people who, when the identification is resolved, are revealed once again as my ego. These identifications should then make it possible for me to bring into contact with my ego certain ideas whose acceptance has been forbidden by the censorship. Thus my ego may be represented in a dream several times over, now directly and now through identification with extraneous persons” (1900a, pp. 322–23). The “my ego” here stood for “the representation of myself” in the sense of identity. This early link made by Freud between the ego and processes of identification is noteworthy.

Over the next fifteen years Freud developed the notion, not so much in topographical terms, for in that sense the ego remained within the Preconscious-Conscious system, but in dynamic and economic

terms, especially with respect to its role in the regulation of pleasure/unpleasure. The notion of “ego instincts,” also known as “self-preservative instincts,” as distinct from the “sexual instincts,” was introduced by Freud as early as 1910; he observed that the two classes of instincts “have in general the same organs and systems of organs at their disposal” (1910i, pp. 215–16). Even if, not long before, he had ironized on “His Majesty the Ego, the hero alike of every day-dream and of every story” (1908e, p. 150), Freud now deemed external reality one of the constraints that the ego was obliged to confront. In “Formulations on the Two Principles of Mental Functioning,” he drew a distinction between a “pleasure ego,” related to the infant’s attempts to achieve a hallucinatory satisfaction of its wishes, and a “reality ego” developed over time in response to life’s failure to supply satisfaction: “Just as the pleasure-ego can do nothing but *wish*, work for a yield of pleasure, and avoid unpleasure, so the reality-ego need do nothing but strive for what is *useful* and guard itself against damage” (1911b, p. 223). The ego was thus being presented more and more as an essential working part in the regulation of a complex mental system.

In the same year of 1911, the problem of psychotic patients led Freud, stimulated in this regard by Jung’s research on the issue, to complete his first reflections on narcissism and identification, begun in his study of Leonardo da Vinci the year before. In his “Psycho-Analytic Notes on an Autobiographical Account of a Case of Paranoia,” he argued that dementias, especially schizophrenic dementia, should be seen as involving “the detachment of libido” from the external world and its “regression on to the ego” (p. 76), in memory of that time when “a person’s only sexual object [was] his own ego” (p. 72). In “The Claims of Psycho-Analysis to Scientific Interest,” he offered this summary of his view of the nature of the neuroses: “The primal conflict which leads to neuroses is one between the sexual instincts and those which maintain the ego. The neuroses represent a more or less partial overpowering of the ego by sexuality after the ego’s attempts at suppressing sexuality have failed” (1913j, p. 181).

Alfred Adler’s theories were doubtless not without their influence, too, on the questions Freud was asking himself at this time, even if he felt that Adler underestimated the importance of unconscious processes, and wrote to Jung on March 3, 1911: “I would never have expected a psychoanalyst to be so taken in by the ego.

In reality the ego is like the clown in the circus, who is always putting in his oar to make the audience think that whatever happens is his doing" (*Freud/Jung Letters*, p. 400). We know that Freud would modify this view later, but for now he kept the emphasis on the socius: "psycho-analysis has fully demonstrated the part played by social conditions and requirements in the causation of neurosis. The forces which, operating from the ego, bring about the restriction and repression of instinct owe their existence essentially to compliance with the demands of civilization" (1913j, p. 188).

In 1912 Freud could still describe the ego as synonymous with the mental personality as a whole, as he did in a letter to Ludwig Binswanger of July 4, 1912: "I have long suspected that not only the repressed but also the dominant aspect of our life, the essence of the ego, is unconscious though not inaccessible to the conscious" (1992 [1908-38], p. 90). But his paper "On Narcissism: An Introduction" (1914b) marked the turning-point which endowed the ego with a new significance in theory as in practice: "Thus we form the idea of there being an original libidinal cathexis of the ego, from which some is later given off to objects, but which fundamentally persists and is related to the object-cathexes much as the body of an amoeba is related to the pseudopodia which it puts out. . . . We see also, broadly speaking, an antithesis between ego-libido and object-libido" (pp. 75–76). Another observation of Freud's raised an issue which has never since ceased being debated, that of the genesis of the ego: "we are bound to suppose that a unity comparable to the ego cannot exist in the individual from the start; the ego has to be developed" (pp. 76–77). The distinction between ego instincts and sexual instincts was preserved, even if Freud stressed that "the hypothesis of separate ego-instincts and sexual instincts (that is to say, the libido theory) rests scarcely at all upon a psychological basis, but derives its principal support from biology" (p. 79). In this same text another idea too was introduced into the theory of analysis, that of the ideal ego against which the actual ego is measured: "Repression . . . proceeds from the self-respect of the ego. . . . This ideal ego [*Idealich*] is now the target of the self-love which was enjoyed in childhood by the actual ego. The subject's narcissism makes its appearance displaced on to this new ideal ego [*Dieses neue ideale Ich*] which, like the infantile ego, finds itself possessed of every perfection" (pp. 93–94). At the same time—and

this was what distanced Freud from the theories of Jung, who had just parted company with him—it was essential not to confuse "homage to a high ego ideal" with the sublimation of the libidinal instincts (p. 94). In the first case repression was reinforced, according to Freud, whereas in the second sublimated instinctual satisfaction made repression unnecessary. As for the "special psychical agency which performs the task of seeing that narcissistic satisfaction from the ego ideal is ensured and which, with this end in view, constantly watches the actual ego and measures it by that ideal" (p. 95), this was clearly the adumbration of the future superego.

In 1915 Freud added the following observation to the third edition of his *Three Essays on the Theory of Sexuality*: "In contrast to object-libido, we also describe ego-libido as 'narcissistic' libido. . . . Narcissistic or ego-libido seems to be the great reservoir from which the object-cathexes are sent out and into which they are withdrawn once more; the narcissistic libidinal cathexis of the ego is the original state of things, realized in earliest childhood, and is merely covered by the later extrusions of libido, but in essentials persists behind them" (1905d, p. 218). In this perspective, progression from auto-erotism to genital heterosexuality could include a moment characterized by a narcissistic or even a homosexual object-choice. In the *Introductory Lectures on Psycho-Analysis*, Freud went on to evoke a possible view of the ego's strength which was destined to have not a little influence on the post-Freudian theory of psychoanalytic technique: "A person only falls ill of a neurosis if his ego has lost the capacity to allocate his libido in some way. The stronger his ego, the easier will it be for it to carry out that task. Any weakening of his ego from whatever cause must have the same effect as an excessive increase in the claims of the libido and will thus make it possible for him to fall ill of a neurosis" (1916–17a [1915–17], p. 387). The suggestion that a weak ego needed "strengthening" gained considerable currency among analysts after the Second World War, along with the idea of the therapeutic alliance which it was felt should be achieved between the therapist and the healthy part of the patient's ego. Both Melanie Klein and Jacques Lacan, each in their own way, contested this approach.

During the 1915–1920 period, Freud's theory of the ego underwent many refinements as his metapsychological papers and summarizing lectures of introduction to psychoanalysis continued to synthesize his

thought. But it would be a mistake to overlook the fact that in a good number of his theoretical speculations the coexistence of old and new ideas was still quite possible, and that contradictions often appear if Freud's formulations are placed side by side. Thus in 1918, on the point of unveiling a completely new view of the ego, Freud could still write: "the neurotic patient presents us with a torn mind, divided by resistances. As we analyze it and remove the resistances, it grows together; the great unity which we call his ego fits into itself all the instinctual impulses which before had been split off and held apart from it. The psychosynthesis is thus achieved during analytic treatment without our intervention, automatically and inevitably. We have created the conditions for it by breaking up the symptoms into their elements and by removing the resistances" (1919a [1918], p. 161).

It would not be long, however, before the said "great unity" was dismantled. His reflections on schizophrenia led Freud to create the class of "narcissistic neuroses." Those on melancholia brought forth the category of "narcissistic identification," meaning the identification of the ego with a lost object: "Thus the shadow of the object fell upon the ego, and the latter could henceforth be judged by a special agency, as though it were an object, the forsaken object. In this way an object-loss was transformed into an ego-loss and the conflict between the ego and the loved person into a cleavage between the critical activity of the ego and the ego as transformed by identification" (1917e [1915], p. 249). It was from this time, too, that identification took on an ever greater significance in Freud's account of the ego's genesis and development. It was said, after all, to be the earliest mode of object-cathexis. And identification was invoked by Freud, in *Group Psychology and the Analysis of the Ego* (1921c), as the bond that structures all social organization.

*Beyond the Pleasure Principle*, however, was the text that contained the first hint of Freud's abandoning the psychical apparatus as described in 1900: "it is certain that much of the ego is itself unconscious, and notably what we may describe as its nucleus" (1920g, p. 19). Furthermore, the introduction of the death instinct in the same work rendered obsolete Freud's earlier distinction between ego instincts and sexual instincts, for both self-preservation and the relief of tension due to unpleasure now fell within the remit of a death instinct which the ego appeared to serve, whether in its inhibiting and repressive functions or in resistances, observed

during treatment, that were linked to the repetition compulsion.

Three years later, in *The Ego and the Id* (1923b), the ego finally achieved the status of an important agency in the description of the mental personality. The starting point of this work was the assertion that "A part of the ego, too—and Heaven knows how important a part—may be *Ucs.*, undoubtedly is *Ucs.*" (p. 18). The old account based on the *Cs./Pcs./Ucs.* schema was discarded, these substantives to be confined henceforward to a solely adjectival use denoting properties, but the processes described earlier to explain "coming to consciousness" remained valid: unconscious thing-presentations still had to be brought into connection with word-presentations in order to become conscious (see "The Unconscious" [1915e]). The ego was now described as wearing a "cap of hearing," the origin of perception and of the memory traces that perpetuated it.

*The Ego and the Id* views the ego primarily as a surface differentiation of the id under the influence of the external world; it conveys the demands of the external world to the instinctual agency of the id, with which it remains in permanent contact at its base. As a messenger of reality, the ego replaces the reign of the pleasure principle by that of the reality principle, imposing the constraints of the social environment. It is the agent of the repression (or the sublimation) of the instincts, of the censorship of dreams, and the cause of resistances to the treatment, and it manages object-cathexes and controls motility. All these responsibilities do not preclude a certain passivity of the ego. Recalling the tale of Itzig, who does not know where he is going, and says "Ask my horse!"; Freud writes: "Thus in its relation to the id it is like a man on horseback, who has to hold in check the superior strength of the horse; with this difference, that the rider tries to do so with his own strength while the ego uses borrowed forces. The analogy may be carried a little further. Often a rider, if he is not to be parted from his horse, is obliged to guide it where it wants to go; so in the same way the ego is in the habit of transforming the id's will into action as if it were its own" (p. 25).

But "The ego is first and foremost a bodily ego; it is not merely a surface entity, but is itself the projection of a surface" (p. 26). This idea was elaborated by Freud in a note added to the English translation of *The Ego and the Id* published in 1927: "the ego is ultimately derived from bodily sensations, chiefly from those

springing from the surface of the body. It may thus be regarded as a mental projection of the surface of the body, besides, as we have seen above, representing the superficialities of the mental apparatus" (p. 26n). (Here it is possible to discern the origins of the "skin-ego" described by Didier Anzieu in 1985 [Anzieu, 1989]). The ego derives energy from narcissistic libido, and in this connection Freud evokes the possibility of a libido (even an Eros) that is "desexualized" or "sublimated," "displaceable and neutral"—and, one can only suppose, not easily reconcilable with the theses of ego psychology on an autonomous and conflictless ego. At all events, according to Freud, "The narcissism of the ego is . . . a secondary one, which has been withdrawn from objects" (pp. 44–46).

The importance of processes of identification is much emphasized in *The Ego and the Id*. Identification is the basis of the earliest object-cathexes and retains this function first in the form of incorporation and later as identification proper. (As early as 1909 Sándor Ferenczi had described the growth of the ego in terms of introjection.) But the fate of object-cathexes is that they must be abandoned in the course of a person's history, and Freud concludes in this connection that the mechanism of melancholia is universally applicable. Thanks to narcissistic identification, the abandoned object is perpetuated within the ego, which seeks on this basis to make itself loved by the id: "I am so like the object" (p. 30). Freud is thus able to frame the following proposition, so often misread since: "It may be that this identification is the sole condition under which the id can give up its objects. At any rate the process, especially in the early phases of development, is a very frequent one, and it makes it possible to suppose that the character of the ego is a precipitate of abandoned object-cathexes and that it contains the history of those object-choices" (p. 29). As we shall see, the restriction here, that only the "character" of the ego and not the ego as a whole is involved in this process, would often be overlooked subsequently; all the same, Freud's evocation of the succession—even the contradictory coexistence—of object identifications in the case of "multiple personalities" (pp. 30–31) shows just how much the ego remains the seat of identifications for him.

We should note lastly in this context that the Other, as object, made its definitive entrance into psychoanalytic theory in *The Ego and the Id*, opening the way to the discussion of "object relations" that was to have a

greater and greater effect on practice in the future. And, along with the Other, the past, tradition, and intergenerational transmission, or in other words the ego's primal identifications with the two parents, which were also placed at the origin of the other agency described, the superego.

The distinction between individual and ego is nevertheless very clearly drawn: "We shall now look upon an individual as a psychological id, unknown and unconscious, upon whose surface rests the ego, developed from its nucleus the *Pcpt.* [perception-consciousness] system. If we make an effort to represent this pictorially, we may add that the ego does not completely envelop the id, but only does to the extent to which the system *Pcpt.* forms its [the ego's] surface, more or less as the germinal disc rests upon the ovum. The ego is not sharply separated from the id; its lower portion merges into it" (p. 24).

As we know, each of the hypotheses set forth in *The Ego and the Id* was subject to theoretical developments, often divergent ones, in later years. Freud himself never ceased working on them, as when, in "Neurosis and Psychosis," he offered a "simple formula. . . which deals with what is perhaps the most important genetic difference between a neurosis and a psychosis: *neurosis is the result of a conflict between the ego and its id, whereas psychosis is the analogous outcome of a similar disturbance between the ego and the external world*" (p. 149). Or when, in "The Economic Problem of Masochism," he clarified the point that "the function of the ego is to unite and to reconcile the claims of the three agencies which it serves; and we may add that in doing so it also possesses in the super-ego a model which it can strive to follow" (1924c, p. 167). Again, in "Negation," Freud recalled that "the original pleasure-ego wants to introject into itself everything that is good and to eject from itself everything that is bad. What is bad, what is alien to the ego and what is external are, to begin with, identical"; and also that "The other sort of decision made by the function of judgement—as to the real existence of something of which there is a presentation (reality-testing)—is a concern of the definitive reality-ego, which develops out of the initial pleasure-ego. It is now no longer a question of whether what has been perceived (a thing) shall be taken into the ego or not, but of whether something which is in the ego as a presentation can be rediscovered in perception (reality) as well" (1925h, p. 237).

In *Inhibitions, Symptoms and Anxiety*, Freud would underscore the ego's functions in the regulation of the instincts, giving back to the idea of "defense mechanisms" a place that had long been usurped by the notion of "repression." He also modified his theory of anxiety, assigning it a source in the ego, which, when confronted by danger, triggered anxiety as a signal and so mobilized defensive processes: "whereas I formerly believed that anxiety invariably arose automatically by an economic process, my present conception of anxiety as a signal given by the ego in order to affect the pleasure-unpleasure agency does away with the necessity of considering the economic factor." It was probable, Freud added, that "the earliest repressions as well as most of the later ones are motivated by an ego-anxiety of this sort in regard to particular processes in the id" (1926d [1925], p. 140).

The question of the ego was raised directly or indirectly, and new considerations on the subject were adduced, throughout Freud's later work. The notion of "disavowal" (1927e) and the study of perversions, even more than the descriptions in *Civilization and Its Discontents* (1930a [1929]) and *An Outline of Psycho-Analysis* (1940a [1938]), were what led Freud to his last great formulation concerning the ego—that on the "splitting of the ego": Faced by a conflict between the instinctual demand for masturbatory pleasure and the apprehension of the reality of the threat of castration, the child embraces two contradictory positions simultaneously, "at the price of a rift in the ego which never heals but which increases as time goes on. The two contrary reactions to the conflict persist as the centre-point of a splitting of the ego. The whole process seems so strange to us because we take for granted the synthetic nature of the processes of the ego. But we are clearly at fault in this. The synthetic function of the ego, though it is of such extraordinary importance, is subject to particular conditions and is liable to a whole number of disturbances" (1940e [1938], p. 276).

On the clinical plane, the ego's role was defined by Freud in the conclusion to the twenty-third of the *New Introductory Lectures*—a passage that has caused a very great deal of ink to flow, especially in France. The "therapeutic efforts of psycho-analysis," Freud writes, are "to strengthen the ego, to make it more independent of the super-ego, to widen its field of perception and enlarge its organization, so that it can appropriate fresh portions of the id. Where id was, there ego shall be. It is a work of culture—not unlike the draining of

the Zuider Zee" (1933a [1932], p. 80). Freud returned to the matter in "Analysis Terminable and Interminable": "As is well known, the analytic situation consists in our allying ourselves with the ego of the person under treatment, in order to subdue portions of his id which are uncontrolled—that is to say to include them in the synthesis of his ego. The fact that a co-operation of this kind habitually fails in the case of psychotics affords us a first solid footing for our judgement. The ego, if we are to be able to make such a pact with it, must be a normal one. But a normal ego of this sort is, like normality in general, an ideal fiction. The abnormal ego, which is unserviceable for our purposes, is unfortunately no fiction. Every normal person, in fact, is only normal on the average. His ego approximates to that of the psychotic in some part or other and to a greater or lesser extent; and the degree of its remoteness from one end of the series and of its proximity to the other will furnish us with a provisional measure of what we have so indefinitely termed an 'alteration of the ego'" (1937c, p. 235).

Anna Freud, in *The Ego and the Mechanisms of Defence*, published in 1936, was the first to revisit and round out her father's hypotheses. This was the start of a series of studies by Anna Freud centered on the psychology of the ego, sometimes to the detriment of the interpretation of unconscious fantasies. In 1939, Heinz Hartmann laid the groundwork of what the psychoanalytical migration to the United States would develop into ego psychology thanks to the work of Ernst Kris, Rudolph Loewenstein, David Rapaport, Paul Federn, and so many others. So influential was ego psychology that for a time this theoretical orientation appeared to constitute the most thoroughgoing expression of Freudian orthodoxy.

In point of fact, Hartmann's idea of the "autonomy" of the ego, which he proposed as early as 1939, was in contradiction with Freud's views on the origins of this mental agency, which for him could never be anything but conflicted, bound up as it was with the relations between instinctual demands and the requirements of external reality. According to Hartmann, certain functions of the ego developed independently of the id and were essentially in the service of the individual's adaptation to the environment; the socialization factor was also underlined by Erik Erikson (1950). The notion of "primary narcissism" and that of a gradual development of the ego and its object relationships then became the subject of lively debate, notably with the Kleinian analysts.

For Melanie Klein, the ego and its object relationships existed from birth, as witness the early split between good and bad objects or the mechanisms of projection and projective identification, which manifested themselves right away. Klein's use of the term "self" should also be noted; her students and followers called upon it more and more, feeling that it helped distance them from the over-"mechanistic" account of the ego put forward by the American school. Things were not so simple, however, for the Americans too adopted the idea of a self—Heinz Kohut even invented a "self psychology"—and some of them sought to give identity priority over the haze in which Freud had ultimately left the definition of the ego as distinct from the notion of the person. In a parallel development, the stress placed on "object relationships" by Anglo-Saxon authors (W. R. D. Fairbairn, Margaret Mahler, Otto Kernberg) or French ones (Maurice Bouvet) shifted theoretical and above all clinical interest away from the state of an ego in need of cure and onto the vicissitudes of the pregenital and genital relations established by a subject who repeated these in the transference.

In France, there was no sarcasm too biting for Jacques Lacan when it came to the proponents of ego psychology, and he based himself on his theory of organization by language to place the ego resolutely in the realm of the Imaginary. His notion of the "mirror phase," first proposed in 1936, was intended to account for the constitution, by means of specular identification, not of the ego but rather of an "I" which foreshadowed the significance assumed later in his theory by the "subject" (Lacan, 1977 [1949]). He nonetheless devoted his 1954–55 Seminar to "The Ego in Freud's Theory and in the Technique of Psychoanalysis" (Lacan, 1993 [1981]). Piera Aulagnier, for her part, abandoned the notion of the ego in favor of a concept of the "I" different from Lacan's.

Present-day psychoanalysis is clearly more interested in synthetic approaches to the individual and the individual's relationship to others than in the ego as the frontier agency to which Freud accorded so much importance, as described above. No doubt the considerable extension of the psychoanalytic approach to psychotic patients has contributed to this tendency to globalize the person and be less attentive to an ego conceived as "weak" or "in pieces." There can be no doubt, either, that the emphasis placed on the adaptive functions of the ego has in the eyes of many amounted

to a bastardization of psychoanalysis favoring more and more "psychotherapeutic" or even political goals, and thus running counter to the liberation that Freud's discoveries imply. At all events, it is vital to keep in mind what clinical and therapeutic issues underlie and determine such theoretical divergences, namely adaptation to reality, the interpretation of unconscious fantasies, social adjustment, autonomy/disalienation, and so on.

## EGO, ALTERATION OF THE

The term “alteration of the ego” refers to changes that the ego undergoes as a function of age or as a result of neurotic or psychotic injuries with which it must deal.

This idea was evoked several times in Freud's work. Though it was referred to in “On Narcissism: An Introduction” (1914c), the mention was brief, for Freud had not as yet taken up the ego as an object of investigation. This was during the period when he went so far as to compare the ego to “a clown in the circus” (1914d, p. 53). Once the important part played by the ego in the unconscious was recognized, the function of defense took on great significance as the origin of alterations of the ego (1937c).

Later, with the advent of ego psychology, whether that of Heinz Hartmann or that of Paul Federn, the concept of “alteration of the ego” came fully into its own. In the first place, these changes were seen to constitute a continual mental process, extending from the primordial form of sucking at the breast to the most complex forms of scientific thinking. This process may be observed most clearly at turning points in life, as for example during the transition from childhood to adolescence or from adolescence to adulthood. Similarly, even though the change is far slower and more subtle, there is certainly a difference between the ego of the adult and that of the individual in old age.

On another level, the ego can be modified as a consequence of neurotic or psychotic disturbances. In the case of neurosis, the mechanisms of defense become so significant that the ego is obliged to transform itself, even though such transformation is never so far-reaching as it is when a psychotic process comes into play. The critical difference between these two kinds of alteration is that in neurosis there is no apparent splitting of the ego, whereas in the case of psychosis such splitting is evident. A split ego, obviously, is an altered ego. In a highly cathected narcissistic ego, transformations are harder to observe, save perhaps a certain behavioral rigidity. It is when the ego collapses under strong pressures that alterations occur. Alterations of the ego, it should be noted, are an aspect of the normal psychology, as well as of the pathology, of the ego.

## **EGO (ANALYTICAL PSYCHOLOGY)**

Carl Gustav Jung proposed the following definition of the ego: “By ego I understand a complex of ideas

which constitutes the centre of my field of consciousness and appears to possess a high degree of continuity and identity. Hence I also speak of an *ego-complex*” (Jung, 1921, p. 425).

Jung actually conceives the ego-complex (or complex of the ego; *Ichkomplex*) as both a content and a condition of consciousness, which is definitive because, he writes, “a psychic element is conscious to me only in so far as it is related to my ego-complex” (p. 425).

The restriction of the ego to the field of consciousness is particularly significant for Jung and the development of his analytical psychology because in his diagnostic studies of associations in 1904 he had already been able to demonstrate unconscious complexes affecting the conscious mind and capable of causing disturbances in ego functioning. It was this work that had formed the basis for his agreement with Freud and his psychoanalytic theories.

However, following his break with Freud in 1913, Jung embarked on a clearer elaboration of his own psychological theories. His personal experience had led him to emphasize the extremely important role of a firm anchoring of the conscious viewpoint in the ego because, as he explained, the ego not only has to manage the conflicts with the external world but also to confront intrapsychic material that manifests and operates from the unconscious.

His entire interest was henceforth directed at investigating the contents of the unconscious. This led him to the following discovery: To the extent that the ego approaches unconscious material in a way that is both receptive and critical, it becomes clear that an organizational element is at work there, such that dreams, for example, can be considered to interrelate with a meaningful process of transformation. This suggested the obvious hypothesis that it is not only our conscious ego that possesses a capacity for organization, initiative and purpose: It is in fact the development of our personality in its entirety, including our potential for consciousness, that is “directed” by a center operating in the unconscious.

To distinguish it from the ego, Jung called this center the “Self.” To the definition of the ego-complex quoted above, he therefore added the following point: “But inasmuch as the ego is only the centre of my field of consciousness, it is not identical with the totality of my psyche. . . . I therefore distinguish between the ego

and the *self*, since the ego is only the subject of my consciousness, while the self is the subject of my total psyche, which also includes the unconscious” (p. 425).

Jung devoted himself principally to the interaction between the ego and the unconscious and to the question of discovering how the ego can gain experience of a Self that is subordinate to it. He demonstrated that this is a task that belongs to the individuation process in the second half of life, which presupposes and requires the existence of a strong enough ego that can allow itself to be substantially influenced by the Self without thereby succumbing to a loss of boundaries that would be pathological if not psychotic. Something that Jung did not undertake to explain at great length was the question of knowing how it is that the Self, as a guiding agency of psychic development, stimulates and guides an appropriate maturation of the ego, and it is principally his successors who have worked on this (Neumann, 1963/1973; Fordham, 1969).

## **EGO AND THE ID, THE**

Published in German in 1923, *The Ego and the Id* was the work in which Freud sought to summarize in the most explicit manner the far-reaching metapsychological revisions he made to his theory in the 1920s. The

text begins by recalling the basic distinctions of the topographical theory: distinctions among the conscious, the preconscious (descriptively unconscious but susceptible of becoming conscious), and the dynamic unconscious (the repressed, which can become conscious only by penetrating the barrier of repression, for example, by means of the psychoanalytic method).

In this work Freud emphasized that the resistances of the ego, as encountered in the work of analysis, were themselves in part unconscious. So even if the conscious-unconscious opposition was still an essential point of reference, the unconscious could no longer be considered a psychic agency. Freud thus had to revisit the whole topographical system of his theory.

Freud concerns himself first with the characteristics of the ego, its relationships with the perception-consciousness system and with language, which underpin the possibility of material becoming conscious. Sense perceptions are immediately conscious; thought processes become conscious through their links with the auditory traces of verbal residues (or word presentations), which endow those processes with a perceptual dimension. Internal perceptions, more deeply seated and elemental than external ones, derive from the pleasure-unpleasure series of sensations and become conscious directly, without any recourse to words, by projecting themselves onto the surface of the body.

The crucial point in Freud's argument concerns feelings. Analytic experience reveals that feelings may occasionally become conscious solely because the ego refuses to discharge them. This idea leads to the paradoxical notion of “unconscious feelings” (notably, the feeling of guilt). The ego thus emerges as an agency derived essentially from the body: Linked to perception and to the body envelope, it is sometimes described as “a surface entity,” but also as “the projection of a surface” (1923b, p. 26).

Freud's rejection of the unconscious as a system led him to include in the mental apparatus the id, which is far more extensive and less organized than just the repressed. He described the id as the great “reservoir” of the instincts, which originate in the somatic realm and express themselves there as dynamic impulses seeking discharge solely in accord with the dictates of the pleasure principle. The ego is that part of the id which has been modified by the influence of the external world: “For the ego, perception plays the part

which in the id falls to instinct" (1923b, p. 25). Freud compares the relationship of the ego to the id to that of a rider to his mount: Often the rider's energy is insufficient for him to do more than lead the horse where it wants to go.

To his structural theory Freud also introduced a third agency, reflecting the fact that the "highest" mental activity, notably that of the moral conscience, may be unconscious. The superego (or ideal ego), as evoked several years earlier in *On Narcissism: An Introduction* (1914c), is the outcome of a differentiation within the ego; the formative mechanism is narcissistic identification with a lost object (1917e [1915], pp. 241, 249–251). Internalization of the object in the ego facilitates replacing the instinctual cathexis of the object with a change in the ego that renders it similar to the object and thus capable of pleasing the id and being narcissistically cathected. The establishment of the superego depends on a mechanism of this sort: Obligated to renounce the cathexes characteristic of the Oedipus complex, the child redirects them onto the ego while identifying with the parents, at once desired and feared. The postoedipal superego, though essentially paternal in character, forms on the basis of two identifications (maternal and paternal), combined in one way or another. These secondary identifications (secondary, that is, to the instinctual cathexes that they replace) continue to reinforce a set of primary object identifications whose point was "to be [like] the other" rather than to "have" the other.

This web of identifications, reflecting the child's long dependency on the parents, gives a permanent character to the infant's relation to primordial objects and the dual protective and punitive significance of that relation. By treating the superego as a mental agency that "dominates" the ego, Freud accentuated the idea that the superego is just as immune as the id to a complete appropriation by the ego.

The tension between the ego and the superego manifests itself as a sense of guilt. The largely unconscious nature of the superego sheds light on negative therapeutic reactions, which, according to Freud, express a need for punishment (an unconscious feeling of guilt) that is satisfied by illness and suffering.

The superego is the agency whereby the heritage of civilization, which individuals must reappropriate for themselves, is transmitted. Here Freud recalled the thesis of *Totem and Taboo* (1912–1913a) concerning the

genesis of guilt and of the social bond created by the killing of the primal father, a thesis with profound implications for religion. The superego, projected and writ large, is the seed from which all religion springs.

The topography of psychic agencies thus outlined was inseparable from Freud's new conception of instinctual dualism. According to this conception, first set forth in *Beyond the Pleasure Principle* (1920g), Eros encompasses the instincts for self-preserved and sex (the conflict between them no longer being considered primary), whereas the death instincts express a primary self-destructiveness mediated by sadism, which redirects the death instincts outward in a partial fusion with erotic impulses. The essential characteristic of these two groups of instincts is their conservatism: The life instincts aim to preserve life by binding life with ever vaster wholes; the death instincts strive for a return to an inanimate state by unbinding and reducing tension to zero (the Nirvana principle).

Life presents itself as an unending struggle between the two kinds of instincts, always more or less blended or fused. But the process of identification, a consequence of the desexualization and transformation of cathexes into narcissistic libido, is accompanied by a diffusion that may ultimately result in the superego's becoming "a pure culture of the death instinct" (1923b, p. 53), as in melancholia. The same circumstances also enable the ego to sublimate the instincts, in conformity with the requirements of the ideal: The ego, with its "free" (narcissistic) energy, can transform love into hate (paranoia) or hate into love (homosexuality) (1923b, pp. 43–44).

In concluding *The Ego and the Id*, Freud attempts to sum up the "dependent relationships" of the ego, which has to serve three masters at the same time. As can be seen in the clinical aspects of the sense of guilt, the superego draws sustenance from the renunciations it requires, becoming more severe as aggression is displaced and turned against the ego. With respect to the id, the ego seeks to satisfy instinctual demands while simultaneously seeking to subject them to its will. And as for the external world, the ego is linked to it by being anchored in perception and by the workings of the reality principle, which constrains its use of judgment.

Three dangers and three types of anxiety are correlated with these three masters of the ego: moral anxiety (arising from conscience), neurotic anxiety (arising

from instincts), and realistic anxiety (arising from the reality principle). Freud emphasized the fact that the fear of death, seemingly so real, in fact derives from “moral” anxiety, itself the result of castration anxiety and of loss of love.

*The Ego and the Id* is a difficult text, not least because it is extremely concise as a result of its synthesizing ambitions. Freud himself was less than satisfied with it. The work was a recapitulation of ideas advanced by Freud since the completion of his metapsychology, and more particularly since *Beyond the Pleasure Principle* (1920g), but its implications would emerge only gradually with the appearance of later articles, most notably “The economic problem of masochism” (1924c), where Freud assessed the consequences of the repetition compulsion and the death instinct on the concept of the pleasure principle.

## EGO AND THE MECHANISMS OF DEFENCE, THE

This work was first published in Vienna in 1936 and in English translation in London the following year, two years before Sigmund Freud’s death. The whole of Anna Freud’s work was marked by her clearly stated desire to win scientific status for psychoanalysis. With this in mind, she sought to integrate analysis into psychology,

to create what she called a “psychoanalytical psychology.” At the same time the schoolteaching career that she embarked upon before becoming a psychoanalyst would seem to be the origin of the pedagogical cast of her written work and her practice as a child analyst.

The frame of reference of *The Ego and the Mechanisms of Defence* is Freud’s second topography (structural theory). The subject of the book is the defenses developed by the individual ego in order to confront or avoid the conflicts provoked by the id in its relations with the ego and the superego. Anna Freud approaches psychoanalytic technique and theory, along with defensive formations, from the specific perspective of the observation of the ego through the mental conflicts in which it is involved. Thus the ego in its relations with the id and with the outside world—relations which may be the source of unpleasure or of feelings of fear—is analyzed in the light of its avoidance mechanisms (the various forms of negation), in the light of its aggressive or altruistic strategies. Special significance is assigned to the phenomena of puberty and to the defense mechanisms triggered by the re-emergence of sexuality at that time.

Anna Freud considers it the analyst’s task, “in relation to the ego, to explore its contents, its boundaries, and its functions, and to trace the history of its dependence on the outside world, the id, and the superego; and, in relation to the id, to give an account of the instincts, i.e. of the id contents, and to follow them through the transformations which they undergo” (p. 5). The fact is that when id derivatives make incursions into consciousness, the ego is prone to “counterattack” by deploying defense mechanisms (p. 7). But while the analyst is aided by the tendency of id derivatives to surface, at the same time no help is to be obtained by analyzing the ego’s defenses, for these can be reconstructed only by reference to the effects they produce in the patient’s associations. According to Anna Freud, the analysis of resistance to transference and the analysis of the compulsion to repeat need to be refined by analysis of the resistances of the ego. The purpose of these various psychoanalytical procedures is to bring into consciousness the ego’s unconscious defenses, which are liable to strengthen the patient’s hostility toward the analyst.

Anna Freud subjects the ego’s defenses to meticulous scrutiny and inventories their varieties on the basis of Freud’s descriptions. The list is as follows: regression, repression, reaction-formation, isolation, undoing, projection, introjection, turning against the self, and reversal into the opposite. To these Anna

Freud adds a tenth defense mechanism, namely sublimation or the displacement of instinctual aims.

Anna Freud's work, and in particular the book with which we are here concerned, has directly nourished a line of thinking that might be called a "psychoanalysis of consciousness," and that has achieved its greatest success in the United States thanks to the proponents of ego psychology (Hartmann, Kris, and Loewenstein, 1964); most importantly, however, it has indirectly made possible a psychological use of the findings of Freudian psychoanalysis in a number of areas, among them the field of what is known as "psychoanalytical pedagogy" and that of so-called personality testing.

## EGO AUTONOMY

Heinz Hartmann introduced the concepts of primary and secondary ego autonomy in 1939, and elaborated on them in later writings (Hartmann, 1964). Within the framework of his description lies a conflict-free sphere of the ego. The notion of "ego autonomy" implies that the ego and the id derive from a common matrix where certain ego precursors prefigure functions destined to develop autonomously, independently of the instincts and their vicissitudes.

Primary and secondary autonomy involve two sets of hypotheses, which together constitute the conflict-free ego sphere. Hartmann replaced Freud's view that the

ego grows out of the id with the hypothesis that both ego and id are derived from a common undifferentiated medium.

Related concepts are change of function, neutralization, automatization, and ego interests. Hartmann focused especially on the autonomy of specific ego functions, and stressed that ego autonomy is relative, since both primary and secondarily autonomous components can be drawn into conflict.

Prior to Hartmann, psychoanalytic theory held that all psychic mechanisms and processes result from the effects of the influence of life experience on the instinctual drives. In primary autonomy, Hartmann identified constitutional factors influencing ego development in addition to instinctual drives and external reality. The ego apparatuses of perception, object comprehension, intention, thinking, and language capacity are all congenital, and are influenced by maturation and learning. But they are neither derived from conflict, nor are they developmentally dependent on conflict. Even so, these structures of primary autonomy can become caught up in conflict, resulting in inhibition of their functioning. This formulation took some of the explanatory burden off the concept of sublimation.

In secondary autonomy, behaviors and attitudes which are initially associated with a conflict between drive manifestations and defenses can become detached from their sources. This takes place through a change of function, made possible by a de-sexualization and a de-aggressivization of the associated mental energy. The degree of secondary autonomy is defined by how resistant the trend is to regressive re-instinctualization. More generally, both the stability of secondarily autonomous functions and ego strength can be defined by the capacity of the various ego functions to withstand regression in the face of a focal conflict. Insufficient secondary autonomy interferes with the ability to bind id strivings, and increases vulnerability to ego regression.

Neutralization is seen as the basis for secondary autonomy of ego interests, habits and skills, while ego interests include sets of ego functions that mostly entail secondary autonomy. They encompass what Freud called the ego instincts. Two ego interests in conflict are an example of an intrasystemic conflict.

Secondary autonomy is seen to be established through the structure-building process called automatization,

by means of the change of function via neutralization. Automatisms are ego apparatuses, somatic and preconscious, that are adaptive themselves, or are utilized by adaptive mechanisms.

David Rapaport (1951/1967; 1957/1967) saw a reciprocal relationship between the ego's autonomy from the drives on the one hand, and from the environment on the other. Autonomy from the drives is insured by the reality-related autonomous apparatuses, and from the environment by the endogenous drives.

Hartmann's formulations of ego autonomy have been highly influential in psychoanalysis. Most of his contributions stand, but serious questions have subsequently been raised about the scientific status and validity of energy transformations, which are part of the neutralization-deneutralization hypothesis.

## **EGO BOUNDARIES**

Ego boundaries, a key concept in the theory of Paul Federn, form a necessary basis for distinguishing real from not real. Federn saw it as a kind of sense organ that differentiates what is part of the ego at a given moment from all other psychic elements.

Federn employed the term ego to refer to a person's ongoing bodily and psychic experience, the "I," the self, one's identity. This phenomenological description can be contrasted with that of the ego in Freud's structural model.

Victor Tausk (1919/1933), in his paper on the "influencing machine," first utilized the concept of the regressive loss of ego boundaries as a symptom of schizophrenia. Paul Federn (1926/1952; 1928) viewed ego boundaries as a key element in all ego functioning and postulated a boundary between the ego and the external world, which is subject to perception. He further extended the boundary concept by identifying an internal boundary between the ego and the unconscious, open to introspection.

In agreement with Freud, Federn understood the earliest differentiation between external and internal to result from body movements. Such a distinction eventually results in the establishment of dynamic (continually expanding and contracting) ego boundaries.

Federn's concept of ego boundary is closely associated with his other key concepts of ego feeling, ego state, and ego cathexis. Both ego boundary and ego feeling require for their maintenance an ego cathexis, which may be a blend of three kinds: libidinal, destructive, and self-preservative. When the inner boundary is critically weakened or lost, the return of repressed ego states falsifies reality and can result in delusions and hallucinations. When the cathexis of the outer boundary is weakened or lost, the sense of reality is disturbed, and external objects are discerned as unknown, strange, and unreal. Federn utilized his concepts of ego boundaries and sense of reality to clarify such phenomena as estrangement, depersonalization, delusions, hallucinations, dream experience, and drug effects.

Edith Jacobson (1954) has employed ego boundaries in psychoanalytic conceptualizations of the boundary between self and object representations. A remaining challenge is to work out the relationships among inner, outer, and self-object boundaries.

## EGO, DAMAGE INFLICTED ON THE

A conception of the ego as a decisive agency of the mind was the point of departure of psychoanalytical ego psychology, which teaches that the ego may have a normal development (the approximate meaning of “normal” being “socially adapted”). According to Heinz Hartmann, adaptation is an essential task of the ego, one performed in a conflict-free, autonomous dimension of the ego distinct from the dimension of the ego dominated by the instincts. But this independent domain of the ego is liable to suffer many sorts of damage, whether at the beginning of life or later on. The most recent research on infancy has shown that one of the causes of such damage is a lack of adequate bonds with the mother or mother substitute. Genetic causes no doubt also play a part, but in this area the state of our knowledge is still rudimentary.

Apart from bonds with the mother or mother substitute, there are particular social conditions that can inflict severe damage on the ego, damage that in some cases is irreparable. The later in life that these injuries occur, the easier it is for the ego to repair them with dispatch. But if instinctual forces have inflicted added damage, then the ego may not prevail, because the libido is too weak or a destructive instinct is too powerful.

According to Paul Federn, damage of this kind may be sustained as a result of an early breakdown of ego boundaries. Where these boundaries are not well developed, they may at any time be overwhelmed by the destructive instinct, and death or suicide may ensue. Both these eventualities are possible in the course of childhood. In adolescence and adulthood, suicide is always the result of injuries to the ego; in old age, however, these considerations no longer apply.

ERNST FEDERN

## EGO (EGO PSYCHOLOGY)

The theories of the ego grouped under the rubric of “ego psychology” originated in Vienna before the Second World War and were developed in the United States by virtue of the migration of their chief proponents, namely Heinz Hartmann, Ernst Kris, and Rudolf Loewenstein. To these names must be added those of Paul Federn, of Hermann Nunberg, and of a good many other authors who helped give wide currency to conceptions of the ego that were destined to attract violent criticism, in France, from Jacques Lacan.

The substantial “*das Ich*” was so common in German (as was its equivalent in various other languages), that Freud, in the early part of his career, when he was actively searching for the new, paid it little mind. To begin with, Freud took the ego to be an indivisible unity, largely coextensive with the body, and therefore with consciousness. As Goethe had written, “To produce in oneself a new and better ego, thus to construct oneself as permanent, to live in oneself and create” (“*Ein neues besseres Ich in uns erzeugen, uns so ewig bilden, in uns fortleben und schaffen*”).

In 1914, however, Freud would write that the ego may at times “play the ludicrous part of the clown in a circus” (1914d, p. 53). We may say, in other words, that from the historical point of view psychoanalysis did not undertake an investigation of the ego before the First World War: Psychoanalysis was the science of the unconscious, whereas for Freud the ego belonged to the realm of consciousness. The notion of the ego is very hard to circumscribe and it has a different meaning for each psychological theory, so here we shall confine ourselves to the psychoanalytic sense. The translation of the term into languages other than

German further complicates the issue. The great confusion in English stems from the use of the Latin “ego” rather than the English “self” or “me.” In French there is ambiguity too, between “*le je*” and “*le Moi*.”

Freud believed that the ego developed like a skin over the unconscious (or, in his later accounts, over the id) and that it was not present from birth. The phenomenon of narcissistic cathexis led him to conclude that the ego was in part unconscious. The Unconscious/Preconscious/Conscious scheme thus came to seem inadequate, and Freud spent fifteen years working out a new subdivision of the mind into id, ego, and superego—“agencies” that his followers treated as structures. This was an error, for structures are static, whereas agencies are dynamic.

The origin of the ego became an essential issue for psychoanalysis, and has been responsible in part for the latter growth of research into early childhood. Historically speaking, after Freud’s death the notion of the ego eventually became the central preoccupation of psychoanalysis, to the detriment of the id. One reason for this was the increase of ego disturbances as compared with neurotic complaints, at least among analytic patients. Such disturbances were seen as the cause of perversions and other human behavioral problems. Certainly, the aphorism “*Zwei Seelen wohnen, ach, in meiner Brust*” (“Two souls reside, alas, in my breast”) had long been familiar, but it had engaged no clinical application. Further research into the psychology of the ego was undertaken in Freud’s wake, first by Anna Freud—who indeed began during her father’s lifetime—and then by Heinz Hartmann and Paul Federn.

According to Freud, the formation of the ego was a process that grew out of the bonds established with the mother or mother-substitute. Those bonds could in fact be looked upon as subject-object relationships, after the fashion of the English school. From its beginnings, the ego was the agency of the mind whose task it was to address the realities of life. Only thanks to the love and continual care of the mother or mother-substitute could adaptation to reality be achieved. Freud felt that this normally occurred during the third year of life, when the child’s ego was ready to adapt itself also, beyond the family circle, to the outside world as represented by the kindergarten.

The ego’s development did not stop at this point, however, but continued into adulthood, continually exposing the ego to innumerable dangers which

orientated it in this way or that. Genetic factors surely played a major role, even if this could not as yet be proved. Anna Freud emphasized that its development in childhood shaped the most important portion of the ego. Only when this development was arrested or when it regressed was therapeutic intervention called for.

In summary, the ego may be described as that agency which protects the id and which must come to terms with the demands of the superego. It represents in large part the individual’s social environment, although it is also strongly determined in its development by familial factors. A lack of love and acknowledgment during the first years of life may have two kinds of consequences: an autonomous ego may develop which is concerned only with itself, which is narcissistically cathected, and which is capable of achieving remarkable successes in reality without making genuine contact with other individuals or with society; alternatively, the ego may wither, failing either to fashion links with the outside world or to draw satisfaction from within. Between these two extremes every imaginable intermediate situation—or “ego state”—may be met with. But such ego states also depend on an outside world with the capacity to transform the ego-ideal into an ideal ego which, as early as the third year of life, allies itself with the superego to form an agency of great power in the life of the individual.

Thus the earliest object relationships produce distinct character types: an ego strong in its narcissism but socially ill-adapted; an ego that is weak, and undeveloped in all respects; or an ego that is bound to a strong superego and thus able to assert itself in the world. This last type is represented by highly religious individuals and probably constitutes the commonest form of human life.

The psychoanalytic psychology of the ego was inaugurated in 1923 with the publication of Freud’s major work *The Ego and the Id* (1923b). For Freud, the ego was intimately linked to the body, thus ensuring the basic unity of the human being. Assuming that everyone knew what the ego was, he offered no definition and confined himself to describing its functions. In 1929 Hermann Nunberg developed the notion of the ego’s synthetic function. Whereas Freud thought that after an analysis synthesis occurred spontaneously, Nunberg showed that it was in fact the work of the ego, whose essential task was to bring together the various tendencies of the human individual and place

them in the service of social life. Nunberg felt that the higher functions dependent on the ego, such as artistic and scientific activity, were in fact governed by it; Freud for his part thought they remained under the influence of the id, like a horseman on his mount.

In 1930, Anna Freud published a book dealing with other ego functions, notably the defenses. She argued that a set of human behaviors arose from the need to fend off danger, and that responsibility here fell to the ego. One of the most important defense mechanisms was identification with the aggressor as a way of conjuring away threats, but of course this ploy was not always successful. Repression, forgetting, and the splitting of the ego were other defensive tactics. The positive ego functions were synthesis and identification with the ideal ego.

After Freud's death, Heinz Hartmann expanded some ideas that he had presented earlier, proposing that the ego's most significant function was adaptation, made possible by virtue of the ego's two forms: on the one hand, the ego ruled by the instincts, and on the other, an ego free of conflict, which Hartmann called the self. For Hartmann the ego was entirely defined by its functions. He also held that a conflict-free ego was present from birth. Aberrant human behavior was in large measure the result of a failure to adapt to social conditions. This outcome occurred quite independently of the instincts, and it also had constitutional determinants. The "autonomous" ego could be overwhelmed by the aggressive instinct, which was the path to psychosis.

This account was defining for psychoanalytic ego psychology after the Second World War. It brought psychoanalysis back towards academic psychology, as also closer to individual psychology. It tended to make it more compatible with sociology and opened the way for it to become a natural science. It supplied the foundation for a psychoanalytic sociology that would trace the development of the social ego from infancy to old age, an approach pioneered in Erik Erikson's book *Childhood and Society* (1950). This conception of the ego also constituted a link to behavioral studies and relied on the observations of Jean Piaget, whose work on the development of intelligence in children buttresses the notion of an "autonomous ego." Finally, Hartmann's ego psychology led eventually to the psychology of the self developed by Heinz Kohut.

Hartmann's approach was in part the result of the transplantation of psychoanalysis to the English-speaking

world. An accurate English translation of *Ich* would have been "self"; the use of the Latin "ego" turned *Ichpsychologie* into "ego psychology—into something both strange and foreign-sounding. And "self," meanwhile, was translated into German as the *Selbst*.

Paul Federn's approach here was very different to Hartmann's. Drawing on his experience of analyzing a schizophrenic artist as early as 1905, as well as on his observations of other mental patients, and of himself, Federn concluded that the ego was the feeling of "*Ich bin Ich selbst*,"—"I am I myself," the sense of self-identity in time in space. He thus posed the question not in terms of the function but rather in terms of the essence of the ego.

## **EGO FEELING**

Ego feeling is central to Paul Federn's ego psychology, together with ego boundary and ego state. It is one's experience of one's own bodily and mental existence, a phenomenological description of a connected psychic sensation, and involves the experience of space, time, and causality as an entity.

It is the experiential aspect of the ego boundary, the feeling by which the person is able to sense what is ego

and what is non-ego, and thus, what is real and not real. Paul Schilder also focused on the phenomenology of ego experience, especially in depersonalization and the experience of time. Federn (1926/1952) affirms a connection between his conception of ego feeling and Schilder's (1923/1953) concept of body schema.

For Federn, ego feeling is the simplest but also the most extensive psychic state present in the personality. Through a process of egotization, bodily and psychic elements attain ego feeling and inclusion within the ego boundary. He described bodily ego feeling (motor and sensory memories pertaining to one's person), mental ego feeling (reflecting inner perceptions), and superego feeling (the superego being an ego state with its own boundaries). Federn demonstrated how interrelationships among these different ego feelings change in different states of consciousness, such as in a normal awake state, in falling asleep and waking up, in dreams, in fainting, in ecstasy, in regression, and in the major psychopathological conditions.

An ego feeling pervades one's whole being while one is awake. But under conditions of fatigue, sleep, illness, and psychosis, the ego feeling is prone to serious restrictions. Ego feeling is intact when the ego is cathected, and is absent when there is no cathexis. Repression results in a depletion of ego cathexis. Disturbances in ego feeling reflects changes in ego cathexis and may result in severe anxiety and other mental symptoms, especially feelings of estrangement and depersonalization. Depersonalization involves de-egotization and is related to a fixation in the development of ego feeling.

Mental ego feeling is experienced as located inside the bodily ego during waking. In sleep, bodily ego feeling is the first to vanish, then superego feeling, while mental ego feeling remains the longest. There is an absence of ego feeling during states of dreamless sleep.

The formulation of the concept of ego feeling is one of Paul Federn's most original and valuable contributions, and presents a challenge to psychoanalytic theorists to utilize its potential.

## **EGO FUNCTIONS**

Sigmund Freud, and later Anna Freud, assigned to the ego tasks that involve the management of instincts and defenses against them. Some of their successors, among them Robert Waelder (1936), treated these tasks as "functions" that the ego was expected to fulfill. Thus such functions as integration, synthesis, and so on, were eventually distinguished. According to Heinz Hartmann, the ego should be evaluated according to how it performs these functions.

It is hard to say what the primitive function of the ego might have been, but, historically speaking, self-preservation is not only a function of the ego but also an instinct in its own right, originating in the ego—in short, an ego instinct. Freud first presented the concept of an ego instinct in *Beyond the Pleasure Principle* (1920g), where he also developed his theory of the death instinct. Briefly, the instinct for self-preservation can be subdivided into positive tendencies governed by the libido or Eros and negative tendencies subject to the death instinct. This account of the functions of the ego, which Freud himself always considered to be only a speculative hypothesis, was never accepted by more than a handful of analysts, even among those who granted the existence of aggressive and destructive instincts.

In the psychoanalytical ego psychology of 2005, these issues have ceased to carry much weight. The ego described in terms of its functions is no longer envisaged in the same way. True, Anglo-American psychoanalysis recognizes the notion of the death instinct, but the Anglo-American use of it is somewhat different from Freud's.

One essential function of the ego, according to Freud, is to synthesize all the impulses and energies of body and mind. This synthesis depends entirely on the

strength of the two psychic forces of the libido and the destructive, or death, instinct. To begin with, Freud (1930a, p. 117) had adopted Friedrich Schiller's antithesis of love and hunger, with love being equivalent to the libido and hunger standing for the self-preservation instinct. During the 1920s Freud replaced this idea by postulating the ego's synthetic function.

Another important ego function was defense and the signaling of danger. Danger might come from within (from the id), from without (from reality), or even from the superego. Against these threats the ego could defend itself in a variety of ways, depending on the individual. Among the ego's defensive functions were identification with the aggressor, forgetting, disavowal, and repression. Recognition, reflection, and above all action were also ego functions, yet the ego could feel pain, as in states of mourning or joy, and thus serve as vector of the emotions. The body ego, as the locus where instinctual impulses are discharged, was liable to come under the sway of the instincts, which could lead to brief depressions or to chronic mental illness.

Freud held that as a general rule the ego was the dominant mental agency, so long as it was functioning normally. Ego malfunction, in contrast, led to deep anxiety, and the weaker the ego the greater the anxiety. For this reason infantile anxiety was a normal state, whereas in adults it was a signal of danger. Its absence—loss of the feeling of anxiety—constituted a serious mental disturbance. Enumeration of the ego's functions pointed up the importance of the ego as an agency. Because it brought so many functions together, the ego was central to treatment and the nucleus of resistance. Freud recognized the ego as a major obstacle to psychoanalysis.

After Freud's death, ego psychology underwent considerable development, partly to the detriment of id psychology. This was a deviation in that when Freud set out on his research program, he was interested exclusively in unconscious mental life, in the depths of the mind, in a cauldron of energies that fulfilled no specific functions. Yet such energies are capable of modifying the ego in important ways, whether for good or for evil.

## **EGO IDEAL**

The concept of the ego ideal appeared for the first time in Sigmund Freud's "On Narcissism: An Introduction" (1914c). The ego ideal takes the place of the narcissism lost during childhood and promises the possible realization of narcissism in the future. Freud's concept of the ego ideal provided support for other, earlier concepts, such as moral conscience, censorship, and self-esteem, and made possible an original understanding of the formation of a mass movement and its relationship to a leader (1921c).

The ego ideal and superego, together with the ideal ego, form a group of agencies that should be clearly distinguished, even though Freud sometimes used the first two interchangeably. Freud introduced the superego in *The Ego and the Id* (1923b). It enabled him to distinguish the normative aspect of the psyche (the superego) from the motivational aspect directed toward a goal (the ego ideal). Originally, however, the two aspects were present in the ego ideal, which was also not differentiated from the ideal ego. This lack of differentiation reappeared in *New Introductory Lectures on Psycho-Analysis* (1933a [1932]), where the ego ideal became a function of the superego.

The ego ideal is formed when the child, through the crucial influence of parents, educators, and others in the environment, is forced to abandon its infantile narcissism. This is made possible by the formation of this substitute, the ego ideal, which leaves open the possibility that in the future the child will be able to rejoin ego and ideal. This development of the child's ego ideal, here conflated with the superego, occurs through the child's identification with the parents or, more precisely, with the parents' superego. In *The Ego and the Id* (1923b), Freud

indicates that the superego develops from identification with the paternal model. For identification to take place, the erotic component has to be sublimated. As a result, it no longer has the strength to bind the destructive component of the psyche. All of this creates a libidinal split. Consequently, the superego becomes harsh, even self-destructive. Out of this arises a feeling of unconscious guilt, and in melancholia the child finds the same ego ideal, dissociated from the ego, raging against it.

The ego ideal demands that the subject make changes to achieve the ideal, but the existence of the ego ideal does not mean that the subject has succeeded in achieving this goal. "A man who has exchanged his narcissism for homage to a high ego ideal has not necessarily on that account succeeded in sublimating his libidinal instincts" (1914c, p. 94). Thus, the idealist may refuse to see reality, including that of his own libidinal experience, even though he has not sublimated anything, in the sense of modifying the goal and object of the drive.

To the extent that the ego ideal is conflated with the superego, it includes the moral conscience, which continuously compares the actual ego with the ego ideal. Similarly, dream censorship and repression can be associated with the ego ideal. In fact, the ego ideal comprises all the restrictions to which the ego must submit to conform with the image detached from its own narcissism and projected before it. The ego ideal is not only a critic; when something in the ego coincides with the ego ideal, it can also produce a sensation of triumph, in which self-esteem is enhanced.

When the ego ideal is replaced by an idealized object, the ego ideal can be short-circuited in inciting the ego. "It is even obvious in many forms of love-choice," Freud wrote, "that the object serves as a substitute for some unattained ego ideal of our own" (1921c, p. 112). This notion led Piera Aulagnier (1979) to develop the concept of alienation, where the relationship is libidinal in nature since it involves another subject, an object (gambling or drugs, for example), or even an activity (sports, work).

With the concept of the ego ideal, Freud considerably enriched the understanding of group psychology. Starting from an analysis of the relation between hypnotizer and hypnotist, he defined the group as "a number of individuals who have put one and the same object in the place of their ego ideal and have consequently identified themselves with one another in their ego" (1921c, p. 116). All in the group are then collectively capable of

being subjected to whatever represents this now collective ego ideal. The consequences are well known. "The criticism exercised by that agency [the ego ideal] is silent; everything that the object does and asks for is right and blameless. Conscience has no application to anything that is done for the sake of the object; in the blindness of love remorselessness is carried to the pitch of crime. The whole situation can be completely summarized in a formula: The object has been put in the place of the ego ideal" (1921c, p. 113).

Daniel Lagache (1961), in discussing the structure of the personality, identified the notion of "heroic identification," the narcissistic ideal of omnipotence, which allowed him to explain certain aspects of criminal behavior. Janine Chasseguet-Smirgel (1985) identified various possible outcomes for the ego ideal, perverse as well as creative.

## EGO IDEAL/IDEAL EGO

The two notions of *ideal ego* and *ego ideal* might seem to be used interchangeably by Freud. However, their first appearance in “On Narcissism” (1914c) showed them to be different insofar as the ideal ego is taken to be the recipient of the self-love that the ego enjoyed in infancy. The distinction is between reality and an idealization of that reality, enforced by the fact that from infancy on, that reality seems forever lost. The ego ideal, on the other hand, is a dynamic notion: The person, as Freud wrote, seeks to regain the narcissistic perfection of its infancy under the new form of the ego ideal, which is deferred as a goal to be attained in the future. Thus the ideal ego could be seen as the nostalgic survival of a lost narcissism, while the ego ideal appears to be the dynamic formation that sustains ambitions towards progress.

The ideal ego is a modification of infantile narcissism and the omnipotence that accompanies it. What differentiates it from the ego ideal is that in the case of the latter, the ego only obtains the self-esteem that it yearns for by obeying the injunctions arising from what Freud later called the superego. On the other hand, the ideal ego is not completely equivalent with the ego since omnipotence is lost with infantile narcissism. Such omnipotence is only partially regained in daydreams and fantasies that make the person a hero and victor. The difference here is that the ego ideal, which is closely related to the superego, is not formed on the basis of an illusory omnipotence, but modeled after that of the parents, and more precisely after the superego and its ideals. The ideal ego thus appears to be a way of short-circuiting the work that the ego ideal requires by assuming that its goals, or any others that might be still higher, have already been attained.

Hermann Nunberg defined the ideal ego as the combination of the ego and the id. This agency is the outcome of omnipotent narcissism and is manifested as

pathology. Daniel Lagache (1961) developed the implications of this notion of the ideal ego, notably in terms of delinquency. The ideal ego appears in contrast to the superego and is linked to the primary identification with another being who is invested with omnipotence, as is the case with the infant’s identification with the phallic mother. Lagache emphasizes that in adolescence “the ideal ego is reinvested or its investment is strengthened, often by new identifications with eminent people. The adolescent identifies him- or herself anew with the ideal ego and strives by this means to separate from the superego and the ego ideal” (Lagache, pp. 227–28).

Lacan took up Lagache’s analysis of the concept in these terms: “In a subject’s relation to the other as an authority, the ego-ideal, obeying the law to please, leads the subject to displease himself as the price of obeying the commandment; the ideal ego, at the risk of displeasing, triumphs only by displeasing in spite of the commandment” (1966, p. 671). For Lacan, the ideal ego is a narcissistic formation linked to the mirror stage.

## EGO IDENTITY

It is too easy to see a patient only as a group of symptoms. Rather, according to Erik Erikson, the main issue is to determine whether it is a question of a person having a neurosis, or of the neurosis “having” the person. He insisted on the need to see fears and anxieties as two very different things: The former

apprehensions focus on realistic responses to dangers, whereas the latter, provoked by dysfunction in the internal controls, magnify obstacles without providing the means to surmount them.

Adaptive responses that are appropriate to reality are all too likely to be discounted if one understands the ego as being essentially a collection of defenses against the internal drives. The key, according to Erikson, is to seek in the ego the organizational capacities that create the strength necessary for reconciling discontinuities and ambiguities.

Like Sigmund Freud, Erikson envisioned an unconscious ego. But like other post-Freudians, he emphasized that the ego has a unifying function and ensures coherent behavior and conduct. The ego does not only have a negative function, that of avoiding anxiety; it plays as well the positive role of ensuring efficient functioning. The ego's defenses are not necessarily pathogenic: Some are adaptive, while others are the source of maladaptations. It is true that anxiety and feelings of guilt can disrupt adaptation. Moreover, the external environment has its own inherent deficiencies. But in attempting to measure the strength of the ego, Erikson did not limit himself to the earlier psychoanalytic norm and seek, in a personality, only that which is denied or cut off. Rather, he was interested in measuring the limit that the individual's ego is capable of unifying.

The ego protects the person's indivisibility, and everything that underlies the strength of the ego adds to its identity. If Freud understood identity as being in part acquired, this was due to the very particular types of patients he had treated.

For Erikson, identity is what maintains in the individual inner solidarity with the ideals and aspirations of social groups. The ego has a general balancing function: It puts things in perspective and prepares them in view of possible action. The strength of the ego, as Erikson conceived it, explains the difference between the feeling of being whole and the feeling of being fragmented. In the best of cases, it enables the individual to understand that the feeling of being at one with oneself comes through growth and development.

In addition to a feeling of continuity, according to Erikson, every individual needs a sense of novelty, obtained only through the leeway inherent in an assured identity. By "leeway," he meant maintaining in our experience a centrality, an evident self that, alone, enables us to make fully aware choices.

Early in his work Erikson called this identity "ego identity" after the model of Freud's "ego ideal." As a subsystem of the ego, identity's task is to choose and integrate self-representations derived from childhood psychosocial crises. Too often, in the history of psychoanalysis, there has been a tendency to forget that on the clinical level, the ego was posited as an enduring agent of selection and integration that plays a central role in the sound functioning of the personality. This inner "synthesizer," which silently organizes a coherent experience and guides action, is precisely what is so often lacking in present-day patients. By contrast, the patients of the earliest psychoanalyses were for the most part suffering from inhibitions that prevented them from being what they were, or what they believed themselves to be.

## EGO-INSTINCTS

In Freud's first theory of the instincts (or drives), the ego-instincts were contrasted with the sexual ones. In psychic conflict, a portion of instinctual energy is placed at the service of the ego. But even though their aim is the self-preservation and the self-affirmation of the individual, the ego-instincts nevertheless provide anaclitic support to the sexual drive. Freud later replaced this first opposition by another, that between the life instinct and the death instinct, assigning both the ego-instincts and the sexual instincts to Eros (the life instinct).

The term appeared first in the *Minutes of the Vienna Psychoanalytic Society* for March 10, 1910, where it was stated that reaction was made up of the "vicissitudes of the ego instincts," and soon after in Freud's "The Psycho-Analytic View of Psychogenic Disturbance of Vision" (1910i): "From the point of view of our

attempted explanation, a quite specially important part is played by the undeniable opposition between the [instincts] which subserve sexuality, the attainment of sexual pleasure, and those other [instincts] which have as their aim the self-preservation of the individual—the ego-[instincts]” (p. 214). Freud stated the idea more clearly apropos of the Schreber case: “We regard the [instinct] as being the concept on the frontier-line between the somatic and the mental, and see in it the psychical representative of organic forces. Further, we accept the popular distinction between ego-[instinct] and a sexual [instinct]; for such a distinction seems to agree with the biological conception that the individual has a double orientation, aiming on the one hand at self-preservation and on the other at the preservation of the species” (1911c [1910], p. 74). The sources of the ego-instinct are excitations emanating from the great organic functions, such as nutrition and vision, that ensure the continuation of life. The ego-instinct is thus quickly obliged to take the reality principle into account, and this consideration gives rise to the idea of a reality-ego that “need do nothing but strive for what is *useful* and guard itself against damage” (1911b, p. 223).

Thanks to Freud’s researches into narcissism, the notion that instinctual pressure was a kind of energy (earlier described as “interest”), led to the idea that ego-libido, or narcissistic libido, was the “great reservoir” from which object-cathexis is sent out and into which it may be withdrawn. The object of the ego-instincts is at first the object of need (food), and later anything that can contribute not only to strengthening the ego’s own operations, but also to inhibiting the primary process by the binding of ideas. Thus, secondarily, the ego becomes the object of libidinal cathexis. Its aim is self-preservation and the self-affirmation of the individual.

In 1915, Freud, showed that “only primal [instincts]—those which cannot be further dissected—can lay claim to importance” (1915c, p. 124). He then distinguished between two classes of primal instincts: “the *ego*, or *self-preservative*, [instincts] and the *sexual* [instincts]” (p. 124). The sexual instincts are at first “attached to the [instincts] of self-preservation, from which they only gradually become separated; in their choice of object, too, they follow the paths that are indicated to them by the ego-instincts” (p. 126).

In “A Difficulty in the Path of Psycho-Analysis” (1917a [1916]), Freud drew a parallel between the libido, as the force of the sexual drives, and hunger and the will to power as the power of the ego-instincts.

He then derived a certain category of neuroses from the conflict between the ego-instincts and the sexual instincts. Since the introduction of narcissism in 1914, however, he had contrasted two types of libido connected with the sexual drives, one type that was directed towards the object and the other that was directed towards the ego. The opposition between object-libido and ego-libido eventually replaced the distinction between ego-instincts and sexual instincts and paved the way for Freud’s final theory of the instincts.

In *Beyond the Pleasure Principle* (1920g), where Freud formulated his theory of the death instinct, he wrote: “The upshot of our enquiry so far has been the drawing of a sharp distinction between the ‘ego-instincts’ and the sexual instincts, and the view that the former exercise pressure towards death and the latter towards a prolongation of life. But this conclusion is bound to be unsatisfactory in many respects even to ourselves” (1920g, p. 44).

In *Civilization and Its Discontents* (1930a [1929]), Freud elaborated on the antithesis between ego-instincts and the object-instincts (p. 117). Then, in “The Dissection of the Psychological Personality,” the thirty-first lecture of the *New Introductory Lectures* (1933a [1932]), he specifically named the ego-instincts as a resisting force, insofar as they repelled and repressed the claims of sexual life (p. 57). In the thirty-second lecture, “Anxiety and Instinctual Life,” he attributed to the ego-instincts the same qualities as to the sexual instincts, apart from hunger and thirst, which were “inflexible, admit of no delay, [and] are imperative” (p. 97).

Though Freud continued to contrast ego-instincts and sexual instincts until 1920, the dualism between the life and death instincts inevitably relegated the ego-instincts to a subsidiary note. But some ambiguity remained, however, in Freud’s second topography (or “structural theory”), for in *Beyond the Pleasure Principle* (1920g), he subsumed the ego-instincts under the death instinct while still maintaining that they were at least partly libidinal in character.

**EGO INTERESTS**

The notion of ego interests points up a distinction between what serves the ego and what may harm it or place it in danger, as for example the pressures of the id, the commands of the superego, or simply love of an external object.

Freud used the term at least twice in his writings, once in the twenty-sixth Introductory Lecture, “The libido theory and narcissism” (1916–1917a, p. 414) and again in the paper “Analysis terminable and interminable” (1937c). In both contexts, Freud used the concept of the ego to mean an autonomous agency of mental life that makes no secret of its interests and can defend itself against the id and the superego. This defense can go as far as a refusal of all analysis, thus putting the treatment in jeopardy. In such cases one is confronted by resistance from the ego.

Even if it is rare, Freud’s use of “ego interests” demonstrates that in his work he by no means neglected to take the ego into account. It is true, however, that Freud long concentrated his attention on the depths of the unconscious part of the mind, as shown by the epigraph he chose for *The Interpretation of Dreams* (1900a): “Flectere si nequeo Superos, Acheronta movebo” (“If I cannot move the Higher Powers, I will move the Infernal Regions”), from the *Aeneid* (7.312). He thus declined to attend to the “higher world” of which the ego was an integral part. He nevertheless acknowledged that exploring the depths of the psyche represents a threat to the ego, that it is in the ego’s interest to recognize nothing beyond the conscious realm. But if this interest becomes too strong, overwhelming the functions that the ego is responsible for in company with the id and the superego, then behavioral problems will likely arise. Otherwise stated, it is in the ego’s interest to establish a working balance with the id and the superego, but if for whatever reason the ego is so strongly cathected that it no longer heeds either the id or the superego—a state known as “narcissism”—then there will occur disturbances of the kind that characterize what are now called “borderline cases,” disturbances that Freud considered unsuitable for psychoanalytic treatment.

With these considerations as his starting point, Heinz Hartmann brought to the fore a particular group of tendencies of the ego—the “ego interests”—embracing several disparate behaviors such as egoism, the pursuit of the “useful,” that is, of wealth, prestige, or power, but also that of intellectual acquisition.

**EGO-LIBIDO/OBJECT-LIBIDO**

In “On Narcissism: An Introduction,” Freud introduced a major modification in psychoanalytic theory,

particularly in libido theory, by making a distinction between two forms of libidinal cathexis: ego-directed and object-directed.

It was Carl Gustav Jung's studies on psychosis that led Freud to deepen and develop his own theory of the libido, which had hitherto been regarded solely as the energetic expression of the outwardly-directed sexual drives, leading to a break with his former student. At a period when there was a clear theoretical distinction between the sexual drives and the self-preservative drives, the case of the psychotic, cut off from reality and withdrawn into the self, seemed to substantiate the view (held by Jung) that the libido could be separated from sexuality and therefore had to be considered as a form of energy that was close to Henri Bergson's concept of *élan vital*.

In *Beyond the Pleasure Principle* (1920g), Freud commented that agreeing with "innovators like Jung who, making a hasty judgement, have used the word 'libido' to mean instinctual force in general" gives too much credence to "critics who have suspected from the first that psycho-analysis explains *everything* by sexuality" (p. 52). He then gave a response in theoretical terms in "On Narcissism: An Introduction" by suggesting that the libido initially cathected the ego, which he called "primary narcissism" and that it was only at a second stage that it was directed at the external world and towards the objects targeted by the drives: "Thus we form the idea of there being an original libidinal cathexis of the ego from which some is later given off to objects, but which fundamentally persists and is related to the object cathexes, much as the body of an amoeba is related to the pseudopodia which it puts out . . . We see also . . . an antithesis between ego-libido and object-libido" (1914c, pp. 75–76). In the same work, he went on to explain: "I should like at this point expressly to admit that the hypothesis of separate ego-instincts and sexual instincts (that is to say, the libido theory) rests scarcely at all upon a psychological basis, but derives its principal support from biology" (p. 79).

In the years that followed, Freud refined his description of this ego-libido that was soon to be called "narcissistic libido" by theorizing that it was possible for it to be turned back from an objectal current on to an ego that had itself become a love object: "secondary narcissism." He also drew a distinction between the repression in the transference neuroses, consisting in withdrawal of libido from consciousness and involving "the dissociation of the thing and word representa-

tions" from repression in the narcissistic neuroses, "which consists in the withdrawal of libido from the unconscious thing representations, which is of course a far deeper disturbance" (1965, p. 206; letter to Karl Abraham dated December 21, 1914).

From *Beyond the Pleasure Principle* onwards, the emphasis shifted from the conflict between ego-directed and object-directed libidinal drives to the conflict within the ego between Thanatos and Eros, as the concept that then subsumes the life drives in a constant attempt at cohesion (1920g).

Having assigned to the ego the role of "the great reservoir from which the object-cathexes are sent out and into which they are withdrawn once more" (p. 218) in a 1915 addendum to the *Three Essays on the Theory of Sexuality* (1905d), Freud later modified this proposition in his elaboration of the structural theory and wrote: "we must recognize the id as the great reservoir of libido" (1923b, p. 30, n. 1) and: "At the very beginning, all the libido is accumulated in the id, while the ego is still in process of formation or is still feeble. The id sends part of this libido out into erotic object-cathexes, whereupon the ego, now grown stronger, tries to get hold of this object-libido and to force itself on the id as a love-object. The narcissism of the ego is thus a secondary one, which has been withdrawn from objects" (p. 46). It is this secondary "ego narcissism" that is observed in psychotic states and narcissistic neuroses (dementia praecox, paranoia, melancholia, as Freud specified in his article "The Libido Theory" [1923a], written for the *Encyclopaedia Britannica*), in which the subject withdraws his libidinal cathexes from objects.

Should the metaphor of the "accumulators" found in the controversial book *Thomas Woodrow Wilson, Twenty-Eighth President of the United States: A Psychological Study* (1966 [1938]) be attributed to Freud? This text certainly states: "We have noted that the libido of the child charges five accumulators. Narcissism, passivity to the mother, passivity to the father, activity toward the mother and activity toward the father, and begins to discharge itself by way of these desires. A conflict between these different currents of the libido produces the Oedipus complex of the little boy" (p. 39).

The theoretical uncertainties relating to the sources of the libido and consequently to the validity of the opposition between the self-preservative "ego drives"

and the narcissistic ego-libido, a point on which Freud and Jung diverged, have led to a certain amount of debate and criticism, especially among English-language authors such as Heinz Hartmann, Rudolph Loewenstein, Michael Balint, and Heinz Kohut. This debate has given rise to most of the post-Freudian theories concerning narcissism and the distinction to be drawn between the “ego” and the “self.”

## **EGO PSYCHOLOGY**

Publication of *The Ego and the Id* (1923b), where Freud initially described the tripartite model of id, ego, and superego as the key macrostructures of the mind, ushered ego psychology into psychoanalytic theory. Precursors can be found in Freud’s earlier publications: the “Project” of 1895; *The Interpretation of Dreams*; the metapsychological papers of 1915 on instincts, repression, and the unconscious; and the works on narcissism, mourning, and group psychology.

Freud’s book on anxiety (1926d) elaborated the structural theory of ego psychology and played a key role in its evolution. Its new model for symptom formation saw symptoms as arising from compromises among conflicts of the id, ego, and superego. This new formulation of the workings of the mental sphere was introduced as a revision Freud’s topographic model, an earlier theory centered on the relationship of mental contents to consciousness. For Freud, the antagonism between what is dynamically unconscious and what is conscious, and the significance of this difference for psychopathology, is fundamental to psychoanalysis. But he came to realize that both the repressed and repressing forces, as well as the sense of guilt, are unconscious—a clinically significant factor that he wanted to highlight. Freud saw that to enhance theoretical clarity and more accurately conceptualize the data from clinical psychoanalytic work, he needed a new framework for the mind.

In the inner workings of the theory, the id, which includes much of what had been the dynamic unconscious in the topographic model, operates as a primary process and is the major repository of psychic energy, the instincts, and a significant portion of what has been repressed, except for the unconscious aspects of the ego and the superego. The id seeks satisfaction of basic needs and wishes. The superego, in contrast, issues moral directives, self-reproach, and self-punishment and establishes values and ideals. Freud saw the ego as a coherent set of mental functions and a distillation of abandoned object cathexes. It represents reality, curbs impulses, and seeks the best compromise among the claims of the id, the superego, and the external environment. Freud’s concept of the ego has many different aspects and functions.

Delineating these aspects and functions constituted a major task for psychoanalytic theorists for the following half century and beyond. Anna Freud’s (1936/1966) depiction and organization of the major mechanisms of defense emphasized the defensive aspects of the ego. She stated the principle that id, ego, and superego derivatives merited equal attention from the psychoanalyst. Hartmann’s (1939/1964) notion that primary and secondary ego are autonomous delineated the ego as a substructure of the mind defined by its functions: broadly, its defensive, autonomous, and synthetic functions and their interrelations.

Therapy in the topographic model centers on making the unconscious conscious, and uncovering

universal-drive-related fantasies related to the various psychosexual stages of development. Therapy in ego psychology seeks to increase the scope of the ego at the expense of that of the id and, as a clinical correlate, to understand how the subject uniquely deals with danger and inner conflicts, encompassing id impulses, superego responses, and defensive, adaptive, and integrative ego solutions. Another technical implication of ego psychology is that the therapist should pay close attention to the organization and detail of conscious content while listening for its unconscious substrate. The emphasis on defense also brought into focus the issue of character resistance, systematically developed by Wilhelm Reich. Exploring character resistance later became an aspect of ego-psychology technique. Increasing knowledge of ego development and its relation to early object relations played a key role in the evolution of psychoanalytic ego psychology.

Current psychoanalytic approaches derived from ego psychology are Jacob A. Arlow's delineation of the unconscious fantasy, Charles Brenner's focus on conflict and compromise formation, and Paul Gray's development of close monitoring of the defensive process. Otto Kernberg has provided an integration of ego psychology and object-relations theory.

## **EGO-PSYCHOLOGY AND THE PSYCHOSES**

*Ego-Psychology and the Psychoses* consists of Edoardo Weiss's compilation of sixteen of Paul Federn's papers on ego psychology, his primary field. Federn (1871–1950), a member of Freud's inner circle, was one of the first psychoanalysts to treat psychotics. His psychoanalytic understanding was influenced by a phenomenological focus, his definition of the ego was experiential, and his major concepts were ego feelings, ego boundaries and ego states. As he understood it, in schizophrenia the ego is too weak to sustain the dominance of advanced ego states essential for mature functioning, due to overly-strong fixations on primitive ego states. Federn saw the prodromal phase of psychosis as beginning with a loss of ego cathexis, while Freud (1911c [1910]) emphasized the withdrawal of object cathexis. Federn supported his position by the observation that psychotics may maintain object interest in the presence of feelings of estrangement. Part of the difference in their respective formulations lay in the fact that Freud was attempting to explain the rapid appearance of delusions following a traumatic disappointment, while Federn focused on the incremental development of delusional ideas.

Federn recognized that psychotics were capable of strong transferences, which rendered them analyzable, but he also emphasized the challenge presented by the psychotic's mal-developed ego, idiosyncratic understanding of reality, and excessive, pathological narcissism. Federn held that these factors require a different application of psychoanalytic knowledge than the approach developed for the neurotic. His detailed treatment recommendations for psychotics were based on the implications of ego weaknesses. Regarding the understanding of the treatment of psychoses, Federn's concept of ego feelings preceded later interest in the sense of self, his view of faulty ego cathexis anticipated deficit theories of schizophrenia, and his work on the outer ego boundary shed light on contemporary con-

cerns with narcissistic object relations. His phenomenological insights and the problems with which he grappled have been of more lasting value than some of his detailed theoretical formulations.

## EGO PSYCHOLOGY AND THE PROBLEM OF ADAPTATION

This work by Heinz Hartmann, some one hundred pages long, was presented to the Vienna Psychoanalytic Society in 1937, then published in book form in 1939. David Rapaport's English translation appeared in 1958. The ideas presented by Hartmann were already well known by then in the United States thanks to the German version, although in Europe, because of the Second World War, they gained wide currency only in the 1950s.

With these nine chapters, Hartmann extended Freudian psychoanalysis to the entire field of the psychology of consciousness, and in so doing brought aspects of modern ego psychology into that field for the first time. As his starting point, he took the idea that the ego was determined by its functions, thus

avoiding the question of its essence. According to Hartmann, the ego had many conflict-free functions whose basic task was adaptation to the external world. The ego and the id had emerged originally from a common matrix; obliged to define the boundaries between them, they created a zone of conflict whose essential *raison d'être* was defense. Simultaneously, a conflict-free zone developed that was dedicated fundamentally to adaptation to the outside world, and which included the body.

In this way psychoanalytic research was opened up to somatic and social phenomena and to all scientific disciplines concerned with these areas: primarily, the study of behavior, academic psychology, sociology, and anthropology. Although adaptation has features in common with defense, it is a function of a completely different order. It is the part played by resistance, above all, which distinguishes the two. The hypothesis of a conflict-free ego implies an autonomous status for that agency within a psychoanalytical psychology of the ego on a par with other human sciences.

## EGO STATES

An ego state is a coherent organization of cathected mental contents and related affects that are experienced as within the ego boundary at a given point in time. Federn's (1926/1952) concept of ego states is related to Schilder's (1930/1951) discussion of varieties of conscious experience and to David Rapaport's (1951/1954) view of states of consciousness. Federn's use of the construct ego state underscores mental content.

Ego states are correlated with particular ego boundaries, and the current contents included within a given

boundary will determine a particular ego state. Conversely, given ego states include particular qualities of ego experience. Ego states range from developmentally primitive to advanced. Any ego state may be repressed, and thus de-egotized. When a conflicting idea is repressed, the ego state in which it is found will also be repressed. For a repressed memory to become emotionally meaningful, there must be recall of the whole ego state in which it is embedded. A repeatedly cathected ego state may become dominant, and when this ego state is repressed, a fixation point is created. Fixations are associated with highly rigid ego boundaries. Activation of a particular ego state will result when there is a regression to that fixation point.

Manifest dream elements may primarily signify, in addition to unconscious fantasies, repressed ego states. The very concept of pathological fixations implies the notion of a number of repressed ego states. The unconscious segment of the ego consists of all repressed ego states. An active ego state reflects how one is presently experiencing oneself.

Ego states succeed one another, but a person may also experience different ego states at the same time. Even so, in most cases, one is aware of only one ego state at a given time. In ego states characterized by fatigue, sleep, illness, and psychosis, the ego feeling is often seriously restricted. In general, the greater the mental disturbance, the more the person's functioning is limited by current ego states. Such a person is unable to do in one ego state what he can do in another. Regression to earlier ego states is one of the main pathological features of psychosis.

## **EGO-SYNTONIC**

The notion of ego syntony plays an important part in psychoanalytic ego psychology. The implication of the term is that the ego represses only those tendencies with which it is at odds, that is, with which it is incompatible. Freud used the term only once, in the encyclopedia article "Psycho-Analysis," which first appeared in Max Marcuse's *Handwörterbuch der Sexualwissenschaft* (Manual of sexual sciences). "Since these impulses are not *ego-syntonic*," he wrote, "the ego has repressed them" (1923a, p. 246).

Obviously, compatibility between the ego and the id must vary according to the individual and also as a function of cultural and social affiliation. Sexual relations, for example, were long condemned by the Catholic Church unless their purpose was procreation. This position has gradually changed, but it is worth recalling that as recently as a hundred years ago Protestant circles subscribed to the same idea. In Asian societies attitudes towards sexuality are very different, although there too change is under way.

If much of sexuality is rejected by the ego of Westerners, this is not to say that other instinctual tendencies are likewise "ego-dystonic," and therefore repressed. In many aspects of aggression one can also see wide individual differences, depending not only on social position but also on historical period. In fact, if one considers the course of history from a psychological point of view, it is reasonable to say that up until the end of the Second World War most men experienced a resort to violence, even to killing, as perfectly ego-syntonic. In countries where the death penalty is still in use, as in the United States, inflicting this sanction on criminals is generally ego-syntonic, whereas in other countries this attitude has changed radically within the ego, and capital punishment is condemned by most people.

In the psychotherapy of present-day individuals, the therapist thus needs to bear in mind the historical trend for the ego to repress destructive impulses when it encounters them. Indeed, it is possible that sexual

impulses will become fully ego-syntonic, even as the ego rejects destructive wishes. In short, what is ego-syntonic and what is ego-dystonic must be determined in a historical, cultural, and social context.

### **EISSLER, KURT ROBERT (1908–1999)**

Physician and psychoanalyst Kurt Robert Eissler was born in Vienna on June 2, 1908, and died in New York on February 17, 1999.

Eissler was a Freud scholar of distinction, one of the most accomplished psychoanalysts of his generation, and a prolific and original writer. He was immensely learned, and a captivating and engaging speaker whose somewhat wry but engaging sense of humor augmented the liveliness with which he enriched discussion. His interests were wide ranging. The arts always appealed to him: His knowledge of them was extensive and he spoke and wrote of them with learning and wisdom. His book on Leonardo da Vinci (1962) was followed by his two-volume psychoanalytic study of Goethe (1963), and he made important contributions to the study of *Hamlet* (1953, 1968) and Freud's approach to literature (1968). He wrote about ageing and death, and his book, *The Psychiatrist and the Dying Patient* (1966), is of permanent value. In all, he wrote twelve books and nearly one hundred papers, among which his studies of psychoanalytic technique attracted wide attention. His writings cast light on many subjects, of which schizophrenia, dream analysis, female sexual development, memory and lightning calculation, psychological factors in hypertension, esophageal spasm, psychology of jealousy, body image disturbances, and suicide will serve as more or less typical random examples.

Eissler studied psychology at the University of Vienna. He took his Ph.D. in 1934 and his M.D. in

1937. After training at the Viennese Psychoanalytic Institute, he joined the Viennese Psychoanalytic Society. There he became an assistant to August Aichhorn, a pioneer in the study and treatment of adolescent delinquency, whose *Wayward Youth* became a classic text. Following the Anschluss in 1938, Eissler left for Chicago and obtained the diploma of the American Board of Psychiatry. During the Second World War, in 1943, he became a captain in the US Army Medical Corps, specializing in neuro-psychiatry. That autumn, his brother Erik was killed in a concentration camp, though it was only later that Eissler learned of his fate.

He moved to New York when the war ended, and set up in private practice. In 1949, he edited *Searchlights on Delinquency*, dedicated to his old teacher Aichhorn. In 1952, he was one of the founders of the Sigmund Freud Archives, deposited in the Library of Congress, Washington, DC, and it was as its tireless secretary that he collected so many invaluable documents about, by, or related to Freud and his associates. In this unending task he was greatly helped by Anna Freud, in the context of a warm relationship of mutual esteem. He had known her from Viennese days, and she found his friendship a great comfort. He established the Anna Freud Foundation in the United States, also in 1952, thus facilitating tax-free donations for the benefit of the Hampstead Child Therapy Course in London, and the associated clinic she had just set up. He strongly supported the work of what quickly became the world's leading center for child analytic training and for child analytic research. Anna Freud was secure in the knowledge that the Freud Archives were in safe hands, and that Eissler's devotion to all that her father stood for was absolute. She was grateful, too, for the invaluable assistance that he gave to Ernest Jones in his extensive three-volume biography of Freud, and to the help he gave to James Strachey in preparing the standard edition of Freud's psychological works.

Eissler was actively and deeply concerned about the growing flood of uninformed Freud criticism and the publicity it attracted. In particular, he objected to the misinterpretation of the early seduction theory. While Freud never denied that seduction in childhood had serious consequences for development, he was obliged to abandon his views of its role in the etiology of hysteria. Certainly, he would have hated the "recovered memory syndrome." All this is well known to serious

students of psychoanalysis, but Eissler brought to the bare facts an erudition that cast fresh light on the entire issue. An unexpectedly bitter dispute over his successor to the Archives, stemming from allegations that Freud had suppressed the truth about his early seduction theory, achieved wide publicity, while Eissler's refutation of the charges failed to be given due weight. Some other criticisms of Freud sprang from misunderstandings within the profession, and these were subject to Eissler's searching scrutiny. Again, this did not always attract the attention it deserved.

Eissler could not be said to be optimistic, either about psychoanalysis in particular or civilization in general. *The Fall of Man* (1975) makes melancholy reading. But, when reaffirming his pessimism during conversation, he would often add: "You have to go on fighting." He was certainly no idolater of Freud or Anna Freud, but vigorously defended those principles without which, he felt, psychoanalysis would cease to be psychoanalysis.

He was sometimes accused of imposing undue restrictions on access to the Freud Archives. Peter Gay, for example, in his biography of Freud (1988), after praising Eissler for his diligence in historical research, accused him of "an addiction to secrecy" (p. 784) in making a great deal of Freud's correspondence unavailable to scholars. That view is widespread, and Eissler (1993) felt obliged to defend the policy pursued by the Archives—a policy, he argued, seriously misrepresented. It was not, he said a matter of secrecy, but of making material available only to scholars and translators who were committed to accuracy: He pointed to the mischief already done by misreadings (not necessarily wilful) of Freud's difficult script, and pointed to the "glaring inaccuracies" in some translations previously published. It is a matter of some importance to read Gay's charges (p. 784f) and Eissler's reply (1993, pp. 202f, 212f) in full, in view of the widespread misunderstandings of the position then taken by the Freud Archives.

Eissler retained to the end an old-world charm and the courtesy and consideration of a Viennese gentleman. His stimulating observations were matched by a lively interest in the activities and opinions of his visitors, and his warm hospitality was a delight to those who knew him. His wife Ruth, for many years an editor of *The Psychoanalytic Study of the Child*, died in 1989.

### EISSLER-SELKE, RUTH (1906–1989)

A physician and psychoanalyst, Ruth Eissler-Selke was born February 21, 1906, in Odessa and died October 7, 1989, in New York. She was born into a Jewish family, her father being the director of a German bank and then a grain exporter. After moving several times and attending schools in Odessa, Hamburg, and Danzig, Eissler-Selke completed her studies in 1925 in Freiburg-im-Breisgau. She studied medicine at the University of Freiburg, graduating in 1930. She specialized in psychiatry and, following graduation, practiced in Heidelberg and Stuttgart. Her dissertation, which she defended at the University of Heidelberg in 1932, was entitled "Medical Histories of Six Cases: The Contribution of Social Hygiene to the Question of Alcoholism and Tuberculosis."

After Hitler came to power, Eissler-Selke went into exile in 1933 in Vienna and worked at the psychiatric hospital in Rosenhügel. In December 1933, she requested admission to the training institute of the Vienna Psychoanalytic Society and began an analysis with Theodor Reik. After Reik's emigration to the Netherlands, she turned to Richard Sterba for her analysis. She was accepted as a member of the Vienna Psychoanalytic Society in 1937. While in Vienna she met Kurt R. Eissler, a doctor, philosopher, and later a psychoanalyst. They were married in 1936.

In March 1938, Kurt and Ruth Eissler emigrated to the United States and settled in Chicago. She became a member and training analyst of the Chicago Psychoanalytic Society and worked as a child psychiatrist at the Michael Reese Hospital. During the Second World War, she was a consulting physician in an institution for young delinquent women in Chicago. In 1948 she and her husband moved to New York and she became a member of, and training analyst with, the New York Psychoanalytic Society. From 1951 to 1957 she was secretary, then vice president of the International Psychoanalytic Association and, from 1950 to 1958, one of the editors of *The Psychoanalytic Study of the Child*, an annual publication founded in 1945 by Anna Freud, Heinz Hartmann, and Ernst Kris.

Aside from her teaching activities and psychoanalytic publications, she wrote poetry and a novel (unpublished), as well as several short stories. In 1976, to celebrate her seventieth birthday, a collection of her poems in German was published in New York.

## **EITINGON, MAX (1881–1943)**

Max Eitingon, a medical doctor, was born in Mohilev, Russia, in 1881 and died in Jerusalem on July 3, 1943. He was cofounder and president of the Berlin Psychoanalytic Polyclinic (1920–1933), director and patron of the Internationaler Psychoanalytischer Verlag (1921–1930), president of the International Psychoanalytic Association (1927–1933), founder and president of the International Training Committee (1925–1943), and founder of the Palestine Psychoanalytic Society (1934) and of the Psychoanalytic Institute of Israel.

Eitingon was born into an orthodox Jewish family. His father, Chaim Eitingon, had a large successful fur business, with a store in New York City. Max was the last of his four children (the others were Esther, Fanny, and Vladimir). Around 1893, when he was twelve, the family moved to Leipzig, Germany, where Chaim became a generous patron to the Jewish community, financing the construction of a hospital and a synagogue. In 1929 he was ruined by the stock market crash and died in Leipzig in 1932.

Educational problems, most likely associated with his stuttering, prevented Max from taking classes at the local high school, and he became a student in a private school that had a curriculum based on the study of modern languages. He learned to speak ten languages and later was able to take medical notes in several languages and dialects. However, because he did not have an opportunity to take his baccalaureate exams, he was not allowed to enroll in medical school and had to obtain a degree equivalent to the baccalaureate. He studied at various universities in Halle, Heidelberg, and Marburg, where Hermann Cohen, a specialist in Judaism, taught.

After this educational odyssey he began his medical studies in 1902 at the University of Leipzig. Eitingon completed everything but his dissertation when he left to become an intern at the Burghölzli Clinic in Zurich. Eugen Bleuler, head of the clinic, sent Eitingon to Freud with a patient because he wanted to discover what a psychiatrist could learn from a psychoanalyst. The “Minutes of the Vienna Psychoanalytic Society” note the presence of “Mr. Eitingon, of Bleuler’s clinic,

as guest” at the Wednesday evening meetings of January 23 and 30, 1907.

Eitingon was the first doctor from the Burghölzli Clinic to meet Freud. He served as an intermediary between Freud and psychiatry, but also asked to see him privately as a patient. Between 1908 and 1909 he underwent a five-week analysis during evening walks with Freud, a somewhat unusual venue for psychoanalysis. This was Freud’s first training analysis. We can assume that Eitingon discussed with Freud his relationship with his father and his inhibition about working. Presented these difficulties of Eitingon’s, Freud, who was very indulgent in his countertransference, appears to have been inclined to make Eitingon a “doctor of psychoanalysis.”

Eitingon, with the help of Carl Jung, finally managed to complete his dissertation: “Effect of an epileptic attack on mental associations.” He settled in Berlin, where his father’s fortune provided him with a life of comfort and ease among the intellectual and artistic elite of the city. On April 20, 1913, he married Mirra Jacovleina Raigorodsky, an actress from the Moscow Art Theater. During this period he had some time to help Karl Abraham introduce psychoanalysis to Berlin.

During the First World War, Eitingon became an Austrian citizen and joined the army as a physician. He was sent to Prague, Kassa, Iglo, and Miskolc (his birthplace), where he recommended Sándor Ferenczi as an expert for a military trial. In the hospitals Mirra worked with him as a volunteer nurse. He successfully treated cases of war trauma with hypnosis and was decorated several times for his work. He attended meetings of the Budapest Psychoanalytic Association, worked with Ferenczi on a psychoanalytic clinic, and attended the 1918 psychoanalytic congress.

At the end of the war, faced with an unstable political climate in Hungary, Eitingon left for Berlin, where he began his lifelong commitment to psychoanalysis. He had become a close friend of Freud in 1910 and remained his confidant during difficult times. In Freud’s words, he was the “first messenger [of psychoanalysis] to approach a solitary man [Freud].” With Ferenczi he played the role of a supportive disciple throughout the war years. A reliable individual, he was in a sense an administrator of the Freudian enterprise, resolving any problems that arose in the various local psychoanalytic societies (Zurich, for example).

He replaced Anton von Freund as a member of the Secret Committee (of Freud’s supporters) and continued his work in introducing psychoanalysis. In 1920 he took over work that had been done in Budapest and succeeded in creating a polyclinic in Berlin, whose construction he entrusted to Freud’s son, Ernst, an architect. He financed the polyclinic out of his personal fortune and ran it with the help of Karl Abraham and Ernst Simmel until the rise of National-Socialism in 1933.

The polyclinic was the first center in the world for treating patients with the Freudian psychoanalytic method and the first training institute for young analysts. The clinic trained candidates from all over the world to address the mental and social problems of postwar Europe. The curriculum lasted two years, then three, and comprised three separate tracks: theory, personal analysis, and supervised analysis.

After the death of his father, a cerebral thrombosis left him paralyzed in the left arm. On June 13, 1933, Eitingon presented Ferenczi’s funeral elegy in Budapest. Ruined, handicapped, and no longer able to bear the persecution in Berlin, he left Germany, on Freud’s advice, in September 1933. Because of his Zionist sympathies, he decided to emigrate to Palestine. He settled in Jerusalem, on Balfour Street, and there founded the Palestine Psychoanalytic Association (1934). In spite of Freud’s support, he failed to obtain a chair in psychoanalysis at the Hebrew University of Jerusalem.

In 1938 he was involved in a court case in Paris (the “Plevitskaya affair”) and suspected of being a Soviet spy. Vladimir Nabokov used this episode for the short story “The Assistant Producer.” Marie Bonaparte and René Laforgue testified on Eitingon’s behalf. Despite the French government’s official acknowledgement of “strategic error,” he was again accused of being a spy, this time posthumously, in the United States in 1988. A new controversy followed, but Eitingon’s reputation was cleared (Moreau Ricaud, 1992).

Eitingon was the author of some thirty articles, including “Genie, Talent und Psychoanalyse” (1912), “Gott und Vater” (1914), “Ein Fall von Verlesen” (1915), and twelve reports to various international psychoanalytic congresses, from Berlin 1922 to Paris 1938.

## ELASTICITY

"The Elasticity of the Psychoanalytic Technique" is the title of a paper that Sándor Ferenczi gave to the Budapest Psychoanalytic Society, and which was first published in 1928. In essence he described the procedure he had introduced in his paper on the "contra-indications of the active technique" (1926), in which he recommended using relaxation to reduce tension in certain difficult cases. In two other articles from the same period ("Family Adaptation to the Child" and "The Problem of the End of Analysis") he dealt with difficulties in the educational environment. The question became one of how far the idea of elasticity could be taken. In 1967, Michael Balint would write on Ferenczi's problem, "His earlier experiences had familiarized him with two models: one was the classic technique with its objective and benevolent passivity, and apparently imperturbable and unlimited patience; the other was the active technique with its well-directed interventions founded on attentive observation and empathy."

In the 1928 paper, Ferenczi developed the technical importance of tact in deciding on the right moment to

communicate to the patient any conjectures the analyst may have made, "based essentially on the dissection of our own Self." He stressed the notion of modesty, which should be "the expression of the acceptance of the limits to our knowledge," and to this end he preferred from the beginning of treatment to adopt a rather pessimistic attitude, in order to avoid creating enthusiastic confidence in the future patient, a confidence that often camouflaged "a healthy dose of distrust." Nothing could be more harmful, he continued, "than the attitude of a schoolmaster or an authoritarian doctor." He thus spoke of *Einfühlung* (feeling-with, empathy) as of a rule, from which he deduced the necessity, for the analyst, of developing "a rigorous control of his own narcissism and intense vigilance with regard to his own affective reactions." Analysts would have to "guess when the patient's esthetic sentiments have been offended by our own attitude" and, supporting this displeasure, behave like those little "culbutos" (small figures with lead ballast in their base that always return to a vertical position). Ferenczi proposed "a perpetual oscillation between feeling-with, self-observation and judgment activity."

He concluded this reflection on the counter-transference with a "metapsychology of the technique," denouncing the "fanaticism of interpretation as an infantile disease of analysis" because, in order for patients to become free of all emotional binds, they must "abandon, at least provisionally, all sorts of superegos, including that of the analyst." This position borders on "a demand for elasticity in the analysts themselves," a "metapsychology of the analysts." This then makes it absolutely essential to comply with the second rule of psychoanalysis, already problematic at the time, that analysts must themselves be analyzed.

## ELEMENTI DI PSICOANALISI

Published by Ulrico Hoepli (Milan, Italy) in 1931, Edoardo Weiss's work was the first complete and accurate exposé of psychoanalysis in Italy. Freud spoke approvingly of the work of his Italian disciple when he wrote in his preface that the book recommended itself to anyone who was able to appreciate the "seriousness of a scientific effort," the "honesty of the researcher," and the "skills of the teacher." Some chapters were translated into German in the *Psychoanalytische Bewegung*. A second edition appeared in 1932, and a third in 1936. The most recent edition was published in 1985.

The book is based on five lectures given by Weiss in Trieste, Italy, at the initiative of the local medical association in the spring of 1930. He covered the following subjects: (1) the nature of psychoanalysis and the concept of the id and unconscious inhibition, (2) symbolism, (3) the origin of the superego and social and religious sentiments, (4) drive theory, (5) psychic systems. In an appendix Weiss added a glossary of basic psychoanalytic vocabulary in Italian, with approximately ninety terms accompanied by their German equivalent. This small dictionary was the first, and for a long time the only, instrument of its kind available in Italy.

Although Weiss attempted to summarize Freud's thought, he did not simply reproduce it passively. He introduced a conceptual neologism, the "inhibitory id," to refer to the oldest part of the superego and the feeling of unconscious guilt that accompanies it. The problem of unconscious guilt appears clearly in the fourth lecture, where he describes Freud's death impulse and refers to Ernst Federn's statement concerning the intermediate character of the life and death drive.

The *Elementi* was a qualitative leap over the handful of works on psychoanalysis available in Italy until then, works that were often badly informed and tentative. Therein lies its historical importance.

## ELISABETH VON R., CASE OF

"Fräulein Elisabeth von R." is the pseudonym Freud gave to Ilona Weiss, a young woman of Hungarian origin, whose case is described in the *Studies on Hysteria* (1895d) and whom he treated in the fall of 1892 and July 1893. The third daughter in a well-to-do Hungarian family, Elisabeth von R. was twenty-four years old when Freud treated her in the autumn of 1892 for pains in her legs and difficulties walking, problems she had been experiencing for two years. He confirmed the diagnosis of hysteria that had been made and noted that "if one pressed or pinched the hyperalgesic skin and muscles of her legs, her face assumed a peculiar expression, which was one of pleasure rather than pain. She cried out—and I could not help thinking that it was as though she was having a voluptuous tickling sensation—her face flushed, she threw back her head and shut her eyes and her body bent backwards" (1895d, p. 137).

After an initial period of four weeks during which he prescribed electrical treatments, he suggested to her the use of a cathartic cure that "turned out, however, to be one of the hardest that I had ever undertaken" (1895d, p. 138). Resistant to hypnosis, the patient stretched out with her eyes closed but was able to move, open her eyes, and sit up. Freud then applied his "concentration technique," the same one he was using on another patient of his at the time, Miss Lucy R.

It was this that persuaded Freud that she was hiding a secret, but her initial remarks had no effect in spite of their dramatic nature. Her family history was characterized by heart disease and the death of her father, whom she deeply loved, for whom she "took the place of a son and a friend with whom he could exchange thoughts" (1895d, p. 140). Freud understood that her illness had begun with pains in her legs, which first occurred while she was caring for her sick father, even

though she was not aware of them until two years after his death. The sickness and death of her sister, who was also afflicted with heart disease aggravated by pregnancy, followed by a quarrel between her brothers-in-law, had coincided with the two years of the development of her illness.

During this period of the treatment, she repeated to Freud that she was not doing better in spite of her confession and Freud remarked that “when she looked at me as she said this with a sly look of satisfaction at my discomfiture, I could not help being reminded of old Herr von R.’s judgment about his favorite daughter—that she was often ‘cheeky’ and ‘ill-behaved’” (1895d, p. 141).

An improvement occurred when she herself provided the source of her hysterical conversion: Her pains began at the spot on her thigh where, every morning, her father placed his inflamed leg so she could change his bandages. From then on “her painful legs began to ‘join in the conversation’ during our analyses” (1895d, p. 141), a period of abreaction when, Freud writes, “I sometimes followed the spontaneous fluctuations in her condition; and I sometimes followed my own estimate of the situation when I considered that I had not completely exhausted some portion of the story of her illness” (1895d, p. 149). He then experimented with the phenomenon that would soon modify his conception of psychotherapy: “In the course of this difficult work I began to attach a deeper significance to the resistance offered by the patient in the reproduction of her memories and to make a careful collection of the occasions on which it was particularly marked” (1895d, p. 154). It was on her account that he used publicly for the first time (this information is found six months later in Draft H, dated January 24, 1895, in 1950a) a key theoretical concept: “it can be shown with likelihood that complete conversion also occurs, and that in it the incompatible idea has in fact been ‘repressed’ [*verdrängt*], as only an idea of very slight intensity can be.”

In the spring of 1893 a sharp pain reoccurred when she heard, in a room adjacent to Freud’s office, her brother-in-law who had come to pick her up. This enabled Freud to track down her “secret”—she had fallen in love with her brother-in-law. She had grown closer to him as a result of her sister’s illness, and upon her death was unable to repress the thought that he was now free. In spite of his patient’s denials, Freud insists on, and goes so far as to solicit the testimony of

the young woman’s mother, who confirmed that she had suspected as much. The treatment concluded in July 1893 with the appeal to the mother for assistance. This was to have repercussions later on, since the daughter rebelled and refused to see Freud again because he had betrayed her secret.

Freud, confident in his treatment, notes with pleasure: “In the spring of 1894 I heard that she was going to a private ball for which I was able to get an invitation, and I did not allow the opportunity to escape me of seeing my former patient whirl past in a lively dance” (1895d, p. 160). When he prepared the case study for the *Studies on Hysteria*, he learned from Wilhelm Fliess (to whom he had given it to read) on July 14, 1894, that she had just gotten engaged.

Elisabeth von R., if we are to believe her daughter’s revelations, told the story somewhat differently. “She described Freud as ‘just a young, bearded nerve specialist they sent me to. He had tried ‘to persuade me that I was in love with my brother-in-law, but that wasn’t really so.’ Yet, her daughter adds, Freud’s account of her mother’s family history was substantially correct, and her mother’s marriage was happy.” (Gay, p. 72).

It was in this context that Freud wrote, “This was my first complete analysis of a hysteria. It allowed me for the first time, with the help of a method that I would later use as a technique, to eliminate psychic material in layers, which I like to compare to the technique of unearthing a buried city” (1895d, p. 139). Yet the treatment is less important historically for the spectacular discovery of the “love secret” that is revealed than because it demonstrates to Freud the mechanism of conversion, his link to a father with whom he identifies without yet drawing the relevant conclusions, and the resistance he must overcome through belief in his method, in order to eliminate, beyond the relative freedom of association he allows his patient, through speech, layer by layer, the psychic material that blocks the return of repressed memories.

## ELLENBERGER, HENRI FRÉDÉRIC (1905–1993)

Henri Frédéric Ellenberger, physician, psychiatrist, and historian of psychoanalysis, was born in Nanolo, Rhodesia, on November 6, 1905, and died in Montreal on May 1, 1993. He was born into a family of Swiss protestants. His father, Victor Ellenberger, a naturalist and anthropologist, was a member of the Société des missions évangéliques de Paris (Society of Evangelical Missions of Paris), and his mother, Évangéline Christol, was the daughter of a pastor.

Ellenberger completed his medical studies in Strasbourg, France, and it was there that he was introduced to historical research. He moved to Paris to specialize in psychiatry and, after being appointed a resident in psychiatry, worked at the Sainte-Anne Hospital alongside Henri Ey. In November 1930 he married Esther von Bachst, a Russian émigrée with a passion for zoology, and they had four children.

Ellenberger settled in Poitiers, but because he was not a naturalized French citizen, in 1941 he emigrated to Switzerland. He worked as a psychiatrist at the Breitenau Hospital in Schaffhausen and was part of the Jung Circle in Zurich, through which he met Carl Gustav Jung. In 1950 he began a training analysis with Oskar Pfister, who was then seventy-seven years old. In 1952 he traveled to the United States, met Karl Menninger, and was appointed professor at the Menninger School of Psychiatry in Topeka, Kansas. In 1953 he encountered immigration problems, and in 1959 he moved to Montreal, where he became a professor of criminology at McGill University.

In 1962 he began the historical research that resulted in the publication of *The Discovery of the Unconscious: The History and Evolution of Dynamic Psychiatry* in 1970. In contrast with the oral tradition of the history of psychoanalysis and Ernest Jones's biography of Sigmund Freud, and in spite of the paucity of documentation, Ellenberger's work provided a

detailed history of the theories and practices that, since antiquity, made use of the forces of what would come to be theoretically designated as the unconscious. Ellenberger traced the "dynamic" tradition in psychiatry back to Franz Mesmer. In this tradition he placed Jean Martin Charcot, Pierre Janet, Sigmund Freud, Alfred Adler, and Carl Gustav Jung. Ellenberger wanted to show that the hagiographies of Freud were mistaken: Freud did not receive some heavenly illumination. Rather, his theories are only one link, albeit an important one, in a tradition that included sorcerers, shamans, the Catholic confession, Alfred Schopenhauer, and Gustav Fechner.

After learning about Ola Andersson's discovery of the true story of Emmy von N., which Ellenberger published, he continued working as a historian of psychoanalysis, intent on removing the doubts and omissions that littered a historiography divided between worship and calumny. His position has been judged by a number of psychoanalysts as unfavorable to Freud and psychoanalysis, for it served as a point of departure for several openly hostile research efforts. Although his attitude was seen as largely negative, especially in Freudian circles, where his work received a poor reception, he remained a dedicated researcher, conscious of establishing the first principles of a psychiatric historiography that stood in marked contrast to a cult of hero worship.

## EMBIKOS, ANDREAS (1901–1975)

Andreas Embirikos, a poet and psychoanalyst, was born on September 2, 1901, in Braila, Romania, and died in 1975 in Athens. His father's family was originally from the island of Andros. His mother was born in Russia. He had three brothers. Shortly after his birth, the family settled on the island of Syros, then in Athens, where Embirikos completed his secondary education and enrolled at the University of Athens to study philosophy.

Between 1926 and 1931 he lived in Paris. Interested in psychoanalysis, he underwent analysis with René Laforque and made contact with the surrealists. He became friends with André Breton. After his return to Athens in 1931, he worked for a while as director in the shipping company that belonged to his father, but he soon left his position to devote his life to poetry and psychoanalysis.

Embirikos, the first psychoanalyst in Greece, was actively involved in psychoanalysis from 1935 until the end of 1950. In 1947 he was one of the founding members of the first psychoanalytic group in Greece and in 1950 was made a member of the Paris Psychoanalytic Society.

His friends referred to Embirikos as “brilliant and unlike anyone else.” One might assume that he combined the glory of the poet with the perseverance of the psychoanalyst, but this was not the case. In 1951, believing he was under the threat of a lawsuit for practicing therapy without a medical license, Embirikos closed his psychoanalytic practice. He had been badly treated by the police at the end of the civil war and now believed he had become a target of the medical establishment. He left for Paris.

Two years later Embirikos returned to Greece to devote himself to his poetry. He was a prolific poet and produced work of high quality. His poetry was a broad erotic fresco with occasional references to psychoanalysis. His only psychoanalytic publication appeared in 1950: “Un cas de névrose obsessionnelle avec éjaculations précoces.” Embirikos married twice. He died at the age of seventy-four from lung cancer.

## EMDEN, JAN EGBERT GUSTAAF VAN (1868–1950)

Jan van Emden, Dutch physician and psychoanalyst, was born in Paramaribo, Surinam, on August 5, 1868, and died in the Hague on March 23, 1950, aged 82. He was trained as a medical doctor at the University of Leiden and received his degree in 1896 for his dissertation “Bijdragen tot de kennis van het bloed” (Contributions to knowledge of the blood). Van Emden met Freud in 1910 when the latter was vacationing in Noordwijk, the Netherlands, and they subsequently became good friends. During the First World War van Emden functioned as intermediary between Freud and Ernest Jones, who was instrumental in introducing psychoanalysis in England, and also arranged for Anna Freud's return to Vienna.

In 1912, after a short training with Freud, van Emden established himself in the Hague as one of the first practicing psychoanalysts there. He was a member of the Vienna Psychoanalytic Society from 1911 to 1914. One of the founders of the Nederlandsche vereeniging voor psycho-analyse (Dutch society for psychoanalysis) in 1917, he was chairman from 1919–1929. In 1934 he became president after the split of the society and the founding of the Vereeniging van psychoanalytici in Nederland (New Dutch society of psychoanalysis).

Van Emden's contributions to psychoanalysis are modest. He was a regular participant in the Congresses of the International Psychoanalytical Association, at which he presented four papers (in 1913, 1918, 1924, and 1925). As a member of the Dutch society for psy-

choanalysis, he gave a number of presentations. He translated two works of Freud into Dutch: *Five Lectures on Psycho-analysis* and *Thoughts for the Times on War and Death*.

## EMMA, CASE OF. See Eckstein, Emma

---

## EMMY VON N., CASE OF

Frau Emmy von N. was the pseudonym given by Sigmund Freud in the *Studies on Hysteria* to his patient Fanny Moser, who was born Fanny Sulzer-Wart in 1848 and died in 1925. In her autobiography her daughter Mentona speaks of “the famous professor that [her] mother went to see in Vienna” (referring to either Josef Breuer or Rudolf Chrobak), who soon referred the patient to “his first assistant,” Doctor Sigmund Freud. “He was small and thin, his hair was blue-black, large black eyes, he looked timid and very young. He made a profound impression on me.” (in Ellenberger, Henri F., 1977).

On May 1, 1889, during her first visit, Freud described his meeting with this forty-year old woman, which would have made her seven years younger than Freud: “This lady, when I first saw her, was lying on a sofa with her head resting on a leather cushion. She still looked young and had finely-cut features, full of

character. Her face bore a strained and painful expression, her eyelids were drawn together and her eyes cast down; there was a heavy frown on her forehead and the naso-labial folds were deep. She spoke in a low voice as though with difficulty and her speech was from time to time subject to spastic interruption amounting to a stammer.” He also noted the clicking sound she made with her tongue when upset.

This intelligent but very anxious patient provided him, without his awareness, with a premonitory indication of the future therapeutic framework when she cried out: “Keep still!—Don’t say anything!—Don’t touch me!” She made use of this incantatory remark on several occasions, whenever she was frightened by some particularly terrifying memory, but Freud, after ten days of therapy, decided to eliminate it through the use of suggestion, which he succeeded in doing.

His treatment was consistent with customary practice, which consisted in her case of a stay at a clinic, separated from her two daughters, with whom she did not get along. Freud prescribed warm baths and massages twice a day. The patient was completely accessible to hypnosis and, in this state, recounted the origin of the delusional fears and visual hallucinations (rats, frogs) from which she suffered, retracing them to her childhood. “My therapy consists in wiping away these pictures, so that she is no longer able to see them before her. To give support to my suggestion I stroked her several times over the eyes.”

The systematic pursuit of her memories enabled Freud to state that the case of Emmy von N. was the first in which he had employed the “cathartic method.” One day, when she was irritated, the patient also made a remark whose practical consequences Freud did not fail to draw. She asked him to stop interrupting her with questions and to allow her to speak freely. At the time Freud still played the role of the grand magician, the antithesis of the future psychoanalytic attitude, and his authority was necessary to erase the patient’s pathogenic memories through the process of suggestion.

It is interesting to note that there exists an 1894 note Freud added to the case history—this still a year before the dream of the injection given to Irma—in which he indicates that he wrote down his own dreams and traced them back to two factors: “(1) to the necessity for working out any ideas which I had only dwelt upon cursorily during the day—which had only been

touched upon and not finally dealt with; and (2) to the compulsion to link together any ideas that might be present in the same state of consciousness. The senseless and contradictory character of the dreams could be traced back to the uncontrolled ascendancy of this latter factor.” Although here is evident a clear glimpse of clinical intuitions that, in retrospect, appear anticipatory, at this point Freud’s therapy continues to be a blend of such “purgative retellings” and electrotherapy.

Freud’s notes stop on June 20 and Emmy von N. apparently left, quite improved, for her château in Switzerland. Freud visited her on July 18, traveling along the road to Nancy, where he was to meet Hippolyte Bernheim.

In January 1890 Emmy had a relapse. She went to see Breuer, complaining of nervous disturbances from which her daughter was suffering and blaming Freud and Chrobak. She was so agitated that they had her admitted to a sanatorium, from which she ended up escaping with the help of a woman friend. No doubt she came to represent one of the cases Freud referred to later to explain why he abandoned hypnosis: “On one occasion a severe condition in a woman, which I had entirely got rid of by a short hypnotic treatment, returned unchanged after the patient had, through no action on my part, got annoyed with me; after a reconciliation, I removed the trouble again and far more thoroughly; yet it returned once more after she had fallen foul of me a second time.” (1916–17a [1915–17])

In May 1890, the anniversary of his first therapy, she came back to see Freud for additional therapy, which lasted eight weeks—until July. She felt better but suffered from mental confusion, “storms in her head,” and insomnia, and the clicking tic and stammering had reappeared. Freud analyzed the origin of the return of these symptoms and again succeeded in eliminating them.

In the spring of 1891 Freud saw Emmy von N. at her home, where he stayed for several days to help resolve the problems she was having with her older daughter. She was feeling better but Freud resumed the therapy to eliminate her phobia of train travel. Because she claimed to be less docile than before, that is less attached to him, he reestablished his authority and his position through his little drama of being a hypnotist, which he exposed with such candor that it is obvious he was entirely unaware of his unconscious motives.

In an addendum that dates from 1924, Freud reports that, several years after this last visit, he met a doctor with whom she had behaved as she had with him: easy to hypnotize in the beginning then irritable and subject to relapses: “It was a genuine instance of the ‘compulsion to repeat.’” He added that around 1920 her elder daughter had written him to request a report, because she wanted to initiate a lawsuit against this “cruel tyrant” who had chased away her two children.

It has become fashionable to question Freud’s diagnoses, and the case of Emmy von N. is no exception: melancholia, schizophrenia, nervous tics, the neurosis of a rich and idle woman, according to the various reports. Although Anna O. alone was successfully treated and managed to create an exemplary life for herself, Henri F. Ellenberger has remarked that it was Emmy’s daughter, Mentona Moser, who benefited from the intellectual and social emancipation her mother never achieved.

## EMOTION

The word *emotion* is derived from the Latin *emovere*, “to set in motion.” It initially referred to the idea of physical movement and then assumed a figurative meaning associated with mental movement.

The term is infrequently used in psychoanalysis, where the term *affect*, derived from German *Affekt*, is preferred. Sigmund Freud, however, in a text written in French in 1895, used the expression “état émotif” (“emotive state”) to designate what was translated in the German editions as *Affekt*. It is with the theoretical developments associated with Kleinian psychoanalysis that the term emotion reappeared. The reasons for the change are significant.

Freudian metapsychology is centered on the study of the mental apparatus, which is considered, if not as an isolated entity, at least as one that can be isolate. In the Freudian model the mental apparatus is charged with drives, whose effects—affect and representation—are observable. Affect corresponds to the quantitative aspects, and mental representations correspond to the qualitative aspects of the drives. Positive affects accompany the satisfaction of drives, negative affects accompany the state of tension within the mental apparatus (pleasure/unpleasure principle). The object of satisfaction, that is, the object that triggers the discharge of the impulse, is contingent, vicarious. For Daniel Widlöcher, the affect refers to internal regulatory functions of the mental apparatus: a discharge of impulses and signals intended to provide information to the mental apparatus, as Freud suggested in his second theory of anxiety, and that emotion adds a third reference, that of communication with the external object, “a modality of expression intended to inform others of a particular situation, laden with value for the subject.”

It should come as no surprise therefore that the theories assigning greater importance to object relations have given a central place to the concept of emotion. Compared to affect, it contains levels of additional complexity, because it is a means of communicative exchange between self and other, through its behavioral (especially facial) expressions, which have been extensively studied by specialists in development and cognitive function, and because it refers to nuanced qualitative aspects rather than simply quantitative aspects combined with a positive or negative valence.

Melanie Klein insisted on the extreme nature of the baby’s emotions at the start of its extra-uterine existence, associated with love and hate relations directed at the (partial) object in what she called the “paranoid-schizoid position.” Later, when the infant achieves the “depressive position,” emotions become more nuanced, hate is tinged with guilt, love with ambivalence. Wilfred Bion gave the concept of emo-

tion an essential role in his description of the intrapsychic world as a world of relations between internal or interiorized objects. For Bion the links between internal objects are emotional links, just as the links between the subject and its external objects are emotional in nature. He chose three types of emotional links: these correspond to love relations (L link = love), hate relations (H link = hatred), and knowledge relations (K link = knowledge). The first two, L and H, are emotional links; these are unstable and associated with splitting. The K link is the psychoanalytic link par excellence and has the advantage of stability. It does indeed involve an emotional link, in the sense that it corresponds to an emotion associated with uncertainty and the tension experienced in the face of the unknown in anticipation of meaning. Psychoanalytic therapy develops K links.

## **EMPATHY**

*Empathy* is the capacity for concrete representation of another person’s mental state, including the accompanying emotions. The English term is a translation of

the German word *Einfühlung*, coined in 1873 by the German philosopher Robert Vischer. Vischer used it to refer to a modality of aesthetic sensibility. In contrast to the theory that categorized objective qualities inherent in the object as beautiful, Vischer described the subjective nature of an experience where beauty resulted from the projection of human sensibilities onto natural objects. Theodor Lipps (1851–1914), a philosopher who taught in Munich, gave *empathy* a broader, psychological range, attributing to this form of intuition access to knowledge of another's subjectivity. It is in this sense, and most likely from reading Lipps, that Sigmund Freud used the term, which was still uncommon at the time.

Freud used the term in a number of his essays. He used it for the first time in *Jokes and Their Relation to the Unconscious* (1905) in relation to the economic explanation of the pleasure associated with humor. He returned to it several times to refer to a form of intuitive understanding of others essential to psychoanalytic communication. For Freud, however, the term had no specific psychoanalytic meaning but rather a general psychological meaning, moreover, one that was still poorly understood. This is likely one reason that James Strachey did not feel the need to propose a single English translation; the other reason being that the term *empathy*, which had already been proposed in 1909 by the psychologist Edward Bradford Titchener and taken up by Ernest Jones, did not generate much enthusiasm from Strachey. In France the term *empathie* came back into use following the publication of the translation of Freud's works under the direction of Jean Laplanche. This resulted in the misunderstanding of a precise concept for Freud, in particular, in his correspondence with Sándor Ferenczi.

The concept did not become important until 1960, when Ralph Greenson studied it, no doubt influenced by the interest in countertransference that occurred after the work of Heinrich Racker and Paula Heimann. Since then a number of studies have emphasized the importance of the concept for communication during analysis. There have been some reservations arising from what was felt to be the somewhat obscure and slightly irrational nature of the phenomenon. Other authors (Buie, 1981; Widlöcher, 1993) have tried to specify the psychological mechanisms operating in this complex form of intuitive understanding, specifically emphasizing the role of identification and inference.

From the metapsychological perspective, the debate continues between those who assign empathy a decisive role in the discovery of the unconscious and the therapeutic activity of the psychoanalyst (Heinz Kohut) and those who deny that empathy can play a role in identifying the unconscious.

## **EMPTY FORTRESS, THE**

The saga of *The Empty Fortress* began in 1952. Two years earlier, in his book *Love Is Not Enough*, Bruno

Bettelheim had reported his first findings concerning the disturbed children in the school he had directed in Chicago since 1944. That book had captured the interest of thousands of Americans. The popularization of psychoanalysis was in full bloom in the United States, and psychiatric research was very much in fashion. High hopes seemed in order: Americans had defeated Hitler; surely they could overcome madness. There was no shortage of research funding, and in 1956, ahead of Anna Freud's Hampstead Nurseries, Bettelheim received a five-year Ford Foundation grant of \$342,500 to finance his study of autism. *The Empty Fortress* is based in part on the reports that Bettelheim submitted to the Ford Foundation each year.

It was hardly automatic that autistic children were referred to Bettelheim's Orthogenic School, which was run like a family home and where diagnostic labels and psychiatric drugs were forbidden. "If you give them drugs," Bettelheim wrote, the children "cannot believe that you really want them to be the way they would like to be. If you manipulate their bodies like that, how could they fail to think that you also want to manipulate their minds?" (personal communication, 1980). After a great deal of discussion with his colleagues, in 1950–1951 Bettelheim finally received a few "children who don't speak" (as their playmates would call them), children whose pathology Margaret Mahler distinguished from other forms of infantile psychosis at the 1951 Congress of the International Psychoanalytical Association in Amsterdam.

The first sentence of Bettelheim's book sums up his credo: "Much of modern psychology seeks to know about others; too much of it, in my opinion, without an equal commitment to knowing the self. But I believe that knowing the other—which is different from knowing about the other—can only be a function of knowing oneself" (p. 3). This was the foundation on which he trained (sometimes very roughly) the educators in his school. The sentiment also illustrates the secret of Bettelheim's remarkable clinical intuition.

While observing the wolf-child-like behavior of little Anna, Bettelheim writes, he was struck by the parallel between his own experience of concentration camps and his therapeutic work (pp. 7–8). Anna had been born in Poland during the Second World War to Jewish parents who did not get along but were obliged to live together, holed up in an earthen cellar and afraid to make the slightest sound. By the age of ten, the little girl, now mute, had almost killed her young brother several times.

No treatment facility would keep her more than a few hours; even a psychiatric hospital had been unable to cope with her for more than a month. In her eyes Bettelheim recognized a terror that he himself could never forget—the terror of someone placed in an environment that seeks to destroy him without his knowing why or whether he will ever escape. Bettelheim had been evoking this "extreme situation" since his article on Buchenwald (1943). In *The Empty Fortress* he defined it, for the first time, as a situation "when we ourselves respond to an external danger—real or imagined—with inner maneuvers that actually debilitate us further" (p. 77). Later he added that in the face of an extreme situation, the individual rejects his normal personality because his ordinary reactions are now liable to place his life in danger (1980, pp. 11, 116). Convinced that, however senseless little Anna's actions might seem, they in fact had meaning, Bettelheim studied her symptoms closely enough to be able to make the striking claim that he was describing autism as if from the subject's point of view.

Traditionally, autistic subjects are characterized in terms of their shortcomings. In *The Empty Fortress*, by contrast, the children are alive and active, and each of their gestures is understood as an attempt to reduce their suffering. The three case histories that Bettelheim recounted in detail, those of Laurie, Marcia, and Joey (the "boy-machine" who could not move or even say hello without first "plugging himself in" with an imaginary cord to an equally imaginary wall-socket), make such a powerful impression on readers that they often forget the first part of the book, "The world of encounter," in which Bettelheim gives an account of the birth and decline of the self.

The first hundred or so pages of the book, permeated with notions of the "self psychology" then being developed by Heinz Kohut, are nevertheless the strongest ever written by Bettelheim on mental illness. They even prompted Donald Winnicott to make the following somewhat ruffled remark: "I find him difficult to read simply because he says everything and there is nothing to be said that one could be certain has not been said by him. But I must read him because he can be exactly right, or more nearly right than other writers. This applies especially to his opening chapters in *The Empty Fortress*" (1989, p. 246n).

This book made Bettelheim famous worldwide; it also defined him narrowly as a specialist of autism. He was partly responsible for this, for he inflated his suc-

cess rate to help quiet his behaviorist opponents. His overriding priority was to give voice to the mental suffering of his patients and remind the medical world of the respect it owed to such suffering. *The Empty Fortress* was in effect a clinical sourcebook, and it had a decisive effect on the evolution of institutional attitudes towards autism.

## ENCOPRESIS

*Encopresis* is the name for problems with control of the anal sphincter after the age when such control is normally acquired (two or three years). The condition may be primary or secondary after a period of continence, and is characterized by bowel movements, usually during the daytime, under socially unacceptable conditions and excluding true incontinence, as produced by organic disorders of the sphincter or its related nerve structures. The term, used in clinical pediatric psychiatry, was introduced by Siegfried Weissenberg in 1926.

A clearer understanding of this symptom can be achieved by considering it in relation to the erotogenicity of the anal zone (Freud, 1905d), with its various components, including excitation of the mucous membranes and the pleasures derived from expulsion and muscular control. Michel Soulé views the erotization of retention as the central phenomenon. Non-renunciation of these instinctual satisfactions is rooted in the individual's conflictual relations with the people surrounding him during the period of toilet training—that is, the anal-sadistic stage, which is focused on issues of possession, on mastery of one's own body, and of others. The child's stools are cathected as a part of his or her own body and as representing internal objects; the subject refuses to give them up for exchange and instead saves them, often owing to a deficiency in symbolization that impedes the displacement of interest onto other objects. Anxiety plays a role, sometimes manifesting itself as a genuine defecation phobia with archaic contents, such as the destruction of internal objects, or the destruction of links, often in connection with the traumatic effects upon the child of intrusive parental fantasies or existential events involving loss.

Symptoms of encopresis can also arise from an inadequate cathexis of the body on the part of a child subject to some forms of deprivation. The secondary gains are proportionate to the involvement of the child's entourage: maintaining regressive ties to the mother; feelings of omnipotence; masochistic gratification. The failure of repression and the non-establishment of reaction-formations attest to the resistance of pregenital fixations to oedipal resolution—the definitive aim of toilet training, according to Anna Freud. Although encopresis can have a bearing on all types of psychopathology in the child, ranging from psychosis or perversion to quasi-normality, Bertrand Cramer has noted that the majority of cases involve neurosis.

## ENCOUNTER

The word *encounter* designates the coming together of two elements, fortuitous or not, that are going to have an impact on each other. This notion is central to the theories of Piera Aulagnier, as it correlates to potentiality (psychotic potentiality). “To live is to experience in a continuous way what results from the situation of encounter,” she wrote in 1975 (p. 2).

The notion of encounter in the wider sense of the word for psychoanalysis concerns everything that has the character of an event, when it seems as if it is not predetermined. Nevertheless, Freud had demonstrated that an event has no sense and meaning, except as a part of a preexisting structure. Therefore the event never has a purely objective meaning, even if it results from an encounter that comes from the outside. Such an event has, in fact, already been shaped by the psyche according to mnemonic traces anterior to the encounter. Piera Aulagnier, however, accorded the notion of encounter a more fundamental meaning, that of a permanent rapport established between the body and the psyche, or between the subject's psyche and that of the mother. The relation between the psyche and the world is born at the time of the primordial event of the encounter.

Aulagnier opted to situate the inaugural encounter at the beginnings of the rapport between the mouth and the breast, a prototype of what she called the “complementary object-zone” (1975/2001, p. 19). “At the moment when the mouth meets the breast it meets and swallows a first mouthful of the world” (p. 15). The representation that the psyche has of itself will be a function of further encounters, either the encounter of the psyche with the body, on the one hand, or with the productions of the maternal psyche on the other.

Nevertheless, every encounter confronts psychic activity with an overload of information, up to the point where whatever was unrecognized returns to refute the representation (for example, the frustration of the real breast being missing, when a presence of the breast has been hallucinated).

This shows why the notion of encounter has been a useful one: It is opposed, in fact, to representations of the mother/infant relation in terms of fusion or dyad. Piera Aulagnier, on the contrary, affirmed that in the two psychic spaces, that of the mother and of the child, “the same object, the same experience of encounter will be inscribed by using two forms of writing and two *heterogeneous* relational schemata” (1975/2001, p. 15).

The notion of the “encounter” is also a necessary complement of “potentiality”, since it is precisely on the occasion of the encounter that potentiality can be actualized. In this context it is close to the notion of the event, when the latter is thought of as a triggering cause. However, in the context of psychosis, Aulagnier proposed a more specific definition of encounter: “The passage from a potential state of identificatory conflict to one that is manifest can result from an encounter that takes place long after childhood is past; an encounter between the subject and another, to whom is imputed the same power, which in childhood was exerted by actors in a reality scene of such a nature that it was not internalized at the time” (1984).

It is evident that the notion of encounter allows Aulagnier to avoid any overly strict determinism, one that would isolate a particular moment, in the subject or family environment, to account for its later psychic destiny.

In one of her last writings, dating from 1990, and so liable to serve as a conclusion, she remarked: “The essence of the relation of cause and effect in the psyche . . . is that it is the effect alone that can make a cause of the event. Now this effect is not fixed once and for all; it is itself the effect of an encounter, to be recalled, renegotiated, reinterpreted by future experiences. Only over the course of a long and arduous work of reinterpretation of lived experiences and past traces can a current experience reactivate things, or the I transform its past—to make of it the source and cause of its present” (1992 [1990]).

## ENRIQUEZ-JOLY, MICHELINE (1931–1987)

Micheline Enriquez, a French psychoanalyst, was born on September 11, 1931, in Châlons-sur-Marne and died in an automobile accident on October 18, 1987, in Vaux-le-Pénil. She spent her childhood and adolescence in Sézanne, where she attended grammar school and high school. She passed her baccalaureate degree in modern literature. In 1949 Enriquez went to Paris to study at the Institut de psychologie (Institute of Psychology), where she obtained diplomas in applied psychology, psychopedagogy, and psychopathology, and at the Sorbonne, where she obtained a certificate in social psychology. She also studied Russian at the École des langues orientales (School of Oriental Languages) and took courses at the Institut d'études politiques de Paris (Paris Institute of Political Studies).

After working with Professor Jean Maisonneuve (social psychology) on the process of affinity and evaluating training activities, she was appointed a psychologist at the mental health clinic of Paris Medical School (under Professor Jean Delay of the Centre psychiatrique Sainte-Anne). She worked with Professors Pierre Pichot, Thérèse Lampérière, and J. Perse, with whom she wrote a study on hysteria. She also worked at the Versailles Hospital.

She underwent her training analysis with Serge Leclair of the Société française de psychanalyse (French Society for Psychoanalysis) before the 1964 split that led Jacques Lacan to found the École freudienne de Paris (Freudian School of Paris).

Her monitor was Piera Aulagnier. She joined the École freudienne at the time of its creation but, at the time of a second split, participated in the creation of the Quatrième groupe, Organisation psychanalytique de langue française (Fourth Group, Francophone Psychoanalytic Organization) in 1969. She served as secretary for analysis and secretary for research before becoming vice president in 1985 and president in 1986. She underwent a second analysis with Serge Videman. For several years she was responsible for teaching projective techniques at the Institut de Psychologie (Institute for Psychology) at the University of Paris.

Enriquez wrote a number of articles in the review *Topique* and in the *Nouvelle revue de psychanalyse*. She was awarded the Maurice Bouvet Prize in psychoanalysis in 1978 for three of her articles: “D'un corps à l'autre: réflexions sur le masochisme” (1971), “Fantasmes paranoïaques: différence des sexes, homosexualité, loi du père” (1974), “Analyse possible ou impossible” (1977a). She contributed an article to *Comment l'interprétation vient au psychanalyste* (1977b) and, in 1984, published *Aux carrefours de la haine*. Her last published work, “L'enveloppe de mémoire et ses trous” (1987), appeared shortly after her death. Two of her essays, “Le délire en héritage” and “Incidence du délire parental sur la mémoire des descendants,” a transcription completed the day before her death, were published in 1993.

As shown by the case studies she wrote, her work is based on her analytic practice and reflects on violence, lethal withdrawal of cathexis, the desire for historical and psychic reality, suffering, and the conditions for harmonious treatment, which, while not excluding the expression of negative affects, can mobilize life impulses and stimulate thought in analyst and analysand alike.

Enriquez provided new insights into paranoia, masochism, and what she referred to, after the Marquis de Sade, as apathy. She showed that paranoiacs and masochists eroticize suffering and hatred, and she found in paranoia and masochism the mechanisms of their object choices. Those who are apathetic reject affect and hatred to distance themselves from others in order to survive. She insisted on the need for the child, when confronted by delusional speech from one of its parents, to negotiate the violence imposed to avoid repeating it. She stressed the importance of a common memory between analyst and analysand, a condition

for remembering to be fruitful and for access to history. For Enriquez, everything that fell within the sphere of love and reciprocity was capable of struggling against the spread of evil that resulted in anger against the self or others.

Enriquez has been referred to as one of the most highly esteemed psychoanalysts in France, where her clinical work and theoretical contributions were highly regarded, independently of her institutional associations. She was a member, since its foundation, of the Association internationale d'histoire de la psychanalyse (International Association of the History of Psychoanalysis). Issue no. 42 of *Topique*, "Mémoire et réalité" (1988), was dedicated to her memory. Her work has been translated into English, Spanish (she is well known in Argentina), Italian, and Greek. Her influence in Brazil continues to remain strong.

## **ENURESIS**

*Enuresis* is incomplete, or total lack of, bladder control in children past the age of four to five years, when bladder control is normally achieved. It is considered primary when a child has never been consistently dry. In secondary nocturnal enuresis, bedwetting begins after a period of adequate bladder control and suggests regression due to such traumatic factors as separation, loss, or illness. Enuresis is distinguished from genuine organic urinary incontinence. Enuretic urination, as a rule, is nocturnal and involuntary. It may be also associated with daytime events.

As a disorder that attracts the interest of a number of medical specialists, enuresis has spawned a variety of hypotheses concerning its etiology. The deep sleep of the enuretic child has been implicated, though without evidence of any unusual sleeping habits, save increased resistance to specific waking stimuli. The bladder capacity of the enuretic child is usually normal, although in some cases an immature bladder has been demonstrated, and this can cause a nocturnal surge in bladder pressure. In a few cases, disorders (or delayed maturation) of circadian rhythms due to secretion of antidiuretic hormones may disrupt, or delay the development of, the normal relationship between diurnal and nocturnal production of urine, and this can produce functional nocturnal polyuria. Finally, studies of families and twins have established a genetic component.

Although psychological and environmental factors have often been investigated, a specific psychological profile for enuresis has not yet emerged. Complicating matters is that relevant factors differ according to whether the symptom is an isolated one or forms part of a more complex clinical picture and a definite psychopathology.

Freud emphasized the libidinal dimension of primary enuresis. Beginning with the case of Dora (1905e [1901]), he interpreted enuresis as a substitute for genital gratification, noting consistent links between enuresis and fire, a theme that he discovered in dreams as representative of frightening, aggressive, or erotic drives. As the gratification of an organic need, Freud suggested, urination counts as one of the autoerotic and infantile pleasures; the infant renounces it only with reluctance under the pressure of toilet training (1916–1917a [1915–1917]).

Even if this classical conception must be viewed today in connection with other considerations, psychotherapy of enuretic children often demonstrates the

relevance of Freudian intuition. Gérard Schmidt and Michel Soulé (1985) stress the significance of primary enuresis in the libidinal economy of the enuretic child, together with various direct instinctual gratifications that indicate continued and persistent eroticization of urination. Gains in controlling secondary enuresis are correlated with reactions of the child's caregivers and the availability of other means of gratification.

The study of the psychological factors involved in enuresis must take into account several factors implicated in successful toilet training: (1) the gradual maturation of control over the somatic functions, with individual inborn variations; (2) the affective investment in excretory functions in different stages of libidinal development; and (3) interactions with the environment, ranging from the child's privileged relationship with its mother to familial and social customs concerning the child's acquisition of sphincter control.

## **ENVY**

Envy is a primitive force in the personality that is opposed to, and therefore mounts destructive attacks

upon, parts of the object felt to be good. It attacks aspects of the libido—love, constructiveness, integration—simply because of their life-giving characteristics. This notion first appears in *Envy and Gratitude* (Klein, 1957).

Freud was uncertain about the clinical usefulness of the concept of the death instinct. Klein found ways of showing its clinical relevance, especially in her work with children. The primary destructive force, the death instinct, aims at destroying the ego. Freud (1926) recognized that the ego needs to escape this very early experience of threat, and that it can do so by projecting the death instinct outwards. Thus the ego contrives to see the danger to itself as coming from external objects. This danger may then coincide, he thought, with some real external threat. As Klein (1932) added, the external object may be a harsh critical parent (then internalized as a persecuting superego). Then the external enemy can be attacked, as can other aspects of the death instinct turned against an external object. In both these processes of establishing outwardly directed impulses, the libido may fuse to some degree with the death instinct.

Later and in contrast with the above, Klein described a very different manifestation of death instinct: primary envy. In this instance the destructive force is directed against an external object that is not a threat but a good object, typically the mother's breast, which feeds and comforts. To the external good object is attributed a wish for life and a wish to preserve life in the ego. In this case, the good object represents a part of the libido projected into an external object. And it is attacked there by impulses derived from the death instinct now turned away from the ego itself. The death instinct, directed against those (libidinal) parts of the ego concerned with the wish to live, remains a destructive force against them when they are projected. Klein's view is a generalization and extension of Freud's notion of penis envy.

Klein developed the idea of the death instinct in terms of relations to the object and to the self. Rosenfeld (1971) described states in which the ego is dominated by aspects of the death instinct. Since Freud's theory of the death instinct was never fully accepted, Klein's idea of envy was also contentious (Joffe, 1969). Envy represents a primary kind of evil, and it is difficult often to accept such a state in an innocent infant.

Others have attributed aggression in infancy and childhood to frustration of libidinal impulses. Wilfred

Bion described paroxysms of aggression arising in infants when an infant's insistent projection meets an uncontainable mother frightened by the infant's fear of death. Here the anger of frustration can appear much like envy.

## **ENVY AND GRATITUDE**

*Envy and gratitude* is the last of Melanie Klein's major contributions to psychoanalytic theory. She presented a paper, "A study of envy and gratitude," at the Geneva International Congress of Psycho-Analysis in 1955. This was later expanded into a short book for publication in 1957.

From her first publications Melanie Klein reported that a major source of anxiety from the beginning of life is destructiveness. At first she was interested in aggression and the paranoid cycles of fear and violence as the origins of anxiety (Klein, 1929a). Later she understood anxiety in terms of damage to internal objects (the depressive state), which then gave rise to guilt (Klein, 1935). Still later she understood self-directed aggression, in the form of splitting and fragmentation of the ego itself, to arise from the death instinct (Klein, 1946). The ego, as it begins to develop, protects itself from its inherent self-destruction by an

immediate projection onto an external object of that destructiveness toward the life-affirming side of the ego (Klein, 1932).

Finally, in 1957 she developed a new understanding. Envy projects onto an external object the affirmation of life and attacks it there. Envy, which Klein referred to as "primary envy," is an attack on life itself in the form of an external object that represents the wish to keep the ego alive and hence on which the ego is utterly dependent. Those attacks are achieved, in fantasy, by the very earliest methods available to the infant: orally scooping out the good object, the mother's breast. She believed that primary envy is the process underlying other forms of envy, including penis envy.

The consequence for the infant is that it has difficulty in finding a good object in the external world that, when introjected, can be definitely and stably good to the ego. However, there is also the libido, and in its earliest form, it too relates to the external source of life in a powerful surge of feeling that Klein later called "gratitude."

Envy, however, causes trouble and leaves potentially disturbing traces in the later personality. For this reason, Klein and her colleagues subsequently concentrated on envy. Klein regarded envy as such an early and primary mode of defense against the self-destruction of the death instinct as to be a constitutional, or innate, reaction.

With this stand she called down great criticism on herself. The death instinct was always contentious; Freud regarded it as silent. A primary source of aggression against objects was held by many to be unnecessary, as frustration of libido was a sufficient source and explanation. And many, perhaps most, analysts found it impossible to conceive of a bounded ego operating in relation to a clearly defined external object. Throughout her career Klein had had to confront disbelief of her observations on violence and aggression in children. To postulate innate violence as the first force preoccupying the infant redoubled that disbelief.

The publication of these contentious ideas came, ironically, at a time when Klein might have felt satisfied that her psychoanalytic work was becoming appreciated. After the controversial discussions with Anna Freud in the early 1940s, the group of her close associates and colleagues had been reduced to a handful, with a number of students. By 1952 her views had

survived, and her papers from the controversial discussions were published in book form. Her ideas had also developed enormously with experimental work on the psychoanalysis of schizophrenia.

Colleagues marked her seventieth birthday with a festschrift containing the papers of fifteen contributors apart from herself (Klein et al., 1955). At this moment of success her new book on envy (1957) brought more setbacks. The pace of her ideas had gone so fast that many followers became increasingly reserved about their support. Paula Heimann (1962) and Donald Winnicott (1965) made a distinct break from Klein at this time. In contrast, those who remained loyal to Klein fervently embraced the idea of envy.

From then to the present (2004), allegiance to the concept of envy has been a kind of badge of membership in the Klein group within the British Psycho-Analytical Society. Because of these group allegiances, the concept has been seriously studied only by Klein's followers.

---

## ERIKSON, ERIK HOMBURGER (1902–1994)

Erik Homburger Erikson, American psychoanalyst, was born on June 15, 1902 in Frankfurt-am-Main, and died on May 12, 1994, on Cape Cod, Massachusetts.

Erikson was the son of a Danish mother and unknown father. His step-father was a German pediatrician in Karlsruhe, and after Erikson left home his mother and step-father, both Jewish, moved to Palestine. In Vienna, Anna Freud became Erikson's analyst in 1927, and he graduated as a child analyst from the Vienna Psychoanalytic Institute in 1933. Artistically inclined, Erikson said that he was first attracted to Freud's ideas by the magnificence of his German prose.

He entered Freud's circle in the summer of 1927, when he was working as a painter of children's portraits without any firm professional goals. An old school friend was at that time the director of a small progressive school in Vienna run by Dorothy Burlingham and Eva Rosenfeld, both close friends of Anna Freud.

Most of the children at the school were in psychoanalytic treatment, and a number of the parents were undergoing analysis. Erikson was hired to paint the portraits of the four Burlingham children. After a brief period as a tutor, Erikson was asked whether he would consider becoming a child analyst—a profession he had not heard of before.

By the end of 1933 Erikson had settled in Boston, Massachusetts. He worked in private practice as a

child analyst, the first male in that field. He also was associated with the Harvard Psychological Clinic under Henry A. Murray, and did research at Yale. In 1939 Erikson became an American citizen, changing his name from his step-father's Homburger to the self-created Erikson. Later he moved to Berkeley, California where he became one of the founders of the San Francisco Psychoanalytic Society. After a 1951 loyalty oath controversy at the height of the McCarthy period, Erikson resigned from the University of California and moved to the Austin Riggs Center in western Massachusetts. In 1960 he accepted a prestigious university professorship at Harvard College.

Always uncomfortable in academic life, since he himself was without any formal training aside from being an analyst, Erikson retired from Harvard in the early 1970s to return to California where he worked at the Mt. Zion Department of Psychiatry in San Francisco. In 1987 he returned to Cambridge, Massachusetts where an Erikson Center was established under Harvard's auspices. Erikson's final days were spent at a nursing home at Harwich on Cape Cod, near Cotuit where he and his wife Joan had long had a summer home.

Erikson's *Childhood and Society* first came out in 1950, and was reprinted more than any of his other books. *Young Man Luther* (1958) was a study in psychoanalysis and history, as Erikson treated Luther as an innovative psychologist whose Christian teachings complemented those of classical analysis. While *Identity and the Life Cycle* (1959) was a collection of his papers on ego psychology. *Insight and Responsibility* (1964) was a set of papers on the ethical implications of psychoanalytic insight. *Gandhi's Truth* (1969), a prize-winning book, sought the origins of militant non-violence in Gandhi's life. Erikson also gave the 1973 Jefferson Lectures in the Humanities, which appeared as *Dimensions of a New Identity* (1974). *Life History and the Historical Moment* (1975) was another collection of essays, and so was *A Way of Looking at Things* (1987).

Erikson used his concept of ego identity in order to move psychoanalytic theory away from Freud's libido approach; Erickson saw society as a constructive source of ego strength. Erikson also developed the notion of psychohistory as part of his effort to bring psychoanalysis into the modern social sciences.

## **EROS**

In ancient Greece the word *Eros* referred to love and the god of love. In his final theory of the drives, Sigmund Freud made Eros a fundamental concept referring to the life instincts (narcissism and object libido), whose goals were the preservation, binding, and union of the organism into increasingly larger units.

Eros the unifier is opposed to, and yet was blended into, the death instinct, an antagonistic force leading to the destruction, disintegration, and dissolution of everything that exists. "In this way the libido of our sexual instincts would coincide with the Eros of the poets and philosophers which holds all living things together" (Freud, 1920g, p. 50).

The term *Eros*, understood as a life instinct antagonistic to the death instinct, appeared for the first time in *Beyond the Pleasure Principle* (1920g), where Freud used it to establish a dynamic polarity that would define a new instinctual dualism. Freud wrote, "Our speculations have suggested that Eros operates from the beginning of life and appears as a 'life instinct' in opposition to the 'death instinct' which was brought into being by the coming to life of inorganic substance. These speculations seek to solve the riddle of life by supposing that these two instincts were struggling with each other from the very first" (p. 61). In this essay Freud refers to the doctrine of the Greek physician and philosopher Empedocles of Agrigento

(c. 490–430 B.C.E.), for whom the production of all things results from the interplay of two forces, Love and Discord, conceived of as the impersonal forces of attraction and repulsion.

Yet Freud's theoretical innovation is more than the pure speculations of philosophy, biology, or physics. Revision of his concepts was called for by his experience in psychoanalytic practice. He posited within the organism a primal masochism derived from the action of the death instinct to account for certain clinical problems: ambivalence in affective life, nightmares associated with traumatic neurosis, masochism, and negative therapeutic reactions.

Freud's uses of the term *Eros* (86 of 88 occurrences, according to Guttman's *Concordance*) is contemporary with his final theory of the instincts developed after 1920. The word itself, with its multiple meanings, enabled Freud to combine many things that he had previously separated and contrasted: love between the sexes, self-love, love for one's parents or children, "friendship and love among mankind in general," "devotion to concrete objects and abstract ideas," and partial sexual drives (component instincts). This expanded concept of love led Freud to evoke, on several occasions (1920g, 1921c, 1924c, 1925e [1924]), "the all-inclusive and all-preserving Eros of Plato's *Symposium*" (1925e, p. 218).

Although the concept of Eros, properly speaking, emerged late in Freud's work, this did not prevent him from claiming that all his earlier discoveries about sexuality can be seen in terms of Eros. Psychoanalysis showed that sexuality did not conceal "impulsion towards a union of the two sexes or towards producing a pleasurable sensation in the genitals" (1925e, p. 218), and that sexuality was thus different from genitality.

Though the term *Eros* does not appear in the original texts, two notes, one from 1925 in *The Interpretation of Dreams* (1900a) and the other from 1920 in *Three Essays on the Theory of Sexuality* (1905d), reinforce the use of "Eros" as a synonym for "sexual" in the discovery of psychoanalysis: "The situation would be different if 'sexual' was being used by my critics in the sense in which it is now commonly employed in psychoanalysts—in the sense of 'Eros'" (1900a, note 1925, p. 161). Freud even justified his failure to use the word earlier: "Anyone who considers sex as something mortifying and humiliating to human nature is at liberty to make use of the more genteel expressions 'Eros'

and 'erotic.' I might have done so myself from the first and thus spared myself much opposition. But I did not want to, for I like to avoid concessions to faintheartedness. One can never tell where that road may lead one; one gives way first in words, then little by little in substance too" (1921c, p. 91). Occurrences of the terms "Eros" (after 1920) and "eroticism" (after 1894) overlap in Freud's writings without ever leaving the field of sexuality.

Freud early on recognized the erotic character of repressed representations that lie at the heart of neurotic symptoms. He cites "the case of a girl, who blamed herself because, while she was nursing her sick father, she had thought about a young man who made a slight erotic impression on her" (1894a, p. 48), and who is then constrained to treat this unwanted representation of a sexual nature as if it had "never occurred." Freud conceived mental conflict as a moral conflict in which the troublemaker Eros stirs up trouble in the form of a symptom. He saw sexuality as a trauma that goes far beyond the well-known scenes of sexual seduction. Eros forces the ego to defend itself and thus participates in the division and fragmentation of the psyche. Repressed erotic representations later return in the form of symptoms or compromise formations that substitute for sexual activity or "precipitates of earlier experiences in the sphere of love" (1910a, p. 51). Such instances of deferred or aborted love are remote from sexual attraction and genital activity. Sexuality exists from infancy, is fundamentally perverse and polymorphous, and consists of a bundle of partial sexual drives that seek satisfaction independently of one another, in autoerotic fashion. The oral drive, for example, is seen as a mouth that kisses itself.

The 1920 footnote in *Three Essays on the Theory of Sexuality* retroactively referring to Eros (1905d, p. 266n) serves Freud's theoretical interests: to recognize infantile sexuality as something distinct from genitality, to emphasize the diphasic nature of sexual life, and to provide the concept of the drives with a mythical status, infantile in appearance and dominated by an ongoing and insatiable quest. Here Eros appears to conflict with the ego's instinct for self-preservation. The Oedipus complex determines the outcome of this conflict through the possibilities it offers for orienting the libido toward a sexual object (one that is no longer only sexual) by means of the phallus. The Oedipus complex is responsible for ensuring that the subject becomes satisfied in love after the reorganization at puberty, when the partial

drives (component instincts) are enlisted in the service of an organized genital apparatus. Failing this, the subject will fall ill unless an alternative object is found through sublimation.

Eros is not only a cause of symptoms but can also become the means for their relief. The theoretical model of Eros as healer is beautifully illustrated in *Delusions and Dreams in Jensen's "Gradiva"* (1907a [1906]).

Love was also at the center of the psychoanalytic experiment from the time of its initial discovery via transference. In the middle period of the development of psychoanalysis (1912–1915), the homage to love in *Delusions and Dreams* would butt up against its limitations in a theory of transference, which shows love to support resistance to remembering, and hence to analysis. Moreover, Freud discovered in cases of sexual impotence of psychological origin that a conflict exists between the “affectionate current” and the “sexual current”: “Where they love they do not desire, and where they desire they cannot love” (1912d, p. 183). This text anticipates Freud’s comments in “On Narcissism: An Introduction” (1914c). In this text, Freud saw the narcissistic libido as conflicting with erotic love of the object: Narcissus versus Eros. The ego claims a place among the sexual objects, and the self-preservation instincts have a libidinal nature. What distinguishes Eros is its link with objects: “A strong egoism is a protection against falling ill, but in the last resort we must begin to love in order not to fall ill, and we are bound to fall ill, if, in consequence of frustration, we are unable to love” (1914c, p. 85).

*Beyond the Pleasure Principle* (Freud, 1920g) overturned these earlier constructions. The theory of a death instinct, which worked in silence, forced Freud to combine the ego instincts and sexual instincts directed at objects, grouping them under the umbrella of a single force whose goal was union: Eros. Such an Eros is no longer a troublemaker, a divisive agent that disturbs the mental apparatus. It is the power of creation, of reproduction; it makes existence possible and postpones the return to an inorganic state. When discussing the life-preserving sexual instincts (object libido and ego), Freud explicitly refers to the myth of Eros recounted by Aristophanes in Plato’s *Symposium*. But the life and death instincts rarely come into play in isolation: They form various amalgams in which each attempts to make use of the other’s strength to its own advantage. Freud shows that moral masochism, for example, “becomes a

classical piece of evidence for the existence of fusion of instinct. Its danger lies in the fact that it originates from the death instinct and corresponds to the part of that instinct which has escaped being turned outwards as an instinct of destruction. But since, on the other hand, it has the significance of an erotic component, even the subject’s destruction of himself cannot take place without libidinal satisfaction” (1924a).

In Freud’s last work, it is as if the scandal of the discovery of sexuality was displaced in favor of the theoretical innovation of the death instinct. Eros as the embodiment of Aristophanes’ myth or Empedocles’ theories appears to get the better of Eros as the embodiment of desire, an Eros whose birth is given in the myth recounted by Diotima in *The Symposium*.

Jacques Lacan distances, without completely separating, love and desire (Eros). Love is the mirage in which desire is caught. The phallus is the fulcrum between the object that gives rise to desire and the part of the subject, minus language, that is forever lost. “Therefore, to love is to give what one does not have, and we can only love by acting as if we don’t have, even if we do” (Lacan, 1991).

## EROTICISM, ANAL

The term *anal eroticism* is defined as sexual pleasure predominantly linked to the excitation of the anal sphincter and the functions of excretion in infancy.

In his correspondence with Wilhelm Fliess, Freud observed that sexually-based emotional discharges originating in the anal region, like those in the mouth and throat, had ceased by the time the normal person reached adulthood (letter of November 14, 1897, 1950a). He continued, “the memory of [stimulation] will produce by deferred action ... not a release of libido but of an unpleasure” (p. 269). In January of 1898, he sent his friend a summary of his “*Drekkologie*” (1985c [1887–1904], p. 291), a neologism that he coined during his self-analysis to designate the science of filth.

In his *Three Essays on the Theory of Sexuality* (1905d), Freud described how the child’s sexual activity could be anaclitically supported by the anal zone: sexual activity in the infant is propped up by another physiological function, namely defecation; this occurred in accordance with Freud’s general conception of anaclitic erogenous zones. There were, in his view, three erogenous zones that could thus prop up physiological functions: oral, anal, and genital. Freud noted that to a certain degree the excitability linked to these zones could remain connected to genitality throughout life. The human sexual drive was thus a highly complex mechanism, produced by the contributions of numerous components, of partial drives. One of those components was anal eroticism, which defines one of the pregenital organizations of the libido. Freud wrote that “The playing of a sexual part

by the mucous membrane of the anus is by no means limited to intercourse between men: preference for it is in no way characteristic of inverted feeling” (1905d, p. 152). He thus initiated all the psychoanalytic research that would later define the role of anal masturbation in relation to the constitution of the ego in both men and women.

In “Character and Anal Erotism” (1908b), Freud described a specifically anal character. As with all other elements of eroticism, a part of the excitation contributes to sexuality while another part was diverted from sexual aims and directed towards other ends by the process of sublimation. He recognized the traits of the anal character (orderliness, parsimony, and obstinacy) as the results of the sublimation of anal eroticism. In particular, the way of handling money merges with psychic interest in excrement, the product of the anal zone.

Freud suggested in a letter to Sándor Ferenczi that anal eroticism might have the same relation to hypochondria as sadism did to obsessional neurosis. In “The Disposition to Obsessional Neurosis” (1913i), he suggested that the passive current of sexuality was fed by anal eroticism, while activity coincided with sadism. The accentuation of anal eroticism during the pregenital stage of organization could predispose a man, in the genital stage, to homosexuality.

Within the framework of a discussion of stages of the libido, anal eroticism was at the center of the dialogue between Freud and Karl Abraham. Their common research led to Freud to write, among other essays, “Mourning and Melancholia” (1916–1917g [1915]). One of melancholia’s striking characteristics derives from an anal eroticism which is torn from its connections and regressively transformed. For Freud, the regression connected with this illness allowed him to discover the importance of anal eroticism and its involvement with relationship to the object, whether this was expressed in terms of retention or expulsion.

Freud’s writings on narcissism and object relations were clarified by this insight. In his article “On Transformations of Instinct as Exemplified in Anal Erotism” (1917c), he hypothesized that defecation provided the infant with its first opportunity to choose between a narcissistic attitude and one of object-love. Stubbornness and obstinacy came from the narcissistic persistence of anal eroticism. The stool was the object of a loss that gave rise to feelings of ambivalence. Toilet

training supplied a model for object relations, for the ego latched on to this experience, which would color its future relationships. Later Freud theorized, in *Civilization and Its Discontents* (1930a), that “Anal erotism . . . succumbs in the first instance to the ‘organic repression’ which paved the way to civilization” (p. 100n).

Anal eroticism and its links with introjection and projection were studied clinically by Karl Abraham. According to him, each of the two early stages of psychosexual development, the oral and the anal, included a substage. The ambivalence arising during the second, oral-sadistic substage of the oral stage was reinforced during the immediately following anal-sadistic substage (Abraham, 1924/1949). Freud later (1933a [1932]) adopted Abraham’s substages, characterizing the first as destructive and the second as possessive and conservative with respect to the object.

The work of Abraham and Freud made it possible to understand how “the fear of becoming poor . . . is derived from anal erotism” (1917e, p. 252). This idea inspired Melanie Klein (1935) when she conceptualized the tendencies to idealize and denigrate of the object, and also the manic defenses related to such regressive states that would eventually define her notion of a paranoid-schizoid position.

Ernest Jones (1918), for his part, took up the connections between anal erotism and the capacity for concentration as the origin of thought. Leonard Shengold (1985) asserted that an excess of control prevented anal erotism from being manifested. This excess was dehumanizing because of links that forced narcissism and anal erotism into a deobjectalizing regression.

Note that anal eroticism should be seen in relationship with the mastery of the ego functions and with the mastery wielded over the object as separate from the subject. André Green (1993/1999) has considered the importance of primary anality for subjectivation and its influence on the object relation.

## EROTICISM, ORAL

Sexual pleasure that is linked predominantly to the excitation of the oral cavity and the lips, first experienced through an infant’s feeding, is defined as oral eroticism.

Freud spoke of the “oral sexual system” as early as his letters to Wilhelm Fliess (letter of January 3, 1897, in 1950a, p. 222). Sucking was from then on considered as a sexual activity, and the lips, together with the surrounding area, as the oral erogenous zone. The sexual drive acquires an autonomy vis à vis the vital functions (nutrition) which support it, and satisfies itself in autoerotic fashion. Freud remarked that this

excitability may remain, to a certain degree, linked to genitality. The human sexual drive can appear therefore as a highly complex montage, born of the confluence of numerous factors, some of which are drives known as “partial,” which at the beginning were independent.

One of the components of the pregenital organization of the libido, consequently, issued directly from oral eroticism. In *Three Essays on the Theory of Sexuality* (1905d), Freud distinguished between two pregenital phases: the oral or cannibal phase and the anal-sadistic phase. He added: “[During the oral phase] the sexual aim consists in the incorporation of the object—the prototype of a process which, in the form of identification, is later to play such an important psychological part” (p. 198). This constituted, therefore, a way of relating to the object (note of 1915).

In his article, “Mourning and Melancholia,” (1916–1917g) Freud described identification as a “preliminary stage of object-choice, that it is the first way—and one that is expressed in an ambivalent fashion—in which the ego picks out an object” (p. 249). It would like to incorporate the object, and that by way of devouring it. Therefore in the phase of the oral organization of the libido, the loving attachment to the object still coincides with the annihilation of the latter, as Freud affirmed in *Beyond the Pleasure Principle* (1920g).

In “The Economic Problem of Masochism,” (1924c) he emphasized that the existence of masochism is expressed erogenously, in all phases of libido development; erogenous masochism often changes its psychic dress. So, “The fear of being eaten up by the totem animal (the father) originates from the primitive oral organization” (p. 165).

Karl Abraham, in “A Short Study of the Development of the Ego, Based on an Analysis of Mental Problems” (1924), said that sadistic drives always have a special affinity with anal eroticism, rather than oral eroticism.

In terms of relation to the object—the mother—from the point of view of the child, never gave enough milk; it is “as though they had never sucked long enough at their mother’s breast,” said Freud in his article, “Female Sexuality” (1931b, p. 234). Taking up the conclusions of Karl Abraham of 1924, Freud conceived of two stages in the oral phase, one pre-ambivalent regarding the breast, the second oral-sadistic; linked to the development of dentition and characterized by the appearance of ambivalence, which will be intensified in the following phase, that of anal-sadism (1933a).

Melanie Klein would later connect an oral fixation, in both sexes, to sucking the father’s penis, with the exacerbated phase of sadism.

## EROTICISM, URETHRAL

Urethral eroticism is characterized by pleasure associated with micturition (or urination). In “Character and Anal Erotism” (1908b), Freud wrote, “We ought in general to consider whether other character-complexes, too, do not exhibit a connection with the excitations of particular erotogenic zones. At present I only know of the intense ‘burning’ ambition of people

who earlier suffered from enuresis" (p. 175). In "Fragment of an Analysis of a Case of Hysteria" (1905e [1901], p. 74), Freud emphasized the pleasure and erotic significance of micturition and considered enuresis as equivalent to masturbation. In his *Three Essays on the Theory of Sexuality* (1905d), he specified that urethral eroticism occurs more particularly in the "second phase of infantile masturbation," the phallic phase.

In "Character and Anal Erotism" (1908b), Freud returned to the idea that enuresis is the source of intense ambition. The character traits that persist are either the unchanged continued primal drives or their sublimation, or reaction formations that conflict with primal drives. Freud emphasized the connections between urethral eroticism and ambition in *Civilization and Its Discontents* (1930a [1929]) and between fire and genital eroticism in "The Acquisition and Control of Fire" (1932a).

In "The Narcissistic Evaluation of Excretory Processes in Dreams and Neurosis" (1949), Karl Abraham later pursued a similar line of thought when he noted that subjects inclined to urethral eroticism have a sense of unlimited power, believing that they can create or destroy any object.

In "Early Stages of the Oedipus Conflict" (1928), Melanie Klein emphasized a specifically urethral form of sadism in which fantasies contribute to difficulties of sexual potency in men and unconsciously help attribute a cruel role to the penis.

## EROTOGENIC MASOCHISM

Erogenic masochism is the primary, biological, and constitutional masochism that results from libidinal excitation, which provides the physiological basis. It is the psychic superstructure that supports the other forms of masochism, feminine and moral, that Freud described along with it in "The Economic Problem of Masochism" (1924c).

In *Three Essays on the Theory of Sexuality* (1905d) Freud noted that "it may well be that nothing of considerable importance can occur in the organism without contributing some component to the excitation of the sexual instinct" (pp. 204–205). Earlier, he had specified that in the case of pain, in particular, a quantitative factor was added to the qualitative factor characteristic of the erotogenic zones.

Freud explained in "The Economic Problem of Masochism" that erotogenic masochism, as "pleasure in pain," subverts the pleasure principle, which would otherwise tend toward the zero excitation characteristics of the Nirvana principle and would be "entirely in the service of the death instincts" (p. 160). He further elaborated that the portion of the death instinct that the libido has not diverted outward toward objects remains inside the organism and "with the help of the accompanying sexual excitation . . . becomes libidinally bound there. It is in this portion that we have come to recognize the original, erotogenic masochism" (pp. 163–64). It is thus vestigial evidence of the earliest fusion of the instincts, which, by a kind of assimilation, binds the essential core of the death instinct that continually threatens the individual's existence.

According to Freud in this essay, erotogenic masochism is present in all of the developmental phases of the libido: the oral stage, as manifested in the "fear of being eaten up by the totem-animal (father)" (p. 165);

the anal-sadistic stage, especially with the erotogenic role of the buttocks (the wish to be beaten by the father); the phallic stage, as shown by the traces of (disavowed) castration in masochistic fantasies; and finally the genital stage, in “characteristically female” situations, namely, “being castrated, or copulated with, or giving birth to a baby” (p. 162).

It can be noted that in this libidinal sequence, Freud mentioned only the father as the object of masochistic desire, including during the oral stage, when this is manifested in the form of a defense—the fear of being devoured—whereas it is the wish to be beaten that is used as an example for the following stage. This attests to Freud’s difficulty in conceptualizing early relations, including masochistic ones, with the mother. However, the fact that he was dealing with early developmental stages is not what caused the difficulty, as he did not hesitate at the time, in 1924, to posit erotogenic masochism as being primary in psychic life.

Melanie Klein did not concur with this explanation, which construed anxieties about being devoured in terms of an erotogenic masochism that would cause the subject to wish for them. Given her emphasis on projection onto an object, conceived as present almost from the outset—and despite both her taste for the archaic and her agreement with the second theory of the instincts—she theorized them as anxieties about retaliation for oral sadism, in a view that is thus closer to secondary masochism, the existence of which, moreover, Freud recognized.

## **EROTOGENIC ZONE**

Any part of the body susceptible of becoming excited, of being a seat of pleasure, is an erotogenic zone. Freud nevertheless used the term to refer primarily to a num-

ber of specific areas, notably, the genitals, mouth, and anus. These zones he saw as locations of particular instincts known as “component instincts.” In neurosis, on his account, nongenital erotogenic zones come to function as substitutes for the genitals. The idea of erotogenic zones was inseparable from the theory of libidinal stages, each of which, at a certain age, is fixed upon a particular zone.

Freud found support in the work of the pediatrician S. Lindner for his assertion that the child pursues the kind of sucking that develops anaclitically from feeding at the breast, for the pleasure obtained from excitation of the oral erotogenic zone. “The child’s lips, in our view, behave like an erotogenic zone, and no doubt stimulation by the warm flow of milk is the cause of the pleasurable sensation” (1905d, p. 181). Sexual activity centered on an erotogenic zone rests first on its utility for self-preservation but is subsequently repeated independently of that function. Erotogenic zones are thus seen as the source of the sexual instinct, its place of origin, and (for the appropriate instinct) its place of residence.

Freud nevertheless broadened his definition of an erotogenic zone well beyond its original link with a bodily function, noting that “any other part of the skin or mucous membrane can take over the functions of an erotogenic zone, and must therefore have some aptitude in that direction” (1905d, p. 183). An area may be affected by chance as the child explores the body and discovers its potential for pleasure through an association with the simultaneous pleasure of sucking. For the adult who represses the sexual nature of the genitals, this opens up the regressive possibility of instating any part of the body as an erotogenic zone. In this case, hysterogenic zones present the same characteristics as erotogenic ones.

How is pleasure produced at the level of the erotogenic zone? The pressure of the need for satisfaction, which is of central origin, is projected outward, stimulating a peripheral erotogenic zone, whose manipulation, in a manner analogous to sucking on the breast, relieves the feelings aroused and so generates satisfaction. The erotogenic zone may also be stimulated directly, in which case it by itself creates a need, which, to be satisfied, calls for further stimulation of the zone in question.

Each particular erotogenic zone (the mouth, anus, genital organs) is wedded to a habitual stimulation

that will vary according to the life stage reached. Like the labial zone before it, the anal zone is eroticized by means of an anaclitic dependence on a corresponding bodily function, in this case excretion. The genital zone (the penis in the case of a boy, the clitoris in that of a girl) first becomes erotogenic through an anaclitic relationship with the function of micturition, the first sexual excitation of this zone constituting the point of departure for a normal sexual life. Freud (1908b) associated specific character types with adult fixations on the erotogenic nature of this or that zone.

The sexual life of early childhood is not confined to the stimulation of erotogenic zones, for so-called component instincts can emerge independently of those zones. The instinct to see and be seen, even though it is not autoerotic in nature and calls for an outside object, may turn the eye into the equivalent of an erotogenic zone. Likewise, the cruelty component of the sexual instinct, which seems at first even more independent of the erotogenic zones, is in fact linked to the instinct for mastery and to the musculature. By contrast, the skin of the buttocks, because of the chastisements it so often receives, can easily become an erotogenic zone and the site of passive masochistic pleasure.

With the introduction of narcissism, Freud added an important dimension to the theory of erotogenic zones by joining it with the ego-libido: "We can decide to regard erotogenicity as a general characteristic of all organs and may then speak of an increase or decrease of it in a particular part of the body. For every such change in the erotogenicity of the organs there might then be a parallel change of libidinal cathexis in the ego" (1914c, p. 84). The withdrawal of libido into the ego and the libido's cathexis of organs, as erotogenic zones now become painful and sensitive, may be thought to underlie hypochondria, and in such cases of hypochondria, health can be restored only by redeploing libido to objects external to the subject's own body.

The erotism aroused in these zones is essentially polymorphous in the young child. Save in the case of perversion, the child's erotism is later unified under the primacy of the genital zone, but the fate of this infantile sexuality varies: repressions, reaction-formations, and sublimations come into play as ways of dealing with the excitations emanating from the erotogenic zones, excitations that are normally unusable, or largely unusable, for the adult. In such cases, the instinctual object of the drive is often modified. Sándor Ferenczi (1916) showed, for instance, that an interest in money was founded on

the anal erotogenic zone and the possibility of establishing a symbolic link between feces and money.

In this light, and in view of the potentially infinite number of transformations of instincts deriving from the erotogenic zones, it is fair to say that any form of human activity might be attributable to erotogenic sources. The psychoanalytic theory of the erotogenic zones appears to fall under the rubric of autoerotism, for it is the component instincts, independent of these zones, that are said to be directed straight at the object. Yet, as has often been pointed out, it would seem impossible to dissociate the emergence of these multiple erotogenic zones from pleasure-generating encounters with the object, especially in the context of maternal care.

It is worth mentioning that theorists since Freud have considered other erotogenic zones, such as those that affect the functions of respiration and hearing.

## **EROTOGENICITY**

The term *erotogenicity* designates the capacity of any part of the body, whether muco-cutaneous surfaces or internal organs, to become the site of sexual excitation.

Rarely used by Freud, the term first appeared in "On Narcissism: An Introduction." (1914c) Freud

wrote: "Let us now, taking any part of the body, describe its activity of sending sexually exciting stimuli to the mind as its "erotogenicity," and let us further reflect that the considerations on which our theory of sexuality was based have long accustomed us to the notion that certain other parts of the body—the "erotogenic" zones—may act as substitutes for the genitals and behave analogously to them. We have then only one more step to take. We can decide to regard erotogenicity as a general characteristic of all organs and may then speak of an increase or decrease of it in a particular part of the body. For every such change in the erotogenicity of the organs there might then be a parallel change of libidinal cathexis in the ego" (p. 84).

This term *erotogenicity*, or *erogeneity*, appeared contemporaneously with a conceptual change whereby Freud partitioned the libido (into the ego libido and narcissistic libido), this being indispensable in order to explain the processes at work in the psychoses, the "actual neuroses" (particularly hypochondria), and love life. This energetic and quantitative meaning of erotogenicity is directly linked to the concepts of libido, ego, and object. It would thus modify though not replace the qualitative conception of the erogenous zones from which it derived and which were previously defined as the sources of the autoerotic component instincts (partial drives).

Freud very early recognized the sexual excitability (*Erregbarkeit*) of certain parts of the body apart from the genital zones, in the strict sense, and referred to these as *erogenous zones*. This expression is derived from Charcot's *hysterogenic zones*, a term used to designate "more or less delimited regions of the body, on which pressure or merely rubbing determines, more or less rapidly, the phenomenon of the aura, which is sometimes succeeded, if we continue to apply pressure, by an hysterical attack. These points, or rather these surfaces, also have the property of being the seat of permanent sensitivity." (Charcot, 1890). When speaking of the case of Elisabeth von R. in *Studies on Hysteria*, Freud extended the meaning of *hysterogenic zone* by giving it its full value as a corporal inscription of a mnemonic trace and describing the sexual pleasure within the conversion symptom. Elisabeth von R's pains always started from a particular point on the right thigh and the analysis revealed that her father used to rest his leg there when she was caring for him. Freud states: "In this way she gave me the explanation that I needed of the emergence of what was an atypical

hysterogenic zone" (1895d, 148). The notion of hysterogenic zone came to be modified between Charcot and Freud because it now meant a place with a sexual "stimulability" (*Reizbarkeit*) that was determined by the subject's history and not by anatomy.

The equivalence between erogeneity and hysterogeneity is clearly defined in two of Freud's letters to Wilhelm Fliess, one dated December 6, 1896, in which the term *erogenous zone* appears for the first time, the other dated November 14, 1897, in which he wrote: "I have often suspected that something organic played a part in repression; I have told you before that it is a question of the attitude adopted to former sexual zones. . . . We must suppose that in infancy sexual release is not so much localized as it becomes later, so that zones which are later abandoned (and possibly the whole surface of the body) stimulate to some extent the production of something that is analogous to the later release of sexuality" (p. 232). These sexual zones that are abandoned in the course of development constitute infantile sexuality proper, and are recathected in perversions and neuroses. In *Three Essays* Freud shows that through the action of displacement and condensation these erogenous zones "then behave exactly like the genitals (1905d, p. 183) and produce the symptoms that are conceived of as substitutes for sexual satisfaction. The paradigm is that of hysteria: "erotogenic and hysterogenic zones show the same characteristics" (1905d, p. 184).

He then goes on to describe the development phases of infantile sexual organization (oral, anal, and phallic). The erogenous zones are the source of the component sexual impulses that seek autoerotic satisfaction until they are subordinated to and take part in genital activity. Freud's model for the excitation of the erogenous zones is based on the erection, including the tension (unpleasure) it mobilizes, and the demand for discharge (pleasure) that it prescribes. The fact that certain parts of the body are predestined to be erogenous is explained by the Freudian concept of *anaclysis*. The term is used to designate the relationship of leaning and implication that exists between the sexual instincts and the needs of self-preservation. For example, Freud postulates for the oral instinct that, "the satisfaction of the erotogenic zone is associated, in the first instance, with the satisfaction of the need for nourishment" (1905d, p. 181).

Without recanting on this theory of erogenous zones as presented above, Freud modified his concep-

tion of erogeneity in 1914 toward an energy-based and quantitative model where the hysteria paradigm is replaced by that of hypochondria. It was now the whole body that behaved like a male genital organ. The distribution of the libido and its capacity to go beyond the frontiers of narcissism conditioned suffering and love equally.

*Inhibition, Symptoms and Anxiety* (1926d) describes the relationship between the ego-function of an organ and erogeneity: “It has been discovered as a general fact that the ego-function of an organ is impaired if its erotogenicity—its sexual significance—is increased. It behaves, if I may be allowed a rather absurd analogy, like a maid-servant who refuses to go on cooking because her master has started a love-affair with her” (pp. 89–90). Freud gives other examples of inhibitions following a risk of conflict between the ego and the superego, as when profit and success are prohibited and when failure satisfies a need for self-punishment. Thus, in the second theory of the instincts erogeneity is equivalent to a libidinal satisfaction that can be accomplished up to and including self-punishment and self-destruction as in, for example, moral masochism.

The Freudian notion that erogenous activity is anaclitic in relation to the satisfaction of the fundamental needs of self-preservation favored the theoretical illusion of a progressive organization of instinctual stages with maturation being almost biologically determined. This conceptual model compromises the importance of the Other and its constitutive intervention in infantile sexuality. By referring to anaclysis in another sense, the choice of love object being based on the model of the mother who feeds or the father who protects, Freud’s 1914 text introduces another perspective, but not without some hesitation and aporia.

Jacques Lacan (1964-1966) developed a theoretical model that denies the genetic point of view of instinctual stages and its “naturally” programmed organization. He writes: “There is no relation of engendering between one component instinct and the next,” and states: “The passage from the oral instinct to the anal is not produced by a process of maturation but by means of the intervention of something that has nothing to do with instincts—by the intervention, the reversal, of the demand of the Other.”

Serge Leclaire (1968) demonstrated that erogeneity depends closely on the “sexual value” projected onto the

child’s body by another. The mother who caresses her child’s dimple with her finger inscribes a difference there, a flaw, a point of focus, an erogenous center: “What makes the erotogenic inscription possible is the fact that the caressing finger is itself, for the mother, an erotogenic zone. This finger, in its essential libidinal value, can be called a “letter-holder” or inscriber to the extent that, as an erotogenic zone of the mother, a letter fixes into its flesh the interbal of an exquisite difference” (p. 50).

## **EROTOMANIA**

Erotomania, the “delusion of being loved,” is a morbid fascination that is clinically classified as a form of delusion, accompanied by insistent demands and jealousy. Emil Kraepelin associates it with the paranoid psychoses and Sigmund Freud interprets it psychoanalytically (1911c [1910]). For Freud the inverse projection of erotomania serves as a defensive function against latent homosexuality:

Another element is chosen for contradiction in *erotomania*, which remains totally unintelligible on

any other view: 'I do not love *him*—I love *her*.' And in obedience to the same need for projection, the proposition is transformed into: 'I observe that *she* loves me.' 'I do not love *him*—I love *her*, because SHE LOVES ME.' Many cases of erotomania might give an impression that they could be satisfactorily explained as being exaggerated or distorted heterosexual fixations, if our attention were not attracted by the circumstance that these infatuations invariably begin, not with any internal perception of loving, but with an external perception of being loved. But in this form of paranoia the intermediate proposition 'I love *her*' can also become conscious, because the contradiction between it and the original proposition is not a diametrical one, not so irreconcilable as that between love and hate: it is, after all, possible to love *her* as well as *him*. It can thus come about that the proposition which has been substituted by projection ('*she loves me*') may make way again for the 'basic language' proposition 'I love *her*' (1911c [1910], pp. 63–64).

The initial core can be traced back to the narcissistic root through idealization (projection of the subject's ideal ego), split personality, and double bind situations.

In 1920 Gatian de Clérambault defined his conception of erotomaniac delusion in a letter to the Société Clinique de Médecine Mentale (Clinical society of mental medicine) as the "coexistence of two delusions: persecution and erotomania." In 1921 he isolated "pure erotomania" within the context of emotional delusion. This emotional syndrome, which is generated by feelings of pride, desire, and hope, revolves around a "fundamental postulate": "It is the object that began and that loves the most or that loves alone." This revelation, generally found in women, initiates the phase of hope. A number of topics are derived from this, for example, the belief that "the object cannot experience happiness without being loved." From then on their protection, their efforts at closeness, and indirect manifestations of their love are combined with paradoxical behavior patterns. Interpreted as hardships and especially as demonstrations of love, they appear as persecutory during the stages of spite and bitterness that are part of a chronic, persistent development. The associated erotomania is a fluid entity, an expression of a paranoid, a schizophrenic psychiatric condition.

In spite of our clinical (found in DSM IV) and psychopathological understanding, there have been few

therapeutic advances for such patients, who are often intrusive and consequently rarely succeed in attracting attention for very long.

## ERYTHROPHOBIA (FEAR OF BLUSHING)

Erythrophobia or ereuthrophobia describes a pathological fear of blushing in public.

In the Minutes of the Psychoanalytical Society of Vienna (Nunberg and Federn, 1962–75) the session of February 3, 1909, was devoted to "A case of compulsive blushing" presented by Alfred Adler in the presence of Freud, Paul Federn, Max Graf, Edouard Hitschmann, Albert Joachim, Otto Rank, Isidor Sadger, and Fritz Wittels.

According to Freud, we cannot classify this state among the sexual neuroses because it is situated somewhere between anxiety hysteria and paranoia. These two assertions are to be found in the comments he made after Adler's conference: "Erythrophobia consists of being ashamed for unconscious reasons [...]. The first thing these patients were ashamed of was usually masturbation; more generally, the secret of their precocious knowledge with regard to sexuality."

And: “Neuroses cannot be expressed with a single current but only by a pair of opposites which are shame and rage in this case. Only the coexistence of these active and passive current explains the case of erythro-phobia: it is the meeting of these two currents that produces the attack.”

Ernest Jones, for his part, distinguished between “ereuthrophobia,” the fear of blushing, and “erythro-phobia” or fear of the color red (1913).

## **ESSENTIAL DEPRESSION**

The notion of *essential depression* was introduced by Pierre Marty in his 1966 article “La dépression essentielle,” shortly after the notion of “operative thought,” and it became a clinical construct in the treatment of psychosomatic disorders. The term *essential depression* emerged after “depression without an object” and is a more appropriate name than the latter because the phenomenon it describes constitutes the very essence of depression.

Essential depression involves a reduction in the level of both object-libido and narcissistic libido, without any positive economic counterpart, and thus without any libidinal connection at the relational level; this distinguishes it from other depressions of the neurotic or even psychotic type. This specificity of the relational mode with the investigator, an analogue for the overall relational mode, indicates a diagnosis of this type of depression, which can be difficult to detect. Everything seems to take place without visible emotion, flattening any underlying drama or internal conflict. This absence of any nameable affect is comparable to the hypothesis of alexithymia: We find something like an erasure of the dynamic capacities of the basic mental functions across the entire spectrum—the absence of any vital link gives the impression of a functional breakdown. According to

Marty, this abrasion of libidinal bonds and impression of fragmentation constitute the very definition of the death instinct (it should be recalled that Marty envisions the death instinct as a deficiency of individual movements of life without the opposing destructive charge carried by the death instinct as theorized by Sigmund Freud). However, adds Marty, “although essential depressives thus seem always to carry phenomena of death within themselves, the libido seems to be extinguished only when life is extinguished, except in certain rare cases.” In such cases, he contends, the ego ceases to exist as an agency within the psychic apparatus.

Marty subsequently introduced this clinical construct into his work as a pivotal notion, along with “operative thought”—all within the framework of “disorganization” that is part of his model of the somatization process. His most extensive account is found in *Les mouvements individuels de vie et de mort. Vol. 2: L'Ordre psychosomatique* (Individual movements of life and death. Vol. 2: The psychosomatic order; 1980), where he emphasizes one of the main signs of essential depression: The disappearance of unconscious feelings of guilt in an ego that only poorly fulfills its roles of linking, distribution, and defense. He once again underscores the fragility of the preconscious at this stage. The deficit of this symptom is thus situated within the psyche, and somatic disturbances are the result within a system that is defensive and yet disorganizing in response to trauma. He theorizes that this phase is preceded by an automatic, diffuse anxiety that is related to anxiety neurosis, which for its part cannot be understood as an alarm signal that should trigger the mental defenses. In the first volume of *Les mouvements individuels de vie et de mort*, subtitled *Essai d'économie psychosomatique* (Essay on psychosomatic economy; 1976), Marty hypothesizes that the passage into essential depression occurs through depletion of the “anxiety apparatus” at the expense of psychic functioning.

## ESTRANGEMENT

The term *estrangement* connotes an idea of novelty or even bizarreness. Freud, in his essay “The Uncanny” (1919h), added an additional meaning when he emphasized that this feeling, an experience close to a sensation, is at its peak when it is triggered by the reappearance of a familiar object that has been forgotten or repressed for a long time. The feeling of estrangement can be compared to the phenomena of *déjà vu* or *déjà vécu* (previously lived). Although the concept is developed in *The psychopathology of everyday life* (Freud, 1901), it is referred to as such only in his short essay “A Disturbance of Memory on the Acropolis” (Freud, 1936a).

The concept of estrangement has been extensively described in classical psychiatry, which views it as a delusion associated with the inability to recognize a known object or person. Pierre Janet considered estrangement to be a disturbance of the reality function and a breakdown in the process of mental synthesis. Freud, however, distinguished such phenomena (which he also studied) from those described in the literature, where uncertainty about the nature of objects (living or dead, human or automata) is voluntarily maintained to create in the reader a feeling of anxiety, a sense of the uncanny.

Starting from Friedrich Schelling's idea that the feeling of estrangement arises from exposure to something that is revealed but should have remained hidden, Freud went on to stress the return of the repressed. In terms of symptoms, the feeling of estrangement appears as an anxiety that something is about to be revealed. It can be seen as a form of transgression, like crossing to the other side of an imaginary line without knowing how or why one got there. This transgression is not only prohibited by the superego but is associated with the subject's identity and simultaneously concerns the limit between internal and external, the limits among past, present, and future, and the limit between life and death. The feeling of estrangement is associated with a mysterious imaginary time before life, which is therefore

unrecognizable and yet insists on revealing its familiarity.

Freud had already developed these ideas in *Totem and Taboo* (1912–1913a). There he wrote that what is felt as strange in the outside world initially belonged to the self and was then projected to the exterior. The nonself, the object of perception, is only recognizable through this process of projection (an animist conception of the world). This feeling of estrangement is also related to the dialectic between the strange and the familiar among the dead, who are not completely separated from the living but rather continue to hover around them (the taboo against the dead).

The psychoanalytic feeling of estrangement arises from a sudden confrontation between a perception of the outside world and repressed primitive internal perceptions. These internal perceptions are not apprehended as such and appear in the subject's mental space only after having been projected onto the outside world. Consequently, they are bound to the objects that support them. This crossing of a limit, whether it involves the before or after, the animate or inanimate, the internal or external, is always associated with the death drive, whose final goal is the initial state—an expression of the inertia of organic life.

In “A Disturbance of Memory on the Acropolis” (1936a), Freud, deepening and restricting the feeling of estrangement, saw it essentially as a defense mechanism that attempts to distance something from the ego (depersonalization) or include something external (false recognition, *déjà vu*, previously narrated). The oedipal explanation of Freud's disturbance of memory (guilt for surpassing his father, realization of his desire to escape his family) does not cover all there is to estrangement.

The feeling of estrangement, which is so difficult to grasp, is an inherent part of psychoanalysis itself when it attempts to revivify repressed contents. It is associated with what Freud defined in *Beyond the Pleasure Principle* (1920g) as the demonic, which characterizes the repetition compulsion. To a considerable extent, it has the characteristics of a drive, yet it is hostile to the pleasure principle. In a sense, estrangement, in its unconscious dimension, may impose limits on our understanding, like an iceberg, which remains largely submerged.

## ETHICS

Ethics concerns mores: human moral attitudes in general and, more specifically, rules of behavior and their justifications. This system of rules attributes values to behaviors by judging them to be good or bad according to their intrinsic moral qualities or their concrete social consequences. For Freud, ethics takes up where totemism and taboos leave off, and constitutes the basis of all religion.

In *Civilization and Its Discontents* (1930a [1929]), Freud noted, “The cultural super-ego has developed its ideals and set up its demands. Among the latter, those which deal with the relations of human beings are comprised under the heading of ethics” (p. 142).

As early as the *Studies on Hysteria* (1895a), Freud analyzed hysterical conversion symptoms as the result of a conflict between patients’ erotic thoughts and moral ideals. The adjective “ethical,” *ethisch* in German, appeared for the first time in 1898 in “Sexuality in the Aetiology of the Neuroses.” In that essay, Freud raised the question of whether physicians have the right to intrude into the sexual lives of their patients and whether their “ethical duty” might not be “to keep away from the whole business of sex” (p. 264).

The notion of ethics in Freud’s work refers primarily to those moral ideals in the name of which individuals renounce any instinctual impulses that are irreconcilable with the narcissistic ideals of the ego. These ideals are based on images of loved objects and the

esteem of the superego. For Freud, the symptoms of the transference neuroses were substitutes for the remains of old loves that were forbidden by morality.

The reign of “civilized morality” begins when the drives are renounced. This forms the basis of religion and culture. Yet when individuals renounce the drives, they are deprived of the sexual and aggressive satisfactions demanded by the id, and so run the risk of neurosis.

This traditional conception of ethics is emphasized when the German word *Ethik* is translated as *morals* or *morality*. In what Angélo Hesnard calls “the morbid universe of guilt,” the unconscious feelings of guilt that cause neurotic symptoms do not relate to the material reality of the patient’s actions. Neurotic patients are guilty only of their secret intentions. The psychic reality of the forbidden and repressed wishes of “the child that is in man” (Freud, 1910a [1909], p. 36) is accessible to us by dream interpretation and is realized in the course of analytic treatment in the love/hate relationship of the transference. And yet, by reawakening the demons banished by morality, does not psychoanalysis run the risk of destroying the very foundations of culture, which always demands sacrifices of the individual?

This question leads to another conception of ethics, one that is specific to psychoanalysis. The ethics of psychoanalysis is a consequence of how its practice implements its method and rules. Psychoanalysis does not aim to make the individual adapted to his or her environment. In other words, it does not serve the good; rather, it seeks the truth. When Freud recommended that physicians not give in to the amorous advances of their patients, he was giving voice less to traditional morality than to a psychoanalytic ethics conceived in terms of the requirements of a praxis founded on a method. The patient, by engaging in transference love, aggravated by a resistance to remembering, aims to reduce the analyst to a lover. The analyst is ethically bound not to respond, because he does not mistake the transference for true love. He wants to frustrate the analysand’s love so that it can be analyzed. Otherwise, the analyst would become allied with the resistance. Here moral motives converge with psychoanalytic technique.

This psychoanalytic notion of ethics serves philosophical, religious, and moral causes. In *Moses and Monotheism* (1939a), Freud showed that ethics originates in “a sense of guilt felt on account of a suppressed hostility to God” (p. 134). Using Judaism, he

returned to the myth of the murder of the father that he developed in *Totem and Taboo* (1912–1913a). Freud argued that people have always known that at one time they had a primitive father (which in religion becomes the godhead) and that they put him to death. The resulting “nostalgia for the father” reflected an insatiable need to appease a sense of guilt by changing the father’s prohibitions into ethical obligations. When sons ingest the dead father’s body, they come to identify with someone whom they simultaneously love and hate. Thus, the dead father becomes the superego, demanding self-sacrifice. When the subject obeys the superego and renounces his sexual and aggressive impulses, he can both hate and love the parental authority within himself.

Freud revealed the role that masochism and narcissism play when the drives are reined in by ethics. A subject who suffers by sacrificing his or her desires to the supposed demands of the Other feels loved and chosen by this Other while unconsciously reproaching the Other for sadism.

Jacques Lacan discussed how the death drive functions in the dialectic between the pleasure principle and the reality principle. He began by declaring the prohibition of incest to be the only universal law. All other rules of morality are merely historical and cultural variations of this law. Desire for the mother can never be satisfied, even after the murder of the deterring father, because acting out incest would cause the social order to collapse. For this reason, the “naturalist liberation” of pleasure fails (Lacan, p. 4), *jouissance* remains forbidden, and the prohibition is reinforced by the work of mourning. The human condition is tragic because the more the subject renounces pleasure, the more his superego demands greater sacrifices. Nevertheless, the superego is necessary to produce the economy of pleasure and to introduce desire into the world of symbolic mediation.

In the character of Antigone, Lacan found an incarnation of a “pure and simple desire for death” (p. 282). This “raw,” “inflexible” “kid” (pp. 250, 263) opposes the ethics of the good, represented by Creon. With her sacrifice, Antigone becomes the pure and simple relation between being human and “the break introduced by the presence of language in the human life” (p. 279). The result is that “when an analysis is carried through to its end the subject will encounter the limit in which the problematic of desire is raised” (p. 300).

Jacques Lacan emphasized the human subject’s debt to language in becoming human and thus proposed a psychoanalytic ethic that did not concern itself with happiness and the good. The idealization of the figure of Antigone produced a Hegelian imperative to “pure action” that could conceivably be added to or substituted for traditional ethico-religious ideals. What Patrick Guyomard refers to as “the enjoyment of the tragic” must give way to the specific requirements of psychoanalytic work, a work of mourning that, according to Conrad Stein, leads to a “crossing of the tragic.” Thus the ethics of psychoanalysis is a consequence of its specific method.

## ETHNOPSICHOANALYSIS

Ethnopsychanalysis is a form of psychotherapy that makes use of two complementary fields of knowledge: psychoanalysis and anthropology. Early in his career

Sigmund Freud was careful to test the cultural diversity of his principal psychoanalytic concepts. The Oedipus complex, shortly after its introduction, was at the heart of the controversy between universalism and culturalism, and even today the question remains unresolved. Bronislaw Malinowski (1927) was one of the first anthropologists to take an interest in the relation between the psyche and culture through an analysis of the Oedipus complex among the Trobriand islanders, a matrilineal society. After Malinowski, the question was investigated by Géza Roheim and especially Georges Devereux (1970/1980, 1972), who further refined the relation between psychoanalysis and anthropology. Devereux postulated two fundamentals: psychic universality, toward which every human being tends, and cultural encoding, which is the effect of a culture on the content of the mind. Devereux held that researchers should focus on particulars without speculating about an abstract universal, which cannot be known a priori but was frequently inferred.

Ethnopsychanalysis is based on the methodological principle of complementarity, which “does not exclude any method, any valid theory, but coordinates them” (Devereux, 1972). It is pointless to forcibly and exclusively integrate certain human phenomena into the field of psychoanalysis or anthropology. Human phenomena, Devereux asserted, are so specific that they require a two-pronged multidisciplinary approach that can neither be fused together nor carried out simultaneously.

In France and the United States, Devereux developed a theory of ethnopsychanalysis based on the methodological principle of complementarity. Later in France, Tobie Nathan (1986) provided practical methods for its application, methods that are still being developed. Some parameters, however, appear to be well established (Moro, 1998): the need for a group of therapists in some cases, the importance of the patient’s native tongue and the need to make a transition to the patient’s language, the need to start from the patient’s cultural representations, the need to construct intermediate spaces halfway between culture and psyche that enable the individual to speak more freely and creatively, the need to modify of the duration of sessions (longer sessions designed to comply with the cultural temporality of the patient), and so on. Finally, to encourage discussion, Western therapists must learn to look beyond the Western worldview and to modify their system of reference.

In this context it is important to implement, in addition to the mechanics for analyzing transference and affective countertransference, a specific method for analyzing the therapist’s “cultural countertransference.” In concrete terms, at the end of each interview, the group of therapists should attempt to elucidate the countertransference of each therapist by discussing the affects they have experienced, implicit elements, and theories that led them to believe certain things (inferences), and by planning activities (interventions) at the individual and cultural levels.

Ethnopsychanalysis, which integrates the mental and cultural dimension of human dysfunctionality, is not a specific method, strictly speaking. Rather, it involves creating a complex cross-cultural psychotherapeutic setting that allows therapists to step outside of their own cultures and recognize the cultural differences of emigrant patients.

## **ETHOLOGY AND PSYCHOANALYSIS**

Ethology is a biology of behavior. It has developed a nomenclature for describing the behavior of all living things in their natural environment using an approach that is naturalistic, experimental, and comparative. It

describes the structure of a behavioral sequence, its immediate causes, its adaptive benefits (its function), and its origin in the evolutionary development of the species and the biological development of the individual. Ethology has established itself as an observational method in some of the existing social sciences, including genetics, ethoecology, ethoneurology, ethosociology, etholinguistics, and ethopsychanalysis.

After World War II, René Spitz, faced with the behavioral pathology of abandoned children, following the work of Anna Freud, studied the genesis of object-relationships and the construction of the ego within a Freudian perspective. Strongly influenced by Konrad Lorenz and the then-new theory of cybernetics, he observed and manipulated the “eyes-nose-mouth” stimulus signal that triggers the suckling’s motor smile. He subsequently developed the concept of ego organizers and showed how the child’s mastery of the headshake, meaning “No,” marks the behavioral emergence of the process of symbolization.

In 1958, John Bowlby, then president of the British Psycho-Analytic Society, described the effects of a lack of maternal care. These findings showed an “astonishing convergence” (Zazzo, 1974) with the Harlows’ experiments on Rhesus monkeys, which demonstrated that the affective relationship between a mother and her infant was built not on nutritional needs but rather on a primary need for sensory exchange.

At the Twenty-First International Congress of Psychoanalysis in Copenhagen (1959), a stimulating debate was initiated. Some psychoanalysts felt that experiments on imprinting, epigenesis, stimulus-signals, synaptic facilitation, and the behavioral ontogenesis that constructs human ties buttressed the Freudian concept of drives. Others, however, felt that these ran counter to Freudian theory, since the idea of attachment as a primary bond contradicted that of an anaclitic relationship to drives. They also felt that direct observation added nothing to clear pictures of subject’s mental world that could be obtained from a historical approach.

In contemporary ethnopsychanalysis, the ethological method is used to observe the structuring of the primary bond and to evaluate it in terms of life events and cultural pressures with, as a base-line, the observation of the “strange situation” (Ainsworth et al., 1978).

The three levels of interaction distinguish the body, the affect, and the fantasy (Lebovici, 1991), which, as “psychic representative of the drive” (Freud), enables

the unconscious to give shape to the drive and thereby fashion the words and gestures (Cosnier, 1984) that act on the other. Interestingly, Jacques Lacan invoked ethology as early as 1936. His study of such phenomena as animal behavior in front of a mirror and the “dance” of sticklebacks enabled him to develop the fundamental concepts of the mirror stage and the interaction of the Real and the Imaginary in humans.

The psychoanalytic development an ethological anthropology allows us to situate man in the living world by emphasizing how the emergence of symbols and signs has created a specifically human, historicized world.

## ÉTUDES FREUDIENNES

*Études Freudiennes* is a journal launched in 1969 by Conrad Stein, with Lucio Covello as recording secretary and Julien Bigras as Canadian correspondent (Stein was the French correspondent for the Canadian journal *Interprétation*). Its birth resulted from a schism in the editorial board of *L’inconscient*, on which Stein was a key figure, along with Piera Aulagnier–Spairani (editor in chief) and Jean Clavreul. According to their

last editorial (no. 8, October 1968), “The editors have not been able to agree about the orientation appropriate for a review of psychoanalysis, nor on the part they would like it to play.”

The first issue of *Études Freudiennes*, “Du côté du psychanalyste” (with the psychoanalyst), came out in November 1969. The first issue of *Topique*, “La formation du psychanalyste” (training the analyst), came out at the same time, with an announcement by Piera Aulagnier of the creation of a new psychoanalytic association: the Quatrième groupe, Organisation psychanalytique de langue française (Fourth Group, Francophone Psychoanalytic Organization).

Stein’s orientation is apparent in his short introduction to “Le patient inconnu” (The unknown patient) by Theodor Reik. He presents this text as being about “a kind of truth, unconnected with any school, about psychoanalysis.” This sums up what became the spirit of the journal.

*Études Freudiennes* is open to all tendencies in Freudian psychoanalysis, as long as authors show a serious commitment to psychoanalysis, are creative, and write well. It takes up questions relating to the training of psychoanalysts, their course of studies, and their supervision (nos. 1–2 and 31). Other areas of focus are the history of ideas (Sigmund Freud, Sándor Ferenczi, Jacques Lacan), the history of concepts (interpretation, femininity, transference love), and the practice of psychoanalysis in relation to its principles and the exigencies inherent in Freudian methodology.

From May 1982 (nos. 19–20) to September 1987 (no. 29), each issue gave rise to “study days,” when articles were discussed in the presence of their authors. Another special feature of *Études Freudiennes* has been the ongoing scientific debates, parallel to the published essays, in which experienced psychoanalysts associated with the review since its beginnings have encounters with younger colleagues invited to expound their points of view independently of ties to any organization and without fear of censure. This feature has added to its reputation in France and abroad, where some numbers have been translated (Italy, Germany, Brazil).

With a history of more than thirty years, *Études Freudiennes* has encountered its share of obstacles. Yet its flexibility in matters relating to the mind has helped it to overcome them.

## EUROPEAN PSYCHOANALYTICAL FEDERATION

The European Psychoanalytical Federation (EPF) is a scientific organization that consolidates all the European psychoanalytic societies affiliated with the International Psychoanalytic Association. In 2002 there were approximately 3,900 individual members in twenty-two countries, speaking eighteen different languages. It comprises twenty-five societies and three study groups (the Romanian Group, Belgrade Group, and Polish Group). A study group is the first level of integration of a psychoanalytic body within the International Psychoanalytic Association (IPA), followed by a provisional society and finally a member society.

The EPF was founded in 1966 by Raymond de Saussure, a well-known member of the Société suisse de psychanalyse (Swiss Society for Psychoanalysis), with Evelyne Kestemberg as secretary. The idea of a European psychoanalytic organization was first discussed at a series of European conferences on training, which had been organized every two years from 1960. The need for guidelines for psychoanalytic training in Europe contributed greatly to the creation of a European organization similar to the American Psychoanalytic Association, which had a unified training policy.

However, the European societies, concerned about their autonomy and independence in training matters, refused to accept this initial proposal and preferred the

model of a federation of independent societies. The EPF is administered by an executive board, composed of an executive committee of seven members (president, president-elect, two vice presidents, secretary, treasurer, newsletter editor) and the presidents of the member societies and study groups.

The EPF has always served as a clearinghouse and forum for psychoanalytic societies in Europe. In this sense its function is essentially scientific, unlike the International Psychoanalytic Association, which also serves as a political entity in that it establishes common standards for training and practice for all member psychoanalysts.

In its bylaws, the EPF has set forth six major goals: to promote the development of psychoanalysis; to maintain and improve the standards for practice, training, and teaching; to promote psychoanalytic research and distribute information about the theory and practice of psychoanalysis; to improve communication among psychoanalysts by means of various publications, newsletters, scientific conferences, and other meetings; to create a discussion space for scientific fields related to psychoanalysis and other subjects of concern to psychoanalysts; to promote contacts between psychoanalysis and other disciplines.

Although initially the EPF limited itself to organizing an annual conference on training and to publishing an annual twenty-page bulletin, in 2004 it organized more than ten annual or biannual scientific gatherings: colloquia and conferences on training and on child and adolescent analysis, a large conference open to all members and candidates, a clinical seminar for members, a scientific symposium on a controversial theoretical issue, a seminar and summer university in Eastern Europe for Eastern Europeans, a clinical seminar for Europeans and North Americans. As of 2004, was the *Bulletin de la Fédération européenne de psychanalyse* (120 pages) is now (in 2004) published semiannually in the three official languages of the EPF (German, English, and French) and includes papers presented at the various conferences held throughout Europe. These papers reflect contemporary psychoanalytic dialogue and the problems encountered in the various European psychoanalytic societies.

At the beginning of the twenty-first century the EPF is at a point where it will have to define its role inside and outside the world of analysis. European psychoanalytic societies need to address a range of issues, including the professional status of the psychoanalyst

(psychoanalyst or psychotherapist), the development of psychoanalysis in Eastern Europe, evaluation of the various methods of training, the difficulties associated with the many languages in Europe and the EPF's relation to diverse cultures and psychoanalytic traditions, and finally, the role of the EPF in light of the restructuring of the International Psychoanalytic Association, which, as an association of individual members, is evolving toward more adequate representation of the societies themselves. By providing a forum for discussing these issues, the EPF has agreed to promote a European psychoanalytic identity that allows for differences among European psychoanalysts while enabling them to focus on a limited number of scientific, ethical, and democratic values that reflect the Freudian tradition.

## **EVENLY-SUSPENDED ATTENTION**

Evenly-suspended attention describes the necessary state of the analyst's mind when listening to the patient during a psychoanalytic session. It is the mirror image of the method of free association required of the patient.

Freud set forth the notion of free-floating attention in *The Interpretation of Dreams* (1900a) in connection with the secondary revision of the dream and the atti-

tude the interpreter must take: “For the purposes of *our* interpretation it remains an essential rule invariably to leave out of account the ostensible continuity of a dream as being of suspect origin, and to follow the same path back to the material of the dream-thoughts, no matter whether the dream itself is clear or confused” (p. 500).

His technical prescription is found in “Recommendations to Physicians Practising Psycho-Analysis” (1912e): “[I]t rejects the use of any special expedient (even that of taking notes). It consists simply in not directing one’s notice to anything in particular and in maintaining the same ‘evenly-suspended attention’ (as I have called it) in the face of all that one hears . . . . It will be seen that the rule of giving equal notice to everything is the necessary counterpart to the demand made on the patient that he should communicate everything that occurs to him without criticism or selection. If the doctor behaves otherwise, he is throwing away most of the advantage which results from the patient’s obeying the ‘fundamental rule of psychoanalysis.’ The rule for the doctor may be expressed: ‘He should withhold all conscious influences from his capacity to attend, and give himself over completely to his ‘unconscious memory.’ The doctor must put himself in a position to make use of everything he is told for the purposes of interpretation and of recognizing the concealed unconscious material without substituting a censorship of his own for the selection that the patient has forgone” (pp. 111–12). The psychoanalyst must be able to interpret everything he hears in order to discover everything that the unconscious disguises, and this without substituting his own censorship for the selectivity the patient has renounced.

In his 1923 encyclopedia article “Psycho-Analysis,” Freud returned to the topic: “Experience soon showed that the attitude which the analytic physician could most advantageously adopt was to surrender himself to his own unconscious mental activity, in a state of evenly suspended attention, to avoid so far as possible reflection and the construction of conscious expectations, not to try to fix anything that he heard particularly in his memory, and by these means to catch the drift of the patient’s unconscious with his own unconscious” (p. 239). Two years later, in a letter to Ludwig Binswanger dated February 22, 1925, he tempered the somewhat excessive aspect of this description: “In a more systematic formulation, unconscious must be replaced with preconscious” (2003, p. 179).

Some authors (notably James Strachey in the Standard Edition) have proposed as alternatives the terms *evenly-suspended* or *evenly-hovering attention* (in French, both *attention également flottante* and *attention flottante* are used). This prescribed attitude for the analyst has been considered one of the constitutive elements of the analytic setting. Associated with “neutrality,” it has also been compared with Theodor Reik’s notion of “listening with the third ear.” Since it requires that the analyst suspend judgment and eliminate his or her internal resistances and all personal censorship, it is clear that only prior analysis of the analyst can ensure that this state is maintained. In this special state, identifications and projections must be able to float freely, but some authors have emphasized the risk of falling asleep if the analyst is too intent on conforming to it (Fenichel, 1941). This observation has incited other authors to see in free-floating attention a state of self-hypnosis parallel to that triggered in the patient by the analytic setting (François Roustang).

Contrary to the passivity and static aspect suggested by this description, Joseph Sandler has argued that the dynamic back-and-forth between this state and the return to a countertransference analysis of what is perceived are conducive to “free-floating responsiveness” in the analyst (Sandler 1976, 1993).

## ÉVOLUTION PSYCHIATRIQUE (L'-) (DEVELOPMENTS IN PSYCHIATRY)

Before becoming the title of the review first published in 1929, with chief editors Henri Codet and Eugène Minkowski contributing to the first issues, *L'Évolution psychiatrique* was already the title of a collective work in two volumes (1925 and 1927), directed by Angélo Hesnard and René Laforgue.

In 1930 a study group was formed around the nucleus of collaborators in the review. This group contained no fewer than seven of the founding members of the Paris Psychoanalytic Society in 1926, but it did not seek to institutionalize psychoanalysis. Psychiatry was constantly evolving thanks to new acquisitions, including psychoanalysis which, although it appeared to be the most innovative, was not the only one, and the members of the group wanted their discipline, which was still stuck in declining alienism, to evolve. The philosophical ideas of the time would also contribute to this movement.

The name chosen was an obvious indication of the influence of Henri Bergson and his *Évolution Créatrice* (Creative evolution; 1907). *L'Évolution psychiatrique* (EP) would present the work of Eugène Minkowski, who published the first French-language volume of phenomenological psychopathology, *Le Temps vécu* (Time lived; 1934), and also Ludwig Binswanger, Karl Jaspers, and Viktor von Gebsattel. In 1934, Henri Ey used the review to present Eugen Bleuler's ideas on the group of schizophrenic psychoses (1911), an application of the nascent psychoanalysis to Emil Kraepelin's *dementia praecox*. Jacques Lacan's thesis, *De la psychose paranoïaque dans ses rapports avec la personnalité* (Paranoid psychosis and its relations to the personality; 1932) is another example of this psychoanalytic rereading of Kraepelin's entities that was to renew psychiatry. After the war, the exchanges between Ey and Lacan were milestones in the life of the society, which had interrupted its activity during the German occupation of France and suspended the publication of the review between 1940 and 1947. On the occasion of the *Journées de Bonneval*, Ey brought

together psychiatrists, psychoanalysts, and philosophers, and their debates on the psychogenesis of neuroses and psychoses (1946), schizophrenia (1958), and lastly the unconscious (1960), would go down in history.

In 1950, *L'Évolution psychiatrique* organized the first World Congress on Psychiatry in Paris, the presence of Anna Freud and Melanie Klein testifying to the importance attached to psychoanalysis. And in 1956 the centenary of Freud's birth was marked by an issue devoted to his work.

In 1955, the publication, under the direction of Ey, of the *Traité de psychiatrie* (Treatise on Psychiatry) in the *Encyclopédie médico-chirurgicale* (Medical and surgical encyclopedia) written by one hundred and thirty-two authors, psychiatrists, and psychoanalysts and almost all of the members of *L'Évolution psychiatrique*, marked a major moment in the history of the society. The unity in diversity thus realized was shattered soon afterwards, when psychiatry was recognized as a medical specialty distinct from neurology. The distinction was influenced by various factors: schisms in Freudian France, progress in psychopharmacology, different "anti-psychiatry," the success of behaviorism and cognitivism, and the appearance of the "neurosciences." The Seventh World Congress on Psychiatry, held in Vienna in 1984, could have declared psychoanalysis dead. For a quarter of a century the astonishing increase in the number of psychiatrists in France caused a multiplication in the number of societies with one approach and made *L'Évolution psychiatrique* the only place where phenomenologists, structuralists, biologists, psychotherapists, cognitivists, and analysts from different schools could confront each other's views. It is therefore not surprising that when psychiatrists again felt the need to reflect together on recent progress in their discipline, *L'Évolution psychiatrique* played an essential role in the creation of the French Federation for Psychiatry (1992).

## EXAMINATION DREAMS

In examination dreams, which Freud considered to be “typical dreams,” the dreamer sees himself back at school taking an examination.

Freud mentions this type of dream several times in *The Interpretation of Dreams* (1900a). The dreamer is embarrassed to see himself as an adult among much younger fellow students and obliged to retake an examination that he already passed a long time ago. “It would seem, then, that anxious examination dreams (which, as has been confirmed over and over again, appear when the dreamer has some responsible activity ahead of him next day and is afraid there may be a fiasco)” (1900a, p. 274). The meaning of the dream would be: “Don’t be afraid of tomorrow! Just think how anxious you were before your Matriculation, and yet nothing happened to you” (1900a, p. 274).

The interpretation can nevertheless prove to be more complex: In Chapter 6, Freud recounts one of his own dreams, an “absurd dream about a dead father” (1900a, p. 435), which is marked by uncertainty about the dates of his own birth and his father’s death. Freud analyzes the uneasiness about filiation and hostility to the father (who in this dream admits to having been arrested for drunkenness) by associating it with his memory of having been a slow medical student: “In my circle of acquaintances I was regarded as an idler and it was doubted whether I should ever get through” (1900a, p. 450). It is therefore about an oedipal issue (particularly from the point of view of rivalry with the father).

Freud never returned to examination dreams, and the theme seems to have received little attention outside of the United States. However, these dreams are encountered frequently in clinical practice.

## EXCITATION

*Excitation* is a term borrowed from the lexicon of commonplace words derived from the Vulgar Latin *excitatio*: “the action of exciting”; it is used notably in physics and physiology. Sigmund Freud, and other psychoanalysts after him, expanded this term for use in metapsychology, particularly the economic dimensions of that approach. In this usage, the word carries with it the connotations of the Latin *excitare*: “to awaken, wake up, push, or stimulate at the level of the psychic apparatus.”

This psychic apparatus, the fictional representation of metapsychological topography, appears as the locus of reception, transformation, and capacity for adequate discharge of excitation. Even before his analytic period per se, Freud in “The Psycho-Neuroses of Defence” (1894a) envisaged the sum of excitation as a quantum of affect that is spread over the memory traces of representations. It is in this light that, for want of a connection with affect, he posits an “abreaction” caused by the excess of excitation. It is also necessary that endogenous excitations reach a certain threshold in order to become mental excitations. In *The Interpretation of Dreams* (1900a) he conjectures that “during certain psychical processes the systems may be traversed in a temporal sequence determined by excitation”

Excitation may be external in origin, in the form of a stimulus coming from the object or the environment, and the problem becomes the manner in which it is handled, bound, and evacuated. Here Freud advances the concept of the “protective shield” that serves to protect against an overflow of excitation, which he views as being traumatic. Envisioning trauma as a “breaking through of the protective shield” is one of the perspectives he offers. But overflow can also originate internally. In cases where sound psychic defensive systems are lacking—above all, a failure of defense through repression, which would prevent satisfaction and discharge toward the outside—the result is the mental symptom as a sign and

substitute for an instinctual satisfaction that has not taken place, like a foreign body that keeps producing phenomena of excitation and reaction in the (mental) tissue in which it is implanted.

Excitation is thus also included in the register of the pulsional system. Instinct, a borderline concept between the psychic and the somatic, is posited as an excitation for the psyche. It is found in connection with the terms *drive*, *aim*, and *source*.

- Drive: driving factor, the measure of the amount of impulse toward a particular action or end.
- Aim: a satisfaction that is only attainable through successfully suppressing the very cause of the initial excitation. Following Freud, we could say that the psychic apparatus serves the intention of mastering and eliminating quantities of excitation, whether this excitation arrives from without or within.
- Source: any somatic process in an organ or part of the body whose excitation is represented in mental life by the instincts. The raw material of psychic disturbances is posited as being inherent in this register of excitation of somatic origin; here we find the physiological notion of excitation. This excitation must undergo a process of mental work to enter into the pulsional system, or indeed must transform its quantum of energy into mental energy. If this transformation does not occur, somatic sexual excitation, for example, ostensibly remains in that form and does not turn into psychosexual excitation; this is the Freudian approach to the concept of “actual (or defense) neurosis,” advanced relatively early on. This approach requires levels of discharge rather than repression as the constituents of its symptoms.

Beyond a certain threshold of excitation, Freud evokes the notion of “libidinal coexcitation,” which ostensibly disappears over time; this is supposedly the point from which fixation begins. Thus the instincts, in contrast to stimulus or external excitation, never act as a force of momentary impact, but rather as an ongoing force. Thus too, the final goal of mental activity—the tendency to obtain pleasure and to avoid unpleasure—can be envisioned, in economic terms, as an effort to master the masses of excitation that reside in the psychic apparatus.

The concept of conversion brings with it the enigma of the leap from mental excitation to the somatic

level—the true “vicissitude” of the instincts, a process that is above all discernible in the structures of hysteria. Jean-Paul Valabrega takes up this notion of discharge through conversion in approaching psychosomatic phenomena, while other authors invoke the idea of a return of excitation to its earliest source, the somatic level, in the absence of successful mentalization. In the view of Pierre Marty, the flow of the excitations from the instincts and the drives, essentially aggressive and erotic, constitutes the central problem in somatization. He contends that in the absence of sound regulation by the psychic apparatus and thus of the possibility for adaptation, the excess or deficit of excitation causes a trauma that can become the point of departure for the process of somatization.

Finally, following the introduction of the death instinct in *Beyond the Pleasure Principle* (1920g), Freud somewhat reconsiders excitation within the framework of the life and death instincts. The force and the flow (or retention) of excitation are reexamined, in light of the principles of constancy and inertia that he had already developed but further elaborates here. It should be recalled that, for Freud, although the animistic process is automatically regulated by the pleasure-unpleasure principle, the economic viewpoint accepts that the mental representatives of the instincts are invested with determined quantities of energy and that the psychic apparatus tends to maintain at the lowest possible level the sum total of excitations it carries. But the very essence of instinctual functioning is also envisioned: the tendency toward inertia under the influence of the death instinct. Repetition compulsion (the instinct’s instinct, according to Francis Pasche) is arguably a way to deal with the surplus of excitation that is not bound to the instinct as the result of post-traumatic defusion. Freud’s example of the repetition of traumatic dreams provides an illustration of this. In this view, the aim of repetition compulsion is the extinction of traumatic excitation through exhaustion—and this to the point of inertia, the aim of the death instinct.

This posited aim enables Freud to propose a notion drawn from the philosophy of the Far East: the nirvana principle, whose aim is total discharge—a quasi-metaphysical and existential approach that transcends the metapsychological economic register. This principle takes to its extremes and goes beyond another of Freud’s principles, the principle of constancy.

## **EXHIBITIONISM**

“Exhibitionism” commonly denotes a sexual perversion in which satisfaction is linked to the displaying of one’s genital parts. Psychoanalysis broadens this notion by acknowledging many early manifestations of this tendency in the sexual life of the child. Freud showed how infantile sexuality, prior to the establishment of the genital functions, was governed by the interplay of various component instincts which manifest themselves most often as pairs of opposites and each of which is linked to a particular erotogenic zone. In this context exhibitionism is one of the elements of instinctual life, making its appearance in conjunction with its opposite, namely pleasure in looking, both being related to the eye as the relevant erotogenic zone. Seen in this light, exhibitionism as a perversion in the adult bespeaks regression to an earlier fixation of the libido.

It was chiefly in his *Three Essays on the Theory of Sexuality*, including the notes added to this work over its successive editions, that Freud outlined his conception of exhibitionism: “exhibitionists, . . . if I may trust the findings of several analyses, exhibit their own genitals in order to obtain a reciprocal view of the genitals of the other person.” A note added in 1920 elaborates: “Under analysis, these perversions . . . reveal a surprising variety of motives and determinants. The compulsion to exhibit, for instance, is also closely dependent

on the castration complex; it is a means of constantly insisting upon the integrity of the subject’s own (male) genitals and it reiterates his infantile satisfaction at the absence of a penis in those of women” (p. 157 and n.). The anxiety aroused by the perception of this real lack of the penis in women—in the mother, for example—led Freud to describe how, by the mechanism of disavowal, such a perception could be so thoroughly denied that an object, a fetish, could come to stand for the absent penis and “become the chosen object determining the achievement of sexual pleasure” (Green, 1990). For Guy Rosolato (1967), “fetishism is at the heart of all perversion in that it disavows the difference between the sexes”; it must therefore, and a fortiori, be central to exhibitionism.

Let us note, lastly, that exhibitionism as a manifestation of childhood sexuality is a common phenomenon and a part of sexual play. The desire to show off the genitals is linked to the needs for reassurance and knowledge. Child psychologists underline the importance of such play, though they insist that it should be confined to children of the same age, generally within a group where the curiosity is shared.

## **EXPERIENCE OF SATISFACTION**

In *The Language of Psychoanalysis*, Jean Laplanche and Jean-Bertrand Pontalis gave the following definition of “experience of satisfaction”: “Type of primal experience postulated by Freud, consisting in the resolution,

thanks to an external intervention, of an internal tension occasioned in the suckling by need. The image of the satisfying object subsequently takes on a special value in the construction of the subject's desire. This image may be recatheted in the absence of the real object (hallucinatory satisfaction of the wish). And it will always guide the later search for the satisfying object" (1967/1973, p. 156).

The concept of the experience of satisfaction—real or hallucinatory—is obviously a cornerstone in Sigmund Freud's metapsychological construction in that it raises the issue of the mnemonic registration of the encounter with the object and in that it tries to articulate the problematic of the assuagement of need and the fulfillment of desire. Freud evoked the experience of satisfaction as early as the "Project for a Scientific Psychology" (1950c [1895]): "The residues of the two kinds of experiences [of pain and of satisfaction] which we have been discussing are affects and wishful states are affects and wishful states. These have in common the fact that they both involve a raising of Q<sub>é</sub> tension in  $\Psi$ —brought about in the case of an *affect* by sudden release and in that of a *wish* by summation" (pp. 321–322).

Freud also referred to this concept several times in *The Interpretation of Dreams* (1900a), after which it faded somewhat before reappearing in "Formulations on the Two Principles of Mental Functioning" (1911b): "It was only the non-occurrence of the expected satisfaction, and the disappointment experienced, that led to the abandonment of this attempt at satisfaction by means of hallucination. Instead of it, the psychological apparatus had to decide to form a conception of the real circumstances in the external world and to endeavour to make a real alteration in them. A new principle of mental functioning was thus introduced" (p. 219).

He returned to the concept yet again in "Negation" (1925h) in an attempt to link together the experience of satisfaction, on the one hand, and the reality principle, on the other: "[I]t is evident that a precondition for the setting up of reality testing is that objects shall have been lost that once brought real satisfaction" (p. 238). In other words, not only does the experience of satisfaction serve as a bridge between need and desire, it is also the basis for reality testing, which is set in motion by the absence of the real object and by insufficient compensation for that absence through the reactivation of memory traces.

The discussion of the experience of satisfaction thus raises the whole question of primitive hallucination, which Freud, as we know, deemed crucial to the emergence of the infant's very first mental representations. Initially, the experience of satisfaction is linked to the baby's fundamental immaturity—that is, its state of helplessness, its primary and fundamental powerlessness (*Hilflosigkeit*). Incapable on its own of affecting the tension produced by endogenous excitations, the infant must rely on intervention by an outside person. (Guy Rosolato would later interpret this as being the germ of the differentiation between the realm of need and that of sexual difference and autoerotism.) Satisfaction thus comes to be associated with the image of the outside object that has relieved tensions, and when these reappear, there is an active recathexis of the image of the object. Should this recathexis be overly intense, it is liable to produce the same "indication of reality" as the perception itself (hence the possible confusion between the real and hallucinated object, a confusion that is at the heart of the dynamics of desire). According to Laplanche and Pontalis, "the wish, though it originates with a search for actual satisfaction, is constituted on the model of the primitive hallucination" (p. 156). The formation of the ego is what puts an end to this confusion between hallucination and perception by means of its inhibiting role, which prevents an overly intense recathexis of the image of the satisfying object.

Involved here are the notions of "thought identity" and "perceptual identity," which Freud introduced as early as *The Interpretation of Dreams*: what the subject seeks through the direct path of hallucination (thought identity) is invariably something identical to the perception formerly associated with the satisfaction of a need (perceptual identity).

Recent work has attempted to distinguish between the experience of satisfaction and the experience of instinctual gratification, conceived as being broader. In reality, the main discussions have focused more on the nature of primitive hallucination than on the experience of satisfaction itself. Or rather, what is debated is the place of primitive hallucination in the process of the emergence of thought. Some authors have continued to place the absence of the object at the center of this process, while others have emphasized the presence of the object and its relationship with the subject or future subject. Clearly, the experi-

ence of satisfaction is what links these two approaches, the first of which is characteristic of classical psychoanalysts and the second of so-called developmental psychoanalysts, who in particular want to introduce attachment theory into their thinking (John Bowlby).

The absence and presence of the object appear in fact to be fundamentally inseparable, and it is undoubtedly in the experience of satisfaction that the dynamic interactions of need and desire, and even of demand, are most tightly enmeshed.

## **EXTERNALIZATION-INTERNALIZATION**

The terms *externalization* and *internalization* refer to a specific psychic modality of externalizing and internalizing the object. In general, externalization and internalization do not bear on aspects of the object, but rather on the relationships and conflicts that are inherent in the object and that it maintains with other objects. Therefore, if a given aspect of the object is internalized or externalized, a relationship is internalized or externalized. In "Analysis Terminable and Interminable" (1937c), Freud noted that "the ego grows accustomed to removing the scene of the fight from outside to

within and to mastering the *internal* danger before it has become an *external* one" (p. 235). Freud was describing the ego's capacity for internalization, but was adopting a phylogenetic perspective: "[I]n the course of man's development from a primitive state to a civilized one his aggressiveness undergoes a very considerable degree of internalization or turning inwards; if so, his internal conflicts would certainly be the proper equivalent for the external struggles which have then ceased" (p. 244). His essential concern here was to argue for the dualism of instincts and to suggest that the death drive is equal in importance to Eros.

It was Anna Freud who introduced the clinical perspective in *Normality and Pathology in Childhood, Assessments of Development* (1965/1980). In evaluating pathology in terms of the type of anxiety and conflict experienced by the child, she distinguished internalized external conflicts, which correspond to anxieties linked to fear of object-loss and feelings of guilt, from conflict she described as "truly internal" (p. 133). The latter derives from the relationship between the id and the ego and their conflicting aims. According to her, only analysis can give access to this type of conflict.

## **EXTROVERSION/INTROVERSION (ANALYTICAL PSYCHOLOGY)**

Extroversion and introversion are, for Carl Gustav Jung, two typical attitudes of the personality. These terms describe and distinguish two directions of energy within consciousness that attract the individual toward, on the one hand, the external world and its objects, and on the other hand, the internal world and its images. This typological distinction is to be understood as a function of the unconscious dynamics particular to each person. It is not intended to group

together specific and superficial traits of individuals in a characterological way.

The terms *extroversion* and *introversion* were first used in 1913 at the Fourth International Congress of Psychoanalysis in Munich, the occasion of the last meeting between Sigmund Freud and Jung and of their irrevocable rupture. At the time, the terms corresponded to personal concerns: At issue, for Jung, was understanding the conflicts dividing the psychoanalytic movement. This was the thrust of his lecture entitled “The Question of the Psychological Types,” which he concluded by opposing Alfred Adler’s theory, which he termed *introverted*, to Freud’s theory, supposedly *extroverted*, in that the one was centered around a subjective wish (for power), while the other was centered around a sexual quest (for the object). But, beyond this contrast, the importance that Jung attached to the typology illustrates one of his main intellectual choices: the relativization of all theories, including his own.

Extroversion and introversion coexisted in each person, according to Jung, but in different modes. In the normal subject, both were available to consciousness and came into play in alternation to meet the dual necessities of internal adaptation (the unconscious) and external adaptation (outer reality). Type—whether extroverted or introverted—was defined by the relative predominance of one or the other of the two attitudes in the realm of consciousness, the other attitude being partially relegated to the unconscious, where it acted in a compensatory unconscious mode. Finally, in pathological personalities, a single attitude predominated systematically and chronically; the opposing attitude was inaccessible to consciousness, and the compensatory role of the unconscious was manifested only in the form of symptoms.

Extroversion and introversion are in keeping with Jung’s conception of, and practical approach to, the unconscious and with Jungian practices. In this perspective, the unconscious is not solely pathogenic, but also has the potential to create balance, in particular through its compensatory role: it can bring into conscious awareness thoughts, tendencies, and impulses that consciousness neglects or rejects. Dreams, symbols, and parapraxes—also in addition to symptoms—serve as vectors of these unconscious compensations.

Extroversion and introversion cannot be conceived without four functions that are their modes of expres-

sion: thought, feeling, intuition, and sensation. It is important not to confuse a particular feeling, thought, sensation, or intuition with the function that mobilizes it. The former are contents of different values, while the latter is an operating system that makes it possible to utilize the corresponding content. Jung situates these four functions in systems of oppositions. He especially emphasizes the dynamic relation between the privileged function, which partakes of the power of consciousness, and the inferior function, which, by virtue of the fact that it is relegated to the unconscious, is less differentiated, but also contains a strong potential for change. The integration of this inferior function into consciousness is one of the paths to individuation.

Among criticisms of these Jungian views, the most vehement are directed less at the categories of extroversion and introversion than at the functions, their division into rational-irrational pairs, their number, and the nature of their opposition.

Admittedly, the typology of attitudes proposed by Jung and his theory of the functions could be further refined, but, far from having been conceived after the fashion of a personality test, they provide the stimulus for conceptualizing and dealing with the workings of the psyche as a system that is structurally complex, dynamic, and ever-evolving.

## **EY, HENRI (1900–1977)**

Henri Ey, a French psychiatrist and philosopher, was born on August 10, 1900, and died on November 9, 1977, in Banyuls-dels-Aspres, in the Pyrénées-Orientales region of France. After completing his secondary educa-

tion in Sorèze, Ey began studying medicine in Toulouse. He was accepted as an intern at the Asiles de la Seine in 1925 and completed his studies in Paris, where he also studied philosophy at the Sorbonne and attended classes by Pierre Janet at the Collège de France. During this period he became friendly with several other interns, in particular, Jacques Lacan, Pierre Mâle, and Julien Rouart.

In 1931, while working at the Clinique des maladies mentales (Mental Health Clinic) at Sainte-Anne Hospital, Ey, a senior psychiatrist under Professor Henri Claude, met the first French psychoanalysts invited to practice there: René Laforgue, René Allendy, and Édouard Pichon. These men were among the founders of the Société psychanalytique de Paris (Paris Psychoanalytic Society). Together with Eugène Minkowski, they were among the first contributors to the journal *L'évolution psychiatrique* (Psychiatric evolution), launched in 1925 and published since then by the group of the same name that it gave birth to. The reference to *L'évolution créatrice* (Creative Evolution) by Henri Bergson, who critiqued Freud's first publications from a philosophical point of view, helps explain the genealogy of ideas. During the war and occupation *L'évolution psychiatrique* suspended activity, but afterward Ey succeeded Minkowski as manager and editor-in-chief of the journal.

Ey spent most of his career working in hospitals. In 1931 he was appointed as doctor of psychiatry, his first and only position, at Bonneval Psychiatric Hospital (today the Henri Ey Hospital), where he remained until his retirement in 1970. The only interruption occurred when he was mobilized as an army doctor during the war, from 1939 to 1940, and at liberation.

Ey's theoretical work was devoted to applying to the study of mental disorders the ideas of the English neurologist Hughlings Jackson, who was himself inspired by the organicism of the philosopher Herbert Spencer (1820–1903). In organicism (not to be confused with "organicism" in the medical sense), psychic life is characterized by its hierarchical organization, the development of individual functions, their ontogenesis (which reflects the order of their appearance among the species), and phylogenesis. This approach influenced the neurological work of Sigmund Freud, whose *On Aphasia: A Critical Study* (1953) is nothing more than the application of Jackson's principles to aphasia. In 1938 Ey published, together with Julien Rouart, the *Essai d'application des principes de Jackson à une conception dynamique de la*

*neuropsychiatrie* (The application of Jackson's principles to a dynamic conception of neuropsychiatry), though Rouart distanced himself from the ideas expressed in the monograph when it was reissued in 1975.

One of Ey's last psychoanalytic essays to appear before the four years of silence that ensued under the occupation was his "Réflexions sur la valeur scientifique et morale de la psychanalyse" (Reflections on the scientific and moral value of psychoanalysis; 1939). The essay was a response to ideas that Roland Dalbiez had expressed in 1936 in *La méthode psychanalytique et la doctrine freudienne* (Psychoanalytic method and Freudian theory). Ey's article was a brilliant measured attack against psychoanalysis as it existed in France, and the conclusion provides a clear overview of a position he never wavered from: "By attempting to reduce psychoanalysis to its exact limits and by showing that it operates within a zone of indeterminacy greater than Mr. Dalbiez appears to be aware of, we have attempted to be somewhat more relaxed in our criticism of the ideology that has crystallized around a major discovery—Freud's exploration of the unconscious." Throughout his life Ey expressed the same reservations, but these reservations did not prevent him from organizing meetings and discussions that were among the most exhilarating in the history of psychoanalysis in France.

Ey organized a number of famous conferences at Bonneval. Two of the best known are the third, "Le problème de la psychogenèse des névroses et des psychoses" (The problem of the psychogenesis of neuroses and psychoses; 1946), with contributions from Jacques Lacan, who discussed the organodynamism of his friend Julien Rouart, and the sixth, "L'inconscient" (The unconscious; 1960), the text of which was published in 1966 after considerable revision.

Ey had little doubt that psychoanalysis was part of the medical science of psychiatry. It was with this in mind that he organized the first Congrès mondial de psychiatrie (World Congress of Psychiatry), which was chaired by Jean Delay in Paris in 1950. The participants included several of leading names in psychoanalysis at the time: Franz G. Alexander, Anna Freud, Melanie Klein, Jacques Lacan. The congress was so successful that the organizing association transformed itself into the World Psychiatric Association, whose first executive secretary, until 1966, was Ey.

In 1955 Ey edited the first edition of the *Traité de psychiatrie* (Treatise on psychiatry) in the *Encyclopédie*

*médico-chirurgicale* (Medical-surgical encyclopedia). He assigned several chapters to some of the best known analysts of the time, especially those working on neuroses and psychoanalytic theory and practice. Jacques Lacan wrote the chapter “Variantes de la cure-type” (Treatment alternatives).

In 1960 Ey published, with Paul Bernard and Charles Brisset, the *Manuel de psychiatrie* (Manual of psychiatry), which went through six French editions and numerous translations. The manual introduced medical doctors to an approach to psychiatry that transcended the mechanical, linear model that arose out of medical organicism at the end of the nineteenth century. Ey strongly opposed abandoning the ethical dimension of medicine in the treatment of mental patients, which, in his view, was happening in the antipsychiatric movement and could be found as well in the misuse of psychiatry for purposes of political repression.

At the end of his professional life, Ey returned to his home in Catalonia, France, but remained active. There he wrote the *Traité des hallucinations* (Treatise on hallucinations; 1973), in which he devotes an important chapter to the psychodynamic study of hallucinations and, in an organodynamic approach to psychosis, introduces the concept of the “psychic body.”

## FACE-TO-FACE SITUATION

The expression *face-to-face situation* is used to describe the sitting arrangement in psychotherapy, as opposed to psychoanalysis where the patient is on the couch facing away from the psychoanalyst.

Sigmund Freud's prescription is clear as early as 1904 when he wrote, in "Freud's Psycho-Analytic Procedure," "Without exerting any other kind of influence he [the analyst] has them [patients] lie down in a comfortable attitude on a sofa, while he himself sits on a chair behind them outside their field of vision" (p. 250). He was even more explicit in 1913 when he wrote, in "On Beginning the Treatment (Technique of Psycho-Analysis)," "I must say a word about a certain ceremonial which concerns the position in which the treatment is carried out. I hold to the plan of getting the patient to lie on a sofa while I sit behind him out of his sight. This arrangement has a historical basis; it is the remnant of the hypnotic method out of which psycho-analysis was evolved. But it deserves to be maintained for many reasons. The first is a personal motive, but one which others may share with me. I cannot put up with being stared at by other people for eight hours a day (or more). Since, while I am listening to the patient, I, too, give myself over to the current of my unconscious thoughts, I do not wish my expressions of face to give the patient material for interpretations or to influence him in what he tells me. The patient usually regards being made to adopt this position as a hardship and rebels against it, especially if the instinct for looking (scopophilia) plays an important part in his neurosis. I insist on this procedure, however, for its purpose and result are to prevent the transference from mingling with the patient's associations

imperceptibly, to isolate the transference and to allow it to come forward in due course sharply defined as a resistance" (pp. 133–134).

The patient's obligation to lie down, according to the *fundamental rule*, is the second of the two main conditions of treatment that Freud expressed to the Rat Man, who quickly attempted to transgress it (Freud, 1909). Sixteen years later, Freud returned to this issue with Smiley Blanton, as the latter's *Diary of My Analysis with Freud* (1971) reveals: "The position is only a matter of convenience, but one point remains essential: The analysand must not see the analyst's face. If it were otherwise, the analyst's expression would influence him." In *The Fabric of Affect in the Psychoanalytic Discourse*, André Green writes: "Analytic speech is speech delivered lying down . . . addressed to a *hidden partner*" (1999 [1973], pp. 232–233).

The broadening of the types of cases in which psychoanalytic treatment has been deemed possible (psychosis, drug addiction, borderline personality disorders, behavioral disorders, and so on) has modified this previously inflexible rule and led to proposals that certain treatments take place face-to-face, known as "psychoanalytically inspired psychotherapies" (Held). Such therapies have been seen as a means of controlling the narcissistic regression to which the reclining position on the couch is conducive, along with the feelings of depersonalization, overwhelming anxiety states, or mechanisms of defensive rigidification it can entail. A more rational verbalization is thus encouraged; only psychotics are truly uninhibited in communicating their delusional fantasies in face-to-face situations. Better mastery over terrifying impulses to destroy the object can be achieved because of the

constant possibility of seeing that the object—here represented by the therapist via the transference—is still present and intact (which at times necessitates, on the part of the therapist, a no less effective mastery over his or her own countertransference anxieties).

The visual *gaze* intervenes less often as a satisfaction of voyeuristic or exhibitionistic drives than as a testament to the vigilance and security felt by a patient who does not have to fantasize the presence, behind him or her, of an invisible power who sits in judgment and can at any time, without warning, unleash punishment or destruction. The making or avoidance of eye contact is a harder burden for the therapist to bear than for the patient, as Freud noted; behind their elaboration, the crudest countertransference affects are liable at any time to manifest themselves in body language, facial expressions, or a change in attitude that patients unfailingly perceive and interpret.

Can psychoanalytic treatment, in the full sense of the term, take place in the face-to-face situation? Opinion is divided on this issue, although the majority of authors believe that the blocking of fantasies and the difficulty of developing a transference neurosis within a face-to-face situation make it unlikely that an authentic psychoanalytic process can be established. Certain practitioners begin treatment of difficult cases with a period of face-to-face interaction, or insert into classical treatment an interval of face-to-face interaction, which may vary in length, when excessive anxiety makes it dangerous to proceed with treatment within a strictly defined psychoanalytic setting. Such an approach can also be put forward with patients who return to see a psychoanalyst after having finished with classical analysis—a situation that is now increasingly in demand—and, in these cases, must address the often excessive length of treatment and the maintenance of an idealized transference (whether positive or negative) that has been insufficiently analyzed.

In current practice, it is increasingly common for psychoanalysts to interact with patients face-to-face, particularly when only temporary support is required or because a current life event—a trauma, for example—calls for a type of help that remains on the surface of the psychic processes, “at the level of the ego,” to use an accepted phrase.

In the face-to-face situation, where all the parameters of a permanent erotic-aggressive confrontation seem to converge to produce a pure and simple repeti-

tion of a patient’s archaic relational modalities, it is above all important that the psychoanalyst’s listening and physical perception of verbal and intraverbal reality, beyond any reductive fantasmatic project, bring the patient a progressive and profound refutation of their life-sustaining certainty that “nothing can change” and that he or she would run tremendous risks by giving up habitual defenses.

## **FACILITATION**

*Facilitation* refers to the repeated passage of an excitation along the same pathway; this brings about a gradual and permanent decrease in resistance to this progression, and thus this channel develops into the preferred pathway for future excitations.

This term was used very early by Sigmund Freud (1888r, 1892g, 1893k). In the first article, Freud contrasts “facilitation and inhibition” to “reflex” and, in the two other articles, he separates “facilitation” and

“inhibition” as the two modes of reflex transmission. The maximal usage of the term, as defined above, is found in Freud’s 1895 “Project for a Scientific Psychology,” with its neurological model of mental functioning.

Josef Breuer, in the *Studies on Hysteria* (1895), mentions the “attentional facilitation” invoked by Sigmund Exner (1894), who was dealing with the problem of energy and considered attentional facilitation to be pathological. In the “Project for a Scientific Psychology,” Freud reworked the same notion differently to describe learning operations at the level of the “w neurons” and the memory, which tends to establish a type of operations similar to those of the  $\psi$  system governed by the principle of inertia. In this text, facilitation is conceived as a sort of double of the process of cathexis, the other important element in the management of bound energy.

Subsequently, Freud all but abandoned the term *facilitation*, which he uses only three times in *The Interpretation of Dreams* (1900a), where he opposes it to “resistance,” and a final time in “Beyond the Pleasure Principle” (1920g), where facilitation is defined as a “permanent trace of the excitation” (p. 26) obtained through a decrease in the resistance against the progression of excitation.

### FAKEL (DIE-)

A Viennese satirical review published by Karl Kraus, *Die Fackel* (The Torch) played an important role in the intellectual life of the early twentieth century. From April 1899 until February 1936, it appeared three times a month, then at least once every four months. Kraus published it by himself and was the only writer on the review’s staff after 1911. His primary target was the press and its promoters, who were the servants of the moneyed classes. Kraus was in favor of sexual freedom and an ethic of right-speech. Because of his antimilitarist position during the First World War, the publication was censored. A number of Kraus’s articles and aphorisms have been collected in anthologies.

Sigmund Freud, who was already a reader of the publication in 1903, is quoted in it for the first time in 1905 with reference to his *Three Essays on the Theory of Sexuality*. In 1906 *Die Fackel* sided with Freud when he was accused of plagiarism by Wilhelm Fliess. Freud wanted to “join forces with Kraus,” who showed an appreciation for Freud even though believing that art is more important than science and expressing reservations about the interpretation of dreams.

The tone changed in 1910 after Fritz Wittels, who had been a prolific contributor to the publication, presented a paper at the Vienna Psychoanalytic Society entitled “The Neurosis of the *Torch*,” in which he caricatures Kraus’s aversion to the *Neue Freie Presse* as an expression of a desire to kill his father. Kraus then sharpened his barbs against psychoanalysis in aphorisms such as, “Psychoanalysis is a mental disease for which it assumes it is the therapy” (no. 376, June 1913).

**FAILURE NEUROSIS**

The nosographical category of failure neurosis was created and applied mainly in France, as a result of René Laforgue's writings. It is defined in his book *Psychopathologie de l'échec* (The psychopathology of failure; 1941): "We thus speak of the failure of an individual's emotional life or social activity[...]. The person derives from the affective failure itself the strength and the voluptuousness that transforms the unhappiness into happiness."

He used the concept in *L'échec de Baudelaire* (The defeat of baudelaire; 1931), and in chapter eleven of *Clinique psychanalytique* (Clinical aspects of psychoanalysis; 1936/1984) he described it as a specific nosographical category. He was then criticized by Edward Glover in 1939 for following the current trend among French psychoanalysts of isolating multiple clinical syndromes without putting much effort into systematizing them into general categories. Although the chapters devoted to Napoleon and Hitler disappeared mysteriously during the troubled period of the Second World War, his book, which appeared in 1941, took Jean-Jacques Rousseau and Robespierre as examples in order to review and develop the psychopathological variations that clinicians encounter. Laforgue also pointed to Freud's treatment of the subject: "Freud was the first to speak of this syndrome in a short article on *Those Wrecked*

by *Success* but he did not accord to the question all the importance it deserved."

Freud did indeed describe this "character-type" among the causes of resistance to the symptom analysis (1916d). Taking the examples of Lady Macbeth and Rebecca West, a character in Ibsen's *Rosmersholm*, he showed how guilt linked to the possible realization of forbidden desires could lead to a failure as soon as the consciously desired goal was achieved in reality. Laforgue continued this oedipal theme, elaborating it from the notion of the superego (which he called the super-I). Because of his work on "family neurosis" (another syndrome that has since been forgotten), he considered the family environment important.

Failure as "fear of success" translates psychically into inhibitions, depression, even delusions, or physically into clumsiness or accidents of varying degrees, perhaps even fatal. These disorders can correspond to punishment for transgressing a prohibition (appearing after a significant success) or the impossibility of successfully completing a task required by the ego ideal. Other forms have been linked to survivor guilt after the death of a highly cathected object or a catastrophic experience (the Holocaust, for example). These states are usually accompanied by a depressed tone but, as Roy Schafer pointed out, we must be careful not to see all these subjects as "masochists" because this description would imply a sexualization of suffering, which is not always present.

The notion of "fate neurosis," which is quite vague, somewhat clouded the issue of the failure syndrome, which suffered further decline after the Liberation, during the debates around *The Psychopathology of Failure*, first published in 1941 and reprinted in 1944 despite the fact that it was rejected by Matthias Göring, from whom Laforgue had requested a translation. Certain considerations, like "this love of suffering, whether it translates as persecution or worrying about money, is one of the characteristic aspects of the Jewish psychism, as it developed in the ghettos" (1941, p. 42), helped discredit this theory, and since 1945 it has received only rare and brief mention in psychoanalytic literature, being generally associated with studies of adolescence (Mâle; Weil).

## FAIRBAIRN, WILLIAM RONALD DODDS (1889–1964)

British physician and psychoanalyst William Ronald Dodds Fairbairn was born in Edinburgh on August 11, 1889, and died there on December 31, 1964.

Ronald Fairbairn was the only child of middle-class parents with strict Protestant morals and strong academic traditions in Scotland. He studied moral philosophy at Edinburgh University, and divinity and Hellenistic Greek at Edinburgh, Kiel, Strasbourg and Manchester.

Fairbairn made the decision to study medicine and psychotherapy after serving in the First World War. As a medical student he started analysis with E. H. Connell, and shortly after qualifying began thirty years of working with war neuroses. Despite being without the requisite formal training, he began psychoanalytic work in 1925 and obtained his MD in 1927. In 1926 he married and began a family; he started his clinical writing soon after. From 1927 to 1935 he was a lecturer in psychology at Edinburgh University, his special subject being adolescence, and held a post at the Clinic for

Children and Juveniles where he treated the delinquent and sexually abused.

He was introduced to the British Psycho-Analytical Society by both Ernest Jones and Edward Glover, who admired his thinking and intellectual rigor. Fairbairn was elected as associate member of the British Psycho-Analytical Society after presenting a paper to the Society in 1931. He became a full member in 1938.

During the Second World War he held a post in the Emergency Medical Service, and later a government post, while beginning to publish his most important contributions. Isolated from the conflicts in the British Psycho-Analytical Society, he was able to develop his original and independent ideas, and towards the end of his life was increasingly recognized. Fairbairn's first wife died in 1952, and he remarried in 1959.

Fairbairn's principal contributions can be found in his book *Psychoanalytic Studies of the Personality* (1952), and his article "An Object Relation Theory of the Personality" (1954). Several of these contributions are outlined below.

Fairbairn moved from a biological model to a psychological one, in which the early unitary ego is genetically geared towards object relationships. Energy is inseparable from structure in this model, and "drive" is seen as the struggle for integration, individuation and recognition within a human environment.

He described a theory of development based on a maturational sequence of relationships throughout life, from infantile dependence to "mature dependence." To this he added a theory of endopsychic structure and its development, in which the ego, as it becomes attached to different (ideal, exciting, rejecting) aspects of mother, internalizes them and splits (this is the "schizoid condition," inevitable and basic). The ego divides into a "central" ego, partly conscious and available for real relationships; a "libidinal" ego; and an "antilibidinal" ("internal saboteur") ego, both unconscious. The central ego also internalizes what Fairbairn called the "ideal object," and in order to earn its approbation develops the "moral defense" of guilt; it is the central ego, operating in the "real world" and also in touch with inner structures, that can mediate between them and lead to the opening up of the inner world to reality.

Fairbairn also developed a theory of psychopathology based on real environmental failure, in which the infant internalizes and identifies with the bad aspects

of its parent(s), and represses the relationships, together with memory, fantasy, and attached affect. The type and severity of psychopathology depends on the degree of splitting and repression required, the defenses against it, and the amount of remaining central ego available for external relationships. Here there are implications for psychoanalytic technique, particularly in the understanding of repetition compulsion.

One of the most important founders of object-relations theory, Fairbairn left work that has been increasingly influential, both in the United Kingdom and internationally. Those particularly influenced include members of the British Independent Group, attachment theorists, self-psychologists, and intersubjective theorists.

## **FALSE SELF**

The false self, in Donald Winnicott's developmental schema, refers to certain types of false personalities that develop as the result of early and repeated environmental

failure, with the result that the true self-potential is not realized, but hidden. This idea appears in many papers and is fully presented in "The theory of infant-parent relationship" (Winnicott, 1965c).

From 1945 onward Winnicott described the infant's development. In the earliest object relationships the infant is most of the time unintegrated and absolutely dependent, requiring at first the mother's totally reliable and empathic response (primary maternal preoccupation). Later the infant accepts her gradual but tolerable failures in provision (good enough mothering) and proceeds to ego integration and relative dependence. "Not good enough mothers," those who are unable to satisfy the excited infant's needs or who demand an inappropriately integrated response from an infant unable to give it, Winnicott describes as impinging and traumatizing. When repeated traumas occur very early in development, the infant experiences extreme dread or primitive agony, and psychosis may result. To such a mother, who fails to meet the infant's gesture and substitutes one of her own, the older and more integrated infant responds in a compliant fashion. In this way the infant may develop a false self that builds up a set of relationships based on compliance or even imitation, the potential true self being unrealized and hidden.

Winnicott described five degrees of false self. In the extreme case, the true self is completely hidden, and the false self appears authentic and is frequently successful, though failing in intimate relationships. In nearly normal cases, the false self is bound by the ordinary restraints necessary for social adaptation. Winnicott emphasizes a particular type of false self in which intellectual activity is dissociated from psychosomatic existence.

Winnicott is elusive in style, because he writes from an object-related point of view. In this viewpoint, the undifferentiated infant ego exists from the beginning in a relationship without knowing it, because the sense of self and other does not yet exist. Winnicott's developmental approach, of which the concept of a false self is one aspect, differs from those of Freud and Klein. He does not directly address instincts in themselves, for instance, since his focus is on the developing and dynamic relationship between what will become the individual and the environment in which that individual will grow. His theory parallels but also differs from that of Fairbairn. On Fairbairn's theory, environmental failure and lack of early intimacy must result in

defensive splitting, schizoid mechanisms being the most basic. From there, there are many subsequent possibilities in terms of character development and psychopathology. Winnicott held that one can ameliorate false-self organizations of personality only by facilitating regression in analysis.

## **FAMILY**

Family is usually defined as a group of persons related by marriage or blood ties, or even by adoption—and also by the family bond.

Psychoanalysis contains an implicit concept of family. It emphasizes the functions of each family member and the prescriptions and prohibitions governing the relationships between them, which influence conflicts, fantasies, and the psychic agencies.

The family is a unit that consists of something more than a series of individuals; it is a group to which they belong and that provides support with its rules, which are as obscure and powerful as those of the unconscious and that thus ensure the family's coherence and cohesion. The family has many purposes: providing for its members' material and psychic needs and conceiving and developing the child until his accession as a subject. Each parent transmits a legacy that the child will have to negotiate in connection with its wishes. The family also has a function in terms of play, creating the space and time for leisure and reverie.

Before Freud, doctors took little interest in the family. The patient was studied in the present, without reference to childhood history, to the context in which he had developed, or to his father or mother, except to identify any hereditary predispositions that would reinforce the prevailing hypothesis concerning degeneration in mental patients. Freud raised the family to a preeminent position. However, after he quickly abandoned the seduction theory, the family headed by a seducer changed its status from a real entity to a theoretical fantasy. Freud still addressed the family as a real entity in the form of the primal horde (1912–1913a), with the authoritarian father put to death by his sons who were excluded from sharing the women. Freud subsequently returned to this hypothesis as to the origin of culture. For example, his group psychology (1921c) helped to explain family psychology. It may even be that he envisaged the functioning of the group and the crowd as an archaic family dominated by a leader (father) at whom his subjects direct their (ego) ideal cathexes. This model bears a curious resemblance to the family of ancient Rome, in which the father was the uncontested leader around whom the life of the household revolved. There are some revealing exceptions to this lack of interest in the real family, for instance, the account that the child's father gives to Freud in the analysis of "Little Hans" (1909b). It was not unusual at the time for a single analyst to treat different members of the same family.

As the real family receded from the picture, the representations of the parents gained ground, particularly through the increased interest in object relations. The shifting importance of the family relates to developments in the theory of trauma. However, the real problem is discovering not whether the original theory of trauma was definitively abandoned by Freud but whether it was given anything

other than a factual status. It would then not simply be the presence of the object or the primary maternal care that contributed to introjections but the parent's subjectivity, desires, fantasies, and affects—in other words, the force of his unconscious desire, which orients the child's ideals by proposing an ideal that reinforces his self-esteem when he experiences it as an important part of himself and which awakens the life of the drives by seducing him.

The analytic theory of the family is based on this model. It addresses the way in which the reciprocal cathexes between its members are managed and mobilized. Donald Winnicott explained this unconscious functioning as a productive network of interrelated fantasies giving rise to a generative illusion on the part of the mother and her child, whose attuned psyches are connected by primary narcissistic identifications. This generates the concept of the bond: An object relationship would be inconceivable without its counterpart, in other words, without the cathexis that the external object creates of the former and applies to him (Eiguer, 1987).

Furthermore, the concept of the bond is complicated by the dual nature of filiation. The family romance (Freud, 1909c [1908]) is a fantasy in which the child gives himself another origin by imagining himself to be adopted or illegitimate. While assuaging his oedipal anxieties, he seeks, by inventing better or prestigious parents for himself, to preserve the previous idealization of his own parents. However, in giving himself other parents (or one other) than his own, he acknowledges an essential dimension of filiation: The parental roles are not equivalent to the procreative functions—they can even be independent of these. In matrilineal cultures in particular, the father's role of strict educator reverts to an uncle who is related to the mother. Although Freud's discovery relates to a set of fantasies, this nevertheless accords with the idea of an underlying imago-based structure. The transgenerational figure of the ancestor ultimately evokes this spiritual fatherhood in the other of the father, the fourth family member.

## FAMILY ROMANCE

The family romance is a conscious fantasy, later repressed, in which a child imagines that their birth parents are not actual but adoptive parents, or that their birth was the outcome of maternal infidelity. Typically, the fantasy parents are of noble lineage, or at least of a higher social class than the real parents.

The family romance (Freud, 1909c[1908]) differs from children's sexual theories in that it does not address general questions about the origins of life but rather the question, "Who am I?"—where "I" denotes not an agency of the mind (or ego) but the result of an effort to place oneself in a history, and hence the attempt to form the basis of a knowledge.

The family romance fantasy has several possible aims and sources: revenge against frustrating parents; rivalry with the parent of the same sex; separation from idealized parents by means of their transformation into fantasy parents; and the elimination of brothers and sisters for competitive or incestuous purposes.

The family romance is built on the basis of the child's intuitive knowledge of their parents' emotions, although the parents may believe these perfectly con-

cealed (see Freud, *Totem and Taboo* [1912–1913a]; also, apropos of the paranoid's intuitiveness, "Some Neurotic Mechanisms in Jealousy, Paranoia and Homosexuality" [1922b [1921]]).

Other intellectual capacities are necessary for the creation of a family romance, notably the ability to compare and to relativize. The fantasy may thus be considered the result of a basic psychological attainment, that of the right to doubt—here, to doubt the absolute aspect of parental figures ("*Pater semper incertus est*"). The family romance is, in fact, linked to the unconscious of the parents. For the father, there can be only one true father, his own, that of the "primal horde"; while the mother associates her child psychologically, particularly her first-born, with her own oedipal attachments (Mijolla). This first childhood romance is often maintained in daydreams well beyond puberty. Its influence is also discernible in the pleasure novel-readers derive by identifying with different fictional characters.

## **FANON, FRANTZ (1925–1961)**

Frantz Fanon was born on July 20, 1925, in Fort-de-France on the Caribbean island of Martinique and died on December 6, 1961, in Washington, D.C. He is best known for his work in fighting against colonization.

Fanon was the son of a native Martiniquan father (the descendant of slaves and a member of the island's middle-class community), and a French (Alsace) mother (herself the daughter of a mixed marriage). Between 1939 and 1943 he studied at the Lycée Schoelcher, where he was taught by Aimé Césaire, a poet who helped destroy the image of the African created by European colonization. In 1943, then a young man, Fanon became a dissident and agitated against representatives of the Vichy regime in the Antilles. He traveled to the island of Dominica to rally the free French forces in the Caribbean. In 1944 he fought on the European front. Wounded near the Swiss border, he received a citation for his courage, signed by Colonel Raoul Salan, whom he would later fight against in Algeria.

After receiving his baccalaureate at the special session of March 1946, he went to Lyon, France, to study medicine (1946–1951). After a brief stay in Martinique at the end of 1951, he returned to Lyon to specialize in psychiatry under the direction of Professor Tosquelles. There he met Octave Mannoni. The two men became friends, but Fanon was highly critical of Mannoni's *Psychologie de la Colonisation* (Psychology of colonization). He became a psychiatrist in June 1953. In 1954 he was appointed to a post in Blida, Algeria. He saw patients during the day and, at night, participated in the struggle for Algerian independence. He was expelled from Algeria in January 1957. At the end of the summer of 1958, Fanon settled in Tunis to resume his double life. He died in 1961 from leukemia.

He developed an interest in psychoanalysis fairly early in his career; he speaks of it in his first book, *Black Skin, White Masks* (1967a), published when he was twenty-seven. His attitude is that of a colonized subject who, disappointed by racism, grows skeptical of European universalism. Yet he began this work with the following statement: "Only a psychoanalytic interpretation of the black problem can reveal the emotional anomalies responsible for the resulting complexes." Fanon saw Sigmund Freud, Alfred Adler, and Carl Gustav Jung as more or less the same. His form of psychoanalysis is more of a social therapy based on liberation than of a talking cure.

**FAMILY THERAPY.** *See* Psychoanalytic family therapy

His ideas, as represented in his books—*Studies in a Dying Colonialism* (1965a), *The Wretched of the Earth* (1965a), and *Toward the African Revolution* (1967b)—can be summarized as follows: There is a specific pathology associated with colonization. The core of the emotional disturbances affecting black people is an inferiority complex, in the Adlerian sense. The Oedipus complex does not occur in families from the Antilles. The unconscious, as described by Jung, is collective. Analysis of the social-historical development of the individual must take precedence over any other approach. Freud, Jung, and Adler were not thinking about black people when they formulated their theories. He rejected the idea of determinism, believing that humankind was abandoned to its own fate.

He was unable to overcome his resistance to psychoanalysis at the time of his premature death at the age of thirty-six.

## FANTASY

A fantasy is a product of the imagination in the form of a script in the theatrical or cinematic sense and deployed in support of a wish-fulfillment. It may be a conscious creation, a daydream created by the subject to procure an imaginary satisfaction that is erotic, aggressive, self-flattering, or self-aggrandizing in nature. This wish-fulfilling function likens the daydream, or reverie, to night dreams, but it may also be com-

pared to symptoms or behavior with similar aims. It must therefore be supposed that all these manifestations have a common origin, namely unconscious fantasy.

The term *Phantasie* was part of everyday language, where it signified “fancy,” “imagination.” It appeared very early in Freud’s writings, notably in the *Studies on Hysteria* (1895d), where he noted the frequency of daydreams among hysterics. However, the word soon took on a more precise meaning and the concept was expanded centrally in the burgeoning science of psychoanalysis. In a letter dated May 2, 1897, to Wilhelm Fliess, Freud wrote, “I have gained a sure inkling of the structure of hysteria. Everything goes back to the reproduction of scenes. Some can be obtained directly, others always by way of fantasies set up in front of them. The fantasies stem from things that have been heard but understood *subsequently*, and all their material is of course genuine.” (p. 239). Later, in Draft M (May 25, 1897), we find this: “Fantasies arise from an unconscious combination of things experienced and heard, according to certain tendencies. These tendencies are toward making inaccessible the memory from which symptoms have emerged or might emerge. . . . As a result of the construction of fantasies like this (in periods of excitation), the mnemonic symptoms cease” (1985a [1887–1904], p. 247).

Already, then, at this early moment, Freud posited unconscious fantasy as the source of the symptom, of the dream (soon to be elaborated on in *The Interpretation of Dreams*, 1900a), of daydreams, parapraxes, and so on. But the claim that “all [this] material is of course genuine” was significantly revised. On September 21, 1897, he famously announced to Fliess, “I no longer believe in my *neurotica*” (p. 264)—that is, in an etiology for hysteria attributable in all cases to a trauma actually experienced during childhood. This is not to say that Freud now abandoned his seduction theory. But in the wake of a sudden disillusionment, he entered a long period leading to his recognition that the traumatic event was never recorded exactly per se, and never endured in unmodified form but, quite to the contrary, was subject to incessant reworking after the fact. From that moment, indeed, Freud was convinced that “there are no ‘indications of reality’ in the unconscious, so that one cannot distinguish between truth and fiction that has been cathected with affect” (p. 264); or in other words between historical (or event-defined) reality and fantasy. It was possible,

then, that in some cases the hysterical symptom was the product of “pure fantasy”; seduction nevertheless existed, especially in view of the fact that a child might read this connotation into “innocent” events.

The birth of the psychoanalytical concept of fantasy may thus be dated 1897; in Freud’s self-analysis, its advent coincides with that of the Oedipus complex. As Freud wrote to Fliess on October 15, 1897, “I have found, in my own case too, [the phenomenon of] being in love with my mother and jealous of my father, and I now consider it a universal event in early childhood” (p. 272). This twin birth was acknowledged by Freud a quarter of a century later in *An Autobiographical Study* (1925d): “When, however, I was at last obliged to recognize that these scenes of seduction had never taken place, and that they were only phantasies which my patients had made up or which I myself had perhaps forced upon them, I was for some time completely at a loss. . . . When I had pulled myself together, I was able to draw the right conclusions from my discovery: namely, that the neurotic symptoms were not related directly to actual events but to wishful phantasies, and that as far as the neurosis was concerned psychical reality was of more importance than material reality. . . . I had in fact stumbled for the first time upon the Oedipus complex” (p. 34).

There are references to fantasy throughout Freud’s work, especially prior to the major theoretical revision of the 1920s. In his paper on “Screen Memories” (1899a), he revealed the role of adolescent fantasies in the work of reconstructing childhood memories. *The Interpretation of Dreams* (1900a), based on the idea of the dream as a wish-fulfillment, was itself a study of nighttime expressions of fantasy, while *Delusions and Dreams in Jensen’s “Gradiva”* (1907a) and “Creative Writers and Day-Dreaming” (1908e) were centered on the eruptions of fantasy during waking life. “Hysterical Phantasies and their Relation to Bisexuality” (1908a) was a reconsideration, ten years after its initial formulation, of the theory of symptom production through fantasy. In spite of its title, “On the Sexual Theories of Children” (1908c) also examined the role of fantasy: certain “theories” were constructed by the child to explain the mysteries of sexuality, conception, and birth, but they were in effect also imaginary productions similar to reveries. In the “Wolf Man” case history (1918b [1914]), Freud, returning at length to the problem of the relationship between event-defined “historical reality” and fantasy creation, ended by

re-embracing the notion of “phylogenetically” transmitted primal fantasies, previously discussed in *Totem and Taboo* (1912–1913a). Of special importance too is the essay “A Child is Being Beaten” (1919e), where Freud analyzed the genesis and structure of a particular fantasy in which erotic pleasure was tied to the evocation of punishment experienced by a (different) child.

The notion of fantasy nevertheless remained rather vague in Freud’s work. It presented a number of problems for him, especially that of the relationship between fantasy and representation. More generally, there was the question of the role played by fantasy in mentation. For Freud, the instinct was the living source of all mental activity, as he clearly asserted in *The Interpretation of Dreams*. The dream was a wish-fulfillment, but the dual action of primary processes and secondary revision could bring about transpositions and distortions that permitted the latent thoughts of the dream to cross over into the dream’s manifest content, to transform from unconscious fantasies into explicit images better able to break through the barrier of the censorship. In Chapter 7 of *The Interpretation*, Freud extended this model to psychic work as a whole in order to account for the transition from fantasy to mental representation, which were closely akin because of their common origin. The result, paradoxically, was that the difference between them was clearly pointed up: whereas the fantasy was an internal formation, created without reference to reality, mental representations drew their very substance from their relationship with the outside world. In “Formulations on the Two Principles of Mental Functioning” (1911b), Freud reiterated that fantasy served the pleasure principle exclusively, while mental representation, though it might transpose fantasy, answered strictly by the reality principle. Both the close kinship and the basic difference between fantasy and mental representation are easy to discern in Freud’s account of hallucinatory wish-fulfillment, where he describes that founding moment when the infant obtains satisfaction by hallucinating the real, but absent, agent of satisfaction, and then, since the need remains, begins to “represent” that absence (the representation of the object arises from its very absence). W. R. Bion was a leader among those authors who have sought to thus develop a theory of mental activity designed to illuminate the relationship between fantasy and representation.

The fact remains that back in 1897 Freud ran into a difficulty that continued to occupy him for the rest of his life and is still a crucial question for psychoanalysis in the twenty-first century: If instinctual forces are indeed the live source of wishes or fantasies, which mediate them, how can the forms of those wishes be explained, and more specifically how is it that *typical* forms, seemingly derived from a common matrix, occur very widely among people whose history and psychic make-up vary considerably? Freud posed this question repeatedly in his account of the “Wolf Man” (1918b [1914]), where he offered a meticulous, albeit hypothetical reconstruction of events that took place in his patient’s life between the ages of eighteen months and four years old in order to explain his subsequent pathology. Yet Freud continued to feel that such an explanation, based on a person’s real history, left something to be desired. He consequently appealed to an even earlier “historical reality”—that of the human species as a whole: “It seems to me quite possible that all the things that are told to us today in analysis as phantasy . . . were once real occurrences in the primaeval times of the human family, and that children in their phantasies are simply filling in the gaps in individual truth with prehistoric truth” (1916–1917a, p. 371). This echoed the “fiction” Freud had developed in *Totem and Taboo* (1912–1913a) according to which, at the time of the “primal horde,” the sons killed their father and committed incest with their mother; ever since, the unconscious memory of that primal drama has left its stamp on every human being.

It is not unreasonable to have reservations about this speculation. Nevertheless, clinical psychoanalysis has verified the role of “fantasies” that can be qualified as “primal,” however one regards their historicity, in that they are the basis of every individual fantasy. Freud mentioned three varieties: “I call such fantasies—of the observation of sexual intercourse between the parents, of seduction, of castration, and others—‘primal fantasies’” (1915f, p. 269). But this enumeration should not be looked upon as definitive; it should no doubt include the fantasy of a return to the mother’s breast (for further discussion of primal fantasies, see Laplanche and Pontalis).

Among post-Freudian developments, Melanie Klein’s contribution is the most important. Continuing the line of enquiry that Freud opened up in “Instincts and Their Vicissitudes” (1915c) and reorganized after 1920 by introducing the life and death

instincts, Klein assigned a leading role to the play of fantasy in the mental life of young children; indeed, she even seemed to make the apprehension of reality subordinate to fantasy in the context of a battle royal between love and hate that aroused massive anxiety. The beginning of mental life was envisaged by Klein as the scene of a tragedy played out by fantasies of invasion, cannibalism, deadly attacks on the breast and by the breast, explosion, laceration, and so forth. This approach was further advanced by some of Klein’s followers, notably Donald Meltzer. Significant theoretical support was supplied by Susan Isaacs in her paper “On the Nature and Function of Phantasy” (1948).

A very different approach was taken by Jacques Lacan, who compared fantasy to freezing the frame of a moving picture. In contrast to the Kleinian view, the emphasis here was on the defensive function of fantasies, which sought to “freeze” the evocation of violent scenes, and first and foremost those responsible for castration anxiety. For Lacan, the neurotic fantasy was an attempt, always fruitless, to respond to the enigma of the desire of the other. However varied individual expressions of fantasy themes might be, the aim of analysis was always to circumscribe the typical basic fantasy of each analysand, its place and role in the symbolic structure that determined that analysand’s particular mode of gratification (*jouissance*).

Michèle Perron-Borelli (1997) has taken an entirely different tack, providing a general overview of fantasy in the context of an original theoretical reformulation of the problem. Noting that every fantasy is centered on a representation of action, whether active in nature (e.g., seducing) or passive (being seduced), she defines fantasy in terms of a three-part structure comprised of an agent, an action, and an object of the action. This structure is analogous, for Perron-Borelli, to the basic grammatical subject/verb/object pattern; this is no accident, perhaps, if one accepts that language reflects the development of thought itself, and its origins in fantasy. All fantasy activity, therefore, and indeed all thought, may be conceived of as a system of transformations of this basic structure by a variety of means: changing of places by the subject and the object relative to the action (change from activity to passivity or vice versa), the replacement of the object or the subject, the assumption by the subject of the viewpoint of an outside observer; and so on. In this view, the subject comes into being and develops by virtue of these transformations themselves. At a deeper level, the starting-

point is sought in a “primal fantasy matrix” in the autoerotic life of the infant.

## FANTASY, FORMULA OF

In his early seminars, especially *Object Relations* (1956–57), Jacques Lacan primarily conceived of fantasy as deriving from psychic projection that screened a more painful image. He compared it to a freeze-frame, where an immobile image is often used to conceal the traumatic image that will come next. Thus he first conceived of fantasy as a defensive structure designed to protect against the perception of “lack” in the maternal other, thus of castration. A study of the different forms of the fantasmatic defense allow for a better understanding of psychical structures.

Following leads found in Freud’s writings—especially “The Wolf Man” (1918b [1914]) and “A Child is Being Beaten” (1919e)—Lacan questioned the

relation between the fantasy and fixation on perceptual traces. He also addressed the larger question of memory. He determined that fantasy need not be radically opposed to memory. Instead, he suggested that fantasy might rework memory depending on the pressure of unconscious desire and the defensive strategies of the subject. Thus Lacan stressed that fantasy fundamentally worked to transform memories of real events.

In particular, he emphasized that the subject is always represented in fantasy, as in the dream, in a more or less obvious way. In fact, the fantasy stages a certain relation and mode of interaction between the subject and the object of desire. Thus conceived, fantasy is a complex structure, a kind of scenario, as opposed to the simple hallucination of an object. Lacan proposed a general formula for it:  $\$ \diamond a$ . Here the diamond,  $\diamond$ , formalizes the specific relation that the subject of the unconscious,  $\$$ , which is “divided” by its relation to the realm of signifiers, maintains with the object “little *a*,” the “lost” object, the “detached” remainder of the first operation of symbolization by the parental other. The famous list of Freudian “detachable” objects (breast, feces, penis, baby), to which Lacan added the voice, the gaze, and the phōneme, all constitute object-causes of desire (objects *a*) that are not representable as such. The subject will spend all his or her life searching for various imaginary and concrete intermediary objects to take their place in the realization of desire.

In April 1961, in his seminar on the *Transference*, Lacan tried to define the various types of fantasies: The hysteric aspires to a master. The obsessional’s fantasy involves an indefinite metonymic substitution. And the pervert’s fantasy seeks to radicalize the subject/other split, so that it can be enjoyed; this fantasy tends to take the form  $a \diamond \$$ .

In his fundamental text, “The Subversion of the Subject and the Dialectic of Desire in the Freudian Unconscious” (1960), Lacan tried to place fantasy in the genesis of the psychic apparatus by locating it within his “graph of desire.” The major difficulty here is that the object of the drive, the object of physiological need, and the object of narcissistic love/hate maintain with each other a relation of fundamental and irreducible heterogeneity.

For Lacan, the psychoanalytic treatment must locate the subject’s more or less unconscious

“fundamental fantasy.” At the same time the subject’s particular mode of enjoyment is exposed, and freed as much as possible from the desire of the Other, in relation to which the fantasy is always a compromise formation. The objective of any treatment is always to produce a change in the subject’s defensive processes, to remove obstacles in order to allow the subject access to his or her own enjoyment.

Lacan fully recognized the power of the image in fantasy, but he insisted on the fact that its functional value derives from the place that it comes to occupy in the larger symbolic structure. In other words, its value derives from the fact that the image in question (a representation of something unconscious) must be able to play its role as a signifier. On this point, Lacan launched an unceasing attack on (primarily Kleinian) currents in psychoanalysis that tended to consider the fantasy as a production of images that were assumed to be symbols in their own right. He devoted an entire year of his seminar (*The Logic of Fantasy*, 1966–67) to unraveling the theoretical implications of the inscription of fantasy in the unconscious signifying structure. Most notably, he insisted that fantasy would perform the essential function of “knotting” the psychological registers of the symbolic, the imaginary, and the real—and thus of constituting what Freud called “psychic reality.”

## FANTASY (REVERIE)

The term *reverie* refers to an imaginary representation created to help realize a desire. The term *Phantasie* was used by Freud to designate such mental activity collectively, whether conscious or unconscious. In French

the term *fantasme* prevailed in psychoanalytic use, for it was felt that the term *fantaisie* was too marked by current usage, where it connotes the idea of capriciousness or gratuitousness. However, following Daniel Lagache (1964), the term *fantaisie* came to refer to imaginary conscious or preconscious creations, without ignoring their continuity with the unconscious fantasies they reflect.

Daydreams, which everyone experiences, are the clearest examples of conscious or preconscious reveries. In general they explicitly satisfy a desire, providing some form of imaginary satisfaction, whether it be erotic, aggressive, ambitious, self-aggrandizing, or uplifting. It is not even unusual for people to visualize painful or humiliating experiences to their own advantage. In all these cases the narcissistic dimension of the process is obvious.

There are references to such daydreams in the *Studies on Hysteria* (1895d), primarily in the case study of Anna O., written by Josef Breuer. Freud wrote about daydreams in *The Interpretation of Dreams* (1900a). For example, when analyzing his dream about the “botanical monograph,” he relates a daydream during which he imagines that, afflicted by glaucoma, he travels incognito to Berlin for an operation and experiences considerable pleasure in listening to the surgeon extol the anesthetic qualities of cocaine (thus being compensated for the pain Freud experienced through being too late to be recognized as the one who discovered its properties). The “fantasies (*Phantasien*), or daydreams, are the immediate predecessors of hysterical symptoms... Like dreams they are wish-fulfillments; like dreams they are based in large part on our infantile experiences; like dreams they enjoy a certain relaxation of the censorship for their creations.”

According to Freud, a daydream is initially the expression of an unconscious fantasy; then, it is used as available material among the latent thoughts used by dreams. However, as he noted, there is an essential difference between night dreams and daydreams: the first is hallucinatory, the second is not, and the person remains more or less clearly aware that his daydream is a an escape from a reality that is not completely suspended.

This distinction can be blurred or even disappear entirely. Freud analyzes this phenomenon in his detailed commentary on Wilhelm Jensen’s *Gradiva* (1907a). In the same period, in “Creative Writers and

Daydreaming” (1908e [1907]), he discusses the function of daydreaming in the genesis of the literary work, and later, in “Family Romances” (1909c [1908]), he foresees the situation where daydreams are used by the child to avoid the oedipal conflict by imagining himself to be adopted, to be really the child of a king and queen.

Robert Desoille (1961) developed an original method of psychotherapy based on the development and analysis of the patient’s daydreams during therapy. For some patients and under certain circumstances, analytic psychodrama can create scenarios that are related to daydreams.

## FASCINATION

Fascination commonly refers to the act of fascinating or of being fascinated. To fascinate is to immobilize by the power of the gaze; as well as to charm, enchant, dazzle, or even attract or capture someone else’s gaze.

In psychoanalysis the concept was used by Sigmund Freud to refer to the bondage of love. He used this term to refer to the paralysis of critical faculties, the dependence, docile submission, and credulity that occur when in love, which he compared to what occurs in the relationship between hypnotist and hypnotized.

The term appears for the first time in *Group Psychology and the Analysis of the Ego* (1921c). Fascination, or love bondage, is the term Freud uses to describe the most extreme developments of being in love. It is possible that he borrowed the term from Gustave Le Bon, whom he quotes and who had noted,

in *Psychologie des Foules*, that the individual in a crowd arrives at a particular state that approximates the fascination of the hypnotized for the hypnotist.

Although the first occurrence of the term *fascination* appears to date from 1921, what Freud describes is the result of earlier considerations that quickly led him to associate being in love with the hypnotic state. Already in 1890, in his article “Psychical, or Mental, Treatment,” (1890a) referring to the docility, obedience, and credulity of the hypnotized individual, he had noted that in a situation of this type “subjection on the part of one person towards another has only one parallel, though a complete one—namely in certain love-relationships where there is extreme devotion.” In 1910, in a note added to *Three Essays on the Theory of Sexuality* (1905d), he again points out this connection. In 1918, in “The Taboo of Virginity,” (1918a) he discusses the question of “sexual bondage,” the expression used by Richard von Krafft-Ebing to define the state of subjugation, dependence, and loss of will experienced during the course of a sexual relationship.

In 1921, what he describes with the term *fascination* is, therefore, not new, any more than the concordance he establishes between this state and that of hypnosis: the same paralysis of critical faculties, the same docility, the same submission toward the loved object or the hypnotist. These findings open the way to the problem of the imaginary relationship of the self to the loved Other or the authority figure, and lead one to believe that fascination is essential to the constitution of the ego—a thesis put forward by Jacques Lacan.

The function of the gaze is central to fascination, so it is surprising that the term doesn’t appear in the 1922 article on “Medusa’s Head” (1940c). The phenomenon is similar to the paralysis (of thought, judgment, and the body) caused, in the myth, by the encounter with the Gorgon. Here mortal hypnotic fascination reaches its apogee. The power of the gaze is the bearer and vector of the “omnipotence of thought,” like the phenomenon of the “evil eye” Freud had analyzed in 1919 in “The ‘Uncanny’” (1919h). It is also surprising that although, in 1916, he presents the goddess Baubo as a representation of castration, or interprets the Medusa’s head, along with Sándor Ferenczi, as a representation of the female genital organs and more specifically the mother, he never explicitly raises the question of fascination and what can cause it, namely, the sight of the

female genitals and the representation of castration they bring to mind.

## FATE NEUROSIS

Helene Deutsch developed the notion of “fate neurosis” on the basis of the notion of “compulsion of destiny” (*Schicksalszwang*), which Freud mentioned at the end of the third chapter of *Beyond the Pleasure Principle* (1920g, p. 23). In that work Freud described the following trait in nonneurotic people: “The impression they give is of being pursued by a malignant fate or possessed by some ‘daemonic’ power; but psychoanalysis has always taken the view that their fate is for the most part arranged by themselves and determined by early infantile influences. . . . Thus we have come across people all of whose human relationships have the same outcome: such as the benefactor who is abandoned in anger after a time by each of his *protégés*, however much they may otherwise differ from one another . . . or the man whose friendships all end in betrayal by his friend; . . . or again, the lover each of whose love affairs with a woman passes through the same phases and reaches the same conclusion” (pp. 21–22).

Helene Deutsch developed this clinical description beginning in 1930 in her paper “Hysterical Fate

Neurosis" (1965), in which she presented a case involving a such neurosis. Hysterical fate neurosis, she explained, "is a form of suffering imposed on the ego apparently by the outer world with a recurrent regularity. The real motive of this fate lies, as we have seen, in a constant, insoluble, inner conflict" (p. 27). She linked the neurosis to a lack of control over an anxiety-inducing childhood situation that arose during the genital phase.

The term *hysterical fate neurosis* then came to be used in a broader sense to describe individuals who lack neurotic symptoms but whose history is marked by repeated painful experiences.

Although some English-speaking writers have referred to this notion briefly, most psychoanalysts have moved away from a "psychopathology of fate" that could not be more clearly defined in metapsychological terms, despite the efforts of such authors as Jean Laplanche and Jean-Bertrand Pontalis. In the entry on fate neurosis in their *Language of Psychoanalysis* (1967/1974), they attempted to give it a more precise meaning and to distinguish it from "character neurosis," noting that the experiences characteristic of fate neurosis had to be "repeated despite their unpleasant character," had to "unfold according to an unchanging scenario," and had to "appear to be governed by an external fate, whose victim the subject feels himself—with seeming justification—to be" (p. 161).

Nevertheless, the notion of fate neurosis continues to be invoked, essentially for descriptive purposes, because it implies a holistic view of the individual, whose past, present, and future are more than a simple succession of random events.

## **FATHER COMPLEX**

The expression *father complex* was used by Sigmund Freud in the period 1910–1913 to designate feelings of guilt and of castration anxiety relating to the father, and therefore to the Oedipus complex.

The expression first appears in the article "The Future Prospects of Psycho-Analytic Therapy" (1910d), when Freud wrote that "in male patients the most important resistances in the treatment seem to be derived from the father complex and to express themselves in fear of the father, in defiance of the father and in disbelief of the father" (p. 144). He attributed specifically to Carl Gustav Jung the coinage of the term *complex*, and in the same year he used it in developing the expression "Oedipus complex," which was at this time nearly synonymous with "father complex."

The expression was hardly ever used by Freud again, except in *Totem and Taboo* (1912–13a), where it took on a more specific meaning. Here, in essence, it referred to the guilt and castration anxiety experienced by the son in the "primitive horde" after the murder of the father, which in turn led to the repression of incestuous wishes toward the mother. Transmitted from generation to generation, this complex explains the permanence and universality of the Oedipus complex.

The expression father complex has almost entirely disappeared from usage in contemporary psychoanalysis.

**FATHER (NAME OF).** *See* Name-of-the-Father

## FATHERHOOD

Fatherhood has been described as the cause and fulfillment of the father's creative, protective, and organizing power in his child. As a physical and symbolic bond between generations, fatherhood implies the authority of the father over the child, expressed through the transmission of the name. The sons use this aspect of paternity in the construction of their own individual and social identities, and in their respect for the law. Fatherhood is the basis of all thought.

Discovering in his self-analysis, through his dreams, that fatherhood satisfied both his desire for immortality, through his children, as well as his ambivalence toward his own dead father, Sigmund Freud fathered psychoanalysis when he published *The Interpretation of Dreams*, and established that the desire of Oedipus to sleep with his mother and kill his father is universal.

Fatherhood is an organizing system indissociable from the Oedipus complex. It links the law to desire and to castration. It structures and restrains sexuality, through the father, who is simultaneously loved, protective, and feared. It condenses conflicts of ambivalence and the castration anxiety. Fatherhood induces repression and prompts progress: It is an inevitable and indestructible origin and obstacle that unites the scattered ego, while showing how to overcome ambivalence through identification with the father. Its dynamic potential is anchored in the father-mother-child triangle it structures, not in the person of the father who supports the paternal function. Hans (1909b), in the throes of an oedipal crisis at four years of age, introjects the cultural treasure linked to fatherhood into the mythical power of language and knowledge. He is ignorant of the procreative function: Paternity, as the hidden cause for the production of children, confutes childhood trust, obstructs independent thought, and betrays the subject's expectation of protection. A child affected by nostalgia for the father will displace it onto God.

Fatherhood was considered to have had a phylogenetic origin, recapitulated by ontogenesis (1912–13a). Having murdered the violent and jealous primal father, the sons discover the symbolic paternity of the father in the work of mourning, made up of ambivalence, guilt, and idealization. Retrospective obedience and the renunciation of the father's omnipotence are at the origin of the social contract and the law. For Freud fatherhood also occupies a central place in the subject's genital organization through the father com-

plex. Linked to death and sexuality, which it transcends, and serving as an atemporal and structuring reference point, it channels through its incarnated generating power the diphasic sexual development of the child-become-adolescent, opening him up to the effects of *Nachträglichkeit*, sublimation, and the wish to become a father in his turn.

Identification is the prototype of this operation; first, the human subject constitutes itself through "primal" identification with the "father of personal prehistory" (1923b), an incorporation of paternity that includes the mother. Fatherhood then, logically, enables the subject's separation from the mother and authorizes relations of generation, dramatized as arising from a primal triangle, with differentiated parental imagos. Secondly, the oedipal crisis ends, with the installation of the impersonal superego.

The bond with the father is essential for a daughter (1933a). Involved in an intense pregenital relation to her mother, she enters late into the Oedipus complex, turning her outwardly directed libido inwards. She displaces her love onto her father, from whom she wants a child-penis. Her major anxiety, that of being no longer loved, often keeps her dependent on her bond with the father. As a mother she offers fatherhood to the man who is substituting for her father, if she has transcended her own claim to the phallus.

The bond of fatherhood is connected for the child with the desire that links the mother to the father. Paternity exerts itself when the child induces a "foreigner" (1939a) who is the father to adoption. For Jacques Lacan, a failure of this metaphorizing recognition is responsible for the foreclosure of the Name-of-the-Father, which leads to psychosis. Melanie Klein prefigured the oedipal complex through the nipple-object guiding the child's access to the breast, a paternity incarnated at the very heart of maternity.

Fatherhood can be considered as a development when becoming a father leads to psychic restructuring.

## **FAVEZ-BOUTONIER, JULIETTE (1903–1994)**

A psychoanalyst and teacher, Juliette Favez-Boutonier was born near Grasse, France, in 1903, and died in Paris on April 13, 1994.

The daughter of teachers in the Alpes-Maritimes, to which she returned nearly every year until her death, Favez-Boutonier studied in Grasse and Nice. She later traveled to Paris to study philosophy at the Sorbonne, for a while with Léon Brunschvicg. In 1926 she was one of the first women ever to take the state doctoral exam in philosophy. She was only twenty-three at the time.

She taught at schools in Chartres and Dijon, while studying medicine, which was a required preparation for anyone who wanted to practice psychology at the time. In 1930 she wrote to Sigmund Freud, who responded personally on April 11 that “philosophical problems and their formulation were so foreign to him that he didn’t know what to say.” In 1938 she wrote her doctoral dissertation on ambivalence (La notion d’ambivalence); the text was reprinted in 1972. In 1935 she obtained a job in Paris teaching

philosophy and it is here that she met Daniel Lagache and began analysis with René Laforgue, with whom she remained friends for many years. During the Occupation, Laforgue entrusted Favez-Boutonier with the Freud letters he had preserved.

At this time she met with members of the Société Psychanalytique de Paris (SPP, Paris Psychoanalytic Society) who had remained in Paris. John Leuba wrote to Ernest Jones on December 31, 1944, the day after the Liberation, that new analysts were now beginning to appear, including “Mlle Boutonier, a gifted physician and philosopher with a sound technique; she was monitored by me and I can confirm that she will be one of the first recruits.”

For Favez-Boutonier the relations between psychoanalysis and philosophy were complex and, in 1985, for the reprint of the memorable session held January 25, 1955, by the Société Française de Philosophie (French Philosophy Society), Juliette Favez-Boutonier wrote about her experience writing her thesis. Her thesis director was Gaston Bachelard, who was using psychoanalysis as a therapeutic method as well as a philosophy. She had said after the publication of her thesis that she was the first to explore Freudian psychoanalysis in a noncritical way, and she was grateful to Bachelard who allowed her to express her experience in psychoanalysis within her interest for psychology and philosophy. Her thesis, *Anxiety*, was published in 1945 by Presses Universitaires de France and, in 1947, was awarded the Prix Paul Pelliot “Junior.” The “Senior” prize went to Henri Wallon.

While working for the Centre national de la recherche scientifique (CNRS) she presented several papers to the SPP and was elected a member in 1946. Having trained in clinical psychopathology at the Sainte-Anne Hospital with Georges Heuyer, she was put in charge of the Centre Psychopédagogique Claude-Bernard, which had been created by Georges Mauco. She was soon replaced by André Berge, for that same year she was appointed professor in the humanities department at the University of Strasbourg.

Close to the circle of analysts around René Laforgue, she participated in meetings and contributed to *Psyché*, the review founded by Marie Choisy in 1946. She argued in favor of “assistant psychologists,” participated in the Section des Psychanalystes d’Enfants, and tried to promote the creation of psychoanalytic groups throughout the country, especially in Strasbourg. This led to a conflict with those who were

setting up the future Institut de Psychanalyse de Paris (Paris Institute for Psychoanalysis). In 1952 she married Georges Favez, one of the future presidents of the Association Psychanalytique de France (French Psychoanalytic Association).

She intervened on behalf of Mrs. Clark-Williams during her trial in 1951–1952, believing that “psychoanalysis was a psychological technique.” This position, joined to her opposition to what she referred to as the “dictatorship” of Sacha Nacht, grouped her with Daniel Lagache and Françoise Dolto at the beginning of the 1953 split in the French psychoanalytic establishment and subsequent creation of the Société Française de Psychanalyse (French Society for Psychoanalysis), of which she would become the first vice president. For ten years she shared the trials and tribulations of the Society in its attempts to join the International Psychoanalytic Association, and was president during its dissolution following the second split in 1964.

Along with her membership activities, she had her own practice and taught psychoanalysis. However, some of her most important work was done within the French school system. She was appointed a professor at the Sorbonne in 1955, where she held the chair of general psychology. Didier Anzieu succeeded her at the University of Strasbourg. Although she encouraged work on group psychology, her own interest was clinical psychology, basing many of her ideas on the subject on those of Daniel Lagache. She appointed Laforgue the head of her laboratory in 1958. Along with Jacques Gagey, Claude Prévost, and Pierre Fédida, she was recognized as a “clinical psychologist” in 1968 after helping with the creation of the department “des Sciences Humaines Cliniques,” which was opened at the University of Paris VII.

Favez-Boutonier’s long life and career were characterized by an intellectual depth and richness that drew from the wellsprings of philosophy and psychoanalysis, which helped to enrich her clinical work in psychology and psychopathology.

## **FAVEZ, GEORGES (1901–1981)**

Georges Favez, a Swiss psychoanalyst, was born on February 15, 1901, in Lausanne, Switzerland, and died on February 15, 1981, in Paris. His family ran a gourmet food store. He had an older sister, who was unmarried when she died, and from his first marriage he had a daughter whose three children Favez adored.

After studying in Leipzig and Strasbourg, Favez wrote his theology dissertation on Luther and worked as a country pastor in a free evangelical church rather than in the national church of the canton of Vaud. In 1936 he resumed his studies in Geneva at the Institut de l'éducation (Institute of Education), then under the supervision of Edouard Claparède, but he failed to sit for the final exam, which he felt he did not need for his future career as a teacher and psychotherapist.

From 1936 to 1938 Favez stayed in Paris with Georges Heuyer. In 1940 he was analyzed by Heinz Hartmann in Lausanne. Shortly after the war broke out, Favez was mobilized, and his analyst went into hiding and later emigrated to the United States. Favez divided his time among his psychoanalytic practice, the Office médico-pédagogique (Medical-Pedagogical Office), and the Maison d'éducation de jeunes délinquents (Home for the Education of Young Delinquents) in Vennes, Switzerland.

During the first Congrès des aliénistes et neurologistes de langue française (Congress of Francophone Psychiatrists and Neurologists), held in Lausanne in 1946, Juliette Boutonier, André Berge, and Georges Mauco visited the first Centre psychopédagogique français (French Psychopedagogical Center) at the Lycée Claude-Bernard in Paris in preparation for its opening. It was at this time that Favez met Boutonier, who became his wife in 1952. He began making frequent trips to Paris as a consultant and colleague at the Claude-Bernard center. He commuted regularly between Lausanne and Paris, and underwent analysis with Sacha Nacht. He was elected a member of the Société psychanalytique de Paris (Paris Psychoanalytic Society) in 1948. After his (third) marriage in 1952 to Boutonier, he settled permanently in Paris, on rue Descartes.

At this time, at the home of either Favez or Françoise Dolto, Favez, together with Daniel and Marianne Lagache and Juliette Favez-Boutonier, formed the Société française de psychanalyse (SFP, French Society for Psychoanalysis). Jacques Lacan joined shortly after its formation. In 1964 the society split into two groups: the École freudienne de Paris (Freudian School of Paris), under the supervision of Jacques Lacan, and the Association psychanalytique de France (APF, French Psychoanalytic Association), presided over by Daniel Lagache. Favez was one of the most active partisans for the association.

Favez devoted a great deal of his energy to the Association psychanalytique de France. He was soon elected secretary of the selection committee (formerly the training committee), a position he held for many years, and was president in 1966–1967. He was convinced that the association had a role to play in the French psychoanalytic landscape.

In 1966 he began to issue a semiannual newsletter, which published the psychoanalytic talks of the APF and reports of association activity. He was actively engaged in the activities of teaching and transmission and helped train many APF students. He also did much to popularize psychoanalysis. For example, after the war he had a program on Radio-Lausanne and gave many talks during the Journées des centres psychopédagogiques (Festival of Psychopedagogic Centers) and at SFP and APF events.

In 1971 and 1974 he published two articles that are still considered important: “L’illusion et la désillusion dans la cure psychanalytique” and “La résistance dans l’analyse.” A number of his articles are collected in *Être psychanalyste* (1976).

Those who knew Favez remarked on his intelligence, depth, and intellectual clarity. In his work he constantly emphasized the framework of psychoanalytic therapy and the psychoanalyst’s thoroughness and resolve. He loved Bach and Mozart, had a wonderful sense of humor, and enjoyed lively discussion. He was, according to Didier Anzieu, a man who lived well. Firmly rooted in clinical practice, he liked to quote Charles Ferdinand Ramuz: “We die making claims about ideas before having made claims to things.” He died in Paris on February 15, 1981, the day of his eighth birthday.

In 1982 the APF journal *Documents et débats* devoted issue number twenty to Favez’s memory. It

included articles by Jean-Claude Lavie, René Henny, André Bourguignon, and François Gantheret, together with a biography by Didier Anzieu.

### **FAVREAU, JEAN ALPHONSE (1919–1993)**

Jean Alphonse Favreau, French psychoanalyst and psychiatrist, was born on February 5, 1919, in Bordeaux, France, and died on May 30, 1993, in Saint-Léger-aux-Bois, France. Favreau belonged to a Catholic family that originally came from Guadeloupe. His father, an obstetrician, became a professor of obstetrics at the Catholic medical faculty in Lille, France, where Jean Favreau began his medical training in 1938. His studies were interrupted by the Second World War. Demobilized in 1940, he finished his studies in medicine in Bordeaux and later in Paris. In Lille he had met Jeanne-Marie Lejenne, whom he married in 1947. A physician herself, she became a psychoanalyst in 1957 and died in 1988. They had six children.

Through the lectures (published in the *Journal de Médecine de Bordeaux*, June 1913) and books of Angélo Hesnard owned by his father, Favreau learned of Sigmund Freud’s theories and was won over. In 1945 he embarked upon what would become a three-year analysis with John Lueba. In 1948, under the supervision of Sacha Nacht and Marc Schlumberger, he began the analysis of his first patients. These cases, taken in the context of his hospital practice, he did for free, which he justified in terms of the poverty and somewhat utopian climate that prevailed in the postwar period. Viewing free practice as a way of experimenting with possibilities for treatment under a different political and economic regime, he focused his

research on the effect of free treatment on the development and resolution of the psychoanalytic process.

This spirit persisted in the orientation and management of the Centre de consultations et de traitements psychanalytiques (Center for Psychoanalytic Consultations and Treatment), which was founded by Sacha Nacht in 1954 and where Favreau served as head physician beginning in 1958. His prior institutional experience dated from 1948, when, with Pierre Mâle, he helped create a hospital service for children aged six to ten years that allowed psychoanalysts to treat not just children but also their families. In this context he gained work experience consulting with families and supervising the psychotherapeutic treatment of children. He worked in a similar capacity at the Centre de consultations et de traitements psychanalytiques until his death, although he was succeeded as director by Jean-Luc Donnet in 1989.

Favreau's work bears the imprint of his practice, since clinical experience remained at the heart of his theoretical contributions. Working from cases of adult analysands, he sought to elucidate the "fantastic" and metapsychological genesis of the psyche and its successive alterations. The birth of the psyche is traumatic, he believed. Hence the object of psychoanalysis is human nature, not psychopathology. He illustrated this point in a report on the psychoanalytic treatment of an alcoholic patient emphasizing process rather than results. This focus on process was an important consideration for him. He also focused on those aspects of the development of human sexuality that are most often passed over in silence because they are subjected to intense repression and give rise to shameful feelings that wound the subject's narcissism, aspects such as anal sexuality and our animal nature in general. In this regard, he, together with his wife, contributed an article titled "Considérations sur les anomalies du comportement sexuel chez l'animal" (Considerations on Anomalies in Sexual Behavior in Animals; 1964) to a book on animal psychiatry. He was guided in his theoretical work by Freudian metapsychology and granted considerable economic importance to the idea of *après-coup* (deferred action).

Favreau transmitted his knowledge of psychoanalysis to younger analysts through supervision groups and seminars. The oral mode of communication was well suited to his thought because it is closer than writing to the experience of treatment and the emergence of the unconscious. In his work one thus finds a

greater concentration on practical aspects of psychoanalysis (such as indications for treatment, the psychoanalytic process, and the training of psychoanalysts) than on purely theoretical issues. Nevertheless, his contributions to child psychoanalysis and the study of children's emotional problems remain remarkably relevant and sound. He constantly insisted that the basis of theory is the drives and language, and he ascribed a determining role to the dialectical relationship among anxiety, suffering, and pleasure. Favreau published twenty-two articles, many of them written collaboratively or given in the form of interviews—yet another indication of his personable style.

### FEAR

The term *fear*, whose metapsychological status remains uncertain, was used by Freud, in contrast to *anxiety*, to refer to the reaction to some real danger. In several works Freud discussed the semantic relationship between the terms *Angst* (anxiety), *Furcht* (apprehension, fear), and *Schreck* (fright). For Freud the distinction between anxiety and fear relates primarily to its

object, a distinction found in his earliest writings. In an article from 1895, which discusses the distinguishing characteristics of phobias and obsessions, he differentiates phobias “according to the object of the fear,” while anxiety refers to the emotional state experienced by the subject, without reference to a specific object (1895c [1894]). Similarly, in 1916, in his *Introduction to Psychoanalysis* (1916–1917a [1915–1917]), Freud, referring to the use of these terms in popular speech, indicated that “anxiety is related to a state with no direct allusion to an object, while in fear the person’s attention is precisely focused on the object.”

In 1920, in *Beyond the Pleasure Principle* (1920g), Freud emphasized the difference between fear and anxiety in terms of their relation to danger: Anxiety is a state characterized by the expectation and preparation for a danger, “even if unknown,” while fear implies a determinate object. In *Inhibitions, Symptoms, and Anxiety* (1926d [1925]), he further insisted on the association of anxiety with a state of expectancy and the use of the term *fear*—“in keeping with current usage”—to represent the situation when anxiety has found an object.

We see that the term *fear* is quoted with reference primarily to contemporary language. According to Catherine Cyssau, fear has no means of representation and its object does not conform to the criteria for repression. Although the status of anxiety, as an affect, occurs early in the development of Freudian theory, fear is more uncertain and seems to fall mostly within the context of behavioral description. Moreover, the opposition between fear and anxiety is hardly ever mentioned in Freud’s later writings, especially in the *New Introductory Lectures on Psychoanalysis* (1933a [1932]), where the theory of anxiety is again discussed.

In fact, another concept appeared in 1916 in Freud’s writings, that of “*Realangst*,” which can be translated as “realistic anxiety” or “anxiety in the face of a real danger,” and which is contrasted with neurotic anxiety or the anxiety of desire. In the *Introduction to Psychoanalysis*, Freud emphasized the rational and comprehensive nature of realistic anxiety, triggered by the perception of an external danger, that is, under conditions that can give rise to fear. From then on the fundamental question, to which he would frequently return, was that of the conditions required for the emergence of anxiety, a signal triggered by an external or internal danger.

In post-Freudian work the concept of fear is essentially used to characterize certain infantile manifestations of anxiety. Anna Freud, in particular, insisted on the structural differentiation between archaic, or primitive, fears and the phobias. It is important to remember that the “fear of the stranger’s face,” which, as described by René Spitz, arises in the infant when it is between six and eight months old, raises the question of determining if this reaction should be interpreted as a realistic anxiety responding to an external danger—the face perceived as unknown—or if it is an expression of unpleasure and the internal threat caused by the absence of the maternal object.

Fright, or *Schreck*, which is associated in several Freudian texts with traumatic neurosis, corresponds to the effects of a danger for which the subject “is not prepared by an earlier state of anxiety” (1916–1917a [1915–1917]). Freud goes on to say that anxiety contains “something that protects against fright” (1920g).

Roger Dorey has remarked that Freud, in *The Interpretation of Dreams* (1900a), described, in contrast to the “primary experience of satisfaction,” an “experience of fright whose origin is external” and which leaves behind a painful memory trace that the primitive psychic apparatus tries to avoid. This flight before the memory of the present pain, is, according to Freud, the “model and first example of psychic repression.” Thus, the prototype of fright is nothing but the experience of object loss, an experience that submerges the primitive psychic apparatus in excitations it is unable to control. For Dorey this “painful memory image” of the absent object forms a representation that contributes to the formation of the primal unconscious.

## FECES

In a letter of December 22, 1897, Sigmund Freud wrote to Wilhelm Fleiss: “[B]irth, miscarriage, and menstruation are all connected with the lavatory via the word Abort (Abortus)” (p. 240). In German this word does effectively carry these different meanings.

Freud was to further develop these reflections in his “Three Essays on the Theory of Sexuality” (1905d), where he describes the phases of libidinal development from birth onward. The retention of fecal matter initially corresponds with an intention to use it for masturbatory purposes. The whole meaning of the anal zone is thus reflected in the fact that “few neurotics are to be found without their special scatological practices, ceremonies, and so on, which they carefully keep secret” (p. 187).

However, another link, that between fecal matter and money, emerged in listening to the discourse of obsessive patients; this link is expressed in one of the traits of the anal character, avarice. Freud writes in “Dreams in Folklore” (1958 [1911]): “How old this connection between excrement and Gold is can be seen from an observation by Jeremias: gold, according to ancient oriental mythology, is the excrement of hell” (p. 187).

Based on these associations, Freud establishes a symbolic equation that he phrases as follows: “[I]n the products of the unconscious—spontaneous ideas, phantasies, and symptoms—the concepts *faeces* (money, gift), *baby* and *penis* are ill-distinguished from one another and are easily interchangeable” (p. 128). When the child perceives that woman does not have a penis, the latter is conceived as being detachable and is thus analogous to excrement when it is separated from the body. In the same text, Freud underscores the importance of this equivalence in terms of the object: “Defaecation affords the first occasion on which the child must decide between a narcissistic and an object-loving attitude. He either parts obediently with his faeces, ‘sacrifices’ them to his love,

or else retains them for purposes of auto-erotic satisfaction and later as a means of asserting his own will” (p. 130). The love object that must be renounced (the mother of childhood), the lost object, will be identified by the Unconscious with feces, the body’s most intimate product, which must necessarily be relinquished; this marks the onset of the dynamics of loss, mourning, and melancholia.

Returning to the connection between feces and money in “From the History of an Infantile Neurosis” (1918b [1914]), Freud emphasizes that an interest in money is libidinal rather than rational in character, and that it thus relates back to excremental pleasure. The various terms in the sequence *filth* = *money* = *gift* = *child* = *penis* are thus treated as synonyms and represented by shared symbols.

In his “New Introductory Lectures on Psychoanalysis” (1933a), Freud completed his views: According to infantile theories of sexuality, the child is born from the intestine as a piece of feces; defecation is the model for the act of being born. “A great part of anal erotism is thus carried over into a cathexis of the penis” (p. 101), he writes.

## FECHNER, GUSTAV THEODOR (1801–1887)

Gustav Fechner, German physician, physicist, and philosopher, was born on April 19, 1801, in Gross-Sächen, Prussia, and died in Leipzig on November 18, 1887. Freud admired Fechner as the pioneer of psychophysics and a founder of scientific and experimental psy-

chology. Together with his boyhood friend Eduard Silberstein, Freud attended Fechner's lectures in Leipzig in 1874.

Fechner studied medicine at the University of Leipzig. While still a student, he began writing articles (under the pseudonym Dr. Mises) that satirized contemporary science, and he did not become a practicing physician after receiving his degree. Instead, he turned his interest to physics and mathematics. His research demonstrating the validity of Ohm's laws in relation to a galvanic current led to his appointment as professor of physics in 1834. About 1839 Fechner was forced to leave his academic post due to an eye ailment that he attributed to exhausting research in optics. In his diary, which has been preserved at the University of Leipzig, Fechner described his experiences while ill and the existential crisis and depression that followed.

In the wake of his illness, Fechner developed his interest in sensation, the relation of mind to body, and panpsychism. "The great G. T. Fechner," as Freud called him, was appointed professor of philosophy and anthropology in 1843. In the course of this second creative period, he set out the foundations of psychophysics, such as the Fechner-Weber law, by which he is remembered as a founder of experimental psychology. His two-volume *Elemente der Psychophysik* was published in 1860.

Fechner's ambitions extended beyond experimental research. He hoped to organize psychophysics and metaphysics in a way that united philosophy and the human sciences. Major works toward fulfilling this aim include his 1848 article on the pleasure principle and *Einige Ideen zur Schöpfungs- und Entwicklungsgeschichte des Organismen* (Certain ideas on the creation and development of organisms; 1873). In this latter work Fechner offers the "principle of constancy" to explain how a progressively ordered and structured system can evolve from a disorganized state, a notion that suggests Freud's famous formula, "Where id was there ego shall be." (In this sense Fechner was also a precursor of the theory of the ego's self-organization [see, for example, Prigogine and Glansdorff].) Although Fechner's works inspired Freud when he conceived his concepts of the pleasure principle and the death instinct (Nitzschke), a systematic study tends to demonstrate that they were separated by fundamental differences in outlook.

## FEDERACIÓN PSICOANALÍTICA DE AMÉRICA LATINA

Formerly known as the Coordinating Committee of Psychoanalytic Organizations of Latin America (COPAL), the Federación psicoanalítica de América latina (FePAL; Psychoanalytic Federation of Latin America) brings together the Latin American psychoanalytic societies recognized by the International Psychoanalytic Association (IPA).

FePAL's objectives are as follows: to stimulate the expansion of member societies and the development of the psychoanalytic movement throughout Latin America within the framework of the IPA's established rules and stated goals, without prejudice to the autonomy of the organizations in the federation; to represent the common interests of member societies and their associates before the IPA; to create a forum for scientific exchange through publications, congresses, and meetings, among other activities; to facilitate scholarly exchanges among member organizations, the establishment of teaching programs, and training criteria in the various institutes; to encourage the

spread of psychoanalysis in Latin America; and to develop and offer advice and assistance to the psychoanalytic movement in areas where there is no member organization.

The Third Latin American Psychoanalytic Congress (the two preceding congresses were held in Buenos Aires, Argentina, and São Paulo, Brazil) was held in Santiago, Chile, in 1960, under the aegis of the Chilean Psychoanalytic Association. Ignacio Matte-Blanco was president of the organizing committee. At the administrative meeting, the decision was made to establish a Coordinating Committee of Psychoanalytic Organizations of Latin America (COPAL), presided over by Arnaldo Rascovsky—a veritable impresario for the idea of bringing Latin America's psychoanalysts together as an association.

COPAL was provisionally made up of the representatives of the societies or groups present at the meeting: for Bogotá (Colombia), Carlos Plata Mújica; for Mexico City, Avelino González; for Montevideo (Uruguay), Willy Baranger; for Porto Alegre (Brazil), Cyro Martins; for Rio de Janeiro (Brazil; Sociedade Brasileira de Rio de Janeiro), Fabio Leito Lobo; for São Paulo, Darcy de Mendoça; for Santiago, Carlos Whiting D'Andurain; and for Buenos Aires, Arnaldo Rascovsky.

COPAL acted as a pressure group before the IPA and succeeded in gaining representation on the IPA's steering committee. Léon Grinberg was the first Latin American representative to sit on the steering committee, followed by Avelino González, from Mexico, and later Luiz Dahleim, from Brazil. They were in turn succeeded by Carlos Plata, from Colombia; David Liberman, from Argentina; and Paulo Grimaldi, from Brazil. Later, this trend toward authorizing Latin American participation on the committee stabilized, and Angel Garma was elected honorary vice president of the IPA. Latin America's active political presence in psychoanalysis worldwide led to the granting of two vice presidencies for that continent. Thanks to the active intervention of this group, led initially by COPAL and later by FePAL, Latin America has obtained three vice presidencies on the IPA's governing board. The first IPA congress in Latin America was held in Buenos Aires in 1989; the second was held in Santiago in 1999.

During the 1960s and 1970s, through the efforts of teaching analysts who traveled to various regions to disseminate psychoanalytic knowledge, COPAL was extremely effective in promoting the scientific devel-

opment of the discipline, particularly in areas where the discipline was not yet well developed.

The exercise of political power brought internal frictions to COPAL, and at the International Congress of Psychoanalysis held in New York in 1979, a meeting between the organization's governing authorities and its delegates led to the resignation of a number of dignitaries, not without expressions of tensions, attitudes, and demonstrations that became extremely subjective in the case of some participants. This institutional crisis led to a new organization with participation of the societies, established groups, and groups-in-formation. An assembly of delegates was convened in Rio de Janeiro on June 6, 1980; the delegates approved the statutes of a new organization called the Federación psicoanalítica de América latina (FePAL), charged with the scientific development of Latin American psychoanalysis and organization of its congresses and exchanges between various regions. Primacy was given to democratic participation, and an order of succession to leadership of FePAL was established and has been respected ever since. Since its inception, FePAL has organized ten congresses; it serves as the umbrella organization for psychoanalysis throughout Latin America.

The successive presidents of COPAL were: Arnaldo Rascovsky, Marie Langer, Santiago Ramirez, Carlos Plata Mújica, David Zimmermann, Willy Baranger, Darcy M. Uchoa, and Fernando Cesarman. FePAL's successive presidents include: Joel Zac, Fernando Cesarman, Néstor Goldstein, Victor Aiza, Fábio Antonio Herrmann, Eustachio Portella Nunes, Alberto Pereda, Saul Peña, Alejandro Tamez Morales, Guillermo Carvajal, and Cláudio Laks Eizirik (1998–2000).

As of 2004, the federation included twenty-seven societies and study groups. New realities and the need for a more flexible and representative structure that would benefit from a more active participation by the presidents of member organizations have prompted debate on the reform of FePAL's statutes. The congress held in September 2000 in Gramado, in the state of Rio Grande do Sul (Brazil) was organized around the theme of "Psychoanalysis and Culture: Between the Couch and the Community." The pre-congress teaching workshops held in conjunction with the congress and focusing on "Children and Adolescents," "Myths," and "OCAL" attracted increased participation. At a meeting in February 2000 in Manaus (Brazil) there was a new edition of the Clinical Meetings of FePAL-

NAIPAG to mark the opportunity for Latin American and North American psychoanalysts to come together to discuss their clinical material and to share and compare their experiences.

The federation is in negotiation with the European Psychoanalytical Federation (EPF) to resume and establish regularity in the scheduling of FePAL-EPF Clinical Meetings. FePAL's *Boletín* (Bulletin) is published every six months; the *Revista Latinoamericana de Psicoanálisis* (Latin American revue of psychoanalysis) was restructured in keeping with the format and policies of the main international psychoanalytic journals. FePAL offers societies and study groups the possibility of an annual scientific exchange with invited participants from other Latin American institutions, and is considering an exchange program with analysts in other regions.

In 1998, FEPAL held its XXII congress in Cartagena de las Indias, Colombia, whose title was Cumbre Psicoanalítica Latino-Americana (Latin American Psychoanalytic Summit), under the presidency of Guillermo Carvajal. Several international authors gave lectures. In 2000, its XXIII Congress was in Gramado, Brazil, about *Psicanálise e Cultura: Entre o Divã e a Comunidade* (Psychoanalysis and Culture: Between the Couch and the Community), under the presidency of Cláudio Laks Eizirik. This was an extremely well attended congress, where the leading authors of the analytic field were present, and psychoanalytic research and the history of psychoanalysis in Latin America, were formally included in the program, as well as joint discussions with outstanding members of Latin American culture. The XXIV Congress was in Montevideo, in 2002, under the presidency of Marcelo Viñar, having as main theme *Permanencias y Cambios en la Experiencia Psicoanalítica* (What is permanent and what changes in the psychoanalytic experience). This Congress privileged small groups discussions, was also very well attended and introduced sending previously all papers by disc to all those registered, so that there were no formal presentations, but immediate discussions among the participants. In 2004, the XXV Congress was held in Guadalajara, Mexico, under the presidency of Serápio Marcano, with the main theme *Psicoanálisis en Latinoamérica Hoy: Teoría y Práctica en tiempos de Crisis* (Psychoanalysis in Latin America Today: Theory and Practice in a Period of Crisis).

Several clinical meetings were organized, in recent years, with North American colleagues, which stimulated fruitful exchanges. In recent congresses, from

Fepal as well in those organized by the European Federation, and the North American institutions, there are invited members from the other two regions, which indicates a growing interchange. Fepal holds its administrative meetings regularly, publishes its *Revista Latino-Americana de Psicanálise* (Latin American Journal of Psychoanalysis), and has an ongoing scientific program of exchanges among its component societies. In spite of difficult social and economic conditions in most countries of Latin America, psychoanalysts and candidates affiliated to FEPAL keep a continuous and passionate interest and commitment with psychoanalysis and contribute to its development both as a theory and a clinical practice.

In the next IPA Congress to be held in Rio de Janeiro, in July, 2005, the first one in Brazil, the second Latin American will become the IPA president, Cláudio Laks Eizirik, following the pioneer role of Horacio Etchegoyen, in 1993.

Beyond these activities, another dimension should be taken into account: FePAL provides a forum for meetings and joint reflection on psychoanalytic theory and clinical practice in the specific context of the particular cultures of the countries it represents and within the framework of a broader Latin American identity, with all the challenges currently posed by that condition.

### **FEDERN, PAUL (1871–1950)**

Paul Federn, an Austrian physician and psychoanalyst, was born in Vienna on October 13, 1871, and died in New York on May 4, 1950.

The son of a famous Viennese doctor and nephew of a celebrated Prague rabbi, Federn was raised in a family with a longstanding liberal tradition. After receiving his medical diploma in 1895, he interned in general medicine with Hermann Nothnagel, who introduced him to the works of Sigmund Freud.

Deeply influenced by Freud's *Interpretation of Dreams*, in 1904 he devoted himself to psychoanalysis and, with Alfred Adler, Wilhelm Stekel, and Rudolf Reitler, became one of Freud's early disciples.

Federn was as interested in the analysis of social phenomena as he was in prevention and treatment of disease. In *Zur Psychologie der Revolution: die Vaterlose Gesellschaft* (On the psychology of revolution: the fatherless society; 1919), he analyzed the challenge to authority by the postwar generation as unconscious parricide aimed at creating a "fatherless society." In line with his interest in applying psychoanalysis to public health, in 1926 he published, together with Heinrich Meng, *Das psychoanalytische Volksbuch* (Popular psychoanalysis).

Of the Viennese disciples, Federn worked longest with Freud and was highly esteemed by him. He was such a loyal supporter of Freud that he was referred to as the "Apostle Paul" of the psychoanalytic movement. His position within the Psychoanalytic Society continued to grow over the years. In 1922 he helped Eduard Hitschmann and Helene Deutsch establish the Vienna Ambulatorium, and during the 1930s he was one of the coeditors of the *Internationale Zeitschrift für Psychoanalyse* and editor of *Zeitschrift für Psychoanalyse und Pädagogik*. But the most important source of official recognition came from Freud himself, who, in 1924, made him, along with Anna Freud, his official representative and vice president of the Vienna Society, a position he held until 1938.

After emigrating to America in 1938, Federn settled in New York. Though he got recognition for his medical diploma (which he received before 1914), it was not until 1946 that he was officially recognized as a training analyst at the New York Psychoanalytic Institute. He committed suicide after the recurrence of what he felt was an incurable cancer.

In addition to ego psychology, Federn was interested in the therapy of psychosis. Even his earliest writings, devoted to the sources of sadism and masochism and typical dream sensations (1914), manifest his interest in the nature and function of the ego, along with considerations of narcissism.

The results of Federn's research took time to come to fruition, since his ideas about the ego required a long period of gestation. In 1926 his important essay "Some Variations in Ego-Feeling" appeared, followed in 1928 by "Narcissism in the Structure of the Ego,"

and in 1929 by "Das Ich als Subjekt und Objekt im Narzissmus" (The ego as subject and object in narcissism). His phenomenological description of the ego as experience coinciding with "ego feeling" diverged considerably from Freud's structural approach. Although his conclusions were far removed from Freud's, out of loyalty Federn preferred to downplay his own theoretical contributions, such as "ego feeling," the "sense of reality," the "limits" and "states" of the ego, "ego cathexis," the "median" nature of narcissism, and the death drive. For although Freud had a great deal of respect for Federn, he did not value Federn's theoretical proposals very highly.

In his studies of schizophrenic patients, Federn came to the conclusion that, far from being excessively cathected with libido, their egos possessed inadequate cathectic energy. On Federn's hypothesis, contrary to the hypotheses of Freud and Karl Abraham, it was an absence rather than an excess of narcissistic libido that determined the psychotic's problems with the object. As a result, Federn's approach to treating psychotics, described in "The Analysis of Psychotics" (1934) and other important texts he wrote while in America, involved supporting the patient's efforts at integration by trying to prevent the emergence of the repressed and by strengthening the patient's defenses. According to Federn, transference in psychosis should not be interpreted. He felt that it was important to avoid negative transference and to help the psychotic confront problems by means of female support figures.

Although the response to Federn's ego psychology was limited, he had several illustrious followers, including Edoardo Weiss and Hermann Nunberg, along with a small group of American analysts such as Bertram D. Lewin, I. Peter Glauber, and Martin Bergmann. In psychiatry the influence of his ideas is obvious. His ideas also served as a foundation for the transactional analysis of Eric Berne, who refers to the theory of "ego states." Weiss was responsible for the posthumous publication of Federn's writings, *Ego Psychology and the Psychoses* (1952), a book that contributed greatly to spreading the ideas of one of the earliest and most faithful pioneers of psychoanalysis.

## FÉDIDA, PIERRE (1934–2002)

The French psychoanalyst Pierre Fédida was born in Lyon, France, on October 30, 1934, and died in Paris on November 1, 2002. He was a full member and president of the Association psychanalytique de France (French Psychoanalytic Association), a member of the International Psychoanalytical Association, and cofounder, with Daniel Widlöcher, of the *Revue Internationale de psychopathologie* (International journal of psychopathology).

He passed the *concours d'agrégation*, a prestigious teacher-qualifying exam, in philosophy, and in 1962 he was appointed to a university-level teaching position.

He began his clinical training in psychiatry and neuropsychiatry at the age of twenty-three, notably at the Bellevue Sanatorium in Kreuzlingen, Switzerland, with Professor Ludwig Biswanger and in Münsterlingen, Switzerland, with Professor Roland Kuhn. His thinking on the treatment of psychotics was thus stamped with a distinctive phenomenological orientation that remained with him throughout his career.

All his psychoanalytic training (both individual analysis and professional training) took place under the Association psychanalytique de France, where he enrolled as a student in the 1960s and entered into analysis with Georges Favez. Although his background in phenomenological philosophy initially concerned some, he quickly established himself in the eyes of professionals as a very astute clinician with an exceptional mastery of the theory of treatment. After he became a training analyst, he was elected president of the Association psychanalytique de France in 1988 and undertook significant statutory reforms. Notably, he expanded the cadre of training analysts to include all tenured members of the association. He then played an active role in the European Federation of Psychoanalysis and the International Psychoanalytical Association, where, from 2000, he was responsible for contacts with psychologists, psychiatrists, and other psychoanalytic schools throughout Europe.

Concurrent with these developments, in 1966 he became senior assistant in clinical psychology at the Sorbonne with Juliette Favez-Boutonier. This led to his participation in the events that revolutionized the French university system in May 1968, with Jean Laplanche and others soon joining in.

Fédida taught at the Université de Paris VII from 1969 to 2002, and at the university he founded the Laboratoire de psychopathologie fondamentale et psychanalyse (Laboratory of basic psychopathology and psychoanalysis). Within the university's research and training program in human clinical sciences, which he helped establish, he served in many scientific and administrative capacities, including that of program director.

From the outset he brought a perspective transcending disciplines to his teaching, aiming to critique and bring together the main approaches in psychopathology, whether phenomenological, biological, or psychoanalytic. This open approach led him to establish a research laboratory in 1989 and an advanced degree program in basic psychopathology in 1990,

which he wanted to link with biology and then to the Centre d'études du vivant (Life studies center) at the Université de Paris VII (where he also served as vice president from 1987 to 1989). He also traveled widely to universities abroad, where he established a solid network of relationships, especially in Brazil and other Latin American countries.

Fédida wrote a substantial number of works: 320 publications on a wide variety of subjects. In addition to ten to twelve articles each year from 1962, he penned such major works as *Corps du Vide et Espace de Séance* (The body of the void and the space of the session; 1977); *L'Absence* (Absence; 1978), *Crise et Contre-Transfert* (Crisis and counter-transference; 1992), *Le Site de L'Étranger* (The site of the alien; 1995), and *Les Bienfaits de la Dépression* (The benefits of depression; 2001). These works have been translated into many languages. Unifying themes of his work are the concealed, the stranger within, and enigmatic knowledge of the self.

A man of dialogue conscious of his own charisma, Fédida fashioned an atypical discourse combining psychoanalysis, psychopathology, philosophy, literature, architecture, and art history. His writings present a complex blend of scientific rigor, human openness, and confidence in diversity.

## **FEMALE SEXUALITY**

Freud's observations on female sexuality were made between 1923 and 1933, late in his career. They cannot be understood without reference to his thesis of the primacy of the phallus, according to which, for both sexes, "only one genital"—the male one—played a structuring role (1923e, p. 142). Structurally speaking, the phallic phase defined the girl as much as the boy, but the girl's embrace of the phallic—at once real (experienced directly), imaginary (fantasized in an oscillation between power and impotence), and symbolic (thought-cathexis)—was centered on the clitoris. Even though the Freudian theorization of the girl's psychosexual development toward femininity took as its sole basis the psychosexuality of the boy, Freud continually emphasized the differences between the sexes in this regard, and hence too the specificity of the female Oedipus complex.

Penis envy and the castration complex play the major, organizing roles that made access to femininity possible. As Freud wrote in "Some Psychological Consequences of the Anatomical Distinction between the Sexes," little girls "notice the penis of a brother or playmate, strikingly visible and of large proportions, at once recognize it as the superior counterpart of their own small and inconspicuous organ, and from that time forward fall a victim to envy for the penis" (1925j, p. 252). This injury, at once phallic and narcissistic, was experienced to begin with as a personal punishment, then accepted as part of a broader truth: women do not have them. That the mother should have omitted to "give her a proper penis" (1931b, p. 234) constituted the main motive, specific to the little girl, for transferring her affections to the father. This reversal was more a flight from the mother than a choice of the father as object. It was this disillusionment, coupled with the depreciation of the mother contingent upon the discovery that she was castrated, that occasioned the abandonment of the relationship with the mother as object.

The renunciation of phallic activity (clitoral masturbation) allowed passivity to come to the fore: "The transition to the father-object is accomplished with the

help of the passive trends in so far as they have survived the catastrophe. The path to the development of femininity now lies open to the girl" (p. 239). The girl placed all her hopes on her father, waiting for him to give her the penis that her mother had "refused" her. The feminine attitude would be reached only if an equivalence was established between penis and child and the wish for a penis transformed into the wish for a child.

What Freud had discovered in 1931 was that for the little girl the mother as dispenser of the earliest bodily care is the object of a particularly intense and long-lasting archaic cathexis. He compared this first bond between mother and daughter to the Minoan-Mycenaean civilization so long obscured from view by the civilization of Athens: "Our insight into this early, pre-Oedipus, phase in girls comes to us as a surprise, like the discovery, in another field, of the Minoan-Mycenaean civilization behind the civilization of Greece" (p. 226). He immediately pointed up the ambivalence of this earliest bond: primary homosexuality, the idea of which was to be further developed by Freud's successors, was built upon the amorous or tender current in mother-infant coexcitation, which was nevertheless not devoid of aggressiveness. Attachment and hostility toward the mother were differently inflected depending on whether they related to the oral or the anal phase. During the oral phase, after the withdrawal of the breast, they arose in response to the little girl's fears of being devoured, poisoned or killed by her mother. During the anal phase, the pleasure associated with various maternal manipulations was related to the intrusive anal mother (described by Ruth Mack Brunswick as arousing the girl's aggressiveness).

His discovery of a primal coexcitation sensorily uniting daughter and mother, and of the dramatic rift that ensued between the two female members of this initial dyad, supplied Freud with much support for his conclusion that the mental bisexuality of women was more marked than that of men. The subsequent route to femininity was a long one, marked by the detachment from the pre-oedipal mother and calling for both a change in the erogenous zone cathected (the shift from clitoris to vagina), and a change of object. Taking the father as love-object is thus seen as a second phase in the little girl's mental development, so that it is possible to speak of a two-phase oedipal period for women (Jeanne Lampl-de Groot, Julia Kristeva). Freud went so far as to say that he saw no dissolution of the

Oedipus complex in the female. Whereas in the boy the complex succumbed to the threat of castration, it would have no end in the case of women and would manifest itself as such in both the need for motherhood and in the character of "females as social beings" (p. 230). In addition to the path leading to the choice of the father as object, Freud evoked two other possible routes: the young woman might turn away from sexuality into neurosis (inhibition), or she might refuse to renounce the phallus and develop a masculinity complex.

Freud's phallogocentric account, which he took up again in the *New Introductory Lectures on Psycho-Analysis* (1933a [1932]), has been widely criticized. In the first place, a number of psychoanalysts, among them Karen Horney, Ernest Jones, Melanie Klein, and Helene Deutsch, have in particular contested the claim that penis envy is a primary given rather than a construction developed or used in a secondary way in response to primitive wishes. At the same time feminists have castigated Freud for incorporating his own phallogocentric and bourgeois prejudices into his theory. But it must not be forgotten that Freud's theorizing here addresses the Unconscious, so that only criticisms doing likewise have relevance (André, 1994). Furthermore it is essential to bear in mind that according to Freud the phallic organization in fantasy is based on the "infantile" genital organization, and that the primacy of the phallus, for the girl as for the boy, is deemed an aspect of the child's development and can in no way be conflated with the adult genital organization. Last, and most important, the idea of phallic primacy must be understood as the primacy of a symbolic dimension, not an organic one. In his *Écrits* (1966), Jacques Lacan describes the dynamics of a human psyche, dependent on language, which necessarily embraces both the male and the female speaking subject. Even though the "detachability" of the penis inevitably makes it the "signifier of the lack," and hence the symbol of the signifying function itself, men and women nevertheless relate to it differently. Recent psychoanalytical research has paid particular attention to the exploration of this difference, and notably to the "strangeness of the phallus" for the female (Kristeva).

## **FEMININE MASOCHISM**

Feminine masochism, “an expression of the feminine being nature” (p. 161), is one of the three forms of masochism described by Sigmund Freud in “The Economic Problem of Masochism” (1924c), along with moral masochism and primary, erotogenic masochism. Based “entirely . . . on the primary, erotogenic masochism” (p. 162), feminine masochism, according to Freud, is clinically accessible through the fantasies

of masochistic men, who obtain sexual satisfaction primarily through masturbation. Behind such men's need for punishment and humiliation (which form a transition with moral masochism by way of guilt) there is an infantile staging of a “characteristically female situation” that signifies “being castrated, or copulated with, or giving birth to a baby” (p. 162).

In Freud's view, the passivity of masochism is linked to femininity, and the active nature of sadism to virility, as he wrote in *New Introductory Lectures on Psycho-Analysis* (1933a [1932]). He first described this connection between active/passive and masculine/feminine in *Three Essays on the Theory of Sexuality* (1905d). However, in 1933, taking bisexuality into consideration, he relativized this opposition and stressed the role of the instinctual aim: “to achieve a passive aim may call for a large amount of activity” (p. 115). He also acknowledged that the social repression of aggressiveness in women could lead to secondary masochistic impulses, “which succeed . . . in binding erotically the destructive trends which have been diverted inwards” (p. 116).

Freud's discomfort on the issue of woman's sexuality is apparent in his description of feminine masochism in men, even though his 1924 essay rehabilitates masochism as a form of protection in the individual against the death instinct and as a factor in the organization of the ego. Yet we can deduce from his thinking that he thought that a woman's intimate acquaintance with passivity, and thus her capacity for masochism, also play a part in her strength, and not just in her weakness stemming from her need for love. Masochism is part of the intensity of her sexual pleasure, but also of the strength of her love as a woman and mother.

## FEMININITY

Freud refused to put forward a definition of femininity: “In conformity with its peculiar nature, psychoanalysis does not try to describe what a woman is . . . but sets about enquiring how she comes into being” (1933a [1932], p. 116). He posits a primary bisexuality as the starting point for this process.

In Freud’s view, the genesis of femininity differs from the genesis of masculinity because its linearity is interrupted. In the pre-oedipal phase, the girl’s libido, instead of taking the opposite-sex parent as its object, as the boy does, is directed at the mother as object. This period is difficult to investigate because of the “inexorable repression” (1931b, p. 226) that overshadows it.

Therefore, the development of girls’ sexuality is studied in an indirect way based on the process that the boy undergoes. In the early stages a similar path is traced: “the little girl is a little man” (1933a, p. 118), with the clitoris being interpreted in the phallic phase as a miniature penis. Then there are two shifts in perspective, shifts in which there is an explicit moral imperative. The girl has the duty of turning from the mother to the father (1939a [1934–1938]): the zone of sensitivity moves from the clitoris to the vagina, and there is a change of object to the father.

Reconversion is made possible by the differential impact of the castration complex on boys and girls. In boys, the castration complex puts an end to the Oedipus complex. But for girls, the castration complex makes the Oedipus complex possible.

The girl sees her mother as castrated, while her love is “directed to her *phallic* mother” (1939a, p. 126). This gives rise to a penis envy that later radiates beyond the desired object to imbue the woman’s psychic life with envy and jealousy. The girl then chooses

the father as object because he possesses the envied organ, and this new libidinal orientation is superimposed on the orientation of the mother as object, without replacing it entirely. The woman often transfers her early relationship with her mother onto her male partner. The need to anticipate from someone else what the woman once wanted to possess herself makes her dependent in a way that leads both to masochism (with the castigation she receives relating to her position in coitus) and to narcissism (which is expressed in her greater need to be loved than to love). Presenting another perspective in “On Narcissism: An Introduction” (1914c), Freud stated that following puberty, women, “especially if they grow up with good looks, develop a certain self-contentment” that exercises “a great attraction for those who have renounced part of their own narcissism” (p. 89).

Although the texts that present a synthetic view of femininity are focused on lack, Freud’s incursions into mythology and literature emphasize something beyond the phallic stage in girls. This something is a place in the female body characterized by its internal nature (the “jewel-case”) or by disorientation, as in the sense of the uncanny. The woman then appears not as an externally definable form but as a “hollow space” (1916–1917a [1915–1917], p. 156) that can receive what penetrates it. The spatial disorientation is coupled with a temporal disorientation, in which the representation of femininity becomes confused with the notion of birth linked with the fear of death, as if the third of the Fates had come to embody a femininity that governed all of destiny. Freud’s study of femininity thus diverges into a theoretical synthesis derived from phallic logic and a representation of femininity that mythologizes woman as a place—whether of birth or death—where the processes of life are played out for every human being.

The idea of taking a foreign element into the self appears as the crossroads where the representations of psychoanalysis intersect with those of female sexuality. When Freud noted how the transference configuration enabled a repressed element to be taken in, he usually gave an example—Elisabeth in *Studies on Hysteria* (1895d) or Irma with her dream about the injection—of a patient struggling against accepting a proposed solution or repressed representation (1900a). Recourse to these terms had a clear impact on the paper “Negation” (1925h), because acceptance into the ego enabled repression to be effectively lifted.

Freud noted the conjunction between such acceptance and the outcome of female sexuality in “On the Sexual Theories of Children” (1908c), where he referred, in connection with the mother representation, to the discovery of the “cavity which receives the penis” (p. 218). In the moment of affirmation associated with the lifting of repression, the psychic apparatus has to receive the repressed element just as the female “hollow space” has to receive the penis. This correlation reappears in “Analysis Terminable and Interminable” (1937c), where Freud describes the man’s refusal to accept the cure from the psychoanalyst as his rejection of femininity. Does a refusal of this kind arise from the fear of losing masculinity or the fear of invasion occasioned by opening the self as a “hollow space”? Two different definitions of femininity clash at this juncture.

Post-Freudian psychoanalysis both extended and revised Freud’s lines of approach to femininity. The phallic primacy attributed to both sexes became a matter of dispute. Karen Horney asserted that the girl discovers vaginal sensations early on. As a result, recourse to the penis takes on a defensive significance. Ernest Jones did not consider woman as a form of failed man, and he related female anxiety not to castration anxiety but to aphanisis anxiety, the fear of losing her internal sensitivity. Janine Chasseguet-Smirgel challenged the passive concept of the vagina. She saw the vaginal aim of incorporation as conferring a capacity for mastery, as with anality.

Conrad Stein sought to define a specifically feminine outcome by positing “castration as a negation of femininity.” He argued that insofar as masculinity carries a “symbolic representation of itself,” it is a guardian of identity. In contrast, the female pole, situated close to being, is governed by a tendency toward “destruction of the self’s identity,” which, when it gives rise to anxiety, “is negated by the act of regarding woman only as a castrated being.” The risk of destruction to which the woman is exposed leads to a focus in the analysis on the dimension of invasion (André; Schaeffer).

Is there a fundamental difference between masculine protest and feminine protest organized around a receptive hollow space? In accordance with some of Michèle Montrelay’s theories, François Perrier emphasized the girl’s relationship with her mother, in which her fantasy involvement does not involve risking a part of herself but diving in head first. To reduce the risk of

being sucked in, the girl appeals to the male organ, on which she confers investigative properties. Penis envy is thus governed not by rejection of femininity but by the girl’s desire to orient herself in this space.

Wladimir Granoff examined the tendency for theory to construct femininity in negative terms. He regards femininity as a defense that resembles the child’s decision to prefer the father to the mother. In this view, thought needs to turn away from femininity to construct an intellectualized universe. This turning away resembles the son-in-law’s prohibition against turning toward his mother-in-law in Freud’s analysis and is related to Freud’s invitation to explore, beyond classical Greek culture, cultures that have been repressed by “turning from the mother to the father” (1939a, p. 114).

Because the female genital opening is feared as a place of absence, pubic hair has been ascribed the function of a veil, though it can equally well belong to fantasies surrounding fertility and growth, reminiscent of Demeter (Schneider). Marcel Detienne’s observation concerning the dual character of the founding sites of Greek culture—“Eleusis is the counterpart of Athens”—can be used to inform the study of femininity. Freud’s *Moses and Monotheism* (1939a [1934–1938]), drawing on Aeschylus’s *Eumenides*, belongs in the mythical tradition that began with the founding of Athens. Accordingly, it pays tribute to Athena, a virgin born without a mother. It might well be appropriate to unearth those underworld entities that Athena proposes at the end of the tragedy, to lead “Into the earth/ The cavern timeless as the tomb.”

## FEMININITY, REJECTION OF

Rejection of femininity refers to a man's rejection of the feminine elements inherent in his constitutional bisexuality.

The concept first appeared in Freud's article "Analysis Terminable and Interminable" (1937c), where he introduced it in his discussion of the "bedrock" beyond which analytic work cannot continue. It also formed a part of his ongoing argument against the term proposed by Alfred Adler, "masculine protest." This bedrock, which takes the form of penis envy in women, appears in men as a rejection of femininity. Specifically, what the man rejects is a passive position towards another man.

The question of the exact nature of this rejected femininity is taken up again when Freud specifies what it is that the man is defending himself against: "He refuses to subject himself to a father-substitute . . . and consequently he refuses to accept his recovery from the doctor" (1937c, p. 252). The notion of "acceptance" (*Annahme*) is related to femininity, but without reference to the phallic organization. It refers to the act by which the vagina, as "cavity," "receives the penis" (1908c, p. 218).

Thus the rejection of femininity might be viewed as the refusal of inner space (as representative of mental space as a whole) to admit a foreign body. Jacqueline Schaeffer (1997) has spoken in this connection of anxiety about a femininity perceived as the "penetration of the ego and the body by a stranger, the agent of an incursion that feeds the constant pressure of the drive."

## FEMINISM AND PSYCHOANALYSIS

Freud's discovery of the unconscious is centrally linked to the study of female sexuality. In listening to the hysterics, Freud gave them a voice and attributed a meaning to what they said. As Juliet Mitchell noted, feminist movements have tended to equate what Freud said about the hysterics and his other female patients as prescriptions for patriarchal domination of women rather than understanding his writings as an analysis of women's position in patriarchal societies.

Feminist movements, especially in the 1960s and 1970s, were hostile to psychoanalysis, as they viewed it as a major factor in the oppression of women. The issues that feminists challenged in psychoanalysis centered on Freud's formulations of the differentiation between the sexes, in terms of the association of masculinity with activity and femininity with passivity; Freud's emphasis on the existence of penis envy in women; female masochism; and the emphasis on the role of the father as opposed to feminists' reassessment of the mother-daughter relationship.

Simone de Beauvoir's *La deuxième sexe* (1949) and Betty Friedan's *The Feminine Mystique* (1963) both viewed psychoanalysis as regarding women as inferior and as defining them only with reference to men. Then in the 1970s another wave of feminist writings, such as Kate Millet's *Sexual Politics* (1970), Shulamith Firestone's *The Dialectic of Sex: The Case for Feminist Revolution* (1970) and Germaine Greer's *The Female Eunuch* (1970), called for changes in society that would help to eliminate sexual inequality. Mitchell's *Psychoanalysis and Feminism* (1972) was a marker in the recovery of psychoanalysis, by explaining its revolutionary understanding of women.

From a very early stage, psychoanalysis maintained that the psychic reality of sex had to be distinguished from the anatomical reality, that there was no one-to-one correlation between biology and psychology. Men and women are not physically or socially "made" as male or female but become such.

Initially, however, Freud assumed a symmetry in the development of what he called the Oedipus

complex. It was only in an essay written in 1925 that Freud distinguished between the psychosexual history of boys and girls and recognized the importance of the pre-oedipal phase in which boys and girls love the mother, and both have to relinquish her in favor of the father (1925j). The girl has to move from loving her mother to loving her father, whereas the boy gives up his mother with the understanding that he will later have a woman of his own. In this model, boys identify with their fathers as their masculine identity is established. The little boy learns his role as the heir of his father. The little girl, on the other hand, has to identify with her mother while at the same time abandoning her as a love object and turning to her father instead. For Freud this turning away from the mother is based on frustration and the disappointment that she cannot satisfy her mother, and is accompanied by hostility.

The importance of the "pre-oedipal" relationship with the mother has been more fully discussed since Freud's time. More recently interest in the nature of female identity can be found in the works of Ethel Person, Irene Fast, and Jessica Benjamin in the United States, as well as in the works of Janine Chasseguet-Smirgel, Catherine J. Luquet-Parat, Maria Torok, and Joyce McDougall in France.

In the 1920s a controversy took place over the perception of femininity. If for Freud libido is identical in the two sexes, for the English School, feminine libido is specific. Karen Horney and Ernest Jones participated in a series of interchanges and opposed Freud's views by putting forward a "positive" view of female sexuality, not linked to an idea of a lack. For Jones, femininity's development is linked to instinctual constitution. In debate with him, Freud asserted that Jones profoundly misunderstood the fundamental nature of sexuality and that Jones had returned to a biological reductionism. Mitchell has pointed out that the Freud-Jones controversy shifted from the question of what distinguished the sexes to what each sex has that is specific to it alone.

Developments in psychoanalytic theory in England, with the school of object relations, led to an emphasis on the mother-child dyad, and on motherhood. Psychoanalytic work from an early stage concentrated on primitive states in infancy, and progressively attention was paid to the impact of these primitive states on transference. Melanie Klein's theory carried on Freud's shift in the emphasis from the father to the mother and the mother's importance for children of both

sexes. For her, the relationship of the child to the mother's body shaped subsequent emotional life. Particularly, the relationship to the breast is crucial in the child's early experiences. Klein's concepts of introjective and projective identification are metaphors for the bodily processes of taking in and expelling. According to Klein, the little girl believes her mother's body contains everything that is desirable, including the father's penis. As a consequence the little girl is filled with hatred towards her mother and wishes to attack and rob the inside of her body. She is then filled with a persecutory anxiety of "having the inside of her body robbed and destroyed." In 1928 Klein argued that it was the deprivation of the breast rather than the discovery of the lack of penis that turned the little girl away from the mother towards the father. Later she downplayed the child's original envy of the breast and wrote about an essentially heterosexual drive in little girls. Klein's views on this early relationship between mother and baby had an impact on some of the early writings on femininity in the British society, such as the work of Joan Riviere and Sylvia Payne.

Progressively psychoanalysts from all the groups in the British Society, inspired by the works of Klein, Donald Winnicott, Marjorie Brierly and Wilfred Bion, have emphasised the connection between primary affective development and object relations. One can trace these themes throughout the writings of Marion Burgner and Rose Edcumbe, Egle Laufer, Dinora Pines, Dana Breen, Joan Raphael-Leff, and Rosine Perelberg. In a more recent collection presenting work of the three schools of psychoanalysis in the British Psycho-Analytical Society, Raphael-Leff and Perelberg stress the primitive tie to the mother and its manifestations in transference and countertransference.

American feminists have perceived psychoanalysis as reproducing patriarchal inequalities. Nancy Chodorow is one of the most well-known writers in the United States on the relationship between psychoanalysis and feminism. *The Reproduction of Mothering: Psychoanalysis and the Sociology of Gender* (1978) introduced the work of Winnicott, W. Ronald Fairbairn, and Harry Guntrip to American readers. Chodorow emphasizes the development of the self in relation to others, stressing the pre-oedipal relationship between mother and child. She views the function of mothering as creating an asymmetrical relationship between boys and girls. The girl has more permeable boundaries in the relationship with the other because

of having been mothered by someone of the same gender. Girls are themselves, therefore, more committed to mothering. Boys, in contrast, develop a sense of self in opposition to the mother and establish more rigid boundaries. The masculine sense of self is more separate.

Jean Baker Miller and Carol Gilligan, from the interpersonal school of analysis, emphasize women's attributes of relatedness, empathy and nurturance which are viewed as devalued in the male-dominated culture. These interpersonal theoreticians stress cultural emphases on different attributes for men and women and are less concentrated on the internal world of unconscious phantasies and internal object relationships.

Jessica Benjamin in *Bonds of Love* (1988) sees both boys and girls as looking to the father for confirmation of themselves. While the boy's identity is confirmed by the father, the girl in contrast has her identification with the father's power denied, and he becomes the object of her ideal ego. This prevents her from having a "desire of her own," and her longing for the father becomes tinged with masochism. Issues of power and submission are located in the sphere of relationships.

Chodorow has argued that what all these authors have in common, in spite of their differences, is the emphasis on the qualities of the "self in relation" (or denial of relation). She suggests that this view radically breaks with an essentialist view of gender and moves towards a view that perceives masculinity and femininity in a contingent, relationally constructed context. These schools, however, end up by constructing a more fixed view of femininity and masculinity than Freud, who basically indicated that there is a fluidity between masculinity and femininity in both men and women.

These views can be contrasted with the major trends in French theories on psychoanalysis and feminism, where there is an emphasis on unconscious fantasies and desire and an attempt to find a language to express the feminine. Among the French psychoanalysts in particular there is a view that the discovery of the unconscious in itself reveals the precariousness of identity in the forces of fantasy and desire. This is the radical perspective that psychoanalysis can offer to feminism. The impact of Jacques Lacan's work pervades the numerous writings, from those who accept basic tenets of Freudian theory to those who, like Julia Kristeva, Helene Cixous, Michele Montrelay, Sarah

Kofman, and Luce Irigaray, remained highly critical of psychoanalytic assumptions.

Lacan pointed out that the distinction between penis and phallus is fundamental to Freud's differentiation between biological and psychic reality. The phallus exists outside anatomical reality and is the signifier of the mother's desire. Joël Dor has suggested that the central question of the Oedipus complex thus becomes "to be or not to be the phallus," i.e. to be or not to be the object of the mother's desire. The role of the father also becomes symbolic—he represents the impossibility of being the object of mother's desire. The phallus, unlike the penis, is possessed by nobody (male or female) and represents the combination of both sexes.

Chasseguet-Smirgel, McDougall, Torok, Luquet-Parat, Monique Cournut-Janin, and Jacqueline Schaeffer have all argued from a position inside psychoanalysis. Chasseguet-Smirgel indicated her perception that the little girl is aware of the existence of the vagina virtually from the beginning, although she also suggests that this "knowledge" may be held unconsciously, so that the little girl both knows and does not know. In her various works, "penis envy" is understood as having a defensive function.

For many of the French feminist writers the body is the locus of femininity, and numerous writings attempt to capture its rhythms (such as Luce Irigaray's *Ce sexe qui n'en est pas un*). In her book *Speculum* (1974), Irigaray perceives psychoanalysis as unaware of the historical and philosophical determinants of its own discourse and unable to analyse its own unconscious fantasies. Furthermore, being a product of patriarchal society, it cannot analyse what it owes to the mother. She consistently puts forward the view that women in patriarchy have no identity as women. She also emphasises the relationship of the little girl to the mother's body. The girl, says Irigaray, "has the mother, in some sense, in her skin, in the humidity of the mucous membranes, in the intimacy of her most intimate parts, in the mystery of her relation to gestation, birth and to her sexual identity."

Kristeva relates psychic repression to the actual structures of language, and describes the pre-oedipal stage as a play of bodily rhythms and pre-linguistic exchanges between infant and mother. Kristeva refers to what Plato, in *Timaeus*, called the *chora* as the site of the undifferentiated bodily space the mother and the

child share. Within the Oedipus complex it is the symbolic that is dominant; the domain of unified texts, cultural representations, and knowledge. This distinction between the semiotic and the symbolic is retrospective, as it is only through the symbolic that one has access to the semiotic. For Kristeva, subjectivity is founded on a constitutive repression of the maternal, the *chora*, the semiotic, and the abject (liminal states, like pregnancy). Kristeva has been accused of reducing women to the maternal function, but she is also seen as providing a deepening in the understanding of the pre-oedipal.

In these French feminist writings, there is a profound search for the multiplicity which characterizes femininity (as opposed to masculinity), which may be expressed in a language which itself attempts to capture the feminine. In a paradoxical way one may be referred back to Freud's thinking about hysteria. The symptoms of the first patient of psychoanalysis, Anna O., included mutism, paralysis, "time-missing," and gaps in memory: all expressing interruptions in the domain of a reality which is being denied. Psychoanalysis indicates that sexuality is only created through division and discontinuity, although femininity is the side that both represents, and tends to be represented as, the negative (of masculinity).

## FENICHEL, OTTO (1897–1946)

Otto Fenichel, an Austrian physician and psychoanalyst, was born in Vienna on December 2, 1897, and died in Los Angeles on January 22, 1946. He was born into a family of Viennese Jewish lawyers. As a student he took

part in the Viennese youth movement that had coalesced around Siegfried Bernfeld. He took an interest in cultural and educational reform and was especially interested in information about sexuality and its scientific study. Released from serving in the military, he began, after the winter of 1915/1916, to attend Sigmund Freud's presentations at the University of Vienna, and after 1918 he participated in discussions held by the Vienna Psychoanalytic Society. In February 1919 he organized, at the university, a Viennese Seminar on Sexology, a working group to study psychoanalysis and sexual matters. In 1920, while still a student, he was accepted as a member of the Vienna Psychoanalytic Society after his talk on sexual problems in youth movements. He received his medical degree in 1921.

Fenichel began an analysis in Vienna with Paul Federn and continued, after moving to Berlin, with Sándor Radó. In 1926 he became a teacher at the Berlin Psychoanalytic Institute and that same year organized a seminar on child psychoanalysis, an open forum on the problems of clinical and applied psychoanalysis. He was a member of the German Psychoanalytic Society from 1926 to 1934. After 1932 some members of the seminar began discussing psychoanalytic issues from a Marxist perspective. Fenichel had to flee to Oslo, Norway, in 1933. There he became secretary of the Dansk-Norsk Psykoanalytisk Forening (Danish-Norwegian Psychoanalytical Society).

In Norway, in the spring of 1934, he continued the meetings on Marxist psychoanalysis, writing clandestine circular letters that he sent to his colleagues in exile. By 1945 he had written 119 such letters. In 1935 he moved to the Czechoslovak city of Prague, where he ran the Prager Arbeitsgemeinschaft (Prague Study Society), which was associated with the Vienna Psychoanalytic Society.

After the introduction of National Socialism in Vienna and the dissolution of the Prague group, in the spring of 1938 Fenichel and his family left for Los Angeles. There he joined the Los Angeles Psychoanalytic Study Group. In 1942 he helped found the San Francisco Psychoanalytic Society and in 1944 became vice president. After 1939 he was an editor of the *Psychoanalytic Quarterly*. In the summer of 1945 he began studying psychiatry to obtain his California license at the Cedars of Lebanon Hospital in Los Angeles.

The focus of his interest, which he shared with Siegfried Bernfeld, Wilhelm Reich, Erich Fromm, and

others, lie in the development of a form of psychoanalysis that provided sociological explanations and was capable of making contributions to politics. His most important work, *The Psychoanalytic Theory of Neurosis*, appeared in 1945 and became a key source for analytic training. One of Fenichel's most important contributions to psychoanalysis, overlooked until 1998, has been his circular letters, which have shown him to be an important historiographer of the psychoanalytic movement.

## **FERENCZI, SÁNDOR (1873–1933)**

A Hungarian neurologist and psychoanalyst, Sándor Ferenczi was born in Miskolc on July 7, 1873, and died in Budapest on May 22, 1933. He was the eighth of eleven children of Baruch Fraenkel (who changed his

name to Bernát Ferenczi), a bookseller, printer, and ticket agent, and Róza Eibenschütz, both of whom were Jews from Galicia, Poland. His father died when he was fifteen. After studying at the Protestant school in his home town, Ferenczi went to Vienna to study medicine, obtaining his diploma in 1894. He became interested in psychology while still a student.

Ferenczi first practiced medicine at the Rókus Hospital in Budapest and then specialized in neurology at the Szent Erzsébet (Saint Elizabeth) Hospital. After 1899 he contributed to the medical journal *Gyógyászat* (Therapeutics). These early articles demonstrate Ferenczi's interest in clinical medicine and psychology.

Ferenczi read Freud's *Interpretation of Dreams* shortly after its appearance but was not impressed by the work. A few years later, after he adopted Carl Gustav Jung's association test, he became more receptive to Freud's ideas, and on February 2, 1908, together with another Hungarian doctor, he made his first visit to Freud. This was the beginning of a close friendship between the two men that lasted until Ferenczi's death. In 1908 they began their correspondence (comprising approximately one thousand four hundred letters), an exchange that had a profound effect on the history of psychoanalysis. At the first psychoanalytic meeting, which took place in Salzburg on April 27, 1908, Ferenczi presented the paper "Psychoanalysis and Pedagogy," the first psychoanalytic work devoted to the subject.

Because many of his friends were writers and artists, Ferenczi played an active role in the cultural life of Budapest, which was being swept at this time by currents of modernism. The Freudian ideas for which he became the spokesman were well received by his writer friends but rejected by most medical doctors.

To help introduce psychoanalysis to Hungary, Ferenczi gave a number of talks. He gradually became Freud's closest disciple and spent a number of summer vacations with the Freud family, often traveling with Freud. In 1909, when Freud visited Clark University in the United States, Ferenczi accompanied him (along with Jung) and helped prepare his presentations. In 1909 Ferenczi published "Introjection et transfert" (Introjection and transference; 1990a), his first theoretical work.

In 1910, following a suggestion by Freud, he proposed the creation of the International Psychoanalytical Association with Jung as president, and in 1913 founded the Hungarian Psychoanalytic Association

with István Hollós (a psychiatrist), Lajos Lévy (a doctor), Sándor Radó (a medical student), and Hugo Ignotus (whose real name was Hugo Veigelsberg and who was the editor-in-chief of the avant-garde literary review *Nyugat* [The Occident]). That same year Ernest Jones began analysis with Ferenczi.

After experiencing a series of personal problems in 1911 (his interminable hesitation between Gizella Pálos, a married woman and his mistress since 1905, and Elma, her eldest daughter), Ferenczi asked Freud to analyze him. The analysis took place in three parts, one in 1914 and the other two in 1916. The analysis was cut short by the First World War, but also by Freud's reluctance to get involved in matters he feared, not without reason, would have negative repercussions on their relationship. In the end Ferenczi married Gizella in 1919 without ever completely forgiving Freud for having influenced his decision. In 1916 Ferenczi undertook the analysis of Géza Roheim and Melanie Klein and played a key role in discovering their talent.

September 1918 marked the highpoint of psychoanalysis in Hungary. The Fifth International Congress took place at the Academy of Sciences in Budapest, with participation of representatives from the government, who were interested in psychoanalytic work on war neuroses. During the congress, Ferenczi was elected president of the International Psychoanalytical Association. A few months later, because of political and social events in Hungary, which was then independent of Austria, Ernest Jones succeeded him as president. The following year, during the short-lived Hungarian Commune, Ferenczi obtained a chair in psychoanalysis at the university. This was taken from him when the right-wing government under Miklós Horthy came to power. In 1920 he was also expelled from the Hungarian medical association.

After 1919 Ferenczi devoted himself exclusively to the care of his patients and the development of the psychoanalytic movement. In 1925, with Vilma Kovács, one of his analysands and students, he worked out the methods of a system of training, and in 1931 he founded a psychoanalytic clinic, with himself as director. At the same time he continued his research and theoretical work, which focused primarily on technique.

In 1924 Ferenczi and Otto Rank published *Entwicklungsziele der Psychoanalyse* (*The development of psychoanalysis* [1925]). The book was criticized,

principally by Karl Abraham and Ernest Jones, and then by Freud. When Rank broke with Freud, Ferenczi reaffirmed his commitment to Freud and published an article criticizing Rank's work. In 1924 he published *Thalassa* (1963), a work highly regarded by Freud for its use of Lamarckian ideas.

In 1926 and 1927 Ferenczi spent six months in the United States giving lectures and training candidates, not all of whom were doctors. His position in favor of lay analysis alienated a large part of the American psychoanalytic community, which was committed to limiting psychoanalytic practice to medical doctors.

Ferenczi's technical experiments between 1918 and 1932, which were conducted to make psychoanalysis accessible to patients who showed signs of pregenital disturbances, created dissension between him and Freud. The conflict embittered his final years and affected the entire psychoanalytic community. He gave his last lecture, "Confusion of Tongues between Adults and the Child" (1949), in 1932 at the Wiesbaden Congress. Already suffering from pernicious anemia, he died on May 22, 1933, in Budapest.

Ferenczi made an important contribution to psychoanalytic theory and technique. On the theoretical level, he introduced the concept of introjection, was the first to focus on object relations, and developed theories of trauma and regression. In *Thalassa* he presented a number of fertile hypotheses on the ontogenesis and phylogensis of genitality, or a sex life.

Above all, Ferenczi thought of himself as a doctor and held that it was not up to the patient to present himself as analyzable but up to the analyst to find suitable techniques for healing his patients. He successfully developed several therapeutic techniques:

1. He developed the so-called active technique, whereby the analysand is asked to do whatever will promote free associations or to refrain from doing whatever might impede them.
2. To help mediate the authoritarian nature of the active method, he developed the technique of elasticity and permissiveness. Here, pushing tolerance of regression to its extremes, he allowed the traumatized patient to experience his symptoms anew.
3. He developed what is known as mutual analysis—an attempt doomed to failure and quickly abandoned—which was intended to spare

traumatized patients the consequences of misunderstanding and blind spots on the part of the analyst.

Ferenczi occupies an important place in the development of psychoanalysis and psychoanalytic theory and played an important role in propagating psychoanalytic ideas and contributing to the understanding and global awareness of psychoanalysis. His disagreement with Freud during the last years of his life, as well as the uneasiness caused by the almost superhuman demands he made on the analyst, have relegated his work to obscurity for nearly fifty years. However, on closer examination of the history of the twentieth century, the relevance of his ideas becomes obvious. Owing to the efforts of Michael Balint, who edited Ferenczi's collected works, and the appearance in 1988 of his *Clinical Diary*, a unique document in the field of psychoanalysis, the value of his ideas has been recognized wherever psychoanalysis is practiced.

## FETISHISM

Fetishism first interested psychoanalysts as a sexual perversion, in the strict sense. The term referred to a man's compulsive use of an inherently nonsexual object as an essential condition for maintaining potency and achieving pleasure when having sexual relations with a person of the opposite sex. This view emphasizes that perversion, as originally understood, was viewed as a strictly masculine phenomenon. Freud presented his thinking on the subject in three texts, which represented his changing ideas on the subject: *Three Essays on the Theory of Sexuality* (1905d), "Fetishism" (1927e), and "The Splitting of the Ego in the Process of Defense" (1940e [1938]). The views expressed in those essays are as relevant in the early twenty-first century as when they were first written.

In all observed cases, the fetish, in the fetishist's unconscious fantasy, is a substitute for a woman's "penis." It "completes" the woman by making her phallic. Consequently, the woman's genital organs lose any erogenous quality, in the eyes of the fetishist, erogeneity being completely transferred to the fetish. The fetish becomes the source of excitement, an idealized object capable of providing sexual pleasure to the fetishist.

The psychopathological behavior of the fetishist can be considered exacerbation of a universal anxiety. Freud saw in this perversion one of the clearest demonstrations of the difficulty that some men (perhaps all men) experience in accepting the differences of the sexes.

It has become clear that the most important factor behind this perversion is castration anxiety experienced to an extreme degree. Fetishism arises entirely from defensive measures unconsciously adopted to reject castration and eliminate it from the field of possibility. Only a part of the man believes that a woman does not have a penis. So as far as the fetishist is concerned, castration is still possible under these circumstances. But if both sexes are equipped with a penis, castration cannot occur in this world. It thus becomes essential to remedy this unacceptable reality by attributing a penis to the woman at any cost. Creating such a reality is the primary function of the fetish in the unconscious imagination of the fetishist. The fetishist must then shelter his fragile mental apparatus from the return of disturbing sexual perceptions. He does so by choosing as a fetish an object that is always available, like a high-heel shoe. One fetishist is quoted as saying, "Every time I am in the presence of a naked woman, I imagine a high-heel shoe; I couldn't tell what a vagina looks like." As Freud demonstrated, the fetish makes the woman "acceptable" as an object of sexual love.

Freud considered fetishism important because this pathological structure can be used to observe the workings of two important defense mechanisms that had been partially ignored until then: splitting and denial. Fetishism enabled Freud clearly to identify the mechanism of splitting for the first time, that is, splitting of the thinking ego (to be distinguished from the splitting of the object representation). The fetishist demonstrates that he can accommodate two clearly contradictory conceptions of a woman within himself: a conscious affirmation ("The woman does not have a penis") and an unconscious fetishistic affirmation ("The woman has a penis"). The first is unimportant in the mental representations of the fetishist. These two modes of thought operate in parallel and have no effect on one another. The second mode of thought, a defense mechanism, denies castration, the lack of a penis, the crucial difference between the sexes. Most authors see splitting as arising to ensure the continuity of the denial, though it may be that splitting and continuity of denial occur simultaneously.

Since splitting and denial are observed in psychosis, some see fetishism as a protection against an otherwise threatening psychosis. Fetishism is also thought to protect against homosexuality. We should not conclude, however, that the fetishist is homosexual. In terms of his own feelings of identity and his own self-representations at all levels of thought, he sees himself as a man, a man in relation to a woman, except that the woman in this case also has a penis, according to the man's unconscious imagination. This is a major difference with the transvestite, who sees himself as a woman, in this case, a woman with a penis. Overall, in spite of the exceptions encountered, the transvestite is much closer to homosexuality than the fetishist. Rare cases of fetishism alternating with homosexuality have been observed, however.

It follows from the above that fetishism is a sign of narcissistic pathology, with mental operations functioning at a very archaic level, primarily through the extensive use of primitive identification (which some authors refer to as "narcissistic identification" or "projective identification"). This assertion is based on the fact that by endowing the woman (the mother, in the unconscious) with a penis, the fetishist preserves his own sexual organ by identifying with the mother. In doing so, the fetishist exhibits considerable narcissistic vulnerability regarding the integrity of his physical image.

Although opinions are divided, it seems justified to view the mechanism and structure of fetishism as resulting from a massive regression following the oedipal stage. The oedipal conflict was traumatic and results in significant regression to all levels of pregenitality, accompanied by strong anal and oral components. These components are manifest in an anxiety of disintegration, which is very noticeable during psychoanalysis. Another school of thought suggests viewing fetishism as essentially determined by pregenital conflicts.

Psychoanalytic work in the 1990s has shown that the fetish can also take on, in most cases, several other functions in varying proportions. These secondary functions include protection against trauma and depression, release from the outward expression of hostility and contempt while expressing them secretly, relief from psychosomatic symptoms, control over separation anxiety. As a partial delusion, fetishism protects the subject from the delusion. And finally, fetishism provides access to the maternal breast and full possession of the idealized mother.

## **FINLAND**

Psychoanalysis was practically nonexistent in Finland until it experienced rapid growth during the 1960s.

The first Finnish psychoanalyst, Yrjö Kulovesi (1887–1943), underwent analysis with Eduard Hitschmann in Vienna in 1924, then with Paul Federn in 1925. He became a member of the Vienna Psychoanalytic Society in 1931 and in 1934 went on to found, together with the Swedish psychoanalyst Alfhild Tamm, the Finno-Swedish Psychoanalytic Society, which was dissolved in 1943 after Kulovesi's death. A training analyst, he wrote several articles and an introduction to psychoanalysis, published in 1933.

A number of Finnish psychoanalysts emigrated to Sweden during the 1940s. After the war most of them were members of the Swedish Psychoanalytic Society. They included Stig Björk, Pentti Ikonen, Tapio Nousiainen, and Veikko Tähkä. A few years later Mikael Enckell, Reijo Holmström, Eero Rechartt, Matti Tuovinen, and Gunvor Vuoristo also traveled to Sweden for training in analysis. During this same period, three other psychoanalysts underwent similar training in Switzerland: Henrik Carpelan in Geneva, and Leena-Maija Jokipaltio and Lars-Johan Schalin in Zurich.

The biggest problem at the time was the shortage of psychoanalysts in Finland. Psychoanalysts trained abroad needed certification from the International Psychoanalytic Association (IPA) to work as training analysts in Finland. In 1964 Björk and Tähkä, trained in Sweden and members of the Swedish Psychoanalytic Society since the mid-1950s, formed a study group and became recognized as training analysts. The group, approved by an IPA committee presided over by Donald Winnicott and composed of members from Denmark, Sweden, and Great Britain, was formally recognized in 1967 as a provisional society and became an IPA affiliate in Rome in 1969. By 1974 there were already twenty-six candidates in training. Winnicott was the first honorary member of the Finnish Psychoanalytic Society. At the end of the 1950s, a psychotherapeutic organization, *Therapeia*, was founded, its methods inspired by existential analysis.

Academic resistance to psychoanalysis was less severe in Finland than in the other Nordic countries. The majority of Finnish psychoanalysts were psychiatrists. Tähkä, a professor of psychiatry at the University of Turku, twice visited the Austin Riggs Center in the United States for two years each time. The use of American ego psychology at the center led him to follow in this tradition, which is obvious from his book on psychoanalytic therapy (1970). Tähkä was most interested in research on alcoholism and schizophre-

nia. Kalle Achté was a professor of psychiatry and senior psychiatrist at the University of Helsinki. He conducted research on persecution and projection as defense mechanisms. Rechartt worked on psychosomatic illnesses and the evolution of ego psychology toward self psychology.

Yrjö Alanen, like Tähkä, studied the role of family factors in schizophrenia and applied psychoanalytic therapy in a family context. Tuovinen, a psychiatrist and lawyer, did psychoanalytic research on delinquent behavior and in particular analyzed aggression as a form of parental murder and suicide. Mikael Enckell, another important Finnish psychoanalyst, wrote several works on the Jewish question, the novelist Marcel Proust, the poet Friedrich Hölderlin, the filmmaker Luchino Visconti, and his own father, the poet Rabbe Enckell.

Finnish psychoanalysis was generally associated with ego psychology. Carpelan, trained in Geneva, is one of the few Finnish analysts to have a Kleinian orientation. He was president of the Finnish Group Therapy Association.

The traditional theoretical training period for psychoanalysts in Finland was extended from three years to four. The fourth year of training is devoted to the study of the relationship between psychoanalysis and the other sciences and of the theoretical and technical aspects of psychotherapy.

During the 1980s the Finnish Psychoanalytic Society (Suomen Psykoanalyttinen Yhdistys) underwent a period of rapid growth. In 2004 it had as many members as the Swedish Psychoanalytic Society. In the early 1980s it began offering training in child analysis, and in 1983 four candidates entered the program. In 1983 the Finnish Psychoanalytic Society had twenty-two full members, fifty-four associate members, and twenty-seven candidates. In 1993 there were forty-eight full members, ninety associates, and thirty-seven candidates.

During the late 1980s, several translations of Freud's work were published in Finland.

## FIRST WORLD WAR: THE EFFECT ON THE DEVELOPMENT OF PSYCHOANALYSIS

In July 1914 Sigmund Freud was more preoccupied with Carl Gustav Jung's resignation ("Finally, we are rid of Jung, that crazy brute, and his acolytes!" he wrote to Karl Abraham on July 26) than the war that Austria, following the assassination of Archduke Ferdinand in Sarajevo on June 28, had declared against Serbia. "This may be the first time in thirty years that I feel Austrian," he added. He was so unaffected that he allowed his daughter Anna to leave for Great Britain at the beginning of the month. The real problem was organizing the international congress that was supposed to take place that fall in Dresden, but that ultimately took place four years later in Budapest.

The general conflict let loose in August disturbed this sense of calm. Freud's sons weren't mobilized at the start of the war, and the progress of German troops made him hope for an early victory. "My heart would be with the combatants if I didn't know that England finds itself on the wrong side," Freud wrote on August 2, preoccupied with Anna's repatriation through Gibraltar and Genoa, which took place at the end of the month with the help of Ernest Jones ("he is obviously our 'enemy'"). Martin Freud joined the artillery: "According to his letter," his father wrote, "he didn't want to lose the opportunity to cross the Russian border without changing his religion." Karl Abraham wrote to Freud on August 29, 1914, "The news is excellent now, isn't it? The German troops are barely one hundred kilometers from Paris, Belgium has been liquidated, and England is on its last legs. Russia isn't doing much better." On September 13 he added, "During the next few days, we hope to have favorable news of the fighting along the Marne. If this ends well, France's fate will be pretty much sealed, that is, securing fortified positions in the southeast will be only a matter of days."

The principal concern appears to have been the publication of *Zeitschrift* and *Imago* with the help of Otto Rank, while Sándor Ferenczi traveled to Vienna at

the end of September for an analysis with Freud. Freud had begun writing the "Wolfman," which was published in 1918, but his morale was shaken by the announcement on October 17 of the death of Emanuel, his half-brother, after falling from a train, and then by the global expansion of the war on November 2.

On December 24, 1914, he wrote to Jones, "I have no illusions and realize that the expansion of our science has now been interrupted, that we are heading toward a bad period, and that all we can hope for is to maintain the embers in a few hearths, while waiting for a more favorable wind to help us build it up into a blaze. What Jung and Adler have left of the movement is now crumbling because of the dissension among nations. The *Verein* is no more tenable than anything having an international dimension. Our reviews will soon cease publication; we may manage to continue the *Zeitschrift*. . . . The future of the cause, which is so dear to you, does not bother me, naturally, but the immediate future, the only one I can take an interest in, appears desperately dark and I wouldn't cast a stone at the rat abandoning the ship." Because he had fewer patients, he had more time, and so announced, "I am again going to try to put whatever I can contribute into a summary."

These were the twelve essays on metapsychology that were to occupy Freud throughout 1915 not only as a necessary synthesis at a time of upheaval but as an essential next step in developing his ideas. This followed the publication of "On Narcissism: An Introduction" at the beginning of the year, which shook the foundations of psychoanalytic theory by questioning the opposition between "libidinal drives" and "self-preservation drives." The essay on melancholia was the subject of extensive correspondence with Karl Abraham, which allowed Freud to stress the fact that in the future any psychoanalytic explanation of an "affect can only be provided through its mechanism, considered from a dynamic, topological, and economic point of view" (letter of May 15, 1915). On that same day he wrote, "My work is taking shape. I have completed five essays: the one on Instincts and their Vicissitudes, which is of course somewhat dry but essential as an introduction, and will be justified in the following articles, then Repression, the Unconscious, A Metapsychological Supplement to the Theory of Dreams, and Mourning and Melancholy. The first four will be published in the *Zeitschrift* series currently underway; I will keep the rest for myself. If the war lasts long

enough, I hope to be able to combine about a dozen similar essays and publish them, in calmer times, to the uncomprehending public, with the title *Preliminary Essays on Metapsychology*. I feel that, overall, this represents progress. Same genre and same level as section VII of the *Interpretation of Dreams*.” In 1915 he also published “Thoughts for the Times on War and Death” (1915b), the first in-depth essay on violence, hatred, and the illusion of primal kindness, an essay that provides perspective for the future conceptualization of the death drive. On July 30, 1915, he wrote to Lou Andreas-Salomé, “It is impossible to say when we will be able to meet, we, the scattered members of an apolitical community, nor, when the moment arrives, will we know the extent to which we have been corrupted by politics.”

Ernst Freud fought in Galicia, Martin was slightly wounded, most of Freud’s followers were mobilized except for Hanns Sachs who had been deferred for nearsightedness, and meetings of the Vienna Psychoanalytic Society became increasingly less frequent. The fall of 1915 was a busy one. Freud gave a series of lectures that, after being continued during the winter of 1916–1917, formed the basis for the *Introductory Lectures on Psychoanalysis* (1916–1917a). In December Rainer Maria Rilke visited Freud and unsuccessful efforts were made to obtain the Nobel Prize for him. In January 1916 Freud’s isolation increased with the departure of Otto Rank for Krakow.

The year 1916 was relatively quiet for psychoanalysis, other than Freud’s sixtieth birthday in May. Like the rest of the population, Freud had grown weary of the incessant slaughter, the lies, the cold and hunger. The first generation of psychoanalysts were scattered across enemy territory but, being for the most part mobilized in the medical corps, they largely escaped death. The first really good news came in 1918 when Freud discovered Ernst Simmel’s book *Névroses de guerre et Traumatisme psychique*. “Here for the first time, a German doctor, who relates unequivocally and without condescension to psychoanalysis, who has made use of his position to advocate for the treatment of war neuroses, provides examples to prove it, and shows himself to be completely honest regarding the question of sexual etiology. True, he has not followed psychoanalysis on every point, supports the cathartic point of view, makes use of hypnosis, a method that cannot fail to mask the resistance and strength of the sexual drives; but he alleges with reason the need for

prompt results and the imperatives of sequential efforts. I think that with a year of training he would be a good analyst.” Freud went on to write to Simmel, “few writings by psychoanalytic novices who I do not know personally have given me as much satisfaction as your article” (February 20, 1918).

The time had come to organize a new congress, the first since the Munich congress of 1913. Planned to take place in Breslau, it was ultimately held in Budapest, a city that assumed considerable importance for Freud, primarily because Anton von Freund, one of his analysts, provided material and financial support to the cause of psychoanalysis. “We are going to become materially powerful, we will be able to maintain and develop our publications, have influence; our current poverty is coming to an end. The man to whom we owe all this is not only rich, he is also well intentioned, highly intelligent, and very interested in psychoanalysis. . . . From now on Budapest is going to become the center of our movement.”

The Fifth International Congress on Psychoanalysis was held in Budapest on September 28 and 29, 1918, and Freud spoke on “Wege der psychoanalytischen Therapie” (The paths of psychoanalytic therapy)—an essay that was to have considerable influence on the evolution of the psychoanalytic movement in the next few years. He planned the extension of psychoanalysis for social purposes, the need to blend the copper of suggestion with the pure gold of psychoanalysis, and introduced the idea of providing free treatment for the poor, which was to lead, two years later, to the creation of the Berlin Polyclinic and the Psychoanalytic Institute, which was needed to train psychoanalysts for the growing number of patients. The congress was a success, especially because the increasing problems introduced by war neuroses attracted the attention of the government authorities to the benefits of employing psychoanalytic methods. One month later a revolution broke out in the Hungarian Republic. Béla Kun’s revolutionary government appointed Ferenczi “professor of psychoanalysis” on May 12, 1919; he then assumed direction of the Batizfalvy Sanatorium (from the end of March to the beginning of August 1919).

The armistice on November 11, 1918 provided considerable relief, but Freud was worried about Martin, because he had not heard from him. At the end of the year, he learned that he was a prisoner in Italy and wouldn’t be released until October 1919. From Great Britain, Jones wrote on December 21, 1918, “In

Germany and America there has been much progress of late. Here, psychoanalysis has awakened general interest in every circle and it is even being taught in medical schools; the younger generation is impatient to learn more about it." He went on to say that he was preparing to "hunt down the 'remaining Jungians'" and establish the new British Psycho-Analytical Society and create the *International Journal of Psychoanalysis*.

On April 18, 1919, Freud was able to confirm, "I am still standing and in no way hold myself responsible for the world's absurdity. Psychoanalysis is flourishing, I am delighted to learn, on all sides, and I hope that the science will provide consolation to you as well."

## **FIVE LECTURES ON PSYCHO-ANALYSIS**

Freud delivered his *Five Lectures on Psycho-Analysis* in September 1909 at Clark University in Worcester, Massachusetts. He had been invited by Stanford Hall in honor of the university's twentieth anniversary. He was accompanied by Carl Gustav Jung, Sándor Ferenczi, and Ernest Jones. Upon their arrival in New York, he was welcomed by Abraham Arden Brill. These lectures were a key moment for the recognition and dissemination of psychoanalysis on an international level. Freud delivered these five lectures in German, without notes, and wrote them up later.

The text was published in English in the *American Journal of Psychology* in 1910. The work went through

eight editions in German, and it was translated into ten languages. In the course of these lectures, Freud first revealed Josef Breuer's role in the discovery of psychoanalysis. Freud recapitulated the case of a young girl (Anna O.) who was suffering from conversion hysteria and whom Breuer had treated. Freud described how catharsis (remembering traumatic events and their attendant affects under hypnosis) suppressed Anna's symptoms. But he quickly abandoned this technique. Research on hysteria being carried out at the same time by Jean Martin Charcot and Pierre Janet, in Paris, and Hippolyte Bernheim, in Nancy, allowed Freud to confirm his own theory. He discerned that a symptom is a disguised form of conflict between the conscious and the unconscious, provoked by incompatible desires, and he discovered the phenomena of resistance and repression.

Next Freud explained the basis for psychoanalytic technique: free association and the interpretation of slips of the tongue and, in particular, dreams, which he called "the royal road to knowledge of the unconscious." Making use of free association, the analyst identifies the latent content hidden behind dreams' manifest content (the actualization of hidden repressed desires) and the processes of condensation and displacement that are an obstacle to understanding the repressed desires.

Freud then approached the central issues of infantile sexuality, the Oedipus complex, and the sexual origins of neurosis. He showed the existence of transference by noting that in the relationship with the analyst, the patient relives old affects and repressed desires that have become unconscious and are returned to consciousness under the influence of transference. Finally, Freud refuted objections against psychoanalysis stemming from the fear that the liberation of repressed desires might endanger morality and social life. He believed that psychoanalysis, by bringing these desires back into consciousness, enabled people to accept and master them—or better yet, sublimate them.

These five lectures, written in a simple, lively style and filled with anecdotes, describe the origins of psychoanalysis and the trajectory of Freud's thinking up until the end of 1909.

**FIXATION**

The notion of fixation involves a certain mode of connection that a drive has with its ideational representatives (its objects) as a function of a primitive phase of the subject's sexual organization. This mode of connection is characterized, at the economic level, by the withdrawal from general circulation of more or less significant quantities of libido. On the dynamic level it is marked by the absence of mobility of the drive in question. On the topographical level, the connection is inscribed in the unconscious.

In Freud's work, the idea of fixation is theoretically associated with four other notions: traumatism, regression, repression, and predisposition. These form the successive stages of Freud's elaboration of the concept of fixation.

The notion of fixation first appeared in a context, which would later turn up again, that is associated with Freud's first work on the psychoneuroses of defense around the time of the *Studies on Hysteria* (1895d): "The traumatic neuroses give a clear indication that a fixation to the moment of the traumatic accident lies at their root" (1916–17a, p. 274). The fixation to the trauma accounts for the neurotic disorder and for the patient's inability to master the affect contained in the traumatic events. Thus the first version of fixation is dominated by the economic dimension.

The notion of fixation next appeared in the *Three Essays* (1905d): "[W]e propose to describe the lagging behind of a part trend at an earlier stage as a *fixation*—a fixation, that is, of the [drive]....[T]he portions which have proceeded further may also easily return retrogressively to one of these earlier stages—what we describe as regression" (p. 340).

In the Freudian conception of infantile sexuality, the sexual function develops according to a graduated rhythm. A partial drive may either pursue a development that achieves the ability to organize freely circulating energy under the aegis of the oedipal genital

structures, or stop at some point along the way, lagging behind by fixing upon an earlier stage of sexual development or a primitive object of satisfaction. In clinical work, perversions, just like neurotic symptoms, are evidence of libidinal vestiges from the past.

Fixation appeared in a third context in regard to the case of Daniel Paul Schreber: "The libidinal current in question then behaves in relation to later psychological structures like one belonging to the system of the unconscious, like one that is repressed" (1911c, p. 66). For Freud, in fact, the psychical representatives of component drives are made the object of a fixation that then falls under repression. Similarly, in the formation of symptoms the return of the repressed goes back to the very point of fixation to which the libido has regressed.

Finally, the notion of fixation is associated, in Freud's teaching, with that of sexual constitution insofar as it brings together the various ways in which the different components of the libido are inscribed in the early stages of its development. Fixation thus represents predisposition as a factor in the etiology of neuroses.

The notion of fixation can be found in other currents of psychoanalytic thought, particularly in that of Pierre Marty, whose work represents an original contribution to the concept. For him, the fixation-regression system forms the basis of any functional organization and has a field of influence that stretches from mental to somatic functions. In the course of any psychosomatic disturbance, the presence of fixations, whether psychical or somatic, constitute the stopping points of a counter-developmental current, points from which a psychosomatic reorganization can take place. According to this point of view, the fixation-regression system represents the set of defensive capacities in the development of each individual.

## FLIESS, WILHELM (1858–1928)

Wilhelm Fliess, a German physician, was born October 24, 1858, in Arnswalde (Markbrandebourg) and died in Berlin on October 13, 1928. He came from a family of Sephardic Jews. His mother observed the orthodox rituals, a tradition her son did not follow. He had a brother who was stillborn and a sister, Clara, a year younger, who died of pneumonia when Wilhelm was twenty. His father was in the grain business and committed suicide when Wilhelm was nineteen years old. He never spoke of this suicide, neither to Freud—to whom he related a different version of the father's death—nor to his own children, who didn't discover the truth until after their own father's death.

Fliess studied medicine in Berlin; in 1883 he opened a practice as a general practitioner and then as an otorhinolaryngologist. The number of patients grew along with his fame. He traveled a great deal, most importantly to Paris, in 1886, a year before meeting Freud, whose lectures he attended in Vienna. This was the start of their friendship, which resulted in a lengthy correspondence from 1887 to 1902, reaching its peak in 1899. Fliess married a Viennese woman from among the circle of Josef Breuer's patients named Ida Bondy, and together they had several children: Robert (1895) who became a well-known psychoanalyst after his emigration to the United States, Pauline (1898), Conrad (1899), and a stillborn daughter in 1902. Freud was treated by Fliess and was his enthusiastic collaborator; the two men met approximately once a year.

Fliess initially thought there was a correlation between the genital organs and the nose, based on the

principle of what he called the reflex nasal neurosis. In May 1895, when his wife was pregnant with their first child, he had a revelation of the theory of periods as a solution to the question of when conception occurred and the determination of the sex of the child. From that moment on he began constructing his system, postulating a cosmic harmony governed by the solar cycles, measured in days and years, between personal, family, and social events, but also affected by the animal and plant kingdoms. All vital events are determined by two periods, a male period of twenty-three days, and a female period of twenty-eight days, which are transmitted from generation to generation, from mother to child. Added to this bisexual periodicity was the idea of bilateralism, which represents the imprint of the simultaneity of the two periods on the body, the left hand bearing the positive and negative qualities of the opposite sex. Freud was interested in several aspects of the theory but doubted the cohesion of the three features (biperiodicity, bisexuality, and bilateralism) that were essential for Fliess and its predictive nature, which Fliess viewed as a rejection. He experienced this as a kind of persecution and in 1900 began distancing himself from his friend although Freud was not fully aware of it.

Their final break occurred in 1906. At the same time as the appearance of his major work on the theory of periods, *The Course of Life*, Fliess wrote a scathing pamphlet, "Pour ma propre cause," in which he accused Freud of having served as an intermediary in the plagiarism of his work by two young Viennese authors, Hermann Swoboda and Otto Weininger, who each had appropriated half of his ideas.

After breaking with his friend, Freud destroyed all his letters from Fliess and developed a theory of paranoia based on these experiences, which he also applied to Daniel Paul Schreber. Having done so, he failed to take into account the fact that his friend's delusion had first appeared in 1895 and he had encouraged it even as he took comfort in it. It was almost a reversal of the accusation of plagiarism to the extent that Fliess copied nature through his unshaken conviction that the determination of periods mimics natural cycles.

Ignorance and the censorship of the relations between Freud and Fliess have contributed to a fabricated version of Freud's self-analysis as the mythic origin of psychoanalysis, which projects a later schema of standard analytic therapy onto the original discovery. Fliess was not the analyst of Freud's unconscious

desires, but he represented a kind of precursor of the subject assumed to have knowledge of biology, and in doing so helped combine Freud's desire to be an analyst with a future science (that both men would divide between them).

After his break with Freud, Fliess continued to devote himself to his medical practice, caring for several analysts (Alix Strachey and Karl Abraham among them), and writing numerous articles, always on the same subjects, which were anthologized in books. With Ivan Block and Ernst Haeckel, he was a member of the Berlin Medical Society for the Sexual Sciences and Eugenics. He died of intestinal cancer on October 13, 1928. He was eulogized as a great doctor from Berlin.

## FLIGHT INTO ILLNESS

The Freudian notion of a "flight into illness" should be understood in terms of symptom formation and the primary and secondary gains of illness. The symptom is regarded here as a secondary defense against unconscious conflict, having value as a compromise between a wish and a defense.

Early in his work, Freud discussed this kind of symptom in terms of a psychological conflict, leading to repression and followed by compromise formation: "one portion of the symptom corresponds to the

unconscious wish-fulfillment and another portion to the mental structure reacting against the wish" (1900a, p. 569). The concept of gain through illness helps clarify the concept of flight into illness. In a note on the Dora case, added in 1923, Freud mentioned that "The motive for being ill is, of course, invariably the gaining of some advantage" and, further on, "In the first place, falling ill involves a saving of physical effort; it emerges as being economically the most convenient solution where there is a mental conflict" (1905e, p. 43).

Thus, in the case of a hysterical attack, the flight into illness might serve what Freud calls the "primary gain." Aside from the hysterical crisis, Freud noted in 1926 that there are cases in which neurosis is the most harmless solution to a conflict and, from a social point of view, represents the most advantageous solution. For the neurotic, flight into illness is a favorable avoidance of an unsatisfactory reality, a form of self-defense in the struggle to survive. Freud also noted, along the same lines, the desire to remain ill.

Insights associated with flight into illness also operate outside the framework of neurosis and neurotic conflict. As early as 1894 Freud wrote: "One is therefore justified in saying that the ego has fended off the incompatible idea through a flight into psychosis" (1894a, p. 59). In the contemporary context, some authors consider somatic symptoms to be a system of defense and resolution, an avoidance in the face of tension of all kinds.

## FLOURNOY, HENRI (1886–1955)

Henri Flournoy, a Swiss medical doctor and psychiatrist, was born on March 28, 1886, in Geneva, where

he died on May 6, 1955. He was the son of Théodore Flournoy. One of his sisters, Ariane, married Raymond de Saussure. His son, Olivier, became a psychoanalyst in Geneva. Flournoy studied medicine in Geneva and then took internships in Berne, Warburg, Munich, and Baltimore (at Johns Hopkins University). During the Balkan War, from 1912 to 1913, he served as a Red Cross doctor. A man of insatiable curiosity from an early age, he developed an interest in heraldry, to which he became a devoted amateur.

In 1920 he became a privatdocent and lecturer in psychopathology at the University of Geneva. He was president of the Société genevoise de prophylaxie mentale (Geneva Society for Mental Prophylaxis) and of the Conseil de surveillance des aliénés (Supervisory Board for Mental Illness) for the canton of Geneva.

In 1922 he opened a psychiatric and psychoanalytic practice in Geneva. There were four phases to his psychoanalytic training: an initial series of twenty-six sessions with Carl Gustav Jung, a six-month analysis with Johan Van Ophuijsen in the Netherlands, a three-month analysis with Sigmund Freud in Vienna, and a final six-month analysis with Hermann Nunberg, also in Vienna.

He was a close friend of Charles Odier, Raymond de Saussure, and Princess Marie Bonaparte and played an important role in the Swiss Society for Psychoanalysis. He was an active, though unofficial, participant in establishing the acts of incorporation of the Paris Psychoanalytic Society. In 1933 he presided at the eighth Conférence des psychanalystes de langue française (Conference of Francophone Psychoanalysts).

He worked intermittently after 1939, many foreign patients (mostly from the League of Nations) having left Switzerland and local demand having fallen off because of the war climate. As a result, Flournoy concentrated increasingly on psychotherapy.

He was appointed an expert for providing women who intended to have abortions with advice consistent with current legal requirements. Flournoy expended considerable energy in demonstrating that mental distress is a sufficient, more than sufficient, justification for abortion and advocated legalizing it. This contributed greatly to his celebrity, or notoriety, well beyond the borders of Switzerland. It was also the origin of an extensive correspondence with various medical, psychological, and legal publications.

As a psychoanalyst, Flournoy contributed to the development of the young Swiss Society for Psychoanalysis and to the acceptance of psychoanalysis in Switzerland. In addition to his many articles, in 1949 he published *Erreurs et dignité de la pensée humaine*.

## FLOURNOY, THÉODORE (1854–1920)

A medical doctor and professor of physiological psychology at the University of Geneva, Théodore Flournoy was born in Geneva on August 15, 1854, and died, also in Geneva, on November 5, 1920. He was the son of Alexandre Flournoy and Caroline Claparède, sister of the naturalist Édouard Claparède.

Interested in philosophy and religion, Théodore Flournoy spent time in Germany to familiarize himself with the philosophy of Immanuel Kant, whose work he later taught at the university. After becoming a medical doctor, he was appointed a professor of physiological psychology at the University of Geneva in 1891.

His studies of the medium Hélène Smith were turned into a book, *Des Indes à la planète Mars*, which caused a considerable sensation in psychological and parapsychological circles in Europe and the United States. In it he described the phenomenon of “cryptamnesia,” forgotten memories that reappear without being recognized by the subject, who believes they are new. These memories disappear because of their

association with childhood sexual emotions. These involve a “subliminal process capable of achieving a degree of complexity and extent comparable to the work of composition and reflection in the thinker or novelist.” They are “reminiscences or momentary returns to earlier phases, which have long since been forgotten and which, normally, should have been absorbed during the individual’s development instead of recurring in strange forms.”

Cryptamnesia is unconscious. “The unconscious possesses a marvelous ability for dramatization, personification, and psychological proliferation; it is endowed with a creative imagination.” Flournoy went on to claim that “The unconscious, [is a] submerged sphere from which our instinct for physical and moral preservation confusedly arise, our feelings about sex, about spiritual and physical shame, everything that is most obscure and the least rational in the individual.” Concerning dreams, he wrote “By rising up from our hidden source, by throwing light on the intrinsic nature of our unconscious emotions, by revealing our ulterior motives and the instinctive slope of our associations of ideas, the dream is often an instructive probe into the unknown layers that support our ordinary personality.”

Flournoy used these hypotheses to explain the supranormal or parapsychological phenomena he studied. They helped compensate for the obscurity and misery of everyday life, attempted to realize sexual desires arising from a forgotten childhood, and served as defenses against internal threats of madness.

Freud was writing about the process of infantile amnesia at the same time, and it is clear just how close Flournoy’s claims were to Freud’s position. However, unlike Freud, Flournoy does not mention repression or the return of the repressed—the concept that enabled Freud to conceive of a dynamic therapy—but limited himself to cryptamnesia, locating the path to consciousness in subliminal activity. Like his friends William James and Frederick Myers, Flournoy did not treat patients; these men were observers—though that did not prevent them from proposing hypotheses for acting on and modifying phenomena.

Concerning the principle of parallelism, Flournoy’s aims were diametrically opposite those of Freud. Both men excluded transcendence from their investigations, but Flournoy did so in the hope of discovering it, free of human taint, while Freud tried to eliminate it,

especially in postulating the existence of erogenous zones at the start of life and the death instinct at the end, hoping to see the reign of science govern the study of the mind.

In 1901 Flournoy, with his cousin Édouard Claparède, founded *Les Archives de psychologie*, a review that was later taken over by Jean Piaget. He corresponded with Ferdinand de Saussure, whom he knew personally, along with other well-known linguists. His son Henri and his grandson Olivier became psychoanalysts. His daughter, Ariane, married psychoanalyst Raymond de Saussure.

## FLOWER DOLLS: ESSAYS IN CHILD PSYCHOTHERAPY

In an article that appeared in the *Revue française de psychanalyse* in 1949, “Cure psychanalytique à l’aide de la poupée-fleur” (A Psychoanalytic Cure with the Help of a Flower Doll), Françoise Dolto described her experience with this green doll—which is often referred to as a marguerite doll—in the treatment of a child named Bernadette.

At the age of five Bernadette was already suffering from *anorexia nervosa*. She was vomiting up her meals and spoke in a monotone. She dragged her left leg and her hand was folded back over her forearm, the consequence of a hemiplegia. She played with toys that she constantly punished. In the course of the seventh session, she began to speak about the monkey inside her

that said bad things, and then hammered her tummy with her fists to make the monkey come out.

Françoise Dolto noticed the child's interest in flowers, particularly marguerites. When her mother said that the little girl liked neither her animals nor her dolls, Dolto responded: "Perhaps she'd like a flower doll?" Bernadette responded, "Oh, yes, yes, a flower doll!" Her mother was asked to make a faceless doll with no hands out of green material and to crown it with a marguerite.

In the eighth session, Bernadette came with her flower doll, which she had named Rosine. She said she was horrible and naughty. "Do you know why she's so naughty?" Bernadette whispered into the analyst's ear: "For her being naughty means being nice because she has an arm and a leg that don't work. Her way of being nice is hurting others. She's not naughty, but she's ill. You're going to treat her!" And the doll stayed with the analyst while the little girl went away quite happy.

When Bernadette arrived for her ninth session, she came with a teddy bear dressed as a human doll, and she looked after it tenderly so that it wasn't too hot. From the day she left the flower doll for treatment, Bernadette had changed at home. "I treated her every day, you know," Explained Dolto. Then Bernadette spoke quietly to her doll, listened to her answer, made her dance on the table, and suddenly cried out in a modulated voice: "She's cured, her arm and legs work very well! You looked after her very well." Then she thrust forward her folded-back hand, like a sort of claw. "She's a wolf girl, so when she loves she scratches! Because the wolf girl is very fond of you she's going to show you how strong she is!" She began to dig her nails into the analyst's skin, saying: "Don't be afraid, she has to see blood because she loves you."

From that session onward, Bernadette used her good right hand to stroke the other hand, and she began to create many objects with clay, and her behavior changed. Dolto theorized that the flower doll was the support for the girl's narcissistic affects, which were wounded during the oral stage. Afflicted with serious somatic disorders, this sick little girl's oral, then anal, aggression turned against herself, then projected itself into this human and plant form without a head, a form that was unable to speak and not responsible for its actions. Bernadette used it for her treatment, which gave Dolto the idea of using it with other children and adults.

## FLÜGEL, JOHN CARL (1884–1955)

The English psychoanalyst John Carl Flügel was born on June 13, 1884, in London, where he died on August 17, 1955. An honorary fellow of the British Psychological Society and an honorary member of the Indian Psychological Association, he was president of the Programme Committee of the International Congress on Mental Health in 1948 and president of the psychology section of the British Medical Association in 1950.

His father was German and his mother English, and the family had close ties with France; John Carl grew up learning all three languages. Because of a congenital malformation of his feet, he did not follow a normal school program, and he attended Oxford University when he was only seventeen. He studied philosophy and grew interested in hypnotism, becoming a member of Frederick W. H. Myers's famous Society for Psychical Research. He obtained a doctorate in philosophy at Oxford and a doctorate of science from the University of London, where he taught as an auxiliary professor from 1929 to 1944 in the experimental psychology laboratory. In 1913 he married Ingeborg Klingberg, who also became a psychoanalyst and with whom he had a daughter.

Flügel was an active member of the British Psychological Society: he was honorary secretary from 1911 to 1920, honorary librarian from 1911 to 1932, and president from 1932 to 1935. During the First World War he made a number of important psychological contributions to the society. After undergoing psychoanalysis with Ernest Jones, the two became friends, and Flügel became involved in the refounding of the British Psycho-Analytical Society in 1919. He also served as secretary of the International Psychoanalytic Association from 1919 to 1924. With John Rickman, Douglas Bryan, and Ernest Jones, he helped create the *International Journal of Psychoanalysis* in 1920, and with Ernest Jones and Joan Riviere, he helped translate

Sigmund Freud's *Vorlesungen (Introductory Lectures on Psycho-Analysis; 1916–1917a [1915–1917])*.

His knowledge of biology, experimental psychology, and philosophy, and his involvement in psychoanalysis enabled him to produce a considerable number of literary works, although these works are rarely read in the early twenty-first century. Ernest Jones wrote to Freud, "Flügel is certainly not predisposed to self-sacrifice, but what he does, he does very well and he is our best report writer. In non-medical circles he is of inestimable value and always uses his influence for the PAS [Psycho-Analytical Society]" (April 10, 1922). He wrote many books and articles, including *The Psycho-Analytic Study of the Family* (1921), which was the third volume (but the first English contribution) in the then recently created International Psycho-Analytical Library of Hogarth Press; "Psychoanalysis: Its Status and Promise" (1930a); *The Psychology of Clothes* (1930b); and *Man, Morals, and Society* (1945).

Upon Flügel's death, Ernest Jones wrote of his "good nature, kindness, humor, and fondness for an exceptionally large circle of good friends." Jones was less charitable, however, in a letter to Freud dated December 7, 1921: "Flügel has excellent written English and is intelligent, but he has two weaknesses. He is somewhat egotistic and the only thing he enjoys is doing his own work, not helping others; and he has not overcome a strong reaction to a sadistic complex that has paralyzed his efforts to criticize or disagree in any way, with very rare exceptions. He is thereby inhibited when he is asked to carry out any work of this sort (the same holds true for the correction of the American translation of the *Vorlesungen*), and he returned the manuscript almost in the same condition as it was. A mixture of laziness and inhibition. But he has to work with the tools available to him and I am trying to find out what interests him most and what is most suitable for him (which is to say, not much)."

### FLUSS, GISELA (1859–?)

Gisela Fluss, born on September 26, 1859, was the daughter of Ignaz and Eleonora Fluss, a family friendly with Jakob and Amalia Freud after the Freuds left Freiberg, Moravia. She was the sister of Emil Fluss, who became a friend and correspondent of Freud during his adolescence. She is known as Freud's first "love experience." The date of her death is not known.

Gisela met Freud when he was staying with the family in 1871. Gisela appears to have been associated with the romantic infatuation that had gripped the fifteen-year old Freud—Gisela was only twelve—during his return to his birthplace, an infatuation that Freud cryptically referred to in "Screen Memories" (1899a).

When he was again in Freiberg the following year, Freud mentioned Gisela in letters describing his vacation written to his friend Eduard Silberstein (1989a [1871–1881, 1910]). On August 17, 1872, he wrote, "So let me just say that I took a fancy to the eldest, by the name of Gisela, who leaves tomorrow, and that her absence will give me back a sense of security about my behavior that I have not had up to now." On September 4 he again wrote to Silberstein: "I have soothed all my turbulent thoughts and only flinch slightly when her mother mentions Gisela's name at table. The affection appeared like a beautiful spring day, and only the nonsensical Hamlet in me, my diffidence stood in the way of my finding it a refreshing pleasure to converse with the half-naïve, half-cultured young lady."

In fact, these letters show that the young Freud harbored greater enthusiasm for Eleonora, Gisela's mother, "a woman none of her children can completely equal." In the letter of September 4, Freud went on to write, "She [the mother] can never have been beautiful, but a witty, jaunty fire must always have sparkled in her eyes, as it does now. Gisela's beauty, too, is wild,

I might say Thracian: the aquiline nose, the long black hair, and the firm lips come from the mother, the dark complexion and the sometimes indifferent expression from the father.”

Allusions to Gisela appeared in letters from 1873 and 1874 but disappeared after Gisela told Freud's sisters, in 1875, of a trip to Italy. Her engagement in 1874 and her being called an ichthyosaur by students among themselves remain in dispute. It is known, however, that on February 27, 1881, in Vienna, she married a businessman from Presbourg (near Bratislava) by the name of Emil Popper.

There is some mystery about her reappearance in Freud's report of his November 18, 1907, session with the Rat Man, when, instead of the name of his patient, Freud wrote her name “Dame Gisela” (1955a [1907–1908]). He added three exclamation points after this slip, which was never analyzed by Freud and has remained unexplained.

## FORECLOSURE

Jacques Lacan used the French word *forclusion* (foreclosure) to translate the German term *Verwerfung*, previously rendered in French as *rejet* (repudiation). Sigmund Freud had introduced the term along with negation (*Verneinung*) and repression (*Verdrängung*) as a defense mechanism.

Foreclosure is a primordial defense because it does not act on a signifier that is already inscribed within the chain of signifiers, but rather, it rejects the inscription itself. Foreclosure is thus antithetical to *Bejahung* (affirmation).

This operation of repudiation especially affects highly meaningful signifiers such as the Name-of-the-Father,

the guarantor of castration. Lacan viewed the foreclosure of this signifier as the characteristic mechanism of psychosis. In “On a Question Prior to any Possible Treatment of Psychosis” (*Écrits*), he wrote: “I will thus take *Verwerfung* to be foreclosure of the signifier. At the point at which the Name-of-the-Father is summoned—and we shall see how—a pure and simple hole may answer in the Other; due to the lack of the metaphoric effect, this hole will give rise to a corresponding hole in the place of phallic signification” (p. 191). To paraphrase, let us say that when the subject calls upon the Father to guarantee the law that situates both the subject and his desire in the Other, he encounters only an echo in a void that triggers a cascade of delusional metaphors. These readily become organized around the fantasmatic presence of an authority who is suspected of having intrusive or criminal intentions; it is as if the foreclosure of the Name-of-the-Father made present in the Real a malevolent authority desiring to commit sexual abuse or homicide.

Why does foreclosure come about? One explanation is that the child has been exposed to a mother who has refused to recognize the law, either because it does not situate her in accordance with her desires, or because it compels her to separate herself from its product. It may also happen that the real father reveals himself to be incapable of inscribing himself into a symbolic lineage, and consequently invalidates it (cf. Schreber's father in “Psycho-Analytic Notes on an Autobiographical Account of a Case of Paranoia [Dementia Paranoides],” 1911c). But not infrequently, skipping a generation, the child of a psychotic couple may validate the Name-of-the-Father on its own, based on what he finds in language and verifies with the help of substitute parent figures.

Could specific forms of foreclosure be responsible for the division of the psychoses into paranoia and schizophrenia? Nothing points to this conclusion, even if paranoia is an attempt at a cure through the designation of a real, albeit a persecutory father. This designation turns the signifier into a sign of certain truth.

Many have asked whether psychoanalytic treatment can repair a foreclosure. Case histories do not provide any clear answers.

Let us recall that Schreber, for his part, found a kind of stabilizing by accepting emasculation as being “consonant with the Order of Things” (p. 48); by becoming a woman, he could attract the divine presence that

safeguarded him. Equally interesting are studies of borderline cases. It seems that the latter more likely result from a denial or annulment of the Name-of-the-Father, with a predictable failure of the law, but without producing the reshaping of the real (its fragmentation or its investment by a persecutory figure) that are characteristic of foreclosure.

## **FORGETTING**

In *The Psychopathology of Everyday Life* (1901b), Freud discussed forgetting under the rubric of psychosis. The typical example is awareness of having forgotten a proper noun (a name, for example). Like amnesia (where one is unaware that one has forgotten), forgetting is the result of repression. The forgotten name inhabits the preconscious and quickly returns to consciousness. It is attracted by an unconscious mental complex that primarily operates by displacement.

The concept of forgetting in general is present in Freud's earliest works on the theory of neuroses (1894a, 1895b, 1896a). But in "*The Psychological Mechanism of Forgetfulness*" (1898b) and *The Psychopathology of Everyday Life*, Freud considered forgetting, like slips of the tongue, to be a parapraxis symptomatic of ongoing repression. To demonstrate the existence of the unconscious, Freud uses the example of forgetting because it was one way of talking about repression before 1900. Forgetting appears in his first theory of neuroses, which explains hysteria as a traumatic

infantile sexual seduction that has to be rejected and repressed because the child finds it unacceptable.

Forgetting is associated with a painful sense of awareness (the "name on the tip of the tongue"), while repression is most often unconscious. Forgetting is associated with the psychology of consciousness and the preconscious, while repression is associated with the metapsychology of the unconscious, like memory traces. As a form of parapraxis, forgetting combines partial failure with partial success and must be distinguished from the customary psychological form of forgetting, a successful act of repression.

The dreamer who has forgotten his dream tries to reconstruct it, but in doing so, constructs it anew: "It is indeed possible that while trying to retell it, we fill in the blanks created by forgetting using new material arbitrarily chosen" (Freud, 1900a). We cannot completely remember what is forgotten, and so we prefer to construct likely hypotheses, capable of introducing conviction about what was forgotten (Freud, 1937d).

The person who has forgotten a name, by concentrating on it, only reinforces the ongoing repression. To remember, Freud tells us, we need to abandon the willful attempt to control what initially appears to be a cognitive disturbance, a shortcoming, and give in to the associations that come to mind.

Freud provides an autobiographical example: Forgetting the name of the painter Signorelli during a conversation, he seeks memories, ideas, and words similar to the name. These bring to his mind other paintings with the sensory acuity typical of a screen memory (an early memory used as a screen for a later event), along with the names of other Italian painters (Botticelli, Boltraffio). The value that Freud attributed to the forgotten name had been transferred to neighboring elements, through displacement, as is the case with a mnemonic symbol, which is also a form of metonymy. "Botticelli" is a metonym of Signorelli, "Botticelli" and "Boltraffio" are metonyms of Bosnia-Herzegovina, which Freud was visiting when he forgot Signorelli's name and which is related to the castration complex involved in this forgetting, since Freud attributes to the Turks in Bosnia-Herzegovina a strong attraction to sexuality and a considerable castration anxiety. "Boltraffio" was a metonym of Trafoi, an Italian city where Freud learned of the suicide of one of his patients, which triggered his thoughts on "death and sexuality." The sentence "Herr, was ist da zu

sagen? (Sir, what is there to say)” reported to Freud by his interlocutor as reflecting the Turks’ attitude toward the inevitability of death, evoked their attitude toward sexuality (“You know very well, Lord, if that fails, then life has no value”), the source of psychic conflict and repression behind his act of forgetting. The representation of death Freud associated with that of castration (the Turkish sentences imply that a life without sexuality is worth no more than death). Moreover, *Herr*, present in Herzegovina, refers to *Signor* (Lord), to the father figure, and to *Herz*, the heart, an organ likely to grow sick and cause death. Forgetting the name of Signorelli is thus associated with an oedipal dimension that Freud had discovered through his self-analysis: his repression of sexuality, his attraction for his mother, his rivalry with his father, and his ambivalent identification with his father caught up in a desire for parricide and a fear of losing his father.

Freud analyzed two levels at the same time, the psychology of consciousness and the preconscious and the metapsychology of the unconscious. He thus provided an example of the psychoanalytic method, although repression is not associated with the name “Signorelli” so much as the unconscious complex he represents. The names substituted for the forgotten name are composed of verbal memory traces and other proper nouns. They are substituted for the forgotten name through a process that acts on the phonemic material of words (the signifier) through association, metonymy, homology, as well as translation from one language to another, metaphor, and polysemy (*Herr* has multiple meanings, as does *Herz*). In the process of forgetting the name, displacement is metonymy, and condensation is metaphor.

Forgetting, like remembering, belongs more to the phenomenology of consciousness than to the metapsychology of the unconscious. As a specific form of parapraxis, it also signifies repression according to popular convention. Because it occurs in the preconscious and is attracted by the unconscious, forgetting and the rediscovery of the forgotten are similar to what occurs when the subject clearly formulates for himself something he had always known. There have been few developments in psychoanalysis concerning the preconscious ego. As a result, it is easier to formulate psychoanalytic approaches that emphasize the cognitive causality of forgetting.

## FORMATIONS OF THE UNCONSCIOUS

Dreams, the forgetting of words and names, slips of the tongue, parapraxes in general, and jokes are all examples of formations of the unconscious, the forms by which the unconscious expresses itself. *The Formations of the Unconscious* is also the title of Jacques Lacan’s fifth seminar, given in 1957–1958. The expression also establishes, as a distinct group, different symptoms that were all discussed by Freud in his earliest works.

These formations of the unconscious are, in fact, symptoms, insofar as they are an expression and fulfillment of an unconscious wish. In psychoanalysis, they constitute the royal road to the unconscious. But knowledge of the unconscious can only be hypothesized, because “it is only as something conscious that we know it, after it has undergone transformation or translation into something conscious” (Freud, 1915e, p. 166). By proposing a generic expression for the symptomatic elements that Freud listed, Lacan emphasized that as “overdetermined” and “structurally iden-

tical” elements, they are “only conceivable, strictly speaking, within the structure of language” (Lacan, 2004a/1958, p. 260).

Freud isolated two principle mechanisms at work in the process of unconscious formations: condensation and displacement. Lacan suggested redefining these mechanisms as “the two aspects of the signifier’s effect upon the signified” (Lacan, 2004b/1957, p. 152), namely *metaphor* and *metonymy*, terms that had been analyzed by the linguist Roman Jakobson.

The notion of formations of the unconscious is related to Freud’s ideas of substitute formation, the return of the repressed, and symptom-formation.

## **FORNARI, FRANCO (1921–1985)**

Franco Fornari, an Italian surgeon, psychiatrist, and psychoanalyst, was born in Rivergaro, Piacenza, on April 18, 1921, and died in Milan on May 20, 1985. A student and analysand of Cesare Musatti, Fornari went on to become president of the Società psicoanalitica Italiana (Italian Psychoanalytic Society) and director

of the Psychology Institute of the Department of Literature and Philosophy at the State University of Milan.

Fornari introduced the ideas of Melanie Klein to Italy. In his early writings, to treat schizophrenia and depression he advocated deepening our understanding of the primal psychotic dimension by examining the mental development of the child’s affective life. He also studied group dynamics and social conflict, his research on these subjects appearing in an essay titled *Nuovi orientamenti nella psicoanalisi* (New directions in psychoanalysis; 1966).

Fornari’s Kleinian convictions are most apparent in his wartime research, which gave rise to several interesting psychological studies, including *The Psychoanalysis of War* (1974). In this work Fornari located the anxieties and psychotic fantasies that govern the behavior of individuals in groups, and he revealed the ensuing loss of responsibility in various social and political situations. War, he said, arises from the external projection of an internal danger and the negation of death in the face of an alleged external persecutory entity, and these forces make the individual destroy to survive.

Fornari then investigated the theme of sensuality in relation to affective symbolization. In *Genitalità e cultura* (Genitality and culture; 1975), he examined the notion of perversion, determining that culture is the antithesis not of sensuality but of pregenitality, which arises from a lack of infantile symbolization and from destructive impulses dominating in one’s behavior. He subsequently proposed an evolutionary reading of libidinal development.

Though elements of symbolization are already present in *Genitalità e cultura*, Fornari directly studied this topic in *Simbolo e codice* (Symbol and code; 1976), *I fondamenti di una teoria psicoanalitica del linguaggio* (Foundations of a psychoanalytic theory of language; 1979) and *Codice vivente* (Living codes; 1981). In these essays Fornari reexamined psychoanalytic theory in cognitive terms, establishing the foundation for a psychoanalytic anthropology that could also be of use to nonpsychoanalysts. He resolved the relation between body and mind by positing a code that preserves and transmits information in both directions between body and mind. Such a code, which he called the “living code,” is assumed in the programming of affects, which in fact is driven by one’s erotic materiality and parental bonds. Fornari developed a “coinemic” theory, in which the minimum unit of affective meaning is the “coineme.” Fornari saw this living code as an

instrument and methodology that could be used to apply psychoanalysis to a broad range of cultural phenomena: speech, images, behavior.

In *La riscoperta dell'anima* (The rediscovery of the soul; 1984), Fornari attempted to understand the human effort to rediscover the primal symbiotic unity with one's mother. And in *Affetti e cancro* (Affects and cancer; 1985) he investigated the role that psychoanalysis could play in treating incurable diseases.

## FORT-DA

“Fort!” and “Da!” are exclamations that Sigmund Freud heard his grandson Ernst utter while playing. This pair of words—meaning “Gone!” and “There!”—has become shorthand for repetition in early childhood, and for the primary processes that such behavior mobilizes.

In psychoanalysis, allusions to *fort/da* refer to the second chapter of *Beyond the Pleasure Principle*, where in a few celebrated pages Freud described and interpreted a game played by the little Ernst at the age of eighteen months. At the time, Freud was tackling the thorny problem of the compulsion to repeat in traumatic neurosis, and this digression into normal childhood experience was in fact meant to help contextualize the question. Ernst was a “good little boy,”

manifested no particular symptoms, was rather calm by disposition, and “never cried when his mother left him for a few hours.” But he “had an occasional disturbing habit of taking any small objects he could get hold of and throwing them away from him into a corner, under the bed. . . . As he did this he gave vent to a loud, long-drawn-out ‘o-o-o-o,’ accompanied by an expression of interest and satisfaction. His mother and the writer of the present account were agreed in thinking that this was not a mere interjection but represented the German word ‘fort.’” Freud interpreted this behavior as a way of obtaining satisfaction by causing things to be “gone.” A short time later he observed the child playing with a reel that had a piece of string tied around it: He would toss the reel away from him to where it could no longer be seen, before pulling it back into view and hailing its reappearance with a gleeful “Da!” (“There!”). Freud also noticed that the boy would utter his “o-o-o-o” sound with reference to *himself*—notably when, by crouching down below a mirror, he made his image “gone.” Freud stresses the fact that the *fort* part of the game was much of the time sufficient unto itself, and was “repeated untiringly” by the child (1920g, pp. 14–15).

This observation leads to a number of fundamental questions: Are we confronted here by a method of mastering a painful experience by reproducing it oneself in an active manner, as children so often do, for example when playing frightening games? Or is the child literally taking revenge for the treatment visited upon him by redirecting it onto the other, or onto himself? In the end, the answer is not of any great consequence, for the real problem is the contradiction, which here is seen to arise very early, between the compulsion to repeat and the pleasure principle. How is it that satisfaction is to be derived from repeating actions that have been sources of unpleasurable feelings?

The great interest of this discussion of Freud's is that it sums up and condenses his subsequent exploration of the issue of the repetition compulsion. This very early children's game shows this compulsion to be one of the fundamental processes of the psyche, with two enigmatic aspects, one making manifest “mysterious masochistic trends” that resist all attempts at analysis (p. 14), the other revealing an irreducible primordial violence that takes an especially virulent form, according to Freud's account, when little Ernst, at thirty months, throws aside a toy and unequivocally identifies it with his absent father who has been “sent to the front” (p. 16).

The *fort/da* game has inspired very many authors who have seen it as the embodiment of the institution of fundamental structures of the infantile psyche, though their emphasis varies according to tendency or school. Thus Melanie Klein and Donald Winnicott both drew a number of lessons from it as they sought to cast light on the origins of the child's mental life and develop play techniques for use in child therapy. For Jacques Lacan, the game expressed the child's accession to the symbolic order, and the purpose of making something appear and disappear was to replace it with elementary signifiers. Jean Laplanche, for his part, sees this play as the first attempt to respond to the adult's enigmatic messages.

It must be noted that Freud's original discussion actually focused in turn on first one and then another game, each dominant at a different moment. The first, at eighteen months, is based on *fort*, on throwing the object far away, with the accompanying "o" sound, and it indicates the pleasure obtained from making the other disappear, or making oneself disappear, a pleasure that makes it possible to tolerate absence and reflects the violence that absence implies; this game endures, for it is still available when, at thirty months, Ernst is gratified by his father's going off to war. The second game is founded on disappearance and reappearance, and shows a quite different kind of pleasure, that felt by the child when he sees what he had thought gone forever return from the void, and thus discovers the possibility of permanence, of continuity—the necessary basis for introjection and the working out not only of the symbolic order but also of the imaginary one. As much as the first game, if it is associated with nothing else, is governed by death-dealing repetition, the second, by contrast, is connected to a constructive repetition and partakes of a process of binding and transformation.

It is thus the *fort* game that is the more problematical, in that the subject obtains from the disappearance of the other or of himself an unconscious gratification which runs counter to the most fundamental prohibitions. In view of his belief in the omnipotence of thoughts, the child cannot conceive of death or disappearance otherwise than as the outcome of a wish; he can form an idea of these concepts solely through seeing and losing sight of objects, so he links these to the deployment of visual desire, thereby transforming trauma into pleasure, albeit a forbidden pleasure. In his account of *fort/da* play, Freud hints that the game

was beneficial to Ernst, for, even though he was not free from feelings of jealousy upon the arrival of a new sibling, he was well able to cope with the death of his mother a short time later. This was not to say, however, as Freud had noted in discussing "dreams of the death of persons of whom the dreamer is fond" (1900a, pp. 248ff), that once the subject reaches adulthood, and becomes aware of the true meaning of death, they will not be assailed in a deferred way by the guilt-driven anxiety that is to be seen in so many neuroses.

## **FOULKES (FUCHS), SIEGMUND HEINRICH (1898–1976)**

Physician and psychoanalyst Siegmund Heinrich Foulkes was born on September 1898 in Karlsruhe, Germany, and died on July 8, 1976 in London.

He was the youngest child of a comfortably-off, assimilated Jewish family (the Fuchs). After service in the telephone and telegraph section of the German army in World War I, he studied medicine at Heidelberg, qualifying at Frankfurt.

Foulkes soon determined to become a psychoanalyst but first spent two significant years as an assistant to the neurologist Kurt Goldstein. The work centered on rehabilitation of brain-damaged soldiers from World War I, who were intensively studied neurologically and with methods derived from Gestalt psychology by Adhemar Gelb. Goldstein's holistic approach to the function of the central nervous system later influenced Foulkes's concept of the group: as a whole where each person represents a nodal point in the group's network, analogous to the function of the neurone in the cortical network of the central nervous system.

In 1928 Foulkes went to Vienna for psychoanalytic training and postgraduate psychiatry. His analyst was Helene Deutsch and his supervisors Eduard Hitschmann and Herman Nunberg. Paul Schilder was also a significant influence. His close friend was Robert Waelder.

In 1930 Foulkes returned to Frankfurt as director of the outpatient clinic of the newly founded Frankfurt Psychoanalytic Institute directed by Karl Landauer. Erich Fromm and Frieda Fromm-Reichman were colleagues. There were fruitful exchanges in Frankfurt between psychoanalysts and sociologists, as both the Psychoanalytic Institute and the Sociological Research Institute (led by Theodor Adorno and Max Horkheimer) shared the same building. Foulkes developed a close friendship with the sociologist Norbert Elias whose theories were influential in his later group analytic theories. During this time he also became acquainted with the American analyst Trigant Burrow's writings on group analysis.

Foulkes emigrated to England in 1933. After psychoanalytic practice in London he moved to the provincial town of Exeter, where he first began group psychotherapy. He further developed group work in the British Army, notably at Northfield Military Hospital where he collaborated with Thomas Forest Main, Harold Bridger and others. Foulkes was the principal architect in transforming the hospital to a therapeutic community. Wilfred Bion and John Richman had preceded him in their short experiment in group work. In 1948 Foulkes published his Northfield experiences in his first book where he laid down the bases of group analytic theory and practice.

After the war Foulkes was a training analyst for the Anna Freud Group in the British Psychoanalytic Society and Consultant Psychotherapist at the Maudsley Hospital where he taught generations of psychiatrists the rudiments of both individual and group psychotherapy. With James Anthony he founded the Group Analytic Society and later collaborated in forming the Institute of Group Analysis, both in London.

Foulkes's approach is that of "psychoanalysis by the group"—developing the group members' therapeutic capacities as co-therapists to each other, in contrast to the approaches of Wilfred Bion and Henry Ezriel's "psychoanalysis of the group," or Franz Alexander and Alexander Wolf's "psychoanalysis in the group."

His principal contributions, as described in his book *Therapeutic Group Analysis* (1964) are the Matrix and the therapeutic power of mirroring. The Matrix is the hypothetical basis of all group transactions that provides the group's capacity for containment and holding. Mirroring and resonance are the group's specific therapeutic factors. The value of communication is a vital therapeutic factor as well: the ability to translate the language of symptoms into articulate, exchangeable communications. The therapist's main contribution is to facilitate this process. Foulkes valuably emphasizes the therapist's responsibility to be the "dynamic administrator," organizing and protecting the group situation, as well as his responsibilities as group conductor. Foulkes died during a seminar he was leading for his senior colleagues.

## **FOUR DISCOURSES**

In his seminar "The Other Side of Psychoanalysis," Jacques Lacan introduced four types of discourses. The discourses are the discourse of the master, the discourse of the hysteric, the discourse of the university, and the discourse of the analyst. They represent a matrix in which everything comes in fours. The discourses too are made up of four elements: S1, the master signifier; S2, knowledge; *a*, surplus enjoyment; and  $\$$ , the subject. Their positions above and below the bar on either side of the diagram represent four different values or functions: the agent, the other, the production, and truth.

In this fourfold structure, manipulating the minimal signifying chain, S1→S2, is both necessary and sufficient to represent the subject,  $\$$ , in relation to both the big Other (the unconscious) and the small other (the object *a* as the object cause of desire) (Fig. 1).

FIGURE 1

In each discourse, the *agent* addresses an *other*, and the *truth* that the discourse seeks is attained through a certain *production*. Insofar as there is a connection between S1 and S2, between the master-signifier and knowledge—a connection that depends on the essential mediation of speech—the subject is separated from the production of the discourse, and this results in a discourse that is always inadequate. In this case an unbridgeable gap separates the subject \$ and the object *a*.

If we take the discourse of the master as the starting point, the four terms generate each of the other discourses by making four successive ninety-degree turns in a clockwise direction. As each term takes the place of the agent, it assumes the dominant position and gives meaning and value to the discourse it generates. S1, the master-signifier, in the dominant position gives rise to discourse of the master. S2, knowledge, in that position produces discourse of the university. \$, the subject, as agent leads to discourse of the hysteric. In this case, the symptomatic signifier affects and marks the subject so that the subject's body displays the symptom and speaks metaphorically in the place of the repressed signifier. And finally, *a*, the object of desire, in the dominant position produces discourse of the analyst. But it is not because analysis is the “science of desire” that the analyst has direct access to the object *a*. If the analyst can assume the place of the agent and thus to know something about the patient's desire, it is only because the analyst is not duped into believing the agent's discourse. Something of the truth of the patient's desire has a chance to emerge within the framework of the treatment through the transference and by means of interpretation.

These four different social bonds constitute what Lacan claims is an essential support for communication. The four discourses go beyond speech, but “without going beyond language's actual effects” (Lacan, 1998, p. 93).

In the 1960s Lacan theorized the four discourses on the basis of a minute study of the social field that each discourse both reveals and conceals, because he wanted to ensure the transmission of psychoanalysis. He certainly knew that the discourses of the master and the university had existed for a much longer time. He credited Freud with having discovered the discourse of the hysteric, but argued that Freud had not known how to define the discourse of the analyst. So Lacan attempted to establish this discourse by defining its occurrence and its effects and by positing its limits so that analysis could be developed in a community and be taught in the community on both the theoretical and clinical levels. Lacan considered the discourse of the analyst to be one of his original contributions to psychoanalysis.

## FOURTH ANALYSIS

“Fourth analysis” (*l'analyse quatrième*), a contribution of the French Fourth Group, or OPLF (French-Language Psychoanalytical Organization), is a new approach to the part of analytic training traditionally known in psychoanalytic societies as “control” or “supervised” analysis. “Thus fourth analysis is in the first place a theory of the control analysis and of the conditions of supervision — a theory never outlined until now — that takes into account the entire group of figures and persons involved in it, as well as their visible and hidden interactions” (*Topique*, 1983). The

term “fourth” refers not only to the Fourth Group itself, but also to the number of protagonists, namely, the analysand, the analyst, the analyst’s analyst, and the analyst who carries out the fourth analysis.

The term *fourth analysis* did not appear in the Fourth Group’s “Principles and Modalities of Functioning” (or “Blue Book” [1969]), even though the idea of a “multi-referential” analysis effectively prefigured it. Such a multi-referential analysis, it was felt, was an adequate characterization of a key moment of analytic training, always assuring that training was not to be reduced to some kind of academic “curriculum.” “Indeed, as soon as the candidate takes on his or her first patient, it is no longer the didactic contract, but also the clinical experience, with all its unknowns, that regulates the relation of the subject to the unconscious. Thus the patient, who is only spoken of indirectly, confronts three analysts with the partiality (in both senses) of their knowledge: the novice, who is striving towards mastery, but also the supervisor and the didactician” (*Topique*, 1969). It is notable that these were still the very terms that the Fourth Group would later question, specifically the term *supervisor*, which is replaced by *fourth analyst*, and *didactician*, which would become “the analyst of the analyst”.

Stress on the multi-referential serves in the first place to highlight and to clarify the harmful effects specific to this plurality when it is not recognized as such. For example, playing the didactician and the supervisor off against each other, or making what one expects from the patient dependent on what one might want to hear or on what one thinks the supervisor wants to hear. Hence the formula that gave birth to the term *fourth analysis*: “There are three chairs and a fourth unconscious, which language does not express fully in known dialects” (*Topique*, 1969).

At the same time, the multi-referentiality specific to fourth analysis is not limited to it, which leads to the necessity of organizing “interanalytic sessions” with other analysts of the Fourth Group and possibly analysts from other societies. “The exemplary character of this four-term situation does not exhaust the diversity of third-party references. The candidate must be able, according to his or her own analytical, theoretical, and clinical progress, to organize in due course debates of variable lengths with other analysts” (*Topique*, 1969).

In the supplement to the “Blue Book” produced by the Fourth Group’s 1970 congress, dedicated

mainly to the notion of the “didactic effect,” the term *fourth analysis* is defined as follows: “The discipline of fourth analysis based on multi-referentiality implies access to the conditions that make the didactic affect possible: not just some regulatory mechanism designed to facilitate experimentation, scholarship, or initiation, but what may be called a *topography*. . . . To become an analyst is to gain access to this tetradimensionality of Freudian training as a process” (*Topique*, 1971).

This points up the important idea that the didactic effect is constructed in a dialectical movement made possible by the shift from a dual relation to a fourfold one. The risk of a major alienation, that is, alienation in knowledge, can thus be counteracted and the didactic effect is defined as never being the direct consequence of the transmission of knowledge.

In 1979, Jean-Paul Valabrega, who had participated in drafting the “Blue Book” in 1969 and 1970, undertook a more thoroughgoing theorization of fourth analysis (Valabrega, 1979), which he defined as a “theory of supervision.” He set out “to better delimit the ‘analytic material’ itself and above all to prevent its potential loss, to insure as much as possible against its unintended erasure” (*Topique*, 1983).

The principle of the fourth analysis has not been modified further. On the other hand, it has been integrated into the greater aim of emphasizing the crucial consideration of the transference and countertransference. The work being carried out on the analysis of the analyst on the basis of fourth analysis allows for, or at least contributes to, a limitation of countertransference effects in the treatment, notably the deafness towards the analysand that comes about when listening to oneself and not the other overwhelms the analyst’s psychic space.

To reopen and to reinstitute, without ever taking as given what must be perceived as a process, is in fact the ideal not only of analytic training, but also of analytic practice, including that of established analysts. The existence, and even the necessity, of interanalytic sessions that bring several analysts face to face around a trainee constitutes a test of each one’s clinical practice; and, at least in principle, it represents an abiding recommendation for every analyst after his or her accreditation. Fourth analysis and interactive sessions, by virtue of their very stringency, are an effective response to what Freud (1937c) said in “Analysis

Terminable and Interminable” about the necessity of the analyst’s putting his or her own analysis to work.

## **“FRAGMENT OF AN ANALYSIS OF A CASE OF HYSTERIA” (DORA/IDA BAUER)**

Freud’s case history for Ida Bauer, alias Dora (1905), covers approximately seventy hours of treatment. The eighteen-year-old adolescent was forced to go to Freud by her father, Philip Bauer, who was allegedly most concerned by her fainting spells and recent suicide note. Her presenting symptoms included dyspnoea, tussis, nervosa, aphonia, depression, and hysterical unsociability. Combining anamnestic data, reconstruction, and an extensive analysis of two dreams, Freud portrays his patient as a young child observing the primal scene and falling sick from related masturbation. Her subsequent psychic disorder was directly related to her father’s liaison with Frau K. (Peppina Zellenka). Philip denied the liaison and, in his own version of Dora’s analysis, wanted Freud “to talk Dora out” of her belief. Furthermore, Dora had been traumatized twice by Herr K. (Hans Zellenka). Until therapy she had kept the first traumatic occasion to herself, and the second was denied by Hans, who, with his wife and Philip, accused Dora of fabrication. Mrs. Bauer’s “housewife psychosis” and self-absorption further increased Dora’s alienation and desperation.

Freud attempted to demonstrate to Dora that her reproaches toward her adulterous father were self-reproaches, rooted in her unacknowledged love for Hans, who continued to solicit her. Surprisingly, Freud also wanted Dora to stop resisting and to accept Hans, for it “would have been the only possible solution for all

parties concerned.” Dora, however, abruptly terminated treatment—an action Freud considered as another manifestation of her vengeance. Freud pointed out two other shortcomings of his handling of the case: he neglected Dora’s transference, and he overlooked Dora’s homosexual strivings, found at her deepest unconscious level.

Freud’s case history was an organizing clinical experience for him and for the psychoanalytic movement and stands as a paradigmatic record of both psychoanalysis and contemporary culture. It is Freud’s longest text on a female patient and also one of Freud’s memorable trilogy including *The Interpretation of Dreams* (1900a) and *Three Essays on Sexuality* (1905d). It is the first of Freud’s great analytic cases and the first involving an adolescent. Ernest Jones called the case “a model for students of psychoanalysis,” and for Erik Erikson, it was “the classical analysis of the structure and the genesis of a hysteria.” Other critics have described the case as a canonical specimen of conversion hysteria, as Freud’s most graphic demonstration of psychosomatics, and as the case of Freud’s most discussed in psychiatry and psychoanalysis as well as in sociology, anthropology, history, and literary criticism.

Granted, Freud’s various theoretical discoveries in the Dora case, from a practical point of view, must be reevaluated. Freud either downplayed or entirely disregarded Dora’s triple burden of being a woman, a Jew, and an adolescent victimized by two pairs of adults. In his quest to genetically reconstruct the psychic truth, Freud dismissed Dora’s concern about current historical truth and her need to validate her experience. The case lacks indispensable desiderata of psychoanalysis in that there is virtually no interpretation involving transference and in that indoctrination and forced association replace free association.

Even as a case of therapy, Freud’s treatment of Dora was disastrous. By bullying his patient and even wanting her to return to the middle-aged adulterous pedophile who twice traumatized her, Freud subjected her to a third, iatrogenic trauma. There are further indications of Freud’s counter-transferential perturbation: he lied twice and misdated the case twice in his prefatory remarks; he repeatedly errs about Dora’s age and refers to her at different developmental levels (“girl,” “child,” “woman,” “female person,” “lady”); he confusedly traces Dora’s coughing and aphonia to ages eight and twelve; he attributes to Dora an adult-like love of Hans during her “first years” in Merano, Italy (she was there from age six to age seventeen); and he grossly

misinterprets Dora's silence as agreement when he mistakenly tells her that at age seventeen (she was really fifteen), she was committed to her traumatizing seducer, much like her mother at the age of seventeen.

According to his own words, he wrote up the case "during the two weeks immediately following" termination; his correspondence with Wilhelm Fliess contains explicit statements that he was writing the case history between January 10 and 24, a two-week period in 1901. The implications of the duration of Freud's composition have gone completely unnoticed. When Dora decided to quit therapy two weeks before she actually did, Freud irritably charged that she was reacting like a maid who gives a two-week notice before leaving her employer. But Freud himself unconsciously behaved immaturely during his composition of the case, which partially took on the character of an acting out, or better yet, a writing out. His two weeks of writing up the case was a way of dismissing it and of trying to rid himself of Dora.

As a follow-up to Dora's treatment, Freud proceeded to write up her case history. Pertinently, Freud never considered Dora's bisexuality and transference together; his defensive typographic separation of these two dynamics enabled him to ward off any notion of maternal transference. However, far from dissolving his countertransference toward Dora, Freud re-enacted it with the reader, whom he tried to seduce into agreement.

## FRAGMENTATION

*Fragmentation* describes a state of the self that is the opposite of cohesion. It is a diagnostic sign.

This notion appeared in Heinz Kohut's 1968 article "The Psychoanalytic Treatment of Narcissistic Personality Disorders." A sign of the narcissistic personality, as compared with the neuroses, fragmentation triggers disintegration anxiety, a counterpart of castration anxiety. The fragmentation corresponding to the autoerotic stage is total in psychosis, in contrast to the narcissistic personality, in which the self is cohesive. In narcissism, transient fragmentation is seen during analysis and during certain periods when the self is vulnerable, such as adolescence.

This notion was developed throughout Kohut's work, becoming one of the four fundamental concepts of self psychology set forth in "Remarks about the Formation of the Self" (1974). To Kohut, narcissistic pathology tends to be progressively reduced to variations in the state of the self, which is fragmented at the preoedipal and oedipal levels. Fragmentation of the self triggers an intensification of the drives, which are redefined as products of the disintegration of the self in the service of its restoration.

Fluctuations in the state of the self are important clinical data for diagnosis and treatment, but the drives become secondary to the self.

## FRAMEWORK OF THE PSYCHOANALYTIC TREATMENT

The “frame of psychoanalytic treatment” refers to the formal and contractual means necessary for establishing the situation that characterizes psychoanalysis compared to other forms of psychotherapy. Although the frame has been at the heart of psychoanalytic practice ever since its origins, considerations of its structure and function are more recent, dating from the Second World War. One of the first to investigate this frame was José Bleger in an article entitled “Psychoanalysis of the Psychoanalytic Frame” (Bleger, 1967).

This frame was gradually developed by Freud for what were often circumstantial or personal reasons, but he eventually developed a set of uniform recommendations consistent with the theoretical and practical modalities of treatment. As early as 1904 he described his “psychotherapeutic method”: “Without exerting any other kind of influence, he invites them to lie down in a comfortable attitude on a sofa, while he himself sits on a chair behind them outside their field of vision. He does not even ask them to close their eyes, and avoids touching them in any way, as well as any other procedure which might be reminiscent of hypnosis. The session thus proceeds like a conversation between two people equally awake, but one of whom is spared every muscular exertion and every distracting sensory impression which might divert his attention from his own mental activity” (1904a, p. 250). Nine years later he provided additional details such as frequency and duration of the sessions and method of payment—parameters that were as important for proper treatment as the mutual obligations of free association or the prohibition to act out on the part of the analysand and free-floating attention or the rule of abstinence on the part of the analyst (1913c).

The restrictions imposed by the treatment setting apply to both parties, even if its contractual nature is

often overlooked in order to emphasize the pseudo-power attributed to the psychoanalyst by virtue of the patient’s masochism. The frame appears to function as the representative of the incest prohibition in the analytic situation, a prohibition that in fact favors expression and analysis. The frame can be considered an “excluded middle” that hovers over the protagonists during the session, reminding them that every “dualistic” relationship is illusory, even during moments of the most intense regression.

Opinions vary regarding these interpretations since the elements that characterize the frame are rich with symbolization. José Bleger (1967) distinguishes the frame within the psychoanalytic situation as a “non-process” consisting of “constants within whose bounds the process takes place” (p. 511), and he locates its origin in the “most primitive fusion with the mother’s body” (p. 518). He subdivides the frame into two elements: the frame proposed by the analyst and accepted by the patient, and the frame formed by projections of the patient’s most primitive symbiotic associations. It is with this last point that the concepts of “container-contained,” the analyst’s alpha function (Wilfred Bion), and Donald Winnicott’s “setting” are associated. For Winnicott, the analyst “expresses” his love for the patient by his reflected interest and his hatred by his observance of the rites of payment and scheduling (Winnicott, 1958). According to Jean-Luc Donnet, “the frame is both protection and threat, just as its symbolization is forced and liberating” (1973). Jean Laplanche, with his image of the psychoanalyst’s “tub,” describes a “double-wall setting” wherein the outside wall, “purely legalistic and formal” but contractual, is necessary to preserve the inner wall, which is subject to the uncertainties of the analytic process and is needed for sexual issues and the transference neurosis to manifest themselves (Laplanche, 1987).

The arrangement of the frame for psychotic patients or as a function of what Lacan and his students refer to as the temporal scansion of the session introduces the question of its relationship with the establishment and ongoing coherence of a psychoanalytic process. There are a number of parameters involved and each of them raises the question of its role and importance in managing the situation: the number and duration of sessions (four sessions of fifty minutes at a minimum according to official American guidelines, three of forty-five minutes for French members of the International Psychoanalytic

Association, shorter for others, longer for Freud), distribution throughout the week (frequent sessions, sometimes several a day for patients who live far away), payment (cash or check), accepting third-party payment or not, problems associated with days off, with vacations, with changes to the ritual (moving, for example), the intrusion of the telephone, contact during, or outside, the session (Sándor Ferenczi's "active technique" or "mutual analysis," Michael Balint's or Donald Winnicott's physical holding), and so on.

Rigid attitudes on one side, transgressive relativism on the other, reference to the paternal prohibition against incest versus a conception of the frame as a womb implying a total return to a primal state, a setting for hypnosis or a condition for working-through—the conditions associated with the unique nature of psychoanalytic treatment possess a non-alienating value only because they are based on a contract that circumscribes them and that can at any moment be torn up by either of its cosignatories.

## **FRANCE**

Freud spent several months, from October 1885 to February 1886, studying in Paris with Jean Martin Charcot at the Salpêtrière Hospital. This experience greatly determined his orientation toward psychopathology. In his article "Heredity and the Aetiology of the Neuroses," published in French in 1896 in the *Revue neurologique*, the word *psychoanalysis* appeared for the first time.

In France, Jean Martin Charcot's legacy gave rise to bitter disputes on the nature of the mind, and Pierre Janet's theories were widely accepted in medical and philosophical circles. These two factors explain the poor reception given to Freud's ideas for many years. The article that Freud called "the first article on psychoanalysis written in France," by Doctor René Morichau-Beauchant, professor of medicine in Poitiers, appeared as late as November 14, 1911, in *La gazette des hôpitaux civils et militaires*. In 1913 a French translation of Freud's essay "The claims of psychoanalysis to scientific interest" in the Italian journal *Scientia* went unnoticed.

In 1914 Professor Emmanuel Régis and his assistant Angelo Hesnard, a naval doctor in Bordeaux, wrote the first book on psychoanalysis, *La psychanalyse des névroses et des psychoses*, but the First World War cut short further interest in the field. It was not until December 1920 that the *Revue de Genève* and Éditions Payot published a French translation of Freud's essay "On the History of the Psycho-Analytic Movement" (1914).

With Freud's support, Eugénie Sokolnicka, a Polish psychiatrist who had settled in France, began analyzing young psychiatrists working at the Clinique des maladies mentales at the Sainte-Anne Hospital under the direction of Professor Henri Claude. Psychoanalysis became fashionable in France around 1921: In October 1921 André Breton traveled to Vienna to meet Freud, the "greatest psychologist of our time." Henri-René Lenormand's play "Le mangeur de rêves" (1921) turned out to be a success. And the Belgian journal *Le disque vert* published a special issue in 1924 titled "Freud et la psychanalyse" (Freud and psychoanalysis).

Though the medical profession remained overtly hostile to psychoanalysis, a number of young psychiatrists interested in psychoanalysis, including René Allendy, Angélo Hesnard, René Laforgue, and Eugène

Minkowski, decided to launch a journal that was clearly psychoanalytic in orientation. The first volume of *Évolution psychiatrique* appeared in 1925, followed by a second in 1927. In 1930 the journal founders formed a learned society of the same name, which was still in existence in 2005. In July 1926 these psychiatrists, along with Raymond and Ariane de Saussure, Édouard Pichon, and Adrien Borel, organized the *Conférence des psychanalystes de langue française* (Conference of French-Speaking Psychoanalysts) in Lausanne, the origin of the *Congrès des psychanalystes de langues romanes* (Congress of Romance Language Psychoanalysts) and the *Congrès des psychanalystes de langue française* (Congress of French-Speaking Psychoanalysts), which take place annually.

On November 4, 1926, the *Société psychanalytique de Paris* (SPP; Paris Psychoanalytic Society) was formed under the guidance and with the assistance of Princess Marie Bonaparte, Napoleon's great-grand-niece, who was being analyzed by Freud and who later became close friends with him. Her circle included Eugénie Sokolnicka, Angélo Hesnard, René Allendy, Adrien Borel, René Laforgue, Georges Parcheminey, Édouard Pichon, and Rudolf Loewenstein. (The last was a Polish Jewish émigré who, after training at the Berlin Institute, settled in France, where he became the first and best known teaching analyst. He was naturalized in 1930.) Also in her circle were a number of French-speaking Swiss analysts. They included Charles Odier, Henri Flournoy, and Raymond de Saussure (the son of the linguist), all of whom made important contributions to the growth of the new society. The first issue of the *Revue française de psychanalyse* appeared on June 25, 1927, and on January 10, 1934, the *Institut de psychanalyse* was created and remained active until 1940.

The development of psychoanalysis encountered some difficulties, however, notably with the International Psychoanalytical Association (IPA) and because of Freud himself. The French welcomed Freud's "psychoanalytic method" but in general rejected Freudian "doctrine," to paraphrase the title of a critical essay by Roland Dalbiez published in 1936. Because of this tendency, Marie Bonaparte played a crucial role. She was not a physician, and by being jealously faithful to Freud, she prevented psychoanalysis in France from falling completely under the sway of institutional psychiatry (Mijolla, 1988b). She also began translating Freud's writings intermittently until 1988, when a

team led by Jean Laplanche began a new translation of Freud's complete works (Mijolla, 1991).

During the 1936 international IPA congress in Marienbad, Czech Republic, the young Jacques Lacan presented a paper titled "Le stade du miroir" (The mirror stage, or phase). He became a member of the *Société psychanalytique de Paris* in December 1938, nine years after Sacha Nacht (October 1929) and eighteen months after Daniel Lagache (July 1937), his future rivals, both of whom, like Lacan, were analyzed by Rudolf Loewenstein. Though there were few truly innovative French presentations aside from Lacan's paper, many presentations helped spread Freudian theory and technique, which was for the most part based on the work of Sándor Ferenczi. The recommendations made by René Laforgue (on scotoma, schizophrenia, and family neurosis) went unanswered, as did the many articles and essays by Angélo Hesnard, Édouard Pichon, and René Allendy.

Freud received assistance in emigrating from Austria from U.S. Ambassador William C. Bullitt and Marie Bonaparte, who paid the "departure tax" demanded by the Nazis and saved his antiquities collection. Following his departure from Vienna, Freud stayed in Paris on June 5, 1938, while waiting to embark for London. Because of Nazi persecutions, Jewish psychoanalysts had begun to leave Germany in 1933, usually passing through Switzerland or France. They included René Spitz and Heinz Hartmann. They too received help from Marie Bonaparte, as well as from Anne Berman (Bonaparte's secretary), René Laforgue, and Paul Schiff.

On June 13, 1940, the day before Hitler's troops entered Paris, Sophie Morgenstern, one of the first child analysts, committed suicide. The *Société psychanalytique de Paris* and the *Institut de psychanalyse* closed their doors, and the *Revue française de psychanalyse* ceased publication. There was no overtly psychoanalytic activity in France during the four years of German occupation. Rudolf Loewenstein succeeded in leaving for America, where he settled for good. Marie Bonaparte went into exile in Cape Town, South Africa. Sacha Nacht, who worked with the Free French forces, barely escaped deportation. Daniel Lagache continued teaching in Clermont-Ferrand, where the University of Strasbourg had temporarily reestablished itself. Paul Schiff joined the troops that would later liberate Italy and France, while Jacques Lacan, Françoise Dolto, Marc Schlumberger, and John Leuba

continued their activities in Paris. Only René Laforgue attempted, from 1940 to 1942, to create a French section at the Göring Institute, but his efforts were in vain. His subservient attitude toward the occupation authorities resulted in his exclusion from the Société psychanalytique de Paris following liberation (Mijolla, 1988a).

After 1945 psychoanalytic activity resumed in France. A number of new figures appeared on the scene: Maurice Bouvet, Serge Lebovici, René Held, Maurice Bénassy, Francis Pasche. On July 25, 1946, the annual Congrès des psychanalystes de langue française (Congress of French-Speaking Psychoanalysts) resumed in Montreux, Switzerland. In November, Maryse Choissy founded the Centre d'étude des sciences de l'homme (Social Sciences Study Center) and launched the journal *Psyché*, both of which were influenced by the Catholicism of Pierre Teilhard de Chardin. That same year the Centre psychopédagogique Claude-Bernard (Claude Bernard Psychopedagogical Center) was created, with Georges Mauco as nonmedical director. Juliette Boutonier was the medical director, but she turned the position over to André Berge in order to replace Daniel Lagache at the University of Strasbourg. Lagache had been appointed to a position at the Sorbonne, where he created a degree program in psychology. In 1948 a new publisher, Presses universitaires de France, began publishing the *Revue française de psychanalyse*.

The Cold War began, and the Communist journal *La nouvelle critique* published an article in 1949 referring to psychoanalysis as a "reactionary ideology." The article, written by four psychoanalysts, one of whom was Serge Lebovici, reinforced the criticisms made by Georges Politzer before the war. Years later, between 1973 and 1977, Lebovici was the first French psychoanalyst to be made president of the International Psychoanalytical Association.

The success of psychoanalysis continued to attract candidates and presented the problem of training them. Moreover, a suit brought against Margaret Clark-Williams between 1950 and 1952, a psychoanalyst but not a medical doctor, for illegally practicing medicine, though concluded in her favor, exposed the collective responsibility of the psychoanalytic community and the need to establish criteria for practice.

After three years of violent debate, flip-flopping alliances, and maneuvering between the three French

leaders who acquired their positions after the war, the decision to create a new Institut de psychanalyse caused a split in the Société psychanalytique de Paris. None of the three were especially interested in making the institutions democratic, and they waged a kind of open warfare with one another that would leave scars on the psychoanalytic community in France for years to come. Aside from their personal ambitions, they had opposing ideas about the theory, practice, and institutional organization of psychoanalysis. Sacha Nacht wanted to remain faithful to the norms of the International Psychoanalytical Association and aligned with medical education. Daniel Lagache favored academic training. The third, Jacques Lacan, developed original theories and methods of therapy, and the latter, especially his "variable-length sessions," did not comply with international standards.

On June 16, 1953, a motion of no confidence was passed against Jacques Lacan, then president of the Société psychanalytique de Paris. Daniel Lagache, Juliette Favez-Boutonier, and Françoise Dolto then announced that they would be leaving the society to form the Société française de psychanalyse (SFP; French Society for Psychoanalysis). Lacan joined them and was followed by nearly half the students, who were behind the split. But the defectors, in their desire to create an institute free of Sacha Nacht's authority, had overlooked the fact that they would be excluded from the International Psychoanalytical Association and would have to undergo a lengthy period of scrutiny by the international community before they could prove their ability to train new analysts (Mijolla, 1996).

In September 1953, the sixteenth Conférence des psychanalystes de langues romanes took place and, at the end of the SPP meeting, Lacan presented to the members of his new society, the Société française de psychanalyse, his "Discours de Rome" on the function of language in psychoanalysis.

The Institut de psychanalyse de Paris (Paris Institute for Psychoanalysis) was officially established on June 1, 1954. Sacha Nacht remained the director until 1962, when Serge Lebovici replaced him. Through the Centre de diagnostic et de traitements psychanalytiques (Center for Diagnostics and Psychoanalytic Treatment), run by Michel Cénac and René Diatkine, Nacht was to become, for nearly thirty years, the symbol of traditional psychoanalysis in France, to the detriment of the Société scientifique, which did not

return to its former prestige until 1986. To strengthen its image, the Twentieth International Congress of the International Psychoanalytical Association was held in Paris in 1957. The IPA had met there once before, in 1938, and would meet in Paris again in 1973.

Around this time new directions in psychoanalysis were explored. For example, in Paris in 1958 Philippe Paumelle, Serge Lebovici, and René Diatkine created the Association de santé mentale (Mental Health Association), which provided doctors and social workers with training in psychoanalysis. Also established that year were the Groupe Lyonnais, the first regional branch of the Société psychanalytique de Paris, and the Séminaire de perfectionnement, an annual meeting for psychoanalysts working throughout France, similar to the Journées provinciales run by the Société française de psychanalyse.

The rivalry that developed between the two societies promoted the growth of theoretical developments as well as new institutional forms. The work of Maurice Bouvet is a case in point. Through his writing, Bouvet attempted to counteract the growing interest in the ideas of Jacques Lacan. Unfortunately, he died at the early age of forty-nine in 1960. In 1962 an annual prize in psychoanalysis was created in his name.

There were a number of psychoanalysts for children working in France at this time. In the Société psychanalytique de Paris there were Serge Lebovici, René Diatkine, Roger Misès, Michel Soulé, Pierre Mâle, Jean Favreau, Ilse Barande, and Pierre Bourdier. In the Société française de psychanalyse there were Jenny Aubry, Françoise Dolto, Maud Mannoni, and Victor Smirnoff. In the field of psychosomatics were Jean-Paul Valabrega (SFP) and the team formed around Pierre Marty: Michel Fain, Michel de M'Uzan, and Christian David (all SFP members). David went on to found the Institut de psychosomatique (Institute of Psychosomatics). Those working in psychodrama and group psychoanalysis included Jean and Evelyne Kestenberg, Jean Gillibert, and Robert Barande (SPP), and Didier Anzieu, Angélo Bejarano, René Kaës, André Missenard, and Jean-Bertrand Pontalis (SFP). Primary representatives in the field of psychogenesis and the treatment of psychosis were Sacha Nacht and Paul-Claude Racamier of the SPP, and Jean-Louis Lang, Serge Leclair, François Perrier, and Guy Rosolato of the SFP. Worthy of note is that there was a certain coolness in France toward Melanie Klein's theories, which remained relatively unknown until the

1970s, following the work of James Gammil, Jean Begoin, and Florence Begoin-Guignard.

Jacques Lacan became increasingly important in French psychoanalysis and as a leader of young analysts. He published articles in *La psychanalyse*, the SFP review created in 1955 (the eighth and last number appeared in 1964), and in 1953 began giving his famous seminars. The increasingly well-attended sessions were held every Wednesday from 12 noon to 3 p.m., initially at the Sainte-Anne Hospital, then at the École normale supérieure, and finally at the Paris law school. On November 7, 1955, in Vienna, he introduced his call for a "return to Freud," which met with tremendous success. Interest in the work of Claude Lévi-Strauss and structuralism during the 1960s contributed to the dissemination of a conception of psychoanalysis unrelated to psychology and without any therapeutic aims (in 1957 Lacan had spoken of "excessive healing"). The impact of Lacan's ideas can be judged from the October 1960 Sixth Colloque de Bonneval, organized by Henri Ey on the unconscious. In the presence of Jean Hyppolite, Maurice Merleau-Ponty, Eugène Minkowski, Henri Lefebvre, and Paul Ricoeur, members of the two societies confronted one another. In that setting the work of a number of hitherto unknown psychoanalysts came to light: André Green and Conrad Stein of the Société psychanalytique de Paris, and Jean Laplanche, Serge Leclair, and François Perrier of the Société française de psychanalyse.

Lacan's success guaranteed him a role within the Société française de psychanalyse that did not always sit well with his colleagues, especially since his theoretical development, together with the unusual nature of his personal practice, made him persona non grata within the traditional international psychoanalytic community. There were increasing conflicts within the SFP over Lacan, and these grew worse as the conditions for the society's readmission to the Institut de psychosomatique were communicated to him in 1961 during the twenty-second international congress in Edinburgh, just as it received the status of a study group. The SFP was asked to adhere to the guidelines for didactic analysis and training (four sessions of forty-five minutes per week and a year of therapy after the beginning of supervised therapy). Everyone knew that Lacan would never accept these requirements.

In spite of diplomatic efforts by the three-member group within the SFP known as the "troika"—Wladimir

Granoff, Serge Leclaire, and François Perrier—the situation grew worse until several members of the SFP, including some of Lacan’s former analysts, urged that he, along with Françoise Dolto, be removed from the list of teaching analysts, a decision that was ratified in November 1963. This led to a split within the SFP. One group of members formed the Association psychanalytique de France (French Psychoanalytic Association), which chose Daniel Lagache as its first president and was accredited by the Institut de psychosomatique on July 28, 1965, during the twenty-fourth international congress in Amsterdam.

On June 21, 1964, Lacan founded the École Freudienne de Paris (EFP; Freudian School of Paris), which, over a period of sixteen years, became one of the leading forces in the French psychoanalytic movement. Organized into groups known as “cartels,” it published an annual list of members. This did not mean that the organization recognized them as psychoanalysts, for according to Lacan, “The psychoanalyst’s authority can only come from himself.” Since the school was intent on making a difference within the psychoanalytic community, some members were designated “EFP analysts,” and on October 9, 1967, Lacan instituted a test to enable members to obtain the title. As a result of this action, Piera Aulagnier, François Perrier, and Jean-Paul Valabrega quit the École Freudienne de Paris in January 1969 to create the Quatrième groupe, Organisation psychanalytique de langue française (The Fourth Group, or Francophone Psychoanalytic Organization). (Piera Aulagnier, in 1967, founded, together with Jean Clavreul and Conrad Stein, the journal *L’inconscient*, of which only eight issues were published.) This group introduced new criteria of membership admission and methods of training: “the fourth analysis.”

Lacan’s claim that “the unconscious is structured like a language” helped rally to the cause of psychoanalysis Marxists like Louis Althusser and several priests, including the Jesuit Louis Beirnaert. Subsequently, the French Communist Party and the Catholic clergy, both of which had been hostile to Lacan, softened their position. More significantly, Lacan won over to his cause the French intelligentsia, along with a number of foreign students, thereby mobilizing the forces for a media campaign unique in the field of psychoanalysis.

The ground for Lacan’s success had already been prepared, as Serge Moscovici showed in his dissertation, “La psychanalyse: Son image et son public”

(Psychoanalysis: its image and public), completed in 1961. In 1958 Jean-Paul Sartre worked on the screenplay for the first film about Freud. *Freud: The Secret Passion*, directed by John Huston, appeared in movie theaters in 1962. Between December 1962 and July 1963, Marthe Robert presented a series of radio broadcasts titled *The Psychoanalytic Revolution: The Life and Work of Sigmund Freud*.

The literature on psychoanalysis began to grow. The Presses universitaires de France published Freud’s letters to Wilhelm Fliess and Ernest Jones’s biography of Freud in its series Bibliothèque de psychanalyse (Library of Psychoanalysis), edited by Daniel Lagache and later Jean Laplanche. In 1961 Gérard Mendel founded the series Science de l’homme (Science of Man) at Éditions Payot. This was followed, in 1964, by the series Le champ Freudien (The Freudian Field), edited by Jacques Lacan, then by Jacques-Alain Miller, at Éditions du Seuil, and in 1973 by L’espace analytique (The Analytic Space), edited by Maud Mannoni and Patrick Guyomard at Denoël. This last press published memoirs about Vienna and the early years of psychoanalysis in its series *Freud et son temps* (Freud and His Time), edited by Jacqueline Rousseau-Dujardin. Gallimard launched the series *Connaissance de l’inconscient* (Knowledge of the Unconscious), edited by Jean-Bertrand Pontalis, as well as the journal *Nouvelle revue de psychanalyse*, which appeared in the spring of 1970 (it ceased publication in the fall of 1994 with number 50). Laplanche and Pontalis were also the authors of the celebrated *Language of psychoanalysis*, first published in 1967. A number of academic journals were launched at this time: *Cahiers pour l’analyse* in 1966, *Scilicet* in 1968, *Topique* and *Études freudiennes* in 1969, *Ornicar?* in 1975, *Confrontation* in 1979, and *L’écrit du temps* in 1982. In 1965 Paul Ricoeur published *De l’interprétation: Essai sur Freud*, an example of what was most attractive about psychoanalysis to philosophers and academics.

Jacques Lacan’s *Écrits* appeared at the end of 1966 as part of the series Le champ freudien, published by Éditions du Seuil. The book achieved considerable success with the public in spite of the difficulty of the author’s style and ideas. As the popularity and longevity of Lacan’s seminars show, the École Freudienne de Paris and Lacanian thought in general began to occupy an increasingly prominent place in French psychoanalytic circles. Lacan’s ideas soon spread around the world, especially in South America.

The student movements of May 1968 were attracted to a Marxist version of Freud inspired by Herbert Marcuse and Wilhelm Reich. In October of that year the school reforms led to the creation of a department of psychoanalysis at the University of Paris VIII in Vincennes by Serge Leclair and Jacques-Alain Miller, Lacan's son-in-law, and a department of clinical social science at the University of Paris VII. In October 1968 Gérard Mendel, the founder of socio-psychoanalysis, published *La révolte contre le père* (A revolt against the father), an explanation of the student protests. At the opposite end of the spectrum, in 1969 there appeared *L'univers contestationnaire* (The universe of conflict) by Béla Grunberger and Janine Chasseguet-Smirgel, writing under the pseudonym André Stéphane.

Opposition to psychoanalysis arose with the publication in 1969 in *Les temps modernes* of "L'homme au magnétophone" (The man with a tape recorder), with a commentary by Jean-Paul Sartre. Its publication led Jean-Bertrand Pontalis to resign from the journal's editorial board. In 1972, Gilles Deleuze and Félix Guattari published *Anti-Oedipus: Capitalism and Schizophrenia*, and Pierre Debray-Ritzen published *La scholastique freudienne*, a caricature of past, present, and future criticisms of psychoanalysis in France.

In the 1970s the French psychoanalytic movement split into mutually exclusive factions. In 1974 René Major and Dominique Geahchan created the group Confrontation, which claimed to be independent of the various psychoanalytic societies but over time grew closer to the Lacanians. They organized animated discussions led by Serge Leclair (1977) and representatives of the French feminist movement, led by Antoinette Fouque (1979). Although theoretical and clinical advances continued to be made in the Société française de psychanalyse and the Association psychanalytique de France, as well as the Quatrième groupe, public and media attention focused on Jacques Lacan and his students.

With age, Lacan's health and productivity declined. Jacques-Alain Miller undertook the publication of an "official" transcript of Lacan's seminars (often contested by Miller's adversaries) and assumed a guiding role in managing the École Freudienne de Paris, which displeased Lacan's older students. In the face of all this dissension, Lacan, by now quite ill, ordered his school dissolved on January 5, 1980. This led to a court trial and the division of his followers into mutually hostile groups. In his letter to the thousand, Lacan announced, on February 21, 1980, the foundation of

the Cause Freudienne. Shortly thereafter Jacques-Alain Miller founded the École de la cause Freudienne. In the years that followed the school developed an international reputation and became especially well established in South America. Jacques Lacan died on September 9, 1981.

In November 1980 Dominique Geahchan helped create the Collège de psychanalystes (Council of Psychoanalysts), which, despite its name, was not a training organization. It ceased functioning in June 1994. Following the dissolution of the École Freudienne de Paris, several new groups came into existence: in 1982 the Cercle Freudien (Freudian Circle) and the Association Freudienne internationale (International Freudian Association); in 1983 the Cartels constituants de l'analyse Freudienne (Constituent Cartels for Freudian Analysis), the Convention psychanalytique (Psychoanalytic Convention), and the Mouvement du coût Freudien (Freudian Cost Movement) the École Lacanienne de psychanalyse (Lacanian School of Psychoanalysis); and in 1986 the Séminaires psychanalytiques de Paris (Paris Psychoanalytic Seminars). Also in 1982 the Centre de formation et de recherches psychanalytiques (Center for Psychoanalytic Training and Research) formed around Octave and Maud Mannoni. Its dissolution in 1994 led to the creation, in 1995, of the Espace analytique (Analytic Space), of which Maud Mannoni was president until her death in 1998, and the Société de psychanalyse Freudienne (Freudian Society for Psychoanalysis), under the direction of Patrick Guyomard. Many of these associations were subject to internal dissension and disappeared (at least in their initial form) during the 1990s.

In France and elsewhere in the world, a crisis followed as a result of the excessive enthusiasm—in particular, excessive psychiatry and excessive ideology—generated by an idealized image of psychoanalysis. This enthusiasm was clearly associated with the personality and fame of Jacques Lacan. Subsequently, psychiatrists began to focus on the neurosciences. On another front, renewed enthusiasm for philosophy and religion led to a decline in interest in Freudian theory in the universities. Within the field of psychoanalysis, interactions over the years among the various psychoanalytic groups, which the first meetings of Confrontation had in its time attempted to establish, began to overcome the violent splits of the past.

The Société psychanalytique de Paris continued to assert its authority as the chief French psychoanalytic

institution, partly through the increased readership of the *Revue française de psychanalyse* at a time when a number of publications ceased publication, many because of poor sales. In fact, the association came to be viewed as akin to a public institution by 1997. Around this time André Green became internationally well known for his writings on the “dead mother,” “the narcissism of death,” and “the negative,” and Joyce McDougall became well known, especially in North America, for her work on the concept of normalcy and addiction. Although less well known, Conrad Stein, following the publication of his *L'enfant imaginaire* (The imaginary child; 1971) and the organization of a number of conferences through *Études Freudiennes* (Freudian Studies), continued his research on Freud and his criticism of the institutionalization of psychoanalysis.

Some APF members too made important contributions to the field. Worthy of mention are Guy Rosolato's work on the symbolic order and sacrifice, generalized seduction, and deferred action (a topic proposed by Jean Laplanche after a detailed reading of Freud); the theoretical work and fiction of Jean-Bertrand Pontalis; Daniel Widlöcher's work on change; and Didier Anzieu's research on Freud's self-analysis, the “skin ego,” psychodrama, and group analysis, a field also investigated by René Kaës.

Through the publication of *La violence de l'interprétation: Du pictogramme à l'énoncé* (The Violence of Interpretation: From Pictogram to Statement; 1975), Piera Aulagnier's work provided original theoretical material for understanding and treating psychosis (Mijolla-Mellor, 1998). Although somewhat less synthetic, the work of Octave and Maud Mannoni broadened the scope of psychoanalytic research, especially in the area of child psychoanalysis, a field greatly influenced by the work of Serge Lebovici, René Diatkine, and Michel Soulé. Françoise Dolto had a considerable impact on psychoanalysis in France through her original and provocative ideas, some of which generated considerable controversy. Her radio presentations and the creation of the *Maisons vertes*, psychoanalytic facilities for children, brought her considerable public recognition in France, and her books have remained successful.

A number of other authors—Béla Grunberger, Michel Fain, Jean Bergeret, Jean Guillaumin, Jean-Paul Valabrega, Serge Leclair, François Perrier—made important contributions to specifically French psychoanalysis, which has been characterized by a tendency

toward clinically based theorizations and is generally less empirical than the work of Anglo-American authors. In particular, Lacanian psychoanalysts have emphasized the importance of language and are probably closer to postwar French philosophy than any other branch of psychoanalysis. They have been influenced by thinkers as diverse as Jean-Paul Sartre, Maurice Merleau-Ponty, Claude Lévi-Strauss, Michel Foucault, and Jacques Derrida (who included psychoanalysis in the curriculum when he created the *Collège de philosophie* in 1983).

Psychoanalysts in France remain unlicensed in spite of several attempts by the government to institute licensing. Although psychoanalysts have managed to obtain a number of rights as private practitioners through psychoanalytic associations, it is as accredited psychologists that they are authorized to practice psychotherapy and analysis. The attempt in December 1989 by Serge Lebovici, then head of the *Association pour une instance*, to create a professional body consolidating all psychoanalysts in France was rebuffed by associations that were members of the International Psychoanalytical Association. These organizations had no desire to merge with the numerous practitioners operating in the Lacanian tradition, because they felt that training requirements in this tradition were inadequate.

There has been considerable interest in the history of psychoanalysis as well. In June 1985 the *Association internationale d'histoire de la psychanalyse* (International Association for the History of Psychoanalysis) was created. In 1984 this association merged with the *Société internationale d'histoire de la psychiatrie* (International Society for the History of Psychiatry), created in 1982, to become the *Société internationale d'histoire de la psychiatrie et de la psychanalyse*. In 1991, encouraged by Joseph Sandler, the International Psychoanalytical Association formed an Archives and History Committee within its organization.

French developments in psychoanalysis have also expanded and exerted influence outside the country. One sign of this is the election, in 1999, of Daniel Widlöcher as president of the International Psychoanalytical Association and of Alain Gibeault as secretary general, both of whom are French. Although no other French theoretician has achieved Jacques Lacan's global recognition or, like Lacan, has created schools and institutions, the body of theoretical and clinical research in French is considerable. In spite of the often irreconcilable differences within the French psychoanalytic

community, this work has continued to enrich the development of psychoanalysis throughout the world.

## FRANCO DA ROCHA, FRANCISCO (1864–1933)

Francisco Franco da Rocha, Brazilian physician and psychiatrist, was born on August 1864 in Amparo, in the state of São Paulo, Brazil, and died there on April 8, 1933.

Franco da Rocha received his medical degree from the national faculty of medicine of Rio de Janeiro in 1890; he was a student of Teixeira Brandao, com-

monly considered to be the first Brazilian psychiatrist. Upon his return to São Paulo in 1893, Franco da Rocha was named hospital practitioner at the Hospício dos Alienados (a mental hospital created by a state law in September 1848); prior to his arrival, only general practitioners had worked at the facility, and there was no specialization in the treatment of psychiatric patients. Franco da Rocha was thus a pioneering psychiatrist and the first specialist to work in a public institution in São Paulo. In 1896 he was named head physician and director of the Hospício dos Alienados.

That same year he succeeded in establishing an agricultural colony for nearly eighty patients in Sorocaba. This pioneering experiment in the field of work therapy was intended to serve as a pilot for a far more ambitious project: a welfare institution for the mentally ill near São Paulo. Franco da Rocha received government approval for this project and chose as the site a plantation near the railway center of Juquery, the name by which this large psychiatric hospital was first known. Completed in 1902 and since renamed after its founder, the hospital is, as of 2005, still in operation, and many generations of psychiatrists have been trained there. Franco da Rocha served as director of the institution until his retirement in 1923.

Franco da Rocha began his teaching activities in the faculty of medicine of São Paulo in 1913. In 1918 he became that institution's first professor of clinical neuropsychiatry. In his courses, he made the earliest presentations on psychoanalytic doctrine in Brazil. His inaugural lecture in 1919 dealt with Sigmund Freud's psychoanalytic theory. Transcribed and published in the newspaper *O Estado de São Paulo* on March 20, 1919, under the title "Do delírio em geral" (On delusions in general), it marked the beginning of the dissemination of Freudian thought in São Paulo.

In 1920 Da Rocha published *O pansexualismo na doutrina de Freud* (Pansexualism in the doctrine of Freud), a popular scientific work that was well received by the general public but that provoked a discreet negative reaction in medical circles. In 1930, on the advice of Durval Marcondes, he published a second edition of this book in which he eliminated the word *pansexualism*.

According to Marcondes's unpublished biography of Franco da Rocha, "In the presentations he made at this institution, he included a Freudian approach to

mental illness, which at the time was something new for us. This was the beginning, in the scientific circles of São Paulo, of the move from an exclusively descriptive and organicist psychiatry toward a psychiatry that was also becoming descriptive and psychodynamic.”

Although he was a specialist in Freudian doctrine, Franco da Rocha came into contact with it relatively late in his career and was thus unable to incorporate it into his clinical work.

## **FRANKL, VIKTOR EMIL (1905–1997)**

Viktor Emil Frankl, Austrian physician, psychoanalyst, philosopher, and professor of neurology and psychiatry at the University of Vienna Medical School, was born on March 26, 1905, in Vienna, where he died of heart disease on September 2, 1997.

Frankl was a twelfth-generation descendant of Rabbi Judah Loew, the Maharal of Prague who created the Golem, Yossele, to save Jews from the blood libel. At sixteen, while still a student at the lycée, Viktor sent Freud a text concerning “the origin of the mimic movements of affirmation and negation” (Frankl, 1997, p. 48), which in 1924 was published in the *International Journal of Psychoanalysis*. But Frankl would turn away from psychoanalytic formulations in favor of the work of Igor Caruso, humanistic psychology, and existential analysis, of which he was a founder.

During the Second World War, Frankl was arrested in September 1942 and spent nearly three years in several concentration camps, including a brief stay at Auschwitz, at Dachau (where he encountered Bruno Bettelheim), and at Theresienstadt. Frankl’s parents, brother, and wife died in the camps. While a prisoner, Frankl drafted a manuscript that was later published as *The Doctor and the Soul*. After being liberated in 1945, he wrote *Ein Psycholog erlebt das Konzentrationslager*, which sold over a million copies when it was published in 1947. Translated in English as *Man’s Search for Meaning*, Frankl drew on his concentration camp experience to develop the theory of “logotherapy,” where *logos* signifies the will to discover meaning in one’s existence.

After the war Frankl was appointed professor of psychiatry at the Vienna Neurological Policlinic. A psychotherapist, he lectured throughout the world and held numerous visiting professorships. In 1970 the first Institute of Logotherapy was founded at the United States International University at San Diego, California. Subsequently, a number of independent institutes were founded and as of 2005 operate in more than 25 countries, including the Viktor Frankl Institute in Vienna. Frankl wrote over thirty books, which have been translated into more than twenty-five languages. “The meaning of your life,” Frankl once explained, “is to help others find the meaning of theirs.”

## **FREE ASSOCIATION**

Free association (considered the “fundamental rule”) is the method used in psychoanalytic treatment. In free association the patient says whatever comes to mind without exercising any selectivity or censorship. It is based on Freud’s deterministic concept of psychic phenomena: “We start, as you see, on the assumption, which he does not share in the least, that these

spontaneous thoughts will not be arbitrarily chosen but will be determined by their relation to his secret—to his ‘complex’—and may, as it were, be regarded as derivatives of that complex” (1906c, p. 108–109). The origin of this new method of therapy can be dated from Emmy von N’s irritation with Freud for interrupting her when she spoke. The method was not codified until later and would become the keystone of the technique of psychoanalytic treatment. There is no mention of this in the *Studies on Hysteria*. At that time a pressure on the forehead was intended to bring forth an idea or an image with the help of which the cathartic method could be exercised.

The first mention of the fact that redirecting the patient’s attention can allow connections to emerge between a forgotten word and repressed ideas appears in the analysis of the forgetting of “Signorelli’s” name (1898b). But it is in the chapter on “The Method of Interpreting Dreams” (1900a) that the process is described in detail: “We . . . tell him that the success of the psycho-analysis depends on his noticing and reporting whatever comes into his head and not being misled, for instance, into suppressing an idea because it strikes him as unimportant or irrelevant or because it seems to him meaningless” (p. 101). The technique was used in the analysis of Dora and Freud specifies that he managed to “the pure metal of valuable unconscious thoughts can be extracted from the raw material of the patient’s associations” (1905e, p. 112). For example, “It is a rule of psycho-analytic technique that an internal connection which is still undisclosed will announce its presence by means of a contiguity—a temporal proximity of associations; just as in writing, if ‘a’ and ‘b’ are put side by side, it means that the syllable ‘ab’ is to be formed out of them (p. 39) . . . in a line of association, ambiguous words . . . act like a point at a junction (p. 65n) . . . I am in the habit of regarding associations such as this, which bring forward something that agrees with the content of an assertion of mine, as a confirmation from the unconscious of what I have said (p. 57) . . . [the unwillingness on Dora’s part to follow the rules of dream-interpretation] coupled with the hesitancy and meagreness of her associations with the jewel-case, showed me that we were here dealing with material which had been very intensely repressed” (p. 69n).

It is in “On Beginning the Treatment” (1913c) that Freud made these ideas explicit: “One more thing before you start. What you tell me must differ in one

respect from an ordinary conversation. Ordinarily you rightly try to keep a connecting thread running through your remarks and you exclude any intrusive ideas that may occur to you and any side-issues, so as not to wander too far from the point. But in this case you must proceed differently. You will notice that as you relate things various thoughts will occur to you which you would like to put aside on the ground of certain criticisms and objections. You will be tempted to say to yourself that this or that is irrelevant here, or is quite up important, or nonsensical, so that there is no need to say it. You must never give in to these criticisms, but must say it in spite of them—indeed, you must say it precisely because you feel an aversion to doing so. Later on you will find out and learn to understand the reason for this injunction, which is really the only one you have to follow. So say whatever goes through your mind. Act as though, for instance, you were a traveler sitting next to the window of a railway carriage and describing to someone inside the carriage the changing views which you see outside. Finally, never forget that you have promised to be absolutely honest, and never leave anything out because, for some reason or other, it is unpleasant to tell it” (p. 135).

This method of free association was often confused with the association experiments involving stimulus words that Eugen Bleuler and Carl Gustav Jung were doing at the same time at the Burghölzli clinic. Even though he referred to the method in “Psycho-Analysis and Establishment of Facts in Legal Proceedings” (1906c), Freud was careful to differentiate his own work from it and, on February 26, 1908, referred to this technique as a “coarse method, to which psycho-analysis is far superior” (Nunberg and Federn, 1962–1975, p. 335). But for years commentators, especially in France, have attributed its use to him.

In 1920, in “A Note on the Prehistory of the Technique of Analysis,” Freud recognized the “cryptamnesia” that led to his claiming to be the inventor of a method, a description of which he had read when he was fourteen in a text by Ludwig Börne, entitled, “The Art of Becoming an Original Writer in Three Days.” In it he stated that the best way for the writer to banish inhibitions and censorship was to write down everything that came to mind for a period of three days.

Once again we see how an isolated idea that circulates in the popular mind is inadequate on its own and what developments are needed for it to be integrated

within a body of thought that transcends it. The method of free association, by freeing speech in its search for a hidden truth, has become the principal method of producing the material for analysis, even if, through overproduction, the freedom it offers sometimes becomes a form of resistance to any form of interpretation.

## **FREE ENERGY/BOUND ENERGY**

Freud regarded energy as a capacity with two modes of functioning: that of free energy, in which energy proceeds towards an immediate and total discharge, and that of bound energy, in which it is blocked and accumulates.

Freud used the concept of energy in his theory in an attempt to explain a point of transition between the “quantity” of energy and the “quality” of the representation. To this end, he addressed the question of energy in the “Project” (1950a; Laplanche and Pontalis, 1967/1974; Laplanche, 1976) in a far more radical way than Josef Breuer had done. There he described “primary process” as an energetic state of disorganization that the ego on its emergence seeks to regulate during the “secondary process” by managing the energy according to the constancy principle.

As concerns energy, however, the distinction clearly does not always work perfectly for Freud because in this text he only used this term twice and without the qualification “bound” or “free.” Although Freud’s idea of energy used the inevitably sexual encounter between the child and the adult as a metaphor here, unfortunately he combined this with

a genetic perspective in which primary-process disorganization precedes the organization that characterizes the secondary process. Accordingly, this hierarchical Jacksonian perspective prevented him from the outset from fully conceiving of the primary process as the result of the absorption of adult sexuality into the child’s psychic apparatus.

It should also be noted that with its excessively cut-and-dried oppositions, the dynamics posited by Freud are no more satisfactory in relation to the matter of life. In Freud’s concept of the child, he has no chance of survival, whether this is in terms of an excessively organized or an excessively withdrawn system. The latter perspective very clearly leads to the theory of narcissism, while the former leads to the conceptualization of the death drive.

In *The Interpretation of Dreams* (1900a), Freud reattributed the role of binding to the preconscious. It is also here that the expression “cathexing energy” appears, described as “mobile and capable of discharge” (p. 597), which conflicts with the theories of the “Project,” in which cathexis had been conceived as a way of producing bound states. In fact, this concerns an energy in search of representations and, furthermore, an “object.” The cathexis of energy is next conceived (1915d) as an approach to the unconscious and its decrease (decathexis) is attributed to repression. In “The Unconscious” (1915e), Freud stated that Breuer had distinguished between “two different states of energy in mental life; one in which energy is tonically ‘bound’ and the other in which it is freely mobile” (p. 188). In fact, Breuer (1895d) had superimposed on psychic states two types of energy that accorded with the knowledge of the time but which Freud had gone on to use in a much more imaginative way. In *Beyond the Pleasure Principle* (1920g), still unaware of a further distortion, Freud also attributed the idea to Breuer by maintaining that he had established the distinction between “two kinds of cathexis of the psychical systems or their elements—a freely flowing cathexis that presses on towards discharge and a quiescent cathexis” (p. 31).

Freud thus established the foundation for his theory of a death drive that unbinds and an Eros that binds. This could be considered as a diluted view of sexuality, simultaneously binding and unbinding, which he had encountered from his first analyses. The main impetus for this development may be the

theory of narcissism in which Freud had exalted the theme of happiness found in love of the external object, a theme that had already appeared in embryonic form in the “Project,” with its Jacksonian perspective of a possible transition from unbinding to binding.

In conclusion, Freud did not succeed in resolving the question of free energy or framing it in dialectic terms because it simultaneously applied to both conscious (1933a [1932]) and unconscious functioning. The theoretical problem arises, in terms of the conscious, from the perception that leaves no trace and, in terms of the unconscious, from the primary process. If free energy cannot be specific, the solution would be to remove the distinction between free and bound energy because this adventitious hypothesis, since Breuer’s proposition, has confused energy and state. In fact, a system that possesses what can be (wrongly) described as a disordered state can operate with the same energy as an ordered system.

### **FREUD, ANNA (1895–1982)**

Psychoanalyst and pioneer in child analysis, Anna Freud was born on December 3, 1895, in Vienna, and died on October 9, 1982, in London.

Anna Freud was Sigmund and Martha Freud’s third daughter and sixth and last child. When she was a year old, Martha’s sister Minna joined the family. The two women had carefully defined roles, but a warm and affectionate Catholic nursemaid, Josefine Cihlarz, to whom Anna felt very close, took a very active part in the upbringing of the three youngest children. The children were treated leniently but firmly: disciplined behavior and punctuality were emphasized and expected. Anna Freud displayed these traits throughout her life. Her love of animals may, in part, have reflected Josefine’s influence.

She started elementary school at six, and at ten entered the Salka Goldman Cottage Lyceum for girls. She read widely and wrote poetry. Her remarkable memory was a major asset at school and throughout her life; later, as a psychoanalyst, she never forgot the details of any case reported to her, and could make telling use of them in clinical discussion.

She was on holiday in England when war broke out in 1914. Now an enemy alien, she managed to return to Austria with the Ambassador and his entourage, traveling by an adventurous route. She trained as an elementary school teacher at the Lyceum, and her industry and rare intelligence ensured her appointment to the teaching staff.

She was always a wonderful teacher, but her interest in psychoanalysis was evident in early adolescence. She became Librarian of the Viennese Psychoanalytic Association, and was analyzed by her father—unthinkable perhaps nowadays, but not such a rare event at this time. She read her first paper (on beating fantasies) to the Association in 1922, and was thereby granted membership.

Her teaching experience served her well as a pioneer in child analysis. Melanie Klein was already analyzing children in Berlin; but the two leaders in the field used children’s play differently in their techni-

ques. Anna Freud disputed Klein's belief that play was the child's equivalent of free association in adults, but this was only one of many later differences. Klein went to England in 1927 and became a powerful influence in the British Society. Disparities of view between the Viennese and British Societies became pronounced, initially on the basis of child analytic practice.

Anna Freud's new ideas, charm, and lifelong capacity for winning collaborators quickly secured her a large following. Her seminars in Vienna attracted colleagues from Prague and Budapest. A wide range of disorders were treated and discussed, but Anna Freud's attention to normal development matched her interest in pathology. She believed it was impossible to understand the one without the other. She applied her growing knowledge to the field of education and gave lectures to teachers and parents. With her friend and colleague Dorothy Burlingham, she set up what she called "a cross between a crèche and a nursery school," financed by the wealthy psychoanalyst Edith Jackson, for the poorest children in Vienna who were given both bodily and psychological care. These experiences fuelled Anna Freud's interest in the psychological consequences and concomitants of physical illness and laid a foundation for her interest in pediatric practice.

Her work with adults fostered her need to know more about psychiatry and she attended, on a regular basis, ward-rounds at the University's Psychiatric Clinic, headed by Wagner-Jauregg, the Nobel Prize winner, and staffed by Paul Schilder and Heinz Hartmann. She retained this interest for the rest of her life.

Earlier publications were followed by her first book in 1936, appearing one year later in English as *The Ego and the Mechanisms of Defence*. This major work was the first to distinguish between recognized defenses against instinctual drive derivatives and defenses against painful affects, newly observed and described by her.

The Nazis annexed Austria in 1938, and Princess Marie Bonaparte and Ernest Jones together secured safe transfer to London for the Freud family and a number of associates. Freud, Anna, and other psychoanalysts were admitted to the British Psycho-Analytical Society. Though well received, clinical and theoretical differences between the two groups were

pronounced and culminated in a series of controversial discussions between 1941 and 1945. The disagreements were beyond resolution, and two parallel training courses were set up in recognition of this fact.

Freud died in 1939 from the cancer of the jaw that had plagued him for fourteen years, and Anna Freud was his devoted nurse. She continued to support the principles behind his psychoanalytic thinking, but she had a highly original mind and never followed him slavishly. After the outbreak of war, the predicament of children made homeless through bombing led her to establish, with Dorothy Burlingham, the Hampstead War Nurseries. Careful observations and meticulous records, made with the help of staff who rarely left the premises, vastly increased existing knowledge of child development and problems of residential care. The findings are collected by Anna and Dorothy in *Young Children In Wartime* (1942) and *Infants Without Families* (1944).

In 1947 Anna Freud founded a course in child analysis, and in 1952 established the Hampstead Child Therapy Clinic. With these unequalled facilities clinical research expanded substantially. In this Anna Freud's charm and authority served her unsurpassed capacity to draw staff and students into the work and make substantial contributions. She herself continued to publish major papers, but her most important book was *Normality and Pathology of Childhood* (1965). Her writing continued apace, with major contributions to psychoanalytic diagnosis and to clinical and theoretical understanding of a wide range of developmental problems and disturbances. Her work in the fields of education, pediatrics, and family law (*Beyond the Best Interests of the Child*), in which she collaborated with Professors Albert J. Solnit and Joseph Goldstein from Yale University, won her wide recognition within those disciplines. She received many honors and was appointed Commander of the British Empire (CBE) in 1967. Of her many honorary degrees, she was especially proud of the MD from the University of Vienna (1975) and the PhD from the Goethe Institute in Frankfurt (1981) where, half a century earlier, her father had been awarded the Goethe prize for literature.

By this time Anna Freud was seriously ill with an advanced anemia of old age, but her mind remained clear and active throughout the slow physical deterioration that led to her death. Her ashes were

placed next to her father's at Golders Green crematorium in London.

## FREUD-BERNAYS, MARTHA (1861–1951)

Martha Bernays was born on July 26, 1861, the second daughter of Berman Bernays (1826–1879), a merchant, and his wife Emmeline (née Philipp, 1930–1910). Isaac Bernays, Martha's paternal grandfather, was Chief Rabbi of Hamburg, and Berman continued the religious tradition. Emmeline Bernays was intelligent, resolute, well-educated, and shared Berman's Jewish orthodoxy. Martha obeyed her with true devotion. Berman moved to Vienna in 1869 as secretary to a well-known economist. Emmeline loved Hamburg and disliked the move. On December 9, 1879, Berman died suddenly of a heart attack. Martha became an intelligent young woman without intellectual pretensions, svelte, attractively pale, and gracious, and she had a warm personality that brought many male admirers.

Freud met Martha in April 1882; though previously uninvolved with women, he quickly fell in love. His great passion (it was nothing less) was more slowly returned by Martha, but with unwavering steadfastness, and they were soon engaged. The betrothal was secret at first, since Freud was without the means to support a wife. The engagement is well documented by Ernest Jones (1953), who was privileged to read, in their entirety, the love letters that almost daily passed between them. Jones declared that the vast set of letters "would be a not unworthy contribution to the great love literature of the world."

During the engagement (1882–1886) Freud was at times despairing, both because of his poverty and his agonizing attacks of jealousy, not only of men Martha knew, but even of her mother and brother. Martha, by contrast, was unchangingly certain of Freud's love. Freud's eldest sister Anna became engaged to Martha's brother, Eli, at Christmas 1882, and Freud and Martha then declared their own commitment. The hardest tribulation came in June, when Emmeline returned to her former home at Wandsbek, near Hamburg, and Martha, protesting, went with her. Freud had been obliged to give up research work, and was struggling to establish a private practice. Finally, their civil wedding, on September 13, 1886 at Wandsbek, was not recognised in Austria, where a Jewish marriage was obligatory, much to Freud's distaste. In spite of her upbringing, Martha joined Freud in his religious antipathy, and Jewish practices formed no part of their life together.

The honeymoon was largely spent in Holstein on the Baltic, and the bride, just 25, and the husband, 30, settled in Vienna at 8 Maria Theresienstrasse. Their first child, Mathilde, arrived on October 16, 1887. The marriage was remarkably happy, with no return of Freud's early, intermittent doubts of Martha's love. Martha was an excellent wife and mother; both were devoted parents. Two sons were born: Jean Martin (after Charcot) on December 6, 1889, and Oliver (after Cromwell) on February 19, 1891. More space was needed, and it was at 19 Bergasse that the three remaining children were born: Ernst (after Brücke) on April 6, 1892; Sophie on April 12, 1893; and Anna (after Freud's sister) on December 3, 1895. Josefina Cihlarz, a Catholic *Kinderfrau*, then looked after Anna, Sophie and Ernst. About a year later, Martha's sister Minna, whose fiancé had died, joined the family.

Minna differed from Martha in both looks and temperament: large as opposed to petite; a little imperious as opposed to retiring; outspoken as opposed to discrete. But they got on well enough, and ran the home with clear boundaries between responsibilities. Freud found Minna an intellectual companion who, unlike Martha, took an interest in his developing psychological theories. Martha made it her duty to facilitate Freud's professional work with a supportive daily routine, and their mutual devotion was unshakeable. Martha read widely and discussed with her husband the major works she read. They quoted poetry together—by Goethe, Heine, Uhland and others. Martha, whose letters were sometimes in verse, kept up with current literature to the end of her life. She entertained well; and distinguished visitors included Thomas Mann, one of her favorite authors.

There were misfortunes in the family. Martha was severely ill in 1919, and in the following year Sophie's death from a similar illness was a bitter blow. Many years later the savage disruption of the *Anschluss*, on March 11, 1938, signalled the end of life in Vienna. Through the good offices of Marie Bonaparte and Ernest Jones the family able to move to London, and accorded diplomatic privileges. Eventually, Martha, Sigmund Freud, and Anna settled for good at 20 Maresfield Gardens. Dorothy Burlingham was unable to join for some time; Paula Fichtl, the maidservant, was first interned in the Isle of Man; and Minna was soon admitted to a nursing home.

Martha was efficient in the home even without Paula's help. She did the shopping daily, became well

known to the local shopkeepers, and remained a hostess of considerable charm to the many visitors. Although Martha was deeply worried about Freud's health, it was Anna who nursed him, making his care a duty above all others. By March 1939 he began to deteriorate, and died on the 23 September, 1939.

In a response to Margarethe Nunberg's condolences, Martha said they would have to live without his goodness and wisdom (Young-Bruehl, 1988). In spite of all her children's love, and support from all over the world, her life, she said, had lost its sense and meaning.

Minna died in 1941, and Martha's sense of loneliness intensified. At the end of the war came the horrific news of the deaths of members of the Freud family in concentration camps, of which, hitherto, there had been no intimation. Bereaved relatives were accommodated and comforted at Maresfield Gardens.

In due course Martha became chronicler of the lives of herself and her husband, and as such, a unique resource for biographers, though family letters remained private. She wrote to friends worldwide, and composed short poems for family occasions. She stayed in charge of home and garden but, increasingly frail as she approached ninety, needed home nursing. She died on November 2, 1951.

## **FREUD, ERNST (1892–1970)**

Ernst Freud was born on April 6, 1892, in Vienna and died April 7, 1970, in London. The fourth of six children of Sigmund and Martha Freud, he was named in honor of Ernst Brücke. As a child there were references

to him in his father's correspondence, where Sigmund Freud discussed the child's angina and various fevers. On June 12, 1900, Freud wrote, "Ernst had a fever again for four days. He has unflagging energy, even with a 38.5 [°C] fever he continues to cry out: I won't be able to get well, I want to get up; it was only at 39.5 [°C] that this cantankerous fellow took note and became amiable."

He seems not to have been overly influenced by his father's fame and chose his profession without interference. On June 15, 1909, Freud wrote to Oskar Pfister, "Ernst, who was your favorite and has almost become ours, is taking his final examination, although he is suffering from an ulcer of the small intestine and is not doing well at all. He wants to become an architect. I don't know if I'm supposed to agree with this." In fact he did become an architect, though he was often referred to as the "fortunate child" or, as Freud wrote to his friend Max Eitingon in London in 1938, "a tower of strength."

A militant Zionist, he participated in the Zionist Congress held in September 1913 in Vienna. Along with his brother Martin, he joined the army in 1914; he left for Galicia in August 1915 but returned a year later on leave to see his family, "as sprightly as ever." He was demobilized without problem but suffered for years from the results of pneumonia contracted during the war.

After the war he completed his studies at the Munich Technische Universität and, in December 1919, settled in Berlin, where he became engaged to Lucy Brasch, marrying her shortly afterward ("Lux," 1896–1989). "To all appearances a good and beautiful creature," Freud wrote to Lou Andreas-Salomé. That same year Karl Abraham had, on March 13, told his father that Ernst "had attained lasting merit in setting up the clinic [and would be] universally admired."

Ernst and Lucy's first child, Stefan (Stephen) Gabriel, was born July 31, 1921, "He is my fourth grandson, but I regret the absence of a grand-daughter," Freud wrote to Ernest Jones, who wrote back, "I was delighted to learn that Ernst has a son: a new acquisition for Zionism." Lucy, who was not Jewish, "had been so sure of having three sons that she decided from the beginning to give each of them the name of an archangel in addition to a more earthly first name." (Jones, 1959, III) There followed Lucian Michael on December 8, 1922, who became a well-known painter, a friend of Francis Bacon, and of Klemens (Clement)

Raphael, who was known in Great Britain as a television host, a specialist in gastronomy, and a deputy in the Liberal Party. Freud met these friends for the first time in Berlin during Christmas 1925, and it was in Berlin, while staying with his son, that he was visited by Albert Einstein and his wife.

The "architect," as Ernst was known, helped renovate the Tegel clinic between 1927 and 1928. It was also in 1928 that he worked on the Berlin Psychoanalytic Institute. On October 22, 1930, Freud wrote to Lou Andreas-Salomé, "Today, I gave my son Ernst the order to send you a thousand marks from the Goethe prize money he is holding for me."

In 1933 the rise of Nazism forced Ernst to emigrate, in spite of the fact that "he was sheltered because of his wife," as Freud wrote to Jones. Moreover, it was because of his wife that he chose Great Britain, where he arrived during the summer. On June 3, 1933, Jones told Sigmund, "We were able to provide Ernst with good introductions and he has certainly lived up to his reputation as being a *Glücksind* (lucky person). You have nothing to worry about as far as he is concerned. We will be delighted to have him in England, even though I have wondered if, with his bubbly personality, he wouldn't be better off in France."

His integration in British society was not without difficulties, in spite of the help of Jones, who commissioned him to build a wing for his cottage in 1935–1936. On October 14, 1937, Arnold Zweig wrote to Freud, "I need to get in touch with you and let you know that I was pleased with my visit to your Ernst in London. He is tranquil, serene, and full of juvenile enthusiasm, and his home is delightful in its nobility and simple modernity."

Ernst traveled to Paris to meet his parents when they arrived in June 1938 and was also close by when they settled in London. Together with his sister Anna, he found the house in Maresfield Gardens, where he had an elevator installed, which Freud needed to reach his bedroom.

At the time of his father's death, he was, with Martin and Anna, appointed an executor of the will. He ran the corporation that was formed to manage the rights for Freud's work and, with Lucy's assistance, worked on all the major Freud publications that were to help popularize his work and psychoanalysis in general after the 1950s: his correspondence with Wilhelm Fliess (1950a), his general correspondence (1960a),

and so on. Shortly before his death, in late 1969, he had the pleasure to be given by Franz Jung, also an architect, the letters that had been kept by his father “in a document box covered with linen cloth, on which had been written in large capital letters, ‘FREUD LETTERS.’”

Ernst Freud died on April 7, 1970. After his death, Ilse Grubrich-Simitis was asked to complete the pictorial biography he had planned to publish and on which he had worked with Lucy. The work finally appeared in 1976 as *Sigmund Freud: His Life in Pictures and Words*.

### **FREUD, JAKOB KOLLOMAN (OR KELEMEN OR KALLAMON) (1815–1896)**

Jakob Freud, the father of Sigmund Freud, was born on April 1, 1815, (a date arbitrarily chosen by Jakob Freud) in Tysmenitz (Galicia) and died in Vienna on October 23, 1896. Of his father's family Freud wrote, “I believe they lived a long time in Rhenish territory (Cologne), that during the persecution of Jews in the fourteenth or fifteenth century they fled east, and in the nineteenth century returned from Lithuania, through Galicia, to a German-speaking country, Austria” (1925d).

In the “Gedenkenblatt,” where he entered the birth date of May 6, 1856, and circumcision on May 13 of

the following year of “my son Schlomo Sigmund,” Jakob Freud refers to his grandfather “Rabbi Ephraim” and his father “Rabbi Schlomo,” who died in Tysmenitz on February 21, two months prior to the birth of Freud, who was given the same first name. The sources of Freud's unconscious identifications (Mijolla, 1975/1981 [1975]) have been traced to the references to honorifics appearing in this genealogy.

The son of Schlomo Freud and Peppi (Pesel) Hofmann, Jakob had, out of admiration for Bismarck, chosen the date of April 1 as his birth date, although in reality the date is assumed to be December 18, 1815. Born in Tysmenitz, Galicia, he was the eldest of four children. His younger brother Josef (1825–1897), arrested in 1865 and condemned in February 1866 to ten years in prison for trafficking in counterfeit rubles (Gicklhorn, 1976), was the “criminal” uncle (*Verbrecher*) who appeared in the *Interpretation of Dreams* and caused so much grief for his older brother.

Freud wrote to his fiancée about another “uncle from Breslau,” Abae. “He is a younger brother of my father, a rather ordinary man, a merchant, and the story of his family is very sad. Of the four children only one daughter is normal, and married in Poland. One boy is hydrocephalic and feeble minded; another, who as a young man showed some promise, went insane at the age of nineteen, and a daughter went the same way when she was twenty-odd. I had so completely forgotten this uncle that I have always thought of my own family as free of any hereditary taint. But since I have been thinking about Breslau it all came back to me, and I am afraid the fact that one of the sons of the other (very unhappy) uncle in Vienna died an epileptic is something I cannot shift to the mother's side, with the result that I have to acknowledge to a considerable ‘neuropsychological taint,’ as it is called” (letter of February 10, 1886).

Jakob married young, in 1832. His wife was Sally Kanner and together they had four children, two of whom survived. The elder, Emanuel, was born in 1833 (or 1832), followed by Philipp, born in 1836 (or 1834). A fabric salesman, there are references to a trip Jakob is supposed to have made with his father Schlomo and maternal grandfather Siskind Hoffmann to Freiberg in 1838–1839, then of extended stays in 1844–1845 as “tolerated Jews.” He spent several months there before joining his family in Tysmenitz, then received the authorization to settle in Klogsdorf, near Freiberg, in 1848. In the “register of Jews,” there is a record from

October 31, 1852, that at their home are: Jakob Freud, thirty-eight, with his wife Rebeka, thirty-two, and the children, Emanuel, twenty-one, with his wife, eighteen years, and Filip, sixteen” (Sajner, 1968; Gicklhorn, 1976). Mention of this “Rebeka,” rather than “Sally” has led to much wild speculation, but it is possible that because of an administrative error or for reasons of concealment, the entry refers to the wife of his brother Joseph, Rebecca Freud-Rawnial.

Whoever this “Rebeka” may have been, Jakob was no longer married when he met Amalia Nathanson, twenty-one years his junior. They were married according to the Jewish rites in Vienna, on July 29, 1855, before settling in Freiberg in the house at Schlos-sergasse 117, owned by the locksmith Zajic. In 1857 his wife was referred to as “the wife of the wool draper” (*Wollhändlersgattin*).

There followed six births in ten years: Sigmund, on May 6, 1856; Julius, in October 1857, who died the following April; Anna, on December 31, 1858; Regine Debora (Rosa), on March 21, 1860; Maria (Mitzi), on March 22, 1861; Esther Adolfine (Dolfi), on July 23, 1862; Pauline Regine (Paula), on May 3, 1864; and Alexander Gotthold Efraim, on April 15 (or 19), 1866.

Over this period Jakob’s situation changed. Poor business decisions forced him to emigrate to Leipzig, and then to Vienna, where he settled permanently. His sons left for Manchester, England, where they became prosperous businessmen; his wife and their two first children joined him in August 1859. Establishing a permanent residence in Vienna turned out to be extremely difficult, and bad memories of this period stayed with Sigmund Freud throughout his life.

From this point on nothing is known of Jakob’s activities or the source of his income, which, although modest, allowed him to raise his large family and enabled Sigmund—the talented son he so admired—to attend school without having to earn a living to help the family. This mystery became the source of several malicious assumptions when the counterfeiting operations of Uncle Josef were revealed. The investigation led all the way to Manchester, although no evidence was found incriminating Jakob or his two émigré sons.

A tall man, who according to his son resembled Garibaldi, Jakob was a calm and respected patriarch. An observant Jew close to the Haskala movement, he appears to have been more traditional than Freud claimed. Although it is not known if Sigmund himself

was bar-mitzvahed, he learned to read with the Philippson Bible, which was presented to him on his thirty-fifth birthday with a dedication in Hebrew: “My dear son Schlomo (Salomo), in the seventh . . . [illegible] of your life, the spirit of the Lord began to move you [cf. Judges, 13:25], and said to you: Go, read in My book that I have written, and there will be opened to you the sources of wisdom, or knowledge and understanding . . . For a long time the book has been hidden [kept safe] like the fragments of the Table of the Law in the shrine of his servant, [yet] for the day on which you have completed your thirty-fifth year I have had it covered with a new leather binding and given it the name ‘Spring up, O Well! Sing ye unto it’ [cf. Numbers 21:17], and offer it to you for a remembrance and a memorial of love—From your father, who loves you with unending love—Jacob son of Rabbi [probably “Reb,” meaning Mr., M.K.] Sch. Freud. In the capital city of Vienna, 29 Nissan 5651, May 6, 1891” (Krull, 1979, p. 160).

Martin Freud, his grandson, recalls his amiable nature, and his granddaughter, Judith Bernays-Heller, recalls, “[He] divided his time between reading the Talmud (in the original) at home, sitting in a coffee house, and walking in the parks. . . . Tall and broad, with a long beard, he was very kind and gentle, and humorous in the bargain—much more so than my grandmother. . . . It was not a pious household, but I do remember one Seder at which I, as the youngest at the table, had to make the responses to the reading of the song about the sacrifice of the kid. I was greatly impressed by the way my grandfather recited the ritual and the fact that he knew it by heart amazed me.” (1973, p. 336).

For Sigmund, the son, things were less simple. There are references in *The Interpretation of Dreams* to his reprimands, his irritated comment, “Nothing will ever come of this boy,” the reproaches for his expenditures on books. On several occasions he attributes his father’s compulsion for earning money to his poor financial management. For example, on December 18, 1916, he wrote to Karl Abraham, “I have little to do, so that at Christmas, for instance. I am again faced with a blank. Leisure is not good for me, because my mental constitution urgently requires me to earn and spend money on my family as the fulfillment of my well-known father complex” (1965a).

He also remembered being terribly disillusioned by the sight of his father, without saying a word, picking

up a hat thrown into the mud by an anti-Semite. But during the republication of the book in 1908, Freud recognized, “I understood that it was part of my self-analysis, my reaction to the death of my father, the most important event, the most terrible loss in a man’s life.”

In fact, after his father’s illness, which began in June 1896, and his death on October 23, Freud wrote to Wilhelm Fliess, “He bore himself bravely to the end, just like the altogether unusual man he had been” (letter dated October 26, 1896), and “By one of those dark pathways behind the official consciousness the old man’s death has affected me deeply. I valued him highly, understood him very well, and with his peculiar mixture of deep wisdom and fantastic light-heartedness he had a significant effect on my life. By the time he died, his life had long been over, but in [my] inner self the whole past has been reawakened by this event. I now feel quite uprooted” (letter to Wilhelm Fliess, November 2, 1896).

However, on February 8, 1897, he remarked, “Unfortunately, my own father was one of these perverts and is responsible for the hysteria of my brother (all of whose symptoms are identifications) and those of several younger sisters. The frequency of this circumstance often makes me wonder.” We know that the doubt would disappear during his self-analysis, which began in July, and Freud could write, on September 21, “I no longer believe in my *neurotica* [theory of the neuroses]” after being confronted by his “surprise that in all cases, the *father*, not excluding my own, had to be accused of being perverse.” On October 3, shortly before the anniversary of Jakob’s death, he confirmed, “the old man plays no active part in my case.”

But the history of psychoanalysis bears witness to the fact that Jakob Freud did play a role in the genesis of Freudian theory and the place given in it to the representation of the father. And it was to him that, in 1904, standing on the Acropolis with his brother Alexander, Sigmund Freud’s thoughts turned, “It must be that a sense of guilt was attached to the satisfaction in having gone such a long way: there was something about it that was wrong, that from the earliest times had been forbidden. It was something to do with a child’s criticism of his father, with the undervaluation which took the place of the overvaluation of earlier childhood. It seems as though the essence of success was to have got further than one’s father, and as though to excel one’s father. . . . Our father had been in

business, he had no secondary education, and Athens could not have meant much to him. Thus what interfered with our enjoyment of the journey to Athens was a feeling of *filial piety*” (1936a).

### FREUD, (JEAN) MARTIN (1889–1967)

Martin Freud, a lawyer and the eldest son of Sigmund Freud, was born on December 6, 1889, in Vienna, and died in 1967 in London. He was named Jean Martin in honor of Charcot. Writing to Freud, Charcot exclaimed, “Best wishes; may he be welcomed; may the Evangelist and the generous Centurion be propitious for him; may their names, which are now his as well, bring him happiness!” Later he dropped “Jean” from his name. Sigmund Freud considered his son Martin to be “very intelligent” and in his letters to Wilhelm Fliess, along with news about childhood illness, he made several references to the poems the boy wrote between the ages of eight and ten. He was “a strange

bird; sensitive and good-natured in his personal relationships, completely wrapped up in a humorous phantasy world of his own.” (letter dated July 3rd, 1899, 1985c, p358). This lightheartedness would remain with him all his life.

After completing his “matura” (equivalent to the first year of college) in 1908, he entered the university to study law. An enthusiastic sportsman, “he had his face cut in a duel,” as Freud informed Carl Gustav Jung on July 7, 1909. He was also politically engaged and had joined a Zionist movement, the Kadimah.

In 1910 he joined the Imperial horse artillery as a so-called one-year volunteer. In January 1911 he broke his leg in a skiing accident. When the First World War broke out, he immediately volunteered for the artillery service and was sent to Galicia in January 1915. After being slightly wounded in August 1915, he was soon promoted to lieutenant but was taken prisoner, something his uneasy family didn’t learn about until after the armistice. “Martin’s captivity has sapped my moral. Do you know anyone in Genoa? He is being held at San Benigno inferiore,” Freud wrote to Ernest Jones on February 18, 1919.

He was released shortly thereafter, and Freud wrote to Pastor Pfister on October 5, “My son Martin, barely back from his captivity in Italy, has made himself a captive again through his engagement to the young lady of his choice, the daughter of a Viennese lawyer.” On December 7, 1919, he married Ernestine Drucker (Esti, 1896–1980), with whom he had two children, Anton Walter Freud, born April 3, 1921, and Myriam Sophie Loewenstein-Freud, born August 6, 1924.

Because of his background—he had a law degree and was working in a bank—he became increasingly involved in Freud’s investments and helped him to manage his books. When the retirement of Adolf Joseph Storfer in 1931 revealed the poor financial situation of the Internationaler Psychoanalytischer Verlag, Martin took control and with his father’s help appealed to the international community to obtain the necessary funds for its survival. But in 1936, after the Nazis had come to power in Germany, they sequestered the firm’s publications and shortly after the *Anschluss* did the same in Vienna, where Martin was troubled by the Gestapo.

Family affairs went badly, for Martin had several extramarital relations (including a very ambiguous relationship with an American patient of Freud,

Dr. Edith Jackson), which his wife didn’t discover until shortly before their departure from Austria on May 14, 1938.

His wife remained in France with their daughter, while Martin went on to London, shortly before his parents. His life there was not simple. From July to November 1940 he was interned as a “foreign enemy” in a camp near Liverpool, Huyton Camp, under terrible conditions. Freud, in his will, had made Ernst, Martin, and Anna the executors of his estate, but by 1946 an organization, which was run for many years by Ernst, was created to ensure the survival of his work and his memory in the field of psychoanalysis. Martin had many jobs and ended up running a smoke shop near the British Museum. In 1958 he published, against Anna’s advice, his book of memoirs, *Sigmund Freud: Man and Father*, which remains one of the primary sources for all biographers of Freud. He died on April 25, 1967, at the age of seventy-seven.

His wife Esti managed to escape France in 1940 with her daughter Sophie. They left Nice, where brother-in-law Olivier Freud lived, and traveled to Morocco, where they boarded a ship for the United States. She began a practice as a speech pathologist in the United States, where she lived until her death in 1980. She and Martin were never divorced.

## FREUD, JOSEF (1826–1897)

Josef Freud, ten years younger than his brother Jakob Freud, was born in 1826 in Tysmenitz, Galicia. We would have had no record of his existence if Freud hadn't referred to him in *The Interpretation of Dreams* (1900a, chap. 4) in the "dream of the uncle with the yellow beard." Freud was quite open in writing, "For I have only one uncle, my Uncle Josef. His story was a sad one. More than thirty years earlier his desire for gain had misled him into an act severely punishable by the law, and he was punished accordingly. My father, whose hair turned gray with grief in a few days, always used to say that Uncle Josef had never been a bad man, he had been a numbskull; that was the expression he used." For decades the complete story remained unknown, and Ernest Jones's biography even claimed that "he was only given a fine, for the Austrian police records show no sign of his imprisonment."

In reality, on June 20, 1865, Uncle Josef was arrested by the police as he was about to sell counterfeit rubles. He was involved in an international money trafficking ring that had contacts in Manchester, where his nephews Emanuel and Philipp Freud lived. Although suspected, they were never implicated in the crime. The news was published in the newspapers the following day, but Freud's name did not appear. However, during sentencing in February 1866, the Viennese press gave the story considerable coverage, announcing "ten years of forced labor for Freud." He was released after four years for good behavior, but little is known about what became of him after that, or about his wife Rebecca, whom he married in 1849 in Jassy (possibly this is the "Rebeka" who was elsewhere documented as brother Jakob's wife). Of their two children, only Deborah is mentioned by name; a friend of Adolfine Freud, she was a child at the time of his sentencing. He died at the Rudolf Hospital in Vienna on March 5, 1897 (Peter Swales, quoted in Grinstein, Alexander, 1990), at about the time that Freud had his dream.

Requested by Siegfried Bernfeld to inquire about Freud's youth, it was the wife of a Viennese professor, Mrs. Renée Gicklhorn, who unearthed the story, which came to light when Sigmund Freud was between nine and ten years old. It is easy to understand the affect this had on the Freud family. Josef, who had already been referred to as the "other—very

unfortunate—uncle from Vienna" in a letter Sigmund wrote to his fiancée in February 1886, twenty years after the affair, now reappeared—this *Verbrecher* (criminal), as he is known in one of the most frequently cited passages from *The Interpretation of Dreams*—as the symbol of the obstacle to his nephew's ambitions in 1897, the year Freud was so anxious to become a professor.

It should not come as a surprise that this dramatic episode from Freud's childhood has been extensively written about since its discovery. Freud's biographers have provided more or less accurate psychological analyses of the inventor of psychoanalysis, often in the hope of clarifying what they believe to be cracks in his theory.

## FREUD: LIVING AND DYING

Dr. Max Schur was a psychoanalytically oriented internist who became Freud's physician in 1929. He treated Freud and members of his family until 1939, when Freud

died. Schur then emigrated to the United States. There many people tried to persuade him to write about Freud, but he was reluctant to do so out of respect for Freud's privacy. When the correspondence between Freud and Wilhelm Fliess was published in 1950, he was impressed by the historical and scientific value of his documents on Freud and agreed to make his notes available to Ernest Jones, who was preparing a biography of Freud. Disagreeing with some of Jones' assessments of Freud's physical and neurotic symptoms, Schur decided to craft a "biographical study" of Freud's life, concentrating on his changing attitudes toward life and death as revealed in his life, work, and correspondence.

Schur's book begins with a brief biographical review of Freud's early life, incorporating recently published material that threw light on some of Freud's reconstructions. Then, subjecting Freud's descriptions of his symptoms in his letters to Fliess in the early 1890s to a careful review, he disputes Jones's conclusion that Freud had a cardiac neurosis. Schur believed that the most likely diagnosis was a small coronary occlusion with typical anginal pains, arrhythmias, and mild cardiac insufficiency, aggravated by nicotine. As is well known, Freud was addicted to cigars, and he continued to find them necessary for creative concentration even when they were clearly contributing to his cancer during his last years. Schur believed that "neurotic anxiety was much less pronounced in Freud than excessive swings of mood, which at their low ebb had a definite depressive quality." He also described Freud's obsessive preoccupation with death and with dying at a certain age. During the cardiac episode Freud's relationship with Schur, which began in mutual admiration, intensified and took on characteristics of a "transference-like" relationship.

Schur examines Freud's self-analysis in the light of such transference. His discussion of Freud's "Irma dream" demonstrates that the dream was also an unrecognized attempt to exonerate Fliess in order to preserve Freud's idealization of Fliess. Schur also demonstrates how Freud's self-analysis led to a breakup of his friendship with Fliess in 1904 and how ghosts of the relationship continued to haunt Freud in the form of a preoccupation with death dates based on Fliess's numerical periods. Schur also pursues the broader theme of Freud's attitudes toward death throughout Freud's works, most notably when he discusses Freud's notion of the death instinct.

The last third of Schur's book is a painfully moving description of Freud's cancer, the surgical procedures

he endured, the tormenting prostheses he had to suffer, and the fortitude and remarkable capacity he demonstrated to continue to analyze and write despite everything. When Freud interviewed Schur before appointing Schur as his physician, he asked for two promises: that he would be told the truth and nothing but the truth, and that he would not be required to suffer unnecessarily. Schur ends with a description of how he fulfilled the second of these promises.

## FREUD MUSEUM

The Freud Museum, at 20 Maresfield Gardens in London, was Sigmund Freud's "last address on this

planet,” as he wrote to Jeanne Lampl-de Groot on August 22, 1938. He and his family moved in on September 27, 1938, and he died there on September 23, 1939.

After his death his family remained in the house: the last occupant was his youngest daughter Anna, who died in 1982. As stipulated in her will, the house was turned into a museum under the auspices of the Sigmund Freud Archives and the New-Land Foundation, a charitable fund run by the family of her friend, the American psychoanalyst Muriel Gardiner. The Museum was opened to the public in 1986.

Its centerpiece is Sigmund Freud’s working environment, preserved as it was during his lifetime. The study contains his personal library, his collection of antiquities, and the original couch that witnessed the discovery of psychoanalysis. When the Freud family fled from Nazi Austria in June 1938, they arrived virtually empty handed, but all their possessions were sent on afterwards. Consequently, the Museum contains all their furniture, carpets, pictures, and other belongings, in addition to Freud’s books and antiquities. Most of his papers were subsequently removed to the Sigmund Freud Archive at the U.S. Library of Congress. However, copies of many of these documents remained in the museum, and this copy archive forms a valuable resource for European scholars. The archive also includes many of Anna Freud’s papers and related documents. In addition, the Freud family photo albums form the center of an extensive photo archive.

The museum attracts fourteen thousand visitors each year from all over the world. In little over a decade of existence it has also established itself as a workplace and study center, as well as a vibrant memorial to Freud’s life and work. It hosts regular national and international conferences on cultural and psychoanalytical themes, as well as lectures and study seminars, and its education program reaches out to students and schoolchildren in the local community.

## **FREUD-NATHANSON, AMALIA MALKA (1835–1930)**

Sigmund Freud’s mother, Amalia Malka Freud-Nathanson, was born, according to family tradition, on August 18, 1835, in Brody, in Galicia, and died in Vienna on September 12, 1930.

The daughter of Jacob Nathanson and Sara Widens, Amalia had three older brothers and one younger brother, Julius. The Jewish calendar makes Amalia’s date of birth somewhat uncertain, as Freud once told Wilhelm Fliess, but it was celebrated the same day as the birth of Emperor of Austria, Franz Josef, and the annual national holiday made it the occasion of humorous family banter.

The Nathansons had lived in Galicia before moving to Odessa, then to Vienna, where Amalia, at age twenty, met Jakob Freud. Jakob shared her father’s first name and was twenty years older than she; they were married in a synagogue in 1855. She went to live with him in Freiberg, in Moravia, where on May 6, 1856, she gave birth to her son Sigmund.

Other children soon followed: Julius in October 1857 (the namesake of Amalia’s younger brother, who was tubercular, both to die within a year); Anna on December 31, 1858; Regine Debora (Rosa) on March 21, 1860; Maria (Mitzi) on March 22, 1861; Esther Adolfine (Dolfi) on July 23, 1862; Pauline Regine (Pauli) on May 3, 1864; and Alexander Gotthold Efraim on April 15 (or 19), 1866.

Diagnosed with tuberculosis, Amalia took frequent cures at Roznau, twenty-five kilometers from Freiberg, even after moving to Vienna in the wake of Jakob’s failed financial ventures. In August 1859 she and her two children left Freiberg on a railway journey that Freud would recall among his earliest memories during his self-analysis: At the railroad station in Breslau gas jets made him think of the “flames of hell” and he also recalled seeing his mother nude (“*matrem nudam*” [Anzieu, Didier, 1986, p. 14]).

In other of Freud's memories he recalled his mother as "slim and beautiful" (Gay, 1988, p. 7), and as teaching him to read and write German. Once, while at work in the kitchen, she responded to his questioning the idea that people are made of dust and therefore mortal by rubbing her hands to elicit the blackish bits of epidermis. When Freud was about ten years old, he had an anxiety dream in which he saw his "beloved mother with a peculiarly calm, sleeping facial expression, being carried into the room by two (or three) persons with bird's beaks . . ." (p. 504).

Amalia appears to have been an anxious mother, if one considers as exemplary the precautions that Freud took to conceal from her his adolescent plans to travel to London, or her response to the 1873 cholera epidemic that raged in Vienna while she was staying in Roznau. But she was also a supportive mother who foresaw a great destiny for Sigmund, a gifted child to whom she granted many favors, triggering jealousy among her other children. Freud would help his mother financially as soon as he began to earn a living and, together with his brother, Alexander, he would continue to support her to the end of her life.

Coquettish as a young woman, she enjoyed card parties, but Amalia became difficult as she grew older. According to her grandson Martin Freud, she was a typical Galician Jewish woman; she "had great vitality and much impatience; she had a hunger for life and an indomitable spirit" (1958, p. 11).

After she became a widow, Amalia lived with her daughter Adolfine (Dolfi), and made yearly trips to Ischl for her lung ailment. In her home on Grüne Thorgasse, by family custom, she would receive her "goldener Sigi" and other children and grandchildren every Sunday.

Freud hid from Amalia the deaths of his daughter Sophie and her child, Heinele, and he cautiously told her about surgery on his jaw without mentioning cancer. Indeed, her old age and death presented Freud with a problem he discussed with Karl Abraham as early as May 1918: "My Mother will be eighty-three this year and is no longer very strong. I sometimes think I shall feel a little freer when she dies, for the idea that she might be told that I have died is a terrifying thought." (Jones, Ernest, 1955, Vol. 2, p. 196) He brought up the problem again after the death of Max Eitingon's mother on December 1, 1929, repeating almost word for word what he had written to Ludwig

Binswanger the previous January: "The loss of a mother must be something very strange, unlike anything else, and must arouse emotions that are hard to grasp. I myself still have a mother, and she bars my way to the longed-for rest, to eternal nothingness; I somehow could not forgive myself if I were to die before her." (Freud, 1960, p. 392)

Three days after her death on September 12, 1930, Freud wrote to Ernest Jones: "I will not disguise the fact that my reaction to this event because of special circumstances been a curious one. Assuredly, there is no saying, what effects such an experience may produce in deeper layers, but on the surface I can detect only two things: an increase in personal freedom, since it was always a terrifying thought that she might come to hear of my death; and secondly, the satisfaction that at last she has achieved the deliverance for which she had earned a right after such a long life. No grief otherwise, such as my ten years younger brother is painfully experiencing. I was not at the funeral; again Anna represented me as at Frankfort. Her value to me can hardly be heightened." (Jones, p. 152)

For all intents and purposes, Freud's relationship with his mother may be said to have been excellent and his comment concerning Goethe is usually cited: "[I]f a man has been his mother's undisputed darling he retains throughout his life the triumphant feeling, the confidence in success, which not seldom brings actual success along with it." (Freud 1917b, p. 156)

## FREUD, OLIVER (1891–1969)

Oliver Freud, named after Oliver Cromwell, was the third son of Sigmund and Martha Freud. Born in Vienna on February 19, 1891, he died in Williamstown, Massachusetts, in February 1969. His mother's favorite, Oliver's life was less tied to that of his parents than his other brothers and sisters, in spite of the compliments paid to him by Freud for his precocious interests in mountains and railways and his gift for construction.

After completing his "matura" (equivalent to the first year of college), in 1909 he entered the Vienna Polytechnic, a private school. He graduated with a degree in civil engineering in 1915. He was not enlisted when the First World War broke out but was put to work building a barracks, then a tunnel, until December 1916. After this he was inducted as an officer in an engineering regiment.

Married in December 1915, he was divorced by September 1916. Sent to Galicia in 1916, then Hungary, he returned at the end of hostilities and was discharged on December 2, 1918. In July 1919 Freud remarked that Oliver was the only one of his three sons who found work after his return. He lived in Berlin, like Ernst, and both brothers traveled to Hamburg for the funeral of their sister Sophie in January 1920.

But the boy was a problem for Freud. He confided in Max Eitingon on October 30, 1920, that he was often worried about this son, who "had been his pride and secret hope," and suggested that Oliver "would need to be analyzed" because of the symptoms of obsessional neurosis. In 1921 Oliver, upon the advice of Hans Lampl, a fellow student and friend of Martin, began analysis with Franz Alexander (Roazen, 1993).

After a stay in Romania, he married Henny Fuchs (born February 11, 1892, in Berlin, died 1971 in North America) in Berlin on April 10, 1923. His mother, Martin, and Anna, after returning from Göttingen to visit Lou Andreas-Salomé, were present for the marriage. On September 3, 1924, their daughter Eva Mathilde Freud was born. Freud warmly greeted the family on Christmas 1924, not wishing to "delay any further making the acquaintance of the adorable new grandchild."

While living in Berlin, Oliver went without work from 1932 until April 7, 1933. Freud wrote to Ernest Jones, "My unemployed son Oliver, whom I have been supporting for a year, is coming to Vienna tomorrow to discuss his future. There is little doubt that he will never find work in Berlin again (he is a civil engineer)."

Oliver emigrated to France that same year, 1933. He first lived in Brittany, near Dinard, then in Paris, where Freud sent a letter of introduction to Arnold Zweig on October 25, 1933, "But I have a son in Paris—Oliver, who with his wife and child lives in 16me, rue George Sand. He is a civil engineer, a very talented man [*ein hochbegabter Alleswisser*], knows everything, excellent at his job; nice wife and charming little daughter. I'm afraid he will not achieve anything in Paris. I'd be very pleased if you could meet him."

In 1934 he went to Nice, where he began working as a photographer, about which Freud remarked, "At least he has found a job that satisfies his passion for tinkering" (letter to Zweig, June 13, 1935). Oliver remained in Nice, aside from a visit to Vienna in November 1936, until 1943.

After obtaining a visa for America in 1942, Oliver, Henry, and Eva tried to leave France through Spain, but fear of deportation led them back to Nice, now under Italian occupation. René Laforgue, whose property of Garéoult was nearby, is said to have helped them obtain forged papers and leave France for the United States in 1943.

But their daughter Eva, who was nineteen years old at the time, refused to go with them and remained with her fiancé on the Mediterranean coast. She was later analyzed by René Laforgue and then by Henri Stern. She died tragically from septicemia contracted after an abortion, complicated by a cerebral abscess, in the Hospital of La Timone in Marseille, on November 4, 1944.

Her parents reached Philadelphia, where Oliver found work as an engineer with the Budd Company. He and Henny retired in Williamstown, in western Massachusetts, where he died in February 1969.

Arnold Zweig wrote to Freud from Haifa on January 21, 1934, "And since I've been here I have been thinking very much about this son of yours, who is also too decent to find it easy to adapt himself to life. It was shattering to observe how he talked most vividly

and warmly when speaking about his wartime service. Just like all other men of his generation and of his circumstances who now find that they have to begin all over again at a time when they are firmly set in their ways of thought and feeling, habits and ambitions. No one can take it amiss if these men do not wish to have anything to do with the contemporary business scene and prefer to take refuge in memories of a time when a man (especially a young man) merely needed to risk his life to be fulfilling all the demands that society made upon him.”

**FREUD, PHILIPP.** *See* Freud, Sigmund (siblings)

---

### **FREUD, SIGMUND (SIBLINGS)**

Sigmund Freud, born May 6, 1856, was Jakob Freud's third child. From a previous marriage, in 1832 to Sally Kanner, he had two sons, Emanuel and Philipp. After Sally died in 1852, a brief second marriage to a woman named Rebekka also ended with her death. Jakob's third marriage, to Amalie Nathanson on July 29, 1855, produced eight more children. In addition to Sigmund (Sigmund), the firstborn, were born Julius, Anna, Rosa, Marie, Adolfine, Pauline, and Alexander.

#### **Freud, Emanuel**

Born in 1833 in Tysmenitz in Galicia, then part of the Austro-Hungarian Empire, Emanuel Freud worked in his father's textile business. In 1852, he married (Kokach), who was born in Milow in Russia in 1834 (perhaps 1836). In Freiberg he settled a few blocks from his father's home at 42, place du Marché. His

children's nurse, Monika Zajicova, was said to also have been Sigmund's "Nannie."

Freud's oldest nephew, Johann, was born in Freiberg on August 13, 1855. I have also long known," wrote Freud to Fliess in 1897, "the companion of my misdeeds between the ages of one and two years; it is my nephew, a year older than myself, who is now living in Manchester and who visited us in Vienna when I was fourteen years old. The two of us seem occasionally to have behaved cruelly to my niece, who was a year younger" (Freud, 1985c, p. 268) "Until the end of my third year we had been inseparable; we had loved each other and fought each other, and, as I have already hinted, this childish relation had determined all my later feelings in my intercourse with persons of my own age" (1900a, p. 424). Freud also wrote, "An intimate friend and a hated enemy have always been indispensable to my emotional life; I have always been able to create them anew, and not infrequently my childish ideal has been so closely approached that friend and enemy have coincided in the same person; but not simultaneously, of course, as was the case in my early childhood" (1900a, p. 483). Johann's whereabouts cannot be traced after 1919, and what happened to him in later years is unknown.

On November 20, 1856, Pauline Freud, Sigmund's niece, was born in Freiberg; she would die a spinster in Manchester in 1944. The games she played with John and Sigmund in the meadow covered in yellow flowers, which Freud recalled in "Screen Memories" (1899a), are thought to have taken place during the summer of 1859. Freud's unconscious fantasy of Pauline's defloration by John and himself led some to believe that both boys sexually assaulted the little girl (Krüll, 1979). Towards 1875, it seems that Jakob Freud had the idea of sending Sigmund to England with his brothers and having him marry Pauline.

On February 22, 1859, Bertha Freud was born in Freiberg. She died accidentally from a fall on a staircase in 1944.

Toward 1859–1860, while Jakob and his family left Freiberg for Vienna, Emanuel emigrated with relatives and his brother Philipp to Manchester, England. Solomon Samuel (Sam) Freud, Emanuel's fourth son, was born there on June 28, 1860. His correspondence with Sigmund Freud was eventually published (Freud 1996 [1911–38]). He died in 1945.

On May 12, 1862, Matilda Freud was born in Manchester.

In 1900 Freud described Emanuel to Wilhelm Fliess (Freud 1985c, p. 417) on the occasion of his half-brother's trip to Vienna with his son Sam: "He brought with him a real air of refreshment because he is a marvelous man, vigorous and mentally indefatigable despite his sixty-eight or sixty-nine years, who has always meant a great deal to me."

Freud paid visits to Emanuel in August 1875 and to his sister Rosa in 1884–1885. He went to England for a second two-week visit to his brothers in September 1908.

Emmanuel died from a fall from a train traveling between Manchester and Southport on October 17, 1914, just six days before the anniversary of Jacob's death—a coincidence noted by Freud.

Marie, Emanuel's wife, died in Manchester in 1923.

### **Freud, Philipp**

Philipp Freud was born in Tysmenitz around 1835. He would play an interesting role in his brother's life that Freud would only reconstruct in October 1897 during his self-analysis. It was Philipp who "locked up Nannie in prison" for stealing shortly before the family's departure from Freiberg. He was living across the street from Freud's parents and was the same age as Freud's mother, Amalie. Some authors have imagined from Freud's fantasy that Philipp and Amalie were together as a "couple" with the suggestion that he had an affair with her (Krüll, 1979). He contributed in any event to the confusion of generations in Freud's mind that was only clarified in 1875 during his visit to England.

Philipp married at about forty years old, in Manchester on January 15, 1873, to Matilda Bloomer (Bloomah), from Birmingham (1839–1925). They had two children. Pauline Mary (Poppy) was born on October 23, 1873, married Frederick Oswald Hartwig and died in Bucklow/Chester on June 23, 1951. Morris Herbert Walter was born on April 2, 1876, and died in Port Elizabeth, South Africa, on November 28, 1938.

Philipp died in Manchester on August 29, 1911.

Freud (1989a, pp. 126–127) described this part of his family in an 1875 letter to Eduard Silberstein: "You will, no doubt, wish to know about my relatives in

England and about my attitude toward them. I don't think I've ever told you much about them. There two brothers on my father's side, from my father's first marriage, twenty-two years older than I, the older, Emanuel, having married in early youth, the younger, Philipp, two and a half years ago. They used to live with us in Freiberg, where the elder brother's three oldest children were born! The unfavorable turn their business took there caused them to move to England, which they have not left since 1859. I can say that they now hold a generally respected position, not because of their wealth, for they are not rich, but because of their personal character. They are shopkeepers, i.e., merchants who have a shop, the elder selling cloth and the younger jewelry, in the sense that word seems to have in England. My two sisters-in-law are good and jolly women, one of them an English woman, which made my conversations with her extremely agreeable. Of those persons in our family whose uncle I may call myself, you are already acquainted with John, he is an Englishman in every respect, with a knowledge of languages and technical matters well beyond the usual business education. Unknown to you, and until recently, to me, are two charming nieces, Pauline, who is nineteen, and Bertha, who is seventeen, and a fifteen-year-old boy by the name of Samuel—which I believe has been fashionable in England ever since Pickwick—and who is generally considered to be a 'sharp and deep' young fellow" (pp. 126–7).

Sigmund Freud was born on May 6, 1856, the first of Jacob and Amalie Freud's eight children.

### **Freud, Julius**

Julius Freud was born in October 1857 in Freiberg, when Sigmund was eighteen months old. He died the next April, the same year that Amalie's brother, Julius's namesake, also died.

On October 3, 1897, Freud (1985e, p. 268) wrote to Wilhelm Fliess about one of the discoveries of his self-analysis: "that I greeted my one-year-younger brother (who died after a few months) with adverse wishes and genuine childhood jealousy; and that his death left the germ of [self-] reproaches in me."

### **Bernays-Freud, Anna**

Anna Bernays-Freud was born on December 31, 1858, in Freiberg and died on March 11, 1955, in New York. Her relationship with her older brother was often difficult, but she was her father's favorite daughter. In her

memoirs (Bernays-Freud, 1940), she recalled Sigmund's special privileges, the fact that he enjoyed his own room, and that it was forbidden to play the piano in order not to disturb him; he also censored what she read.

Anna married Martha's oldest brother, Eli Bernays (1860-1923) on October 14, 1883, with whom Freud, who didn't attend their wedding, felt for a time resentful regarding his sister's dowry.

Anna and Eli emigrated in the United States in 1892 with their two children, Lucy, born in 1886, and Judith born a year earlier. In 1973 the latter, Judith Bernays-Heller, published a brief memoir of her visits to grandparents Jacob and Amalie (Bernays-Heller, 1973). Anna and Eli had three more children: Edward Louis was born in 1891, and Hella and Martha in 1893 and 1894, respectively.

Eli, who enjoyed a brilliant career in business, was in charge of Freud's works in the United States and he had some disagreements with Ernest Jones concerning their English translations. After Eli's death, in 1925 Freud wrote to his son Edward in reply to the latter's proposition: "What deprives all autobiographies of value is their tissue of lies. Let's just say parenthetically that your publisher shows American naivete in imagining that a man, honest until now, could stoop to so low for five thousand dollars. The temptation would begin at one hundred times that sum, but even then I would renounce it after half an hour." On March 8, 1920, he wrote to Ernest Jones, describing Edward as "an honest boy when I knew him. I know not how far he has become Americanized" (Gay 1989, p. 568) and in September he announced, to Jones's chagrin, that his nephew would serve as literary executive for American rights to his works.

### **Graf-Freud, Regina Deborah (Rosa)**

Regina Deborah Graf-Freud (Rosa) was born on March 21, 1860, and died in the Treblinka concentration camp in 1942. Considered his favorite sister, Freud in 1886 acknowledged that the beautiful Rosa, like himself, had "a nicely developed tendency toward neurasthenia" (Freud 1960, p. 210). On October 22, 1874, Freud wrote to Eduard Silberstein: "Rosa has entered a school of drawing and design newly established for the perfection of feminine handicrafts. I have taken charge of the rest of her education and am sacrificing one of my lectures to that end. The gods cannot possibly have rejoiced at this sacrifice as much as I did" (Freud 1989a, p. 67). She would return the

favor in various ways, by taking care of his laundry, for example, during his stay in Paris, later by caring for his children during vacations.

Rosa's fate was particularly unfortunate. After a disappointing love affair, she married Heinrich Graf (b. 1852), a physician, on May 17, 1896, but he died in 1908 at the age of fifty-six. Her son, Hermann Adolf, was born on July 13, 1897 and died in action during World War I, in early 1917. Finally, her daughter, Cäcilie, born October 18, 1899, and nicknamed Mause, whom Freud called "my favorite niece," a dear girl of 23, was unmarried and pregnant when she committed suicide with an overdose of the barbiturate veronal on August 18, 1922.

The last document from Rosa is a letter transmitted by the International Red Cross to Freud's address in London. Twenty five words only were authorized: "Geliebte Martha! Tief bewegt grüssen Dich Alle. Erbitten Deiner Alexanders Familie Befinden. Vier einsam. Traurig. Leidlich. Gesund. —S. freundschaftlich. Ganze Einrichtung bestens engleagert. Graf Rosa" ("Dear Martha! Greetings with heartfelt emotion. Wondering about the state of your Alexander's family. Four alone. Sad. Painful. Health. Yours warmly. Best furnishings in storage. Graf Rosa.")

Rosa was deported in Theresienstadt on August 28, 1942, at the same time as her three sisters, with whom she was living in a increasingly cramped apartment. According to a witness, during the Nuremberg trial, in October 1942 in the Treblinka concentration camp, the commandant of the camp to whom she introduced herself as Sigmund Freud's sister, examined her identification and "said that there was probably some mistake and showed her the railroad signs, telling her that there would be a train to take her back to Vienna in two hours. She could leave her belongings, go into the showers and, after bathing, her documents and her ticket to Vienna would be ready. Rose naturally went into the showers and never returned" (Leupold-Löwenthal, 1989).

### **Moritz-Freud Maria (Mitzi)**

Maria Moritz-Freud (Mitzi) was born on March 22, 1861, and died in the Maly Trostinec, the extermination camp, in 1942. In 1885 she had to work as a governess, which led Freud, then in Paris, while observing nannies with young children, to write Martha: "I couldn't help thinking of poor Mitzi and grew very, very furious and full of revolutionary thoughts" (Freud 1960, p. 173).

In 1887 Mitzi married her Romanian cousin Moritz Freud (1857–1920). They had four children, Margarethe, born in 1887; Lilly Marlé-Freud, born in 1888, who became a well-known actress; Martha Gertrude, born in 1892, who illustrated children books under the name “Tom” and would commit suicide in 1930, a year after her husband the journalist Jakob Seidmann, killed himself; Theodor (Teddy) and born in 1904, whose twin was stillborn and who died from drowning in 1923 in Berlin. Martha’s daughter, Angela Seidmann, was in the care of Freud and Anna for a while before emigrating to Haifa.

Mitzi, reunited with her sisters in Vienna after her husband’s death, shared their fate in the Holocaust. She was deported to the concentration camp of Theresienstadt, on June 29, 1942, then to Maly Trostinec where she disappeared (Leupold-Löwenthal, 1989).

#### **Freud, Esther Adolfine (Dolfi)**

Esther Adolfine (Dolfi) was born on July 23, 1862, and died in 1943 in the concentration camp at Treblinka. She was unmarried and cared for her father Jakob when he fell ill, then of her mother, becoming impetuous Amalie’s constant companion, which her nephew Martin considered could not have been a welcome fate. “She was not clever or in any way remarkable, and it might be true to say that constant attendance on Amalie had suppressed her personality into a condition of dependence from which she never recovered” (M. Freud, 1958, p. 16).

Dolfi was deported with Mitzi and Paula to the concentration camp of Theresienstadt on August 28, 1942, where she died from “internal hemorrhages” on February 5, 1943, according to information gathered by Harry Freud after the war, perhaps due to malnutrition. (Leupold-Löwenthal, 1989).

#### **Winternitz-Freud, Pauline Regine (Pauli)**

Pauline Regine Winternitz-Freud (Pauli) was born on May 3, 1864, and died in the Holocaust in 1942. She was married to Valentin Winternitz and emigrated to the United States, where their daughter, Rose Beatrice (Rosi), was born on March 18, 1896. After her husband’s death in 1900, on Freud’s advice, she returned to Berlin, where she lived with her husband’s family before joining relatives in Vienna. Deported from that city in June 1942, she was taken first to the concentration camp of Theresienstadt, then to the exter-

mination camp or Maly Trostinec (Leupold-Löwenthal, 1989).

In 1913, Rosi, just seventeen years old, developed psychological problems that suggested psychosis. Ten years later and pregnant, she married Ernst Waldinger, a young poet, but the couple was not happy and, in 1931, she had a relapse. Rosi successfully emigrated to the United States and in 1946 entered analysis with Paul Federn in New York, probably with the financial assistance of Anna Freud.

#### **Freud, Alexander Gotthold Efraim**

Alexander Gotthold Efraim Freud was born on April 15 (or April 19), 1866, in Vienna, and died in 1943 in Canada. The youngest of the family, his name was chosen by Freud himself at a family meeting.

For a number of years Alexander was closest to his older brother, sharing with him, until Freud married, Easter and summer vacations, mainly in Italy after a first visit there in 1895. He took part in the 1897 trip during which Freud contemplated Luca Signorelli’s frescoes, and in the visit to Rome at the end of August 1901. “It was a high point of my life” as wrote Freud to Wilhelm Fliess. He was also with his brother on the Acropolis, during the sudden “disturbance of memory” in Athens in September 1904.

Merry and whimsical and a music-lover, Alexander “was an excellent story-teller who could imitate the various accents of the characters in his stories, as his nephew would write (M. Freud, 1958, p. 17). He did not pursue an education but, intelligent and hardworking, became a specialist in transportation and worked at the Vienna Chamber of Commerce. On August 20, 1899, Freud wrote to Fliess: “Alexander was here for four days; he will lecture on tariff rates at the Export Academy and will be given the title and rank of professor extraordinarius after one year—much earlier in fact than I” (Freud, 1985c). With his expertise, he was responsible for organizing Freud’s voyage to America in 1909.

Also in 1909, Alexander married Sophie Sabine Schreiber in a synagogue, in a double ceremony with his niece Mathilde. His wife gave birth on December 21, 1909, to Harry, their only child. With an excellent livelihood, he shared with Freud the support of their mother and Dolfi. He was, according to his brother, much more upset than he by Amalie’s death in 1930. In 1936 he commissioned Wilhelm Victor Krauss to paint Freud’s portrait.

In March 1938, shortly after the Alexander emigrated to Switzerland. Sigmund, at the time still in Vienna wrote Ernest Jones (April 28, 1938) that his brother caused him considerable worry; he had reacted badly to the loss of his business and was in poor health. By shared decision, the brothers left a large sum (160,000 Austrian Schillings) to their four sisters that would have been sufficient for a comfortable living in Vienna; they saw no serious danger to their remaining in Vienna. Freud soon realized his mistake and at his request Marie Bonaparte attempted to secure their passage from Austria, but without success.

Alexander gave up his Anglophobia and pro-German sentiments that dated to the First World War to emigrate to London in September 1938, where he also joined his son Harry. It was this latest who wrote to his aunts a letter they never receive and in which he described Sigmund's last days.

Alexander and his wife would emigrate to Canada, where he died in 1943.

## **FREUD, SIGMUND SCHLOMO (1856–1939)**

Sigmund Schlomo Freud was born on May 6, 1856, in Freiberg (now Priborg), Moravia (now the Slovak Republic), and died on September 23, 1939, in London. He was the son of Amalia Nathanson and of Jakob Freud, a draper, who had two children (Emanuel and Philipp) from a previous marriage. Freud was the first child of a couple in which the husband was forty years old, twice as old as his young wife. Over the next ten years, five daughters and two more sons would be born.

He was circumcised a week after birth. When he was two years old, a younger brother, Julius, died at the age of seven months, the first of several traumas of his early childhood. Others included the arrest for theft of “Nanie” his nurse; the departure of his father for Austria after a series of bad business dealings; the emigration to Great Britain of his older half-brothers and their children, his first playmates; and, most crucially, his own exile at the age of three. He rejoined his father in Vienna in the company of his mother after a lengthy train trip that left a deep impression on him.

He remembered his constant poverty following his arrival in the Austrian capital in 1859 and during his childhood, but alluded only once to the family's shame after his uncle Josef was condemned to ten years of forced labor for trafficking in counterfeit currency in 1866. He was a brilliant student, however, and after completing his “matura” (equivalent of the first year of college), was able to choose between law and natural science. He enrolled in medical school and after briefly studying philosophy (Franz Brentano was one of his teachers), decided to major in zoology.

In the summer of 1875, after a brief stay in Great Britain with his half-brothers in Manchester, he was able to put together a better idea of his place in the family genealogy. The following year he obtained a research grant to work at the Experimental Zoology Station of the University of Vienna in Trieste, where his work helped demonstrate the existence of testicles in the male eel. His work was presented to the Academy of Sciences in March 1877 and published in April (1877b), signaling his entry, at the age of twenty-one, into the world of science. In the following years his research and personal interest led him to study the anatomy of the nervous system; he hoped that through his research he would be able to achieve what he had

always dreamed of—financial security. But in spite of his success, his material life remained precarious.

In October 1876 he entered Professor Ernst Brücke's Physiologisches Institut, where he remained until 1882. He became friends with the two assistants, Ernst von Fleischl and Josef Breuer, and investigated the posterior nerve roots of the Petromyzon, or sea lamprey. Impressed by Ernst Brücke's personality, he became an adept of the positivist school of Emil Du Bois-Reymond, who claimed that biology could be explained by physico-chemical forces whose effects are strictly deterministic. In March 1881, Freud was made doctor of medicine, while continuing his research and writing on subjects as distant from human clinical practice as the nerve cells of crayfish.

But his future as a laboratory researcher was called into question when he met Martha Bernays, who became his wife four years later. He needed to provide an income for his future household, and followed the advice Brücke had given him in June—to abandon pure research and go into medical practice. This prospect failed to excite Freud, as he wrote many years later, "After forty one years of medical activity, my self-knowledge tells me that I have never really been a doctor in the proper sense. I became a doctor through being compelled to deviate from my original purpose; and the triumph of my life lies in my having, after a long and roundabout journey, found my way back to my earliest path. I have no knowledge of having had any craving in my early childhood to help suffering humanity. My innate sadistic disposition was not a very strong one, so that I had no need to develop this one of its derivatives. Nor did I ever play the 'doctor game'; my infantile curiosity evidently chose other paths. In my youth I felt an overpowering need to understand something of the riddles of the world in which we live and perhaps even to contribute something to their solution" (1927a).

Freud worked in various departments of the Vienna General Hospital to complete his training. While continuing his research on cerebral anatomy and pathology, he became interested in psychiatry (while working with Professor Theodor Meynert) and the nascent field of neurology. This very likely contributed to Freud's failure to reap the rewards of his research on cocaine, which he had begun in 1884. More preoccupied with its euphoric effects and what he incorrectly believed to be its ability to serve as a substitute for the opiates, he missed the opportunity to discover its local

ocular anesthetic properties. For several years he continued to ingest a certain amount of cocaine to overcome his timidity and increase his ability to work, which he discussed openly in his correspondence.

Appointed privat-docent in July 1885, he requested a grant to study neurology with Jean Martin Charcot in Paris. His internship at the Salpêtrière Hospital from October 13, 1885, to February 23, 1886 derailed his other projects, by exposing him to disturbances of mental origin. In terms of etiological research as well as his career as a specialist in neurology, the clinical lessons of the Parisian master, then at the height of his glory, demonstrated to Freud the importance of syndromes that had until then been characterized as "hysterical." Charcot's personality fascinated Freud and this first trip outside the Viennese family circle was to have a decisive effect on his future.

After returning to Vienna he set up a private practice on April 25, 1886, after a short stay in Berlin working with Professor Joseph Baginsky, where he familiarized himself with pediatrics. This enabled him, over a ten-year period, to maintain a steady practice in the department of neurology that the pediatrician Max Kassowitz (1842–1923) had opened at the Vienna Institute for Child Diseases. Once established he was finally able to get married, which he did on September 13, 1886. But his attempt to become Charcot's spokesman among Viennese neurologists and psychiatrists met with open rejection, especially from Theodor Meynert. Demanding, vulnerable, and passionate, for years he interpreted criticism or ignorance of his contributions as a form of systematic hostility that he often attributed to anti-Semitism, which was widespread in Vienna, especially in academic and medical circles.

His solitude was broken by a meeting that would later develop into a close friendship that lasted for nearly fifteen years. Wilhelm Fliess, an otorhinolaryngologist (ear-nose-and-throat specialist) in Berlin, gradually became a confidant who could share some of Freud's doubts and research activities, and a witness to the clinical experiments and theoretical hypotheses that littered the long road leading to the birth of psychoanalysis. An extensive correspondence and several meetings, referred to as "conferences," enabled them to exchange ideas about their research, which often fell upon deaf ears when Freud clearly overestimated his friend's comprehension. They also exchanged personal information. For Freud it was the anxiety about

money and the birth of six children in succession, something Fliess's theories on menstruation and the hope that they brought of a possible method of contraception failed to resolve.

Their friendship gradually took the place of an earlier friendship with an older Viennese doctor, Josef Breuer. Breuer, who had helped Freud financially and professionally early in his career, had also related to him, in 1882, the story of his patient Anna O. and her treatment by the "cathartic method" that she and Breuer had invented. Having experimented with hypnosis for a period of time, Freud had determined that it was ineffective, especially after an 1889 visit to Nancy to see Hippolyte Bernheim, Charcot's rival. He then decided to make use of the "talking cure" Breuer had mentioned. This involved, in the attempt to overcome the patient's resistance, bringing back to consciousness an apparently forgotten memory, which had been repressed, of the first appearance of a symptom. This made hypnosis no longer necessary; gradually, the technique of incessant questioning it had given way to was in turn abandoned, in favor of the free association of ideas. Freud had developed the hypothesis of the unconscious, together with the idea that disturbances had their origin in the history of the subject's infantile sexuality.

These statements were shocking to many, especially because of Freud's public intransigence concerning them, and it was not without considerable reluctance, ultimately leading to the end of their friendship, that Josef Breuer agreed to cosign the *Studies in Hysteria* in 1895. Wilhelm Fliess remained his only confidant and the only one who listened to his theoretical suggestions and the results of his day-to-day clinical observations. Sexual etiology and childhood seduction by a parent were among the earliest etiological ideas, but the death of his father in October 1896 led Freud to question these ideas, and to practice the same methods on himself he had been using on his patients. His self-analysis continued throughout the summer and fall of 1897 and the discoveries followed: psychic reality, the Oedipus complex, and so on. Under various forms Freud would continue to question himself, as shown by his statement to James Jackson Putnam in 1911—"A self-analysis must be continued indefinitely. I note, in my own case, that each new attempt has brought surprises" (November 5 letter)—and the article dedicated to Romain Rolland, "A Disturbance of Memory on the Acropolis." (1936a)

Prompted by the frequency with which his patients spontaneously reported their dreams to him, Freud began to investigate their unconscious meanings. The first dream to which he applied his new method of interpretation through the fragmentation and association of ideas was the "injection given to Irma," of July 23, 1895. His systematic investigation of this dream became the origin of *The Interpretation of Dreams*, published at the end of 1899, but dated 1900 (1900a). It is a fundamental work in what Freud had referred to for the first time in 1896 (in an article published in French in the *Revue neurologique*) as "psychoanalysis."

The book was widely praised but sold poorly (421 copies in six years), although this did not impede his work. It was a period in which he described himself as a "conquistador," thereby summarizing the mixture of enthusiasm and obstinacy that characterized his personality. Anxious, suffering from hypochondriacal illnesses of the stomach and heart, preoccupied with the calculation of dates predicting his death, undecided about whether to continue or abandon smoking; there is nothing of the austere scholar depicted by his biographers. But he was primarily an indefatigable worker, who stayed up late at night to answer letters (a correspondence estimated at more than twenty thousand letters) and would fill large sheets of paper with his broad gothic handwriting.

As his friendship with Fliess waned, he prepared the *Psychopathology of Everyday Life* (1901b) and took notes for the Dora case, which was not published until 1905. Some of those who attended his courses at the university went to see him, either to be treated, like Wilhelm Stekel, or to discuss innovative theories with him. They formed the "Wednesday Psychological Society," which met every week and, in 1908, became the first Vienna Psychoanalytic Society. The publication of *Jokes and their Relation to the Unconscious* (1905c) and *Three Essays on the Theory of Sexuality* (1905d); followed by a collection of his earliest articles, *Sammlung kleiner Schriften zur Neurosenlehre aus den Jahren 1893–1906* (1906b); helped him break out of what he described as his "splendid isolation." Readers intrigued by the originality of his hypotheses came to visit him in Vienna: Max Eitingon in January 1907, Ludwig Binswanger and Carl Gustav Jung in February, Karl Abraham in December 1907, Sándor Ferenczi in February 1908. They were to form the core group of his future disciples.

In response to the growing number of followers and the high level of interest, the first International Psychoanalytical Congress was held in Salzburg on April 27, 1908. Freud spoke for nearly five hours on the Ratman (1909d), a case which, by systematizing non-directivity, helped establish the parameters of the psychoanalytic “framework.” Here the patient was stretched out on a couch with the psychoanalyst seated behind him, out of sight of the patient, sessions were held daily and lasted for about an hour, the patient was free to say whatever he wished. Freud laid down the groundwork for the theory of “transference” with the therapist and, in 1910, in response to Carl Gustav Jung’s affair with his patient Sabina Spielrein, the theory of the “counter-transference.” That same year, the risks of “wild” psychoanalysis led to the creation, at Ferenczi’s initiative, of an international psychoanalytic association to monitor the development of “die Sache” (the cause) and distinguish the wheat from the chaff among its practitioners.

Although Freud maintained friendly relations with Sándor Ferenczi—notwithstanding periods of tension and the short analysis his younger colleague began with him in 1914—until Ferenczi’s death in 1933, his relationships with his other students were often strained. Alfred Adler, who developed a theory based on aggression, the will to power, and organ inferiority, and rejected sexual etiology, distanced himself from Freud to found a new school in 1911. He was followed by Wilhelm Stekel in 1912. But the greatest disappointment came from Carl Gustav Jung, who in 1909 had been declared “successor and crown prince” by Freud, who had glimpsed the doors of academic psychiatry opening to him, along with the possibility that psychoanalysis would no longer be viewed as a “Jewish matter.” Their personal relationship, as shown in their correspondence, and the intellectual exchange this involved, encouraged Freud to study psychosis, using the *Memoirs of My Nervous Illness* by Daniel Schreber (1911c), and to speculate on anthropological issues, of which *Totem and Taboo* (1912–1913a) is the first expression.

However, Jung’s personality was such that he could not remain for long in the position of the submissive son, and his religious training and interest in mysticism led to no more than a superficial acceptance of Freud’s materialism and insistence on sexual etiology. This rejection of what was considered an outrageous and obscene “pansexualism” was fairly general, even

though Freud gradually enlarged the concept of sexuality, which the majority of his critics reduced to adult forms of genital sexuality. The concepts of “infantile sexuality” and “polymorphous perversity” were even more unacceptable to those who believed they sullied what was believed to be an original infantile purity.

As is often the case in such situations, Jung’s departure in 1914 served as a spur to Freud’s creativity, who wrote “On Narcissism: An Introduction” (1914c) and developed his analysis of the primal scene in his essay on the Wolfman, which he also completed that year (1918b [1914]). He also provided the first historical overview of the origins of psychoanalysis in *On the History of the Psycho-Analytic Movement* (1914d), which was intended to sway those who were still undecided between him and Jung.

The First World War seemed to sound the death knell for the young science of psychoanalysis. Freud’s sons were at the front and he initially supported a German victory. However, he soon revised his position, which he explained in “Thoughts for the Times on War and Death” (1915b). Times were difficult and material scarcity became a growing problem as war progressed. However, it was also a period of considerable intellectual creativity, and Freud laid out the groundwork for the broad theoretical foundations of psychoanalysis, primarily the twelve essays on metapsychology, only five of which (and the newly discovered draft of the twelfth) were published. In spite of his pessimism there was renewed interest in psychoanalysis among the public and within the medical establishment when it proved useful in treating war neuroses. The end of hostilities brought about a minor institutional triumph for, following the Fifth International Psychoanalytical Congress in Budapest (September 28–29, 1918), Béla Kun’s revolutionary government offered a university chair to Sándor Ferenczi. Another Hungarian, the rich brewer Anton von Freund, whom Freud analyzed, invested his fortune in “the cause,” which led to the creation of the Internationaler Psychoanalytischer Verlag, but he died of cancer in 1920.

Freud was sixty-five at this time, and around him he saw sickness and death. *Beyond the Pleasure Principle* (1920g) reflected this, with its theory of the repetition compulsion and the duality between a life impulse, Eros, and a death impulse, Thanatos, whose theoretical necessity Freud maintained until his death, despite the opposition of many psychoanalysts to such

“speculation.” In real life his daughter Sophie (he called her “Sunday’s child”) died during the Spanish flu epidemic, on January 25, 1920. Three years later, in April 1923, he experienced the first signs of cancer of the jaw, which had a profound effect on the remaining sixteen years of his life; that same year, on June 19, his favorite grandson, Heinele, died.

He was now sixty-seven years old and, although he often complained of growing old, this was but one of the many hypochondriacal conditions he had always referred to in his letters. His fear of death is most evident in his superstitious fears and morbid calculations, borrowed from Wilhelm Fliess, but the fateful days passed without event. Freud also showed considerable interest in telepathy and clairvoyance, and conducted experiments in this field, often together with Sándor Ferenczi.

In spite of his shortness, he was still the “professor” and was authoritarian with his family, his students, and his patients. He showed himself to be the undisputed leader of the psychoanalytic movement, interest in which he stimulated through his many publications. He had overcome pain and disappointment, and watched as the “cause” to which he had devoted his life continued to grow. Interest spread to France, and its identification with a founding father, a Moses—for Freud the creator of monotheism—seemed increasingly justified. It is in this context that his decision to become his daughter Anna’s analyst must be understood. This is not as unusual as it may seem, especially for the time, and Freud speaks of it in his letters. It was only after the Second World War that Anna Freud’s accession to the status of guardian of Freudian orthodoxy cast into oblivion a form of training so inconsistent with the strict criteria that had been laid out. There was a risk the lapse would be viewed as something very nearly incestuous.

With the onset of his cancer, old age and death became a reality for Freud. It was at this time that he strengthened the death instinct and deepened the concept of identification discussed in *Group Psychology and the Analysis of the Ego* (1921c). He also revised the theoretical model that he had been developing for the past quarter-century with the “second topographical” structure introduced in *The Ego and the Id* (1923b). Some of his contemporaries, like Otto Rank, were reluctant to accept Freud’s newest theories, which appeared to disturb the fantastic and somewhat unreal experience represented by the birth of psychoanalysis

for those who had lived through it. Freud’s life was now marked by painful and disfiguring operations that forced him to interrupt his activities while he recovered in the Weiner Cottage-Sanatorium or the Schloss Tegel clinic, which Ernest Simmel ran from 1927 to 1931 in Berlin. The uncomfortable prosthetic devices he was required to wear caused him to remain silent for long periods of time.

Change was in the works, however. There were disagreements within the secret committee, formed at the request of Ernest Jones in 1912 to provide support for Freud during Jung’s defection, and it ceased to exist entirely in 1927. The quarrels weren’t so much about who would inherit Freud’s mantle, as they were about jealousies and rivalries, all of which helped feed Freud’s increasingly pessimistic—some would say realistic—vision of the human race. The first generation of psychoanalysts had evolved and began to develop their own theories. It often fell to Freud to resolve the resulting theoretical disputes and arbitrate personal conflicts.

Freud never claimed to be a great therapist and was often irritated by the “*furor sanandi*” shown by some of his followers, notably Sándor Ferenczi, as being contrary to a strictly psychoanalytic attitude. Although he had encouraged the use of “active technique” in 1918–1920, he hesitated to complete the project for a “psychoanalytic method” that his followers demanded of him and which he had begun to write down in 1908. During this last period of his life, he devoted himself almost exclusively to training analyses. Having been a patient of Freud was widely viewed as a kind of diploma, and there was an unending stream of candidates, especially from North and South America.

His theoretical interest turned increasingly to what he felt to be his most important contribution: the importance of psychoanalysis to culture. It was in keeping with this that he resumed his anthropological ideas about the primitive horde and the murder of the primitive father, which had been introduced in *Totem and Taboo* (1912–1913a), extending their scope with the new theory of impulses, the importance of primal fantasies, and the concept of primary identification (in 1923b). In *The Future of an Illusion* (1927c), Freud analyzed religious sentiment; aside from being an affirmation of his scientific and materialist beliefs, the book also served as a warning against the religious leanings that jeopardized psychoanalysis. *Civilization and its Discontents* (1930a) resumed the discussion of

human destiny, torn between its contradictory impulses and condemned to negotiate the avoidance of suffering for its survival. Freud's focus on culture in his writings became increasingly obvious; he described a "process of civilization" whose evolution paralleled the process of mental development in the individual. The last essay, "*Weltanschauung*," in the *New Introductory Lectures on Psychoanalysis* (1933a) resumed these themes, which had also been discussed in his letter to Albert Einstein, "Why War?" (1933b), but it was in *Moses and Monotheism* (1939a) that Freud outlined the last great fresco of man's relation to culture, which continued to preoccupy him.

Freud continued to refine psychoanalytic theory. The second topographical model and the theory of impulses, "our mythology," as he called it in 1933, as well as upheavals in the psychoanalytic movement, led to new considerations and refinements. *Inhibitions, Symptoms and Anxiety* (1926d) is a response to the reduction of the Oedipus theory to the "birth trauma" proposed by Otto Rank in 1924, the first manifestation of a defection that would continue until 1926. "The Dissolution of the Oedipus Complex," (1924d) "Some Psychical Consequences of the Anatomical Distinction between the Sexes," (1925j) and "Female Sexuality" (1931b) provide an outline of the libido that was supported by the work of the first female psychoanalysts. The emphasis on a phallic phase responded to the criticism of Ernest Jones on Freudian views about femininity, discussed in chapter 30 of the *New Introductory Lectures* (1930a). There, Freud insists on the primordial role played by the threat and fear of castration. The ego defenses raised to counter the threat led Freud to introduce elements for a new approach to perversion, which he did in "Negation" (1925h). "Fetishism," (1927e) and his final manuscript, "Splitting of the Ego in the Process of Defense." (1940e [1938]) Freud gave increasing consideration to the death impulse in his clinical work and eventually it became not speculative but a key element of his theory, in spite of the opposition of many of his students.

Some of his older students passed away—Karl Abraham in 1925 and Ferenczi, who had grown distant from him, in 1933. The most important person in Freud's circle was now Anna, his daughter. While she was undergoing analysis, Freud arranged her initial contacts with the Vienna Psychoanalytic Society, to which she was elected a member in 1922. The worsening of his cancer and subsequent infirmity led to his

becoming increasingly dependent on his "Antigone," who began to represent him at conferences and accepted the Goethe Prize in his stead, when it was awarded in 1930 by the city of Frankfurt to acknowledge the literary value of his writing. She took his place at the funeral of his mother, Amalia Freud-Nathanson, who died at the age of ninety-five in September 1930. It is easy to understand why Freud looked askance at Ernest Jones and English psychoanalysts when, in 1925, they welcomed Melanie Klein and her theories, which contradicted the views of Anna Freud on child psychoanalysis.

Moreover, the Old World was crumbling, incapable of stopping the rise of Adolf Hitler. Freud's books were burned publicly in May 1933, and Jewish psychoanalysts were forced to flee or condemned to death. Initially, Freud negotiated in the hope of preserving the "cause," but the *Anschluss* forced him to face the bleak reality. With the assistance of Princess Marie Bonaparte, who, after an analysis begun in 1925, had become an attentive and influential friend, and the U.S. Ambassador William C. Bullitt, with whom he had attempted to write a psychological study of President Woodrow Wilson (1966b), he was able to emigrate with his wife and daughter to Great Britain on June 6, 1938. His other children as well as his brother Alexander left Austria, but his four sisters remained in Vienna; they died in the Nazi concentration camps in 1942 and 1943.

The "*peau de chagrin*" (Balzac's novel was one of the last books he read) began to tighten around Freud, who had settled on the outskirts of London, where he continued to write and see patients. The onset of the Second World War on September 1, 1939, and his physical decline led him to ask Max Schur, his doctor, to keep the promise they had made when they first met: not to give him a sedative but to shorten his suffering when he felt the hour was near. He died on September 23, 1939, and three days later his ashes were placed in a Greek urn that, knowing his fondness for antiques, Marie Bonaparte had given him.

Freud's death did not go unnoticed in spite of the upheavals in Europe and elsewhere. Aside from the eulogies and numerous critical assessments, it marked the beginning of a considerable expansion of psychoanalysis that began in the United States, a country Freud claimed to have little liking for. It also resulted in an astonishing idolization of Freud in the years following the war. For a time, under the impetus of the

lengthy biography written by Ernest Jones, Freud became a subject for hagiography; mention of his name took the place of original thinking and the “return to Freud” served as a theoretical pretext, for others as for Jacques Lacan in France. The home at Maresfield Gardens, where Martha Freud died in 1951, became, under the watchful eye of Anna Freud, the center of Freudianism and, after her death in 1982, was transformed into a museum, as was Freud’s apartment at Berggasse 19 in Vienna. In New York, Kurt Eissler began gathering documents and eye-witness accounts of Freud for the Freud Archives. However, because of his demand for secrecy, this material was for years kept from researchers, arousing their anger, exciting their curiosity, and giving rise to a number of spiteful rumors.

By the 1960s Freud’s books were often bestsellers. The body of Freud’s writings increased with the publication of his correspondence to his students and friends. His letters to Wilhelm Fliess, purchased in 1937 by Marie Bonaparte and miraculously preserved throughout the Second World War, provided insights into the birth of psychoanalysis, a theme that was to serve as inspiration for filmmakers and dramatists (among others, John Huston’s film, *Freud*, of 1962). Unfortunately, some passages were censored, which led to the growth of research on an unexpurgated history of Freud and psychoanalysis. Paul Roazen helped promote these efforts with his study on the relationship between Freud and Viktor Tausk (1969), which emphasized Freud’s responsibility in the suicide of this brilliant student and triggered a backlash against “orthodox” Freudians by adversaries who, thirty years later, would be labeled “revisionists.” Ardent supporters and angry critics confronted one another on a regular basis. Freud and his ideas were called into question by an increasingly large number of people, in a way compensating for the glorious early years psychoanalysis. The number of essays and criticisms multiplied with the discovery of historical documents—some authentic, some not. The anger and bitterness of his critics became increasingly obvious, betrayed by the excess of the accusations: there was an alleged attempt on Fliess’s life, reports of lies about his patients or errors of diagnosis by a Freud who was hungry for glory, tales of a ménage à trois involving Minna Bernays, and rumors of an abortion. A band of “moralists” obsessed with the “truth” about Freud and Freudianism kept up the pressure, especially in the United States.

On a more serious note, after the leading biography by Fritz Wittels, which had irritated Freud in 1924, and the monument erected by Ernest Jones from 1953 to 1957, a number of books have been written to describe Freud’s life and work, by serious scholars: Max Schur (1972), Ronald W. Clark (1980), Peter Gay (1988). Some of these presented original, and often questionable, interpretations of Freud’s work, such as the biographies by Frank Sulloway (1979) and Marianne Krüll (1979). The gradual appearance of new documents and the opening of the secret archives opened the door to future research and new assessments of Freud’s importance for the history and evolution of the civilization of his time and for human thought.

## FREUD'S SELF-ANALYSIS

Although Didier Anzieu's doctoral thesis (1975; trans. 1986) treated Freud's self-analysis, he had already published a briefer, more general text: *L'auto-analyse: Son rôle dans la découverte de la psychanalyse par Freud, sa fonction en psychanalyse* (Self-analysis: its role in the discovery of psychoanalysis by Freud and its function in psychoanalysis; 1959). There one finds, in addition to research on the self-analysis of the young Freud, a study of self-analysis in general, both in literature (the surrealists) and in the clinic, before and after treatment.

*Freud's Self-analysis* (1986) dropped the study of self-analysis in general and featured an epistemological and historical approach to Freud's self-analysis, primarily as revealed in *The Interpretation of Dreams* (1900a), in relation to the discovery of psychoanalysis.

Anzieu avoided classic biography (such as the one by Ernest Jones [1953–1957]) in order to apply the psychoanalytic method to its creator. His work is supported by a thorough chronological inventory of the documents of the self-analysis (dreams, screen memories, slips, instances of forgetting, and parapraxes) from 1895 to 1902, the date of the break with Wilhelm Fliess and the foundation of the Psychoanalytic Society of Vienna. A chronological list of the inventory itself is appended at the end of the work.

The central focus of the book is essentially an investigation into the subjective conditions that led Freud to create psychoanalysis. This focus is also part of a major preoccupation of Anzieu's, the psychoanalysis of creative genius (1974).

Especially notable in *Freud's Self-Analysis* are the creative subject's masochism, the mother's favoritism for the future genius, Freud's mentally active attitude in relation to the primal scene, the creative subject's "heroic identifications," and also the castration anxiety that tends to paralyze or destroy creativity. In this regard Anzieu emphasizes the supportive role played by Fliess, remarking along the way that there is no serious self-analysis if it is not spoken to someone.

At a time when the history of psychoanalysis still captured only limited interest in France, Didier Anzieu produced both a reference work for researchers and a valuable example of the inseparability of psychoanalytic theory from the history of the discovery of its concepts, and thus from its authors.

## FREUD, THE SECRET PASSION

The first film made about Sigmund Freud, *Freud, the Secret Passion* was directed by John Huston and was based on a very long script proposed by Jean-Paul Sartre in 1958 but reworked by Charles Kaufmann and Wolfgang Reinhardt (Sartre insisted that his name not appear in the credits); it featured Montgomery Clift in the role of Freud and Susannah York in the role of Cecily Koertner. Released in 1962, it was distributed in France under the title *Freud, désirs inavoués*.

The film tells the story of the treatment by hypnosis of an hysterical patient, Cecily, by the young Freud, who struggles to bring her into awareness of the sexual origins of her problems and runs up against hostility from those close to her. Freud almost invariably looks furious, “somber,” “stiff,” “ashen-faced”—stuck in the shackles of his neurosis until he achieves a state of lucid Sartrean consciousness by getting rid of the protective and hated father figures with whom he had surrounded himself. Pushed by the hostility of the Viennese medical community, spurred on by anti-Semitism, he becomes “engaged,” according to Sartre’s ideas, in a revolutionary combat for the liberation of oppressed hysterics, unjustly called “fakers.” He is constructed in the image of the author-philosopher, who was known for repeatedly taking a stand in defense of blacks, the Algerians, Jews, workers, or those who, like Jean Genet, had been labeled from childhood and condemned to be what others had designated them to be.

It is these violent external conflicts, symbolized by the three “fathers” who appear—an alcoholic Theodor Meynert, a senile Jakob Freud, and a lame Josef Breuer—that for Sartre constitute the main motivation for Freud’s actions, although Sartre poses an additional, underlying question: What was Freud’s sexuality? The film glosses over this aspect of the script and of Sartre’s explanation of Freud’s violence by means of a sexual contention that remains inexplicable and unexplained. “But your Freud, he was neurotic down to the marrow!” Sartre once said jubilantly to Jean-Bertrand Pontalis (Pontalis in Sartre, 1984/1985).

On July 15, 1958, considering Ernest Jones’s hagiography of Freud, Simone de Beauvoir noted in her journal: “Jones doesn’t explain very well what Freud’s particular neurosis was, nor how he got rid of it. Perhaps the fact that Freud’s daughter is still alive embarrasses him, but there are certain questions he doesn’t ask: Freud’s relationship with his wife, for example. It’s

easy enough to say that they [sic] were ‘excellent’; but Freud’s depressions and migraines are either directly linked to his domestic life or they are not. Which? After all, he was an extremely vital man; witness his passionate love of travel. Monogamous, all right; but why, exactly? Jones avoids the question. . . . The most moving moment is the one where he discovers his mistake about hysteria. He had believed that all his women patients had been ‘seduced’ by their fathers . . . and he realized that his patients had invented it all. What a slap in the face! What a shock! . . . It is moving to watch these concepts that have become so scholastic, mechanical—transference for example—reveal themselves in such vital experiences” (1963/1965, pp. 430–431).

In a 1965 interview, Huston confided to Robert Benayoun: “The basic idea of Freud the adventurer, the explorer of his own unconscious, was mine. I wanted to concentrate on this episode like in a detective plot.” He also explained: “To me, hypnosis is something magical, almost sacred” (Benayoun, 1965).

And indeed, the hypnotic treatment and catharsis are what are presented to the public. Huston’s Freud conforms to the classic movie character who, one against all, and above all, against himself, must make triumphant a truth that he reveals through pain. Despite the sugar-coatings he added to the original script, Huston had to submit to the explicit and implicit imperatives of American censorship and adapt his film to the then-dominant ideological demands of the world of psychiatry and psychoanalysis. He later deplored the fact that his film had been “literally mutilated of its essential scenes” (Benayoun, 1965).

Many were concerned that Freud’s image might be ruined by his promiscuity in overly shocking scenes. It was essentially Anna Freud who opposed the idea of any film on her father. It is known, for example, that through the intermediary of Marianne Kris, she convinced Marilyn Monroe (who had consulted her during a shoot in London) not to play the role of Cecily, which Huston had in mind for her, according to Donald Spoto’s *Marilyn Monroe: The Biography* (1993). She also opposed the idea of any living member of the family being represented, which explains the childless marriage attributed to Freud onscreen. The theme of prostitution, which Sartre emphasized so constantly that it can be wondered whether this was his answer to his questions about Freud’s sexuality, was also strongly challenged by Hollywood’s censors, advised by some

eminent psychoanalysts (Walker, 1993). At the time, as Pontalis pointed out, studies of the history of psychoanalysis were virtually nonexistent.

Although the film can be criticized on many counts, its great merit must be acknowledged; it helped to shatter the conventional portrait of an old, stern, bespectacled, and white-bearded Freud. Even though it may seem artificial, excessive in the grimaces and wounded looks given by Montgomery Clift, the character seen onscreen made it possible, in its day, to imagine a Freud who was closer to the young viewers discovering him for the first time.

## **FREUND TOSZEGHY, ANTON VON (1880–1920)**

Anton von Freund Toszeghy, director of a brewery in Budapest, Hungary, a doctor of philosophy, and a patron of the psychoanalytic movement, was born in 1880 in Budapest and died on January 20, 1920, in Vienna, Austria. The son of a rich, ennobled industrialist who founded the state brewery of Steinbuch A. G., von Freund spent an idyllic childhood with his

brother, Emil (later codirector of the brewery with him), and two sisters on a magnificent property, the remains of which are still visible next to the brewery. Here Sigmund Freud spent the summer of 1918, far from the penury of wartime, receiving visits from Sándor Ferenczi, going for carriage rides along the Danube, correcting proofs of his articles, and analyzing one of von Freund's sisters, Kata (the future wife of Lajos Lévy, a physician, analyst, and director of the Jewish Hospital).

Von Freund underwent analysis with Freud and even directed a course of an analysis, which he reported on to Freud. The two men became friends, and von Freund went on to play an important role in the psychoanalytic movement. An eminent figure in Budapest, and practical and generous in temperament, he was initially the main organizer of the Fifth Congress of 1918 and was the founder of the first center for research on child psychology (for which he recruited Melanie Klein, one of Ferenczi's patients). He financed the publishing house Internationaler Psychoanalytischer Verlag in Vienna as well as an analytic outpatient clinic in Budapest (the latter was never actually created). He died prematurely of cancer, and Freud composed a moving obituary for this "providential" man.

## **FRIEDLÄNDER-FRÄNKL, KATE (1902–1949)**

Kate Friedländer, psychoanalyst and physician, was born in Innsbruck, Austria in 1902, and died February 20, 1949, in London.

Kate Friedländer's birthplace was one of the most anti-Semitic parts of Austria, and her parents were middle-class Jews. Her two brothers both died in early childhood, and she had a gifted younger sister whom she greatly admired.

She obtained her medical degree at the University in 1926, but frustrated by the narrow outlook in her

native town, she left for the Weimar Republic and settled in Berlin. There she became an assistant to Professor Karl Bonhoeffer at the University psychiatric clinic (The Charité), where many of the young doctors were interested in psychoanalysis. In 1930 Kate Friedländer obtained her second medical degree. She was interested in neurology and in 1932 published a paper titled "A Clinical Entity to be separated from Multiple Sclerosis." She wrote other papers, including one on general paresis and the social integration of those who had been treated for this condition with malaria therapy. This reflected her keen interest in social affairs and strong social conscience, an interest reflected in her involvement in the Juvenile Court in Berlin. Her interest in delinquency lasted all through her professional life. Two of her early papers, "The Somatic Origin of Anxiety" (1933) and "The Biological Basis of Freud's Theory of Anxiety" (1935), proclaimed her deep interest in this subject.

Friedländer's achievements in Berlin, and her pleasure in them, were overshadowed by the success of the Nazis. Together with her husband and two-year-old daughter, she emigrated to London in 1933, to become first an associate and then a full member of the British Psychoanalytical Society. In 1936 she took her third medical degree in Edinburgh, and in 1943 her D.P.M., in London. Her husband became increasingly mentally ill and, although she fought hard to save her marriage, the first steps toward an eventual divorce were taken in 1935.

Although her interests were wide, Kate Friedländer's contributions to psychoanalysis developed along two main lines, one linked closely with Edward Glover and the other with Anna Freud. In the 1930s she had already pursued her interest in delinquency and joined Glover in the Institute for the Study and Treatment of Delinquency; she published a book, *The Psycho-Analytic Approach to Juvenile Delinquency*, in 1947. With the arrival of Anna Freud she was greatly stimulated by her work with children and by the eventual creation of the War Nurseries. It was she above all who persuaded Anna Freud to found the child training course, in which she took an active part and which later became an integral part of the Hampstead Child Therapy Course and Clinic—an enterprise that would have delighted her had she lived to see it.

It was her remarkable vision and energy that led her to set up Britain's first Child Guidance Clinic—that of West Sussex, of which branches were opened in Horsham, Chichester and Worthing, supported by

enthusiastic students who had worked in the Hampstead Nurseries. These are the achievements for which she is best remembered. She played as well a full part in the life of the British Psychoanalytical Society, and submitted a number of written statements to the special meetings on the Controversial Discussions. But when Edward Glover, whom she strongly supported, resigned from the Society in 1944, she withdrew as well.

She was a keen and active sportswoman, an adventurous swimmer who defied tide and uncongenial weather, fond of tennis, skiing, ice-skating, and mountaineering. She died, with a great deal still to offer, on February 20, 1949, from carcinoma of the lung with brain secondaries, at the early age of forty-six, with her second husband, a well-known radiologist, at her bedside.

## FRIENDSHIP

From a psychoanalytic viewpoint, friendship is one of the bonds that arise from sexual impulses when their attainment of a directly sexual goal is inhibited. However, this is a process of inhibition rather than sublimation. This approach to a sexual satisfaction that is never consummated forms the basis for especially strong and enduring ties between people.

Both in adolescence and in adulthood, Freud had some intense and deep friendships, but he did not

write on this subject at any great length. However, friendship, as he defined it, plays a key role between individuals to the extent that it appears as a metaphor for those relationships between two people that, unlike the state of romantic love, lead to a broader form of unity. In this sense, Freud connects it with these other ties that are based on the aim-inhibited sexual impulses: the tender relationship between parent and child, and conjugal love in which the sexual relationship has gradually fallen into second place. These two bonds form the basis for the broader unity that is constituted by the family, just as friendship is the foundation for the creation of social ties.

However, these different kinds of bond should not be confused, because the homosexual libido can develop into friendship whereas the conjugal bond is in essence heterosexual and the parent-child relationship involves an elaboration of the parent's narcissistic libido. These ties can even conflict: "a pair of lovers are sufficient to themselves, and do not even need the child they have in common to make them happy" (1930a [1929], p. 108).

At the theoretical level, Freud refined the concept of sublimation by distinguishing it from the inhibition of the aim of sexual satisfaction and, in this respect, friendship constitutes a good example. Using the examples of Plato and St. Paul (1921c), Freud emphasized that the libido corresponds to love understood in a wide sense, including, along with the state of romantic love, self-love, filial and parental love, friendship, and even the attachment to physical objects and abstract ideas. The sexual basis of these ties is attested to by the fact that they retain some of the primary sexual aims: "Even an affectionate devotee, even a friend or an admirer, desires the physical proximity and the sight of the person who is now loved only in the 'Pauline' sense" (pp. 138–139).

However, these aim-inhibited drives are not only capable of being combined with non-inhibited drives but can also be transformed back in the opposite direction to revert to the directly sexual form from which they have originated. Friendship, admiration, and even the religious bond therefore remain close to the sexual bond itself.

There is a particular kind of friendship that merits further consideration—the form that is shared by male homosexuals and leads to the formation of social ties. In relation to Daniel Paul Schreber, Freud wrote

that homosexual tendencies "help to constitute the social instincts, thus contributing an erotic factor to friendship and comradeship, to *esprit de corps* and to the love of mankind in general. How large a contribution is in fact derived from erotic sources (with the sexual aim inhibited) could scarcely be guessed from the normal social relations of mankind" (1911c [1910], p. 61). He bases this on the hypothesis that the shared homosexual impulse is generally aim-inhibited and constitutes a source of unused libido that is therefore available for these various ties. Moreover, the degree of homosexual drive in an individual determines their particular capacity for forming such ties, provided that they continue to inhibit it from direct satisfaction.

This highly simplistic economic perspective, which ignores the entire tradition of homosexual friendship in antiquity and mentions only the form that is not aim-inhibited, is somewhat baffling. This is a long way removed from the depth of Freud's analysis of the resexualization of sublimated homosexual ties that leads via narcissism to paranoia (1911c [1910]). However, Freud continues to subscribe to this specific affinity between the homosexual bond and the constitution of the group through friendship and *esprit de corps*: "It seems certain that homosexual love is far more compatible with group ties, even when it takes the shape of uninhibited sexual tendencies" (1921c, p. 141).

While the "social sense," a "sublimated" (or, rather, inhibited) form of the male homosexual libido, may take the form of love of humanity, it can also be extended to a relatively large group. Solidarity is therefore the form of expression given to the recognition of what is identical to the self.

**FRIGHT**

Fright, a state of sudden, extreme fear, is provoked either by a situation experienced as an external danger or by the feeling of a high probability of danger. Situations capable of causing fright are often associated with a risk of physical or mental death.

The term *fright* appeared in the Freudian corpus for the first time in the “Preliminary communication” (Breuer and Freud, 1893a) to the *Studies on Hysteria* (1895d). In this paper Freud evokes the links between certain forms of hysteria and traumatic neurosis, combined in the term *traumatic hysteria*. Unlike the physical expression of hysteria, the affect of fright is mental trauma.

In a clinical context, fright is accompanied by a state of shock and stupor or, more rarely, by disordered agitation. But ever since Freud, psychoanalytic clinical practice and theory have always emphasized the passivity of fright and total lack of preparedness of the subject in the face of the situation, which are due as much to the totally unforeseeable nature of the event as to the potential for concrete danger. It is in this sense that fright must be differentiated from fear (a concept implying a definite object) and anxiety (a central psychoanalytic concept connoting the anxious expectation of an external or internal danger that needs to be confronted). As with many concepts, this distinction between internal and external is primarily metaphoric. For example, “sexual fright” designates a cataclysmic eruption that has a disorganizing effect on the subject’s mental life. Fright is associated with the splitting of the ego, the castration complex, and the perception of reality.

In light of the distinctions above, the concept of fright deserves a place in modern psychoanalysis, for it allows psychoanalysts to accurately assign theoretical and clinical categories and to avoid terminological ambiguity.

**FRINK, HORACE WESTLAKE (1883–1936)**

Horace Westlake Frink, American psychoanalyst and physician, was born in 1883 in Millerton, New York, and died on April 19, 1936, in Chapel Hill, North Carolina.

A physician uncle in Hillsdale, NY, raised Frink, an orphan. He studied with Adolf Meyer while attending Cornell University Medical College, from which he received his medical degree in 1905.

Although Abraham Arden Brill, Frink’s first analyst in 1909, considered himself the most prominent analyst in America, after James Jackson Putnam’s death in 1918 Freud was unhappy with the prospects of the direction of his movement in the United States. Between 1921 and 1923, for two periods of analysis, Frink was in treatment with Freud in Vienna, and Freud decided Frink was the most brilliant of his American disciples, and picked Frink to replace Brill as his deputy in America.

Frink was married and had two children. He was a Gentile in a movement known for its many Jews, which could help account for Freud’s enthusiasm for him. At Freud’s direction he became president of the New York Psychoanalytic Society.

During Frink’s second analysis with Freud, Frink underwent a psychotic breakdown which Freud failed to recognize as such. Frink suffered so much depersonalization that he had to be taken care of for a time by a male attendant. Freud interpreted Frink’s difficulties as simply part of the analysis.

Earlier, back in New York, Frink had fallen in love with a patient of his, an immensely rich, Jewish, married woman named Angelika Bijur. Her husband, also in analysis, threatened a legal suit against what he thought was the misconduct of his wife’s analyst. Frink had guilt feelings about abandoning his first wife who, however, was willing to divorce for the sake of his health. Freud saw Frink’s new fiancée in Vienna and encouraged the new union. Shortly before the wedding the bride had her doubts about Frink’s stability. Freud, however, insisted that Frink’s analysis was “complete” and that he was fully able to go through with the marriage. Freud thought that the match would be good for the analytic movement.

Bijur’s first husband died of cancer, and shortly after the wedding Frink’s own first spouse passed away. Frink felt he was unable to carry on, and put himself under the psychiatric care of Adolf Meyer. Frink’s second wife repudiated Meyer’s recommendation of patience, and ended the marriage. She was furious at the way she thought that Freud had misled her, and irritated that he had blamed her for supposedly having failed Frink over money.

Frink did attempt a professional comeback after leaving the hospital. But at an analytic meeting in New York, Brill read a letter from Freud to another analyst stating that Frink was unfit to execute the commission to which Freud had appointed him, because he was suffering from a mental disorder.

Frink spent the next decade raising his children. He was able to live on the money they had inherited from their mother, which Angelika had given as part of the divorce settlement. Frink re-married in 1935, but was suffering from heart disease; he died at a hospital in a state of manic excitement.

Frink’s textbook *Morbid Fears and Compulsions* (1918) was the best psychoanalytic book of its kind in English at the time.

Frink, who had become the center of a great scandal, turned against analysis but did not in the remotest way blame Freud for what had happened. Freud thought that Frink’s demise was the last straw in Freud’s efforts to help the Americans, and it confirmed Freud in his anti-American prejudices.

## **“FROM THE HISTORY OF AN INFANTILE NEUROSIS” (WOLF MAN)**

The twenty-three-year-old Dr. Sergueï Pankejeff, alias the Wolf Man, first consulted Freud in the beginning of February, 1910, and became the subject of the longest and, by general consent, greatest of Freud’s case histories. Dr. Pankejeff’s health had collapsed in his eighteenth year after a gonorrheal infection, and by the time he met Freud, he was incapacitated and entirely dependent on an attendant. In Freud’s eyes, he had an obsessional neurosis; modern opinion favors the diagnosis of borderline pathology.

Dr. Pankejeff felt that he was caught off from the world by a “veil,” which could be torn away only after he received an enema. In a letter addressed to Sándor Ferenczi at the very beginning of the analysis, Freud wrote about his patient, “He would like to use me from behind and shit on my head.”

In the case history, Freud focuses on the patient’s early life. The very title of the case history, “From the history of an infantile neurosis,” indicates a drastic expository selection from the four and a half years of the patient’s first analysis with Freud. Freud used the case to demonstrate the lasting neurotic impact of conflicted infantile sexuality in order to refute the theories of Alfred Adler and Carl Jung. Despite Freud’s claim of a complete cure, the Wolf Man continued to be seriously ill for the remaining half century of his life and was seen by many therapists (for accounts of Dr. Pankejeff’s second analysis with Freud and the subsequent prolonged analysis with Ruth Mack Brunswick, see Gardiner, 1971).

The case history is noteworthy for having brought to attention the psychodynamics of the following phenomena: the primal scene (adults engaged in sex), the early oral organization of the libido, primary feminine impulses, deferred effects, the rare instance of a trauma arising from a manifest drama, the complexities of anal eroticism and the castration complex, and the multiple vicissitudes of an obsession. In a technical sense, the case is remarkable as an example of a most elaborate analysis of a dream, a detailed reconstruction of an infantile scene, and strategic reliance on forced

termination of the analysis. Given the paucity of transference between Dr. Pankejeff and Freud in the clinical setting, one may suspect that the case material was immeasurably better understood and more highly organized in Freud's mind than in the patient's.

Freud described a whole range of mental disturbances in Pankejeff's young life, ranging from infantile anorexia and panic attacks to deficient impulse control, phobia, entrenched sadomasochistic tendencies, and various symptoms of obsession. Because he emphasized oedipal-derived pathology, Freud attributed major importance to the primal scene and the castration complex. Capital events determining the patient's young life were a primal scene observed when he was one and a half, a threat of castration from his nursery maid Grusha about a year later, his sister's seduction when he was three and a quarter, his traumatic dream when he was four, the outbreak of symptoms of obsession a half year later, and hallucinations at the age of five.

In a mimetic gesture, Freud devotes part 4 of his case history to the traumatic dream that Pankejeff had at age four about wolves (whence the patient's pseudonym). According to Freud's minute reconstruction, which mined each detail of the dream, the primal scene of *coitus a tergo* (vaginal penetration from behind) observed by the patient as an infant finally returned much later in a dream when he was capable of a deferred understanding. After writing up the case in 1914, Freud himself had a deferred understanding about the authenticity of the early primal scene (Freud did not include that revision in part 4 but deferred its inclusion, and hence his readers' ability to understand it, until part 5).

Notwithstanding Freud's reserve about the factuality of the primal scene, his comparative elaboration of clinical material in the case history remains problematic. According to Freud, the Grusha scene was more certain than the primal scene (1918, 113 ff.), yet he mentions the Grusha scene on 12 pages, or 10 percent of the case (115 pages), whereas he refers to the "less certain primal scene" on 46 pages, or about 40 percent of the case. Such a discrepancy over what is salient in the very showpiece of Freud's case histories proportionately undercuts its intrinsic value.

Another salient feature of the case history is that the initial years of treatment produced hardly any change. Freud submitted his patient to a "long education"

before Pankejeff would share in the work of analysis, and once he did with any success, he forsook further cooperation. He thus became "unassailably entrenched behind an attitude of obliging apathy." Freud then took the drastic measure of unilaterally setting an irrevocable, fixed date for terminating treatment. Reacting to the pressure of a deadline, Pankejeff reportedly lessened his resistance and came forth with a flood of material that clarified Freud's comprehension of the infantile neurosis. In light of the patient's passive character and superficial compliance, many analysts hold that only Freud believed that there was a clinical breakthrough, not his patient.

## FROMM, ERICH (1900–1980)

Erich Fromm, a German psychoanalyst and sociologist, was born on March 23, 1900, in Frankfurt, Germany, and died on March 18, 1980, in Locarno, Switzerland. He grew up in a Jewish family in Germany. From age eighteen to twenty-two he attended the University of Heidelberg, where he studied sociology, receiving his doctorate under the supervision of Alfred Weber. He wrote his thesis on Talmudic law in three separate Jewish communities. In 1924 he met Frieda Reichmann, who became his first analyst and

later his wife. At the time she was running a small sanatorium in Frankfurt. Fromm had two other analysts before he moved to Berlin, where in 1927 he was analyzed by the Viennese Hanns Sachs.

From the 1930s, after about ten years of being a traditional Freudian, Fromm began to look critically at the central moral and philosophical bases of Freud's writings. As a Marxist, Fromm was shrewd in spotting the middle-class, liberal assumptions Freud had taken for granted. As a psychologist, Fromm's special theoretical contribution was an understanding of the social forces that stabilize or undermine the political community. In *Escape from Freedom* (1941), a landmark in modern social science, Fromm enunciated the important concept of "social character" in building theoretical bridges between the study of the individual and the study of society. He was fascinated with the problem of social change and how sociological issues can be understood in the light of depth psychology. He also wanted to examine people in their social milieus. Fromm had his predecessors within psychoanalysis, the most notable perhaps being Wilhelm Reich, who also tried to synthesize Marxist and Freudian principles. Fromm has his detractors: not only strict psychoanalysts but also Marxist hardliners, who have been determined to dismiss Fromm as a so-called social democrat.

After Fromm fled from Nazi Germany in 1933, he moved to the United States, where he was soon in contact with a whole new school of analysts, anthropologists, and sociologists that became known as the neo-Freudian movement. This group included analysts like Harry Stack Sullivan, Karen Horney, Abram Kardiner, and Clara Thompson, as well as academics such as Margaret Mead, Ruth Benedict, and Ralph Linton. Fromm found that he had been quietly dropped as a direct member of the International Psychoanalytical Association. Despite this setback, he was made clinical director of the William Alanson White Institute in New York City, which focuses on training psychoanalysts, and served from 1946 until 1950.

In 1949 Fromm moved for much of the year to Mexico for his second wife's health. There he founded the Mexican Institute of Psychoanalysis, where his ideas are still being taught in a clinical context as of 2005. He also continued to write in his isolated retreat near Mexico City. Especially in Germany, where the International Erich Fromm Society is headquartered,

but also in Italy and elsewhere, Fromm's clinical concepts are still being extended.

Millions of people around the world read Fromm's works, but it has usually been his social philosophy that catches the public's attention. Works like *The Sane Society* (1955) represent a serious indictment of modern capitalist culture. *Man for Himself* (1947) was an early popular effort to extract a humanitarian core from analytic teachings. *The Art of Loving* (1956) is perhaps Fromm's best-selling book. *The Anatomy of Human Destructiveness* (1973) showed the comprehensive nature of Fromm's system of thought. *To Have or to Be?* (1976) was a widely read restatement of his attempt to connect humanistic Marxism with analysis. More technical works like *The Forgotten Language* (1951) and *Psychoanalysis and Religion* (1950) are of direct clinical relevance, even though they are no longer studied at most professional training centers.

Fromm was one of the first and boldest to challenge the ideological underpinnings of Ernest Jones's quasi-official three-volume life of Freud. In *Sigmund Freud's Mission* (1959) he gave a path-breaking response to the orthodox version of Freud's career and its controversies. For example, he asked some serious questions about Freud's relationship with his mother—a subject that has not received adequate attention in the literature. Fromm also discredited Jones's account of the supposed mental deterioration of both Sándor Ferenczi and Otto Rank.

Fromm, one of the most conceptually clear-cut thinkers in the tradition of dissenting analysts, claimed to be truer to the intellectually radical implications of the spirit of Freud's thought than the organized following generally supposed to be Freud's heirs. One cannot correct some central problems where Freud could be mistaken by piously fixing translations or re-editing Freud's writings. By pointing out some of these central problems, Fromm ranks as an important critic of Freud's. Part of Fromm's strength came from a deep identification with Freud as a warrior of the spirit; to be genuinely like Freud meant also to be independent-minded. Fromm proved fearless in expressing his analytic convictions, even though the orthodox-minded to reacted to him by branding him as a dissenting voice.

## **FROMM-REICHMANN, FRIEDA (1889–1957)**

Frieda Fromm-Reichmann, psychoanalyst and physician, was born on October 23, 1889, in Karlsruhe, Germany, and died on April 28, 1957, in her cottage on the grounds of Chestnut Lodge, Rockville, Maryland, in the United States.

Fromm-Reichmann was the oldest of three daughters. Her father was a Jewish bank personnel manager and her mother founded a girls' school, which well prepared Frieda to be among the very first German university-trained women. She graduated in 1913 from the University of Königsberg medical school where her dissertation mentor was Kurt Goldstein, with whom she worked during World War I. As a major in the Prussian Army she ran a hospital for soldiers with

brain injuries. She then joined the psychotherapy staff of the Lahmann Sanatorium, Weisser Hirsch, under J. H. Schultz's directorship (1920–1924).

Fromm-Reichmann received her psychoanalytic training at the Berlin Psychoanalytic Institute (1925), where her training analyst was Hanns Sachs. She opened her own sanatorium where kosher food was served (nicknamed the "Thorapeuticum"), working closely with Georg Groddeck, as well as Sándor Ferenczi. She was married to Erich Fromm, who was ten years younger than she. This marriage lasted for about four years. Along with Karl Landauer, Heinrich Meng, Georg Groddeck, Siegfried Fuchs, and Franz Stein, they founded the Frankfurter Institut. With the onset of World War II she went first to Alsace-Lorraine, (1933–1934) then Palestine (1934), and in 1935 to the United States.

At Chestnut Lodge, as its Director of Psychotherapy, she helped its owner and medical director, Dexter M. Bullard, Sr., make it the premier center for the psychoanalytically-oriented treatment of schizophrenia, and worked closely with Harry Stack Sullivan. She was a training analyst of the Washington-Baltimore Psychoanalytic Institute and president of its Society (1939–1941), and a popular teacher at the Washington School of Psychiatry.

Her central thesis was that psychotic patients' communications are understandable, that they magnify their sense of their destructive potential and thus isolate themselves, suffering enormous loneliness and dread. If the therapist understands his or her countertransference and thus is not made anxious by the psychotic patient, recovery is possible. Essentially all psychiatrists trained during the 1950s, 1960s and 1970s read her book *Principles of Intensive Psychotherapy*. Joanne Greenberg, a patient of hers who recovered from schizophrenia, wrote the bestseller *I Never Promised You a Rose Garden*, in which Fromm-Reichmann appears as Dr. Fried.

## FRUSTRATION

The word *frustration*, now in common usage, refers to the state of someone who denies himself, or who is denied, drive satisfaction.

Beginning with “Heredity and Aetiology of the Neuroses” (1896a), a paper written in French, Freud identified sexual frustration as conducive to anxiety neurosis. In “My Views on the Part Played by Sexuality in the Aetiology of Neuroses” (1906a), to refer to frustrated excitation, he used the word “frustrane,” a word probably formed from the German verb “frustrieren” (to frustrate), which was in everyday usage. The German language has no equivalent to the substantive form “frustration,” which was later used in English and the romance languages to translate “Versagung,” the word used by Freud in a slightly different sense from the meaning it then had of renunciation and sometimes refusal to describe frustration. Freud was aware of this difficulty and did not neglect to discuss it.

In his article “Types of Onset of Neurosis” (1912c), Freud used the word “frustration” (*Versagung*) for the first time to describe both internal and external factors that cause neurosis. He wrote, “Psycho-analysis has warned us that we must give up the unfruitful contrast between external and internal factors, between experience and constitution, and has taught us that we shall invariably find the cause of the onset of neurotic illness in a particular psychical situation which can be brought about in a variety of ways” (p. 238). In essential particulars he continued to hold this view, going on to write, for example, about a narcissistic form of frustration.

The concept of frustration seems to cover the idea of privation, while sometimes going beyond it. Freud was aware of a conceptual difficulty here, and he attributed its resolution to psychoanalysis rather to the

innate genius of the German language. In *The Future of an Illusion* (1927c), he wrote, “For the sake of a uniform terminology we will describe the fact that an instinct cannot be satisfied as a ‘frustration,’ the regulation by which this frustration is established as a ‘prohibition’ and the condition which is produced by the prohibition as a ‘privation’” (p. 10). Later in this work he specified the drive urges subject to frustration, prohibition, and privation: incestuous, murderous, and cannibalistic wishes.

In the view of English-language authors, Melanie Klein in particular, frustration incites the reality principle and modulates psychic functioning. “Neurotic children do not tolerate reality well, because they cannot tolerate frustrations. They protect themselves from reality by denying it. What is fundamental and decisive for their future adaptability to reality is their greater or lesser capacity to tolerate those frustrations that arise out of the Oedipus situation” (Klein, 1975, pp. 11–12). Here the feeling of frustration appears to complement the idealizing impulse pointed out by Jean-Michel Petot (1982), who also suggested that the English term “deprivation” was closer to the German *Versagung*.

The connections made by Freud among frustration, prohibition, and privation form the basis for Lacan’s discussion of the connections between castration, privation, and frustration in his seminar on the object relationship (1994). Frustration there appears as an imaginary formation caused by the symbolic mother but related to the real breast; it prevents the subject from entering the symbolic dialectic of giving and exchange. Lacan writes, “Frustration essentially belongs to the realm of protest. It relates to something that is desired and not possessed but that is desired without reference to any possibility of gratification or acquisition. Frustration itself constitutes the realm of unbridled and lawless demands. This core of the concept of frustration as such is one of the categories of lack and an imaginary damnation. It exists at the imaginary level.” And later, “The early experience of frustration is only of importance and interest insofar as it leads to one or other of the two levels that I have set out for you—castration or privation. In truth, castration is simply that which accords frustration its true place, transcending it and establishing it within a law that gives it another meaning.”

Frustration for Lacan is nonetheless more than a mode of object relationship; it extends from an object

relationship to the very organization of speech and the ego. There is an inherent frustration in the discourse of the subject, and the feeling of frustration is a basic characteristic of the ego (Lacan, 1994). These propositions can be connected with Kleinian theories of the genesis and organization of the psychic apparatus.

It should be mentioned that on two occasions Lacan made Freud's use of the term *frustration* unnecessarily problematic. He asserted that it was of marginal importance in Freud's thought, whereas in fact it is central to his thought and Lacan himself deploys it as such (1994 [1956–1957]). Ten years later, far from correcting this viewpoint, he went so far as to assert that there was not the slightest trace of the term *frustration* to be found in Freud's works (1966). Lacan's persistent slip suggests that the expansion of the concept of frustration in psychoanalysis is the result of a misunderstanding or a translation error not only among German and English and the romance languages but above all between psychoanalysis and psychology, which at the time essentially based its observations, experiments, and theories on the conflict between frustration and gratification.

## FUNCTIONAL PHENOMENON

In his study on “hypnagogic” states (states between being awake and falling asleep) (1909/1951), which earned immediate publication and led him to make contact with Sigmund Freud in 1909, Herbert Silberer designated by the name “autosymbolic phenomenon” the visual image he saw when falling asleep that, upon analysis, could be understood as a representation in image form of his ideas at that moment. He gave the name “functional phenomenon” to what, in this process, represented not the object of his thought but how his mind was functioning—effortlessly, cumbersome, or vainly. In other words, the term refers to a symbolization of the thinking process itself, of the current activity of the mind, its affects, and its intentions.

In “On Narcissism: An Introduction” (1914c), Sigmund Freud, in his discussion of the role of moral conscience, offered a commentary that is as clear as it is full of praise: “It will certainly be of importance to us if evidence of the activity of this critically observing agency—which becomes heightened into conscience and philosophic introspection—can be found in other fields as well. I will mention here what Herbert Silberer has called the ‘functional phenomenon,’ one of the few indisputably valuable additions to the theory of dreams. Silberer, as we know, has shown that in states between sleeping and waking we can directly observe the translation of thoughts into visual images, but that in these circumstances we frequently have a representation, not of a thought-content, but of the actual state (willingness, fatigue, etc.) of the person who is strug-

gling against sleep. Similarly, he has shown that the conclusions of some dreams or some divisions in their content merely signify the dreamer's own perception of his sleeping and waking. Silberer has thus demonstrated the part played by observation—in the sense of the paranoid's delusions of being watched—in the formation of dreams. This part is not a constant one. Probably the reason why I overlooked it is because it does not play any great part in my own dreams; in persons who are gifted philosophically and accustomed to introspection it may become very evident" (pp. 96–97).

In Silberer's thought, analysis of functional phenomena resulted in an interpretation that increasingly evolved toward abstraction and generalization—"anagogical interpretation," which Freud criticized.

At the end of a lengthy critical examination of Silberer's theories in his article "The Theory of Symbolism" (1916/1948), Ernest Jones concluded, "Silberer, by first extending the term 'functional symbolism' from its original sense to cover the concrete representations of concrete processes in general, and by then confining it to the cases where these are secondary in nature, recedes from the conception of true symbolism and reaches once more the population conception of symbolism as the presentation of the abstract in terms of the concrete" (p. 127).

## **FUNDAMENTAL RULE**

The fundamental rule, as set forth in "Freud's Psychoanalytic Procedure" (1904a [1903]), urges that patients say "whatever comes into their heads, even if they think it unimportant or irrelevant or nonsensical . . . or embarrassing or distressing" (p. 251). Implicitly, the rule urges analysts to adopt a corresponding listening technique ("evenly suspended attention"), for which they are prepared by virtue of what Ferenczi (1928, pp. 88–89) called the second fundamental rule, namely the requirement that future analysts be analyzed themselves.

The fundamental rule was an end-point in Freud's development of his technique. He had begun with the "cathartic method," using hypnosis to elicit a verbal discharge of affects attached to buried traumas. In an intermediary stage, he used "free associations" as a way of uncovering the latent meaning of manifest phenomena such as memories, symptoms, or dreams, but without as yet forgoing the constraining use of suggestion. His adoption of the fundamental rule marked the renunciation of suggestion and of all prior assumptions on the part of the therapist. By initially and always giving the right to speak to the patient, the rule designated him or her as the source of all knowledge. By insisting that both partners in the work of analysis proceed "without any purpose in view" (1912e, p. 114) the rule claims implicitly to institute a kind of independent authority or "third party" before which the sequence of psychic material demanded by the rule might be manifested, perceived, and put into words. This initial positive rationality for the rule gradually came into question as the complexity of what was involved became apparent.

By examining significant variations in the way the rule has been stated, it is possible to get the measure of its metapsychological implications.

1. The statement of the rule was at first intended as a purely negative recommendation: the patient must not, as he would in an ordinary conversation, reject the incidental thoughts that cross his or her mind. The idea is to lift the censorship so that the products of unconscious mental activity could be expressed.

To resolve the paradox resulting from the fact that this negative prescription assumes a patient who is already in the process of speaking, the rule was subsequently pared down by Freud to: "Say whatever goes through your mind" (1913c, p. 135). Thus, the

patient's "choice" of a topic was no longer differentiated from "any intrusive ideas that may occur to you" (p. 134). The result of this was that the patient had to attribute two functions to the rule simultaneously, making it both a source of freedom and an obligation to "tell all."

2. Freud's formulation of the rule created a basic disjunction between "whatever goes through the mind" and words used to report it. At first this distinction seems clear enough: The patient's utterances presumably result from a voluntary act, whereas "whatever goes through the mind" is involuntary and passively "received." Thus understood, the logic of the rule combines the supposed "immunity" of the act of speaking with an acceptance of the idea of a "passivity" that implies the suspension of the usual way in which meaning is assigned. This logic is supposed to lead the patient to a positive cathexis of "whatever goes through the mind" and its enigmatic origins. And "whatever goes through the mind," it should be recalled, is a heterogeneous category, including as it does not just ideas, images, or wishes, but also representations, sensations, feelings, pure affects (such as anxiety), bodily states, and so on.

3. Further reflection confronts us with the fact that this as-yet un verbalized material comprises "word-presentations"; it is therefore discursive in nature, which means that the discrepancy between what comes to mind and the act of reporting it is either invalidated or limited to the sphere of linguistic activity.

We can see how Jacques Lacan, as a result of this primordial importance of speech and language, was led to propose the following wording for the rule: "Say anything at all, without being afraid of saying something stupid." However, the disjunction evident in Freud's work remains in full force. An eloquent expression of it is the metaphor of traveling in a train. The patient is compared to the passenger seated by the window, who must describe to his traveling companion the scenery passing by, without paying special attention to any given aspect on a priori grounds. For Freud, the most important point was that the countryside being traversed can never be reduced to what the passenger can perceive of it and say about it. The disjunction between psychic activity and the activity of speaking preserves the heterogeneity of relationships that word-presentations may have with the various registers of psychic and physical reality. According to Freud, "whatever comes to mind" tends,

through the favored mode of regression toward the visual image, toward a hallucinatory realization that is similar to the dream and its primary processes.

The crucial phenomenon remains the transference, through which "what comes to mind" is aimed at the analyst to whom, simultaneously, the patient's speech is addressed. The postulate of the rule is that discourse can invest this transference relationship.

The statement of the rule alludes to certain critical judgments that the patient must disregard. The judgments that something is unimportant or nonsensical naturally attest to the ordinary aspiration to say important and logical things. The judgment against things that are "distressing" to say summarizes all the others. Thus, the conflict whose onset is postulated in the wording of the rule is one that, by attesting to the consistency of the patient's inner psychic conflict, ensures that the attempt to put the rule into effect will have a dynamic value. The analyst's task is thus to confront the unpleasure of telling. At the price of this unpleasure, overcoming resistance can be productive.

From a metapsychological point of view, we can consider that by requiring the lifting of repression, the rule opens up the unconscious, gives the repressed access to consciousness, under the sign of the pleasure principle. The resistances that attempt to close this door are based on ordinary rationality. However, under the aegis of an accepted rule, they are no longer anything other than rationalizations; they express the action of repression, which also derives from the pleasure principle, since its aim is to substitute a sort of flight by avoidance for the action of a psychic "reality principle" and the free judgment it makes possible.

We can conceive that "intrusive ideas" are derivatives of the repressed: They can be perceived and spoken because they are not too threatening to the censorship. At a certain threshold of instinctual investment, a certain proximity to the unconscious kernel, signal-anxiety triggers repression, which manifests itself as resistance. It is because the conflict between repressing and repressed is well "organized" that it reveals the topographical contradictions of the pleasure principle (what is pleasure in one place becomes unpleasure in another), and that by following the associative chains and the "compromises" whose traces they bear and the context this process creates, the analyst is enabled to "discover the repressed instinctual impulses which are feeding the resistance," according to Freud in "Remembering,

Repeating and Working Through (Further Recommendations on the Technique of Psycho-Analysis II)" (1914g, p. 155). In the same essay Freud defined the cure as a "working-through of the resistances" (p. 155). The aim of the rule is not to "free" unconscious material (as in hypnosis), but rather to support the most complete and most "free" manifestation of conflicting forces so that their interplay may be modified.

Let us highlight the complexity of the rule's inherent stakes and their metapsychological correlates:

a) The rule cannot be described as either impartial or exterior to the forces at work in the analysis. It is directly involved in the phenomena inherent in the processes of the cure and its indirect "goals" (symbol-formation, sublimation, transference onto speech, becoming-conscious): Putting it into effect is an end as much as a means.

b) Accordingly, the rule inevitably plays a role in the transference. Far from remaining a third locus, it is invested as an emanation of the analyst's desire that it will thus be possible to satisfy or disappoint. Mobilization of the conflict in response to the rule can be expressed in the form of a transference acting out (*Agieren*) inherent in the logic of the situation. But the massive nature of this mobilization and the instantaneous nature of making the rule the locus of conflict do not facilitate the task of interpretation.

c) It is thus clear that the rule necessarily summons up the transgressions that contest it, the events that illustrate the impossibility of completely putting it into effect. It is only realized through that which seems to negate it: the activation of modes of "magical" or animistic thinking, which subvert the very existence of an observing ego, of a reality principle applied to psychic space. Any reference, even implicit, to the rule, seems to disappear at times, and it is then the sustained analytic setting that ensures through its vicariousness, until such time as a successful interpretation or a working-through makes it reappear, along with the meaning of the play of psychic forces that it represents.

d) The putting into effect of the rule has its optimal relevance when, as is the case in the neurotic, the topography of the repression attests to a tempered conflict between the pleasure principle and the reality principle. Clinical work has brought to light forms of resistance linked to the unconscious of the ego and the superego that subvert the dynamics of the analytic

situation (interminable analysis, or even disorganizing regression). Here we shall mention only the need for punishment, linked to unconscious guilt, that can be appeased only in and through suffering. The dynamic of the rule is perverted when the unpleasure it involves satisfies this need in an overly masochistic way. The work of analysis can then no longer be based on the logic of the pleasure principle to modify this need. This is but one of the many examples that could illustrate the limits of the rule's relevance and the need, in many cases, to situate the analysis outside its bounds.

The discrepancy between the apparent programmatic rationality of the rule and the complexity of its metapsychology explains that both its practical value and the function of its statement have been relativized and indeed called into question. Many analysts believe it is superfluous to state it. Others even deem it antianalytic, because it introduces an alienating representation of a goal, that of speaking "according to" the rule, and they believe it is preferable that the dynamics of the analysis begin spontaneously, allowing the patient to discover its inherent rule when they can make sense of it.

By contrast, one can underscore that the analytic situation could not be established by acting as if the superego-linked register of the prescription could be abolished. In this vein, one can point out that the statement of the rule, in its brilliant economy, condenses that which can be directly transmitted at the outset of the cure, and which the analyst states in the name of the analysis. In this way, it dismisses other, more implicit or more insidious prescriptions, and places the patient in the position of assuming responsibility for his or her own analysis.

The statement of the rule thus takes on the meaning of a repetition of an original, founding statement of the analytic situation. While the rule was initially intended as a third locus excluding suggestion from the analytic process, through its ineluctable transference evolution, it has proved to be the means and the place through which the effects of suggestion can be identified and analyzed in the transference.

## **FUSION/DEFUSION**

The concepts of fusion and defusion essentially apply to the life and death instincts, which are initially closely united but later become partially differentiated, under the influence of various psychic movements. Some portion of these instincts remains fused together in the self, in the form of erotogenic masochism (Laplanche and Pontalis, 1967, pp. 244–245).

The elaboration of the second theory of the instincts in “Beyond the Pleasure Principle” (1920g) led Sigmund Freud to postulate the existence of two types of instincts: the life instinct, which forms ever-larger units, and the death instinct, which disintegrates these units. Fusion of the life and death instincts is primal. Outward projection of the death instinct, when it is redirected inward toward the self, constitutes secondary masochism, Freud asserted in “The Economic Problem of Masochism” (1924c). But, according to Freud, a psychic movement that inhibits libidinal satisfaction, such as the movement that is the basis for the existence of the superego or the process of sublimation, by its very nature brings about a defusion of the instincts and thus unleashes destructiveness. This is what endows the Superego with a brutal and cruel aspect, Freud explained in “The Ego and the Id” (1923b).

Benno Rosenberg, in his thorough study of the consequences of this theory of fusion of the instincts, postulated the existence of a form of “life-saving

masochism,” so named because it restrains primal destructiveness in its structures. Nevertheless, there is a remaining ambiguity: When Jean Laplanche in *The Language of Psychoanalysis* (1967, trans. 1974) deemed the term *union* preferable to *fusion*, he introduced the concept of binding (Wilfred R. Bion), which has generally supplanted the concept of fusion in the current psychoanalytic literature. However, the concept of binding/unbinding applies to that which interrelates or separates the ego and the object, and no longer applies to the two types of instincts.

It has come to the point where the term *fusion* is often used instead of *binding*; there is thus a confusion between that which pertains to the integration of opposite qualities, with all the mental work that entails, and what was originally conceived as a primal attribute of the psyche. This confusion particularly affects the concept of ambivalence, which is the maintaining of two distinct qualities that exist in conjunction but not in a state of fusion.

## **FUSION/DEFUSION OF INSTINCTS**

Freud used the terms “fusion” and “defusion” (*Mischung/Entmischung*), in the context of his second theory

of the instincts, to account for the “mixing” and separation of the life instincts and the death instincts.

Throughout his work, Freud relied upon the notion of an instinctual dualism, on an opposition between two fundamental kinds of instinct, to explain the conflict inherent in mental life. In his first theory of the instincts, he contrasted sexual instincts on the one hand and self-preservative instincts (or ego-instincts) on the other. In his second theory, the life instinct, or Eros, stood opposed to the death instinct, and Freud emphasized that the antagonistic relationship between the two reflected their essential nature. The life instinct, for its part, was a force that strove to unify, and this included unifying the two fundamental instincts themselves; their intimate fusion came about through their simultaneous cathexis of the same object, which rendered them well-nigh indissoluble. At the same time, the death instinct, which promoted dissolution, worked to defuse them through a decathexis of the object, thus threatening the unity of the psyche itself.

These theses were first set forth in *Beyond the Pleasure Principle* (1920g), where Freud, postulating the self-destructive character of the death instinct, sought to show how a portion of its self-destructiveness was immediately neutralized by the life instinct, which eroticized it. In the first edition of the work, in introducing the notion of instinctual fusion, Freud cited Alfred Adler (p. 53n), who had indeed, many years earlier, argued that instinctual energy stemmed from “two originally separate instincts,” the one sexual, the other aggressive, “which had subsequently intersected” (Adler, 1908). Freud would observe later, in “Analysis Terminable and Interminable” (1937c), that “The two fundamental principles of Empedocles—love and strife—are, both in name and function, the same as our two primal instincts” (p. 246).

With *The Ego and the Id* (1923b), the fusion and defusion of instincts became a feature of Freud’s second topography (also known as the structural theory): defusion was now viewed as a function of the id and of the severity of the superego, while fusion was the task of the ego, both constitutionally and in its role as unifier of the three mental agencies. Instinctual defusion caused regression, and identification and sublimation themselves tended to bring about defusion. The clinical prototype of instinctual fusion was to be found in the action of sadism (which facilitated the turning of the death instinct toward the external world) and of masochism; its metapsychological prototype was

primary erotogenic masochism. The physiological basis of this last, namely sympathetic sexual excitation, constituted the very foundation of the Freudian theory: “It may well be that nothing of considerable importance can occur in the organism without contributing some component to the excitation of the sexual instinct” (1905d, p. 205; 1924c, p. 163).

The fusion and defusion of the instincts (*Triebmischung/Triebentmischung*) needs to be clearly distinguished from the processes known as binding and unbinding (*Bindung/Entbindung*). Freud first used these last terms in connection with energy flows: the self-preservative instincts of the ego, he argued, tended to bind the free energy that flowed continuously from the sexual instincts; unbinding, therefore, was a discharge of free energy by the ego. In 1920, when Freud advanced the notion that union was the aim of the life instincts, he saw such union as dependent for its quality and its strength on this internal capacity of the ego’s to bind self-preservative impulses to free sexual energy (Rosenberg, 1991). The best way to keep the distinction clear between the two above-described levels of instinctual interaction—the binding/unbinding processes internal to the ego and the fusion/defusion of the life and death instincts—is to confine the original economic reading to binding/unbinding. Variations in the quantitative factor may then be said to bring about a qualitative modification of the instinctual fusion, notably in “the advance from the earlier [genital] phase to the definitive genital one” (1923b, p. 42).

Attention to the variations of the binding/unbinding internal to the ego and the fusion/defusion of the life and death instincts has played a heuristic role in the understanding of psychosis (in the work of Melanie Klein, Piera Aulagnier, Benno Rosenberg, and others), of psychosomatic illness (for Pierre Marty), and of borderline conditions (in the “objectalizing/ deobjectalizing function” described by André Green).

Jacques Lacan has criticized an approach that casts a positive light on instinctual binding and its agency, the ego, while condemning the fascinating and immobilizing aspects of the process. Jean Laplanche (1981) has for his part argued that sexuality should not be reduced to the unifying function of the life instinct lest it thereby be divested of its non-bound aspect, with its fundamentally destructive and even demoniacal features.

## FUTURE OF AN ILLUSION, THE

The publication of a *The Future of an Illusion* followed *The Question of Lay Analysis* (1926e) and preceded *Civilization and its Discontents* (1930a [1929]). *Die Zukunft einer Illusion* soon reached a wide audience, and was translated into English in 1928 by W. D. Robson-Scott as *The Future of an Illusion*, and into French in 1932 by Marie Bonaparte as *L'Avenir d'une illusion*.

In a letter to the Swiss Calvinist pastor Oskar Pfister (November 25, 1928), Freud wrote: “I do not know if you have detected the secret link between *Lay Analysis* and the *Illusion*. In the former I wish to protect analysis from the doctors and in the latter from the priests.” Freud keeps his distance from the two principal custodians of secrets protected by the law. Moreover, he considers priestly knowledge, or religious dogma, a “neurotic relic” that it is time to replace “with the results of rational mental labor.”

The link between *The Future of an Illusion* and *Civilization and its Discontents* was made by Romain Rolland. *Liluli*, the title of a play he wrote, was a play on the word “illusion.” In *The Future of an Illusion* Freud discusses the religious feelings then so essential

to Rolland’s thinking and which Freud refers to as “oceanic sensations”; these he considers both eternal and infinite. In *Civilization and its Discontents* Freud explicitly refers to this concept to differentiate himself from it: “I cannot discover this ‘oceanic’ feeling in myself.”

Freud considered religion to be a phenomenon of culture or civilization, based, like all culture, on the “rejection of instincts” by means of “prohibitions.” The gods retain “their threefold task: they must exorcize the terrors of nature,” (especially death), “they must reconcile man to the cruelty of fate, particularly as is shown in death, and they must compensate them for the sufferings and privations which a civilized life in common has imposed on them.” Religion thus constitutes a “treasure of ideas born of the need to make human misery supportable.”

Freud used as an example one of the phases of religious evolution, “which roughly corresponds to the final form taken by our present-day, white, Christian civilization.” Here he makes a clean break with Jung, who based many of his ideas on the religions of India (Hinduism and Buddhism primarily). Logically, he insists on an essential characteristic of Christian religion, “the father-son relationship.” He asserts that “God is an exalted father, the nostalgia for the father is the root of religious need.”

The entire work is marked by Freud’s desire to placate his friend, Pastor Pfister, who responded the following year with the publication of a pamphlet titled *The Illusion of a Future* (1928). Freud distinguished illusion from error: an illusion, the product of desire, is not necessarily false. Moreover, he adds a condition to a claim present in his article on “Compulsive activities and religious exercise” (1907b): “Religion could thus be the universal obsessional neurosis of humanity.” He even considers that “devout believers are safeguarded in a high degree against the risk of certain neurotic illnesses; their acceptance of the universal neurosis spares them the task of constructing a personal one.”

Freud, who spent his life trying to destroy illusions and complete what Max Weber called the “disenchantment of the world,” seems to hesitate when it comes to the future of religious phenomena. He says

he is in favor of “retaining the religious doctrinal system as the basis of education and of man’s communal life.” Just as Charles Maurras at the time defended Catholicism as an element of political order in spite of his naturalist positivism, Freud, in spite of his atheism, defended Christian education (the teaching of religion was required in Austrian schools) “which is so important for the safeguarding of civilization.”

He concludes his work with a case study of conversion, without confusing the beliefs of “inert and unintelligent” crowds with the more certain achievements of science. “No, our science is not an illusion.”

### GADDINI, EUGENIO (1916–1985)

Eugenio Gaddini, president of the Italian Psychoanalytic Society from 1978 to 1982, was born in Cerignola, Foggia, Italy, on January 18, 1916, and died in Rome on September 27, 1985. A brilliant student, he developed a precocious interest in literature and philosophy. In 1942 he received his medical diploma. In 1956 he gave up his position as chief physician in a hospital in Rome to devote himself to psychoanalysis.

After completing an analysis with Emilio Servadio, he was admitted in 1953 to the Società Psicoanalitica Italiana (Italian Psychoanalytic Society), in which he served as secretary (1957), vice president (1967–1969), and president (1978–1982). During his tenure as president, he worked hard to expand the society, primarily by revitalizing the *Rivista de psicoanalisi* (Review of psychoanalysis), of which he was editor for several years. After 1970 he worked as a teacher at the Centro Psicoanalitico Romano (Rome Psychoanalytic Center) and the Centro di Firenze (Florence Center), which he founded, surrounding himself with a circle of students who were receptive to his original ideas. Gaddini was highly esteemed within the International Psychoanalytical Association, where he assumed several high-level positions, and was known for his original contributions in the fields of metapsychology and clinical therapy.

Combining Freudian psychoanalysis with the techniques of Donald Winnicott, he formulated an innovative theory of early mental states, postulating the existence of a “fundamental mental organization,” which serves as the basis for the formation of the self. According to Gaddini, “nonintegration anxiety” occurs during the transition from the “psychosensory zone,” characterized by a preponderance of physical

sensations, to the “psycho-oral zone” (1987). During this process, when the basic outlines of mental structure are laid down, the mechanism of imitation plays an important role (Gaddini, 1969). Gaddini distinguished imitation from introjection and identification, which he associated with the psycho-oral zone, where the tension to “attain the object” was a sign of distinctness and separation. Imitation he associated with the psychosensory zone and “correlative bodily fantasies.” In other words, fantasies of fusion respond to bodily changes associated with becoming “the object.” During the course of analysis (1981), disturbances of the psychosensory zone become manifest in transference through the patient’s use of mechanisms of imitation to reestablish fusion, as if by magic, and avoid recognition of the object as an other distinct from the self.

In his writing, Gaddini suggested reconsidering the function of the father in the oedipal triangle (1989) and in aggression. Adopting the fusion theory of instincts, he hypothesized that aggression shifted the libido from its initial narcissistic position to objects (1972). His essay “Transitional objects and the process of individuation,” published in 1970 with his wife Renata, continued the work of Donald Winnicott. Gaddini’s writings have been collected in *Scritti*, published posthumously in 1989 and translated into English in 1992.

## GAIN (PRIMARY AND SECONDARY)

Primary and secondary gains correspond to the direct or indirect advantages that individuals gain from their illness. The primary gain is a constitutive element of the illness that is present in the very motive of the illness. The secondary gain is an addition to the primary gain and comes into play at a later stage. It consolidates the disorder.

The specific term “gain” in relation to an illness appeared in 1897 in a letter from Freud to Wilhelm Fleiss. Secondary gain is described for the first time in 1913 in *On Beginning the Treatment*: here the symptom has a secondary function (1913c). In 1916 in Lecture twenty-four of *Introductory Lectures on Psychoanalysis* Freud clearly articulated the distinction between primary and secondary gain (1916–17a, [1915–17]), and again in 1923 in a footnote to the study of the case of Dora (1905e [1901]).

Primary gain subdivides into two parallel aspects. In the internal part, illness remains the most economic solution in cases of conflict, and this is the “flight into illness.” The external part is linked to profitable arrangements occasioned in the individual’s relational life. The secondary gain “helps the ego in its effort to incorporate the symptom.” (1916–17a [1915–17]) It procures a satisfaction that is narcissistic or linked to self-preservation.

## GARDINER, MURIEL (1901–1985)

An American psychoanalyst and psychiatrist, Muriel Gardiner was born November 23, 1901 in Chicago, Illinois and died February 6, 1985 in Princeton, New Jersey.

The daughter of Edward Morris and Helen Swift, she was born into a family of wealth and privilege. During her childhood she became aware of the plight of the poor and disenfranchised and subsequently developed a life-long commitment to social and political reform. After graduating from Wellesley College in 1922 she traveled to Europe where she lived until the outbreak of World War II.

In 1926 she settled in Vienna where she underwent the first of two periods of analysis with Ruth Mack Brunswick. During this period she developed an interest in applying psychoanalytic insights to education. Simultaneously with her psychoanalytic training she attended the Vienna Medical School, graduating in 1938. In 1934, in the midst of her training and a second period of analysis with Mack Brunswick, a fascist dictatorship was installed in Austria. Witnessing the brutality that accompanied these events was a turning point in Gardiner’s life. She resolved to help endangered individuals escape from fascist Europe, and for the next six years worked tirelessly in the Austrian underground. These years are vividly described in her memoir *Code Name “Mary”* (1983).

After returning to the United States in 1939 Gardiner completed her analytic training at the Philadelphia Association for Psychoanalysis, with which she was associated for many years. Gardiner was appointed a training and a supervising analyst in 1955, but she never accepted any candidates. Rather she found fulfillment by using her training in psychoanalysis in her work as a consultant in schools, hospitals, and residential settings. Here she was able to offer help to children and adolescents, and to their teachers, social workers, and doctors.

Gardiner’s publications include *The Deadly Innocents: Portraits of Children Who Kill* (1976), a book which grew out of her work with children and adolescents; and

*The Wolf-Man by the Wolf-Man* (1971), which she edited. This is a compilation which includes his autobiographical reminiscences, Freud's original case report, Ruth Mack Brunswick's 1928 essay, and Gardiner's paper recording her contacts with the Wolf Man over three decades. After the Wolf Man's death in 1979 she wrote *The Wolf Man's Last Years* (1983a) wherein she described his final years and gently but pointedly took issue with Karin Obholzer's portrayal of the Wolf Man in her 1982 book, *The Wolf Man, 60 Years Later*.

Muriel Gardiner's contribution to psychoanalysis goes beyond her books and papers, her generous support of the Hampstead Clinic, the Freud Archives, and the Freud Museum, and her long relationship with the Wolf Man, characterized as it was by her concern for his dignity and psychological well-being. Of equal significance was the fact that she took psychoanalytic insights and her counsel into settings—schools, hospitals, and prisons—where they are usually not found.

## **GARMA, ANGEL (1904–1993)**

A Spanish psychiatrist and psychoanalyst, Angel Garma was born June 24, 1904, in Bilbao, and died January 29, 1993, in Buenos Aires.

Garma, a Basque by birth and temperament, went to Madrid at the age of seventeen to study medicine.

After completing his studies he left for Germany, where he was a student of Robert Gaupp and Karl Bonhoeffer. In 1929 he began a training analysis with Theodor Reik at the Berlin Institute of Psychoanalysis.

When he was twenty-seven Garma became a member of the Berlin Psychoanalytic Association (BPV) after presenting his now classic paper, "Die Realität und das Es in der Schizophrenie" (Reality and the Id in Schizophrenia), which he read in October 1931. This innovative essay questions the Freudian conception of psychosis. While Freud believed the psychotic repressed reality to satisfy the id, Garma claimed that the psychotic represses the id more than the neurotic, which disturbs his relation to reality.

At the end of 1931 Garma settled in Madrid. Although he had completed his training with the Berlin Psychoanalytic Association, he soon quit the organization, decrying its growing discrimination. He remained a "direct member" of the International Psychoanalytic Association (IPA) for several years. In July 1936, before the start of the Spanish Civil War and in spite of his sympathy for the Republicans, Garma went to France to avoid the fratricidal struggle taking place in his homeland. Through the Société Psychanalytique de Paris he met Celes Ernesto Cárcamo, an Argentinean who had trained in Europe before returning to Buenos Aires. He invited Garma to accompany him. Garma preferred to remain in Paris, but spurred on by the impending world war, he eventually decided to leave.

Garma arrived in Argentina in June 1938 and quickly adapted to life in Buenos Aires, a progressive city where psychoanalysis was already being taught. Cárcamo's return in 1939 gave a new impetus to the nascent psychoanalytic movement, which was soon reinforced by the arrival of Marie Langer.

In late 1942 the Asociación Psicoanalítica Argentina (APA) was founded. Garma was its first president (1942–1944), a position he held on three other occasions during his life. He founded the Institute for Psychoanalysis, where he was a teacher for thirty-two years. During his tenure as APA president, Garma promoted scientific activity, established annual conferences, and helped organize Latin-American and Pan-American conferences.

Garma's work was widely recognized during his lifetime. He was honored publicly on his seventieth birthday and, in 1983, was named honorary vice

president of the IPA. In 1989 King Juan Carlos I of Spain decorated him and the APA named the Institute of Psychoanalysis after him. A year later he was elected honorary president of the Psychoanalytic Federation of Latin America (FEPAL).

An important pioneer, Garma developed a body of scientific work of considerable importance. He made significant contributions to the study of the psychoanalysis of dreams, psychoses, perversions, psychosomatic medicine, and technique. Within his extensive body of work his detailed and careful work on gastric ulcers and headache deserve special mention.

Dream-like phenomena were a constant preoccupation for Garma. The doctoral dissertation he presented in Argentina, “Psicoanálisis de los sueños” (1940, [Psychoanalysis of Dreams]) became a classic. Garma continued to make contributions to the theory of dreams, focusing his work on the *Traumdeutung*, even though he sometimes disagreed with Freud’s findings.

Garma’s research primarily involved the theory of the traumatic genesis of dreams, the characteristics of dream-like thought, the origin of dream hallucinations, and the relation to reality. The dream originates in unconscious conflicts that configure a traumatic situation, so that, ultimately, all dreams are nightmares. The satisfaction of desire is merely an attempt to mask the traumatic situation. The dream work is not limited to providing mental content with a new form, it is a creative process, a particular type of thought, archaic and vast. Garma’s theory on the origin of dream hallucination and the relation to reality, which contradicts Freud, is discussed in his essay “La realidad exterior y los instintos en la esquizofrenia” (External Reality and the Instincts in Schizophrenia), published in 1931. Here, the relation of the subject to reality is disturbed whenever he has to abandon the satisfaction of impulsive demands and submit to internal persecutory objects that channel the death impulse.

These ideas, along with others, are crystallized in two important books. *Nuevas Aportaciones al psicoanálisis de los sueños* (1970, [New Contributions to the Psychoanalysis of Dreams]) covers thirty years of his work, although it by no means exhausts his contributions to the field. His *Tratado mayor del psicoanálisis de los sueños* (1990, [Comprehensive Treaty on the Psychoanalysis of Dreams]) incorporates the work done during the last twenty years of his life. All of Garma’s work is a sustained and consistent effort to unmask a

fundamental structural conflict, the submission of a masochistic ego to a sadistic superego that serves as an obstacle to the free exercise of genitality.

Angel Garma had two daughters, Lucinda and Isabel, with Simone Mas, his first wife. Elisabeth Goode Rasmussen, his second wife, who was with him at the height of his career, remained a steadfast caretaker during the years of his illness. An eminent psychoanalyst in her own right, she assumed the difficult role of being the wife of a great man. Angel and Elisabeth had two daughters, Carmen and Sylvia.

## GATTEL, FELIX (1870–1904)

Felix Gattel, a medical doctor, was born in Berlin on December 14, 1870, and died in 1904. He is known in the history of psychoanalysis as Sigmund Freud’s first student.

Gattel traveled from San Francisco to Würzburg, Germany, to complete his studies. Though he specialized in neurology, he spent May to October 1897 in Vienna, studying with Freud (Masson, Jeffrey M., 1985). He published a few articles but after 1899 all trace of Gattel was lost. The exact date of his death is not known, but Wilhelm Fliess indicates in his writings that he died in 1906. Subsequent research by Michael Schröter and Ludger M. Hermanns has led to the conclusion that he died on October 17, 1904.

Gattel followed the same initial scientific education as Freud, beginning his career in pathological anatomy. His interest then turned to neurosis and sexuality. He

learned about Freud while he was doing research, in particular, through an article written by Freud in collaboration with Oskar Rie on infantile cerebral hemiplegia (1891a). Gattel, aware of Freud's growing reputation in the field of neurasthenia and hysteria, contacted him before settling in Vienna, most likely to take advantage of Freud's clinical experience.

Gattel remains something of a mystery to us, since there is little available biographical material. He was one of Freud's earliest supporters and, with Emma Eckstein, can be considered one of his first students—at least in the traditional academic sense, where a young medical student might work under the guidance of an older colleague. Eckstein can be considered the first student of analysis, since she was analyzed by Freud and then began analyzing others in turn.

Gattel's importance—although minor—in the history of psychoanalysis shows up in several ways. Freud, eager to communicate his research results, conducted experiments with him, as he did later with Heinrich Gomperz; this was classic scientific research as practiced in academic circles. As an academic Freud assigned Gattel the job of conducting field research in neurasthenia (letter to Wilhelm Fliess, January 20, 1898). Gattel was an enthusiastic and enterprising student, but not up to the theoretical level his teacher would have liked. It was through these early experiments with Gattel that Freud came to understand that conventional scientific research was not the best method for communicating his ideas. During this work, he came to understand the importance of transference between student and teacher. It is easy to understand the importance of Freud's first students by examining the concept of the correspondent in scientific discovery. Gattel and Fliess, although in different ways, assumed this role before the creation of the Wednesday Psychological Society. It was during these meetings that Freud was able to express himself most fully, for his audience was able to follow his ideas and spurred him on intellectually. At the same time, given the inevitable diffusion of transference in a small group, he was not overly concerned with the intensity of two-way transference. This activity preceded the evolution of the small group of the "savage horde" that Freud later became interested in.

Gattel appears in the Freud-Fliess correspondence as someone inclined to plagiarism. He was the quintessential mediocre student. In the Swoboda affair, which

signaled the end of Freud's friendship with Fliess (Porge, Erik, 1994; Le Rider, Jacques, 1982), he is mentioned as an example of an unreliable personality. Frank J. Sulloway (1979) exaggerates his importance, but Schröter and Hermanns (1992) provide a more accurate assessment of him as a talented and hard working young man, capable of recognizing the value of a scientific discovery but unable, during his short life, to live up to the promise of his talent.

### **GELEERD, ELISABETH (1909–1969)**

Psychoanalyst Elisabeth Geleerd was born on March 20, 1909 in Rotterdam, the Netherlands, and died May 25, 1969 in New York.

Elisabeth Geleerd's parents were Moses and Bertha (Haas) Geleerd. The eldest of three children, she and her two younger brothers, Yap and Benedictus, grew up in comfortable circumstances in Rotterdam where her father's business was outfitting ships. When she was nine or ten her mother died of tuberculosis and she was sent to live with an aunt and uncle. This was an unhappy experience and she returned to her father's house in her early teens. Several years later Yap also died of tuberculosis. The deaths of her mother and brother influenced Elisabeth's decision to study medicine at the University of Leyden. Her father supported her ambition to become a physician.

After receiving her M.D. in 1936, she moved to Vienna in order to undertake psychoanalytic training at the Vienna Psychoanalytic Institute, where her analyst was Anna Freud. In 1938 the deteriorating political situation led her to move to London, where she completed her analytic training at the Institute for Psychoanalysis, the training arm of the British Psychoanalytic Society. In 1940 she arrived in the United States and worked for several years at the Menninger Clinic in Topeka, Kansas before finally settling in New York in 1946. That same year she married the prominent psychoanalyst, Rudolph M. Loewenstein.

In 1947 Geleerd was appointed a training analyst at the New York Psychoanalytic Institute and, as a member of the Educational Committee, played a formative role in the development of the Child and Adolescent analysis program at the Institute.

Recollections of Geleerd invariably note her intelligence and beauty. Her countenance has been described as neoclassical and delicate, her temperament as sensitive, searching and romantic. The congruence between her face and her character, each mirroring the other, left an indelible impression on her friends and colleagues. She was by all accounts an empathic therapist, but her approach to patients was based on a thorough grasp of psychoanalytic theory and technique. In a series of papers on the psychodynamics of childhood schizophrenia, the developmental vicissitudes of adolescence and the psychological states of fugue and amnesia, she delineated the defenses the ego utilizes in its attempt to master early, often overwhelming trauma originating in the mother-child relationship. She also sought to suggest new techniques for treating seriously disturbed children and adolescents.

## **GENDER IDENTITY**

The term *gender identity*, meaning a person's relative sense of his or her own masculine or feminine identity, was first used in 1965 by John Money (Money, 1965). The term was introduced into the psychoanalytic literature by Robert Stoller in 1968 (Stoller, 1968).

Money used the term to distinguish the subjective experience of gender from the concept of “gender role” which he used to describe the socially determined attributes of gender.

Stoller (1968) developed the idea further to distinguish between the psychological and biological dimensions of sex. He used *gender* to distinguish ideas and experiences of masculinity and femininity—both socially determined psychological constructs—from *sex*, the biologically determined traits of maleness and femaleness. This usage has become the standard in psychoanalytically derived discussions of gender and sexuality to refer to the psychological aspects of sexuality, what Freud (1925) called “psychical consequences of the anatomical distinction between the sexes.”

Stoller (1968) further distinguishes the general sense of masculinity and femininity—*gender identity*—from the earlier awareness of sexual difference, what he calls *core gender identity*, a relatively fixed sense of maleness or femaleness usually consolidated by the second year of life, prior to the oedipal phase.

Stoller identifies three components in the formation of core gender identity: 1) Biological and hormonal influences; 2) Sex assignment at birth; 3) Environmental and psychological influences with effects similar to imprinting.

In contrast to Freud's belief that the primary identification is masculine, Stoller believes that both the boy and the girl begin with a female core gender identity obtained from the maternal symbiosis. Core gender identity is derived non-conflictually through identification and, in essence, learning. Failure to interrupt the maternal symbiosis pre-oedipally with boys may

result in permanent core gender identity disorders like transsexualism. Otherwise, normal development facilitates the boy's shift to a male core gender identity and the subsequent oedipal conflicts associated with obtaining a masculine gender identity.

The concept of gender identity is important historically because it separates masculine and feminine psychology from the innate biological determinism suggested by Freud. Increasing attention to the diversity and multiplicity of the origins and workings of gender have made even the terms gender identity and core gender identity less than adequate to describe the nuances of such a central organizing factor of personality and behavior. It is important to differentiate the term, gender identity, which describes the individual's sense of gender, from Stoller's speculative theory about the origins of core gender identity.

## **GENERAL THEORY OF SEDUCTION**

Sigmund Freud developed the theory of seduction in the years 1895–1897, and then he abandoned it. The theory accounted for the genesis of the psychopathological unconscious on the basis of a complex mechanism that brought two moments into play: a scene in which a child is seduced by an adult, and the “deferred” reactivation of this scene at a later time.

Jean Laplanche has proposed a “general theory of seduction,” extending the Freudian seduction theory to the genesis of the unconscious in general, and broadening its foundations to include primacy of the other's enigmatic message and the theory of repression as a partial failure to translate this message.

It has been said, and is incessantly repeated, that Freud abandoned his first theory of the neuroses and announced this to Wilhelm Fliess in his letter dated September 21, 1897 (*SE* 1, p. 259). Recrudescences and relics of this theory are nonetheless legion in Freud's work. What is perhaps the most surprising fact is that it was effectively tabooed and misrepresented until 1964 (Laplanche and Pontalis, 1964). Even then, when it began to attract a new interest, this was directed not to the highly complex mechanism described by Freud but instead to anecdotes of manifest sexual abuses and to the issue of whether Freud had fled, or “repressed,” this reality and taken refuge in the hypothesis of a pure and simple production of fantasies (Masson, 1984).

Freud's original seduction theory was strictly confined to the realm of the psychoneuroses. It is even tempting to think that Freud posited the existence of the unconscious in neurotics alone, and that he nourished the hope that cure might come to mean the elimination of the unconscious.

The theory sought to explain the development of the unconscious by the repression, in the child, of memories of sexual scenes usually experienced while in the charge of an adult. It brought three interconnected levels into play: a temporal dimension, a topographical dimension, and a language-related dimension. The temporal aspect of seduction was

bound up with the concept of deferred action (or “afterwardness” [Nachträglichkeit]), which was to survive in Freud’s later thought. The thesis was that nothing was inscribed in the human unconscious save by way of the interrelationship between at least two events separated from one another by a period of mutation, a lapse of time that made it possible for the subject to react differently to the memory of the first experience than to the actual experience as lived. Left in suspense, the initial memory became pathogenic and traumatizing when revived by the occurrence of a second scene having some association or resonance with the first.

The topographical aspect involved the theory of an ego in the process of formation, armored against attack from without but not against attack from within. Since what attacked it at the second moment was not an outside event but a memory, this ego was unprotected and could react only by repression.

Lastly, a linguistic aspect of the theory was suggested by Freud’s analogy between the barrier separating the two moments of the psychical trauma and a translation, or a partial failure of translation (letter to Fliess of December 6, 1896, *SE* 1, p. 235).

It is thus apparent just how inadequate a response it is to reduce the seduction theory to the simplistic assertion that the adult’s seduction of the child brings on mental disturbance. Freud’s first theory was in fact intimately interwoven with the clinical doctrine of the time.

At the close of 1897, Freud undertook a systematic critique of his theory which led him to abandon it, surrendering hysterics to their “seduction fantasies,” and those fantasies themselves, ultimately, to a phylogenetic determinism.

The critique of a theory—its “falsification”—may have several outcomes: rejection, partial modification, or a reexamination of its foundations. It is the last of these that Jean Laplanche has sought with his “general theory of seduction.” In the first place, he argues, the unconscious should not be looked upon as invariably pathological. The unconscious is part of the human condition, and there is therefore no reason to rebuke a theory or a practice for not being able to eliminate it. Secondly, the adult-child relationship ought to be viewed in a way that transcends psychopathological features specific to particular cases of perverse sexual abuse. Generally speaking, there is a basic asymmetry between the infant and the adult, stemming from the

fact that adults have already constructed a sexual unconscious for themselves and that their way of addressing themselves to children, in gestures or words, is necessarily shot through by that unconscious. Thirdly, the general theory of seduction aims to bring considerations to the fore that played little part in Freud’s thinking. These include: the notion of the message; the priority of the adult other in the message received by the infant; and, lastly, the idea of “translation” as the basis for a model of repression less mechanistic than that of a pure interplay of forces, as set forth in classical psychoanalytic thought.

### **GENITAL LOVE**

*Genital love* corresponds to the type of object relation organized during the adult genital phase of libidinal development. It is characterized by the unification, under the primacy of the genital, of pregenital sexual aims and, in particular, by the reunion of the two currents of sexuality—sensuality and affection.

It is difficult to provide a univocal definition of love. The Greeks differentiated among *eros*, *philia*, and *agapè*,

distinctions that were picked up by Freud, who distinguished sensual love from affection and from love in the more general sense of the term. Although he leaves discussions of love to the poets, Freud refers to the polysemy of the term “love,” which he judges to be well founded: sexual and amorous relations between men and women, love between parents and children, friendship, self-love, the love of truth or humanity. “We are of the opinion, then, that language has carried out an entirely justifiable piece of unification in creating the word ‘love’ with its numerous uses, and that we cannot do better than take it as the basis of our scientific discussions and expositions as well” (1921c).

The concept of “genital love” has meaning only if it is associated with the concept of the “genital phase” of libidinal development. It would thus stand in contrast to that which characterizes the object relations of the preceding “pregenital” phases. Genital love should not be understood here solely as love in the form of sexual congress, but as the type of love organized after the oedipal phase and the latency period, at the moment when the libido is sufficiently evolved to enable the organization of the adult genital phase.

Thus, genital love is characterized by the unification, under the primacy of the genital, of all the sexual components that have not been repressed or sublimated, and of those pregenital sexual aims that have been maintained as preliminary pleasures. This unification is prepared during the infantile genital stage and is “completed” only after puberty with the development of adult sexuality.

During the period of oedipal decline, a new distribution of impulse cathexes will leave its traces throughout the sexual life with a new distribution of inhibited or sublimated erotic investments. In particular, there is a conjunction of the sensual erotic current and the affectionate current of adolescence following their relative disjunction during the latency phase. There is a reunion of “genital satisfaction and pregenital affection” (Balint, Michael, 1947). The union of these two currents brings about an equilibrium that is rarely static but can rather be compared to an interlacing, a struggle (Parat, Catherine, 1996).

The model of adult genital organization implies the choice of a heterosexual object, which leads to the reproduction, in a couple, of what was for the child the representation of the couple created by his or her parents. This assumes that the sexual nature of the

images of the parents that were internalized during the oedipal phase have been sufficiently differentiated. In this sense genital love, that is, adult genital organization, is indeed the successor of the oedipal complex, and assumes further that it renounces the oedipal objects formed during childhood (Perron, Roger, Perron-Borelli, Michèle, 1994). Genital, or post-oedipal love, is the form of love best able to articulate the two currents—heterosexual and homosexual—of oedipal love. Positive oedipal erotic investments are reflected onto the sexual partner in the couple, while homosexual investments will nourish, in a more or less desexualized form, social and professional relations.

Michael Balint (1947) emphasized the idealist nature of a concept that would manifest no trace of ambivalence or pregenital object relation. This type of ideal object relation would, therefore, contain no oral characteristics, would have no desire to devour the object; there would be no desire to dominate or master the object, no sadistic traits and therefore no vestige of anality; there would be neither envy nor fear of the genital organs of the other sex, therefore no trace of the phallic phase or castration complex, and so on. Clearly, such love does not exist. The pregenital components cannot all be integrated and every love assumes the destruction of the narcissistic “shell.” We are justified, then, in emphasizing the idealist nature of such a concept, even its normative aura. This does not mean that a certain maturation of the ego and its abilities does not take place gradually when the genital phase of libidinal development is achieved. The state of being in love (David, Christian, 1996) then becomes possible: it is the result of the simultaneous activity of free sexual tendencies and inhibited tendencies and, in particular, of the union of sensuality and affection.

## GENITAL STAGE

A stage or phase of psychosexual development, the *genital stage* is characterized by the organization of the component instincts under the primacy of the genital zone. It is divided into two periods separated by the latency period: first, the infantile genital organization, or phallic phase, dominated by the phallus, that is, by the male genital organ alone, and, secondly, the genital organization properly so-called, which is established at puberty.

Many authors feel that the terms “genital stage” or “genital organization” should be reserved for this second period, and that the “infantile genital organization” or “phallic phase” should properly be classed with the (oral and anal) pregenital organizations that precede latency. Freud himself at first described the genital organization as linked to the discovery of the sexual object at the time of puberty (1905d). Under the primacy of the genital zone, a prerequisite to the union of the sexes, the component instincts of the young child’s “polymorphously perverse” sexuality were unified and integrated into sexual activity as fore-pleasure.

In a paper of 1923, “The Infantile Genital Organization,” intended as a complement to his *Three Essays on the Theory of Sexuality*, Freud moved away from the standpoint of biological maturation, reduced the significance previously accorded to puberty, and described an organization that approximated “(in about the fifth year) to the definitive form taken by [sexuality] in the adult” (1923e, p. 141).

There are two important points here. Object-choices, as first made during this phase, are in every way analogous to post-pubertal choices, and this is “the closest approximation possible in childhood to the final form taken by sexual life after puberty” (p. 142). The second and even more important point is that the infantile genital organization, which is simultaneous with the emergence of the Oedipus complex, is marked by the presence of a particular sexual theory:

the child at this time conceives of but one kind of genital, namely the male sexual organ. This is the reason for the denomination “phallic phase”: “At the same time, the main characteristic of this ‘infantile genital organization’ is its *difference* from the final genital organization of the adult. This consists in the fact that, for both sexes, only one genital, namely the male one, comes into account. What is present, therefore, is not a primacy of the genitals, but a primacy of the *phallus*.” (p. 142)

The idea of the primacy of the male genital organ thus became the foundation of the general theory of the castration complex, of which Freud sought thenceforward to frame feminine as well as masculine versions: “the significance of the castration complex can only be rightly appreciated if its origin in the phase of phallic primacy is also taken into account” (p.144). In *An Outline of Psycho-Analysis*, Freud placed the phallic phase as a pregenital organization following the oral and anal organizations, and reserved the term “genital organization” or “phase” for the pubertal period only. He reasserted the idea that “The complete organization is only achieved at puberty, in a fourth, genital phase” (1940a, p. 155).

It is worth recalling here the importance of the notion of organization. Each phase of development sets up a functional system that organizes not only the current state of mental operation but also its future state. Thus, in 1923, Freud summarized the transformations that the polarity between the sexes undergoes during infantile sexual development as follows: “At the stage of the pregenital sadistic-anal organization, there is as yet no question of male and female; the antithesis between *active* and *passive* is the dominant one. At the following stage of infantile genital organization, which we now know about, *maleness* exists, but not femaleness. The antithesis here is between having a *male genital* and being *castrated*. It is not until development has reached its completion at puberty that the sexual polarity coincides with *male* and *female*” (1923e, p. 145).

Even though the evolution of Freud’s view of psychosexual development led him to assimilate infantile sexuality more and more to adult sexuality, he did not alter his initial assertion: he continued to maintain that it was only with the advent of the sexual organization of puberty that the component instincts were definitively unified and a hierarchy established; the child could not emerge from the anarchy of the component

instincts until, at puberty, the primacy of the genital zone was assured.

## **GERMAN ROMANTICISM AND PSYCHOANALYSIS**

Romanticism, according to Thomas Mann, was “the most revolutionary and most radical” movement of the “German spirit.” Along with Judaism and the Enlightenment, it was one of Sigmund Freud’s main sources of inspiration. The culture of the age of Johann Wolfgang von Goethe infused his childhood and youth, but also the whole of the nineteenth century, which was steeped in post-romantic elements such as Darwinism and the resurgence, in Germany, of *Naturphilosophie*, forgotten at the end of the century (Ellenberger, 1974). Freud’s knowledge of certain romantic works of literature is attested by their presence in his library and by the 130 citations of them that appear in his writings.

If Freud was ambivalent with regard to romanticism, this may have to do with his disillusionment, during his youth, with the pan-Germanism (part of the post-romantic trend) of student circles in Vienna when he arrived at the university in 1873 and joined the Reading Circle of Viennese Students, whose “Wagnerism” soon veered toward nationalism and anti-Semitism (MacGrath, 1974).

On the other hand, all of the themes for which romantic science and medicine had laid the groundwork were to be found in psychoanalysis a century later: dreams and their “psychic value,” instinct, repression, the lifting of which is the source of “the uncanny” (Friedrich von Schelling)—the *unheimlich* being a central concept in both romanticism and psychoanalysis, Friedrich Schleiermacher’s secularized interpretations, which he even applied to speech, and of course *Witz*, that alloy of Jewish thought and romantic irony theorized by Jean Paul and August Wilhelm von Schegel, on whom Freud relied, along with Heinrich Heine, whose work he cited numerous times in his writings. A “defrocked romantic,” Heine was also Freud’s model as an atheist Jew, a “brother in unbelief” to Spinoza, one of the romantics’ sources. They gave Eros and sexuality an essential place, and, by elevating the individual ego, took on the conquest of inner freedom. We should also recall the “conquistador” status of Freud himself and the open, “interminable” form of his work.

Freud’s teacher Ernst Brücke had trained him in experimental physiology in a spirit of physico-chemical reductionism, which, in its opposition to the *Naturphilosophie* of his own teacher, Johannes von Müller, nevertheless allowed a romantic heritage to filter through in Freud’s work. It was brought forth by his self-analysis—in the tradition of the knowledge of self of the romantic *Bildung*—with Wilhelm Fliess, an adept of romantic biology who transmitted to him, notably, the idea of primal bisexuality. Freud then practiced hypnosis—the heritage of animal magnetism—to create, through a radical transformation, the psychoanalytic cure. At the same time, he drew upon the post-romantics of his own time to support his work: the theosophist Gustav Fechner, from whom he borrowed the concepts of topography and the pleasure principle, Theodor Lipps, for the unconscious, and Karl Scherner for dreams. At the time of the shift in his thinking in the 1920s, with the dualism of the instincts, Freud can be seen as returning to the “primal

antithesis of the world” of *Naturphilosophie*, and he later took part in an essential discussion with Romain Rolland, “the last of the great French romantics.”

In “A Short Account of Psycho-Analysis” (1924f) Freud alluded to romanticism as an element in the prehistory of psychoanalysis, while Ludwig Binswanger pointed out Freud’s faithfulness to the concept of nature as “mythical essence,” and Thomas Mann assessed psychoanalysis as a romanticism turned scientific.

## **GERMANY**

The first contacts between psychoanalysis and Germany occurred during the discussions and correspondence between Freud and Wilhelm Fliess at the end of the 1890s and continued through Freud’s student Felix Gattel. Between 1907 and 1910 psychiatrists who formed part of the entourage of Otto Binswanger, professor of psychiatry at Jena, became familiar with the “cathartic method.” They included Wolfgang Warda, Wilhelm Strohmayer, Arnold Georg Stegmann, Georg Wanke, Iwan Bloch, Arthur Muthmann, Otto Juliusburger, and Jaroslav Marcinowski.

The first systematic application of psychoanalysis in Berlin was carried out by Karl Abraham, a student of

Carl Gustav Jung and Eugen Bleuler. Abraham was in close contact with Freud since 1908 and was responsible for the first meeting of the Berliner Psychoanalytische Vereinigung (Berlin Psychoanalytic Association) on August 27, 1908, which involved a group of local doctors, including Magnus Hirschfeld (a sex researcher), Iwan Bloch (dermatology, human sexuality), Otto Juliusburger (psychiatry, abstinence), and Heinrich Koerber (circle of Monists). Later its members included Max Eitingon and Mosche Wulff. In 1910 the International Psychoanalytical Association was founded on the occasion of the second international congress of psychoanalysis in Nuremberg, with the Berlin Psychoanalytic Association the leading regional group. By the end of 1911 the Berlin association had eleven members, including three women, Tatiana Rosenthal, Karen Horney, and Margarete Stegmann, the first women analysts. In June 1912 two other nonphysician women were admitted as members at large.

Since German psychiatrists resisted psychoanalysis, recognition took place through various cultural movements (sexual liberation, the emancipation of women, judicial reform, monism). At the time two psychoanalytic congresses were held in Germany: the Weimar congress on September 21, 1911 and the Munich congress on September 7, 1913. The Berlin Psychoanalytic Association underwent qualitative consolidation in an effort to set itself apart from the sexual sciences (after the exclusion of Magnus Hirschfeld in 1911) and in reaction to the defection of Carl Jung, who gave up the presidency of the International Psychoanalytical Association in 1913 and was supported by the Munich group.

Aside from its institutionalization, psychoanalysis received a welcome reception in literature (from authors Lou Andreas-Salomé, Hermann Hesse, Rainer Maria Rilke, Alfred Döblin). Indeed, the city of Frankfurt awarded Sigmund Freud the Goethe Prize in 1930. It was also well received in art (though the mediation of Otto Gros, who was part of the action group that included F. Pfemfert, F. Jung, E. Mühsam). Georg Wilhelm Pabst’s film *Geheimnisse einer Seele* (The mysteries of a soul; 1926) was made in collaboration with Karl Abraham and Hanns Sachs.

Georg Groddeck, the “wild analyst” and the “father of psychosomatics,” opened a fifteen-bed clinic in Baden-Baden. During World War I, an opportunity arose to prove the effectiveness of psychoanalysis in

treating war neuroses. This had the effect of identifying the majority of analysts with the objectives of the war (with the exception of Helene Stöcker and Siegfried Bernfeld) and enabled them to maintain international scientific dialogue (for example, through the publication of the *Internationale Zeitschrift für Psychoanalyse*). Official recognition of psychoanalysis grew, as demonstrated by the presence of government representatives from Austria, Germany, and Hungary at the 1918 Budapest congress, whose theme was the use of psychoanalysis in treating war neuroses. It was here that Sigmund Freud spoke in favor of the use of mass psychoanalysis. In 1919 the Internationaler Psychoanalytischer Verlag (International Psychoanalytic Press) was founded in Leipzig (later in March 1936 the Nazis confiscated the firm's inventory).

The executive board of the Berlin Psychoanalytic Association appointed Max Eitingon, Ernst Simmel, and Karl Abraham on September 26, 1919, to head the Poliklinik für psychoanalytische Behandlung nervöser Krankheiten (Polyclinic for the Psychoanalytic Treatment of Mental Illnesses), which opened on February 16, 1920. Though the Berlin Psychoanalytic Association managed the Berlin Psychoanalytic Institute and the polyclinic, Max Eitingon owned the physical assets and library. He financed the association with an annual fund of 16,000 Reichsmarks. Annual elections were held for the various positions (polyclinic, teaching, candidate, cash management, and subventions). The association grew through an influx of Hungarian analysts fleeing the revolution and counterrevolution, as well as the arrival of analysts from other countries, who were attracted by the freedom and liberality of the Weimar Republic and the then favorable economic situation in Germany. From 1923 the training of analysts was systematized according to guidelines established by Max Eitingon, Carl Müller-Braunschweig, and Sándor Radó and included theoretical courses, a required analysis, and supervised analyses. In 1925 analytic treatment was recognized by a new Prussian order on honoraria (PREUGO) and the German doctor's agreement (ADGO). Following the death of Karl Abraham (on December 25, 1925), Ernst Simmel became director of the association (Sándor Radó was secretary, and Karen Horney was treasurer). On April 24, 1926, the association, in compliance with the international guidelines introduced by Ernest Jones, president of the International Psychoanalytical Association, became the Deutsche psychoanalytische Gesellschaft (DPG; German Psychoanalytic Society).

Germany was host to international psychoanalytic congresses in 1922 (Berlin), 1925 (Bad Homburg), and 1932 (Wiesbaden), as well as a couple of national conferences in 1924 (Würzburg) and 1930 (Dresden). Psychoanalytic work groups were formed in Leipzig in 1919 around Karl H. Voitel (from which a second group formed in September 1922 with Therese Benedek at its head), in Frankfurt in 1926 (with members Karl Landauer and Heinrich Meng), in Stuttgart in 1930 (with members Gustav Hans Graber and Hermann Gundert), and in Hamburg in 1930 (with members Clara Happel and August Watermann).

In 1929 the Südwestdeutsche psychoanalytische Arbeitsgemeinschaft (Southwest German Psychoanalytic Work Group, with members Karl Landauer, Heinrich Meng, and Frieda Fromm-Reichmann) was formed in Frankfurt in close collaboration with the Institut für Sozialforschung (Institute for Social Research) (with members Max Horkheimer and Theodor Adorno). This work group sought to diffuse psychoanalysis by providing training analysis and classes on theory held at the university for candidates without any therapeutic training. A few psychoanalytic clinics were established, though they soon closed for lack of financing. There were the Therapeutikum (from 1924 to 1928, with room for fifteen patients), founded by Erich Fromm and Frieda Fromm-Reichmann in Heidelberg to create a bridge between orthodox Judaism and psychoanalysis, and the Schloss Tegel sanatorium in Berlin (from April 1927 to August 1931) for the treatment of serious neuroses, addictions, and character disturbances.

In 1928 Max Eitingon became president of Internationaler psychoanalytischer Verlag. On January 13, 1931, he was elected president of the DPG, and was assisted by Felix Boehm, Hanns Sachs, and Ernst Simmel.

On April 7, 1933, a law restoring the "office of professions" was issued by the National Socialist government, followed, on April 9, 1933, by an "Aryanization" order directed at medical organizations. On April 22, 1933, medical health insurers started excluding "non-Aryan" doctors, and psychoanalysis was attacked as a "Jewish" science. Yet many eminent non-Jewish representatives of the profession, such as Felix Boehm and Carl Müller-Braunschweig, believed, as did National Socialism itself, that psychoanalysis was an effective therapeutic practice. Many eminent leftist psychoanalysts, including Wilhelm Reich, Otto Fenichel, and

Ernst Simmel, considered psychoanalysis to have a worldview opposed to National Socialism.

At the annual DPG meeting of May 6, 1933, when Boehm and Müller-Braunschweig proposed Aryanizing the presidency, most members voted against the change (eight out of fifteen, with five abstentions). On May 10, 1933, the works of Sigmund Freud, along with those of other psychoanalysts, were burned. On November 18, 1933, Boehm and Müller-Braunschweig assumed control of the society, and on December 31, 1933, Max Eitingon left Berlin.

At the annual DPG meeting held on December 1, 1935, the society, with the assistance of Ernst Jones, president of the International Psychoanalytical Association, refused to dissolve and decided to remain within the association. However, it required its Jewish members to leave the society. By 1936, 74 analysts had left Germany. Salomea Kempner, August Watermann, and Karl Landauer did not survive their incarceration by the National Socialists.

Some members of the DPG resisted the regime: Edith Jacobsohn fought with the socialist resistance group *Neu Beginnen* (New Beginnings). She was arrested on October 24, 1935, but managed to escape and fled to the United States. The DPG then passed a resolution that required members to abstain from politics. In February 1937 Käthe Dräger became head of the Berlin committee of the KPD-Opposition (the opposition group formed to fight the German communist party, or KPD). She wrote and distributed antifascist writings and tracts, and helped the families of comrades who had been jailed. In 1937 John Rittmeister was forced to flee Switzerland for “communist activity,” and in 1941 he joined the resistance group that had formed around H. Schultze-Boysen (the *Rote Kapelle*, or Red Orchestra). He was arrested on September 26, 1942, and executed on May 13, 1943. Fourteen psychoanalysts remained in Germany.

Discussions between Felix Boehm (president of the DPG), Sigmund and Anna Freud, and other leading analysts gave Boehm the impression of a certain neutrality toward or even support for his and the DPG’s adaptation to the National Socialist regime. But those involved did not want to further complicate matters, though they did not agree with his political views or the ideological conformism of Müller-Braunschweig. The Ministry of the Interior told Boehm that to obtain authorization to teach, he, as president of the DPG,

had to fold the other psychotherapeutic organizations into the *Deutsches Institut für psychologische Forschung und Psychotherapie* (German Institute for Psychological Research and Psychotherapy), which was to be under National Socialist control and run by Professor Matthias Heinrich Göring.

The new institute was founded in May 1936, and Max Eitingon’s assets “inventoried.” This was the beginning of the development of a “German psychotherapy,” an eclectic mix of different psychotherapeutic theories. The DPG was dissolved on November 19, 1938, after an aborted attempt by Müller-Braunschweig to transfer the *Wiener Psychoanalytische Vereinigung* (WPV; Vienna Psychoanalytic Society) and the publishing house to the German Institute for Psychological Research and Psychotherapy, within which it would become working group A.

Although Boehm and Müller-Braunschweig were officially banned from teaching and publishing, they were both important collaborators of the institute. They ran the polyclinic, and Boehm coordinated the working group on homosexuality, while Müller-Braunschweig coordinated the teaching program. The ban on the use of psychoanalytic terminology did not affect Harald Schultz-Hencke, however, who in 1933 developed a form of “neopsychanalysis,” an amalgam of current psychoanalytic teachings, by abandoning metapsychology and other essential elements of analysis.

Of the 300 members of the medical staff of the German Institute (including 17 members of the DPG/WPV), 41 were members of the Nazi party (the *Nationalsozialistische Deutsche Arbeiterpartei*), and of the 145 members who were not doctors (25 of whom were members of the DPG/WPV), 22 were party members. Although most of the DPG members remaining in Germany had managed to adapt to the Nazi regime, only Doctor Gerhard Scheunert was a member of the Nazi party. The German Institute, by then solidly established, was recognized by the union of German workers, financed by the *Luftwaffe* and private insurers, and, during the war, was “assigned to the war effort.” Eventually it was raised to the level of a government institute within the Reich’s research council (*Reichsinstitut im Reichsforschungsrat*), with an annual budget of 880,000 Reichsmarks.

After the war, though participants claimed to have sought to “save psychoanalysis” by their underground

presence, they faced considerable skepticism and criticism from colleagues living abroad. On October 16, 1945, the DPG was reestablished with Müller-Braunschweig as its first president, Boehm as representative, and Werner Kemper as the third member of the office staff. It had 35 ordinary members and 2 members at large, 12 of whom had been trained between 1936 and 1945. On April 29, 1946, it resumed activities (as the Berliner Psychoanalytische Gesellschaft until December 3, 1950), but the British military authorities forced the DPG to strike any mention of being a “member of the International Psychoanalytical Association.” On May 9, 1947, the Institut für Psychotherapie was founded in Berlin, with teachers from a variety of psychotherapeutic backgrounds, to provide training in psychotherapy; in 1948 the institute also began training “education counselors,” or *Psychagogen* (child and adolescent therapists).

During the first postwar International Congress of Psychoanalysis, which took place in Zurich in 1949, the confrontation between Harald Schultz-Hencke’s neops psychoanalysis and the conventional Freudian position of Müller-Braunschweig reached its culmination. The DPG was provisionally admitted to the International Psychoanalytical Association, subject to the requirement that its members state their position openly.

On May 13, 1950, Müller-Braunschweig, unsuccessful in his attempts to obtain recognition from Schultz-Hencke, secretly founded the Deutsche psychoanalytische Vereinigung (DPV; German Psychoanalytic Association). The DPV was admitted to the International Psychoanalytical Association at the 1951 Amsterdam congress, but not the DPG. The DPG only succeeded in regaining membership as the IPA Executive Council Provisional Society at the IPA Congress in Nice in 2001. In 2004 the DPV was the second largest group within the International Psychoanalytical Association in terms of number of members. At the suggestion of Werner Schwidder (member of the DPG and student of Schultz-Hencke), the DPG, in 1962, joined with other neops psychoanalytic groups to form the Internationale Föderation psychoanalytischer Gesellschaften (International Federation of Psychoanalytic Societies), comprising twenty individual societies in Europe, North America, and South America.

In spite of struggles for influence between the DPG and the DPV, which were just beginning to ease, in 1949 Wilhelm Bitter founded the Deutsche Gesellschaft für

Psychoanalyse, Psychotherapie, Psychosomatik und Tiefenpsychologie (German Society for Psychoanalysis, Psychotherapy, Psychosomatics, and Depth Psychology), a professional organization incorporating the major trends in depth psychology (neops psychoanalysis, conventional Freudianism, Jungian analysis, Adlerian analysis). The member societies took turns supplying presidents. As of 2004, it had approximately 3,150 members in 45 institutes, which are recognized by the kassenärztliche Bundesvereinigung (German association of registered physicians) and German medical associations as establishments providing further education to become child and youth analytical psychotherapists. Outside Berlin, working groups and psychotherapeutic establishments were created in Munich (the successor of the German Institute for Psychological Research and Psychotherapy and the mobile psychosomatic service of Johann Cremerius), Stuttgart (the working group in 1946, and in 1948 the Institut für Psychotherapie und Tiefenpsychologie [Institute for Psychotherapy and Depth Psychology], representing the various forms of depth psychology and founded by Wilhelm Bitter, Hermann Gundert, and Felix Schottlaender), Heidelberg (the department of psychosomatics run by Alexander Mitscherlich), Bremen (the working group founded by Hildegard Buder in 1949, and an institute founded by R. W. Schulte and Franz Rudolf Haarstrick in 1951), and Göttingen (the Tiefenbrunn regional hospital, founded by G. Kühnel and W. Schwidder). Later, institutes were created in all the major cities of the Federal Republic of Germany. The Berlin institute gradually lost its importance and was overshadowed by the institute founded in Frankfurt in 1961 under the direction of Alexander Mitscherlich and associated with the university. This was the Institut und Ausbildungszentrum für Psychoanalyse und psychosomatische Medizin (Institute and Learning Center for Psychoanalysis and Psychosomatic Medicine), which was renamed the Sigmund Freud Institute in 1964.

Mitscherlich and his wife, Margarete Mitscherlich-Nielsen, not only renewed relations with the Institute of Social Research (where Max Horkheimer and Theodor Adorno were central figures) but also initiated a dialog with the international psychoanalytic community concerning the controversies associated with Germany’s National Socialist past. Sparked by criticisms from the student movement, interest in social policies, group therapy, and family therapy grew (relevant authors include Horst-Eberhard Richter, Franz Heigl, Anneliese Heigl-Evers). The “Bernfeld Circle”

(Johannes Cremerius) began to question the training and qualifications of analysts, the issue of feminism, and the various polemics surrounding psychoanalysis (Christa Rhode-Dachser).

In the German Democratic Republic, ideology interfered with the resumption of a psychoanalytic tradition, although there was relative tolerance for neopsychoanalysis. In an initial phase running from 1945 to 1949, the analysts Werner Kemper (West Berlin), Alexander Mette (Weimar), and Franz Baumeyer (Arnsdorf) were among the dozen psychiatrists responsible for training and accrediting “mental health caretakers and psychotherapists.” In Leipzig, the neurologist A. Beerholdt, although he never completed his analytic coursework, was able to introduce psychoanalysis to several psychiatrists (Wendt, Starke, Behrendt, Böttcher). The only trained psychoanalyst remaining in the German Democratic Republic, Alexander Mette, left psychoanalysis to start a career in politics (he pursued an initial interest in health policies, then a university career, and eventually became a member of the chamber of deputies of the German Democratic Republic and a member of the central committee of the Socialist Unity Party). The contents of psychoanalytic discussions were determined by Harald Schultz-Hencke and his followers, Werner Schwidder, U. Derbolowsky, and G. Kühnel. Schultz-Hencke’s appointment as professor at Humboldt University on September 29, 1949, led the DPG to issue a resolution forbidding members from taking posts in both East and West Germany, and Schultz-Hencke gave up his professorship. Following the creation of the German Democratic Republic on October 7, 1949, psychotherapeutic establishments were created in Jena and Leipzig.

From 1950 to 1962, while psychoanalysis was expanding in the United States and an antipsychoanalytic movement was taking place in the Soviet Union (where Freud’s work represented a facet of National Socialist ideology), the trend in the German Democratic Republic turned to Pavlovianism. Associated with the therapeutic tradition of Otto Binswanger, Johannes H. Schultz, Ernst Speer, and O. Vogt, in 1951 a department of psychotherapy was opened at the medical polyclinic. There they developed a medical-materialist “rational psychotherapy” intended to replace neopsychoanalysis.

The period from 1963 to 1976, when H. Kleinsorge was president of the DPG, was characterized by greater

openness in discussions of psychotherapies and in international relations. In the society a number of sections were set up, organized according to method rather than their theoretical leanings: psychodynamic therapy, group therapy, autogenic training and hypnosis, infant therapy, music therapy. Between 1976 and 1984 recognition was granted to “medical specialists in psychotherapy” and “medical psychologists” (August 1978), and individual therapy was reintroduced. Fifteen regional societies of psychotherapy were created to cover psychotherapeutic needs and the basic training of doctors, and interdisciplinary working groups were formed to further integrate psychoanalysis with the medical field. After 1985 efforts were made to institutionalize psychotherapy in the universities by creating autonomous chairs of psychotherapy and medical psychology, and psychoanalytically oriented research on the body helped to conceptualize group therapy. Access to the psychoanalytic literature was still limited, however: Freud was first published in the German Democratic Republic as late as 1983.

In September 1947, the Studiengesellschaft für praktische Psychologie (Research Society for Practical Psychology) was formed in West Germany for representatives of all the academic professions concerned with the individual. Ever since 1945, in the university exams given to psychologists, psychoanalysis appeared under “depth psychology and education counseling.” After the educational reforms of 1973, it appeared in the larger field of “clinical psychology,” comprising the study of testing, prevention, rehabilitation, counseling, and other areas outside the field of depth psychology.

Gradually, psychoanalysis disappeared from higher education to be taught in training institutes and the psychosomatic departments of medical schools. Nonetheless, in experimental psychology, psychoanalysis remained the most systematic and most studied psychological theory in 1977. At the beginning of the 1980s, the emphasis on the interpretation of psychoanalytic texts brought about through the influence of Jacques Lacan made its appearance in German scholarship. After 1970 medical psychology and sociology, as well as psychotherapy and psychosomatics, became required material for students of medicine and resulted in the creation of the corresponding chairs and, in some cases, university departments. In 1979 the DPG created a psychoanalysis section alongside psychotherapy, and psychoanalysis became a part of the continuing training of doctors. At the start of the

1990s, specialist medical training included fields such as “psychotherapeutic medicine,” “psychiatry and psychotherapy,” “psychiatry and psychotherapy of children and adolescents.”

With respect to the relations between psychoanalysis and insurers, the Einheitskrankenkasse and the Rentenversicherung, in Berlin, had financed the Zentralinstitut für psychogene Erkrankungen der Versicherungsanstalt Berlin (Central Insurance Institute of Berlin for Mental Illness), founded by Werner Kemper and Harald Schultz-Hencke. By 1955 insurance reforms in Berlin had gradually done away with many of these organizations, but the Central Insurance Institute remains. Empirical follow-up work on outpatients by Franz Baumeyer and Annemarie Dührssen made legal recognition of psychotherapy possible. In 1960 the “Munich model” was instituted; this system involved the sharing of medical expenses among the government (for employees), insurers, and patients, each paying a third. In 1967 psychological and psychoanalytic therapies became covered general medical expenses for which insurers were responsible, following verification of the illness. In 1968 insurers (and in 1971 mutual insurance companies as well) started covering psychotherapy under certain conditions, and they also covered child therapies. On July 1, 1976, the medical committee and insurers modified the guidelines for analytic therapies to recognize neurosis as an illness. Psychosomatic treatment became covered from October 1, 1987. In therapy, if the symptoms are recognized, reimbursement covers 160 fifty-minute hours of treatment, with 80 to 140 additional hours possible. Psychologists who have received analytic training can provide psychoanalytic treatments. With the passing of a law regulating psychotherapists (June 16, 1998), “psychological psychotherapists” and child and youth therapists now require a license to practice medicine.

Among journals, one of the most important is *Psyche*, which began by focusing on depth psychology but later broadened its coverage to include cultural trends. *Jahrbuch der Psychoanalyse* published contributions to the theory, practice, and history of psychoanalysis. *Forum der Psychoanalyse* and *Zeitschrift für psychoanalytische Theorie und Praxis* are clinical in orientation. Other journals include *Praxis der Psychotherapie und Psychosomatik* and *Zeitschrift für psychosomatische Medizin und Psychoanalyse*.

Until the end of the 1960s, the DPG and the DPV were separated by their divergent theoretical positions

concerning Harald Schultz-Hencke’s neopsychanalysis. Since then, the DPG’s orientation has shifted to a more international position focused on the ego and the self and on the theory of object relations. Moreover, it has generally supported the classical Freudian position. However, there has been growing interest within both the DPV and the DPG for the Kleinian position, and contacts have developed with the “Middle Group” of the British Psycho-Analytical Society. Though there are a few theoretical differences (Rudolf, 1987), there are more differences in practice. For example, in training analysis the DPV recommends four sessions, and the DPG three.

After accounts were settled over Alexander Mitscherlich’s involvement with National Socialism, a reckoning that took place over a twenty-five-year period following the war, the first postwar congress of the International Psychoanalytical Association in Germany was held in Hamburg in 1985. At the congress there was a growing interest in the history of psychoanalysis, its development (Karen Brecht, Volker Friedrich, Ludger Hermanns, Dierk Juelich, Isidor Kaminer, and Regine Lockot), and its interpretation (Hermann Beland, Ermann). In 1995 and 1996 conferences between groups of German and Israeli psychoanalysts took place (H. Beland). In 1996 the first joint DPG-DPV conference was held on “the division of the psychoanalytic community in Germany and its consequences.” In 1996 the two societies, the DPG and DPV, had nearly the same number of members (approximately five hundred each).

## GESAMMELTE SCHRIFTEN

The twelve volumes of the *Gesammelte Schriften* constitute the first publication of Freud's complete (or almost complete) works in his native language. They were published by the Internationaler Psychoanalytischer Verlag.

This edition was undoubtedly planned when Freud was ill with cancer in 1923, and it was originally limited to ten volumes. Volumes 4, 5, 7, 8, and 10 appeared in 1924, volumes 1, 2, 3, 6, and 9 in the following year. Since Freud remained productive despite his illness, an eleventh volume containing his writings from the interim was published in 1928, and in 1934 a final volume appeared that brought together "the writings of 1928–33" and various additions to Volumes 1–11. Anna Freud and Adolf Josef Storfer served as editors for Volumes 1–11 and Otto Rank as their co-editor on Volumes 4, 5, 7, 8, and 10. Anna Freud and Robert Waelder made the selection and provided editorial commentary for Volume 12. As indicated on the endpapers, all volumes were "prepared with the collaboration of the author," and in correspondence Freud several times referred to the *Gesammelte Schriften* as the "complete edition" of his works.

This was not a critical edition, however. The somewhat random composition of Volumes 11 and 12 was the result, to be sure, of their belated conception. Volumes 1–10, envisioned as a whole, were organized by theme. Scholarly apparatus and commentary were minimal. There was no introductory statement of the principles governing the editors' choices and aims, nor was any bibliography or index provided. The only editorial decision of any moment concerned *The Interpretation of Dreams*, the first edition of which magnum opus, Freud's dream-book in its initial form, was offered as the second volume of the *Gesammelte Schriften*, while Volume 3 assembled the many and often voluminous additions that Freud made to the book in its subsequent editions. It was Freud himself who proposed this original way of presenting his great work.

Prior to the publication of the *Gesammelte Schriften*, Freud had for the most part published his work in the form of monographs, articles in journals or annals, or contributions to anthologies and collections. After the founding, in 1919, of his own publishing house, the Internationaler Psychoanalytischer Verlag, he generally published there. It was thus the "twelve volumes in dictionary format" (to quote the publishers'

promotional matter) of the *Gesammelte Schriften* that gave readers their first general view of the full scope and import of Freud's work.

## GESAMMELTE WERKE

The eighteen-volume *Gesammelte Werke*, along with an unnumbered supplemental volume (the *Nachtragsband*) constitutes the second complete edition of Freud's work in German.

In 1939, having emigrated to London, Freud founded the Imago Publishing Company as a successor to the Internationaler Psychoanalytischer Verlag, shut down by the Nazis. The chief purpose was to preserve the Viennese *Gesammelte Schriften*, duly modified, as a new *Gesammelte Werke*. Work on the project was begun as early as the fall of 1938, with Freud participating.

At the outset, the editorial committee consisted of Anna Freud, Edward Bibring, and Ernst Kris. Volumes 1 through 17 appeared between 1940 and 1952, which is to say after Freud's death. Bibring and Kris migrated to the United States in 1940–41, to be replaced by Willi Hoffer and Otto Isakower, who served as co-editors for every volume except 9 and 15, both of which were published in 1944. Marie Bonaparte's collaboration was acknowledged in every volume. Volume 18, planned as a *Gesamtregister* or General Index, was prepared by Lilla Veszy-Wagner, but before the manuscript could be sent to the printer, Imago Publishing Company went bankrupt in 1961. When S. Fischer Verlag of Frankfurt acquired the rights to Freud's works in 1960, they also came into possession of the remaining stock of the seventeen volumes of the *Gesammelte Werke* and the

manuscript of the *Gesamtregister*. After a thoroughgoing revision, Volume 18, the very first general index to Freud's work, finally appeared in 1968. In 1987 the *Nachtragsband*, edited by Angela Richards with the assistance of Ilse Grubrich-Simitis, brought together all of Freud's psychological and psychoanalytical texts that for one reason or another had not been included in the first seventeen volumes of the *Gesammelte Werke*.

Like the *Gesammelte Schriften*, the first seventeen volumes of the *Gesammelte Werke* cannot be described as a critical edition of Freud's work. Editorial comment is reduced to the bare minimum. In contrast to the approach of the *Schriften*, the contents of the *Gesammelte Werke* are ordered chronologically. Volume 2 and 3 reproduce the eighth edition of *The Interpretation of Dreams*, including all the added material.

The *Nachtragsband*, however, is supplied with a serious editorial apparatus and may be considered a critical edition. It is organized by theme, but its overall arrangement is chronological.

The main aim of the editors of Volumes 1-17, working from London during and immediately after the Second World War, was to make Freud's work available in its original language through the book trade. The editorial shortcomings resulted in part from the difficult conditions under which this second edition of Freud's collected works had to be produced; in light of the circumstances the undertaking constituted a remarkable rescue operation. The *Nachtragsband* eked out the set of texts in Volume 1-17 by adding writings that had come to light later, some of them lacking even in the *Standard Edition*, as for example the "Übersicht der Übertragungsneurosen" (Overview of the transference neuroses) of 1915. Some texts, among them the "Project for a Scientific Psychology" and Freud's original notes on the "Rat Man" case, appeared in the *Nachtragsband* in freshly corrected transcriptions.

Until such time, then, as a historico-critical edition is produced, the *Gesammelte Werke* and the *Nachtragsband* together constitute the most comprehensive presentation of Freud's work available in its original language.

## GESTAPO

It was not long after the *Anschluss* of March 13, 1938, that the Nazis began to take an interest in the Jew Sigmund Freud. The number of "visits" to the Berggasse residence increased in frequency and were often accompanied by demands for money. One Tuesday evening, on March 22, Anna Freud was held "bei Gestapo" for questioning, which sealed her father's decision to leave Austria.

It has been suggested that "humor is a polite way of expressing despair" and it is not surprising that a number of jokes circulated in Austria at the time. One of them, attributed to Freud himself, has been frequently repeated ever since Ernest Jones reported it: "One of the conditions for being granted an exit visa was that he sign a document that ran as follows, 'I Prof. Freud, hereby confirm that after the Anschluss of Austria to the German Reich I have been treated by the German authorities and particularly the Gestapo with all the respect and consideration due to my scientific reputation, that I could live and work in full freedom, that I could continue to pursue my activities in every way I desired, that I found full support from all concerned in this respect, and that I have not the slightest reason for any complaint.' When the Nazi officer brought it along Freud had of course no compunction in signing it, but he asked if he might be allowed to add a sentence, which was: 'I can heartily recommend the Gestapo to anyone'" (Jones, 1957, p. 226).

This "story" has been repeated many times and commented on by those who treated it as genuine. Some commentators have reproached Freud for a "recommendation" they felt to be ambiguous; others admired his audacity. Eventually, some people ended up believing that Freud had actually added this sentence to the Nazi document.

It is hard to imagine that Freud, who was aware of the difficult and costly negotiations by the U. S. ambassador to France (William C. Bullitt), Marie Bonaparte, and Ernest Jones to obtain his visa, and

who was responsible for the fate of his daughter and wife within the climate of the anti-Semitic hatred that had taken hold in Vienna, would have taken the risk of making a joke that in a matter of seconds might undo all their efforts. Moreover, he was depressed by the powerlessness resulting from his age and poor health, as he wrote in a letter to his son Ernst on May 12, 1938, "I am writing to you for no particular reason because here I am sitting inactive and helpless while Anna runs here and there coping with all the authorities, attending to all the business details" (letter number 297, p. 442). But his "official" biography maintained this fiction, and none of those close to Freud denied it, especially Anna Freud.

The original text of the statement was found during a 1989 public auction of documents concerning the emigration of Freud's family. It is a more sober statement, closer to the horrible truth of those years, than the theatrical version given by Jones, and more consistent with the customary bureaucratic indifference of the Nazi machine. It was written by Alfred Indra and signed by Freud, without any additions by him. It reads: "*Erklärung. Ich bestätige gerne, dass bis heute den 4. Juni 1938, keinerlei Behelligung meiner Person oder meiner Hausgenossen vorgekommen ist. Behörden und Funktionäre der Partei sind mir und meinem Hausgenossen ständig korrekt und rücksichtsvoll entgegnetreten. Wien, den 4. Juni 1938. Prof. Dr. Sigm. Freud.*" (Declaration. I hereby confirm of my own free will that as of today, June 4, 1938, neither I nor those around me have been harassed. The authorities and representatives of the Party have always conducted themselves correctly and with restraint with me and with those around me. Vienna, June 4, 1938. Prof. Dr. Sigm. Freud.)

Freud's comment was most likely introduced to mask the anguish of his departure—a form of black humor, which had close links, throughout Freud's life, with the tradition of Yiddish *Witze*, which were often also tinged with despair.

## **GIFT**

Gifts and money are unconsciously associated with anal eroticism. In "On Transformations of Instinct as Exemplified in Anal Eroticism" (1916–1917e), Sigmund Freud writes, "It is probable that the first meaning which a child's interest in faeces develops is that of 'gift' rather than 'gold' or 'money.' . . . Since his faeces are his first gift, the child easily transfers his interest from that substance to the new one which he comes across as the most valuable gift in life. Those who question this derivation of gifts should consider their experience of psycho-analytic treatment, study the gifts they receive as doctors from their patients, and watch the storms of transference which a gift from them can rouse in their patients" (pp. 130–131). The gift is meaningful because of its connection to the libido and eroticism. Freud's investigation led him to the discovery of the unconscious link with defecation and its relation to treasure hunting.

Karl Abraham (1916) examined the connection between excessive giving and anxiety. He investigated (1919) the transference meaning of the associations—occasionally excessive—presented by the patient to the psychoanalyst as a gift. This attitude is an expression of narcissism and is characterized by its view of analysis as something governed by the pleasure principle.

What happens to the instinctual impulses of anal eroticism after the genital organization has been established? Freud in "On Transformations of Instinct as Exemplified in Anal Eroticism" (1916–17e) responds with the idea of the transformation of instinct. In this schema, gift equals excrement according to the symbolic language of the dream and daily life.

The first gift is excrement, a part of the infant's body he gives up only upon the mother's insistence and through which he manifests his love for her. Defecation and its relation to the object thus become the first opportunity for the infant to choose between bodily pleasure (narcissism) and object love (sacrifice).

Later in life the interest in excrement is transferred to an interest in gifts and money. The concepts of excrement, infant, and penis are poorly distinguished

and are frequently treated as if they were equivalent; they can easily be substituted for one another. Freud perceived the identity of the infant with excrement in the linguistic expression: “to give a child.” Similarly, Freud wrote in the “Wolf Man” (1918b), “By way of this detour demonstrating a common point of departure in their significance as gifts, money can now attract to itself the meaning of children, and in this way take over the expression of feminine (homosexual) satisfaction.”

Freud views the transference relation of certain patients as a vague recollection of this problematic, arising whenever the patient wants to interrupt the unfinished treatment and place himself in a situation of disdain that originates in the outside world. The patient then replaces the urgent desire to have a child with promises of significant gifts, most often as unrealistic as the object of his past desire. This concept is developed in *Beyond the Pleasure Principle* (1920g).

Melanie Klein (1932–1975) demonstrated the importance of the theme of poison gifts as a source of depression and melancholy toward the object. “For the child gifts attenuate his guilt by symbolizing the free gift of what he wanted to obtain by sadistic means.” In this same article, Klein clarifies the role of ambivalence and sees it as a step forward compared to archaic mechanisms. The gift provides access; it is a preliminary form of sublimation within the compulsions of reparation and restitution associated with obsessive behavior.

## **GLOVER, EDWARD (1888–1972)**

Edward Glover, British psychoanalyst and physician, was born on January 13, 1888 in Lesmahagow, Scotland, and died August 16, 1972, in London.

Born in a small Scottish village, he was the third and youngest son of a country schoolmaster, Matthew Glover, who, for reasons of health, had previously given up a very promising scholastic University career. His mother, Elizabeth Shanks Glover, had been raised by her uncle, a Minister of the Reformed Presbyterian Church, and she was privately educated in its very firm tenets and strict Sunday observances, as well as in domestic arts. By contrast, Edward's father was Darwinian and agnostic, but Edward was raised in what he regarded as his mother's oppressive religious convictions.

Glover is said to have inherited his literary gifts from his mother, but his father's linguistic expertise and thorough knowledge of Greek, Latin, Hebrew, French, and English must have deeply influenced him. Matthew Glover's interest in natural philosophy, his intellectual rigor, scientific attitude, and capacity to teach was likewise reflected in Edward's selfsame gifts.

But the boy hated his early years of schooling and religious instruction, describing himself as “reluctant, rebellious, contumacious, and obstinate” as a pupil, though he seems otherwise to have had a happy childhood. But, on entering secondary school—under his father's direction—he threw himself into his work with energy and gusto, matriculating at sixteen, starting medical training, and qualifying M.B., Ch.B. with distinction at the age of twenty-one.

He was appointed House Physician to the well-known cardiologist Professor John Cowan at Glasgow Royal Infirmary, and in the next few years learned to apply scientific method to clinical practice and undertook research. Four years later he became Senior Resident at the Glasgow Children's Hospital, and remarked

that there “the facts of psychological life could no longer be gainsaid.” He became Assistant Physician at the Edward VII Sanatorium at Midhurst, greatly admiring the pathologist there, J.A.D. Radcliffe, whom he felt provided him with a disciplined understanding of natural scientific method. Glover’s experience led to significant published contributions to the field of pulmonary medicine.

In following his medical career he had been greatly influenced by his oldest brother, James. His dissatisfaction with a strictly organic approach to medicine—the limitations of which he discovered in the course of his own clinical practice—led him to follow his brother James’s interest in Freud’s psychology. James had moved to Brunswick Square in London to set up a psychiatric practice with Drs. Jessie Murray and Julia Turner. In 1920 the brothers went to Berlin to undergo training analyses (Edward preferred to call his an apprenticeship) with Karl Abraham, studying alongside Ella Freeman Sharpe and Mary Chadwick—also to make their names as psychoanalysts in London. Glover had an honorary appointment there, and learned as much psychiatry as he could from the hospital facilities in Berlin before returning to London, becoming an associate member of the British Psycho-Analytical Society in 1921 and a full member the following year.

James, who was close to Ernest Jones, died in 1926, and Edward took over many of his commitments. He was appointed Scientific Secretary of the British Society, Director of Research, Assistant Director, under Jones, of the London Clinic of Psychoanalysis, and then Secretary of the training committee of the International Psychoanalytic Society. His influence in the British Society was second only to Jones, while his reputation among doctors outside the Society was unsurpassed. He was a fine public speaker and a very gifted writer; and although he sometimes lapsed into polemics, he produced some memorable and witty sayings in the process.

Glover was sufficiently self-critical to recognize that, for a time after his qualification, he had allowed his enthusiasm for psychoanalysis to undermine, at times, the critical and scientific discipline that had become so important to him during his strictly medical work. But it was an error that he soon set about correcting. He became an enemy of what he called “unchecked speculation,” and became, in a series of telling critiques of analysts and former analysts published over the years (most notably, perhaps, *Freud or*

*Jung* [1950]), what someone in another field once called “the necessary antidote to everything.” In this he held firmly to the common ground of basic psychoanalytic concepts. Unhappily, he lived to see that ground becoming increasingly less common.

Much of his work, however, consists of original contributions covering a wide range of psychoanalytic interest. These included: drug addiction; prostitution; *War, Sadism, and Pacifism* (1933); *The Technique Of Psycho-Analysis* (1955); the classification of mental disorders; the early development of mind and the nuclear theory of ego formation; education; and research methods in psychoanalysis. A selection of many key papers appeared in 1956. A classic textbook on psychoanalysis was published in 1939 and substantially enlarged for a second edition in 1949. But, perhaps above all, his contributions to the study of psychopathy and crime reflected his single greatest interest, about which he wrote a large number of papers, the bulk of them gathered together in his book *The Roots of Crime* (1960). From small beginnings in 1922, and in association with Grace Pailthorpe and others, the foundations were laid on which Glover later founded the Institute for the Study and Treatment of Delinquency (ISTD), the clinical wing of which was later adopted by the National Health Service as the Portman Clinic, while the scientific and research division was funded separately. Together with Hermann Mannheim and Emanuel Miller, Glover founded *The British Journal of Delinquency* (later *The British Journal of Criminology*) in 1950 and, together with the ISTD, launched the International Library of Criminology. He was a founding member of the editorial board of *The Psychoanalytic Study of the Child*.

Glover is often remembered in the British Psychoanalytic Society, perhaps unfairly, for the part he played in the series of Controversial Discussions, recorded with great thoroughness and scholarship by Pearl King and Riccardo Steiner in *The Freud-Klein Controversies 1941–45* (1991). Glover’s critique of Klein, later published separately, is still perhaps the most thorough and exhaustive on this topic. His dissent led him to leave the Society in 1944, but he continued to be a member the International Psychoanalytic Association through his honorary membership of the Swiss and American Societies. Glover’s first wife, whom he married in 1918, died eighteen months later from septicemia. He married for a second time in

1924, and their only child, a mentally handicapped girl, was born in 1926.

## **GLOVER, JAMES (1882–1926)**

English psychoanalyst and physician James Glover was born in Lesmahagow, Lanarkshire, Scotland. Six years older than his well-known brother Edward, James was, after Ernest Jones, the most notable British (Scottish) psychoanalyst of his era. As he died prematurely from diabetes at the age of forty-four, after only eight years of training and practice of psychoanalysis, he left few publications. Had not Ernest Jones devoted eight pages of the *International Journal of Psychoanalysis* (volume 8, 1926) to his obituary, there would be little record of his life and the name of Glover would exclusively be associated with his younger brother.

James and Edward were the sons of Matthew Glover, country schoolmaster and academic, and Elizabeth Smith Shanks, who came of a farming family. There was a middle brother who died. James was regarded as the genius of the family and Edward as the more pedestrian. James received a fine Scottish

education, which stimulated and trained his intellect; throughout his life he maintained his knowledge of science and philosophy. At the same time, he was a writer of short stories and a great reader of literature.

James qualified as a physician and surgeon in Glasgow at the early age of twenty-one. As he was already in poor health, he undertook sea voyages and spent some years in Brazil where he practiced both medicine and surgery. After some ten years his health deteriorated further and he returned to Britain where he practiced chest medicine and ear, nose, and throat surgery.

His philosophical interests turned to psychology and to an interest in Freud. In 1918 he joined the Brunswick Square Clinic, the first psychotherapy center in the United Kingdom, founded by Julia Turner and Dr. Jessie Murray. They practiced an eclectic form of psychotherapy, influenced by Pierre Janet and Dejerine. James underwent a “pseudo-analysis” with Julia Turner and quickly became co-director of the clinic with her after the illness and death of Dr. Murray. He was very active in training psychotherapists at the clinic and was in charge of the rehabilitation of resident patients. But his skeptical and enquiring mind and strict scientific and philosophical outlook soon made him dissatisfied with eclectic psychotherapy and he decided to become a psychoanalyst. In 1920 he attended the Hague Congress of Psychoanalysis and went on to Berlin for some months of analysis with Karl Abraham and returned to him for more analysis the following year. At this time he insisted that psychoanalysis should be the only form of psychotherapy at the Brunswick Square Clinic and persuaded both the patrons and the staff to close the clinic and to transfer its funds and activities to the Psychoanalytic Society. Jones writes that he displayed tact combined with a steel-like resolution in order to get his way. Amongst the psychoanalysts who were drawn to psychotherapy through the Brunswick Square Clinic were Sylvia Payne, Mary Chadwick, Ella Sharpe, Nina Searle, Susan Isaacs, Iseult Grant-Duff, Marjorie Brierley and the Jungian Constance Long.

Glover became an associate member of the newly formed Psychoanalytic Society in 1921, full member 1922, and in 1924 was appointed to the council. He arranged the transfer of the International Library of Psychoanalysis to the Hogarth Press of Leonard and Virginia Woolf. Glover was untiringly active in the Psychoanalytic Society, training, lecturing (particularly on anxiety states), and establishing the clinic of the society, and was its assistant director.

Glover was a fine lecturer and a fierce polemicist, a trait shared with his brother Edward. He was appointed chair of the medical section of the British Psychological Society, which was the meeting ground for psychotherapists of different persuasions. One of his few published papers is his contribution to a symposium “The conception of sexuality” (1925), in which he savagely criticized the contribution of J.A. Hadfield, a leading figure at the Tavistock Clinic. Reading his paper gives a vivid insight into the quality of Glover’s mind; he was described by Ernest Jones as lucid, ironic, as a master of metaphor, and a searcher for truth.

Glover hesitated to publish and had to be persuaded. He gave a paper “Notes on an unusual form of perversion”, at the 1924 Salzburg Congress and it was published in *The International Journal of Psychoanalysis*. He gives a clear and rigorous account of the analysis of his patient who was an alcoholic fetishist. Glover showed that there was a marked oral fixation underlying the genital oedipal level: the attitude to the maternal nipple was as a source of pleasure and a focus for oral sadism. He wished to take revenge on the nipple for his weaning and for his mother’s betrayal of him through her genital relationship to her husband. The patient’s fetishist behavior involved shoes, which represented both the maternal phallus and a disgust for smell, which was a fecal displacement. Particularly interesting is his discussion of the fetish having been established at a phase when clear self-object differentiation had not been established.

Glover died of severe diabetes: Ernest Jones wrote that this was “an inestimable loss” to psychoanalysis.

## GOETHE AND PSYCHOANALYSIS

Johann Wolfgang von Goethe (born August 28, 1748; died March 22, 1832), poet and dramatist, dominated the German literary scene of his time. The *Aufklärung*, *Sturm und Drang*, of which he is the principal representative along with Johann Herder and Friedrich von Schiller, the German classicism he embodied along with Schiller, and German romanticism have all been referred to by Heinrich Heine as “Goethean.” He is one of the principle sources of Freudian thought.

Freud noted Goethe’s scientific interests (Freud, 1930e). After reading the poem, “Hymn to Nature”—then attributed to Goethe but in reality written by Georg Christoph Tobler, a Swiss pietist—Freud decided to enter medical school, and according to Ludwig Binswanger, throughout his work remained faithful to nature’s “mythical essence.” A theoretician of evolution fifty years before Darwin, Goethe inspired Freud, as shown by the “sheep’s head” dream, where the dreamer’s associations make reference to Goethe’s research on the intermaxillary bone of the sheep.

Goethe introduced the ideas of Spinoza—another of Freud’s models—into Germany, and Freud often quoted Goethe’s maxim: “The best of what you know/ You could not tell your students,” which reflected the need for dissimulation imposed by the revelation of essential truths.

Freud often quoted Goethe’s *Faust*; speaking through the devil, he assumed his role as (metapsychological) sorcerer in the creation of his work. He also referred to the “eternal feminine” and the “Mothers,” using the poet’s words to flesh out his conception of the representation of the mother and woman. He made use of a number of Goethe’s lines, such as “in the beginning was the Deed,” (for example, 1912–13a, p. 161) and “What thou hast inherited from thy fathers, acquire it to make it thine” (e.g., 1912–13a, p. 158n).

Goethe was a secret advisor to the Duke of Saxe-Weimar and had Johann Fichte and representatives of the first phase of German romanticism appointed to the University of Jena. Nearly contemporary with the universalism of the Enlightenment and the French Revolution, he opposed a number of romantic ideas, even though the concept of *Naturphilosophie* was a logical outcome of his scientific research. In Goethe’s work, the word *Trieb*—which became a core concept in psychoanalysis—assumes the meaning of instinct,

need, and mental impulse, *Bildungstrieb* being the secret force that animates living creatures. The model of the *Urphänomen* influenced the model of the primal in mental life (Vermorel, 1995).

Goethe was one of Freud's principal models and he quotes him a hundred and ten times, according to the Concordance. He even shows up in Freud's dreams as a familiar character, like his family and friends. Freud identified with this creative genius, who, like him, was coddled during childhood by his mother but deeply wounded by the death of family members. According to Alain de Mijolla (1981), because he often held his father in low esteem, Freud created a double of his grandfather Schlomo in the idealized figure of the sage of Weimar.

In his acknowledgments for receiving the Goethe prize, Freud recognized that the poet had emphasized Eros in mental life and appreciated the value of dreams. He said his inspiration for the term "psychoanalysis" came from the "chemistry" found in the *Elective Affinities* (the alchemy to which Goethe was introduced as a young man). He went so far as to turn him into a precursor of psychoanalysis, for having described in *Iphigenia* a kind of spiritual cure, and using conversation to heal a mental symptom experienced by Mrs. Herder (Freud, 1930e).

## GOETHE PRIZE

The Goethe prize was awarded by the city of Frankfurt to Sigmund Freud on August 28, 1930 in Frankfurt-am-Main. The prize, instituted in 1927, was awarded annually on August 28, the anniversary of the birth of Johann Wolfgang von Goethe. The sum of ten thousand Deutsche Marks was awarded to individuals "whose creative activity served to honor the memory of Goethe." Before Freud the prize had been given to Stefan George (1927), Albert Schweitzer (1928), and Leopold Ziegler (1929).

In 1927 Heinrich Meng and Stefan Zweig had begun a promotional campaign to propose Freud for the Nobel Prize. Members of the Frankfurt Psychoanalytic Institute (1929–1933), especially Heinrich Meng, also worked to ensure that Freud was awarded the Goethe prize. Because of his poor health, Freud, then seventy-four years old, was unable to accept the prize in person and sent his daughter Anna Freud to Frankfurt for the awards ceremony (1930d).

The award of the Goethe prize by Frankfurt in 1930 was considered by Freud to be the culmination of his public life. Discussions by the award committee appeared to idealize psychoanalysis, but in fact it was criticized. Among the adversaries of psychoanalysis there was a general refusal to accept psychoanalysis and a converse movement to idealize Goethe, which, given the regressive nature of German society of the time, was soon to become a permanent characteristic. A few years later, in 1933, Freud's writings were burned by the National Socialists in Frankfurt and in other German cities.

The reaction of the media to the award simply repeated the controversy that divided the award committee. The periodical *Die Psychoanalytische Bewegung* (1930), contains a review of the event in German.

## GOOD-ENOUGH MOTHER

The “good-enough mother” is a mother whose conscious and unconscious physical and emotional attunement to her baby adapts to her baby appropriately at differing stages of infancy, thus allowing an optimal environment for the healthy establishment of a separate being, eventually capable of mature object-relations.

Evolving slowly, and underpinning Donald Winnicott’s theory of early integration, personalization and object-relating, this concept includes the “ordinary devoted mother” (1949), and “the good-enough environment”. It first appears clearly in Winnicott’s “Mind and its Relation to the Psyche-Soma” (1949).

Winnicott’s emphasis on the particular need for maternal sensitivity begins in his paper “The Observation of Infants in a Set Situation” (1941), and is referred to repeatedly in his work. His statement, “There is no such thing as a baby” implies that without a mother, an infant cannot exist. He describes “primary maternal preoccupation” (1956), the psychophysiological preparedness of a new mother for motherhood, as a special phase in which a mother is able to identify closely and intuitively with her infant, in order that she may supply first body-needs, later emotional needs, and allow the beginnings of integration and ego-development.

The good-enough mother is described as responding to the infant’s gesture, allowing the infant the temporary illusion of omnipotence, the realization of hallucination, and protection from the “unthinkable anxiety” (primitive agonies) that threatens the immature ego in the stage of “absolute dependence.” Failure in this stage may result, ultimately, in psychosis.

As the infant develops, the good-enough mother, unconsciously aware of her infant’s increasing ego-integration and capacity to survive, will gradually fail to be so empathic. She will unconsciously “dose” her failures to those that can be tolerated, and the infant’s

developing ego is strengthened, the difference between “me” and “not-me” clarifies, omnipotence is relinquished, a sense of reality begins to emerge, mother can be increasingly seen as a separate person, and “the capacity for concern” can develop. Failure in this stage may result in the formation of a “false self.”

Winnicott describes how the capacity to be alone can develop out of the experience of the infant of being alone in the presence of another. Ego-immaturity is balanced by ego-support from mother, and this ego-support is in time internalized, so that aloneness is tolerable (1958).

Many writers approach environmental failure (Fairbairn, Kohut, Balint, and others); however, few describe the optimal situation in health as described by Winnicott. Winnicott is accused of romanticism, idealism and optimism in his description of the mother whose adaptation is so exquisite, and of “blaming the mother” when things go wrong. It is important in reading his work to realize the lack of moralism he evinces. Winnicott certainly regrets the failure of those mothers who cannot reach the state of being “good-enough,” but acknowledges that this state arises out of their own early relationships, and he emphasizes repeatedly the strength of innate maternal capacity.

## GÖRING, MATTHIAS HEINRICH (1879–1945)

Matthias Heinrich Göring, a German physician, psychiatrist, and Nazi, was born on April 5, 1879, in Düsseldorf, Germany and died in 1945 in captivity in Poznan, Poland.

He earned a doctorate in law at Freiburg/Breisgau in 1900 and a doctorate in medicine at Bonn in 1907. Specializing in psychiatry and neurology, in 1923 Göring set up practice as a *Nervenarzt* in Elberfeld and subsequently underwent a training analysis with Adlerian Leonhard Seif in München. In 1928 he established an educational counseling service in Elberfeld and in 1929 founded a study group of psychotherapy in Wuppertal.

Like fellow Adlerians Seif and Fritz Künkel, Göring placed an emphasis upon “community feeling,” to which he added German patriotism and Christian pietism. He was therefore critical of psychoanalysis for its alleged materialism and pansexualism.

Göring’s significance in the history of psychoanalysis stems from his career after 1933. His position as leader of organized psychotherapy in Nazi Germany stemmed from the fact that he was an elder cousin of Nazi boss Hermann Göring. In part to protect the fledgling institution of psychotherapy against Nazi medical activists and university psychiatrists, Göring (who joined the Nazi party in 1933) preached against “Jewish” psychoanalysis and supervised the exclusion of Jewish psychoanalysts from his society and institute.

In 1934 Göring assumed leadership of the German General Medical Society for Psychotherapy and from 1936 to 1945 was director of the German Institute for Psychological Research and Psychotherapy in Berlin. In 1938 he presided over the destruction of the Vienna Psychoanalytic Institute and the dissolution of the German Psychoanalytic Society, although also protecting and employing psychoanalysts August Aichhorn, Felix Boehm, and Carl Müller-Braunschweig.

At the German Institute for Psychological Research and Psychotherapy in Berlin and at branches elsewhere in Germany and in Vienna, however, non-Jewish psychoanalysts continued to practice, study, and train. Göring himself allegedly expressed appreciation for the expertise of the Freudians, who were especially active within the Berlin outpatient clinic. Göring’s wife Erna was in analysis with Werner Kemper and his son Ernst underwent a training analysis with Carl Müller-Braunschweig. Outpatient director and psychoanalyst John Rittmeister, however, fell victim to charges of espionage and was executed by the Nazis in 1943.

The legacy for psychoanalysts in Germany of the institutionalization of psychotherapy that Göring occasioned during the Third Reich has been one of both professional advancement and internecine ethical debate.

## GRAF, HERBERT (1904–1973)

Herbert Graf is broadly known in psychoanalysis by the name of “Little Hans.” Born on April 10, 1904 in Vienna, he died on April 5, 1973 in Geneva.

Graf was the Stage Director at the Metropolitan Opera in New York 1936–1960, and Director of the Grand Theatre in Geneva (1965–1973). He also authored several books on opera production in America.

The son of Max Graf, musicologist and critic, and Olga Graf (nee Hoenig), apparently a one-time patient of Freud’s, Herbert Graf grew up in the avant-garde intellectual atmosphere of fin de siècle Vienna. His godfather was Gustav Mahler. He describes, in a four part interview with Francis Rizzo later in life, how he “invented” his study program in order to become an opera director, for which there was at that time no prescribed curriculum.

In 1922 Freud published a postscript to “Analysis of a Phobia in a Five-year old Boy” in which he describes a visit from “Little Hans” when he was a young man. Graf himself refers to this visit in the Rizzo interviews and reports that he had no recollection of the treatment until he came across Freud’s paper in his father’s study. Several place names that Freud had not altered led him to believe that the article referred to him. He sought Freud out in Berggasse 19 and the meeting is described in Freud’s publication.

Graf’s publications were not in the field of psychoanalysis. The interviews with Rizzo are interesting for the light they shed on the attitudes towards Freud’s theories amongst intellectuals in Vienna in the early part of the twentieth century. Graf’s later biography had no relevance to psychoanalysis. As “Little Hans” he was of fundamental importance. His treatment was the very first example of a child analysis, although an unusual one, as it was carried out by his father under Freud’s “supervision.”

## GRAF, MAX (1873–1958)

Max Graf, a composer and music critic, the father of “Little Hans,” was born October 1, 1873, in Vienna, where he died on June 24, 1958.

The son of Joseph Graf, a Jewish writer and editor, he was educated in Vienna and Prague. After 1891 he studied at the law school of the University of Vienna but devoted most of his time to music and it was his intention to become a composer, according to Louis Rose (1986). He finished his legal studies in 1896 but devoted much of his time to music composition and criticism, and regularly took part in meetings of the literary group *Jung-Wien*. From 1902 to 1938 he taught the history of music and musical aesthetics at the Vienna Academy of Music, where he was appointed professor in 1909.

Graf met Sigmund Freud in 1900 and his wife, Olga Graf (born Olga Hoenig), from whom he separated a few years later, was probably a patient of Freud’s. Within the psychoanalytic movement he is known for being the father of “Little Hans,” Herbert Graf, who was born in 1903. It was Max who supplied Freud with the material for his paper “The Analysis of a Phobia in a Five-Year Old Boy” (1909b).

At the end of 1904, he took part in sessions of the Wednesday Psychoanalytic Society and, in December 1907, wrote an essay entitled “Methodik der *Dichterspsychologie*” (Methodology of the Psychology of the Poet). In early 1906 Freud wrote a short text on a somewhat unexpected topic, “Psychopathische Personen auf der Bühne” (Psychopathic Characters on the Stage). The text was never published in German, but Graf, to whom Freud had given the manuscript, kept it and had an English translation published (1942a [1905–1906]).

In 1909 Graf settled in Paris as a correspondent for the *Frankfurter Zeitung* and translated Romain Rolland into German. “In 1910–1911 he gave up all work

with the Society. His book on the psychology of creativity appeared in 1910 and his pamphlet on Wagner in 1911. In February 1909 Freud had asked him to prepare an essay on ‘Mozart and his Relation to Don Juan,’ but Graf did not follow up on the idea. He officially withdrew in 1913” (Rose, 1986). On the list of members of the Vienna Psychoanalytic Society for October 1913, his name is crossed off.

Graf emigrated to the United States in 1938 and taught until 1947 at the New School for Social Research in New York, where, in 1940, he created the first seminars in music criticism. He was a guest professor at the Carnegie Institute of Technology in Pittsburgh and at Temple University in Philadelphia. In 1947 he returned to Austria and taught music criticism at the Mozarteum in Salzburg and elsewhere. In 1953 his autobiography, *Jede Stunde war erfüllt: Ein halbes Jahrhundert Musik- und Theaterleben* (Every Minute Filled: A Half-Century in Music and Theater), was published in Vienna, where he died in 1958.

## GRANDIOSE SELF

The grandiose self, described and developed as a normal narcissistic configuration by Heinz Kohut in 1971

in *The Analysis of the Self*, corresponds to or replaces the “purified pleasure-ego” posited by Sigmund Freud: The subject, center of the world, expels what is unpleasurable and preserves what is pleasurable. In theory, the instinctual grandiose self is integrated into the self to form the nucleus of the ambitions (strivings), but it cannot constitute itself or be the object of fixations, repression, or splitting.

The grandiose self, also called the narcissistic self, first appeared in Kohut’s work in 1964. A description of an aspect of the narcissistic personality, it acquired a metapsychological status in Kohut’s 1971 book.

From a developmental point of view, the infant attempts to restore narcissistic perfection by establishing narcissistic configurations, among them the grandiose self, a structure invested with energy that is rooted in exhibitionist part-instincts. In narcissistic pathology, the activity of the grandiose self explains the intensity of the demand for attention; if it is repressed, no source is available to nourish the reality-ego, which is characterized by a lack of self-esteem, feelings of inferiority, and a tendency toward depression. In Kohut’s *The Restoration of the Self* (1977), the grandiose self is the pole of the self that draws its strength from the self objects’ responses to mirroring needs.

The notion is related to mirror transference.

Initially instinctual, the grandiose self was desexualized with Kohut’s generalized self psychology advanced in 1977.

## GRANOFF, WLADIMIR ALEXANDRE (1924–2000)

Wladimir Alexandre Granoff, a French psychiatrist and psychoanalyst, was born September 7, 1924, in Strasbourg, and died in Neuilly-sur-Seine on February 2, 2000.

His family, part of the Russian intelligentsia, had moved to Alsace after emigrating from Russia. Young Granoff attended secondary school in Strasbourg. During the war, as a refugee in Nîmes, he discovered Freud's work in the local library. He began studying medicine and psychiatry in Lyon and continued his education in Paris.

With the Société Psychanalytique de Paris (Paris Psychoanalytic Society) he began a training analysis with Marc Schlumberger; Maurice Bouvet and then Jacques Lacan directed his group control analysis, and Francis Pasche his individual control analysis. In 1953 he began organizing the student rebellion at the Institut de Psychanalyse with Serge Leclair and François Perrier, whom he followed during the June 1953 split. The three men were later referred to as the "Troika." After their secession they participated actively in the Société Française de Psychanalyse (SFP) (French Society for Psychoanalysis), founded in 1953, leading seminars on clinical psychoanalysis together and working to ensure the organization's admission into the International Psychoanalytic Association (IPA). During a colloquium on female sexuality organized by the SFP in September 1960 in Amsterdam, Granoff and François Perrier presented a report on "Le problème de la perversion chez la femme et les idéaux féminins," which reopened the question of female sexuality (*La Psychanalyse*, 1964).

He played an important role in negotiations with the IPA (Pierre Turquet, Max Gitelson) because of his multilingualism (he spoke Russian, German, English, and French). In 1963, together with his friend Victor Smirnoff, he prepared a "Histoire de la psychanalyse en France," in order to convey to the Anglo-American psychoanalytic community the originality and specificity of psychoanalysis in France. The article was mimeographed and translated into English, but remains unpublished at this time. Despite these efforts, Granoff sensed that their request would be rejected and that Lacan would never be admitted to the IPA. He also felt he himself had been betrayed by Lacan. So, in 1964, he helped found the Association Psychanalytique de France (French Psychoanalytic Association) and abandoned any further involvement in institutional politics, refusing even to attend IPA congresses.

After years of absence from public life, he presented a paper in 1973–1974, "Filiations, l'avenir du complexe d'Œdipe," a psychoanalytic interpretation of the

history of psychoanalysis, characterized by a return to Freud's writings. In 1974–1975 he gave another talk on "La pensée et le féminin." These presentations were contemporaneous with those given by François Perrier and it was at this time that the two men renewed their former friendship.

He was one of the first to introduce Sándor Ferenczi in France and held a conference in 1958 entitled "Ferenczi: faux problème ou vrai malentendu" (published in *La Psychanalyse*, 1961). In 1983 he published, together with philosopher Jean-Michel Rey, *L'Occulte, objet de la pensée freudienne*, in which he investigated Freud's interest in telepathy.

His withdrawal from organizational work did not mean retirement from active life, and Granoff always maintained relations with French Lacanians and foreign colleagues. Because of his broad exposure to European culture and his Slavic background, he was perhaps the most cosmopolitan, the most international French psychoanalyst of his generation. His work—in large part appearing in individual articles—focused on Freudian practice as well as the problems of translating and transmitting psychoanalysis.

## GRAPH OF DESIRE

The Graph of Desire is a schema, or model, that Jacques Lacan began developing in his seminar on *The Formations of the Unconscious* (1957–58). It achieved

its definitive form in his essay “Subversion of the Subject and the Dialectic of Desire in the Freudian Unconscious” (1960/2004). Its four successive stages represent the constitution of the human subject and his desire. Nevertheless, Lacan never intended it to describe the genetic stages of a biological development. Rather, it represents the “logical moments” of the birth of a speaking subject.

Lacan starts with what he calls the “quilting point” (where an upholsterer attaches a button to a sofa or mattress to prevent the batting from moving around) a kind of looping by which the signifying chain of the parental Other’s “discourse”—not to be understood here as merely verbal, of course—intersects with the baby’s expressions of need (See Figure 1).

This pressure of need is represented by a retrograde trajectory beginning at delta ( $\delta$ ). In the course of its reverse looping, this line intersects at two successive points the vector  $S \rightarrow S'$ , which represents the chain of the Other’s discourse. Because they travel in opposite directions, the two trajectories carry out this double intersection in a retroactive manner that calls to mind Freud’s concept of “deferred action.” For Lacan, the point of intersection on the right,  $A$ , represents the “treasure trove of signifiers” (p. 292), which is Lacan’s definition of the Other as the “locus” of the signifying battery on which the subject depends. On the left, the other point,  $s(A)$ , represents the moment at which a meaning is produced in the heart of the Other, which henceforth makes it a sign for the infant.

This first stage of the graph forms a “circuit” of vectors that first follows the chain of the Other’s

discourse, from  $s(A)$  to  $A$ , and then returns, from  $A$  to  $s(A)$ , along the path of the baby’s biological impulses. In this circularity, everything comes back to the signifying structure of the Other’s discourse. The demand of the newborn must conform the Other’s “code” in order to be understood.

In spite of this apparently closed circularity, Lacan also situates the constitution of the ego ideal at this level. By grasping upon an insignia of the Other’s parental power,  $s(A)$ , the child anticipates its own future access to any power whatsoever. From then on, the ego ideal,  $I(A)$ , is inscribed at the endpoint of trajectory delta, as an anticipated function that the child can attain in relation to the parent.

The process where the ego is constituted makes up the second stage of the graph. A right-to-left vector goes from the specular image,  $i(a)$ , to the constitution of the ego,  $m$  (Figure 2). This vector is essentially imaginary, which means that it belongs to the register of spatial-corporeal representation, and it is grafted as a short circuit onto the delta trajectory, which represents the pressure of need.

From then on, a second circuit can be taken by returning along the signifying chain,  $S \rightarrow S'$ . This return circuit, by which the constitution of the ego is implicated in the discourse of the Other, might constitute in itself an impasse, from which no subject could extricate himself. And this is where Lacan made one of his specific contributions to psychoanalysis by emphasizing the intrinsic doubling of the Other’s discourse.

We have seen that effects of meaning are manifested in the Other,  $s(A)$ , where they are interposed between

FIGURE 1

FIGURE 2

**FIGURE 3**

the needs of the baby and certain signals and statements coming from the mother. The baby comes to feel capable of provoking these maternal manifestations, and at the same time develops a paranoid tendency to interpret their intentionality when they appear.

Lacan developed an account of this essential phenomenon on the basis of certain linguistic facts that led him to distinguish, beyond the subject of the *statement* evident in the parental discourse, a more or less obscured subject of the *enunciation*. This implied that quite another dimension of unconsciousness was possible (Figure 3).

The intentionality that is assumed to exist in the manifestations of the Other causes the child to ask—*What does he want from me?* This question forms the basis of the first experience of anxiety (*Hilflosigkeit*). Given the fundamental mirroring nature of the imaginary relation that gives the ego substance, this paranoid question—*What does he want from me?*—returns in the form of a question addressed to the nascent subject—*What do you want?* (or “*Chè vuoi?*” as Lacan puts it). This form of address, characteristic of the superego leads to the upper stage of the graph, which it takes the form of a question mark rooted in A, the place of the Other. But the Other at this stage is still not in any way the “barred” by the symbolization of its possible absence and not yet marked by the incompleteness of its sexual identity. At this point the Other is still the all-embracing expression of the two parents merged into a single non-castrated parent figure. It is the perception of the mother’s lack of a penis that now plays the crucial role of representing the incompleteness of the maternal Other.

For the nascent subject, this is a transformational moment that leads to a recognition that the Other is desiring/lacking. From that moment on, the Other will be “barred,”  $S(\bar{A})$ , and submitted to the symbolic system of exchange that is instituted in the aftermath of the of the superego’s question (*Chè vuoi?*). It is from this point that we can conceive of the emergence of a subject in its own right. Lacan designates it with a barred S because of its fundamental dependence on a relation of at least two signifiers, one of which is necessarily the signifier of the lack in the Other—without which, Lacan said, no signifier would ever be able to represent a “person.”

This is what can be formalized in a fourth imaginary stage wherein the subject that is detached at the point of symbolization by the Other finds a way to represent itself as having a relation with the object of desire through an unconscious fantasy, as shown in the formula  $\$ \diamond a$ . The operation by which the Other is recognized as lacking is inscribed in a symbolic system of exchange that nevertheless includes a real “remainder” made up of objects that are detachable from the mother. These are the Freudian partial objects, which Lacan designates with a small *a*, that become part of the fantasy. Any persistent difficulty in symbolically marking the mother’s lack interferes with the constitution of the fantasy and leads to a failure in the process of subjectivation (Figure 4).

At the upper level of the graph, along the imaginary vector ( $d \rightarrow \$ \diamond a$ ), desire and fantasy maintain a relation similar to the one that at the lower level governed the constitution of the ego in relation to the image of the small other,  $i(a)$ . However, Lacan noted that these two imaginary stages are not in any way analogous to each other, since unconscious desire tends to present itself regularly to the ego as precisely what the ego does not want. The subject of the unconscious fantasy, in contrast to the ego, represents for Lacan “the ‘stuff’ of the *I* that is primally repressed” (p. 302). In treatment, this subject would be the analyst’s true interlocutor.

The two levels of the graph are modeled on a split that is structural in the human being (in Lacan’s terms *parlêtre*, or “speaking-being”). The first level, that of the statement and of specular relations of the ego, is prior to castration. It manifests a phallic-narcissistic logic where the nascent ego remains trapped in the circle of the Other’s all-importance. The upper level, on the other hand, has as its keystone the signifier of the lack in the Other,  $S(\$)$ , the guarantor of a discourse

For some years, having failed to obtain recognition in London, Jones had worked in Toronto and was one of the founders of the American Psychoanalytic Association. Though Jones must be regarded as an outstanding figure in the development of the psychoanalytic movement, he was not alone. David Eder gave the first paper on psychoanalysis to a medical audience in 1911 at a Congress of the British Medical Association; the audience left in disgust before he had finished speaking. Henry Butter Stoddart, a distinguished psychiatrist who became a convert to psychoanalysis, was better received. He gave a series of lectures titled "The New Psychiatry" in Edinburgh in 1915. There he found converts as well as opponents, the most significant of the former being George Robertson, Professor of Psychiatry at Edinburgh, who thereafter declared himself a Freudian. Stoddart, a stout, good-humored man, played a quiet yet important role in establishing psychoanalysis within psychiatry, through his well respected textbook "Mind and its Disorders."

In these early days psychoanalytic ideas were supported and propagated by important psychiatrists and psychologists who nevertheless maintained a critical attitude and did not become members of Jones's reformed British Psycho-Analytical Society (1919). Eder was accepted as, after some analysis with Sándor Ferenczi, he left Jung. Bernard Hart was significant both because of the respected position he held and as author of a textbook, "The Psychology of Insanity" (1912), which ran through many editions and was the principal textbook in support of psychoanalysis. The influential psychologist William McDougall, the research psychologist Sir Cyril Burt, the well-known clinician William Browne, all made Freud's ideas accessible to their professions. Perhaps the most brilliant figure was William Halse Rivers, psychiatrist, research psychologist, and anthropologist, who died prematurely in 1922. Rivers, along with other dynamically-minded psychiatrists, treated psychiatric casualties during World War One with a psychotherapy that was strongly influenced by psychoanalysis. Rivers's work and personality became well known through the autobiography of the poet Siegfried Sassoon who had been Rivers' patient during the war. The novelist Pat Barker used Rivers as a central character in her three novels about psychiatry and the First World War: *Regeneration*, *The Eye in the Door*, and *The Ghost Road* (London, Viking).

Psychoanalysis made great strides through the treatment of psychiatric cases during World War One, and

there were many chronic cases of these war casualties who had to be treated after the war. The Ministry of Pensions set up clinics to deal with these patients and their senior psychiatrist was the analyst David Forsyth. Attacks upon psychoanalysis came from many psychiatrists, notably a disciple of Hughlings Jackson, Charles Mercier. He attacked psychoanalysis as a German importation that would corrupt the minds both of doctors and of children. In his attacks he was supported by many other psychiatrists, amongst whom was the first Professor of Psychiatry in England, Shaw-Bolton. In a critical article, "The Myth of the Unconscious Mind" (1926), Shaw-Bolton stated that it had been a repugnant task to write but that psychoanalysis was an insidious poison being inserted into the minds of the young.

Jones reformed his Society more carefully and retained a strong control over its development for over two decades. Its outstanding supporters included the brothers James and Edward Glover. James, who died early, had been to Karl Abraham in Berlin for analysis and on his return dissolved the Brunswick Square Clinic which had been an important training institution for psychotherapy that was not psychoanalytic (Boll, 1962). Amongst its students who later became analysts were Mary Chadwick, Ella Freeman Sharpe, Nina Searl (a pioneer in child analysis), Iseult Grant-Duff and Marjorie Brierley, the last of whom was to become a very influential psychoanalytic theoretician.

In the 1920s psychoanalysis increased both in popularity and notoriety. The British Medical Association set up a committee to investigate and report on the subject of psychoanalysis following public disquiet over breakdowns and suicides said to be the result of psychoanalysis. This committee sat for three years and took evidence from both supporters and opponents of psychoanalysis. Ernest Jones represented psychoanalysis, and his impressive performance carried the day for the cause. The result was that the British Medical Association acknowledged psychoanalysis as an authentic form of treatment and determined that the term psychoanalysis should not be used for any other technique or theory than that of Freud. However, the committee did not record its support of psychoanalysis, solely its recognition.

In the 1920s and early 1930s the Psychoanalytic Society remained quite small and London remained the only training center. Some British analysts went to Vienna for analysis (the Stracheys, Money-Kyrle,

Riviere), some to Berlin (James and Edward Glover, Ella Sharpe), some to Budapest (David Eder). Interest grew in child analysis and Nina Searle began to write on this topic before Melanie Klein's arrival in 1926 at Jones's invitation. Klein was introduced through Alix Strachey who had gone to Berlin for further analysis with Abraham, being dissatisfied with her experience in Vienna with Freud. The correspondence between James and Alix Strachey gives a vivid picture of the two cities, Berlin and London, and their psychoanalytic communities.

It should be recognized that a distinct "English" school of psychoanalysis had begun to emerge. The distance from Vienna led to independent thinking; consideration was being given to the psychic consequences of bereavement and mourning following from the great number of casualties and bereaved families left by the war. This led to a consideration of object relations in addition to libidinal forces. John Carl Flugel, who held an academic position at London University, wrote the influential "Psychoanalysis of the Family," and John Bowlby researched the psychological and socially deprived backgrounds of juvenile delinquents. Donald Winnicott applied his extensive experience as a pediatrician to child analysis.

Melanie Klein made a powerful impact in Britain through her writings on early psychic development. She was supported by Susan Isaacs, Joan Riviere, Ernest Jones and others, although many analysts considered her ideas to be unsystematic and overly speculative. Among them, her clearest critic was Marjorie Brierley. Ronald Fairbairn, working in isolation in Edinburgh, was considerably influenced by Klein, and in turn Melanie Klein recognized that she also learned from him; impressed by his work on the schizoid personality she added "schizoid" to her "paranoid" early infantile stage, hence "paranoid-schizoid." Fairbairn was the strongest revisionist of psychoanalytic theories, establishing a full object relationship theory.

Jones continued to be the dominant figure in British psychoanalysis, as a result both of his writing and his personality. Influenced by Melanie Klein's exploration of early psychic development, he wrote on female sexuality in a way that Freud perceived as a challenge both to himself and to his daughter Anna. Jones tried to achieve a balance between the innovative British work and the more conservative Viennese mode, instituting a series of exchange lectures in an attempt to build bridges.

Edward Glover was Jones's close collaborator and for many years the presumptive next president of the Society. He produced the first enquiry into the theories and practices of psychoanalysis by issuing a questionnaire to members of the British Society which later he elaborated into his authoritative textbook on the technique of psychoanalysis. Though Glover had supported Melanie Klein for some years, later he strongly opposed her, and for this reason found himself against strong opposition when preparing to succeed Jones as president.

British psychoanalysis was dramatically changed by the flight of Sigmund and Anna Freud and their supporters to London in 1938. It is not pleasant to find it on record that Melanie Klein thought it unfortunate that the Freuds had come to London as it would prejudice her intellectual hold on the Psycho-Analytic Society. Indeed, conflict soon broke out between the Viennese and the supporters of Melanie Klein which in wartime led to the famous "Controversial Discussions" that set the scene for the tripartite division of training in the British Psycho-Analytical Society after the war, the three groups of Kleinians, Freudians and the Middle, later Independent Group. This group consisted of those who did not wish to be identified with either of the warring camps. Influential teachers during this period included: for the Klein Group, Susan Isaacs, Joan Riviere, Paula Heimann, Roger Money-Kyrle; for the "Middle Group"; Ella Freeman Sharpe, James Strachey, Sylvia Payne, Donald Winnicott, William Gillespie, Marjorie Brierley, and later Michael Balint; for the Anna Freud Group were Kate Friedlander, Ilse Hellman, and Willie Hoffer. Anna Freud virtually retired from the British Psycho-Analytical Society to build her own training center in child analysis at the Hampstead Child Therapy Clinic, though on the international scene she retained her pre-eminence in psychoanalytic theory.

British psychoanalysis has been regarded as leading the way in child analysis. This is due to several factors. The Hampstead Child Psychotherapy Clinic provided thorough training in child and adolescent analysis, as systematically organized by Anna Freud and her close collaborators. Research initiated by Joseph Sandler on the Hampstead Index (representing the Clinic's collection and collation of clinical experience) has led to several important publications. Anna Freud's concept of "developmental lines" has been a significant clarification in the study of child development. Melanie

Klein's theories have had a major impact and many child analysts have adopted her theories. The training in infant observation and child analysis at the Tavistock Clinic is largely Klein-oriented. Some of her ideas have eventually been partly accepted by those who previously opposed them, including Anna Freud's followers. Klein retained a stronghold on the writings of her followers, which eventually led Paula Heimann to leave her group. In contrast to Anna Freud, Klein did not develop a systematic training in child analysis, though her influence on the Tavistock training is noticeable. Donald Winnicott's writings represent a distinct and different viewpoint. His vast experience as a pediatrician and his acute observational powers led him to the concepts of transitional space and transitional object, tracing the infant's move away from total dependence on the maternal environment. His original concepts such as holding, the use of an object, and the object's survival of the infant's destructiveness, have been influential internationally. Originally a supporter of Melanie Klein, he became a strong critic of what he saw becoming a proselytizing movement within the British Society. Khan, an analysand of Winnicott, was a blazing comet who burnt himself out. His sparkling, erudite papers, which also bridged British and French psychoanalysis, were notable contributions though his polemical debating style demonstrated an equally noticeable self-inflation. In his later years he became isolated, somewhat paranoid and was asked to resign from the Society because many members were outraged by the anti-Semitic tone of his last book, written during his final illness.

The balance between the size and influence of the three groups varies: the "Group of Independent Analysts" is the largest in number, followed by the Klein group and then the "Contemporary Freudian" as the former "B" (Anna Freud) group was called. There is a "gentleman's agreement" that each group should be represented on committees and take turns in the significant roles of President, Scientific Secretary and Chairs of important committees. Total membership as of 2005 was 443 Members and Associate Members, many of whom live abroad. On qualification the student is elected to associate membership. Candidates for full membership are obliged to take part in a membership course with seminars and advanced supervision.

The Institute is responsible for the International Journal of Psycho-Analysis, founded by Jones in 1920;

the New Library of Psycho-Analysis, which is the successor to the original library which Jones founded in 1921 and which was published by Leonard and Virginia Woolf at the Hogarth Press; and also for the Standard Edition of Freud's work, which was undergoing a new revision as of 2004. Riccardo Steiner has demonstrated the political aim that Jones and his translators held in "standardizing" the language of psychoanalysis in the English version. In recent years there has been more activity devoted to making psychoanalysis better known to the general public through systematic courses of lectures and daylong and weekend meetings, which are more directed to interested professionals.

It is obligatory of psychotherapy training institutions to submit to regulation and registration which has brought psychoanalysts into closer collaboration but also into conflict with other psychotherapeutic training institutions. The United Kingdom Council for Psychotherapy was formed to represent and regulate psychotherapy trainings. The British Psycho-Analytical Society, together with the Society of Analytical Psychology (Jungians), the Tavistock Clinic and some other broadly psychoanalytic organizations have broken away from UKCP to form the British Confederation of Psychotherapists, so as to affirm their group identities as "psychoanalytic."

University College of the University of London has a privately funded Chair of Psychoanalysis which must be occupied by a psychoanalyst. Students can gain PhDs for research in the field of psychoanalysis and these students do not have to be members of the Psycho-Analytical Society. The Tavistock four-year training in psychoanalytic psychotherapy can lead to a PhD as well. For several years it has been possible to achieve psychoanalytic training in Scotland through a joint venture of the Scottish Institute of Human Relations and the Institute of Psycho-Analysis in London. Training is also possible in Northern Ireland and may become possible in other regions of the British Isles.

The British Psycho-Analytical Society has coped with great dissension without splitting into conflicting units and is likely to remain one body. Psychoanalysis is still regarded as a prestigious qualification and attracts good candidates, although the number of medically-qualified applicants has diminished. The Institute has always accepted women and non-medically-qualified applicants and has recently declared itself to operate a non-discriminatory admissions policy regarding sexual orientation and ethnicity.

A full account of this movement, principally associated with Ronald D. Laing and David Cooper, has been provided by Digby Tantum (1991). Laing wrote his most famous and influential book, *The Divided Self*, when he was a senior registrar at the Tavistock Clinic and in training analysis with Dr. Charles Rycroft. Although he was accepted as an associate member of the British Psycho-Analytical Society, he rapidly distanced himself from it and he and Cooper founded their own Philadelphia Association. Together they ran a community named Kingsley Hall on “anti-psychiatric” lines. The basic tenets of anti-psychiatry are as follows: Schizophrenia is not an illness, but a label arbitrarily fixed by society and confirmed by psychiatrists; the symptoms of madness are understandable as communications; what psychiatrists call schizophrenia is either a reaction to a disturbed family or a healing voyage which would be of benefit if it could be completed without interference; and, lastly, psychiatrists and psychiatric hospitals degrade people and cause mad behavior.

Laing and Arnold Esterson carried out research on families in 1958 and 1967, partly at the Tavistock Institute of Human Relations and at Villa 21, Shenley Hospital, which was directed by Cooper and which treated young schizophrenics. From their researches they concluded that schizophrenia was a reaction to familial or social pathology and that symptoms were caused by disturbed family communications. Their findings were published as “The Politics of Experience” (1967) and by Cooper as *Psychiatry and Anti-Psychiatry* (1967). As Tantum described it, “Many readers agreed with Laing that a plausible account of symptoms in terms of disturbed family communication was tantamount to proving that disturbed family communications caused symptoms. ‘The Politics of Experience’ was written at the height of the 1960’s rebellion by young people against their parents generation. It was the apogee of flower power and a year before the Paris Events. Drug induced mysticism was fashionable and was presented as a voyage of self-discovery. It was tempting to pretend that schizophrenia was not only intelligible but intelligent” (1991).

Laing’s legacy survives in the Philadelphia Association and in the Arbours Association, which is led by his former associate Joseph Berke. Both these organizations have training programs and the Arbours Association provides shelter and treatment for psychotic patients in residential homes, thus avoiding hospitalization. The

other legacy of the anti-psychiatry movement is found in the refinement of psychiatric diagnosis and in a more psychodynamic approach to both the schizoid character and to schizophrenia. The movement has also increased the momentum away from psychiatric treatment and toward self-help circles for persons who have suffered psychotic breakdowns and who try to avoid further psychiatric involvement. Laing had relatively little direct influence within the British Psycho-Analytical Society and his theories and practices were marginalized by lack of attention.

The Tavistock Clinic has a reputation for psychoanalytic psychotherapy. Founded after World War I by Hugh Crichton-Miller, it began as an eclectic center for psychotherapy where Freudians, Jungians, and Adlerians, among others, provided psychotherapeutic services. During the Second World War the director of the Tavistock Clinic, John Rawlings Rees, who was not himself a psychoanalyst, was appointed director of British Army Psychiatry. Through his influence, several future leaders of psychoanalysis, including Wilfred Bion, John Rickman, and Thomas F. Main, were given posts of high responsibility. When they returned to civilian life at the end of the war they succeeded in making the Tavistock Clinic a psychoanalytic clinic, no longer eclectic. John D. Sutherland, who succeeded Rees as director, held an early enthusiasm for group psychotherapy under the leadership of Bion (and later of Henry Ezriel). This movement eventually faded and was replaced by individual psychoanalytic psychotherapy. Over the years the Kleinian Movement became predominant and those who did not follow this school were to some extent marginalized. The most conspicuous example is that of John Bowlby, whose research into the links between ethology and psychodynamic theory was regarded as extraneous. Bowlby had created the Department of Family and Children and introduced a systems approach to the pathology of the family and because of his “contamination” by such ideas he was also marginalized in the British Psycho-Analytical Society, of which he had been a prominent member since the 1930s. Before his death, however, the importance of his contribution was recognized internationally and thereby he regained recognition within Britain.

Michael Balint did a great deal to make the name of the Tavistock Clinic known internationally through his work with family doctors. Together with his wife Enid, he carried out extensive research into

psychodynamic aspects of general practice, and “Balint Groups” spread worldwide. Balint had succeeded Ferenczi as the Director of the Hungarian Psychoanalytic Institute but came to Britain in the 1930s as a refugee. He quickly established a strong position for himself as a representative of the Hungarian school of psychoanalysis and was recognized as one of the leaders of the “Independent” group, in time becoming President of the Society. He also stimulated research into brief psychotherapy, which was carried out by a group of psychoanalysts drawn from the Tavistock Clinic and the Cassel Hospital.

The Cassel Hospital, too, was founded following World War I, to provide inpatient psychotherapy, and between the wars it became more psychodynamic in its approach. Following World War II, Thomas Main became its director, and the hospital became a center for psychoanalytic inpatient psychotherapy. Many psychoanalysts in training were employed there. The hospital gained a worldwide reputation for its innovations in psychodynamic nursing and for its contributions to the therapeutic community movement. The Cassel can be contrasted to the Henderson Hospital which under Maxwell Jones took an approach to inpatient psychotherapy that was socio-psychological rather than psychoanalytic.

## **GREECE**

Reference to the history of psychoanalysis in Greece lends itself to reflection along two different lines.

First, there is the history of events—that is, the diachronic line of events that, between 1915 and the 1980s and 1990s, sustained the slow (and somewhat difficult, owing to discontinuities) establishment of a framework for the psychoanalytic movement in Greece, with all of the consequences, both positive and negative, that such a framework entailed for psychoanalytic circles. This chronology shows that, around 1920, a circle of intellectuals and teachers were actively studying the works of Sigmund Freud and publishing on practices in psychotherapy and psychoanalysis. However, the official medical community and the broader public remained indifferent or even hostile to these currents of thought.

The active presence of Princess Marie Bonaparte in Athens beginning in 1946 seemed to offer a way of changing things. The interest of academics and doctors was mobilized on the occasion of a visit by Anna Freud, who was invited to Athens in 1949, but this lasted only for the short duration of her stay. Only two psychiatrists, Démétrios Kouretas and Georges Zavitzianos; a poet, Andreas Embirikos; and a physician, Nicolas Dracoulides, were interested in pursuing more in-depth psychoanalytic training. These four men formed a working group, and, supported by Marie Bonaparte, were accepted as members of the Société psychanalytique de Paris (Psychoanalytic Society of Paris) in 1950. However, the group was to be short-lived: It disbanded a year later, the four analysts having chosen to settle in three different countries.

After the end of World War II and the civil war that ravaged Greece, the creation of a few institutional, psychodynamically oriented mental health centers made it feasible to organize lecture series, seminars, and group discussions in Athens; these developments seemed to portend a possible new beginning for analytic work. Colleagues from abroad—Serge Lebovici was the first—were prepared to offer assistance, beginning in 1957. Three Greek analysts working in different areas—Kouretas at the University of Athens, Pangiotis Sakellaropoulos at the Center of Thétokos, and Anna Potamianou at the Center for Mental Health and Research—provided the impetus, as hopes for a new beginning took shape. And once again, the central

figures comprised two psychiatrists and one person from outside of that field.

Numerous attempts to ensure sustained and systematic collaboration did not yield results. It was not until 1982, after countless efforts and failures, and with the help of a group of analysts who had trained overseas (Athena Alexandris, Pierre Hartocollis, Stavroula Beratis), that a “Greek psychoanalytic group” gained formal recognition as a study group of the International Psychoanalytic Association (IPA). This group, which includes four teaching analysts, ten members, eight corresponding members, and twenty-six candidates, was designated by election as an IPA member society in 2001.

Between 1989 and 1995, two groups inspired by the work of Jacques Lacan, the Freudian Praxis, and the Athenian Circle of the European School of Psychoanalysis, as well as another group whose members wished to remain independent of any school, were formed. Still two other groups follow the teachings of Alfred Adler. Thus, the diachronic axis in Greece reveals considerable oscillation between forward movement and movements of regression-repetition, attesting to an unconscious, but definite, fidelity to Freudian thought in connection with the psychic trajectory of individuals and groups.

A second line of reflection brings out even more clearly the similarities between the course of development of psychoanalysis in Greece and the very essence of the Freudian *Logos*. Marked by a convergence between the Jewish soul and the Hellenistic spirit, Freud’s thought engraved a path of complementary opposites and constraints that mirrors the history of psychoanalysis in Greece. That history, it seems, is the fruit of conflicts whose unexpected violence often astonished spectators; it is also the result of harsh schisms and mutilating projections, the revelatory details of which can be found in the writings of those involved in its difficult and laborious gestation.

Opposition and indifference arose within the group; analysts departed to seek training abroad. There were abortive attempts, productive convergences, jolts, and contacts. It is certain that the development of psychoanalysis was not exempt from tumultuous adventures in any country. However, it is equally certain that in this land that engendered what for Freud doubled as the alien element of the unconscious—that is, the discourse and

myths of the ancient Greeks—the constraint of rejection and exclusion of analytic thought exerted its influence for too long. There are a variety of reasons for this, and they have been studied and discussed by such authors as Gerosimos Stephanotos, Athanase and Hélène Tzavaras and Anna Potamianou. Currently, this constraint has been eased somewhat. For Freud, the journey leading to Athens was not easy; the price he paid in terms of his autoanalysis was considerable. For Greek analysts today, there is certainly a price to be paid so that analysis may “be” in their country.

With regard to publications in Greek: Kouretas and Zavitzianos published numerous works, mainly concerning clinical practice and applied psychoanalysis. More recently, Greek psychoanalysts have mostly tended to publish in the language in which they received their training (English, French, or German), but numerous articles and several books, including four collaboratively written volumes, have also been written in Greek.

### **GREENACRE, PHYLLIS (1894–1989)**

Phyllis Greenacre, American psychoanalyst and physician, was born May 3, 1894 in Chicago, Illinois, and died October 24, 1989 in Ossining, New York.

Greenacre was the fourth of seven children of Isaiah Thomas, a prominent lawyer, and Emma Russell. After graduating from Rush Medical College in Chicago, in

1916, she became an intern and resident at the Phipps Clinic at the Johns Hopkins Hospital in Baltimore (Harley and Weil, 1990).

At the Phipps Clinic, where Greenacre remained for twelve years, she came into contact with the great Swiss-American psychiatrist, Adolf Meyer. Her exposure to Meyer reinforced her conviction of the inextricable link between biology and psychology. In 1932 she began psychoanalytic training at the New York Psychoanalytic Institute, graduating in 1937. In 1942 she was appointed a training analyst and henceforth served in a number of important institutional positions at the Institute.

During this period there was a growing influx of émigré analysts to the United States and particularly to New York. Greenacre was influenced by two of these émigrés, Heinz Hartmann and Ernst Kris. Her friendship with Kris was particularly significant because he encouraged her to value her unique analytic vision.

Greenacre's written contribution falls into three categories: clinical papers on development; psychoanalytic training and therapy; and studies of creativity. Her first paper, "The Predisposition to Anxiety" (1941), was criticized for its exploration of preverbal stages of development, and her argument that the roots of anxiety might predate the existence of the ego. This paper and its companion, "The Biological Economy of Birth" (1945), are also noteworthy because they announce her interest in memory and its vicissitudes. Greenacre's clinical work took as its point of departure her conviction of the importance of reconstruction in analytic work. She paid close attention to screen memories, believing them the path by which early preverbal experiences could be traced.

In the early 1950s Greenacre began writing on fetishism, and observed that fetishists had an especially mutable body image. The fact that descriptions of bodily changes were central to the writings of Lewis Carroll and Jonathan Swift led to the biographical study *Swift and Carroll* (1955). She wrote a number of papers on creativity, and proposed a theory of aggression, in *The Childhood of the Artist* (1957), as a manifestation of a positive developmental force; aggression as a positive response by the infant to the circumstances of its earliest experiences, both frustrating and gratifying.

Greenacre's contributions to psychoanalysis include original insights about the bodily and psychic

experiences of the preverbal child, fetishism, and the creative individual. Of equal note is the fact that she presented this material in papers and books that are characterized by beautiful, evocative prose, in the service of imaginative and bold theoretical ideas and the sensitive interpretation of clinical material.

## GREENSON, RALPH (1911–1979)

Ralph Greenson, American psychoanalyst and physician, was born on September 20, 1911 in Brooklyn, New York, and died on November 24, 1979 in Los Angeles, California.

He was the eldest child (by ten minutes, as he was a twin) born to his physician father and pharmacist mother in Brooklyn. He completed his premedical studies at Columbia University and his medical training at the University of Bern (1930–1934) in Switzerland. In Switzerland he met Hildi Troesch; they married and had two children, Daniel and Joan.

In 1935 he began an analysis with Wilhelm Stekel and undertook analytic training in the Active Psychoanalytic Institute in Vienna. Dissatisfied with the therapeutic effect of this work, he began "classical"

training in Los Angeles in 1938 and had a personal analysis with Otto Fenichel. He held various positions in organized psychoanalysis, but mostly enjoyed teaching candidates, residents and medical students. He gave many public lectures which were very popular and well received. These were published in book form, as *Loving, Hating, and Living Well* (1993).

He published 65 articles in the psychoanalytic literature, almost all of which were clinically based. Thirty-two of these appear in his book *Explorations in Psychoanalysis* (1978). *The Technique and Practice of Psychoanalysis* (1967) is still considered a classic book on analytic technique. In addition to his books on technique, his major contribution to psychoanalysis involved his emphasis on aspects of analytic work: the working alliance—the “real” relationship with patient’s empathy and counter-transference, apart from transference interpretations.

## **GROSSOT, MICHEL (1918–1975)**

Michel Gressot, a Swiss physician, psychoanalyst and teacher with the Société Suisse de Psychanalyse (Swiss Society for Psychoanalysis) was born in Porrentruy in 1918 and died in Geneva in 1975. He attended the Collège de Saint-Maurice (Valais), where he acquired

an extensive background in humanism and philosophy that was to have a profound affect on his psychoanalytic work. After studying medicine in Fribourg, Basle, and Lausanne, he specialized in psychiatry in Lausanne, in Malévoz (Valais), and in Geneva, where he settled in 1950 as a psychiatrist and psychoanalyst. In 1969 he was appointed *Privat Dozent* at the School of Medicine of the University of Geneva.

Gressot was introduced to Freud’s work through his teachers at Saint-Maurice. Subsequently, during his psychiatric training, he began a personal analysis with Charles Odier in Lausanne. Once settled in Geneva he devoted himself almost exclusively to psychoanalysis. Raymond de Saussure, upon his return from the United States in 1952, relied on Gressot’s assistance in providing a new impetus to the development of psychoanalysis and training (after 1956 he worked with Marcelle Spira). These psychoanalytic educators played an important role in the later growth of psychoanalysis in French-speaking Switzerland, especially in Geneva. Gressot regularly gave seminars and conferences, and was an enthusiastic participant in the Congrès des psychanalystes de langue romane (Congress of romance language psychoanalysts). His career was interrupted suddenly in 1975, when he died in Geneva at the age of fifty-seven.

Gressot’s most important contributions were collected by Michel de M’Uzan in a posthumous volume entitled *Le Royaume intermédiaire* (1979), with a preface by Michel Roch. It contains his essay, “Le Mythe dogmatique et le Système moral des manichéens,” which emphasizes the psychoanalytic advantage in studying Manichaeism. The book also contains two important reports on congresses held in Paris. The first, from 1955, “Psychanalyse et Connaissance: Contribution à une épistémologie psychanalytique,” sketches a psychoanalytic theory of knowledge. The second, from 1963, “Psychanalyse et Psychothérapie, leur commensalisme: L’esprit de la psychanalyse est-il compatible avec la psychothérapie?” studies the interaction of the fields of psychoanalysis and psychotherapy from a dialectic point of view that was typical of Gressot’s style.

Gressot trained a number of psychoanalysts during his career. The depth of his thought, his attention to detail as a writer, and his openness to different ideas all had a strong influence on the growth of psychoanalysis inside and outside Switzerland.

## GRID

The grid is an instrument for classifying psychoanalytic material, coming from either the patient or the analyst, proposed by Wilfred R. Bion in his *Elements of Psycho-Analysis* (1963). Classification is made along two axes, with the vertical axis representing the genetic evolution of thoughts or ideas, and the horizontal axis representing the uses or functions attributed to thoughts or ideas. By combining the vertical categories with the horizontal uses or functions, a grid is obtained that makes it possible to classify the “elements of psycho-analysis”—the term Bion applies to the thoughts and emotions of the patient-analyst dyad.

Bion does not advocate using the grid as a working method during sessions. Rather, it is conceived as a tool that the analyst can use outside of the sessions to clarify their ideas or reexamine material.

By means of the grid and other abstract systems of notation, Bion sought to bring a greater degree of specificity to psychoanalytic theory. For example, in the theory of the Oedipus complex that helped Sigmund Freud to found psychoanalysis, there are elements that are constants, fixed through their association with other elements. Thus, in the classic oedipal scheme, it would be impossible to detach any of the following from the whole: sexual agitation, sexual curiosity, or castration. Bion's use of new methods of notation began with his book entitled *Learning from Experience* (1962) and reached its height with *Transformations: Change from Learning to Growth* (1965), where the reader finds a profusion of mathematical signs, Greek words, arrows, dots, and lines, the assimilation of which (when it is possible) adds little to analytic understanding. Bion himself admitted his failure, referring to his mathematics as

“Dodgsonian,” in reference to Charles Dodgson (Lewis Carroll), the author of *Alice's Adventures in Wonderland*. The grid was not as ill-fated as Bion's other notation systems and has even become emblematic of his research.

Arranged along the vertical axis of the grid are the following: A) beta-elements; B) alpha-elements; C) dream thoughts, dreams, and myths; D) preconception; E) conception; F) concept; G) a scientific deductive system; H) algebraic calculus.

The horizontal axis essentially presents the functions the mind uses to have access to the real: 1) definitory hypotheses; 2) denial; 3) notation; 4) attention; 5) inquiry; 6) action.

If, in the horizontal axis, Bion draws from Freud's 1911 article, “Formulations on the Two Principles of Mental Functioning,” the vertical axis instead reflects the influence of Immanuel Kant's epistemology.

As a whole, the grid recalls Kant's categories (much more than it does Dimitri Mendeleev, contrary to what some have suggested). Like in Kant's faculty of thought, there are three levels in the grid: sensibility, understanding, and reason. Sensibility, in Kant's work, is predominantly passive and serves to receive impressions from the outside (the equivalent of Bion's lines A, B, and C). Understanding is active; it takes sensibility's components and forms them into judgments and real knowledge (the equivalent of Bion's lines D, E, and F). Reason is the final stage in the operations of knowledge, which are begun by the senses and continue through the understanding.

For all its interest, Bion's grid did not achieve the degree of abstraction he believed was desirable in the development of any scientific theory. The grid did not produce the desired combinatory effects, in the same way that psychoanalytic theory is not at the level of a predictive scientific system. Perhaps the ascent into abstraction is not possible for psychoanalysis, just as it is not possible for the other human sciences. Walking in the footsteps of Ludwig Wittgenstein, Ernst Mach, and Bertrand Russell, Bion did not take into account the methodological obstacles raised when one attempts to assimilate the natural and human sciences—obstacles evoked by Wilhelm Dilthey in his *Introduction to the Human Sciences: An Attempt to Lay a Foundation for the Study of Society and History* and by Georges Politzer in his *Critique of the Foundations of Psychology: The Psychology of Psychoanalysis*, among others.

**GRODDECK, GEORG WALTHER (1866–1934)**

A German physician and the director of a clinic in Baden-Baden, in the Black Forest region, Georg Walther Groddeck was born on October 13, 1866, in Bad Kösen

an der Saale, Germany, and died on June 11, 1934, in Knonau bei Zürich, Switzerland. Groddeck detailed his upbringing in his autobiographical writings. A saying of his mother's, "Big ears mean great accomplishments," became his life motto. The youngest of five children in a family of aristocrats, he was educated at the school in Schulpforta where Gotthold Lessing, Otto Rank, and Friedrich Nietzsche also studied. He was a great admirer of Nietzsche and Johann Wolfgang von Goethe, among others. He studied medicine with Ernst Schwenger, Otto von Bismarck's personal physician, in keeping with a Romantic tradition of medicine based on experience, in contrast to the scientific mindset of his era. As a result of his exceptionally powerful personality, Groddeck became a renowned doctor whom patients throughout Europe came to consult about somatic and psychosomatic illnesses. He initially used hydrotherapy, dietetics, massage therapy, and psychotherapy based on authority and the power of suggestion; he later refined this approach into a form of psychoanalytic-psychosomatic therapy.

In 1910, during a life crisis, he discovered the writings of Sigmund Freud, and he completed his self-analysis in the course of the 115 lectures on psychoanalysis that he delivered to patients in his clinic between 1916 and 1919. These lectures later became famous.

He began corresponding with Freud in 1917 and met him personally in 1920, at the international psychoanalytic congress in the Hague. Groddeck drew a mixed reception with his presentation at the congress, which he supposedly introduced by saying, "I am a wild psychoanalyst," and in which, associating freely, he spoke of his childhood enuresis. In 1920 he became a member of the Deutsche psychoanalytische Gesellschaft (German Psychoanalytic Society). But he did not fully integrate himself into the psychoanalytic movement, and he followed his own path whenever personal ties were important and institutional constraints bothersome. He took a skeptical view of the new ego psychology.

Throughout his life he remained involved in sociopolitical activist groups. He refused to accept the National Socialists' reining in of German psychoanalysts after 1933 and ran up against insurmountable problems with them. Finally, he had to take refuge in Switzerland.

In 1917 he put forward his psychoanalytic-psychosomatic agenda in *Psychische Bedingtheit und psychoanalytische Behandlung organischer Leiden* (Psychic

determination and psychoanalytic treatment of organic disorders). Using examples from his clinical work and vignettes from his self-analysis, he described the relationship between somatic disorders and unconscious psychic processes. In 1921 he published *Der Seelensucher: ein psychoanalytischer roman* (The soul-seeker: a psychoanalytic novel), a humorous account of the adventures of a psychoanalytic Don Quixote. Groddeck considered this his best work, as did Freud; others complained that it was sexually indecent and unscientific. With the publication of the *The Book of the It* (1923/1928), Groddeck became famous. This was yet another extremely personal book: clinically oriented, spontaneous, unconventional. This work was followed by many lectures, articles in the journals *Satanarium* and *Die Arche*, and, in 1933, *Der Mensch als Symbol: unmassgebliche Meinungen über Sprache und Kunst* (Man as symbol: considerations, without pretension, on language and skills). Groddeck's correspondences with Freud and with Sándor Ferenczi are well known. Most of his works are available in translation in many languages.

Groddeck was important above all in psychoanalytic psychosomatics. He was the first to argue for the value of psychoanalysis in theorizing about the mind and for the treatment of not just conversion but all somatic disorders, which he supported with a large amount of clinical data. His work is still controversial because his method was neither rational nor scientifically rigorous. Instead, he followed the primary processes in both his therapeutic work and his writings. Using this way of thinking, which Hanns Sachs described as a "self-portrait of the unconscious," he presented psychoanalysis as an activity, not a theory. Drawing on Nietzsche and the critical philosophy of consciousness, he stressed the concept of the id, a concept that Freud took up, but in a modified form. (He advocated saying, "The id thinks in me," and not "I think.") He recognized the significance of regression, pre-oedipal desires, and maternal transference, and thus had an enormous influence on Ferenczi, with whom he became friends. He was also in contact with Ernst Simmel, Frieda Fromm-Reichmann, and Michael Balint. The educated public and several writers (Lawrence Durrell and Ingeborg Bachmann, among others) took a great lay interest in his work, and the French psychoanalysts Roger Lewinter, Pierre Fédida, Jean-Bertrand Pontalis, Octave Mannoni, and François Roustang were receptive to his ideas for their scientific content.

## GROSS, OTTO HANS ADOLF (1877–1920)

Otto Gross, a neurologist and psychoanalyst, was born March 17, 1877, in Feldbach (Styria), Austria, and died February 13, 1920, in Berlin. His father, Hans Gross, was a celebrated professor of criminal law and his mother Adèle came from a middle-class family. Young Otto Gross grew up in a well-to-do family environment and was a precocious child.

On the advice of his father, he began studying medicine and completed his degree at the University of Graz in 1899 at the age of twenty-two. He was hired as a

doctor on a cruise ship, which introduced him to South America—and drugs. He was also involved with several women during this time, something that earned him a rebuke from his father on his return, the beginning of a conflict that would last until 1907 and their final break. In 1903 he married Frieda Schloffer, “one of the only Germans I have ever liked,” wrote Freud. But his sexual life remained agitated, the reflection of the “sexual immorality” he would turn into a theoretical credo.

In 1901–1902 he specialized in neurology and was especially interested in the hypotheses of Carl Wernicke on associative circuits and their separation (in a February 1908 letter to Carl Gustav Jung, Freud humorously referred to this as “sejunction”). In 1902, he began a detoxification cure at the Burghölzli Clinic, where Jung was working, and discovered psychoanalysis.

In spite of his appointment as *Privat Dozent* at the University of Graz, he left the city—where his father had also received an appointment—to settle, in September 1906, in Munich. Here, as an assistant to Emil Kraepelin, he spent time among the artistic and literary circles in the Schwabing quarter. The following year he went to Amsterdam for the first International Congress on Psychiatry, Psychology, and Aid to the Mentally Ill and, with Jung, defended Freud’s theory of hysteria. His intellect and creativeness caught Freud’s (who felt that “unfortunately he was not quite sane”) and Ernest Jones’s attention, and he was present at the Salzburg Congress of April 27, 1908.

Gross was again hospitalized at the Burghölzli, where Jung began treating him. Jung kept Freud informed of his progress, for both men felt that because of Gross’s intelligence this was a unique opportunity to develop further theoretical insights. Jung diagnosed an “obsessive neurosis” in 1908, which was confirmed by Freud. Gross’s condition seemed to get better. He gave up drugs—opium and cocaine—but things soon got worse, and in June 1908 Jung diagnosed him as suffering from “precocious dementia” after Gross escaped from the clinic and displayed increasing symptoms of pathological behavior. Nonetheless, he continued to work and publish articles in which he explained his theories on the social origin of nervous disturbances. He became involved with anarchist circles, but spent increasing amounts of time in psychiatric clinics, which were paid for by his father.

In 1909, his book *Über psychopathische Minderwertigkeiten* (On Psychopathic Inferiority) was published.

On June 3, Freud referred to Gross's book, in which he establishes a connection between genius and degeneracy, as a "bold synthesis overflowing with ideas." The "degenerate," although appearing unsuited to current social life, can also represent the future of the culture. In 1913 Gross published, in the Expressionist review *Aktion*, an essay entitled "Zur Überwindung der kulturellen Krise" (How to Overcome the Cultural Crisis), in which he affirmed that "the psychology of the unconscious is the philosophy of revolution." He referred to Friedrich Nietzsche and Sigmund Freud, and one can only wonder what influence this early work may have had on the Marxist psychoanalysts of the following decades.

A few months after its publication, at his father's request, Otto Gross was expelled from Germany, held in Austria at the Tulln Asylum, and placed under his father's care. The international press began to print articles about his arbitrary internment and, on January 25, 1914, he was transferred to the Troppau Asylum in Silesia, where he remained until July 8. He then followed a treatment with Wilhelm Stekel, who refused to diagnose him as a schizophrenic and spoke only of a serious neurosis accompanied by drug addiction. In the *Zentralblatt für Psychoanalyse und Psychotherapie*, Gross published an article on the symbolics of destruction.

His father's death in 1915 left Gross distraught. At the start of the First World War, he worked as a volunteer in several military hospitals but was himself hospitalized again in Romania for drug addiction at the end of 1916, before being transferred to Munich to stay with his mother, then to Vienna. His writings appeared in various political reviews and made use of psychoanalysis to criticize education, society, and the patriarchy, which communism would supposedly abolish in favor of a matriarchy ("The Fundamentally Communist Conception of the Symbolics of Paradise," July 1919). He is mentioned in a letter from Sándor Ferenczi to Freud on February 7, 1918: He "made his circle of disciples there, who, among other things, had the duty without exception to enter into sexual relations with Dr. Gross's lover, named 'Mieze.' They supposedly classified the young colleague, who found that repugnant, as 'morally unreliable' for that reason. Incidentally, the young colleague had some time ago received news of Dr. Gross's death, which has, however, not been substantiated. He will still pop up here and there as a 'Golem'."

In 1920 he published his last book, *Drei Aufsätze über den inneren Konflikt* (Three papers on the inner

conflict), this conflict being situated between the "self" and the "foreign," which established a conflict between Freudian sexual drives and the Adlerian ego drive.

He was found unconscious on a Berlin sidewalk on February 11, 1920, and died in the Pankow sanatorium two days later from pneumonia. He was buried "by mistake" in the Jewish cemetery of Berlin.

Known to Franz Kafka, Max Brod, Max Weber, Blaise Cendrars (who protested against his internments), and the Dadaists, this "Golem" continued to be referred to in connection with D. H. Lawrence (whose wife Frieda, born Frieda von Richthofen, had been his mistress in 1912) and the Bloomsbury group. Guillaume Apollinaire had written "La disparition du Dr Gross" in the *Mercure de France* on January 16, 1914, to protest his internment, and Sándor Ferenczi wrote to Freud, on March 22, 1910, "There is no doubt that, among those who have followed you up to now, he is the most significant. Too bad he had to go to pot." Ernest Jones wrote in his memoirs that "[h]e was the nearest approach to a romantic ideal of a genius I have ever met. . . . He was my first instructor in the technique of psychoanalysis" (Jones, 1959, p. 173). Paradoxically, the Marxist Freudians seem to have forgotten Gross, their earliest precursor.

## GROUP ANALYSIS

Broadly defined, group analysis is a psychoanalytic approach to the experience of the unconscious in the group situation and a method for investigating the psychic structures and processes that manifest themselves in that context. It uses concepts and techniques from individual psychoanalysis, as well as original psychoanalytic observations from the study of groups. In a more restricted sense, group analysis is a technique of group psychotherapy.

Trigant Burrow proposed the notion of “group analysis” in 1927, but it was only at the beginning of the 1940s that Siegmund Foulkes, John Rickman, and Henry Ezriel founded the “Group Analysis” tendency in London. Their work was informed by the structural perspective of Gestalt theory. At around the same time, Wilfred R. Bion was developing original ideas about group structures and processes based on basic concepts of psychoanalysis and Sigmund Freud’s speculations on group psychology. Foulkes’s initial objective was to propose an alternative to the limitations of individual therapy, while Bion’s aim was to explore the ways in which group processes could be specifically mobilized in the treatment of certain traumatic, borderline, and psychotic pathologies.

In the theoretical current inspired by Foulkes, the group is a totality; the individual and the group form a figure-ground whole. Within the group, the individual is like the nodal point in a neural network. Foulkes believed that all illness is produced within a complex network of interpersonal relations. In *Therapeutic Group Analysis* (1964), he writes: “Group psychotherapy is an attempt to treat the entire network of problems, either at the point of origin in the primitive group of origin, or by placing the disturbed individual into the conditions of transference within an alien group.” The group possesses specific therapeutic properties, which are expressed in the five basic tenets of Foulkesian group analysis: the capacity to listen to, understand, and interpret the group as a totality in the “here and now”; taking into account only the transference “of the group” on the analyst and not lateral transferences; the notion of “unconscious fantasmatic resonance” among the members of the group; “shared tension” and the common denominator of the unconscious fantasies of the group; and the notion of the group as a “psychic matrix” and frame of reference for all interactions.

In his 1961 book *Experiences in Groups*, Bion distinguishes and articulates two modes of psychic functioning in groups: the “work (or *W*) group,” dominated by the processes and requirements of secondary logic; and the “basic-assumption group” defined by the concept of group mentality (p. 105ff). “Group culture” is the structure acquired by the group at a given time, its self-assigned tasks, and the organization adopted to perform them. Bion defines “group mentality” as the mental activity that takes shape within a group based on the opinions, will, and the unconscious, unanimous, and anonymous desires of its members. It ensures that group life will correspond to the basic assumptions that determine its course. Basic assumptions are made up of intense emotional states, primitive in their origin, that play a determining role in a group’s formation, the performance of its task, and the satisfaction of the needs and desires of its members. An expression of unconscious fantasies, these assumptions submit to the primary process and remain unconscious. Basic assumptions are also defensive group reactions used as magical techniques, especially for combating the psychotic anxieties reactivated by the regression the group situation imposes. Three basic assumptions govern the course of psychic phenomena specific to the group and satisfy the desires of its members. The basic assumption of dependency (*baD*) is grounded in the conviction that the group has come together to receive security and the satisfaction of all the needs and desires of its members from someone (therapist, leader, master) or something (idea, ideal) upon whom (or which) it is absolutely dependent. The corresponding group culture is organized around the search for a more-or-less deified leader and manifests itself in passivity and loss of critical judgment. The basic assumption of fight-flight (*baF*) rests on the collective fantasy that there exists an internal or external bad object embodied in an enemy: a group member, illness, an adverse or erroneous idea that the group must either attack or flee. The group finds its leader among paranoid personalities likely to feed this idea. The basic assumption of pairing (*baP*) is sustained by the collective fantasy that some being or event will resolve all the group’s problems: Messianic hope is placed in a couple whose child will save the group from hatred, destruction, or despair. Group culture is organized around the idea that the future will bring long-awaited solutions, but for the future to come, their messianic hope must never be realized. In his book *Group*, the Italian writer Claudio Neri

extended and further elaborated Bion's ideas into field theory.

The French current of thought in group analysis has focused its research on the unconscious function the group fulfills for its members. Jean-Bertrand Pontalis (1963) emphasized the importance of instinctual cathexis and representations whose object is the group. According to Didier Anzieu in *Le Groupe et l'Inconscient*, the group, like the dream, is essentially a means and a locus for the imaginary fulfillment of the unconscious desires of its members. Although the group's structures and psychic processes obey general mechanisms that are characteristic of all products of the unconscious, some of them are specific to the group situation, as witness the group illusion. The model of a group mental apparatus proposed by René Kaës (1976) describes a mechanism for linking and transforming the psychic structures committed to the group by its members. This mechanism produces the group's psychic reality and processes it within the group. In his 1993 book *Le Groupe et le Sujet du groupe* (The group and the group subject), Kaës emphasizes the role of repression, denial, or rejection, and the unconscious alliances underlying the formation of the psychic reality of the group and its members.

## **GROUP PHENOMENON**

Wilfred R. Bion's work on group dynamics, developed in particular in his 1961 book *Experiences in Groups*, established a fundamental difference between individual and group mentalities; individual and group psychoanalysis must be treated differently, even though "the two methods provide the practitioner with a rudimentary binocular vision" and are "dealing with different facets of the same phenomena" (p. 8). In a group, individuals undergo a regression to defend themselves against the conflicts provoked or revealed by their participation in the group. This regression is expressed through formation of a "group mentality"—a unanimous expression of the group's will, a defensive system of avoidance and denial, and a common repository for anonymous contributions that the individual members split off or disavow (such as their hostility toward the therapist). The individual contributes to the group mentality but is nevertheless situated in opposition to it, since it threatens the satisfactions of the individual's needs as a group animal. The group responds to this threat by means of a compromise formation, the "group culture."

Bion emphasizes the importance of the work (W) group: the mental functioning (and not the individual participants) necessary to perform the joint task that the group has implicitly taken on. The work group must take reality into account ("reality testing"); its characteristics "are similar to those attributed by Freud [in *Beyond the Pleasure Principle*, 1920g] to the ego" (p. 143). The work group's methods are "rational, and therefore, in however embryonic a form, scientific" (p. 143), and they depend upon cooperation among the group's members, training, and the type of mental development defined by the aptitude for learning through experience. The members must undergo development rather than rely on magical efficacy.

The work group has come together to undertake a creative task, such as, to resolve the psychological problems of its members. However, the work group's rational intentions are, as a rule, impeded by obscure and chaotic emotional forces, which produce anomalies in the group's mental activity. These emotional forces are given coherence by the supposition that the group is acting as if its goal were motivated by a basic

assumption. In contrast with the requirements of the work group, participation in an activity that depends on a basic assumption does not call for any training, experience, or individual mental development; it is instantaneous, inevitable, and instinctive, and it actually manifests an aggressive refusal to work or develop. The basic-assumption group does not make rational use of verbal communication; it does not develop language as a method of thought and instead uses words as a mode of action. The inability to form and use symbols, observed by Melanie Klein (1930) in an autistic child, extends to all individuals functioning as members of a basic-assumption group. The members seemingly wish to replace any process of elaboration with the ability to know magically, by instinct, without any development or learning, how to live and act in the group. Activity that depends on a basic assumption does not require any ability to cooperate on the part of the individual, but it supposes that the individual—unless he or she is schizophrenic—possesses a “valency,” defined as “the individual’s readiness to enter into combination with another in making and acting on the basic assumption” (p. 116). The hostile reaction against any process of development in the basic-assumption mentality indicates that time has no place in it, and interpretations of disturbed temporal relations elicit feelings of persecution. In fact, the basic-assumption group only exists outside of time; it neither disperses nor comes together. Inevitably, the basic-assumption group develops an intolerable frustration that can only be addressed by an awareness of the passage of time, and to counter this frustration, the group immediately and automatically puts into play behaviors and beliefs that define itself. Because he considered this theoretical model of basic assumption to be inadequate, Bion elaborated it by describing its modes of dependency, fight-flight, and pairing.

Sigmund Freud considered the Catholic Church and the army to be groups faced with the basic assumptions of, respectively, dependency (*baD*) and fight-flight (*baF*)—in effect, “specialized work groups.” One of the goals of these groups is to prevent the basic assumption from being translated into action, which would require work-group methods to remain in contact with reality. The third type of specialized work group, involved in the basic assumption of pairing (*baP*), Bion associated with the aristocracy and its preoccupation with reproduction and good genes. However, the psychoanalytic method itself

constitutes a work group of two people centered around the basic assumption of pairing, which endows the transference with its characteristic features and only accounts for the link between individuals in terms of the libido, the latter designating only the specific quality of the valency characteristic of the pairing group.

A basic assumption can only be manifested in alternation with the two others. When one is active, it relegates the others to prototypes and confines them to the sphere of what Bion calls the “proto-mental.” In this sphere, the physical, the psychological, and the mental are not differentiated and the emotional components are blurred together because they have not yet come into being on the psychological plane. The group expresses (proto-) emotions from this sphere by putting into play a basic assumption, and the psychological expression of these emotions reinforces, invades, or dominates the group’s mental life. The proto-mental phase in the individual is only a part of the proto-mental system. Proto-mental phenomena cannot be understood solely as functions of the individual, but must be studied within the group. Somatic illnesses can be manifested in the individual, but their full context is in the relationship between the individual and the active basic-assumption group and in the proto-mental phases of the two other basic assumptions. The basic-assumption group that sweeps aside the essential part of individual mentality still operant in the work group thus expresses, on a level that is more neurophysiological than psychological, the primitive parts that live a group life within each individual.

## **GROUP PSYCHOLOGY AND THE ANALYSIS OF THE EGO**

Sigmund Freud's second essay, after *Totem and Taboo* (1912–13a), on collective psychology, *Group Psychology and the Analysis of the Ego* is perhaps his fundamental work on that topic. He began contemplating the project in 1919: "I had not only completed the draft of 'Beyond the Pleasure Principle' . . . but I also took up the little thing about the 'uncanny' again, and, with a simple-minded idea [*Einfall*], I attempted a P∇ foundation for group psychology," he wrote to Sándor Ferenczi on 12 May 1919 (Freud and Ferenczi, Letter 813, p. 354). His progress was slow; a first version was finished in September 1920, and the final version was finished in March 1921. It was published that summer. The close relationship between the discovery of dynamics operating in large dimensions—the theory of the life and death instincts, advanced in *Beyond the Pleasure Principle* (1920g)—and the possibility of reconceptualizing group psychology is noteworthy.

In contrast to *Totem and Taboo*, where Freud was applying psychoanalytic ideas to the psychology of groups and simultaneously acknowledging the differences between psychoanalysis and anthropology, here the brief and magisterial introductory chapter makes the claim that group psychology is part of psychoanalysis. Next he tackles a fundamental problem not elaborated in *Totem and Taboo*: What is the mental dynamic that holds together the individuals in a group, creates the group's forms, ensures its continuity and stability, or causes its disappearance? In other words, what is the morphodynamics of groups? Repeating a significant move in psychoanalysis, his abandonment of hypnosis, Freud proposed that the libido accounts for group morphodynamics. He accomplished this epistemological operation in three chapters, borrowing from Gustave Le Bon and William McDougall to describe the prevalence of the primary processes in ephemeral groups.

Freud refined his proposal by showing how two groups, the church and the army, can come apart—in their different ways—through the loss of libidinal bonds to the leader or among members, and how, in keeping with psychoanalytic dynamics, only the power

of love is capable of overcoming the narcissism and hatred that distance us from one another.

It remained to identify the psychic formations that ensure group cohesion. This is the topic is addressed in the next three chapters, where, for the first time, Freud studied in detail the various known identificatory processes and distinguished the ego's identifications from those of the ego ideal. Hence his statement: "A primary group . . . is a number of individuals who have put one and the same object in the place of their ego ideal and have consequently identified themselves with one another in their ego" (p. 116). This statement holds true for passionate love and the hypnotic state, which he had used to shed light on the identificatory processes. Freud then verified its validity in the case of the primitive horde, as a structure, as discussed in *Totem and Taboo*. In the course of his discussion, the generic quality of alienation and submission inherent in group membership is brought to light. A final chapter sharpens the distinction between ego and ego ideal, a distinction that provides an opening for psychoanalytic investigation of the narcissistic psychoses.

In important supplements to this work Freud distinguished three paradigmatic forms and dynamics of groups, based on the degree of the weakening of the ego ideal and the ego that they impose: the horde, the matriarchy, and the totemic clan. He specified that the level of elaboration allowed to groups excluded the thinking of sexual difference. He proposed that the earliest individual psychology in which the ego ideal does not appear in weakened form is that of the poet telling the totemic clan the lie that explains their origins: "the myth, then, is the step by which the individual emerges from group psychology" (Postscript, p. 136). He also examined the relationship between direct sexual instincts and sexual instincts whose aim is inhibited, with only the latter being mobilized and tolerated by social bonds.

The notion of the intrinsic relationship between individual and group psychology—which Freud sustained throughout his work—appears the most clearly in this essay. Freud's bringing to light of the libidinal morphodynamics of groups made possible some fundamental work on identifications, the ego ideal, and the ego and narcissism that would be continued in *The Ego and the Id* (1923b). However, the mode of articulation of object relations and identifications remained enigmatic, in part. The relevance of the three forms and paradigmatic dynamics proposed is unquestionable.

We can assume that these are deployed in every real human group, and that they are constantly in conflict. It should be noted that the horde of *Totem and Taboo* and that of *Group Psychology and the Analysis of the Ego* do not have the same status: The first is mythic and structural, while the second is actual and is endowed with active libidinal dynamics. The essay's lack of resonance among psychoanalysts, with regard to Freud's ideas about group psychology, can be explained by the fact that the majority of psychoanalysts after Freud, when working on groups, have hypothesized oedipal moments in them. Dealing with "the analysis of the ego," which has been referred to frequently, is another matter altogether.

At the beginning of the essay Freud made clear that he was working only on the libidinal dynamics involved in group cohesion. Three parameters were excluded: the influence of external reality on groups, the influence of "great men" on their level of development, and finally, an economic assessment of bonds and the role of hatred. This work was to be carried out in part in *Civilization and Its Discontents* (1930a [1929]) and then in *Moses and Monotheism* (1939a [1934–1938]).

## GROUP PSYCHOTHERAPIES

The notion of group psychotherapies encompasses a considerable number of techniques and different theoretical points of view. Strictly speaking, group psychotherapy is a method for treating psychopathology and its concomitant suffering by means of the specific action of the group's processes on the individuals who comprise it. There is also a model of group psychotherapy that seeks to treat the group as a specific whole. To accomplish its therapeutic aims and bring about the corresponding changes in personality, group psychotherapy mobilizes in the participants the psychological exploration and work that ensues necessarily as a result of the development of intersubjective and transsubjective links. Various appropriate mechanisms are directed toward this end.

This method of psychotherapy is probably the oldest form of mental and psychosomatic care. Treatment regimens practiced in the Asclepion at Pergamon (Bergama) included group sessions of dream interpretation, as the ancient writings of Aelius Aristides reveal. However, the term "group psychotherapy" is recent: It was introduced by Jacob Moreno around 1930. Various attempts had been made prior to that, from Franz von Mesmer's tub to the explorations of J. H. Pratt (1905) or Trigant Burrow (1914). On the eve and at the beginning of the Second World War, Kurt Lewin and his collaborators developed the basics of group dynamics, based on Gestalt theory, observations of experimental groups, and group training programs. Siegmund Foulkes and Wilfred R. Bion established the groundwork for group analysis and psychoanalytic group psychotherapy. During the 1950s and 1960s this trend saw a remarkable upsurge in the United States, Latin America (Enrique Pichon-Rivière, José Bleger), and in Europe, notably in Great Britain, France, and Italy.

There is considerable variation among the theories, practical techniques, and goals of group psychotherapies, but a certain number of characteristics are common to all its forms. The group is composed of a relatively small number of participants (from three to about a dozen) who come together for a limited time. The restricted size of the group enables each of its participants to perceive and enter into relationship with each of the others; the time limitation, whether or not it is predetermined (long-term groups, short-term therapies, groups that gradually become more open), makes it possible to work with the resistance effects provoked by the group's institutionalization.

Several combinable classification criteria can be used to distinguish different types of groups: monotherapy or cotherapy groups; groups centered on the group or on the individual; on speech or on nonverbal modes of expression (ergotherapies, art therapies, writing, music); on psychodramatic role-playing or on the body (bioenergy, primal scream, relaxation); on family relations (psychoanalytic and systemic family therapies); on instituted groups (therapy groups within institutions, therapeutic communities). Regardless of the form of communication used to put the therapeutic processes into play (words, screams, improvised or scripted role-playing, sculpting, painting, music, puppets), each theory has its own way of assessing the therapy's processes and effects.

According to the psychoanalytic conception, the group constitutes a staging ground for the externalization, figuration, and contention of pathogenic representations that are unacceptable in the intrapsychic space; it is a mechanism for linking and dynamic transformation of the formations and processes that cannot be internally bound without this detour through the work of intersubjectivity. Groups result in specific modes of transference and resistance. Interpreting these produces a reorganization of the psyche in its encounter with the object-based reality of others, with the prohibitions and founding statements of psychic life and of intersubjectivity. For its members, the group constitutes a powerful identificatory analysis; it generates creativity and the capacity for symbolization between intrapsychic and bodily reality and intersubjective and social reality. However, numerous clinical, methodological, and theoretical problems have yet to be worked out. Group psychotherapies are not a panacea. They require a personal demand and personal training; their effectiveness

depends on the specific indications, limits, and principles involved.

## **GUËX, GERMAINE (1904–1984)**

Germaine Guex, a Swiss psychoanalyst and psychologist who was a teaching member of the Société suisse de psychanalyse (Swiss Psychoanalytic Society), was born in France in 1904 and died in Lausanne, Switzerland, in 1984. She studied psychology in Geneva and, after receiving her diploma from the Institut Jean-Jacques Rousseau, became Jean Piaget's assistant in the psychology laboratory. However, she was attracted to clinical work above all. In 1930 Guex was recruited by Dr. A. Répond, a psychoanalyst and director of the psychiatric clinic of the Swiss canton of Valais in Malévoz, to oversee a psychoanalytically inspired medical and psychological

unit, the first of its kind. This consultancy was geared toward children, parents, and teachers, and its work was both therapeutic and preventive.

During her years in Malévoz, Guex became acquainted with Sigmund Freud's work, especially through her connection with Dr. Répond, who was both a psychiatrist and, as a psychoanalyst, a member of the Société suisse de psychanalyse. In the 1940s she moved to Lausanne, where she practiced psychoanalysis and was active in developing psychoanalytic training in French-speaking Switzerland. She was the companion of the psychoanalyst Charles Odier.

In 1950 Guex published *La névrose d'abandon* (Abandonment neurosis), revised in 1973 and appearing in a second edition under the title *Le syndrome d'abandon* (The abandonment syndrome). In this book she focused on the intense emotional needs and lack of security of some patients, an aspect of pregenital development that can impede working through the Oedipus complex—a new approach at that time. She believed that psychoanalytic treatment could enable such patients to have a new type of emotional experience of the transference, more conscious than unconscious, based on listening, mutual trust, and stability in the analytic relationship. Only then, she believed, could oedipal issues be analyzed. Because of the importance of its topic, *La névrose d'abandon* established Guex's reputation and has been translated into several languages.

## **GUILBERT, YVETTE (1867–1944)**

A French actress, singer and storyteller, whose repertoire ranged from medieval ballads to suggestive popular songs, Yvette Guilbert shared with Sigmund

Freud a friendship based on mutual admiration. Born Emma Laure in Paris on January 20, 1867, she died in Aix-en-Provence on February 3, 1944.

From a provincial family, her parents settled in Paris shortly before her birth. Her mother Albine owned a boutique, while her father, Hippolyte, a bon vivant who liked spending money in cabarets and enjoyed the company of women, sometimes brought her with him to the café-concerts, where she showed precocious singing talent. Seamstress, shop girl, and model, at age sixteen Guilbert came to the notice of Charles Zidler, later to become director of the Moulin Rouge, who introduced her to the world of show business.

After performing for a time in Parisian theaters, Guilbert sang at the Eldorado in 1890, then at the Moulin Rouge, the Divan Japonais, and other venues. As a storyteller and singer with an inimitable voice, Guilbert crafted in song the Paris of Toulouse-Lautrec—who made several famous sketches of her.

On June 22, 1897, Guilbert married Max Schiller, a Viennese biologist whom she met during one of her tours in New York. After the First World War, she appeared in a number of films and developed a new repertoire based on her research into the history of old French songs and medieval ballads, which she collected and published. She also wrote three volumes of memoirs: *La Chanson de ma vie* (1927), *La Passante émerveillée* (1929), and *Mes lettres d'amour* (1933).

On the advice of Madame Charcot, wife of the famous neurologist, Freud heard Guilbert perform for the first time in Paris in August 1889, while attending the First International Congress of Experimental and Therapeutic Hypnotism. Thereafter he never missed her concerts when she performed in Vienna. Eventually Guilbert and Freud enjoyed a friendly correspondence. In 1931, in reply to one of her letters, Freud wrote that her interpretive artistry surely arose from “repressed desires and traits that haven't had a chance to develop.” Guilbert was furious and rejected the explanation of “her very dear friend.” A few years later, however, in the daily newspaper *Ce Soir* (January 14, 1938), Guilbert wrote an article, “The Actor's Complex,” in which she employed the Freudian theories she had previously rejected.

Her husband's niece, Eva Rosenfeld, became a well-known psychoanalyst as well as a friend and colleague of

Anna Freud, with whom she worked at the Hietzing Schule, which she co-directed. At a musicale presented by Marie Bonaparte in Paris in 1938, during the XV International Congress of Psychoanalysis, Guilbert performed Freud's favorite song, "Dis-moi que je suis belle."

## **GUILT, FEELING OF**

Guilt represents a sensation of intrapsychic tension, sometimes linked to apprehension of a catastrophic threat to oneself. It may also be manifest as humility, suffering, the need for punishment, remorse, and feelings of inadequacy.

According to Jean Laplanche and Jean-Bertrand Pontalis (1968), the term describes an emotional state that arises in consequence of some action that the subject considers reprehensible; it may also refer to a vague feeling of personal unworthiness, unconnected to any particular act.

The "sense of guilt" appeared for the first time in Freud's work in his article, "Obsessive Actions and Religious Practices" (1907b); however, he had previously suggested its outlines in the second section of his "The Neuro-Psychoses of Defence." (1894a) Freud distinguished two sources of the sense of guilt: fear of authority and fear of the superego. The former

compels renunciation of some instinctive pressure or action, while in the latter, internalization of parental authority initiates development of the superego. One of the functions of this agency (the superego), which is responsible for the evaluation and judgment of the actions of the ego, is known as moral conscience (1923b). Aggression stemming from this moral conscience prolongs and intensifies the aggression experienced from authority. Under the influence of the sense of guilt, the ego submits to the superego's demands, out of fear of losing its affection and protection. According to Freud, there is a link between the sense of guilt and the Oedipus complex.

Anxiety occasioned by loss (or potential loss) of the loved object is not the only manifestation of the sense of guilt. There is also the potential for psychic pain and suffering; excessive humility; repeated failures and regrets; constant asking for penitence, expiations, and renunciation; suicidal ideas; and the tendency toward self-punishment.

Melanie Klein (1948), like Freud, also saw a direct relationship between the sense of guilt and fundamental ambivalence arising from the life and death instincts. She stressed that this feeling not only appears in the oedipal conflict, but also in the very earliest relationships with the nourishing mother. In her description, damaged intrapsychic objects become persecutors.

In *Civilization and Its Discontents* (1930a), Freud described how the sense of guilt, together with the methods and mechanisms used to struggle against it, influence the individual's relationships, not only with their immediate family, but also other relationships within the larger social group, and even with civilization as a whole. One of the principal aims of psychoanalysis is therefore to understand how patients manage their guilt, for example, to understand the extent to which they can accept ambivalence and responsibility in the face of instinctual strivings and the feelings that generate guilt. The discovery that patients harbor feelings of both love and hate for their parents underscores the importance of guilt as a nodal area of personality development. In the first years of life, the specific ways that children respond to guilt may predispose them to neurosis and mental instability, but may also prove to be a source of success and fulfillment.

Klein (1945/1975), in opposition to Freud, attempted to show, through observation of children in analysis, that the superego emerges much earlier than Freud suggested. According to her views, the Oedipus

complex also appears much earlier, during the first six months of life. The essential nature of the sense of guilt resides in the young child's impression that its own experience of aggressive instincts have caused hurt to the love object. The desire to undo or to repair this damage derives from the sense of guilt.

To the extent that guilt may be said to reflect, or result from, discordance between the ego and superego, emergence of the latter implies the ineluctable appearance of the sense of guilt.

## **GUILT, UNCONSCIOUS SENSE OF**

The unconscious sense of guilt is an ego state resulting from conflict between the aims of the superego and those of the ego.

As a psychoanalytical term, according to Jean Laplanche and Jean-Bertrand Pontalis (1973), the "unconscious sense of guilt" developed a more specific meaning over time than when it was first used simply to designate a feeling in the unconscious aroused by an act considered reprehensible. Its current definition implies an unconscious relationship between the ego and superego expressed in subjective phenomena from which, in extreme instances, any conscious perception of guilt is entirely absent.

The term itself appeared for the first time in Sigmund Freud's article "Obsessive Actions and Religious Practices" (1907b). "We may say that the sufferer from compulsions and prohibitions behaves as if he were dominated by a sense of guilt, of which, however, he knows nothing, so that we must call it an unconscious sense of guilt, in spite of the apparent contradiction in terms" (p. 123). However, the basic idea had been adumbrated much earlier, in the second part of Freud's "The Neuro-Psychoses of Defence" (1894a).

In accepting the hypothesis that the sense of guilt arises simultaneously with the gradual development of the superego, it is important to stress that they both imply a social dimension, and that the superego also owes its existence to external factors and represents the demands of society to the ego. In addition, the superego not only frustrates certain tendencies of the ego, but also can divert aggression at it. When it does so, it manifests as a repetitive sense of culpability and expiation. In addition, as Freud wrote in *The Ego and the Id* (1923b), "One may go further and venture the hypothesis that a great part of the sense of guilt must normally remain unconscious, because the origin of conscience is intimately connected with the Oedipus complex, which belongs to the unconscious" (p. 52).

The sense of guilt appears to dominate instinctual life not only by acting to deny gratification, but also by leading to an increase in libido and thus the provocation of masochistic pleasure. Psychoanalysts see moral masochism as an expression of an unconscious sense of guilt.

Unconscious guilt is one of the most powerful factors in the gratification of passive libidinal wishes. Narcissistic patients should be helped to acknowledge the unconscious self-criticism and guilt that underlie their hostile demands for love. They must come to see how they project their thoughts and attitudes in order to regain self-esteem. What is in fact a deficiency of the superego is largely manifested as self-destructive

refusal to acknowledge guilt, thereby provoking an obvious disorder of ego functioning.

Trying to help such patients become aware of their unconscious guilt reveals characteristic patterns. One often encounters solid resistance to acknowledging guilt or even accepting its existence, and frequently such patients use projection as a defense. An intense battle is waged with the aim of warding off unconscious guilt, of keeping it silent and hidden. Analysis of dreams may be useful achieving a degree of acceptance.

Inasmuch as unconscious guilt acts as a form of “signal anxiety,” we might expect it to produce defenses against a subject’s wishes. This indeed turns out to be the case, and the inhibitions one observes are its clinical manifestations, seen by some as representing a “signal function” that announces the presence of guilt. But the most important characteristic of the unconscious sense of guilt is that it deploys defenses against passive libidinal wishes, in contrast to guilt caused by active and aggressive libidinal aims.

The origin and nature of unconscious guilt, and the way in which it affects psychological development are both unresolved issues. Some psychoanalytical tendencies are distinguished by the treatment techniques they employ to deal with the sense of guilt. Some analysts focus interpretatively on the necessity to “liberate” the patient from guilt, which they consider pathological and to which the patient is seen as submitting out of masochism. Other analysts, in sharp contrast, believe that the denial of guilt is central to all neurotic conflict, and that guilt itself is due to aggressive fantasies against objects. This controversy arises from a conflation of two distinct ideas.

Grinberg (1965), from a Kleinian perspective, has suggested distinguishing “persecutory guilt” from “depressive guilt.” This distinction permits a better understanding of the dynamic of the sense of guilt and thus fosters a broader understanding of the content and quality of object relations, as well as reactions to different stimuli and the normal or pathological process of mourning.

Persecutory guilt appears very early in life, and is associated with a weak and immature ego. It develops in parallel with the anxieties of the paranoid-schizoid position, or in the wake of some frustration or of a failure of depressive guilt. Despite its early appearance, persecutory guilt has an important influence upon subsequent psychological growth and plays an important role in the development both of inhibitions and masochistic attitudes and behaviors. Despair, resentment, fear, pain and self-reproach are the symptoms of persecutory guilt, as are a compulsion to repeat and a tendency to “act out.” Extreme cases occur with schizophrenia, melancholia and pathological mourning.

To the extent that persecutory guilt diminishes, pain and suffering caused by object loss will increase, along with a more or less depressive manifestations. Concern for self and object, responsibility and, in the final analysis, the capacity for reparation will also increase. These feelings represent a form of depressive guilt which predominates in the normal process of mourning and in activities requiring sublimation.

## **HALBERSTADT-FREUD, SOPHIE (1893–1920)**

The fifth child of Sigmund and Martha Freud, Sophie Halberstadt-Freud was born on April 12, 1893, in Vienna, and died on January 25, 1920, in Hamburg. Freud's "Sunday's child" was named after Sophie Schwalb, the niece of Samuel Hammerschlag, Freud's Hebrew teacher. Admired by her father, and her mother's favorite, Sophie only succeeded in getting out of the house by the sudden announcement of her engagement in 1912. On July 20, Freud wrote to his sister Mitzi, "His name is Max Halberstadt, he's thirty years old, is a distant relative of our family from Hamburg. He's very serious, inspires confidence, and both of them seem to be in love with one another. The terms are appropriate and bourgeois. No wealth, no distinction. Something we would not be pleased with in the case of Max Halberstadt." Engaged on July 28, they were married on January 14, 1913, in Hamburg.

On March 11, 1914, Ernst Wolfgang was born. The child's spool game fascinated Freud and provided the example of repetition in "Fort-da" (1920g, chap. 2). On September 22, 1914, Freud wrote to Karl Abraham, "My grandson is a charming little fellow, who manages to laugh so engagingly whenever one pays attention to him; he is a decent, civilized being, which is doubly valuable in these times of unleashed bestiality. A strict upbringing by an intelligent mother enlightened by Hug-Hellmuth has done him a great deal of good." Later, "little Ernst" would be analyzed by his aunt Anna Freud (Roazen, 1933), who hesitated to adopt him but made him her legal heir. Emigrating to Great Britain in 1938 after having traveled to Palestine, Moscow, and South Africa, he was analyzed by Willy

Hoffer. After marrying Irene Chambers in 1945, he himself became a psychoanalyst and, under the name Ernst W. Freud, practiced in Germany, returned to Great Britain, and finally returned to Germany.

On December 8, 1918, Heinz Rudolf, called "Heinele," was born in Schwerin.

Sophie Halberstadt-Freud died on January 25, 1920, from complications resulting from the Spanish flu that ravaged Europe. Freud wrote to Pastor Pfister on January 27:

This afternoon we received the news that our sweet Sophie in Hamburg had been snatched away by influenzal pneumonia, snatched away in the midst of glowing health, from a full and active life as a competent mother and loving wife, all in four or five days, as though she had never existed. Although we had been worried about her for a couple of days, we had nevertheless been hopeful; it is so difficult to judge from a distance. And this distance must remain distance; we were not able to travel at once, as we had intended, after the first alarming news; there was no train, not even for an emergency. The undisguised brutality of our time is weighing heavily upon us. Tomorrow she is to be cremated, our poor Sunday child! . . . Sophie leaves two sons, one of six, the other thirteen months, and an inconsolable husband who will have to pay dearly for the happiness of these seven years. The happiness existed exclusively within them; outwardly there was war, conscription, wounds, the depletion of their resources, but they had remained courageous and gay. I work as much as I can, and am thankful for the diversion. The loss of a child seems to be a serious, narcissistic injury; what is known as mourning will probably follow only later.

He wrote of this “irreparable narcissistic wound” in a letter to Sándor Ferenczi on February 4. On April 11, 1929, he consoled Ludwig Binswanger, who was suffering from a similar loss: “We know that the acute sorrow we feel after such a loss will run its course, but also that we will remain inconsolable, and will never find a substitute. No matter what may come to take its place, even should it fill that place completely, it remains something else. And that is how it should be. It is the only way of perpetuating a love that we do not want to abandon.”

Early on, commentators claimed that this grief inspired the introduction of the death impulse in Freudian theory. In fact, the war of 1914–1918 and the thoughts it inspired in Freud were sufficient for this change in his thinking (see the discussion in “Why War,” 1933b), but the story continues to be repeated. By December 18, 1923, Freud had indicated to Fritz Wittels, who repeated this “interpretation” in his biography, that the book had been written in 1919, while his daughter was still “healthy and flourishing” (this claim has been discussed and contradicted for some time by Ilse Grubrich-Simitis, 1993). In September he gave the manuscript to several friends in Berlin to read, including Karl Abraham. Concluding, he added, “Likelihood is not always truth.”

Similarly, it has for a long time been believed, wrongly, that the child with the spool was Sophie’s other son, Heinz Rudolf (Heinele), who had a tragic destiny. In 1922, taken in by his aunt Mathilde, he was, according to Freud (letter to Anna von Vest, November 14, 1922), “physically very fragile, truly a child of the war, but especially intelligent and endearing.” He died on June 19, 1923, from military tuberculosis.

On October 15, 1926, Freud wrote to Ludwig Binswanger, “For me, that child took the place of all my children and other grandchildren, and since then, since Heinele’s death, I have no longer cared for my grandchildren, but find no enjoyment in life either. This is also the secret of my indifference—it has been called courage—towards the threat to my own life.” On March 11, 1928, he returned to the subject in a letter to Ernest Jones: “Sophie was a dear daughter, to be sure, but not a child. It was only three years later, in June 1923, when little Heinele died, that I became tired of life permanently. Quite remarkably, there is a correspondence between him and your little one. He too was of superior intelligence and unspeakable spiritual

grace, and he spoke repeatedly about dying soon. How do these children know?”

### HALL, GRANVILLE STANLEY (1844–1924)

Psychologist, educator, and philosopher Granville Stanley Hall was born in Ashfield, Massachusetts, on February 1, 1844, and died on April 24, 1924 in Worcester, Massachusetts.

The son of Congregationalist farmers, he spent his adolescence in rebellion against the strict authority of his father, a model of moral and religious values. He attended Williams College and Union Theological Seminary before abandoning religion for the emergent discipline of psychology. During two trips to Europe, Hall familiarized himself with currents in philosophy, became conversant with the scientific trends in physiology and psychology, and studied with biologist and philosopher Ernst Haeckel. In 1878 at Harvard University he was awarded the first American doctorate in psychology by William James himself. In Leipzig during 1879–80, he also worked with Wilhelm Wundt, who was just then establishing the first laboratory of experimental psychology. There he participated in word association tests based on Francis Galton’s psychometric experiments, which Carl Jung would later modify to confirm Freud’s theory of neuroses in a laboratory setting.

After returning to the United States, in 1880 Hall began his career as an educator and psychologist, devoting himself to a systematic study of child and adolescent development. He edited several journals,

the most important of which was the *American Journal of Psychology*, which eventually became a forum both to disseminate his own ideas and to publish articles on psychoanalysis. He taught at Johns Hopkins from 1883, and his interest in the human sciences and in education led to his appointment as president of Clark University in 1888, where he was also professor of philosophy and psychology and launched more reviews, including the *Journal of Applied Psychology*. In 1892 he also served as president of the newly founded American Psychological Association.

In 1909, Hall invited Freud to deliver the series of lectures that launched the psychoanalytic movement in the United States. The correspondence between the two men, from 1908 to 1923, includes some thirty-one letters. For Hall, Freudian theory was a boon to the hereditarian approach to studying children and adolescents. Like Freud, with whose works he had been familiar since 1894, Hall was inspired by Charles Darwin's theory of evolution, and he shared a lively interest in understanding sexuality. He was electrified by Freud's lectures in Worcester, and believed that they reduced to ashes much of the flimsy theoretical structure upon which philosophically-based laboratory psychology of the time relied.

However, in a letter to Freud four years later (September 26, 1913) Hall indicated areas of skepticism and disagreement with psychoanalytic theory. Rather prophetically, he suggested that one day "specific [hereditary] influences" would be discovered to operate on individuals. He was also critical of extravagant use of sexual symbolism. Subsequently, he made it clear that he regarded as significant the contributions of Alfred Adler, who had rejected castration anxiety as central to the fears and anxieties of childhood.

Learning of Hall's friendly relationship with Adler, Freud wrote that he was sharply stung by what he viewed as a serious defection. However, Hall continued to support psychoanalysts in the American Psychopathological Association, and from 1917 to 1920 he served as president of the American Psychoanalytic Association. Several years later, responding to Freud's admonition that Adler's ideas were incompatible with psychoanalysis, Hall defended his eclecticism, suggesting that Freud should be more generous toward rebellious children of psychoanalysis like Adler and Jung.

Hall's autobiography, published in 1923, indicates that he tried self-analysis and underwent some

psychoanalysis; he was apparently disappointed with the results but did not disclose them. In general, while exasperated by religious and moral restrictions upon happiness and artistic creation, Hall hoped to protect the essential virtues of the ideology that he fought—the cult of work and the intricacies of moral conscience. The influence of psychoanalysis is perceptible in his 1904 two-volume work on adolescence and in his life of Jesus Christ, published in 1917.

Hall died from pneumonia at eighty years of age. He is generally considered, with William James, to be one of the founders of psychology as a scientific discipline in the United States.

## **HALLUCINATORY, THE**

The basis for the transformational dynamics of representation-perception-hallucination, the hallucinatory register is a constant process of mental life, representing the instinctual impulse insofar as it is "pressure" (*Drang*) and movement (*Treiberegung*).

In noun form and detached from any psychiatric connotations, the term *hallucinatory* was introduced as a metapsychological notion in 1990 by César Botella and Sára Botella, in an attempt to broaden an analytic theory that was overly focused on the notion of representation, and that therefore could not explain certain analytic structures or why certain analytic treatments were doomed to failure.

Freud used the expression “hallucinatory satisfaction of need” throughout his writings, and he considered the hallucinatory a basic assumption governing mental life. However, he never really developed the idea.

The same was true of the post-Freudians. In “Le développement du sens de réalité et ses stades” (Stages in the development of the sense of reality; 1913), Sándor Ferenczi described a “hallucinatory stage” but did not explore it in depth. Wilfred Bion took an interest in the topic, but his notion of hallucinosis remained close to that of pathological hallucination. Jacques Lacan, in *Das Ding* (1959), hinted at a “fundamental hallucination,” but he did not develop this idea either.

André Green, in *The Fabric of Affect in the Psychoanalytic Discourse* (1973/1999) was indisputably the first to posit a hallucinatory formation, as a “negative hallucination” (the representation of the absence of a representation; this is a reverse configuration, whose opposite is hallucinatory realization). According to Green, hallucination was fundamental to the structure of the psyche. In “L’hystérie, unité et diversité” (Hysteria, unity and diversity; 1985), Augustin Jeanneau conceptualized a “hallucinatory position” with the value of a mental function.

The hallucinatory represents the instinctual impulse in the same way that affect represents qualitatively the quantity of the instinct, and the idea represents the instinct’s contents. It involves a process that is inseparable from the regressive pathway that opens up in dreams but that must be inhibited during the working hours in favor of ideation and perception.

This notion is indispensable to psychoanalytic practice. At certain times during the session, under the influence of a formal regression of thought, “accidents of thought” or a quasi-hallucinatory “work of representability” can unexpectedly occur in the analyst without his or her conscious awareness; this may be

the only way to gain access to the meaning of the patient’s unrepresentable material.

## **HALLUCINOSIS**

“Hallucinosis” is a term coined by Wilfred Bion in “Transformations” (1965) to denote the mental state of the psychotic part of the personality. Psychotic panic is the experience, the O, which impels the personality to hallucinosis. Psychotic panic arises from a primitive disaster between infant and mother in which the infant’s emotional contents fail to find a container, that is to say, a mother with reverie. Undue envy and greed in the infant are significant factors in this disaster. In an effort to escape overwhelming anxiety, the infant evacuates ego functions capable of the experience of psychotic panic, along with other related contents, including space, time and meaning. Such events are in stark contrast to the normal situation where alpha-function creates a container for violent emotions.

In transformations in hallucinosis there is a failure of realistic projective identification; instead there is an

explosive projection in an unrestricted mental space. In a metaphor that has become well-known, Bion compares the emotional experience of psychotic space to surgical shock, in which the dilation of capillaries so increases the space in which blood circulates that the patient is at risk of bleeding to death in his own tissues.

In the mental space of hallucinosis, words and images float without limits, either as debris, or, in an attempt at synthesis, as conglomerates which are bizarre objects. Such beta-elements and bizarre objects indicate a place where the object should be, but, as the container is destroyed, is not. This place feels very threatening. In transformations in hallucinosis, sense organs, instead of being used for perception, become channels for the evacuation of unwanted mental products; the musculature is also used in this way in the form of acting out. Words, too, become vehicles of evacuation rather than conveyers of meaning. Manifest hallucinations may be visual, auditory, tactile, and olfactory. If the sensorial component has been violently fragmented or pulverized during its expulsion, the hallucinations of the psychotic patient will be evanescent or even what Bion calls "invisible."

Transformations in hallucinosis should be contrasted with transformations in thought. This contrast is of clinical importance. In the area of thought, frustration and the absence of the object facilitate the construction of symbols. In hallucinosis there are no symbols, only representations of concrete things for the psychotic part of the personality. A sentence uttered by a psychotic patient, though it may have the same words as a sentence uttered by a neurotic patient, has a different significance. As Leon Grinberg and others remark in their overall exposition, "... words like *yesterday*, *later*, or some years ago may not be representations but residues of destructive dispersing attacks on time." (1993, p. 94).

The psychotic patient believes that his method of transformation in hallucinosis is superior to transformations in thought in that his universe provides him with freedom from reality—its restrictions, its pains—especially of frustration and absence of the object, and its threats of panic and annihilation. In analysis, hallucinosis is viewed as especially superior to the transformations in thought offered by the analyst.

## **HAMLET AND OEDIPUS**

An original work of applied psychoanalysis, *Hamlet and Oedipus* was initially published in 1910 as an article in the *American Journal of Psychology* with the title "The Oedipus Complex as an Explanation of the 'Mystery of Hamlet.'" It was translated into German in 1911 in a brochure in the series *Schriften zur angewandten Seelekunde* as "Das Problem des Hamlet und der Oedipus Komplex."

In 1923 it appeared as the first chapter of *Essays in Applied Psychoanalysis* (Hogarth Press, London, 1964) as "A Psychoanalytic Study of Hamlet." In its current form the work appeared in 1949 as *Hamlet and Oedipus*, together with an essay on the interpretation of Hamlet, an article on "The Death of Hamlet's Father" signed by Jones, and an article by Ella Freeman Sharpe, "The Impatience of Hamlet," which had previously appeared in 1929 in the *International Journal of Psycho-Analysis*.

There are eight chapters in the book, which is an attempt to spread Sigmund Freud's ideas and improve the recognition of psychoanalysis as a science. With respect to Freud, aside from the theme of parricide, the author also discussed matricide, and the homosexual and homicidal nature of the son's aggression toward the father. Sharpe's essay continues Jones's work through reference to libidinal development, regression, and pregenital attachment, and shows how the difficult confrontation with the oedipal conflict results in procrastination and its transformation into blind action and violence.

**HAMPSTEAD CLINIC**

Founded in London in 1951 by Anna Freud together with Helen Ross and Dorothy Burlingham, the Hampstead Clinic set out to provide therapy and assistance to families, to treat disturbed and handicapped children irrespective of their problems, social background or past history, and at the same time to offer aspiring analysts the most balanced and rich training possible. Anna Freud saw the Clinic as an opportunity to apply the particular psychoanalytic knowledge she had acquired in the area of child guidance.

Located at 31 Maresfield Gardens in Hampstead, London, the clinic began full operation only in 1952. It had many philanthropical supporters, notably the Field Foundation of Illinois, the Foundation for Research in Psychiatry, and the Yale Study Center. The establishment comprised six consulting rooms, a playroom, offices, a library, and a classroom for use in the training of therapists.

In addition to the treatment of children, simultaneous mother-and-child therapy was practiced under the supervision of Dorothy Burlingham. Burlingham also promoted the creation of an index that would record data gathered during child analysis, enter it on cards, and organize it thematically in close correlation with the analytic context and with what children revealed therein. Unconscious contents, anxieties, defenses, character traits, object-relationships, and manifestations of the transference were some of the themes serving as index headings. This classification system had its origins in the methods developed by Burlingham and Anna Freud when they directed the Jackson Nursery in Vienna and later the Hampstead War Nurseries in London.

For her part, Anna Freud perfected a diagnostic tool that later came to be known as the "diagnostic profile." This approach used a psychological questionnaire intended to generate diagnoses on the basis of information garnered from interviews with children and their families. The goal was to increase the reliability of child analysis while making it easier for analysts to take effective therapeutic action much earlier than had hitherto been possible.

The Hampstead Clinic soon achieved a fame that allowed its founders to undertake several pathbreaking experiments. In 1954, Burlingham started the analysis of a blind child, and this marked the beginning of a long collaboration between the clinic and the Royal National Institute of the Blind. She soon opened a nursery school for blind children in a house conceived by Ernst Freud and built in the garden of the main building. Later on, a Well Baby Clinic was set up in order to help mothers respond to the physical and emotional needs of their babies, and the observation of normal children became possible thanks to the institution of a kindergarten.

**HANDLING**

Handling is the way a mother manages the moment to moment physical care of her infant such that the baby gets to know his own body. It necessarily involves the mother and infant going on in a psychosomatic partnership; as if they formed one unit (Winnicott, 1962).

Donald Woods Winnicott presented his ideas of infant care and its relation to psychological development to the lay public in a series of radio broadcasts and child care journals (Winnicott, 1947). He gave detailed descriptions of what happens between the mutually adapted mother and infant, for example with breastfeeding or when a mother picks up her baby. In this paper Winnicott made his famous statement, "there is no such thing as a baby. . . . A baby cannot exist alone, but is essentially part of a relationship" (p. 88). The description of the mother's handling of her baby grew out of Winnicott's detailed observations of mother-infant interactions in his work as a pediatrician and later his psychoanalytic work with both child and adult patients. Mutually attuned and sensitive physical care of the baby gives the baby a sense of his own body: "an indwelling of the psyche in the soma" (1970). The mother approaches her baby and picks him up as if there is a person within the body she approaches. This concept is adapted to the quality of care enacted in psychoanalytic treatment. The mother

adapts herself to what the baby can understand, and to what the baby needs. Thus, Winnicott insisted that the mothering of one's own baby is a personal job, that no one else could do as well. The mother's handling of her own baby is so sensitive as to be unique.

The baby has no experience of being a baby, so it is dependent upon the mother's capacity to adapt to his needs in order to develop the experience of mutuality. The "good-enough mother" manages the baby's body and its needs in such a way that he comes to know his body—that there is an inside and an outside, a body schema integrated with his personal psychic reality, that is: "personalization."

### **HAPPEL, CLARA (1889–1945)**

Clara Happel, a German psychoanalyst, was born on October 1, 1889, in Berlin. She committed suicide on September 16, 1945, in Detroit.

While studying medicine, Happel showed an early interest in psychoanalysis, and after settling in Frankfurt in 1921, she began analysis with Hanns Sachs. The same year Max Eitingon facilitated her admission to the Berlin Psychoanalytic Society. She

attended the Eighth International Congress in Salzburg in 1924, where Olga Székely-Kovacs drew her caricature. In 1925 in Berlin, Happel lectured on male homosexuality.

When the Berlin Psychoanalytic Society became the Deutsche psychoanalytische Gesellschaft (German Psychoanalytic Society) in 1926, Happel, with Karl Landauer, was appointed to head the Frankfurt branch. With Landauer, she participated in the foundation of the Southwest German Psychoanalytic Working Group, which operated from 1929 to 1933 and from which would emerge the Frankfurt Psychoanalytic Institute. In 1931 Happel moved to Hamburg, where with August Waterman she established a study group.

After Hitler came to power, Happel, a Jew, firmly advocated that Jewish members of the Deutsche psychoanalytische Gesellschaft resign in protest. Her motion was rejected at a meeting on November 18, 1933. This episode earned her the enmity of Ernest Jones, who perceived it as at odds with his efforts to mediate the situation and save psychoanalysis in Germany. As late as 1936 he was reluctant to allow her to join after her resignation in protest two years earlier. Anna Freud, however, opposed this restriction.

In January 1936, divorced from her husband (probably because he was not a Jew), Happel left Germany with her two children, emigrating first to Palestine and then to the United States, where she was welcomed by Sándor Radó. Within a year she was certified as training analyst. She joined the Chicago Psychoanalytic Society in 1938 but settled in Detroit, one of the developing outposts. In 1940, with Editha and Richard Sterba and Leo H. Bartemeier, Happel helped establish the Detroit Psychoanalytic Society and its training program, in which she taught, supervised, and lectured.

Happel remained close to fellow émigré analysts, welcoming them as she had been embraced when she arrived in the United States. At the beginning of World War II, she was affected by legal sanctions targeting "aliens" in the United States when a psychotic patient denounced her. She was arrested on the day after the attack on Pearl Harbor and detained for six weeks. Her correspondence with her children, who were then attending school in New York, reveals a life that was lonely, difficult, and sad.

Happel opened a practice in New York, which enabled her to spend more time with her married son. Yet despite this success, she became depressed, and her condition worsened at the end of World War II with revelations about the Nazi death camps and the use of atomic weapons on Japan. In addition, she found it difficult to adjust to life in a country where she was denied citizenship and not recognized as a medical doctor. She recalled Stefan Zweig's suicide several years earlier and ended her own life in September 1945.

Happel's published work includes a paper on substitute formation in masturbation and observations on a case of pederasty. Yet she is better remembered for her training and teaching activities in Germany and United States.

## **HARD SCIENCE AND PSYCHOANALYSIS**

“Hard sciences” are those disposing of a theory of measurement. The development of qualitative mathematics, since the middle of the 19th century, and its diverse applications have made this description questionable.

By the time he was thirty, Freud was a brilliant researcher in the field of natural science, well-versed in neuro-anatomy and neuro-physiology, in addition to having done some work in chemistry. At the laboratory of Brücke (1876–1882) he acquired an expertise in chemistry and physics, including thermodynamics (Helmholtz). As to epistemology, Freud, besides his familiarity with the German positivist school and the debates it carried on with Vienna (Brentano, Mach, Boltzmann), attended, for two years, Brentano's seminar on Aristotle.

In his writing, Freud refers little to the hard sciences as such. He uses the German system of classification: sciences of nature and of mind, situating psychoanalysis among the former, while insisting that it is relevant to “almost all the sciences of the mind” (1924f). There was one exception: “Strictly speaking, there are only two sciences: psychology, pure and applied, and natural science” (1933a, p. 179). Freud was frankly ironic about official sciences, assuming, moreover, the following position: “Scientific thinking does not differ in its nature from the normal activity of thought, which all of us, believers and unbelievers, employ in looking after our affairs in ordinary life” (1933a, p. 170).

The relationship between chemistry and psychoanalysis was formed early on—the former lent some of its prestige to the latter, signifying that the scientific method was common to both of them Freud, and Freud hoped that chemistry would isolate the toxins linked to sexuality and neuroses. The contribution of thermodynamics to his dynamic and economic point of view was evident also; his use of the terms “free energy” and “bound energy” makes this clear. Considerations of stability, carried over from Fechner, equally played a part. At a time when psychoanalysis was still unsure of its foundation, Freud defended the theory of the drives by noting that physics also was unsure of its foundations. Accordingly, he placed the discoveries of Copernicus and Darwin, and his own, on the same plane, for having dealt blows to human narcissism and religious convictions. Finally, a nostalgia for energetics surfaced when he evoked the “quantitative factor,” decisive for symptomatology, yet unattainable.

“Analysts ... cannot repudiate their descent from exact science and their community with its representatives. ... Instead of waiting for the moment when they will be able to escape from the constraint of the

familiar laws of physics and chemistry, they hope for the emergence of more extensive and deeper-reaching natural laws, to which they are ready to submit” (1941d [1921], p. 178–79). Qualitative dynamics, which reinterprets thermodynamics, may prove to be a part of this hoped-for emergence.

## **HARTMANN, HEINZ (1894–1970)**

Physician and psychoanalyst Heinz Hartmann was born in Vienna on November 4, 1894, and died in Stony Point, NY, on May 17, 1970.

Hartmann’s family had been distinguished for several generations. One grandfather, Moritz Hartmann, was a well-known poet, essayist, professor, and member of parliament; the other grandfather, Rudolf Chrobak, was an eminent physician and professor. Hartmann’s father, Ludo Hartmann, was a professor of history and founder of public libraries and adult education; his mother, Grete Chrobak, was a successful sculptor and pianist.

Tutors educated Hartmann until age thirteen; he continued in public schools and at the University of Vienna, where he attended lectures in many fields, earned his medical degree, and became a psychiatrist and faculty member in Wagner-Jauregg’s clinic. He published two papers on quinine metabolism during medical school, and then published several papers on psychiatry with Paul Schilder. Becoming interested in Freud, he published, with S. Betlheim, what became a minor classic paper in experimental psychoanalysis, “On Parapraxes in Korsakov Psychosis,” demonstrating by experiment the validity of some of Freud’s concepts of symbolization.

When Karl Abraham, with whom Hartmann had arranged to have a training analysis in Berlin, unexpectedly died, Hartmann had his first analysis with Sándor Rado; and while in Berlin wrote *Die Grundlagen der Psychoanalyse* (The foundations of psychoanalysis; 1927). Before 1937, he published about two dozen papers, including twin studies and studies of psychoses, neuroses, values, and cocaine; and he contributed to a major handbook on medical psychology. When Adolf Meyer offered Hartmann a full professorship at Johns Hopkins, Freud offered to analyze Hartmann free of charge if he would stay in Vienna. Hartmann was analyzed by Freud, and became a key member of his generation of Freud’s followers at the Vienna Psychoanalytic Society (a group including Helene and Felix Deutsche, Edward Bibring, Ernst Kris, Robert Waelder, Willy Hoffers, Hans Lampl, and Anna Freud), and co-editor of *The International of Journal of Psychoanalysis*. He married Dora Karplus, a pediatrician who later became a child and adult psychoanalyst. They had two sons, Ernest Hartmann and Lawrence Hartmann; one became a psychoanalyst and sleep and dream researcher, the other a child and adult psychiatrist, educator, and President of the American Psychiatric Association.

In 1937, Hartmann read to the Vienna Society a paper on ego psychology that developed into a book, *Ich-Psychologie und Anpassungsproblem* (1939) (later published in English as *Ego Psychology and the Problem of Adaptation*; 1958). Along with Anna Freud’s *The Ego and Mechanisms of Defense*, that work was a decisive landmark in extending psychoanalysis into the ego-psychological areas that would be central for the next several decades. In 1938, after the annexation of Austria by Nazi Germany, the Hartmanns moved to Paris, then to Switzerland, and in 1941 to New York.

There Hartmann became a leader of the New York Psychoanalytic Society and Institute, which was energized by many illustrious immigrants. He served for many years as a training analyst and as the first director of the Institute clinic. His old close friendship with Ernst Kris developed into many years of extraordinary collaboration, and they soon invited Rudolph Loewenstein to join them. Meeting once a year for many years, the three jointly wrote a series of major papers. With Kris and, in London, Anna Freud, Hartmann founded an annual, *The Psychoanalytic Study of the Child*, in 1945; he helped to establish and maintain it as one of the key publications in psychoanalysis for several decades. President of the International Psychoanalytic association in the 1950s, he was then elected their Honorary President for Life, and served as something of a dean of world psychoanalysis in the mid-twentieth century.

Hartmann was considered a major clinical analyst, teacher, theoretician, and metapsychologist, building on and extending Freud's ideas and findings. He was frequently an integrator. A pillar of that era's psychoanalytic establishment but not a cloistered thinker, he welcomed biopsychosocial thinking, contributions from general biology, neurobiology, and medicine; and also psychology, developmental theory, history, philosophy, anthropology, sociology, ethology, mythology, and art. He saw psychoanalysis as central to a general psychology.

Hartmann is best known for his work on ego psychology and adaptation, elaboration of conflict and drive theory, neutralization of aggression, and the conflict-free ego sphere, which serve as structures for much clinical and research work. Familiar analytic concepts such as structural and developmental theory, drive, and conflict were, by Hartmann's time, securely enough established to allow powerful additions, such as contributions from biology and interactions with average expectable (and other) environments, and such as ego functions and adaptation. His success in including mind-brain interactions, as well as centrally defining structures of mind-mind and mind-environment interactions, established some lasting solid ground, and also helped prepare the field for some subsequent analytic schools, notably object relations theory, self psychology, and continuing psychoanalytic attempts at biopsychosocial integration.

## HATRED

In day-to-day use, hatred is a violent feeling that impels the subject to wish another person ill and to take pleasure in bad things that happen to that person.

In "Instincts and Their Vicissitudes" (1915c), Sigmund Freud wrote that the primal structure of hatred reflects the relationship to the external world

that is the source of stimuli: “At the very beginning, it seems, the external world, objects, and what is hated are identical” (p. 136). The determining factor is thus the relationship to unpleasure. Freud thus asserted that “Hate, as a relation to objects, is older than love” (p. 139), for this feeling originates in the ego’s self-preservation instincts rather than in the sexual instincts (although later on hatred can bind with the latter to become “sadism”). It can be inferred from this that “hatred is a kind of self-preservation, to the extent of destroying the other, while loving is a way . . . of making the other exist,” as Paul-Laurent Assoun expressed it in *Portrait métapsychologique de la haine: Du symptôme au lien social* (Metapsychological portrait of hatred: from symptom to the social bond; 1995).

This emotion that aims to destroy thus seems to be radically opposite to love. But as Roger Dorey underscored in “L’amour au travers de la haine” (Love through hatred; 1986), there are deep affinities between the two: Not only does hatred precede love, but no doubt there is love only because there is hatred, at the very origin of the person” Indeed, in both “Instincts and Their Vicissitudes” and “Negation” (1925h) Freud showed that hatred is not exclusively destructive toward the object: Acting as the first differentiating boundary between inside and outside, it ensures the permanence of that boundary and is its constituting principle. Speaking of the purified pleasure-ego, which places the characteristic of pleasure above all others, Freud wrote in “Instincts and Their Vicissitudes” that love “is originally narcissistic, then passes over on to objects, which have been incorporated into the extended ego, and expresses the motor efforts of the ego towards these objects as sources of pleasure” (p. 138).

But prior to the establishment of genital organization, in which love has “become the opposite of hate” (p. 139), the two earliest stages make no distinction between them. The oral stage involves incorporating and devouring the object; in the anal-sadistic stage, “the striving toward the object appears in the form of an urge for mastery, in which injury or annihilation of the object is a matter of indifference” (p. 139). It must be recalled that hatred always expresses the ego’s self-preservation instincts and that both the will to power and the urge for mastery originate in hatred; before the genital stage, self-preservation of the ego is precisely what is endangered by the encounter with the object. The love/hate distinction that forms in the

genital stage allows them to be linked together, bringing whole persons into being.

If hatred is experienced as the unpleasure derived from the encounter with the “other” that threatens the ego’s integrity, the manner of being of this “other” must be reintroduced. With notions involving the determining role, for the baby, of the object, with its expected function as “container” of excitations, “toilet breast,” or alpha function, Donald Winnicott, Donald Meltzer, and Wilfred Bion, among others, have shed new light on the treatment of hatred.

### HEIMANN, PAULA (1899–1982)

Paula Heimann, British physician, psychiatrist, and psychoanalyst, was born Paula Glatzko on February 3, 1899, in Danzig, Germany, and died October 22, 1982, in London.

Heimann grew up in Danzig. She attended the High School for Girls and studied Medicine in Königsberg,

Berlin, Frankfurt am Main, and Breslau. She passed the “Staatsexamen” in 1925.

After attaining her MD, Heimann studied at the Psychiatric University Clinic in Heidelberg, and the Charité in Berlin. She received psychoanalytic training at the Berlin Psycho-Analytic Institute (1928–1932). Her training analyst was Theodor Reik. Other teachers included Otto Fenichel, Hanns Sachs, Franz Alexander, Karen Horney and Sándor Rado. She emigrated to London in 1933, and that year became an associate member of the British Psycho-Analytical Society. Heimann became a full member in 1939, a control supervisor in 1940, and a training analyst in 1944. In 1938, she received her British medical qualification from Edinburgh. She became a Fellow of the Royal College of Psychiatrists in 1971. In 1924, Heimann married Franz-Anton Heimann; they had one daughter and divorced in 1933.

In London Heimann became a close collaborator of Melanie Klein and in 1935 went into further analysis with her. The termination date is not known. In 1955 she left the Kleinian Group of Analysts of the British Psycho-Analytical Society. After years of increasing alienation on both sides, and she became an active member of the Independent Group of Psycho-Analysts. In 1949 she was elected a member of the Training Committee of the British Psycho-Analytical Society, becoming its training secretary in 1954.

She was an esteemed teacher and a sought-after training analyst and supervisor, at first for students of the Kleinian Group and later for those of the Independent Group. After the war she helped to train German analysts and went regularly on weekends to the Psychosomatic Clinic in Heidelberg and later to the Sigmund Freud Institute in Frankfurt am Main. Psychoanalytic institutes in France, Germany, Italy, North and South America invited her to give papers and hold seminars.

Paula Heimann wrote thirty papers. Her earlier contributions are of a Kleinian theoretical orientation, and two of them are contributions to the Controversial Discussions (1942–1944) of the British Psycho-Analytical Society. Her later papers mainly discuss various clinical problems and questions of technique, in particular those of transference, counter-transference, the psychoanalytic setting and different aspects of formulating and making interpretations.

She read her paper on “Counter-Transference” (1950) at the 16th International Congress of Psycho-Analysis in 1949, in which she conceived of the phenomenon as an important tool for the understanding of patients’ communications. The paper was influential for many other authors during the 1950s and 1960s. She never wrote a comprehensive critique of Kleinian theory and technique but it is often implicit in her later papers (1955–1982). She discussed the concept of sublimation and the concept of the death instinct in their clinical relevance in early papers (1942, 1952) from a Kleinian viewpoint, but presented a revision of them in later papers (1959, 1964). Her published contributions to discussions of papers read at International Congress of Psycho-Analysis (1962, 1964, 1966, 1970) are clear critical evaluations of the main papers presented.

### HELD, RENÉ (1897–1992)

René Held, a French psychiatrist and psychoanalyst, was born October 7, 1897, in Paris, where he died on February 18, 1992. He was the second son of a family that had emigrated from Russia after a short stay in Germany. His father was unable to obtain an equivalency diploma for his medical degree and held a series

of relatively minor positions with pharmaceutical companies. Consequently, Held was forced to go to considerable efforts to become fully integrated in French society.

A man with curious mind, cultivated and sharp witted, Held was not immediately attracted to psychoanalysis. He was initially interested in psychiatry, which he had discovered during his medical studies at the Salpêtrière and then at Val-de-Grace during the First World War. It was here that he met André Breton and Louis Aragon. His was an inquisitive mind, and it was difficult for Held to settle into a sedentary and unchanging activity. The uncertainties of life led him to dabble in Russian revolutionary activities while he was an assistant surgeon in Kiev in 1917 (which earned him the Croix de Guerre in 1918). Through his friendship with the painters of the Paris School and his familiarity with the surrealist movement, he developed an in-depth understanding of art.

It is said that the young twenty-nine-year-old psychiatrist was offered an opportunity to participate in the foundation of the Société Psychanalytique de Paris (Paris Psychoanalytic Society) in November 1926 and that he refused—something he regretted all his life. The story is not entirely credible, however, as Held would have been more attracted to the newly formed *Évolution Psychiatrique*, because he was a contributor to the first issue of that organization's review.

During the 1930s, he was much more interested in developing a clientele as an independent psychiatrist than in adopting Freudian theories that were not yet fully accepted. He got married on March 26, 1926, had a son, Jean Francis, in 1930, and had divorced by 1933. His mother, who followed Jewish family tradition closely, almost never left his side from then on.

Miraculously, he managed to survive the Occupation unscathed. A disciplined Frenchman who believed in his country, Held registered as a Jew with the police in his area and returned home with a yellow star, which he decided, two days later, never to wear again. After narrowly escaping a roundup of French Jews, he left the city for the unoccupied countryside but returned to Paris, where, in spite of the seals that had been placed on the door of his apartment on avenue Raymond-Poincaré, he managed to live there, treating American pilots who had been hidden by the Resistance.

It wasn't until the Liberation that Held's name began to appear on the rolls of psychoanalytic meetings. He underwent a teaching analysis with John Leuba, and was then supervised by Sacha Nacht. At a meeting of the Société Psychanalytique de Paris held in October 1947, presided over by his analyst, he gave a talk on "a phobia about knives." It was here that he met Pierre Mâle, a man who was to remain a colleague and friend until his death. That same year he was made a member of the society. The following year, Professor Gilbert-Dreyfus created for him, at the La Pitié hospital, the first department of psychosomatic medicine.

He was not fond of Jacques Lacan and remained faithful to his friends during the 1953 split. He was made a full member of the Société Psychanalytique de Paris on February 16, 1954, when Pierre Mâle was president, and was given responsibility for teaching activities in the new Paris Psychoanalytic Institute. He taught psychosomatic medicine in 1954, and psychoanalytic psychotherapy, with Mâle, in 1957. In 1963, during the 24th Congrès des psychanalystes de langue française des pays romans (Congress of French-speaking psychoanalysts from Romance-language-speaking countries), he presented a "Rapport clinique sur les psychothérapies d'inspiration psychanalytique freudienne," which became a book, *Psychothérapie et Psychanalyse* (1968). He was also president of *Évolution Psychiatrique* and the Société de Médecine Psychosomatique (Society of Psychosomatic Medicine).

Held was a brilliant improviser, simultaneously droll and wise, sometimes carried away by his garrulousness. All of his verbal eloquence has vanished but, as Gérard Mendel, one of his analysts, wrote, "We have his books, four books, in which, regardless of the subject, the man could be seen on the page, thumbing his nose at dogma and obfuscation." His books include *De la psychanalyse à la médecine psychosomatique* (1968) and his memoir of surrealism published in 1973 as *L'Oeil du psychanalyste* (Payot). His last completed book—Held began dozens of unfinished projects for novels, scripts, and other writings—brings his critical faculties to bear on the then-current fashion for all things Freudian: *Problèmes de la cure psychanalytique d'aujourd'hui. Us et abus de la psychanalyse* (1976).

Although there was much that was colorful about Held's character, we must not overlook the originality of his ideas and his numerous contributions to the

psychoanalytic conferences organized by the SPP until the 1970s. As Roland Jaccard remarked, “rationalist, atheist, and materialist, René Held was an old-fashioned psychoanalyst: sensitive and warm, he placed the interests of his patients above those of theory.”

## **HELLER, HUGO (1870–1923)**

Hugo Heller, the second Viennese publisher of Freud's works, was born in Hungary in 1870 and died in Vienna on November 29, 1923.

When he finished his secondary education, he trained as a bookseller and contributed to founding the “first populist bookshop in Vienna.” In 1905, he founded his own bookshop (Hugo Heller & Co.) comprising a publishing house, an art gallery, and a reception hall. Many exhibitions and conferences were organized in this richly endowed bookshop by contemporary poets and artists such as Arnold Schönberg, Rainer Maria Rilke, Hugo von Hofmannsthal, Jakob Wassermann, and Thomas and Heinrich Mann. In response to the cultural orientation of this bookshop, its clients came from the intellectual elite of Vienna.

Freud was one of the regular customers and in 1907 he gave a conference, “Der Dichter und das Phantasieren” (Creative Writers and Day-Dreaming, 1908e), to Heller's literary-minded public. Relations between Hugo Heller and Freud were not based solely on Freud's interest in literature; they were also consolidated by

Heller's interest in psychoanalysis. He was of the small circle of the founding members of the Wednesday Society, where he delivered his first paper: “Zur Geschichte des Teufels” (On the History of the Devil). Even before Lou Andréas Salomé was invited to attend the Wednesday Society, Heller had already given them an account of the work of this author who was already enshrined in the mists of legend. His daughter, Maggie Heller, was one of the pioneers of psychoanalytic teaching. In 1906 she organized a survey of writers and scientists, asking them to list “ten good books.” Arthur Schnitzler, Ernst Mach, and Peter Altenberg, along with Freud and others, responded to the survey, which Heller published under the title *Vom Lesen und von guten Büchern* (Reading and good books).

During World War I, Heller took over the scientific section of the Deuticke publishing house and became the “real publisher of the house of Freud.” For Heller this change in Deuticke also reflected the new interest of psychoanalysis in terms of its applications for the mind sciences and the broadening of its readership toward a more general public. In the literary, but also the social democratic context of this publishing house the following works of Freud were published: *Delusions and Dreams in Jensen's “Gradiva”* (1907a), *Totem and Taboo* (1912–13a), the “Collection of short writings on the theory of the neurosis” (4 volumes, 1907–09) and *Introductory Lectures on Psychoanalysis* (1916–17a). Its catalog of authors also included analysts like Otto Rank and Alfred von Winterstein.

Hugo Heller also took the risk of publishing two psychoanalytic reviews, the *Internationale Zeitschrift für (ärztliche) Psychoanalyse* and *Imago*, after several other publishers had backed down. Theodor Reik, who was working in Heller's bookshop at the time, took charge of the two reviews. During the war the publishing house suffered from production conditions that went from bad to worse, with the result that it became problematic to produce the two reviews. Finally, Heller publications could no longer ensure a regular production of books. As a result, Freud's work *Zur Vorbereitung einer Metapsychologie* (Toward the Preparation of a Metapsychology), which he had entrusted to Heller, never went to print and is considered to have been lost.

After the creation of the Internationaler Psychoanalytischer Verlag in 1919, Heller handled only the distribution of periodicals and books. After World War I, although still a member of the Viennese Psychoanalytic

Association, he no longer attended their meetings. When he died on November 29, 1923, an obituary in the *Internationale Zeitschrift für Psychoanalyse* observed that Viennese Psychoanalytic Society had lost one of its oldest members.

## HELLMAN NOACH, ILSE (1908–1998)

Dr. Ilse Hellman Noach, distinguished psychoanalyst and expert on child development, was born in Vienna on September 28, 1908, and died in London on December 3, 1998. Her parents, Paul and Irene Hellman, were deeply engaged in the cultural climate of the day, encouraging the arts and promoting the talents of musicians who achieved distinction.

Fascinated by children, Hellman, on leaving school, completed a two-year course specializing in juvenile delinquency. She joined a home near Paris for the children of parents unable to care for them, and her fluent French allowed her to attend evening classes in psychology at the Sorbonne. The home was run on family lines, and the same staff member looked after each small group of children. On returning to Vienna, she attended the University and studied under Charlotte Buhler, Professor of Child Development, who was making detailed studies of children from birth onwards. Buhler was invited to London as visiting Professor at University College, retaining her post in

Vienna, and in 1937 she invited Hellman, who by then had been awarded her Ph.D., to join her in the study of retarded children. When Buhler was in Vienna, Hellman took charge. It was then, too, that she met the distinguished analyst and child expert, Susan Isaacs, who became a close friend.

At the outbreak of war Buhler left for the United States, and the Home Office employed Ilse Hellman and other psychologists to work with children evacuated from London to escape the threat of air raids. Taken from their mothers to remote areas, many suffered disturbed sleep, eating disorders and bedwetting, and the psychologists set up special homes to cope with these problems. In 1942, Freud's daughter Anna invited Hellman to join her war nurseries, set up to provide for children whose families were disrupted by wartime bombing, and she remained there until the nurseries closed at the end of the war. The staff was residential and, to facilitate attachment to a substitute parent, each member cared for the same small group of children (as in the French home). The three homes together cared for 150 children, and the staff slept wherever they could. The children's development was rigorously observed and meticulously recorded, and Ilse Hellman found the experience invaluable for the understanding of the effects of separation, the restriction of the damage it occasioned, and child observational research. She continued to meet with, and evaluate, her own "war babies" for over fifty years.

While at the nurseries, she trained in psychoanalysis, and rapidly rose to prominence in the British Psycho-Analytical Society. Her attractive and friendly personality put her on the best of terms with Melanie Klein, Donald Winnicott and other well-known analysts: theoretical differences never interfered with friendship. She joined the Staff at Anna Freud and Dorothy Burlingham's Hampstead Child Therapy Course and Clinic, which had quickly earned a worldwide reputation. The clinic originated major studies on child development, normative and pathological, to many of which Ilse contributed. For some years she was in charge of the department for adolescents, publishing valuable papers about the difficulties encountered with this age group. She wrote on many other subjects. She was a fine teacher. Her deeply empathic understanding of the problems encountered by students in their clinical work made her a valued mentor in work with both adults and children. Her clinical

skills with children of all ages secured her international reputation.

It was not until after the war that she learned that her mother and brother had died in Nazi concentration camps. It was then she met and married the art historian, Arnold Noach, who had survived the Nazi occupation of Holland. He later became Professor of the History of Art at the University of Leeds. His was a fun-loving and warm personality. He died suddenly in 1976. Hellman Noach continued her work for many years, although in the last few years she worked much less intensively. Impressed by the fact that many young people showed great trust, and a readiness to confide in her, she amusingly called herself an “analytic grandmother.” But, at the age of 84, increasing ill health forced her to abandon the practice of, though not the interest in, the profession she had served so well.

She endured a cruelly incapacitating illness with great fortitude, always finding a warm and welcoming word for her visitors. Generations of analysts have cause to be grateful for her guidance, instruction, and, above all, her wisdom. She was survived by her one daughter, Maggie, and grandchild, Sophie.

## **HELPLESSNESS**

The state of helplessness is linked to the infant’s initial powerlessness in the face of its needs. This causes distress, as the protective shield is overwhelmed; only the intervention of another person can relieve this suffering.

The neurophysiological model of Sigmund Freud’s “Project for a Scientific Psychology” (1950c [1895]) posits the baby’s original helplessness as the prototype of all traumatic situations. Helplessness and satisfaction structure the two modes of mental functioning. In the primary mode, the desired object and desired satisfaction are hallucinated immediately through recathexis of the memory traces left by the real experience. In the secondary mode, a lasting discharge forms

the basis for the relationship to the real object, lost and rediscovered thanks to “indications of reality,” and invested with the meaning “mutual understanding.”

Helplessness and the theory of anxiety are closely linked. The helpless baby, powerless to fulfill its needs and without any adequate means of discharging internal excitation, experiences “automatic anxiety.” Anticipation of helplessness triggers “signal anxiety,” the ego’s appeal to the ego (1926d [1925]).

In a state of helplessness owing to its prematurity, the preverbal human infant cries, experiences and recognizes its powerlessness, and urgently alerts the succoring object. The ability to apprehend its helplessness depends on the protective shield against stimuli, whose action is thus the basis of relationships, the precondition of effective communication.

For Melanie Klein (1952/1975), the distress associated with the death instinct, a source of tremendous persecution, precipitates projection. This is the foundation of what she calls the schizoid-paranoid position.

When a human being is reduced to a state of helplessness, subjected to a primal kind of passivity by the impositions of others, he or she may seek to regain mastery through repetition of the experience. For Kreisler et al. (1966), too much distress of this kind may cause psychosomatic disorders; for Tustin (1972), the result may be recourse to autistic defenses.

## “HEREDITY AND THE AETIOLOGY OF THE NEUROSES”

Sigmund Freud first published this article in French in the *Revue neurologique* in Paris. It is important for two independent reasons. The first reason is historical, in that it contains the first occurrence of the word “psychoanalysis.” The second reason is more theoretical, in that the article makes a clear distinction between Freud’s theories and those deriving from Jean Martin Charcot’s teaching on the role of heredity in the etiology of the neuroses. The article goes on to provide a complete exposition of Freud’s thoughts on the sexual etiology of neuroses, and his theory of seduction.

The opening sentence reads: “I am addressing in particular the disciples of J.-M. Charcot, in order to put forward some objections to the aetiological theory of the neuroses which was handed on to us by our teacher” (1896a, 143). Heredity is only a “condition,” to borrow the term used in the distinction already made the year before (1895f), but it is the “specific causes” that must be sought.

Referring back to the nosographical distinctions he made between hysteria, obsessional neurosis, neurasthenia, and anxiety neurosis, he affirms that these “functional pathological modifications *have as their common source the subject’s sexual life, whether they lie in a disorder of his contemporary sexual life or in important events in his past life*” (p. 149). He adds: “I am quite sure that this theory will call up a storm of contradictions from contemporary physicians” (pp. 149–50).

The etiology of neurasthenia lies in immoderate onanism and spontaneous pollutions, and that of anxiety neuroses in forced abstinence, or genital irritation that does not result in orgasm. With regard to the other states: “I owe my results to a new method of psycho-analysis, Josef Breuer’s exploratory procedure; it is a little intricate, but it is irreplaceable, so fertile has it shown itself to be in throwing light upon the obscure paths of unconscious ideation” (p. 151). The origin of the disorders is a memory that is related to the sexual life: “The event of which the subject has retained an unconscious memory is a *precocious experience of sexual relations with actual excitement of the genitals, resulting from sexual abuse committed by another*

*person; and the period of life at which this fatal event takes place is earliest youth—the years up to the age of eight to ten, before the child has reached sexual maturity”* (p. 152). The memory of this act passively suffered in dread: “*The memory will operate as though it were a contemporary event. What happens is, as it were, a post-humous action by a sexual trauma*” (p. 154).

The precocious event can also be found in “obsessional neurosis,” but with a “capital” difference: “it is a question . . . of an event which has given *pleasure*, of an act of aggression inspired by desire (in the case of a boy) or of a participation in sexual relations accompanied by enjoyment (in the case of a little girl). The obsessional ideas . . . are nothing other than *reproaches addressed by the subject to himself on account of this anticipated sexual enjoyment*” (p. 155).

Sent to the *Neurologisches Zentralblatt* on the same day, February 5, 1896, the article *Further Remarks on the Neuro-Psychoses of Defence* reviews the last two etiologies and develops the notion of *repression*, which is missing from the French text. Freud also adds the analysis of a “case of chronic paranoia” that shows that this affection also comes “from the repression of distressing memories and that its symptoms are determined in their form by the content of what has been repressed” (1896b, pp. 174–75).

Of course Freud had sent these considerations to Wilhelm Fleiss a few months earlier, but they find their first public expression here. He made the following comment to Fleiss on April 26, 1896: “A lecture on the etiology of hysteria at the psychiatric society was given an icy reception by the asses and a strange evaluation by Krafft-Ebbing: ‘It sounds like a scientific fairy tale.’ And this, after one has demonstrated to them the solution of a more-than-thousand-year-old problem, a *caput Nili*. They can go to hell, euphemistically expressed” (1985c [1887-1904]).

The seduction theory has often been called into question in the course of the history of psychoanalysis, from Freud’s abandonment of his “neurotica” in September 1897. Taken up again by Sándor Ferenczi in 1932, then by his disciples, the theory has also seen polemical use, by Jeffrey Masson in 1984.

**HEREDITY OF ACQUIRED CHARACTERS**

The expression “heredity of acquired characters” generally refers to the transmission to descendants of modifications taking place in the course of the individual life of a forebear, such transmission being possible by virtue of these modifications being integrated into the forebear’s genotype. Such modifications may be morphological, functional, or even behavioral (acquired through learning). This idea, which was central to the evolutionism of Jean-Baptiste Lamarck, was later very largely rejected. Freud nevertheless accorded it a non-negligible role in some of his theoretical views.

We have to bear in mind that psychiatry and psychology at the end of the nineteenth century were very strongly marked by the idea that individual characteristics were essentially determined by hereditary data (in the genetic sense), whether in reference to normal or pathological development, including mental pathologies. It must also be said that in this domain the theory of degeneration was well established.

It is not surprising that Freud initially stood by the theory. In 1888 he wrote, in agreement with Jean Martin Charcot, that “the aetiology of the *status hystericus* is to be entirely looked for in the heredity” (1888b). However, he made a clear distinction over the following years between the inherited “constitutional” causes that provide the individual’s base psychic terrain, and the “occasional causes,” principally the

vicissitudes of sexual life, which alone could explain the appearance and form of the mental pathology. Publishing his translation of Charcot’s *Leçons du mardi* (Tuesday lectures), he went so far as to contradict him by writing that “the most frequent cause of agoraphobia, as well as the other phobias, does not reside in heredity but in the anomalies of sexual life” (1892–94a).

In *Studies on Hysteria* (1895d) he actively criticized recourse to the notion of degeneration as an explanation of hysterical phenomena, and restated the complementary nature of constitutional and accidental causes. He never departed from this position, which he stated clearly in the manuscripts he addressed to Wilhelm Fliess (Ms B, 1950a), then repeated in his article in French on *Heredity and the Aetiology of the Neuroses* (1896a), and each time over the following years that he discussed the problem of the “choice of neurosis”—the determination of a subject’s evolution toward hysteria or phobia.

The problem took on a greater dimension when Freud undertook to answer the question that cannot fail to rise in such a perspective: where do the “constitutional causes” themselves come from? He answered with a thesis inspired by Charles Darwin, and even more so by Ernst Haeckel, that found its most complete formulation in *Totem and Taboo* (1912–13a): major events in the prehistory of humanity mark all its later development and fashion the individual development of each child. This recourse to “phylogenesis” was coupled with two postulates: the first borrowed from Lamarck (transmission of acquired characters), the second from Haeckel (ontogenesis recapitulates phylogenesis). He focused on the hereditary transmission of general developmental factors and psychic function, remaining more discreet on the subject of differential factors.

These Freudian theses have been vigorously criticized, particularly their Lamarckian aspect which seems to have been eliminated by the victory of neo-Darwinism and modern genetics. Contemporary work in molecular genetics and population genetics seems to suggest new ways of formulating the question of psychic heredity (Chiland C., Roubertoux P., 1975–1976).

## HERMANN, IMRE (1889–1984)

Imre Hermann, Hungarian neurologist and psychoanalyst was born on November 13, 1889 in Budapest and died there on February 22, 1984.

He spent most of his long life in Budapest where he was born. He received his medical degree in 1913. While still a university student, he became interested in experimental psychology. During the 1918–19 revolutions he was assistant professor to Géza Révész at the faculty of psychology. There he met Alice Czinner, also Révész's student, who became an analyst herself and his life companion of fifty-three years (1922–1975).

He set up analytical practice in 1919. Discounting the few months of the siege of Budapest during the German occupation, he continued his psychoanalytical practice without interruption up to the last months of his life. While a university student, he also attended Sándor Ferenczi's lectures, and it was Ferenczi who invited Hermann to join the society. Hermann was a member of the Hungarian and International Psychoanalytical Societies from 1921; Secretary of the Hungarian Psychoanalytical Society from 1925, vice-president between 1936–44, and president between 1945–49. An honorary professor, he lectured at the medical university and the faculty of arts in Budapest between 1946–49.

His first important works were in the field of the psychology of thinking; *Psychoanalyse und Logik*

(1924), *Das Ich und das Denken* (1929). In the first he explored the unconscious background of certain logical steps, such as doubling and reversal, based on observations of patients. In the second, he established a relationship between individual differences in thought processes with sense-organ orientation. In a series of experiments in 1921, he demonstrated, that, given a choice of identical elements, a child will select an external element, while an adult will select a center element, but that in a regressive state external selection returns. Unconscious operations also tend toward external selection. His book, *Pszichoanalízis, mint módszer* (Psychoanalysis as a Method, 1933; published in German in 1934; 1963) is a summary of the results of his teaching of psychoanalysis.

In the 1920s his interest turned toward the behavior of primates. He noted a peculiar instinctive behavior of the offspring of anthropoid apes: they spend the first months of their lives clinging onto the fur of their mothers. He set forth his theory of the clinging instinct in detail in *Az ember ősi ösztönei* (The Primeval Instincts of Man; 1943, 1984). Hermann's interest also extended to a number of other areas. His monographs about Fechner (1925) and János Bólyai (1945) and several other writings show interest in the psychology of creativity. He also published the book, *Az antiszemizmus lélektana* (The Psychology of Anti-Semitism; 1945). Based on clinical observations of obsessional neurosis he identified the dissociated superego. He noted the relationship between affectivity and space perception. Toward the end of his life he found a relationship to exist between musicality and perversions.

Hermann's theory of the clinging instinct prepared the way for the work of John Bowlby and René Spitz, and supported Mihály Bálint's theory of primary object relationship. His studies in the psychology of thinking make him one of the forerunners of ego psychology. In addition, he deserves credit for maintaining the continuity of psychoanalysis in Hungary and for reintroducing psychoanalytic training during the period of liberalization of communist dictatorship.

**HERMENEUTICS**

The term *hermeneutics* is used broadly to describe the process of justifying interpretation through exposing the criteria used to produce it. The form is also used, by extension, to designate a twentieth-century philosophy for which interpretation is either a condition for accessing meaning through thought, and therefore a condition of every science of mind as such, thus implicating the normativity of logic, or the *praxis* of thought itself, no product of thought being capable of escaping infinite reinterpretation since it would then no longer be living thought but dead thought.

In a limited sense, Logic, as understood by Aristotle's *Organon*, has been and remains the framework of hermeneutics. “*Hermeneia*,” Paul Ricoeur writes, “in the fullest sense, is the meaning of the sentence”—and goes on to criticize an “overly ‘lengthy’ concept” of interpretation. But this is also the case when “hermeneutics” is understood as biblical exegesis (an “overly restricted” sense). Here it is theology, understood as an exclusive theory and therefore as a preestablished doctrine, that conditions truth and falsehood, and thus access to the determination of meaning. It should not be surprising therefore to find within the result of the interpretation what we were trying to find from the start.

Understood as philosophy, hermeneutics rejects the fact that logical concepts, in the Hegelian sense, can present and determine meaning, or that the “logic of the concept” can be its concretization; nor can the concept serve as a criterion of signification. However, hermeneutic finality can remain with the concept in

the sense of discourse, or, on the contrary, an interpretation that falls short of the separation of words and things, an interpretation of the constitution of a possible world by each and for all, or even a fundamental process of “leveling” the language of the unconscious.

Freud considered that analytic interpretation, at the clinical situation, transmutes the patient's dreams into the true creative and critical power of subjectivity. For this reason interpretation is not and could not be an “extension” of the dream, as Ludwig Wittgenstein claimed, believing to have found in this a critique of the unscientific nature of Freudian “hermeneutics.” Since, according to Wittgenstein, to interpret a dream is to prolong it, Freud's method of dream interpretation remains within the dream from the point of view of its scientific value. Thus one can also say that hermeneutics risks arbitrariness or relevancy that is only superficial to the extent that it can drift into an imaginary free association of ideas in connection of symbiotic or “esoteric” object, whereas this free association must itself be the object of a rigorous interpretation with reorganized and shared criteria; so hermeneutics also runs the risks of falling into a “delirium of interpretation,” a psychotic hermeneutics used by the schizophrenic, who cultivates a discourse of paradoxes in order to protect himself from ambivalence and conflict (Paul-Claude Racamier).

**HEROIC IDENTIFICATION**

Didier Anzieu proposed the notion of heroic identification in connection with his concept of the group illusion (1971). Anzieu extensively studied group

dynamics and made significant contributions to that field with his ideas of the skin-ego (1984, 1989) and psychic envelopes.

By “group illusion,” he wrote, “I mean a particular mental state that is seen in natural groups as well as in therapeutic or formative groups, and that is spontaneously verbalized by group members in the following form: ‘We are doing well together; we’re a good group; our leader or our supervisor is a good leader, a good supervisor’” (1971). According to Anzieu, three conditions are necessary to establish the group illusion: the designation of one group member as a victim or scapegoat (“One of us is bad”), the formulation of an egalitarian theory (“We are all alike”), and finally, the refusal to take gender differences into account (“We are all born outside of sexual relations”). With regard to this last condition, he further explained, “The group illusion expresses an unconscious statement according to which group members are not born in the same way as individuals, but are instead a product of parthenogenesis, living within the body of a fertile and all-powerful mother” (1971).

With this set of conceptual tools, Anzieu reminded us that the group derives from a founding father, and as Freud showed in “Group psychology and the analysis of the ego” (1921c), the great majority of group members are, or believe themselves to be, equally loved by the founding hero. “For the founder, the group serves as a fantasized resonator that gives body to his ideas, and as a mediator for making these ideas known to a broad public. For the group members, the founder satisfies their heroic desires and proves that they can obtain the love of the superego” (Anzieu, 1984).

Such, then, are group members’ identifications with the heroism of the group’s founder and leader. As was often his practice, Anzieu drew examples from mythology to support this concept, which enriches and complements the classical Freudian views on identification.

## **HEROIC SELF**

The heroic self, as understood by Riccardo Steiner (1999), refers to the creative person’s specific need to associate with, to compete with, and to surpass, the heroes of their own or of some other cultural tradition. Although the heroic self is principally a component specific to the creative personality, it is present, in varying degrees, in every single person.

Steiner’s notion of the “heroic self” is derived, through the work of Daniel Lagache, Hermann Numberg, Alain de Mijolla, André Green, Jacques Lacan, and other French authors, from the phenomenological differentiation of the various aspects of the ego as originally described by Freud in his paper entitled “On Narcissism: an Introduction” (1914c). In this work, Freud spoke of the existence of an “ideal ego” and of an “ego ideal,” and later he also mentioned the existence of a “superego.” The heroic self is one of the ways in which the ideal ego manifests itself. Forming part of the constitutional endowment of the creative personality, it has, of course, constitutional aspects. Yet, understood from a Kleinian point of view, the heroic self can either be fostered or inhibited, from the beginning of life, by the *reverie*, or by the lack of *reverie*, shown by the mother and the parental couple. Later on in life, it can also be fostered, or inhibited, by relatives, by teachers, by cultural or other institutions, depending on the attitude these have towards the potential heroic self of the creative personality.

The heroic self manifests itself through what Steiner calls heroic projective and introjective identifications. The way in which it manifests itself depends on the individual’s previous vicissitudes. If, for instance, the heroic self has been properly fostered by the creative person’s family, or by their educational environment (by a teacher, school, etc.), at a certain moment the creator will start to feel the specific need to identify parts of the self with the heroes of their own or of

some other cultural tradition. They will do this via heroic projective identifications, as they will also be able to introject those same heroes via introjective identification. Particularly interesting, developmentally speaking, is the period Freud called “the family romance,” and during adolescence, when it is often possible to observe the first manifestations of the heroic self, although Steiner insists that the unconscious roots of the heroic self have to be traced back to the earliest object relationships and to the way they have been dealt with during the depressive position phase.

Conceived in this way, the heroic self constitutes an important aspect of the creative process. Due to the creator’s constant interaction with its chosen tradition or peers, the creative process can never therefore be conceived to be developing in a socio-cultural vacuum, nor can it ever be understood as being a purely subjective process. In other words, there can never be a relationship between the creator and their unconscious which excludes all relationship with the tradition or the peers of the creator’s heroic self.

For various psychopathological reasons, and as a result of events experienced during the course of infantile and adolescent development, the heroic self and its heroic introjective and projective identifications can be deeply disturbed and, in some cases, can almost cease to exist. All this can result in a megalomaniac distortion of the heroic self, which comes to feel narcissistically and destructively superior to any form of dependence on peers or cultural traditions. In such cases, creators isolate themselves and refuse to learn from peer or cultural traditions. The disturbances can also manifest themselves as a profoundly paralyzing and melancholic “apathic” which again leads to impossibility of the individual being able to relate constructively to peers or cultural traditions, or to be able to learn from them.

In order for the creative personality to be able to use their own heroic self and their heroic projective and introjective identifications, it is vitally important that help is given to the damaged creative personality, via psychoanalytic treatment, to repair not only their own internal and external objects, but their heroic self as well. This leads to it being possible for the creative personality to learn from their heroic peers, or from the heroes of the chosen tradition. And, in the case of genuinely creative personality, it leads to a capacity to tolerate the specific anxiety related to the need not

only to bypass their biological parents and their creativity, but also to bypass and to compete constructively with the great heroes of their cultural tradition, and, sometimes, with great heroic peers. Particularly important is the possibility for the creator’s heroic self to be able to identify with the creative intercourse of their parents, at least in fantasy. This does not necessarily mean that the creator has to generate children! Very often, their “children” are their creative results. All this is possible, according to Steiner, if the creator and their heroic self have achieved a good enough, even if not absolute, capacity to function according to what Klein and her followers have called the depressive position (Segal, 1991).

The notion of the “heroic self” and its heroic projective and introjective identifications may help one to acquire a better understanding of certain general aspects of the creative process, particularly those concerning the creator’s relationship with the cultural tradition or traditions to which they belong, or of which they make use in their own work. It can therefore lead to a better psychoanalytic understanding of cultural movements such as classicism, romanticism, futurism, and the like, because these all involve a particular unconscious and emotional relationship between creativity, individuality, originality, and the role played in it by tradition. It can also shed light on the way it is possible, from a psychoanalytic point of view, to evaluate a creative work in general. Even the reader, the literary or art critic, and so on, all have to mobilize their heroic selves and their heroic projective and introjective identifications in order to understand and evaluate a creative work.

If one looks at its psychopathological manifestations, the notions of a megalomaniac psychopathic heroic self (and this is something Daniel Lagache has pointed out at an individual level) can help to clarify some aspects of what could be called a “folie à plus,” which is to say a stimulation of the megalomaniac and psychopathic aspects of the heroic self at a mass level. In order to do this, the mass needs a megalomaniac and psychopathic leader. All this could help towards a better understanding of the unconscious roots of the power which appeals to groups and to the masses, based on their reference to the “heroes,” past or present, of a particular cultural or historical tradition, not least certain past and present-day religious figures and movements. These heroes, religious figures and movements have been used, and continue to be used, in a

distorted and destructive way by both old and more recent totalitarian and fundamentalist regimes.

## HESNARD, ANGÉLO LOUIS MARIE (1886–1969)

A psychoanalyst, doctor with the French Navy, and professor at the École Principale du Service de Santé de la Marine, Angélo Louis Marie Hesnard was born in Pontivy in the Morbihan, on May 22, 1886, and died in Rochefort-sur-Mer on April 17, 1969. He was co-author of the first French work on psychoanalysis and one of the founding members of the Société Psychanalytique de Paris (SPP). He was the son of Angélo Théodose Hesnard and Lélia Célénis Rosalie Blancon, from a family of judges. His brother Oswald, who had a degree in German, helped him understand Freud's writings.

After completing his studies in Pontivy, he entered the École de Santé de la Marine et des Colonies in Bordeaux on October 20, 1905. A student of Albert Pitres, then of Emmanuel Régis, he wrote his dissertation in 1909 on “Les troubles de la personnalité dans les états d’asthénie psychique,” in which there is a reference to Freud. He continued his military career in Toulon, then, from 1910 to 1912, on the armored cruiser *Amiral Charner* in the Middle East.

Upon his return in 1912 he was appointed assistant at the Clinique des Maladies Mentales at the University of Bordeaux, where he rejoined Emmanuel Régis, who encouraged Hesnard to study Freud. On January 2,

Freud wrote to Karl Abraham, “Today I received a letter from a student of Régis, in Bordeaux, written on his behalf, apologizing in the name of French psychiatry for its present neglect of  $\Psi$ a.” According to a letter to Ernest Jones on January 14, the reference is to the “apologies from the French nation” that Freud received. This was followed in 1913 by the publication of “La doctrine de Freud et de son école” by Emmanuel Régis and Angélo Hesnard in *L’Encéphale*.

*La Psychanalyse des névroses et des psychoses* appeared in 1914. It was a lengthy précis—and as faithful as it was possible to be at the time—of Freud’s principal theories, as Sándor Ferenczi noted in the review of the book he wrote in 1915. This was followed by an examination of the criticisms the theories had received from various authors, and finally by several commentaries, of which Hesnard claimed, after Régis’ death, that he—Régis—was the principal author.

They recognized that “Freud’s system seems to constitute, regardless of what one may say, one of the most important scientific movements of the current psychological period.” Nonetheless, their remarks essentially referred to what appeared to them to be no more than “ingenious assumptions” that were both original and well understood, since—and this is an argument that would be repeated for decades to come—“Freud’s method of conception is based on that of Janet, whom he has constantly been inspired by. Transforming the term ‘psychological analysis,’ employed by Janet, into psychoanalysis has changed nothing in the method used by both students of Charcot.” The causal importance given to sexuality or symbolism was also criticized. While Freud, in his “On the History of the Psychoanalytic Movement” (1914d), concluded that “Régis and Hesnard (Bordeaux) have recently [1914] attempted to disperse the prejudices of their countrymen against the new ideas by an exhaustive presentation, which, however, is not always understanding and takes special exception to symbolism,” he reproached Hesnard for years for this type of finding. In France the work remained the only extensive essay on psychoanalysis for nearly twenty years and was reprinted in 1922 and 1929.

Hesnard spent the war years in Rochefort and on September 16, 1915, married Henriette Aline Vimont. He was supposed to return to Bizerte, Tunisia, in 1917. When he returned to Paris in 1919, he was named professor at the École Principale du Service de Santé de la Marine and assistant in neuropsychiatry at the

Bordeaux school of medicine. His interest in psychoanalysis did not wane, nor did his reticence, and he was appointed rapporteur to the Congrès des aliénistes et neurologistes de langue française de Besançon (Congress of francophone psychiatrists and neurologists of Besançon) in August 1923. The subject was “La Psychanalyse: Valeur étiologique, méthodologique, thérapeutique et psychiatrique de la doctrine.” In his conclusion Hesnard wrote, “It is in this way that psychoanalysis, freed of its terminological errors, its theoretical exaggerations, and its symbolic fictions of semiological research, joins psychiatry, from which it depends, and clinical psychology. . . . It is in this way that this still unwieldy, but highly perfectible, body of doctrine and method, has an incontestable right to our sympathy as scientists and French nationals.”

While on a trip to Toulon he established contacts with young psychiatrists, who, back in Paris, began to practice psychoanalysis. René Laforgue was the first. It was with Laforgue that Hesnard founded, in 1925, the group and the review of the same name, *L'Évolution psychiatrique*, before his departure in June to the Far East. He returned in November 1925, and in August 1926 was present at the Congrès des Aliénistes in Geneva and participated in the first Conférence des Psychanalystes de Langue Française (Conference of francophone psychoanalysts) that was created at that time.

Although he refused to undergo a teaching analysis (a position he maintained until the end of his life), in November 1926 he became one of the founders of the Société Psychanalytique de Paris, of which he was vice president in 1928 and president in 1930, and in 1927 helped found the *Revue française de psychanalyse*, where he was responsible for the “medical section.” He was also a member of the Commission Linguistique pour l'Unification du Vocabulaire Psychanalytique Française (Linguistic commission for the unification of French psychoanalytic vocabulary), where he fought for the harmonization of French psychoanalytic terminology.

Although supported by Laforgue, he was often criticized by Freud. In 1922, in a preface to the second edition of his first important work, he wrote, “Freud’s doctrine, the product not of the French character of Charcot, as has been claimed, but rather of Germanic philosophy, has had no more useful adversary in the search for truth than Restraint, the muse of Latinity.” Over the years, Hesnard’s position would soften and,

in 1926, he dedicated his book, *La Vie et la Mort des instincts*, to Freud: “To Professor S. Freud, I offer, along with the disavowal of my unfair criticisms, the homage of my pure admiration.” When the book was reprinted for the third time in 1929, he noted that he had spent “ten years in understanding psychoanalysis theoretically and five years in acquiring sufficient practical knowledge,” and he softened his initial criticisms.

Nonetheless, Hesnard remained part of a small group of psychiatrists who opposed the more cultural approach to psychoanalysis represented by Marie Bonaparte. They especially rejected the authority of the International Psychoanalytic Association, and even of Freud himself—a division that would nearly lead to a split among their ranks in the late nineteen thirties. On January 23, 1932, Hesnard wrote to Bernard Grasset, whom he was trying, in vain, to treat, “I beg you, forget all that flashiness, the grandiloquence, all those ‘Oedipuses.’ You, as a subtle and marvelously intuitive Gaul, should not let yourself be misled further by those Judeo-Germanic specters of enchantment” (Bothorel, J., 1989).

He was secretary of the Conseil Supérieur de la Marine in Paris in 1938 and was named head of the Service de Santé de la Marine in Algeria and director of the Service de Santé de la Quatrième Région Maritime in 1940, inspector general of the Service de Santé de la Marine in Africa in 1943, and spent the Second World War in Bizerte. In 1942–1943 he wrote an article entitled, “Sur l’israélisme de Freud,” published in 1946, which claimed to be a refutation of the apparent or claimed Jewish influence in Freud’s writings. Nonetheless, Élisabeth Roudinesco maintained that the article was anti-Semitic in spite of Hesnard’s apparent pro-Jewish sentiments (1982). Calumniated and disgraced after the Liberation, from September 1944 to June 1945, he lived with his wife and daughter in Casablanca, where he joined the Socialist Party and gave several talks before returning to Toulon.

Hesnard participated indirectly in the renewal of the SPP and was also one of the members of the honor committee of the group and the review *Psyché*, founded by Maryse Choisy in 1946, which brought together, aside from René Laforgue, religious and academic scholars and Jungian psychologists who had not been admitted to the SPP. He participated in writing the *Dictionnaire de psychanalyse et de psychotechnique*, which was being prepared in 1949, under the direction of Maryse Choisy and later Daniel Lagache.

At this time Hesnard moved into the “Port-Hesnard” villa in the Mourillon quarter of Toulon, where he practiced psychoanalytic therapy. He was criticized for his lack of rigor in his work, a reproach that was used against him during the negotiations intended to reintegrate the Société Française de Psychanalyse (SFP) into the International Psychoanalytic Association (IPA) because he had sided with Jacques Lacan during the June 1953 split. In June 1957 he was dismissed from the SFP for “non-payment of dues and failure to participate in society activities.”

Although he was elected president of the SFP in 1959, one of the “recommendations” of the IPA committee, made during the Edinburgh congress of 1961, stipulated “that the current practice of keeping Doctors Hesnard and Laforgue out of the training program be maintained. With respect to Doctor Hesnard’s students, these can participate in regular analytic training or they will not be admitted as students of the society.” Hesnard again sided with Lacan in 1964 during the foundation of the École freudienne de Paris (Freudian school of Paris) and, in 1968, became a member of its “accreditation committee.”

In 1964, for family reasons, he left Toulon to settle in Nantes, near where he was born, and where he died on April 17, 1969.

There have been references to the “tall, somewhat Olympian silhouette, the luminous eyes and expressiveness” (Picard, 1972) of this complex character, sometimes sarcastically referred to as “the admiral,” whose extensive body of work has had little impact on theory. Following a number of articles written before the war that fall halfway between proselytism and criticism, the bulk of his output was didactic or historical in nature. These include: *Freud dans la société d’après-guerre* (1946), *L’Univers morbide de la faute* (1949), *Morale sans péché* (1954), *Psychanalyse du lien interhumain* (1957), *L’Oeuvre de Freud et son importance pour le monde moderne* (1960), *Les Phobies et la Névrose phobique* (1961), *Psychologie du crime* (1963).

## HETEROSEXUALITY

The terms to designate sexual orientation arose only in the later nineteenth century. “Homosexuality” owes to work by the Austro-Hungarian journalist and literary figure Károly Mária Kertbeny, who wished to reform prevailing sodomy laws in Prussia; in 1868 he coined the term to avoid the pejorative “pederast.” First used in a letter, it gained some currency and in 1880 its binary opposite—“heterosexuality”—appeared in a book by Kertbeny’s friend and colleague, zoologist Karl Jager. Richard von Kafft-Ebing picked up both terms, though not systematically, for use in his *Psychopathia Sexualis*, first published in 1886. Not long afterward, in 1894, the French intellectual Marc-André Raffalovitch used the term “heterosexual” in an article published in the *Archives of Criminal Anthropology*.

In *Three Essays on the Theory of Sexuality* (1905d), Freud’s developmental stage theory gave special force to the implicitly privileged status of heterosexuality in

a normative context. He outlined a biological and psychological program for each individual, to be elaborated by instinctual objects and aims in a trajectory that moves from a polymorphously perverse disposition in infancy to heterosexual object choice in adolescence.

Heterosexuality in recent years has attracted attention as an aspect of gender and sexuality, a new discipline of study in Anglo-American scholarship, combining traditions of feminist scholarship, psychoanalytic theory, and cultural studies.

## **HEUYER, GEORGES (1884–1977)**

A professor of child psychiatry at the Paris Medical School and member of the Académie Nationale de Médecine, Georges Heuyer was born in Pacy-sur-Eure on January 30, 1884, and died in Paris on October 23, 1977.

Having lost his father when he was only eighteen months old, he was placed in a boarding school in Pacy, then in Évreux, where his supervisor was the director of the psychiatric asylum—the origin of his interest in psychoanalysis. In spite of his poverty he studied medicine in Paris, where he became friendly with Georges Duhamel, Henri Queuille, Paul Chevalier, and Henri Mondor. After continuing his studies in pediatrics, neurology, and psychiatry, he became an intern, resident, and in 1923, a doctor in the Paris hospital system. In 1925 he was made director of the clinic of child neuropsychiatry, which, in

1949, created the first chair of child psychiatry in France.

The founder of child psychiatry in France and an international spokesman for the field, at the time of his death, Heuyer left behind a considerable body of work, comprising at least ten books and more than eight hundred articles and publications.

He was not a psychoanalyst and the great majority of his work was devoted to child neuropsychiatry, maladjusted children, and criminology. It was Heuyer who first introduced the use of trained psychoanalysts in public hospitals (Eugénie Sokolnicka at Sainte-Anne's hospital in 1921). With Emmanuel Régis, Angélo Hesnard, and Édouard Pichon, he was one of the promoters of psychoanalysis in France, writing the first article on the subject for a medical treatise, *Traité de pathologie médicale*, which was edited by Émile Sergent in 1924.

In 1925 he created a “laboratory” of psychoanalysis in his clinic, run by Sophie Morgenstern, with whom he published several articles. However, Heuyer wrote little on psychoanalysis with the exception of some studies in collaboration with other people. He was also far from being an uncritical supporter of the field and was always ambivalent and, somewhat later in life, often unfair in his estimate of the profession. However, he did introduce and encourage the use of psychoanalytic inquiry and treatment in child psychiatry and recommended that its practitioners have themselves analyzed or become analysts themselves. This was the case for the majority of his assistants, especially Serge Lebovici (assistant from 1946 to 1957), and of his residents, who subsequently helped psychoanalysis (“which has provided us with so many new and essential concepts” he wrote in 1964) assume the key position it currently holds in French child psychiatry.

## HIETZING SCHULE/BURLINGHAM-ROSENFELD SCHOOL

Founded in 1927 by Dorothy Burlingham and Eva Rosenfeld under the aegis of Anna Freud, the Hietzing Schule (Hietzing School) was an effort to create a pedagogic experience inspired by psychoanalytic principles with children who were at the same time engaged in analysis.

Small and private (it was sometimes known as the “Matchbox School”), the school was housed in a log cabin built in Eva Rosenfeld’s back yard, in the XIIIe district of Vienna. Peter Blos, who had been engaged as tutor to Burlingham’s four children, was its first administrator. He enlisted his friend Erik Homburger Erikson as one of the teachers.

Rather few students attended the school, about twenty in all. They came from households in which their parents were apt to understand psychoanalysis or to themselves be in analysis. The children of Burlingham and Rosenfeld, Peter Heller (who would eventually write about his experiences), August Aichhorn’s son Walter, and Ernst Halberstadt-Freud, participated in the project, which created something like a “psychoanalytic family.”

Freud’s own 1918 pronouncements on the role that psychoanalysis might play in preventing psychological conflicts (1919a) undoubtedly influenced the way that the school was conceived. Siegfried Bernfeld, close to Anna Freud, a committed socialist who had himself founded the *Kinderheim Baumgarten*, gave a lecture on education on February 25, 1929, the contents of which were published in the *Frankfurter Zeitung*. Psychoanalysis, according to the article, “would provide decisive

arguments in favor of endeavors in modern education to promote the independent creative activity of the child and the retrenchment of authority and punishment” (Heller 1992, p. 80). Similarly, teaching at the Hietzing School was to be free of the constraints of a rigid or official curriculum in favor of a project-based approach. To allow free rein to curiosity and fantasy (though not to acting out) would provide a place for studying topics such as “Eskimos,” for example, around which would be organized ethnographic investigations, creation of drawings and objects, and games.

Important debates took place between the school’s progressives and latitudinarians (Peter Blos and Erik Erikson) and others who thought it was necessary to impose some unpleasant tasks on children, including Anna Freud, Eva Rosenfeld, and August Aichhorn, who managed the school from 1931 to 1932.

Anna Freud, with her teaching experience in a primary school in Vienna and analysis with her father (who was also analyst to both Dorothy Burlingham and Eva Rosenfeld), was one of the first to plan teaching programs based on psychoanalytic principles. She had almost all the children and some teachers in analysis, including Erik Erikson. Although she appreciated progressive advances in education, she was fairly conservative.

The school closed in 1932, in part due to Eva Rosenfeld’s departure for Berlin. Some students found it difficult to adapt to public education; this factor subsequently influenced Anna Freud and Dorothy Burlingham when they founded, in London during the Second World War, the Hampstead War Nurseries and Child Therapy Clinic.

## HILFERDING-HÖNIGSBERG, MARGARETHE (1871–1942)

Margarethe Hilferding-Hönigsberg, an Austrian physician and psychoanalyst, was born on June 20, 1871, in Vienna, and died while being deported to Maly Trostinec in September 1942.

She was from a family of Jewish doctors, who were deeply involved in the social-democratic movement. She was trained to be a teacher in public and private schools, received her baccalaureate degree, and, in 1898, enrolled in the philosophy department of the University of Vienna. She switched from philosophy to medicine and obtained her doctorate in 1903—one of the first female doctors in Vienna. In 1904 she married Rudolf Hilferding, a socialist economist, future minister of finance of the Weimar Republic. In 1907–1908, the family was living in Berlin but Hilferding-Hönigsberg returned to Vienna with her two sons following her divorce. In 1910 she began practicing medicine in a workers' quarter of Vienna, where she was also politically active with the social democrats from 1927 to 1934, working as a district councilor.

In April 1910 Paul Federn proposed Margarethe Hilferding as a candidate for the Vienna Psychoanalytic Society, which led to an in-depth discussion on accepting women into the organization. On April 27, 1910, she became the first woman in the society and, until her resignation, a year-and-a-half later, regularly attended meetings. During the winter 1910–1911 season, she was an auditor at Sigmund Freud's talks at the school of medicine. In January 1911 she gave her first presentation to the Vienna Psychoanalytic Society; it was titled "The Basis of Maternal Love."

In 1911, at the time of the split between Alfred Adler and Sigmund Freud, she sided with Adler and cosigned his letter of withdrawal. After the First World War she was very active in the Verein für Individualpsychologie (Association for Individual Psychology). She worked as a chief physician in offices providing educational counseling in individual psychology and at the Mariahilfer Ambulatorium day hospital. Her seminars, talks, and publications concerned educational issues and the problems of women. In the collection edited by Sofie Lazarsfeld in 1926, "Volkstümliche Schriftenreihe" (Popular Collection), she published *La Régulation des naissances* with a postscript by Alfred Adler.

When the National Socialists came to power, Margarethe Hilferding-Hönigsberg was unable to get out in time. She lost her apartment and was placed in a Jewish old-age asylum in Vienna. On June 28, 1942, she was deported to Theresienstadt. She died while being transported to Maly Trostinec in September 1942.

## HIRSCHFELD, ELFRIEDE (1873–?)

Born in 1873 and raised in Frankfurt-am-Main, Elfriede Hirschfeld was a patient of Sigmund Freud. She was treated between 1908 and 1914, and appears anonymously in several articles and in his correspondence. The work of Ernst Falzeder (1994) has enabled us to identify the person behind these references.

Freud was reticent about treating Hirschfeld after she had already undergone ten years of psychiatric treatment. She continued to receive treatment from several other psychoanalysts and psychiatrists but the results were inconclusive. She appears for the last time in the correspondence between Freud and Ludwig Binswanger on May 10, 1923, while she was being treated in Binswanger's clinic.

Hirschfeld appears as "Frau A." in the Freud-Abraham correspondence, "Frau H." in the Freud-Pfister correspondence, "Frau C." in the Freud-Binswanger correspondence, and finally as the "thirty-seven year old patient" in the Freud-Ferenczi correspondence. She was the subject of six articles and the origin of three articles from 1913: "An Evidential Dream" (1913a), "Two Lies Told by Children" (1913g), and "The

Disposition to Obsessional Neurosis” (1913i). She is also directly implicated in the following articles: “Psycho-Analysis and Telepathy” (1941d [1921]), “Some Additional Notes on Dream-Interpretation as a Whole” (1925i), and finally in the chapter “Dreams and the Occult” in *New Introductory Lectures on Psycho-Analysis* (1933a [1932]). The list is long enough to establish the importance of Falzeder’s discovery, but we can also confirm that her case serves as the background for the technical articles “Remembering, Repeating and Working-Through” (1914g) and “Observations on Transference Love” (1915a [1914]).

Hirschfeld’s case was described in the three articles from 1913 and, in greater detail, in the article on obsessional neurosis. In it Freud introduced the erotic-anal phase, following the phases of autoerotism and narcissism, which was not present in the first edition of the *Three Essays on the Theory of Sexuality* (1905d). He also introduces the idea of “symptom mobility,” which he does not describe in detail.

After six years of analysis, three articles, references in his correspondence, and in spite of the fact that Freud claimed to have “reached the hard kernel of the illness,” the patient had not made much progress. She was passed from doctor to doctor, seeing Carl Gustav Jung, Oskar Pfister, and finally Ludwig Binswanger, who treated her in his clinic. Freud made a comment to Binswanger that was to have considerable technical significance: “Analytic treatment should be accompanied by institutionalized control” (letter of April 27, 1922). This comment, along with others on then “current” methods of treatment that preceded analysis, appears in Freud’s correspondence with Karl Abraham. It demonstrates Freud’s pragmatism when faced with clinical difficulties.

Based on the evidence, Hirschfeld pushed Freud toward his final position on transference and countertransference. We can now accept that Freud formulated his first ideas about countertransference with reference to Hirschfeld. Everyone understood the notion of healing through love, as formulated by Carl Jung and Max Eitingon (and which is also found in the *Minutes of the Vienna Psychoanalytic Society* [Nunberg, Hermann; and Federn, Ernst, 1962]), in their own way. It is important to remember that it was during this time that Jung was deeply involved with Sabina Spielrein and Sándor Ferenczi with Elma Palos (Haynal, André, and Falzeder, Ernst, 1991). Freud was dealing with a patient who would not now be termed

neurotic, as he wrote, nor schizophrenic, as Eugen Bleuler claimed, but very likely borderline or suffering from “pseudoneurotic schizophrenia.” In these pathologies the symptoms do not mark the return of the repressed but serve as a defense against psychotic collapse.

Of the hundreds of patients that Freud treated in his practice, few were the subject of a monograph (Dora, for example) or an article (the young homosexual of 1919). Some are mentioned in an article and others appear only as signs or abbreviations in the correspondence. It is clear that psychoanalysis is not a purely empirical science and that its theory is firmly based on clinical practice (Lipton, Samuel D., 1977). Additionally, contemporary witnesses and belated analyses of Freud’s treatments have contributed greatly to our understanding of Freudian practice, as well as how its theorization developed over time (Cremerius, Johannes, 1980).

The case of Elfriede Hirschfeld can be read as a female pendant to the Wolfman, to the extent that their treatments took place almost simultaneously. It is worthwhile rereading the introduction of pregenitality based on this case and the use of the primal scene in Freud’s theorization of the Wolfman’s symptoms. It is certain that Freud made progress as a researcher who experimented within this atmosphere of psychiatric nihilism that consisted in providing a diagnosis, then waiting for the illness to run its course. It is likely that his patients recognized this and, depending on their capabilities, benefited from it.

## HISTORICAL REALITY

“Historical reality” refers to the real facts and events of the past as they occurred historically, whether they were external or internal to the subject confronted by them. In general, historical reality stands opposed to wishful fantasies and to everything within the mind that may be said to answer to the pleasure/unpleasure principle and its principal mechanism: hallucinatory wish-fulfillment.

To better understand the relevance of historical reality to psychoanalysis, it is important to realize that the conflict between the two fundamental principles of the mental apparatus—the pleasure/unpleasure principle and the reality principle—also has an impact on the past and on the subject's ideas about the past.

On the one hand, history as retained in memory is capable of being reinterpreted and transformed on behalf of the pleasure/unpleasure principle by means of the individual's fantasies, wishes, and defenses. A fantasy that has been cathected and activated by hallucinatory wish-fulfillment behaves as an actual reality,

interfering with the ego's ability to differentiate real events from imagined and hallucinated ones. This view supports the belief in memory's poor reliability when it comes to historical reality, since any memory is likely to have been reorganized on behalf of the pleasure/unpleasure principle.

On the other hand, Freud—and many other psychoanalysts as well—was never able completely to overlook the impact of certain traumatic historical events in the etiology of mental suffering and symptomology. While history can be transformed for the sake of the libidinal economy of the subject, the repression of the historical reality would be incomplete, since it would leave traces as psychic events unfolded. The reality principle must also be capable of being applied to the past and of opposing the pleasure principle. In a way fantasies themselves might be said to indicate the existence of a kernel of historical reality.

Fantasy and historical reality are not strict opposites. Fantasies, as Freud wrote early in his career, are of “mixed blood”—intermediary formulations that fall somewhere between lived reality and the way in which the subject has given it meaning within his libidinal organization of the moment.

Thus in addition to representative forms of the “memory” of events and facts in the past, forms that are likely to be subjected to different kinds of “deferred” reinterpetations and wishes, there are ways of directly recording lived experience that bear witness to the impact of historical reality. The work of reconstructing historical reality is, therefore, potentially possible, and indeed one of the essential goals of psychoanalytic work (Freud, 1937d) is to extend the influence of the reality principle to the past and its representation.

Historical reality and mental reality are not, therefore, strictly at odds. The reality of experience marks history with an imprint that has significance within the current psychic organization, in particular during childhood, on the basis of infantile sexual theories and the narcissism of infantile animism. Debate continues to erupt, however, within psychoanalysis, over the disjunction between historical reality and mental reality, and this suggests the fragility of the synthesis mentioned above. It would seem that the question of the distribution of what is part of actual history—and therefore, “outside” the subject—and what is part of desire still needs to be re-examined, as if the boundary

between inside and outside was fluid and admitted a degree of undecidability essential to mental functioning and internal conflict.

## **HISTORICAL TRUTH**

Historical truth, as Sigmund Freud conceived it, can be defined as a lost piece of the subject's lived experience that is accessible only through the work of construction. The term *historical* here refers to origins, which explains why historical truth can be presented as a kernel of truth in formations as diverse as legends, religions, or delusions.

The problem of historical truth can be theorized in a number of ways in the field of history. The fundamental split between the approach of the historian and that of the psychoanalyst has to do with their respective ways of conceiving temporality. For the psychoanalyst, time is blended: Present and past live together in repetition and in the reliving that is a part of the transference. For the historian, by contrast, the past is separate from the present, and even if there are causal links between the two, their order of succession remains immutable, since what endows an event with its historicity is precisely the fact that it occurred at one time that will never be repeated. Thus, seen from a psychoanalytic perspective, historical truth is not the material truth of an event, even if Freud may have believed this early on his works, but rather the truth of a history as it appears through an event. It is the truth of a sequence and not of a point; it requires the reconstruction of phases leading up to the constitution of an

element that can claim the status of truth. Accordingly, historical truth is to be distinguished from material truth—literal truth that is presumed to have a direct referent in reality.

Although Freud spoke a great deal about truth throughout his work, it was toward the end of his work that he essentially developed the notion of historical truth, mainly in connection with “Constructions in Analysis” (1937d) and “Moses and Monotheism: Three Essays” (1939a [1934–38]).

The idea of historical truth is very important in psychoanalysis, because it makes it possible to take off from a realistic conception of the analytic process, as it was present in Freud's early theory centered around trauma, and move toward a more refined, perspective-based conception where the main focus is on the notion of construction and the process of an indirect confirmation of the construction by the analysand, who can thus give it a truth value, even in the absence of a recovered memory. However, the notion of truth remains dependent upon a feeling of certainty. It is not formal, in the sense that it could be considered to be the same thing as exactness.

Two factors must be taken into account here. The first relates to what Freud called intellectual feeling and concerns the degree of conviction brought by an isolated and repressed piece of truth that returns. This “kernel of truth,” a veritable fossil, is the basis for the irresistible claim to truth contained in religious faith as well as in delusional beliefs. This is a “historical” truth, that is, the truth of both the fossil kernel and the sense the subject may have of the process of distortion that is attached to it. In *Moses and Monotheism: Three Essays*, Freud wrote: “An idea such as this has a compulsive character: it *must* be believed. To the extent to which it is distorted, it may be described as a *delusion*; in so far as it brings a return of the past, it must be called the *truth*” (p. 130). “Historical truth” is thus revealed to be distinct from historical exactitude when the latter does not involve this passage by way of the repressed, and the truth is not implicit in historical narration, for this is, on the contrary, the site of compromise and dissimulation, which this time are conscious. However, as Freud wrote in *Moses and Monotheism*: “In its implications the distortion of a text resembles a murder: the difficulty is not in perpetrating the deed, but in getting rid of its traces” (p. 43); the only possibility is thus to follow these guiding fossils

(*Leitfossil*) that open a pathway toward truth through these distortions.

In “Constructions in Analysis,” the dialectic concerning truth is even more subtle, since an erroneous construction can lead the patient to remember a fragment of his or her historical truth. In this case, said Freud, citing Shakespeare’s Polonius, it is as if “our bait of falsehood had taken a carp of truth” (p. 262). The work of interpretation thus entails freeing the fossil from the aggregate of current material encasing it and bringing it back to the point in the past to which it belongs.

## **HISTORY AND PSYCHOANALYSIS**

Freud wrote little about history, in the sense that professional historians understand that term, or about its relationship to psychoanalysis. Nevertheless, three remarks are in order.

From the outset, Freud posited psychoanalytic investigation as being linked to the reconstitution of the patient’s personal history. The aim was to restore this history to patients, with the goal of helping individuals emerge as the subject and agent of their own history through the lifting of the repressions that weighed

it down, and breaking the pattern of repetitions that resulted from it. Initially Freud conceived of this process as a restitution of buried traces in their entirety; he thus readily compared it with the task of the archaeologist who brings to light the strata of a buried past layer by layer. Although he always maintained his fundamental hypothesis—that the psyche forgets nothing—he came to believe that these “traces” undergo constant change as they are reshaped through deferred action and that they can therefore only be known through analysis in this reworked form, as he explained in “Constructions in Analysis” (1937).

If Freud showed little interest in History as it is written by historians, by contrast he took a great interest in the prehistory and anthropology of so-called primitive peoples, above all at the time when he was seeking to substantiate his views on phylogenesis as the basis for individual psychogenesis. This was the period when he wrote *Totem and Taboo* (1912–13a) and *A Phylogenetic Fantasy: Overview of the Transference Neuroses* (1987 [1915]).

Finally, on several occasions Freud undertook a psychoanalytic interpretation of significant personalities from both the past, such as Leonardo da Vinci (“Leonardo da Vinci and a Memory of His Childhood,” 1910), and the present, such as President Woodrow Wilson (*Thomas Woodrow Wilson, Twenty-Eighth President of the United States: A Psychological Study*, with W. C. Bullitt, 1966). Returning to the story of Moses in *Moses and Monotheism: Three Essays* (1939a), he sought to show that the theory that Moses was an Egyptian would account for his mythical role of founder of a monotheistic religion.

It was this type of work, known as psychobiographical studies, that was most influential on certain of his successors. Notably, in this regard, reinterpretations of Nazism in terms of Adolf Hitler’s personality and psychopathology can be cited; see, for example, Saul Friedländer’s *History and Psychoanalysis: An Inquiry into the Possibilities and Limits of Psychohistory* (1975/1978). These studies have often drawn criticism (for example, from Alain Besançon, after a 1974 work in which he tried this approach) for the reductionist tendency of some authors to overlook factors (cultural, economic, social, etc.) operating outside of individual psychic functioning.

The historian and the psychoanalyst would seem to have common interests: both work on memory,

forgetting, and the restitution of traces; for both, the temporal dimension is essential. Both admit that they construct their object of study through the combined use of techniques for gathering factual data and the work of interpretation that endows these data with meaning by fitting them together; moreover, both use narratives as their starting point, and they accept that these narratives come to them constructed through meaning and must be deconstructed and reconstructed within the framework of their discipline.

One difference between them is the fact that while the historian focuses on the effects of time in the collective memory, the psychoanalyst focuses on these effects in the case of an individual person considered as such. This difference might seem to be a minor one, were it not for the substantial difficulties in assessing how these two levels of analysis are connected: How do collective history and individual history fit together? To what extent does History depend on the contingencies of individual fates, and to what extent are these fates shaped by History? The main difficulties, however, are epistemological in nature.

These difficulties have to do with methods: While the historian is at leisure to verify and tally sources using every means at his or her disposal, the analyst is, as a matter of principle—within the framework of “classical” treatment—limited to only what the patient says in the analytic setting. It is impossible to establish whether a given event in the past actually took place as the patient says it did. It has been argued, justifiably, that this is a moot question, that the only event that is certain is that something has been said this way in the here and now, and that therein lies all the “material” of the analysis (see Viderman, 1970, 1977).

The divergence between history and psychoanalysis exists also, and perhaps above all, at the theoretical level. Time does not have the same status in the two disciplines. The psychoanalyst, who can only know past events through their narration in the present, is led to accept two temporalities: a one-directional, linear time in which the narrated events, with their possibility causality, are ordered; and another, two-directional time, in which an event has modified, sometimes profoundly, an earlier event that is thus reshaped. This means accepting a principle of “antegrade” causality that has no analogue in the study of history or, perhaps, in any other discipline.

## HITSCHMANN, EDUARD (1871–1957)

Austrian physician and psychoanalyst Eduard Hitschmann was born in Vienna on July 28, 1871, and died in the United States on July 31, 1957. He was one of Freud's early disciples and remained loyal to him throughout a long career.

Raised in Vienna, Hitschmann was the son of a banker and the grandson of a physician. He attended the University of Vienna Medical School, received his degree in 1895, and initially practiced internal medicine. In 1905 Paul Federn brought him into the Wednesday Psychological Society. By then a well-known physician, he served for a time as the Freud family doctor.

In April 1909, Hitschmann read before the Vienna Psychoanalytic Society a paper entitled “A General Presentation of Freud's Theories” (Nunberg and Federn, 1962) in which he proposed to write a brief exegesis of psychoanalytic ideas. Freud cautioned Hitschmann not to present psychoanalysis as a closed system and insisted on openly acknowledging that there are

domains in which psychoanalysis could lay no clear claim to knowledge. “Furthermore, this work would require that the writer refrain from expressing any of his own ideas” (Nunberg and Federn, 1962, p. 210). Hitschmann went on to write the first concise presentation of psychoanalysis, *Freuds Neuosenlehre: Nach ihrem gegenwärtigen Stande zusammenfassend dargestellt* (1911), which was translated into English as *Freud’s Theories of Neurosis*.

He also wrote numerous biographical studies, including those of Franz Schubert, William James, and Emanuel Swedenborg; these studies were published in *Great Men: Psychoanalytic Studies* (1956).

Hitschmann’s many psychoanalytic publications did not always receive a friendly appraisal by Freud, who maintained a certain intellectual distance in spite of their friendship. He viewed Hitschmann as “quite orthodox” (Freud 1974, p. 400), as he remarked to Jung. However, Freud entrusted Hitchensmann to direct the psychoanalytic outpatient clinic, or “Ambulatorium,” when it was established in Vienna in 1922. Hitschmann fled the Nazis in 1938 and sought refuge in London; in 1944 he emigrated to Boston where he worked as a training analyst until his death.

## **HOFFER, WILLI (WILHELM) (1897–1967)**

Willie Hoffer, British physician and psychoanalyst, was born in Luditz, Austria in 1897, and died on October 25, 1967, in London.

Educated in Pilsen and Vienna, he became keenly interested in biology and psychology, and took a Ph.D., the thesis for which concerned play as a means of education. He was analyzed by Herman Nunberg from 1921 to 1922. Although he first joined the Viennese Psychoanalytical Society in 1923 as a non-medical member, he studied and qualified in medicine in 1929.

In Vienna, Hoffer worked closely with Anna Freud, and when the Freud family and others left for London in 1938, he too came to London and remained a staunch supporter and in many ways a protector of Freud’s youngest daughter. Anna Freud repeatedly consulted him on many important matters and strongly relied on his judgement. He was a consultant at the Hampstead Child Therapy Course and Clinic, which was founded by Anna Freud and Dorothy Burlingham.

Hoffer obtained a British medical qualification in 1943 and taught at the Maudsley Hospital, as Consultant Psychotherapist, from 1954 to 1962. In 1949 he was elected Editor-in-Chief of *The International Journal of Psycho-Analysis*. In 1957 he resigned this post to become President of the British Psycho-Analytical Society for the following three years; he had already, in 1957, been elected an Honorary Vice-President for life of the International Psychoanalytical Association. His many other honors included appointments as Abraham Flexner Lecturer in Nashville, Tennessee in 1953 and Sigmund Freud Lecturer in New York in 1966. Of his tours abroad, his help in re-establishing psychoanalysis in post-war Germany through repeated visits to teach in Frankfurt were particularly appreciated.

Hoffer wrote a great deal. His best-known work is perhaps his paper on “Mouth, Hand and Ego-Integration” (1950), followed the next year by a paper on oral aggressiveness and ego development. He was also fascinated by young children and what could be learned by studying them. Anna Freud, in a memorial address in 1968, emphasized his “unique role in laying the foundations for a sound and well-planned approach to the study of children of all ages” and reminded her audience that he had set up, in Vienna, a

psychoanalytic training course for teachers, graduates of which were spread all over the western world.

His interest in children was reflected in his writings on play, fairy tales, and education, but his interests were wide and his papers included work on the psychoanalytic investigation of brain damage, schizophrenia, group formation, metapsychology and analytic technique. Hoffer based much of his work on clinical observation and he was at all times a careful writer whose works were frequently revised before publication.

His warmth and personal qualities made him very popular in the British Society, and his work was appreciated by many outside his own group. His wife Hedwig was a non-medical psychoanalyst with whom he lived happily and to whom he was close in every way; her death in 1961 was a very heavy blow to him, and although he faced it bravely, it left its mark.

## **HOGARTH PRESS**

The Hogarth Press was born in the dining room of the home of Leonard and Virginia Woolf (Hogarth House) in Richmond, Surrey. It was devised largely as a hobby for its owners, with whose literary views it was closely identified; but their standing as writers and critics of substance meant that the small press, concerned more with standards than with profit, attracted

a reputation for quality that brought the imprint renown.

In 1924 the Press moved to more substantial premises in Tavistock Square in London. Between 1921, when Virginia Woolf's *Monday or Tuesday* was launched, and 1938, thirty-three titles are listed in the *Annals of English Literature 1475–1950*, all of high quality, though the first pamphlet was published in 1917. The press became a self-supporting business with a high reputation, particularly in the area of literature. It became an allied company of Chatto and Windus in 1946. By that time, if pamphlets and little series of essays are included, 527 titles had appeared. Apart from writers either famous or later to become so, such as T.S. Eliot, Robert Graves, Katherine Mansfield, C. Day Lewis and Virginia Woolf herself, issues such as disarmament, the League of Nations, educational reform and racial prejudice were tackled. Hogarth was recognized as a foremost publisher of challenging new ideas and major writing. The Press retained this reputation after the alliance with Chatto and Windus.

Seven psycho-analytic works, including Freud's *Beyond the Pleasure Principle* (1920a), *Group Psychology and the Analysis of the Ego* (1921c) and the first volume of his *Collected Papers*, were translated from the German under the editorship of Ernest Jones, assisted by James Strachey and published in Britain between 1921 and 1924. But in that year, negotiations were completed with the Hogarth Press, who added the seven numbers of what was entitled *The International Psycho-Analytical Library* to its list. A partnership was struck with the Institute of Psycho-Analysis in London, who became co-publishers, Leonard Woolf retaining a right of veto, though there is no record that this was ever exercised.

The Library accepted for publication only works of the highest standard, most of which were kept in print for long periods. Karl Abraham, Sandor Ferenczi, Anna Freud and Heinz Hartmann were among its many distinguished authors. The enterprise was so successful that Leonard Woolf agreed to publish a *Standard Edition of the Complete Psychological Works of Sigmund Freud* in a new translation under the general editorship of James Strachey, with the collaboration of Anna Freud and the assistance of Alix Strachey and Alan Tyson. The first of twenty-four volumes appeared in 1953 and the last in 1966. The whole is a triumph of scholarship, with extensive notes and editorial

introductions: no comparable collection of Freud exists anywhere in the world. Woolf is said to have described the decision to publish the work, with understatement, as “rather fortuitous.”

Unhappily, for reasons that have never been fully disclosed, the Institute of Psycho-Analysis, against the wishes of the then editor of the *International Library*, Clifford Yorke, decided to discontinue the Library, and the last of the series, number 118, *Freud's Self-Analysis* by Didier Anzieu, was published in 1986. However, the link with Hogarth as co-publishers of the *Standard Edition*, which has maintained its international success, continues. A new edition is now planned, with a scholarly update of Strachey's editorial apparatus, with additional papers by Freud that were either unknown or unavailable at the time of the first edition, with new refinements. In this venture, the American publisher Norton will join the Hogarth Press and the Institute of PsychoAnalysis. It will be two or three years before the new edition is ready for publication.

The Hogarth Press has maintained its identity, together with Chatto and Windus, even though it is now part of the Random House publishing group.

## HOLDING

Holding is the process by which the mother's capacity to identify with her infant enables her to provide sensitive physical support, especially when the child is physiologically vulnerable. This provision of ego support is a “form of loving” that provides the basis for the establishment of integrated psychological development.

Donald Winnicott presented his ideas on holding and infant development to the public, and to those directly responsible for infant care (1947), and formulated these in psychoanalytic terms at the 22nd International Psychoanalytic Congress at Edinburgh in his seminal paper “The Theory of the Parent-Infant Relationship” (1960).

Sensitive physical handling by the mother allows the baby to tolerate frustrations such as hunger and discomfort and experience the gradual diminishment of his sense of omnipotence without going to pieces. Holding, at the beginning, is a series of physical acts which include responding to the baby's skin, feeding, and a group of sensory sensitivities built into the whole routine of day to day care. This is continued as necessary ego support throughout childhood and adolescence.

When practicing as a pediatrician during and after World War II, Winnicott addressed many groups, including parents and nursery care workers, about the essential qualities of infant care. In describing the minute details of ordinary breast-feeding, he was able to demonstrate how the “good-enough mother” provides sensitive physical and psychological holding of her baby. She identifies with her infant to know how the child feels and to provide just what it needs. In the holding phase, this fosters the baby's apparent belief that what it wanted, it created. It has then a hopeful sense of itself in the present and over time. Successful holding provides the baby with the feeling of reliability in the world, both internal and external. The average mother provides this reliability almost without thinking; and by small increments of frustration allows her baby to become “disillusioned” and aware that there is a “me” and “not-me” and a world that in fact it cannot control. Successful holding is the mothers handling of her infant through a “mutuality of cross identifications” and leads to an integration of the self.

Winnicott is clear that these processes in infancy are not the same as the pathological mental mechanisms of the disturbed or borderline adult patient, but those infants who have been significantly “let down” (1970) experience unthinkable anxieties and the later possibility of schizoid states. Winnicott also described holding within the analytic relationship and more broadly in casework with adult patients (1960). When the analyst's mind wanders, it can be experienced by the patient as a failure to “hold” the mind.

Although mention is made of the father's role in later phases (1960), Winnicott focuses his attention more on the immediacy of the mother-baby interaction and less on the conditions within the adult couple and family needed to foster a successful holding phase.

## **HOLLITSCHER-FREUD, MATHILDE (1887–1978)**

The eldest daughter of Sigmund Freud, Mathilde was born on October 16, 1887, in Vienna, and died in London on February 20, 1978.

Mathilde, named after Josef Breuer's wife, appeared in Freud's dreams as his only reference to oedipal and fatherly feelings (1900a). A sickly child, Mathilde suffered from several serious illnesses, including bouts with diphtheria, and references to her health problems as an adolescent and even after her marriage appear often in her father's correspondence.

When she was twenty and doubted her physical appearance, Freud wrote:

You know that I have always intended to keep you at home until you are at least twenty-four, until you are strong enough for the duties of marriage and possibly of bearing children, and until the weakness, which those three serious illnesses in your early life left behind, has been repaired. In social and material circumstances like ours, girls quite rightly do not marry during their early youth; otherwise their married life would be over too soon. . . . I think you probably associate the present minor complaint with an old worry about which I should very much like to talk to you for once. I have guessed for a long time

that in spite of all your common sense you fret because you think you are not good-looking enough and therefore might not attract a man. I have watched this with a smile, first of all because you seem quite attractive enough to me, and secondly because I know that in reality it is no longer physical beauty which decides the fate of a girl, but the impression of her whole personality. Your mirror will inform you that there is nothing common or repellent in your features. . . . The more intelligent among young men are sure to know what to look for in a wife—gentleness, cheerfulness, and the talent to make their life easier and more beautiful (March 26, 1908) (Freud 1960, pp. 271–272).

Despite Freud's vague plan that she marry Sándor Ferenczi, seven months later he announced her engagement to "a young Viennese businessman named Robert Hollitscher" (1875–1959) whom she married at the synagogue the same day (February 7, 1909) as her uncle, Freud's brother Alexander, married.

In September 1912 Freud interrupted his vacation to go to Mathilde's bedside. A botched appendectomy from six years earlier, which had then carried a risk of peritonitis, had caused her to suffer a miscarriage.

Mathilde remained childless but, after the death of her sister Sophie in 1920, she took charge of young Heinele (Heinz Rudolf Halberstadt). "My eldest, Math[ilde], and her husband," Freud told some friends, "have virtually adopted him and have fallen in love with him so thoroughly that one could not have predicted it." (Gay 1988, p. 421) But Heinele died on June 19, 1923.

In Vienna, Mathilde became friends with Ruth Mack Brunswick, who named her eldest daughter after her. After her husband's business suffered during the Great Depression, Freud helped financially while Mathilde opened a fashionable women's clothing store.

Mathilde and her husband managed to emigrate to London on May 26, 1938, and so welcomed Freud at his arrival shortly thereafter. Mathilde Hollitscher opened another clothing store on Baker Street. She retired in 1960 and died on February 20, 1978 at age ninety-two.

## **HOLLÓS, ISTVÁN (1872–1957)**

István Hollós, the Hungarian physician, psychiatrist, and psychoanalyst, was born in Budapest in 1872 and died there in 1957.

The son of a modest artisan (a Jewish tailor, called Heszler before he Magyarized his name), he studied medicine at the Royal School in Budapest. He met Sándor Ferenczi at the beginning of the century and participated in the foundation of the Psychoanalytic Association of Budapest (1913), of which he was vice-president. He worked as an analyst, then did a short analysis with Freud in 1918, followed by control analysis in Vienna with Paul Federn, an analyst specializing in psychotic patients. He was president of the Hungarian Psychoanalytic Society from 1933 to 1939.

He was appointed director of the famous Lipotmező clinic near Budapest, also known as the “Yellow House.” He was close to Ferenczi’s circle and opened the doors of his asylum to writers (Kosztolányi and Karinthy) who were interested in psychotic patients and their linguistic productions. During the period of the Hungarian Commune he taught in the university as a psychiatric “exhibitor.” He translated Freud into Hungarian, first *The Interpretation of Dreams*, finished in about 1917, revised by Ferenczi and published by Somlóin about 1934–1935; followed by *The Ego and the Id* with Géza Dukes, published by Pantheon in 1937. In 1925, under the anti-Semitic regime of Miklós Horthy he had to resign his position as director of the asylum. He wrote a moving testimony to the work he did there and addressed it to Freud, who was prompted to wonder about his own “intolerance” with regard to psychotic patients. He continued to

translate Freud and practice as an analyst while maintaining close relations with Ferenczi.

In 1944 thanks to the last minute intervention of the Swedish diplomat Raoul Wallenberg, he and his wife, along with a few other Jews, escaped a tragic death. He wrote an account of the trauma: *Letter from a Survivor (Psyche, 24 (3), 1974)*. Following the death of his wife and a manic episode for which he received treatment, he returned to the Yellow House, where he ended his days.

Hollós was one of the pioneers of a new approach to mental patients who were, as he put it in 1927, “on strike from life.” His sensitivity, empathy, humanistic principles, and analytic practice helped him to transform asylum conditions, thus making him a forerunner of the movement to apply psychoanalysis in psychiatric institutions.

## **HOMOSEXUALITY**

The term *homosexuality* designates a sexual orientation in which a person of the same sex is the object.

The term was apparently coined in 1869, from the Greek *homos* (“same”), by K. M. Benkert, a writer who published his works under the pseudonym Kertbeny Karoli. He was a defender of sexual rights, and he used the term “homosexual” during discussions on whether to change paragraph 143 of the Prussian Constitution of April 14, 1851, which punished acts of “unnatural

indecent" committed between men, or between a man and an animal.

It is highly surprising that Freud took no interest in this manifestation of sexual life during the first years of psychoanalysis, despite the abundant literature on the topic by such writers as Jean-Martin Charcot, Valentin Magnan, Richard von Krafft-Ebing, Albert Moll, Magnus Hirschfeld, and others. Though Freud views neurosis as the "negative of perversion" (without mentioning homosexuality), this is because he supposes that psychic processes do not undergo repression in the "pervert." Moreover, the theory of bisexuality (Freud-Fliess) introduces the question, albeit under the veil of biology. However, Freud did undertake to analyze a homosexual patient at the end of the nineteenth century, but the patient concerned apparently committed suicide at Trafoi.

The arrival of Isidore Sadger in Freud's circle in 1906 was to be decisive. As dialogue between him and Freud led to the laying down of an "etiological formula": masculine homosexuality results from a boy's childhood repression of the existence of a "strong" mother and a weak or absent father (Freud, 1910c). In the debate with Sadger, who adhered to the seduction theory, Freud proposed etiological variants in which the boy's arousal is transposed from the mother onto men (1905d [1910]), or else there is identification with the mother, hatred towards boys is converted into love, there is a "narcissistic" fixation on the penis, or we see identification with the mother leading to repression of love for the mother (Nunberg, Federn, 1962–75). The theory of narcissism that developed in tandem with that of homosexuality opened up a path that Freud left relatively unexplored: the transmission of narcissism. Thus, Freud's descriptions in "On Narcissism: An Introduction" (1914c)—"A person may love . . . according to the narcissistic type . . . (a) what he himself is (i.e., himself), (b) what he himself was" (p. 90)—could be supplemented by formulae such as "a person loves that which the other wants him to be" and, eventually, "a person loves in himself that which the other would have liked to have or to be" (p. 90).

The other area barely outlined by Freud in the discussions of the Vienna Psychoanalytical Society is that of the passage from autoerotism to narcissism: "In general, man has two original sexual objects and his later life depends on the one upon which he remains fixated. These two sexual objects are, for each

individual, the woman (the mother, the children's nurse, etc.) and his own person. It is a question of getting rid of both of them and not lingering over them. One's own person is the one which, most often, is replaced by the father; the latter soon enters the hostile position. Homosexuality bifurcates at this point. The homosexual is unable to detach himself from himself so soon" (1914c). This heavily significant appearance of the father-figure was not followed up in the etiology of masculine homosexuality but it was later to be found in the analysis of male paranoia (the Schreber case, reported in "Psycho-Analytic Notes on an Autobiographical Account of a Case of Paranoia [Dementia Paranoides]": 1911c [1910]), in which a pathological defense against homosexuality develops, though the role of the father is never specified. Is he an agent of culture because he brandishes castration in the name of the law that forbids masturbation and the mother? Might he not also fill a role as seducer?

In 1910, homosexuality was defined by the characteristics of the object or the subject, but in 1915, in place of this distinction, Freud returned to the conception he had earlier developed with Fliess: the object is merely the reflection of the bisexual nature of the subject ("Three Essays on the Theory of Sexuality," 1905d [1915]).

Homosexuality in women would remain less well explored ("The Psychogenesis of a Case of Homosexuality in a Woman," 1920a), because the transposition of the etiological formula for men—specifically, excessive love for the father—often works less well.

As Sándor Ferenczi remarked in 1914, drawing a distinction between "subject homoerotism" and "object homoerotism" (*Three Essays on the Theory of Sexuality*, note added in 1920, p. 147), psychoanalysis relied right from the start on a model of the "feminine man" and thus neglected the masculinity present in other homosexual men, just as it ignored the femininity of certain lesbians.

Since the 1970s, as homosexuality became more openly discussed, several authors (Chasseguet-Smirgel, J., et al., 1964; Isay, R. A., 1986) have communicated clinical observations that suggest other etiologies. But the psychoanalytic perspective has again become clouded by the way the question of "gender" has been biologized (Robert Stoller). Gays themselves have embraced theories of innate or physiological homosexuality in order to defend themselves against

the inquisitorial persecution long meted out to them by justice, medicine, and even psychoanalysis.

Nonetheless, a first step towards the lessening of homophobia, on a basis other than that of moral principles, was taken by Freud, who put forward the idea that a manifest sexual tendency (heterosexuality, for instance) could conceal another, opposite tendency that remains latent (such as homosexuality). However, although Freud went along with increasingly progressive attitudes in society, he remained just as reserved as did society—witness this rather ambiguous and nuanced letter that he wrote in 1935 to the mother of a homosexual, whose sexuality he did not view as an illness but as a case of arrested development (while only heterosexuality is treated as normal): “Homosexuality is assuredly no advantage, but it is nothing to be ashamed of, no vice, no degradation; it cannot be classified as an illness; we consider it to be a variation of the sexual function, produced by a certain arrest of sexual development. Many highly respectable individuals of ancient and modern times have been homosexuals, several of the greatest men among them. (Plato, Michelangelo, Leonardo da Vinci, etc.) It is a great injustice to persecute homosexuality as a crime—and a cruelty, too. . . . By asking me if I can help, you mean, I suppose, if I can abolish homosexuality and make normal heterosexuality take its place. The answer is, in a general way we cannot promise to achieve it. In a certain number of cases we succeed in developing the blighted germs of heterosexual tendencies, which are present in every homosexual; in the majority of cases it is no more possible” (*Letters of Sigmund Freud, 1856–1939*, p. 423). However, such permissiveness was contradicted by the fact that from 1920 onwards many psychoanalytic societies refused to admit openly homosexual candidates.

The response to the theoretical and practical debate around homosexuality was nevertheless present, in embryonic form, in Freud’s conceptualization of the sexual instinct in 1905. Indeed, at the beginning of the *Three Essays on the Theory of Sexuality* following Charcot and Magnan, he used the highly inappropriate word “inversion” to prove demonstrate that the instinct has no predefined object.

## HORNEY-DANIELSON, KAREN (1885–1952)

Karen Horney, physician and psychoanalyst, was born Karen Danielson in a suburb of Hamburg, on September 15, 1885, and died December 4, 1952, in New York.

Her father was a sea captain of Norwegian origin, her mother of Dutch-German extraction. She studied medicine at the Universities of Freiburg, Göttingen, and Berlin, and married Oskar Horney in 1909. She entered analysis with Karl Abraham in 1910, and became a founding member of the Berlin Psychoanalytic Institute in 1920.

Having separated from her husband in 1926, Horney emigrated to the United States in 1932, when Franz Alexander invited her to become associate

director of the newly formed Chicago Psychoanalytic Society and Institute. She moved to New York in 1934 and became a member of the New York Psychoanalytic Institute. In 1941, she organized the American Institute for Psychoanalysis, of which she was dean until her death in 1952. She was founding editor of *The American Journal of Psychoanalysis*.

Horney's thought went through three phases: in the 1920s and early 1930s, she wrote a series of essays in which she tried to modify orthodox ideas about feminine psychology while staying within the framework of Freudian theory. In 1930s, she tried to redefine psychoanalysis by replacing Freud's biological orientation with an emphasis on culture and interpersonal relationships. In the 1940s, she developed her mature theory in which individuals cope with the anxiety produced by feeling unsafe, unloved, and unvalued by disowning their spontaneous feelings and developing elaborate strategies of defense.

Disagreeing with Freud about penis envy, female masochism, and feminine development, Horney's early essays were largely ignored until they were published in *Feminine Psychology* in 1967. Since then, there has been a growing recognition that Karen Horney was the first great psychoanalytic feminist.

As the author of *The Neurotic Personality of Our Time* (1937) and *New Ways in Psychoanalysis* (1939), Horney is often thought of as a neo-Freudian member of "the cultural school," a group that also included Erich Fromm, Harry Stack Sullivan, Clara Thompson, and Abram Kardiner. These two books proposed a model for the structure of neurosis in which adverse conditions in the environment as a whole, and especially in the family, create a "basic anxiety" against which the child defends itself by developing strategies of defense that are self-alienating, self-defeating, and in conflict with each other. In a striking departure from Freud, Horney advocated focusing on the current constellation of defenses and inner conflicts rather than with infantile origins.

In her next book, *Self-Analysis* (1942), Horney presented her fullest account of how the psychoanalytic process works in terms of her structural paradigm. The object of therapy for Horney is to help people relinquish their defenses, which alienate them from their real selves, so that they can get in touch with their true likes and dislikes, hopes, fears, and desires.

In her mature theory, developed in her last two books, Horney argued that people defend themselves against their anxieties by developing both interpersonal and intrapsychic strategies of defense. She described the interpersonal strategies most fully in *Our Inner Conflicts* (1945). They involve moving toward, against, or away from other people and adopting a compliant, aggressive, or detached solution. Since people tend to employ more than one of these strategies, they are beset by inner conflicts. In order to avoid being torn apart or paralyzed, they adopt a strategy consistent with their culture, temperament, and circumstances; but the repressed tendencies persist, generating inconsistencies and rising to the surface if the predominant solution fails.

Karen Horney emphasized intrapsychic strategies in *Neurosis and Human Growth* (1950). To compensate for feelings of weakness, inadequacy, and low self-esteem, people develop an idealized image of themselves that they seek to actualize by embarking on a search for glory. The idealized image generates a pride system, which consists of neurotic pride, neurotic claims, and tyrannical shoulds, all of which intensify the self-hate against which they are intended to be a defense. The idealized image is inwardly divided, since it reflects not only the predominant interpersonal strategy but also the conflict between it and the subordinate tendencies.

Horney's mature theory helped to inspire the interpersonal school of psychoanalysis, provided a model for therapies that focus on the current situation, and influenced some of the descriptions of personality disorders in the DSM-III and -IV. It has made an important contribution to the study of literature, biography, gender, and culture. Because of her emphasis on self-realization as the goal of life and the source of healthy values, Karen Horney was recognized by Abraham Maslow as one of the founders of humanistic psychology. Her theory has most in common, perhaps, with the work of Erich Fromm, Ernest Schachtel, Carl Rogers, and Abraham Maslow. Many of Horney's ideas have made their way, often unacknowledged, into the array of concepts and techniques that are currently employed in clinical practice.

## **HOSPITALISM**

René Spitz introduced the term *hospitalism* in his work defining disorders in infants who were institutionalized for long periods and deprived of substitute maternal care. The notion was later expanded to refer more generally to severe and lasting maternal deprivation.

Linked to Sigmund Freud's concept of maternal care according to, hospitalism refers to the most radical effects of deficiencies in this area. Spitz's defining study of the phenomenon concerned abandoned children who had been separated from their mothers at around three months and had lived for five to six months in a nursery that was said to be beyond reproach in terms of nursing care but that was isolated and devoid of human bonding relations for the babies. The pathology analyzed showed the following: overall developmental deterioration; stagnation in height-weight growth; a shift in development ratios; relational

or affective expression reduced to silence; motor and behavioral deviancies; and increased morbidity/mortality rates. Many of these forms of damage were deemed to be irreversible. Spitz categorized hospitalism as "total affective deficiency" and distinguished it from anaclitic depression, categorized as "partial deficiency," which followed at least six months of satisfactory relations with the mother and which could improve once the child was reunited with the mother.

Spitz described these two pathological forms in a pair of publications (hospitalism in 1945, anaclitic depression in 1946) jointly subtitled "An Inquiry into the Genesis of Psychiatric Conditions in Early Childhood." His work emphasizes the vital importance of object relations and the serious consequences of its failure. Additionally, it underscores the relevance of direct infant observation. The baby in reality and the reconstructed baby, placed in a relation of reciprocal reassessment, make possible a wealth of discoveries that validate the research method promoted by Spitz. His concept thus brings us back to the very origins of infant psychiatry, and the first World Congress on Infant Psychiatry, in 1980, was dedicated to his memory.

As a model of deprivation in institutional settings, hospitalism holds a historical place in the design of children's shelters and child-care facilities. The notion received international exposure through a World Health Organization monograph (No. 2, 1951) entitled "Maternal Care and Mental Health"; it was coordinated by John Bowlby, already an established presence in this field ten years prior to his shift in focus to attachment theory.

Spitz's concept of hospitalism drew a number of critical analyses, some on specific points (the inaccuracy of the term itself, lack of precision in pediatric terms, the omission of frequent repeated separation, failure to consider the father's role, etc.), others more general in their scope. These criticisms resulted in some major reassessments in a new World Health Organization monograph published in 1962, whose principal authors included Serge Lebovici and Mary D. Ainsworth.

Study of the short- and long-term consequences of a young infant being separated from its mother remained one of the foremost focuses of childhood psychiatry (Michel Soulé), constantly revised in the light of new discoveries and approaches: the competencies of

infants, relational pathologies, advances in knowledge about the infant's mental functioning, psychosomatic repercussions as the top-ranking psychopathological expressions of frustration in early infancy (Léon Kreisler). With a few major exceptions, forms of hospitalism at the turn of the millennium are less connected to stays in institutions and more often concern the complexity of social and intrafamilial deprivation that children face in contemporary society.

## HUG-HELLMUTH-HUG VON HUGENSTEIN, HERMINE VON (1871–1924)

The Austrian psychoanalyst Hermine Hug von Hugenstein (usually known as Hermine von Hellmuth) was born in Vienna on August 31, 1871, where she was murdered on September 8 or 9, 1924. She is often regarded as the first child psychoanalyst.

Hug-Hellmuth was the second daughter of Hugo Hug von Hugenstein, who served in the Austrian war

ministry both as a military officer (rising to the rank of lieutenant colonel) and as a civilian. The family was Catholic. After the death of her mother, who had served as her tutor, Hermine entered public school and eventually trained to become a teacher. She taught in public and private schools before entering the University of Vienna in 1897, where she studied the physical sciences. In 1909, she obtained a doctorate in physics.

While a patient of the Viennese analyst Isidor Sadger, Hug-Hellmuth became interested in psychoanalysis. In 1910, she resigned her teaching post and the next year published her first paper on psychoanalysis in the *Zentralblatt für Psychoanalyse*, even before she began to take part in the meetings of the Vienna Psychoanalytical Society. The title of that paper, “The Analysis of a Dream of a 5-Year Old Boy” already indicated her principal interest. In 1913 she published “The Nature of the Child’s Soul (Or Psyche).” The title of that paper subsequently served as the name of a section on child psychoanalysis that she wrote for *Imago*; she also became a regular contributor to the *Internationale Zeitschrift für (ärztliche) Psychoanalyse*. Hug-Hellmuth first participated in meetings of the Vienna Society in 1913, and became a member of the society that fall.

Active and well-known beyond Vienna, Hug-Hellmuth became the first child analyst and contributed to the evolution of child psychoanalysis. At the International Congress in The Hague in 1920, she reported on her early efforts in her paper “On the Technique of the Analysis of Children.” A year later she became director of the Educational Counseling Center associated with the “Ambulatorium” of the Vienna Psychoanalytic Society. Her work, critiqued by both pedagogues and psychologists, was based on observation and analysis of children’s behavior and on the possibility of applying psychoanalytic theory to education and the psychology of children. Her broad application of psychodynamic hypotheses to child behavior contributed to the rejection of psychoanalysis by the field of educational psychology.

Hug-Hellmuth’s *A Young Girl’s Diary* was first published anonymously in 1919 by the Internationaler Psychoanalytischer Verlag, the official psychoanalytic publishing house. The book created a sensation, and was discussed in the daily newspapers as well as in medical and psychological reviews, but its authenticity was questioned. Hug-Hellmuth, who was named as

the book's "editor" in 1922, would not admit to being its real author. In 1927 Freud, who had written an introduction to the book, asked that it be withdrawn from bookstores.

On the night of September 8–9, 1924, shortly after the completion of her book *New Ways to the Understanding of Youth*, Hug-Hellmuth was murdered by her eighteen-year-old nephew, Rolf. The illegitimate child of her half-sister Antoine, he had been raised by Hug-Hellmuth since the death of his mother. According to Rolf, his aunt's writings contained many observations of him and he testified at his trial that she had attempted to psychoanalyze him. After his trial he was sentenced to twelve years in prison. After being released from prison, he attempted to get restitution from the Vienna Psychoanalytic Association, as a victim of psychoanalysis.

## **HUMOR**

*Humor* is the name given to the psychic process that operates in the field of the preconscious, based on the dynamic interrelation between the agencies of the mind, and akin to a defense mechanism, consisting of an unexpected re-evaluation of the demands of reality that reverses their painful emotional tone and thereby offers to the triumphant ego that yield of pleasure

which enables it to demonstrate its invulnerable narcissism.

Freud's first insight into the mechanism of this phenomenon, which was entrenched in the family and community life in which he was deeply involved, came in the last pages of *Jokes and their Relation to the Unconscious* (1905c). It was, in fact, on the death of his father that he started to collect Jewish jokes (*Witze*) and, at the insistence of Wilhelm Fliess, developed a theory to explain them, bringing out how their very condition of possibility lay in the activity of this process within the humorist. Although he pointed out (1908c) the kinship between this process and children's games, he did not elucidate it in metapsychological terms until the brief article of 1927 (1927d).

Unlike comedy and wit, or even irony, all of which aim at the satisfaction of erotic or aggressive drives and necessitate, for this purpose, the effective presence of a real third party, humor involves a strictly intrapsychic process of indirection whose purpose is economic, viz., sparing the subject from the painful feelings (pity, irritation, anger, suffering, disgust, tenderness, horror, etc.) that the situation ought to occasion. The energy of these feelings is thus diverted and transformed into the moderate but triumphant pleasure (so different from the explosion of hilarity) that is expressed in the smile of humor. As a result, the humorist reaffirms his narcissistic invulnerability, assuring himself that nothing traumatic can affect him, and that he can in fact find in such things a yield of pleasure.

This being the case, although humor is an autonomous process, it is encountered most often mixed with other forms of the comic, in which it finds a mode of expression, with which it is often confused, and for which it intervenes as a mechanism that inhibits any emotions that would obstruct its development.

Nonetheless, Freud considers humor as a particularly salubrious activity, making of it the rarest and most elaborate form of defense. Yet its benefits turn out in fact to be costly, necessitating a large outlay, since while this economic process, being neither denial nor repression, leads to a reversal of emotional tone, it does not eliminate the painful representation. Freud explained this as the result of a new topographical arrangement: the humorist takes the psychic emphasis off the ego and displaces it onto his superego: "Look! here is the world, which seems so dangerous! It is

nothing but a game for children—just worth making a jest about!” (1927d, p. 166).

In fact, humor leads to a set of notions whose origin, nature, history, and development thus all need to be re-examined, as they all indubitably hark back to the genesis of the ideal psychic agencies and their function in establishing a humorous attitude towards reality. All of these dimensions, indeed—whether it be the invulnerable narcissistic kernel of which the humorist is a living testimony, the exercise of the reality principle, the experience of pain, the mechanism of illusion, or the alchemy of the emotions that it produces—invite reflection on the precocious relations that were formed between the humorist and his mother who bequeathed to him this precious gift (Donnet, J.-L., 1997; Kameniak, J.-P., 1998). For example, we need to reflect—as did Freud—on the enigma of the “essence of the Super-ego,” a superego that manifests itself in an atypical form of functioning: as a reassuring and consoling agency—even a maternal one—that is barely consistent with the severity usually associated with it, whether in the commands it issues or in its role as representative and guardian of the reality principle.

While humor was initially considered as a variety of the comic genre, in the same way as wit (with which it is often confused), Freud early on endeavored to distinguish it through topographical localization, the kind of gratification it affords, the absence of the need for a third person, and, finally, the specific nature of the process, all of which make it a character disposition or trait rather than a random production. Consequently, over and above the defensive use that has been classically recognized and associated with the process of humor, we might want to ask whether it could have a specific function of working-through, very different from the relaxation which is brought about by the comic effect, thus tempering any excess of emotion; how any real “work of humor” is actually accomplished; and what its nature might be. Whereas, when faced with the hostility of events, the risk of trauma may appear to be significant, humor does allow the subject to maintain the integrity of his psychic functions and their availability while also acknowledging the “disruptive” nature of reality. We can surely envisage the possibility (Bergeret, 1973) that there are hints of a working-through involved in humor, or, at the very least, the establishment of the framework needed for any possible integration of the sufferings inflicted on the subject.

Nevertheless, it cannot escape notice that there has been a general lack of interest and a relative silence on the part of contemporary analysts when it comes to this subject, apparently so frivolous though in fact it raises fundamental questions. Up until now, analytic literature on this theme has scarcely extended beyond a few scattered remarks or occasional articles, and most of them use humor as a generic category succeeding that of “the comic” proposed by Freud. Consequently, they are more likely to discuss the techniques and procedures of the modes of expression to which humor resorts than to examine the process of humor itself.

## **HUNGARIAN SCHOOL**

Fundamentally, the “Hungarian School” denotes a trend of thought developed by psychoanalysts who worked in Budapest between the two world wars. Its representatives worked independently. They shared a theoretical view that did not recognize primary narcissism. From the beginning, they attributed a prominent role to the mother-child relationship. As part of this work, they contributed to the instinct theory (clinging instinct, Imre Hermann) and the role of psychological deficiency (Sándor Ferenczi, Michael Balint).

Commitment to treatment was emphasized, which gave rise to methodological experiments (Ferenczi) and led to two-person psychology (Michael Bálint). They contributed to the development of ethno-psychoanalysis (Geza Róheim) and psychoanalytical psychosomatics (Franz Alexander), and the introduction of psychoanalytical pedagogics (Ferenczi, Imre Hermann, Michael Bálint).

The school was founded by Ferenczi as an analytical circle around him in Budapest. In 1913 the Hungarian Psychoanalytical Society was founded which, together with the Viennese Society, became the most important intellectual center in Europe. The cultural-social atmosphere of the age was, in many respects, favorable for the development of psychoanalysis; reputed writers and also joined the group. Freud supported the idea that psychoanalysis should have several centers. At the end of WWI in 1918, the International Congress was held in Budapest and plans were made to found the first psychoanalytical institution there.

The 1920s were the golden age of the Hungarian School. Ferenczi's theoretical work and methodological experiments mark this period. Several creative analysts among his students acquired worldwide repute (Alexander, Alice Bálint, Melanie Klein, Róheim, René A. Spitz). With regard to training, Ferenczi advocated the introduction of compulsory personal analysis of greater depth than in the case of patients. This gave rise to the development of the Budapest model of supervised analysis (Vilma Kovács).

Ferenczi's death and the political situation in the 1930s, and specifically the persecution of Jews, caused many to emigrate (Sándor Radó, C. Robert Bak, Alice Bálint, Michael Bálint, Róheim), and many of those who remained in Budapest fell victim to fascism during WWII. By the end of the 1930s the Hungarian School as an intellectual community had lost its significance. Many of the emigrant analysts preserved the spirit of the School in their work in their adopted country (the Bálints and E. Gyömrői in England; Alexander, Therése Benedek, Sándor Lóránd, Margaret Mahler, Radó, Danièle Rapaport, Róheim, and Spitz in the U.S.). The small group in Budapest continued their scientific activity.

After 1945, there was a brief period of upswing, but in 1949 the communist government banned the society and psychoanalysis was forced into semi-illegality. Its representatives—led by Imre Hermann—

ensured the survival of psychoanalysis, passing on the spirit and traditions of the Hungarian School. In the 1970s, psychoanalysis was reinstated (1975—study group; 1983—provisional society; 1989—component society).

The Hungarian School may be said to have two distinctive features. One is that its original representatives catalyzed the development of psychoanalytical theory and techniques. They discovered and described a number of phenomena which have continued to constitute the foundation of psychoanalysis. The other is the "Ferenczi phenomenon," according to which only the essential development of psychoanalysis makes the integration of theoretical and methodological work possible.

## HUNGARY

Hungary, a country that was primarily agricultural until the mid-nineteenth century, entered the modern era in 1867 with the creation of the Austro-Hungarian monarchy. At the start of the twentieth century, in Budapest, which had become a center of cultural life, a group of radical intellectuals demanded the democratization of a country that had remained semi-feudal. Unable to compete in the political sphere, they created institutions like the Free School of Social Science,

reviews like *Huszadik Század* (Twentieth Century) and *Nyugat* (Occident), to achieve their goal by means of education. For psychoanalysis the Hungarian intelligentsia was fertile terrain, for it held that the liberation of the individual and the liberation of society went hand in hand.

Psychoanalysis was introduced to Hungary by Sándor Ferenczi, who was its leading exponent. A young neurologist, Ferenczi encountered Freudian theory through Carl Gustav Jung's word association test and through the literature of analysis. After his first visit to Freud in February 1908, he quickly became an integral part of the Vienna group and assumed the responsibility of bringing psychoanalysis to Hungary. His efforts were well received in literary and artistic circles, as shown in the writings of Géza Csáth, Dezső Kosztolányi, Mihály Babits, and Frigyes Karinthy, while most physicians remained reticent.

The Hungarian Psychoanalytic Association was founded by Ferenczi in 1913. In addition to Ferenczi, its members included the psychiatrist István Hollós, the physician Lajos Lévy, the medical student Sándor Radó, and the journalist and writer Hugó Ignó (Hugó Veigelsberg), the editor-in-chief of *Nyugat*.

During World War I, Ferenczi, who had been mobilized, cared for soldiers who had suffered trauma during combat. The psychoanalytic treatment of war neuroses drew the attention of Hungarian officials, with the result that the Fifth Congress of Psychoanalysis, organized in Budapest on September 28 and 29, 1918, was held at the Academy of Sciences in the presence of government representatives. During the congress, Antal (Anton) von Freund, who ran a large beer hall, but also had a PhD in philosophy, a patient and friend of Freud, provided funding for the creation of a psychoanalytic clinic and publishing house. Ferenczi was elected president of the International Psychoanalytic Association, but the political upheavals that shook the country, especially Hungary's independence from Austria, the democratic revolution, the Bolshevik revolution in Budapest in 1919 and its brutal repression, forced him to yield the presidency to the Briton, Ernest Jones.

During the democratic government of Mihály Károlyi, students and progressives demanded that psychoanalysis be officially recognized. Their demand reached the Commune and Ferenczi was appointed professor of psychoanalysis at the university, the first

in the world. When the right-wing government of Miklós Horthy came to power, the position was eliminated and, in 1920, Ferenczi was excluded from the Hungarian medical association.

The 1920s turned out to be a phase of expansion for psychoanalysis in Hungary. At the end of the war, Géza Róheim, Imre Hermann, Zsigmond Pfeifer, and other leading figures joined the Hungarian Psychoanalytic Association. Cut off from playing a role in Hungarian public life, psychoanalysts consulted, taught, and published. Róheim developed the notion of psychoanalytic anthropology, Hermann worked on the psychology of creativity, Pfeifer on children's games. This was also the period of the first wave of emigration. Sándor Radó and Jenő Hárnik moved to Berlin and participated in the creation of the Institute for Psychoanalytic Training. During the twenties, József Eisler, Sándor Feldmann, Erzsébet Révész, Béla Felszeghy, Vilma Kovács, and Alice and Mihály Bálint joined the association.

Efforts were made to organize the teaching of psychoanalysis. Seminars on theory were established in 1919, and in 1925 a training method specific to Hungary was developed by Ferenczi and Vilma Kovács.

In 1925, István Hollós was fired from his position as head physician at the psychiatric hospital of Lipótmező because of his Jewish background. Two years later he published *My Farewell from the Yellow House*, in which he investigated psychosis from a new and innovative point of view.

In 1928, Géza Róheim traveled to central Australia, Normanby Island, and America. During his research, financed by Marie Bonaparte, he combined anthropological research with psychoanalytic theory.

In 1930, a psychoanalytic clinic for children was created under the direction of Margit Dubowitz. That same year Lilian Rotter and Fanny Hann joined the association. In 1931, in spite of several administrative problems, a polyclinic was opened at 12 Mészáros Street, with Ferenczi as director. The building and funding were provided by Vilma Kovács and her family; analysts from the association provided free consultations.

Ferenczi's students prepared *Psychoanalytic Studies* for his sixtieth birthday, but the book wasn't published until after his death in 1933. István Hollós then

became president of the association and Mihály Bálint director of the polyclinic.

In 1935 and 1937 two meetings, known as the Four Nations, were organized by the psychoanalytic associations of Vienna, Prague, Italy, and Hungary, the first in Vienna, the second in Budapest, and devoted to the problems of psychoanalytic training. At the second meeting, Vilma Kovács detailed the characteristics of the Hungarian method and Anna Freud read a paper by Helene Deutsch criticizing the method.

Hungarian analysts also began a program to develop public awareness of psychoanalysis. Kata Lévy organized seminars with teachers, Alice Bálint with mothers, and Mihály Bálint held discussion groups with general practitioners. In 1933, Lilly Hajdu, a psychiatrist, joined the association.

During the late thirties, threatened by the rise of anti-Semitism and fascism, a number of analysts decided to emigrate. Among them were the Bálints, Géza Róheim, Sándor Feldmann, and Edit Gyömrői. The association continued to function under police surveillance and under the direction of its non-Jewish members, Endre Almássy and Tibor Rajka. In 1944, when German troops invaded Hungary and put Hungarian Nazis in power, several analysts, including Zsigmond Pfeifer, Géza Dukes, László Révész, Miklós Gimes, and József Eisler, became victims of persecution. Imre Hermann and István Hollós barely escaped with their lives.

After 1945, psychoanalysts in Hungary resumed their activities. They participated in the creation of a mental health institute and worked in dispensaries. But the Stalinist government, which came to power in 1948, forced the association to dissolve. From then on psychoanalysis survived in a semi-clandestine fashion, primarily through the help of Imre Hermann, who trained the new generation of analysts: György Vikár, Livia Nemes, Agnes Binét, Teréz Virág. The dark years after 1956 were marked by the suicide of Lilly Hajdu, whose husband was murdered by the Nazis and whose son, a friend of Imre Nagy, had been executed along with the prime minister. During the sixties, the Kádár government became more tolerant of psychoanalysis. István Székács, a member of the Hungarian Psychoanalytic Association since 1939, also began to train psychoanalysts, although not initially a member of Hermann's group.

During the seventies, Hungarian analysts still did not have an officially recognized association, but some public manifestations of recognition took place. In 1969, for example, Imre Hermann was decorated on his eightieth birthday and, in 1974, a commemorative celebration was organized for the Ferenczi centenary. In 1987 an international congress of psychoanalysis was held in Budapest.

After democracy was restored in 1989, the Hungarian Psychoanalytic Association was reconstituted and affiliated itself with the International Psychoanalytic Association. A new generation of analysts was able to practice, teach, and publish openly.

The Ferenczi Society, a broad-based group of people interested in psychoanalysis, began to publish the review *Thalassa*. While the first generation of analysts trained by Imre Hermann was affected primarily by his ideas, contemporary psychoanalysts were reevaluating the ideas of Ferenczi, which they were forced to read in foreign editions since his complete works had not yet been published in Hungarian because of a lack of funding. They also served as an inspiration for Otto Kernberg.

Hungarian psychoanalysts of the 1930s developed a number of specific ideas that justify referring to them collectively as the Budapest School. These include the importance of trauma in the etiology of mental pathology, the attention given to object relations, consideration of dyadic relations and regression, and insistence on the importance of experience in therapy. Hungarian training methods differed from other methods in that the candidate's first control analysis was undertaken by his own analyst to further an understanding of the countertransference and better understand his own transference to the analyst.

Ferenczi's students demonstrated considerable creativity. Imre Hermann developed the theory of clinging, Géza Róheim the ontogenetic theory of culture, and Mihály Bálint the theory of primal love (and several others after his emigration). Lilian Rotter developed a body of original work on female sexuality and Alice Bálint on the mother-child relationship. István Hollós and Lilly Hajdu examined psychoses from a psychoanalytic point of view.

## HYPERCATHESIS

Freud employed the term “hypercathesis” to designate an additional charge of instinctual energy cathecting any already cathected psychical element. The word’s primary application was in the description of the economy of consciousness, but it also served in connection with the regulation of the flow of psychical energy and the constitution of the preconscious realm.

The term was first used by Freud in the “Project for a Scientific Psychology” (1950c [1895]), where it referred to a mobile cathexis of the ego specific to consciousness, necessary to the mechanism of attention, and consisting in a supplementary cathexis of neurones already cathected by perception. In Freud’s account consciousness affected indications of quality. It arose from the excitation, during perception, of particular neurones belonging to the system W. Attention first addressed the indications of quality transmitted by these already cathected neurones, and then, via a facilitated pathway, focused on the perceptions themselves, which were thus hypercathected. “By this means [the ego] is led to cathect precisely the right perceptions or their environment” (p. 362). The ego was hence able to distinguish cathexes of real perceptions from cathexes of wishes, and the reality principle could be established.

According to Freud, the regulation of cathexes within the psychical apparatus remained unconscious,

and was effected automatically in accordance with the pleasure/unpleasure principle. In *The Interpretation of Dreams* (1900a), he pointed out that this initial mechanism was fine-tuned by virtue of a cathexis of attention, described as a “hypercathesis set up . . . by the regulating influence of the sense organ of the Cs.” (p. 617), which at times could even work counter to the primary mechanism by cathecting elements that were a source of unpleasure and that would otherwise succumb to repression.

In “The Unconscious” (1915e), Freud attributed the emergence of the preconscious to a hypercathesis of word-presentations by thing-presentations: “It is these hypercathexes, we may suppose, that bring about a higher psychical organization and make it possible for the primary process to be succeeded by the secondary process which is dominant in the Pcs. . . . A presentation which is not put into words, or a psychical act which is not hypercathected, remains thereafter in the Ucs. in a state of repression” (p. 202).

In considering the question of traumas, in *Beyond the Pleasure Principle* (1920g), Freud described the anti-traumatic regulatory function of hypercathectic energy, in the operation of the protective shield against stimuli, as the last line of defense in the attempt to bind the sum of excitation: “In the case of quite a number of traumas, the difference between systems that are unprepared and systems that are well prepared through being hypercathected may be a decisive factor in determining the outcome” (pp. 31–32).

## HYPNOID STATES

The notion of hypnoid states appeared in section 3 of “On the Psychical Mechanism of Hysterical Phenomena: Preliminary Communication,” published in January 1893 under the joint authorship of Sigmund Freud and Josef Breuer in preparation for their *Studies on Hysteria* of 1895. Hypnoid states involve a “splitting of consciousness” or “double conscience” (1893a, p. 12), in which ideas and affects are fragmented and then cut off from normal waking consciousness, but which, owing to what Freud a short time later called “false connections” (1895d, p. 302), can give way to new, pathogenic associations that engender hysterical symptoms.

The notion of hypnoid states originated from Freud and Breuer’s interest in hypnosis. Freud and Breuer wrote that they wanted to replace “the familiar thesis that hypnosis is an artificial hysteria by another—the basis and sine qua non of hysteria is the existence of hypnoid states” (1893a, p. 12). In themselves, such hypnoid states are not abnormal (as witness the daydreams “to which needlework and similar occupations render women especially prone” [p. 13]), but the hysteric is especially predisposed to them.

In fact, the notion of hypnoid states came from Breuer, who used it in a major explanatory principle in his account of the case of Anna O. and developed it in the fourth paragraph of the chapter on “theoretical considerations” that he wrote for *Studies on Hysteria*. By the time of that work, it is clear that Freud was only paying lip service to this idea as a concession to Breuer to obtain joint publication of their work. To be sure, Freud agreed that hysterical phenomena should be explained in terms of “dissociation” and a faulty recomposition, but unlike Breuer (who in this regard held views similar to those of Pierre Janet), he did not see in these phenomena a weakening of psychic functioning. On the contrary, he saw them as the mark of the active work of the defenses, above all repression. Freud later explained his stance on these issues, notably in “On the History of the Psycho-Analytic Movement” (1914d) and in “An Autobiographical Study” (1925d [1924]). Indeed, the notion of hypnoid states seems so contrary to metapsychology as a whole that it cannot be accepted as being a part of psychoanalysis.

## HYPNOSIS

Hypnosis is the altered state of consciousness brought on by a hypnotist using various techniques (staring at an object, verbal commands, etc.). The English physician James Braid, in his *Neurhypnology* (1843), popularized, or may even have coined, the word “hypnotism.” “Hypnosis” appears to have come into use later.

Braid sought to replace unscientific ideas and practices with a scientific conception of a “peculiar state of the nervous system induced by a fixed and abstracted attention of the mental and visual eye.” He also hoped to do away with what magnetizers called “rapport.” In the mid-nineteenth century, the English physiologist William Carpenter provided scientific support for “Braidism” by making hypnosis the paradigm of the reflexive and automatic activity that he called “unconscious cerebration.” Introduced to the topic by the young physiologist Charles Richet, Jean Martin Charcot experimented with hypnosis on hysterical patients in his clinic starting in 1878, basing himself on Braid’s and especially Carpenter’s neurological approach. In 1882, in an article that was noted by the Académie des Sciences, he identified a pathology unique to hysterics, the “grand hypnotism” characterized by three specific nervous states (catalepsy, lethargy, and somnambulism).

Starting in 1860 in Nancy, where he had set up a “clinic,” Ambroise Liebeault also made use of hypnosis, employing methods established by J.-P. Durand de Gros, one of the proponents of Braidism in France. He paid special attention to Braid’s experiments with suggestion, using hypnotic suggestion for therapeutic purposes, unlike Charcot, whose practice was almost

purely experimental. Hippolyte Bernheim went even further and treated hypnosis as a particular type of suggestion. He also popularized the term “psychotherapy,” which he borrowed from the Briton Hack Tuke, and practiced psychotherapy by means of suggestion with and without hypnotism. After 1884 two opposing schools of hypnosis developed around Charcot and Bernheim. In Paris, the emphasis was on the idea of a pathological nervous state; in Nancy, on that of a link or psychological influence that was not necessarily pathological.

Nonetheless, although they often took their cue from a particular school, some practitioners and researchers tried to look beyond prevailing theoretical and therapeutic dogmas. The psychotherapist could thus refuse merely to issue commands, and attempt through hypnosis, to discover memories forgotten during waking life that could be at the root of neurotic symptoms (see the case of Pierre Marie in *L'Automatisme psychologique* by Pierre Janet, 1889). Several stories of cures associated with the return of forgotten memories were published at the end of the nineteenth century.

In discussions of hypnotic suggestion the question of “rapport” was again raised. Joseph Delboeuf introduced the idea of reciprocal suggestion. Pierre Janet and Alfred Binet spoke of “electivity,” of “somnia-lant passion” and “experimental love.” Additionally, there was interest in the psychology of hypnotic states of consciousness. These were described in terms of dissociation (Janet) or hypnoid states (Sigmund Freud and Josef Breuer). Finally, contrary to the dominant medical view at the time, the idea arose that the unconscious was not only reflexological but psychological. Experiments with post-hypnotic suggestion, in which a subject, while awake, obeys an order given during a hypnosis that he has apparently forgotten, seemed to the philosopher Henri Bergson to prove the existence of unconscious ideas and a psychological unconscious. Freud the psychoanalyst undoubtedly emerged from this plethora of research and debate: 1885–1886 (Paris), 1889 (Nancy), and 1895 (publication of the *Studies on Hysteria*).

Hypnosis refers both to a state of consciousness (or unconsciousness) and to a relationship. True to the legacy of Charcot and Bernheim, present-day proponents of hypnology are still divided into “statists” and “relationists.” Some points of view, especially within the relationist school, draw on psychoanalysis, while

others seek to reinstate hypnotism as part of an anti-psychoanalytic tendency. For hypnosis, like animal magnetism before it, does not refer only to a state or to a relationship. Since the nineteenth century it has become a magical word with strong negative or positive connotations and as many staunch advocates as militant opponents—a tireless vector of fascination and stigma.

The practice, phenomenology, and theory of hypnosis have evolved, of course, since the time of James Braid, and hypnosis can now be seen as a largely cultural phenomenon. All the same, some questions, contradictory and probably unanswerable, seem to remain after more than a century. Is the hypnotic state akin to sleep and dreaming, or to wakefulness and lucidity? Does it imply an unconscious dispossession, or is it a form of playacting? And is “hypnosis” a functional concept that can explain certain phenomenon, or a word that precipitates the very state it is supposed to account for?

## HYPOCHONDRIA

Hypochondria is a psychopathological formation whose locus of suffering, anxiety, or even (fantasized) erasure is the body or one of its parts or functions, even though the symptoms in most cases appear to have no material cause. Symptoms can range from minor, transient forms to massive, debilitating forms. Despite some strong lines of evidence pointing toward a link with various specific structural organizations of the psyche, hypochondria is currently seen as transnosographic, as present as an element in a neuropsychosis or preceding certain psychoses.

For centuries, hypochondria has challenged medicine, philosophy, and even religion. Some ancient lines of inquiry are echoed by modern investigations, notably on the enigmatic link between psyche and soma and on similarities between hypochondria and melancholia. The absence of any material organic cause has elicited a variety of hypotheses from psychoanalysts, including accounts of pathogenicity that extend to delusions in the subject.

Has the enigma of hypochondria been fully deciphered by contemporary psychoanalysis? Freud acknowledged this poorly understood disorder as an awkward gap in his theories. Later it was deemed surprising that hypochondriacs had been the object of so little psychoanalytic research, but in the 1990s there were a number of studies on the topic. One reason that psychoanalysis has paid little attention to hypochondria is that the autocratic attitude of hypochondriacs has made analysts unreceptive to types of transference uncondusive to analytic listening. However, a broadening of treatment indications seems to have made psychoanalysis more receptive to hypochondriacs, and this has allowed psychoanalysis to draw conclusions from them that go beyond Freud's hypotheses. It is also true that hypochondriacal behavior can emerge in the course of any treatment, as a displacement or means of discharge when the patient's psyche is placed under stress.

Freud encountered hypochondria early on in his work. On the basis of the semantics and nosology of his era as well as his own theories, he placed hypochondria among the pure forms of "actual neurosis," alongside neurasthenia and anxiety neurosis, and thus outside of the realm of the defensive neuropsychoses. His description of the actual neuroses contains the same elements as hypochondria: the patient's representational contents have a basis in current reality and not in what has been repressed into the unconscious; the patient's meaningful contents or unconscious overdeterminations capable of being symbolized do not indicate an internal conflict with current reality.

In "On Narcissism: An Introduction" (1914c), Freud revised his account of hypochondria in light of his theory that the libido is divided into the object-libido and the (narcissistic) ego-libido. He placed (bodily) ego-libido, the realm of hypochondriacal anxiety, in opposition to object libido, the realm of neurotic anxiety. As a function of this opposition, the more one realm absorbs, the more the other is impoverished. Therefore, the idea of excessive, dammed-up narcissistic libido is essential to understanding hypochondria. The chosen organ of hypochondria, which has strong erotogenic potential, is nevertheless a source of unpleasure, suffering, and anxiety owing to this increase in tension, this damming up of libido. Many authors have viewed this account, a schematic model of dynamic energies, as problematic and fraught with questions.

During the same period, Freud tried to understand the possible relationship between hypochondria and paraphrenia. In "On Narcissism: An Introduction" (1914c) he wrote, "We may suspect that the relation of hypochondria to paraphrenia is similar to that of the other 'actual' neuroses to hysteria and obsessional neurosis: we may suspect, that is, that it is dependent on ego-libido just as the others are on object-libido, and that hypochondriacal anxiety is the counterpart, as coming from ego-libido, to neurotic anxiety" (p. 84). In this perspective he viewed hypochondria as the first stage in delusion and linked it to narcissistic pathologies affecting the body. Three years earlier he wondered about the connections between hypochondria and paranoia. For example, in "Psycho-Analytic Notes on an Autobiographical Account of a Case of Paranoia (*Dementia Paranoides*)" (1911c [1910]), his text on Daniel Paul Schreber, he wrote, "I shall not consider any theory of paranoia trustworthy unless it

also covers the *hypochondriacal* symptoms by which that disorder is almost invariably accompanied” (pp. 56–57, n. 3). Freud thus viewed hypochondria as a precursor to psychosis and sometimes as an independent condition.

Some authors have interpreted hypochondria in terms of true projections that are no longer directed outward but instead are directed at the body, like an internal paranoia. In his subsequent writings Freud did not return to the comparison with melancholia, nor did he reexamine his hypotheses in light of his second theory of the instincts or in terms of the concept of primary masochism, as later authors did, thereby somewhat undermining Freud’s classification of hypochondria as an actual neurosis.

Many others, notably followers of Melanie Klein, have emphasized the close relationship between hypochondria and melancholic depression. Others have inferred a masochistic dimension or a “locked-up” autoerotism. In the view of still others, the “hypochondriacal solution,” despite its fragile and largely unstructured nature and despite being pregnant with the death instinct, is the subject’s last bastion against madness.

## HYPOCRITICAL DREAM

A hypocritical dream is one that in which the dream’s wish is distorted (most often by the reversal of affect) such that it cannot be discerned in the manifest dream thoughts. Thus the wish is expressed “hypocritically,” in disguise.

Freud referred to hypocritical dreams in several passages of *The Interpretation of Dreams* (1900a). He first used the term in connection with a dream in which he felt a great affection towards his friend R. But the analysis of the dream showed that in fact the latent wish was to portray R. as a simpleton (1900a, pp. 137 ff.). Freud also referred to a dream about a reconciliation with a friend in which the latent wish was to free himself from this friend completely (p. 145n.). He returned to the topic later in the book, writing that “There is one class of dreams which have a particular claim to be described as ‘hypocritical’ and which offer a hard test to the theory of wish-fulfillment” (p. 473). Witness the repetitive dream of the poet Rosegger in which he found himself each night back in the unfortunate situation of a apprentice tailor ill-suited for his craft (pp. 473–75).

Freud referred to a similar dream of his own in which he found himself back in a laboratory where he had once worked in his younger days, ill-suited to the chemical analyses he was required to perform. This was, Freud says, a “punishment dream” (p. 476) that followed upon his daytime thoughts of being too proud of the success of his psychoanalyses. Such a punishment dream, he goes on, is nothing but the inverted expression of a wish. He modified this theory considerably in his theoretical revisions of the twenties (1920g, 1923b, 1924c). And the question of hypocriti-

cal dreams was, for Freud, closely linked to that of repetitive dreams.

The term “hypocritical dream” is not frequently used in present-day psychoanalysis. However, the question that Freud posed under this rubric remains essential: Is every dream the realization of a wish?

## **HYSTERIA**

*Hysteria* refers both to a personality type and to a cluster of psychoneurotic symptom formations. Its manifestations—dramatic, physical, and affective—may be viewed as an attempt to express and symbolize a psychosexual conflict and, at the same time, to defend against acknowledging that conflict. Symptoms range from mental anxiety and phobia to the physical signs of conversion disorder.

The term derives from *hysteria*, the Greek word for uterus, and was historically considered a female disorder. Writings on hysteria date to ancient Egypt and the Kahun papyrus (ca.1900 BCE), which described the disturbances caused by the “wandering uterus” that manifested as symptoms in various parts of the body. Greco-Roman doctors continued to associate hysteria with the uterus and to treat it as a female complaint. From the end of antiquity through the Middle Ages and the Inquisition, recourse to supernatural explanations made it possible to consider hysteria a form of demoniacal possession or witchcraft. The theatrical and contagious nature of hysterical symptoms may have been at the root of phenomena such as the “possessed” nuns of Loudun, the convulsionaries of Saint-Médard, and the Salem witches. Hysterics and their putative victims were often burned at the stake.

Identification of hysteria as a distinct entity dates to 1870, when Jean Martin Charcot, a doctor at the largest hospice in France, the La Salpêtrière, segregated hysterics from other mental patients for purposes of research and investigation.

As a concept hysteria acquired several meanings:

1. Conversion hysteria was a convulsive attack characterized by paralysis, muscular contractions and bodily contortions, visual disturbances, including hallucination, pain and anesthesia, and so on.
2. As a psychoneurosis, studied by psychoanalysis, it was manifested by various symptoms and inversion of affect. Thus, Sigmund Freud's patient Dora experienced sexual excitation not as desire but as disgust, a hysterical displacement of a genital sexual conflict (1905e).
3. The term “hysteric” also qualifies, pejoratively, a certain type of distaff personality in which prominent use is made of dramatization, emotional exuberance, colorful and exaggerated language, continuous erotization, and seductiveness.
4. Finally, in everyday language, hysteria is the stuff of “emotional outburst” and “making a scene.”

Broadly speaking, conversion hysteria led to the discovery of psychoanalysis as a method of understanding and treating psychopathological symptoms. Freud, who famously attended clinical demonstrations by Charcot, was struck by the indifference that hysterical patients displayed toward their suffering. Although for a time he suspected traumatic childhood seduction to be at the root of hysteria, he came to view such patients suffering “mainly from reminiscences” (1895d, p. 7)—that is, from a repressed traumatic event that remained mnemonically unintegrated, and could therefore only be expressed by conversion—through a corporeal memory, so to speak.

The death of his father in 1897 and subsequent self-analysis with Wilhelm Fliess led Freud to the discovery of his childhood passion for his mother and of his hostile feelings toward his father. Although the Oedipus complex did not appear as part of Freudian theory until later, he abandoned the theory of traumatic seduction; his key discovery was the notion of infantile sexuality, together with the importance of fantasy as a force that was both creative and disorganizing. At the same time he developed the concept of psychic defense

and discovered in dreams and dream-work a link with hysteria.

In psychoanalytic theory, a hysterical crisis might be thought of as the embodiment of a dream. Its symptoms included the same mechanisms of condensation, displacement, symbolization, and disguise through censorship. Hysteria expressed a conflict that, incapable of being elaborated mentally, is translated in altogether enigmatic fashion into physical symptoms. The associative method of psychoanalysis could be used to identify the fantasies and symbolic pathways within it. Thus Freud described a hysterical woman who, with one hand, tore off her clothes, and with the other, held them against her body, simultaneously expressing the struggle between impulse and defense, enacting in effect a sexual scene in which she represented partners of both sexes (1908a). Hysterical neurosis and hysterical relationships involve identification, constant repression, and counter-cathexis that uses the Other as the theater of conflict.

Due to the absence of an organic lesion and the tendency for symptoms to disappear without a trace, as mysteriously as they came, hysterical conversion represented a provocative challenge to medicine. In general, hysterics have historically triggered irritation, accusations of lying and malingering, and rejection.

Hysteria has always defied medicine and the social order because sexuality is mixed up in it—in particular, female sexuality and the associated desire for sexual pleasure. Freud, in 1937, referred to the “repudiation of femininity” (p. 252) in both sexes as “bedrock,” a stumbling block because of the mental association of the female with castration. Symptomatically, hysteria is an illness of repudiated femininity. More specifically, the anxiety that leads to this repudiation reflects the considerable libidinal energy required by the constant pressure of libido, a pressure that may be destructive of the ego.

## HYSTERICAL PARALYSIS

*Hysterical paralysis* designates various forms of loss of mobility of the upper or lower limbs that are present in certain patients without any indication of a direct neurological cause.

Even before the *Studies on Hysteria* (1895d), the problems that hysterical paralysis posed for the medical diagnostic model led Freud to introduce the first elements of psychoanalysis in a work called, “Some Points for a Comparative Study of Organic and Hysterical Motor Paralysis” (1893c).

To Freud, hysterical paralysis seemed too precisely delimited in relation to their “excessive intensity”

(1893c, p. 164), and they appeared to be related more to the way patients imagined their bodies than to any distribution of lesions in real anatomy. Based as it was on the fact that peripheral points on the body are grouped at the level of the nerves that represent the medullary centers of the cortex, Freud's neurological conception of "representation paralysis" went far beyond what Charcot himself (1880–1893) called a "disease of representation." Freud was in effect seeking "permission to move on to psychological ground" (1893c, p. 170), and he crossed that border on the basis of the difference between organ and function.

This amounted also to placing paralysis on the level representing both fantasy and action. By defining the hysterical paralysis of the arm as "the abolition of the associative accessibility of the conception of the arm" (1893c, p. 170), he raised both the question of trauma and that of the affective value of a function, so anticipating what would later be known as associative links and breaks, isolation and repression.

We see here too that what would later become the "innervation" of the repressed idea—"psychical excitation that takes a wrong path," as Freud wrote in 1894 (1950a, p. 195)—did not restrict the notion of conversion to a single idea of discharge, but installed it within conflictual ambivalence, and this whether it was muscular contraction, paralysis, or anesthesia that was at issue. Thus the symptom achieves the repression of the representation and the return of the related affect to its original innocent status as action. This disconnection between affect and symptom is what Charcot referred to as the "*belle indifférence*" of hysterics (cf. Freud, 1915d, pp. 155–56).

Thus conversion holds a precise position between hypochondria, which seeks to mentalize the unrepresentable depths of the body's interior, and, at the other extreme, psychosomatic disturbances where improvement or somatic recovery dispense with the symbolic level entirely. Between the two, conversion involves the striated musculature in order to play out a drama at the level closest to the body. The involvement of the vegetative level is not excluded here, so long as it is introduced into a fantasy, the desire of which was expressed in its negative form as a paralysis (Jeanneau, 1985).

The concept of the “I” appears in Jacques Lacan’s work as a function that derives from the mirror stage. Piera Aulagnier later develops this term in a different way and defines it as nothing other than a knowledge of itself: “the I is nothing more than the I’s knowledge of the I” (1975/2001, p.114).

Despite their semantic proximity, the I, for both Lacan and Aulagnier, is something clearly distinct from the Freudian ego; the latter is an agency, even if it claims to represent the totality of the person, and it has to be understood in relation to the other agencies (id, superego) and to the demands of reality and the object, which it can also oppose by occupying its position and turning, narcissistically, to the love of the id.

Towards the end of his work (1923b), Freud ascribes a different origin to the ego, no longer considering it as a psychic agency or no longer defining its “character” only as a product of identifications but regarding it as “the mental projection of the surface of the body” and thus primarily as a “bodily ego” that is derived from sensations.

Jacques Lacan introduced the concept of “I” with the mirror stage (1936, then 1949), in opposition not to the Freudian ego but to the philosophy derived from the Cartesian *cogito*. The mirror stage constitutes an identification; namely, the transformation that occurs in a subject when he assumes an image as his own. This stage constitutes a fundamental identification that precedes the moment when the subject identifies with others through the mediation of language. It comprises several phases: in the first, the child reacts

joyfully to the image but identifies it as belonging to an other; in the second, he perceives its imaginary nature and seeks the other behind the mirror; in the third, the child recognizes the image as his own. For Lacan, this entails the progressive and structuring conquest of the I through the intermediary of the subject’s own body. “This *Gestalt*... symbolizes the mental permanence of the *I* at the same time as it prefigures its alienating destination; it is still pregnant with the correspondences that unite the *I* with the statue in which man projects himself, with the phantoms that dominate him, or with the automaton in which, in an ambiguous relation, the world of his own making tends to find completion” (1949/2002, p. 3]). Therefore the *I* simultaneously is alienated in this image, because it is always external to it, and finds a stability, if not a permanence, there. Here Lacan adduces the concept of alienation: “[the subject] identifies his sense of self with the image of the other and the image of the other then captivates this sense in him” (1946–50). In a second temporal phase, the subject is mediated by language, thereby returning to the unconscious everything that does not pass into discourse.

Piera Aulagnier fundamentally modifies the Lacanian concept of I by historicizing it, that is, by defining it in terms of the dual processes of “self-historicization” and the “identificatory project.” However, it is principally in the mother-child relationship, well before the mirror stage, that she locates the primary identification from which the I will subsequently emerge. For the child, this identification develops from the first experience of pleasure, and it is the mother who identifies the child as the seeker of what she is offering, which thus makes him dependent on her own imagination. Similarly, in the mirror stage,

Aulagnier emphasizes that the child, having recognized the specular image as his own, turns to his mother to seek approbation in her gaze and thus to find the “junction between the image and the legend” (1975/2001, p. 124). “She alone will be able to complete the narcissistic image, to add that ‘something more’ that is indispensable to its sheen and without which it would cease to be anything more than it is in the real: an effect of the laws of optics” (1975).

For Aulagnier, however, the I is not to be confused with the precursor of the I that is constituted by the subject’s representational activity in these early stages. The I is first of all anticipated by the mother (as “word-bearer”) and as this still-idealized I that is formed during the “representative” stage, that is to say the child’s psyche that represents itself as possessing an absolute and immediate power over reality.

How does the I come into being? It is through the act of enunciation, but rather than just any act, it is that which names the affect: “*the act of uttering a feeling is therefore at the same time the utterance of a self-naming by the I*” (p. 97). To name the other with the term of beloved, for example, is to designate the subject who is naming as that of the lover. Hence the author’s formulation: “It is therefore in and by the deferred action of naming the cathected object [affect and kinship system] that the I comes about . . . the I is nothing more than the knowledge that the I may have of the I” (p. 98).

This knowledge has a sole purpose: to guarantee to the I a knowledge of its past and its future, the former being the precondition for the representability of the latter. The I will be characterized by its work, which differs from the enacting fantasy because it entails a work of making-sense based on “ideational representations.” Despite being anticipated by the mother at a primitive stage, the I can subsequently occur only by itself. The Other, the mother, no longer has the power to respond to questions such as “who am I?” or “what am I to become?”: “To these two questions, which must necessarily find an answer, the I will respond on its own behalf by the continuous self-construction of an ideal image that it claims as its inalienable right and which assures it that the future will prove to be neither the result of pure chance, nor forged by the exclusive desire of another I” (p. 116).

What is possessed in this case is nothing but an outline, but what is cathected is the ideal image, as well as

the ability to construct it and to recognize oneself through this process of construction. No philosophical observation about freedom can be dissociated from this definition of the I, as the author establishes it on the basis of the preconditions for the emergence of the I, and the way in which these preconditions can be lacking in the case of psychosis.

## ID

Linked with the ego and the superego, the id (*das Es*) is the mental agency, in Freud’s “second topography” of 1923, that answers to the instincts and to the greater part of the unconscious processes. In German, *es* is the neuter personal pronoun. Its use as a noun, with an initial capital—*das Es*—is perfectly regular. From the standpoint of linguistics, *es* presents problems at the border between semantics and the syntax of anaphora: in order to understand what it signifies one must refer to another part of the discourse that interprets it. Thus *es* may be interpreted as any neuter noun in German and is also used, like the English “it,” in many

impersonal constructions. Syntactically, *es* may be the subject or object of transitive verbs. Consequently, an idea designated “*das Es*” is liable to be indefinite and impersonal, universal, diverse, ambiguous and equivocal, even contradictory.

Georg Groddeck used this term to refer to the universal unconscious agency—as force and as substance—that he considered to be his interlocutor and object of study when he treated patients suffering from somatic illnesses: “There is something common to the body and the soul; there is an Id in them, a force by which we are lived, even as we believe we are living ourselves” (Groddeck to Freud, May 27, 1917). Groddeck borrowed the term from the Berlin physician Ernst Schwenger, who had written, “The id cures.” The idea of an energetic monism was in any case a commonplace of the German culture of the time. And of course Groddeck had been reading Freud in the 1913–1917 period.

Freud first encountered the notion of the id in Groddeck’s letter. His response in a letter of June 5, 1917, was critical: “The notion of the *Ucs* requires *no extension*.” The *Ucs* (unconscious) system was adequate for dealing with organic illnesses, for it influenced somatic processes. And why “cancel the difference between psychological and physical phenomena”? “I am afraid,” Freud concluded, “that you are a philosopher as well and have the monistic tendency to disparage all the beautiful differences in nature in favor of a tempting unity” (1960a, pp. 317–318). But in the same letter Freud had dubbed Groddeck “an analyst of the first order,” and subsequently he supported him, having his *Book of the It* published by the International Psychoanalytischer Verlag just before his own *The Ego and the Id*. Apropos of *The Book of the It*, he wrote to Groddeck on March 25, 1923 that “The work . . . expounds the theoretically important point of view which I have covered in my forthcoming *The Ego and the Id*” (1960a, p. 342).

The Freudian conception of the id, which he worked out in the summer of 1922, was presented in *The Ego and the Id*. That work, along with *Beyond the Pleasure Principle* and *Group Psychology and the Analysis of the Ego*, constituted what Freud called “the third step in the theory of the instincts” (1920g, p. 59). The life and death instincts (*Pleasure Principle*) opened up a dynamic space for the accommodation and study, in *Group Psychology*, of the large-scale mental formations of the “second step”: ego, ego ideal, identifications. In

*The Ego and the Id*, moving “closer to psycho-analysis” (1923b, p. 12), Freud confronted the ego and its unconscious resistance on the one hand and the unconscious/preconscious-conscious (*Ucs./Pcs.-Cs.*) distinction on the other. As a result, this last system was now seen as local, confined to the superficial layers of the mental apparatus where the *Ucs.* was synonymous with the repressed; it was unable to explain the resistance of the ego and inadequate as far as practice was concerned. In order to take the ego into account it was now necessary to move from the “local” examination of the symptoms and their treatment to a global view of the mental personality and of psychoanalytical treatment. This shift of level implied different dynamics and forms, although it did not necessarily mean that local forms and dynamics were surpassed or modified.

Freud introduced the id as alien to the ego, as “the other part of the mind,” global and unconscious, incorporating the repressed and the forces by which (in Groddeck’s terms) we “are lived”: a realm large enough to be that which the ego resists (1923b, p. 23). “We shall now look upon an individual as a psychical id, unknown and unconscious, upon whose surface rests the ego, developed from its nucleus the *Pcpt.* [perceptual] system.” (p. 24). The resistance of the ego was not identical to the familiar local resistances, for it had a global aspect that it manifested in the treatment (often after the local symptomatic features had been worked on) precisely at the point where it was confronted by something alien to it. The inadequacy of the *Ucs./Pcs.-Cs.* opposition was thus bound up with the countertransference and with the orientation of the treatment, issues that could not be addressed solely in terms of the first topographical theory.

The introduction of the notion of the id bespoke a fresh overall approach on Freud’s part to treatment and the mental personality. Because of the life and death instincts, it was possible to claim a place for this new point of view “in the structure of science” (1923b, p. 23) without falling into monism. The attribution of the id’s paternity to Nietzsche, inaccurate on its face, perhaps may be taken as a semantic reference to the philosopher who, in criticizing philosophies of consciousness and of the subject, did the most to thematize the dynamics of the psyche.

The division of the mental personality into three provinces, id, ego, and superego, would not have been relevant had each of the three agencies not been

characterized by Freud, beginning in *The Ego and the Id*, by sufficient ambiguity, diversity, and even contradiction. Since he did, the concept of the id would remain stable until the end of his work. A main interpretant of the id is instinctual life. “We approach the id with analogies: we call it a chaos, a cauldron full of seething excitations. We picture it as being open at its end to somatic influences, and as there taking up into itself instinctual needs which find their psychical expression in it, but we cannot say in what substratum.” (1933a [1932], p. 73). Since psychoanalysis is a dynamic theory of the psyche, the “whole person” is an interpretant of the id (p. 105), and psychoanalysis is “a psychology of the id (and of its effects on the ego)” (1924f, p. 209). The prevalence of the dynamic aspect means that the ego and the superego emerge from the id as “superficial strata” differentiated during ontogenesis; “id and ego are originally one” (1937c, p. 240); the superego “is in fact a precipitate of the first object-cathexes of the id” (1926e, p. 223). So the ego and the superego are interpretants of the id. (In *The Ego and the Id*, “es” is related to ego and superego in an ambiguous manner.)

External reality is not an interpretant of the id (since we are not dealing here with the instinctual point of view), but it does illuminate the dominance of the pleasure principle in the id. The id knows nothing of logic, nothing of negation; contrary instinctual impulses coexist within it; the mechanisms of displacement and condensation are normal; dispersal and disorganization reign. And if, “in its blind efforts for the satisfaction of its instincts, it disregarded that supreme external power,” the outside world, if it did not have the ego as its protective shield and guide vis-à-vis reality, then the id, motor of the psyche, “could not escape destruction” (1933a [1932], p. 75).

The id is not only a motor—it is also the locus of the motor; and in this respect, passive—it is a reservoir, or a storehouse (in which case reality is indeed an interpretant of the id). The id is the original reservoir of libido and of the destructive instincts that cathect and nourish the ego and the superego and their cathexes; it is also a storehouse for active memory-traces and, in this capacity, indifferent to time: “Wishful impulses which have never passed beyond the id, but impressions, too, which have been sunk into the id by repression, are virtually immortal.” (1933a [1932], p. 74). The id embraces the repressed, and by extension the unconscious: “The impressions of early traumas

... are either not translated into the preconscious or are quickly put back by repression into the id-condition. Their mnemonic residues are in that case unconscious and operate from the id” (1939a, pp. 97–98). The id also stores up human history: “The experiences of the ego seem at first to be lost for inheritance; but, when they have been repeated often enough and with sufficient strength in many individuals in successive generations, they transform themselves, so to say, into experiences of the id, the impressions of which are preserved by heredity. Thus in the id, which is capable of being inherited, are harboured residues of the existences of countless egos; and, when the ego forms its super-ego out of the id, it may perhaps only be reviving shapes of former egos and be bringing them to resurrection” (1923b, p. 38). Such an archaic inheritance may include symbolism, the schemata of primal fantasies, or memory-traces of the killing of the primal father by the primal horde (1939a, pp. 98–101).

Although the id-ego-superego system entails not only conflicts between these agencies but also intra-agency conflict, there is no conflict within the id. Clinical experience allows for part of the id’s operations to be inferred. The repressed is transformed there; the id can destroy a repressed impulse, the libido of which is diverted into other channels. The liquidation of the Oedipus complex, which is not repression but rather destruction in the id, is an example. A regression of the libidinal organization can be brought about by the id, as for example in compulsive neurosis.

Since psychoanalysis is an interpretant of the id, any notion may be related to it. Furthermore, the id is neither separated nor separable from the areas onto which it opens: the somatic realm, the ego and superego, even external reality; from its dynamic dimension, where the life and death instincts are to be found; from its constituent elements: instinctual life, libido, hate, repressed material, memory-traces, the unconscious; or from the pleasure principle.

The articulation of the mental personality in accordance with the ego-superego-id scheme revived discussion on the following issues: the distinction between neurosis and psychosis; the classification of individuals into “libidinal types” defined by the particular conflicts that predominate in each case between id, ego, superego, and reality; and the forms of resistance and the dynamics of working-through: Freud describes as “arising from the id” the form of resis-

tance that, even after ego-resistances have been relaxed, demands a “period of strenuous effort” in order to undo repressions (1926d, pp. 160, 159).

The conduct and aims of analysis were described by Freud as follows: “During the treatment our therapeutic work is constantly swinging backwards and forwards like a pendulum between a piece of id-analysis and a piece of ego-analysis. In the one case we want to make something from the id conscious, in the other we want to correct something in the ego. . . . The therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id.” (1937c, p. 238). “Its intention is, indeed, to strengthen the ego, to make it more independent of the superego, to widen its field of perception and enlarge its organization, so that it can appropriate fresh portions of the id. Where id was, there ego shall be. It is a work of culture—not unlike the draining of the *Zuider Zee*” (1933a, p. 80).

Lastly, the question of anxiety was modified by the advent of the division into id, ego, superego, and reality. Whereas anxiety had hitherto been seen as arising from repressions, it was now acknowledged as intrinsic to the psyche and indeed as a factor in the institution of these divisions: “. . . the expression ‘anxiety of the id’ would stand in need of correction, though rather as to its form than its substance. . . . The id cannot have anxiety as the ego can; for it is not an organization and cannot make a judgement about situations of danger. On the other hand it very often happens that that processes take place or begin to take place in the id which cause the ego to produce anxiety. Indeed, it is probable that the earliest repressions as well as most of the later ones are motivated by an ego-anxiety of this sort in regard to particular processes in the id” (1926d, p. 141). Freud distinguishes two cases: something in the id may activate a danger-situation for the ego and spark anxiety in it; alternatively, “a situation analogous to the trauma of birth is established in the id and an automatic reaction of anxiety ensues” (1926d, pp. 140–41).

“But one cannot flee from oneself; flight is no help against internal dangers. And for that reason the defensive mechanisms of the ego are condemned to falsify one’s internal perception and to give one only an imperfect and distorted picture of one’s id” (1937c, p. 237). Depending on the epistemology to which one subscribes (and on the resistance by which this choice is motivated), one will be more or less inclined to

accept the aspects of the unknown and the possible that Freud introduced into the metapsychological realm along with the id; these aspects are correlated with intrinsic and universal psychic dynamics and cannot be reconciled with positivism, pragmatism, or structuralism. In the history of psychoanalysis, what Freud had called “the third step in the theory of the instincts” came, after him, to be known as the “second topography.”

After Freud, the dynamic dimension of the id and the importance of the instincts were concealed rather than further developed by a good many psychoanalytic tendencies. The ego psychology of Heinz Hartmann and his followers, the emphasis on object relationships (Ronald Fairbairn or Michael Balint in Great Britain, Margaret Mahler and Otto Kernberg in the United States), the foregrounding of the Self (Donald Winnicott, Heinz Kohut)—all either play down the notion of instinct (or drive) to the benefit of the object or sideline it completely; in all cases the id no longer has any *raison d’être*. Jacques Lacan’s “unconscious structured like a language” gives no room to the id. Melanie Klein, although she preserves the priority of the instincts, gives pride of place to the aggressive and death instincts. However, some French analysts who are not exclusively Lacanian continue to work on the id.

Freud himself gave his followers a free hand, as witness the following observation on the division into id, ego, and superego: “It must not be supposed that these very general ideas are presuppositions upon which the work of psycho-analysis depends. On the contrary, they are its latest conclusions and are ‘open to revision.’ Psycho-analysis is founded securely upon the observation of the facts of mental life; and for that very reason its theoretical superstructure is still incomplete and subject to constant alteration” (1926f, p. 266).

A coherent advance in metapsychology that respected Freud’s requirements with respect to mental dynamics would certainly not be able to dispense with the conceptual tools of qualitative dynamics, as developed during the nineteenth century. This approach posits spaces articulated with each other by sets of dynamics that give rise to specific forms. It would make it possible to illuminate the way in which the ego and the superego arise from the id and from reality; to specify and explain the various processes of identification; to characterize inherited memory-traces as well

as types of governing dynamics; and to distinguish between energies of different kinds—and this while respecting the diversity of the id.

## **IDEA / REPRESENTATION**

The term “representation” has two meanings in psychoanalysis: sense “A,” which is the conscious or pre-conscious evocation in internal mental space of an object or person, even an event in the external world;

and sense “B,” which refers to one of the two expressions (or “translations”) of a drive within psychic processes, the other being the “quota” or charge, of affect.

Sense A is the conventional meaning in philosophy and psychology. It is also found in Freudian metapsychology, a fundamental contribution of which was to describe it according to sense B, which is specific to psychoanalysis. Thus, there are two dimensions to representation, the first focused on the internal/external distinction (internal space of representation/external space of perception and action), the second on psychic topography (whether it involves the first topographical subsystem of conscious/preconscious/unconscious or the second of id/ego/superego, which does not replace the first). A full description of these two “orthogonal” dimensions does entail certain problems, however.

At this point it would be useful to introduce some terminological guidelines.

The term *representation* translates at least three terms used by Freud, although he never clearly distinguished among them:

- *Vorstellung*. This is an everyday word that literally means “that which is placed before, in front of, in the foreground.” The implication of the word “representation” is obviously quite different since it can mean that a second presentation is involved (this implication is dominant in sense A, but plays a less obvious role in sense B).
- *Repräsentant*. This is a much less common word, derived from Latin, which means “delegate,” “representative” (*Repräsentantenhaus*: “House of Representatives”), and is primarily applied to sense B (the drive “delegates” a representation in psychic life).
- *Idee*. The word means idea, conception, thought, and so on. It is the term Freud often used to refer to “dream thoughts.”

It is useful to distinguish the various senses of the concept of representation from related concepts such as “figuration” (especially in the dream work but also in the case of many creative activities), “symbol” (sometimes used by Freud as a synonym for “representation”), and “fantasy” (which can be considered as a representation or as a system of representations of a particular kind).

Freud's interest in these distinctions was evident even before the advent of psychoanalysis. In "On Aphasia: A Critical Study" (1891b), he defined aphasic disorders from a structural perspective, as disorders of semantic systems and, consequently, as disorders of representational systems—the "things" evoked by words. (We can trace the origin of the distinction he made in 1915 between "thing representation" and "word representation" to this essay.)

Freud then transposed these ideas onto the problem of the psychoneuroses. Even in his earliest descriptions of the affects, he emphasized how "irreconcilable ideas [representations]" come to be rejected by morality. But psychoanalysis truly came into being when he referred to this rejection as "repression," an active process that changes the status of representations, now unconscious but potentially active (through the return of the repressed); and when, at the same time, he also distinguished the vicissitudes of the two expressions for drives, representation and affect. Strictly speaking, it is only the representation that is subject to repression. It would be contradictory to speak of unconscious affects, emotions, or feelings, even though Freud subsequently referred to an "unconscious feeling of guilt." For what is unconscious is not the feeling itself, which has disappeared, but the still active mechanisms that generated it.

At this point we are confronted with, on the one hand, "floating" affects that are deprived of representational support and, consequently, are easily converted into anxiety, and, on the other hand, unconscious representations that attempt to return to satisfy the desire, as well as unrepressed conscious representations that in general are not, or only slightly, imbued with affect. It is these last, "suspended representations," that the floating affect will invest (in the military sense of blockading, or investing, a stronghold as well as in the economic sense, the way a fluid fills a container). Through this mechanism, the unconscious representation "delegates" the satisfaction of the desire to a representation or a group of representations that can enter consciousness. These views, which were clearly expressed between 1894 and 1896 (Freud, 1894a, 1895c, 1895d, 1896b), were developed in 1915, especially in "Repression" (1915d) and "The Unconscious" (1915e). André Green (1973) discussed these issues in a remarkable essay.

We see, then, how Freudian metapsychology attempted to differentiate the two senses: the representation

carries libidinal impulses that are cathected to it to the extent that it is potentially engaged with the external world, where the satisfaction will necessarily be sought. But this also raises serious problems concerning the relation between psychic reality and the reality of the external world—problems that Freud continued to struggle with throughout his career.

These problems are related to the activity of perception and memory. When the representation is, in the A sense, the internal "double" of an object, event, or person in the external world, it is assumed that the external reality has already been perceived and some trace of the perception has been retained. It is only under these conditions that the representation, in the B sense, will be able to be invested with a "quantum of affect."

Freud at first followed a rather simplistic theory of perception that was consonant with the empiricist-associationist school that dominated the late nineteenth century: perception functions like a recording device that faithfully transcribes the formal qualities of the perceived object, supplying "raw" material for the associative process. The resulting representations are themselves preserved unchanged in the form of "memory traces." But this raises a rather difficult problem: By what criteria can the subject distinguish a true perception (the German verb for perceiving is *wahrnehmen*, "to take to be true") from an illusion or hallucination?

Moreover, clinical work soon revealed the extent to which memory traces were manipulated through repression when they reappeared during the return of the repressed, were recathected by an affect, or were used for the disguised fulfillment of a desire. The perception itself, initially subject to psychic conflict, cannot be mistaken for a simple record, or inscription. It took a long time before Freud was able to acknowledge that every perception, every memory trace, and therefore every representation, is "constructed" by the dynamics of the psyche itself and undergoes a constant process of retroactive reworking (Perron, 1995). The controversies that ensued, advanced by "ego psychology," concerning basal cognitive functions conceived as "zones free of conflict," fell within the framework of these problems.

What enabled Freud to escape the empiricism of his early work (rather than associationism) was the awareness of desire. In "A Project for a Scientific Psychology"

(1950c), he states that desire originates with psychic life: under cover of need it reactivates the memory of the satisfaction and “supplies something similar to a perception, in other words, a hallucination” (1950c.). We must learn to distinguish between them and it is at this point that the difficult question of the “reality test” arises. A solution was indicated in a series of Freudian texts, including “Negation” (1925h) and *Inhibitions, Symptoms and Anxiety* (1926d).

The difference can be found in the introduction of disappointment, which should be added to the schema of maternal care. While the infant’s needs are satisfied by the mother (or her substitute), his desire is associated with an object, an object that will be progressively situated “externally” (and verified as such through its absence). If there is no satisfaction, the need persists (or is reborn, independent of hallucinatory satisfaction), and the child situates the desired object “inside himself.” Subject and object come into being together, along with the representation, now defined (as distinct from hallucination) as that which exists here, in me, in my internal space, but (not necessarily) there, in the external world. In this case, the child must determine “if something present in the ego as representation can also be found in the perception (reality). As we have seen this is again a question of outside and inside. The non-real, simply represented, the subjective, is only inside; the other, the real, is also present outside” (1925h).

Based on this information, a number of authors attempted to construct a coherent theory of the “origins of psychic life” (Perron-Borelli, Perron, 1997), including Donald Winnicott (transitional objects and transitional space), Wilfred Bion (the transition from beta elements to alpha elements, the function of the maternal daydream, preconceptions), and Piera Aulagnier (from the pictogram to utterances, primal—primary—secondary succession).

Fundamentally, as we have seen, representation is constituted as a double of the absent object, which it can evoke or cause to exist even when it is absent from the world of perceptions and actions; it is an absent presence. However, the same is true of the symbol. And Freud often used the two terms synonymously. He established a term-for-term correspondence, where the relation between representant and represented was equivalent to the relation between symbol and symbolized. But elsewhere he introduced a completely different approach, one—referred to as “structural”

above—in which the material of psychic life consists of “systems” of representations that are more or less cathected by affects. In these systems a representation only assumes meaning and functionality through its connection to other representations. This has analogies with linguistics, especially the work done by Ferdinand de Saussure and extensively employed by structural linguistics. We know, for example, that Jacques Lacan used this as the basis for constructing a profoundly original metapsychology.

It is appropriate at this point to examine the sense of the term “representation” that no longer refers to the product of psychic work but to the work itself, the process of representation. How is it distinguished from the process of symbolization (Gibeault, 1989)? Symbolization can be said to make use of material supplied by the systems of representation, which are themselves constantly changing. This, however, raises questions about the problem of fantasy.

It is difficult, in Freud’s writing as well as in the later literature, to differentiate the two concepts. However, by consensus, the following distinctions are generally accepted: Fantasy, much more so than representation, which need not be heavily cathected with affect, is invested with desire and the hallucinatory (or quasi-hallucinatory) satisfaction of this desire. Fantasy, however, cannot simply be characterized as a strongly cathected representation. It would be preferable to treat fantasy as a particular type of representation centered on satisfaction: the typical structure of the fantasy would, therefore, comprises an agent, an action, an object of the action. Transformations of this structure (through agent/object or active/passive reversals, the substitution of agents and objects)—a good example of which is provided in Freud’s article “A Child is Being Beaten” (1919e)—are part of the process of representation (Perron-Borelli, 1997).

The psychoanalytic process is obviously an incessant process of binding and unbinding representations and affects, giving them mobility in place of rigid and repetitive bindings. In therapeutic procedures, like those that make use of children’s drawings or psychoanalytic psychodrama, we see how perception, memory traces, figuration, and representation are interrelated. The procedure consists in encouraging the patient to produce figurations (drawings, mimetic actions) as perceptual objects. And it is preferable, to avoid confusion, to use the term “figuration,” which is precise where “representation” is ambiguous.

These figurations are based on psychic realities known as representations (and their variant, fantasies). They are present as objects of perception to the therapist and give rise in him to representations that are more or less in line with those of the patient, although not always perfectly aligned with them. These overlapping representations and their constant reworking are the very material of the therapeutic process to the extent that it attempts to remobilize the psychic life of the patient. Donald Winnicott, with his squiggle technique, and Marion Milner after him, have done a remarkable job in describing these processes.

## **IDEALIZATION**

Idealization is a concentrated libidinal investment in an object that is thus exalted and overvalued. The term first appeared in connection with Freud's definition of narcissism (1914), but the concept can already be found in *Leonardo da Vinci and a Memory of His Childhood* (1910), where Freud speaks of the biographer who sacrifices the truth to idealize the biographical subject, "reviving in him, perhaps, the child's idea of the father" (p. 130). From the time of the *Three Essays on the Theory of Sexuality* (1905), Freud used the notion of "sexual overvaluation" in relation to fetishism and sexual deviations. This overvaluation makes the subject dependent and submissive toward an object

containing traces of the earliest oedipal attachments: "One always returns to one's first love" (1905d, p. 154). This attitude reappears in the subject's passionate dependence on an idealized object.

Idealization involves an object of a drive, but not the drive itself. Since the origin of this libidinal overinvestment is unconscious, the investment appears to be an effect of the superior value of the object itself. The subject denies, however, that he is overinvesting and allows the overvalued object to remain overvalued. The subject thus overcomes ambivalence toward the object. This defense mechanism promotes an illusion that has effects in reality, both for the subject and those around the subject. The latter are at times forced to conform with an alienating image, as members of an idealized nation or race.

Idealization must be distinguished from both sublimation and identification with the ego ideal, even if the notion of value is prominent in each. Idealization and sublimation are comparable in that both notions involve a modification of early object choices and sexual aims. These two notions also involve a psychical working through that detaches the drive from its primitive support and sets it off in another direction as a partial drive. Finally, both concepts involve valuations expressed in the social sphere. But whereas sublimation allows the drive to deviate from its goal, idealization blocks it from attaining its goal—thus creating an inhibition—because of a feeling of inequality between the great object to be attained and the small subject who feels libidinally impoverished in comparison with the idealized object. Thus, in place of libidinal fulfillment, the subject experiences an inhibiting fascination or, as the case may be, a destructive rage.

Similarly, idealization of the object is different from identification with the ego ideal, first of all because in the former case the ego has impoverished libido, while in the latter case the ego introjects both the object and its qualities. Furthermore, in idealization the object is external to the ego, while in identification the object becomes internal. Most important, in idealization the object is set up in place of the ego ideal, while in identification it is the ego that takes the place of the object.

Idealization results from a failure of the superego and the ego ideal to form at the outcome of the oedipal conflict. In idealization, the ego cannot serve as the ideal in a healthy process of identification that would insure that the first idealized objects belong to the ego.

Instead, the ego is dispossessed of its narcissistic libido for the benefit of the independently existing, and thus alienating, object. It is thus forced to externalize its most important constitutive element, the ego ideal. This results in an infantile situation of helplessness, a “paralysis derived from the relation between someone with superior power and someone who is without power and helplessness” (1921c, p. 115). The notion of idealization thus enables one to understand both individual psychological mechanisms (such as passion, perversion, and psychotic identification) and collective ones (such as a group’s fascination with its leader).

Numerous authors have contributed to enriching the concept of idealization. Melanie Klein (1952) has developed the notions of the idealized good object and the persecutory bad object, Piera Aulagnier (1979) has written on idealization in passion and psychosis, and Janine Chasseguet-Smirgel (1975) has discussed the disease of ideality.

## **IDEALIZED PARENTAL IMAGO**

The idealized parental imago is a narcissistic configuration that arises from the child’s attribution of former, lost narcissistic perfection to an admired and omnipotent self-object. A precursor of the Freudian ego ideal, it can be the object of a fixation and not be integrated into the self in order to lead to ideals, but instead remain a concrete self-object.

This notion appeared in Heinz Kohut’s article, “Forms and Transformations of Narcissism” (1966), and was formalized in his *Analysis of the Self* (1971). The idealized parental imago accounts for the need to merge with an all-powerful object and for religious and idealistic feelings of varying degrees of intensity. It gives rise to an idealizing transference in analysis.

In *The Restoration of the Self* (1977) Kohut conceived of it as a pole of the self, a possibility or potential for the self, which acquires its cohesion by responses of the self-objects that promote a sense of merging and calm. One pole can compensate for the other; idealization can compensate for deficient mirror responses. The self will be fragile only if both poles fail in their function.

These views of Kohut have been criticized on metapsychological grounds because they are based on the notion of an independent line of development for narcissism.

## IDEALIZING TRANSFERENCE

An idealizing transference—in which an individual seems to say “you are perfect, and I am a part of you”—is defined as the mobilization of an all-powerful object, either spontaneously or as a reaction to the loss of narcissistic equilibrium. It illustrates the need for maintaining a narcissistic fusion against feelings of emptiness and powerlessness. It emerges from a fixation point—a “prestructural imago,” that is, one prior to the formation of agencies.

The term first appeared in 1968, in Heinz Kohut’s “The Psychoanalytic Treatment of Narcissistic Personality Disorders,” and he developed the concept starting in 1971, within the framework of narcissistic transferences, which are defined as the reactivation of narcissistic configurations in analyzable narcissistic personalities.

It is important to distinguish three different phenomena: the idealizing transference, the pseudo-idealizations, and idealization in the treatment of neurosis. The idealizing transference central to the treatment is stable even if it is present in different degrees, from the archaic fusion to a more evolved ideal. A break in this transference leads either to a more archaic idealizing transference, or a mirror transference when the libido is withdrawn from the archaic object.

The idealizing transference refers back to the imago of the idealized parent.

Kohut has been accused, particularly by the Kleinians, of letting patients develop an idealization that is not a factor of development, but rather a defense.

## IDEATIONAL REPRESENTATION

The notion of ideational representation was proposed by Piera Aulagnier. She distinguished three levels of representation: the pictogram, the fantasy, and the idea. Involved here are the three modes (representable, figurable, thinkable) through which the psyche metabolizes the information it draws from its encounter with reality. These three modes coexist, according to Aulagnier in *The Violence of Interpretation: From Pictogram to Statement* (1975/2001): “Every act, every experience, gives rise conjointly to a pictogram, to a *representation* and to ‘sense-making’” (p. xxx). The ideational representation is thus at the basis of the thinkable, which can be defined as a relational schema that the I imposes on the elements of both its own internal reality and the outside world in order to make them conform and cohere with the logic of the discourse from which the I itself is produced.

What distinguishes the ideational representation from the pictogram and the fantasy is the appearance on the mental stage of the word-presentation and the changes it will impose. On this point Aulagnier’s theory converges with that of Sigmund Freud, for whom an idea becomes conscious in conjunction with the appearance of the word-presentation. As he stated in “The Unconscious” (1915): “[T]he conscious presentation comprises the presentation of the thing plus the presentation of the word belonging to it, while the unconscious presentation is the presentation of the thing alone” (p. 201). Aulagnier emphasized the importance of the dimension of what is heard for the mental inscription of word-presentations in *The Violence of Interpretation*, recalling Ernest Cassirer’s description of “the infant’s first encounters with language as a series of sound fragments, attributes of a breast that he endows with the power of speech” (p. 55). There is then an adjunct of this “heard” to the thing-presentation, but this is still within the primary system, for the system of signification remains organized based on the postulate of the omnipotence of the desire of the Other. There is thus a first step in the infant’s psychic activity during language acquisition, in which libidinal meaning has priority over linguistic

meaning. Nevertheless, according to Aulagnier, this libidinal meaning traces an access to linguistic signification “by leading the psyche to accept that this meaning exists, that it is part of the representative’s inheritance and that this meaning is not unconnected to the offer or refusal present in the psyche’s response” (p. 65).

Alongside this, the infant’s thinking activity and thus the formation of ideational representations and language acquisition are part of what the mother expects for the child; at the same time these elements are also what will enable to child to gain its independence by keeping its thoughts secret. In contrast, if thinking is attacked by psychosis such secrecy is impossible. Aulagnier did not situate this attack, as Freud did in “The Unconscious,” in terms of a regressive treatment of word as thing, or of metaphor as concrete object (as Harold Searles did in “The Differentiation between Concrete and Metaphorical Thinking in the Recovering Schizophrenic Patient” [1962]) but instead on the basis of the fact that thinking, which constitutes the equivalent of an erogenous zone-function, can become the object of mutilations or amputations, depending on the relational field in which it develops.

## **IDEATIONAL REPRESENTATIVE**

The ideational representative is one of the two components of the instinctual representative (the mental

expression of the instinctual drive), the other being its charge, or “quota” of affect.

It was essentially in his 1915 articles brought together under the title “Metapsychology” (“Instincts and Their Vicissitudes,” “Repression,” and “The Unconscious”) that Freud dealt with these issues. The ideational representative can be conceptualized as a mnemonic trace of old perceptions. Strictly speaking, repression affects only this portion of the instinct; accordingly, it can be rendered unconscious, but can later return to consciousness in disguised form, with new, “innocent” associations, when, under the pressure of the instinctual drive, it manages to cross the barrier of censorship (this is the “return of the repressed”). Because of this, ideational representatives undergo constant transformations, during which they can again take on the charge of affects that had become “empty” at the time of repression. The other component of the psychic expression of the instinctual drive, the “quota of affect,” is not subject to repression; it can be “suppressed” (that is, undergo a quantitative attenuation that may go as far as nullification), undergo a qualitative change in nature (be felt differently), or be transformed into “free-floating” anxiety.

Of course, questions about what becomes of ideational representatives thus rejected “into the unconscious” have been raised: Are they really voided of affective charge there? Do they also, in the unconscious, undergo transformations in such a way that they change from there? Such issues quickly reach the point of unknowability, since it is not possible to talk about them except on the basis of returns of the repressed. Undoubtedly, then, from a perspective that is too exclusively topographical, the danger is to reify the agencies of the psyche as “contents” (a notion implicit in the expression “in the unconscious”) and to wonder about the status and fate of ideational representatives conceived as discrete elements that preserve their individuality and that can be traced. This trap can be avoided by returning to the very basis of the definition of the instinct, that is, the primacy of the economic, and by examining the conflictual dynamics at work in the transformations in question.

## IDENTIFICATION

Identification is an unconscious mental process by which someone makes part of their personality conform to the personality of another, who serves as a model. Described cursorily by Freud in the context of psychopathology, the mechanism of identification has come to refer to a principal mode of relating to others and has been integrated in the processes that constitute the psyche. Identification should be distinguished from imitation, which is a voluntary and conscious act.

The notion of identification, in spite of its novelty and originality in the scientific or psychological vocabulary of the time, first appeared in Freud's writings in a letter to Wilhelm Fliess on December 17, 1896. It has always retained the meaning he gave it then: "I have confirmed, for instance, a long-standing suspicion about the mechanism of agoraphobia in women. You will guess it if you think of prostitutes. It is the repression of the impulse to take the first comer on the streets—envy of the prostitute and identification with her" (1985c, p. 182).

Freud often associated identification and hysterical symptoms with each other in subsequent writings, but he gave the concept a greater role in the *Interpretation of Dreams* (1900a), especially in the commentary that follows the dream of the "spiritual butcher," as Jacques Lacan referred to the dream of the dinner party where Freud refers to the wife's identification with a friend and presumed rival (chapter 4). Freud remarks that patients can "suffer as it were for a whole host of others, and to play all the roles in a drama solely out of their own personal resources." The classic definition follows: "[I]dentification is not simple imitation but assimilation on the basis of a similar aetiological

pretension; it expresses a resemblance and is derived from a common element which remains in the unconscious" (1900a, p. 150).

There is little doubt for Freud that this "aetiological claim" and "some factor held in common" are sexual in nature. Freud completes his description by demonstrating the dynamic use of identification under cover of another personality or composite formation, through the process of condensation and the use of a shared trait (the *einzigster Zug* that Jacques Lacan translated as "unary trait"), overcome censorship and realize the forbidden infantile wishes in the dream. The concept changed little in the following years, and in the Dora case it is used to account for the complexity of hysterical phenomena.

But in 1909 Sándor Ferenczi focused interest on the concept of identification when he introduced the similar notion of "introjection." For Ferenczi the ego "is always searching for objects to identify with, transference objects," and introjects them in order to grow. Object love is nothing but introjection. In the following years, in the study of Leonardo da Vinci (1910c), Freud explored this new pathway when he wrote that the young man who will become a homosexual "represses his love for his mother; he puts himself in her place, identifies himself with her, and takes his own person as a model in whose likeness he chooses the new objects of his love" (p. 100).

Likewise, "little Hans's" identification with the phobogenic animal, and therefore with his father (1909b), of the Rat Man with his father or mother (1909d), of little Arpad with a cock (Ferenczi, 1913), or the Wolf Man united with his parents during the primal scene (1918b [1914])—all are based on the model found in *Totem and Taboo* (1912–1913a), namely, the identification with the dead father during the totemic meal. The oral cannibalistic precursor of the mental mechanism of identification, named "incorporation," is clearly indicated in a note added in 1915 to the *Three Essays on the Theory of Sexuality* (1905d).

In 1915 the concept of identification was significantly modified, becoming a process integral to the history of the libidinal bonds woven between the ego and the other, even within the subject. The loss of an object narcissistically invested resulted in a phenomenon that Freud described in *Mourning and Melancholy* (1916–1917g [1915]) as "an identification of the ego with the abandoned object" (p. 249). It is

important to understand that this identification, here referred to as “melancholic,” is no longer partial and determined by a common trait as was hysterical identification, but total and brought about by withdrawal of the libido, which returns from the lost object to the ego. This was soon after referred to as “narcissistic identification” and considered to be more primal than ordinary identification.

In *Group Psychology and the Analysis of the Ego* (1921c), Freud describes three forms of identification: “First, identification is the original form of emotional tie with an object; secondly, in a regressive way it becomes a substitute for a libidinal object-tie, as it were by means of introjection of the object into the ego; and thirdly, it may arise with any new perception of a common quality shared with some other person who is not an object of the sexual instinct” (107–108).

The first of these modalities provides an opportunity for Freud to express the dialectic of being and having, which he used later on several occasions. “A little boy will exhibit a special interest in his father; he would like to grow like him and be like him, and take his place everywhere. We may say simply that he takes his father as his ideal” (p. 105). But the initial ambivalence evolves under the pressure of the Oedipus complex, either toward rivalry with the father or homosexual cathexis through identification with the mother. “It is easy to state in a formula the distinction between an identification with the father and the choice of the father as an object. In the first case one’s father is what one would like to *be*, and in the second he is what one would like to *have*” (p. 106). Seventeen years later, on July 12, 1938, this opposition would continue to disturb Freud, who left a brief trace in his writings: “‘Having’ and ‘being’ in children. Children like expressing an object-relation by an identification: ‘I am the object.’ ‘Having’ is the later of the two; after loss of the object it relapses into ‘being.’ Example: the breast. ‘The breast is a part of me, I am the breast.’ Only later: ‘I have it’—that is, ‘I am not it’” (1941f [1938], p. 299).

The second modality indicates the replacement of an erotic attachment, associated with the Oedipus complex, through identification and regression. A little girl coughs like her mother. “You are like her, but through suffering.” Dora coughs like the love object, her father. In both cases identification is only partial,

entirely limited, the ego restricting itself to borrowing only one of the object’s traits.

The third modality is original. It introduces the new concept of the ego ideal and embodies it in the person of the “leader.” This projection of the ideal promotes the social life of subjects who will be able to identify with one another through this common bond to an other, instead of considering one another as rivals to be destroyed. Young girls with a crush on the same singer are not jealous of one another; the loyal partisans of a leader forget their quarrels and differences. One point needs to be remembered, however: Identification is not here determined by the sexual bond that characterized the community of hysterical identification, which introduced the use of groups and “masses” in sociological research.

With the introduction of the “mythology” of the life and death instincts, and the description of the second topographical subsystem, the concept of identification changed in ways that would continue to enrich it. The nodal situation given to the Oedipus complex led to the description of complex interconnected identifications with each of the parents, which are made and unmade based on the number of possibilities for change and the data concerning their bisexual constitution.

Along with these “hysterical” forms of identification, narcissistic identification assumes particular importance in the formation of the subject. “Since then we have come to understand that this kind of substitution has a great share in determining the form taken by the ego and that it makes an essential contribution towards building up what is called its ‘character’” (1923b, p. 28). A number of post-Freudian authors like Theodor Reik went so far as to see this as a formative process for the ego itself. This insight helps contextualize the following remarks by Freud concerning the necessary withdrawal of cathexis from libidinal objects, which evolutionary change forces the id to abandon: “It may be that this identification is the sole condition under which the id can give up its objects. . . . When the ego assumes the features of the object, it is forcing itself, so to speak, upon the id as a love-object and is trying to make good the id’s loss by saying: ‘Look, you can love me too—I am so like the object’” (p. 29–30).

Subsequently, Freud defined what he referred to as “primary identification” (*primäre Identifizierung*), a

fundamental process in human mental development that represents a mythical moment similar to that of primary narcissism, primary repression, or even the murder of the father by the primitive horde. The term led to a number of contradictions and misunderstandings, for the term “primary identification” was used to refer to infantile identification of the baby with its mother, something not intended by Freud. As a sign of becoming human he understands it to mean an identification with the “father in his own personal prehistory” (1923b, p. 31) that occurs prior to any form of object choice. It splits the id from the ego ideal, the first split that signifies their connection, which the theory of the formation of the superego subsequently refines. The injunction associated with identification, to “You ought to be like this (like your father),” contradicts the later admonition: “You may not be like this (like your father)” (p. 34). In response to the evolution of the Oedipus complex and the fear of castration, the superego imposes itself as the introjection of the father in his controlling capacity through a later resumption of the primary identification. “Thus we have said repeatedly that the ego is formed to a great extent out of identifications which take the place of abandoned cathexes by the id; that the first of these identifications always behave as a special agency in the ego and stand apart from the ego in the form of a super-ego, while later on, as it grows stronger, the ego may become more resistant to the influences of such identifications. The super-ego owes its special position in the ego, or in relation to the ego, to a factor which must be considered from two sides: on the one hand it was the first identification and one which took place while the ego was still feeble, and on the other hand it is the heir to the Oedipus complex and has thus introduced the most momentous objects into the ego” (1923b, p. 48).

In “The Dissolution of the Oedipus Complex” (1924d), Freud returned to his description while emphasizing the role of the fear of castration. Because of this, “the object-cathexes are given up and replaced by identifications. The authority of the father or the parents is introjected into the ego, and there it forms the nucleus of the super-ego, which takes over the severity of the father and perpetuates his prohibition against incest, and so secures the ego from the return of the libidinal object-cathexis. The libidinal trends belonging to the Oedipus complex are in part desexualized and sublimated (a thing which probably happens with every

transformation into an identification) and in part inhibited in their aim and changed into impulses of affection” (p. 176–77). Here Freud uses the notion of introjection as a sign of a form of assimilation that is more stable and less labile than identifications would be, being closely associated with fantasy. This is a modification of the concept defined earlier by Sándor Ferenczi and another example of the terminological misunderstandings that have hampered the evolution of the concept of identification. In any case “the super-ego retained essential features of the introjected persons—their strength, their severity, their inclination to supervise and to punish” (p. 167), Freud wrote in “The Economic Problem of Masochism” (1924c).

Freud’s final thoughts on identification reveal his confusion in the face of its conceptual complexity. In chapter 31 of the *New Introductory Lectures* (1933a), entitled, “Decomposition of the Psychic Personality,” he again attempts—and for the last time—to clarify the various processes he designates as being part of identification and concludes, “I am absolutely not satisfied myself with these developments concerning identification.” But he adds a comment that will open a pathway to research on the phenomena of transmission between generations:

As a rule parents and authorities analogous to them follow the precepts of their own super-egos in educating children. Whatever understanding their ego may have come to with their super-ego, they are severe and exacting in educating children. They have forgotten the difficulties of their own childhood and they are glad to be able now to identify themselves fully with their own parents who in the past laid such severe restrictions upon them. Thus a child’s super-ego is in fact constructed on the model not of its parents but of its parents’ super-ego; the contents which fill it are the same and it becomes the vehicle of tradition and of all the time-resisting judgments of value which have propagated themselves in this manner from generation to generation.... Mankind never lives entirely in the present. The past, the tradition of the race and of the people, lives on in the ideologies of the super-ego, and yields only slowly to the influences of the present and to new changes; and so long as it operates through the super-ego it plays a powerful part in human life, independently of economic conditions (1933a, p. 67).

The “cruel” father himself had a father whom he took as a model, as well as a mother, and they too had

a mother and a father. Every parent replays in his child the world of his own childhood as it has remained engraved in his unconscious and his preconscious fantasies, far removed from the versions he communicates to others or keeps hidden from his conscious memories. It is this universe of origins that the investigative drive of every child explores to discover the secrets of its birth and identity. For its personality is formed with this material of composite images that may one day return in the form of “visitors of the ego” (Mijolla).

Post-Freudian authors have emphasized the psychoanalytic situation surrounding the concept of identification, which Freud did not examine in terms of identification. They have insisted on the necessity and limits associated with transference identification from the patient to the analyst, emphasizing that the analyst must possess a certain amount of empathy (*Einfühlung*), the ability to “understand what is foreign to our ego in other persons” (Freud, 1921c), and even to understand and interpret the analysand’s unconscious. Identification with Freud, the founding father, although the source of intense disagreement among his contemporaries and immediate successors, nonetheless remains one of the most vital areas of interest for the analyst. Fantasies of identification, with Freud or with individuals within the “psychoanalytic genealogy” of analysts, can lead to an understanding of certain theoretical propositions and events in the history of psychoanalysis.

Both Anna Freud, through her work on identification with the aggressor, and Melanie Klein, through her work on projective identification, have helped clarify various modes of identification that have confirmed the heuristic benefits of this evasive concept. The interest in relations with the mother has led to a misreading of primary identification, whose paternal-phallic nature was identified by Freud. Following Edith Jacobsen, other authors have presented it as a pre-object archaic mother-child relation situated in a state of fusion/confusion between the self and the not-self (Sandler), and have distinguished it from the concept of “imitation” borrowed from psychological models.

The distinction between “internalization,” comprising incorporation, imitation, and introjection, and associated with the construction of identity (Hartmann, Kris, and Loewenstein), and “externalization” as the distinction between internal objects and

external objects, has placed identification at the crossroads of these different systems. Its narcissistic pole has also been elucidated in the so-called “mirror” relation between mother and child, which is distinct from the specular identification of the child at the mirror stage, described by Jacques Lacan (1949). “Secondary identifications” have been isolated to describe the identificatory processes associated with the appearance and growth of the object relation, of pre-oedipal, oedipal and post-oedipal relations, and so on.

Psychoanalytic interest in more serious pathologies has drawn attention to the challenges to identity, whether these involve the behavioral disturbances of adolescence or the depersonalization observed in borderline or psychotic patients. Long before he addressed these issues in his essay on Justice Schreber (1912a), Freud, in a letter to Wilhelm Fliess (December 9, 1899), noted that “paranoia dissolves the identification once more; it re-establishes all the figures loved in childhood which have been abandoned ... and it dissolves the ego itself into extraneous figures” (1950a, p. 280).

More recently, research on identification has branched off in several directions: “counter-identification,” the “identificatory project” (Piera Aulagnier), “archaic identification,” “heroic identification” (Didier Anzieu), and “fantasies of unconscious identification” (Mijolla). The number of statements made to account for the richness of the concept seems interminable and psychoanalysts are still trying to determine its nature and formation.

## IDENTIFICATION FANTASIES

The term *identification fantasies* originally referred to imaginary constructions or even genuine unconscious fantasmatic scenarios through which the subject replaces a part of their Ego or Superego with a primordial figure from their family history, particularly the father, mother, or grandparents, such that this figure lives a small or large fragment of the individual's own existence as a substitute.

Only an interpretation that is integrated into an ongoing analytic process, where the psychoanalyst's own identification fantasies are also activated, makes it possible to detect these fantasies and understand their meaning as expressed through symptoms, behaviors, or even *delusions*, in the sense that Sigmund Freud spoke of delusions in the case of the Rat Man (1909d).

Used similarly by Alain de Mijolla in “La désertion du capitaine Rimbaud” (“Captain Rimbaud's desertion”; 1975/1981), the notion of identification fantasies was later used in the description of less pathological phenomena. It was especially useful in bringing a new theoretical perspective to the study of *transgenerational* phenomena, an area previously dominated by the overly mythical idea of “transmission from unconscious to unconscious,” by providing the conditions for a more psychoanalytic consideration of the fantasmatic genealogy of each individual. Transmission does indeed occur, but by way of preconscious processes involving the third-party transmitters that are the earliest objects: parents or grandparents establish a relationship between the child and preceding generations via stories, traditions, secrets, and legends, which are thus perpetuated from generation to generation with varying degrees of alteration along the way. Given this fact, it is important from a psychoanalytic point of view to substitute the term *intergenerational* for *transgenerational* (the latter in any case being borrowed from other theoretical systems).

Identification fantasies often assume the guise of *screen-identifications* that involve a staging of personalities that are foreign to the subject, such as fashionable celebrities, idealized versions of people close to the subject, or legendary figures, but analysis can reveal their original, more modest, familial models.

The notion of fantasies is essential, for the “truth” the child refers to in exploring his or her prehistory is not necessarily that of actual, recognized and dated events (although why not, if such information is available?), but can be made up of more or less disparate fragments of representations and affects. These elements are often organized into “scenes” that fill gaps in the individual's history, and whose assimilation, or *introjection*, to use Sándor Ferenczi's first definition of that term, enriches the Ego by providing additional coherence to the subject's psychic universe. Such fantasies are not decorative but rather, like any other fantasy, offer libidinal satisfaction and an outlet for the actualization of desires within the dynamics of the drives.

Grandparents, whether living or dead, are an essential part of this process of fantasmatic genealogical organization, since the conscious and unconscious representations of them that are kept and transmitted by the child's parents are as essential to the formation of identification fantasies as the child's own perception of external reality, if not more so.

Psychoanalytic treatment is the best-adapted context for the recollection and opening up of identification fantasies, and for a repetition of the primitive quest that led to their construction. It is because the psychoanalyst allows the patient's fantasies to resonate within himself or herself, where they awaken echoes of the analyst's own intrapsychic explorations, that these fantasies can become a common ground where interpretation is possible and communicable.

## **IDENTIFICATION WITH THE AGGRESSOR**

Identification with the aggressor was first described by Anna Freud in her book *The Ego and the Mechanisms of Defence*, first published in German in 1936.
