## **SUBJECT**

Unable to separate the term *subject* from the notion of consciousness, Freud placed it in opposition to the external world or the object, or in their reciprocal reversal (1915e). In “New Introductory Lectures on Psycho-Analysis” (1933a [1932]) Freud said the ego was “in its proper sense a subject” (p. 58)—not as an essence, but a function to be filled.

Jacques Lacan (1966) changed this by referring to the subject as “the subject of the unconscious” in its “unwitting” dimension, its ex-centricity in relation to itself. The subject is the “it” that the “I” speaks of when the I wishes to refer to itself as unconscious. Or rather, the subject is this very split between the “I” and the “it.” The ego, for its part, is not the “I”: a precipitate of identifications, it becomes the locus of misapprehension. How, then, is it possible for “the subject to recognize and name his desire”? The answer is that the truth speaks, even if the words spoken convey both the lie of desire and its truth, and even if “the I that speaks is not the same as the I that is spoken.”

The Other gives language its sense and the subject is an effect of that sense. The subject of the unconscious is “the subject represented by a signifier for another signifier,” and the only important thing is the degree of difference between the two signifiers. The Imaginary also enters into its determination through that which is imagined about the object *a*, the only object that can be transferred for transference into the place occupied by phallic lack. Thus, “the truth that the I of the unconscious tells us is that only this nothingness sustains it.”

Accordingly, for Lacan, the aim of treatment was not to fill this gaping nothingness, but to manifest it and potentially to express it through sublimation . . . or by training psychoanalysts. He emphasized that the kind of listening that took place in analysis often took wrong turns, and thus attempted, in his last years, to reequilibrate his system, notably by using the topological figure of the Borromean knot, to give “consistency” to the Real, the Symbolic, and the Imaginary: “The subject is what is determined by the figure in question: Not that he is in any sense its double, the subject is conditioned by the points at which the knot catches and tightens in these points.”

The Lacanian subject is thus very different from the one based on Freudian metapsychology. Lacan’s approach upends the theory of subjectivity by making the subject the subject of the drives, who sometimes directs them and at times is directed by them.

This subject is alien to itself, split between the Self and itself, though there is a constant reciprocity of relations between the mind’s agencies, and reversibility of the economic and dynamic transformations within the personality as a whole. Among the various modalities of representance, representation appears as the bridge or articulation between the economic dimension and that of meaning, the product of work whose conscious or unconscious quality constitutes modalities that are more or less contingent or necessary, depending on the case, within the figure of tension that is desire.

If, for Freud, the lifting of repression produced conscious awareness, today the emphasis has shifted onto whether or not a new, “subjectivable” meaning can possibly emerge, be assumed by the subject, and through the effects of deferred action [*après coup*] that constitute psychic reality, itself become a function of both internal constraints and effects of the psychic

reality of the object. Piera Aulagnier's "I," the study of the originating conditions of the process of subjectification (Cahn), and the related *Aufhebung* (sublation, supersession) illuminated by the notion of transitionality (Roussillon) are new approaches centered on the internal and external elements at stake in the splittings and exclusions that oppose this subjective appropriation. Here, in contrast to the problematics of neurosis, where the work of analysis naturally predominates, it is the work of the analyst that is revealed to be determinant, to contain that work, absorb it, and connect its productions.

## **SUBJECT OF THE DRIVE**

In his seminar on *The Four Fundamental Concepts of Psychoanalysis* (1964), Jacques Lacan reread Freud's essay "Drives and their Vicissitudes" (1915c) in order to emphasize that the four components of the drive—pressure, object, aim, and source—are not natural phenomena: the drive is a montage.

The constancy of the drive's pressure differentiates it from vital needs, which vary according to their own rhythms (Lacan, p. 171). Thus hunger is not the same as the oral drive. Satisfaction does not consist in fulfilling a need, but in completing a circuit of three stages. The "mouth that is involved in the drive," Lacan stated, "is not satisfied by food" (p. 167). The drive begins at an erogenous zone, and then makes a circuit around the object cause of desire, the object *a*. Thus Lacan saw drives as distinct from vital needs.

Lacan reserved the term "drive" for the sexual drives. Instincts of self-preservation—the *Ichtriebe*, Freud's ego-drives—were a function of narcissism. The subject of the drive emerged once the three stages of the drive's circuit were completed. Along with the active and reflexive stages, Lacan emphasized the importance of a third stage, in which, as Freud had said, a new subject would appear. This new subject is an other. When the "I" is, like an object, subjected to this other, it may experience pain and become a subject itself. It will seek to attach itself to the enjoyment of this other, which from then on plays the role of real Other. Only by completing the circuit of the drive does the subject come into contact with the dimension of the Other as the treasure trove of the signifiers. For Lacan, the concept of the drive is the pivot between the body, enjoyment, and language.

Clinical work allows us to see infantile autism as the result of a failure at the third stage in the circuit of the drive.

## SUBJECT OF THE UNCONSCIOUS

It has often been remarked that Freud hardly ever made use of the term “subject.” The only exception (which is surprising, because it was never noticed) was his respected use of the term in “Instincts and Their Vicissitudes” (1915c). While describing the normal instinctual “vicissitude,” where the drives turn back on the subject’s body and where the mode of satisfaction is reversed from active to passive, Freud wrote of “a new subject,” which he situated outside of the person proper. This subject wants to be watched (or violated) to satisfy the infantile need to be looked at (or treated sadistically). Freud thought that this instinctual subject-agent had been created at the stage where goals became passive—an idea that he took up again four years later with regard to the origin of the fantasy of “A Child is Being Beaten” (1919e). There he declared that the fantasy acquired its full subjective power only when it was being lived through passively: “I am beaten by the father.”

Subsequently, when Freud considered the love-hate dyad, he did not think of it as in the same category as instinctual dyads like the sadomasochistic and voyeur-exhibitionistic dyads. Instead, he conceived of it as being determined by narcissism. Then he returned to his former conception of an “ego-subject” after seeming to introduce the notion of an unconscious instinctual object in the first part of his study (Freud, 1915c).

Jacques Lacan took up the challenge of developing this concept of the subject of the unconscious in his

teaching. From 1945 on, he worked on defining the different meanings of the term “subject.” He wrote of the Cartesian subject of certainty, the negated subject of science, the personal subject of self-affirmation, and of course the two subjects of a sentence: the grammatical subject and the intentional subject. This duplication is at the basis of his conception of the intrinsically divided subject,  $\$$  (barred S), which accounts for his famous definition of the subject as being whatever a signifier represents for another signifier (Lacan, 1966/2002).

But Lacan was always led back to the “subject of unconscious desire”: the subject of the desires of *The Interpretation of Dreams*, the subject of the witticism and other expressions of the unconscious, which he saw as structured like a “language.” However, having reduced the subject of human desire to an effect of language (“the speaking being”), he didn’t reduce it any further to a grammatical subject. His subject was either instinctual or empty (like the word).

This drive-based vision of the subject prompted Lacan, in his first seminars (1975, 1978), to differentiate it categorically from the ego. On this point he broke openly with Freud’s notion of the global ego. In effect, he saw the ego as an imaginary function whose purpose is to provide the person with a sense of corporeal unity and continuity. Lacan emphasized that the ego was necessarily involved in a struggle against the instinctual registers, and this stance caused him to view the ego, as it reflects the image of the Other, as opposed to the subject (S), which emerges as the id. His interpretation of Freud’s famous statement “Wo Es war, soll Ich werden” (“Where the id was, there I should come to be”) led him to play on the homophony of “S” and “Es.”

Lacan viewed the newborn subject, because it was always born prematurely, as implicated in the “demands” through which it makes known its needs. It borrows these demands from the maternal signifying code. In so doing, the subject makes a first effort to attach itself (instinctively) to a desiring maternal Other, thus confirming the incompleteness of the latter. When the young subject observes the lack in the Other, it will disengage from its mother. Lacan said that the signifier of the Other’s lack showed how “all the other signifiers represent the subject,” but on the other hand he conjectured that “when this signifier is missing, all the other signifiers represent nothing” and no one (1977, p. 316).

The subject, in its fantasies, is able to represent itself as maintaining a desire through the partial (real) objects that Lacan called “little *a*’s.” These little *a*’s are residues of the operation through which the first Other recognizes itself as being subject to the rules of symbolic exchange.

The neurotic in analysis obstinately refuses to imagine the Other as a subject, “the subject who is supposed to know,” and refuses to accept that the Other is animated by a desire toward him. This is what sparks the transference in the cure.

## **SUBJECT'S CASTRATION**

Lacanian notions of castration are linked to frustration and deprivation, lacking and giving, and ultimately to object relations. These represent a certain culmination of the history of psychoanalytic thought on the subject. To better define their importance, let us examine their history.

Starting in 1905, Freud posited a theory of object relations that would be linked to the stages of libidinal development (Freud, 1905d). He later proposed that the loss of feces should be considered as the precursor of the castration complex (Freud, 1916–1917e). Thus the Freudian concept is “absolutely realist.”

It fell to August Stärke, in a long and important article published in 1921, to expand this theory by

proposing that the breast no longer be considered the first lost object and the model for castration anxiety. Instead he recommended that masochistic pleasure also be connected with castration anxiety, which is expressed as a desire to receive the penis.

In 1928, building on theories advanced by Karl Abraham in 1924 and on thoughts that Freud expressed in 1926 about the peculiarities of the castration complex in the woman (Freud, 1926d), Melanie Klein differentiated between early anxiety in boys and girls. A boy's anxiety involves castration and a girl's the good internal functioning of her body.

Thus there is a continuous strand of Freudian thought that considers the object as tangible and castration as a reality. Even an author like Bion did not depart from this line (Bion, 1959). For him, links and attacks, the breast and the penis, are always quite real—even if their reality is only fantasmatic.

Jacques Lacan revolutionized this tradition. For him, castration fundamentally pertains to the subjectivity of the subject. It derives from a symbolic debt, linked to the prohibition against incest and murder. In the real, the subject observes that a woman lacks a penis. Thus the relation to an object is just as much a relation to the lack of an object, the object existing just as much by its absence as by its presence.

Lacan claimed that the necessity of this revolution was justified by what had become the “heteroclit nature of the castration complex” (Lacan, 2002, p. 306). He suggested this in the complete form of his graph of desire, where we find the unconscious and the Other on the one hand and the barred subject on the other. Then, successively, there are the signifier and the voice and then *jouissance* and castration related to “the drive as the treasure trove of signifiers” (p. 302). Castration means, “that *jouissance* has to be refused in order to be attained on the inverse scale of the law of desire” (p. 311).

For both sexes, the phallus is “the signifier destined to designate meaning effects as a whole” (p. 275) and “the signifier of the Other's desire” (p. 279). As such, castration is not directly related to the reality of the penis. In fact, this relation is problematic and requires several operations: “It is thus that the erectile organ—not as itself, or even as an image, but as a part that is missing in the desired image—comes to symbolize the place of *jouissance*,” that is, as “the function of a missing signifier: (–1)” (p. 307). “The shift of (–/)

(lowercase phi) as phallic image from one side to the other of the equation between the imaginary and the symbolic renders it positive in any case, even if it fills a lack. Although it props up (−1) it becomes Φ (capital phi) there, the symbolic phallus that cannot be negated, the signifier of jouissance” (p. 308). The castration complex is “incited” by the object (−/) that designates it in its imaginary function.

The Lacanian revolution corresponds to a complete separation of dialectic from intersubjectivity, the very kernel of Freudian thought. This dialectic is expressed in the schema RSI, which represents the real, the symbolic, and the imaginary. Castration is inscribed therein as related to frustration and deprivation, as Lacan showed in his seminar on object relations (Lacan, 1956–57).

## **SUBJECT'S DESIRE**

Although it was introduced into French by Ignace Meyerson's inaccurate translation of the Freudian term *Wunsch* (wish), desire went on to become a

major Lacanian concept. For Lacan as well as for Freud, desire is the subject's yearning for a fundamentally lost object. Thus for Freud, any search for an object is, in fact, an attempt to refind it. For Lacan, however, the object of desire is located prior to desire and functions as its cause.

Lacan subverted the Freudian aphorism that “a dream is the fulfillment of a wish” (Freud, 1900a, p. 121): “If Freud accepts, as the reason for a dream that seems to run counter to his thesis, the very desire to contradict him on the part of a subject whom he had tried to convince of his theory, how could he fail to accept the same reason for himself when the law he arrived at is supposed to have come to him from other people?” (Lacan, *Écrits*, p. 58). Moreover, in what Freud called the rebus-like structure of the dream, Lacan found support for assimilating condensation (*Verdichtung*) and displacement (*Verschiebung*) to the tropes of metaphor and metonymy. Thus he was able to conclude that “the unconscious is structured like a language.”

Freud used dreams to derive both his first topography and a model of the psychic apparatus that defined desire as the “cathexis” of a mnemonic image linked to the satisfaction of need. Thus for Freud desire is satisfied just once, and any subsequent manifestation of desire is only an impulse (*Regung*) that aims to reestablish, sometimes to the point of (psychotic) hallucination, the image of an irretrievably lost object. This is the “empirical” failure of hallucinatory satisfaction that leads to thought—which, Freud says, “is nothing but a substitute for a hallucinatory wish” (p. 567)—and thus to voluntary activity that aims at the satisfaction of need, not desire.

Dreams, which realize desires in the quick, “backward” way, serve as an example of the psychical apparatus's primary mode of functioning, abandoned because of its inefficacy. Censorship, the guarantor of our mental health, prevents the impulses of unconscious desire from being manifested during the day. Symptoms must be considered as the realization of wholly unconscious desires. Dreams, on the other hand, express the attainment of these desires with the consent and control of the preconscious, which tilts in the end toward the desire to sleep.

On the basis of the “burning child dream” (Freud, pp. 509–511), which expressed this desire to sleep, Lacan constructed his graph of desire (Lacan, 1958–59,

session of December 10, 1958). The sentence of the dreamer, “His father was dead,” is situated at the lower level, that of the statement. At the upper level, that of the enunciation, Lacan placed the sentence, “He did not know it.” And finally, it is between the statement and the enunciation that Lacan inserted Freud’s interpretation, that is, the desire of the dreamer: “according to his wish.” The sentence “He did not know it” showed the way in which the dreamer protected the paternal function, which he was deprived of by the death of the real father, and that was the origin of the dream. The desire of the dream was to throw a veil of perpetual ignorance over oedipal desire.

At the intersection of the imaginary and the symbolic, human desire is established by a loss that can be symbolized by the separation from the placenta at birth. This primal castration gives birth to the subject of an impossible enjoyment sustained by the object *a*. Later losses, which constitute the possible objects of human desire (the nipple, feces, the phallus), are always manifested more or less by the anxiety that indicates the reappearance of this lost primal enjoyment, that is, the lack of lack. That is why the speaking being can only “symbolize” this lack by the minus phi ( $-/$ ), which is the image of the capital phi,  $\Phi$ . Likewise, this lack can only be “imagined” in the articulation of the fantasy,  $\$ \diamond a$ , in which the barred S is the subject and the symbol  $\diamond$  means “desire of.” This is the form that is best suited to defending against the desire of the Other.

This desire “is neither the appetite for satisfaction [Need] nor the demand for love [Demand], but the difference that results from the subtraction of the first from the second” (Lacan, *Écrits*, p 276). It protects the subject from the enjoyment of the Other by means of the forms that its object takes. In phobia the object is prohibited; in hysteria it is unsatisfying; and in obsession it is merely defended against. In any case, desire remains marked by—and serves as a reminder of—a lost enjoyment. The object of this enjoyment, the phallus, becomes the signifier of the very lack of a signifier, and thus the signifier of castration as imposed by language. And so the object of desire is always a metonymic object, always a desire for “something else.”

This Lacanian rereading remains oddly in agreement with Freud on the basis of the analogy that Lacan establishes between desire and dream, and it raises the question of the place of language in their theory. If language for Freud is a kind of superstruc-

ture linked to the life instinct, and thus an ideal to be attained, for Lacan it is also the insurmountable limit and metaphor of being.

## SUBLIMATION

Sublimation is a process that diverts the flow of instinctual energy from its immediate sexual aim and subordinates it to cultural endeavors.

The idea of sublimation leads back at once to the alchemical metaphor of the transmutation of base metal into gold, and to aesthetics, which from the ancient world (Longinus) to Romanticism (Goethe) saw the sublime as the transcendence of the individual’s limitations. The concept evolved in Freud’s work from the idea of the ennoblement or embellishment of a fantasy (Draft L [1950a (1895)]) to that of a genuine intra-instinctual process, the transformation of object libido into ego libido before it could assume new aims (1923b).

The unresolved complexity of the notion of sublimation means, however, that the term designates a set of questions rather than a well-circumscribed concept (Laplanche, 1980).

Sublimation would appear to be a very special vicissitude of the instinct, for its diversion of libidinal energy harnesses instinctual impulses in a way congenial to the superego and its society. Retransformation is possible, however, and therein the original instinc-

tual force may regain the upper hand (resexualization of sublimated homosexual impulses (1911c [1910])). Desexualization alone cannot define the process of sublimation, which is not to be confused with inhibition or reaction formations, even if it plays a fundamental role because of its ability to exchange an originally sexual aim for another, which is its “psychical parent” (1908d).

As for the effect of sublimation on the object it valorizes in the eyes of society, Freud took great care to discourage any risk of confusion between sublimation and idealization, the latter implying an *overestimation* of the supposedly “sublime” object (1914c).

The development of the ability to sublimate (“*Fähigkeit zur Sublimierung*”) was related for Freud both to the individual’s constitutional disposition (the initial strength of the sexual instinct) and to the events of childhood (the link between trauma and the intensity of infantile curiosity; cf., the case of Leonardo da Vinci being a good example). Sublimation occurred at the expense of the polymorphously perverse drives of childhood (especially bisexuality), which were diverted and applied to other aims, as witness the sublimation of anal eroticism into an interest in money, or the link between urethral eroticism and ambition. This process contributed to the formation of character traits. The component instincts were of particular significance here: the instinct to see could be sublimated into artistic contemplation and into the instinct to know (1910c), while sublimated aggression could manifest itself as creative and innovative activity.

But Freud always emphasized the risks associated with sublimation of the instincts when it takes place at the expense of the sexual and deprives the subject of immediate satisfaction. Although sublimation appears as the guarantor of the social bond and promoter of culture, it is, nonetheless, a dangerous demand, a “ruse of civilization” (Mellor-Picaut, 1979) when it presents individual sublimations as ideal models. For Freud, sublimation is not the core of an axiological approach to psychoanalysis, and the introduction of narcissism represented an important turning point in his theory. Sublimation took place “through the mediation of the ego, which begins by changing sexual object-libido into narcissistic libido, and then perhaps goes on to give it a different aim” (1923b, p. 30). Sublimation no longer occurs at the expense of the object-libido but offers the narcissistic libido a needed extension. However, it does not pro-

tect the individual, who is left at the mercy of the death instinct.

Freud was against making sublimation a privileged goal of the treatment, one that could even be advocated by the analyst (1915a [1914]). In this, he disagreed with Carl G. Jung (1914d), as well as Lou Andreas-Salomé, whom he had also accused of “blabbering about the ideal” in his letters to Jung (January 10, 1912), James J. Putnam (May 4, 1911), and Oskar Pfister (October 9, 1918). In all these cases he was struggling against the temptation of an anagogic approach to psychoanalysis. It may be assumed that this threat of having such a complex concept corrupted contributed to the fact that it has never been thoroughly developed. One thinks in particular of an unpublished draft on sublimation written for Freud’s projected book on metapsychology.

The concept of sublimation has been discussed by many of Freud’s followers, though without any significant contributions being made to metapsychology. In later years Melanie Klein became one of the most important commentators on sublimation, primarily in connection with epistemophilia. In France, Daniel Lagache (1962) and Jean Laplanche (1980) have both written essays on sublimation.

Sublimation, which is often mentioned in the literature, by emphasizing the desexualization of goals and the social valorization of the object, remains both an essential concept and an unresolved question for psychoanalysis.

## SUBSTITUTE/SUBSTITUTIVE FORMATION

"Substitute" or "substitutive formation" refers to the psyche's replacement of a fact or mental object through unconscious chains of association. In the substitution, an idea, thought, or object perceived as incompatible with the ego is repressed and exchanged for another. A number of synonyms are found in Sigmund Freud's writings: "ersatz," "substitutive formation," "equivalent," "stand-in," and "replacement."

In "The Neuro-Psychoses of Defence" (1894a), Freud described the formation of an obsessional idea as a substitute for an incompatible sexual idea. The ego wishes to deal with the sexual idea as though it had never arisen, and so affect is detached from it. However, since that affect remains "unaltered and

undiminished" (p. 54) in the core of the psyche, it attaches itself to a compatible idea, making it obsessional. Initially limited to obsessional ideas, the notion of substitution was eventually generalized and conceptually modified. For instance, in "Obsessions and Phobias: Their Psychical Mechanism and Their Aetiology" (1895c [1894]), Freud described symptoms as substitutes for ideas of coitus. In "Obsessions and Phobias," he posited premature sexual climax as the source of reproaches, for which the psyche substitutes ideas, actions, or impulses providing relief and protection. In "Further Remarks on the Neuro-Psychoses of Defence" (1896b), the object of the substitution is no longer mnemonic contents, but rather the reproach associated with them, which is transformed into another unpleasurable substitutive affect that can become conscious (shame; social, religious, or hypochondriacal anxiety; etc.).

In later works, the substitute was associated with different metapsychological objects. It was associated with object relations, with maternal and paternal substitutes being associated through family romances and the totem. It was associated with anxiety contents in the case history of Little Hans (1909b), where the paired terms bitten/castrated correspond to the paired objects horse/father. It was associated with dreams in "Some General Remarks on Hysterical Attacks" (1909a [1908]), where the dream is a substitute for the hysterical attack, itself a substitute for an autoerotic satisfaction from childhood. Dreams there became more extensively recognized as substitutive formations. Finally, *Inhibitions, Symptoms, and Anxiety* (1926d [1925]) brought the substitute back to the level of the symptom, in that the substitute represents a return of the repressed. In this sense, symptom formation and substitutive formation have the same upshot: replacing the forbidden satisfaction of instincts and making such satisfaction unrecognizable.

Even though the terms are synonymous, the expression "substitutive formation" is preferable to "substitute" because it attests to the dynamic process that forms the substitute: the transformation of gratification in the defensive conflict.

## **SUBSTITUTIVE FORMATION**

The name “substitute formation” has been applied to the defensive process by which a symptom—but also, more generally, a failed act, slip of the tongue, or dream—is produced. The result of this process—for example, the act or manifest text of a dream—is that desire can find a way out, and its economic charge find an outlet.

The notion of substitute formation appeared in Freud in 1895, in his article on anxiety neurosis (1895b), but it was anticipated in the previous year in his work on “The Neuro-Psychoses of Defense” (1894a). In this, he described a “transposition,” a “displacement” connected with an economic charge (for example, anxiety or sexual excitement) and with a “complex of representations” (in a process of symbolic transposition), these two processes being able to function separately.

Freud resorted frequently to this idea in the following years: this was, in fact, a key notion in the metapsychology he was drafting, since he was describing the mechanism by which the repressed element could succeed in returning to conscious life and to behavior. At first, he limited the application of this mechanism

to obsessional neurosis. But the dual function attributed to it (economic discharge and symbolic transposition), the unification of the field of the return of the repressed (including neurotic symptoms, dreams, slips of the tongue, failed actions, and some “normal” behavior), its contiguity with related notions (like those of compromise formation or reactive formation), and the deepening of Freud’s thoughts on mechanisms of defense, all led him to the expression of much wider views on the subject in 1915 (notably in “Repression” [1915d] and “The Unconscious” [1915e]). He revised it even further in *Inhibitions, Symptoms and Anxiety* (1926d), as part of his overall views on symptom formation and his second theory of anxiety.

## **SUCKING/THUMBSUCKING**

In *Three Essays on the Theory of Sexuality* (1905d), Sigmund Freud describes thumb-sucking as “rhythmic repetition of a sucking contact by the mouth (or lips). There is no question of the purpose of this procedure being the taking of nourishment” (pp. 178–180). Sucking itself is defined as a sexual autoerotic pleasure, “as a sample of the sexual manifestations of childhood” (p. 179).

From this point on, the infant’s sucking activity served for Freud as an exemplary case, enabling him to demonstrate how the sexual instinct seeks satisfaction

through a separate, vital, self-preservative function; it subsequently becomes autonomous and seeks satisfaction through auto-erotism. At the end of his life, in *An Outline of Psycho-Analysis* (1940e [1938]), Freud reaffirmed its significance: “The baby’s obstinate persistence in sucking gives evidence at an early stage of a need for satisfaction which, though it originates from and is instigated by the taking of nourishment, nevertheless strives to obtain pleasure independently of nourishment and for that reason may and should be termed *sexual*” (p. 154). Beginning in 1915, Freud described an aggressive “cannibalistic” oral stage that aims at incorporation, with emphasis not only upon the erotogenic zone but also upon the object to be incorporated.

A number of analysts have investigated the broader issues surrounding the activity of sucking and the oral stage. Freud suggested that an infant would “pronounce the act of sucking at his mother’s breast by far the most important in his life” (1916–17a [1915–17], p. 314); in fact, the act of sucking can be recognized from the twelfth to the thirteenth week of intrauterine life, as the fetus opens and closes its mouth in a more or less rhythmic manner. From the twenty-second week, the fetus is able to taste amniotic fluid and can suck its thumb.

Karl Abraham distinguished the passive sucking of the first stage of oral activity from the sadistic pleasure in the second, after teething, and he developed the concept of a cannibalistic oral stage that Freud discussed after 1915. René Spitz accorded sucking a principal role, which he integrated into his global approach of the genesis of the object. The “primal cavity” (Spitz, 1955) serves as a juncture for activities occurring around the mouth, tongue, and hand; sucking thus occurs at the juncture of inside and outside.

Michael Balint, after objectively recording the breast-feeding of about one hundred infants, maintained that rhythmic sucking is one of the most archaic qualities of human life and that each infant has an individual rhythm that adumbrates character traits. John Bowlby (1969) challenged Freud’s concept of “anaclitic” object choice as well as the primacy of sucking, suggesting instead that an innate need for social contact is at the root of attachment-seeking behavior. Sucking is only one of several instinctive behaviors at the child’s disposal; others include grabbing, following with the eyes, crying, smiling, and rooting behavior. Bowlby, while questioning the primacy of the oral

stage and sucking, did not take into consideration intrapsychic processes; new approaches to understanding these issues developed out of work on autism.

Frances Tustin, in *Autism and Childhood Psychosis* (1973), has suggested that the pain endured by autistic children in their experiences of bodily separateness as “amputation” would include an unbearable disjunction of the mouth and nipple. Sucking prevents the intolerable pain of this disjunction and thereby protects infants from anxieties of catastrophic separation. Donald Meltzer believed that the infant may experience the nipple, while sucking at the breast, as an eye-breast, or primitive, archaic superego.

Geneviève Haag has suggested that the thumb-in-the-mouth forms part of what she calls the “corporeal identification” with “assembly along the median.” This “self-junction” which infants create via the thumb-in-mouth represents a kind of clinging to self that precedes auto-erotic activity. According to her, the eye-to-eye visual exchanges that accompany breast-feeding go on to form the early feeling of being enveloped, the internal center of early attachment.

Whether conceived as auto-sensual or autoerotic behavior, bodily symbolization, intracorporeal identification, or incorporation, sucking is an activity that the understanding of which, ever since Freud, has been central to attempts at understanding normal and pathological development in the human infant.

## SUDDEN INVOLUNTARY IDEA

Sudden involuntary ideas (*Einfälle*) appear at the borderline between images and words; they come to mind without apparent relation to what preceded them and have a quality of certainty linked to their immediacy.

This notion appears several times in Sigmund Freud's writings. It refers to preconscious thought activity as it is found in free association, jokes, or poetic creation that escapes critical reason, allowing the outcome of an earlier development to emerge into consciousness.

In *The Interpretation of Dreams* (1900a), Freud gave *Einfälle* a status analogous to that of “involuntary ideas” (p. 102) that are transformed into visual or auditory images. Divided diffuse attention is responsible for these representations, as they are found in a semi-sleeping state or under hypnosis. In this work Freud discussed the associationist hypotheses of Eduard von Hartmann, saying that although *Einfälle* appear when there has been a renunciation of purposive ideas, this does not mean that they are arbitrary; rather, there are other, unconscious purposive ideas that take over and determine the course of involuntary ideas. The work of analysis thus relies on *Einfälle*, but attempts to guide them back into the realm of the interpretable and eliminate their “sudden” and “involuntary” quality, which is a result of repression.

*Einfälle* are particularly important in creative thought in general, whether in the discovery of unconscious contents in psychoanalysis, the punch line in a joke, poetic creation, or invention in theoretical or abstract thinking (cf. Archimedes's “Eureka!”). Nevertheless, their origin, unknown because it is repressed, has something troubling about it—hence Freud's inclusion, in *The Interpretation of Dreams*, of the following quotation by Friedrich von Schiller: “[W]here there is a creative mind, Reason—or so it seems to me—relaxes its watch upon the gates, and the ideas rush in pell-mell, and only then does it look them through and examine them in a mass.—You critics, or whatever else you may call yourselves, are ashamed or

frightened of the momentary and transient extravagances which are to be found in all truly creative minds and whose longer or shorter duration distinguishes the artist from the dreamer. You complain of your unfruitfulness because you reject too soon and discriminate too severely” (p. 103).

## SUFFERING

Suffering is the result of a feeling of alienation and insurmountable ambivalence; being a defensive attitude, its aim is the reduction of anxiety.

When Sigmund Freud asserts in *Civilization and Its Discontents* (1930a) that “the three sources from which our suffering comes” are “our own body... the external world... and our relations to other men” (pp. 86, 87), he could not make it clearer that human suffering opens up the entire field of psychopathology. The classical medical tradition has always sought to name the condition that causes the patient to suffer, thus to satisfy the patient's wish for their suffering to be less mysterious. Psychoanalysis escapes this preoccupation with diagnosis in that it demonstrates the ubiquity of a suffering that is at once undergone and created by the subject.

If suffering marks the entry into the treatment, the orientation of the treatment itself is towards a demonstration of how this suffering is provoked by the individual subject, in the name of a particular search for pleasure “in a different place” (Laplanche, Jean, 1976 [1970], p. 104). Suffering is thus not only the source of

the complaint, but also the necessary lever of its own mobilization and even its own transcendence by the treatment.

In the tradition of Freud's work on "Mourning and Melancholia" (1916–17g [1915]), Melanie Klein (1935) treated accession to the depressive position as a fecund moment in the development of the child's object-relationships and the harbinger of the processes of symbolization. The same intimate connection between suffering and thought-processes informs Christian David's notion that man is in a sense "destined to suffer": "We cannot avoid being permanently confronted by separation and loss, by absence, by intersubjective and intrapsychic splits whether fantasied or actual... If the psyche drew no strength from its own division, it would no doubt be unable to tolerate this state of affairs for long and would be liable to disintegrate at the first jolt" (1983).

Interpretation during the treatment depends largely on the effectiveness of a process of working-through, toward the relief of suffering. As arduous as this work may be for those who embark on it, they feel motivated to do so by a wish to live better, even to be "cured." It is by no means certain that insight leads to cure. Analysts are only too well aware of the effects of the repetition compulsion and of primary masochism, only too familiar with clinical pictures that lie beyond the reach of the regulatory mechanism of the pleasure-unpleasure principle. The "work of the negative" may even become indistinguishable from what is irreducible or radically unthinkable due to the opacity of suffering—merging, in effect, with what Jean-Bertrand Pontalis (1981) calls the principle of pain, *jouissance*, or agony (in the sense of Donald Winnicott's "primitive agonies" [1974]): "The logic of unpleasure/pleasure seems to give way to, or even to be completely overwhelmed by a logic of despair that reduces our logic, that of the primary as much as that of the secondary processes, to despair."

## SUGGESTION

James Braid, the British doctor who popularized hypnotism, was the first to use the term "suggestion" to describe experiments in which the hypnotist, using a gesture or word, triggers the subject's automatic obedience. Around 1860 Ambroise Liebeault decided to make use of suggestion for therapeutic purposes: orders, formulated in an authoritarian or well-meaning manner, would help trigger hypnosis and the therapeutic process. Hippolyte Bernheim extended this by claiming that suggestion had explanatory powers. In 1891 he defined suggestion as "the act through which an idea is introduced into the brain and accepted by it." According to Bernheim, an idea suggested verbally by the operator triggered a representation-adherence on the part of a subject endowed with "*crédibilité*." Unless inhibited, this idea tended to be translated into actions ("ideo-dynamism").

Bernheim noted that some subjects were more susceptible than others and used the term "suggestibility" to describe the ability to respond to suggestion. Contrary to Jean Martin Charcot, he did not see this as pathological, but as a very general psychological phenomenon, present to a varying degree in everyone. Thus, suggestion helps to explain hypnosis as well as

the mechanism or process of education, the adherence to a belief, and so on.

Gabriel de Tarde in *Les Lois de l'imitation* (1890), and Gustav Le Bon, in *La Psychologie des foules* (1895), used suggestion to describe the connection between two or more people that serves as the basis for a society or a crowd. For Bernheim, however, hypnosis only facilitated therapeutic suggestibility, and suggestive psychotherapies could be practiced in a waking state. This identification of hypnosis with suggestion resulted in criticism from Liebeault, and especially from Charcot and his followers.

Originating in the School of Nancy, for which Bernheim was the spokesman, all of Europe took an interest in experiments, therapies, and models of suggestion. Experiments were conducted on “suggested” crimes, which triggered theoretical, ethical, and juridical polemics. Although experiments with suggestion were met with trepidation, its therapeutic use generated tremendous hope. It was believed it would be able to eliminate certain symptoms, like pain, associated with organic illnesses and heal “nervous disorders” such as hysteria, as well as sexual inversion and alcoholism.

Suggestion, as a therapy and as a concept, raised questions and criticisms from many of its practitioners. Bernheim remarked that some subjects can present resistance to “direct suggestion.” In such cases it is better not to give a direct order, but rather to tell the patient nothing can be done, and the problem will heal itself. In this context Bernheim also spoke of “indirect suggestion,” an expression used in a similar sense by Charcot and his school. The Belgian Joseph Delboeuf emphasized self-suggestion, the ability to resist, and the will of the patient. The Dutch practitioner Frederik Van Eeden, who was, like Delboeuf, part of the Nancy School, pointed out that suggestive psychotherapy must involve collaboration between the doctor and his patient, respecting the patient’s autonomy to as great an extent as possible. Pierre Janet criticized the overly broad extension given to the concept of suggestion and proposed, in 1889, in *L’Automatisme psychologique*, a more limited definition: “The influence of one person on another, who carries it out without the intermediary of voluntary consent.” At the same time he reactivated the older notion, associated with animal magnetism, of “rapport.” Auguste Forel, a Swiss practitioner, noted the ambiguity of the word suggestion, which designates both a therapeutic procedure associated with an order from the practitioner

and a psychic process that leads the subject to respond to someone else’s influence.

The articles Freud wrote in 1895 on hypnosis and suggestion situate him within the critical movement outlined above. He subsequently abandoned suggestion both as a therapeutic practice and as a psychological explanation. Nonetheless, he claimed in the *Introductory Lectures on Psychoanalysis* (1916–17a) that “in our technique we have abandoned hypnosis only to rediscover suggestion in the shape of transference” (p. 446). Although we can do away with suggestion, the problems associated with the process remain and have been shifted toward the transference. In 1921 Freud returned to the question of hypnosis and suggestion, and of suggestion as a model of the social bond.

Looking at contemporary techniques of hypnosis, we find that the therapies inspired by Milton Erickson have reactivated the identification of hypnosis with suggestion. The procedures used (the proposal of metaphors, paradoxical orders, or prohibitions) seem less authoritarian than those employed at the end of the nineteenth century, but may still be compared to the “indirect suggestion” used in the past.

## SUICIDAL BEHAVIOR

The term *suicidal behavior* is understood to mean both suicidal equivalents not recognized as such (accidents, repeated risk-taking) and repeated suicide attempts whose chronic and unsuccessful nature certainly constitutes a real risk, but which are also acts of essentially relational significance.

The idea that accidents can be interpreted as unconscious suicide attempts appeared in Sigmund Freud's *The Psychopathology of Everyday Life* (1901b): “[I]n addition to consciously intentional suicide there is such a thing as a half-intention self-destruction [sic] (self-destruction with an unconscious intention), capable of making skillful use of a threat to life and of disguising it as a chance mishap. There is no need to think such self-destruction rare. For the trend to self-destruction is present to a certain degree in very many more human beings than those in whom it is carried out” (pp. 180–181). This essentially involves the person waiting for the occasion that will divert the forces of personal preservation, and there is thus a “meeting” between the event and the unconscious intention. Involuntary mutilations, which constitute a compromise between the self-destructive tendency and self-preservation, are also included within the framework of accidental suicidal behaviors.

Similarly, with regard to accidents that happen to babies, Melanie Klein spoke of suicide attempts with inadequate means, as if the infant did not yet have the ability to fantasize and premeditate its own death, and that it could only realize by unconsciously putting itself in danger.

In a letter to Freud dated 1 June 1911, Ernest Jones proposed a comparison between accidental suicide and “with the way in which the unconscious seizes on unassociated indifferent material in dream making” (1993 [1908–39], p. 105).

Systematic risk-taking requires a different psychic disposition. The idea of the possibility of death is present and even hypercathected, but at the same time denied in a megalomaniacal narcissistic affirmation. Death is thus “provoked” in the sense of a challenge

that is also a relational challenge to those whose fantasized omnipotence cannot effectively protect the subject, the idealized parents. These situations are very common, especially during adolescence, and can involve the risk of accidents, but also toxic risks or even anorexia. Such risk-taking has a function similar to that of the *ordalia*, or trial by ordeal, in the sense that the subject expects to get from it an affirmation, if not of their own innocence, at least of their invulnerability. In the face of this excessiveness, the accident imposes a limit and brings the person into contact with reality, including that of the body's fragility.

Authors such as Philippe Jeammet and Elisabeth Birot who have studied suicide attempts in adolescents have emphasized the fact that the idea of death has an organizing function during adolescence. It can be noted that the idea of death is unavoidable at this age in conjunction with the obligation to renounce childhood, to which there is no possible return. The idea of death is linked to a sense of the ephemeral—hence the ease during this period of identifying with romantic heroes (as seen in Freud's Manuscript N., 31 May 1897, regarding Goethe's hero Werther).

Beyond gambling with the idea of death, a suicide attempt can represent a way of trying to restore a lost identity (the prepubescent body of the anorexic) or a delusional identity. Similarly, the integration of the drives during adolescence, notably with respect to homosexuality, is a factor that can be conducive to suicidal behavior. Such behavior then appears in its relational significance, whether in the form of a threat, or even blackmail against those close to the subject, or a call for help when communication has broken down. Chronic suicidal behavior can have various etiologies; it remains the case that it cannot be dissociated from suicide proper, the potential for which is inherent in it.

## SUICIDE

Suicide is a symptomatic act connected most frequently to the framework of depression and melancholy. Its etiology is varied and complex, since it is characterized by the collapse of the ego, along with self-reproach and a diminution or a loss of self-esteem—and, at the same time, by a magic omnipotence which allows the annihilation of internal persecutors, as well as a manic feeling based on the denial of death itself. While suicide may appear to be a response to persecutory guilt, it is also a projection of this guilt onto objects as well as a liberation from their control through the death the subject has chosen for himself.

Suicide was discussed in the psychoanalytic literature as early as 1907, as recorded in the *Minutes of the Vienna Psychoanalytic Society* (Nunberg, Hermann, and Federn, Ernst, 1962–75), but it was a rather superficial discussion, centered on the fact that the differing choice of means by men and women reveals a primal sexual symbolism. From this came the formula that “suicide is the climax of negative autoerotism” (*Minutes*, Vol. 1, February 13, 1907, p. 114). This should be understood in the context of the opposition between the ego instincts and sexual instincts in Freud’s earliest theorization: “In suicide the life instinct is overwhelmed by the libido” (Vol. 2, April 20, 1910, p. 494).

In this approach, suicide, interpreted as a substitute for psychosis, seems linked both to an inability to tolerate reality and to autoerotic regression: “Suicide is an act of defense of the normal ego against psychosis” (June 6, 1907). Drive regression is equally central to Freud’s ideas on the subject of the suicide of high school students; at school “Teachers. . . must exercise a

life-maintaining influence. [The function of] school is to give the child, in this stage of his detachment from his parents, a new footing within a larger relationship” (Vol. 2, April 20, 1910, p. 495). This should extend as far as not to “deny them the right to linger even in those phases of their development that seem vexing.” There might well have been some evolution in Freud’s thought here, especially if it is considered that, at the very beginning he insisted on the connection between neurasthenia, masturbation, and the risk of suicide. However, Freud also stressed that “in many cases it is the fear of incest itself that drives [children] to suicide” (p. 494), because of the enormous augmentation of their need for love at puberty; Freud went so far as to suggest, this being the case, that homosexuals make the best teachers, the worst being those whom the repression of their homosexuality has turned into sadists, pushing their students to suicide.

Later psychoanalytic thought on suicide followed the main ideas of Freud on the subject. First of all, in the depressive context, suicide was considered self-punishment for the desire to kill, primarily directed toward another, as Freud himself stated in *Totem and Taboo*: “The law of talion, which is so deeply rooted in human feelings, lays it down that a murder can only be expiated by the sacrifice of another life: self-sacrifice points back to blood-guilt” (1912–13a, p. 154). Since then, the risk of self-mutilation or suicide with infantile or borderline personalities has been much emphasized (Kernberg, Otto, 1984); this risk is especially a factor during fits of rage following disappointments which are blamed on others; or else there is a risk of suicide because of failure to achieve success (guilt), or, even the failure of the cure (negative therapeutic reaction).

In fact, the idea that suicide is self-punishment for the desire to kill someone else cannot be understood completely apart from the process of melancholia, whereby the loved/hated object has been introjected within the ego and has become the target of the attack. More even than “self-punishment,” suicide would be murder of the other within oneself. “Probably no one finds the mental energy required to kill himself unless, in the first place, in doing so he is at the same time killing an object with whom he has identified himself, and, in the second place, is turning against himself a death-wish which had been directed against someone else” (1920a, p. 162). Freud explained that “the ego is destroyed by the object.”

The enigma constituted by suicide in relation to the self-preservative or ego instincts has also been approached in another way, through considering that it is accompanied paradoxically by a tentative intent to reappropriate vital energy, or, indeed, is even prompted by the fantasy of beginning a new life (Grinberg, León, 1983). Accordingly, suicide would result from a state of crisis dominated by the feeling that something must change. The person committing suicide “convokes death imaginally to assure himself paradoxically that life exists” (Triandafillidis, Alexandra, 1991). Ideal images of oneself and others can then survive, at the price of the death of the bad objects cluttering the ego.

The vital stakes involved in this symptomatic conduct have inclined authors not only to attempt to understand the suicidal mechanism, but also to describe its advance symptoms, evaluating the risk of suicide in order to decide on a therapeutic approach, especially in a care-giving institutional setting. León Grinberg (1983) emphasized suicidal premeditation and the fact that a suicidal plan follows the idea of suicide, which was at first only a way of dealing with anxiety. Continuing to the act of suicide depends on an “encounter,” which might favor tipping the fantasy into reality. This author also examined factors of present or past vulnerability (feeling of culpability, narcissistic wound, loss of loved object, and so forth). Otto Kernberg (1984) emphasized the need for the therapist not to be fooled by an accentuation of the manic element; he stressed the seriousness of cases where “aggressiveness has infiltrated the grandiose Self,” joined to an inability to enter into interpersonal relations and feel emotions. These considerations, however, concern psychotherapeutic strategies rather than the etiology of suicide.

## **SULLIVAN, HARRY STACK (1892–1949)**

American psychiatrist and psychoanalyst, born on February, 21, 1892, in Norwich, New York, and died on January 14, 1949, in Paris.

The only son of a farming couple in rural upstate New York, Sullivan had a very lonely childhood and went through a deep psychological crisis upon entering Cornell University. He graduated from medical school in Chicago in 1917, but only in 1921 did he start working in psychiatry, under William Alanson White (1870–1937) at St. Elisabeth’s Hospital, Washington, D.C. Between 1923 and 1930 he worked at Sheppard-Pratt Hospital, Maryland, where he devised a very successful combination of milieu and individual therapy aimed at young schizophrenic patients. A good friend of Abraham Brill and a charter member of the Washington Psychoanalytic Society (1930), Sullivan progressively withdrew from Freudian psychoanalysis in order to concentrate on initiatives like the Washington School of Psychiatry (1936), the journal *Psychiatry* (1938), and on the development of his own interpersonal theory. In the early 1940s, on the invitation of Dexter Bullard, he worked as teacher and supervisor at Chestnut Lodge Hospital, where he influenced a whole series of colleagues, among them Frieda Fromm-Reichmann (1889–1957).

In New York City in 1943, Sullivan, together with Clara Thompson, Erich Fromm, Frieda Fromm-Reichmann, and Janet and David Rioch founded the William Alanson White Institute, which became the major institution committed to the teaching and development of interpersonal psychoanalysis.

With the exception of *Conceptions of Modern Psychiatry* (1940), six of his seven books available in

English were published posthumously. *The Psychiatric Interview* is considered a classic and is still widely read.

## **SUM OF EXCITATION**

In his earliest psychological investigations Freud explored the interface between the psychological and the physical, a context in which a “sum of excitation” had the following connotations: (1) a quantity of energy present in the nervous system and its psychical manifestations: the greater or lesser strength and vividness of ideas and memories and of the affects bound to them; (2) a regulatory dynamic governing that energy: the tendency to establish constancy through abreaction and the failures of this tendency in neurosis; (3) the aggregate of excitations and their limits, in accordance with neurophysiology, in the emergence and overdetermination of symptoms; and (4) the idea that the energetic processes involved here are quantifiable and measurable.

As he worked on a proposed joint publication with Josef Breuer in 1892, Freud spoke of “the constancy of the sum of excitation” and “displacements . . . of sums of excitation” (1941a, pp. 147, 148; see also 1940a, p. 153–54). In his lecture “On the Psychical Mechanism of Hysterical Phenomena” (1893h), he introduced the notion as follows: “If a person experiences a psychical impression, something in his nervous system which we

will for the moment call the sum of excitation is increased. Now in every individual there exists a tendency to diminish this sum of excitation once more, in order to preserve his health. . . . and when someone cannot get rid of the increase in stimulation by ‘abreacting’ it, we have the possibility of the event in question remaining a psychical trauma” (pp. 36, 37).

Freud continued to use this expression until 1897. In its initial context, it was synonymous with “affect” or “amount of affect”; the fate of the sum of excitation in the event of repression was somatic innervation in the shape of hysterical conversion, and in the case of compulsive neurosis it underlay the creation of substitute ideas. But the notion that a principle of constancy affected the sum of excitation led Freud into overarching issues of dynamic and economic neuropsychology; this emerging set of problems was already present in the “quantities” Q and Qg of the “Project for a Scientific Psychology” (1950c [1895]).

An intuition in the early days, the idea of the sum of excitation and its attendant problems were bound to evolve. The notion of “cathexis” was soon added to those of affect and amount or quota of affect. The instincts and instinctual impulses refined the energetic model of the psyche, while the tendency toward constancy was broken down into principles of inertia, constancy, pleasure, reality, and eventually even into the death instinct. The vividness of repressed memories led to the notions of the timelessness of the unconscious and of repetition. And, lastly, the economic standpoint became the tool with which to study the centrality of the quantitative factor in the etiology of mental disturbances.

This idea was thus a rich theoretical seed, but it remained neurophysiological in character, and ultimately embodied too many other notions to survive in its original form.

## SUPEREGO

The superego is one of the three agencies making up the psychic apparatus in Freud's second topography, the structural theory (1923b). It results essentially from the internalization of parental authority. From the outset, as psychoanalysis uncovered the defensive conflict that arose from a repressed unconscious (childhood sexuality), it encountered the need to posit a repressing agency, a censor associated with self-esteem. In contrast with hypnosis, which put the censor to sleep, psychoanalysis is essentially aimed at acknowledging and working out of the ego's resistances.

As early as "On Narcissism: An Introduction" (1914c), Freud already deemed the ego ideal to be autonomous. Two works of Freud's dating from the early 1920s firmly differentiated between the ego and the superego (ego ideal) and integrated this distinction into the whole set of Freud's metapsychological reworkings of the period. In *Group Psychology and the Analysis of the Ego* (1921c), to describe the functioning of groups, Freud developed a generalized conception of identification in which individuals identified their egos by creating a common ideal, incarnated in a leader. *The Ego and the Id* (1923b) went on to link the superego as a mental agency to the recognized fact that the greater portion of the ego was unconscious. Within the psychic apparatus, the superego makes permanent the effects of the infant's dependence on primary objects, and it is just as insusceptible of complete integration into the ego as the id and its instinctual impulses. The term "superego" itself indicates that the superego dominates the ego; the tension between the two agencies take the form of moral anxiety.

Freud did not detach the superego from the ideal (one of its functions). The superego is responsible for transmitting the constraints that culture exercises over the individual, and for imposing the necessary and ultimately excessive sacrifices of instinct demanded by civilization. It is also the carrier of a cultural past that each subject must appropriate and master (the reference being to Goethe's *Faust*) through processes of

object idealization and sublimation of the instincts. The main dynamic remains the conflict-laden work of differentiation between the ego and the superego. How the superego is transmitted (it is formed in the image of the parents' own superegos), establishes itself, and develops entails in the final reckoning that the Freudian superego is an intersubjective and even intergenerational agency.

When, in *Civilization and Its Discontents* (1930a), Freud raised the issue of a (collective) cultural superego, he was revisiting his earlier reflections on the origins of civilization in *Totem and Taboo* (1912–1913a). There, evoking the myth of the primal horde, he had associated the killing of the primal father with the prohibition on incest. After investigating the genesis of guilt in *Civilization and Its Discontents*, he attempted, in *Moses and Monotheism* (1939a), to account for the strength of tradition. With the concept of the superego, Freud tackled the thorny subject of what humankind elevates and makes sublime. Strictly opposed to any kind of spiritual approach, which the theme of the conscience readily encouraged, he focused on the concrete development and instinctual aspects of agency.

In seeking to expose the structural dimension of the split between the ego and the superego, Freud based his findings on two pathological phenomena: delusions of observation and manic-depressive psychosis. In delusions of observation, the monitoring and judging internal agency (the superego) is reprojected outward. Manic-depressive psychosis illustrates the cyclic operation of the moral conscience and the changes that occur in the relationship between the ego and the superego: in melancholic self-reproach, the superego persecutes the ego, and in manic euphoria, the ego and its ideal coincide (as in the ritual festivity of a carnival).

From the ontogenetic viewpoint, the superego is "heir to the Oedipus complex." This means that the advent of the superego prolongs the core affective relationships of childhood by rendering permanent the conditions that brought about its establishment. The identifications that constitute the superego are the bearers at once of parental prohibitions and of instinctual cathexes relating to the parents as objects, cathexes that these identifications replace according to a regressive logic in which the wish to be like dislodges the wish to have (Freud, 1933a, p. 63). Broadly speaking, the identifications of the superego owe their autonomy, their constraining role vis-à-vis the ego, to the

child's crucial dependence on its objects. "At the beginning . . . what is bad is whatever causes one to be threatened with loss of love" (Freud, 1930a, p. 124). If establishing the superego through identifications has far-reaching consequences, this is because the relationship of the ego to the superego reproduces the relationship of the child to the all-powerful parents. Real anxiety related to the parents is transformed into moral anxiety arising from the tension between the ego and a superego that draws no distinction between the wish and the act. The superego first appears, therefore, as the upshot of a regressive defensive process that tends to lend permanence in mental reality to a world determined above all by parental desire and parental protection. Freud conceived of religious belief as underpinned by a projection outward of the child's superego, motivated by a nostalgia for the father. This helps explain why the task of the ego during adolescence is to escape from the authority of the superego.

In Freud's detailed metapsychological description of the genesis and development of the superego, the superego begins to form very early on, and this formation involves permanent rearrangements of identifications and changes in their very nature as they become less narcissistic and more symbolic.

There is thus a clear dividing line between a primitive realm of the superego (as described by Melanie Klein) and a distinctly postoedipal realm. The primitive realm is founded on archaic mechanisms (identification with the aggressor and the law of talion [an eye for an eye]). In the postoedipal realm of the superego, a bisexual superego "consisting of these two [paternal and maternal] identifications in some way united with each other" (1923b, p. 34) bears the mark of the subtle mental developments that for Freud are specific to the phallic phase and the "complete" Oedipus complex (love and hate for each parent, identification with both). Under this later configuration, the structuring effects of the castration complex and the integration of the fantasy of the primal scene make it possible for the superego to resolve and protect the ego from what are now incestuous wishes. Successful development of the superego is indicated by the individual's acquisitions of culture during the latency phase and by an ability of the individual to traverse the reactivation of instinctive desires that occurs in adolescence and to achieve autonomy. Progression along these lines correlates with a reduction of the superego's demands to essential social rules alone, with its gradual detachment. Such progres-

sion tends to turn the superego into a more purely symbolic agency. The profoundly paternal character of Freud's superego has been further developed by Jacques Lacan's concept of the Name of the Father. A consequence is the possibility of a more personal ego ideal. All these modifications of the superego depend on the desexualization inherent to the identification process, for desexualization allows a secondary narcissism in which the ability to idealize and sublimate buttress the cathexis of new objects and social bonds.

At the clinical level, making the superego into a mental agency was one of Freud's theoretical responses to the difficult practical problems posed by certain kinds of resistance—needs for punishment, negative therapeutic reactions, moral masochism—that represent diverse expressions of unconscious guilt. Freud observed how the superego had a general propensity for cruelty, for a severity out of all proportion to that of the child's actual upbringing. This was a crucial insight, for it led him to recognize the endogenous, instinctual origin of cruelty and hence to form the hypothesis of the destructive death instincts.

Unconscious guilt was thus seen in essence as turning such destructiveness back against oneself. This explains the paradoxical fact that the superego is made stronger by the renunciations it imposes, and that anxiety is increased even by misdeeds never performed (as witness crimes committed out of a sense of guilt). The narcissistic desexualization involved in the process of identification, upon which the superego is founded, permits a diffusion of instincts whereby the superego tends to become the focus of a liberated death instinct (the "pure culture of the death instinct" seen in melancholia).

By contrast, the proper functioning of the postoedipal superego, which results in a dynamic of conflict between the ego and the superego, presupposes that the environment allows a balanced apportionment of love and discipline that result in a fusion of instinct. The coherent superego that results makes for a tempered guilt capable of underpinning a sense of responsibility in the subject.

## **SUPERVISED ANALYSIS (CONTROL CASE)**

Control analysis (also known as “supervised analysis” or “analysis under supervision”) is a cure during which the analyst reports back the “material” and progress to an experienced colleague for discussion. Although supervised analysis is a mandatory stage for trainee analysts, it is not exceptional for an analyst to feel the need to discuss a difficult case with an experienced colleague even after the end of the supervised analysis.

The practice dates from the origins of psychoanalysis and we may even consider that it was present when psychoanalysis came into being, because Freud laid down the bases for it in his correspondence with Wilhelm Fleiss and in the course of their periodic “congresses.” He then went on to institute the practice of open discussion with the analysts he trained, enabling them to discuss their cases during the Wednesday meetings of the Psychological Society, later the Vienna Psycho-Analytical Society (cf. *The Minutes of the Vienna Psycho-Analytical Society* 1962, 1967, 1975), and in the course of private conversations. These new analysts themselves continued this practice with their own students.

However, it was quite frequent in those early days for the same person to act as analyst and supervisor within a limited circle. The obvious drawbacks of such a confusion of roles precipitated a call for better regulation of the process. A first directive was adopted during the congress of the International Psychoanalytic Association (IPA) in Bad Homburg, Germany, in 1925. It was agreed that the training process, regulated and supervised by the societies comprising the IPA, or their training institutes, should include at least two supervised analyses, the supervisor being distinct from the analyst. (An earlier congress in 1918 had already

established the necessity of personal analysis for candidates.)

These principles still apply. The IPA rules stipulate that only the body of training analysts of a regional society can authorize supervised analyses; that two adult analyses must be conducted, and that at least one child analysis is desirable in addition; that the supervisors must themselves be accredited by their society; that the supervision must be weekly; and that each of these supervisions must last at least two years (the analysis itself may obviously extend beyond this period).

Those are the general rules. They are compatible with differing approaches depending on the country or psychoanalytic group. In practice, admission to supervised treatment generally coincides with admission to training as a psychoanalyst (including, in addition, lectures, attending work groups, and seminars). Candidates may be admitted following personal interviews with several training analysts whose mission is to assess the state of progress of their personal analysis (whether applicable), as well as their potential as future analysts, and who report back to a commission in charge of making the actual decision. Several IPA societies exclude the candidate's analyst from this procedure (the Paris Psychoanalytic Society preferring to extend this exclusion to all stages of the training process, including final certification).

Supervision can have two formats: the weekly meeting may be personal, limited to the candidate and the supervisor; or a "group meeting," comprising several candidates (but never more than five or six) who may meet with a shared supervisor. Both systems have advantages and drawbacks. It is often stressed that group supervision has the great advantage of enabling candidates to compare their experiences and thus to avoid a too closely dyadic relationship with their supervisor. Individual meetings, on the other hand, facilitate more open discussion, free from the reserve and self-conscious attitudes to be expected in groups; also they facilitate discussion of counter-transference issues, more difficult in a group setting. There is a risk here, however, of reviving and importing transference effects from the candidate's personal analysis (which is often ongoing during supervision).

Generally speaking, the idea in supervisions is not to dictate to trainee analysts what they should do and say, even less to equip them with theoretical precepts

or technical recipes. The aim is to help them detect the meaning of the material that is presented to them, its instinctual and affective charges, as well as the patient's defenses, all this with reference to the transference and counter-transference. This consideration is especially vital to the training of analysts. The supervisor's task is therefore a difficult one, because he or she must draw the attention of the supervised analysts to their own counter-transference without ever transforming the supervision into an analytic session.

The procedure raises many delicate questions, calling for continual work on the part of psychoanalytic institutions (Lebovici, Solnit, 1982). This has led certain groups to work out original formulas, such as the "fourth analysis," proposed by the Quatrième Groupe OPLF (France) as its foundation.

## **SUPPRESSION**

Suppression is a defense mechanism aimed specifically at affect, which intends to abolish it from consciousness without allowing its re-entry into the unconscious.

The term "suppression" in its broadest sense was used by Sigmund Freud (1900a) to describe a conscious mechanism intended to eliminate undesirable psychical content from consciousness. The difference between suppression and repression (1915d) lies in the

fact that this latter defense mechanism is unconscious and under its influence repressed content becomes or remains unconscious. Repression is concerned essentially with the “ideational representatives” of the drive/instinct, which are distinct in that they may remain unconscious. In Freud’s early theorizing of affects, though, affects are suppressed and do not pass into the unconscious.

Throughout the metapsychology, however, this distinction between suppression and repression is not quite so clear-cut: “We know, too, that to suppress the development of affect is the true aim of repression and that its work is incomplete if this aim is not achieved” (1915e, p. 178). In this passage from “The Unconscious,” the suppression of affect appears as a specific mode of repression destined to eradicate affect from consciousness. Moreover, in the same essay, Freud devotes a chapter to “unconscious feelings” in which affects begin to find a definite position within the unconscious.

This notion of “unconscious feelings” was progressively elaborated on, and in “The Ego and The Id” (1923b), Freud wrote: where feelings are concerned “the *Pcs.* here drops out—and feelings are either conscious or unconscious” (1923b, p. 23). With the introduction of the second topography the affects described by Freud typically become complexes. An unconscious sense of guilt, anxiety as signal, grief, sorrow, etc., are all affects that are articulated through various fantasies, notably around the loss of the object. The signal of anxiety that the threat of the loss of the mother represents for the child is the paradigmatic example of this new conception of affects associated intimately with fantasies (from Freud’s second theory of anxiety). Since affect and representation are thus considered to be closely imbricated with fantasies, the defense mechanisms relating to affects are not differentiated in any specific way, and as a result the affects themselves are also likely to become unconscious.

Melanie Klein, who had adopted Freud’s second theory of anxiety from the outset, considered affects subject to the same defensive vicissitudes as fantasies. Anxiety, however, very quickly became central to her technique; thus interpretation, for example, inevitably has a bearing on the fantasies of the subject in analysis, when anxiety is at its height. As her theoretical system developed, affects would progressively come to occupy a crucial site in the functioning of mental life (1948). In a conception bound up with the “positions” of the two general modes of organization of psychic life, the

type of anxiety, either paranoid or depressive, constitutes a key concept beside the modality of the object, whether partial or total, and alongside mechanisms of defense, whether psychotic or neurotic.

The type of defense mechanism to which the ego might have recourse is dependent on the intensity of depressive anxieties, revealed through the fantasies that manifest them. When they are too intense—in sorrow, but in guilt above all—they are expressed in fantasies involving the catastrophic destruction of objects. The ego will have to mobilize extreme and even psychotic defense mechanisms. Between these, massive disavowal will attack, very specifically, these depressive affects in order to annihilate and erase them; however, other psychotic defense mechanisms such as splitting, projective identification, or projection also contribute to their eradication. Furthermore, their action will give rise to other affects, notably persecution anxiety. Where depressive anxieties are not too extreme, and in instances where considerable fantasies of injury, of death (and thus of the loss of objects) prevail, more or less intense disavowal permits the alleviation or even the transformation of these anxieties, with the help of obsessive defenses, into their opposite—euphoria. Where depressive anxieties are limited and where fantasies of the loss of the love object and exclusion predominate, the depressive conflictual situation opens up the way to the neurotic problematic and the conflictual affects are repressed.

When the repression of affects, the neurotic defense mechanism *par excellence*, becomes more extensive, its effect seems closer to that of disavowal. The analysis of severe neurotic disorders with serious depressive conflicts reveals the interchange between these two defensive modes in the treatment of the conflictual affects: repression and disavowal. When the repression of conflictual affects is too forceful, the intense pressure on the repressed content towards the internal world of the individual seems to transform those aspects of the external world that arouse or recall these affects into denial.

## SURREALISM AND PSYCHOANALYSIS

Begun as an investigation of poetic images and language, their sources, their nature, and specific features, surrealism is a movement of ideas, of artistic creation and action based explicitly on Freudian discoveries, which were used to develop an original theory of language and creativity. In later years it adopted Hegelian dialectics and Marxist-Leninist historical materialism. The “social and martial cataclysm” (Breton, 1934) provoked a revolt by an entire generation.

The movement was founded in Paris in 1924 by French poet André Breton, with the support of a group of poets and painters. The presence of Max Ernst, from Germany, Man Ray, from the United States, and Joan Miró, a Catalan, gave the group its international flavor. Surrealism’s goal was to “change life” (Arthur Rimbaud) by freeing humanity from the constraints of mental or social censorship as well as economic oppression: “Poetry is made by everyone. Not by one” (Lautréamont).

The project made little sense to Freud, who refused his patronage (Freud to Breton, 1933e [1932]; to Zweig, July 20, 1938 (1960a [1873–1939])). Breton visited Freud in Vienna in 1921 and corresponded with him in 1932 about *The Interpretation of Dreams*. In 1937 he asked him to contribute to a planned anthology (*Trajectoire du rêve*, 1938). Freud answered: “A collection of dreams without their associations, without understanding the circumstances in which someone dreamed, doesn’t mean anything to me, and I have a hard time understanding what it might mean to others” (Breton, 1938, I).

These associations were generally omitted by the surrealists when they narrated their dreams. They appear in André Breton’s *The Communicating Vases* (1932), but there the author, denying the “dream navel” for the sake of Marxist-Leninist materialism, felt he could use them to bring into focus all his dream thoughts. He claimed, contrary to Freud, that the dream was a creator, an instigator to action, and capable of dialectically resolving the contradiction between desire and reality. Surrealism ignored therapy.

There are several periods to the history of surrealism. Its “prehistory” dates from 1916 (Breton discovers Freud) to 1924. This was the period of the review *Littérature* (1919). Together with Breton, a group of young artists invented surrealist techniques intended to liberate the unconscious: automatic writing and drawing, hypnotic sleep, hypnagogic visions, dream narratives, group creation, oral and written games, collage, rubbings, decals, experimental photography and theater. The publication of the first *Surrealist Manifesto* (Breton, 1924) ushered in Surrealism’s formative period. The group had a journal of its own, *La Révolution surréaliste*. “We must be thankful for Freud’s discoveries,” wrote Breton, “the imagination may be on the point of winning back its rights.”

In 1927 André Breton, Louis Aragon, Paul Éluard, and Benjamin Peret joined the Communist Party. Breton did not, however, abandon Freud: “The Surrealism that, as we have seen, has adopted Marxist beliefs does not intend to treat lightly the Freudian critique of ideas” (Breton, 1930). Breton soon quit the Communist Party, which reproached him for his Freudianism. Surrealism embraced cinema (Luis Buñuel), the construction of objects (“Situation surréaliste de l’objet,” Breton, 1935), and produced important works of art in every field.

But in 1930, in his *Second Manifesto of Surrealism*, Breton acknowledged the existence of a profound crisis. The third period of Surrealism was about to begin. A new review was introduced, *Le Surréalisme au service de la Révolution*. In 1930 the review published two articles by the French-American psychoanalyst Jean Frois-Wittmann, in 1933 the Breton-Freud correspondence of 1932, a favorable critique of Jacques Lacan’s doctoral dissertation by René Crevel, and, also by Crevel, an attack on an article in the *Revue française de psychanalyse*. The review also published the first texts by Salvador Dalí, where he developed the idea of “critical-paranoia,” the use of the interpretative processes of paranoia for creative ends, and the exploration of the unconscious.

In 1933 *Minotaure* appeared. Although it was not the official voice of the group, it was strongly influenced by it. The first issue included articles on the “contributions of psychoanalysis.” Lacan and Dalí explained their conceptions of paranoia as an active psychic phenomenon, which Dalí compared with the passivity he associated with dreams and automatic writing. Several large-scale international exhibitions

confirmed the growth of surrealism around the world, a phenomenon that accelerated during the Second World War following the exile of Breton, André Masson, and Max Ernst in the United States, and Benjamin Péret in Mexico, and continued after the war.

Breton, the principal theorist of the group, maintained a close association with Freudian thought throughout his career. He was most interested in the logic of the unconscious, in conflicts between the ego, the id, and the superego, relating them to the process of artistic creation, to Freudian ideas of sexuality, fantasy, desire, repression, the death instinct, whose opposition to Eros he assumed to be dialectical (Breton, 1930), and especially to ideas about representation and perception (Breton, 1933). Beginning with his concept of “pure mental representation,” situated “beyond true perception,” he examined, in the context of the *Essais de psychanalyse* (1927), how the transition from the unconscious to the perception-consciousness system takes place in the creative individual. For Breton, as a reader of Freud, it was at the preconscious level that language and the traces of acoustic and visual perceptions were united and charged with affect. But Breton went further: he saw in these preconscious elements the raw material of creation, obtained by the removal of repression with the help of automatic writing and drawing. In creating a work of art, the artist would make the individual universal (Breton, 1935).

In a letter to Stefan Zweig, Freud, who had met Salvador Dalí in London, also associated the fundamental elements of the work of the artist with the preconscious, but he added a principle of economy: “From the critical point of view it could still be maintained that the notion of art defies expansion as long as the quantitative proportion of unconscious material and preconscious treatment does not remain within definite limits” (July 20, 1938). The specific task of the creative individual, the result of his “initiative” (Breton) is to manipulate the relation between unconscious and preconscious elements, and objectify them in a work of art. Repression would have to be removed using “surrealist techniques” (Breton). Freud’s meeting with Dalí seems to be the only time when Freud made an effort to understand the surrealist use of psychoanalysis and compare it with his own beliefs.

There were other points of contact between surrealism and psychoanalysis: Adrien Borel discussed his

surrealist experiences (1925); Salvador Dalí and René Crevel interviewed Jacques Lacan; Crevel, Antonin Artaud, and Robert Desnos were analyzed by René Allendy, which they later wrote about. André Embircos, a surrealist poet and theoretician as well as a psychoanalyst, founded, together with Marie Bonaparte, the Greek Psychoanalytic Society.

Lacanian thought developed throughout the nineteen-sixties, and, although it has a number of affinities with surrealism, it has always remained distinct. In 1971 the surrealist painter and philosopher René Passeron, with his research team at the C.N.R.S., founded *Études poïétiques*, which analyzed the creative process and made use of Freudian theory. A number of psychoanalysts (André Berge, Jean-Bertrand Pontalis, Guy Rosolato) were interested in the surrealists. As Breton found in 1934, the scope of surrealism, through the upheaval of sensibility it entails, “is socially incalculable.” As a movement it has frequently helped the spread of psychoanalysis.

## SWEDEN

Toward the end of the nineteenth century, the Swedish writer August Strindberg, wrote several plays, novels, and short stories dealing in a pertinent fashion with religion and doubt, the relations between men and women, the father and his position in the family. He described the hypocrisy and the destructive forces, the unconscious motivations, the representations and specific conflicts of man at the turn of the century. In 1893 the name of his contemporary, Sigmund Freud, was mentioned in Sweden for the first time in a medical review, along with those of Josef Breuer, Pierre Janet, and Jean Martin Charcot. The article, dealing with traumatic neuroses, was written by Frithiof Lennmalm, a professor of nervous pathology.

Freud wrote *On the History of the Psychoanalytic Movement* in 1914. Nine years later, in 1923, he felt obliged to specify in a note: "At the present time the Scandinavian countries are still the least receptive."

Psychoanalysis was introduced to Sweden in a manner that was at least unique. The two pioneers, Emanuel af Geijerstam, installed in Göteborg from 1898 to 1928, and Poul Bjerre, who worked in Stockholm and its surroundings for almost half a century, shared a similar attitude: they were both interested in psychoanalysis but were keenly critical of it. Geijerstam, a researcher and psychotherapist, approved of the theses of Alfred Adler and Carl Gustav Jung, without however being hostile to psychoanalysis. He wrote about Freud in 1902 but, from 1916 until his death, he persistently stressed that "anagogic analysis" constituted a progression on Freudian psychoanalysis. And when Geijerstam went on a study trip it was not to Vienna but to Zurich.

Poul Bjerre met Freud in December 1910. At a conference of the Swedish medical association the following year he introduced a part of Freudian theory. He went on to translate and in 1924 to publish some articles by Freud. From the time of his first encounter with the founder of psychoanalysis, and particularly after 1912, he was convinced that his own work was more important. For Bjerre, Freud had become bogged down in a mechanistic science that specifically prevented him from understanding the scope of psychosynthesis. Thus, for thirty years Freud was represented in Sweden by two physicians specializing in nervous diseases, having different points of view,

but who shared their refusal to take on board the totality of Freud's theory.

In the bulletins of the Swedish medical association we find criticism of Freud as early as 1910. The tone was set by two eminent physicians, Bror Gadelius (1862–1938) and Olof Kinberg (1873–1960). Gadelius, a psychiatrist, adopted the following stance: "Freud has overestimated the importance of sexuality; this is because of the nature of his clientele who, in a cosmopolitan city like Vienna, have a particular propensity for exaggeration. We cannot never overstress the fact that alongside the sexual complexes—whose role in the appearance of hysteria I in no way wish to underestimate—there exist other complexes charged with affect that can give birth to neuroses and hysteria, and how much these complexes go hand in hand with the "*Ich Triebe* [ego-instincts]." However, this point of view did not prevent Gadelius from acknowledging the merits of Freud's theory. In his important work on psychiatry, *Det mänskliga Själsivet* (The Human Soul), he specifically wrote that "in recent years, largely thanks to Freud and his school, much more attention has been accorded than previously to the importance of the sexual instinct in psychic life." To sum up, Geijerstam and Bjerre, who are generally considered to have introduced psychoanalysis to Sweden, and Gadelius, the greatest critic and opponent of the discipline, adopted a similar position.

Simultaneous with the growing interest in psychoanalysis in Sweden at the end of the 1920s, we find the increasing hostility of several influential physicians and academics. This resistance had already made its appearance in 1911 when Poul Bjerre tried to publish his conference, "The Psychoanalytic Method," in which he gave the most positive presentation of psychoanalysis and met with what he considered to be unjustified criticism. Presentations delivered within the framework of the Swedish medical association were normally published in the review *Hygiea*. Bjerre's was refused on the pretext that it was too long. In addition, Gadelius indulged in a methodical criticism of psychoanalysis in his work *Tro och helbräddagörelse. Jämte en kritisk studie av psykoanalysen* (Faith and Healing. A Critical Study of Psychoanalysis), published in 1934.

The review *Clarté*, which had socialist leanings, was a branch of the international Clarté movement and acted as a platform for psychoanalysis. In the latter

half of the twenties it published the texts of the Swedish pioneers of Freudianism. A few intellectuals believed that psychoanalysis could perhaps be used to formulate a radical theory of society. Interest in psychoanalysis was essentially linked to this aspect and was marked by its pragmatism. In the thirties literary circles little by little began to take an interest in psychoanalysis. This interest took many forms, including the creation of the review *Spektrum*, which published modernist poetry and translations of psychoanalysts like Anna Freud, Erich Fromm, and Wilhelm Reich. One of the Swedish pioneers, Per Henrik Törngren, who went into analysis with Ludwig Jekels a few years later, was part of the editing committee and published his own texts in the review. During this same period Sweden saw the publication of considerable extracts from *The Interpretation of Dreams*, as well as, in their entirety, *The Future of an Illusion* and *Civilization and Its Discontents*.

In August 1931 the pioneers of psychoanalysis in the Scandinavian countries met to discuss for the first time the formation of a psychoanalytic society. Among the participants were Sigurd Naesgaard, a Dane; Harald Schjelderup, a Norwegian; Vriö Kulovesi, a Finn, and Alfhild Tamm, a Swede. Tamm, who organized the meeting, had international experience and had been a member since 1926 of the Vienna Psychoanalytic Society. The Scandinavian group then split into two societies, a Danish-Norwegian society and a Finnish-Swedish society, for which she became the spokesperson. Tamm was the first woman psychiatrist in Sweden. Her theoretical work was of minimal importance. She invoked the tradition of the Enlightenment to combat prejudice with regard to masturbation and sought to understand the mechanisms of aphasia. Tamm was too much on her own for the first ten years to enable the society to become influential and the activities of the pioneers of psychoanalysis were somewhat limited.

The early thirties saw the arrival in Scandinavian countries of psychoanalysts who had been trained in Central Europe, particularly Vienna and Berlin. The Viennese Ludwig Jekels, a student of Freud's, settled in Sweden from 1934 to 1937. He saw his work as a training analyst in Stockholm as a difficult and thankless task and he finally left Sweden with the feeling that he had failed in his mission. As was common at the time, some Nordic pioneers made the journey to Vienna, Berlin, or Zurich to be analyzed by August Aichhorn,

Helene Deutsch, Paul Federn, Eduard Hitschmann, Oskar Pfister, or Harald Schultz-Hencke.

The Nordic psychoanalysts were looking for more competent colleagues than themselves who would be capable of training them, and from 1926 onward they began to organize themselves along the lines of the model fixed by the International Psychoanalytic Association (IPA). Scandinavian countries simultaneously witnessed the creation of new psychotherapy societies based on an eclectic concept of psychotherapy and the exclusion of some of the bases of psychoanalysis, such as the theory of infantile sexuality and dream theory.

In 1932 Norway saw the formation of the Nordisk Psykoanalytisk Samfund (Nordic Psychoanalytic Society) under the presidency of Alfhild Tamm with, among its most notable members, Poul Bjerre and Sugurd Naesgaard. In Denmark the Psykoanalytisk Samfund was founded in December 1933, with Swedish Poul Bjerre, Danish Sigurd Naesgaard, and Norwegian Irgens Stromme playing the leading roles.

During World War II the Dutch psychoanalyst René de Moncy, a personal friend of Freud, went to live in Sweden as a result of his encounter in Vienna with the Jewish Swedish psychoanalyst Vera Palmstierna, who had been in analysis with Freud. The couple settled in Stockholm. René de Moncy had played a major role in the Dutch Society and was to play an equally important role in Sweden during the eight years that he lived there. He was psychoanalyst to Ola Andersson (1919–1990) and the Hungarian psychologist Lajos Székely (1904–1995) who was practicing in Sweden. Székely was a Jewish émigré who had arrived in 1944 with his wife Edith, a physician and psychoanalyst. He had trained as an analyst firstly in Hungary, then in Germany and Holland during the 1930s, and finally in Sweden. He was to play a major role in the 1950s by providing analytic training for Swedish physicians and psychologists. He wrote on a variety of subjects, among them the links between the unconscious and creativity. Székely spoke several languages and published articles in English, French, Swedish, German, and Hungarian.

Stefi Pedersen (1908–1980) began her analytic training in the Berlin Psychoanalytic Institute. She was first analyzed by Otto Fenichel in Berlin and later joined him in Oslo. In Sweden—where she arrived with a group of Jewish children after a stay in Norway—she worked in the Swedish Psychoanalytic

Society (Svenska Psykoanalytiska Föreningen). She did a second analysis, this time as trainee, with René de Monchy. Her status as a member of the Society did not prevent her from adopting an independent and critical position. She was rather radical in her thinking and was attracted by Alexander Mitscherlich's theses. She wrote articles on vulnerability and the effects of the Nazi terror on psychoanalysts and clinical work. She published texts in English, German, Norwegian, and Swedish.

In August 1943, Tore Ekman (1887–1971) returned to Sweden after practicing for nearly twenty years in Berlin and Leipzig, as well as working as “*Lektor*” in Leipzig University. He trained under Therese Benedek, a close friend of Alfhild Tamm, and went on to play a role of capital importance in the Swedish Psychoanalytic Society, although he published very little. The psychoanalyst and theorist of science, Carl Lesche (1920–1993), a Finnish émigré in Sweden in the early 1950s, was also to occupy an important position in the Swedish Society between the 1960s and the 1980s. Among his influences were philosophers Wilhelm Dilthey, Edmund Husserl, and Karl-Otto Apel. The question of the classification of psychoanalysis was to take on a new dimension with him. He claimed that it was essential to define what made psychoanalysis more of a hermeneutic discipline than a natural science and to point out where it differed from psychotherapy. However, the influence of Lesche has not extended beyond the borders of Sweden.

Swedish psychoanalysts have done little research work and have made few important contributions to the history and theory of psychoanalysis. Ola Andersson's thesis, “Freud before Freud. The Prehistory of Psychoanalysis” (1962) constitutes a remarkable exception, as does academic Gunnar Brandell's more substantial essay, “Freud a Child of his Century” (1961). Ola Andersson wrote an in-depth study of the context in the history of ideas that saw the birth and evolution of Freud's thinking up to 1896, the time when he formulated the concept of psychoanalysis. Andersson stressed the importance of the influence of Herbart on Freud and conducted original research into the true identity of Emmy von N. Andersson and Brandell. Both took part in Uppsala University seminars conducted by Wilhelm Sjöstrand, a pedagogue and history enthusiast who organized seminars at the end of the 1950s, during the time Michel Foucault was teaching at this university.

Few psychoanalysts in Sweden have taken an interest in philosophy, the theory of science, or the history of ideas, just as few Swedish philosophers and academics have studied Freudian theory, with one exception: researchers in the psychology department of Lund University have taken an interest in psychoanalysis since the 1940s.

The Swedish Psychoanalytic Society now numbers more than one hundred and ninety members and there is ever growing interest in its training program. Toward the middle of the 1960s, voices were nevertheless raised in criticism of this training. In 1963 one of the society's psychoanalysts, Margit Norell, secretary to the training group, founded a work group with some of the analysts. This work resulted in 1968 in the formal creation of the Swedish Society for Holistic Psychotherapy and Psychoanalysis (SSHPP), which joined the International Federation of Psychoanalytic Societies (IFPS) in 1972. The SSHPP was initially supported by neo-Freudians, Erich Fromm, Frieda Fromm-Reichmann, and Harry Stack Sullivan. Harold Kelman, an American closely allied with Karen Horney, greatly contributed to its development. He organized seminars and was thesis director for many teachers. Toward the end of the 1970s, the SSHPP took an increasing interest in the theory of object relations, particularly in the work of theoreticians like Melanie Klein, Ronald Fairbairn, Donald Winnicott, and even Wilfred Bion. This same period saw intensified relations between the Swedish Psychoanalytic Society and the Swedish Society for Holistic Psychotherapy and Psychoanalysis, which began to study Freud more than ever. In May 1992 it was decided in agreement with the majority of the members to request affiliation with the IPA. Since then the IPA has never ceased to grow and it now numbers about seventy-five members.

In the 1970s, Swedes began to take an interest in Jacques Lacan and French psychoanalysis. This interest coincided with the publication in Swedish of the works of the French structuralists. A first translation of Lacan's work appeared, entitled *Écrits*, but containing less than 15 percent of the French edition of *Écrits*, and was followed by pirate publications of other translations of texts by Lacan. Inspired by Lacan's work, a few rare researchers in human sciences were seduced by the idea of establishing links between psychoanalysis and modern linguistics. For a short period during the 1970s and 1980s, psychoanalysts from South America and the United States trained psychologists and physicians at

Göteborg. In 1974 the Göteborg Institute for Psychotherapy (Göteborg Psykoterapi Institut) was founded, its founders, the Argentinean psychoanalysts Angel and Dora Fiasché, having been trained in their own country by the IPA. Dora Fiasché is a philosopher and still a member of the IPA. Angel Fiasché is a physician and has since left the IPA. The Fiaschés, who consider themselves to be socialists, are close to Kleinian psychoanalysis in terms of theory. They have worked with, among others, León Grinberg, Maria Langer, and Enrique Pichon-Rivière. They regularly return to Göteborg and several members of the Institute have been to Buenos Aires for professional reasons. In terms of its orientation the Göteborg Institute for Psychotherapy is eclectic and pragmatic and adopts a radical position on social questions. It now has more than forty members. Just as in Göteborg, the interest in the theoretical works of Melanie Klein has also increased elsewhere.

In Sweden the dawn of the twenty-first century has seen renewed criticism of psychoanalysis, coming in equal parts from academic psychology and biological psychiatry. This has not prevented psychoanalysts and researchers from all quarters from taking part in a joint project: the publication in Swedish by a major publishing house of the complete works of Sigmund Freud. In 2002, the review *Psykoanalytisk tid/Skrift* began publication in Göteborg; it is mainly orientated toward French psychoanalysis and thought.

## SWITZERLAND (FRENCH-SPEAKING)

Freud's ideas found their first echo in Geneva, a psychological milieu infused with scientific tradition and thus offering a more favorable reception in French-speaking Switzerland than in France. As early as 1900 Théodore Flournoy and his student and successor Édouard Claparède, professors of psychology in the science faculty of the University of Geneva, enthusiastically welcomed these new ideas and contributed to spreading them.

The psychoanalytic movement began in French-speaking Switzerland in the 1920s when the first French-speaking psychoanalysts joined the *Société suisse de psychanalyse* (Swiss Psychoanalytic Society), founded in Zurich on March 24, 1919, by Emil and Mira Oberholzer and Oskar Pfister. At approximately the same time, in September 1920, physician and non-physician psychoanalysts created the Geneva Psychoanalytic Society. This short-lived society, which was never enrolled with the International Psychoanalytical Association, disappeared at the end of the 1920s.

During the first period (1919–1952), the first psychoanalysts, for example, Charles Odier and Raymond de Saussure, worked to make Freud's ideas known not only in French-speaking Switzerland but also in Paris, where they helped found the *Société psychanalytique de Paris* (Paris Psychoanalytic Society), the *Revue française de psychanalyse*, and the *Conférence des psychanalystes de langue française* (Conference of French-Speaking Psychoanalysts). During the 1920s contacts with Swiss German psychoanalysts were rare, but came to be strengthened after the departure of the Oberholzer group in 1928 and under the presidency of Philipp Sarasin, who instituted the Swiss society's teaching commission. Psychoanalytic life in Geneva was initially dominated by Henri Flournoy, Charles Odier, and Raymond de Saussure, along with Charles Baudouin, who later founded his own school of psychoanalysis. Henri Flournoy (1886–1955), physician and psychoanalyst and son of Théodore Flournoy, trained with Johan H. W. Van Ophuijsen in Holland, then with Freud and Hermann Nunberg in Vienna. His teaching played an important role, and along with Odier, he introduced training analysis to French-speaking Switzerland. Odier set up in Paris in 1922, and Saussure followed suit in 1937. Marguerite A. Sechehaye (1887–1964) developed symbolic realization, a method of psychoanalytic therapy for schizophrenics.

Prior to the Second World War, psychoanalysis began to spread through French-speaking Switzerland outside of Geneva. In the Valais canton its development was linked to Dr. André Repond (1886–1973), director of the Hôpital de Malévoz psychiatric clinic, as well as Dr. Norbert Benoziglio and Germaine Guex, who helped create the first psychoanalytically informed medical-psychological consultations. The outbreak of World War II saw the return of Odier to Switzerland to settle in Lausanne, whereas Saussure left for the United States in 1940, where he remained until 1952.

As soon as he returned to Geneva in 1952, Saussure gave a distinct impetus to psychoanalysis in French-speaking Switzerland by organizing training. In Geneva he was assisted by Michel Gressot, physician and psychoanalyst, then in 1956 by Marcelle Spira, a Swiss psychoanalyst trained in the Melanie Klein school in Argentina, and in Lausanne he was assisted by Germaine Guex, Marcel Roth (1911–1992), Etiennette Roch-Meyerhof (1914–1989), and Madeleine Rambert (1900–1973), child psychoanalyst. These psychoanalysts had a lasting influence by virtue of their scientific accomplishments and the training they provided for many psychoanalysts from various parts of the world. They were later joined in Geneva by Olivier Flournoy, son of Henri, who trained in Paris and the United States, and in Lausanne by René Henny, child and adult psychoanalyst and professor of child psychiatry, and by Christian Müller and Pierre-Bernard Schneider, who were psychoanalysts and directors of psychiatric institutions. René A. Spitz stayed in Geneva for six years during the 1960s and contributed to training there. Julian de Ajuriaguerra, director of the psychiatric institutions at the University of Geneva from 1959 to 1973, and René Diatkine, on regular visits from Paris, also stimulated the development of child and adult psychoanalysis. In the Tessin canton, the Swiss Italian region under the authority of the teaching commission of French-speaking Switzerland, Pier Mario Masciangelo organized psychoanalytic training from 1959 onward.

The Centre Raymond de Saussure (Raymond de Saussure Center) was inaugurated in Geneva in 1973. This equipped French-speaking Switzerland with premises specifically for psychoanalytic seminars, conferences, and a library. Prior to that, meetings were organized in university psychiatric institutions. From this point onward psychoanalysis developed considerably, particularly in Geneva, around Janice

de Saussure, Raymond's wife, an active member and vice president of the International Psychoanalytical Association, as well as around Marcelle Spira, Olivier Flournoy, and Claire Degoumois. In Lausanne psychoanalysis developed around Marcel Roch, Étienne Roch, and René Henny. In the 1990s there were too many French-speaking Swiss training analysts to mention them all, yet it may be helpful to cite those who have made names for themselves through their psychoanalytic publications. Some of them practice as psychoanalysts while occupying positions in university psychiatric institutions for adults, like André Haynal and Antonio Andreoli; in institutions for children, like Bertrand Cramer, Juan Manzano, and Paco Palacio; and in institutions for adolescents, like François Ladame. Others engage mainly in private psychoanalytic practice, like Georges Abraham, Graziella Nicolaïdis, Nicos Nicolaïdis, Danièle Quinidoz, and Jean-Michel Quinodoz, all based in Geneva. Psychoanalysis in Switzerland is characterized by pluralism, a fact reflected in the variety of schools of thought, French-speaking psychoanalysts being influenced by French psychoanalysis, as well as British, mainly Kleinian, psychoanalysis, and German-speaking analysts being influenced mainly by ego psychology.

Psychoanalytic institutions have adopted a federalist structure that reflects Swiss trilingualism (German, French, and Italian) and its cultural diversity. For this reason the activities of psychoanalysts in French-speaking Switzerland are centered around institutions that are both national (monthly meetings of the Société suisse de psychanalyse with simultaneous translations, generally held in Berne) and regional (meetings in the Centre Raymond de Saussure in Geneva). Daisy de Saugy, historian and psychoanalyst, is responsible for keeping the archives.

The entirely bilingual German-French *Bulletin de la Société suisse de psychanalyse* appeared from 1965 to 1969 and then appeared regularly twice a year from 1979 onward.

In French-speaking Switzerland other trends now claim to represent psychoanalysis, but their practice and technique is closer to psychotherapy than to the psychoanalysis instituted by Freud. Geneva has a Charles Baudouin center for psychoanalysis and psychotherapy, as well as a Jungian group, and a Freudian study group unites Lacanians around Mario and Mireille Cifali in Geneva and around François Ansermet

in Lausanne. This group has published the journal *Le Bloc—Notes de la psychanalyse* since 1980.

## SWITZERLAND (GERMAN-SPEAKING)

Switzerland was the first country, and Zurich and Geneva the first cities outside of Vienna, where psychoanalysis found a corresponding echo. From Zurich it went on to find its way into academic psychiatry, which developed modern psychodynamic psychiatry. As elsewhere, German-speaking Switzerland had its rifts and defections. Some particularities of the country helped contribute to this evolution: Switzerland is a federation of small states (cantons) professing different religions, speaking different languages, and asserting their own autonomy. Individualism and particularities, alongside tendencies toward pragmatic egalitarianism, are part of the national tradition. There are also great class differences.

The two psychiatrists from Freud's generation who paved the way for the introduction of psychoanalysis in Switzerland represent this tradition in a particular manner: Auguste Forel (1848–1931), a French-speaking Swiss who directed the Burghölzli university asylum in Zurich, and his successor from 1898, Eugen Bleuler (1857–1939). They were both close to the patients through daily contact and were socially very committed. Forel devoted a lot of time to hypnosis and sexual education, but kept his distance from psychoanalysis, while Bleuler greeted Freud's book on

aphasia (1891b) with enthusiasm and recognized the global significance of *Studies on Hysteria* (1895d). "My personal experience with schizophrenics confirmed Freud is right, much to my surprise," he wrote in 1910, when successfully defending psychoanalysis against attacks from every quarter. His book on schizophrenia (1911) is influenced by psychoanalysis and in 1901 he encouraged his new assistant, Carl Gustav Jung (1875–1961), to study *The Interpretation of Dreams* (1900a), which had just been published, and to apply the "test of free association" to patients suffering from dementia praecox. Psychoanalysis thus acquired new certainties and Jung met Freud in 1907. Led by Jung, a group of his young colleagues, among them Franz Riklin, Alphonse Maeder, Johann Jakob Honegger, and Ludwig Binswanger, were fired with enthusiasm for psychoanalysis. "The nucleus of the small band who were fighting for the recognition of analysis," as Freud described it (1914d), consisted of foreigners who were attracted by the worldwide reputation of Bleuler's clinic and who came there to train. This was the case of Karl Abraham, Max Eitingon, Hermann Nunberg, Johan H. W. Van Ophuijsen, Abraham A. Brill, Sabina Spielrein, and many more. The essential contribution of the Zurich group consisted of its in-depth research into the psychoses. In Jung, Freud found an expert partner who was gifted with a creative imagination and interested in the history of cultures and religions. The publication of the five volumes of the *Jahrbuch* between 1909 and 1913, the creation of a psychoanalytic association in Zurich in 1907 and its transformation into a regional group of the International Psychoanalytic Association (IPA), founded in 1910, were very largely due to Jung's exuberant activity.

In 1908 the Zurich pastor Oskar Pfister discovered the extent to which psychoanalysis could contribute to spiritual directorship and teaching. He became a zealous propagator, especially in teaching circles, for example with Ernst Schneider, director of a seminary, and his student Hans Zulliger in Bern, whereas theologian Paul Häberlin, a pedagogue and an influential professor of philosophy, came into contact with psychoanalysis through Ludwig Binswanger.

This whole flowering was quickly swept away by the split between Jung and Freud in 1913, when the majority of the Swiss followed Jung. The theoretical differences centered around Jung's "dilution" of the theory of the libido, but the difficulty of the Swiss in separating themselves from the outside world through

principles also had a role to play in it. “Jung was Freud’s great disciple who tried by diplomatic means to reconcile the world to psychoanalysis,” as L. Marcuse wrote with much insight (1956).

The Swiss Psychoanalytic Society (SGPsa) was founded in Zurich on March 21, 1919, and still exists to this day. Pioneering member Oskar Pfister worked there with younger colleagues such as Emil Oberholzer and his wife Mira Gincburg, Hermann Rorschach, Hans Zulliger, and many more. What changed was the growing professionalism; candidates were progressively required to have really experienced analysis. Eminent members like Ernst Blum (Bern), Philipp Sarasin (Basel), Henri Flournoy, Charles Odier, Raymond de Saussure (Geneva), and the two Oberholzers (Zurich) had been analyzed by Freud himself. This fact had a stabilizing and unifying influence until the middle of the twentieth century. But conflict grew rapidly; it was triggered by technical questions, such as short analyses without elaboration of the transference and resistance, a technique introduced by Oskar Pfister in the heroic period.

Emil Oberholzer, the president, hit on a summary solution in 1928 by founding a new society, the Schweizerische Ärztgesellschaft für Psychoanalyse (Swiss Medical Society for Psychoanalysis), from which “lay” members, like Oskar Pfister, were automatically excluded, but also Zulliger. The IPA did not recognize his group and after a few years it had no more than a token existence.

With fewer members (forty members in 1927, five of them residents of French-speaking Switzerland, thirty-three members in 1929) the SGPsa enjoyed a peaceful existence until 1961 under the judicious presidency of Philipp Sarasin. Training requirements and conditions of membership had become stricter. The SGPsa did not have many representation activities, but some of its members were known for their publications and local actions that helped spread psychoanalysis. Basel became particularly important when Heinrich Meng moved there from Frankfurt and was appointed professor of “psychic hygiene” at the university. In a collection devoted to this subject he published not only his own works, but also important works by members of the SGPsa, for example, Rudolf Brun’s *General Treatise on the Neuroses* in 1942 and, in 1944, *Trieb und Kultur* (Instinct and Culture) by Hans Christoffel, a native of Basel. This collection enabled the representatives of the different trends in the intense

intellectual life of Basel to familiarize themselves with the treasures of psychoanalytic thought. The first edition of Oskar Pfister’s work, *Das Christentum und die Angst* (Christianity and Fear) appeared in 1944.

A new split appeared after World War II with the creation of “*Daseinsanalyse*” (“existential analysis”; Ludwig Binswanger and Maeder Boss), an attempt to base psychoanalysis on the philosophy of Husserl and Heidegger. A few analysts, who generally remained true to Freud, found elements there, for example, Gustav Bally and Ernst Blum. Rudolf Brun, of Zurich, violently opposed his strictly biological approach to this trend. But the real split took place in Germany with Alexander Mitscherlich in relation to a clinical case (1950).

In the meantime, the next generation, the “descendants of Freud,” were actively engaged with two of Brun’s students: Paul Parin (born in 1916) and Fritz Morgenthaler (1919–1984). Parin (1949) appealed for greater consideration for the social criticism function of psychoanalysis, and Morgenthaler (1951) illustrated by means of a case history his virtuosity at picking up on unconscious intentions. Both of them represented a renewal of analytic thinking with the same unusual intensity and radicalism that we can also detect in their work in ethnopsychanalysis (1963, 1971). For two decades they represented the center of gravity of psychoanalysis in German-speaking Switzerland. They were relentless guardians of the SGPsa training institute until, in the wake of May 1968, they demanded greater participation for candidates at the Zurich seminar of the SGPsa. As a result of the activism of extreme-left candidates this led, after long discussions in 1977, to the secession of the Zurich Psychoanalytic Seminar (PSZ), which declared itself autonomous and in which members became psychoanalysts upon their own authorization. For this reason, and also because an eminent group of analysts, primarily Parin and Morgenthaler, declared themselves in sympathy with the PSZ, there was a massive influx of analysts (about eight hundred participants in the eighties with a delegation at Bern and branches in Germany [cf. *Luzifer-Amor*, 1993]).

The SGPsa had to be reconstituted in 1977 as the Freud-Institut Zürich. The situation stabilized again, and the Basel and Bern groups, which were growing in importance, played a major role in this. One consequence of the crisis, however, is that psychoanalysis in Switzerland is, as of 2004, mainly concentrated in the

French-speaking part of the country. As of 2003 lists members in the SGPsa. In 2004 there were 45 training analysts who bore the main responsibility for passing psychoanalysis along to Swiss students. Twenty-seven of them worked in Francophone Switzerland (including a few in the Italian-speaking parts); 18 worked in the German-speaking areas.

## SWOBODA, HERMANN (1873–1963)

Hermann Swoboda, professor of law and philosophy, was born on November 23, 1873, in Vienna, where he died on June 18, 1963. The son of a pharmacist, he attended the University of Vienna, where he also spent his career. After receiving a doctorate in law in 1897 and in philosophy in 1901, Swoboda was appointed privatdocent in psychology four years later. He was named professor extraordinarius (full professor without chair) in 1925. By his wife, Marie Felgel von Farmholz, he had three children. Passionate about music, Swoboda became intrigued with studies of the periodic rhythms in human life. He seems to have experienced financial difficulties during the course of his career. His last publication dates to 1940.

Swoboda's encounter with psychoanalysis was short but explosive. In correspondence with Otto Weininger

from 1899 to 1902, he exchanged numerous ideas that helped Weininger to develop his monograph *Sex and character* (1906), published in German in 1903. Several years after Weininger's suicide in 1903, Swoboda wrote a book about his friend, *Otto Weiningers Tod* (The death of Otto Weininger), published in 1911. Meanwhile, in 1900 Swoboda began an analysis with Freud that lasted only a few months. During one of their sessions, Swoboda remarked on contrasting fantasies of "overcoming" and "succumbing," as he later explained, "now *incubus*, now *succubus* toward the events." Freud explained the contrast by reference to the "bisexual disposition of each human" (Swoboda 1906, p. 7; quoted in Schröter, p. 151). Swoboda immediately conveyed this information to Weininger, who incorporated it into *Sex and Character*.

This chain of events would become one of the arguments by which, in 1906, Wilhelm Fliess accused Freud of having transmitted ideas to those he characterized as plagiarists of his work: Weininger (on bisexuality) and Swoboda (on periodicity). In addition, in August 1901 Swoboda advised Weininger to visit Freud to seek his help in finding a publisher for his manuscript. In 1904 Swoboda published *Die Perioden des menschlichen Organismus* (Periodicity in the life of the human organism) and sent a copy to Fliess, who at the time received it with pleasure. (Extracts can be found in Porge, 1994.) Only after reading *Sex and Character* and learning from Freud that Swoboda was his pupil did Fliess initiate accusations of plagiarism. Swoboda reacted by suing for defamation and lost; he also published the pamphlet *Die gemeinnützige Forschung und der eigennützige Forscher* (Research of interest to the public and the researcher's own self-interest; 1906). (Again, extracts can be found in Porge, 1994.)

In *Die Perioden* Swoboda presents his psychological experiments on the spontaneous recurrence of memory representations after 18-hour, 23-hour, and 23-day periods. He included an adulatory chapter on Fliess's work but did not mention Freud's *Interpretation of Dreams* (1900a). These works stand against Wundt's associative psychology. In 1917, in *Siebenjahr* (Septenary periods), Swoboda suggested that there are seven-year rhythms. Freud discusses Swoboda's theses in the revised editions of *The Interpretation of Dreams*.

## SYMBIOSIS/SYMBIOTIC RELATION

In Margaret Mahler's theory of the mother/child relationship, the symbiotic relation is a very early phase of development that follows the phase of normal primary autism and precedes the separation/individualization phase. The symbiotic relation is characterized by an omnipotent sense of the total enmeshing of mother and child, who thus form a "unity of two."

The concept of symbiosis and symbiotic relation came out of Margaret Mahler's observations of the mother-baby relationship, and was later applied to clinical practice. Although a psychological concept, it is also part of the phenomenology of object relations.

Its origins can be found in the description of the "purified ego-pleasure" (1915c) and the "oceanic feeling" of Freud (1930a [1929]), what Margaret Mahler considered as the experience of a baby who has not yet differentiated its identity from that of its object.

The specific features of symbiosis can best be seen against the description of the phase that precedes it as well as those that follow it: as Margaret Mahler points out, symbiosis overlaps the other phases. In the very first phase of life, that of normal primary autism, narcissism is absolutely primary and under the sway of physiological rather than psychological processes. There is a prolongation of the fetal state as Freud described it in 1911; its aim is the homeostatic equilibrium of the organism with the environment (1911b). The shell surrounding this egg forms a protective barrier that is not positively cathected.

With symptoms, the shell begins to crack and—an essential point for Mahler—cathexis passes from the center to the periphery. This marks the beginning of a displacement from the self to the object that is still only obscurely perceived. The object exists in a partial state: that is, it is only apprehended through parts of the body that are experienced as having an object nature. The fully external character of the object is not yet constituted.

From the point of view of energy, while the primary autistic phase is characterized by the existence of an "undifferentiated" energy, differences start to appear in the symbiotic phase between the "good" or "bad" qualities of experience, making of this phase a "quasi-ontogenetic basis for splitting," long before the separation between the ego and the object occurs. This phase starts around the second month of life, and reaches its peak at around four or five months, just at the time when the phase of separation-individuation is filtering into the symbiotic relation. The relation between the inside and the outside of the body emerges progressively from what Margaret Mahler calls a "hallucination" or a "somato-psychic fusion."

Although Margaret Mahler is here describing a state rather than a defense enabling one to reach that state, she thinks that projective mechanisms play a role in maintaining, thanks to a displacement outwards of anything that disrupts or disturbs the symbiotic relation. In her view, failure in the development of the processes of individuation makes the child regress to the stage of symbiotic relation with the mother, thus running the risk of shutting it off in a psychotic disorganization, a "symbiotic psychosis" characterized by a delirious state of undifferentiation between the ego and the object. Leaving the symbiotic phase entails the risk of depression.

Even if Margaret Mahler sees it as closer to secondary narcissism (Freud), the concept of symbiosis can constitute a bridge between primary and secondary narcissism. It corresponds to what René Spitz calls the “pre-objectal stage” (1965), which in his view partly covers that of the symbiotic phase. But René Spitz links these processes to those of primary identification with the mother. Donald Winnicott also comes close to the description of the mother-baby symbiosis with his concept of “primary maternal preoccupation,” in which the state of maternal hypersensitivity leads the primitive mother-baby couple to live in a particular environment, a prolongation of the uterine environment in which communication between mother and child is immediate and not subject to the vagaries of separation. Wilfred Bion (1970), in his work on bonding, takes up the idea of a so-called “symbiotic” relation being set up between the leader of a group and the group in question. In this case, the encounter is beneficial for both parties, as opposed to the indifference of the commensal bond and the destructivity of the parasitic bond.

Margaret Mahler did not sufficiently develop the link with psychoanalytical clinical practice and in consequence, left to one side the active role played by the processes of identification. Unlike Melanie Klein, who considers the role of anxiety right from the start of life, in the act of introjection-projection on the basis of narcissistic and secondary identifications, Mahler wants to separate the early infantile problematic from the necessary perception of separation—whatever form it might take—between the ego and the object. We can say that the idea of a fundamental “transitionality,” as developed by Winnicott, leading from the fetal state to the individuation of the human being, is very influential in Mahler’s thinking on the concept of symbiosis.

In spite of the deep truth that it contains, insofar as it presides over all psychological development, in Margaret Mahler and those who place it at the center of their theorizing, this idea tends to evade the question of the suffering of mourning, which presides over any passage towards individuation, or towards “psychological birth,” as Mahler calls it.

## **SYMBOL**

From a psychoanalytic perspective, the symbol refers to all indirect and figurative representations of unconscious desire (symptoms, dreams, slips of the tongue, parapraxes, etc.). This conception of the unconscious symbol depends on a relation of general substitution where one thing takes the place of another; but unlike the term’s conventional meaning, defined by the conjunction between the symbol and what is symbolized, the unconscious symbol is defined by a disjunction between symbol and symbolized.

Freud clarified this conception of the symbol following the “Project for a Scientific Psychology” (1950c [1895]), describing it as a mnemonic symbol subsequent

to his research into hysterical symptoms. In the case of a “standard” symbol, the connection between the symbol and what is symbolized remains, as in the example that Freud gives of the knight who fights for his lady’s glove but who knows full well that the glove owes its importance to her. In this synecdoche of part for whole the conjunction of meaning is clear. With hysteria however, it is the loss of the connection between the symbol and what is symbolized that is noteworthy: “The hysteric, who weeps at A, is quite unaware that he is doing so on account of the association A-B, and B itself plays no part at all in his psychological life. The symbol has in this case taken the place of the thing entirely” (1950c, p. 349).

As a result of this disjunction of meaning, the affect that was bound to what is symbolized attaches itself to the symbol. In both instances the substitution assumes a similarity between the symbol and what is symbolized (A/B), and thus emerges the tension at the very heart of symbolic substitution between a nonsensical literal interpretation and a symbolic interpretation that supports a surplus of meaning because of the very denial or negation [*négation*] precluding the pure and simple assimilation of the two terms in question. In the case of the hysterical symbol, it is the impossibility of invoking denial that would explain the symptom’s apparent absurdity.

What might appear here as a simple relation of substitution between two terms—the symbol and what is symbolized—allows, in fact, for an interpretation where meaning might be attributed according to context. The symbol’s abundance derives from its polysemy, but only reference to a regulated system of interpretation can lend precision to the symbol, hence the requirement to define the system and determine what it is that permits this regulation.

Freud hesitated between two rules of interpretation. Either it depends on individual context—specifically, a person’s individual associations, which permit them to discover hidden meaning, as in the hysterical symptom or in dreams—or on collective context—specifically, a work of transindividual culture that clarifies meaning, as in “symbolic dream-interpreting” (1900a, p. 97). On the subject of the dream, he depicted sexual symbols that did not arouse associations for the dreamer but that the analysis would supply by referring to the symbolism of collective compositions (myths, tales, proverbs, songs, etc.); this enabled him to rediscover the correlation between the manifest and latent symbol.

This obscure and concealed comparability appeared to be based on a relationship of equivalence (a tree for the male sex organs, a cave for the female sex organs), but also occasionally on a relationship of proximity (nudity symbolized by clothes and uniforms).

If symbols are multiple, the field of what is symbolized is highly limited, relating ultimately to the domain of sexual instinct. The theory of a predetermined and stereotyped sexual symbolic, in the service of an oneiric representability, corresponds with Freud’s wish to contest Jung’s theory of symbolism, whose conception of the “libido-symbol” ends up denying the importance of the sexual instinct in psychic behavior. Ernest Jones’s key paper, “The Theory of Symbolism” (1916), seeks moreover to reinforce the Freudian theory of “symbolic dream-interpretation”; for Jones all true symbolism is the substitute for repressed drives/instincts: “Only that which is repressed is symbolized and only that which is repressed requires symbolization.”

It is a question then of finding a rule of interpretation that can substantiate the discovery of the unconscious. To back up his theory Freud adopted the linguist Hans Sperber’s theory of a primitive language [*langue*] parallel to the primitive language system [*langage*] of sexuality in which all symbolic connections would appear as traces and relics: “That which today is linked symbolically was in all probability formerly linked conceptually and linguistically.” Freud is thus compelled to set out from a real anteriority, in a proximate association, or identity even, that belongs, through a similar association, to language and to a process of symbolization that is inseparable from the work of instinct.

Thus, the theory of the symbolic designates more of a structural demand than a clinical truth. In clinical terms, Freud always mistrusted instant symbolic interpretations and preferred to rely on individual associations that allowed him to uncover a linguistic usage that would justify the use of a symbolic representation.

Freud’s theory of the symbol cannot therefore be separated from a conception of symbolization, which bears out the fact that the psychoanalytic approach is more a tripartite theory of interpretation, where it is necessary to consider the subject who symbolizes, than a theory of translation seeking to proceed via the simple substitution of one term for another. Freud’s

uncertainty demonstrates the difficulty of constructing a theory of the symbol while making allowances for the symbol both as a motivated sign (the symbol for Ferdinand de Saussure, corresponding to a natural analogy between symbol and symbolized) and as an arbitrary sign (the symbol for Charles Sanders Peirce, corresponding to the standard rule governing the signifier and signified, in other words to the arbitrary linguistic sign).

What is problematic with this theory of the symbolic is the conception of symbolization as a failure of sublimation rather than as its accomplishment. This opposition marks a return in too radical a fashion to the opposition between a symbolism of the unconscious and a symbolism of language. Post-Freudian theorists have sought to reconcile these different aspects of the symbol, whether through a semantic perspective associated with the image, as in the case of Melanie Klein and post-Kleinian theorists, or through a syntactic approach associated with language, as in the case of Jacques Lacan. It is a question in both cases of reviving the Freudian intuition of the symbol as the result of a process of symbolization. To Klein's interpretation of the imaginary, which retains a certain psychological realism, Lacan opposed reference to the symbolic order that represents an intellectualization of the unconscious.

The approach to symbolization as a process presupposes the preservation of that which Freud, rather awkwardly, wished always to have prevail: namely, the necessity for a dualism, for the articulation of a viable distinction between the symbolism of the image and the symbolism of language. The truth of Freudian empiricism in the theory of primitive language, like the original proximity of the symbol, is no doubt to mark the importance of this fundamental proximity of the psyche with the body as the juncture between representation and affect, between meaning and primitive animism, characteristic of the hallucinatory satisfaction of desire.

## **SYMBOLIC EQUATION**

The concept of *symbolic equation* appears for the first time in Hanna Segal's first paper, "Some Aspects of the Analysis of a Schizophrenic" (1950), in connection with her schizophrenic patient's difficulty with symbolizing. The patient made no distinction between symbols and the objects they symbolized. For him, being like something and being something were the same. Symbols were equivalent to the things symbolized. There was an unconscious equation between the two. In her second paper, "A Psycho-Analytic Contribution to Aesthetics" (1952), Segal describes symbol formation as a precipitate of mourning.

In "Notes on Symbol Formation" (1957), Segal formulates a theory of the dynamics of symbol formation and the role played by projective identification. Symbolism as a tripartite relation among self, object, and symbol. When projective identification is excessive, part of the ego becomes identified with the object, and the symbol, a creation and function of the ego, becomes identified with the object symbolized. In the depressive position, the object is given up, and a symbolic representation of the object is formed in the ego in the process of mourning. Segal offers the differentiations in Figure 1.

In normal repression, there is communication between the unconscious and the conscious through symbols. In the kind of repression that Freud called excessive, the unconscious is split off from the con-

FIGURE 1

Symbolic Equations	Symbols
<ol style="list-style-type: none"> <li>1. Arise in the paranoid-schizoid position through projective identification.</li> <li>2. The symbol's own characteristics are not recognized. They are treated as though they were the original object.</li> <li>3. The symbolic equation is used to deny the loss of the object.</li> <li>4. scious, and in the return of the repressed, consciousness is invaded by concrete symbols, as in hallucinations.

Under stress, there may be a regression from symbolic functioning to symbolic equation. For instance, in the schizophrenic patient described in Segal's first paper, thoughts and words formed in the depressive position became concretized, so that the patient could not, for instance, use names, because he experienced a name as biting into the person named. In "Depression in the Schizophrenic" (1956), Segal cites the example of a girl who wrote a story about Lancashire witches and in a breakdown felt herself persecuted by Lancashire witches.

In her later papers, Segal, following Wilfred Bion, views pathological projective identification, not excessive projective identification, as responsible for disturbances in symbol formation. She made connections between her work on symbol formation and Bion's alpha- and beta-elements.

## SYMBOLIC REALIZATION

Symbolic realization is a psychoanalytically-inspired technique that is used in psychotherapy with schizophrenic patients.

In 1947, in a supplement to the *Revue Suisse de psychologie et de psychologie appliquée*, Marguerite A. Sechehaye (1887–1964), a psychoanalyst in Geneva, described the technique in the article: "La réalisation symbolique: Nouvelle méthode de psychothérapie appliquée à un cas de schizophrénie (Symbolic realization: A new method of psychotherapy applied to a case of schizophrenia). In 1950 the patient's own account of her illness and treatment was published, as she described them to her therapist. It was accompanied by a psychoanalytic interpretation of how the therapy developed (Sechehaye, *Journal d'une schizophrène* [Autobiography of a Schizophrenic Girl]).

Symbolic realization is a psychotherapeutic technique that combines the active support of the psychotherapist for the psychotic patient (this implies adjusting the frame) with interpretations of the patient's unconscious fantasies in terms of libidinal development. This approach is based on the importance Sechehaye accords to real frustration in the disintegration of the ego, which lies at the root of schizophrenic psychosis. It follows from this perspective that the role of the therapist is to seek to satisfy the fundamental needs of the patient and repair the initial frustrations not only by interpreting the patient's fantasies but also by establishing a real, even a physical, contact with the patient. This attitude is considered to help the patient to regress in order to be able to progress, resume the interrupted course of infantile development, and thus recover the sense of reality.

This notion, which is akin to that of therapeutic regression (Donald W. Winnicott, Michael Balint), represents a pioneering and original approach to psychotic disorders. However, the active intervention of

the therapist in the patient's life in order to satisfy her needs constituted an acting out that was not interpreted as such in a transference the importance of which was underestimated.

## **SYMBOLIC, THE (LACAN)**

For Jacques Lacan, *the symbolic*, or the *symbolic order*, is a universal structure encompassing the entire field of human action and existence. It involves the function of speech and language, and more precisely that of the signifier. It appears as an essentially unconscious, latent apparatus.

The idea of the symbolic is contemporaneous with the birth of psychoanalysis since the traces linked to repressed infantile sexual experiences are symbolically reactualized in adulthood as defensive symptoms. The fact that Freud emphasized memory and reminiscence in his earliest theoretical work is enough to indicate the primacy of symbolic traces in psychopathology. The Oedipus complex, the avatars of the primal relationship with the mother, and the function of the dead father all take on their importance because they function on the same axis where the signifier emerges as

the mainspring of the symbolic. As Lacan wrote in the "Function and Field" essay, "Freud's discovery was that of the field of effects, in man's nature, of his relations to the symbolic order" (2002, p. 63). Further, Lacan's entire body of work testifies to the fact that he was trying to restore the symbolic to its full status in psychoanalysis.

The impact of the symbolic is felt on several levels: first in limits placed on social alliances and relationships by a certain number of mechanisms, for which the traditional model is the pact. At another level, the symbolic intervenes in the form of discrete elements, namely signifiers, that are overdetermined as the prevalent forms of the imaginary, affective relations, and the choice of sexual objects.

Lacan repeatedly referred to the canonical example of the "child with the reel" from *Beyond the Pleasure Principle* (Freud, 1920g) in order to emphasize that the mark of the absence of the beloved object is realized by the fort-da game of phonetic opposition that represented the appearance and disappearance of the mother. This correlation between the missing object and a symbolic signifying mark inscribed in language removes the object's concrete features and grants it a level of conceptual force.

The emergence of the signifier in the symbolic is best shown by the infant's initiation into the dialectical field of demand and desire, for it is in the experience of vital distress and the appeal to a caretaker that a split occurs. Even if this caretaker satisfies a vital need, there is still a gaping lack of being. This equivocal division is brought about by the signifier of the first demand. It brings with it consequences beyond the frontiers of infancy and perpetuates a radical division in subjectivity. It also grants to the unconscious Other its symbolic place because the ultimate meaning of this signifier is assumed by the subject to reside in this other scene.

In the demand, the inexpressible, originally repressed part of the signifier becomes the cause of desire by the process of repetition. Later, the Oedipus complex normalizes the structure by assigning a definitive meaning to a lack previously put in place—namely that the mother, as primordial Other, is assumed to possess the phallus, and the father, by prohibiting incest, reinforces the fact that the phallus is absent by conferring on it a symbolic function. Thus the father's prohibition makes the phallic signifier cause desire in the very place where repression had left

a hole. From that point on, this operation links the lack (symbolic castration) to the law of language, in order to make it reappear as symbolic debt. The symbolic order is thus constituted as an autonomous system of signifiers, a system that is governed from the Other and to which the subject is subjugated. The primary character of the symbolic led Lacan to conceive of it as one of the dimensions constituting the Borromean knot, a formalized structural schema that also includes the imaginary and the real.

## **SYMBOLISM**

The evolution of representational capacities and symbolic expression has contributed essentially to human thought, language, and culture. There are different symbolic processes, and the symbolism particularly described and interpreted in psychoanalysis differs, in many respects, from what is designated by the same term in other disciplines. While psychoanalysis is interested in language and other forms of symbolism, psychoanalytic or unconscious symbols were early recognized as universal and ubiquitous expressions of the dynamic unconscious mind. In ordinary linguistic usage, a flag may represent a country, and a cross may

represent a Christian religious reference. In the case of the flag and the cross and other emblems or pictorial metaphors, the relationship between the signifier and its referent is both within conscious awareness and in accord with social and cultural convention. In contrast to psychoanalytic symbols, these symbols are consciously understood by the individuals within a society in which they are used. They are not disguised, and they serve conscious communication.

In contrast, psychoanalytic symbols are usually disguised by and from the individual who uses them and may not serve any conscious or intended internal or external communication. The meanings of psychoanalysis symbols are relatively independent of social, cultural, and historical settings and are neither taught nor learned. Psychoanalytic symbolism is not a product of education and evolves spontaneously in human development. Given the fact that these symbols are universal in individuals as well as cross-cultural, the capacity for such symbols is innate, though their development depends upon human development and experience.

Psychoanalytic symbols emerge as a result of the interaction of the instinctual drives, defenses, and other ego functions with the developmental experience of the infant and child. Although psychoanalytic symbols may take on additional meanings in later phases of development and may become linked to metaphor, they are essentially products of archaic, infantile processes. These symbols emerge in conjunction with the development of the body ego and object relations, so that there are symbols of both body parts and of the parents and siblings. Spontaneous in origin and typically sensorial, the symbols create a concrete bridge between the body and the primary object world. In a “symbolic equation” (Segal, 1978), the person cannot distinguish between the symbol and the thing symbolized. The symbolic equation denies separateness between self and object, whereas symbolic representation bridges prior loss.

Psychoanalytic symbols are typically linked to external, perceptual reality, manifest in the closeness of the symbol perceptually toward what is signified. Thus, sticks, swords, and wands resemble the phallus; tunnels, caves, houses, boxes have a perceptual similarity to the female genitalia. The body image and body surface are the locus of initial, symbolic representation of self and object, which are then extended or projected to other surfaces. Symbols thus arise in the potential to other surfaces. Symbols thus arise in the potential space between the “I” and the “non-I,” more

closely related to the primary process rather than to verbal language and rational thought.

As Freud (1900a) noted, psychoanalytic symbolism is ubiquitous in myths, legends, art, literature, slang, jokes, obscenities, etc. Psychoanalytic symbols unconsciously represent, in addition to aspects of the self and childhood objects, coitus, pregnancy, birth, rebirth, castration, and death. Symbolism is utilized in symptom-formation, for example, a paralyzed limb representing impotence or castration. The name *Oedipus* or “swollen foot,” unconsciously represents erection and mutilation-castration.

Ernest Jones (1916) summarized that only what is repressed is symbolized and needs symbolic expression as a psychoanalytic or unconscious symbol. The symbol condenses unconscious wish and defense, a compromise formation permitting disguised “symbolic gratification.” The most frequent symbols are probably those of the male and female genitals, and these symbols more commonly appear in regressive states such as daydreams and dreams. Psychoanalytic symbols, however, may be found in association with all developmental phases. There are symbols referring to the breast as well as to the mouth, tongue, and teeth; similarly, feces may represent money, gifts, and denigrated aspects of the self or object. Psychoanalytic symbols are often overdetermined as in the bisexual and biparental symbolism of animals, exemplified in the many meanings of rats for the “Rat Man” (Freud, 1909d). The rat was interpreted to mean penis, feces, money (rates), baby, as well as despised greed, rate, etc.

Psychoanalytic symbols may have multiple stratified meanings and, in contemporary analysis, there is appreciation of overdetermination and possible change of function. For example, the “pit and the pendulum” may symbolically represent the vagina and the penis but also castration and the threat of castration. In oral terms, the pit may represent the mouth, and the pendulum the tongue.

That symbols may acquire cultural and religious significance and take on other metaphorical meanings does not alter the original and primary meaning of the symbol (Blum, 1978). A cave may represent a grave without losing its earlier meaning of a womb or female genital, with the earth having acquired the meaning of mother.

Clinically, symbols are not pursued as an end in itself and are not the primary locus of psychoanalytic

interpretation. There are no rigid formulas for symbolic decoding or interpretation, and patients may not directly associate to symbolic expressions. Symbols are interpreted in the context of the psychoanalytic process.

Comparable to an ancient language, symbolism may be adaptively appropriated in linguistic communication inside and outside psychoanalysis (Blum, 1995).

## SYMBOLIZATION, PROCESS OF

The term *symbolization* is hardly discussed by Freud, although the process is fundamental to mental activity. We can define symbolization as the operation by which something comes to represent something else for someone. While it may appear as the substitution of one object for another, it is primarily the result of a process that assumes both the ability to represent an absent object and a subject capable of knowing that the symbol is not the symbolized object.

In this sense it promotes the ability to fantasize and the organization of mental space. From this point of view it is primarily a mechanism enabling the subject to fight against the depression associated with object loss and to limit the flow of affects.

Aside from allowing one term to substitute for another, symbolization designates back and forth flow of meaning between subject and object, between mental reality and external reality, between past and present. This is the effect of the symbolization process, which makes possible a system of intra- and intersubjective exchanges. This can be verified in analytic therapy, which, in the standard model, assumes a relation between two centers of meaning, the analyst and the patient, whose work is possible only on condition that it is referred to an outside agency, which is the “frame” of analysis. The analytic situation thereby appears as both symbolic and symbolizing, in that its mode of operation is based on a structure with three points of reference.

The experience of satisfaction—that of the infant at the breast, as described by Freud in terms of images and memory traces—is a prototypical model that delimits the scope of the symbolization process in the transition from need to drive. Freud defined the drive as a borderline concept between the psychic and the somatic, formed by reworking the hallucination of satisfaction at the breast, and whose constant thrust (as distinct from the momentary or periodic nature of the satisfaction of organic need) relates to the permanence of the object during perception of the total object.

It is, as we know, a postulate also found in the experience of the dream and unverifiable by experience, according to which hallucination is a form of satisfaction. Into this Freud introduced a temporal dimension by distinguishing the period during which the sexual drives are attached to functions of self-preservation (corresponding to the hallucination of satisfaction and the increase in automatic traumatic anxiety) from the period of object-formation, and hallucination of the object, when the mother is perceived as a total object. The structure so described occurs in two stages, which the *análisis* or propping of the drive on organic self-preservation enables us to comprehend as a retroactive reorganization. The symbolization process thus emerges during the split between the framework of need (ingesting milk) and the framework of the drive (incorporating the breast). It is this difference that Jean Laplanche (1980) described in great detail, noting that the displacement from need to drive was simultaneously metonymic with respect to the object (from milk to breast) and metaphorical with respect to the aim (from ingesting to incorporating).

Between narcissistic cathexis (I am the breast) and object cathexis (I have it, that is, I am not it) the dimensions of a psychic space—a topological space—and time are organized. Psychic time evolves through acceptance of a delay, a waiting period, the succession from the time of being to, as Freud himself said, only after the fact, the time of having. Beneath these abstractions, at a more concrete level, we find analyses of symbolic assimilation (Melanie Klein), symbolic equation (Hanna Segal), and pathological projective identification.

From this viewpoint the hallucinatory experience of satisfaction designates the dialectic between the non-optative (I am) and the optative (I want, I am not), which is articulated only on condition that enough time is allocated to the non-optative dimension. This is probably one of the major contributions of Donald Winnicott (1951), namely, to have insisted on the importance of duration during this period of non-optative illusion so that the optative period, the period of disillusion, might become possible.

Thus the experience of object loss results in different outcomes for symbolization given the possibility of forming a dialectic between the time of being and the time of having. This essential difference and the dialectic it involves can be terminated by the illusory wish to unite, at the “same time,” subject and object, memory and perception, in the effort to exclude the object as well as the effort intended to include it.

In this way different modalities of symbolization are designated. The symbolic assimilation controlled by the search for sameness seeks to implicate projection, leaving nothing but the search for immediate satisfaction through action and degrading the symbol, which represents the object, to the status of a signal. Symbolic assimilation can, on the contrary, seek to include the object in the act of projection, which, although it dehumanizes the world by transforming it into abstract entities, nevertheless maintains a link to a universe of indexical signs, where the categories of certainty, foreseeability, and univocity prevail. There are, therefore, two different economies which, depending on the use of the object, can lead in one case to a repression of affects and a splitting of the body through the exclusion of all symbolization (this is the register of non-delusional psychoses and psychosomatic disorganization); and in the other to the preservation of those affects in the psyche through symbolic efflorescence, which, although it seeks to eliminate

difference and distance, nonetheless indicates an attempt at a solution through representation (as shown by delusional psychoses). As Wilfred Bion noted (1970), we cannot say that the psychotic patient is incapable of symbol formation, but that he symbolizes excessively and prevents himself from learning through knowledge of the world.

From this point of view the interiorization of psychic bisexuality becomes the source of unfettered symbolization and creativity. The essential point is to be able to confront maternal invisibility and the terror of the unlimited or the infinite. This assumes the organization of the dialectic of conservation and loss inherent in anal eroticism, which contributes to the differentiation of the inside and outside of the body and ensures that the control of mental activity and sphincter control are cathected in the same way.

The fort-da game (Freud, 1920g) is often considered to be the key experience revealing the formation of symbolization. However, this activity of symbolic substitution through gestures and speech that bear witness to the development of object loss, assumes the manipulation of a simultaneously preserved and expelled internal object, which defines anal eroticism. The experience of mastery demonstrates that the anxiety of destruction by the object associated with orality (to consume or be consumed) is here contained within limits through a third possibility, the external object.

The fault lines in this mediatory function of the third object determine the recourse to variant techniques (face-to-face psychotherapy, psychoanalytic psychodrama) compared to the usual therapeutic situation on the couch. From this viewpoint the analytic framework can be considered a genuine “intermediate region of experience,” to use Winnicott’s phrase, the crucible or matrix of all symbolization, which triggers the operation of the intermediary intrapsychic region known as the preconscious. The movement is of course asymptotic.

Accordingly, the semantic function of the symbol as content is inseparable from its mediatory function, intra- and intersubjective, providing we realize it is less a universal and univocal function (the archetype for Carl G. Jung or the symbolic order for Jacques Lacan) than a personal and polysemic one, making possible processes of sublimation and creation. Rather than being enclosed in a private dimension, true symbolization reveals, on the contrary, as Bion (1970) suggested,

its essentially social dimension. This assumes symbolization is capable of being instructed by the body and the world so it is able to produce other figures, while leaving room for the indeterminate, the uncertain, and the unexpected.

## **SYMPTOM**

Freud created psychoanalysis by giving meaning to symptoms. In his writings following *Studies on Hysteria* (1895d), he continued to investigate the symptom. At that time, psychiatry reduced the symptom to an opaque and incongruous phenomenon of psychic life. Freud focused on the salient and unusual features of the symptom to understand the dynamics of the unconscious and the development of conflicts.

The symptom cannot be considered equivalent to a defense, since the mechanism of defense is more general and its role less obvious. Moreover, defenses function effectively when repression is successful, when projection is obvious, and when the effects of projection are natural. Similarly, insofar as neurotic behavior and parapraxes prove useful to the subject, their unconscious causes are not apparent and are ignored.

The symptom is also distinct from anxiety. Anxiety is far noisier than the symptom, though it is also closely related. Anxiety sounds the alarm that leads from a sense of urgency to the symptom. In fact, the symptom appears to be extinguishing the fires of anxiety, but it does not possess the means to accomplish this. More precisely, the symptom puts an end to anxiety by organizing a new situation different from the one that triggered the anxiety. Thus the symptom corrects the inadequate internal discharge of anxiety by offering the psyche other possibilities for linking and representation. The new situation defines the nature of the symptom and indicates its scope. In the end, it is the drive that constitutes the symptom, and this is why Freud distinguished between symptom and inhibition (1926d [1925]).

When repression fails, the drive can break through, but repression has sufficient power to divert it. Thus, the symptom is formed as a compromise. At one level, the compromise concerns the censorship between the unconscious or preconscious and consciousness. At another level, there is a conflict between the different agencies, with the superego taking the organizing role. Later Freud argued that the conflict between the ego and the id defines neurosis, while that between the ego and reality characterizes psychosis (1924b [1923]).

Thus the course that the symptom takes always depends on the unconscious. Eventually, the play of affect and representation get the better of repression. This happens with the conversion hysteric, who suffers from quasi innervation because she marks her own body with an affect that has regressed to its original state as action. Thereafter, every fantasy is converted into a symptom that is incapacitating, but comfortable. Soon this same process is projected by a phobia and frozen in a representation, which leaves a gap in affect that is filled by anxiety (Freud, 1915d, 1915e). Because of the ambivalence of desire and defense, the symptom that the ego has established in a state of “extraterritoriality” (1926d [1925], p. 97) gains ground bit by bit, just like a foreign army, by extending its surveillance beyond the phobic object to any fantas-

matic object that can resonate with it. The defensive rituals of the obsessional become similarly eroticized by invading thought.

Finally, beyond the borders of the ego, the symptom may bring a relative gain, and the individual and other people may derive from it what Freud called a “secondary gain” (1926d [1925], pp. 99–100). For instance, the symptom may establish an internal equilibrium in the structural field from which it arises or that it organizes. Such is the diversity of pathology that it may also perform a preventive or reparative function outside of itself, as when an obsession precedes or follows a depressive episode or a hallucination makes real what mental life can no longer accept.

## SYMPTOM-FORMATION

Symptom-formation is the process leading to the production of a symptom—the production, that is to say, of a “sign” or “indication” of a functional disturbance.

The word *symptom* was borrowed by psychoanalysis from medical language. Even its etymology (Greek, “that which is held together”) suggests a link between the symptom and what it indicates (and it is worth noting, too, that *syndrome*, a set of symptoms, is likewise derived from Greek elements, meaning, in this case, “that which proceeds together”). That having been said, it is important to bear in mind that there is a broad difference between a sign (implying an intentional designation) and a mere indication (implying merely coincidence, without intentionality).

As early as his first psychoanalytical writings, Freud plumbed for the former sense, arguing that to produce a symptom was to produce a sign, that a symptom always had a meaning, even if that meaning were lost on the patient himself. *Studies on Hysteria* (1895d), or at any rate Freud’s contribution to it, is largely dedicated to the illustration of this thesis: “I have examples at my disposal,” he wrote, “which seem to prove the genesis of hysterical symptoms through symbolization alone” (p. 179).

Indeed, for Freud, the symptom, like the dream, was a compromise-formation via which a wish struggled to achieve fulfillment, albeit merely a partial one: “A symptom arises,” he wrote to Wilhelm Fliess on February 19, 1899, “where the repressed and the repressing thought can come together in the wish-fulfillment” (*SE*, 1, p. 278). Like dream-images, the symptom was overdetermined, and its formation relied on the processes of condensation and displacement. Unlike the dream-work, however, which led to the creation of images, symptom-formation resulted in the kind of bodily expression of which hysterical conversion was the paradigm; in the emergence of obsessive ideas as in obsessional neurosis (in which case secondary symptoms might arise also as defenses against the primary ones); in phobic avoidances; and so on.

More generally, the work of symptom-formation gave rise to mental processes and types of behavior that were repetitive and relatively “isolated”—that were not, in other words, integrated into other aspects of the patient’s personality. The patient would usually recognize these as pathological in nature, and seek

treatment, a fact which distinguished such symptoms from fixed “character traits.”

The fact is that Freud’s entire work, in its attempt to elucidate the neuroses, continually strove for a better understanding of the processes of symptom-formation. Thus in a letter to Jung dated June 15, 1911, distancing himself from his first theory of the trauma, he made the following essential correction: “symptoms spring not directly from the memories but from the fantasies built on them” (1970a, p. 260). He would later review the whole problem once more in the light of his second topography (structural theory) and his second theory of the instincts, in *Inhibitions, Symptoms and Anxiety* (1926d).

To summarize, Freud’s theory viewed the formation of symptoms from the standpoint of “semiology” in both the medical and the linguistic senses of the term (a fact pointed up notably by Jacques Lacan, whose position is famously encapsulated in the claim that “the unconscious is structured like a language”). This view did not hold good, however, beyond the sphere of neurosis proper: in the “actual neuroses,” the manifest symptoms had no psychic meaning (Freud, 1916–17a). Absent the mentalization of fantasies, libidinal energy flowed directly into somatic processes—a mechanism that has been studied in more recent times by the Paris school of psychosomatic medicine (Marty, 1976, 1980).

Inasmuch as the symptom expressed a compromise between instinctual satisfaction and defense, its motor was a dynamic that in all cases sought to reestablish an equilibrium, but that also determined the form of individual symptoms as well as the place each would occupy within a specific clinical entity.

It was unpleasure, first and foremost, that triggered the mechanism of symptom-formation—an unpleasure that derived from pleasure and that could not be accounted for save in terms of the confrontation between the internal pressure exerted by fantasy and the idea of the external danger that depended directly upon it. Hitherto, this calculus of pleasure has been the responsibility of repression, along with the other defenses that either collaborated with repression or ensured mastery over the instincts by their own efforts. The formation of a symptom was invariably necessitated by a strengthening of the instinct, whether this increased pressure was attributable to biology, to fantasy, to reality, or to external events. The failure of defense in all cases resulted in the first instance in the

emergence of anxiety. Whereas in the actual neuroses anxiety was nothing more than an almost reflexive return to the pathways of discharge of the first great traumas, the situation here made it into a signal of danger and a call for the symptom to arise.

The interplay between affects and ideas—the components of the instinct, whose reciprocal links and independence from each other constituted the dynamic of mental life—was thus the crucible of the symptom (Freud, 1894a). Repression functioned by dissociating the two, working on the idea in order to contain the affect and the action that the affect prefigured. The symptom, for its part, was effective because it operated in the interstice, restoring the rights of the instincts by creating new links, more acceptable to the ego, between affect and idea. The simplest instance of this in the context of neurotic repression was doubtless displacement, which was a function of the instinctual shift with respect to the symbol and the resulting decline in the symbol's significance, but other more complex defensive ploys were the locus of the same dynamic: thus the "Wolf Man" used displacement to transform his homosexual desire into a phobic fear of wolves (1918b [1914]), while Schreber was well able to handle fantasy by means of a similarly discrete action of the component instincts, but one which relied not on repression or displacement, but rather on the projection of the idea and the turning of the affect into its opposite, so producing the symptom of feelings of persecution (1911c).

This amounted to an introduction of differences with respect to the formation and the form of the symptom. Both clearly depended on the nature of the conflict: the threat of castration, the loss of the object, narcissism at risk, or alienation; neurosis, depression, borderline state, or psychosis. It has rightly been pointed out that in this account no symptom can exist independently of a corresponding clinical entity.

Two caveats apply in this connection. The first concerns the specificity of defensive modes to given pathological structures, so that each mode is perforce related to a corresponding symptomatic form of decompensation: whether object-dependency is defended against external reality by disavowal, idealization, projection, or some other means, will serve to explain why breakdown occurs in a particular subject, delusion in another, and so on. Within a single neurosis, to take the case of the obsessional, the oedipal situation is the starting-point of a regression to the

anal level of fixation which will determine the compulsiveness and mental retentiveness characterizing the symptoms (Freud, 1926d). Apropos of phobia, however, Freud describes three different phases of symptom-formation: preconscious decathexis, anticathexis of the substitutive idea, and an expansion of this idea's associations and of the vigilance it demands (1915e, pp. 181ff).

The second difficulty is related to the strength of the symptom with respect to the point reached in a particular clinical development. Thus in schizophrenics phobia may rapidly be overwhelmed by the haziness of the dividing-line between inside and outside, so that all projection becomes ineffective. Projection is scarcely more functional in agoraphobics, whose narcissistic inadequacy precludes the establishment of any external protective focus. Cancerphobics, on the other hand, being mentally more obsessional and more objective in their verification procedures, can keep the conflict out of the clutches of depression for some time before it eventually succeeds in bringing the struggle back within the ego. It should be noted, though, that while the neurotic conflict between the ego and the id confines phobia, in its exclusiveness, to a single line of defense, it nevertheless confers on the symptom, not efficacy, for that remains limited, but durability and solidity.

## SYMPTOM/SINTHOME

Lacan defined the *symptom* in several ways: as a metaphor, as “that which comes from the real,” as “that which doesn’t work,” and at the end of his teaching, as a structural fact, whose necessity must be questioned. In 1953 (2002a) Lacan emphasized that the analytic symptom—a neurotic, perverse, or even psychotic symptom; a dream; a slip; and so on—was sustained by a linguistic structure, by signifiers, and by the letters that serve as their material element.

In contrast to medical symptoms, the meaning of which is determined in relation to a referent, the neurotic symptom is blocked speech wanting to be heard and deciphered. Lacan saw the mechanism of metaphor at work in the symptom: when a trauma-inducing signifier is substituted for an element of the current signifying chain, it fixes the symptom and produces its meaning (2002b, p. 158). But interpreting its meaning is not enough. Interpretation works only by focusing on the articulation of the signifiers connected to the symptom; signifiers in themselves are meaningless (1995, p. 270).

**FIGURE 1**

Still, these signifiers must be addressed to an analyst. Because the symptom is a self-sufficient source of jouissance (enjoyment), the subject must be made to feel that behind the symptom is unknown knowledge and a related cause, and that the analyst has become the one who maintains it. The analyst has the responsibility for half of the symptom, Lacan said. He added that analytic training shows how the symptom completes itself.

Starting in 1974 with the Borromean knot with three rings, Lacan envisioned the relationship of the symptom with the real (R), the symbolic (S), and the imaginary (I). The symptom became “that which comes from the real” (1975, p. 185). It is marginally imaginary, while it unfolds in the symbolic (Figure 1).

The symptom, what is going wrong, uses speech to search for meaning. If we respond to it in this register, we can cause it to develop in the imaginary. Equivocal symbolic intervention can undo the certainties of the symptom and cause it to recede.

Lacan makes the function of the symptom specific by starting with a knot with four rings. Freud showed that the formation of symptoms is determined by psychic reality, which is organized by the Oedipus complex. Lacan called this reality “religious,” because it is founded on the belief that the father castrates, even though the laws of language require a renunciation of reality and an assumption of the phallus. Thus the symptom seems to maintain a link with the father, which sustains identification and sexual jouissance. In this knot, the symptom ring knots the real, the symbolic, and the imaginary together (Figure 2).

An unresolved case is that of a subject unsustained by his symptom. This case is represented by a Borromean knot with three rings (Figure 3).

FIGURE 2

FIGURE 3

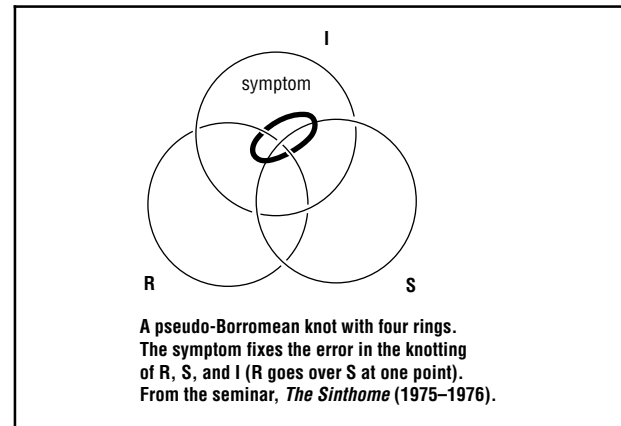

Lacan also asked what would happen if there were an error in the knotting of the three rings. Such an error would be fixed in a non-Borromean fashion by a fourth ring, that of the *sinthome*. In his study of James Joyce (2001), he used Joyce as his example of such a case (Figure 4).

For Lacan, the symptom is the fixed manner in which subjects enjoy their unconscious. Thus, the path that leads to oedipal normalization, even if it is neurotic, is also clearly marked. Treatment aims not at such a normalization but rather at learning “what to do with the symptom” instead of enjoying it.

## SYNCHRONICITY (ANALYTICAL PSYCHOLOGY)

Carl Jung offered synchronicity as an acausal “principle of explanation” to account for “certain remarkable manifestations of the unconscious.” He saw the principle of synchronicity as an addition to the principle of psychic causality, which Freud had emphasized so strongly.

Jung “found that there are psychic parallelisms which simply cannot be related to each other causally,” such as “the simultaneous occurrence of identical thoughts, symbolism or psychic states” in analyst and analysand. In cultural history, one can also observe uncanny parallels, such as the coincidence of Chinese and European periods of style pointed out by Jung’s friend Richard Wilhelm, the German translator of the Confucian classic *I Ching* (Book of changes; also romanized as *Yijing*). This ancient book of wisdom has been used throughout its history as an oracle. Jung tested Wilhelm’s translation by counting out yarrow stalks and tossing coins—the traditional chance operations of Chinese divination—to locate specific chapters and verses in the *I Ching*, which he found would speak, like well-timed analytic interpretations, to his psychological situation at the time.

In his memorial to Wilhelm in 1930, Jung enunciated the synchronistic principle as an explanation. But it was not until the 1951 Eranos Conference that he fully described the “meaningful coincidence” and other sorts of facts that the concept “is intended to cover.” “Synchronicity: An Acausal connecting principle,” Jung’s full-blown development of the notion, appeared, together with an article by Nobel Prize-winning physicist Wolfgang Pauli, in German in 1952. There Jung offers synchronicity as a law of nature as important as the laws of causality and chance, which it supplements in governing the connections of events. Jung quotes Schopenhauer (2000): “All the events in a man’s life would accordingly stand in two fundamentally different kinds of connection: firstly, in the objective, causal connection of the natural process; secondly, in a subjective connection which exists only in relation to the individual who experiences it, and which is thus as subjective as his own dreams.” Jung understood this “subjective connection” to be the significance a subject finds in the linkage of events, but he located this meaning beyond the subject experiencing it in the psychoid nature of the archetypes themselves. An archetype, for Jung, is a field of meaning in the unconscious that may be registered simultaneously as a psychic event in the mind and as a physical reality in the outer world. As Robert Aziz (1990) has noted, such “simultaneity” need not mean occurring at the exact same moment of time; it is enough that events having a common meaning be linked without a plausible causal sequence. One of Jung’s favorite examples of such a meaningful coincidence occurred while he was analyzing a young woman patient. She was telling a dream in which she was given a golden scarab. Jung

heard a flying insect knocking against the window-pane, opened the window, and caught the creature—a scarabaeid beetle. This unexpected concretization of her fantasy helped his patient give up an intellectual defense against psychic reality that had kept her analysis from becoming a transformative experience, the scarab being, in Egyptian mythology, a classic symbol of rebirth. For a synchronicity to enhance consciousness rather than merely build up superstitiousness, it is important that the individual grasp its compensatory meaning.

## SYSTEM/SYSTEMIC

A *system* is a self-regulating complex of interactive elements. It is a general model. Applied to the group or family as a unit, this notion is the basis for the systemic perspective.

In the United States the Palo Alto researchers (Gregory Bateson, Paul Watzlawick), using cybernetic and systems theory, studied the modalities of communications in the families of schizophrenics. They created notions such as the double bind, the paradox, and the existence of the “identified patient” (IP; the family member in whom the family’s symptom has emerged or is most apparent) necessary to the maintenance of family homeostasis. These new concepts have been

used in treating dysfunctional families using various “systemic family therapies.”

The first-generation systems theorists who used and developed the ideas of the Palo Alto group challenged psychoanalytic theories. Implementing a logic that is circular rather than linear, sessions relied on positive connotations, counter-paradoxes, and behavioral prescriptions. In this treatment option, intrapsychic phenomena were not denied but were deliberately disregarded. The emphasis was placed on information seen as “input” to and “output” from the “black box,” whose contents and workings were intentionally ignored. Further developments in theory and practice in this area have led to a taking into account of the effects produced by the presence and personality of the practitioner.

## **SZONDI, LEOPOLD (1893–1986)**

The Hungarian physician, psychopathologist, and psychoanalyst Leopold (or Lipot) Szondi was born in the Slovakian city of Nitra (then in Hungary) on March 11, 1893, and died on January 24, 1986 in Küsnacht, near Zurich.

In 1898, Szondi’s family moved to Budapest, where Leopold was an excellent student, first in Greek and Latin and subsequently in medical school at the Uni-

versity of Budapest. He was fascinated by Dostoevsky and Freud, and *The Interpretation of Dreams* became his vade mecum at the front during World War I. In 1919, as neuropsychiatrist and assistant to Paul Ranschburg, he published a series of analyses of personality based on constitutional and genetic factors; from 1921, he worked in private practice.

In charge of the state orthopedagogy program for secondary education from 1924 to 1927, Szondi served as professor of psychopathology at Pazmany-Peter University Medical School and also served as director of the Royal Hungarian Institute for Psychopathology and Psychotherapy. A decade of research followed together with self-analysis in which Szondi developed his method as an extension of psychoanalysis. That and regular contact with Imre Hermann moved Szondi beyond his earlier work on the constitutional and genetic bases of personality and destiny to psychoanalysis and the concept of the “familial unconscious.” Shortly after publication of an investigation of marriage in 1937, which won Freud’s stamp of approval, anti-Semitic legislation enacted by the pro-Nazi Hungarian government doomed Szondi’s laboratory.

Dismissed from his state appointments in 1941, Szondi was eventually banned from practicing privately; in 1944 he was deported with his wife and two children to Bergen-Belsen; eventually released, he found refuge in Switzerland. He spent some months as a psychotherapist at the Forel Clinic in Prangins before settling in Zurich in 1946. Excluded from academic psychiatry, he continued his practice, wrote, and trained students from Switzerland and abroad through analysis and supervision.

An international research association was created, today known as the Szondi Society; beginning in Zurich in 1957, it organized triennial symposiums. Funding enabled foundation of the Szondi Institute in 1969. The recipient of honorary degrees from the University of Louvain in 1970 and the University of Paris in 1979, Szondi continued to work as long as his health permitted, dying in 1986 in a nursing home near Zurich.

Although remembered as inventor of a simple and controversial projective test, Szondi always conceived of his technique as an adjuvant to *Shicksalanalyse* (Fate Analysis) which was inspired by depth analysis. Five large volumes formed the discipline’s basic program. *Shicksalanalyse* (1944) presented results of laboratory

research that aimed to reveal how people are motivated to make the “choices in love, friendship, professions, illness and death” that determine personal destiny. The test that was developed from this work was published in 1947, and translated into English in 1952 as *Experimental Diagnostics of Drives*.

Freud's influence, already present in Szondi's thinking, would be further manifest in subsequent work in Zurich. *Triebpathologie* (Drive pathology; 1952), aimed to move classical descriptive psychiatry in a psychoanalytic direction. *Triebpathologie II* appeared in 1956, dedicated to Freud on the occasion of the centenary of his birth, fulfilling his wish that one day successors would carry on an analysis much as he had done with sexuality. Finally, *Schickalanalytische Therapie* (Fate Analysis Therapy), published in 1963, used a Freudian cast to investigate problems associated with active techniques (such as Ferenczi had employed) and the application of analysis to psychosis and mood disorders. Szondi's work in later years included articles in various reviews and *Szondiana*, and, most memorably, the complementary volumes in which he reprised his theme of paroxysmality as clarified by the contrasting figures of the murderer *Kain* (Cain; 1969) and the law-giver *Mose* (Moses; 1973).

For a variety of reasons, Szondian analysis has remained fairly obscure. To the effects of war and relocation in Switzerland, which occurred just as his research was moving him toward a radical shift in perspective, must be added the occultation of the work due to reception of the test and some difficulty on Szondi's part in clearly describing that change, together with its new foundation. Finally, Szondi's

clinical genius and the effective range of his work were obvious only to patients and disciples with whom he had a close relationship in Zurich. Some followers took it upon themselves to lay a new foundation for his work; with a presence at university centers in Louvain and Liège, Szondian analysis at last found indispensable ground for further development and the opportunity to better explain and propagate the core of his teaching—paradoxically, primarily in francophone and Latin countries. Szondi, by moving beyond his own test, brings us to a broad view of his work as constituting the most significant attempt yet to create a global psychiatry undergirded by the spirit of psychoanalytic thought.

# T

## TABOO

The word *taboo* was borrowed by Captain Cook, in 1769, from the Polynesian language spoken in the Hawaiian Islands. A report of his voyage was published in 1884 but the word appeared earlier in Europe in the narratives of expeditions by Adam J. von Krusenstern, 1802, and by Otto von Kotzebue, 1817. They reported on the number and variety of prohibitions the word *taboo* refers to. Cook further specified that *taboo* was applied to anything forbidden to the touch. British anthropology took over the term, subsequently reworked by the German schools on the psychologies of various peoples, and the French schools of sociology. Freud later made use of this work to define taboo as an adjective with opposite meanings—simultaneously sacred and consecrated, as well as dangerous, forbidden, impure. Taboo was the name for prohibitions that were self-imposed along with their sanctions in the event of transgression, and which lacked meaning or any obvious referent. Anyone who violated a taboo was also taboo, which illustrates the taboo's power of contagion.

The term *taboo* appears in a short text of Freud's entitled "The Significance of Sequences of Vowels" (1911d), which discusses the names of God in Hebrew. "Taboo and Emotional Ambivalence," the second chapter of *Totem and Taboo* (1912–13a), was published in 1912. This work continues an earlier investigation into obsessional neurosis, the analogy between its symptoms and religious rites, and the psychology of religion ("Obsessive Actions and Religious Rites," 1907b). Freud also published "The Antithetical Meaning of Primal Words" (1910e), with *taboo* being one such example. Thus Freud's studies on taboo are limited in scope,

inserted into a broader investigation that was to be further elaborated in Freud's larger works on collective psychology, especially *The Future of an Illusion* (1927c), *Civilization and Its Discontents* (1930a [1929]), and *Moses and Monotheism* (1939a [1934–38]).

Freud associated taboo with ambivalence from the start. As early as the preface to *Totem and Taboo*, he writes that "the analysis of taboos is put forward as an assured and exhaustive attempt at the solution of the problem" (1912–13a, p. xiv) (as opposed to the totem), whose differences with taboo he goes on to point out. "The difference is related to the fact that taboos still exist among us. . . . They do not differ in their psychological nature from Kant's 'categorical imperative,' which operates in a compulsive fashion and rejects any conscious motives" (p. xiv). However Freud introduces fresh complications into this idea by postulating for the first time, in the chapter "Taboo and Emotional Ambivalence," the existence of a primal ambivalence of emotions which the taboo's prohibitions express. Freud then relates their existence to totemism: "The most ancient and important taboo prohibitions are the two basic laws of totemism: not to kill the totem animal and to avoid sexual intercourse with members of the totem clan of the opposite sex" (p. 31–32). Still this ambivalence becomes apparent as totemism only after the murder of the primal father, in the first acts of mourning and the transition to the totemic clan. The hypothesis of life and death drives could be used to make the taboo autonomous, which Freud does not do. Therefore, the taboo's existence is secondary, and follows upon that of the totem: given the thesis of totemism and the persistence of unconscious wishes, the "must not" is really a form of "must no longer." "The basis of taboo is a prohibited action,

the performing of which a strong inclination exists in the unconscious. . . . There is no need to prohibit what no one desires to do” (p. 32). The analogy with obsessional neurosis enabled Freud to clarify the dynamics of conflict and the topographical structure that gives rise to the existence of taboos: “I will now sum up the respects in which light has been thrown on the nature of taboo by comparing it with the obsessional prohibitions of neurotics. Taboo is a primaevial prohibition forcibly imposed (by some authority) from outside, and directed against the most powerful longings to which human beings are subject. The desire to violate it persists in their unconscious; those who obey the taboo have an ambivalent attitude to what the taboo prohibits. The magical power that is attributed to taboo is based on the capacity for arousing temptation; and it acts like a contagion because examples are contagious and because the prohibited desire in the unconscious shifts from one thing to another. The fact that the violation of a taboo can be atoned for by a renunciation shows that renunciation lies at the basis of obedience to taboo” (pp. 34–35). Therefore, “taboo conscience is probably the earliest form in which the phenomenon of conscience is met with” (p. 67).

The analysis of taboos touches on a number of themes. As psychic formations actualizing a dynamic of unconscious conflict amongst drive-impulses, they make use of primary processes; the propagation of this dynamism based on representations of contiguity and similarity—touch for the Unconscious—is clear and further elucidates the contagion, the “mana” of taboo as well as “delusions of touching.” At the same time these psychic formations attribute hatred and dangerousness to taboo objects and enable us to analyze projection. Moreover the conviction the taboo entails, owing to its dependence on the Unconscious, points toward animism, magic, and the omnipotence of thought—in short, to a study of narcissism. And the analogy, almost the identity, between the forms and dynamics of individual rites and rituals and those associated with taboos makes them a key element in the connection Freud creates between individual and collective psychology. The primal conflict of ambivalence that taboo allows us to postulate relates it to the hypothesis of the life and death drives, and the troubles encountered by moral conscience: anxiety, guilt, the superego, as well as their genesis via the primal murder. Even if *Totem and Taboo* “exhausts the problem” of taboo, Freud’s later work modified our viewpoint of it. Freud’s proposed analysis of the feminine in “The

Taboo of Virginity” (1918a) transforms the concept of taboo. Whereas the ambivalence of those subject to the taboo was in general the cause for prohibitions and prescriptions; in the case of the young girl to be deflowered, it is the real danger she represents (penis envy, revenge) that makes her taboo for others.

When anthropologists rejected the universalist perspective Freud invoked, the concept of taboo became subject to criticism. The structuralist viewpoint interpreted all taboos for *each* society as a single global symbolic system of classification, organization, and interpretation of the real, independently of any possibility for dynamic change—a claim taken up by the structuralist movement in psychoanalysis. The renewal of studies into dynamic change in the exact sciences may renew interest in Freud’s works on this subject.

### “TABOO OF VIRGINITY, THE”

Freud presented “The Taboo of Virginity” to the Vienna Psychoanalytical Society on December 12, 1917. He published it in 1918 as the third of three

essays entitled “Contributions to the Psychology of Love” (*Beiträge zur Psychologie des Liebeslebens*), the first two of which were revisions of his earlier papers, “A Special Type of Choice of Object Made by Men” (1910h) and “On the Universal Tendency to Debasement in the Sphere of Love” (1912d).

By regrouping these papers under a common title, Freud wanted to express the continuity of his thought concerning love, including sexual attitudes and conduct. The 1910 article, appearing about the same time as his first explicit formulation of the Oedipus complex, is concerned principally with male conquest and rivalry with other men; two years later, the second essay addresses the problem of male impotence, with specific reference to the psychological dissociation of tender from sexual feelings. “The Taboo of Virginity” in certain respects complements the first two.

Freud begins by asking why a young women’s virginity is so highly valued in so many societies. He turns to anthropology to show that, in some groups, defloration is carried out just before the wedding ceremony by a third party officially charged with that duty. Such practices form part of the constraints that continue to regulate sexual life of all civilizations. In fact, “it cannot be disputed that a generalized dread of women is expressed in all these rules of avoidance. . . . The man is afraid of being weakened by the woman, infected with her femininity and of then showing himself incapable” (pp. 198–199). This fear is due to castration anxiety, from which arises the idea that women are “a source of such dangers, and the first act of sexual intercourse with a woman stands out as a danger of particular intensity” (p. 200). Women contribute to such dread by the persistence of their own oedipal and castration complexes, from which arise the burdens of sexual prohibition, penis envy, and “hostile embitterment” towards men, together with the fact that their desire remains fixated on the father, for which “[t]he husband is almost always so to speak only a substitute, never the right man” (p. 203). Defloration by a third party serves such conflicts in women as much as it wards off men’s fears. When such conflicts are particularly severe, they can help explain frigidity in women.

“The Taboo of Virginity” is thus an integral part of Freud’s work on the Oedipus complex and castration. As a text particularly concerned with the psychoanalytic view of female sexuality, it has occasioned much critical discussion (for example, Laplanche).

## TACT

The notion of *tact* is basic to psychoanalytic know-how, implicit in the work of Sigmund Freud, and explicit in that of Sándor Ferenczi. In France, for example, it was developed by Sacha Nacht under the category of “presence of the psychoanalyst.”

This deceptively simple notion, to which Ferenczi returned a number of times in articles he wrote near the end of his life, deserves to be discussed, as he himself did in his article of 1928, “The Elasticity of Psychoanalytic Technique”: When and how should something be communicated to the analysand? “It is above all a question of psychological tact,” he replied. “But what is ‘tact’? The answer is not very difficult. It is the capacity for empathy. If, with the aid of knowledge we have obtained from the dissection of many minds, but above all from the dissection of our own, we have succeeded in forming a picture of possible or probable associations of the patient’s of which he is still completely unaware, we, not having the patient’s resistances to contend with, are able to conjecture, not only his withheld thoughts, but trends of his of which he is unconscious” (p. 89).

Ferenczi supplemented the general import of this formulation, making it more widely applicable, because he had been treating patients, who, as a consequence

of early traumatism, were affected by a narcissistic split of the self. He postulated the parent-child interactions as the elements “which make the trauma pathogenic,” speaking particularly of parental disavowal: “Probably the worst way of dealing with such situations is to deny their existence, to assert that nothing has happened and that nothing is hurting the child. Sometimes he is actually beaten or scolded when he manifests traumatic paralysis of thought and movement. These are the kinds of treatment which make the trauma pathogenic” (1931, p. 138).

In 1932 Ferenczi wrote a corrosive little article whose title alone expressed clearly his insistence on not harming his patients who were in a state of regression: “Repetition in Analysis Worse than Original Trauma.” In such patients there is “self-sacrifice of one’s own mind’s *integrity* in order to save the parents!” (p. 268); the whole problematic of the idealization and sacrificial function of the mistreated and sexually abused child was again presented; but he insisted: “much *encouragement* is needed” (p. 138), much tact.

## **TAUSK, VIKTOR (1879–1919)**

Psychiatrist and psychoanalyst Viktor Tausk was born on March 12, 1879, in Zsilina, Slovakia, and committed suicide on July 3, 1919, in Vienna.

The eldest of nine children, Tausk came from a German-speaking, non-religious Jewish family that, soon after his birth, moved to Croatia. His parents had an unsuccessful marriage. His father, Hermann, was a bright, ambitious, and popular newspaperman, who at one point managed the press office of the government of Bosnia-Herzegovina. Tausk would oppose his father’s attachment to the Austro-Hungarian Empire by supporting the Yugoslavian nationalist movement and by becoming fluent in Serbo-Croatian.

Tausk, in fact, grew up hating his father while maintaining strong affection for his mother, Emilie. Brilliant in school and multilingual, he initially chose to study law rather than costly medical studies. At Mostar, where he practiced for a time as a lawyer’s assistant, he preferred to defend impoverished clients, not excepting accused murderers.

Tausk visited Vienna for the first time in 1897, and there in 1898 met Martha Frisch, a distant relation of Martin Buber, the theologian-philosopher and social activist. Jewish by birth and Marxist by persuasion, she was also a Christian, and Tausk was baptized in order to marry her in 1900. Their first child was stillborn, but a son, Marius, was born in 1902; a second son, Victor-Hugo, followed in 1904. They returned to Yugoslavia, where they separated in 1905 and divorced three years later.

Resettled in Berlin by 1906, Tausk began working as a journalist while writing poetry and plays and immersing himself in artistic endeavors. In 1907 his health, already precarious while a student, worsened with both physical illness (including weak lungs) and depression. He entered a sanatorium and during his stay was apparently impressed by an article by Freud, wrote to him, and received an invitation to study psychoanalysis in Vienna. There he moved in 1908 and began analytic training. He became interested in the psychoses just about the time of Carl Jung’s rupture with Freud; the former had published *The Psychology of Dementia Praecox* in 1907.

At the same time, Tausk began medical studies, due to financial help he received from Freud and other Viennese analysts. He worked both at the outpatient neurological department directed by Frankl von Hochwart and at the psychiatric clinic at the University of Vienna, presided over by Wagner von Jauregg, the psychiatrist and neurologist who would later win a Nobel Prize. Tausk obtained his medical degree in 1913.

Lou Andreas-Salomé, highly reputed among intellectuals, met Tausk in 1912; she admired his brilliance while perceiving the extent of his psychological conflicts. (Kurt R. Eissler suggested a retrospective diagnosis of manic-depressive illness.) Analysts at the time were not required to undergo a personal psychoanalysis, which in any event was more often didactic than therapeutic. The facts concerning the presumed affair between Tausk and Andrea-Salomé are controversial.

In 1915 Tausk was mobilized and served as a psychiatrist in Lublin. Although he continued to attend psychoanalytic meetings, the dreadful economic conditions in Europe at the end of World War I found Tausk living like an impoverished student. He had opportunities for work in Belgrade and Zagreb but did not want to leave Vienna. Freud declined to accept Tausk as an analysand and referred him to Helene Deutsch. But Deutsch found that treating Tausk contaminated her own sessions with Freud, who instructed her to choose between himself and Tausk (Roazen, Paul, 1972, p 31). Three months later, in 1918, she terminated Tausk's analysis.

On the question of Tausk's suicide, Paul Roazen has stressed the impact of his conflicts with Freud, which he viewed as based on deep-seated rivalries, including issues of plagiarism and intellectual priority of ideas. Eissler by contrast emphasized Tausk's "severe" psychopathology, qualifying him as "talented" but no "genius." However disturbed he may have been, he impressed Melanie Klein when she met him at the Budapest Congress in 1918.

Tausk, in any event, ended his own life by shooting himself in the head after wrapping a curtain cord around his neck, so that he strangled himself as he fell. He had been drinking, but a rumor of his prior emasculation was unfounded. Though attractive to women, Tausk's affairs had often ended in failure and abandonment. Before his death he had become engaged to Hilde Loewi, a young concert pianist whom he seduced while his patient. She may have been pregnant with his child when he committed suicide.

Tausk's fourteen published articles are remarkable for adumbrating certain psychoanalytic concepts. The best known is "On the Origin of the 'Influencing Machine' in Schizophrenia" (1919), the last of his writings to be published during his lifetime. Indeed, after his death Tausk curiously disappeared from the psychoanalytic horizon, only to return in the 1970s.

Tausk's actual influence has been indirect and often gone unattributed, consonant with his posthumous occultation in the history of psychoanalysis.

## **TAVISTOCK CLINIC**

The Tavistock Clinic, also called the "Tavi," is the premier psycho-dynamic psychiatric out-patient clinic in the British Isles, with Health Service departments for adults, adolescents, and children and families. It provides consultations to other institutions. The Academic Services Directorate provides post-graduate trainings. Human development, inter-personal relationships within families and social structures are researched. The chief executive in 2005 was Nicholas Temple.

The Tavistock Clinic was opened in 1920 at No. 51, Tavistock Square, Bloomsbury, London, by Hugh Crichton-Miller, who had used Freud's theory of neurosis in the treatment of soldiers suffering "shell shock" from the First World War.

Crichton-Miller was a Christian influenced by Jung and Freud. The clinic embraced a wide range of psychological approaches, and applied psychoanalysis and eclectic training, which resulted in a mutual antipathy with Ernest Jones, who officially banned psychoanalysts from staffing the clinic.

Staff and trainees undertaking psychoanalytic training later were Wilfred Bion, Margaret Little, Clara Thompson, C. Phillip Wilson, and Eric Wittkower. Michael Fordham trained with the Jungians. A few psychoanalysts, including Susan Isaacs and Karin Stephen, took part in the clinic's training.

During the World War Two, several staff members served in the Armed Forces; J. R. Rees becoming chief of Army psychiatric services, G. R. Hargreaves Assistant Director of Army Psychiatry. They brought together Bion, John Bowlby, Bridger, Dicks, Foulkes, Kelnar, MacKeith, Main, Morris, Phillipson, Rickman, Rodger, Trist, Wilson, and Wittkower, forming an "invisible college" working on officer selection, training, morale, civil resettlement, therapeutic communities, and group therapy. In 1946 some of these formed the Tavistock Institute of Human Relations (TIHR), an interdisciplinary group interested in the problems of organizational and societal change. This group established a journal, *Human Relations*, and Tavistock Publications Ltd. With the Family Welfare Association (Enid Eicholz, later Balint) they created the Family Discussion Bureau (Tavistock Marital Studies Institute). In the clinic they established a unit for adolescents, developed the School of Family Psychiatry and Community Mental Health (Academic Services Directorate) and the joint Library.

The relationship between the clinic and psychoanalysis improved after the war, due to the work of John Rickman and Sylvia Payne. Bowlby headed the children's department and John Sutherland became medical director. Michael Balint joined in 1949. Many staff and trainees were in psychoanalytic training. The adult department focused on group-analytic therapy and the children's department on the total family. Bion wrote on groups, Dicks on marital difficulties, Malan on short-term psychotherapy, Sandler on the psychodynamic personality inventory, Parkes on bereavement, Laing on pathological family processes, Ainsworth on attachment, Bowlby on attachment and loss, and the Robertsons made films on separation. Training for lay child-psychotherapists was set up by Bowlby with Esther Bick and Martha Harris.

The clinic, with TIHR, moved to new premises in 1967, also housing the Child Guidance Training Center. The adolescent unit incorporated the Young People's Consultation Service headed by Walter Joffe.

The present-day clinic provides service, training, and research, complementary to psychoanalysis, and attracts visitors and trainees from afar.

## **TECHNIQUE WITH ADULTS, PSYCHOANALYTIC**

The difficulties Freud experienced in writing the *General Method of Psychoanalysis* ("Allgemeine Methodik der Psychoanalyse"), which he had announced in 1908 to Carl G. Jung, Sándor Ferenczi, Karl Abraham, and Ernest Jones, are well known. The need for such a manual had become more urgent by 1906, as more students and colleagues showed interest in being initiated into the new method of treatment. Scattered in cities across the world—Zurich, Budapest, London, New York, and Toronto—these followers were busy with their professional responsibilities, and so were unable to complete an apprenticeship under the personal tutelage of the sole master of psychoanalysis.

Freud did not get much past page 36, and it was only after 1910 that he decided to publish the few articles that, until 1915, were generally grouped under his "technical writings." These involved merely a few recommendations, generally of the nature of what should *not* be done during treatment, lessons learned from years of slow and progressive elaboration of the psychoanalytic method.

The history of Freud's method was marked by some important turning points, especially the progressive abandonment of hypnosis, the substitution of free

association for the technique of concentration (1898a), the stress on the interpretation of dreams (1900a), and the emphasis on the analysis of resistance rather than the forced search for “primal scenes,” in addition to the primordial role eventually accorded to transference neurosis.

Although the framework of the treatment was in place from 1903, at least in its formal aspect (1904a [1903], 1905a [1904]), it was only in October 1907, with the treatment of the “Rat Man” (1909d) that the last great technical recommendation was announced: “The technique of analysis has changed to the extent that the psychoanalyst no longer seeks to elicit material in which he is interested, but permits the patient to follow his natural and spontaneous trains of thought” (Nunberg and Federn, p. 227).

While questions were raised concerning possible modifications of technique to include psychotic patients, the First World War and its social implications led Freud to anticipate the need to mix the practical aspects of psychotherapy with the ideals of classical psychoanalysis (1919a [1918]), paving the way for multiple modifications in technique, which appeared one after another in the years to come.

Salient among the first modifications were Ferenczi’s experiments with “active technique,” which, following Freud’s example, he pushed at first to an extreme, in opposition to what he denounced as the “fanaticism of interpretation.” The work which he published in 1924 with Otto Rank, *Perspectives de la psychanalyse* (Perspectives on psychoanalysis), was less shocking for the public than the theory that Rank espoused shortly afterwards in *The Trauma of Birth*, but both Rank and Ferenczi aimed at reducing the length of treatments, and bringing to greater prominence the maternal role of the analyst in the transference. In April, 1926, Rank distanced himself even further from Freud with his book *Technik der Psychoanalyse* (Technique of psychoanalysis), and in the 1930s, Ferenczi did likewise, especially with his emphasis on [sexually] gratifying behavior, and his experiments with “reciprocal analysis.”

On the other hand, Abraham, Ernst Simmel, and Max Eitingon, at the Berlin Polyclinic and Institute, which they created in 1920, codified the technical rules that were to be taught to candidates in psychoanalytic training, based on a “didactic analysis” and supervision. These continue to constitute the basis of teaching at most psychoanalytic institutes.

Among the significant technical “innovations” was doubtless “character analysis,” which Wilhelm Reich developed in 1933, and which marked the last great discussions contemporaneous with Freud, apart from the debates concerning analytical technique with children that took place between the disciples of Anna Freud and Melanie Klein. After the war, Jacques Lacan’s suggestion to permit sessions varying in length was severely censured by the members of the International Psychoanalytic Association, without discussion, its originator not having supplied sufficient supporting materials for such a proposal.

In the area of classic analytic treatment, modifications multiplied, along with the creation of new techniques loosely connected with psychoanalysis: “psychoanalytically oriented psychotherapy,” psychodrama, group psychoanalysis, and so forth.

Freud himself never established rules that were fixed and absolute, commenting even, in introducing his “Recommendations”: “The technical rules that I am putting forward here have been arrived at from my own experience in the course of many years, after unfortunate results had led me to abandon other methods. . . . I must however make it clear that what I am asserting is that this technique is the only one suited to my individuality; I do not venture to deny that a physician quite differently constituted might find himself driven to adopt a different attitude to his patients and to the task before him” (1912e, p. 111).

A reading of the memoirs of his analysands well illustrates the liberties he constantly allowed himself in the analysis of his daughter and that of Ferenczi, whom he advised, on June, 1, 1916: “As you’ve wanted, if your fates allow, I’ll save two sessions for you every day. I hope to see you a lot otherwise, and would like you to dine with us at least once a day. Technical rules demand, however, that, outside of the sessions nothing personal be mentioned.”

In 1928, at the Hague Conference, Ferenczi, in his presentation on tact, mentioned that “Freud had said ‘negative’ and ‘positive’ things about ‘tact’; with the result that obedient subjects did not understand how elastic the conventions were, submitting to them as if they were written in stone.”

In fact, the technical rules that Freud initially wanted to make more flexible gradually became rigid; his early flexibility was shown by his remark recorded in the *Minutes* of February 8, 1910: “It is inconsistent

to say: I must not impart this or that. This simply cannot be said in such a general way. It is evident that the technique can be practiced with understanding and tact, or otherwise” (Nunberg and Federn, p. 417). Smiley Blanton, his patient, recalls that Freud said, in March 1930: “Now in the matter of papers on technique, I feel that they are entirely inadequate. I do not believe that one can give the methods of technique through papers. It must be done by personal teaching. Of course, beginners probably need something to start with. Otherwise they would have nothing to go on. But if they follow the directions conscientiously, they will soon find themselves in trouble. Then they must learn to develop their own technique” (p. 48).

All the same, freedom is not license, and Freud was clear about this in a letter to René Laforgue, dated July 2, 1928: “If you want to give the beginner the feeling of being a free man, of not being obliged to stick submissively to the rule, to trust his intuition and give free rein to his humanity, I fear that the results will be quite disappointing. His intuition will lead him, unflinching, in the wrong direction, and as far as his humanity is concerned, any position is closer to this than the analytic position” (1977h [1923–33]).

Since then, hundreds of articles and many books have been published on this subject; among them Edward Glover’s (1955) and Ralph Greenson’s (1967). The variety and the diversity of their positions show the need to distinguish, in psychoanalytic practice, between a simple “procedure,” whether on a trial basis or in an emergency, and a “method” that qualifies as properly psychoanalytic, within which such a procedure will find a place, or not (Mijolla). Processes recognized as effective, along with the theoretical goals that structured them when they were initiated, as well as the definitions of the goals and means of psychoanalysis, all changed as Freud continued to discover things, and were subject to further modification after his death. There is no “method,” except one based on a theory of analysis. Method and theory enrich each other in a permanent process of evolution, one that absorbs the lessons of experiments with sometimes ephemeral procedures, together with particular attention to their favorable or unfavorable consequences.

## TECHNIQUE WITH CHILDREN, PSYCHOANALYTIC

The psychoanalysis of children represents an area of research and practice whose definition and progressive formation, through the twentieth century, were not established without clashes, conflict, and polemics. There have been successive waves of interest, with competing views, sometimes resulting in fixed oppositional positions, depending on the period.

The psychoanalysis of children is perceived by some as heretical, difficult to practice, even fundamentally utopian or impossible; by others, it is seen as an informative and reflexive paradigm, capable of enriching the theory and the technique of adult psychoanalysis. On one hand, it has been presented as intrinsically impure, on the other, much more rarely, it has seemed to be a kind of unrealizable ideal, fecund but somewhat vague.

These debates relate of course to the status accorded the mind of the child viewed on its own terms, and not only insofar as it is evolving into the mind of an adult, but also involve inevitable modifications in technique, since it is obvious that the framework defined by Sigmund Freud for the adult (with the couch, the basic rule of free association, absolute priority accorded to language and so forth) cannot be applied as such to children, especially to very young ones.

In this connection, two remarks should be made: first of all, one must be very careful to distinguish the psychoanalysis of the child from various applications of psychoanalysis to the domain of childhood (psychoanalytically inspired psychotherapies, combined parent-child therapies, analytic observation of newborns, so-called psychoanalytic family therapies, psychodrama, group therapies—with analytical overtones—or even the application of psychoanalytic concepts in education, pedagogy, and social fields). Of concern here will be only the psychoanalysis of the child, in its strictest sense, and not any of its looser applications.

Furthermore, any science—and psychoanalysis has a legitimate claim to this status, scientific pretensions, even if that is not its only possible definition—defines

itself at once by the presence of a framework, and also by its epistemological field. For psychoanalysis, there is a strict framework, and not only the formal appearance of one. In other words, as important as it is, merely having a framework is not enough to entitle something to be named a science; and the definition of psychoanalysis cannot be reduced to this feature. The essence of psychoanalysis is centered, at the minimum, on the dynamics of transference and countertransference, on the concept of resistance and the function of interpretation, and it is reasonable to judge that there is no effective analysis possible, without real work on these different planes.

All the same it is quite possible to imagine that this work can be conducted in different settings and, notably, in settings adapted to the various ages of the children. The whole purpose of the psychoanalysis of children is to succeed in developing these different aspects; for so long as these are not addressed fully, the risk of conflict and misunderstanding between those who treat adults and those who treat children will remain, a risk that René Diatkine evidently was trying to parry when he said: “I am not a psychoanalyst of children, I am a psychoanalyst who treats children.”

Regarded historically, the evolution of ideas concerning the technique of analysis of children has been marked by a some significant turning-points, linked to the work of the pioneers in this domain. Concurrently with the recommendations of Freud, who, from 1905, advised psychoanalysts to observe the psychosexual development of their own children, in an attempt to verify the reconstructed findings of the first adult treatments (Freud following his own advice, Karl Abraham observing his daughter Hilda, and Melanie Klein her youngest son), Herminie von Hug-Hellmuth was doubtless the first to undertake an authentic analysis of a child, in Berlin, during the First World War, recognizing the existence of transference and already utilizing, although in an unsystematic manner, games and drawings. Next was Eugenia Sokolnicka, in Warsaw, in 1919. In 1921, Klein settled in Berlin to practice the psychoanalysis of children, and Didier Houzel and Gilles Catoire remarked that “what can be considered as the prehistory of the psychoanalysis of children ended at the beginning of the 1920’s” (1986).

Subsequently, one of the great debates in the history of psychoanalysis occurred between Anna Freud and Klein, precisely on technical aspects that were due to a basic theoretical-clinical divergence. Donald W.

Winnicott eventually assumed an intermediary position in this debate, fairly close to the positions of Klein, especially on the question of the place of games in technique, but reproaching her, nevertheless, for what he saw as her insufficient attention, to the child's environment and particularly to the role of the real mother.

In France, a number of names should be mentioned, dividing, during the second half of the twentieth century, along the line of scission between Lacanian psychoanalysts and the non-Lacanian: Serge Lebovici, René Diatkine, Michel Soulé, among the latter; Françoise Dolto, Jenny Aubry, Rosine and Robert Lefort, among the former. These differences concerned theoretical references that were also reflected on the level of technique (the importance accorded to the child's wishes, and to the place of language, in particular). In the early twenty-first century the influence of the post-Kleinian movement is dominant in many countries in the conception and technical choices of child psychoanalysis (importance of counter-transference, exploration of archaic or primal levels of mental functioning, work on psychic boundaries, and so forth).

In 1926, in four lectures she gave at the Psychoanalytic Institute of Vienna, Anna Freud described an intermediary technique between the analytical and educational approaches. The limits she placed on the analysis of children were calculated on the basis of the following arguments: no transference neurosis is possible with the child (too great dependence on real parents); modification of the framework is required, having nothing in common with the free association technique of adults (absence of symbolic associations with games and drawings); there is need for a so-called preparatory phase during which the analyst "induces" the child by way of a certain charm to become involved in the treatment, by establishing a positive transference with the child, an educative role that is necessary if the analyst is to avoid the consequence of the lifting of repression and liberation of the drives.

In 1927, at a colloquium of the British Society, Klein refuted the propositions of Anna Freud, point by point. For her, analysis was incompatible with any educative attitude; the preparatory phase was in no way justified, because it was the interpretation of the anxieties in the transference which allowed the child to enter into the analytical process, the child being quite capable of developing an authentic transference neurosis.

Progressively, Anna Freud drew closer to the Kleinian positions, but for a long time there remained serious differences between the two schools as a legacy of this early opposition. It wasn't until 1990 that the first joint colloquium took place, between the Anna-Freudian Hampstead Clinic and the Kleinian Tavistock Clinic (this colloquium was to have been presided over by John Bowlby, who, in fact, died a few months before the event). These two institutions have remained, through 2005, very important centers for reflection on the subject of child psychoanalysis, certain names deserving mention, among many others: Anne-Marie and Joseph Sandler, Peter Fonagy, Hansi Kennedy, George Morane, of the Hampstead Clinic; Hanna Segal, Esther Bick, Martha Harris, Donald Meltzer, and Juliet Hopkins, of the Tavistock Clinic.

Given that there is no such thing as a purely technical problem, but that technical problems always refer to underlying theoretical-clinical issues (hence, the historical survey, above), it can be said that the question of psychoanalytic technique with children is based on four main elements: the place of parents in the process, the framework, the transference-counter-transference dynamic, and the function of interpretation.

Working with parents should be distinguished from the treatment, properly speaking, but it conditions it, in great part. Depending on the age of the child and the technique of each practitioner, positions vary as to the analyst's role in the family. In most cases, the work is effectuated by a consultant, not by the child's analyst, so that the child's "mental space" is better respected, but some technical variations are possible in this respect.

As far as the framework is concerned, a point in common with adult analysis concerns the number of sessions per week, which should be enough for a veritable analytical process to be begun (all the more so with psychotic, as opposed to neurotic children). Three visits a week seems to be the generally accepted frequency, alas not very often realized in practice. The question of payment has been also the source of much reflection, the notion of "symbolic payment" having been particularly developed by Françoise Dolto, in France, and by other authors influenced by her.

In addition, the place of the body and of preverbal communication, have attracted much attention, and have caused some changes in the way children are

treated, compared to adults. In the early twenty-first century, means such as games, drawings, or modeling clay are in very wide use, and usually considered as analogous to the adult's words, and as a basis for the practice of free association.

The counter-transference and corporal involvement of the child analyst is often more intense than that of the analyst of adults, which is why, unfortunately, analysts rarely continue until an advanced age to treat children, as Donald W. Winnicott was able to do. The difficulty of the task should not, however, be reduced to rationalizations as to its basic impossibility. The child, just like the adult, is living in "deferred action" from the very beginning, even if current developments in psychoanalysis of the very young might cause some modifications in the Freudian theory of deferred action; for example, by diffraction over a number of generations.

The major difficulty connected to the framework of analysis of children has to do with the role of the analyst himself, who has to find a balance between the freedom children are given to express themselves and the limits one must at the same time impose on them to avoid colliding with infantile omnipotence.

As to transference, particular attention deserves to be paid to the therapeutic alliance, already mentioned, which lies at the very heart of the controversy between Anna Freud and Klein. This is a particularly difficult notion when it comes to children: some authors see it as a precondition for the later development of the transference dynamic; others as a preliminary but conscious and ego-like version of the transference, properly speaking. It is clear, in any case, that with the child, in most cases, the therapeutic alliance depends in large measure on what kind of bond has or has not been established with the parents.

Interpretations can be metonymical, metaphorical, historical, or flatly transference, as with adults, but should have, over time, a containing effect, which gives them their therapeutic value, and this because the children treated are, mostly, those whose capacity for containing is defective, and whose psychic boundaries are still in the process of being formed. The kernel of this problem is knowing how to create for such children, while their internal framework is still in formation, an external structuring framework, one specifically derived and internalized from the framework of the treatment. The analysis of children's resistance has proven to be wholly indissociable from the analysis of the fantasy-contents and of the transference.

As with adults, many positions, often quite opposed to each other, have been taken regarding the conclusion of the child's analysis, it being understood that ideally the child should be the one to decide, even beyond the eventual disappearance of the symptoms that motivated the analysis—which would make sense, obviously, only in relation to the existence of suffering and intrapsychic conflicts obstructing the development of the child.

Following authors such as Hanna Segal and Donald Meltzer, the post-Kleinian movement has contributed much to the discussion of the technique of analyzing children. Meltzer (1967) even suggested describing the therapeutic process in five successive phases: gathering the elements of transference, sorting through confusions of place, sorting through confusions of bodily zones and modalities, [passing] the threshold of the depressive position, and, finally, the process of separation. Such a description, of course, risks being overly schematic, but it has had the virtue of being able to account for the dynamic of the process, as well as to allow the articulation of a certain number of technical approaches.

At the end of this introduction, it is fitting to recall, with Antonino Ferro (1997), that psychoanalysis is basically a single entity; and that there is really nothing to be gained by dividing the psychoanalysis of the child from that of the adult. Each is in a position to enrich the other, notably by way of a calm, comparative meditation on the various technical problems that are posed in the two fields.

## TEGEL (SCHLOSS TEGEL)

The Schloss Tegel was the first establishment in the world to provide psychoanalytic treatment in an institutional framework. It was inaugurated on April 10, 1927 at Berlin-Tegel by neurologist Ernst Simmel, who directed it until its economic collapse in August 1931.

Convinced by his experience treating war neuroses acquired in the course of World War I, Simmel first sought the financial support of the state for his project to open a clinic. Having failed to obtain this support in spite of his efforts and pleading, he founded, with the help of three administrators (Dr. Nussbrecher, director of the Phönix insurance company; Dr. Ludwig Jekels; and Prof. Julius Hirsch, state minister) a SARL (private limited company), the Sanatorium Schloss Tegel, as a psychoanalytic clinic. On November 6, 1926 a lease was signed with the owner of the castle, state councilor Reinhold von Heinz, concerning a “treatment center with accommodation for physicians, a pleasure garden and a park . . . for use as a sanatorium, authorizing the reception and treatment of patients suffering from various illnesses with the exception of physical deformities, sexually transmissible diseases, and mental patients.” (Schultz-Venrath, 1995).

Unfortunately, the clinic was never free of financial difficulties and had to be permanently supported by Sigmund Freud, who instituted a help fund for it, to which Marie Bonaparte, Dorothy Burlingham, René Spitz, Franz Alexander, Max Eitingon, Raymond de Saussure, and Hugo Staub contributed. In spite of this the closure of the clinic in August 1931 became inevitable in the economic crisis of the declining Weimar Republic, because patients could no longer afford to pay the hospitalization costs.

The clientele that Ernst Simmel treated in his seventy-four-bed clinic consisted of seriously ill neurotics; addicts of various kinds, including inveterate gamblers; children and adolescents presenting deficits in character development (kleptomania, for example); patients in acute life crises; and chronic patients with complications. The Schloss Tegel Sanatorium was destined to become a center for systematic psychotherapy

for patients suffering from organic illnesses. Among the collaborators having received analytic training we find Rudolf Bilz, Ludwig Fries, Alfred Gross, Irene Haenel-Guttman, Karl Maria Herold, Hellmuth Kaiser, Eva-Maria Rosenfeld, Francis Deri, Ilja Schalit, Edith Weigert-Vowinkel and Moshe Wulff.

In order to deal with multiple transference situations in a therapeutic fashion, the nursing personnel, who had received analytic training, had to function as an extension of the psychoanalysts. Simmel was the first to introduce the concept of psychoanalytic treatment for patients suffering from organic illnesses, a concept with a dyadic orientation. There were as yet no examples of group psychoanalysis. The therapeutic technique stressed the importance of avoiding regression by, on the one hand, taking social reality into account and, on the other, by offering timely analytic interpretations.

Three case histories were published from this clinic, two of them being posthumous: the spectacular treatment of a case of heart failure with pulmonary edema (Simmel, 1931b), a feminine perversion (Simmel, 1990) and a young pyromaniac (Simmel, 1949). With the exception of two patients who were paid for by a charitable organization, all the others were private patients.

## TELEPATHY

“The process of telepathy is said to occur when a psychic act by one person results in the same psychic act in another person” (1933a [1932]). Sigmund Freud developed several hypotheses about the direct transmission of thought, or telepathy, seeing it as an archaic mode of communication between individuals and possibly a physical process that had become mental at the two ends of the communications sequence.

Carl Jung and, later, Sándor Ferenczi, were, along with Freud, interested in the question of telepathy. Freud’s attitude toward it was simultaneously one of openness, because of its proximity to the unconscious, and reserve, fearing that psychoanalysis might find itself compared to occultism. His interest was essentially personal and longstanding, since he believed that he was able to communicate remotely with his fiancée Martha by thought alone when he was in Paris (Jones, 1957, vol. 3). Later, he attempted to conduct experiments of this kind, which is reflected in his correspondence with Ferenczi in 1910 and with his daughter Anna in 1925. But Freud maintained that the notion of telepathy was outside psychoanalysis, which was only interested in using a scientific, not a mystical, approach in the investigation of psychic activity. In fact, in discussing the telepathy performed by mediums, he recommended that we investigate their psychology, as well as that of their customers. Nonetheless, he felt that the phenomenon in question, namely the transmission of thought, was at least probable even if it was not demonstrable.

Freud advised Jung, and especially Ferenczi, to be cautious about revealing their attitudes about telepathy, which might have risked jeopardizing the status of psychoanalysis. He expressed this sentiment publicly on several occasions, the first time in 1921, in a short text entitled “Psychoanalysis and Telepathy,” which was read during a scientific meeting with his followers (1941d [1921]), the second time in an essay, “Dreams and Telepathy” (1922a), and then in 1925 in a note on “The Occult Meaning of Dreams” (1925i), published in the *New Introductory Lectures on Psychoanalysis* (1933a).

In fact Freud couched his own interest in the occult, in the form of a critique of a skeptical and limited rationalism, in rather sharp terms: “Not for the first time would [psychoanalysis] be offering its help to the obscure but indestructible surmises of the common people against the obscurantism of educated opinion”

(1941d [1921], p. 178). However, this interest did not lead him to accept telepathy as such, but to examine with greater attention the examples of premonitions or of premonitory dreams, which led him to question the after-the-fact reconstruction of narratives of partially falsified acts.

The value of Freud’s investigation, therefore, extends well beyond telepathy, touching upon the epistemological justification of the interpretative process used for dreams and analytic constructions. At the same time, as a question, telepathy is most certainly related to that of the unconscious through the hypothesis of telepathic communication in primitives and animals. Animism, the occult, and the uncanny, therefore, form a field that is neither inside nor outside psychoanalysis, but which psychoanalysis attempts to approach using its own methods.

## TENDERNESS

The term *tenderness* is derived from the Latin *tener*, which expresses the idea of a young life filled with freshness. By extension it can apply to a person who is soft, easily wounded morally, and sensitive to altruistic feelings.

Freud distinguished between “the affectionate and the sensual current” (1912d, p. 180): the older of the

two is tenderness, which corresponds to the choice of the primary infantile object, which is based on the drive for self-preservation and directed toward those who care for the infant. “These affectionate fixations of the child persist through childhood, and continually carry along with them erotism, which is consequently diverted from its sexual aims” (p. 181). It is only at puberty that the “powerful sensual current that no longer fails to recognize its aims” (p. 181) is added. The objects of the primary infantile choice are then invested with powerful libidinal forces that conflict with the prohibition against incest. It is by displacement toward a new object with which sexual fulfillment is possible that the current of tenderness and the current of sensuality are reunited in the love relationship.

Tenderness emits from an aim-inhibited sex drive (libido). It is parental, and in particular maternal, tenderness that “rous[es] her child’s sexual instinct and prepar[es] for its later intensity” (1905d, p. 223). If it is excessive, it will lead to “a precocious sensuality that will spoil the child” and lead to a predisposition to neurosis.

Using this as his starting point, Sándor Ferenczi distinguished a tenderness stage, or passive object love stage, and a passion stage (1933). Michael Balint, his student and follower, developed the concept of archaic or primary object relation (*Primary Love and Psychoanalytic Technique*, 1952). The most precocious phase of psychic life “is not narcissistic in nature: it is directed toward objects, but this precocious object relationship is a passive relationship—I must be loved and satisfied without having anything to give in return.” “This form of object relation is not associated with any erogenous zone”; mother and child do not have separate identities, their reciprocal instinctual goals are interdependent. This results in active infantile behaviors where the impulse to cling plays a preponderant role.

Paul-Claude Racamier summarized these issues and developed them further. Primary love “is a relation that unites by separating: uniting to the extent that it differentiates and distinguishing to the extent that it reunites; this is the primal paradox of narcissistic seduction” (1995). Tenderness is used to convey this relation: “It is both a mode of cathexis and an affective tone.” It is not directly sexual but it is not without sensuality; well-being—a developed form of self-preservation—is sought instead of a push toward discharge. “Its special feature is to envelop; its specific site, the skin.” Maternal

gestures consist of gentle caresses, based on continuity and tact within a climate of “temperate warmth.”

During the 1950s, John Bowlby, relying on the direct observation of babies interacting with their mothers and on ethological data, hypothesized the existence of a primary and fundamental need for attachment. This was manifest very early in the newborn’s archaic behavior (crying, glances, holding) and became more diversified as the infant grew. This work had considerable impact and led to additional research in the field of precocious interaction. These authors identify the need for attachment as based on physical contact, primarily through the skin. In 1968 Esther Bick proposed the concept of a first psychic skin whose aim was to keep the parts of the personality together “as experienced by them passively.” In 1974 Didier Anzieu developed the concept of the “skin ego,” “an original parchment that preserved the marks of a ‘primal’ preverbal writing made of cutaneous traces,” which culminated in the idea of the psychic envelope. After birth the skin fulfills functions that were formerly provided in utero by the maternal envelope.

Julian de Ajuriaguerra studied the constitution of the clinging-hugging gesture in children. Initially it is an extension of the arm toward the selected person, then the closing of the arm in an embrace. This gesture, in its complexity, is only fully realized after the age of nine months. Prior to this, one can observe, early in the life of the child, the use of clinging (Moro) and gripping reflexes. Then, around the age of two to three months, the child attempts to open and extend its arms. At around six months, the baby can coordinate the gesture with speech intonation mimicry. At around nine months, an organized pattern of clinging is established, and will develop, around one year of age, into more elaborate forms of related behavior. Hugging, squeezing, caressing, kissing, and other gestures of skin-to-skin contact are the most frequent manifestations of tenderness in mother-child interactions. This “tonic dialogue” forms a secure foundation for emotional development.

## TERMINATION OF TREATMENT

Very early on Sigmund Freud determined what for him was the sign of the end of a psychoanalytic treatment, that is to say that it is complete with the “practical recovery of the patient, the restoration of his ability to lead an active life and of his capacity for enjoyment” (1904a, p. 253), criteria that he repeated in the Lecture 28 of the *Introduction to Psychoanalysis* (1916–17a). But almost as soon, noticing the unpredictability of the resolution of the transference, he remarked: “In the early years of my psycho-analytic practice I used to have the greatest difficulty in prevailing on my patients to continue their analysis. This difficulty has long since been shifted, and I now have to take the greatest pains to induce them to give it up (1913c, p. 130).

In “Analysis Terminable and Interminable” (1937c) he specified the ideal conditions for termination of treatment: “An analysis is ended when the analyst and the patient cease to meet each other for the analytic session. This happens when two conditions have been approximately fulfilled: first, that the patient shall no longer be suffering from his symptoms and shall have overcome his anxieties and his inhibitions; and secondly, that the analyst shall judge that so much repressed material has been made conscious, so much that was unintelligible has been explained, and so

much internal resistance conquered, that there is no need to fear a repetition of the pathological processes concerned” (1937c, p. 219).

Eight years earlier Sándor Ferenczi suggested: “The proper ending of an analysis is when neither the physician nor the patient puts an end to it, but when it dies of exhaustion, so to speak, though even when this occurs the physician must be the more suspicious of the two and must think of the possibility that behind the patient’s wish to take his departure some neurotic factor may still be concealed. A truly cured patient frees himself from analysis slowly but surely; so long as he wishes to come to analysis, he should continue to do so” (“Termination of Analysis,” p. 85). He also indicated the “ideal goal” to aim for: “The far sharper severance between the world of fantasy and that of reality which is the result of analysis gives them an almost unlimited inner freedom and simultaneously a much surer grip in acting and making decisions; in other words it gives them more economic and more effective control” (p. 81).

Extending the duration of treatment and the perennial problem of the “interminable analysis” have always been issues of concern to the psychoanalytical community and have been ceaselessly discussed in many articles, congresses, and seminars. Multiple and disparate criteria to judge when a treatment may be considered ended have consequently been proposed, in accordance with changing theory and practice.

On the analysand’s side the following has been recommended: behavior adapted to reality, an ability to handle suffering and depression, overcoming of penis envy and castration anxiety, access to genitality in psychosexual behavior, reinforcement of sublimations, diminution of guilt, and the like. Sacha Nacht (1965) recommended taking account of the “lessening of the fear of suffering, the acceptance of the patient of himself, his ability to satisfy his desires, compatible at once with his ideals and his milieu, and the possibility of his engaging in action, while avoiding submission to the automatism of repetition” (Lebovici, 1980). Attachment to a new external libidinal object was regarded with suspicion by Wilhelm Reich (1949) and especially by Annie Reich, who saw therein a defensive *acting-out*, like the divorces that occur at the end of an analysis.

On the analyst’s side there is an “intuition” by unconscious perceptions that termination is necessary,

that the transference neurosis is on the way to being “liquidated.” Melitta Schmideberg (1938) has even recommended that the analysis be systematically interrupted after six years so that the bond with the analyst won’t make separation impossible.

With the “Wolf Man” case (1918b), Freud used the technique of fixing a date of termination to the analysis, but the results led him to rarely ever repeat this, nor to recommend it. Sándor Ferenczi, with the “active technique,” like Otto Rank, with the application to treatment of the principles of *The Birth Trauma* (1924), both aimed at shortening the duration of the treatment, but their attempts were criticized by most of their contemporaries and by Freud himself. Franz Alexander suggested experimental interruptions (1963), while, in France, Sacha Nacht (1965) recommended breaking “the closed world” of the transference by making the analyst more “present,” to “demythify” him, so as to favor “integration, by successive, nuanced phases into external, objective reality”—suggestions that have since been severely criticized. A process based on progressive severance, consisting in diminishing gradually the frequency of sessions is doubtless the easiest and the most often employed.

Whatever the criteria utilized to recognize that an analysis is in process of termination, they can only be based on the evolving conception that the protagonists of the situation have been maintaining of the goals of the treatment, as their special relation proceeds, and as they analyze the conscious and unconscious motivations inciting them to conclude it. Freud’s realist positions on the two “rocks,” which any psychoanalytic pretension to omnipotence will come up against, should not be forgotten either: the male “refusal of femininity” and the “penis envy” of the female. The end of the analysis is also a recognition of the unanalyzable, even if every treatment should involve an attempt to gain on a little bit of its territory.

Generally there has been agreement that the traditional framework of the treatment should be maintained until the very last session, while a few face-to-face sessions have been recommended in some cases where working through the separation was particularly difficult.

## THALASSA. A THEORY OF GENITALITY

Freud described Ferenczi’s *Thalassa. A Theory of Genitality* as “the boldest application of psycho-analysis that was ever attempted” (1933a, p. 228). It is worth noting that the Hungarian edition of the work (Budapest, 1929) bore a different title: “Catastrophes in the Development of the Genital Function: A Psychoanalytic Study.”

Ferenczi takes as his first axis of reference the parallelism between catastrophic moments in the development of the embryo (or ontogenesis) on the one hand, and in the evolution of the species (or phylogenesis) on the other. Proposing a vast fresco, summarized in a synoptic table of presumed parallels (p. 69) and based on Lamarck’s evolutionary theories and on Haeckel’s fundamental rule of recapitulation, which it rounds out, he brings together two seemingly distinct temporal perspectives: the time of the germ cell, when the human was a mere monoblast destined by fertilization to become an egg, then an embryo, and after birth to continue living in an extended dependency on the environment; and the time that begins with the emergence of organic life on earth, and which can be described by reference to the various ice ages of the Quaternary era. How many tens of thousands of years were thus recapitulated in the transformation of the

ovum into the newborn? As Nicolas Abraham (1962) notes, this “cosmogonic epic seeks its meaning in the automatism of repetition itself.”

The second yardstick introduced by Ferenczi in his interpretation of the erotic meaning of reality, of coitus, of sleep, or of sexual impotence is regression. For the adult man, coitus embodies a striving on the part of the ego toward a threefold identification: a symbolic identification of the whole organism with the phallic function; a hallucinatory (or specular) identification with the feminine partner; and a real identification, effected as “the genital secretion [does] in very truth penetrate into the uterus” (p. 74), as the biology of pleasure makes the regeneration of the human being into a material reality. Ferenczi ascribes a traumatolytic function to the orgasm. To buttress these analogies, he takes as a model the fusion of sexual cells familiar to embryology, extrapolating the notion of “amphimixis” to account for the partial erotisms of different organs. By analogy with disturbances of language, he describes erectile dysfunction as “a kind of genital stuttering” (p. 9). He dubs his working method “utraquism,” meaning that a single phenomenon may be viewed in two complementary perspectives, so that technique and theory have a recursive relationship.

The ramifications of this text of Ferenczi’s were considerable. In *Totem and Taboo* (1912–13a), Freud had constructed a myth of the origin of civilization on the basis of an animal, human, and/or divine parricide, reparation for which was due “out of love for the father” and not just “in the name of the father” (fraternal alliances, codification of the prohibition against incest); in *Thalassa*, Ferenczi evokes a carnival of bodily organs whose regressions serve to actualize symbolic remnants (marriage bonds, the search for the child within the adult after post-traumatic fragmentation, and so on). With respect to later psychoanalysts, it is clear that *Thalassa* is an anticipation of Jacques Lacan’s thinking on the logic of the unconscious and of his topography of the Imaginary, the Symbolic, and the Real. The work also foreshadows future psychosomatic studies (which Ferenczi calls *bioanalysis*). It is worth noting that such authors as Pierre Teilhard de Chardin, André Leroi-Gourhan, Konrad Lorenz, Yves Coppens, and René Thom have arrived in this connection at equally original hypotheses.

### “THEME OF THE THREE CASSETS, THE”

In “The Theme of the Three Caskets,” Sigmund Freud presents a wealth of extremely complex thoughts in just a few short pages. At the beginning are two scenes from Shakespeare, in which the number three plays an essential role: First, the choice of *three* pretenders to Portia’s hand between *three* metal caskets in *The Merchant of Venice*; and second, in *King Lear* the dying King’s partition of his kingdom between his *three* daughters, according to the love they show for him. In both these two plots, the humblest thing is shown to be the most precious: plain lead on one side, the mute love of Cordelia on the other. Although Freud initially draws on Shakespeare as his source for the choice between caskets; he ends up relying on myths that deal with the choice a woman must make between three pretenders, but which is inverted (as in the case of the choice between the three caskets and in the logic of the dream) into the choice a man makes between three caskets, that is, three women.

This leads Freud to evoke other scenes that turn on the number three in myths, folklore and literature, for instance constellations of three sisters where the choice always fall upon the third one who is the most unique. Freud identifies this uniqueness of the third as her

“muteness,” and then recalls how muteness in psychic life is typically a representation of death. The third daughter, seen from this perspective, may be viewed as Death, the Goddess of Death. The sisters appear, consequently, as the three daughters of Fate—according to mythological tradition, the three Moirai, Parcae, or Norns. Freud’s detour through mythology makes the goddesses of fate represent the inexorable Law of Nature, and thus of the passing of time and the ineluctability of death as well.

Returning to the choice between three sisters, Freud seeks to soften any resultant contradictions between this detour through mythology and the specific choice itself by reminding us that fantasy activity typically inverts what is disagreeable into its contrary. Fatality, the inexorability of death, is transformed into a free choice. In *King Lear* the old man appears at the end carrying the dead Cordelia in his arms. Freud refers the powerful effect this produces to the latent message transpiring behind the manifest representation of the scene: in fact it is Cordelia, Goddess of Death, who carries the dead king off the battlefield.

Although a minor work, this magisterial essay demonstrates concretely, even in its use of free association, the fecundity of the analytical method when applied to literature, myths, and folklore; while at the same time illustrating the laws of psychical functioning, such as the inversion of a wish into its opposite.

In a letter to Sándor Ferenczi dated July 9, 1913, Freud revealed that the “subjective condition” he was in when writing this essay was occasioned by the fact that his third child, Anna, was beginning to occupy a very unique place in his life.

## THERAPEUTIC ALLIANCE

*Therapeutic alliance* refers to the mutual collaboration established between a psychoanalyst and a patient to overcome the neurotic or psychotic resistance that blocks change and the healing process. Freud provided a clear description of this in his *Outline of Psychoanalysis*, “The analytic physician and the patient’s weakened ego, basing themselves on the real external world, have to band themselves together into a party against the enemies, the instinctual demands of the id and the conscientious demands of the super-ego. We form a pact with each other. The sick ego promises us the most complete candor—promises, that is, to put at our disposal all the material which its self-perception yields it; we assure the patient of the strictest discretion and place at his service our experience in interpreting material that has been influenced by the unconscious. Our knowledge is to make up for his ignorance and to give his ego back its mastery over lost provinces of his mental life. This pact constitutes the analytic situation” (1940a [1938]).

Following his theorization of “resistance,” Freud abandoned contemporary psychotherapeutic thinking to begin developing “psychoanalysis.” The discovery that his patients unconsciously refused to provide themselves with the means for improvement, no matter how much they asked for it, was to lead him to his description of the “secondary benefit” of the illness and his understanding of the need to support the work of therapy through positive transference in order to overcome the unconscious obstacles represented by negative transference or the resistance to change.

“Healing is achieved through love,” he wrote on December 6, 1906, in a letter to Carl Gustav Jung. This belief was often repeated and led Freud, during his therapeutic work—as exemplified in his work with the “Rat Man” (1909d)—to encourage, through words or signs, the confidence of his patients and their attachment to him.

On several occasions Freud mentioned this “analytic pact” concluded between the conscious ego of the patient and the therapist. Freud did not fail to point out the constant shortcomings, the most important of

which has to do with the transference neurosis, which, if it is not recognized and analyzed, risks blocking the patient's associative process. The patient then "behaves as if he were not in treatment, as if he had not concluded a pact with the doctor." (1916–17a)

Subsequently, a number of analysts have described the modalities of an alliance that is essential to overcoming the inherent difficulties associated with therapy. Richard Sterba, in 1934, described the split in the ego that would allow the analyst to appeal to his patient's powers of reasoning to fight against his impulses and repression. But it was Edward Bibring who first referred to the "therapeutic alliance" (1937) between the analyst and the "healthy" part of the patient's ego. In this he was faithful to Freud, who wrote that same year in *Analysis Terminable and Interminable*: "The analytic situation consists, as we know, in our alliance with the ego of the person-object to conquer the unconquered parts of his id and therefore to integrate them in the synthesis of the ego. The fact that such a collaboration often fails in the psychotic provides, in our judgment, an initial point of support. The ego with which we are able to conclude such a pact must be a normal ego" (1937c).

After the Second World War the concept of a therapeutic alliance enjoyed considerable success in the United States when Elisabeth Zetzel, in 1956, made it a component of psychoanalytic technique, especially during the initial stages of therapy. She compared the therapist's attitude to the mother's intuition toward her infant and made this alliance the condition for the emergence and resolution of the transference neurosis (1965).

This approach, felt to be too thoroughly infiltrated with Kleinian thought, was criticized by Ralph Greenson, who, the same year, proposed the notion of a *working alliance*. The term was used for subjects capable of object relations (thereby excluding overly narcissistic personalities) and is described as "a relatively rational, desexualized transference phenomenon," capable of controlling aggressive impulses (1965). But Greenson also insisted on the fact that this working alliance, based on the "mature and rational" ego, was established outside the analysis of transference and necessitated actions or comments by the psychoanalyst on the reality of the relationship (for example, recognizing that the patient's criticism is justified rather than interpreting the need to criticize the analyst). Several authors judged Greenson's concept to be outside

the framework of analytic neutrality and abstinence (Jacob A. Arlow and Charles Brenner, 1964; Mark Kanzer, 1975, for example).

The question arises of the limits of action for the psychoanalyst, a question presented in terms of the weight of his reality in the therapeutic relationship. Just how far can the maintenance of positive transference, or the appeal to the rational by a split part of the ego—which in its theorization is very similar to the concept of the "conflict free ego" integral to ego psychology—get, before outside factors present the emergence of, or submerge, the psychic reality that the psychoanalytic situation is in fact supposed to promote? It was Joseph Sandler (1973) who insisted on this distinction when he emphasized the necessity of a therapeutic alliance sustained by interpretation alone.

## THING-PRESENTATION

In many of Freud's writings, "thing-presentation" means solely what it means for empiricist psychology, as his concept of the mnemonic image or trace would suggest. In his paper "The Unconscious" (1915e), however, Freud defined "thing-presentation" as "the

cathexis, if not of the memory-images of the thing, at least of remoter memory-traces derived from these” (p. 201).

This definition refers to the theory that Freud had worked out on the contrast between perception and memory and on the sequence of mnemonic systems. The psychic apparatus, he had concluded, has a spatial structure in which presentations are related to one another as a function of different types of associations. This means that a thing-presentation is significant less by virtue of its individual character than by virtue of its being coded as a link in a network. Rather than being a direct duplication of an object, a thing-presentation is an inscription in the systems of the mind of certain aspects of the object relative to an instinctual cathexis.

In his monograph on aphasia (1891b) Freud first drew the distinction between the presentation of a thing (which at that time he called an “object-presentation”) and the presentation of a word. In this neurological work, he classified the different forms of aphasia on the basis of a psychology of mental representations independent of the nervous system, thus parting company with his predecessors, who had constructed associationist models based on the search for cerebral localization. Freud defined the link between a thing-presentation and a word-presentation as the result of an association (which in terms of the theory of signs might be called arbitrary) between a sound image specifically representing the word and the visual image that of all possible mnemonic images is especially representative of the thing.

There is an inescapable connection here with the signifier/signified relationship that Ferdinand de Saussure would later be the first to describe, for Freud explicitly asserted in his work on aphasia that “a word . . . acquires its *meaning* by being linked to an ‘object-presentation,’” and not by reference to the thing itself (*SE* 14, p. 213). By embracing this account of meaning, Freud preserved differences internal to language and differences external to it, for thing-presentations, on this view, still refer to things in the outside world.

The compounds “thing-presentation” and “word-presentation” thus acquired a double sense, depending on how the relationship between the two component terms was understood. On the one hand, one could take the thing or word concerned to be represented by the corresponding thing- or word-presentation, that is, by mental visual images and sound images that can

be assimilated to the linguistic concepts of the signified and the signifier respectively. On the other hand, one could understand thing-presentations and word-presentations as referential signs, in which case these terms would denote representatives of things and words in the outside world. As a mnemonic image, a presentation in a sense indicates the referential or denotative function, and thus restores the sign-thing relationship that the signifier/signified opposition, immanent to the sign, excluded.

More than twenty years later, Freud, in his article “The Unconscious” (1915e), called once more on the distinction between thing- and word-presentations, this time to help overcome the difficulties inherent in topographical and economic hypotheses advanced to explain the differences between actual experience and what was heard during analysis. His aim was to relate such differences, not to varied forms of aphasia, but rather to distinct mental systems: “The conscious presentation comprises the presentation of the thing plus the presentation of the word belonging to it, while the unconscious presentation is the presentation of the thing alone” (p. 201).

This hypothesis once again raised the vexing question of the relationship between thought and language. It promoted the idea that a thought precedes language: thought is initially unconscious and concerned with the sense impressions left by objects; when it later becomes conscious, it does so only by means of word-presentations. The question of thought thus led back to a realm prior to language, a realm that Freud occasionally compared to Kant’s noumenal realm, the realm of the thing-in-itself.

On this view, thing-presentations correspond less to images than to thoughts or ideas of things that have lost all the sensory vividness of perception. These thing-presentations are incorporated into an associative process along with other presentations, thus constituting a thought process that, by definition, is devoid of quality or feel. Hence there is an essential need for word-presentations, which re-endow thing-presentations with their former sensory vividness. Freud did not exclude the possibility of thing-presentations directly becoming conscious; dream images and hallucinations were evidence of such a process. But he stressed that nonverbal thought is a very imperfect means of bringing items into consciousness—witness how we picture topographical relationships in dreams (1923b, p. 21).

The specificity of the notion of thing-presentation in psychoanalysis lies in the difference between cathected external objects and internal objects resulting from the processes of introjection and projection directed at external objects. In the primitive splitting of ego and object that occurs when the object relationship is established, when the mother is first perceived as a whole object, it is possible to discern the origin of a topographical distinction between psychic systems, and thus the origin of the unconscious. This moment, which correlates with the defense mechanism of primal repression, is the starting point of representation.

## **THING, THE**

In the apparatus of the psyche, *the Thing* represents the secret center of human desire, the nucleus of pleasure/unpleasure. This nucleus is opposed to the reality principle, which it threatens to undermine. The Thing, also called the “lost object,” acts as the cause of desire and a sign of longing for an impossible reunion with the object.

Sigmund Freud first referred to the Thing in 1895, in “A Project for a Scientific Psychology” (1950a). He used the term again in 1925 in his essay “Negation.”

Jacques Lacan fully elaborated this Freudian notion in his seminar *The Ethics of Psychoanalysis* (1992).

An instance of the Thing develops from a complex set of cathected perceptions and memory images that have given pleasure in the past. This set includes a stable kernel, called the Thing, and a variable element, or predicate. The Thing arises in the primordial relation between the infant seeking fulfillment of its vital needs and the primary caregiver, the “fellow being,” who is also the first hostile object. The kernel or nucleus is inaccessible to judgment, while the predicate is the object of a judgment that must verify whether the memory image corresponds to reality. In Lacanian psychoanalysis, this process of judging forms the basis for the ego.

The Thing is situated in the unconscious articulation of desire. In its origin, it posits the Other as unconscious, as the force withholding the signifier of satisfaction, while reality is subverted by the symbolic function of memory traces of the lost object, from which the subject’s desire is alienated.

## **THOMAS WOODROW WILSON, TWENTY-EIGHTH PRESIDENT OF THE UNITED STATES: A PSYCHOLOGICAL STUDY**

The Freud bibliography by Ingeborg Meyer-Palmedo and Gerhard Fichtner attributes to Freud the preface of *Thomas Woodrow Wilson, Twenty-Eighth President of the United States: A Psychological Study*—a hybrid work; it has remained one of the most ignored of all the works to which Freud has contributed. Peter Gay, who scrupulously reconstructed the genesis of the text (1988), noted, quoting William C. Bullitt, how

Freud's "eyes brightened" when, in May 1930, during a visit to the clinic at Schloss Tegel in Berlin, Bullitt spoke to him about a book he wanted to write on the Treaty of Versailles (p. v). Haunted by death and having just gone through another operation, Freud at once suggested that he contribute a study of President Wilson.

Although—or because—Wilson's personality and actions had been "from the beginning unsympathetic to me" (p. xi), Freud immediately began writing. His steps can be traced up to August 1931, when Ambassador Bullitt informed Colonel House, a former adviser of Wilson, who was growing impatient, that "the first version of the book is almost complete," then, at the end of April 1932, that "the book is finally finished." The only thing remaining was for the text to be revised, so, at the end of November, Freud told Max Eitingon he had learned from "his collaborator . . . when it would be possible to publish the Wilson book." It is important to remember that the situation at the Internationaler Psychoanalytischer Verlag was dire at this time and Freud was counting on the success of the book, as he did the *New Introductory Lectures* (1933a [1932]), then being printed, to restore the firm to solvency.

Nothing happened however. There were disagreements; Freud wanted to add new material that Bullitt rejected. The day after his arrival in London in June 1938, which owed a great deal to the ambassador's intervention, Bullitt finally obtained from Freud the authorization to publish the text. According to Max Schur (1972), Freud's notes and letters were supposedly burned by an absent-minded butler during Bullitt's hurried departure from Paris in 1940. "Why did my father agree, after a repeated (and quite understandable) refusal?" asked Anna Freud when the book finally made its appearance in 1966—"after the death of Mrs. Wilson" noted Bullitt.

While it is easy to understand the extent to which this text was part of Freud's preoccupation with the dangers of a personality impregnated with religious illusions and the political and economic fallout caused by the misinterpretation of external reality by the "world's leading idealist," the final result is perplexing and Freud's style comes through only in short bursts.

The subtitle, "A Psychological Study," is clear, and Freud explains that it "expresses our conviction that psychoanalysis is nothing but psychology, one of the parts of psychology, and that one does not need to apologize for employing analytic methods in a psycho-

logical study which is concerned with the deeper psychic facts" (p. xiv). This could not have been done during Wilson's lifetime, but "when . . . an individual whose life and works are of significance to the present and future has died, he becomes by common consent a proper subject for biography and previous limitations no longer exist" (p. xiv).

After an introduction written by Bullitt—"Digest of Data on the Childhood and Youth of Thomas Woodrow Wilson"—there follows the "Psychological Study" signed by both authors. The book contains thirty-five short chapters of commentary on the principal episodes of Wilson's life, from his rise to power until his paralysis in September 1919 and death on February 3, 1924. Like a pale caricature of certain essays on "psychohistory," the book is a heteroclitic patchwork of simplified psychoanalytic concepts for an ignorant public, remarks that are not without finesse, and reductive and repetitive interpretations. It is easy to see why so many readers have refused to see this as Freud's work.

This can be explained by the connection between Wilson's masochistic submissiveness and his "overpowering father" (p. 59), the Reverend J. R. Wilson. A "paternal complex," the repression of a hostility that was impossible to bear, since the father was assimilated to the supreme Being, the identification of the son with Jesus Christ and his mission as Savior of the world, the creation of an "tremendously powerful and exalted Super-Ego" (p. 60), a libido that found release in his speeches—the list of explanations is not all that long and each chapter could be concluded with the *quod erat demonstrandum* that Freud had grown fond of using during his friendship with Fliess.

But there was a fundamental difference with the cases he had discussed until then, something both authors recognized, in fact: "We shall never be able to achieve a full analysis of his character. About many parts of his life and nature we know nothing. The facts we know seem less important than those we do not know. All the facts we should like to know could be discovered only if he were alive and would submit to psychoanalysis. . . . It is a psychological study based upon such material as is now available, nothing more" (p. 35).

In fact this work, unlike that on Leonardo da Vinci and the *Memoirs* of Justice Schreber, cannot be considered a truly "psychoanalytic" work because not only is it not based on clinical experience but it makes no

attempt to illustrate a theoretical premise based on other examples taken from clinical practice. It is purely descriptive in nature, journalistic in a sense, and, like any work of this nature—although it bears Freud’s signature—the book is not an example of applied but of superficial psychoanalysis.

The concluding sentence of Freud’s preface is worth repeating, however: “We cannot, however, deny that, in this case as in all cases, a more intimate knowledge of a man may lead to a more exact estimate of his achievements” (p. xvii).

## THOMPSON, CLARA M. (1893–1958)

American physician and psychoanalyst Clara M. Thompson was born in Providence, Rhode Island on October 3, 1893, and died in New York City on December 20, 1958.

Thompson grew up in a religious, middle class family. She was closer to her father, while her brother Frank, nine years her junior, was closer to her mother.

Thompson was a serious student and a tomboy in elementary and high school where her goal was to be a medical missionary. In 1912 Thompson enrolled at the Women’s College of Brown University. College was a difficult time for her; she is described as quiet and lonely. A formative experience occurred in her sophomore year when she read George Eliot’s *Mill on the Floss*. Thompson deeply identified with its rebellious protagonist, Maggie. She stopped going to church and decided not to be a missionary. This precipitated a twenty-year rupture with her mother. In her senior year Thompson was engaged to be married, but her boyfriend insisted that she chose between him and medical school. She chose medical school and never married.

In 1916 Thompson began medical training at Johns Hopkins University, where she also completed her internship. She worked at St. Elizabeth Hospital under Edward Kempf and William Alanson White, and had a psychiatric residency at the Phipps Clinic where she studied under Adolph Meyer.

In 1923 Harry Stack Sullivan heard Thompson give her first scientific paper. He was very taken by her work and thus began a friendship of twenty-five years. Sullivan encouraged Thompson to go into treatment with Sándor Ferenczi, whom she first met in the spring of 1927, while he was lecturing at the New School. She went to Budapest in the summers of 1928 and 1929 and then moved to Budapest in June of 1931 where she stayed until Ferenczi’s death in 1933. Prior to moving to Budapest, in 1930, she had become the first president of the Washington-Baltimore Psychoanalytic Society.

Thompson’s treatment deeply affected her. People felt that she was deeply changed by this analysis. Ferenczi’s ideas about the impact of the real relationship between patient and analyst and the importance of real events in childhood were compatible with Sullivan’s Interpersonal Theory, but Thompson strongly disagreed with Ferenczi’s ideas about regression.

After Ferenczi’s death Thompson moved to New York where she, Sullivan, Karen Horney, William Silverberg, and later Erich Fromm met to discuss their work. Thompson taught at the New York Psychoanalytic Institute from 1934 until 1941, when she left after Horney was forced to resign. She joined with Horney, Silverberg, Robbins, and Fromm in forming the Association for the Advancement of Psychoanalysis, but

she left two years later after Horney insisted on only including medical doctors, and excluded Fromm. Thompson, Fromm, and Janet Rioch, with the help of Sullivan and Frieda Fromm-Reichmann, then started the New York Branch of the Washington School of Psychiatry, later to become the William Alanson White Institute. Thompson was co-founder and director of the William Alanson White Institute, from its creation as the New York branch of the Washington School of Psychiatry in 1943, until her death in 1958.

Thompson wrote over fifty articles, many of which are reprinted by Maurice Green in *Interpersonal Psychoanalysis. The Selected Papers of Clara Thompson* (1964). These include: “Notes on the Psychoanalytic Significance of the Choice of Analyst,” (1938) “The Role of Women in This Culture,” (1941) “Some Effects of the Derogatory Attitude toward Female Sexuality,” (1950) “Transference as a Therapeutic Instrument,” (1945) and “Counter-Transference” (1952).

Thompson was a central force in the creation of the interpersonal school of psychiatry. Thompson analyzed or supervised many of the most influential members of the second generation of interpersonal analysts who greatly expanded and extended her ideas on transference and counter-transference. Her understanding of the unique difficulties facing professional women led her to be the analyst of choice for many groundbreaking women. In addition, Thompson’s dedication to training lay analysts set an important precedent in the United States.

## THOUGHT

Thought may be defined in general as mental activity, conscious or unconscious, based on the various modes of representation, including the most archaic. More narrowly, the meaning of thought may be confined to ideational activity, dependent on the faculty of judgment and on the faculty that brings into conjunction images of things and images of words. The discussion here will be restricted to the narrower conception of thought as ideational activity, but always bear in mind that the narrower meaning is deeply rooted in the more general one.

Freud approached ideational thought from three different angles, which did not necessarily overlap. The first was the “psychological” approach, as outlined in the “Project for a Scientific Psychology” (1950c [1895]) and further developed in *The Interpretation of Dreams* (1900a), “Formulations on the Two Principles of Mental Functioning” (1911b), and “Negation” (1925h). In this perspective, Freud analyzed the thought process in relation to perception, language, memory traces, and action, for which, in Freud’s view, thought was a substitute. The second approach, a “genetic” one, was a response, in essence, to the question of the origins of thought as a search for knowledge. This line of enquiry was concerned primarily with the child’s urge to find things out and sought the libidinal origins of this drive and the circumstances that set it in motion. The four main Freudian works pertinent here are *Three Essays on the Theory of Sexuality* (1905d), “On the Sexual Theories of Children” (1908c), the case history of “little Hans” (1909b), and the analysis of Leonardo da Vinci (1910c), which situate thought activity relative to the instinctual realm and describe the various fates for which thoughts may be destined: inhibition, obsessive intellectualization, or sublimation. Freud’s third approach to thought was an original way of looking, not at the actual activity of thought, but at what is expected of it. This was the “anthropological” approach, to be found notably in *Totem and Taboo* (1912–1913a), which developed the concepts of magical thought and animistic thought in relation to thought activity during childhood and in pathology.

In the “Project for a Scientific Psychology” (1950c [1895]), Freud argued that thought processes are provoked by dissonance between a memory imprinted by a wish and a cathexis that seems to belong to the wish. When the two do not coincide, a biological signal trig-

gers thought; when they do, another signal terminates such activity and precipitates a discharge (action). Sixteen years later, in “Formulations on the Two Principles of Mental Functioning” (1911b), Freud proposed a similar account of the act of judgment, which “had to decide whether a given idea was true or false—that is, whether it was in agreement with reality or not—the decision being determined by making a comparison with the memory-traces of reality” (p. 221). Already in the “Project for a Scientific Psychology,” he had stressed that it was possible for judgment to have no objective beyond itself, such as mnemonic activity, which is self-sufficient, or the examination of new perceptual elements. In Freud’s theory, the role of judgment is in fact circumscribed both by recollection and by investigation.

In “Formulations on the Two Principles of Mental Functioning,” Freud defined thought as an activity that enabled the psychic apparatus to postpone discharge (action) when it would be inappropriate, and that brought together the impressions left by objects (“presentations”) and their linguistic designators (words). Freud also set off a “species of thought-activity . . . kept free from reality-testing and . . . subordinated to the pleasure principle alone,” namely fantasizing, which began with children’s play and survived in day-dreams (1911b, p. 222). Here Freud was broadening the concept of thought in a way also met with in *The Interpretation of Dreams* (1900a), where Freud divided the notion of “dream-thoughts” into “essential dream-thoughts” (the dream itself, uncensored) and “latent dream thoughts.” The latter comprise the much broader set of thoughts originating in the multiple channels linking the latent to the manifest and of associations arising from contiguity and resemblance and produced during the work of interpretation. Even though an intellectual activity, such as calculation or deduction, may appear in a dream, “an act of judgment in a dream is only a repetition of some prototype in the dream-thoughts,” a repetition that may be “so neatly employed that to begin with it may give the impression of independent intellectual activity in the dream” (1900a, p. 459).

Whereas the psychological approach offered a description of thought activity, the genetic approach raised an entirely different question: What makes us think? The question calls for identifying causes sufficient to account for the large quantities of libidinal energy devoted to thought activity. Freud posited an “instinct for knowledge or research” (1905d, p. 194).

This independent and atypical instinct was not bound to any erogenous zone but drew pleasure from other so-called component instincts, namely the instinct to see and the instinct for mastery. Freud needed the difficult concept of sublimation here to explain this diversion of the instinct’s aim and the change of its object. As early as the “Project for a Scientific Psychology” (1950c [1895]), Freud had pointed up the importance of the visual function for understanding. He stressed it even more in his essay on Leonardo da Vinci, who famously observed that the eyes are “the window to the soul.” Freud’s logical progression from the desire to look (*Schaulust*) to the instinct for knowledge (*Wisstrieb*) was based primarily on the fact that the wish to see was not satisfied with contemplating or even scrutinizing, but strove to compare. The perception of difference and the comparison of several variants of what is recognized as the same thing are steps toward the abstraction that enables us to think and classify.

According to Freud, the instinct for knowledge is awakened when children become interested in birth—a practical interest aimed at coping with the arrival of younger siblings (1908c). This curiosity, not satisfied by the parents’ answers, leads the child to engage in intense theorizing and to devise answers, sometimes the classical ones, sometimes not, to unanswered questions. This theorizing is associated with masturbation and, like it, remains unfulfilled. Freud considered this lack of fulfillment as one of the sources of intellectual inhibition.

In his write-up of the case of “little Hans” (1909b), his write-up of the case of the “Wolf Man” (1918b [1914]), and his analysis of Leonardo da Vinci (1910c), Freud explores the fate of this instinct for knowledge, which may either fall prey to inhibition, in tandem with a violent surge of sexual repression, or overcome inhibitory forces and re-emerge from the depths of the unconscious in the form of an obsessive thought. Or again, in the “rarest and most perfect” cases, the instinct may escape both fates: “The libido evades the fate of repression by being sublimated from the very beginning into curiosity and by becoming attached to the powerful instinct for research as a reinforcement” (1910c, p. 80).

Melanie Klein continued this line of investigation by developing the notion of an *epistemophilic instinct*, a very early curiosity concerning the inside of the mother’s body and the babies presumably found there. Beginning with a consideration of the sadistic and destructive dimension of this curiosity, she pointed out that one of the sources of intellectual inhibition was the

inability to obtain clarity of thought because of anxiety over what might be found (Klein, 1931).

After its fashion, Freud's third approach to thought, the anthropological approach, also addressed the question of the origin of the human desire to know. Freud felt that primitive thought was characterized by a belief in the "omnipotence of thoughts," a term that he had originally used in connection with an obsessional neurotic, the "Rat Man" (1909d, pp. 233–235), and that denoted an overestimation of the power of thought, resulting in things being erased by their representations. In such cases, intellectual processes are strongly sexualized, and this formed the basis of the belief in the omnipotence of ideas, which led primitive man to attempt to control the world with magic (1912–1913a, p. 89).

But if Freud believed that the question of the origin of life sparked the instinct for knowledge in children, by contrast, "the survivors' position in relation to the dead first caused primitive man to reflect" (1912–1913a, p. 93). He added, however, that this was not a purely intellectual problem, but rather an emotional conflict that had to be resolved. For children, just as for primitive humans, Freud thus rejected the notion of a primary need for causality; practical ends always predominate: "It is not to be supposed that men were inspired to create their first system of the universe by pure speculative curiosity. The practical need for controlling the world around them must have played its part" (1912–1913a, p. 78).

Whether Freud is concerned with the connection between the thought of the obsessive neurotic and that of primitive people, or with how the philosopher resembles the schizophrenic in mistaking words for things, his wide-ranging reflections on thought and its origins raise a multitude of issues, including that of psychoanalytic thought itself. For, as Freud himself wrote, "When we think in abstractions, there is a danger that we may neglect the relations of words to unconscious thing-presentations, and it must be confessed that the expression and content of our philosophizing then begins to acquire an unwelcome resemblance to the mode of operation of schizophrenics" (1915e, p. 204).

## **THOUGHT IDENTITY**

Thought pursues identity in order to unify its causality; the term *thought identity* designates the process of cognitive determination that it forms with its object, even if the latter is of an imaginary order.

With Sigmund Freud's work in *The Interpretation of Dreams* (1900a), the problem of identity saw a radically new approach in relation to the notion of perceptual identity and the respective aims of the primary and secondary processes.

Formal logic, a legacy from Aristotle, establishes identity as the criterion of unity of the thinkable, as the condition of possibility of thought itself, independent of its "matter." Practical thought makes effectiveness—that is, the successful transformation of the object—the criterion for appropriate, pragmatic thought. Imaginary or fantasmatic thought seeks its "thought identity" in independence—a direct source of pleasure—relative to practical or theoretical ends.

Philosophy, especially speculative philosophy (Hegel) sees the idea, the absolute determination of the concept, as the attainment of the goal of thought, in which an identity relation exists among the relative and exclusive practical, theoretical, and imaginary identities, as absolute knowledge. In this view, "ideological" thought identity represents the alienated current of the goal of identity pursued by a mode of thinking whose method is always and everywhere the active immobilization of thought, resulting in dogmatism, exclusivism, negation of the thought of the other, "group think," and the like.

Freud's distinction between the primary and secondary processes makes it possible to differentiate between thought identity, which is the aim pursued by thought by means of the secondary process, and perceptual identity, which is the aim pursued by hallucination by means of the primary process. In Freud's view, the aim is "practical" in that it always involves passing from one situation to another in accordance with desire. Hallucination short-circuits the detour necessitated in the effort of thinking, meaning that pleasure is not its condition even though it may remain its aim, and it takes the route of the death instinct rather than that of the life instinct; this explains the connection between thought identity and Eros. As Sophie de Mijolla-Mellor showed in *Le Plaisir de pensée* (1992), Freud distinguished practical and fantasmatic thought from thought in the form of true research or critical thinking; the latter do not make pleasure and its production the criteria for thought identity. For this reason, critical thinking and pure research alone are capable of producing a cogitative determination that is independent of perceptual identity.

## **THOUGHT-THINKING APPARATUS**

The term *thought-thinking apparatus*, used by Wilfred R. Bion, emphasizes, from a psychoanalytic standpoint, the distinction between representational aspects (elements of thought such as conceptions and concepts) and operational aspects (discharge and elaboration of thoughts). It is to this latter aspect that Bion refers when he speaks of the "thinking apparatus" (or "thought-thinking apparatus") that develops for manipulating thoughts.

In his 1962 article "A Theory of Thinking," where he first articulated the theory he was to further develop in four volumes published from 1962 to 1967, Bion draws a distinction between the creation of thoughts and their use for reducing tensions and deferring action (both functions that Freud had already attributed to thought). Bion posits that thoughts are anterior in origin to the work of thinking (produced by the thought-thinking apparatus). This approach can be contrasted to the truism of nineteenth-century materialist and physiological psychology that held that the brain secretes thoughts, just as the liver secretes bile.

According to Bion, the infant's first sensory or affective data correspond to a state of frustration, a sensation of the absence of the breast, a sensation of a "hole." To get out of this state, the baby must eject or modify this sensation, which corresponds to a primitive thought or protothought. At this stage, according to Bion, there is no clear distinction between mental representation and emotional or sensory experience.

In a second stage the capacity for thinking appears, dependent upon the infant's ability to withstand frustration, endure delay, and transform the emptiness left by the absence of the breast into a thought. In Bion's

view, in the course of development the “non-thing” or “non-object” becomes a thought. The breast that is present is not a thought, but will finally become the thing-in-itself (which is not “phenomenal” because it is seemingly “known”).

This theory of the origins of thought is slightly different from that of Sigmund Freud. Thought is no longer considered as a “hallucinatory substitute for desire.” (SE 22, p. 221) It is not the absent breast that is “thought” in order to appease hunger, but rather the “non-breast,” which is the first thought and which can then be the object of “thinking.” In Bion’s theory, thought is partly objectified instead of being deobjectified, as in the theory of the autonomous ego.

Bion’s model is close to Freud’s model of the *fort-da* game involving the wooden reel: The experience of frustration leads to the creation of other possibilities (fantasies, symbols, actions) that provide a new means to achieve satisfaction in reality. Once the earliest thoughts relating to the “non-object” have been established, the psyche must develop a thinking apparatus to rid itself of thoughts linked to frustration. This development necessarily occurs through contact with the mother, by means of projective identification mechanisms that take the form of a satisfying container-contained relationship, and through a dynamic interplay between paranoid-schizoid and depressive positions.

In the earliest case of a container-contained relation (symbolized ♀♂), the mother’s repeated positive experiences with the child, along with the points of contact between the child’s projections and the “reverie” of the mother, produce the model that the child can then introject as part of the thinking apparatus.

The interplay between paranoid-schizoid and depressive positions (symbolized PS D) develops the thinking apparatus. The earliest splitting operations in the structuring of the psyche, the necessary separation between “good object” and “bad object,” and the choices made in what Henri Poincaré conceptualized as “selection of facts” (but which Bion prefers to call “selected facts”) are dependent upon the paranoid-schizoid position. The depressive position plays a role in the acceptance of the loss that is implicit in all thought, and is also fundamental to progressive integration at the level of thought; that integration process is also dependent upon the container-contained mechanism.

One might also wonder: What can one do with thoughts, besides thinking them? Bion describes several types of thought disturbances linked to the difficulty of maintaining disciplined and cohesive thought. These disturbances are the result of a collapse either at the level of the representational elements of thought (in schizophrenia) or at the level of the activity of thinking, or the thinking apparatus itself (in hysteria or obsessional neurosis).

## **“THOUGHTS FOR THE TIMES ON WAR AND DEATH”**

There are two essays in Sigmund Freud’s “Thoughts for the Times on War and Death,” one on disillusionment and the other on our relation to death as revealed or modified by war. Freud wrote them in March and April 1915, six months after war was declared. Although he did not hide his nationalism, the tone is that of a “European” of the Enlightenment more than that of a partisan, especially in the first essay.

The theme of disillusionment is one Freud returns to often. It features in *The Future of an Illusion* (1927c) and in *Civilization and Its Discontents* (1930a). Here, it is the ideals of the community of mankind, or at least of Europeans, that are damaged and unsettled by war. Freud emphasizes that psychoanalysis has always maintained that behind the civilization we have struggled so hard to create (“Civilized” Sexual Morality and

Modern Nervous Illness,” 1908d), there exist drives that are neither good nor bad in themselves but are classified as such because of their relation to the needs and requirements of the human community. As a result regression is always possible and the reshaping of drives on which the inclination to civilization is based can cause reversion to a previous stage, permanently or temporarily, through various events, primarily war. However, Freud concluded with a question: “Why do individual peoples despise themselves, hate themselves, abhor themselves and others, even during times of peace, and why does every nation treat the others in this way? This is certainly an enigma.”

Bernd Nitzschke discovered the text on which the second essay is based. It appeared in a speech given at the Jewish Masonic lodge of B'nai B'rith in Vienna on February 15, 1915. It discusses our relationship to death and, in reality, has little to say about war, even though this was the pretext for the article. Freud reminds us that individual death cannot be represented unless it appears in a fantasy that negates its terror because we appear in it as a spectator. “In the unconscious each of us is convinced of our immortality.” Consequently, the interpretation given of the causes of death has always tended to treat death as an unfortunate accident rather than a necessity.

However, having exposed the way thought distances us from the inevitability of death, Freud then goes on to show how it is eroticized in two areas: the taking of risks in our active life and relating the death of others with which we identify in literature. He goes on to say that “in fiction we find this plurality of lives that we need.” Civilized man therefore has a contradictory attitude toward death since he denies it for himself and considers it as something that makes life valuable. The same is true of primitive man, who treats death as real in murder and unreal as far as it affects him personally. However, Freud shows that “it is not the intellectual enigma or each particular instance of death but the conflict of feelings experienced during the death of people who are loved and at the same time strangers and hated that has given rise to the spirit of research in humankind.” He then adds that the moral commandments also come into being at this time, the most important of them being the interdiction of murder. This leads him to conclude: “If we are judged according to our impulses of unconscious desire, we are ourselves like primitive men, a band of assassins.”

## THREE ESSAYS ON THE THEORY OF SEXUALITY

According to James Strachey, the *Three Essays on the Theory of Sexuality* should be considered, after *The Interpretation of Dreams*, to be Sigmund Freud’s “most momentous and original contributions to human knowledge” (Freud, 1905d, p. 126). In general, most psychoanalysts would agree. The immediate influence of the *Three Essays* was profound, and fostered change in the way that people thought, behaved, and learned about sexuality; this influence abides today.

Published soon after the turn of the twentieth century, the book’s somewhat scandalous profile heightened its impact. Its contentious reputation was not due, in all likelihood, to the first of Freud’s three essays, which concerned perversions. Havelock Ellis had discussed sexual aberrations and Freud cited and praised his work; Richard von Krafft-Ebing and others had strived diligently to create a literature concerned with sexual deviations. The medical context of these publications justified their sexual content, and they were received with approbation. Nor did the last of the *Three Essays*, on “The Transformations of Puberty” seem to provoke much controversy at a time when personal needs, desires, and social practices only underscored the omnipresence of sexuality.

Rather, the controversy (and enthusiasm) that greeted Freud’s brief volume was primarily due to the

second essay, in which he discussed sexuality in infancy and childhood. From a present-day perspective, it is difficult to imagine the vehement reactions provoked by suggesting the existence of infantile sexuality.

Indeed, sexuality in infancy and childhood is the central theme of the book. Freud's discussion of adult sexual aberrations links them to unexpected or abnormal events during childhood. He similarly understands puberty as the sum of modifications acting upon infantile sexuality. These ideas were clearly spelled out in the first edition of the *Three Essays* in 1905.

The first essay concerns "The Sexual Aberrations." In his treatment of homosexuality (for which he used the term *inversion*), Freud disputed and refuted common wisdom that invoked theories of degeneracy or offered innate or "constitutional" factors as explanatory. He acknowledged that such factors may be at the root of the perversions in some cases, but to those must be added the decisive participation of accidental causes—that is, childhood events that affected sexuality. Such events comprise the only available material for psychoanalytic work. In effect, the etiology of neurosis that Freud had previously proposed, as early as 1896 with reference to hysteria, was here reasserted and further developed.

Starting from two basic concepts, instinct and object, Freud stated that "it seems probable that the sexual instinct is in the first instance independent of its object" (p. 148). He stressed that one must distinguish between types of perversion, according to whether the sexual anomaly is related to the object (as with homosexuality or zoophilia) or to the aim, that is, to the activities that lead to sexual gratification. Freud discussed homosexuality in this general theoretical context—that is, how, from a developmental standpoint, a person would make either a homosexual or heterosexual object choice, the latter representing as much of a problem as the former. Either path might be taken in consequence of the anatomic-physiologic and psychic bisexuality that characterizes every human being, a hypothesis that Freud explicitly attributed to Wilhelm Fliess. Freud sustained his argument with the concept of *component instincts*—several independent impulses, each related to an erotogenic zone or somatic source without being integrated with each other. One can thus better understand why numerous perversions are characterized by sexual behavior that preferentially involves the oral, and especially the anal,

erotogenic zones—they are, that is to say, the result of psychic functions controlled by component instincts. (Component instincts and normal gratifications of childhood would be further discussed in the second essay.) Whereas neurotics repress the desire for instinctual gratification, the anomaly of perversion in adults resides in the fact that their sexual practices are permanently and predominantly based on satisfying component instincts. From this reasoning emerged Freud's concept that "*neuroses are, so to say, the negative of perversions*" (p. 165, Freud's italics), an idea which he had previously taken up in a letter to Fliess (January 24, 1897; 1950a).

Ideas developed in the first essay led logically to the second, which focused on sexuality in infancy and childhood. Freud pointed to the lack of knowledge on this subject while noting, at the same time, that it would be sufficient to carefully observe young children without hastening to declare sexual manifestations as abnormal. Every adult was once a child and should in principle be able to recall childhood in more than a fragmentary way, but most do not. Freud added two important observations. First, infantile amnesia affects everything concerning sexuality in childhood. Second, the strong moral condemnation that impacts all manifestations of sexuality leads to repression or gratification through sublimation.

Freud went on to advance a highly audacious and fertile idea that would lead to many further developments in psychoanalysis, both theoretical and clinical, and which would influence both his own later thought and that of his successors. He stated, in effect, that sucking activity observed in the infant should be considered as the prototype for all future sexual gratification. Thumb-sucking (or "sensual sucking") "consists in the rhythmic repetition of a sucking contact by the mouth (or lips). There is no question of the purpose of this procedure being the taking of nourishment" (pp. 179–180). Thumb-sucking has no other aim but pleasure and is separate from, but attached to or initially dependent upon, the need for nourishment. "To begin with, sexual activity attaches itself to functions serving the purpose of self-preservation and does not become independent of them until later" (p. 182). Herewith emerges implicitly the notion of *anaclysis*, which would later play a major role in developmental theory. Freud explicitly states that oral gratification is a prototype for every sexual gratification, is pleasurable in itself, and is autoerotic inasmuch as it does not

require any other object than the infant itself. He writes that the infant seems to be saying, “It’s a pity I can’t kiss myself” (p. 182). Here we find one of the major sources of discomfort provoked by the second of the *Three Essays*.

Freud, like most psychoanalysts after him, would view any controversy that emerged around the notion of infantile sexuality to be the result of a misunderstanding. If sucking is to be considered sexual and to lie at the root of all later sexuality, this should be understood in the context of an extended definition of the concept of sexuality itself, not confounded with, or reduced to, genital sexuality. However, objections to the idea of infantile sexuality would grow still more vehement with Freud’s further declaration that sensual sucking is masturbatory in nature and serves as a prototype for such gratification which, in addition, shifts from the labial zone to the anal zone, and lastly to the genital zone.

In addition, in a highly rational argument, Freud presented a further fundamental concept. The infant, due to the diverse and polyvalent character of erotogenic zones as invested by instinct and by the various means of gratification, may be characterized as possessing a “polymorphously perverse disposition.” Obviously, this is not to say that the child will become perverse as an adult; quite the contrary, this is merely the foundation of the normal trajectory of psychosexual development. By contrast, adult perversion is characterized by the abnormal persistence of infantile characteristics. In so-called normal development, the genitals become the dominant erotogenic zone, other erotogenic zones become subordinate to it, and there follows integration of the sources of sexual excitation and modes of sexual satisfaction.

In the last of the three essays, Freud described the “The Transformations of Puberty.” In the 1905 edition, this essay might have seemed less original than the previous section. Nevertheless, Freud examined three central themes in psychoanalysis—the libidinal economy of the onset of puberty, female and male sexuality, and object relations.

Again, Freud raised the notion of the integration, “under the primacy of the genital zones” (p. 208), of component instincts and erotogenic zones which serve as gateways to preliminary gratification preceding complete sexual intercourse through coitus and orgasm. But then, Freud faced a problem, the solution

to which he found difficult to accept. He had long reasoned that pleasure lowers tension while unpleasure raises it, writing that “I must insist that a feeling of tension necessarily involves unpleasure” (p. 209). But if the very activity that seeks to decrease tension is perceived as a pleasure, how then to understand the search for sexual excitement, which commonly characterizes every sexual act (including foreplay) before culminating in orgasm and relaxation? Confronting the issue, Freud pursued it in connection with sexual chemistry, largely speculative at the time. In fact, the problem remained without a solution in the 1905 edition; it would only be much later, in such works as “The Economic Problem of Masochism” (1924c), that Freud returned to it in a more satisfactory way.

Freud discussed a second theme in the third essay in a section titled “The Differentiation between Men and Women,” in which he asserted rather baldly that “The sexuality of little girls is of a wholly masculine character” (p. 219), and that “it would even be possible to maintain that libido is invariably and necessarily of a masculine nature, whether it occurs in men or in women” (p. 219). The clitoris, which Freud viewed as the distaff equivalent of the penis, is the site of masturbatory pleasure for little girls. In the woman, the clitoris may be viewed as the organ of forepleasure that transmits excitement to the “adjacent female parts,” writes Freud, “just as—to use a simile—pine shavings can be kindled in order to set a log of harder wood on fire” (p. 221). Freud’s subsequent discussion of these ideas, particularly in *New Introductory Lectures on Psychoanalysis* (1933a [1932]), would eventually incite considerable and lively controversy regarding the nature of female sexuality.

Still another theme in the third essay concerned “The Finding of an Object” during the transformations of puberty and (as we would say today) adolescence. In 1905, Freud still subscribed to an overly simplistic theory that he would later modify in fundamental ways. To infantile sexuality, which he supposed to be essentially auto-erotic, he opposed object-directed sexuality developed during puberty. The primal object, the mother’s breast, has by then been long lost, so that libidinal investment in the sexual partner after puberty is in fact a “rediscovery,” Freud notes. He adds, “The finding of an object is in fact a refinding of it” (p. 222). This was a proposition that spawned fruitful and interesting developments. In effect, from this point on, Freud acknowledged the object-relations nature of

infantile sexuality. He went on to consider infantile anxiety and the “barrier against incest” (p. 225) that forbids sexual relations between child and parent. Freud clearly established here what, beginning in 1910, he would call the “Oedipus complex.” The *Three Essays* ends with Freud’s summary of the major themes of the book.

This in brief reprise is Freud’s rich and provocative *Three Essays* as the book was published in 1905. But to understand its place in terms of Freud’s later work, it is important to realize that he revised the text with each new edition, of which there were six in his lifetime. He is not known to have considered publishing an entirely new edition, such as might have seemed necessary in light of all the developments in psychoanalytic theory. In any event, from 1910 to 1924 Freud made a host of emendations, some of which were quite significant yet difficult to reconcile with the original text to which they were attached. Freud himself admitted that this could create difficulties for the reader. In a later paper, “The Infantile Genital Organization” (1923e), he wrote, “Readers of my *Three Essays on the Theory of Sexuality* will be aware that I have never undertaken any thorough remodeling of that work in its later editions, but have retained the original arrangement and have kept abreast of the advances made in our knowledge by means of interpolations and alterations in the text. In doing this, it may often have happened that what was old and what was more recent did not admit of being merged into an entirely uncontradictory whole” (p. 141).

The *Standard Edition* accurately indicates all the modifications, suppressions, and additions to the text as Freud revised it in 1910, 1915, 1920, and also 1924; the 1915 emendations are particularly important, appearing as they do during the period that he wrote his papers on metapsychology; so too those of 1920, which came during the transition to the second theory of instincts and what is sometimes referred to as the “second topography” or structural theory. All these emendations appear either as notes at the bottom of the page, sometimes numerous and often quite long, or are included as extensions within the text itself. Three of these extended interpolations are of particular importance.

In the second essay, a section added in 1915, on “The Sexual Researches of Childhood” fundamentally reprises the Freud’s work in “On the Sexual Theories of Children” (1908c) and in “Analysis of a Phobia in a Five-Year-Old Boy” (1909b).

Another section, also added to the second essay in 1915, discusses “The Phases of Development of the Sexual Organization” (p. 197ff). This represented a major departure inasmuch as Freud introduced the notion of pregenital organizations—oral and anal stages—preceding the genital organization. In 1923, he added a note to the emendation itself in which he mentioned that he had advanced that same year (1923e) the idea of an intermediary stage, called infantile genital organization. “This phase, which already deserves to be described as genital, presents a sexual object and some degree of convergence of the sexual impulses upon that object; but it is differentiated from the final organization of sexual maturity in one essential respect. For it knows only one kind of genital: the male one. For this reason I have named it the ‘phallic’ stage of organization” (pp. 199–200). This idea implies, importantly, that the development of object choice arises in two periods separated by latency. First, from the first stage of infantile genital organization, then once again, after the final genital organization that emerges at puberty.

In the third essay, a section added in 1920 concerning libido theory largely summarizes Freud’s seminal article on narcissism (1914c), in the context of the economic problem (pleasure/unpleasure) of sexual excitation and discharge.

In sum, the *Three Essays* is indeed one of Freud’s major works. However, it would be a mistake to imagine that, at first publication in 1905, it was entirely novel in terms of Freud’s own thinking. So far as infantile sexuality is concerned, the text represents a key moment on a long path, pursued over the course of at least a decade and marked by progress and reversal, doubt and hesitation. In fact, the question of infantile sexuality arose with Freud’s theoretical efforts to create an etiology of neurosis, and can be traced to *Studies on Hysteria* (1895d). In Freud’s early view, hysteria, and neuroses more generally, are pathological conditions triggered by a sexual “seduction” sustained in childhood. But “sexual” for whom? The adult “seducer,” clearly; but, for the child “seduced,” what do we mean by “sexual”?

Freud wrote to Fliess on October 8, 1895, (letter 29) that he suspected “that hysteria is conditioned by a primary sexual experience (before puberty) accompanied by revulsion and fright; and that obsessional neurosis is conditioned by the same accompanied by pleasure” (1950a, p. 126). Just a week later, on October 15, 1895,

(letter 30) Freud wrote Fliess with some excitement, “Have I revealed the great clinical secret to you, either in writing or by word of mouth? Hysteria is the consequence of a presexual *sexual shock*. Obsessional neurosis is the consequence of presexual *sexual pleasure* later transformed into guilt (p. 127).

One can sense Freud’s dilemma. Is “presexual” sexual? Does infantile sexuality exist? No, if the incident only arises later as a memory. Yes, if it incites “pleasure” in the child—but this occurs only in those who will later develop obsessional neurosis, and these are, in fact, boys. “In [cases of obsessional neurosis] the primary experience has been accompanied by pleasure. It is either an active one (in boys) or a passive one (in girls)” (“Manuscript K” in Freud 1950a, p. 149). He adds that hysteria “necessarily presupposes a primary unpleasurable experience—that is, one of a passive kind. The natural sexual passivity of women accounts for their being more inclined to hysteria (p. 154). Thus, at this stage, some ten years before the *Three Essays*, Freud was far from seeing infantile sexuality as part of every child’s experience; he believed it might only in boys, some of whom, taking pleasure in being “seduced,” would later suffer from obsessional neurosis.

This early state of affairs clearly did not satisfy Freud. On one hand, he was tempted to assert the universality of infantile sexuality, while on the other, he hesitated before the audacity of it. Soon thereafter, in “Further Remarks on the Neuro-Psychoses of Defence” (1896b), he tried a kind of compromise, suggesting that pathogenic trauma acts in two stages, that “it is not the experiences themselves which act traumatically but their revival as a *memory* after the subject has entered on sexual maturity” (p. 164, Freud’s italics). In other words, the childhood trauma (which is traumatic, stressed Freud, because the child suffers a frightening assault, the nature of which he or she does not understand) will become sexual only in puberty. By this view, there is no infantile sexuality strictly speaking, and yet, one must admit “[E]ven the age of childhood is not wanting in slight sexual excitations” (“The Aetiology of Hysteria,” 1896c, p. 202). If infantile sexuality were universal, however, does the trauma theory collapse? Freud noted that, “It is true that if infantile sexual activity were an almost universal occurrence the demonstration of its presence in every case would carry no weight” (pp. 209–210).

Facing these theoretical difficulties, with direct implications for clinical practice, and also perhaps

facing his own resistances, Freud would need another ten years to develop a coherent theory of infantile sexuality. Understanding the progression of his thought can produce a better appreciation of the audacity and novelty of the *Three Essays*.

## TICS

Tics can be described as abnormal movements characterized by suddenness, inopportune occurrence,

nonproductivity, and variability. They can affect the muscles of the face, neck, or shoulders, and are sometimes generalized. We distinguish between simple tics, which are often transient, multiple tics, and the chronic tics found in Gilles de la Tourette's syndrome.

In *Studies on Hysteria* (1895), Sigmund Freud posited that tics are a compromise between an idea and its counter-idea (countercathexis) and constitute a particular mode of expression of neurotic conflicts. In the view of Sándor Ferenczi, subjects with tics, owing to the very fact of their strong narcissism or a fixation at this stage, have an increased tendency toward discharge and a reduced capacity for psychic binding. A traumatic memory that affects the body-ego spontaneously comes to the fore each time it has the opportunity to do so: Tics are thus the hysteria of the ego. Noting that tics have a veritable muscular eroticism, Ferenczi considered them the equivalent of repressed masturbation. He also drew attention to the importance of anal-sadistic components in tics and to the connection between them and coprolalia.

According to Melanie Klein, tics are based on genital, anal-sadistic, and oral tendencies directed against the object; her uncovering of these original object relations upon which tics are based led her to consider them as a secondary narcissistic symptom. She confirmed Ferenczi's conclusion—equating tics with masturbation—but added that masturbatory fantasies are closely linked to them. Analysis of these masturbatory fantasies appears as the key to understanding the tic. Behind the homosexual content of these fantasies can be discerned the child's identification with the father, that is, the heterosexual fantasy of sexual relations with the mother. The sublimation of these fantasies in other interests leads to the disappearance of the tic.

Margaret Mahler discussed "organ neurosis." Subjects with tics experience the drives as mechanical events that are in a sense foreign to the ego. Otto Fenichel viewed tics as a pregenital conversion comparable to stuttering, which Karl Abraham had noted; for Abraham, the tic was a symptom of conversion to the anal-sadistic stage.

Serge Lebovici proposed a psychosomatic explanation: Unrepresented excitation can lead to uncontrolled psychomotor discharges. Tics have the weight of an unelaborated discharge, but on the therapeutic level, the latent meaning can be sought by means of construction. He noted the fairly close relationship between isolated or complex tics and the structured

completedness of obsessional neuroses, but at the same time mentioned that they are also found with conversion hysteria or in psychotic organizations. According to Bernard Golse, obsessive traits with fixation on the aggressive tendencies of the anal-sadistic stage are discernible in the subject with a tic; but whereas with obsessional neurosis the aggressive content is not apparent because it is repressed by the visible ritual, with tics, the aggressiveness is directly externalized in motricity, without prior mental working over of the conflicts.

The etiology of tics is complex. The difficulties described occur in children who show a neurobiological predisposition, and are registered within an intersubjective relational economy that contributes to their persistence.

### **TIME**

The notion of *time* in psychoanalysis intersects several other concepts such as repetition, regression, fixation, and rhythm, though Freud also discussed the idea of

time directly. He began by emphasizing the atemporal-ity of unconscious processes: The unconscious ignores time, and he suggested that the origin of the representation of time could be found in the discontinuous relation the preconscious-conscious system maintained with the external world, the time dimension then being associated with acts of consciousness. He related the representation of time to the representation of space, in that space could replace time in unconscious processes. Finally, pathology shows how temporal progression is ignored, a characteristic which is also seen in fantasy, where past, present, and future are united in one representation, and in the transference neurosis, which is based on the anachrony of affect.

The atemporality of unconscious processes is present in Freud's earliest writings. In Manuscript M (1950a [1892–99]), James Strachey refers to a sentence in which Freud points out that the chronological information ignored in fantasy is dependent on the conscious system. But it is in *The Interpretation of Dreams* (1900a) that the indestructibility of unconscious processes is proposed, along with its corollary—the impossibility of recognizing the passage of time that would bring about the end of something; its belonging to the past; and eventually its forgetting. In a note added in 1907 to *The Psychopathology of Everyday Life* (1901b), concerning the indestructibility of memory traces, Freud wrote that “the unconscious is completely atemporal.”

Freud continued to repeat the same ideas, devoting considerable space to it in his essay on the metapsychology of the unconscious. “The processes of the system *Ucs.* are *timeless*; i.e. they are not ordered temporally, are not altered by the passage of time; they have no reference to time at all. Reference to time is bound up, once again, with the work of the system *Cs.*” (1915e, p. 187). In the November 8, 1911, session of the Minutes of the Vienna Psychoanalytic Society (Nunberg and Federn, 1962–75), Stekel and Meinhold were rapporteurs for the topic under discussion, “the supposed timelessness of the unconscious,” (Vol. 3, pp. 299–310) and during the discussion there arose a number of difficulties concerning the definition of time. In his conclusion Freud pointed out five arguments in favor of the atemporality of unconscious processes: the incorrect temporal orientation of dreams; the fact that condensation is possible; the lack of effects of temporal transition; the attachment to

objects; the characteristic tendency of neuroses to become fixed. He concludes: “If the philosophers maintain that the concepts of time and space are the necessary forms of our thinking, forethought tells us that the individual masters the world by means of two systems, one of which functions only in terms of time and the other only in terms of space” (p. 308).

While the processes of the unconscious are atemporal, Freud continued to remind us of the importance of the temporal factor as an element of reality. This is true of the process of maturation, which is the central element of the theory of libidinal states, but which also distinguishes normal from pathological mourning. (Time appears to be inevitable, to the extent that it seems endowed with intrinsic action while it is, in fact, the duration necessary to establish a process, work of some kind.) Conversely, time as experienced, the feeling of time, is shown to be relatively independent of the objective reality of the time shown on clocks and watches. We see this in the painful acceleration of duration constituted by the feeling of the ephemeral (1916a [1915]), but also, and in reverse, in the interminable extension of the boredom or impatience of the child who wants to “grow up,” that is, who wants to abolish the time that separates him from the age of his parents. Passion and the illumination or rush of the drug addict reduce duration to a point, the instant when the alpha and the omega meet.

Freud believed that the temporal dimension is accessible to us only as a function of acts of consciousness. Because these acts are not continuous but, like the “mystic writing pad,” depend on the innervation of the cathexes directed from the interior by rapid, periodic bursts into the preconscious-conscious system, this perception of time is also discontinuous. “I assumed,” Freud wrote, “I further had a suspicion that this discontinuous method of functioning of the system *Pcpt.-Cs.* lies at the bottom of the origin of the concept of time” (1925a, p. 231). Although time is ignored by unconscious processes, this does not mean it can't be represented in unconscious formations, which translate it as they see fit. This corresponds to what could be called “psychic temporality.”

After Freud other authors returned to the question of time in analysis and in psychopathology. Piera Aulagnier has shown the importance of anticipation in the relation between mother and child and in the process by which a subject identifies with it, a process

that, as it turns out, the psychotic is unable to complete (1975), being condemned to repeat the same thing over and over again.

## **TOMASI DI PALMA DI LAMPEDUSA-WOLFF STOMERSEE, ALESSANDRA (1895–1982)**

Alessandra Tomasi, an Italian psychoanalyst, was born in Nice in 1895 and died in Rome in 1982. She spent the first twenty years of her life in St. Petersburg, where her father, the Baltic Baron Wolff Stomersee, was a high dignitary at the czar's court. In 1917, at the start of the Russian revolution, she moved to Riga, then to Berlin. There, during the 1920s, she was analyzed by Felix Boehm and attended courses and seminars at the Berlin Institute; her supervised analysis was monitored by Max Eitingon and H. Liebermann. In 1927, during a brief stay in Vienna, she had the opportunity to “see” Freud. That same year she joined her Italian-born mother in London, where she was about to marry (this was her second marriage) the Italian ambassador to the court of S. Giacomo.

At the home of her father-in-law, she met his nephew, Giuseppe Tomasi, Duke of Palma and Prince of Lampedusa, the future author of *The Leopard*, who

became her husband in 1932. After their marriage she settled in Sicily. In 1934 she met Edoardo Weiss in Rome. They had corresponded with one another since 1929 and it was Weiss who sponsored her entry in the Italian Psychoanalytic Society. Through the society she became friends with Emilio Servadio, Nicola Perrotti, and Cesare Musatti.

Once her value as a teacher and trainer became recognized, she was asked, in 1946, to help with the reorganization of the SPI and, that same year, helped organize the historic First National Congress on Psychoanalysis, which marked the official resumption of psychoanalysis in Italy. At this time, and during the next national congress (Rome, 1950), she presented two important essays: *Sviluppi della diagnostica e tecnica psicoanalitica* and *L'Aggressività nelle perversioni*. She was president of the SPI from 1955 to 1959.

It was through her assistance, and hers alone, that Freud and psychoanalysis penetrated Sicily, where she initially encountered strong resistance from prejudice arising from the region's inherent conservatism. Of the first core group of people that formed around her, it was Francesco Corrao, following the departure of the princess for Rome in 1957, who assumed the psychoanalytic mantle and continued the work she had begun in Sicily.

In Rome she lived in a state of partial isolation, but was very active as a psychoanalyst, and increased her efforts to popularize the work of her husband, who became one of the most important writers on the Italian landscape following the posthumous publication of *The Leopard* in 1958. According to Michael David (1966), the work of Giuseppe Tomasi di Lampedusa contains the traces of an awareness of Freudian theories—easily understandable for a writer whose wife had devoted her life to psychoanalysis. For David the fact that “the Lampedusa apartment, and even their library, was filled with neurotic patients—to the point that the author preferred to take refuge among friends or in a café to write—gave rise to the husband's ambivalence concerning psychoanalysis.”

Alessandra di Lampedusa's most important articles include the following, all of which appeared in the *Rivista di psicoanalisi*: “Le componenti preedipiche dell'isteria di angoscia” (1956), “Necrofilia e istinto di morte” (1956), and “La spersonalizzazione” (1960). In one of her last seminars, she analyzed a case of lycanthropy, referring to the Kleinian notion of *projective*

*identification*, for which she coined the neologism, *identificatory introjection*.

## **TOPIQUE**

A French Freudian review founded in 1969 by Piera Aulagnier, who directed it until her death in 1990, *Topique* is, as of 2005, co-directed by Sophie de Mijolla-Mellor and Jean-Paul Valabrega, who continue its work and pursue its objectives in the spirit that has animated this review since its beginnings.

*Topique* was born in 1969, the same year that saw the creation of the Quatrième Groupe O.P.L.F., following what was the third scission in the psychoanalytic movement in France. The founder of *Topique* played a central role in this scission as well as in establishing the principles of the new group presenting itself both as an alternative to the International Psychoanalytical Association (IPA) as well as to the Lacanian group. However, from the very beginning, the review emphasized that *Topique* would belong to no particular school nor be tied to any group. Its goal was exclusively to participate in the advancement of psychoanalysis, with an intention of being open, both towards psychoanalysis itself and other disciplines too, notably psychiatry.

The review has been published successively by the Presses Universitaires de France (from 1969 to 1974, 12 numbers), Desclée de Brouwer (L'Épi; from 1974 to 1987, 28 numbers), Dunod (from 1987 to 1996, 22 numbers) and by L'Esprit du Temps (since 1996), three times a year.

*Topique* is independent, and is not the official organ of the Quatrième Groupe; however it is close to it, because its founder belonged to it, as well as those who

continue to edit the review. The first numbers had published the “Principles and Modalities of Functioning” (of the Quatrième Groupe), and the following issues took cognizance of its organizational modifications, as well as printing texts from its scientific conferences.

As *Topique* has been developing for more than thirty years, a retrospective view seems in order, involving at once a historical approach to the development of psychoanalysis in France, as well as a consideration of issues that were of special interest to the review. Especially noteworthy is the attention *Topique* has paid to the theory and technique of psychoanalysis in many texts, particularly in its early years—when it was anxious to construct an original perspective both regarding Lacanism and the norms of the IPA. However, *Topique* has always been a review of confrontation between different theoretical currents and their practitioners, publishing authors belonging to diverse psychoanalytical societies. Additionally, works representing psychoanalytical groups have always been welcome; as well as research centered on the practice of analysis, its clinical experiences and impasses; and challenges that psychosis continues to pose for Freudian metapsychology, in spite of the advances in current research and the new conceptual tools available because of it.

Finally, there have been special numbers involving psychoanalytical perspectives on cultural and social issues, with contributions from specialists from other domains, as well as psychoanalysts, who were interested in confronting psychoanalysis as a heuristic method. This was the case with the juridical domain in Number 52 (“To Have the Right” [Avoir droit], with art in Number 53 (“Powers of the Image” [Pouvoirs de l’Image]), anthropology in Number 43 (“Birth” [La naissance]), or Number 50 (“Twins and the Double” [Les jumeaux et le double]).

This diversity does not constitute a diversion in rapport to the central purpose, which remains linked to clinical practice and the theoretical elaboration rising out of it; it aims instead to restore to psychoanalysis the place Freud provided for it from the beginning, that is to say not that of a simple therapeutic process, but also as an adventure in human thought.

## TOPOGRAPHICAL POINT OF VIEW

Like the economic and the dynamic points of view, the topographical point of view is one of the three main dimensions of Freud's metapsychology. It introduced the idea that the mental apparatus was composed of different areas of the mind, different "territories" governed by different processes.

The idea of a mental topography was present in Freud's thought as early as the "Project for a Scientific Psychology" of 1895 (1950c), where it arose as a direct consequence of his conception of the history and successive stages of construction of the psychical apparatus.

In Freud's first topographical approach, three mental regions were distinguished: the conscious, the location of ideas that had direct access to consciousness; the preconscious, the location of material susceptible of becoming conscious fairly easily; and the unconscious, the location of whatever had been repressed from consciousness and was thus inaccessible to it. This initial spatial organization of the mind, known as the first topography, later proved inadequate for dealing with the clinical view of pathological narcissism, for it failed to locate the ego or the internalization of values and principles acquired in the course of the individual's development.

Beginning with *Beyond the Pleasure Principle* (1920g) and especially in *The Ego and the Id* (1923b), Freud proposed a new topography of the mental personality and apparatus in terms of the id, the ego, and the superego. The unconscious per se could no longer be treated as a single location in the psyche, for there were in fact several unconscious realms, and of different kinds. From then on, the term *unconscious* was used only as a qualifier applicable to mental processes, irrespective of their topographical location. A portion of the ego and of the superego were thus said to be unconscious, while components of the id could not become conscious without being transformed into representations, their original forms remaining unconscious.

The second topography did not replace the first, however. Rather, it remained in a dialectical relationship with it, thus complicating the model as a whole.

Some French psychoanalysts have taken the view that the two topographies are not merely metapsychological constructs but also correspond to specific organizational modes of the psyche. Different ways of mental functioning could thus be described in terms of the first or second topography, and the metapsychological account remained closely bound up with clinical practice.

## TOPOLOGY

*Topology* refers primarily to the branch of mathematics that rigorously treats questions of neighborhoods, limits, and continuity. Psychoanalysts have applied it to the study of unconscious structures.

In what have been called his two "topographies" (the first dating from 1900 and the second from 1923), Freud resorted to schemas to represent the various parts of the psychic apparatus and their interrelations. These schemas implicitly posited an equivalence between psychic and Euclidean space.

**FIGURE 1**

Early on, Jacques Lacan noted that the limitations of such a naive topology had restricted Freudian theory, not only in the description of the psychic apparatus (a description that in the end required an appeal to the economic point of view), but also in the specificity of clinical structures. The hypothesis that the unconscious is structured like a language, that is, in two dimensions, led Lacan to the topology of surfaces. The concept of foreclosure, for example, which he constructed on the basis of this topology, confirmed the heuristic value of his approach.

In his seminar “Identification” (1961–1962), Lacan unveiled a collection of topological objects—such as the torus, the Möbius strip, and the cross-cap—that served pedagogical aims. But already he saw them as more than just models. With the Borromean knot, introduced in 1973, he took the position that these objects were a real presentation of the subject and not just a representation. Below are several of Lacan’s topological objects.

### 1. The Cut and the Signifier

Far from being given a priori, every space is organized on the basis of cuts and can actually be considered as a cut in the space of a higher dimension. We are familiar with the subjective impact of this: The events of our lives only become history through the castration complex, which organizes our reality at the price of an imaginary cutting off of the penis. According to Freud, by introjecting a single trait of another, the subject identifies with the other (at the price of losing this person as a love object). In the single trait Lacan found the very structure of the signifier: A cut allows the lost object to fall away. He called this cut the “unary trait.”

The linguist Ferdinand de Saussure insisted on the fundamentally negative, purely differential character of the signifier. Lacan formalized this property in the double loop, or “interior eight,” in which the gap

created by the cut is closed after a second trip around a fictional axis. The difference of the signifier from itself is indicated by the difference between the two trips around the loop (Figure 1).

### 2. The Möbius Strip and Interpretation

If a signifier represents the subject for another signifier, then the subject would be supported by a surface whose edge would be a signifying cut. Note that the plane—the usual screen for the subject’s images, figures, and dreams, that is, plans—is a surface that does not meet these conditions. The double loop cannot be drawn on a plane without showing a cut. The same is true of a sphere, a simple representation of the universe.

The Möbius strip, on the other hand, can represent this cut and symbolize the subject of the unconscious. Since a Möbius strip only has one surface, it is possible to pass from one side to the other without crossing over any edge—an apt representation of the return of the repressed. The Möbius strip also has certain other peculiarities. A cut that runs one-third from the edge and parallel to the edge divides the strip into a two-sided strip linked to what remains of the original Möbius strip. But if this cut is made in the center, it does not divide the Möbius strip in two. Instead, the entire strip is transformed into a strip with two sides. This characteristic illustrates the equivalence between the Möbius strip (the subject) and the medial cut that transforms it, and also provides a model of how interpretation functions. Interpretation does not abolish the unconscious. On the contrary, it makes the unconscious real for the subject by its transformed appearance as another (an Other) surface (figure 2).

**FIGURE 2**

**FIGURE 3**

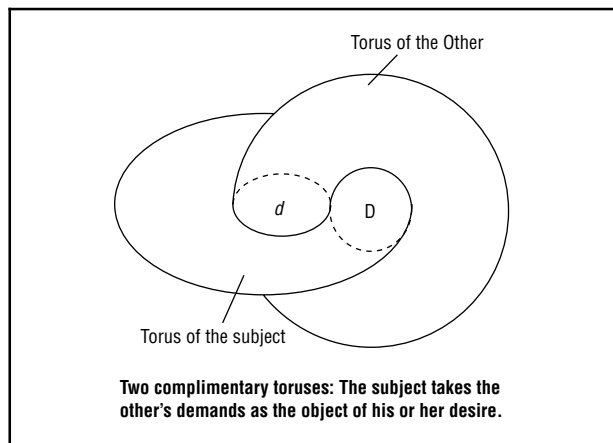

**FIGURE 4**

**FIGURE 5**

**FIGURE 6**

**3. The Torus**

Lacan made different uses of the torus. By drawing Venn diagrams, traditionally used to illustrate basic logical operations, on the surface of the torus, he demonstrated the extent to which our thinking depends upon the plane surface, and he also provided another possible basis for the logic of the unconscious (Figure 3).

By inscribing the same circles on the surface of the torus, Lacan revealed the logic of the unconscious discovered by Freud (Figure 4).

On the torus, only symmetrical difference is consistent. Thus we have a demonstration of how the signifier can be different from all other signifiers and also from itself.

Lacan also used the torus to represent the subject as the subject of demand. In this sense, the torus can be conceived as the surface created by the iteration of the trajectory of the subject's demand. This trajectory turns around two different empty spaces, one that is "internal,"  $D$ , the lack created in the real by speech, and one that is "central,"  $d$ , corresponding to the place of the elusive object of desire that the drive goes around before completing the loop (Figure 5).

For every torus, there is a complementary torus, and the empty spaces of the two are the inverse of each other. Lacan made this structure of complementary toruses the support of the neurotic illusion that makes the demand of the Other the object of subject's desire and, conversely, makes the desire of the Other the object of subject's demand. This structure also arises from the fact that on a torus, the signifying cut (the double loop) does not detach any fragment. Neurotic subjects, insofar as they give in to neurosis, insofar as they are "in the torus," are not organized around their

**FIGURE 7**

own castration, but instead excuse themselves by substituting the Other's demand for the object of their fantasy (figure 6).

**4. The Cross-Cap**

The cross-cap, or more precisely, the projective plane, can represent the subject of desire in relation to the lost object. A double loop drawn on its surface in effect divides this single-sided surface into two heterogeneous parts: a Möbius strip representing the subject and a disk representing object *a*, the cause of desire. The disk is centered on a point that is related to the irreducible singularity of this surface, which Lacan identified with the phallus. Unlike the representation of the subject produced on the torus, here a single cut, which symbolizes castration, produces both the subject and the object in its divisions (figure 7).

**5. The Borromean Knot**

Introduced by Lacan in 1973, the Borromean knot is the solution to a problem perceivable only in Lacanian theory but having extremely practical clinical applications. The problem is: How are the three registers posited as making up subjectivity—the real (R), the symbolic (S), and the imaginary (I)—held together?

Indeed, the symbolic (the signifier) and the imaginary (meaning) seem to have hardly anything in common—a fact demonstrated by the abundance and heterogeneity of languages. Moreover, the real, by definition, escapes the symbolic and the imaginary, since its resistance to them is precisely what makes it real.

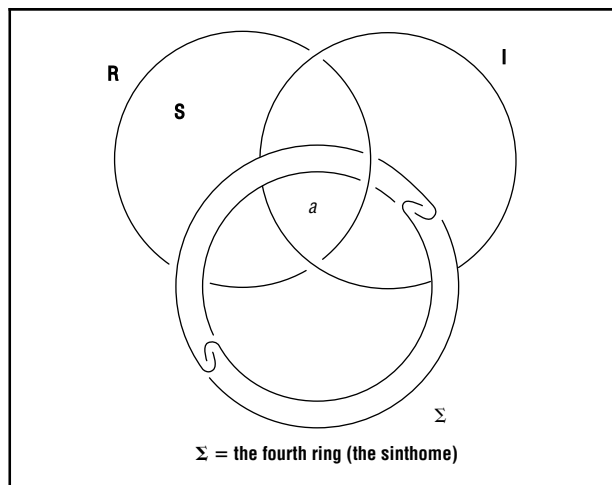

**FIGURE 8**

(This is why Lacan identified the real with the impossible.) In psychoanalysis, the real resists, and thus is distinct from, the imaginary defenses that the ego uses specifically to misrecognize the impossible and its consequences.

If each of the three registers R, S, and I that make up the Borromean knot is recognized to be toric in structure and the knot is constructed in three-dimensional space, it constitutes the perfect answer to the problem above, because it realizes a three-way joining of all three toruses, while none of them is actually linked to any other: If any one of them is cut, the other two are set free. Reciprocally, any knot that meets these conditions is called *Borromean*. Note that the subject is now defined by such a knot and not merely, as with the cross-cap, as the effect of a cut (figure 8).

FIGURE 9

Unfortunately, this ideal solution, which could be considered normal (without symptoms), seems to lead to paranoia. Lacan considered this to be the result of failure to distinguish among the three registers, as if they were continuous, which indeed occurs in clinical work. Being identical, R, S, and I are only differentiated by means of a “complication,” a fourth ring that Lacan called the “sinthome.” By making a ring with the three others, the sinthome (symptom) differentiates the three others by assuring their knotting (figure 9).

In this arrangement, the sinthome has the function of determining one of the rings. If it is attached to the symbolic, it plays the role of the paternal metaphor and its corollary, a neurotic symptom.

Lacan also drew upon non-Borromean knots, generated by “slips,” or mistakes, in tying the knots. These allowed him to represent the status of subjects who are unattached to the imaginary or the real and who compensate for this with supplements (Lacan, 2001). In such cases the sinthome is maintained.

By using knots, Lacan was able to reveal his ongoing research without hiding its uncertainties. The value of the knots, which resist imaginary representation, is that they advance research that is not mere speculation and that they can grasp—at the cost of abandoning a grand synthesis—a few “bits of the real” (Lacan, 1976–1977, session of March 16, 1976). Even though he knew something about topology as practiced by mathematicians, Lacan advised his students “to use it stupidly” (Lacan, 1974–1975, session of December 17, 1974) as a remedy for our imaginary simpleminded-

ness. He also recommended manually working with the knots by cutting surfaces and tying knots. Finally, for Lacan, topology had not only heuristic value but also valuable implications for psychoanalytic practice.

## TOROK, MARIA (1925–1998)

A French psychoanalyst of Hungarian birth, Maria Torok was born on November 10, 1925, in Budapest and died in New York on March 25, 1998.

She trained as a psychologist at the Sorbonne in the early 1950s; there she met Nicolas Abraham, a philosopher interested in the phenomenology of Husserl and a psychoanalyst, and she became his companion. She was initially a psychological counselor in nursery schools when she went into analysis with Béla Grunberger and later with Margaret Clark-Williams, an American-born psychoanalyst. Torok went on to become an analyst and a member of the Société psychanalytique de Paris (Paris Psychoanalytic Society).

In Torok’s work together with Abraham as well as in their individual work, both were concerned with

differentiating the “shell” from the “kernel” of any theory, a concern that is articulated in their book *The Shell and the Kernel: Renewals in Psychoanalysis* (1978; trans. 1994): “[I]f Freud’s theories form the protective shell around his intuition, simultaneously concealing and revealing it, what of the actual kernel? For it is the kernel which, invisible but active, confers its meaning upon the whole construction. This kernel, the active principle of psychoanalytic theory, will not show through unless all the apparent contradictions have found their explanation of the unity I ascribe hypothetically to Freud’s intuition” (p. 82).

In her 1968 article “The Illness of Mourning and the Fantasy of the Exquisite Corpse,” Torok reexamined the problems of introjection and incorporation, as presented from the works of Sándor Ferenczi through those of Melanie Klein. She distinguished introjection, as a process that allows the ego to be enriched with the instinctual traits of the pleasure-object, from incorporation, a fantasmatic mechanism that positions the forbidden or prohibited object within the self in secret. “Installed in place of the lost object, the incorporated object continues to recall the fact that something else was lost: the desires quelled by repression” (p. 114). She developed a theory of the crypt and the phantom that haunts the subject and begins to speak in the subject’s place. The phenomenon of the phantom results not from the return of the repressed, but from the cryptic inclusion of an Other, in the face of which the illness of mourning and the work of mourning have not been able to take effect.

Torok thus took on the work of a patient and critical rereading of Freud, Ferenczi, and Klein, in an attempt to identify all that remained unanalyzed and “encrypted” in the systems of psychoanalysis. After Nicolas Abraham’s death in 1985, she continued this line of inquiry into psychoanalysis with Abraham’s nephew, Nicholas Rand.

## **TOSQUELLES, FRANÇOIS (1912–1994)**

François Tosquelles, a French physician, hospital psychiatrist, psychoanalyst, and founder of the movement for institutional psychotherapy, was born on August 12, 1912, in Reus (Catalonia, Spain) and died on September 24, 1994, in Granges-sur-Lot (France). He was reared in Reus in a progressive and culture-loving environment until he sat for his baccalaureate at the age of fifteen. He then enrolled in the medical school of Barcelona University, where he met Sándor Eiminder, an Austrian refugee fleeing Nazism, who became his psychoanalyst. As early as 1934 he was appointed to work as a physician in the Instituto Pere Mata and enjoyed the benefits of being psychoanalytically monitored by Werner Wolf, a German refugee who had settled in Barcelona.

In 1936 Spain elected the Popular Front and rapidly found itself facing down fascism. Tosquelles was appointed psychiatric head of the republican army. He implemented group techniques derived directly from psychoanalysis to treat psychological decompensation in soldiers, as Wilfrid Bion and John Rickman were to do in Great Britain during World War II.

Forced to flee Spain after the defeat of the republicans, he arrived in France and settled in Saint-Alban-sur-Limagnole (in the Lozère department) in 1940. As a result of his work with Lucien Bonnafé, André Chaurand, and many others during the period of Resistance, the Saint-Alban-sur-Limagnole psychiatric hospital became the crucible of a unique experiment based on the discoveries of psychoanalysis and aimed at treating the most seriously ill mental patients from a psychodynamic perspective. He worked with a large number of psychiatrists and psychoanalysts, the best known among them being Jean Oury, Hélène

Chaigneau, Jean Ayme, Horace Torruba, Roger Gentis, Philippe Rappard, and Yves Racine. Georges Daumézon and Philippe Koechlin later referred to this system as “institutional psychotherapy.” It greatly contributed to changing the face of French psychiatry by developing the system of “sector psychiatry” set up in the 1960s and 1970s. In this innovative practice of psychiatry, ongoing treatment made it possible to take the psychoanalytic concept of the transference relation into account. We find echoes of this system in Tosquelles’s book *Éducation et psychothérapie institutionnelle* (Education and institutional psychotherapy; 1984).

Tosquelles was very attached to a global conception of the human being. In his psychoanalytic practice he treated children and adults, individuals and groups, using the techniques of classical treatment and psychodrama. A polyglot possessing vast knowledge, he never ceased to establish links between the world of psychiatry and the discoveries of psychoanalysis, phenomenology, and anthropology. The quality of his presence for the other, his clinical intuition, his lively personality, and his indefatigable search to improve conditions for mental patients made him a unique figure in the history of psychoanalysis.

In the domain of psychoanalysis he was mainly responsible for introducing an in-depth approach to the study of psychopathology and the psychoses. Whether in the psychoanalytic study and comprehension of delusional manifestations and other elements in the behavior of schizophrenic and autistic patients or in reflection on the transference relations that come into play in their treatment, both for the patient and the therapist Tosquelles had the capacity to render complex psychoanalytic problems accessible and crystal-clear, irrespective of the status of his listeners.

Tosquelles instituted a movement of institutional psychotherapy that was furthered by Jean Oury, and continued by many psychiatrists and psychoanalysts. Moreover, he greatly contributed to demonstrating the importance of the nursing team. These contributions responded in part to the wish that Freud expressed at the Budapest Congress in 1918: “When this happens, institutions or out-patient clinics will be started, to which analytically-trained physicians will be appointed, so that men who would otherwise give way to drink, women for whom there is no choice between running wild or neurosis, may be made capable, by analysis, of resistance and of efficient work” (1919a [1918]).

A collection of papers, *Actualité de la psychothérapie institutionnelle* (The current state of institutional psychotherapy; 1994), includes Tosquelles’s last publication.

## TOTEM AND TABOO

*Totem and Taboo* is Sigmund Freud’s first work on group psychology. The foundation of the work’s ideas first appears in 1911, in his correspondence with Sándor Ferenczi, through which it is possible to trace the development of Freud’s thought. Two topics appear in the letters: “tragic guilt” and the “libidinal origin of religion.” His competition with Carl Jung, who was writing the *Metamorphoses of the Soul and its Symbols* (1912), is mentioned, and their break in fact occurred while the book was being written.

The work presents a classic and sweeping analogy between two terms: on the one hand, savages, on the other, neurotics and children—us, in other words. The analogy unfolds in three parts, starting in the first essay where the resemblance between the two is related to the horror of incest that Freud identified in savages by analyzing totemic systems as laws of exogamy. The second essay interprets taboo as a manifestation of the ambivalence of emotions. Freud

postulates the primal existence of emotional currents, distinguishes between savages and the rest of us based on the intensity of emotion, and provides the first in-depth investigation of this conception of emotion. The third essay, cutting across similarities and differences, offers, among other things, the first detailed investigation of narcissism (animism). But there is more to the analogy, which Freud develops at the end of the third essay and in the fourth. He establishes the existence of the concepts he examines, the dynamic that governs them, as well as their bearing on his own work, on the following hypotheses: the existence of a primitive horde whose father is omnipotent; the murder of the father by the group of brothers, leading to the growth of the totemic clan, and the conditions for this possibility of thought.

The work is made difficult because of its complex construction, the manner in which Freud uses analogy, the extreme interpretative power of his analysis, the conceptual richness of the book—projection, ontogenesis of moral conscience, the reality-ego and pleasure-ego—and finally because of the “spiny hedge of literature and reference” included (letter to Ferenczi, May 13, 1913). This work also traces the Oedipus complex to a scientific myth that is found, in modified form, in the work of the majority of later psychoanalysts.

Although schematic and structural, *Totem and Taboo* was the basis for Freud’s work on group psychology. Like most of his work, it is more frequently reduced to a simple formula (the murder of the father by the horde) than studied or understood as a whole. The only valid criticism concerns the hypothesis of the phylogenetic transmission of precise memory traces. But the forms assumed by the primal horde and the totemic clan, as well as the foundational moment of rupture that they share, remain pertinent. The libidinal dynamics that constitute such groups were later elaborated in *Group Psychology and the Analysis of the Ego* (1921c), along with the status of the “poet” who invents the myth of origin.

## TOTEM/TOTEMISM

The word *totem* is derived from the Ojibwa language of North America, where it refers to kinship relations between siblings and the exogamous clan. In the nineteenth century, British anthropologists suggested that totemism, characterized by the existence of a fetish, exogamy, and matrilineal descent, was the fundamental institution of primitive societies and the essential basis of their beliefs, as distinct from the religious and scientific thought of western culture. This universalizing, comparative, and evolutionist attitude reached its apogee in James G. Frazer. It disappeared for methodological reasons. Ethnologists abandoned universalism to conduct local research, emphasizing the differences between cultures.

In Freud's work the word *totem* appears in a supplement (1912a), prepared for the Weimar Congress, September 21 and 22, 1911, describing his analysis of Justice Schreber's book (1911). After working for four months on *Totem and Taboo* (1912–13a), Freud announced his intentions as follows: "The assumption underlying these trials [proving the authenticity of children's lineage from a clan's totem] leads us deep into the *totemic* habits of thought of primitive peoples. The totem . . . spares the members of the tribe as being its own children, just as it itself is honoured by them as being their ancestor and is spared by them. We have here arrived at the considerations of matters which, as it seems to me, may make it possible to arrive at a psycho-analytic explanation of the origins of religion" (1911c, p. 81).

*Totem and Taboo* advanced the thesis that Freud developed in all his writing on group psychology, through *Moses and Monotheism* (1939a [1934–38])—and he indicates that he is aware of the criticism of the literature on totemism and undisturbed by it. Initially there was agreement between the two taboo prohibitions of totemism—killing the totem and marrying within the clan—were found to coincide with the two oedipal wishes—killing the father and marrying the mother. Psychoanalysis provided two other findings: childhood phobias showing the animal could function as a paternal substitute, and Ferenczi's observation of a child who identified with a cock (1913), which Freud associated with an "infantile return of totemism." He went on to describe the murder of the archaic father as the nucleus of totemism and point of departure for the formation of religion. The work of William Robertson Smith (1889) analyzing the "totemic meal" confirmed

the hypothesis: Once a year the totem animal was sacrificed and consumed by the members of the tribe. This was followed by a period of mourning and feasting. By adding the Darwinian assumption of primitive hordes, each under the domination of a single male who was powerful, violent, and jealous, the following scientific hypothesis or myth was set forth. The all-powerful and "absolutely narcissistic" father of the primal horde seized all the women and killed, subjugated, or chased away the sons. "One day, however, the sons came together and united to overwhelm, kill, and devour their father, who had been their enemy but also their ideal" (1925d [1924], p. 68). Afterward, none of the sons could take the place of the father. "Under the influence of failure and regret . . . they banded themselves into a clan of brothers by the help of the ordinances of totemism, which aimed at preventing a repetition of such a deed, and they jointly undertook to forego the possession of the women on whose account they had killed their father. . . . this was the origin of the exogamy which is so closely bound up with totemism. The totem-feast was the commemoration of the fearful dead from which sprang man's sense of guilt (or 'original sin') and which was the beginning at once of social organization, of religion, and of ethical restrictions. Now whether we suppose that such a possibility was a historical event or not, it brings the formation of religion within the circle of the father-complex and bases it upon the ambivalence which dominates that complex" (p. 60).

By assigning a collective prehistory to the Oedipus complex, while making an intrinsic connection between individual and collective psychology via the family, the totem hypothesis also bases the possibility of human thought on the murder of the father of the horde. The fulfillment of this act (i.e., murder of the father), studied throughout Freud's work on group psychology, is what leads to the formation of distinct psychic agencies—ego, ego ideal, and superego—along with the development of ambivalence and the appearance of the feeling of guilt, including unconscious guilt. The concept of the taboo depends on the thesis of totemism. Freud also attributed the susceptibility to hypnotism to the phylogenetic memory traces of the horde. Likewise, group psychology and religion are based on the premise of totemism. From this Freud deduced three paradigmatic forms and dynamics of group existence: the horde, matriarchy, and the totemic clan, and three paradigmatic forms of

religion that are related to them: the worship of mother-goddesses, of the son-hero, and of the father. The latter reveals the return of the repressed created by the murder of the father.

Modern ethnology has challenged the universality of Freud's claim and that of the Oedipus complex. The transmission of phylogenetic traces that are valid for the entire human species is problematic, even if Freud defends this idea with a form of Lamarckism. Nonetheless, Freud's arguments have continued to generate interest (Juillerat, 1991). In *Totem and Taboo* and *Moses and Monotheism*, Freud explicitly analyzed the libidinal forms and dynamics of western culture, with its monotheistic religions, its customs, its morality, its science, and its social and state institutions.

## **TRAINING ANALYSIS**

The training analysis is the personal course of psychoanalytical treatment that every psychoanalyst must undergo with a certified analyst prior to, or in parallel with, his or her theoretical training, and before beginning to practice.

As late as 1909, Freud's answer to the hypothetical question "How can one become a psycho-analyst?" was still: "by studying one's own dreams" (1910a, p. 33). This was a shibboleth that he mentioned several times, but by the following year he widened the requirements: "no psycho-analyst goes further than his own complexes and internal resistances permit; and we consequently require that he shall begin his activity with a self-analysis and continually carry it deeper while he is making his observations on his patients. Anyone who fails to produce results in a self-analysis of this kind may at once give up any idea of being able to treat patients by analysis" (1910d, p. 145). Freud continued to use the term *Selbstanalyse* (self-analysis, or analysis of oneself) to include the procedure of being analyzed by a senior and more experienced person; Max Eitingon's analysis with Freud (1909–1909), conducted during evening strolls on the Ring, was the first instance of a training analysis. Freud later considered it "one of the many merits of the Zurich school of analysis that they have laid increased emphasis on this requirement, and have embodied it in the demand that everyone who wishes to carry out analyses on other people shall first himself undergo an analysis by someone with expert knowledge" (1912e, p. 116).

In 1918, with Freud's agreement, Hermann Nunberg proposed at the Fifth Congress of the International Psycho-Analytical Association that training analysis be made obligatory. Otto Rank and Viktor Tausk were opposed. The rule became official only in 1926. Rank and Sándor Ferenczi (1923/1925) made it clear, however, that "the correct didactic analysis is one that does not in the least differ from the curative treatment"; nor, in their view, should it be confined to physicians.

Ferenczi described the necessity for training analysis as "the second fundamental rule of psycho-analysis" (1928/1955, pp. 88–89). The adoption of the principle by the International Psychoanalytical Association (IPA) was the result, chiefly, of the efforts of Eitingon and of the initiative of the Berlin Institute, which had set up a training protocol as early as 1920. The training analysis was a cornerstone of that protocol, and Hanns Sachs was one of the first official *training analysts*.

Writing to Franz Alexander on May 13, 1928, Freud once again raised the bar: "One ought to demand guarantees from the candidates which are not necessary with patients, since regular analytic work has deleterious effects on one's psyche just as work with Roentgen

rays has on one's tissues; it needs to be countered by steady hard work" (Jones, p. 478). A few years later, at a time when the received wisdom was to extend analysis to the limit, Freud even suggested that "Every analyst should periodically—at intervals of five years or so—submit himself to analysis once more, without feeling ashamed of taking this step" (1937c, p. 249).

During the years when psychoanalysis was expanding, thanks both to the dispersal of émigrés in flight from Nazism and to the strengthening of the movement's institutions, training analysis became the subject of innumerable papers, reports, and debates, and the rules governing it were continually changing. A letter from Rudolph Loewenstein to Marie Bonaparte dated February 22, 1953, is eloquent on the prevailing norms: "Here [in New York], as in the American Association, there is a rule requiring training analysis to be conducted on the basis of at least four sessions per week, of between three-quarters of an hour and fifty-five minutes in length. Even the people in Chicago support this. The worst, though, are the Washington lot."

Regulations of this sort were at the root and core of a good many splits in the psychoanalytic movement, notably in France in 1953 and 1963, where Jacques Lacan's short sessions and his relationship with his analysands were challenged by the IPA authorities, who eventually barred him as a training analyst. Lacan retaliated by decreeing in the founding statement of his *École freudienne de Paris* that training analysis was the purest form of analysis, and by proposing (October 9, 1967) the institution of the system of induction of analysts that he called "*la passe*."

Critics of required training analyses variously underscore the antithesis between a professional project and the request for a personal analysis, the possibility of external rivalries corrupting the transference and/or counter-transference in such analyses, the hierarchical medical model implied by the title of *training analyst*, and even the danger of creating a "restricted transference zone" (Stein). There has been a tendency for the term *training analysis* to fade from use in training programs: the Paris Psychoanalytical Society, for example, under the influence of Sacha Nacht, prohibited any participation of a candidate's analyst in his or her training. The function of the training *analyst*, however, has shown remarkable staying power, and the international guidelines that the IPA's member societies are bound by in this connection are still the object of much debate and negotiation. Each group

strives by its own lights to settle on what Freud called "the training most suitable for an analyst" (1926e, p. 252), but the necessity of a preparatory personal analysis is universally acknowledged. Under what conditions, and with whom, are still open questions.

## TRAINING OF THE PSYCHOANALYST

Psychoanalytic training is the process that enables a student to be recognized as a psychoanalyst by the psychoanalytic community and serves as a prelude to psychoanalytic practice. Many attempts have been made to define the optimum conditions for training since the early years of psychoanalysis. Following the creation of the Berlin Institute for Psychoanalysis in 1920, there came into being a number of organizations designed to provide training based initially on individual psychoanalysis.

At present there is no official degree or certification for psychoanalysts. Because of the excesses and pretenses that have inevitably accompanied the success of psychoanalysis, the issue often arises of the need to protect not only patients but also properly trained psychoanalysts, and ultimately psychoanalysis itself. However, the private institutions that represent psychoanalysis do not want the certification they provide to be part of any official legislation. There is a fundamental reason for this. Psychoanalytic training involves, first and foremost, personal experience of the analytic situation, and this experience is valid only if it is a subjective adventure freely undertaken. How could analysts in training reveal the most intimate aspects of their beings if the experience served as a means of obtaining a state-authorized degree or certificate?

Freud himself was aware of the problem early in his career. In a 1926 article (1926e), Freud argued against the idea of restricting analytic practice to medical doctors alone and pointed out the near impossibility of defining criteria for the “illegal practice” of psychoanalysis. His wish was that psychoanalysis be “neither permitted nor forbidden,” and thereby be free of government regulation. At the same time, he felt that organizations like the association he had created could regulate psychoanalysis and thereby resolve, to the extent possible, the problem of integrating psychoanalysis into society. Such an institution could establish methods of training and procedures for certification. In spite of various crises and criticisms, this model and its variants appears to have remained the most pertinent.

It is easier to describe the tripartite model that is generally a part of an analyst’s training than to summarize the contradictions that have arisen with the question of accreditation. There are three components to training, all of which are necessary. In the United States the analyst in training undertakes the three parts of training concomitantly. It is considered essential that a candidate undergo analytic treatment while conducting a supervised analysis so that problems that arise through the counter-transference can be analyzed.

The first component of training is the analysis of the candidate. In France, this requires a commitment to analysis prior to training and ensures that the analysis, when it occurs, calls into question the unconscious sources of the desire to be an analyst. If the candidate is not committed, or is incompletely committed, the candidate should draw the appropriate conclusion and withdraw from the field. Experience shows that this does not always happen, and in such cases the position assumed by the analyst is rarely compatible with the analyst’s performance. It is appropriate to refer such cases to a third party—an organization, for example—for adjudication. The personal experience of analysis is so important that it has been referred to as the *second fundamental rule*. This requirement follows from the demands made on the analyst in practice: evenly suspended attention, benevolent neutrality, the ability to analyze one’s own mental responses to the patient, identification and de-identification with the patient, and so on.

The conclusion of analysis and the criteria for success have been the subject of much spirited debate within the psychoanalytic community. Originally, the analysis was involved in only an aspect of the full potential of psychoanalysis: acknowledging the existence of the unconscious, which provides the subject with greater understanding and conviction. But with advances in the technique of analysis and the emergence of the concept of counter-transference, training analysis moved in the direction of the most complete analysis possible, with each of the major theoretical trends proposing a definition of a satisfactory conclusion in terms of its own criteria. The paradox is that defined criteria of a satisfactory conclusion engenders a normative reference that contradicts the very spirit of the analytic process. It is important to stress, therefore, that the analysis of the candidate has a greater chance of success if its didactic dimension is ignored,

if the ever-present real or imaginary requirements of the collective ideal are abandoned, and if the analysis finds its own *modus operandi*. The process requires only—but this is already asking quite a bit—that candidates, starting from an adequate intellectual base, engage in self-analysis and be able to identify and make use of the effects of counter-transference on themselves. As can be imagined, such a process of analysis exceeds the scope of training. Because of the risks associated with practice of the profession, the analyst should be prepared to undertake additional therapy when needed: one's own analysis being, by definition, open-ended.

The second component of training involves supervised analysis. The novice analyst speaks to a more experienced colleague on a regular basis about a current patient in analysis. This report can assume various forms and involve different kinds of comments and exchanges. What is essential is that the junior analyst talk about what takes place between his patient and himself in terms of transference and counter-transference. When he does so, he will necessarily reveal the unconscious counter-transference, which then can be pointed out and elaborated. One of the goals of supervision is to enable the beginning analyst to transcend identification with his own analyst and develop his own style.

The supervisory situation, typically involving two people, can also be conducted in small groups, in which case it resembles a seminar for clinical discussion. The controlled environment that supervision affords is so vital that all analysts should make use of it whenever problems occur in their practices. Supervision must therefore be considered a separate form of analysis, a process that occurs alongside therapy and serves as the basis for analyzing oneself while analyzing the patient.

The third component involves training in analytic knowledge and metapsychology. Naturally, it is desirable that the analyst be familiar with the key texts in psychoanalysis and be as well educated as possible. Study groups and seminars requiring the trainee's active participation and interaction with older colleagues will contribute to the trainee's education. Below are some additional points about education:

- Possessing knowledge is of limited value for practical competence. For the analyst, knowledge assumes value when a given concept, author, or clinical description arouses his interest, mobilizes his defenses, and encourages his identifications,

allowing him to access the truth at a given moment. And this process is entirely subjective. A theoretical overview intersects with the insights of self-analysis. Because psychoanalysis seeks knowledge of the unconscious, everyone must follow the road of Freudian discovery for himself.

- Studying Freud is a central part of training. This study is justified not only because Freud originated modern psychoanalysis and his depth and scope form an intellectual matrix for the discipline, but also because identification with the inventor of psychoanalysis shifts over time as a result of rejections and contradictions and multiple models. Critical study can weed out defensive adherence to a dogmatic and closed theoretical model. Finally, in view of the pluralism of post-Freudian thought, shared knowledge of Freud's work can be used to identify areas where differences, divisions, and revision occur. A century after Freud's discovery, an analyst's metapsychological grounding must involve some historical awareness, which is indispensable for orienting oneself within the immense body of psychoanalytic writing.
- Training in psychoanalysis also involves initiation into a range of fields opened up by the extension of psychoanalysis (child, psychosomatic, family, group psychoanalysis) and its application (care institutions, education). In all of these fields, what is important is that psychotherapeutic practices more or less follow the analytic model.
- In the ideal program of a psychoanalytic institute, Freud included the teaching of fields that he felt were essential for analytic thinking: anthropology, prehistory, mythology, history of religion, biology, linguistics, as well as others that have been added since, such as the arts. For the well-trained analyst, nothing human is foreign. In pursuit of this ideal the well-trained analyst will undergo continuous education.
- In a more immediately practical sense, the question of appropriate prior training has often been discussed. It is advisable that the analyst have at least a college education, have adequate experience of living and working, and have seen something of human suffering. In the early twenty-first century, the great majority of analysts came from the fields of medicine, especially psychiatry, and psychology, and indeed, knowledge of serious psychopathol-

ogy is indispensable in modern psychoanalytic practice. For these professionals, the encounter with their unconscious and access to metapsychological ways of thinking will still call their training into question, but it is not a bad thing if analytic training is primarily conceived as a form of undoing.

To ensure that a psychoanalytic body is responsible in certifying its members, it must explicitly define the principles on which training is based and the regulatory procedures to which trainers and trainees are subject. The most difficult aspect of this process is ensuring quality analysis of the psychoanalytic candidate while respecting the candidate's extrainstitutional space and time. For this reason and for purposes of maintaining confidentiality, every institutional discussion or decision concerning a candidate must explicitly exclude any interference by his analyst.

Interactions between applicants and institutions (such as offers of employment) reflect the options available and the views held by the various parties regarding the ethics of training and certification. Models range from selection prior to any commitment to analysis (as in the United States), a model that requires a highly organized course of study at an institution, all the way to certification after the fact, which makes candidate analysts fully responsible for the various aspects of their training. In intermediate models, supervised analysis serves as an introduction to the institution and thus as a preliminary form of certification. Logically, candidates' requests to move from couch to chair should coincide with affirmation of their desire to make the move. However, this connection cannot be made a requirement even though the institution requires it, because the affirmation ultimately lies with the subject.

In France, evaluation of a request for admission to a society generally takes place over the course of three meetings with three analysts assigned by the institution. In these meetings the candidate speaks about himself and his analysis. This is an awkward situation, for the candidate needs to transpose, in a conversation with an analyst who is also an examiner, what has until then been his intimate and private experience of the analytic situation. What the examining analysts seek in the candidate is not greater benefits from the analytic work but a display of the necessary distance that reflects the self-analytic ability required of an analyst.

In successful interviews, the candidate clarifies the truth of the dialogue of the meetings, and the examining analysts can consider whether the candidate is qualified for the work of analysis. From the personal nature of these meetings, it is easy to see that they require absolute confidentiality. The outcome of the meetings should be a collective response made on behalf of the institution. Ultimately, the most difficult problem is that of rejecting the candidate.

Further training and certification can assume very different forms. New analysts can be further evaluated in supervised analysis and seminars. Since an institution is defined as much by those it accepts as those it rejects, the problem of rejecting candidates remains. Flexible and controlled modulation of where to draw the line between admission and rejection makes for internal dynamism in scientific exchange, fertile tension between the individual and the group, as well as conflict between generations. Institutional certification acquires meaning only in relation to the duration of training, when supported by older colleagues, and in seeking the transmission of knowledge from one generation to the next.

## TRANCE

According to Gilbert Rouget (1980), a *trance* is a “temporary state of altered consciousness that obeys a cultural model.” In the Middle Ages this term was applied to the agonies of death and the Passion of Christ. The word *trance* appeared in connection with the fakirs in a supplement to the first edition of the book *Neurhypnologie* by James Braid, the British doctor who popularized hypnotism. It was also used at the end of the nineteenth century to refer to the state of depersonalized mediums embodying the spirits of other people. From the perspective of physicians and psychologists of that era, exotic, spiritualistic, or Catholic trances could be explained in terms of provoked somnambulism, hypnosis, hysteria, or neurosis, notions that seemed to give a scientific explanation for these phenomena. Sigmund Freud associated himself with this tradition to some degree when he entitled one of his articles “A Seventeenth-Century Demonological Neurosis” (1923).

This perspective was reversed when ethnologists such as Alfred Métraux, Michel Leiris, or Roger Bastide began to use this term, which in their view was less ethnocentric, less psychologizing, or less psychiatric in tone than the words *hypnosis* or *hysteria*. *Trance* became the general term for experiences, rites, and beliefs relating to possession, shamanism, ecstasy, or divination observed in other cultures. From then on, magnetic somnambulism, hypnosis, and even psychoanalysis were seen as coming out of an Occidental trance culture. Thus, in *The Elementary Structures of Kinship* (1949/1969), Claude Lévi-Strauss described psychoanalysis as a “modern form of shamanism.”

While the question of a psychology or a psychoanalysis of the trance continues to be raised, it has been given away, in many contemporary studies, to that of the relationship between the individual and the cultural realms.

## TRANSCULTURAL

For a long time the question of alterity (Julia Kristeva), and in particular cultural alterity, has been raised by psychoanalysis (Sigmund Freud, Sándor Ferenczi, Géza Roheim): psychic alterity and its avatars, working within the analytic framework, and the transformation of this alterity, which can be painful or difficult to come to terms with, into human creative potential. New ways of shedding light on this question are being found in the areas of both epistemology (Isabelle Stengers) and clinical work (adaptation of the analytic framework to non-Western populations, migrants, and so forth).

There are several modalities of integration of cultural representations into our clinical systems. Advances in anthropology have required practitioners to consider the two-way interactions between outside (culture) and inside (the individual's psychic functioning). Two different currents of thinking have emerged: those that hold that the therapeutic relationship is constituted from the outset by elements inferred to be

universal, and those that hold that the detour through the particular with its own specific coding, including cultural coding, is necessary. And yet, even among those who accept the presence of cultural presuppositions in the therapeutic relationship, two different epistemological positions can be noted, and regrettably, these have led to heated debates, more ideological than clinical, in many Western countries.

Some thinkers have adopted an essentially comparatist perspective: What are the invariant features that are found in our patients' culture and our own? This view leads to the construction of equivalencies and parallels between cultural elements of different worlds, but also between the cultural elements of one group and pathological behaviors of individuals belonging to other groups. This option was present in some of Freud's texts, such as *Totem and Taboo* (1912–1913a). On the clinical level, this choice leads to inserting the patient's language into certain mechanisms, and even becoming familiar with his or her cultural representations. But all of these elements are posited as a particular coloration of the clinical relationship, its nucleus (the effective part) being the same as what would be established in an intracultural situation. The approach here can be psychological (in France, H el ene Stork or Blandine Brill), psychiatric (this is especially the case in English-speaking countries, such as in the United States, with Arthur Kleinman), or, more rarely, psychoanalytic (the field called psychoanalytic anthropology).

Others, following Georges Devereux, have adopted a perspective based on complementarity and make requisite but not simultaneous use of psychoanalysis and anthropology. This complementary approach differs from the comparatist one in that cultural logics are explored as such and are used to support associations. The tool of anthropology makes it possible to establish and explore the framework of the relationship and to co-construct cultural meanings with the patient, to which individual meanings will be linked. This perspective, ethnopschoanalysis, is the most developed one in France. It is represented by the works of Tobie Nathan (1986), for the first generation, and those of Marie-Rose Moro (1994) for the second. In "L'Ethnopsychiatrie" (1978; Ethnopsychiatry), Devereux proposed a classification that recognizes three types of therapies that take into account the cultural dimension of mental disorders: "1. Intracultural, where the therapist and the patient belong to the same culture, but the therapist takes sociocultural dimensions into account....

2. Intercultural (or transcultural, as it was first defined), where although the patient and the therapist do not belong to the same culture, the therapist is well acquainted with the culture of the patient's ethnic group and uses this knowledge as a therapeutic tool. . . .

3. Metacultural: the therapist and the patient belong to two different cultures. The therapist is not familiar with the culture of the patient's ethnic group, but nevertheless has a thorough understanding of the concept of culture and uses it in establishing the diagnosis and carrying out the treatment."

In English-speaking countries, working from Devereux's classification, a distinction is made between cross-cultural psychiatry or psychology (intercultural) and transcultural psychiatry or psychology (transcultural or metacultural).

The term *transcultural* is used in an imprecise way to refer in the broadest sense to the inter-, intra-, and metacultural perspectives. In a more restricted and precise sense, it refers to the metacultural form, which presupposes a perfect understanding of the concept of culture. Thus, in clinical practice the issue of the transcultural takes on very different forms depending on country and on theories relating to intellectual history, and psychoanalysis in a given context.

## TRANSFERENCE

The term *transference* denotes a shift onto another person—usually the psychoanalyst—of feelings, desires, and modes of relating formerly organized or experienced in connection with persons in the subject's past whom the subject was highly invested in. *Transference* (*Übertragung*; literally, “carrying over”) was first used in *Studies on Hysteria* (Freud and Breuer, 1895d), and it gradually developed a more precise meaning over time with progress in the understanding of psychoanalytic treatment in its different dimensions. As of 2005, the term covers all the transference phenomena met with in analytic practice, more specifically, transference love, the transference relationship, transference neurosis, narcissistic transference, negative transference, and so on.

Transference involves transferring libidinal cathexis from one person to the form, personality, or characteristics of another. The quantity of libidinal energy deployed in such transfers varies and may be considerable, comparable in strength even to the original cathexes. There are two important points to note in this connection. First, what is mobilized here is libido; the other forms of instinctual energy evoked by Freud are not involved. Self-preservation, for example, plays no part in transference. Second, the withdrawal of libido from one object and the cathexis of another with it, as in states of mourning, is not a transference phenomenon. Transference implies maintenance of a particular relational form and fidelity to a past relationship that have been preserved in the unconscious.

The experience of psychoanalysis supports the conclusion that transference phenomena occur naturally in the course of ordinary life, especially with love relationships. Such “wild” transferences usually structure new relationships with outcomes very different from what happens during psychoanalytic treatment. As

Freud put it, “Psycho-analysis does not create [transference], but merely reveals it to consciousness and gains control of it in order to guide psychical processes towards the desired goal” (1910a [1909], p. 51). In its full meaning, transference is what is observed in the course of the treatment and what constitutes an essential precondition of the effectiveness of treatment. A subject incapable of any kind of transference is unsusceptible to treatment by analysis.

At first, in *Studies on Hysteria*, Freud viewed transference in terms of the hypnotic analyst-patient relationship, that is to say, solely in its relational, emotional, and amorous aspects. Freud considered establishing such a relationship to be a prerequisite of success with the cathartic method, just as establishing a hypnotic state is a prerequisite for hypnotic suggestion. For patients who put their trust in the analyst, Freud wrote, it is “almost inevitable that their personal relation to him will force itself, at least for a time, unduly into the foreground. It seems, indeed, as though an influence of this kind on the part of the doctor is a sine qua non to a solution of the problem” (1895d, p. 266). On several subsequent occasions Freud again related transference and suggestion, reiterating that transference was a precondition of suggestion. At the same time, he connected the intensity of the patient's relationship with the analyst with what he called a *mésalliance* (false connection) between a memory from the subject's past and the therapeutic situation: The content of a past wish arises “in the patient's consciousness unaccompanied by any memories of the surrounding circumstances which would have assigned it to a past time.” The wish is then linked to the analyst, with whom the patient is already legitimately connected. “As the result of this *mésalliance*—which I describe as a ‘false connection’—the same affect is produced which had forced the patient long before to repudiate this forbidden wish. Since I have discovered this, I have been able, whenever I have been similarly involved personally, to presume that a transference and a false connection have once more taken place” (p. 303).

Thus a transference is not only the patient's love of the analyst but also the transposition of an old relation onto him. Once Freud had reached this conclusion, he perceived that this second aspect of the transference took the form of a new illness, and that it could derive from very ancient relationships indeed. In “Fragment of an Analysis of a Case of Hysteria” (1905e [1901]),

for instance, he writes, “But the productive powers of the neurosis are by no means extinguished; they are occupied in the creation of a special class of mental structures, for the most part unconscious, to which the name of ‘*transferences*’ may be given” (p. 116).

Gradually the notion of *transference neurosis* came into relief for Freud: “Provided only that the patient shows compliance enough to respect the necessary conditions of the analysis, we regularly succeed in giving all the symptoms of the illness a new transference meaning and in replacing his ordinary neurosis by a ‘transference-neurosis’ of which he can be cured by the therapeutic work. The transference thus creates an intermediate region between illness and real life through which the transition from the one to the other is made. The new condition has taken over all the features of the illness; but it represents an artificial illness which is at every point accessible to our intervention” (1914g, p. 154). Repetition in the transference becomes the means whereby the patient remembers forgotten, unconscious mental attitudes: “The part of the patient’s emotional life which he can no longer recall to memory is re-experienced by him in his relation to the physician” (1910a [1909], p. 51).

Thus transference is the motor of the psychoanalytic cure, in more than one sense. For one, the transference introduces a new element into the patient’s mental situation, a “piece of real experience” (1914g, p. 154). For another, the transference is a necessary precondition of the patient’s acceptance of interpretations: “When is the moment for disclosing to [the patient] the hidden meaning of the ideas that occur to him? . . . Not until an effective transference has been established in [him], a proper *rapport* with him. It remains the first aim of the treatment to attach him to it and to the person of the doctor. To ensure this, nothing need be done but to give him time” (1913c, p. 139). Lastly, it is the energy of the transferred affects that supplies the force needed to remove resistances.

At the same time, transference is also responsible for resistance: “In analysis transference emerges as *the most powerful resistance* to the treatment, whereas outside analysis it must be regarded as the vehicle of cure and the condition of success” (1912b, p. 101). A kind of collusion may be struck up between resistance and transference if transference serves the aims of resistance or if a “distortion through transference” (p. 104) is used to mask a conflict. Thus analysis of the transference takes center stage, becoming the very heart, and a

defining part, of the treatment. “The decisive part of the work is achieved by creating in the patient’s relation to the doctor—in the ‘transference’—new editions of the old conflicts; in these the patient would like to behave in the same way as he did in the past, while we, by summoning every available mental force [in the patient], compel him to come to a fresh decision. Thus the transference becomes the battlefield on which all the mutually struggling forces should meet one another” (1916–1917a [1915–1917], p. 454).

Freud described two forms of transference, negative and positive. *Positive transference* covers all aspects of attachment to, and confidence in, the analyst; it is essential to successful treatment. *Negative transference* denotes hostile cathexes or excess cathexis, which may lead the patient to break off the therapeutic relationship.

The treatment, as it progresses, may be accompanied by such ancillary transference phenomena as *lateral transferences*. Lateral transferences are cathexes, parallel with the cathexis of the analyst, of some figure capable of focusing that portion of the subject’s libido and wishes that cannot be directly expressed to the analyst. Such transferences escape the sphere of transference proper, which is intermediate between the inner world and outside reality, and thus are inaccessible to analysis. But the relations they create may in reality be of great value in other ways to the patient.

The erotic dimension of the transference can constitute an obstacle to psychoanalytic cure in patients in whom disparate arguments connected by a nebulous logic prevents any shift in mental processes of the amorous cathexis of the analyst (1915a, pp. 166–167). Concerned by Ferenczi’s experimentation in this regard, Freud warned against offering any direct satisfaction to the patient; the danger was, he felt, that the analyst would find himself in the position of the pastor who attempted the death-bed conversion of an insurance salesman, only to leave with an insurance policy but no convert (p. 165).

## TRANSFERENCE AND COUNTERTRANSFERENCE

Heinrich Racker (1910–1961) became a member of the Asociación Psicoanalítica Argentina (Psychoanalytic Association of Argentina) in 1947. The appearance of his book *Transference and Countertransference*, whose central theme is counter-transference, had considerable impact in Latin America, and also aroused interest and confirmation in other psychoanalytic centers of North America and Europe.

Racker argued that transference and counter-transference are the two components of a unity that

reciprocally give life to one another and create the interpersonal relationship in the analytic setting. The counter-transference encompasses the analyst's total response to the transferences of the patient and to his or her own transference reactions to the person of the analysand. It is a decisive factor for the understanding and interpretation of the patient's psychological processes.

In the establishment of the counter-transference, Racker distinguished between a “concordant identification,” which results from the analyst's identification with the analysand's ego, superego, and id, and a “complementary identification,” produced by the analyst's identification with the analysand's internal objects.

These identifications configure *transference-counter-transference neurosis*. There thus exists a *bipathy*. Within this bipathy, while negative or sexual transference disrupts the patient's collaboration in the analysis, the analyst's negative or sexual countertransference interferes with his or her comprehension of the analysand, and, consequently, his or her interpretive abilities. To successfully dissolve these resistances, the therapist must undertake constant self-analysis throughout the treatment of his or her patients. Paradoxically, counter-transference neurosis can play a positive role when the therapist uses it to understand the patient's neurosis. Racker showed how the analyst's affective position—dependent upon his or her archaic objects—appears as a response to that of the analysand, signaling psychological facts about it. From another viewpoint, the analyst also unconsciously communicates his or her affective contents to the patient. Racker particularly emphasized positive counter-transference, love, as a basic force for understanding that makes possible the development of a positive analytic process. He assigned three meanings to counter-transference, viewing its manifestations as a “danger,” an “instrument” for understanding and interpretation, and a “reliving that is simultaneously a new slice of life.”

## TRANSFERENCE/COUNTER-TRANSFERENCE (ANALYTICAL PSYCHOLOGY)

*Transference* is the projection of unconscious contents. Jung's *Studies in Word Association* (1906) provided evidence for and referred to Freud's concept of transference, published the previous year. In 1912 Jung noted that the analysand's perception of the analyst's more mature personality forms an empathic bridge between his infantile relationship to reality and adult adaptation. He insisted that an analyst undergo analysis himself, and also saw the importance of analyzing the transference, which both hinders and facilitates psychological growth. By 1913 Jung had extended Freud's definition, saying transference was also the basis for normal human relatedness. After breaking with Freud, he analyzed his own projections, resolved them to achieve emotional, intellectual, and spiritual/moral autonomy, and concurrently set forth the elements of his opus. A survey of early work shows recognition of counter-transference, the reciprocal arousal of unconscious content in the analyst in response to patient projections. In 1929 he stated his view that the personality of the analyst contributes to analytic process, and that transformation is mutual. He also observed instances of unconscious identity between doctor and patient, giving it the anthropological term *participation mystique*; later it was recognized by psychoanalysts and called *projective identification*. So convinced was Jung that this unconscious reciprocal influence distorted all analytic discourse that he drew upon another projective system, alchemy, in *Psychology of the Transference* (1946) to demonstrate the ubiquity of transference and to identify stages in its evolution and resolution.

For some students this represents an incomprehensible departure from rational scientific method. To appreciate its logic one must first accept the role of metaphor in psychological theory building and, second, understand Jung's theory of archetypes and

his model of the psyche, which includes a personal and a collective unconscious. Although the concept of archetype has not been accepted by psychoanalysts, the idea has arisen independently in the fields of anthropology, linguistics, behavioral biology, and evolutionary psychiatry. Briefly, the capacity to perceive certain forms and processes is inherent, and these ancient, typical potentials are released, to acquire specific psychological content when, in the course of development, the individual encounters external reality. The collective unconscious contains all realizable human potential.

The analytic process itself is unconsciously directed by the archetype of individuation, the impulse to grow in psychological depth and complexity, and is an inherent property of the self, the archetype that embraces and comprises all other archetypes. Transference thereby acquires a teleological dimension, the symbolic intent and meaning of which is revealed and experienced as analysis unfolds; this is its prospective aspect, in contrast to the regressive projection of unconscious material from infantile or other past experience.

Jung recognized two universal, diametric archetypal urges in the individual psyche: to be separate, complete, and autonomous; and to be intimately bonded to the other, both coupled and enfolded in a group. These longings are primary motivating forces at the root of transference and resistance, constituting a fundamental paradox to be apprehended and resolved in individuation and analysis. Having this profound insight, he sought a metaphor to convey its universal, timeless, and impersonal meaning, to point analysands away from the average dependent/omnipotent transference fantasy. The mythology of medieval alchemy provided an unconscious projective system congenial enough to Western mentality to be accessible, but distant enough to reflect projections made in an analytic process that structures imaginative associations for the purpose of self examination. He chose a sixteenth-century treatise, the *Rosarium Philosophorum*, to reflect evolving transference/counter-transference fantasies in the analytic process.

All analytical psychologists view transference as a multileveled web of transecting relationships, interpersonal and intrapsychic, conscious and unconscious, occurring simultaneously within and between analyst and patient. Since the spiritual urge was regarded by Jung as an archetypal force equal to sexuality, his con-

cept of transference extends into transpersonal realms. For some analytical psychologists this is the major thrust of Jungian theory, whereas others seek to correct theoretical and methodological gaps, (for example, in the areas of child development and transference) through links to the work of psychoanalysts whose constructions are compatible with Jung's basic concepts (Kirsch, 1995). Modern psychoanalytic theories of self, projective identification, mutuality, and intersubjectivity all have antecedents in work Jung completed before 1946.

## **TRANSFERENCE DEPRESSION**

Transference itself reveals transference depression. Transference depression, which is a repetition of an infantile depression marked by narcissistic elements that is expressed within the transference relationship, usually after several years of analysis. Its symptoms are atypical of the depressive series. The difficulties raised by narcissism, on the other hand, concern the considerable demands made by the ideal ego, in addition to feelings of powerlessness and dissatisfaction.

Basing himself on Winnicott's work, André Green describes some of the more striking causes of this infantile depression in "The Dead Mother" (1983/1999). It is often a consequence of the mother brutally withdrawing emotional investment in the child because of a state of mourning before or after the child's birth, often caused by the death of another child or a close relative, or some other major narcissistic wound.

The most serious case involves the death of a very young child. This produces a profound alteration in the maternal imago. The latter, which is constituted in the child's psyche, "brutally transforms the internal object, a source of vitality, into a distant, atonal quasi-inanimate figure that profoundly impregnates the cathexes of its subjects and weighs upon the fate of their object-libidinal and narcissistic development." (Green, 1983) This narcissistic trauma, which the child experiences as a catastrophe, brings with it not only the loss of love but also the loss of meaning, since the child has no explanation or understanding of what has taken place.

The consequences of this catastrophe are decaathexis from the maternal object and the constitution within the psyche of a "dead" zone full of "holes" and, in addition, identification in the mirror with the "dead mother," which can lead the child to organize a pathology that aims to bring the mother back to life fantasmatically. Finally, the loss of meaning experienced by the child structures the early development of the ego's fantasmatic and intellectual capabilities; a development which does not take place in the context of freedom to imagine and create, but as compulsive thinking instead.

Sándor Ferenczi's ambivalent relationship to Sigmund Freud provides a particularly apt illustration of this notion. The "insatiable need for support" Ferenczi felt during his analysis with Freud can be considered as a manifestation of transference depression—the repetition of a childhood depression that has not been psychically worked through.

Transference depression, expressed through the emergence of an eroticized appeal addressed to the analyst, reveals a deprived child in a state of helpless distress, marked by a primary depression that has not been psychically worked through (Bokanowski, 1994). Behind the exacerbated demand for love and reparation deficiencies evident in cases transference-love, there are often developmental deficiencies and failures in the primary environment. The transference is thus eroticized as a defense against the fear of collapse, linked to the primary depression experienced by these patients in the very earliest stages of their development. In their interactions with the analyst they relive their despair and distress, as well as their deficiencies in primary symbolization. The erotic demand is thus an attempt to reconnect in the face of the anguish of the void and a deficit in the function of symbolizing.

## **TRANSFERENCE HATRED**

Transference hatred represents the negative pole of the transference relationship determined by the analytic situation. Negative affects are expressed by means of ambivalent impulses within the transference neurosis (negative transference) and destructive impulses more characteristic of borderline states and transference psychoses, notably in passionate psychoses.

In "The Dynamics of Transference" (1912b), Sigmund Freud proposed "to distinguish a 'positive' transference from a 'negative' one, the transference of affectionate feelings from that of hostile ones" (p. 105), the object in both cases being one and the same person, the doctor. Reminding readers that Eugen Bleuler was to be credited for the notion of "ambivalence" that characterizes these impulses, he gave the example of obsessional neurotics, in whom "an early separation of the 'pairs of opposites' seems to be characteristic of . . . instinctual life" (p. 107).

While positive transference is classically used "in order to" interpret, throughout treatment (distinguishing it from transference "to be interpreted," in the case of resistance; Jean-Luc Donnet), the idea, by contrast, is to "defuse" negative transference before it is possible subsequently to analyze it.

In fact, it is in borderline structures and transference psychoses that hateful and destructive impulses are the strongest, though they are sometimes masked by the apparent features of love. This is especially true with passionate transference. Feelings of love and psychic flooding can invade the transference situation and be expressed in ways that undermine the analytic framework. They attest to mnemonic traces that have not been successfully integrated into the psyche.

Passionate transferences express the violence of the unfulfilled need for love and of the need for reparation. Eroticization of the transference masks the impulses of hate linked to profound developmental deficiencies and failings in the early environment. These patients then make their analyst relive their despair and helplessness. They want to make the analyst feel the powerlessness and despair that they were unable to symbolize in infancy—that is, their deprivation of primary symbolization.

Sándor Ferenczi's ambivalent hatred toward Freud, his analyst, is an example of this phenomenon. Ferenczi's insatiable need for support during his analysis can be considered as the expression of a transference depression, itself linked to a childhood depression that had not been worked over, either by Ferenczi himself or by Freud; Ferenczi's *Clinical Diary* can be read as his eroticized complaint, the culmination of a negative and idealizing transference. According to Thierry Bokanowski's interpretation (1994), Ferenczi, through his innovations in technique, was demanding reparation, maternal in origin, from his analyst, for he had

managed to “freeze” in Freud the mother he was incapable of being. This is what borderline analysands sometimes do with their analyst: they “feed” him or her with the analysis in order to prolong it into an endless process.

After the second topography, in describing the negative therapeutic reaction, Freud emphasized the need for self-punishment, the severity of the superego, and the masochism of the ego. All the self-hatred in these subjects inhabited by what André Green described as a logic of despair (1990) reflects a compromise between the inextinguishable desire for revenge and concern for protecting the object from the hostile desires directed against it. Here, the conflict between love and hate is dominant. The desire for revenge is linked to the wounded narcissism of these subjects, who can no longer differentiate between the harm they want to inflict upon themselves and the harm they want to inflict on their object. From this perspective, “love is always uncertain, hate is always sure,” wrote Green. Thus these subjects arrange to perpetuate their chosen form of sadomasochistic relationship as long as possible.

However, it is possible for the intolerable nature of negative transference not to appear, remaining unconscious for both the patient and the analyst. The only symptoms: a quality of “gloominess” in the treatment (Cournut), disconnected thinking, decathexis or non-cathexis—that is, the “aphanisis” of the transference.

Other patients seek to “weld” their fragile narcissistic position back together again around an opposition to the object (Couvreur). In the transference and their complaints, they repeat early environmental deprivations. In them there is a fundamental hostility against the object, and the latter is thus loved in hate. Negative transference becomes a particular modality of the bond.

In “Hate in the Counter-Transference” (1949) Donald Winnicott showed the importance of the effects of this transference hatred. In the neurotic structures, the patient will tend to project his or her ambivalence onto the analyst and will believe that the analyst needs to negotiate his or her own ambivalence. By contrast, psychotic patients project their confusion onto the analyst. For them, love and hate coincide, and “should the analyst show love, he will surely at the same moment kill the patient” (p. 70). In certain cases, the patient seeks the analyst’s hatred. In Winnicott’s view, this hatred must be reached and experienced

bilaterally in treatment, “or else the patient cannot feel he can reach objective love” (p. 72).

## **TRANSFERENCE IN CHILDREN**

After about a century of psychoanalysis, there is no longer any doubt that children are capable of transference. On the other hand, the characteristics of transference and its themes of love and idealization are the very elements that can cause parents to have reservations about their child undergoing analysis, particularly—but not only—if they have not been sufficiently informed about this type of phenomena.

Moreover, this is what led Anna Freud to believe that the psychoanalysis of children was only possible in families that had already been genuinely won over by the ideas of psychoanalysis. Be this as it may, Donald Meltzer, in *The Psycho-Analytical Process*, went so far as to present child analysis as a much more pure situation than that of adult analysis, describing it in terms of a process divided into five successive phases, the first of which he called, precisely, “bringing together the elements of transference.”

From a historical point of view, it is interesting to note that the first analysis of a child was that of “Little Hans”—related in “Analysis of a Phobia in a Five-Year-Old Boy” (1909) and involving the child’s phobia to horses—and that Sigmund Freud conducted this analysis indirectly, based on the reports and notes of the boy’s father, himself one of Freud’s students. In other words, this analysis poses complex problems from the point of view of transference because it involved analysis of the child’s transference onto the image of his father, against the background of the more or less idealizing transference of the boy’s father himself onto Freud. This is something that is found, more or less, throughout the history of ideas relating to transference in children, particularly with regard to the question of whether or not children can form a joint transference onto their parents and onto their therapist.

It is thought that the child analyst’s main difficulty is not the absence of transference but instead the very opposite: seeing the development of a transference of unusual intensity, with archaic components that are sometimes so massive and so violent that they become difficult for the analyst to tolerate. This massive, archaic transference, mainly linked to the mechanism of projective identification described by Melanie Klein, is a splitting transference that often corresponds to a type of part-object relationship.

The controversy between Anna Freud and Klein must be recalled here, in those aspects that touch upon the issue of transference. One of the arguments that Anna Freud initially made against the possibility of transference in children was the fact of the child’s dependency in relation to his or her real objects, the parents. Klein countered this by arguing that the psychic structures were organized very early on, from the second semester of the child’s life, that the problems for which the child needed analysis were already linked to repetitions of earlier organizations, and that because of this, the child’s relationship with his or her real

objects was already, in itself, a mixture of real and imaginary objects, or, to put things differently, of objective and subjective elements. Whether or not the parents were alive, and whether or not they intervene in the child’s external reality, does not prevent the child from transferring onto the analyst the fantasmatic dimension of the relation to his or her internal parental objects.

The second, Kleinian point of view gradually became the dominant one and as of 2005 is commonly accepted among child analysts. Moreover, after 1926 Anna Freud herself moved perceptibly closer to Klein’s positions on this point. As Didier Houzel and Gilles Catoire wrote in an encyclopedia article on child analysis: “Repetition, in the relationship with the analyst, of these early psychic structures, that is, the relation of the self to its internal objects, is what constitutes the transference.”

This transference must be thought, understood, interpreted, and worked over with the child, but often, initially, it must only be tolerated and contained by the analyst, all the more so in that transference in children is often split—for example, between outside of treatment (the relationship with the parents) and inside treatment (the relationship with the analyst). If the analyst does not accept the extratransferential roles that the child wishes to make him or her play, and if, on the contrary, the analyst is willing to contain in him- or herself all the aspects of the transference (including its negative and destructive aspects), this splitting can then gradually be reduced.

By means of “bringing together the elements of the transference” and analysis of these transferential repetitions, the child’s ego is reinforced, anxieties are modified, and the major psychic functions are differentiated. This process is nevertheless long, often difficult, punctuated by the child’s attempts at avoidance, and lastly, capable of triggering a whole series of different counter-transferential impulses in the analyst. It can be noted that with children, even more so than with adults, the establishment of the transference can produce changes in symptoms that may make it seem, superficially, that the child has been cured. Care should be taken to warn parents about this, to prevent them from falling into the trap of interrupting their child’s analysis prematurely.

This attests to the importance of the therapeutic alliance with the parents, which is an integral part of

psychoanalytic technique with children, as a vouchsafe for the possibility of continuity in the therapeutic process. As with adults, the idea of the therapeutic alliance benefits from being differentiated from transference properly speaking, although this concept of therapeutic alliance, even in 2005, remains controversial.

But there is no transference without counter-transference, with children as with adults. The idea of counter-transference encompasses both unconscious elements of the analyst's psychic functioning that pose an obstacle to the course of the treatment, which must be kept from the patient, and alterations of the analyst's psyche under the influence of the child's projections, which, as is well known, are the basis of a certain very primitive, preverbal level of his or her communication. Only by means of working at self-analysis can the analyst become aware of these different phenomena and sort out these two very different aspects of his counter-transference.

At this cost, the counter-transference is an irreplaceable tool in child analysis (in fact, in analysis in general), and the entire Kleinian and post-Kleinian movement has strongly emphasized it. Indeed, with mute or psychotic children, or with very young children prior to language acquisition (*infans*), analysis of the counter-transference is sometimes the only means of giving meaning to the infraverbal material provided by the child, on the understanding that the dynamics of transference and countertransference are in fact indissociable and that in a way, they are one and the same.

The management of the counter-transference as a means of perceiving a part of the child's communication in fact requires some delicacy, owing, in part, to the closely interwoven relationship between what the child's projections induce in the analyst and what in turn is reactivated in the child by the analyst's counter-transference (which can be caught in the trap of a neutralizing projective counter-identification), all the more so in that it is possible that the child's projections may correspond to real aspects of the analyst's personality. In such cases, the analysis can only progress if the analyst truly gives herself the means to become aware of these aspects of her own personality and at the same time preserve herself from the child's projections, or rather, contain them and work them over.

Antonino Ferro, in *L'Enfant et le Psychanalyste: La question de la technique dans la psychanalyse des enfants* (1997; The child and the psychoanalyst: the question of

technique in child analysis), distinguishes among the three levels of listening among which the analyst must oscillate—the level of events, the level of fantasies, and the level inherent in the two-person field deployed within the analyst/analysand pair—and clearly shows how transference in children is an eminently dynamic process that “speaks” just as much about the present, against the background of the past, as it does about the past against the background of the present.

Finally, with regard to babies, their ability (or lack thereof) to transfer has for several years been at the center of a certain number of debates (Serge Lebovici, Bertrand Cramer, and others) about what has come to be known as joint parent/infant therapies, generally conducted by analysts. What has come out of this is that babies appear to be able to incite in their new relational partners interactive modalities that they have had the occasion to try out with their first objects of attachment, but whether or not it is possible, within this framework, really to talk about transference remains an entirely open question, even though these interactive repetitions can occur without significant intervals of time passing between the different experiences in question.

## TRANSFERENCE LOVE

The term *transference love* designates an emotional relationship, determined by the analytic situation, of which the manifest object is the analyst; the task of the analyst in this circumstance is to trace the relationship back, without either satisfying or smothering it, to its infantile roots.

Transference love is a defining feature of the psychoanalytic method. Psychoanalysis does not cure by love, but love and the analyst play a mediating role therein (Oppenheimer, Agnès, 1996). The set of inner problems generated by transference love, inasmuch as no direct satisfaction is forthcoming, eventually frees love from repression: The truly intermediary role of transference love thus makes love possible.

The transference follows the vicissitudes of love. When it is negative, hostile, or governed by repressed erotic impulses it constitutes resistance. According to Sigmund Freud, the “transference of friendly or affectionate feelings” which are “unobjectionable and admissible to consciousness” can contribute to a successful cure (1912b, p.105). Transference love allows the patient to become attached to the aims of the treatment as well as to the person of the analyst.

Even as resistance, transference love is thus a prerequisite to cure: it “represents an artificial illness which is at every point accessible to our intervention. It is a piece of real experience, but one which has been made possible by especially favorable conditions” (1914g, p. 154). One of the difficulties, or impossibilities, confronting the treatment is that some patients refuse to resign themselves to the fact that the material fulfillment of this surrogate love is not an option; such patients are “accessible only to ‘the logic of soup, with dumplings for arguments’” (1915a, p. 167). But can this still be considered love? It is clear that the manifest demand for love covers up latent considerations of another kind. The patient’s explicit demand for recognition also reflects a both demand for reparation, and shortcomings in their symbolizing capacity.

Where affectionate feelings are transformed into an erotic demand, Freud compares what happens to an outbreak of fire during a theatrical performance. The analyst’s interpretation is what then allows the patient to grasp that they are mistaken as to time and object.

In “Observations on Transference-Love” (1915a), Freud promoted an attitude with respect to the com-

plex phenomenon of transference love that would later be characterized by Michael Balint as “prudent.” Discussing the analyst’s difficulties when faced by transference love, and confining his remarks to the situation of a male analyst and a female patient, he called for prudence on the part of the doctor and warned, apropos of manifestations of transference love, “against any tendency to a counter-transference which may be present in his own mind” (p. 160).

A patient’s passionate attachment to the analyst should indeed never be treated as evidence of the physician’s personal irresistibility, but rather as an effect of the analytic situation itself. For Freud, transference was a *mésalliance*, a “false connection” (1895d, p. 303), and although the conduct of the cure required the analyst to maintain the transference love, they should nevertheless look upon it as “something unreal, as a situation which has to be gone through in the treatment and traced back to its unconscious origins” (1915a, p. 166). At the same time, despite this “unreality,” despite his emphasis on the inauthenticity, as it were, of the transference, Freud acknowledged that “We have no right to dispute that the state of being in love which makes its appearance in the course of analytic treatment has the character of a ‘genuine’ love.” In fact transference love was no different from any other kind of love, for “There is no such state [of being in love] which does not reproduce infantile prototypes” (p. 168). For Freud, it was this infantile aspect which gave love in general, and transference love in particular, “its compulsive character, verging as it does on the pathological” (p. 168).

What is repeated in transference love is frustration, a demand not heard, never answered, which leads the patient to reassume the position of a child with respect to the analyst. A love transference is usually capable of being analyzed and pressed into the service of the treatment, especially when it is moderate, as is most often the case, and when it is first manifested as defensive maneuvers.

Sometimes, however, the demand for love takes on a querulous character in passionate transferences: the patient’s grievance concerning this frustration becomes aggressive and exacting. An insistence on reparation emerges, stressful for the analytic setting and challenging to the analyst’s control over the counter-transference. The handling of the treatment is particularly difficult with patients who come close to erotomania or indeed sink into it. In such cases, as described by Freud, the

situation may have an incendiary character. Behind the exacerbated demand for love and reparation that is seen in passionate transferences lie developmental deficits and failures of the primary environment that have distorted the patient's self. The eroticization of the transference serves as a defense against a fear of disintegration, which in turn derives from the primary depression that such a patient will have experienced in the earliest stages of their development.

The analyst's primary position in the face of transference love is that of the interpreter. As Freud wrote, transference love must be traced back to its unconscious roots. For this reason abstinence must be the rule during the treatment. Considerations both technical and ethical prohibit the analyst from gratifying the solicitations of transference love. Like the physician bound by the Hippocratic oath, they must not draw personal profit from the analytic situation. But they must also never lose sight of the fact that the patient is suffering from a limited capacity to love for which infantile fixations are responsible. The analytic cure should make possible the restoration of a function that is of "inestimable importance" to the patient, one that they should not "dissipate in the treatment, but keep . . . ready for the time when, after [his or] her treatment, the demands of real life make themselves felt" (1915a, p. 169). Likewise, "If the patient's advances were returned it would be a great triumph for her"—and for the resistance—"but a complete defeat for the treatment. She would have succeeded . . . in acting out, in repeating in real life, what she ought only to have remembered, to have reproduced as psychical material." This "distressing episode would end in remorse and a great strengthening of her propensity to repression" (p. 166).

Clearly, the analysis of the counter-transference is necessary so as to prevent the analyst's personal feelings, complexes or inner resistances from hindering the progress of the treatment. The excitation provoked in the analyst by the patient's demands and transference projections, and notably the erotization of the transference, certainly put the analyst's superego to the test, but at a more fundamental level they challenge their relational skills and capacity for symbolization as well as mastery over their own desire for reparation.

Typically, acting-out by the practitioner, in response to the patient's transference love, signals a lack of professional maturity in dealing with the counter-transference anxiety aroused by the interpersonal

situation, as well as a failure to deal with personal narcissistic shortcomings or masochistic tendencies.

## TRANSFERENCE NEUROSIS

Transference neurosis is a phenomenon of the analytic process in certain patients with adequately integrated egos and superegos in which the analyst's perception of the analyst becomes more and more recognizably entwined with core, organizing unconscious fantasy/memory complexes from childhood. These bear the stamp of oedipal conflict, its precursors and latency and adolescent sequelae. Freud first elaborated the concept in "Remembering, Repeating and Working Through," in 1914. There he stressed the analyst's aggressive pursuit of disease.

Three years later, he emphasized the insidious disease process itself, then elaborated on the power that the positive transference afforded the analyst to "divest" the patient's symptoms of libido. In *Beyond the Pleasure Principle* (1920a), he added that what was repeated in the transference neurosis was "some portion of infantile sexual life—of the Oedipus complex and its derivatives" (p. 18). That is, the transference neurosis was then seen to recapitulate an *infantile neurosis*. As he began to concern himself with impediments to cure, however, the concept dropped from his writings.

The concept appears in Freud in conjunction with the concepts of analysability and cure. Freud considered that only patients with transference neuroses were treatable by analysis. He designated the transference neurosis as an artificial symptomatic illness that expanded in the “playground” of the transference while the patient’s other symptoms and external difficulties disappeared. The transference neurosis constituted an “intermediate region between illness and real life” (1914g, p. 154). Cure then involved the annihilation by interpretation of the artificial illness.

Freud did not use the term after 1926. This silence, the increasing interest in character pathology on the part of contemporary analysts, and the greater reliance in some quarters on the structural theory have led to confusion, equivocation, and controversy. Manifest criteria that have been mistakenly offered as definitions such as the patient’s conscious focusing on his or her relationship to the analyst, or the cessation of all extra-transference difficulties, have either not been borne out by clinical data or raise other valid objections. Severed from its role as exclusive means to cure, however, in its modern definition, the transference neurosis continues to capture the essence of clinical psychoanalytic experience. The broader and more modern definition is the following: During the analytic process of certain patients with adequately integrated egos and superegos, a distillation occurs in which the analysand’s perception of the analyst becomes more and more recognizably entwined with core, organizing unconscious fantasy/memory complexes from childhood. These bear the stamp of oedipal conflict, its precursors and latency and adolescent sequelae. The analytic work takes on an intimacy prepared by the working through of narcissistic versions of these core conflicts so that the patient is able to experience a greater degree of libidinal involvement with the analyst. The autonomous willingness of the patient to reveal, explore, and work with the analyst also increases. The discovery of this crystallizing organization occurs simultaneously with the gradual disengagement of the object representation of the analyst from these same core fantasies.

## TRANSFERENCE OF CREATIVITY

The transference of creativity, whose defining example is Sigmund Freud’s transference onto Wilhelm Fliess, is a form of transference whose role is to accompany the fluctuations of creativity in the creator.

Initially implicit in Heinz Kohut’s work, this notion was explicitly mentioned by him from 1966 on. The correlative of the importance given to creativity, and a therapeutic factor or the effect of treatment that is not interpreted, it indicates a transformation of narcissism.

Starting with Freud’s self-analysis, Kohut stipulated in “Selected Problems of Self Psychological Theory” (1980) that Freud’s relationship with Fliess was not

transference in the classical sense—there was no dissolution through insight—but rather a transference of creativity that disappeared at the same time as the narcissistic need. Fliess was a function that filled a void and facilitated Freud’s creativity. During certain creative periods, creators need self-objects in one sector of the self or another, without this necessarily indicating weaknesses in the self. The creator’s narcissistic configurations are more fluid at certain times, and the other person makes possible regulation of self-esteem and confidence possible.

Transference of creativity, a form of narcissistic transference outside of treatment, brings into play all the notions that come out of Kohut’s theory.

## **TRANSFERENCE RELATIONSHIP**

The term *transference relationship* designates those aspects of the patient-analyst relationship involving the patient’s previous object-relationships transposed

onto the analyst (that is, the transference). The transference relationship thus constitutes the heart of the analytic situation, encompassing all aspects of the relationship between the patient and the analyst: the analytic contract, the setting of the analysis, countertransference, and so on.

This notion was implicitly present as soon as transference was discovered, as early as Freud and Josef Breuer’s *Studies on Hysteria* (1895d). Anna O., plagued by the fantasy of giving birth to a child of Dr. Breuer’s, was entangled in a perfect instance of the transference relationship. The term itself, however, appeared very late in Freud’s work, in “Constructions in Analysis” (1937d): “Our experience has shown that the relation of transference, which becomes established towards the analyst, is particularly calculated to favor the return of these emotional connections” (p. 258).

This remark demonstrates that for Freud the transference was a melting pot into which the analysand’s earlier affective relations were drawn prior to being recast. Seen in this light, the transference relationship, determined first and foremost by transference love, has two aspects: first, a “piece of real experience” (1914g, p. 154), whose novelty is most important; and second, an element of repetition, for the transference also embodies the replaying of infantile sexual and affective relations. Sándor Ferenczi (1916) emphasized the link between the transference relationship and introjection: in the transference, the analyst is introjected by the patient as a new internal object.

The newness of the transference relationship is a significant factor in effecting change. The transference involves more than the patient’s reliving an earlier relationship. The analyst’s attitude and interpretations modify the patient’s attempts exactly to repeat the past in the transference, thus allowing something else to take place. In some respects, the analyst plays the part of a new object, an object anchored in reality. The gulf between this “real relationship” and the “false connection of the transference” helps the patient to perceive his own mental impulses.

What many authors have described as a “real relationship” with the analyst thus stands opposed to the transference relationship. Ralph Greenson, for example, wrote, “I intend to use the term ‘real’ to refer to the realistic *and* genuine relationship between analyst and patient—as opposed, that is, to unrealistic and inappropriate, albeit genuine, transference reactions”

(p. 217). “In adults,” Greenson added, “all relationships to people consist of a varying mixture of transference and reality. There is no transference reaction, no matter how fantastic, without a germ of truth, and there is no realistic relationship without some trace of a transference fantasy” (p. 219). So the real and transference relationships are somewhat interdependent. Similar considerations apply to the “therapeutic alliance” described by many authors, to Otto Fenichel’s “rational transference,” and to the “basic transference” evoked by Catherine Parat.

Elizabeth Zetzel’s notion of the “therapeutic alliance,” like Greenson’s “working alliance,” denotes a component of the analytic relationship, yet properly conceived, it should not be brought under the heading of the transference relationship, even though for many authors such an alliance is a necessary precondition of the development of the transference relationship. The transference relationship is predicated on the patient’s ego being reasonable. The patient must be capable of working with the analyst to conquer the neurosis and the negative aspects of the transference. From a different perspective, Richard Sterba (1940) based the therapeutic alliance on the patient’s identification with the analyst, thus giving it a fully transferenceal sense.

For Fenichel (1941), the transference relationship implies what he called a “rational,” positive transference, which brings inhibited drives into play with the aim of the transference relationship. Fenichel’s approach has much in common with Parat’s conception of basic transference. The transference relationship, for Parat, “corresponds to the patient’s cathexis of the person of the analyst, and is colored by feelings of trust. . . . This cathexis is founded on subjective elements which I have elsewhere described as projective, using the term ‘basic transference’ to designate a spontaneous, interhuman link with positive overtones which derives from the earliest attachments, as subsequently enriched by secondary experiences, as well as from objective elements perceived by the patient beginning with his first contacts with the analyst, be they gross or subtle. . . . The basic positive transference has a narcissistic libidinal origin” (1995). Parat stressed the kinship between such a transference cathexis and Freud’s “narcissistic object-choice,” thus more closely assimilating it to narcissistic transferences properly so called.

The capacity of the transference relationship to evolve is what makes it analyzable. In contrast to what occurs in everyday interpersonal relationships, where

transferences tend to jell into more or less stable compromises, in the transference relationship the attitude of the analyst, who does not respond in kind to the patient’s erotic solicitations but instead relates them to their oedipal prototypes, separately exposes the various avatars of the transference—paternal, maternal, fraternal, and so on, corresponding to different periods of the patient’s life. The analyst does not allow himself to be locked into one specific relational mode: he behaves at once as an object, drawing the patient’s cathexis toward him, and as an antiobject, by interpreting the patient’s transference onto him so that the transference image may unfold (Denis, 1988). To paraphrase Freud’s metaphor (1915a, p. 169), the practitioner comports himself like the mechanical rabbit in a greyhound coursing: it is continually moving out of reach, thus ensuring the continuation of the race; were a real rabbit thrown amid the dogs, it would immediately be devoured, and the race abandoned.

## TRANSFORMATIONS

Wilfred R. Bion conceived of transformations as the changes that the analysand's sense impressions of emotional experience undergo to become a progressive series of mental realizations. They are akin to the transformations that food undergoes in the digestive system to become protoplasm. The concept also belongs to the mathematical concepts that Bion employed to bring more rigor to psychoanalytic understanding. In this way, he was attempting to make psychoanalysis more scientific. This period in his work overlaps with the next period in his work, developing psychoanalysis as an “intuitionistic science.”

Briefly put, Bion envisions psychoanalytic transformations as the psychoanalyst's attempt to help the analysand transform that part of an emotional experience of which he is unconscious into an emotional experience of which he *is* conscious. Transforming here would be changing the form but not the fundamental nature or invariant aspect of the emotional experience. In this way the analyst helps the analysand achieve private or personal knowledge about his emotional life. Bion states his theory in a rigorous mathematical notation in which his symbols have the following meanings:  $O$  = the symptom or analytic object;  $T$  = transformation;  $t$  = the representation of the transformation;  $K$  = knowledge link;  $\beta$  = beta elements, sense impressions of emotional experience;  $\alpha$  = alpha elements, elements suitable for further mental processing;  $p$  = patient;  $a$  = analyst. Bion states, “I shall regard only those aspects of the patient's beha-

avior which are significant as representing his view of  $O$ ; I shall understand what he says or does as if it were an artist's painting. In the session the facts of his behavior are like facts of a painting and from them I must find the nature of his representations (or, in terms of my notation, the nature of that which I denote by the sign  $T(\text{patient})\beta$ ). From the analytic treatment as a whole I hope to discover from the invariants in this material what  $O$  is, what he *does* to transform  $O$  (that is to say, the nature of  $T(\text{patient})\alpha$ ) and, consequently, the nature of  $T(\text{patient})$ . This last point is the *set* of transformations in the group of transformations, to which his particular transformation ( $T(\text{patient})$ ) is to be assigned. As I am concerned with the *nature* (or ... meaning) of these phenomena, my problem is to determine the relationship between the unknowns:  $T(\text{patient})$ ,  $T(\text{patient})\alpha$ , and  $T(\text{patient})\beta$ . Only in the last of these have I any *facts* on which to work. ... I shall make three assumptions: (i) that the patient is talking about something ( $O$ ); (ii) that something,  $O$ , has impressed him and that he has transformed the impression by the process represented by  $Tp\alpha$  and (iii) that his representation  $tp\beta$  is comprehensible” (Bion, 1965).

Bion considers the emotional experience of the analysand and of the analyst to be  $O$  (the symptom or analytic object) but each has his distinct experience of  $O$ :  $Op$  (patient), and  $Oa$  (analyst). The analyst must, with his alpha function, deduce the transformation  $O \rightarrow Tp\alpha \rightarrow Tp\beta$ , which is then translated by the analyst as  $O \rightarrow Ta\alpha \rightarrow Ta\beta$ .

Bion considers there to be four kinds of transformations in clinical practice: (a) “rigid-motion transformations,” which involve little alteration and which correspond directly to past events that may now be relived in the (classical) transference; (b) “projective transformations,” which correspond to Melanie Klein's concept of projective identification; (c) “transformations in hallucinosis,” which occur only in psychosis, and (d) “transformation in  $O$ ,” by which Bion seems to mean a transformation both *from* the ineffable nature of the analytic object, the analysand's symptom, and *through*  $K$  (the knowledge link), *to* yet another state, that of Absolute Truth or Ultimate Reality, the Godhead.

Bion states, “The bearing on psycho-analysis and interpretation of what I have said may seem obscure; it is this: The beginning of a session has the configuration already formulated in the concept of the God-

head. From this there evolves a pattern and at the same time the analyst seeks to establish contact with the evolving pattern. This is subject to his Transformation and culminates in his interpretation  $T\alpha\beta$ . I am aware of the problems I have left without attempting an approach to their solution. . . . In this book I draw attention to a few of the problems which present themselves in analytic material and offer suggestions for clarifying, first observation and then, assessment of what has been observed" (1965).

*Transformations* (1965) seems to represent Bion's last venture in employing mathematical notation to bring scientific rigor to clinical psychoanalytic phenomena. Transformations in *O* constitute "a bridge to a new science," the intuitionistic, to which he thereafter bent his efforts. Though mathematical, *Transformations* was the third in a series of foundational works that was gradually to alter how analysts regarded clinical material and their personal ( $T(\text{analyst})$ ) relationship to it. Having already defined the mind that had to develop in order to think "the thoughts without a thinker" (beta elements, emotional experiences in themselves), he then undertook to define how these thoughts evolve from sense impressions of emotional experience (beta elements) to alpha elements suitable for further mental processing. From there he defined the steps of "mentally digestive transformation" that these beta, and then alpha, elements must undergo in the analysand and in the analyst in order to qualify for status in a scientific deductive system or fall by the wayside because of invidious *K*. *O* is the beginning and the end of the transformational cycle. Bion's epistemological transformation of psychoanalytic metapsychology was then in place.

## **TRANSGRESSION**

The notion of *transgression* entered psychoanalysis only gradually. In fact, the word already had a well-established meaning in ethnology, a science from which Sigmund Freud drew inspiration. Its definition was to some extent a negative one, in opposition to *taboo* (a term that was itself borrowed from the Polynesian language), *prohibition*, and *law*.

Transgression is anything that involves the contravention of explicit or implicit rules, both in the course of the treatment and in conflictual unconscious functioning, not to mention within the psychoanalytic process itself.

Thus, real and fantasized transgression is at the heart of all psychological mechanisms, as the result, or source, of a conflict. We also encounter it, during a psychoanalytic treatment, in everything that goes against the framework imposed by the fundamental rule. But it is also found, and this time positively, in the wish of Freud and other psychoanalysts to get to the bottom of secrets that seem to be self-evident. This is what drives all scientific research—the longing to understand and master the laws of human functioning, especially when they are obscure.

Thus it is difficult to date the first appearance of the notion, because only *a posteriori* can its implicit presence be discerned in Freud's first writings and in his wish to become an extraordinary hero. As early as *The Interpretation of Dreams* (1900a, ch. 3), the idea of transgression is contrasted with that of an unsatisfied desire able to reach satisfaction in spite of everything that might restrain and prohibit it, via the detour of the dream. Like sociologists, psychoanalysts find that every law is accompanied by criminal infractions of that law—infractions which the law highlights and describes. Like ethnologists, psychoanalysts also find that the strictest laws are always accompanied by rituals.

It was perfectly natural that, in a dialectical movement, the interest shown in everything that can prevent a desire from being fulfilled—and in particular the formalized, absolute, and non-negotiable limits represented by laws and taboos—should shift to what can corrupt them, deviate them, or violate them, in other words, to the mechanisms of transgression. It is obvious that, given our need for an order in which ethics would have its proper place, transgression

---

**TRANSGENERATIONAL.** *See* **Intergenerational**

should at first have been experienced and presented in its negative or pathological aspects—even though Freud insisted right from the start on the inescapable complementarity of desire and law, of law and transgression. Clinical discussions of perversion, as a pathological manifestation or as a neurotic outlet, all turn on the moral status of transgression, just as the current socio-cultural malaise gets to be played out in various disciplines, including within the psychoanalytical community, with the focus on ethical debates.

The conflictual model that lies at the basis of psychoanalytical thought can be observed from different points of view. One can focus on the place, whether this be the unconscious scene, the framework of the psychoanalytical session, or the huge wealth of psychoanalytical theory. One can focus on the model of representation chosen, essentially the oedipal model or that of the father's murder. Or one can focus on a given level—on the oscillation between the individual intrapsychic level and the more or less specific collective level that makes the performance of forbidden actions possible within certain defined areas, of which carnival is one example. Myths have the same role as dreams with regard to internal prohibitive laws. “The legend of Oedipus sprang from some primaevael dream-material” (1900a, p. 263). Finally, we can focus on the model of functioning chosen: pleasure principle against reality principle, life instinct against death drive, or the relative potency of the superego.

Transgression can be found everywhere in the milieu of the unconscious. Psychological functioning is based on the way conflicts between different agencies are dealt with. One's character is formed by rules of behavior that are based on authorizations and prohibitions.

Over the course of each individual's evolution, certain critical moments or moments of transition favor the temptation of transgression. These are the critical periods of one's development; at these times, evolution is rapid, and behavior is particularly active. During early childhood, the anal period, the “age of no,” is a stage at which the child is forever defying parental law. During adolescence, or more precisely at certain moments during the slow evolution of adolescence, the sense of expansion, of new power, and the desire for discovery, can lead to provocative behavior and the deliberate violation of moral and social rules.

During every session of psychoanalysis, a conflict is set up and staged between the law of repression on one

hand, armed with the patient's resistances and defenses and the law of silence which they entail, and on the other the desire shared by the psychoanalyst and the patient to break through that law. Thus the internal conflict is projected and embodied in the transferential relation.

It can be said that all psychoanalytical thinking is built on a transgressive epistemological curiosity. Psychoanalysis as a scientific corpus comes up against the laws of inner repression, but also against the universal or western ethic of sexual repression, the rejection of aggressive desires and, finally, the norms of a rudimentary and reductive scientific logic.

The oedipal model is the summit of psychoanalytical construction. The child's violent desire for the parent of the opposite sex implies the aggressive wish to take the place of the parent of the same sex. This wish is in its turn strongly repressed, due to the love and fear felt by the child for this same parent. To get beyond this conflict requires a means of transgressing the dual prohibition of incest and rejection. The aggressive violence repressed at the time of the oedipal conflict doubtless has an earlier and more archaic origin: it comes from the wish for the father's murder by the horde of brothers, a wish that aims at possessing, interiorizing, and questioning authoritarian paternal powers, however vague and imaginary they may be.

It goes without saying that the manifestations of transgression in the psychoanalytical sense essentially lie on the individual and intrapsychic level. But Freud saw how important this sector of the structural conflict of human thought is for collective phenomena. From *Totem and Taboo* (1912–13a) to *The Future of an Illusion* (1927c) or *Civilization and Its Discontents* (1930a [1929]), he shows that there is a constant oscillation between repressive cultural forces and “the dangerous attribute [...] the quality of exciting men's ambivalence and tempting them to transgress the prohibition” (1912–13a, p. 32). The more authoritarian society is, the more organized repression impels one to interiorize transgressive yearnings—and Freud remarks that so-called primitive societies make more room for transgressive possibilities, even when these might affect an apparently immutable order, if necessary by organizing festivals at which people can shed their inhibitions.

If the pleasure principle leads to the (potentially repeated) satisfaction of desires, the reality principle opposes it as an obstacle on the path to these

satisfactions. From this conflict between the two structures is born a sense of unease: unsatisfied desires seek an outlet. This may be found in dreams, of course, and transgression is there a sort of compromise; these desires may also try to realize themselves to a greater or lesser degree in criminal and perverse acts—at the cost of incurring guilt. In one way, there is transgression whenever there is a refusal to compromise. The idea of conquering reality is a dream of omnipotence which can degenerate into delirium, this in turn explains both the fanatical dedication of scientists and the fascination for taboos.

The same duality (the same intrapsychic duality) is found in the opposition proposed by some theorists between the life instincts and the death drive. Conflict shifts from the need to fulfill desires when faced with obstacles to the need to fulfill contradictory objectives. Ambivalence rules. These two approaches, however, are still dualistic, and they describe a conflict against an authority such that, whatever the result, a sense of guilt is generated. “Thus we know of two origins of the sense of guilt: one arising from fear of an authority, and the other, later on, arising from fear of the superego” (1930a, p. 127), wrote Freud.

In fact, it is with the advent of the superego that the problem of transgression reaches its apogee, even if it was perceptible beforehand. As Freud put it, “Conscience is the internal perception of the rejection of a particular wish operating within us” (1912–13a, p. 68). Forbidden desires are at the center of neurotic patterns of behavior, and the prohibitions against these are all the stronger as they are more powerfully interiorized, *inter alia* under the influence of culture, and bolstered by family habits and rules.

Whether limits to the emergence of desires impose themselves subtly (as taboos) or whether they are explicit and socially recognized, transgression or the temptation to transgress are part and parcel of the same trend, against which the superego takes shape as an inner law. To see the truth of this, one needs only to recall that the rules of taboos always anticipate a punishment for transgression, and thus anticipate the transgression itself.

Much has been said about the revolution in thought which led to, or accompanied, psychoanalysis. Psychoanalysis has also been associated—either to support it or to denigrate it—with the so-called sexual revolution, which enabled people to think and say things that, until that period, had been kept in silence or

suppressed. Another revolution, less spectacular but just as important, lay in accepting and even giving a positive evaluation to drives that had hitherto been considered as sins, pathological symptoms, or antisocial types of behavior: violence, aggression, and the whole list of transgressions that go with them.

This revolution questions, through the unconscious forces it reveals, the ethical norms of the majority in any given society. Transgression is no longer a residue or a deplorable side effect of psychological functioning. It is an inescapable part of it and, what is more, by favoring inventiveness and complexity of thought, it becomes something positive.

## **TRANSITIONAL OBJECT**

The term *transitional object* was coined in 1951 by Donald Winnicott as a designation for any material object (typically something soft—a piece of cloth, say, or part of a plush toy) to which an infant attributes a special value and by means of which the child is able to make the necessary shift from the earliest oral relationship with the mother to genuine object-relationships.

Winnicott first spoke of the transitional object on May 30, 1951, in a paper read before the British Psychoanalytical Society and published in 1953 under the title “Transitional Objects and Transitional Phenomena. A Study of the First Not-Me Possession.” This article was recast twenty years later and incorporated into Winnicott’s *Playing and Reality*, a book concerned entirely with transitional phenomena.

In his observation of infants, Winnicott noted that between the ages of four and twelve months children would often become attached to a particular object that they invested with a primordial significance. This object would be manipulated, sucked, or stroked, and often became an indispensable aid for falling asleep. Parents recognized its value, taking it along everywhere and allowing it to get dirty in the realization that washing would introduce a break in continuity in the infant's experience and destroy the object's meaning and special worth. Such objects in fact constituted a defense against depressive anxiety.

As early as 1951 Winnicott warned against the risk of his thinking being reified. What interested him was this "first not-me possession" and the zone it occupied between the sucked thumb and the teddy bear, between early oral erotism and a true object-relationship, between subjectivity and objectivity, between primary creativity and the projection outwards of what had been introjected. In 1971, in his introduction to *Playing and Reality*, Winnicott wrote that "what I am referring to . . . is not so much the object used as the use of the object" (1971, p. xii).

To explain the origin of the transitional object, Winnicott went back to the first connection with the mother's breast. The mother, he argued, puts the actual breast in a place where the infant is ready to create it and experience an illusory omnipotence in consequence. Later on, the establishment of the reality principle and the inevitable disillusion associated with this will be tolerated by virtue of the transitional object, which allows the child to exercise its feelings of omnipotence in a playful manner. The child arrogates rights over this object, which, though loved passionately, is also expected to resist and triumph over hate. In libidinal terms, the activity involved here is of an oral kind. The object is just as highly cathected with narcissistic libido as with object-libido. It is not recognized as part of either external or inner reality. There is thus an essential paradox at the heart of this conceptual framework: the baby creates the object, yet the object was already there, waiting to be created and cathected. This paradox will never be resolved: in the course of normal development, the object is destined to be gradually decathected, losing its significance as diffuse transitional phenomena spread over the entire intermediate realm between subjective inner reality and common external reality, until the whole sphere of

culture is included (art, religion, imaginative life, scientific invention, and so on).

The transitional object and transitional phenomena may be conceived of in three ways: as typifying a phase in the child's normal emotional development; as a defense against separation anxiety; and, lastly, as a neutral sphere in which experience is not challenged—an area of play and illusion.

For Winnicott the transitional object could sometimes be part of abnormal development and become associated with some types of pathology. The child could not make use of such an object unless "the internal object is alive and real and good enough" (1917, p. 11), and this depended on the quality of the maternal care received. Should the external object be bad or absent, the internal object could take on a persecutory character. And should the failure of the external object persist, the internal object would be meaningless and the transitional object would likewise lose all significance and possibly take on a fetishistic character. Winnicott also mentioned drug addiction, lying, and theft as ultimately linked in some cases to a pathology of transitional phenomena.

Several authors have criticized Winnicott's view of the transitional object. Melitta Sperling feels that such objects are pathological manifestations of a specific disturbance of object-relationships. Esther Bick (as cited by Michel Haag) evokes an adhesive clinging that results from a defective introjection of the mother's containing function. And in Françoise Dolto's view, children with "enough words of love and opportunities for play of a motor kind" available have no need of transitional objects, which should therefore be treated from the outset as fetishistic.

## TRANSITIONAL OBJECT, SPACE

Transitional objects (Donald Winnicott) originate in that phase of an infant's development when inner and outer reality begin to become apparent. They are at once "me" and "not-me," and are transitional in that they facilitate the transition from the omnipotence of the tiny baby for whom external objects have not yet separated out, to the capacity to relate to "objectively perceived" objects.

Transitional space (intermediate area, third area) is that space of experiencing, between the inner and outer worlds, and contributed to by both, in *which primary creativity* (illusion) exists and can develop ("Transitional Objects and Transitional Phenomena," Winnicott, 1951; further developed in Winnicott, 1971). From as early as 1945, Winnicott, from within his own concepts of object-relations, approached the infant's developing capacity to discover and adapt to reality. He described first the common patterns of infancy in which a very young baby first finds a thumb, or a fist, to suck, and may stroke his own face, gather a piece of material and suck or stroke it, or make babbling noises; Winnicott assumed accompanying fantasy and used the term *transitional* for these phenomena.

Later in infancy it may happen that both the activity and the object become necessary when the baby is going to sleep, or anxious. Babies may discover a particular object, perhaps a soft toy or a blanket, or a sound, or

piece of behavior, that fulfils the purpose, and this, the transitional object, becomes important and is recognized to be so by the parents, who unconsciously know that it represents a continuity of experience that the baby needs. For this reason parents know that it is not to be changed, or even washed, but must accompany the infant, to be loved or attacked as the baby fancies. This "transitional object" becomes the first "not-me" possession, and while it is symbolic of a part-object, is important in that it is neither the baby nor that object. Winnicott listed the special qualities of the relationship with the object, which must survive; must, from the baby's point of view, come from neither without nor within; will become deattached—lose its significance, not forgotten, not mourned, but losing meaning, at that stage when a wider cultural field has come into being. In early infancy the "good-enough mother" provides a near-perfect environment, allowing the baby the illusion of unity and omnipotence—Winnicott stated that the infant "creates" the breast—"primary creativity," which is known as a "subjective object." The disillusion necessary to permit awareness of outside reality must be dosed to the infant in such a way that the infant's creativity survives the passage to the recognition of objective reality.

Winnicott used the term *transitional* to describe the "intermediate" or "third area," "between the thumb and the teddy bear, between the oral erotism and the true object-relationship, between primary creative activity and projection of what has already been introduced, between primary unawareness of indebtedness and the acknowledgment of indebtedness ("Say ta")" (Winnicott, 1951). It is in this area, where fantasy and reality overlap, that creativity, including the basis for adult cultural life, and play originate (Winnicott, 1971). Winnicott compared this with the therapeutic situation, where the worlds of the patient and analyst overlap, echoing Freud's concept of the analytic playground.

Related subjects include:

- Fetishistic objects—one possible fate of the transitional object, according to Winnicott.
- Illusion of unity within a framework—Milner.
- Autistic object—Tustin.
- Self-object—Kohut.
- Transformational object—Bollas.
- Transitional stage/quasi-independence—Fairbairn.

Possibly the most widely known of Winnicott's contributions, especially in the worlds of paediatrics and child care, the concepts of transitional phenomena and the thinking about illusion are firmly rooted in his object-related developmental viewpoint and underlie Winnicott's ideas about creativity, which according to him is a primary human element. The popular acceptance of the idea should not be allowed to disguise the importance of this line of Winnicott's thinking, which, despite the incorporation of his concept of paradox into his style of writing, eventually provides the foundation for his theories of play with its relationship to creative analytic work, and also his late, subtle, and important paper "The Use of an Object and Relating Through Identifications" (1971), in which he charts a further stage of change from that of "object-relating," when the object, while separate, is felt to be still under the omnipotent control of the infant, to that of "object-usage," when the object is allowed reality and autonomy.

## **TRANSITIONAL PHENOMENA**

The original concept of *transitional phenomena* was used by Donald Winnicott to describe the intermediate area of human experience between inner reality and the outside world. The prototypical example is that of the transitional object, the first *not-me* possession of the baby. Thus a real, usually soft object is found by the baby and used as a defense against anxiety. The transitional object represents a real paradox in that it is not an internal object; it is a possession yet it is not an external object either. It grows out of the baby's relationship with the breast (which represents the whole technique of mothering) and his own body. For example, while sucking on his thumb he weaves *not-me* objects into his own autoerotic experience and personal pattern. Thus the transitional object allows for the illusion of infantile omnipotence at the same time as it forms a bridge to the outside world and the process of disillusion and the development of a shared reality. The ordinary care of the mother closely adapting to and meeting her infant's immediate needs fosters in the infant the illusion that what he desires he actually creates.

Transitional phenomena as a class of experiences also represent the use of illusion in allowing the creative co-existence of primary creativity and objective perception based on reality.

Winnicott presented his formulation of transitional phenomena to the British Psycho-Analytic Society in 1951, and this was published in 1952 in a paper, "Transitional Objects and Transitional Phenomena"—subtitled "A study of the first *not-me* possession." The paper was republished in his collected works, *Through Paediatrics to Psychoanalysis* (1958), and is the key paper in his influential and popular book *Playing and Reality* (1971).

The notion of transitional phenomena is central to the framework of ideas which Winnicott uses to chart the course of the development of self, locating the self firmly and inextricably in the context of maternal care, the family and the wider world. Winnicott used his thousands of observations of infants and parents together to build up his idea of the baby's inner world of fantasy, illusion, and omnipotence. The mother, by intuitively anticipating and adapting to the baby's immediate physical needs, allows the infant to build up the illusion that he creates that which his mother provides. Between the age of four to eighteen months

there may then emerge some thing or phenomenon (which may be a sound, mannerism, or the mother herself) which the baby uses to defend himself against anxiety, especially when falling asleep.

Winnicott says the transitional object has specific properties: the infant creates it himself, he can be both affectionate and aggressive to it; it must not change, unless changed by the infant; it must survive loving, hating, and aggression; it must seem to have vitality or reality of its own; it is neither a hallucination nor comes from within the baby; it is gradually detached, but not lost and forms the basis of play, culture, and dreaming.

The patient's use of transitional phenomena can help in understanding psychopathological conditions such as fetishism, lying, stealing, and drug addiction. Winnicott (1971) describes a case of a boy with anxiety and obsessional symptoms where the boy's use of string is central to understanding both these inner and outer experiences. By providing the illusion of omnipotence and gradual disillusionment, parents set up a transitional space within which develop the child's creativity and capacity to play: "on the basis of play is built the whole of man's experiential existence" (1971). Play is a serious and necessary component of psychic life which forms part of adult life and culture. Playfulness and the use of transitional space and transitional phenomena form the foundation of much of Winnicott's psychoanalytic technique.

The transitional object is a concept that has entered the popular culture as the apparently ubiquitous security blanket or the teddy bear. There can be a misapprehension that such physical objects are necessary for healthy psychological development. Winnicott did not imply this but, like many of his concepts, transitional phenomena remain enigmatic and hard to define. This elusive sense seems to be just what he seeks to describe in the child's approach to the "relationship between what is objectively perceived and what is subjectively conceived of." This is indicative of Winnicott's imaginative and at times idiosyncratic metapsychology.

### TRANSLATION

There are a large number of occurrences of the verb *übersetzen* ("to translate") and the noun *Übersetzung* ("translation") in Freud's work, indicative of his interest in translation, although the terms had no specific conceptual value for him within the field of psychoanalysis. However, non-German readers should bear in mind the proximity in German of *Übersetzung* and *Übertragung* ("transference"). What psychoanalysts refer to as "transference" is, in German, also a translation, a carrying over.

Freud's interest in translation was manifest early in his career: while doing his military service he translated an essay by John Stuart Mill and, on his return from his stay at the Salpêtrière, impressed by Charcot's clinical method, he translated two of the Charcot's main works, as well as two works by Bernheim, which he felt were essential for a scientific understanding of hysteria and the use of therapeutic methods in hypnosis. For Freud the experience of translation was contemporary with his discovery of psychoanalysis as a therapeutic practice. Ernest Jones emphasized Freud's gifts as a translator (Pollak Cornillot, 1990). It should come as no surprise, therefore, to find that *translation* infiltrated his thought as a metaphor for a large number of psychic processes.

In his earliest writings and with the appearance of the concept of repression, translation, in its primary sense of "to bring over," became a way of picturing the transformation of those psychic contents reaching consciousness, repression being thus defined (Freud to Fliess, December 6, 1896) as a "defect of translation," an absence of conscious expression. The work of dream interpretation likewise resembles a translation of the language of the unconscious into the language

of consciousness, of the remembered dream content into its hidden sense: “Interpreting a dream consists in translating the manifest content of the dream into the latent dream-thoughts, in undoing the distortion which the dream-thoughts have had to submit to from the censorship of the resistance” (1907a, p. 59). But at the same time Freud cautioned against the tendency to overestimate the importance of symbols and reduce the work of dream translation to the mere decoding of symbols, and to ignore the ideas that present themselves to the mind of the dreamer during analysis. Finding the hidden meaning was more complex than the simple transliteration of the signs of the unconscious system into the signs of the conscious one. Elsewhere (1918b [1914]), Freud uses the term *translation* more generically, to designate the psychoanalyst’s interpretation of a psychic phenomenon: for example, the fear of being eaten by the wolf “is translated” into the fear of being raped by the father. More recently André Green (1997/2000) has rediscovered the richness of the “hypothesis of translation” present throughout Freud’s work.

## TRANSMUTING INTERNALIZATION

Transmuting internalization is a process that participates in the formation of psychic structure, as postulated by Heinz Kohut. It is an extension of Freud’s concept of mourning. For Freud, the loss of an object causes mourning to establish a presence within the psyche. If this model is seen as the basis of all losses, including nontraumatic and phase-specific losses, then it follows that any failure or absence of a sustaining object can lead to the establishment in the psyche of whatever function that object has served. Minute losses or absences lead, not to wholesale identification with the object, but to internal structures that need bear no resemblance to the lost object but merely capture the function served by the object. Nontraumatic loss and internalization, called optimal frustration, is an essential feature of normal development. Parental absences, disappointments, failures, and age-appropriate responsibilities help children gradually develop psychological structure. *Psychological structure* refers to an enduring function, a function that results from the progressive neutralization occupying the area of the psyche not represented by repression. Psychoanalytic treatment parallels normal development when the analyst causes transmuting internalizations by initiating similar phase-specific failures.

## TRANSSEXUALISM

Transsexualism is characterized by the desire to belong to the sex opposite one’s assigned, biological sex, and by the demand for a reassignment of one’s sex with the

help of hormones and surgery—all this in the absence of any biological anomaly that is detectable with current means of investigation. This distinguishes transsexualism from intersex states and pseudo-hermaphrodites. With transsexualism, people speak of an unshakeable conviction of belonging to the other sex. It would be more appropriate to speak of an indomitable desire to live as a member of the other sex, as well as the desire to bear a corporal sign of this belonging, which is what makes transsexualism historically unique.

In 1953 the endocrinologist and sexologist Harry Benjamin was the first to name the syndrome that had previously been confused with transvestism. Perhaps he had retained the expression “Psychopathia transsexualis” used by D. O. Cauldwell in 1949, although he claimed he had no conscious memory of it, or “seelischer Transsexualismus” the expression used by Magnus Hirschfeld in 1923, although he makes no mention of it. It took more than ten years for the term *transsexualism* to become accepted.

In the same year, 1953, the Journal of the American Medical Association (JAMA) published the observations of C. Hamburger, G. K. Stürup, and E. Dahl-Iversen concerning the case of George, operated on in Denmark, who became Christine Jorgensen. Benjamin declared that psychotherapy was powerless to treat transsexualism and that the only possible treatment was sex conversion surgery along with hormone replacement therapy for life. A large number of specialized centers opened in the United States for treating the sexual identity disorders that Norman Fisk called “gender dysphoria” in 1973. However, some of those subsequently closed down.

Hormono-surgical sex reassignment hardly deserves to be called a treatment. A palliative at best, it consists in transforming a healthy, hormonally well-balanced, and functioning organism into an artificial intersex, a mutilated organism that requires hormone replacement therapy. In order to justify such an unusual treatment it would be necessary to prove that although they may be compromising their physical health, patients derive benefits from it in terms of their mental health. However, existing follow-up studies are incomplete and insufficient. Not all subjects continue to be seen. Those who are seen are generally satisfied. With few exceptions they do not regret their operation but they end up realizing that their dearest wish, to really be changed into a human being of the opposite sex, has remained unrealizable.

Compared to female transsexuals becoming male, male transsexuals becoming female constitute a larger group (three biological males for every biological female demanding reassignment) that is more heterogeneous, suffers from more serious pathologies, and is characterized by very mediocre social integration (prostitution, public assistance). Many patients request sex reassignment after a period of their lives spent as transvestites or homosexuals. The most cautious physicians defending hormono-surgical sex reassignment make a point of identifying patients who essentially suffer from identity disorders, whom they refer to as true or primary transsexuals, which they consider to be the only indication for hormono-surgical sex reassignment.

An effort has been made to present primary transsexuals (male to female) as normal subjects who, by reversing their identity, inform their mothers of the truth of their primary identification (Robert Stoller). It is difficult to consider that transsexuals do not suffer from serious psychic disorders at the narcissistic level. Psychoanalysis has extended its field of application from the neuroses to borderline cases, and in this respect it may be possible to try to treat transsexuals. The difficulty is great because denial and splitting dominate the mental organization. They put everything on the corporal level and nothing on the psychic. The availability of medical hormono-surgical sex reassignment makes it more difficult to reach them through psychoanalytic psychotherapy. Interesting attempts have nevertheless been made, often by psychoanalysts from the school of self-psychology (particularly Lothstein).

Treatment of children suffering from sexual identity disorders shows promise if the parents are treated at the same time, and in this way observing how the children respond to their parents' problems by thinking that they should belong to the opposite sex in order to be loved by them.

## TRATTATO DI PSICOANALISI

Cesare Musatti's *Trattato di psicoanalisi* (Treatise on psychoanalysis) was written in the 1930s, when the first generation of Italian psychoanalysts were active and when psychoanalysis was first beginning to reach the public. Unfortunately, its publication was hampered by an idealist, fascist culture that resisted the challenges of psychoanalysis.

The treatise was based on lectures in experimental psychology that Musatti gave from 1933 to 1935 at the University of Padua. He attempted to provide a solid foundation for young physicians who were interested in the new methods of psychotherapy and were considering using them professionally. At the same time he wanted to offer the Italian public a solid popular work about psychoanalysis that would sweep away the prejudices and falsehoods then prevalent about the field.

Although the book was completed in 1938, the political and cultural situation in Italy presented an obstacle to its publication for over a decade. At the time Nazi racism, which existed in Italy in diluted form, considered psychoanalysis a Jewish science and sought to destroy the work of Freud and his followers—physically and in spirit. For years the manuscript remained in Musatti's desk. It was finally published in 1949 by Boringhieri. The work was subsequently reprinted several times, first by Einaudi.

Musatti's *Trattato* consists of six parts. He retraced the origins of Freud's discovery, from dreams to free association, from fantasy to the arts, being careful to define mental pathology as well as the structure of human personality. His goal was to introduce psychoanalysis to scientists and academicians, and thereby win their support. Ironically, errors like the "doctrine of instincts," the name given by Musatti to a section of his book, could have been the source of a certain resistance to his work. This turned out not to be the case, and the confusion remained between drive and instinct—a key Freudian distinction that is ignored in

the *Standard Edition* of Freud's works. Notwithstanding its limitations, the *Trattato*, known as the "freudino" (the little Freud) by students, has the merit of having been the first essay to describe Freud's work systematically without excessive distortion, at least in comparison with earlier Italian-language summaries.

## TRAUMA

In its psychoanalytical sense, *trauma* denotes an event of such violence and suddenness that it occasions an inflow of excitation sufficiently strong to defeat normally successful defense mechanisms; as a general rule trauma stuns the subject and, sooner or later, brings about a disorganization of the psychic economy.

*Trauma* (a wound), a term borrowed from ancient Greek, was at first used in surgery to denote a violent injury from an external cause that breached the body's integrity. (*Traumatism* is used occasionally as a synonym, and occasionally to refer to any condition resulting from trauma.) The term eventually made its way into common usage, its psychological sense coming to the fore as its employment spread from medicine to psychoanalysis.

In the context of late-nineteenth-century causation, the notion of trauma was inseparably linked to the ideas of shock and physical breach, and it was regularly invoked to explain a variety of syndromes, among them traumatic neurosis. Freud was part of this current of thought, and, following Charcot, assigned trauma a determining role in the etiology of hysteria; then, along with Breuer (1893a), he moved from the idea of real, physical trauma to that of a "psychical

trauma” (pp. 5–6), with the stress laid no longer on the reality of the event but rather on its mental representation, experienced as an internal “foreign body,” which is the source of the excitation. This was a radical shift relative to the theories of the time, and an epistemological leap of great import, for it was the foundation stone of psychoanalysis.

What made an experience traumatic for Freud was indeed the incapacity of the psychical apparatus to discharge the excessive excitation in accordance with the principle of constancy, whether that excitation arose from the pathogenic action of a single brutal event or of a series of incidents having a cumulative effect. This economic view of things was part of psychoanalysis from the beginning, and it is crucial to the understanding of the psychoanalytical notion of trauma. Even at this early period, Freud distinguished two models: the first, evidenced by hysteria, involved the absence of discharge, whereas in the second, operative in the actual neuroses, discharge took place but did so at the wrong time and place, and independently of the object. The economic perspective provided the connection and continuity between the successive theories proposed by Freud as he considered trauma in terms of a causal relationship: the first of these theories was modeled on Charcot’s hystero-trauma, but this traumatic theory was very soon replaced by the theory of seduction. Founded on clinical observation, this theory led Freud to assert that the trauma was always of a sexual nature and that it had two moments: the first, the moment of fright, confronted the child prematurely with the sexual conduct of an adult seducer; this the child experienced uncomprehendingly, and its meaning and traumatic effect came into play only after puberty, on the occasion of a second scene that served to reactualize the repressed memory of the earlier one. When the frequency with which his patients produced accounts of such early events obliged Freud to question their reality and treat them instead as products of fantasy, the theory of seduction lost a good deal of its interest; at the same time, its temporal aspect—the process of “deferred action” (*après coup*) of which the case of Emma provided the archetypal instance—remained essential to Freud’s explanation of the trauma, whose importance in the triggering of neuroses, however, he now qualified by taking into account such factors as individual predisposition, the trauma’s place in the subject’s history and mental organization, and the circumstances of the event.

The thinking sparked by the war neuroses gave the notion of trauma a new lease on life, while so reinforcing the energetic point of view that in 1916 Freud did not hesitate to say that “the term ‘traumatic’ has no other sense than an economic one” (1916–17a [1915–17], p. 275). Thus a trauma, by its simple intensity, could produce an instinctual hypercathexis capable of breaching the protective shield against stimuli. In order to stem this influx, which the ego, not having been prepared by anxiety to confront the danger, was all the more incapable of neutralizing, the psychical apparatus would mobilize all available energy and establish countervailing charges. Should these defensive strategies be insufficient, the apparatus would have to bind the excitation compulsively, “beyond the pleasure principle,” so as to lower it gradually to a tolerable threshold (1920g, p. 31).

In *Beyond the Pleasure Principle*, where the importance assigned to the compulsion to repeat led Freud into speculation about the death instinct, the question arose of what principle governed repetition. Was it Thanatos, striving for absolute discharge, as in certain behaviors analogous to the traumatophilia described by Karl Abraham in 1907? Or Eros, aiming to attain mastery through the gradual resolution of tension and thence accede to the power of symbolization, as well illustrated by repetitive dreams recounted in the analytic session and by reproductions in the transference? In fact, where the work of analysis made it possible for the subject to recover and work through repressed material, the binding function could triumph over death-oriented repetition. In that case, deferred effects, by making reorganizations possible, would have been the motor of change.

Finally, in the context of Freud’s revised theory of anxiety (1926d), the stress fell on the state of helplessness: what the baby experiences, subjected without recourse to a state of tension in the absence of its mother, was taken as the prototype of all traumatic situations. In this instance with the signal function of anxiety as yet not developed, the ego is overwhelmed by an eruption of instinctual forces it is powerless to contain.

Freud’s reflections of 1926 have given rise to the present-day notion of *narcissistic trauma*, which refers to the ego’s inability to bind excitation resulting from a loss, whether the loss of an object or a loss of a narcissistic kind. This classification is justified in terms of the symptomatology often presented by patients (rumination, repetitive dreams), who may thus be

thought to be expressing a pathological mourning under the influence of deferred effects (*après coup*).

This category has led to a questionable broadening of the concept, for it tends to water down the specificity assigned to trauma in Freud's early works: Systematically treating all and every physical or psychic injury as a trauma runs counter to the psychoanalytic view, for which a trauma cannot be reduced to the level of events alone; at the same time, this level should always be taken into account, precisely because not to do so is to court the danger of further pathological development in a traumatic mode.

## **TRAUMA OF BIRTH, THE**

First published in 1924, Otto Rank's *The Trauma of Birth* took as its starting point a note that Freud added to his *The Interpretation of Dreams* in 1909: "Moreover, the act of birth is the first experience of anxiety, and thus the source and prototype of the affect of anxiety" (1900a, pp. 400–401n).

Rank set out to identify "the ultimate biological basis of the psychical," the very "nucleus of the unconscious" (p. xxiii). For him this was the physical event of birth, whereby the infant passes from a state of perfectly contented union with the mother to a state of parlous separation via an oppressive experience of asphyxiation, constriction, confinement in the vaginal canal, and so on—all feelings recognizable in anxiety states of every kind. It was the struggle against this traumatic experience of birth, in Rank's account, that structured the fantasy life of the child, including the disavowal of the difference between the sexes, infantile sexual theories, and oedipal scenarios. Castration anxiety was a defensive derivative of the anxiety associated with the birth trauma.

Rank supported his thesis with case notes, notably concerned with terminations which according to him always brought up fantasies of a "second birth." But for the most part he relied on data derived from social myths and rites exemplifying what he called "heroic compensation," religious sublimation, artistic idealization, or philosophical speculation. The very abundance of the material thus adduced, and the author's stated aim of accounting for all processes of hominization and all cultural evolution in terms solely of the trauma of birth, were bound to leave the reader perplexed. Rank's evidence nevertheless warrants more attention than contemporary psychoanalysts were willing to accord it. Indeed a multitude of themes—falling, constriction within a narrow space, feelings of

being lost in limitless space, the importance of very early relations with the mother, or primitive anxieties foreshadowing castration anxiety—were distinctly novel in the psychoanalytic literature as of 1924.

The clumsy presentation of these ideas, however, along with the author's overreaching ambition, the lack of method in his argument, and the failure to buttress his thesis with analytical clinical material, all contributed to the rejection not only of his work but also of Rank himself, who broke with the psychoanalytic movement in 1926 after Freud's condemnation of his ideas in *Inhibitions, Symptoms and Anxiety* (1926d).

Beyond the question of the weaknesses of Rank's book, it is reasonable to consider what psychoanalytic reasons might have occasioned this rejection of his ideas in favor of the primacy of oedipal conflict as crucial to the organization of neurotic pathology, or of castration anxiety as the prototype under which all other forms of anxiety were subsumed. In a postscript to the French edition of *The Trauma of Birth*, Claude Girard points out that the position defended by Freud and his followers tended to exclude non-neurotic pathologies as legitimate objects of psychoanalytic exploration, whereas Rank's propositions encouraged the investigation of very early forms of pathology, along with that of the baby's earliest relations with its mother.

Both these avenues of inquiry were further explored subsequently by American psychoanalysts (Greenacre, 1945; Fodor, 1949; Alexander and French, 1946). More recently, Rank's main theme has been picked up with renewed vigor in the wake of object-relations theory, albeit without Rank's reductionism. Thus Wilfred R. Bion (1977) has used the term *caesura* in theorizing about the experience of a discontinuity in object-relations of which birth is the paradigm case. And Frances Tustin (1981) has described a premature psychological birth in autistic children corresponding to a consciousness of the bodily separation from the object that arises at a stage when the psyche is still unable to form symbols.

## TRAUMATIC NEUROSIS

The term *traumatic neurosis* designates a psychopathological state characterized by various disturbances arising soon or long after an intense emotional shock. In the second half of the nineteenth century, a number of observations corresponding to a clinical picture of this kind were reported, typically in the wake of military action or railroad disasters, and related either to hysteria or to neurasthenia. Yet it was Hermann Oppenheimer who, in 1889, introduced the term itself into the lexicon of psychiatry.

Freud was to construct his theory of the neuroses on the model of traumatic neurosis. However, by stres-

sing the sexual character of the precipitating factor and the possibility that the action of traumatic neurosis could be deferred, rather than the fright occasioned by an accident's actual threat to life, he jettisoned what had hitherto constituted the specificity of the category. Furthermore, by taking into account predisposition for and tolerance of trauma, as well as the trauma's significance in the subject's history and mental organization, Freud relativized and reduced the notion of shock and its etiological import. The whole issue was destined to achieve its full immediacy only when historical events brought the war neuroses to the fore, prompting Freud to reconsider traumatic neurosis, first in 1916 in his *Introductory Lectures on Psychoanalysis* and once again in the context of his great theoretical revision of 1920.

For Freud, the economic point of view then became predominant. He accentuated the character of the trauma as at once somatic (the "disturbance" freed up the flow of excitations) and psychic ("fright"). In Freud's words, "The symptomatic picture presented by traumatic neurosis approaches that of hysteria in the wealth of its similar motor symptoms, but surpasses it as a rule in its strongly marked signs of subjective ailment . . . , as well as in the evidence it gives of a far more general enfeeblement and disturbance of the mental capacities" (1920g, p. 12).

Traumatic neurosis does not have the same meaning for psychoanalysts as it does for psychiatric clinical practice. The psychoanalytic characterization includes repetition: The patient relives the initial trauma, and this manifests itself in every situation, whether transference-related or not. The function of nightmares is to express the anxiety that was absent at the time of the original incident. Such repetitive manifestations reveal a fixation on the trauma as well as an attempt to discharge excessive tension in incremental fashion (that is, to work through it).

Clinically and theoretically, it is important to eschew the mistaken application of the term *traumatic neurosis* to the posttraumatic state (or syndrome), since *posttraumatic syndrome* refers to a physical (usually cranial) trauma and to disorders related to an emotional shock. Such states cannot in fact be brought under the heading of *neurosis* in a psychoanalytic sense. Here Freud himself ran into perplexities that led him to assign traumatic neuroses first to the class of the actual neuroses and then to that of the narcissistic neuroses. Traditional psychiatry, as reflected in the

third edition of *Diagnostic and Statistical Manual of Mental Disorders* (DSM-III), has renamed traumatic neurosis as "posttraumatic stress disorder," and while one might question its objectivizing use of *stress*, this approach does have the merits of avoiding the nosological trap of the neurosis/psychosis dichotomy and of viewing the issue from an interdisciplinary standpoint.

## **TRUTH**

Sigmund Freud's notion of *truth* evolved from a factual conception into a relativistic method where the true and the false are defined both in relation to a conventional and bounded space (that of the cure) and the dynamic effects that "plausible" constructions might have on the psyche. Truth as an objective no longer remains "the fundamental rule of psychoanalysis" (1914g, pp. 147, 150). It inclines towards the notion of reality testing that demands that the subject partially abandon their illusions. Truth as an ideal is inseparable from psychoanalytic inquiry and is unattainable, except partially in the "nuclei" of truth present within individual and collective distortions.

The search for factors that cause psychic suffering can be confused with the search for truth inasmuch as they are both repressed, misrepresented, displaced, represented by their opposite, and the like. Initially Freud imagined rediscovering the traumatic events in the histories of his patients themselves, but promptly noticing “that there are no indications of reality in the unconscious, so that one cannot distinguish between the truth and fiction that is cathected with affect” (letter to Wilhelm Fleiss, 21 September 1897), he ended up privileging the psychical reality of the subject, wherein a dynamic verisimilitude was elaborated which would take on the value of truth. This relativization of truth seems to coincide with a Pirandellian conception of it (*Each in His Own Way*). In fact, truth as a value has not disappeared from the Freudian purview but it has become subtler. Thus interpretation is not about the exhumation of truth but rather construction through the adoption of a coherent paradigm (Viderman, 1970), originating from the unperceived formulations of the subject’s free associations or dreams.

Thus for Jacques Lacan, truth extricates itself from reality: “In psychoanalytic anamnesis, it is not a question of reality, but of truth, because the effect of full speech is to reorder past contingencies by conferring on them the sense of necessities to come” (1956, p. 48). Truth is not precisely being true to reality, rather it speaks and stutters through its symptomatic distortions.

The analyst has to engage with these “nuclei” of truth, then; Freud, for instance, defined them in relation to the sexual theories of children, which despite being untrue nonetheless each contain “a fragment of real truth” (1908c, p. 215). This is an adult, intellectual mode of investigation whose results, because they are limited to the possibilities of human understanding, would have been false in relation to a broader perspective, but which include nevertheless “inspired” partial but significant interpretations.

The quest for truth proceeds from a “truth fantasy” (Mijolla-Mellor, 1985), which relates to an image of lost harmony (transparency, luminosity) within the *I*, the others, and one’s self. Truth, in terms of the demand for truthfulness, is central to the fundamental rule that requires the abandonment of secrecy; however, it also guides the behavior of the analyst in their relationship with the patient, in their vision of the world, and in their research, requiring them to relin-

quish personal illusions for the construction of a coherent schema. Challenging illusion and narcissistic comfort, truth, according to Freud, is a force in its own right: “The hardest truths are heard and recognized at last, after the interests they have injured and the emotions they have roused have exhausted their fury” (1910d, p. 215).

Piera Aulagnier gives truth a central place in relation to the identity of the subject. It is the object of a “battle never definitively won nor lost to which periodically the *I* must surrender in order to modify and defend its positions, failing which it would be unable to turn towards or invest in its own identificatory space” (1984, p. 147).

The notion of truth in psychoanalysis is tied to the history the subject, in the same way as it is to humanity, because it is not simply a case of a balance between understanding and the thing, but of a narrative that is reconstructed using the residues left behind by legend.

## TUBE-EGO

David Rosenfeld, the Argentinean psychoanalyst, introduced the notion of the “tube-ego” in an article written in 1981. Frances Tustin makes several references to it, particularly in chapter 10 of *Autistic Barriers in Neurotic Patients* (1986).

Based on convincing clinical material coming from adult patients, David Rosenfeld shows that in very regressive states they experienced their body image as a system of tubes controlling their bodily fluids. He suggests that this image of the body as a system of tubes seeming to contain the bodily fluids is more elementary than the image described in Esther Bick’s 1968 account of the skin as container.

Frances Tustin seems to agree when she says: “My own clinical work confirms that the body image as a system of pipes is more elementary than the image of the whole body being contained by the skin. However, the ‘system of pipes’ body image implies awareness of ‘insides,’ and also awareness of outside situations and identifications with them. It is a movement away from undifferentiated autism to a transitional awareness of ‘me’ and ‘not-me’” (1986, p. 228). She uses this concept not only to describe infantile autism but also to describe ancient levels of representation of the image of the body in relation to certain anorexic pathologies during adolescence.

Like Frances Tustin, Geneviève Haag in France also relies heavily on this concept in her work with autistic children.

## TURNING AROUND

Turning around is a process that affects the vicissitudes of the instinct in terms of its affective expression (for example, love turning into hate), its aim (for example, active turning into passive), or its object (in particular, the shift from being directed toward another person to being turned back onto the self). These three types of processes are closely related.

Freud gave his essential description of this dynamic in “Instincts and Their Vicissitudes” (1915c). He defined four vicissitudes of the instincts: repression, sublimation, reversal into the opposite, and turning around upon the subject’s own self.

Freud also used the term *reversal* in this article in a different sense involving the transformation of psychic “contents,” that is, an idea, a representation, a dream image, a symptom, or the like, into its opposite. With regard to the instinct itself, or rather its expression as an affect, this dynamic “is found in the single instance of the transformation of love into hate” (1915c, p. 127); moreover, these two affects can coexist, which is the definition of ambivalence. However, it is appropriate to nuance Freud’s statement here, because reversal in the opposite direction, from hate into love, can also occur through reaction formation.

In the same article, Freud discusses two types of turning around onto the self: sadism turning into masochism and voyeurism turning into exhibitionism. The former involves the transformation of sadism (the pleasure of violence being directed toward another person) into masochism (the subject derives pleasure from violence being directed against himself or herself and solicits it from someone else). In this 1915 article, Freud posited sadism as being primary and masochism as being secondary, that is, resulting from turning around, which necessarily implies a reversal inversion of agent and object positions (the relationship in which the subject directs aggression against another person turns into one where the other person directs aggression against the subject) and a reversal inversion

of the aim (the active aim, to direct aggression against the other, becomes passive, to be the object of the other's aggression). Previously, in "Formulations on the Two Principles of Mental Functioning" (1911b), Freud had upheld that at the beginning of life only the pleasure principle holds sway; the instinct knows only autoerotic satisfaction. During the narcissistic phase, the nascent ego, once it begins to distinguish between inside and outside, takes into itself from the outside that which is pleasurable and expels that which is painful, thus constituting itself as "purified pleasure-ego" (1915c, p. 136). As a result, "the external world, objects and what is hated are identical" (p. 136); the object is born in hatred. As we know, this was to become the basis for the theories of Melanie Klein. However, this thesis, which lacks clarity, seemed somewhat forced even to Freud himself. In "The Economic Problem of Masochism" (1924c), he reconsidered this trajectory and proposed to reverse it, by positing masochism as being primary and sadism as being secondarily produced through turning around and projection onto the external object. (These issues have been discussed, in particular, by Benno Rosenberg in *Masochisme mortifère et Masochisme gardien de la vie* (1991; Destructive masochism and masochism as preserver of life.)

Whatever the case may be, the dynamic of suppressing aggressive impulses and turning them against the self and a transformation with regard to the aim of the instinct, which changes from active to passive (the instinct itself, we must recall, is always active) is routinely encountered in clinical practice.

The same is true of the reversal of voyeurism into exhibitionism. Here Freud distinguished three "stages" corresponding to the successive modes of the search for pleasure: looking at the body of another person, looking at one's own body, and displaying one's body so that it will be looked at. Here again, the change from active aim to passive aim and turning around onto the self are closely linked, and the narcissistic phase plays an essential role in this developmental process.

In clinical terms "the turning round upon the subject's self and the transformation from activity to passivity converge or coincide" (1915c, p. 127). It nevertheless remains useful, on a theoretical level, to distinguish these modalities which is what André Green does, notably, in *Life Narcissism, Death Narcissism* (1983/2001) has proposed with the idea of "a double return."

To these two types of turning around analyzed by Freud (sadism-masochism and voyeurism-exhibitionism), it would be possible to add the opposition he defined during the same period between ego libido and object libido, or, in terms of cathexis, between the ego's cathexis of the object or of itself. This opposition, described in "On Narcissism: An Introduction" (1914c), is within the context of the first theory of the instincts (opposition between the sexual instincts and the self-preservation or ego instincts). Freud later revisited this opposition in light of his topographical and economic theories of the 1920s, in particular within the framework of his thinking on the psychoses. However, throughout these successive versions, these same figures of turning around appear, with regard to affect (love-hate), the instinctual aim (active-passive), and the object (self-other).

## **TURNING AROUND UPON THE SUBJECT'S OWN SELF**

The notion of *turning around upon the subject's own self* refers to the process that substitutes the subject's own self in place of the external object of an instinct. This term appeared in Sigmund Freud's writings in "Instincts and Their Vicissitudes" (1915c), where it is discussed as one of the four vicissitudes of the instincts: repression, sublimation, reversal into the opposite, or "turning round upon the subject's own self" (p. 126). Freud described this latter process as

being closely linked to reversal into the opposite and used the study of two clinical models to understand its effects: sadism-masochism and voyeurism-exhibitionism.

In sadism there is a manifestation of aggression toward another person, who is treated as an object. If the object of the instinct becomes the subject's own self, the initial instinctual aim simultaneously changes from active to passive, because the sadism is then directed against the subject. Turning against the self is demonstrably at work even though the subject has not yet subjugated himself to another person. Obsessional neurosis is representative of this intermediary stage, which Freud described as self-punitive rather than masochistic. A final stage consists in the search for another person to play the active role that the subject renounces, thereby submitting to masochistic control. One can see how, over the entire trajectory from sadism to masochism, turning around upon the subject's own self occurs alongside the transformation of activity into passivity, in this inversion of roles between the person who exercises sadism and the person subjected to it.

Another pair of opposites, voyeurism-exhibitionism, provides a clear example of the same mechanisms. The three successive stages played out in the previous example can be found again here. Thus, there is initially "looking" as an activity that the subject directs against an unknown object, followed by the subject's submission to a turning around of the scopical drive onto a part of his or her own body. Finally, the introduction of a third element allows the subject to become the object of another person's gaze.

Freud emphasized that these operations as a whole do not exhaust all the energy of the instinct and that once again, the psyche prefers to work upon small quantities of energy. Moreover, it seems that the three stages previously described as unfolding in a linear fashion are in fact all present in varying degrees and that they develop in conjunction with one another.

Anna Freud included turning against the self in the list of defense mechanisms enlisted by the ego in its struggle against guilt-inducing instinctual impulses. In *The Ego and the Mechanisms of Defense* (1936), she cited this process as one of the most primitive ones, "as old as the conflict between the instinctual impulses and whatever obstacle may be erected against them." However, she revised her attempt to chronologically situate this defense mechanism, as well as others, for lack of confirmation during her clinical work. Thus, in

terms of the mechanism in question, she acknowledged the rarity, in very young children, of true masochistic manifestations resulting from a turning around of the instinct back onto the self.

In the psychoanalytic literature, this notion is at the crossroads of numerous avenues of thought. Freud, for example, let it be understood that the manifestation of the instinctual vicissitude described here depended on the subject's narcissistic organization.

## **TUSTIN, FRANCES (1913–1994)**

Child analyst Frances Tustin was born on October 15, 1913, in Darlington, northern England, and died on November 11, 1994, outside of London. She was the only child of parents who separated in 1926. Traumatic memories of this separation remained with her, especially because she had been very close to her father and would not see him again for some fifteen years. Married for the first time in 1938, she divorced in 1946, and two years later she married Professor Arnold Tustin, an eminent physician who took a close interest in her work and greatly encouraged her in her research. She at first focused on the teaching profession and worked in that field for several years.

In 1943 she had the opportunity to attend courses in child development taught by the Kleinian psychoanalyst Susan Isaacs at the University of London. She was fascinated by this approach to children, which was entirely new to her. Six years later, in 1949, after the death of her first baby, she felt a calling to become a child psychotherapist. She learned of a nascent training program at the Tavistock Clinic and enrolled. As a part of her training, she had to enter into analysis with Wilfred Bion. She decided to end her analysis after fourteen years (with two interruptions, once for an internship in the United States and once for her second pregnancy, which ended, yet again, in the death of the baby at birth). After stopping treatment, she was beset with terrors, which she later understood as an expression of autistic anxieties. Because Bion had returned to the United States, she had to call upon another analyst, Stanley Leigh.

At the Tavistock Clinic, Tustin first heard about autistic children by way of a lecture given by Marion Putnam at the invitation of the clinic's then director John Bowlby. She was fascinated by what she heard. In 1953, her husband having accepted a one-year appointment as visiting associate professor in the United States, she had the opportunity of doing an internship at the James Putnam Center in Boston, one of the first treatment centers for autistic children. Back in London she wanted to apply the Kleinian method of analysis to autistic children. She soon realized that Melanie Klein's theories had to be expanded to account for this new pathology.

Her treatment of her first autistic patient revealed to her the anxiety that is at the heart of this disorder and that is due to the trauma associated with the emerging awareness of bodily separation from the object at a stage when the ego cannot yet form symbols. The child feels as if it were experiencing not just loss of the object but also the sensation of being bodily uprooted. She showed that this uprooted feeling is usually localized in the mouth. It is as if the autistic child felt brutally exposed to a series of discontinuities along the mouth-tongue-nipple-breast axis. These discontinuities not only lead to loss of the illusion of controlling the object of instinctual satisfaction, but also give the child the intolerable anxiety of feeling amputated, emptied, and annihilated, and of feeling that the object too is amputated and emptied. The child then erects defense mechanisms against the anxiety of this traumatic experience. These defense mechanisms consist

of autistic forms (impressions that the autistic subject procures for itself with its own bodily secretions, stereotyped movements, or interoceptive sensations), autistic objects (concrete objects that the child manipulates not for their conventional uses or their symbolic values, but rather for the sensations that they cause against the skin or the mucous membranes, and that procure autistic forms), and the autistic shell (a world of pure sensations made of up autistic forms and objects, without otherness; a two-dimensional world in which the only possible relationship is an adhesive one of "sticking").

Tustin's work broadened and updated the understanding of childhood autism and made possible an effective therapeutic approach to it, but her influence went beyond the realm of autism itself. In effect, she described autistic pockets or barriers present in personalities affected by various disorders: phobias, melancholia, mental anorexia, psychopathy, psychosomatic pathologies, and severe childhood functional disorders (enuresis, encopresia). These autistic pockets are parts of a personality caught in a system of autistic defenses, and they must be analyzed to avoid interminable analyses and negative therapeutic reactions.

An honorary member of the British Psychoanalytical Society, Tustin taught at the Tavistock Clinic, where she trained many students. In addition, many child psychotherapists and psychoanalysts from around the world went to London, and later to Amer-sham, in the greater London suburbs, where she lived at the end of her life, to benefit from her supervision. She was invited to deliver lectures in numerous European countries and in the United States. She published some thirty articles and four books. In addition, there are videos recordings of three interviews with Tustin. Nearly all of her publications and research focused on childhood autism. From her first contact with children afflicted with this disorder at the beginning of the 1950s until her death, she continuously strove to promote deeper understanding and better treatment of this condition.

## TWINSHIP TRANSFERENCE/ALTER EGO TRANSFERENCE

Twinship or alter ego transference is a form of narcissistic transference defined by Heinz Kohut as expressing the analysand's need to rely on the analyst as a narcissistic function possessing characteristics like herself.

Kohut first defined the concept in *The Analysis of the Self* (1971) as one of the possible forms of mirror transference. In *How Does Analysis Cure?* (1984) he made alter ego transference a type of transference unto itself, corresponding to the existence of an autonomous narcissistic need, the alter ego.

It is often in relation to the analyst being experienced as identical or similar that narcissistic tendencies are pinpointed. Kohut believed that oedipal interpretations are often understood by patients as being a repetition of the parents' negation of narcissistic needs, which means that such interpretations are premature. Interpretation of the narcissistic needs of the alter ego, when it is appropriate, causes memories to emerge that can be worked through.

Alter ego transference relates to mirroring and idealizing narcissistic transference, to the grandiose self, and to the idealized parental imago. This conceptualization has been criticized both in terms of narcissistic transferences and the priority given to narcissism over instinctual conflicts, and as an attempt to replace Freudian metapsychology with a metapsychology of the self, understood as being made up of sectors.

## TYPICAL DREAMS

A typical dream is a dream that, in its content and form, is very much alike for a great many people. Freud devoted a long section to typical dreams in *The Interpretation of Dreams* (1900a): these are “dreams which almost everyone has dreamt alike and which we are accustomed to assume must have the same meaning for everyone” (p. 241).

These dreams could be considered to be an exception to the rule that the meaning of a dream can only be deciphered through the dreamer's own interpretation; furthermore, Freud added, associations connected with such dreams are in general weak and vague. He was interested primarily in four kinds of typical dream.

- dreams of nudity, gratifying an exhibitionist desire dating from childhood;
- dreams of the death of loved ones, of which there are two varieties: death of a brother or a sister, an expression of infantile jealousy, and death of a parent, the direct expression of oedipal hatred for a parent of the same sex (it was in this passage that Freud gave for the first time a closely reasoned description of that which he later was to call the *Oedipus complex*). Any dream of the death of a loved person would therefore be an

expression of a death wish, Freud commenting that in this case, contrary to what has been observed in most dreams, the result of the wish—disguised as a fear—is represented without displacement: it really is the death of the loved person that is represented. Freud specified that in these dreams of infantile satisfaction, death does not have the meaning it has for the adult; it is simply absence, which is why the dream is often not very painful;

- dreams of flying. A note added in 1925 suggested that this could be a representation of the primal scene (sexual rapports between parents);
- dreams of being obliged to retake an examination, as an adult, that has been taken and passed successfully at a younger age. The meaning of this is frequently reassurance before a difficult moment (“you have passed this examination before, therefore you will succeed again . .”).

Freud returned to this subject later in the same book, where he maintained that typical dreams deploy symbolic representations rooted in the culture and found in tales, folklore, and myths: “the question is bound to arise of whether many of these symbols do not occur with a permanently fixed meaning, like the ‘grammalogues’ in shorthand” (p. 351). Yet, in most cases, something personal to the dreamer is added to the “universal” symbol. Freud illustrated this proposition with a great number of examples of dreams of stairways, tooth extractions, theft, birth, etc., where, however, this distinction seems to be a little vague.

Thereafter, the subject of typical dreams did not come up much in Freud’s work. It has been discussed by Denise Braunschweig and Michel Fain (1975) from the perspective of castration, these kinds of dreams appearing to them to bear witness to a “hysterical kernel,” which they describe as “a capacity to turn something into its opposite, so creating a double meaning susceptible of satisfying the demands of bisexuality.”

## ULCERATIVE COLITIS

Organic in its etiology, ulcerative colitis remains an enigmatic disease, although current understanding puts it in the group of autoimmune disorders, thus increasing its interest for those involved in psychosomatic medicine.

It involves continuous damage to the mucous lining of the colon but can also affect the rectal mucosa. The latter are eroded, sometimes abscessed, and can rupture, making this a serious condition. It progresses through a series of attacks of varying degrees of severity and can occasionally necessitate a colectomy with a colostomy.

Its main symptom, bleeding (the mucosa “weep” blood), the psychological profile often associated with it (depression, regression), and its evolution, which is variable and unpredictable but is often correlated with a psychoaffective trauma, have put this disease under the spotlight among psychoanalysts specializing in psychosomatic disorders.

The circumstances that trigger the onset of the disease or attacks have been identified by the majority of authors. These appear to be fortuitous during the early stages of investigation but may become more defined in the course of psychotherapy with the gradual emergence of latent content. Often, although not always, the following are found: experiences of object-loss, experiences of wounded narcissism with feelings of worthlessness, self-depreciation, and a sense of the impossibility of taking on new responsibilities. These experiences may result from new real-life situations (with a traumatic valence) or situations that are fantasized and retroactively reconstructed. In “Étude psy-

chosomatique de dix-huit cas de recto-colite hémorragique” (Psychoanalytic study of eighteen cases of ulcerative colitis; 1958), Michel de M’Uzan and his collaborators wrote: “The common element in these factors is their ability to provoke in the patient a loss of self-esteem, along with the belief that he is unloved or incapable of overcoming a difficulty.”

Thus, to a greater degree than with other organic pathologies, these causes point toward a narcissistic destabilization along with a certain degree of melancholia. Inspired by the bleeding mucosa, certain authors have speculated a “melancholia of the organ”—a theoretical fantasy on the part of the analyst or a structural reality?

The fact remains that a somewhat mechanistic approach would posit the existence of: an affective block or immaturity; strong ambivalence (the depressive pole of which is deeply repressed) toward persons close to the patient as well as toward the therapist; and a depressive tendency different from the reactive depression of the disorder. This depression, sometimes carried along on the tide of a massive regression, has even led to indications for treatment with antidepressants (see Guy Besançon’s article “Le corps présent, réflexions sur une série de recto-colites hémorragiques” [The body as presence; reflections on a series of cases of ulcerative colitis]; 1977).

This correlation between ulcerative colitis and a narcissistic axis of depression remains a pivotal element in attempts at a psychoanalytic interpretation. Some authors have thus invoked the idea of a somatic dramatization of melancholia and have sought its source in the mother-child relationship, thereby suggesting that this disorder may be part of a psychogenetic given.

Kleinians see this disease in terms of incorporation of a bad maternal imago: According to Melitta Sperling (1946), “As the object is incorporated sadistically, it is a hostile inner danger and has to be eliminated immediately. The faeces and blood (in severe attacks, only blood and mucus) represent the devaluated and dangerous objects.... The severe form of ulcerative colitis shows a great resemblance in behavior, personality structure and dynamics to melancholia, and seems to represent the somatic dramatization of the same conflict, with relatively little mental pain, that in depression is expressed psychologically” (p. 326).

There is no consensus on this approach. However, it seems probable that these patients have been unable to constitute and develop a mental space wherein they could find themselves by finding objects other than the primary object to which they felt and feel extremely bound, in an inexorable and often conflicted way.

## UNARY TRAIT

According to Jacques Lacan, the unary trait is the elementary form of the signifier as pure difference that supports symbolic identification.

In the second of the three forms of identification described by Freud, the subject identifies regressively with a love object or rival by adopting a “single trait” of the other person (*einzigiger Zug*) (1921c, p. 107). Dora’s cough, for example, was an imitation of her father’s.

Lacan recognized this single trait as a signifier. Or more precisely, insofar as this signifier is isolated and is not part of a chain of signifiers, it is first a sign or an “insignia of the Other” (cf. Lacan, 1957–58, p. 304; 2002, p. 253). This insignia of the Other constitutes the nucleus of the ego-ideal.

In his seminar on *Identification* (1961–62), Lacan used Saussure’s linguistics, to compare the *einzigiger Zug* with the signifier as a distinct element. Thus he translated it as “unary trait” to emphasize its mathematical sense, comparing it with a binary number.

Ferdinand de Saussure defined the signifier negatively. It is not the same, but is different from the other signifiers in a given structure. This implies that a signifier is also different from itself. This pure difference characterizes the unary trait. As an example of the first primitive indication of the existence of the signifier, Lacan referred to a prehistoric hunter carving notches into a piece of bone. One notch signifies each kill, with no reference to the different types of prey or the particular events of each hunt. Each animal killed counts as one, and that is the only aspect of the hunt marked by the trait.

Of course, the traits in a series need not resemble each other. They do not need to be identical in order to be the same. In fact, the contrary is true. Because no simple trait is recognizable as a thing itself, once it becomes part of a series you cannot tell which was the first mark.

When the thing is erased, the unary trait remains as symbolic of its absence. Thus the trait transforms the absent thing into an object of desire. A second mark, indistinguishable from the first, creates a hole in which this object is lost. Thus the unary trait merges with the phallic mark and the castration threat, insofar as it forever prohibits access to the incestuous Thing. The existence of the subject of the enunciation is suspended by the trait that names it, but this subject immediately

disappears in the trait that fixes it, such that the subject only exists between two traits.

To formalize the unary trait, Lacan relied on the topology of the torus, insofar as the unary trait is the mark of a double loss, the loss of an object, which corresponds to the central hole of the torus, and the absence of the subject of the unconscious, which is the uncounted turn of the repeated demand. A single cut that makes a Möbius strip, where the two surfaces are one, corresponds to the structure of the unary trait, identical neither to itself nor to the structure of the subject.

## “‘UNCANNY,’ THE”

When Sigmund Freud’s essay “The Uncanny” appeared in 1919, he had already made a reference to the *Unheimliche*, in *Totem and Taboo* (1912–1913a), as well as bringing up the “omnipotence of thought.” This shows that the question had interested Freud for some time. Here there are passages on repetition compulsion as well that foreshadow *Beyond the Pleasure Principle*, which was published a year later (1920g). A forum for intersecting propositions, the essay is also a compendium of references (Ernst Jentsch, Friedrich von Schiller, Ernst Theodor Amadeus Hoffmann) and yet, Freud does not reference the psychoanalytic literature on related topics, such as Pierre Janet’s déjà-vu, or Joseph Capgras’s illusion of the double.

To establish his evasive concept, Freud follows two approaches at the same time: etymology and linguistic variants, and observations or fantasies that appear in novels. The French, English, and Spanish translations of *unheimlich* all fail to recapitulate the principal reference to the familiar, or family (*heim*, or home), which defines and limits the notion of the uncanny.

*Das Unheimliche* is defined as “that particular variety of terror that relates to what has been known for a long time, has been familiar for a long time.” We are presented at once with a paradox that Freud does nothing to alleviate since the familiar should not be disquieting. This proposition is at the heart of Freud’s ideas about the original pleasure-ego that coincides with the good and rejects the bad. In “Instincts and their Vicissitudes” (1915c), we find the same opposition between ego/non-ego, just as we do in “Negation” (1925h). Still, it is not clear why the familiar should be threatening and therefore, a second element is needed, namely, the secret, the hidden, which gives rise to the notion of hostility and danger. For danger is associated with penetrating what is sealed off, and strangeness—based on an idea Freud borrowed from von Schilling—with the revelation of what should by rights remain hidden because it is the bearer of transgression.

To these linguistic and fantasy associations, Freud, in the second part of the essay, introduces a number of literary examples (many from Hoffmann), centered primarily on the intellectual uncertainty over whether something is living or not (from Jentsch). There it is shown how the repetition compulsion manifests itself through the return of the repressed. This is true even in situations where we expect the new and with it the return of the dead to life.

The theme of the double, developed by Otto Rank, whom Freud quotes, is a source of ambivalence: the assurance of survival and a harbinger of death. Consequently, the *Unheimliche* is connected with the anxiety associated with the return of the repressed and with this the concept receives considerable scope: “With animism, magic, sorcery, the omnipotence of thought, unintentional repetition, and the castration complex, we have for the most part examined all the factors that transform anxiety into the uncanny.”

This essay is certainly one of the most fecund, if not one of the most confused, written by Freud. It represents an exemplary effort at combining literature and psychoanalysis, for Freud helps establish his thesis on the basis

of the study of works of literature. The concepts of anxiety associated with the foreign (René Spitz) and the secret (Piera Aulagnier) have been the subject of research that does not directly extend Freud's work. However, examination of the supernatural (telepathy, for example) and the analysis of literature based on the "anxiety of fiction" (Mijolla-Mellor) are directly related to Freud's study of the uncanny.

## UNCONSCIOUS AS INFINITE SETS: AN ESSAY IN BI-LOGIC, THE

In *The Unconscious as Infinite Sets: An Essay in Bi-Logic*, a major work published in 1975, Ignacio Matte-Blanco introduced an important modification of Freud's notion of the unconscious. His purpose was to save the notion from being progressively forgotten in contemporary psychoanalytic developments. The author refused to consider the unconscious as chaotic (Freud, 1933a [1932]). If a characteristic form of functioning, like the primary process (the processes of the id), may be described as belonging to the unconscious system, then, he thought, one can discover a different organization for it than the one ruling the conscious system. Grounded in this idea, Matte-Blanco studied the logical principles that would allow systematic unconscious violations of classical, asymmetric logic, the basis of consciousness.

Unconscious logic rises from two principles: the principle of generalization and the principle of symmetry. The principle of generalization, also present in classical logic, postulates that in the unconscious each

entity is treated as part of a set with other elements, this set being treated in turn as a subset of a greater set, and so forth. Entities are distinguished one from the other and grouped together again through abstraction of their similarities. The second principle is that in the unconscious, asymmetrical relations are selectively treated as if they were symmetrical (Rayner, 1995), with the result that relations of succession and contiguity, like time and three-dimensional space, disappear. A part can equal the whole, and similarities can be transformed into identities.

The unconscious is conceptualized as an aggregate of infinite sets. According to the definition of the mathematician Richard Dedekind (1831–1916), infinite sets are those in which a specific subset, for example, the even numbers, can be placed in a one-to-one correspondence with the whole set—for example, the set of natural numbers. The part is equal to the whole.

Symmetrical logic is the expression of a symmetrical system, according to which reality is a homogenous and indivisible whole. Asymmetrical logic is the manifestation of an asymmetrical system, where reality divides into parts. In states of intense emotion, the experience and logic of the symmetrical system are dominant, so for the mind, the emotional object is infinite and is also part of an infinite set.

Matte-Blanco succeeded in formalizing (or mathematizing) the study of the unconscious. He discovered a startling isomorphism among the emotional, the unconscious, and infinite logic (Bria and Durst, 1992).

## UNCONSCIOUS CONCEPT

Freud defined the term *unconscious concept* in “From the History of an Infantile Neurosis”: “Feces, ‘baby’ and ‘penis’ thus form a unity, an unconscious concept (*sit venia verbo*)—the concept, namely, of ‘a little one’ [*une petite choses*] that can be separated from one’s body” (1918b [1914], p. 84).

In philosophy, a concept is an idea that is abstract and susceptible to generalization and that allows for the apprehension of content *a priori* (Kant). It also refers to the grouping of objects of experience into classes. It is this latter, empirical aspect that Freud retains, since it is the equivalence of objects within a certain relationship that allows him to speak of a concept. The notion presented by Freud is complicated by the fact that the concepts under discussion are “unconscious.” In other words, they are not the result of a process of judgment.

Unconscious concepts as defined by Freud come very close to the notion of symbolic equivalence, which is fundamental to the symptom. They also illustrate the unconscious origin of thought in its connections with (anal) sensation and the related fantasy elaboration that arises from it.

## UNCONSCIOUS FANTASY

Kleinian psychoanalysts regard the unconscious as made up of fantasies of relations with objects. These fantasies are the mental representation of instincts, and hence are thought of as primary (Isaacs, 1948).

When Freud (1900a) stressed the psychological meaning of childhood trauma, rather than its reality, he moved from a physiological way of thinking to a psychological one, thereby giving priority to the internal world. His paradigm of the psychological world was the unconscious fantasy of the three-person constellation that he named the *Oedipus complex*. Freud contrasted such internal libidinal fantasizing (the Oedipus complex) with the desexualized fantasy that serves as the basis for launching new sorts of sublimated activity in a wide domain. The role of fantasy in sublimating libido in such activities as daydreaming and aesthetic creation is quite different from the primary unconscious fantasies that provoke the conflicts of the early Oedipus complex.

Suzan Isaacs (1948) defined unconscious fantasy as the mental representation of instinct. In other words, the libido, from the outset, is an activity of mind, despite its physiological origins and functions. It takes the form of a fantasy of performing an (oral, anal, or genital) activity with an object. On the basis of such fantasies as the raw expression of instinct, the primitive mind of the infant can start to reorder itself through further primitive fantasies of projection, introjection, splitting, and denial, and in this way it may relieve itself of the experiences and terrors of primitive conflicts.

One developmental sequence starts with the unconscious fantasies of the Oedipus complex in its early stages and evolves, through fear (for example, castration anxiety), into a desexualized form: daydreaming (Freud, 1919e). Daydreaming, expressed by children in their relentless playing (Freud, 1908c), is an important activity. Classical psychoanalysis emphasizes daydreaming and its sublimatory opportunities, while Kleinian psychoanalysis emphasizes the roots of fantasy life in the unconscious.

Child analysis as developed by Melanie Klein (1955) demonstrated the workings of the unconscious in the fantasies of play. Klein developed her technique on the basis of how figures are repositioned in play. This led to a theory of how objects are positioned in relation to each other and to the child’s self. Klein recognized in the details of play the child’s defensiveness as well as the child’s primary and conflicting impulses. The unconscious roots of impulses and defenses are expressed in relations with objects.

The nature of the very early primary fantasies was hotly debated. Anna Freud disputed Melanie Klein’s claim that the infant has coherent fantasies from such an early age. She regarded the unconscious fantasies

that Klein and her colleagues reported as secondary elaboration at later stages of development. For Anna Freud, the infant develops cognitively by establishing representations of reality and the objects in it, but these representations do not cohere into meaningful, motivating fantasies until after phases of autoeroticism and primary narcissism. Jean Piaget (1954) and Margaret Mahler et al. (1975) have plotted the emergence of representations of reality from these early objectless phases. Other infant psychologists, such as Daniel Stern (1985), tend to see the infant as possessing a sophisticated mind early on, as Klein described.

## **UNCONSCIOUS, THE**

“The division of the psychical into what is conscious and what is unconscious is the fundamental premise of

psychoanalysis” (1923b, p. 19). The unconscious emerged from practical treatments, from the theory of repression, and from the theory of sexuality. The adjective qualifies localized formations in a state of repression, various processes, and later on, agencies as well. The noun describes the “locality” that, according to the first topography, is set against the preconscious-conscious system. Both the adjective and the noun imply that psychical life is in conflict (the dynamic point of view); that memory exists without interest, that the energetics, indeed, the structure of psychic processes is determined, on the whole, beyond consciousness (the economic point of view); and that finally inaccessibility to consciousness is undeniable (the descriptive point of view). Freud transformed philosophical and psychiatric tradition with these ideas and his refinement of the terms (Hartmann, 1931; Whithe, 1961).

When he advanced the theory of repression and the psychoneurosis of defense in 1894, Freud managed without the word *unconscious*. Thus ideas (or representations) that were intolerable, irreconcilable, repressed, durable, and pathogenic were beyond association, forgotten, outside of consciousness. Freud then made use of the term *unconscious* three times in *Studies on Hysteria* and called for research: “The ideas which are derived from the greatest depth and which form the nucleus of the pathogenic organization are also those which are acknowledged as memories by the patient with greatest difficulty. Even when [...] the patients themselves accept the fact that they thought this or that, they often add: ‘But I can’t remember having thought it.’ It is easy to come to terms with them by telling them that the thoughts were *unconscious*. But how is this state of affairs to be fitted into our own psychological views? [...] It is clearly impossible to say anything about this [...] until we have arrived at a thorough clarification of our basic psychological views” (1895d, p. 300). The advances made during 1895—childhood trauma, afterwardsness (deferred action), the dream as wish-fulfilment, and finally the “Project for a Scientific Psychology” (1950c [1895]), where the “system of impermeable neurones [w]” figures as a precursor to the unconscious—allow Freud to describe as unconscious pre-sexual sexual childhood traumas and the psychical work that they lead to, which he further constructed through practice and via theory from 1896 onwards (1896b). The discovery of unconscious fantasies and their efficacy (letters to Wilhelm Fleiss from September 21 and October 3

and 15, 1897) contributed to the creation of the unconscious in 1899 in *The Interpretation of Dreams* (1900a). The close and fundamental correlation between the unconscious, the infantile, and the sexual was affirmed.

Freud defined psychoanalysis as the science of the unconscious-soul (*unbewusst-seelisch*) and the psychology of the unconscious (*Ucs.*), which evolved according to the advances of psychoanalysis. Via the local aetiology of neurotic symptoms, he discovered that the dream was similarly constructed and that the *Ucs.* becomes the generic psychic system. It contains wishes—unconscious and indestructible—and the repressed, cathected by the libido through free energy and regulated by the pleasure principle. The primary processes (displacement, condensation) preside over the *Ucs.* The conflict between repressed instinctual motion and censoring force creates the dream, the paradigmatic compromise-formation. “If we look at unconscious wishes reduced to their most fundamental and truest shape, we shall have to conclude, no doubt, that *psychical* reality is a particular form of existence not to be confused with *material* reality” (1900a, p. 620). The reality of the *Ucs.* reveals itself in other localized processes such as joking, in the forgetting of words, and other symptomatic activities.

Freud’s investigations into the “second step in the theory of the instincts” are continued in “The Unconscious” (1915e). The dependence of the *Ucs.* on the instincts and repression is stressed. It is primal repression that creates the *Ucs.* that above all “contains the thing-cathexes of the objects, the first and true object-cathexes” (p. 201) while “the nucleus of the *Ucs.* consists of instinctual representatives which seek to discharge their cathexis; that is to say, it consists of wishful impulses” (1915e, p. 186). Freud notes, in 1917, that the *Ucs.* is the *missing link* (“*chaînon manquant*”) between soma and psyche (in 1960a).

The life and death instincts, as well as the agencies id, ego, and superego, the “third step in the theory of the instincts” (1920g), do not destroy a single previous experience. The id incorporates the *Ucs.* and inherits its characteristics, while the assets of the adjective “unconscious” accrue from the id and to a large extent from the ego, hence its resistance to the sense of guilt, to most of the processes of the superego, and to the conflicts between agencies.

There is no psychoanalytic notion that does not have some connection to the unconsciousness that the

dynamic point of view imposes universally. The more or less localized ideas moving beyond the first topography exist in relation to the *Ucs.* and are included in the id. The “Mystic Writing Pad” delighted Freud (1925a) because it represented the system *Ucs./Pcs.-Cs.* The repository for memory traces, as well as a place of fixation, the *Ucs.* is even assumed to retain an instinctual foundation analogous to animal knowledge, as in inherited psychic formations and the traces of human history.

Having often clarified his views, Freud was always careful to separate the essentially dynamic unconscious from the latent, which was susceptible to becoming conscious. By arguing for posthypnotic suggestion, the dream, and other experiences associated with the first topography, he refuted the philosophers’ view of the unconscious as paradoxical, and taking up this question of the ambiguity of the “Unconscious,” he noted: “no one has a right to complain because the actual phenomenon expresses the dynamic factor ambiguously” (1923b, p. 16) (an intuition verified through the qualitative dynamic). In 1938 he criticized a presentation of the ego and the id as follows: “What is unsatisfactory in this picture—and I am aware of it as clearly as anyone—is due to our complete ignorance of the *dynamic* nature of the mental processes. We tell ourselves that what distinguishes a conscious idea from a preconscious one, and the latter from an unconscious one, can only be a modification, or perhaps a different distribution, of psychical energy. We talk of cathexes and hypercathexes, but beyond this we are without any knowledge on the subject or even any starting-point for a serviceable working hypothesis” (1939a). The qualitative dynamic, which endorses Freudian stylization, permits some working hypotheses.

## **“UNCONSCIOUS, THE”**

“The Unconscious,” a highly structured essay of 1915, is the most important of Freud’s papers of that period on metapsychology. Freud made the unconscious the keystone of psychoanalysis. Written over a period of three weeks in 1915, “The Unconscious” is the culmination of his topographical theory (or “first topogra-

phy”). Freud musters several arguments and points discussed or established earlier, especially in *The Interpretation of Dreams* (1900a).

The work is divided into seven parts, the last being the most original. After reminding the reader that the unconscious encompasses more than just repressed material, which is only one element of it, Freud goes on to justify the hypothesis of the unconscious—that is, to show that it is necessary and legitimate since there are multiple proofs of its existence. To do this he attempts to show that the assimilation of psychic and conscious is unacceptable: “It disrupts psychical continuities, plunges us into the insoluble difficulties of psycho-physical parallelism” (1915e, p. 168); most importantly, it closes off any possibility of effective psychological research. Freud then indicates that the unconscious is not a second, foreign consciousness within us, but that there are “mental processes [that] are in themselves unconscious” (p. 171), an important distinction that emphasized acts rather than reflexes. In this connection Freud did not hesitate to invoke the Kantian view that perceptions are “identical with what is perceived though unknowable” (p. 171).

In part 2, taking it that the hypothesis of the unconscious has been accepted, Freud discusses different meanings of the term *unconscious*, reprising previously discussed material concerning the distinction between the unconscious and the preconscious. He notes in passing that these distinctions do not, “for the present,” imply any claims concerning anatomical areas of the brain; they refer only to “regions in the mental apparatus, wherever they may be situated in the body” (p. 175); the term *regions* should thus be taken in the sense of a fiction (p. 175).

Part 3 refers in part to the second of Freud’s metapsychological papers, “Repression” (1915d), which discusses the instincts. Freud draws an important distinction here: “ideas are cathexes—basically of memory-traces—while affects and emotions correspond to processes of discharge, the final manifestations of which are perceived as feelings” (p. 178). “Affectivity,” he adds in a note, “manifests itself essentially in motor (secretory and vasomotor) discharge resulting in an (internal) alteration of the subject’s own body without reference to the external world” (p. 179n). This clearly raises the issue of the actual neuroses, though Freud does not address it here.

Part 4 deals with the topography and dynamics of repression, and it is here that Freud provides his well-known definition of metapsychology: “It will not be

unreasonable to give a special name to this whole way of regarding our subject-matter, for it is the consummation of psycho-analytic research. I propose that when we have succeeded in describing a psychical process in its dynamic, topographical and economic aspects, we should speak of it as a metapsychological presentation” (p. 181). As in “Repression” (1915d), Freud specifies repression relative to anxiety hysteria, to phobia in conversion hysteria, and to obsessional neurosis.

Part 5, which covers the specific properties of the unconscious system, includes some very important thoughts on time: “The processes of the system *Ucs* are *timeless*—i.e., they are not ordered temporally, are not altered by the passage of time; they have no reference to time at all. Reference to time is bound up, once again, with the work of the system *Cs*” (p. 187). But this is only one aspect of the characteristics of the unconscious system, which Freud lists as follows: “*exemption from mutual contradiction, primary process (mobility of cathexes), timelessness, and replacement of external by psychical reality*” (p. 187).

After discussing the preconscious, Freud goes on in part 6 to examine the relations between the two systems, which are distinct but whose respective impulses may cooperate if they happen to be tending in the same direction. “The content of the *Ucs*,” Freud concludes, “may be compared with an aboriginal population in the mind. If inherited mental formations exist in the human being—something analogous to instinct in animals—these constitute the nucleus of the *Ucs*. Later there is added to them what is discarded during childhood development as unserviceable; and this need not differ in its nature from what is inherited. A sharp and final division between the content of the two systems does not, as a rule, take place till puberty” (p. 195).

The seventh and last part of Freud’s paper is the most audacious; Freud asserts that only the analysis of narcissistic psychoneuroses (what we would now call psychoses), can “furnish us with conceptions through which the enigmatic *Ucs* will be brought more within our reach and, as it were, made tangible” (p. 196). He cites Karl Abraham on dementia praecox and Victor Tausk on schizophrenia, and he develops a number of important themes about the speech of schizophrenics. Using Tausk’s clinical observations, Freud notes that “the schizophrenic utterance exhibits a hypochondriac trait: it has become ‘*organ-speech*’” (p. 198). Discussing Eugen Bleuler and Carl Jung, he writes that “in schizophrenia words are subjected to the same process as

that which makes the dream-images out of latent dream-thoughts—to what we have called the primary psychical process” (p. 199). The relationship to words thus takes precedence over thing-presentations, and substitutions are made based on verbal identity rather than on similarity between the things designated, which is what makes schizophrenic speech so disconcerting. In this way Freud introduces a more general analysis of the thought process, evoking cathexes far removed from perception which “attain their capacity to become conscious only through being linked with the residues of perceptions of *words*” (p. 202).

Freud concludes this most brilliant and profound of his papers on metapsychology as follows: “When we think in abstractions there is a danger that we may neglect the relations of words to unconscious thing-presentations” (p. 204).

## UNDOING

The mechanism of undoing is characteristic of obsessional neurosis, along with isolation. It involves a process of “negative magic” that, according to Freud, tends to undo what has been done. When an action is undone by a second action, it is as if neither had occurred, whereas in reality both have taken place.

In a letter to Fliess written on December 22, 1897, Freud already foresees what he defines at that time as the ambiguity or imprecise meaning characteristic of obsessional neurosis. He would later describe this as an action that occurs in a second moment, and which seeks to

undo an action that precedes it. “Obsessional ideas are often clothed in a remarkable *verbal vagueness* in order to permit of this multiple employment” (1950a, p. 273).

In the “Rat Man” (1909d), Freud describes compulsive acts as unfolding in two moments, during which the first is undone by the second. According to him in obsessional thought “the patient’s consciousness naturally misunderstands them [the compulsive acts] and puts forward a set of secondary motives to account for them—*rationalizes them*, in short” (p. 192). In reality there is an opposition between love and hate. In *Inhibitions, Symptoms and Anxiety* (1926d), he defines more specifically the “magical” nature of this defense that “no longer [has] any resemblance to the process of ‘repression’” (p. 164). Thus the obsessive ceremony strives not only to prevent the appearance of an event but to undo it, which is irrational and magical and most likely arises from an animist attitude toward the environment. Anna Freud (1936) included undoing in her repertory of ego defenses.

The concept of undoing has today acquired a certain psychological connotation. It is often confused with the concept of ambivalent behavior or attitude. It is probably also necessary to distinguish it, because of the “magical” character of the defense, from the series of mechanisms discovered by Freud—repression, foreclosure, negation (or denegation), disavowal (or denial)—a series that is commonly referred to today as the work of negativization.

## **UNITED STATES**

Psychoanalysis came to North America in two major waves, the first one following Freud’s visit in 1909,

and the second one following the Nazi takeover in Germany and Austria. Each wave stimulated the exploration of psychoanalysis’ scientific and curative potentials while encouraging popularizations by the American public. However, this dual, though separate, reception engendered ambiguities and misunderstandings, and built up unwarranted expectations that led to inevitable disappointments.

American physicians had been seeking to cure neurasthenia, which, already in 1869, George M. Beard (1840–1883) had called “the American disease” arising from so-called “civilized morality”—hidden conflicts due to hypocrisy. According to Beard, upwardly mobile citizens professing continence, religious purity, and even married celibacy, were having illicit affairs with “loose” women, which often created “mental problems.”

Around the turn of the century, American neurologists such as Morton Prince (1854–1929), James Jackson Putnam (1842–1918) and S. E. Jelliffe (1866–1945) had been investigating the “French school” of Charcot, Bernheim, and Janet, and were practicing suggestion and (occasionally) hypnosis in order to cure these neuroses. So were psychologists, among them Stanley Hall (1844–1924), William James (1842–1910), and Boris Sidis (1867–1933). When they read that Freud’s patients by talking about previously repressed fantasies had lost their hysterical symptoms, and that this had happened by bringing forth unconscious memories, they wanted to learn about his method, and about the relation between his patients’ symptoms and sexual repression.

Consequently, philosophers, psychologists, and the educated public were as interested in what Freud had to say as were American psychiatrists—who were caring for psychotic patients in institutions and did not know how to cure neuroses—and clergymen who were no longer able to help people by instilling a fear of God.

For these reasons, Freud’s visit to Clark University attracted diverse listeners: the psychologists William James and Edward Bradford Titchener, the anthropologist Franz Boas, the revolutionary anarchist Emma Goldman, and many Protestant clergymen, psychiatrists, and neurologists—among them Abraham Arden Brill (1874–1948), Adolph Meyer (1866–1950), and James Jackson Putnam. Freud’s lectures, which for the first time synthesized his discoveries, turned out to be tailor-made for this audience. He spoke extemporaneously. He stressed his hopes for the scientific exploration of the laws governing the unconscious; the

liberating benefits psychoanalysis would bring to individuals and humanity; the role of sublimation, of trauma and catharsis; and the efficacy and benefits of psychoanalytic intervention. The American press gave him wide, even sensationalist, coverage, so that he was met with an enthusiasm usually accorded entertainers and charismatic heads of state. Then, general physicians and neurologists wanted to understand more about the influence of the unconscious on illness; feminists and other radicals foresaw the end of sexual and social repression; and mind healers perceived answers to troubling questions. To them all, psychoanalysis promised to resolve theoretical dilemmas, while offering a method to help ailing, malingering patients: it became a pivot for disparate intellectual endeavors and disciplines, aims, and interests.

Since the analysis of dreams caught the imagination of the larger American public, psychoanalysis started being cast as the new road to happiness. Broad applications ensued, not only by doctors and clergymen but by social workers, experts in child rearing, and in criminology. And zealous charlatans called themselves psychoanalysts.

Freud was dismayed by these facile applications that bypassed the laborious efforts required to reach the deepest unconscious of patients. As he stated in “On the Question of Lay Analysis” (1926a), “Americans came too easily by truths others had struggled to discover . . . and were too easily satisfied with superficial appearances.”

However, Freud kept in touch with a number of Americans. On November 9, 1909, for instance, Putnam wrote: “Your visit to America was of deep significance to me, and I now work and read with constantly growing interest on your lines.” Less than a month later, he informed Freud that “the real psychoanalysis begins where the primary ‘confessional’ ends.” Freud urged his American correspondents to organize and to affiliate with the International Psychoanalytical Association (IPA)—which had been launched to facilitate communication among followers wanting to exchange scientific information.

By 1911, twelve persons, mostly physicians, set up the American Psychoanalytic Association (APA). In the same year, fifteen physicians, under the leadership of A. A. Brill, established the New York Psychoanalytic Society (NYPS). By 1914, they founded the Boston Psychoanalytic Society, appointing Putnam as president, and soon formed groups in the Washington-Baltimore area and

in Chicago. But despite these organizational setups, the first wave of American Freudians was too geographically and/or intellectually dispersed to make many scientific contributions, and thus crested after a few years.

By then, psychoanalysis was expected to explain nearly every individual and social phenomenon in the culture at large: the American propensity to overgeneralize was casting psychoanalysis as a cure-all. As Nathan Hale summarized, “between 1915 and 1918 psychoanalysis received three-fifths as much attention as birth control, more attention than divorce, and nearly four times more than mental hygiene. . . . The unconscious had become a Darwinian Titan and dream analysis the road to its taming” (Hale, 1971, p. 397). Proselytizing practitioners bragged to journalists of miracle cures, and reporters wedded clichés to exaggerations and heightened enthusiasm.

During these years, Freud wrote to Putnam about the impending splits with Alfred Adler and Carl Jung. But he did not yet realize that the American ambiance would engender other sorts of splits. Since the American groups, mostly, were started by self-selected and self-trained doctors, they differentiated themselves—professionally—from the growing numbers of social workers, clergymen and charlatans who were also doing “psychoanalysis.” This disjuncture between psychoanalysis’ public acclaim and its (flagging) clinical success was unique to North America and, ultimately, created a storm within the movement. By 1924, due to a mixture of professional responsibility and self-interest, and to desperation, the APA voted to keep out *all* lay analysts. At the IPA meetings in Innsbruck, in 1927, twenty-eight papers were presented on the question of lay analysis. Wanting to distance themselves from “impostors,” American Freudians remained adamant and insisted on breaking IPA rules against lay analysts by restricting access to physicians alone. They even referred to Freud as the “Pope in Vienna.” Freud expressed his disagreement with the Americans in “On the Question on Lay Analysis” (1926a).

Nevertheless, American psychoanalysts realized that they were not keeping up with scientific advances and that they needed more training. Therefore they invited a number of Europeans as training analysts (including Freud, who refused for reasons of health). By 1930, they formed the Chicago Institute under the aegis of Franz Alexander (1891–1964), and in 1931, the New York Psychoanalytic Institute under the aegis of Sándor Radó (1890–1972). But the rift between European

and American Freudians continued to widen over training lay analysts. In 1936, the APA declared that it would veto any resolution by the IPA addressing American issues, and by 1938 had set up its own criteria for “minimal training of physicians” at its affiliated institutes, spelled out proper conduct of members, and reaffirmed the ban against laymen. They also put the IPA on notice not to train Americans who had not already been “approved” by the APA.

In a way, Freud had described some of these dilemmas as arising from the fact that psychoanalysis was a social and intellectual movement, a clinical therapy, and a theory of mind. He maintained that these major thrusts were bound to come into conflict from time to time. But he could not foresee that the Nazis would come to power, that most of his disciples would move to America, and that World War II would nearly abolish psychoanalysis on the European continent.

America’s second major wave of psychoanalysis arrived with the émigrés. From the start, Freud had referred to his disciples as pioneers into the workings of the unconscious. After the majority of these disciples arrived in the country of pioneers they, literally, were cast as pioneers for their cause.

At first, their reception was mixed. American psychoanalysts had sent affidavits, and Lawrence Kubie (1896–1973) had organized an extremely efficient Emergency Committee to help them get into the country. But members of the American Medical Association were afraid that the Europeans would compete for their jobs and patients. Legally, immigrants had to become American citizens before practicing medicine in all but five states; and they had to pass medical boards before becoming psychoanalysts. They also had to prove that they would be self-supporting within a year before they entered the country, and they were branded as Jews. They already had to adapt to their delegitimation as psychoanalysts and human beings, to overcome the shock of brutal ostracism. Now, they had to learn English in order to establish themselves in their (still) struggling profession. Many émigré Freudians worked in hospitals. There, they could demonstrate the efficacy of the “talking cure” to colleagues. By 1942, every medical student learned about the unconscious factors that might influence their patients’ behavior. Many of these students later became psychoanalysts.

Under the circumstances, the organizational feuds receded. The émigrés became a resource for American

colleagues. They offered training analyses and held the most prestigious positions in the new institutes that, mostly under their leadership, were springing up around the country. The former disagreements were not settled, but Freud’s death in September 1939 and the war overshadowed IPA concerns. What would have happened to psychoanalysis had most of its proponents not come to America after the Nazis took power (a much smaller contingent went to South America and England) is a moot question.

In North America, the organizational repercussions of the split between medical and lay analysts at first determined who among the émigrés would be allowed into the APA and its affiliates, but later on this differentiation led to the formation of “deviant” associations. Still, some prominent psychologists who had been close to Freud, such as Ernst Kris (1906–1957), Siegfried Bernfeld (1892–1953), Erik Erikson (1902–1994), Otto Fenichel (1897–1946), and Theodore Reik (1888–1970), were accepted as “honorary members.” But Reik, for instance, did not appreciate this distinction and, by 1948, started his own society—to train psychologists in psychoanalysis. His graduates, in turn, taught others. Similar situations arose in cities throughout the country, especially on the two coasts. Already in 1941, Karen Horney (1895–1952) had left the New York Psychoanalytic Institute (NYPI) after a heated controversy over theoretical priorities which would determine, also, what type of psychoanalysis candidates were going to learn and then to practice. Basically, she argued that her colleagues’ ego-oriented psychoanalysis was culture-bound rather than universal, and that they ought to address a patient’s present circumstances in order to understand his or her past rather than to begin by eliciting insights into this past.

By then, Karen Horney’s books, (1937, 1939), as well as Erich Fromm’s (1942) were introducing psychoanalytic concepts to a broad public—which was not all that interested in the theoretical disputes among psychoanalysts, but found their writings more accessible than the works of the “classical Freudians.” In fact, Horney and Fromm were addressing social issues, and, though far from simplistic, were appealing to the American habit of believing in quick fixes, and to the native optimism about the malleability of human nature. But they were only the forerunners of what would become some of the “cultural” or “applied” psychoanalyses and psychotherapies which subsequently flooded the country. In other words,

Freud's influence on the culture—whether appreciated or rejected—from then on became ubiquitous.

Still, the theories based on Freud's postulates in *The Ego and the Id* (1923b) would dominate the profession for a long time. The division into id, ego, and superego as structural components of psychic life converged with the American scientific bent, and with the language of medicine.

But other proliferations of psychoanalysis occurred via the social sciences. For instance, anthropologists such as Margaret Mead, Gregory Bateson, and Ruth Benedict, and psychoanalysts such as Sándor Radó and Abram Kardiner, in the Columbia University Institute for Psychoanalytic Training, were doing research on tribal societies; the Harvard sociologist Talcott Parsons postulated psychoanalysis as a mainstay of his social system, to incorporate the unconscious elements of human motivation into social institutions; and the political scientist Harold Laswell explored the behavior and ambitions of political figures in terms of their psychic make-up.

Like Freud, the émigrés were steeped in the classics. They were products of the Enlightenment, and they foresaw that the future of civilization would be dominated by discoveries science alone could further. But they also kept reading classical and contemporary literature in order to enrich their theories. And they explained human psychology—the typical patterns of mind being formed in response to early experiences that later guide behavior—via literature. They continued to attempt analyzing literary works in relation to the personalities of their authors, and to be particularly interested in having creative individuals on their couches. Therefore, they cooperated with literary scholars such as Lionel Trilling, and art critics such as Ernst Hans Gombrich and Clement Greenberg who, themselves, enriched the studies of literature, art, and criticism by responding to the challenges posed by psychoanalysis. They warmly welcomed psychoanalysts, and arranged meetings and symposia with them, thereby furthering the acceptance of psychoanalytic insights by the intelligentsia.

Because Freud's European disciples had come to psychoanalysis not only from medicine but from art (Erik Erikson and Ernst Kris), education (Anna Freud [1895–1982]), philosophy (Robert Waelder [1900–1967]), and literature (Henry Lowenfeld [1900–1985]), they were attuned to the preoccupations of

American intellectuals. And the self-assurance they had gained from their work with Freud, as well as their range, helped propel them into the maelstrom of American intellectual life.

Heinz Hartmann, for instance, a central figure among the so-called “scientific ego psychologists,” already in Vienna, had addressed questions of adaptation. Now, he investigated individuals' relations with and adaptation to reality as indicators of mental health which, he held, was emotional *and* biological. He maintained that “instinct” has a double meaning: the genetic relations between animal instinct and human drive, and between animal instinct and human ego-function. This brought him back to addressing cultural issues. Together with Ernst Kris and Rudolph Loewenstein (1946), he wrote the definitive paper summarizing the clinical theories Freudians had derived from their (recent) America-based research. These findings were syntheses on a highly abstract, theoretical plane. The general and cultural questions they were addressing, along with the clinical ones, would set the Freudians' extensive research agendas for the coming years. This acceptance in America, at least in part, is what made their work so appealing after the war, when they reconvened on the European continent, and why their theories were referred to as “American” psychoanalysis.

In 1947, David M. Levy, in *New Fields of Psychoanalysis*, delineated the astounding influence psychoanalysis had gained in every sphere. He noted that psychoanalytic terminology in child guidance, such as maternal overprotection, maternal rejection, etc., had become ubiquitous; that psychoanalysis could predict criminals' recidivism; and he outlined collaborations among psychoanalysts, social workers, educators, industrial and military psychiatrists. Clearly, Freud's disciples had become pillars of the American establishment. Inevitably, prestige and research moneys accrued to the profession.

Ego-psychology remained the leading theory well into the 1970s. By then, however, the members of groups outside the APA were increasingly discontent: they resented being peripheral. Their own successes with patients, and their work in hospitals, went nearly unrecognized outside the country. At home, they were analyzing psychologists and social workers who, sooner or later, formed associations and networks—which gave them a certain amount of clout. Belonging to the IPA would allow them, too, to mix and exchange information with European and Latin American colleagues, and to set up collaborative research projects. In 1985, this situation came to a head in a lawsuit by non-medical

American Freudians—some of whose institutes have since then been accepted by the IPA and the APA.

Altogether, by the time Philip Reiff published *The Triumph of the Therapeutic* (1966), America had become the therapeutic society par excellence. But the patients who expected psychoanalysts to cure their neurotic symptoms, or their general malaise, were very different from Freud's repressed, hysterical ones. And the analyses by his many descendants were initiating more and more discussions about changing clinical pictures and problems, and possible solutions to them. Gradually, the clinical techniques based on the "structural theory" (the division of the personality into id, ego, and superego) were being questioned, and no longer seemed to be as efficacious as they had been before. And many people argued that psychoanalysis took too long and was too expensive.

By 1971, Heinz Kohut (1913–1981), a member of both the APA and the IPA, had been dissatisfied enough to have explored, and then moved, Freud's theories of narcissism to the center. He had noted that children tend to make up for the "unavoidable shortcomings" of maternal care, and the concomitant primary narcissism, either by evolving a *grandiose* and exhibitionist *self-image*, or by creating an *idealized parental image*. As the gleam in the mother's eye mirrors the child's exhibitionist display, he found, the child's self-esteem and grandiosity became inflated. This necessitated, he said, more empathic and demanding interactions with patients, rather than the classical analyst's technique of abstinence. His so-called self-psychology, which focuses on the interactions between mother and child, became more integrated into the classical Freudians' practices. Soon thereafter object-relations theory (based primarily on the relationship between mother and infant), which originally had been advanced by Melanie Klein (1882–1960), in London, was being furthered by Otto Kernberg.

Whether or not these approaches were due to changing symptomatology alone, or to the fact that the acceptance of psychoanalysis itself had made promises for cures it could not achieve, is a debatable issue. Certainly, contact with psychoanalysts from Europe and South America, and changing cultural trends, were playing their part as well. (In academic circles, beginning in departments of English and French, Lacanian psychoanalysis made large inroads.) But psychoanalysts, themselves (Kurzweil, 1989, 1995) were both products and shapers of their culture. In sum, in the

United States psychoanalysis has evolved in line with cultural prerogatives and advances in psychoanalytic knowledge. What aspects of psychoanalysis are being stressed or denied keeps changing, and its first and second major waves undoubtedly will be followed by others. On the one hand, Freudian ideas are permeating American society, which, in turn, influences the practice of psychoanalysis itself. On the other hand, there has been a proliferation of therapies. But the popularization has encouraged simplifications and quick modes of treatment at the expense of analyzing the unconscious. Thereby, what Freud called the "gold of psychoanalysis," that is, the mining of the unconscious, has been lost. However, many of his contributions live on in the culture at large, and are applied by many social scientists, especially psychologists.

## UNPLEASURE

From the beginning of psychoanalysis, the term *unpleasure*, in the ordinary sense of a disagreeable impression, was chosen by Sigmund Freud for its dynamic dimension in psychic functioning. He noted the role of "feelings of unpleasure" in the speech of his patients and their defenses against the painful contents of their thoughts. In "On the Psychological Mechanism of Hysterical Phenomena: Preliminary Communication" (1893a) by Freud and Josef Breuer, these painful affects—fear, anxiety, shame, physical pain—are enumerated and their contribution to the formation of hysterical symptoms is explained: The unpleasure they elicit triggers forgetting, repression.

In Freud's position of the primitive psychic apparatus in *The Interpretation of Dreams* (1900a), an economic

perspective predominates: Unpleasure, engendered by the increase in tensions due to excitation, sets in motion the functioning of the psychic apparatus. “The psychical apparatus is intolerant of unpleasure; it has to fend it off at all costs, and if the perception of reality entails unpleasure, that perception—that is, the truth—must be sacrificed” (p. 237), he writes in “Analysis Terminable and Interminable” (1937c). Unpleasure is a broader category than anxiety, although anxiety is certainly unpleasurable. Other affective states such as tension, pain, or grief are also unpleasurable; so, too, is inhibition. Unpleasure is thus not only an affective state, it is set up as a principle that regulates psychic functioning.

from caregivers. The idea was introduced by Robert Stolorow and George E. Atwood in 1989. In their theory of intersubjectivity, the child’s conscious experience is pictured as becoming progressively articulated through the validating attunement of caregivers. Features of the child’s experience may remain unconscious, not because they have been repressed, but because, in the absence of a validating intersubjective context, they were never articulated in the first place.

The concept of the unvalidated unconscious sheds light on certain psychosomatic conditions in which affects fail to evolve from bodily states to symbolically integrated feelings because, without validating symbolic (verbal) responses from caregivers, they were never symbolically articulated. These conditions can be distinguished from other conditions that develop when symbolic articulation of affect is defensively aborted. The concept of the unvalidated unconscious has features in common with Freud’s notion of a primal unconscious and Bion’s discussion of undigested experience.

Analytic attention to the unvalidated unconscious is especially important in the treatment of patients for whom broad areas of early experience failed to evoke validating attunement in caregivers and, consequently, whose perceptions remain ill defined and precariously held and whose affects tend to be felt as diffuse bodily states. In such cases, analytic investigation serves to articulate and crystallize the patient’s subjective reality.

## **UNVALIDATED UNCONSCIOUS**

The term *unvalidated unconscious* refers to childhood experiences that could not be consciously articulated because they never evoked sufficient validating responses

## **URBANTSCHITSCH (URBAN), RUDOLF VON (1879–1964)**

Rudolf von Urbantschitsch, an Austrian physician, was born in Vienna on April 28, 1879, and died on December 18, 1964, in Carmel, California.

He was born into a Catholic and aristocratic family that enjoyed a good reputation in the days of the Hapsburg monarchy. His father, Victor Urbantschitsch, was one of the founders of modern ENT medicine. Rudolf was a student at the Vienna Theresianum, from which he graduated in 1898. In 1914, having finished his medical studies, he became the assistant of Karl von Noordens and directed his clinic.

With the support of Noordens, of influential circles in Vienna, and protected by Archduke Franz Ferdinand, heir to the throne, he was able to realize his project of creating a clinic for the Viennese aristocracy. The Wiener Cottage Sanatorium was opened under his directorship in 1908 and became one of the most prestigious institutions in Europe. The Viennese medical profession cared for its most well-to-do patients there.

At the end of 1907, Fritz Wittels, who practiced as a physician in the Cottage Sanatorium, introduced Urbantschitsch to the group of Viennese psychoanalysts. In January 1908 he presented a paper, "Meine Entwicklungsjahre bis zur Ehe" (From my puberty to my marriage), and went on to become a member of the Wednesday psychology society. He remained a member until 1914. Sigmund Freud hospitalized some of his patients in the Cottage Sanatorium, Sergei Pankejeff (the "Wolf Man") for one.

In 1920, Urbantschitsch lost his position as sole director of the Cottage Sanatorium and the institution was sold in 1922. Following this loss and on Freud's recommendation he began to train as an analyst, first with Paul Federn and then with Sándor Ferenczi in Budapest. As a Catholic, an aristocrat, and a monarchist, Urbantschitsch was an exception in the social makeup of the Vienna Psychoanalytic Society. Through his intense lecturing activity both in Austria and abroad he contributed to vulgarizing the discoveries of psychoanalysis but ran up against the criticism of his Viennese colleagues, particularly the younger ones, for presenting psychoanalysis in a simplistic fashion and according pride of place to his personal publicity. This criticism, and also his love affairs, two of which resulted in suicide, contributed to the Vienna Psychoanalytic Society's rejecting his request to renew his membership and in 1924 he was even refused the status of a guest.

At the end of 1936 Urbantschitsch left for the United States and first settled in Los Angeles as a psy-

chotherapist. He moved to San Francisco during the summer of 1937 and to Carmel in 1941. These peregrinations were not unconnected to the fact that he had fallen foul of Ernst Simmel and the Los Angeles group of psychoanalysts, who considered his therapeutic work and his theoretical conceptions to be non-psychoanalytical in the Freudian sense of the term. In 1944 Urbantschitsch, who still insisted on considering himself as a psychoanalyst and a disciple of Freud, was accused of practicing medicine illegally.

Apart from his many vulgarizing publications, Urbantschitsch also published plays and novels under the pseudonym Georg Gorgone. His autobiography appeared in 1958 entitled *Myself Not Least: A Confessional Autobiography of a Psychoanalyst and Some Explanatory History Cases*.

## **URUGUAY**

The early days of psychoanalysis in Uruguay date back to the 1940s when Valentín Pérez Pastorini, a psychiatrist, began traveling to Buenos Aires to be analyzed by Pichon-Rivière. Pérez Pastorini trained with the Argentinean Psychoanalytic Association. Miguel Sesser then followed his example. Pérez Pastorini analyzed Roberto Agorio and Gilberto Koolhaas, and the group grew to include Jean Carlos Rey,

Héctor Garbarino, Juan Pereira Anavitarte and professors Laura Achard, Marta Lacava, and Mercedes Freire de Garbarino. In 1950 it was proposed to form an institute, a project that required the presence of a training analyst.

In 1954 Willy and Madeleine Baranger, French teachers who were members of the Argentinean Psychoanalytic Association, set up in the country and began to work as training analysts. Argentinean analysts traveled each week for supervisions. The group began to take shape, and from 1955 to 1956 it established bylaws and acquired legal status. It was recognized as a study group at the Twentieth Congress of the International Psychoanalytical Association in Paris in 1957 and was admitted as an affiliate association of the International Psychoanalytical Association at the twenty-second congress, held in Edinburgh in 1961.

This expansion of psychoanalysis initially met with opposition from a group of physicians who accused the psychoanalysts of illegally practicing medicine. The Sindicato médico del Uruguay (Medical Association of Uruguay) finally ruled on the question in favor of the group of analysts. Psychoanalysis then experienced a period of rapid growth. It was taught at the graduate level as part of medical and psychiatric studies, as well as in bachelor courses in psychology in the faculty of arts and human sciences. Luis E. Prego Silva introduced psychoanalytic knowledge into pediatric departments in hospitals. In 1965 the Barangers returned to Buenos Aires after a ten-year stay in Montevideo, but by this time the Uruguay Psychoanalytic Association already had three training analysts: Héctor Garbarino, Laura Achard, and Mercedes Freire de Garbarino. In 1966 the Twelfth Congress of Latin American Psychoanalysis was held in Montevideo.

The psychoanalytic movement went into a noticeably slow period during the “de facto government” from 1973 to 1985, the period of military dictatorship that forced eminent analysts to emigrate, imposed rigorous controls on meetings of the Uruguay Psychoanalytic Association, restricted the appointment of its directors, and monitored publications. All the ground that had been gained at the level of universities, hospitals, and public health was lost. In 1985, with the advent of democracy, the Uruguay Psychoanalytic Association nevertheless rapidly made up for lost time.

Among the founding members of psychoanalysis in Uruguay the following stand out for their contributions to the field in terms of theory and practice: Rodolfo Agorio, Gilberto Koolhaas, Héctor Gabarino, Mercedes Freire de Gabarino, Laura Achard, Juan Carlos Rey, and Willy and Madeleine Baranger. Also worthy of note for their contributions are Luis E. Prego Silva, Vida Maberino de Prego, Marta Nieto, Carlos Mendilaharsu, Sélika Acevedo de Mendilaharsu, Gloria Mieres de Pizzolanti, Isabel Plosa, Alberto Pereda, Myrta Casas de Peredo, Ricardo Bernardi, Marcelo Viñar, Maren Ulriksen de Viñar, Fanny Schkolnik, and Marcos Lijtenstein.

The Uruguay Psychoanalytic Association is the only organization in the country that is a member of the International Psychoanalytical Association. It is also affiliated with the Latin American Psychoanalytic Federation. There have been no splits in the organization. The Executive Committee is elected every two years at a general assembly. The Training Commission is in charge of the study program. The Scientific Commission coordinates activities within and outside the association and organizes meetings, roundtables, and domestic and international conferences. The title “training analyst” has been replaced by “analyst in didactic function,” a title that includes training, supervision, and teaching. Admission is by interview, since one of the criteria governing training is that personal analysis cannot be formally associated with the association in any way. To apply, candidates must have completed three and a half years of personal analysis. Supervised practice consists of three analyses of two years each, two of adults and one of a child. Various laboratories operate under the aegis of the Uruguay Psychoanalytic Association: laboratories that study children, adolescents, psychosis, couples and families, as well as laboratories that take research and group psychoanalytic approaches. The Centro de intercambio (Exchange Center) is responsible for spreading psychoanalysis to neighboring domains of knowledge and culture. It also provides psychoanalytic treatment for low-income patients. The Publications Commission, in addition to publishing books, has published the *Revista uruguaya de psicoanálisis* since 1956 and the journal *Temas* since 1983.

In July 2003 the president of the republic and the minister of education and culture approved the reform of the bylaws of the Uruguay Psychoanalytic Association and the foundation of the University Postgraduate

Institute of Psychoanalysis under the auspices of the association. From then on, training by the association led to a university-level master's degree in psychoanalysis. In the same year a commission was set up whose goal it was to have the Uruguay Psychoanalytic Association recognized by the Graduate School of the Faculty of Medicine of the University of the Republic as an institution entitled to organize adult training programs.

## “VAGINA DENTATA,” FANTASY OF

The fantasy of “vagina dentata” (teeth in the vagina) is a horrifying image of the female genitals that derives from the sexual theories of children. It displaces from the oral cavity to the vagina a threat that children believe to come from women. The equation of mouth and vagina was introduced by Freud (1899a, 1905d) and was advanced by Karl Abraham (1916) as central to the oral-sadistic or cannibalistic stage of the infantile libido (devouring versus being devoured).

Fear of women and the great terror that they inspire, which for men is linked to castration anxiety, encompasses several other fears: a fearful representation of the all-powerful mother, in which men project outside of themselves an oral-aggressive component; fear of punishment for a desire for fusion with the archaic mother, for an incestuous bond with the mother, or for a return to the mother’s womb at the moment of coitus (Sándor Ferenczi); fear of a parent’s sadistic redirection of the sexual aim of the primal scene; a fearful infantile fantasy of incorporation in coitus (Melanie Klein); a fear of a woman’s desire for revenge for her own castration (René de Monchy). This dread of a woman’s mysterious cavity transforms it into a persecutory object that no longer inspires envy (Hanna Segal). In its passive form, the fantasy of being bitten or eaten by the genitals of a woman includes an element of bisexual desire. More often implied than stated, this fantasy turns up in various forms in dreams, stories, legends, and films.

The fantasy of teeth in the vagina must be carefully distinguished from a woman’s vaginismus (an involuntary spasm of the muscles surrounding the vagina that closes the vagina), from the fantasy of a penis with

teeth, from fear of incorporation linked to mourning, and from any nonoccidental anthropological data.

## **VALDIZÁN, HERMILIO (1885–1929)**

Hermilio Valdizán, a Peruvian psychiatrist, was born at Huánuco on November 20, 1885, and died in Lima on December 25, 1929.

Valdizán’s childhood was a difficult time: at the age of eight, following the death of his father, he went to Lima where he entered a charitable institution. Having enrolled for medical studies in the University of San Marcos in 1901, he worked as a teacher and journalist

while still a student. He graduated as a surgeon after presenting his thesis on “Delinquency in Peru” (1910). He went to Europe to study psychiatry and presented his doctoral thesis on “Mental alienation in primitives in Peru” (1915). Valdizán was the first Peruvian psychiatrist, strictly speaking.

He began his European studies essentially in Rome, where he encountered Sante De Sanctis, whose ideas were close to psychoanalysis. De Sanctis was particularly interested in the study of childhood and although he taught experimental psychology before obtaining the chair of neuropsychiatry, he integrated psychoanalytic ideas into his vision of clinical psychiatry. Back in Lima, Valdizán began to lecture on nervous and mental illnesses in the University of San Marcos. Javier Mariátegui wrote that in his lectures, “the stamp of psychoanalysis was everywhere manifest.” From 1918 he directed the Asilo-colonia de Magdalena—later renamed the Víctor-Larco-Herrera Hospital—where he organized psychiatric treatment in accordance with modern criteria. This hospital was long a pioneering arena in terms of psychiatric therapeutics and remained receptive to psychoanalytic ideas, particularly under Honorio Delgado.

Although not a psychoanalytic practitioner in the strict sense of the term, Valdizán deserves credit for initially giving great scope to the official teaching of psychiatry and for introducing into his courses on medical psychology the theme of psychotherapy, “as useful to today’s practitioner as any of the classic disciplines in vocational training.”

His most noteworthy contribution to psychoanalysis was the creation in 1918, with Honorio Delgado, of the *Revista de psiquiatría y disciplinas conexas* (Review of psychiatry and associated disciplines), which was the virtual mouthpiece for psychoanalytic thinking in Peru until 1924. Freud mentions it in “A Short Account of Psychoanalysis” (1924f [1923]) and in a 1924 addition to the note on chapter 2 of *The Psychopathology of Everyday Life* (1901b) where he quotes from Paul Wilson’s article “The Imperceptible Obvious” (1922).

Of Valdizán’s publications, those closest to psychoanalysis are “Extrapsychiatric Psychotherapy” (1918) and two articles written with Honorio Delgado: “Psychological Factors in Dementia Praecox” and “The Revolt of the Sexual Libido in Old Age.”

Valdizán’s main contribution to psychoanalysis is that he contributed to spreading the discipline at a

time and in a place where it gave rise to lively controversy. In 1930, after his death at the age of forty-four, the only chair of psychiatry in the country was taken by Honorio Delgado, who had by then become a fierce opponent of psychoanalysis. It is no idle speculation that Valdizán’s open-mindedness and tolerance with regard to psychoanalytic ideas would have favored their greater development.

## **VENEZUELA**

At the end of the 1950s there were two psychoanalysts in Caracas: Hernán Quijada, trained in Paris, and Guillermo Teruel, analyzed in London. The first reactions of associated groups (psychiatrists, psychologists) were varied, ranging from an attitude of refusal for some to curiosity and affiliation for others. Quijada’s important position in the Ministry for Health made it easier to receive state support.

Quijada, Teruel, Manuel Kizer, Antonio García, Fernando Acuña, Cesar Augusto Ottalagano, Julio Aray, Antonio Briceño, Nicolás Cupello, Hugo Domínguez, Juan Antonio Olivares, Hans Voss, and W. Hobaica formed a work group that was officially recognized by the International Psychoanalytical Association (IPA) at the Copenhagen congress in 1965. Between 1966 and 1969 an IPA committee comprising León Grinberg

and Maria Langer from Buenos Aires, Alfredo Nannum from Mexico, Luiz Guimarães Dalheim and Adelheid Lucy Koch from Brazil, worked at improving the group's training by revising theory and conducting group controls.

In 1969 the international committee appointed Teruel as the first training analyst. That same year, at the international Congress in Rome, the work group was transformed into a definitive association (Asociación Venezolana de Psicoanálisis; ASOVEP), prior to being affiliated to the International Psychoanalytical Association in 1971, at the Vienna Congress. The first group of candidates commenced training in 1969.

In May 1975 power struggles and exclusion anxiety gave rise to conflicts within the association between the oldest analysts and new arrivals. Two groups were formed with their respective orientations, calling for the intervention of the International Psychoanalytical Association at the London Congress in the same year. In 1976 a committee directed by Maxwell Gitelson and comprising Serge Lebovici, Daniel Widlöcher, Edward Joseph, and David Zimmermann went to Caracas to visit the association. Thanks to their intervention, the dissensions were soothed and a joint agreement was signed in 1977.

In 1983 Manuel Kizer, one of the founding members, left the ASOVEP to create a Lacanian group. In May 1989, after more quarrels, fifteen other members decided to constitute a separate group and received recognition as a work group from the International Psychoanalytical Association. This group went on to be recognized at the San Francisco Congress of 1995 as the Caracas Psychoanalytic Association.

The most noteworthy contributions from the ASOVEP includes J. Aray's work on the fetal psychism and abortion; Hugo Domínguez's study of the dynamics of communication; Alfonso Gisbert's work on the identity of the psychoanalyst; Rafael E. López-Corvo's study of femininity, addictions, and *auto-erividia* ("self-envy"); and Guillermo Teruel's work on the interaction between couples and the death instinct. From the Caracas Psychoanalytic Association, Addys Attías stands out for work on adolescent pathology, and A. Torres for work on feminine identification and neurosis.

There are therefore two associations in Caracas, each equipped with a training institute. In terms of publications, the ASOVEP review *Psicoanálisis* appears at irregular intervals, as well as a few monographs. The

Caracas Association publishes a twice-yearly review, *Trópicos*.

## **VERTEX**

The term *vertex*, in Wilfred R. Bion's terminology, refers to the psychic place from which an emotional experience can be represented with the support of data from a sensory modality, which he called the "mental counterpart" (1965, p. 90) of the sense involved.

In common English, *vertex* has the more general meaning of "top." Bion introduced it into his terminology in 1965 in his book *Transformations: Change from Learning to Growth*. He was seeking an abstract definition of the "point of view" from which the mind, through a system of transformations, can bring emotional experiences linked to the absence of the object together into a "constant conjunction" (p. 96) and give them meaning. He thus used the geometric term *vertex*, "clothing" the abstract geometric concept in imaginary flesh. In so doing, he sought to avoid two pitfalls: that of using a term with strong metaphoric connotations such as *point of view*, which privileges the sense of sight, and that of reducing the libidinal objects and their processes of intrapsychic transformation to purely formal entities. He nevertheless recognized the primacy of the sense of sight in these processes of transformation, notably, that it leads more readily to verbal description than the other senses. While he emphasized this primacy, he nonetheless showed that a change of vertex, or the mental equivalent of a sensory modality, can be necessary to represent certain psychic experiences. He also described the reversal of a vertex; for example, the reversal of the visual vertex that leads to hallucinations.

Bion used the concept of the vertex to describe the relationship between patient and analyst and to propose a theory of interpretation. In the analytic rela-

tionship, patient and analyst share the same experience, but each has a different vertex. The patient's vertex is linked to his or her unconscious motivations and their corresponding emotional bonds, the H (hatred) bond or the L (love) bond. The analyst must strive to adopt a vertex that is linked only to the K (knowledge) bond, the emotional bond corresponding to the psychic tension that must be tolerated until meaning emerges. Interpretation for the analyst consists of formulating, when the time comes, his or her experience of the situation based on this vertex. The vertices of the patient and the analyst must be neither too close nor too far apart from one another. This produces a "binocular vision" that enables the patient to take a step back from his or her original vertex, bringing a sort of perspective into the patient's psyche.

## **VIDERMAN, SERGE (1916–1991)**

The Romanian-born French physician, psychiatrist, and psychoanalyst Serge Viderman was born on September 15, 1916 in Rimnic-Sarat, near Bucharest, and died in Paris on November 3, 1991.

The third of four brothers, he was born into a relatively affluent family; his father was a forestry agent. After his secondary education, without prospects owing to the numerous *clausus* against Jews, he decided to go to France to join his eldest brother, who had established himself as a doctor there. He arrived in Rouen in 1934, at the age of eighteen, and entered medical school, perhaps less out of any sense of vocation than of lack of interest in the second career option then available to gifted Jews: the legal profession.

With the outbreak of the war, he finished his studies and, after escaping imprisonment for resistance activities, he took refuge in Grenoble, in the free zone, where he rejoined his brother and his family and enrolled in the bachelor's program in philosophy at the university. In 1943 he was forced to flee again, this time to Paris, where he lived under a false identity until the Liberation.

After the Liberation he became a naturalized French citizen, but, in need of money, he accepted a job in Fribourg (Switzerland) at the National Office of Immigration. Based on the conclusions of his medical examination, "displaced persons" were directed toward either France or the United States. It was here that he met his future wife, Michèle, who came from Burgundy; the couple had three daughters.

As soon as he was able, Viderman returned to France and settled near Poitiers, where the mayor of a small administrative district was in need of a doctor and was offering lodging. Unenthusiastic about being a country doctor, he then moved to settle near Rouen as a generalist in order to be closer to Paris and the practice of psychiatry.

He came into renewed contact with his compatriot Béla Grunberger, who recommended his own psychoanalyst, Sacha Nacht; like both of the other men, Nacht was a Romanian Jew. Viderman entered analysis with Nacht in the spring of 1952, and after another move, this time to the Paris suburbs, in 1955 he found a job as a psychiatrist at Villa-des-Pages clinic, in Le Vésinet, which was headed by two doctors named Leulier; this enabled him to cut his first teeth as a practicing psychiatrist.

His name did not appear on any of the lists of "students in training" that were fought over by the two rival factions of the schism of 1953, but his performance in his degree course was brilliant enough for him to be entrusted, in 1956, with writing, under Nacht's direction, an important article entitled "Aperçu sur l'histoire de la littérature psychanalytique" (Outline of the history of the psychoanalytic literature) for the second volume of *La Psychanalyse d'aujourd'hui* (Psychoanalysis today), published by the Presses Universitaires de France. In this article he painted a broad historical picture that equally embraced child analysis and psychosomatic theories, and he showed no hesitation in approaching the contemporary era, with Nacht ("Nacht's work stands out

for its precision and clear organization”), Maurice Bouvet (whose report on object relations he cited as one of the “studies full of promise that have been published in France in recently years”), Daniel Lagache, whose “substantial report” on transference was noted, and Jacques Lacan, “who has published works written in a singular style, the obscurity and preciousness of which are detrimental to his thinking” (Viderman also rebuked Lacan for failing to cite Henri Wallon, in whose works “he had nevertheless found the clearest part of his inspiration”).

Esteem for Viderman was confirmed by his election to membership in the Société psychanalytique de Paris (SPP; Paris Psychoanalytical Society) in December 1957. After Bouvet’s death in 1960, Viderman was immediately accredited to take over his training analyses; unsurprisingly, he was elected to permanent membership in the society on October 18, 1960. At this time he left the clinic at Le Vésinet and settled definitively in Paris as a psychoanalyst.

Viderman’s position within the institution was always that of a “critic” in the true sense—a position, moreover, that was congruent with the theoretical and clinical views he elaborated over time. He felt close to those who were attempting to open up the SPP to the outside, particularly to the analysts of the Société française de psychanalyse (French Society of Psychoanalysis), which would become the Association psychanalytique de France (Psychoanalytic Association of France), but also, whatever reservations he may have harbored about Lacan, with regard to what he perceived to be lively elements within the Lacanian movement. For example, in 1967 he wrote for *L’Inconscient*, the revue founded by Piera Aulagnier, Jean Clavreul, and Conrad Stein. Although he was one of the founders and, from 1973, codirectors, along with Christian David and Michel de M’Uzan, of the general section of the collection “Le fil rouge” (The red thread) published by the Presses Universitaires de France, he also long maintained close ties with René Major and Dominique Geahchan in the meetings organized by their group, *Confrontation*, from 1974.

In 1978–1979 he tried, although in vain, to promote a “second degree program,” known as *Cursus B*, alongside the traditional curriculum for the training of analysts within the Institut de psychanalyse de Paris (Paris Institute of Psychoanalysis). In 1979 he cosigned the summons issued to the institute by Robert Barande, Dominique Geahchan, René Major, Michel Neyraut

and Conrad Stein to try to annul expulsion orders judged to be illegal and voted for in June, against members who refused to pay their membership fees in protest. Finally, in 1980 he found himself alongside Geahchan, François Roustang, Jacques Sédat, and Stein, among the promoters of the foundation of the Collège des psychanalystes (Collegium of psychoanalysts), which aimed to situate itself “outside of the traditional structures of psychoanalytic societies.”

These stands taken in relation to institutions were not arbitrary, but rather closely linked to the ideas Viderman promoted; these ideas first appeared in fully developed form in his book, *La Construction de l’espace analytique* (Construction of the analytic space; 1970), which marked a real turning point in the thinking of many analysts in the French psychoanalytic community. His ideas incited lively discussions that for a time seemed to take precedence over the usual administrative quarrels. They were viewed as subversive by adherents to a dogmatic psychoanalysis that was dependent upon a certain Freudian scientific ideal, and conducive to the exercise of a will to codify, whose sterility and absurdity Viderman underscored.

His description of the space in which an analytic relationship (which is always an invention in partnership) is born, flourishes, and fades away, is based on a radical putting into doubt of the existence of any external “truth” that could be found in its integrity and could transcend the protagonists in the relationship. The person of the analyst and the counter-transference here have a dimension that renders practice less assured and less reassuring. Interpretations do not “construct” the subject’s history, but rather “construct” a probability that cannot pretend to be an “objective historical truth.” Needless to say, this calling into question of pseudo-certainties was taken for what it was: a relativization of the “power” of those who pretended to legislate in their own name, a caution against the abuses of force in producing meaning.

Book after book, Viderman deepened his explorations, for example with *Le Céleste et le Sublunaire* (The celestial and the sublunar; 1977), or *Le Disséminaire* (The disseminary; 1987), where he pursued his task by dismantling the illusions—extremely similar illusions, in the last analysis, because they are linked to the same sociocultural sources—that inspired the thinking of Freud, Marx, and Einstein, all of whom believed in the existence of a rigorous determinism, a law that orders the tangible world and the psyche alike. For him, the

path was cleared in process, with the passage of the person who walked it.

Viderman did not live to see the publication of his last book, *De l'argent en psychanalyse et au-delà* (Money in psychoanalysis and beyond). It could not be fitted into the publication schedule at the Presses Universitaires de France until shortly after his death, on November 3, 1991, of a cancer that had gradually distanced him from all activity other than writing. It is an incomplete book, not revised with Viderman's characteristic meticulousness, for those close to him had tried, in vain, to get it printed before time ran out, as they knew it was fated to do. Death, moreover, is a constant presence in this work, which gives the sense of a testament, but in reality completed the approach Viderman had begun twenty years earlier. His way of emphasizing our fear of nothingness and the "illusory conjuration" of it represented by money reveals the contours of a meditation on human destiny as well as on the psychoanalyst's place in this process; the book attests to the abiding presence of the philosophical reflection that filled the first years of his training.

As Michel Neyraut wrote in his 1991 obituary for Viderman, printed in *Le Monde*: "Out of the humanist, the thinker, the linguist, the gourmet, the sage, and finally, the psychoanalyst, which was dominant in him? It depended on whether you were asking about a passage from Homer, the bouquet of a Médoc, a translation of Vialatte, or simply the meaning of a word—he, who came from Romania and had learned his French out of Anatole France!"

## VIENNA, FREUD'S SECONDARY SCHOOL IN

After home-schooling and studies at a private primary school during his elementary school years, in 1865 Sigmund Freud enrolled in the first class of the newly constructed Leopoldstädter Kommunalrealgymnasium, and later (1868–1869) at the Obergymnasium, located at Taborstrasse 24 in the second district in Vienna. He completed the degree course, earning high praise, received the school prize in his third year, and in 1873, in his eighth year, received the *Matura* (high-school diploma) with honors after passing his qualifying exams. These included: composition, in German, on the theme "What considerations should guide us in choosing a profession?"; Latin exam: Virgil, Book IX, 176–223; Oskar Seyffert, book XIII"; Greek exam: Sophocles, *Oedipus Rex*, v. 14–57; and mathematics.

The ratio of Catholics to Jews in the second-year class was thirty to twenty-eight; in the eighth-year class it was six to five. As to anti-Semitism in the upper classes, from Freud's fifth year, the name "Sigmund" appears on school documents instead of "Sigismund," probably because of ridicule; otherwise there are no traces of an administrative change of his first name.

There are numerous allusions to Freud's secondary-school years in his scientific works, particularly in *The Interpretation of Dreams* (1900a), for example, the dream of the botanical monograph. His esteem for his high school teachers never diminished: Samuel Hammerschlag, who taught religion and was also librarian to the Jewish community and a friend of Freud's father; Viktor Ritter von Kraus, who taught German, history, and philosophy.

During his eighth year (university preparation), Freud was at the head of his class. His friends included Heinrich Braun, Wolf Knöpfmacher, Salomon Lipiner, Siegmund Lustgarten, Ignaz Rosanes, Eduard Silberstein, Julius Wagner, and Richard Wahle.

Freud contributed to the school's fiftieth anniversary celebration, in 1914, with an article, "Some Reflections on Schoolboy Psychology," that appeared in the commemorative brochure. For the fiftieth anniversary of Freud's death in 1989, the Erzherzog Rainer Realgymnasium was renamed the Sigmund Freud Gymnasium.

## VIENNA GENERAL HOSPITAL

Originally a hospice for the poor, Vienna General Hospital (Allemeines Krankenhaus) was dedicated by Emperor Joseph II in 1784. With about two thousand beds and a design with courtyards and open spaces, the hospital by the 1870s had become one of Europe's leading teaching hospitals, with new and expanding departments and clinics.

After receiving his medical degree in March 1881, Freud was able for a time to continue his research in Ernst Brücke's physiology laboratory, where he also worked as a demonstrator for several semesters. But because Freud had limited financial resources, his hopes of building a career in research were misplaced, and Brücke's attempts to obtain a research position for him in laboratories in Graz and Prague proved fruitless. After becoming engaged to Martha Bernays in June 1882, Freud accepted Brücke's advice to give up research in favor of a more remunerative career as a physician. A month later Freud began his clinical training at the Vienna General Hospital.

Freud spent three years at the hospital and trained in many of its different departments. He worked in surgery (July to September 1882) and studied internal medicine under Hermann Nothnagel (October 1882 to March 1883). His early training in psychiatry was under Theodor Meynert (April to October 1883). Freud subsequently trained in the dermatology clinic and was assigned to the ward for syphilitic patients. At first an unpaid trainee, Freud was appointed assistant physician (*Sekundararzt*) while under Meynert, and in early 1885

he temporarily replaced Franz Scholz as head of the department of nervous diseases and the liver. At the same time, he continued his researches in brain anatomy and pathology in Meynert's laboratory. He published numerous articles in clinical neurology, on brain pathologies, and on cocaine, and for extra income he wrote abstracts of articles in international medical journals.

Freud specialized in nervous diseases on the advice of Josef Breuer, and in June 1885 he was appointed privatdozent in neuropathology. About the same time, with Brücke's support, he obtained a postgraduate travel grant to study in Paris at Salpêtrière Hospital with Jean Martin Charcot. He subsequently concluded his clinical training in Berlin at Adolf Baginsky's pediatric clinic. After his return to Vienna, he established a private practice as a neurologist in April 1886 and married in September of the same year.

## VIENNA, UNIVERSITY OF

After a series of lectures on Darwin by Carl Brühl (1820–1899), an eminent professor of zoology at the University of Vienna, Freud decided to study medicine rather than law and to become a researcher in order to "understand something about the enigmas of nature

and perhaps even contribute to solving them.” His decision was also inspired by “Nature,” a text that has been attributed to Goethe. In the absence of faculties in the natural sciences, medicine substituted as basic training for biologists, zoologists, and physiologists. Freud, however, had no wish to become a physician. The freedom in organizing studies accorded by the edicts of 1872 suited his theoretical penchants.

Prepared by exercises with the microscope, he engaged for six semesters in intensive studies of zoology with Carl Claus (1835–1899), a Darwinian. Claus twice sent him on a university grant to the zoological station at Trieste, Italy, to study the sexual organs of the eel. Although Freud himself underestimated the value of this research, his description of the bisexual disposition of the fresh-water eel is considered a fundamental study in this domain. His studies of Aristotle with Franz von Brentano (1838–1917) caused him to nurture for some time the notion of doing a double doctorate in zoology and philosophy.

In the course of his seventh semester he moved away from Claus, an exceptional though not very directive master, and joined the laboratory of the physiologist Ernst Wilhelm von Brücke (1819–1892), who was assisted by Ernst Fleischl von Marxow (1846–1891) and Siegmund Exner (1846–1926). This was “the inexhaustible center that drove all Viennese medicine in the second half of the century,” where Freud finally found “tranquility and total satisfaction,” as well as individuals that he could “respect and take as models.” Brücke was an outstanding figure whom Freud could identify with, like Jean Martin Charcot later.

Being more of a researcher than a student, Freud published five articles on neurophysiology before his doctorate. With “Über den Bau der Nervenfasern und Nervenzellen beim Flusskrebs” (On the structure of nerve fibers and cells in the crayfish) in 1882, he became a pioneer in neurological research. He nevertheless experienced failures in his work in the Institute for Experimental Pathology, headed by Salomon Stricker (1834–1898), and in the Chemistry Institute, run by Ernst Ludwig (1842–1915).

In 1879 and 1880 he translated works of John Stuart Mill, published in volume 12 of Mill’s *Gesammelte Werke* (Complete works), in order to earn his living, since he found himself in a difficult financial situation in spite of grants from two Jewish organizations. At this time he did his military service while preparing for his doctorate. In the oral examinations for his doctorate he received

grades of “excellent” for the first and third examinations and a grade of “good enough” in the second. He sat for a recapitulation exam in law for physicians and received his medical doctorate on March 31, 1881. Among his friends while he was a student were Carl Koller, Siegmund Lustgarten, and Eduard Silberstein.

## **VIOLENCE, INSTINCT OF**

The word *violence* derives from an Indo-European root that refers to life. The natural instinct of violence is thus not a destructive instinct, much less a death instinct, but a natural life and survival instinct that corresponds to the instinct of self-preservation in Siegmund Freud’s first theory of the instincts.

It involves what Freud saw as a sort of natural “imaginary cruelty” in 1897 and described in “Instincts and Their Vicissitudes” (1915c) as being common to humans and animals. This instinct’s goal is above all to protect life and the narcissistic integrity of the subject. This holds regardless of the potential effects caused secondarily to an object that as yet has only a narcissistic status in the subject’s imagination. Instinctual violence has nothing to do with aggressiveness, sadism, or hatred, whose libidinal components Freud showed to be aimed at an object that had otherwise attained an oedipal genital status.

In *Three Essays on the Theory of Sexuality* (1905), Freud very clearly showed that this brutal instinct can attract to itself a part of the sexual instincts, producing aggressive components. In 1915 he attributed a narcissistic and phallic character to violent dynamism and advanced the hypothesis of a logically necessary anaclysis of the sexual instincts on the brutal self-preservation instincts, so as to reinforce the energy of the sexual instincts in the direction of love and creativity.

The role of the instinct of violence was gradually specified in European and American psychoanalytic studies that since 1960 have focused on a veritable metapsychology of narcissism. In *La Violence fondamentale* (Fundamental violence; 1984) Jean Bergeret, based on such studies and Freud's first hypotheses, proposed an attempted synthesis, forming a theory of instinctual violence. He gave special emphasis to the difficulties Freud encountered in trying to account for the stage of primitive violence within the totality of the Oedipus myth. The first acts of the drama (the oracle of Apollo and the episode of Mount Cithaeron in particular) bear witness to human beings' deep intuitive awareness of their fundamental instinct of brutality in the service of self-preservation.

Freud was never satisfied with his successive theories about the instincts. Rather, he decided to focus on the synchronic aspect of a conflict arising between tendencies within the same psychogenetic generation. His theory of instinctual anaclysis, however, would have enabled him to conceptualize a diachronic conflict pitting the violent pregenital tendencies against the sexual tendencies, with all the possible configurations linked to fusion, defusion, and the different modes of articulation of these two fundamental groups of instincts. His choice of a synchronic model of conflict prevented Freud from better integrating into his psychodynamic and economic conception this brutal instinct of violence and defense, which he had nevertheless clearly described.

### **VIOLENCE OF INTERPRETATION, THE: FROM PICTOGRAM TO STATEMENT**

The *Violence of Interpretation*, originally published in 1975 by the Presses Universitaires de France, was Piera Castoriadis-Aulagnier's first book, although she had already published a number of important articles beginning in 1961, and her research (seminar at the Hôpital Sainte-Anne), institutional involvement (creation of the Quatrième Groupe of the O.P.L.F. in 1969), and editorial work (as head of the revue *L'Inconscient* and, then, *Topique* beginning in 1969) were already widely known.

This book marked an important step in psychoanalysis in France, especially with regard to psychosis. It attracted a huge readership immediately, and has been translated into Italian, Spanish, Portuguese, and English.

Aulagnier's project sought to reexamine the Freudian metapsychological model on the basis of the psychoanalyst's obligation, in therapeutic work with psychotic patients, to rethink the mind and its models. The magnitude of the task and the systematic organization of the new theories presented explain why this book was published relatively late in her career.

*The Violence of Interpretation*, according to Aulagnier, attests to the "prodigious work of reinterpretation carried out by psychosis" (p. xxviii) and thus makes it possible to catch a glimpse of an unthinkable "before" that has been shared by all. Aulagnier did not base her work on the idea of a "psychotic kernel" common to all, a theory she rejected, but rather believed that the psychotic succumbs to the attraction of a mode of representation that has normally been surpassed, even though it remains latent in all subjects. The author's analysis thus culminated in a theory of representation, and more specifically of what she called a "primal" stage of representation, which "ignores word-presentations and has as its exclusive material the image of the physical thing" (p. xxix). Hence Aulagnier's definition of psychosis: "Psychosis is characterized by the force of attraction exerted by the primal, an attraction to which it opposes that 'addition' represented by the creation of a 'delusional' interpretation that makes 'sayable' the effects of that violence" (p. xxx).

Aulagnier innovated a number of new concepts based on this precept, in particular “primary violence,” which is the effect of anticipation imposed by the discourse of the mother (“word-bearer”) upon an *infans* from whom a response is anticipated that the preverbal infant is unable to give, and the “secondary violence” that “leans on” the first.

For Aulagnier psychic activity is subdivided into three modes of functioning, none of which necessarily silence one another: primal process (pictographic representation), primary process (fantasy representation), and secondary process (ideational representation).

The phenomenon of specularization (Jacques Lacan) and the psyche’s “borrowing” from sensory models are characteristic of the primal process. The “pictogram” is defined as “the formation of a relational schema, in which the representative is reflected as a totality identical with the world” (p. 25). This “representative background” does not disappear from the subject, but is “foreclosed to the power of the I’s knowledge” (p. 37), except in psychosis where it is manifest.

The primary process is comprised of fantasy activity, but Aulagnier emphasized that pleasure and unpleasure are always experienced here as being dependent upon an Other’s desire to give or refuse it.

Finally we have the secondary process, which is linked to the appearance of word-presentations. Nomination, once it involves affect, means naming not just the object, but also the relation that links the I to the object: “to name the other with the term beloved is to designate the subject who is naming as lover” (p. 97). The I’s self-naming, with the linguistic signs proper to affect and the kinship system, enable it to come into being. Aulagnier wrote: “The I is simply the I’s knowledge of the I” (p. 5), but the I is also constructed: in relation to its past in “self-historization” and to its future in the “identificatory project.”

The conditions that make it impossible for an I to come into being other than by passing through delusional identification are the topic of the second part of the book, where the author defines what she means by the “psychotic potentiality” or “primary delusional thinking” that can (or cannot) give way to actual psychosis.

Aulagnier developed the two major categories of schizophrenia and paranoia and, based on the hypothesis of secondary violence and delusional theories of

origination, proposed a new psychoanalytic approach to these pathologies.

## VISUAL

As an adjective, the term *visual* designates what is perceptible in the field that presents itself to the eye. As a noun, *the visual* involves the way in which the psychological apparatus organizes this perceptual data.

As early as his study on aphasia (1891b), Freud emphasized the importance of the visual in the representation of things in order to understand its complicated relationship with representation by words. In *The Interpretation of Dreams* (1900a), he both provided an optical model for the psychical apparatus and also noted that the dream material, as well as that of memory traces, are most often presented visually. Thus, modes of representation must fulfill requirements of visual representations. The subsequent recognition of visual component drives provided Freud with the opportunity to verify that their vicissitudes are not homologous to those of the other drives. Finally, in *Moses and Monotheism* (1939a), he insisted that it was necessary to set aside visual stimuli, especially those caused by the maternal body, in order to name the father. He connected this “advance in intellectuality” (1939a, p. 111) to the impact of monotheistic religion on mental life, especially when it prohibits representations.

In Freud’s work, the visual shows the privileged connection between the sexual and the sensorial. Jacques Lacan discussed this in his article on the “Mirror Stage” (1949), where he expanded Freud’s observations of the visual dimension of narcissism. Lacan stressed the importance of the mirror image for the infant held up to the mirror by its mother. When the baby recognizes itself in the mirror, it achieves an identity by assuming the mirror image. But this is also a trap, because once the subject is captured, he confuses himself with the mirror image and thus becomes alie-

nated by a visual definition of self. He is caught in the succession of images.

In a study relating psychotic discourse to the mirror stage, Piera Aulagnier proposed that in the psyche's primal activity of visual representation its invested object should be called a *pictogram*. In doing so, she emphasized the prevalence of the visual in unconscious representations.

It is worthwhile to make another distinction between the visible image and the visual image. Vision exhausts only the empirical reality of a phenomenon, which can become a psychic representation, that is, a visual image, only by passing through the primary and secondary processes. The difference between what is visible and the *visual* of the image explains how dream images are never confused with things seen by the dreamer. Because it is incongruous with the desire to see, the visual image assures the perpetual thrust of the scopic drive. The impossibility of reducing the visual to the visible prevents the image from showing the object of desire and orients vision towards another image. If we grant Freud's assertion that the desire to see is related to seeing the genital organs, the notion of the visual allows us to specify what is involved in the attempt to see, namely the female genitalia that eludes sight. The only way to represent it is by the visual image, which is a fetish that only exposes its unreal opposite, the maternal penis.

Why is the visual the predominant sense? This question can be answered by considering that the visual is overdetermined because there is no penis on the female body. When the child fails to see a penis on a female body, his single sex wavers and he begins to think that there is another sex, which exists even though it is "invisible." Other elements of the visual deserve further attention. For example, the central role that psychoanalysis grants the visual is justified by the fact that there must be a visual reference, a virtual psychical mirror (certain moments in the treatment) or a visual fantasy. The determining function of the visual might be related to the timelessness of the unconscious, because only the visual is in a position to prevent the representation of the fantasy from being eternalized.

## **VISUAL ARTS AND PSYCHOANALYSIS**

The visual arts make use of nonverbal representation and therefore require a different psychoanalytic approach than the language arts. The work of art can be considered as a compromise solution between impulses and defenses. Psychoanalysis can then try to reveal the unconscious ideas behind the creative work. But in the visual arts, even more so than in the language arts, it is form itself, more than the represented subject, that must be interpreted.

The first psychoanalytic text to examine the visual arts was Freud's *Leonardo da Vinci and a Memory of his Childhood* (1910c). Freud opened the way for psychobiography by demonstrating the impact of instinctual and infantile life on the artist's creative work. In his analysis of La Gioconda and Saint Anne, he approached the analysis of formal elements: the Gioconda's enigmatic smile owes its existence to Leonardo's infantile life; the confusion of the bodies of Anne and Mary in the London drawing is said to be a form of condensation.

In 1911 Karl Abraham published an essay on Giovanni Segantini. His goal was to show that psychoanalysis can be applied to the analysis of mental processes other than neurosis. He demonstrated the role of the practice of making art in the psychic economy of the artist, the importance of infantile experience, real or imagined, and the antagonistic interplay of love and hate in the genesis of the work. Unfortunately, his analysis of the paintings themselves does not deepen the interpretation of the manifest subject of the representation.

In 1913 Otto Rank and Hanns Sachs published in *Die Bedeutung der Psychoanalyse für die Geisteswissenschaften* (Psychoanalysis and the humanities) a chapter on the aesthetics and psychology of art, centered on the affects of pleasure and unpleasure of the work of art. They argued that the economy of affect governs the development of the formal aspects of the work of art.

Freud published “The Moses of Michelangelo” (1914b) but did not sign it, proof of his prudence in using psychoanalysis for the interpretation of artistic phenomena. Freud based his interpretation of the statue on his own feelings. Since he identified with the subject of the representation, he understood the statue in terms of his own emotional investment, thus opening a path to an approach to artistic phenomena that was little used by later psychoanalysts, who were primarily interested in an analysis of the process of artistic creation. There were a number of important contributions to this field aside from the work of Freud: Otto Rank, Melanie Klein, Hanna Segal, Ernst Kris, Donald Winnicott, and Didier Anzieu.

Children’s drawings and the work of psychotics have been used as nonverbal material, but strangely they have had little influence on the psychoanalysis of the visual arts. This field owes a great deal to the work of artists and art historians like Anton Ehrenzweig, Meyer Schapiro, Jean Clair, and René D emoris, who have made use of psychoanalytic theory. Along with the approach taken by psychobiography and interpretations of the creative process, both of which are focused on the artist, psychoanalysis can also help us understand the work of art itself, providing it can avoid using verbal language as the only source of reference. When Freud wrote that the lack of expression of the visual arts was due to the material used by those arts, he was referring to this.

The image is not only a metaphor or symbol; it signifies, through its materiality, the setting aside of its metaphoric or symbolic meaning and the context in which our perceptual field has classified it. It comes to prominence through the brilliance of its materiality as a new external perception that we nonetheless are able to recognize. For the visual arts much more than for literature, meaning is hidden in form, the result of the conscious and unconscious intentions of the author.

It is in the formal specifics of the work—that is, its style—that the process of figuration unique to the author is found. This is what Freud called, referring to the dream work, “pictorial language,” our first mode of

expression. The painted or sculpted image should not be considered only the transcription of verbal thought but the expression of a visual unconscious that preserves our earliest impressions. The artist uses a sensory material that bears the traces of his first affective perceptions and experiences, producing a figurative representation that balances desire with external reality, actual perception with what has been irremediably lost.

The psychoanalytic approach to the arts requires a methodology first used by Freud in “The Moses of Michelangelo.” The effect the work has on the spectator is the object of analysis. The image must be considered a libidinal object of investment that is offered to the spectator and apprehended on the basis of the effects it provokes in him. The work of art reactivates the spectator’s unconscious desire and awakens, step by step, the representations he has used as a support. Through this associative process, the spectator-analyst juxtaposes the resonances the work provokes in him and the formal aspects that can be considered traces of the unconscious life of its author. It is through this chain of association that he will be able to reconstruct the fantasies that generated the work of art.

## **VOYEURISM**

Voyeurism is a deviant manifestation of sexuality that involves looking without being seen in order to obtain

sexual pleasure. In *Three Essays on the Theory of Sexuality* (1905d), Freud examines sexual perversion and indicates the circumstances under which “the pleasure of looking [scopophilia] becomes a perversion (a) if it is restricted exclusively to the genitals, or (b) if it is connected with the overriding of disgust (as in the case of *voyeurs* or people who look on at excretory functions), or (c) if, instead of being *preparatory* to the normal sexual aim, it supplants it.”

Later, in “Instincts and Their Vicissitudes” (1915c), he provided a metapsychological explanation for the instinct of looking, which involved the voyeur-exhibitionist pair and the reversal of activity into passivity in connection with a precise object: “the sexual member.” The different instinctual currents of seeing are inflected by the voyeur, who tries to see the other’s genitals while hiding his own, but who also tries to be seen looking, in order to respond to what he believes is the other’s desire to see. Jacques Lacan would later say that the voyeur wants to be seen as a seer.

Freud continued to emphasize the visual component of the perversions, but for him the specificity of voyeurism is important because of the vicissitude of the instinct of looking rather than its role in perversions. Rather than allowing the evolution of the instinct (component) of looking to develop in different directions, the voyeur reduces the sexual and the visual in sex to a narrow, stereotypical sexual situation. He appears to do away with the sexual, the multiplicity of objects and choices, by wrapping them in a rigid fantasy. He tries to block the aggression in the instinct in order to obtain pleasure, to the detriment of the other. By splitting the ego, he uses sex for the purpose of discharging instinctual violence. By appropriating the other as image, the voyeur makes it an object of pleasure, while remaining uninvolved in the other’s intimacy. The voyeur does not seek any form of exchange or relationship, but obtains pleasure by seizing the other’s image against its will. The goal is not only the sight of parts of the body that are concealed out of modesty or cultural opprobrium, but also to dismember the body of the other. The voyeur watches what is forbidden in order to destroy the physical integrity of the person by substituting a dismembered body for the unified image.

Several circumstances can lead to the occurrence of voyeurism. The instinct to see is used through dis-

avowal and fetish formation to deny castration. The fantasy of the phallic mother and the split of awareness of the lack of a penis leads to rage and need for revenge towards her. For Masud Khan, the pervert does not succeed in creating a transitional object when reacting against the encroachment of the maternal unconscious, but manages to fabricate an “internal collage-object,” which he then tries to discover in external reality. The voyeur engages in this type of theatricalization of the sexual relation by manipulation, submission, and humiliation of the object.

Robert Stoller has insisted on the cultural necessity of the perversion “forged by society and the family so that they are not harmed further” by instinctual cruelty. Because voyeurism turns the other into an image, an object of envy and covetousness, it appears to also bear witness to the visual focus of Western society. Seeing at any cost is an imperative that is often confused with science’s objective of mastery. In an “omniversal world,” according to Jacques Lacan’s expression, the voyeur becomes the one who does not allow himself to be blinded by sexual difference but cannot support the truth. He knows exactly what his mother is like, but tries to save his phallic image through some visual sleight-of-hand. More than anyone, he denies what he sees: the rift between the sexes, the fracture of bodies.

## WAELDER, ROBERT (1900–1967)

An Austrian psychoanalyst who taught in the psychiatric section of Philadelphia Jefferson Medical College, Robert Waelder was born on February 20, 1900, in Vienna, and died on September 28, 1967 in Broomall, Pennsylvania.

He was the son of Joseph Waelder, a Jewish merchant. After graduating from Maximilian *gymnasium* with honors in 1918, Waelder entered the university and in 1921 obtained a doctorate in physics.

At the age of twenty-two, Waelder consulted Sigmund Freud about treatment and, following his advice, he started a personal analysis with Robert Hans Joki; he subsequently underwent training analyses with Hermann Nunberg and Anna Freud. In 1924, Waelder became a member of the Vienna Psychoanalytic Society, where he performed a variety of functions as librarian and as a member of the candidate committee. From 1932 to 1939, with Ernst Kris, Waelder edited *Imago*, becoming that journal's editor-in-chief in 1934.

As a representative of the Viennese analysts, and within the context of an exchange of views, in 1936 Waelder presented in London his critique of the teachings of Melanie Klein; "The Problem of the Genesis of Psychical Conflict" was published in 1936. Waelder also presented to the Royal Institute of International Affairs his work on psychology and politics, which was published as "The Psychological Aspects of International Affairs" and suggested how psychoanalytic notions might be applied to the study of war; in a similar vein, he had written a short study on collective psychoses; this was published first in French, and subsequently as *Psychological Aspects of War and Peace*. Another socio-political work, *Progress and Revolution*,

was published in 1967. According to Richard Sterba, Waelder "showed a certain unworldliness that stood in contrast to the vastness of his scientific and literary knowledge" (Sterba, p. 138). He nevertheless created a considerable impression upon colleagues. "Waelder's extensive knowledge and his vast vision are easily seen, particularly in his later writings" (p. 141).

Waelder's first marriage was to Jenny Pollak, who in 1928 also became a member of the Vienna Psychoanalytic Society. In 1938, he emigrated to the United States and taught at the Boston Psychoanalytic Institute. Later, in 1943, he settled in Philadelphia and became a training analyst at the recently founded Philadelphia Psychoanalytic Institute. After a schism, in which members broke away to form the Philadelphia Association for Psychoanalysis, Waelder served as president of that organization from 1953 to 1955. In 1963, he was appointed professor of psychoanalysis at the psychiatry department of Jefferson Medical College in Philadelphia.

## WAGNER-JAUREGG, JULIUS (JULIUS WAGNER RITTER VON JAUREGG) (1857–1940)

Julius Wagner Ritter von Jauregg, an Austrian professor of psychiatry, was born on March 7, 1857, in the city of Wels, in Upper Austria, and died in Vienna on September 27, 1940. He was the son of a high ranking civil servant. While still a student and like Freud, he published the results of his original research in the laboratory of Salomon Stricker, professor of experimental pathology at the University of Vienna. After obtaining his doctorate in medicine in 1880, Wagner-Jauregg, for two years, remained an assistant in Stricker's laboratory, where he met Freud. The two men became friends and colleagues. When he failed to be admitted to a training program in internal medicine, Wagner-Jauregg decided on psychiatry. He submitted his thesis for his habilitation in neuropathology in 1885 and qualified as a privatdozent in psychiatry in 1888. In 1889 he was appointed *professor extraordinarius* at the University of Graz. Four years later, in 1893, he was appointed *professor ordinarius*, or full professor, at the University of Vienna, where he also became director of the First Psychiatric and Neurological Clinic and, from 1902, of the Second Psychiatric Clinic.

The course of Wagner-Jauregg's scientific work includes such empirical discoveries as the central role of iodine deficiency in the etiology of cretinism and the introduction of iodine therapy to treat goiter. Most significant was his use of malarial inoculations to treat general paresis, then a relatively common disorder in patients suffering from tertiary syphilis. This treatment represented his belief that inducing febrile illness could prove therapeutic in cases of psychosis, and in 1927 it won him the Nobel Prize in physiology or medicine.

Wagner-Jauregg was accused of abusing soldier-patients in his clinic by employing extremely painful electrical treatments to treat shell shock. The 1920 debate protocols from the military commission investigating charges of brutality suffered by soldiers at the hands of army doctors during the First World War reveal a fundamental disagreement between Freud and

Wagner-Jauregg in their respective views on the nature of what came to be known as war neuroses. Freud was appointed as an expert in the case after other psychiatrists, former students of Wagner-Jauregg, recused themselves. In Wagner-Jauregg's view, as was commonly thought at the time, soldiers who seemed to be suffering from battle-related shell shock were actually malingerers. In contrast, Freud suggested the importance of the unconscious in such cases; he brought forward positive results of psychoanalytic treatment and proposed that war neuroses be treated more humanely and considered as purely psychological in nature. Freud emphasized that he believed Wagner-Jauregg could not be personally guilty of cruelty to patients.

Despite Wagner-Jauregg's negative attitude toward psychoanalysis, a number of analysts, including Helene Deutsch, Heinz Hartmann, Otto Pötzl, and Paul Schilder, all worked in his clinic as interns or assistants. Psychoanalytic training carried an obligation to work in a clinical setting in a university psychiatric department. Wagner-Jauregg's congratulations on the occasion of Freud's sixtieth birthday led to subsequent regular respectful exchanges between the two men.

## WALTER, BRUNO (1876–1962)

The celebrated conductor and composer Bruno Walter was born in Berlin on September 15, 1876, and died in Los Angeles on February 17, 1962.

Born German, Bruno Walter Schlesinger was naturalized as an Austrian citizen in 1911, took French citizenship in 1938, and became an American citizen in 1948. Dropping his surname in favor of “Walter” represented an identification with Walther von Stolzing, the hero of Wagner’s comic opera, *Die Meistersinger von Nürnberg*. Walter’s musical training took place in Berlin, Cologne, and Hamburg, where he met avant-garde composer Gustav Mahler, who became his mentor and whom he followed to Vienna. There he began a brilliant career as conductor and pianist, and was also Mahler’s staunch defender.

Walter was an active participant on the unique and complex intellectual scene in turn-of-the-century Vienna, and his introduction to psychoanalysis occurred in 1906, while a young conductor and Mahler’s protégé. Then at a crucial stage in life, he suffered from a paralyzing neuralgia and, after consulting a number of specialists, he decided to seek help from Freud. From Walter’s autobiography we know the course and outcome of their meeting, which has been the subject of a small number of studies. Freud’s work with Walter was unusual in that he operated less as psychoanalyst than as a psychiatric consultant.

Indeed, while the young Walter expected months of psychological investigation, Freud, after a physical exam and a single visit, prescribed sojourns in Italy and Sicily. The impact of the consultation had such an effect that Walter obeyed immediately. His subsequent treatment with Freud resembled therapy by suggestion such as was common in the nineteenth century. When Walter asked Freud if he would be able to play in front of an audience because he feared a relapse, Freud took upon himself the responsibility, assuming the role of a protective paternal figure and inducing an almost hypnotic effect upon Walter, traces of which were still discernable forty years later.

The case history of Bruno Walter was discovered by the Austrian analyst Richard Sterba, who also emigrated to the United States and was a great music lover. Since his 1951 publication, this unusual affair has come regularly under scrutiny, whether for purely historical value, as a key example of brief therapy, for Freud’s use of a somatic approach, or even as a method of treating the so-called “actual neuroses.”

The close-knit Viennese artistic milieu fostered fortuitous encounters. Mahler, for example, also had a therapeutic consultation with Freud; and Ernest Jones, in the second volume of Freud’s biography, mentions that it took place to the intervention of Viennese neurologist Richard Nepalpek, who also happened to be a relative of Mahler’s wife, Alma. Others have suggested Walter as the source of the consultation, but have not been able to prove it. It is true that during the 1930s Walter collaborated with Herbert Graf, better known in psychoanalytic circles as “Little Hans.” Whether these experiences intensified Walter’s powerful admiration for Freud, as revealed by Sterba, is not known.

## WANT OF BEING/LACK OF BEING

For Jacques Lacan, human being is a “lack of being.” That was how he designated the subject’s fundamental emptiness as it was caused by the first symbolization and by the fact that desire originates in castration.

From the beginning of his teaching, Lacan noted that for Freud the object is fundamentally lost, and the subject spends his life looking for it. The object of psychoanalysis is the lack of an object, and this lacking object is at the heart of being. Lacan started elaborating on this notion of a lack of being in 1957, when he

set about describing the oedipal crisis in terms of the dialectic of desire and the question of the phallus.

During the mirror stage, the infant identifies with a certain point within the maternal space. In fact, what the subject takes for its own being is an other, both an image in the mirror and an alter ego. This fundamental alienation establishes misapprehension whereby one's being is confused with one's ego. From the beginning the subject is torn. He is divided between the place from which he sees himself, and the image, the other with which he identifies. From this perspective, a human being can never experience a wholeness that would amount to being.

Because language allows the child to symbolize the mother's alternating presence and absence, it makes it impossible for the child to become one with the mother. From this point on, a gap is introduced between the mother and child and any illusion of totality is broken. The subject experiences his lack of being, and when father later appears to put the phallus into play, he proves the lack of being of the maternal phallus. "[T]he child's desire manages to identify with the mother's want-to-be" (Lacan, 2002, p. 197). This desire begins as a quest for an object that might fill this lack.

Paradoxically the subject, as an effect of the symbolic (trapped within language), can only use language to search for the lost object. As Lacan wrote, "The being of language is the nonbeing of objects" (p. 253). Being is only a "lack of being," and the thing that could fill this lack is forbidden. This prohibition maintains desire. Thus desire appears as the metonymy of a lack of being whose signifier is the phallus that marks what the mother lacks. The subject's being is lack, and the cut that produced the symbolic is the object *a*, which is the real insofar as it is articulated in the symbolic and which is also a gap that the ego as image occupies. The image of the body, the principal mirage, indicates the place of desire insofar as it is desire for nothing. This is the relation of human beings with their own lack of being. But at the same time, the image is what prevents the human being from seeing it.

## WAR NEUROSI

Freud's interest, and that of his disciples, in war neurosis (*névrose de guerre*) developed during the First World War (1915b). The first psychoanalysts had an opportunity to observe and to monitor many patients presenting such distinctive symptoms as paralyses, tremors, recurring nightmares, the loss of sexual desire, and the like, all related to the experience of war. Observations and debate on these cases were presented in 1918 to the Fifth International Congress in Budapest, by Freud, Sándor Ferenczi, Karl Abraham, Ernst Simmel and Ernest Jones. As well as the scientific interest in these pathologies there was a need to prove to detractors of psychoanalysis (who were only too happy to see a picture of neurosis emerge that left, according to them, no room for the unconscious) that war neurosis had in effect a definite kinship with transference neuroses and hysteria.

The common denominator would be trauma, which acts by breaching the psychic apparatus, and which may appear either from the outside (traumatic neurosis) or even from the inside (transference neurosis) of the subject. In every case the trauma consists of too great a quantity of excitation, which ruptures the protective shield system, the psychic envelope. Generally the symptoms appear after a clear interval and take hold as a defense against anxiety.

From this period on, psychoanalysts have demonstrated that trauma acts as a precipitating factor, revealing a pre-existing neurotic structure; war then being the second instance or the "afterwardsness" of an infantile trauma. (*Afterwardsness* is Jean Laplanche's neologism to translate *après coup* and *Nachträglichkeit* into English. *Deferred action* is the term used frequently in the Standard Edition.) The symptoms (rumination over the traumatic event, recurring nightmares, insomnia) appear as repeated attempts to bind and abreact the trauma.

As the issue of the psychic after-effects of war is always unfortunately topical, these works are used as a benchmark for the teams who organize the treatment

of war victims in their countries, as the articles of Marie-Rose Moro testify. But furthermore there is a line of thought that results today in “Post Traumatic Stress Disorders,” and which breaks, unfortunately, with metapsychological topography and with the theory of afterwardsness.

## **WASHINGTON PSYCHOANALYTIC SOCIETY**

The organizational history of psychoanalysis in the Washington D.C.-Baltimore metropolitan area is as convoluted and complex as the intellectual weave that created it. Psychoanalysis started early in Washington, embraced by key U.S. psychiatrists, and it mutated and expanded over the better part of a century. Currents of thought and practice, often in conflict, came to include ego psychology, Freudian revisionism, Sullivanian interpersonal theory, and the use of psychoanalytic theory to understand and treat psychoses. Among the important figures in its history must be counted

psychiatric pioneers Adolf Meyer and William Alanson White, the maverick Harry Stack Sullivan and his colleagues Frieda Fromm-Reichmann and Clara Thompson, and the determined Viennese defender of orthodoxy, Jenny Waelder-Hall.

The precursor to the Washington Psychoanalytic Society was founded in 1914, with William Alanson White as its chair. Like several other psychiatrists fascinated by Freudian ideas, White was superintendent of the Government Hospital for the Insane, soon to be renamed St. Elizabeth's Hospital. White, who had been interested in Freud's teachings since about 1909, became the first American author of a book on psychoanalysis when his *Mental Mechanisms* was published in 1911. Other significant figures early on the Washington scene included Adolf Meyer, who was associated with Johns Hopkins University, Ives Hendrick of Sheppard and Enoch Pratt Hospital, and John MacCurdy, one of the founders of the American Psychoanalytic Association. Interest in treating the psychoses was common to all these figures, and the use of analytic ideas for therapeutic ends with severe psychopathology became an enduring feature of psychoanalysis in Washington-Baltimore.

Members of the Washington Society originally met regularly and discussed papers. A hiatus at the end of the First World War lasted for several years, and for a time the organization changed its name to the Washington Psychopathological Society to distinguish itself from a competing society. By the late 1920s, however, distinguished analysts were visiting Washington from abroad and the society had attracted significant local psychiatric talent. Ernest Hadley, one of the first to open a private psychoanalytic practice in Washington, became a major administrative figure in the American Psychoanalytic Association (APA) over the next two decades.

Efforts to create a more formal group culminated with the founding of the Washington-Baltimore Psychoanalytic Society in 1930. From the beginning the institute situated itself as a constituent of the APA, to which it became accredited in 1932; it also subsequently affiliated with the International Psychoanalytical Association. Members soon created a training program, formally established as the Washington-Baltimore Psychoanalytic Institute in 1940. Lewis Hill directed the institute until 1949; he was succeeded by Ernest Hadley for five years thereafter, until the latter's death in 1954.

Background and education of members of the Washington-Baltimore society in its early years distin-

guished them in the broader context of the evolution of psychoanalysis in the United States. "From the beginning," wrote Donald L. Burnham (1978) in an early historical evaluation, "diversity of membership and of approaches was a feature of the psychoanalytic groups which formed in this region." He added, "This may have been partly because of their 'home-grown' quality. There was less leadership and dominance from analysts who had come originally from Vienna or Berlin" (p. 89). Analysts in Washington included Midwesterners, Roman Catholics, and children of rural America.

Harry Stack Sullivan, a representative American who had grown up in upstate New York, strongly affected the whole trajectory of psychoanalysis in Washington-Baltimore; in retrospect, his influence was as pervasive and crucial as it was controversial and divisive. Like Meyer and White, Sullivan came to psychoanalysis via the treatment of psychoses. Soon after establishing the Washington Psychoanalytic Institute, he went on, during the mid-1930s, to help found the William Alanson White Psychoanalytic (later changed to: Psychiatric) Foundation and Washington School of Psychiatry. Active and influential in psychoanalytic circles, Sullivan was also loudly not a conventional analyst and eventually he developed a systematic theory of development that emphasized the interpersonal determinants of psychological life and the cultural components of mental disorders.

Sullivan's predominance also expressed itself through the people he influenced in Washington and Baltimore, as well as those he antagonized. Clara Thompson was a friend, colleague, and ally who became a powerful figure in the Washington-Baltimore Psychoanalytic Society and helped establish and lead the William Alanson White Institute in New York, originally as a satellite of the Washington-Baltimore Institute. Frieda-Fromm Reichmann, who was also influenced by Sullivan, became prominent in treating severe mental illness with intensive psychotherapy, and was active in all the local organizations. On Sullivan's antagonistic side was Jenny Waelder-Hall, a Viennese-trained analyst who arrived in Washington in the mid-1940s. Considerable personal enmity grew up between her and Sullivan, said to be apparent from their first meeting. Donald Burnham (1978) suggested that "it is tempting to view Waelder-Hall and Sullivan not only as eloquent spokesmen but as literal personifications of Vienna orthodoxy and American eclecticism and of the difficulty, if not impossibility, of reconciling the two" (p. 102).

The permutations that occurred in Washington psychoanalysis soon after the end of World War II pro-

ceeded, in any event, along intellectual fault lines with the help of some personal and professional hostility. By 1946 the Washington-Baltimore Psychoanalytic Society split into two groups, although they would share a single training organizations until separate institutes were both officially approved in 1952 and fully accredited by the American Psychoanalytic Association three years later. The Baltimore Psychoanalytic Society represented a strong version of the European and Viennese current of orthodoxy led by Waelder-Hall; while the Washington Psychoanalytic Society, although it included orthodox analysts, also expressed Sullivan's influence, which was to outlast his premature death in 1949.

Using psychoanalysis to treat severe mental disorders followed a unique and separate but intertwined trajectory in Washington-Baltimore. Apart from the early work of Meyer and White, Sullivan, who declined to accept the therapeutic pessimism commonly seen in European psychiatry concerning psychosis, developed a treatment scheme for schizophrenia for which he claimed a high rate of success. By the late 1930s, Chestnut Lodge, a private sanatorium in Rockville, Maryland, became the site of efforts to treat patients with severe mental illness using psychodynamic principles. Invited by director Dexter Bullard, Frieda Fromm-Reichman became the first of a number of psychoanalysts to employ intensive, long-term therapy with schizophrenics at Chestnut Lodge.

Although tensions between orthodox analysis and dissident currents persisted through the 1950s and 1960s in Washington-Baltimore, the period saw steady growth in psychoanalysis at a time when the profession found support at the National Institute of Mental Health and a host of local institutions, including Walter Reed Hospital and Georgetown University Medical School. In the institutional skein, many prominent analysts held multiple appointments. When Fromm-Reichman's celebrated *Principles of Intensive Psychotherapy* was published in 1950, for example, she not only was a leader at Chestnut Lodge but taught at the Washington School of Psychiatry and the Washington-Baltimore Psychoanalytic Institute, as well as the William Alanson Institute of Psychiatry in New York.

By the 1970s, the decline of psychoanalysis as a medical specialty led to modifications in many programs that encouraged postgraduates outside of medicine, and those in Washington and Baltimore were not exceptions. The Washington Psychoanalytic Institute

expanded its theoretical base, and training has come to embrace a diversity of viewpoints in addition to a Freudian core, including object-relations theory, self psychology, intersubjectivist, and constructivist approaches. The Baltimore Psychoanalytic Institute, founded by Jenny Waelder-Hall on classical lines, was now the Baltimore-Washington Psychoanalytic Institute, and relocated to Laurel, Maryland. It modified its programs beginning in the 1960s, and now trains psychologists and social workers as well as psychiatrists.

Other institutes also opened in the Washington-Baltimore metropolitan area in the last two decades of the twentieth century. The International Institute of Object Relations therapy, founded by David E. Scharff and Jill Savage Scharff, is based in Chevy Chase, Maryland, although it has created training modules in nearly a dozen other cities. The Institute of Contemporary Psychotherapy and Psychoanalysis of Washington, founded by Joseph Lichtenberg and Rosemary Segalla, bases its training program on Heinz Kohut's self psychology.

## **WEANING**

Weaning is the name for the suppression or reduction of breast milk and/or baby formula to replace it with more solid food. Weaning is at the crossroads of biology, culture, and the psychic organization of the mother/child dyad.

Weaning involves the interactive process of interruption of the corporeal relationship between mother and child. It begins spontaneously during the second six months of life as an effect of the infant's maturation; the infant manifests a decreased interest in feeding, especially if it has been breast fed, and begins an active search

for autonomy that the mother can perceive and facilitate according to her affective syntony with the infant, as Benjamin Spock described in "The Striving for Autonomy and Regressive Object Relationship" (1963), according to her affective syntony with the infant.

In his *Introductory Lectures on Psycho-Analysis* (1916–1917a [1915–1917]), Sigmund Freud described weaning as traumatic, perhaps owing to syntony, but also as the moment when nostalgia for the mother appears, which is present in all infants, and above all in those who have not been breast fed. Melanie Klein studied the relations between weaning and the depressive position that accompanies it and that continues on thereafter. In "Les complexes familiaux dans la formation de l'individu" (Family complexes in the formation of the individual; 1938), Jacques Lacan organized the various points of view in the following way: Traumatic or not, he explained, weaning leaves in the psyche a permanent trace of the biological relationship it interrupts. This moment also presents the twofold aspect of a crisis in the psyche, the first that unquestionably has a dialectical structure. For the first time, a vital tension is expressed in terms of a mental intention.

Weaning forms the basis for the positive aspect of the weaning complex, that is, the image of nourishment that tends to establish the most archaic and stable feelings uniting the individual with his or her family: It thus constitutes the basis of familial and social life.

In *L'Image inconsciente du corps* (The unconscious image of the body; 1984), Françoise Dolto discussed weaning as an oral castration of the child, that is, an imposed deprivation of what for him or her is cannibalism in relation to the mother. Dolto also elaborated E. Forman's concept of motherhood as a developmental stage and associated the possibility of successful weaning with the mother's ability to accept the interruption of body-to-body contact, and above all, to communicate with the infant in various ways, among them providing food, but also by means of words and gestures, which represent the desire and possibility to speak for the child: "The baby is talking about feeding, but not about the breast."

The time of weaning, ever earlier in our culture, represents the relational conflict characteristic of the late oral or oral-sadistic stage. Bernard Golse emphasized its ambivalent aspect, due to the fact that incorporating the mother becomes destructive with teething. The infant who suckles the breast attacks it and wins nourishment

by inflicting hurt. The cannibalistic impulses of the two partners are reciprocally activated, and both must learn to sense and control aggression. This is indeed what happens in cases of “good” weaning, due both to a simultaneous establishing of distance by the mother and by the infant and to the working out of the child’s aggressive and libidinal requirements in the presence of the mother as an object.

Failures in weaning include late weaning (often because of the mother’s desire to prolong the erotogenic pleasure of nursing), which can be experienced by the infant as punishment and which makes the process of separation/individuation difficult. Inversely, premature weaning—that is, before the infant has been able to invest other objects—has varying effects according to the circumstances. Among the most serious failures, there is fusion of the life instinct and the death instinct, as in cases of mental anorexia or addictions to orally ingested substances. In extreme cases of weaning following abandonment, Dolto explained in *Les Étapes majeures de l’enfance* (The major stages of childhood; 1994), a behavioral regression, due to residual fantasies from before the trauma, compromises the previously acquired sound-producing capability of the larynx and the oral cavity. Psychogenic mutism can ensue, with or without loss of hearing.

James S. Grotstein studied the end of analytic treatment as a weaning that makes possible a liberation of narcissism with the aim of accepting the world as it is. Paul-Claude Racamier more specifically described weaning from the sleeping treatment, during which patients are lavished with maternal care that helps them to emerge from the regression and to establish very deep bonds with the physician providing treatment.

## **WEININGER, OTTO (1880–1903)**

Otto Weininger, an Austrian and Jewish intellectual, was born on April 3, 1880, in Vienna, where he committed suicide on October 4, 1903. Adelheid, Otto’s mother, whose health was frail, was a submissive wife to his father, Leopold, a renowned goldsmith and powerful personality. Of his six brothers and sisters, only four reached adulthood. A gifted student, Otto entered the University of Vienna in 1898 and took courses in all the various subjects he would later treat in his *Sex and Character* (1906). His professors included Friedrich Jodl, Ernst Mach, and Richard von Krafft-Ebing. He also frequently attended gatherings of the university philosophical society. In 1900 he traveled to Paris with Hermann Swoboda to attend a conference on psychology, where he sided with those in favor of an introspective approach to psychology as opposed to an experimental and biological approach.

Weininger began writing *Sex and Character* (originally entitled *Eros and Psyche*) in the autumn of 1900, and the book progressed through an exchange of ideas with Swoboda. In 1901, after having registered the copyright to his manuscript, he sought to publish it, and with this in mind he showed an outline to Freud, who was not favorably impressed. In 1902 Weininger submitted a revised version of the book to obtain his doctorate in philosophy. On the day he received his degree, he converted to Christianity. A third version of his book—with the added chapters “Judaism,” “Women and Mankind,” and “Woman and Her Significance in the Universe”—was published in June 1903 by the major publishing firm Braumüller.

Weininger suffered from severe mood swings of exaltation and depression. During the summer of 1902, he traveled in Northern Europe and, writing to his friend Arthur Gerber, asked, “Am I anything?” Weininger left for Italy in somber spirits. In Calabria on August 21, 1903, he drafted a new will and testament that replaced the one he had written the previous February 13. Returning home depressed, he spent five days at his parents’ home. On October 3 he shot himself through the heart in a rented room in the house in which Beethoven, his favorite musician, had died.

Weininger was buried in a Protestant cemetery; his father wrote the text for his gravestone. Leopold Weininger admired his son’s book and firmly defended Otto’s memory after his death, though Leopold did confide information about Otto to a psychiatrist, who betrayed his trust.

In 1904, texts collected by Weininger’s friend Moritz Rappaport were published as *Über die letzten Dinge* (translated as *On Last Things* [2001]). There Weininger’s suicide was explained as a logical conclusion to *Sex and Character* to insure its success both with a large general audience and among intellectuals. In 1906 Wilhelm Fliess’s charge of double plagiarism, specifically, that Freud had passed on Fliess’s original ideas about bisexuality to Weininger and Swoboda, also fueled the book’s notoriety. In the case of “Little Hans” (Herbert Graf), Freud wrote, “Weininger was completely under the sway of his infantile complexes; and from that standpoint what is common to Jews and women is their relation to the castration complex” (1909b, p. 36n). In his book, Weininger bears witness to the confusion about sexuality and science that was characteristic of the time.

## **WEISS, EDOARDO (1889–1970)**

Edoardo Weiss, a physician and psychoanalyst, was born in Trieste (then a part of Austria-Hungary), on September 21, 1889, and died in Chicago on December 14, 1970. He spent his childhood and adolescence in Trieste, part of a stable, well-to-do Jewish family originally from Bohemia. After studying German in high school, he enrolled in 1908 in medical school in Vienna. In October of that year, he visited Freud, whose essay on the *Gradiva* he had previously read. Weiss suffered from a slight case of agoraphobia and wanted to talk to Freud about his desire to practice psychoanalysis. Freud sent him to see Paul Federn, with whom he began therapy, which lasted until 1911. Weiss, the first president of the Italian Psychoanalytic Society and a member of the Vienna Psychoanalytic Society in 1913, was the real founder of the psychoanalytic movement in Italy.

In 1914 he joined the Austro-Hungarian army as a physician. He was initially assigned to Lublin, Poland, then sent to the Croatian front. It was in Lublin, in a hospital train, that he met his friend and fellow student, Viktor Tausk, whose depression from the war and declining relations with Freud had affected him deeply.

In 1917 Weiss married Wanda Shrenger. Weiss met his wife at the University of Vienna; she would become the first woman admitted to the Italian Psychoanalytic Society. In 1919 he returned to Trieste, then a part of Italy, to work as a psychiatrist in a provincial hospital. He also opened his own practice as a psychoanalyst, introducing the field to men such as Italo Svevo and Umberto Saba—in other words, the leading representatives of Italian literature.

In 1927 he was forced to resign from the psychiatric hospital where he worked, due to his failure to join the Fascist party and Italianize his name. He moved to Rome, where he published *Elementi di psicoanalisi* (1931). In

1932 he re-established the Società Psicoanalitica Italiana and launched the review, *Rivista italiana di psicoanalisi*.

In 1932 Emilio Servadio, who had trained with Weiss and who was interested in parapsychology, organized several sessions with a medium in order to demonstrate the existence of paranormal phenomena. Weiss informed Freud of his conviction in the authenticity of the phenomena he had witnessed firsthand and received the following response: "Given your role as a pioneer of psychoanalysis in Italy, it would be unfavorable to consider you at the same time a pioneer of occultism."

In 1935 Weiss managed to obtain official recognition from the International Psychoanalytical Association (IPA) for the small Italian psychoanalytical society and, with his students Nicola Perrotti and Emilio Servadio, attended the International Congresses in Wiesbaden (1932), Lucerne (1934), and Marienbad (1936).

Having emigrated to the United States in 1939, he joined the Menger Clinic in Topeka, Kansas, in 1940, then moved to Chicago, where, together with Franz Alexander, he became interested in the application of psychoanalysis to psychosomatics. In 1942 he became a training analyst at the Chicago Institute of Psychoanalysis. In 1950 he took on the responsibility of collecting the writings of Paul Federn in order to promote an awareness of phenomenological ego psychology, which in his opinion had been misunderstood by Freud.

In his last years Weiss taught at Marquette College in Milwaukee as a guest lecturer for a couple of years, while he was consistently a training analyst at Chicago for many years, until his retirement. In 1970 his correspondence with Freud was published under the title *Sigmund Freud as Consultant*.

His writings include *Agoraphobia, isterismo d'angoscia* (1936), *Principles of Psychodynamics* (1950), *The Structure and Dynamics of the Human Mind* (1960), *Agoraphobia in the Light of Ego Psychology* (1964), and some seventy articles. It was Weiss who introduced the term *destrudo* to express the death instinct, and the concepts of *projective identification* (created by Weiss in 1925, before Melanie Klein and with a slightly different meaning), *psychic presence*, *resonance*, and *ego transition*, which were critical for understanding the nature and modality of object relations. Weiss was especially interested in agoraphobia, our understanding of which he considerably deepened in several articles and two monographs.

## WELTANSCHAUUNG

The term *Weltanschauung*, literally, "view of the world," had a very specific meaning for Freud, who defined it in the New Introductory Lecture as follows: "A *Weltanschauung* is an intellectual construction which solves all the problems of our existence uniformly on the basis of one overriding hypothesis, which, accordingly, leaves no question unanswered and in which everything that interests us finds its fixed place" (1933a [1932], p. 158).

Indeed Freud had already used this concept as a stick with which to beat philosophies and religions—both lambasted, for example, in his *Future of an Illusion* (1927c). In 1933, however, he broadened the notion, bringing science too under its aegis; this with the proviso, though, that "the *Weltanschauung* of science already departs noticeably from our definition. It is true that it too assumes the uniformity of the explanation of the universe; but it does so only as a programme, the fulfillment of which is relegated to the future." (pp. 158–159). The fact was that the notion of *Weltanschauung* usefully supplemented that of culture,

for it helped specify culture’s different spheres and point up their underlying emotional *raison d’être*.

Freud extolled and defended the virtues of an intolerance that refused, in the name of “truth,” to consider all domains of human intellectual activity to be of equal value: “It is simply a fact that the truth cannot be tolerant, that it admits of no compromises or limitations, that research regards every sphere of human activity as belonging to it and that it must be relentlessly critical if any other power tries to take over any part of it” (p. 160). It has to be said, therefore, that Freud’s views on religion and especially on philosophy were rather narrow—judging, as he did, that they were totally closed to doubt. On the other hand, his opposition to dogmatism is much easier to comprehend if one bears in mind that dogmatism constitutes the major temptation for any theoretician, and no doubt for Freud himself with respect to psychoanalysis. And it was certainly for the sake of psychoanalysis that he defended the ideal of scientific asceticism.

Apropos of the religious *Weltanschauung*, in 1933 Freud articulated ideas he had expressed in *Totem and Taboo* (1912–13a) on the formation of religions, while restating, in essence, some themes of *The Future of an Illusion* concerning the way religion panders to humanity’s “desire for knowledge” and to its infantile need for protection. To emphasize how risky a religious view of the world is to thought, which it limits through its interdictions, he also revisited the ideas expressed in “Civilized Sexual Morality and Modern Nervous Illness” (1908d). Most of Freud’s observations on the notion of *Weltanschauung* were in fact concerned with religion, but he did also mention art, which for him was “almost always harmless and beneficent; it does not seek to be anything but an illusion” (1933a [1932], p. 160), and philosophy, about which he wrote: “Philosophy is not opposed to science, it behaves like a science and works in part by the same methods; it departs from it, however, by clinging to the illusion of being able to present a picture of the universe which is without gaps and is coherent” (p. 160).

Another kind of *Weltanschauung*, about which Freud usually had very little to say, save for his considerations on war, was politics, and specifically Marxism, to which he opposed a conception of the evolution of societies that was just as materialist as Marx’s, but without any real discussion of Marx’s theories, which seemed to him to be derived from “the obscure Hegelian philosophy, in whose school Marx graduated” (p. 177). Nihilism of the anarchist variety he denounced

as pure sophistry; it nevertheless constituted an attack on the very core of scientific ideals, since it abolished the criterion of truth.

Finally, Freud’s reflections on the notion of *Weltanschauung* were generally conflated with an earnest and vibrant pleading of the case of science, as when he said about the common man: “Truth seems to him no more capable of comparative degrees than death” (p. 172). His conclusion was a real rallying cry: “A *Weltanschauung* erected upon science has, apart from its emphasis on the real external world, mainly negative traits, such as submission to the truth and rejection of illusions. Any of our fellow-men who is dissatisfied with this state of things, who calls for more than this for his momentary consolation, may look for it where he can find it. We shall not grudge it him, we cannot help him, but nor can we on his account think differently” (p. 182).

### “WHY WAR?”

In 1931 the Permanent Committee on Literature and the Arts of the League of Nations proposed exchanges of letters between intellectuals. Contacted in June 1932, Freud agreed to respond to Einstein’s letter, which he received in August. The result was a “Letter to Albert Einstein” titled “Why War?” On September 8, 1932, he stated to Max Eitingon that he had finally finished writing the “tedious and sterile so-called discussion with Einstein” (quoted in Jones, 1957, Vol. 3, p. 185). To Einstein’s question “Is there any way of delivering mankind from the menace of war?” (1933b [1932], p. 199), Freud would respond by returning to a number of issues that he had already addressed in his work on this subject,

from “Thoughts for the Times on War and Death” (1915b) to *Civilization and Its Discontents* (1930a). Instead of his correspondent’s proposal to consider the relationship between right and might, he preferred to consider the relationship between right and violence, and he argued that as distinct from the primitive law of the strongest, “right is the might of a community” (p. 205). But right itself cannot be exercised without violence. The wish to prevent war was no doubt embodied in the League of Nations, but that organization remained impotent, except on the level of ideas.

According to Freud, Einstein was correct in positing an instinct of hate in humankind, a notion that fit with “our mythological theory of the instincts” (p. 212). “The death instinct turns into the destructive instinct when, with the help of special organs, it is directed outwards on to objects. The organism preserves its own life, so to say, by destroying an extraneous one” (p. 211). This was a factual circumstance that had to be taken into account; the Bolshevist utopia clearly pointed up the illusion of egalitarian material satisfaction.

Freud acknowledged that he did not have much to propose: “We are pacifists because we are obliged to be for organic reasons” (p. 214). “We are shaped by the long process of the development of civilization, to which we owe the best of what we have become, as well as a good part of what we suffer from. Though its causes and beginnings are obscure and its outcome uncertain, some of its characteristics are easy to perceive. It may perhaps be leading to the extinction of the human race, for in more than one way it impairs the sexual function; uncultivated races and backward strata of the population are already multiplying more rapidly than highly cultivated ones. The process is perhaps comparable to the domestication of certain species of animals and it is undoubtedly accompanied by physical alterations; but we are still unfamiliar with the notion that the evolution of civilization is an organic process of this kind” (p. 214).

“How long shall we have to wait before the rest of mankind become pacifists too? There is no telling. . . . But one thing we can say: whatever fosters the growth of civilization works at the same time against war” (p. 215).

In the spring of 1932, William C. Bullitt presented Freud with the manuscript of their jointly authored “psychological study” of President Thomas Woodrow Wilson (1966). This study was in line with the hope that Freud expressed in the last pages of his letter to Einstein: “One instance of the innate and ineradicable

inequality of men is their tendency to fall into the two classes of leaders and followers. The latter constitute the vast majority; they stand in need of an authority which will make decisions for them and to which they for the most part offer an unqualified submission. This suggests that more care should be taken than hitherto to educate an upper stratum of men with independent minds, not open to intimidation and eager in the pursuit of truth, whose business it would be to give direction to the dependent masses. It goes without saying that the encroachments made by the executive power of the State and the prohibition laid by the Church upon freedom of thought are far from propitious for the production of a class of this kind. The ideal condition of things would of course be a community of men who had subordinated their instinctual life to the dictatorship of reason. Nothing else could unite men so completely and so tenaciously, even if there were no emotional ties between them. But in all probability that is a Utopian expectation” (1933b, p. 212–213). In London in 1948 it was suggested that political leaders be systematically required to undergo psychoanalysis. This naturally elicited particularly acute reactions among psychiatrists who were members of the French Communist Party.

Written in that summer of 1932, on the threshold of the rise of Nazism and the deployment of the death instinct that would result from it, Freud’s reflections later became a premonition whose accuracy he could not possibly have imagined.

## WIENER PSYCHOANALITISCHE VEREINIGUNG

The history of the Wiener Psychoanalytische Vereinigung (Vienna Psychoanalytical Society) is the primal history of psychoanalysis. The members of the Psychological Wednesday Society commenced their meetings in Freud's apartment in 1902. In 1908 the group adopted the designation "Vienna Psychoanalytical Society" and was registered under this name as a local group of the newly formed International Psychoanalytical Association in Vienna. Most of the members of the Vienna Psychoanalytical Society were of Jewish origin and shared the history of the Jews in the twentieth century.

The Society's first president was Alfred Adler, who resigned in 1911, after which Sigmund Freud himself took over the helm until 1938. The founding period was of course characterized by the genius of Freud, who built the Society's fortunes not only through his theories but also by his skills as an organizer. Sándor Ferenczi described this as the time of heroism and guerrilla war. Adler and others resigned at the end of 1911 and formed the Society for Free Psychoanalytic Research, later known as the Society for Individual Psychology. Practically all activities of the Vienna Psychoanalytical Society ceased during the First World War because, as Freud put it, the voice of psychoanalysis could not make itself heard above the thundering of cannon. When the war was over, the society quickly resumed operations. As regards its organization, two groups of members can be distinguished: representatives of the society's "heroic phase" like Paul, Otto Rank, and Eduard Hitschmann; and the second-generation analysts, most of whom had already undergone formalized training, such as Anna Freud, Helene and Felix Deutsch, Edward and Grete Bibring, Wilhelm Hoffer, Wilhelm Reich, Richard Sterba, Otto Fenichel, and Siegfried Bernfeld.

When this new generation of psychoanalysts took over, training was institutionalized and a psychoanalytic outpatient clinic was established. The foundation of the clinic in 1922 was followed two years later by that of the

training institute. The clinic was headed by Eduard Hitschmann, with Wilhelm Reich as his deputy. In May 1936, after many peripatetic years, the Vienna Psychoanalytical Society finally acquired premises of its own at Berggasse 7, where the society itself, the training institute, the outpatient clinic and the Internationaler Psychoanalytischer Verlag (the publishing house) were accommodated. The head of the training institute was Helene Deutsch, who already complained in her report for 1932 that the number of Austrian candidates had dropped sharply owing to the economic crisis. In the summer semester of that year the Vienna Psychoanalytical Society had 22 candidates, of whom 12 were American, 2 German and 8 Viennese. After Hitler's coming to power in 1933, significant numbers of candidates from Germany found a place for themselves at the training institute of the Vienna society.

After falling ill with cancer, Sigmund Freud was no longer able to take part in the society's scientific meetings. Its affairs were managed by Paul Federn, who was elected deputy president after Otto Rank's departure in 1925, and later by Anna Freud, who was elected second deputy and spoke for her father on the executive. A powerful influence on the affairs of the society was exerted by its "expanded executive," which met on Wednesday evenings at the Berggasse premises.

The imposition of an authoritarian constitution in Austria in 1934 and Hitler's coming to power in Germany did not present an immediate threat to the Vienna society. Although many members of the Society sympathized with the then banned Social Democrats, few—among them Siegfried Bernfeld, Otto Fenichel, Hermann Nunberg, Buchsbaum, Wilhelm Reich, and Friedjung—were politically engaged. However, "administrative measures" were adopted to prevent politically "dangerous" activity in the illegal left-wing groups by members and candidates.

The Vienna Psychoanalytical Society's heyday was in the late 1920s and the 1930s. Some of the seminal works of ego psychology originated at this time—for example, August Aichhorn's *Wayward Youth* (1925), Heinz Hartmann's *Die Grundlagen der Psychoanalyse* (Fundamentals of psychoanalysis; 1927), Anna Freud's *Introduction to Psycho-Analysis for Teachers* (1930) and later *The Ego and the Mechanisms of Defence* (1936), or Hermann Nunberg's *Principles of Psychoanalysis* (1932), which was based on lectures at the society. Whereas Vienna already had a rival in the thriving Berlin Psychoanalytic Institute in the 1920s, many Jewish psychoanalysts came to

Vienna or to the society's branch in Prague after the Nazis took power in 1933.

Max Schur (1972) noted in his memoirs that Hitler had made an overwhelming impression on the Austrian people and that many of those in Schur's group were convinced that the country would be unable to withstand the rising tide of Nazism. The first wave of emigration commenced in these years, those who left including Helene and Felix Deutsch, Siegfried Bernfeld, Ludwig Jekels, Wilhelm Reich, Hanns Sachs and Fritz Wittels. However, the endurance of Freud and his comrades who stayed behind was unrewarded. Freud's view that the Austrian people were not quite so brutal, expressed in a letter to Arnold Zweig, proved to be false. The Wehrmacht marched into Vienna on March 12, 1938, and the Vienna Psychoanalytical Society's executive held its last meeting on March 13. It was resolved that everyone who could should flee the country and that the seat of the society should be transferred to wherever Freud settled. The 68 extraordinary and ordinary members of the Vienna Psychoanalytical Society, as well as an estimated 36 candidates, had to leave Vienna; only Alfred von Winterstein and August Aichhorn stayed put.

Freud himself was able to depart with his family on June 4, 1938. At the 15th International Psychoanalytical Congress in Paris, Ernest Jones said in his opening address that it was breathtaking to think that, of all cities in the world, it was precisely in Vienna that psychoanalysis was no longer to be practiced.

From 1938 August Aichhorn gathered a small circle about him. He noted in his "Gedenkschrift" [commemorative review]: "Starting with training analyses and continuing with regular seminars and courses and with the study of the works of the Freud school, the group strove to attain its goal. One of our friends, Count Karl von Motesicky, who had contributed much to the foundation of the group, died in a concentration camp. . . . Without formalities and difficulties, but exercising caution towards the outside world, the group worked on throughout the period in a genuine spirit of loyalty and friendship." From 1938 until 1945, Vienna was a branch of the "German Reich Institute of Psychological Research and Psychotherapy"; it was headed temporarily by Aichhorn, who was replaced by Gebattel in 1943.

After 1945, The Vienna Psychoanalytical Society was spared the fate of the German Psychoanalytical Society and the arduous birth pangs of the German Psychoanalytical Association; it was eventually reopened by Aichhorn,

who wrote: "Now our path is clear; everyone can follow his own research inclinations without hindrance, and everyone is indeed doing so." Nor was it long before IPA recognition was forthcoming. However, it took decades for the Vienna Psychoanalytical Society to re-establish its links with international psychoanalysis. In setting about the task of reconstruction, it was pervaded by the melancholy realization that, while it had to preserve Freud's legacy, it could no longer aspire to the intellectual greatness and influence of the old society. This was the prevailing atmosphere for many years. After the trauma of the expulsion and annihilation of the Jews and the ensuing destruction of psychoanalysis in Vienna, a cloak of silence descended over the unspeakable.

Upon Aichhorn's death in 1949, Winterstein succeeded to the presidency and remained in office until 1957.

In 1950 the Society had just one candidate in training, and the mood emerges clearly from a letter written by Winterstein to Glover: "The only tendency which I have observed in the last few years, and which I have been enjoining the members to follow since I became president, is to immerse themselves in the study of Freud's writings and to explore new ideas with great caution."

Except for the interregnum of A. Becker (1972–74), Wilhelm Solms-Rödelheim and Harald Leupold-Löwenthal occupied the presidency from 1957 until 1982. Solms was one of the founders of the "Mitteleuropäische Arbeitstagung" (Central European Working Conference), which links the German-speaking psychoanalysts to this day, and also played an important part in the formation of the EPF. The International Psychoanalytical Congress held in Vienna in the summer of 1971 renewed the society's ties with international psychoanalysis. The society began to grow again. After fierce argument over the incorporation of group psychoanalysis and the status of child analysis, a new generation of officers took the helm in 1982. Impelled by the candidates and younger members, a period of intense debate about the Vienna Psychoanalytical Society's past commenced. Although the older members were politically relatively untainted after the war, their mentality had been molded by it, and the society effectively continued its subterranean existence.

Peter Schuster became president in 1982 and was succeeded in 1984 by Wolfgang Berner, whose period of office was distinguished by the rapprochement with contemporary psychoanalysis and the holding of the EPF congress in 1993. The society's president from

1993 until 1998 was Wilhelm Burian. A central concern of the organization since the 1980s has been the permanent reorganization of training so as to bring it into line with international standards. An indication of the laboriousness of this process is the fact that the third revision of the training regulations is as of 2005 being discussed. Unfortunately psychoanalysis has remained substantially a Viennese phenomenon for the Austrian public; debate is largely confined to the Vienna Psychoanalytical Society, the Vienna Arbeitskreis für Psychoanalyse (Psychoanalytic study group) and the Freud-Gesellschaft. Like many psychoanalytic organizations, however, the Vienna Psychoanalytical Society has been increasingly preoccupied with itself and has shown relatively little orientation towards the outside world. Around the start of the twenty-first century public relations functions have been assumed with great professionalism by the Sigmund-Freud-Gesellschaft and the Freud Museum.

After prolonged peregrinations, the Vienna society moved into its new headquarters at Gonzagagasse 11 in 1986. By 2005, it had over 70 members and some 100 candidates, thus for the first time exceeding the membership level of 1938. Its work in the 1980s centered on anti-Semitism both within and outside analyses and the working through of the society's wartime and post-war past. Other themes have included the relations between psychoanalysis and psychoanalytic psychotherapy—a debate that culminated in the incorporation of a seminar on psychoanalytic psychotherapy in the training syllabus. In the fields of theory and clinical practice there have been many, sometimes violent, arguments about the future direction of psychoanalysis and the influence of other psychoanalytic schools, such as the “modern Kleinians” and object-relations theory as opposed to classical drive theory. The latter prevailed the late 1990s and still has a not inconsiderable number of adherents. Meanwhile, however, the society had also become an official professional organization, oscillating between the isolation of “toeing the line” and “traitorous participation” in the state bodies for psychotherapists. In 1989 the general assembly of the Vienna Psychoanalytical Society resolved by one vote to join the “Dachverband für Psychotherapie” (Confederation of psychotherapy) and later the Psychotherapiebeirat (Psychotherapy advisory committee). Then, in 1993, the Vienna Psychoanalytical Society became the first training organization to obtain recognition under the provisions of the Psychotherapy Law. The political work on the committees

and vis-à-vis the public has, in truth, not aroused much interest. However, if one were to compile an interim report, it would state that, although the Vienna Psychoanalytical Society is no longer the “hub” around which the other societies revolve, as it was before 1938, it has after a long period of hesitation shrugged off its self-imposed isolation and thereby regained its place in international psychoanalysis.

### WILBUR, GEORGE B. (1887–1976)

George B. Wilbur was the second editor of *American Imago*, following the death of its founder Hanns Sachs, and Wilbur maintained that editorial position from 1947 until 1963. Wilbur was born in Larned, Kansas, on December 22, 1887, and died on Cape Cod in Hyannis, Massachusetts, on April 4, 1976.

Wilbur had first gone as an analytic patient to Otto Rank in New York City in the fall of 1926, at a time when Rank was over on one of his early trips to the United States. At the time there was little publicity about Rank's problems with Freud; Rank's *The Trauma of Birth* (1923) was originally dedicated to Freud, and analytic pupils abroad then thought the book had Freud's

blessings. Wilbur also went to Paris in the spring of 1927 to conclude the analysis with Rank; Wilbur’s wife Joy also went to Rank then for treatment. The Wilburs had put a mortgage on their house to finance the trip to Paris, which cost three or four thousand dollars, with one thousand going to Rank.

When Sachs died early in 1947, he had become a respected Boston analyst who also taught at Harvard Medical School, and Wilbur at that time went through all Sachs’s papers. By then Wilbur was an established early member of the Boston Psychoanalytic Society, although he practiced on Cape Cod. Sachs and Rank had been the original Viennese co-founders of *Imago* in 1912, but their intimate friendship did not survive the problems that arose between Freud and Rank. Wilbur insisted that there were no bitter feelings between Sachs and Rank, but that all the bitterness was in Jones’s biographical works.

Wilbur himself stayed in close contact with both Sachs and Rank; for a time, when the American Psychoanalytic Association (APA) was first considering making the Boston Psychoanalytic Society a branch affiliate, Wilbur’s association with Rank meant that he had to resign temporarily in the early 1930s from his membership in the Boston group, on the understanding that he would be reinstated after the APA’s acceptance of the Boston group had been secured. By 1936 Wilbur was once again a Boston analyst in good standing, although still living in South Dennis. Wilbur became a great expert on the details connected with the intellectual differences between Freud and Rank. Although Wilbur had been stigmatized within psychoanalysis for going to Rank in a year of the worst “vintage,” Wilbur maintained that he had never heard anything at all in his own analysis with Rank about the concept of the birth trauma.

Wilbur remained modest and unassuming, although he had graduated from Harvard College (1912) as well as Harvard Medical School (1916) before practicing as a psychiatrist. Wilbur was originally from Kansas, and heard about Freud first from his teacher, the psychologist E. B. Holt, at Harvard. Holt, like his own mentor William James, had been part of the Boston School of psychotherapy that preceded the coming of the Freudians. For a time Wilbur had practiced analysis in Iowa, until he first moved to South Dennis on Cape Cod in 1923. He preferred seeing patients a couple of times a week, and therefore felt himself more a Rankian than a Freudian, in that he became more interested in therapeutic improvements than in strict analysis. Wilbur, known among his

friends as “Jake,” appears in the American poet Conrad Aiken’s *Ushant* as “Jacob.”

### **“‘WILD’ PSYCHO-ANALYSIS”**

In a letter to Ferenczi dated October 27, 1910, Freud described this short text as a “little didactic paper” (vol. 1, p. 229). In “‘Wild’ Psycho-Analysis,” Freud described a consultation with a divorced woman who had come to him complaining of the crude advice given to her by her regular doctor, who, invoking the authority of psychoanalysis, had told her that she could remedy her anxiety only by returning to her husband, taking a lover, or masturbating.

Freud used this example to make several points. First, he stressed that, contrary to the claims of some of its detractors, psychoanalysis took “sexuality” to mean more than just sexual relations, and he preferred to use the word in a broader sense equivalent to that the verb “to love.” Second, he reasserted the sound basis for distinguishing the “actual neuroses” from those neuroses for which psychoanalysis was indicated, and he recalled that the analyst’s task is not just to explain the psychic causes of their conditions to patients, but also, and more importantly, to weaken the resistances that prevented them from discovering those causes for themselves. Psychoanalysis required an extended contact and the establishment of a transference relationship, without which the sudden revelation of secrets is “technically objectionable” (p. 226), even if on occasion the outcome is more

positive than that achieved by means of a pseudo-scientific explanation. In this connection, Freud evoked the notion of tact, which would later become the subject of an article by Ferenczi (1955).

Finally, because Freud's case involved a doctor who had not been psychoanalytically trained, he was able to point out that psychoanalytic technique could not be "learnt from books" but had to be "learnt from those who are already proficient in it" (p. 226). He also took this opportunity to announce the creation, in March 1910 at the Second Psycho-Analytical Congress in Nuremberg, of "an International Psycho-Analytical Association, to which its members declare their adherence by the publication of their names."

Freud would return to the necessity of psychoanalytic training in *The Question of Lay Analysis* (1926e), where he observed that "doctors form a large contingent of quacks in psychoanalysis" (p. 230).

### WINNICOTT, DONALD WOODS (1896–1971)

Donald Woods Winnicott, British psychoanalyst and pediatrician, was born in Plymouth, England, on

April 7, 1896, and died in London on January 25, 1971. He was the youngest child and only son of a prosperous provincial English merchant. He attended boarding school, where he read Darwin, and studied at the University of Cambridge, where he read Freud as an undergraduate. He entered the navy in 1917. In the First World War, while still a medical student, he both lost friends and saw action on a destroyer in the navy. Winnicott qualified as a physician in 1920. He gained membership in the Royal College of Physicians in 1922 and became a pediatrician.

From 1923 to 1924 he specialized in pediatrics, married, and began his training analysis with James Strachey. Later he had further analysis with Joan Riviere, and became a Kleinian training analyst. He became an associate member of the British Psycho-Analytical Society in 1934, a child analyst in 1935, a full member in 1936, and a training analyst in 1940. However, in the 1941–1945 controversial discussions in the British society between the adherents of Melanie Klein's views and the adherents of Anna Freud's, Winnicott played little part, finding himself unable to ally fully with either side. At that time, his interest in the effect of environmental factors on development made his ideas unacceptable to Klein. During the German blitz of the Second World War, he became a consultant to the Government Evacuation Scheme for London children. This work stimulated his thinking on the relationship between separation, deprivation, and delinquency, and it also introduced him to Clare Britton, a social worker who later became his second wife and lifelong colleague.

In 1944 Winnicott was elected fellow of the Royal College of Physicians. After the war he became director of the Child Department of the London Clinic of Psycho-Analysis and twice served as president of the British Psycho-Analytical Society (1956–1959 and 1965–1968). He lectured and broadcast on infant and maternal welfare, and inaugurated public lectures on psychoanalysis. He became active internationally, writing copiously for many audiences. While not joining any group in the British society, his thinking influenced members of the Middle Group, later the Independents. Winnicott died in his sleep after surviving several heart attacks.

Winnicott's work was informed by his vast experience in observing mothers and babies as a pediatrician, which allowed him to develop his ideas about the early experience of individuation and about ways of assessing psychic development, such as his spatula game and the Squiggle Game, for communicating with older

children. He described the psychophysiological state of a new mother as the “primary maternal preoccupation.” In contrast to Melanie Klein and Donald Fairbairn, who saw the infant as having a definable ego from birth, he saw the young infant as being undifferentiated from the mother, cryptically stating “There is no such thing as a baby,” meaning that a baby cannot exist alone, that there needs to be a mother or mothering person too. Close maternal attunement and repeated bodily care (the “facilitating environment”) allows the baby to begin to become aware simultaneously of its own separateness and that of its mother. Gradual and progressive failure of attunement at a rate at which the baby can increasingly tolerate (“good-enough mothering”) strengthens the emerging ego. The baby thus emerges from “absolute dependence” to “relative dependence” and begins to adapt to reality and the painful awareness of the mother’s separateness and all that this entails. Such adaptation includes the development of concern and capacity for guilt.

As the difference between the baby’s awareness of “me” and “not me” strengthens, many babies need a way of bridging a gap that might be too much for them. Such bridging explains the existence of transitional phenomena. The transitional space in which such phenomena occur provides room for the baby to develop play and an increasing ability to stand being alone. The baby becomes disturbed when lacking a “good-enough” environment, for instance, when a mother is physically or emotionally absent, disturbed, or intrusive, or when the baby has needs that cannot be fulfilled. When the mother cannot respond sensitively to the baby’s gestures but substitutes one of her own, her baby cannot be spontaneous, only compliant, even imitative—thus developing a “false self.”

Winnicott also wrote about the effect of mother’s unconscious states, including her unconscious hatred of her baby, and he linked such hatred with the hate that those responsible for delinquents develop toward their charges and the idea of hate in the countertransference. This developmental framework, with its implication that pathology is linked to environmental failure (either deficient provision for needs or impingement), allowed Winnicott to see that regression in analysis may be a search for the absent experiences, and it led him to emphasize that the analytic setting and the person of the analyst may stimulate the patient’s own inborn maturational tendency toward growth and individuation to bring about self-cure.

Strongly influenced by Klein, Winnicott accepted much of her thinking, particularly with regard to the internal world and its objects, and fantasy. He differed from her on the effect of environmental provision and emphasized the importance of early real relationships.

Together with Klein and Fairbairn, one of the founders of the British object-relations school, Winnicott extended his influence to social work, education, developmental psychology, and the probation service, in addition to pediatrics and psychoanalysis. His writing has been translated into almost all European languages; he has been published in the United States, South America, and Japan, and there is strong interest in his work in France and Italy. In Britain, the Independent Group of the British Psycho-Analytical Society has followed his work, and his ideas have interested those working in the field of infant observation in Great Britain and the United States, as well as those adhering to self-psychology theory and practice.

Since his death, the Winnicott Trust, founded by his widow Clare, has continued and completed publication of his work, and funds raised have supported research in early mother-infant relationships at the Winnicott Research Unit at the University of Cambridge. The Squiggle Foundation, an organization devoted to the study of Winnicott’s thinking, holds an annual program of lectures and courses in London.

---

## **WINTERSTEIN, ALFRED FREIHERR VON (1885–1958)**

Austrian psychoanalyst Alfred Freiherr von Winterstein was born on September 25, 1885, in Vienna, where he died on April 28, 1958.

Educated at the famous Theresianische Akademie and the Franz Josefs-Gymnasium, Winterstein obtained his *Matura* (or baccalaureate) in 1903. He completed his law studies in 1905.

After reading *The Interpretation of Dreams* (1900a), Winterstein contacted Freud, attended his lectures, and in 1910 became a member of the Vienna Psychoanalytic Society. At that time he was writing articles for the *Neue Freie Presse*, a bourgeois liberal newspaper, and publishing poems in Karl Kraus's *Die Fackel*. He also wrote plays and was member of the Pen Club.

Winterstein submitted his thesis in 1911 and worked for a time under the famous experimental psychologist Wilhelm Wundt at the University of Leipzig. During a visit to Burghölzli, while staying with Eugen Bleuler, he began an analysis with Carl Jung.

During the First World War, Winterstein was in the dragoons and, after four years of duty, was promoted to cavalry captain. Returning to Vienna, he continued an analysis with Eduard Hitschmann and began practicing analysis himself. He was interested in the application of analytic ideas to literature and especially in the psychoanalysis of parapsychological phenomena.

After the Nazi Anschluss, Winterstein elected to remain in Vienna, but because by the Nuremberg laws he was not considered a “pure Aryan,” he was forbidden to practice psychotherapy; this was also the case with August Aichhorn, the only other member of the Vienna Psychoanalytic Society who remained in the city during the war.

Winterstein employed the war years to write a book on Adalbert Stifter, the great Austrian writer, poet, and painter. His *Adalbert Stifter, Persönlichkeit und Werk: eine tiefenpsychologische Studie* was published in 1946.

After 1945, Winterstein played a role in reconstituting the Vienna Psychoanalytic Society, serving as its president from 1949. He enjoyed an international reputation and was invited in 1953 and 1955 to lecture at meetings of International Psychoanalytical Association. In 1957, poor health led to his retirement.

## WISH FOR A BABY

The wish for a baby is one of the fantasies of childhood, part of the set of significant motifs transmitted to the child unbeknownst to its parents along with the biological “breath of life” (Bydlowski, 1978), and that evolves in conjunction with individual libidinal development. It is marked by the Oedipus complex, by kinship relationships, by family experiences of death and mourning. In Freud’s account, the woman’s “wish to possess a penis is normally transformed into a wish for a baby” (1933a [1932], p. 101). The wish for a baby is superimposed, repressed, or revived in different forms at different times of life.

From the oral stage, the wish for a baby inherits the urge to destroy the mother’s body entirely, including her belly and everything in it. From the anal stage—inclined to control and revenge—comes the theme of the stolen baby, used to try and compensate for the loneliness of the child confronted by the parental couple. Both the little girl and the little boy long for the power, at once marvelous and uncanny, to have a child: an imaginary child, manipulable at first anally, then mentally (Soulé, 1982). The boy must in due course renounce this wish, whether by means of displacement or sublimation, of repression, or of reaction-formations ranging from the ritual of *couvade* to the disavowal of paternity, or even beyond, to delusion and paranoia (Soulé, 1982).

The wish for a child is also relevant to narcissism. An ideal child, issuing from an ideal mother, is the equivalent of the penis for the mother whom it fulfils. With no third person to come between mother and baby, there is no corresponding denial of the anal, aggressive function of the imaginary child. On the oedipal level, for the girl, the child is a product of incest, obtained from the father without the mother’s knowledge and in rivalry with her.

Maria Torok (1968) relates the wish for a child in its narcissistic dimension to death and mourning: “The wish for a child can be understood as a denial of the loss of a part of oneself.”

## WISH-FULFILLMENT

In Freudian theory, the fulfillment of a wish is an aspiration, theme, or, one might even say, motor principle, of unconscious formations like dreams, hysterical symptoms, and fantasies. In these formations an unconscious, infantile sexual wish is expressed and fulfilled in imagination in a more or less disguised way. From this point of view, the fulfillment in question is neither total nor definitive, but unique and dynamic.

Freud set forth his theory of wish fulfillment in chapter 3 of *The Interpretation of Dreams* (1900a), though he had already mentioned the idea in the preceding chapter, “The Method of Interpreting Dreams,” in connection with his dream of Irma’s injection: “The dream represented a particular state of affairs as I should have wished them to be. Thus its content was the fulfilment of a wish and its motive was a wish. When the work of interpretation has been completed, we perceive that a dream is the fulfilment of a wish” (1900a, pp. 118–119, 121). In fact, four months before his dream of injecting Irma, in his correspondence with Wilhelm Fliess, Freud first alluded to the general principle of the dream as wish fulfillment. The context was in the account of the “dream of convenience” of “Mr. Pepi” (Rudi Kaufmann, a nephew of Josef Breuer), who dreamed he was in the hospital so as not to have to wake up in the morning (Letter of March 4, 1895, p. 114).

Only interpretation and analysis can penetrate the disguise under which a wish-fulfillment is expressed. An unconscious wish is fulfilled in an imaginary way and appears to the dreamer in masked form. Dream work transforms the latent content of the dream into manifest content by means of the processes of condensation and displacement. Wish fulfillment is not the cause of the dream, but it shapes the intentional structure of the dream. Hence the need for the work of interpretation. To be fulfilled, the wish, as an instinctual intrapsychic force, must effect what Freud, in *The Interpretation of Dreams* (1900a), called “perceptual identity” (pp. 566–567). The path followed leads from the triggering of an internal need to its satisfaction in the experience of a hallucinated wish-fulfillment.

Thirty years later, in *New Introductory Lectures on Psycho-Analysis* (1933a [1932]), Freud reaffirmed that “in every dream an instinctual wish has to be represented as fulfilled. The shutting-off of mental life from reality at night and the regression to primitive mechanisms which this makes possible enable this wished-for instinctual satisfaction to be experienced in a hallucinatory manner” (pp. 18–19).

His study of traumatic dreams connected with accident neuroses led Freud, in *Beyond the Pleasure Principle* (1920g), to postulate aims of the dream other than the fulfillment of an unconscious wish. On the face of it, a dreamer whose dreams regularly culminated in anxiety could not be striving to satisfy an unconscious wish, yet even “if you want to take these latter objections into account, you can say nevertheless that a dream is an *attempt* at the fulfillment of a wish,” Freud wrote (1933a [1932], p. 29). With respect to hysterical symptoms, Freud noted that an unconscious, infantile wish was certainly being fulfilled, but so was a preconscious wish, so that two opposing wishes, issuing from two different mental agencies, were being fulfilled. As for fantasies or daydreams, “like dreams, they are wish-fulfillments. . . . The wishful purpose that is at work in their production has mixed up the material of which they are built, has rearranged it and has formed it into a new whole” (Freud, 1900a, p. 492).

A wish never arises in isolation; it always encounters other wishes, opposing it in an open structure, so that desire is always in the process of organizing meaning. Jacques Lacan considered this always-incomplete destiny of desire to be the basis of the dialectic between demand and desire, which for him defined the human condition.

## WISH, HALLUCINATORY SATISFACTION OF A

The notion of the *hallucinatory satisfaction of a wish* is one of the key elements in the Freudian conception of psychic functioning. It postulates that, under certain conditions, there is an intense need, transformed into a wish for an object from which satisfaction is expected, which, under certain circumstances can produce sensations that are attributed wrongly to an external agent, yet present all the characteristics of reality. This is *hallucinatory satisfaction*.

These certain conditions can be of four kinds: the immaturity of the psyche of the newborn baby, dreams, problems in psychic functioning in certain neurotics, or certain psychoses, called, as a matter of fact, delusional.

Concerning the first kind, Freud expressed, from the time of his *Project for a Scientific Psychology* (1950a [1895]), a hypothesis that must be placed among the founding ones of psychoanalysis. What are the possible outlets, he asked, for the “need that has been excited” in the child? The child has no means of autonomous satisfaction at its disposal, so that “the primal powerlessness of the human being becomes *the earliest source of all moral notions*” (in other words: of the entire psychic life, insofar as it is pointed toward the wish—the italics are Freud’s). An “experience of satisfaction” can ensue, because of an intervening adult who creates an

association between the two “mnemonic images,” that of need (or wish) and that of satisfaction. The reappearance of the former can, when the need (wish) is intense, reactivate this association: “Now, when the state of *urgency* or *wishing* reappears, the cathexis will also pass over on to the two memories and will activate them. . . . I do not doubt that in the first instance this wishful activation will produce the same thing as a perception, namely a *hallucination*” (1950c, p. 319), Freud adding forthwith: “If reflex action is thereupon introduced, disappointment cannot fail to occur.”

This idea was taken up again a few years later in *The Interpretation of Dreams*: “The first wishing seems to have been a hallucinatory cathecting of the memory of a satisfaction. Such hallucinations, however, if they were not to be maintained to the point of exhaustion, proved to be inadequate to bring about the cessation of the need or, accordingly, the pleasure attaching to satisfaction” (1900a, p. 598).

As Freud wrote, in 1911, in a text called “Formulations on the Two Principles of Mental Functioning”: “The state of psychical rest was originally disturbed by the peremptory demands of internal needs. When this happened, whatever was thought of (wished for) was simply presented in a hallucinatory manner, just as still happens to-day with our dream-thoughts every night. It was only the non-occurrence of the expected satisfaction, the disappointment experienced, that led to the abandonment of this attempt at satisfaction by means of hallucination.” At this point the *reality principle* is introduced, supplanting the *pleasure principle*. Freud answered a possible objection in a note at the bottom of the page: a being totally under the sway of the pleasure principle could not survive “for the shortest time,” responding, in fact: “the infant—provided one includes with it the care it receives from its mother—does almost realize a psychical system of this kind. It probably hallucinates the fulfillment of its internal needs” (1911b, pp. 219–220). This “provided one includes with it the care it receives from its mother” was well remembered by a number of later authors, especially Donald Winnicott.

The notion returned in “A Metapsychological Supplement to the Theory of Dreams” (1916–17f, p. 231): “At the beginning of our mental life we did in fact hallucinate the satisfying object when we felt the need for it. But in such a situation satisfaction did not occur, and this failure must very soon have moved us to create some contrivance with the help of which it was possible to distinguish such wishful perceptions from a real fulfillment

and to avoid them for the future. In other words, we gave up hallucinatory satisfaction of our wishes at a very early period and set up a kind of ‘reality-testing.’”

There is a certain hesitancy in these texts of Freud between the terms *need* and *wish*; and only in his later work did Freud come to distinguish them more clearly, need being defined as the expression of an organic function (hunger, sexual and so forth), wish as something mental when this need is transformed into the wish to have an object. Accordingly, the status of the drive, as a “border concept” (between psyche and soma) is put into question (cf., among others, Laplanche, 1987).

As a matter of fact, in all his writings Freud insisted on the “disappointment” following “inevitably” on hallucinatory satisfaction (a hallucination of milk supplies no nourishment . . .). Accordingly, a reality principle is set up at the same time representation is born, pointing to what is “here inside,” not, as in the case of perception, to what is “also outside” (1925h).

This notion was utilized by Freud, in very similar terms, in his theory about dreams (1900a): the dream is, in effect, a realization of a wish. In the framework of psychic functioning, cut off from perception and motor functions, “excitation follows a retrograde way.” There is a “topographical regression,” and a restitution of “the identity of perception,” or an association between the “images” of the movement of desire and its satisfaction; but also regression to a primitive functioning as “the dream is a fragment of infantile psychic life.” If the pleasure principle prevails momentarily over the reality principle, this sort of satisfaction is quite liable to take on a hallucinatory quality.

At the same time as he was forming these theories, Freud was also approximating dream functioning to the function of psycho-neurotic defense mechanisms, in particular those of hysteria: certain hysterical symptoms, especially those affecting perception, can be explained by an analogous schema.

Psychoses lend themselves particularly well to the hallucinatory satisfaction of wishes, and, moreover, in a waking state: “In psychoses these ancient and repressed modes of psychic work return in force,” as the analysis of the Schreber case (Freud, 1911c) showed dramatically.

Sándor Ferenczi (1913) took up the schema of Freud and used it to account for the omnipotence of thought, such as is observable in the young child (“stage of hallucinatory magical omnipotence,” char-

acteristic of infantile megalomania), but also of obsessional structures.

Foremost among later authors who were interested in this question is Donald Winnicott (1971), who gave a further nuance to the idea by introducing the notions of *illusion* and *transitional space*, and also by describing the process of progressive re-autonomization of the mother (beyond the “primal maternal madness,” prolonged temporarily by the symbiosis of pregnancy). He saw in this the condition for the advent of disappointments, which in the Freudian model were both inevitable and necessary: the mother became “very good,” but would be also “very bad.” Winnicott wrote that a “perfect” mother, that is to say, one who immediately satisfied all her child’s needs, “could be nothing but a hallucination.” Denise Braunschweig and Michel Fain (1975) developed an analogous idea in a different theoretical context, opposing the “day mother” to the “night mother.”

In this respect, the studies of André Green (1993) should be mentioned; he did significant work on “negativity,” on the basis of a case of negative hallucination (where a perception is banished from existence). Equally the work of César and Sára Botella are relevant, centering on the concept of the “hallucinatory,” the term being taken as a substantive, as a description of a vast processual set.

## **WISH/YEARNING**

A wish may be described as an intrapsychic impulse accompanied by the intention to obtain some denied, forbidden, or withheld satisfaction, or to rediscover a primal satisfaction, mnemonic traces of which are unconsciously inscribed.

In *Studies on Hysteria* (1895d), and in correspondence with Wilhelm Fliess in May 1897, Freud employed the term *wish* to designate a forbidden desire, speaking, for example, of the “wish to be ill” and especially of the “death wish.” This meaning was paramount in chapter 5 of *The Interpretation of Dreams* (1900a), in the section on “Dreams of the Death of Persons of Whom the Dreamer is Fond” (p. 248ff), and again in *The Psychopathology of Everyday Life* (1901b) at the conclusion of chapter 8, where it is considered in light of a neurotic conflict.

Beginning with the seventh chapter of *The Interpretation of Dreams*, Freud placed increasing emphasis on a more precise definition of the *wish*, which became highly influential in the development of psychoanalytic theory. Dream analysis determined, in effect, that the wish was produced by unconscious mnemonic traces that were fixed indelibly by the earliest experiences of infantile satisfaction. The aim of the wish is to recreate that experience, following paths laid down by primary process thought, taking into account the “logic” of unconscious drives to bypass censorship. The wish accomplishes this by being articulated in the language of the most profoundly cathected ideas. This is what led Freud to define the dream as hallucinatory wish-fulfillment.

## WITCH OF METAPSYCHOLOGY, THE

Harking back to a remark of Freud's, "Witch Metapsychology" is occasionally invoked in an ironic or critical way to characterize the resort to general metapsychological principles as a way of avoiding some difficult problem.

In his article "Analysis Terminable and Interminable," Freud posed the following question: how, in the course of the analysis, can an instinct be "tamed"—that is to say, not suppressed, but brought, with its conflicts, "completely into the harmony of the ego." "It is not easy to find an answer," he wrote. "We can only say: 'So muss denn doch hie Hexe dran!' [We must call the Witch to our help after all!]"—the Witch Metapsychology. Without metapsychological speculation and theorizing—I had almost said 'phantasying'—we shall not get another step forward. Unfortunately, here as elsewhere, what our Witch reveals is neither very clear nor very detailed" (1937c, p. 225; the quotation is from Goethe's *Faust*).

And indeed Freud leaves his question unanswered in this paper, except for one sentence where he evokes the opposition between primary and secondary processes. This evasion is characteristic of the very problem he poses in the above-cited passage: when psychoanalytical thought runs into some difficulty or other (theoretical, practical, or technical), it is often tempted to wriggle out by invoking metapsychological principles of great generality. Their very generality renders the response of the "Witch" uncertain, however, for both question and answer can be reframed in such a way as to achieve harmony, opening the door wide to ill-defined disputes among the psychoanalysts themselves with no clear criteria to guide the discussion.

Over and above her picturesque quality, therefore, the Witch metapsychology raises a basic epistemological problem.

## WITTELS, FRITZ (SIEGFRIED) (1880–1950)

Austrian physician and psychoanalyst Fritz (Siegfried) Wittels was born in Vienna on November 14, 1880, and died on October 16, 1950, in New York.

The son of a stockbroker who claimed to be a descendant of Chaim Vital, a seventeenth-century Jewish cabbalist, Wittels attended the University of Vienna beginning in 1898 and completed his medical studies in 1904. He subsequently practiced at Vienna General Hospital and, in 1907, became assistant to Julius Wagner von Jauregg.

From 1905, Wittels attended Sigmund Freud's lectures, and in the spring of 1906 his uncle by his father's second marriage, Isidor Sadger, introduced him to the circle that by then had formed around Freud.

While a member of the Psychological Wednesday Society, Wittels also actively collaborated with Karl Kraus on his satirical review *Die Fackel*. Kraus's criticisms of psychoanalysis from 1908 were not aimed at Freud, whose ideas he valued, but mocked the reductive application of psychoanalytic ideas to literature and art, such as found in publications by Sadger, Wilhelm Stekel, and Otto Rank. However, close ties with both Kraus and Freud affected Wittels's relationship with both; a further complication was a young Viennese actress, Irma Karczewska.

Wittels's ambivalence toward Kraus apparently contributed to the latter's critical attitude towards psychoanalysis; it did not arise suddenly, as legend had it, after Wittels, in a lecture before the Vienna Psychoanalytic Society, criticized *Die Fackel* as a neurotic symptom. The love triangle comprised of Wittels, Karczewska, and Kraus led to a rupture between the two men. Later, Wittels began work on his roman-à-cléf, *Ezechiël der Zugereiste* (Ezekiel the alien), through which he hoped to avenge himself upon his former friend. Kraus attempted to stop publication of the novel by legal means and Freud himself tried to persuade Wittels to forego publication, from fear that it would drag psychoanalysis into a damaging conflict with Kraus. Freud's words, "You are impossible in my

circle if you publish this book,” quoted by Wittels in his memoirs (Timms, 1995, p. 98), led to Wittels’s resignation from the Vienna Psychoanalytic Society in 1910.

Wittels had tried to attract private patients as early as 1908, but with little success and, with time out for World War I, he continued to practice as a psychiatrist and resident neurologist at the Cottage Sanatorium in Vienna. He had a long friendship with Rudolf von Urbantschitsch, the head of the sanatorium, whom he introduced to psychoanalytic circles about 1907.

Wittels spent the First World War in Turkey and Syria as military physician. During and after the war, he lent strong support to the social reformist ideas of Josef Popper-Lynkeus. He also became close to Wilhelm Stekel and his group, and during the early 1920s he was analyzed by Stekel. Wittels’s biography of Freud, partly the result of collaboration with Stekel, was published in 1924, and soon published in England and America. *Sigmund Freud: His Personality, His Teaching, His School* won bitter remarks from Freud, but Wittels nevertheless returned to the Vienna Society in 1925, and two years later he was readmitted as a member. After his reconciliation with Freud he made some corrections and emendations to his biography (1932).

In 1927, Wittels was elected to the propaganda committee of the Vienna Society and directed its publications. He was invited in 1928 by Alvin Johnson to teach at the New School for Social Research in New York; over the next three years he lectured in the United States and in 1932 settled definitively in New York where, the same year, he became a member of the New York Psychoanalytic Society. He made his last visit to Europe in 1934, remaining a member of the Vienna Society until 1936. He joined to the American Psychoanalytic Association and the New York Academy of Medicine; he taught at the New York Psychoanalytic Institute and the New School; and he was also associated with Bellevue Hospital in New York and Columbia University.

Wittels married three times. His first wife, whom he married in 1908, was Yerta Pick, the daughter of a renowned psychiatrist in Prague; she died in 1913. In 1920 he wed Lilly Krishaber; and in 1947, he married Poldi Goetz.

Wittels’s last book, *The Sex Habits of the American Women*, was published posthumously in 1951. In 1995 Edward Timms published *Freud and the Child*

*Woman*, a highly edited version of Wittels’s not entirely frank or reliable memoirs (Lensing, 1996).

### WITTKOWER, ERIC (1899–1983)

Eric Wittkower, although a British subject by birth, was born on April 4, 1899, in Berlin and died on January 6, 1983 in Montreal.

He received his MD at the University of Berlin in 1924. From 1925 to 1930 he was assistant in the Medical Clinic at the Charité in Berlin; from 1930 to 1933 he became assistant in the Psychiatric Clinic at the Charité. From 1932 to 1933 he was privat dozent in psychosomatic medicine at the University of Berlin. Already he numbered among the European pioneers in psychosomatic medicine.

Because of the situation in Germany, in 1933 he and his wife Claire moved to Switzerland, and

thereafter on to England, where he first was a research fellow at the Maudsley Clinic and then at Tavistock. After further training in Edinburgh and Glasgow, he served as a psychiatrist in the British Army from 1940 to 1945. In England, he was analyzed by Eva Rosenfeld, then by John Rickman, and completed his psychoanalytic training at the London Institute in 1950. In 1951 the Kleinian—oriented Wittkower left Maudsley and Tavistock to go with his wife and two children to Montreal, where he taught at McGill University where he conceptually organized the domain of transcultural psychiatry and where he founded and edited the *Transcultural Psychiatric Research Review*. He was also one of the founding fathers of the Canadian Society of Psychoanalysis. In 1970 he helped to found the International College of Psychosomatic Medicine.

The prolific Wittkower authored four books, including *Emotional Factors in Skin Disease* (1953), *Recent Developments in Psychosomatic Medicine* (1954), *Divergent views in Psychiatry* (1981), co-edited three more, and wrote more than two hundred and thirty articles, the great majority being on psychosomatic medicine and transcultural psychiatry. Despite those seminal contributions and his honorary recognition by various psychoanalytic, psychiatric, and psychosomatic organizations on four continents, he prized his teaching most of all—his grateful colleagues and students overwhelmingly agree.

## **WOLFENSTEIN, MARTHA (1911–1976)**

Martha Wolfenstein, a psychoanalyst and writer, was born on November 10, 1911, in Cleveland, Ohio, and died on November 30, 1976, in New York. She graduated from Radcliffe College, and then earned an MA in psychology and a PhD in aesthetics from Columbia University. She was analyzed by the art historian and lay analyst Ernst Kris and attended classes at the New York Psychoanalytic Institute between 1948 and 1953. A lay psychoanalyst, she was not a member of a society belonging to the American Psychoanalytic Association, but nonetheless was a widely admired teacher and supervisor in New York City.

Wolfenstein’s mother died when she was a child, and there is a history of parental (especially maternal) loss extending back several generations in her family. Ellen Handler Spitz has written insightfully about this history and its role in Wolfenstein’s work. Wolfenstein wrote three classic papers on childhood bereavement: “How Is Mourning Possible?” (1966b), “Loss, Rage, and Repetition” (1969), and “The Image of the Lost Parent” (1973). She also wrote important studies of two artists: René Magritte and Francisco de Goya. In her paper, “Goya’s Dining Room” (1966a), she explicated the psychological fantasies portrayed in Goya’s paintings and argued that for Goya the loss of his hearing was linked to his earlier losses, in their infancy, of all but one of his five children. She linked themes of grief, rage, and sexual guilt to the horrifying images that characterize the paintings that Goya painted after his illness in 1792.

Wolfenstein books include *Movies* (1950), *Children’s Humor* (1954), and *Disaster* (1957), a seminal analysis of the impact of catastrophic events on individuals. With the anthropologist Margaret Mead, she edited *Childhood in Contemporary Cultures* (1955). This volume grew out of the project Columbia University Research in Contemporary Cultures, led by Mead and Ruth Benedict. As a member of this project, Wolfenstein made two trips to Paris in 1947 and 1953. While in Paris she observed the behavior of parents and children in parks and noted in her paper “French Parents Take Their Children to the Park” (1955) that French children quickly learn that displays of physical aggression are not permissible, and that verbal disputes are substituted. She concluded that for the French, childhood and adulthood are very distinct, and that the relation between childhood and adulthood is almost completely

opposite in France and in America. In America, childhood is viewed as a nearly ideal time, and adults feel nostalgic for their childhood. Adulthood is a ceaseless round of work, and the enjoyment of immediate pleasures is nearly lacking. For the French, the opposite is true: it is in adulthood that one can live in the present moment and that sensuous pleasures become ends in themselves; concern with such pleasures and ingenuity in achieving them are persistent themes of adult life.

Wolfenstein's books and essays are exemplary for their use of psychoanalytic insights as a prism with which to illuminate and connect the origins and vicissitudes of cultural values and attitudes to psychological imperatives. Her papers on childhood bereavement were important clinical contributions because they demonstrated that the child's or adolescent's inability to fully engage in mourning the loss of a beloved object, as opposed to adapting, is inextricably linked to their particular stage of development at the time of the parent's death.

### WOLFF, ANTONIA ANNA (1888–1953)

Swiss analyst Antonia (“Toni”) Anna Wolff was born on September 18, 1888, in Zürich, where she died on March 21, 1953. Wolff was the oldest of three daughters born to Konrad Arnold Wolff and Anna Elisebetha Sutz. The Wolff family had resided in Zürich since the 1300s and was one of its most distinguished names. The family had been members of the Swiss Reform Church for many centuries. Konrad had been a merchant and a businessman in Japan prior to his marriage. Although the marriage was arranged, it has been described as a happy one. Wolff was her father's favorite. When he died in 1910, her mother sent her to Jung for treatment of what today would be diagnosed as depression. Jung immediately sensed her aptitude for analysis, because in 1911 he invited her, along with his wife and several other women that showed promise, to the Weimar Psychoanalytic Congress.

When Jung began his *nekyia* into the unconscious, Wolff was the one he turned to. He shared his dreams and active imaginations with her, which he recorded in his Red Book. She became his soul mate for psychological matters in a way that Emma could not provide. She maintained this function for most of the rest of his life. Jung described her as his “second wife.” Jung's relationship to Wolff was completely public, and all immediate members of the Jung family, including Emma, were aware of the situation. Emma and Wolff often sat on either side of Jung when he gave a seminar, and Toni frequently traveled with Jung on his lecture tours. This arrangement did not sit well with the children and grandchildren, but it was completely accepted by Jung's analysts. It has been said that Jung, as he got older, turned to her less frequently.

She became a founding member of the Analytical Psychology Club in 1916 and was its president from 1928 to 1945. It was under her presidency that the ten-percent quota on Jews was passed. From 1948 to 1952 she was honorary president of the club. The club, the only Jungian organization at the time, was her domain.

From the 1920s on she worked as a professional assistant to Jung. Most people who entered analysis with Jung also saw her. She was considered to be more practical and worked in the personal aspects with the analyst, whereas Jung dealt mainly with the archetypal issues. She favored the term *Complex Psychology* over any other name for Jung's psychology, and when the Jung Institute was founded she wanted to name it the

“Institute for Complex Psychology”. Her major paper was, “Structural Forms of the Feminine Psyche,” published in German in 1951 and translated into English by Paul Watzliwack. As of 2005 her other papers were being prepared for publication in English by Robert Hinshaw.

On a personal level she was always described as elegant, and dramatic in her dress; a chain smoker who liked her cocktails, but was never drunk. She never married, as Jung was the man in her life. There were rumors of other flirtations, but nothing has been verified. She suffered from severe rheumatoid arthritis, which hampered her mobility toward the end of her life. She worked until the day she died. Gerhard Adler described having an excellent analytic hour with her the day before she suffered her fatal heart attack on March 21, 1953.

## WORD ASSOCIATION

Word association is connected with the work that Carl Gustav Jung was engaged in at the Burghölzli Psychiatric Clinic of the University of Zurich in the early stages of his career (Jung, 1917/1926/1943). Under the directorship of Eugen Bleuler, the Burghölzli Psychiatric Clinic was an international center of excellence in psychiatric research at the turn of the century. Jung became director of research on the Word Association Test. This test usually consisted of a hundred stimulus words that were read out singly to a subject who was to “answer as quickly as possible with the first word that occurs to you.” The reaction time, verbal response, and test behavior were recorded and analyzed. Verbal responses were classified according to several linguistic categories. The test was used to diagnose psychological typology and psychopathology.

The Word Association Test (WAT) was based on earlier theories of the associationism school of psychology, which studied the laws of mental associations.

Jung introduced significant innovations to this method. In addition to the cognitive dimensions, he emphasized the emotional aspects involved. He noted that the words to which subjects offered unusual

responses were connected with themes having an emotional impact on them. He found that subjects invariably do not have conscious control over their responses. Therefore, he argued, this method was tapping both conscious and unconscious phenomena. He found that clusters of ideas, images, and words loaded with much affect (positive or negative) interfered with the ego (as the coordinating agency) by producing unusual responses. He called these clusters *complexes*. Jung used Freud’s theories of repression to account for the autonomous nature of complexes. Freud praised Jung for providing experimental proof of the existence of the unconscious, welcoming him in the early psychoanalytic movement as a much needed hard-nosed scientist. Although the term *complex* was used by Freud and Josef Breuer earlier, it was with Jung’s meaning that it finally entered the psychoanalytic vocabulary.

Jung and his associates applied the Word Association Test to many psychiatric contexts, including forensic diagnoses, publishing some remarkable cases of successful detection. A much-neglected facet of Jung’s early work is his application of this method to families. He gave the test to members of the same families and found that there were psychological subgroupings in the same family. At the time, however, Jung possessed neither the theoretical understanding nor the clinical experience to take these findings further. One can argue that these unfinished questions contributed to the development of his theories about other manifestations of shared unconscious structures in subjects, for example, the archetypes (Papadopoulos, 1996).

Gradually, Jung abandoned this method and the whole experimental approach to psychiatry, especially after leaving the Burghölzli Psychiatric Clinic. Nonetheless, his method of amplification (instead of free association) and his sensitivity to the role of language in psychotherapy owe their origin to the Word Association Test. As of 2005, the Word Association Test is hardly used, though it is taught in some Jungian training programs and some analysts use it as a technique to enhance the therapeutic process (Hill, 1975).

## WORD-PRESENTATION

In the Freudian model, *word-presentations* correspond to verbal language, and *thing-presentations* correspond to visual images. They differ as signifier differs from signified. In Freud's view, although unconscious thing-presentations and thought antedate word-presentations, which are preconscious-conscious, he assigned a special role to verbal language in the mechanism whereby unconscious processes *became* conscious.

In the associationist perspective of his prepsychoanalytic work, in particular, in *On Aphasia* (1891b), where Freud first presented the antithesis between thing- and word-presentations, the thing-presentation constituted an open complex of images, whereas the word-presentation was a closed entity whose special task was to gather the "associations of the object" together as the "complex" that constituted the object's identity. What Freud was apparently referring to here was less the presence of something being represented than the difference between two series of associations, one of which is closed and the other open-ended. The specific role of language is to produce meanings that lie not in things prior to the advent of language but rather in thought before the advent of words.

Upon discovering the unconscious, Freud came to question this nominalist theory of knowledge, inherited from John Stuart Mill, and embraced the idea that unconscious thinking, and by extension thing-presentations, were prior to language and word-presentations. At the same time, however, spoken language acquired a privileged role in the mental processes whereby things become conscious. As early as "A Project for a Scientific Psychology" (1950c [1895]), the word-presentation was seen as a substitute for the hallucinatory satisfaction of a wish. This theoretical conception of the relationship between pleasure and language comports with psychoanalytic clinical

practice: in *Studies on Hysteria* (1895d), Freud said that in the treatment process there is a need to replace acts with words to permit the abreaction of repressed wishes. Freud thus stressed how the motor aspect of language can facilitate an emotional release, in connection with the revival of a memory, that is less costly than alternative adequate reactions (tears, revenge, etc.).

Seen in this light, language constitutes the secondary process (the processes of the ego) and the process of emergence into consciousness, though it is true that Freud never denied the possibility of thing-presentations becoming conscious directly, as for instance in dream images and hallucinations. Verbal thinking nevertheless remained the ideal tool of psychoanalysis, for it allows all parts of the psychic apparatus to be accessible at all times to the thought process. In fact, the impartiality of language makes it possible for the demands of the pleasure principle to be placed in abeyance.

No doubt this property of language later spurred Freud to assert that word-presentations, by virtue of the "hypercathexis" of thing-presentations, "make it possible for the primary process [the processes of the id] to be succeeded by the secondary process" and for "a higher psychical organization" to emerge, namely the preconscious system (1915e, p. 202). In "An Outline of Psychoanalysis" (1940a [1938]), however, he proposed a more restricted view, arguing that language did not in fact constitute the preconscious, though it was an important feature of it. He then acknowledged that for language to develop, the secondary process and the ego must have organized and there must also be in place a preverbal form of thinking correlated with the economic equilibrium between the principles of inertia and constancy. In this connection, in the "Outline" Freud spoke of the opposition between free and bound energy (p. 164), thus confirming his view that at an early, prelinguistic stage, the preconscious-conscious system binds the affects with ideational representatives in a process that is the corollary of primal repression. In this context, Freud viewed preconscious thought as depending on the formation of the categories of space, time, causality, and permanence during the first two years of life, categories that supply the foundation for the development of language.

Should we subscribe to Jacques Lacan's view that language is the precondition of the unconscious and that with regards to the mental organization necessary to constitute objects, "it is the world of words that creates the world of things" (2002 [1953], p. 65)? Or

should we determine instead that the unconscious is a prerequisite of language, that the organization of the topography of the mental apparatus precedes and accounts for the emergence of language? The issue is important, for it decides the status of language relative to the discovery of the unconscious and of childhood sexuality.

The crux of the question is Freud's conception of the thing-presentation. The empiricist notions Freud employed tend to reinforce the idea that the thing-presentation refers only to the mental reproduction of things, just as the concepts of image and mnemonic trace suggest. Contrasting with this Freudian empiricism is Lacan's promotion of an unconscious "structured like a language"—an intellectualizing approach according to which language gives the world meaning.

Both approaches lose sight of the fact that thing-presentations are the outcome of the psychic work of internalizing and reappropriating mnemonic traces bound up with the hallucinatory satisfaction of wishes. This work of representing and figuring the object is the foundation of fantasizing and has its roots in cathectic activity that antedates perception of objects. The object presents itself in the first instance by way of an affect. This totality can never be represented figuratively in a complete way or expressed in words in a discourse adequate to it.

In its relationship with the secondary process, language appears defined essentially by its communicative function. But it is at the same time subject to the primary process, which tends to strip it of this function and to bring into question the signifying-signified relationship, thus introducing a factor ultimately against the linguistic system itself. When a similarity between signifiers serves to justify a conclusion that the things signified are similar, words, as Freud famously observed, are "treated like things" (1900a, pp. 295–296; 1915e, p. 199). Freud's study of dreams and psychoneuroses brought him to this view. Yet dreams only partially bring into question the relationship between signifier and signified, between word-presentation and thing-presentation. As Freud reiterated, dreams modify not the "words themselves" but rather "the thing-presentations to which the words have been taken back" (1916–1917f, p. 229). In short, "treating words as things" means making words not into things but into other words, other signs, that retain their referential function despite successive substitutions.

The primary process, meanwhile, can also alter the relationship between the linguistic sign and the referent. For example, in schizophrenia the elimination of the semantic relationship between signifier and signified also threatens the linguistic sign in its referential function to a thing in the external world. Indeed, psychosis implies a failure in the counter-cathexis of the hallucinatory representation of wishes, which makes it possible for the preconscious to operate. This failure gives rise to a defensive hypercathexis of language, which, though it constitutes an attempt at recovery by "regaining the lost object" (1915e, pp. 203–204), nevertheless relies on a like massive cathexis of the object.

In this context, any word may carry the excitatory force of the primal scene, that is, the force of a sadistic combination of two poorly differentiated imagos. In the thought of schizophrenics, hypercathexis of language is basic to their linguistic distortions and "concrete" thinking, which in actuality, from the point of view of the relationship between language and reality, is an eminently abstract kind of thought. But concrete schizophrenic thought can foster the illusion that language is forever cut off from the world, whereas in fact the sign can have no meaning outside of that opening onto the outside world (thought) that is its very foundation.

The symbolic function, and hence language, are linked to an economic process indicated by instinctual cathexis. Freud's description (1920g, pp. 14ff) of an eighteen-month-old child playing with a reel on a string (the *Fort-Da* game) shows how, in this economic process, the work of symbolic substitution operates by means of signs that represent the mother's absence and indicate acceptance of this fact, as distinct from mere signals (as for instance the child's earlier tears), which are addressed to a mother who is effectively present and are meant as a practical response. Inhibition of the aim of the instinct, which results in a shift to tender feelings toward the object and acceptance of a delay in satisfaction, then allows sublimation and symbolization through play, gesture, and language.

Thus the symbolic function, seen here in the process of the subject's working over the absent object, does not arise from a learning process or from an experienced contiguity between word and thing. Rather, it is the means of articulating the double nature of the sign and its differential value in the linguistic system. This symbolic function is achieved through the work of negation carried out in silence, manifesting itself notably in the early split between ego and object, and find-

ing its true fulfillment, as distinct from its *raison d'être*, in language. As it accedes to speech, this representational function has less to do with language reduced to its role as signal than it does with language as sign, with the sort of sudden advance that can sustain the acceptance not only of a loss but also of a previously instituted social convention regarding the loss.

## **WORK (AS A PSYCHOANALYTICAL NOTION)**

In its general sense, the word *work* denotes an expenditure of energy by a system or organism that produces an effect or transformation. In psychoanalysis, mental work is taken to mean any activity of the psychical apparatus that is designed to deal with instinctual excitations.

As early as “Some Points for a Comparative Study of Organic and Hysterical Motor Paralyses” (1893c), a paper originally published in French, Freud introduced a notion cardinal to his entire work: “Every event, every psychical impression is provided with a certain quota of affect (*Affektbetrag*) of which the ego divests itself either by means of a motor reaction or by associa-

tive psychical activity.... [T]his conception (*Vorstellung*) does not become liberated and accessible so long as the quota of affect of the psychical trauma has not been eliminated by an adequate motor reaction or by conscious psychical activity” (pp. 171–172). It was therefore on the basis of clinical experience that the idea of mental work imposed itself on Freud the therapist as a necessary activity for the patient—as distinct, in particular, from the patient’s more passive role in treatment using hypnosis. In his earliest psychoanalytical writings, it was a cognitive kind of work that was seen as making it possible to resolve the contradiction between an unacceptable idea that had aroused a painful affect and the ego. The aim of such “associative working over (*assoziative Verarbeitung*)” (1894a, p. 50) was to integrate forgotten ideas—which Freud would later call *repressed ideas*—into the realm of consciousness.

By drawing this distinction between associative mental work and a motor discharge comparable to the reflex arc, Freud not only described the aim of such work, namely to deal with the quota of affect, but also offered a first glimpse of what was to become psychoanalysis: the study of the functioning of the psychical apparatus, and at the same time a therapeutic method designed to bring back into consciousness, by means, precisely, of psychic work, ideas that had been repressed. The term *work* appears frequently in Freud’s writings, and very often it refers to one or other of these two aspects of psychoanalysis.

It is significant that Freud chose a term belonging at once to ordinary and to scientific language in order to describe his view of the psychical apparatus: by analogy with the natural sciences, which he so often invoked, he took *work* to mean a physical measure implying a certain expenditure of energy. Throughout Freud’s writings, in fact, the idea of work supplied him with the yardstick with which to gauge every manifestation of mental activity, not only within the treatment (the work performed respectively by analyst and analysand, as discussed for example in the *Studies on Hysteria* [1995d]), but also in respect of the operation of various mental processes (as for instance the dream-work, joke-work, the work of mourning, or the psychic work of repression in the child during the oedipal period).

Beginning with *The Interpretation of Dreams* (1900a), Freud considered—“since nothing but a wish can set our mental apparatus at work” (p. 567)—that the dream was a wish-fulfillment, and that it was governed by the pleasure principle. The task of the dream-work,

whose chief mechanisms Freud described as condensation, displacement, considerations of representability, symbolization, and secondary revision, was to transform the formative components of dreams—daily residues, bodily stimuli, dream-thoughts—into a manifest content acceptable to the otherwise vigilant consciousness of the dreamer. In *Jokes and Their Relation to the Unconscious* (1905c), Freud discussed the work involved in the construction of jokes, an activity designed to produce pleasure, and demonstrated its kinship with the mechanisms of the dream. The *Three Essays on the Theory of Sexuality* (1905d) introduced the sexual instinct as a way of conceptualizing the pressure for work mobilized by desire; the work of the psychic apparatus was thus deemed to be the management of excitations emanating from the sexual instinct.

In “Formulations on the Two Principles of Mental Functioning,” (1911b), Freud reasserted that the activity of the psychological apparatus was governed by the pleasure principle, but he added that in the course of development the reality principle could establish itself and modify things: “Just as the pleasure-ego can do nothing but *wish*, work for a yield of pleasure, and avoid unpleasure, so the reality-ego need do nothing but strive for what is *useful* and guard itself against damage” (p. 223). Later, in “Mourning and Melancholia” (1916–17g [1915]), Freud showed that mourning was responsible for the work of withdrawing libido from the object in situations where the object was highly cathected.

The word *work* was used throughout Freud’s writings, too, to denote effort expended during analytic treatment, whether by the analyst or by the patient. In his paper on “Constructions in Analysis,” for example, he reminded his readers “that the work of analysis consists of two quite different portions, that it is carried on in two separate localities [and] involves two people, to each of which a distinct task is assigned.” Moreover, the “person who is being analysed has to be induced to remember something that has been experienced by him and repressed; and the dynamic determinants of this process are so interesting that the other portion of the work, the task performed by the analyst, [may be] pushed into the background” (1937d, p. 258). The analyst’s said task Freud nevertheless compared first of all to that of the archaeologist; he then distinguished between two kinds of work on the analyst’s part that were undertaken in parallel: construction (or reconstruction) and working-through (*durcharbeiten*), the

second being needed in order to overcome the resistances that the analyst’s constructions were liable to provoke in the patient.

Finally, Freud did not overlook the everyday meaning of *work* as professional activity. Like Voltaire, whom he cited, he underscored the great value of work in this sense, but for his part he viewed it from the standpoint of the economics of the libido, and described it as a form of sublimation offering the possibility “of displacing a large amount of libidinal components, whether narcissistic, aggressive or even erotic”; to the extent that it made possible “the use of existing inclinations . . . or . . . instinctual impulses,” any profession could be “a source of special satisfaction” (1930a [1929], p. 80n).

Many recent approaches to psychoanalysis have given a significant place to the notion of work. A notable example is André Green’s “work of the negative,” which, though it is a product of the death instinct, functions in a sense by making the negative positive: a void, a lack, or a state of mourning itself becomes an object of identification or an object susceptible of cathexis, to the detriment of the absent object itself. Negative hallucination, the function of disobjectalization, negative narcissism, or the complex of the dead mother are so many paradigms of the work of the negative in operation.

René Angelergues (1993) has distinguished between two qualitative orientations of mental work, the one toward sublimation, the other toward erotization. It is also worth mentioning the “work of thought” (Anzieu, 1996; Mijolla-Mellor, 1992). And, lastly, the phenomenon of mentalization, which, according to the *École de Psychosomatique de Paris*, deals with the quantity and quality of an individual’s ideas—and is thus closely akin to that mental work which has the capacity to cope with and manage anxiety and intrapsychic conflicts.

## WORKING-OFF MECHANISMS

The term *working-off mechanisms* describes the work of the psychic transformation that is accomplished by the subject during or at the end of psychoanalytic treatment. This process, developed by the ego's new capacities for binding, indicates the attainment of a psychic liberation or opening-up.

The notion of working-off was mainly introduced by Edward Bibring (1943) in the context of what he called the “tension-controlling methods of the ego” (p. 513). Daniel Lagache (1962) later adopted and further developed it. In Lagache's view, working-off mechanisms are different from defense mechanisms, because the former indicate that the defense has been lifted. The essential point entails the “recognition and assimilation of the fantasmatic conflict,” which opens the way to the psychic capacities for “foresight” and “replacement.”

Sigmund Freud did not explicitly mention the presence of working-off mechanisms. However, in the fifth of his “Five Lectures on Psycho-Analysis” (1910

[1909]) he emphasized how unconscious wishes are liberated by psychoanalysis: a) repression is replaced “by a *condemning judgement* carried out along the best lines” (p. 53), such that the subject's ego can thereafter “master” the “unserviceable” instincts of an incompletely developed ego that could previously only repress them; b) the instincts can then “be employed for the useful purposes which they would have found earlier if development had not been interrupted” (p. 53); c) the individual's unrealizable inclination is replaced by a higher goal situated outside of sexuality: *sublimation*.

Lastly, a reference to such processes can be read between the lines in some of Freud's other texts: the chapter “The Ego's Dependency Relations” in *The Ego and the Id* (1923), and “Analysis Terminable and Interminable” (1937).

The notion of working-off mechanisms is difficult to delimit on the metapsychological level. If it implies an effort to account for the subject's capacity for integration and elaboration, it has often been understood, especially by adherents of ego psychology, as an illustration of the attitudes and behaviors of the “conscious ego.”

## WORKING OVER

Psychical working over is the work of thought that links and associates mental representations among themselves and through the intermediary of language, leading to their evolution, through the successive translations and networks of symbolic associations put into operation by fantasies, from the stage of the primary processes to that of the secondary processes. It is

an expression of the instinct's requirement for psychic work owing to its link with the somatic.

Sigmund Freud borrowed the term *psychical working over* from Jean Martin Charcot, who described a period of mental processing between the time of a trauma and the appearance of hysterical symptoms. As early as 1892, and then in the *Studies on Hysteria* with Josef Breuer (1895), Freud evokes a working out through association that has not been able to take place in hysteria, leading to stasis of the traumatic effect in a separate psychic group, with no possibility of liquidation.

The mechanism takes into account the nucleus of the actual (defense) neurosis that is central to the neuro-psychoses (in this case, hysteria). The lack of psychical working over is even more clear cut in the actual neuroses, properly speaking. In the essay "On the Grounds for Detaching a Particular Syndrome from Neurasthenia under the Description 'Anxiety Neurosis'" (1895), Freud invokes the absence of a psychical working over of sexual tension as the cause of the actual neuroses, through either excessive discharge into the soma (melancholia, neurasthenia) or excessive accumulation (anxiety neurosis).

Different levels of this work of linking and mentalization of the instincts can be described. The first level is the site of transformation of the physical quantity of an excitation tending toward immediate, reflexive discharge into a psychic quality that can be preserved and serve as a tool for thought and a guide for action. This transformation occurs through (1) the inhibitory effects of the lateral cathexes (according to Freud's 1895 "Project for a Scientific Psychology"); (2) representational translations; and (3) the mechanisms of symbolic representation of the Preconscious and censorship (according to Freud's writings from *The Interpretation of Dreams* (1900) through his essays on metapsychology [1915]). This level demonstrates the capacity of the psychic apparatus, by means of its representations, to direct and contain discharges, promote deferred action, and impose a waiting period.

The containment of free psychic energy is accomplished through fixation of that energy within representations and symbolic networks that are relatively stable. In Freud's account, memory traces form a hierarchical system of signs made up of successive strata (like the lava flows he describes in "Instincts and Their Vicissitudes" [1915]). He states this clearly in a letter to Wilhelm Fliess dated December 6, 1896, where he evokes

the "re-transcription" (1950a [1887-1902], p. 233) of memory traces at several registers—at least three, perhaps more—of signs. Each register corresponds to a temporal stage in psychic life, and the passage from one register to the next occurs by means of a process comparable to translation. Each retranscribed memory trace "inhibits its predecessor and draws of the excitatory process from it" (1950a [1887-1902], p. 235).

For Jean Laplanche and Jean-Bertrand Pontalis in their *Vocabulaire de la psychanalyse* (1967), psychical working over constitutes an important junction between the economic register (management of excitation) and the symbolic register (the network of associations) in Freud's theory of the psychic apparatus. In the view of such authors as Michèle Perron-Borelli and Roger Perron (1997), Alain Gibeault (1989), or François Duparc, this symbolic elaboration occurs by means of symbolization processes that construct a network extending from the most primitive fantasies of action to the most elaborate fantasmatic organizations: the family romance, or infantile theories of sexuality. According to Duparc (1997, 1998), each system of signs (images of motion, visual forms or representations of things, representations of words, or elaborated fantasies) has its own capacity for temporal containment, which increases with the psychic delay that precedes discharge.

But in order for psychical working over to be a flexible, creative process that is not limited to containing action and orienting the subject toward abstract signification, it must nevertheless allow for the possibility of the instinct's deployment in all its dimensions, including the affects, resonances among fantasies and representational forms, and controlled breaking of the habits of language and thought. These tertiary processes, which enable regression, have the effect of freeing language from a state of mourning. For Duparc, representation is a living process in that it transports the drives through the various resonances charged with motricity and affect, among the forms pertaining to the most primary level of symbolization (forms conveying motion, primal protofantasies), the visual forms and mechanisms of figuration that fix the instincts' movements within the censorship of the preconscious, and the elaborate forms of the rhetorical figures of language.

## **WORKING-THROUGH**

*Working-through* is the name for an operation resulting from the putting into effect of several processes during treatment; it opposes the work of resistance by making the analysand better aware, through time, of the defensive mechanisms upon which resistance is based, and it sparks “processes of remodeling the ego” (1937c, p. 249). Freud accords it a primary place in the analysand’s domain, to the extent the analyst allows him the time to accomplish it. At the same time however, this activity also seems closely tied to interpretation, and the interpretive modalities of the analyst. It is a term that may only be surmised in relation to economic principles, including those of resistance and elements of timing such as duration and “tempo.”

The German term *durcharbeiten* is difficult to translate. Although the English translation “working-through” does successfully convey its dynamic aspect, it fails to capture the aspect of work that occurs at the surface. In the technical paper “Remembering, Repeating and Working-Through (Further recommendations on the Technique of Psycho-Analysis II)” (1914g), where Freud uses the term for the first time, it was to describe a “consistent technique used today” that prevails over hypnosis because it gives up on privileging the interrogation of the patient concerning a specific problem or factor. It is a technique, writes Freud, used to study “whatever is present for the time being on the surface of the patient’s mind” (p. 147)— though this does not pre-

vent him from deploying metaphors of in-depth work in the same article. The term *durcharbeiten* thus conveys two notions whose co-existence in a single word is difficult to maintain: depth and surface.

Psychoanalytic technique came after that of hypnosis, and Freud sometimes placed the two in opposition in order to highlight ways in which Psychoanalysis represents a departure. Working-through comes out of a fundamental difference between the two techniques in that it assumes a gradual, step-by-step approach to resistance. Hypnosis circumvents the notion of resistance; it allows repressed memories to emerge but in no way involves “processes of remodeling the ego” and repression in its dimension as a part of processes of symbolization. The idea of resistance is necessary given the economic aspects of the drives, notably with regard to excesses of drive energy. But as Freud continually pointed out, the ego defends itself against dangers that are no longer current. Thus “to work through” implies the idea of a repetition that garners small quantities of energy to deal with the compulsion to repeat emanating from the id. Working-through is proposed answer to resistance in “Remembering, Repeating and Working-Through.”

That the form of resistance forwarded at the time is repression, attests to the fact that Freud conceived the psychic apparatus as highly-advanced in the realm of symbolization—flexible and effective in its ability to confront the drives. But the effectiveness of the function of working-through must be relativized in the face of difficulties involving defusions of instinct, narcissistic fragility, and deficiencies in symbolization. Although it remains true in these instances that certain forms of resistance must be recognized, interpreted, and then given up when they no longer further the ends of self-preservation; more recent analytic technique has ways of handling the transference and a conception of the framework for treatment which are based on metapsychological representations that are more complex than in 1914. Thus working-through is no longer indicated at certain times during treatment; and sometimes a poor understanding of negative elements in the transference may lead the analysis into a working-through that is intellectual and falsely effective.

Although Freud did not explicitly come back to this notion after 1920, it is useful to reconsider it while taking into account the upheavals brought about by the dual theory of the instincts and the negative currents it

entails. Although he did not use the term *durcharbeiten*, Freud reworks the idea of it in “Negation” (1925h), when confronted with the negative element that subtends a patient’s denial of the analyst’s interpretation. It would be necessary to wait until “Analysis Terminable and Interminable” (1937c) for him to explore how the joint efforts of the analyst and patient to recognize and conquer resistance run aground upon the negative factor of the “bedrock” of castration.

In theory, the more working-through can relate representational content to its corresponding affect, the more effective it is. We know that most of the defensive forms resistance takes, whether splitting, repression or negation, seek to divorce affect from representation and leave them strangers to one another. Certain defensive formations, notably those that combine splitting and negation, make working-through laborious, and its visible effects appear only in the long term. The forms then assumed by these psychic contents, ruled by resistances which stem from the instability of drive fusion, are subject to the repetition compulsion and are difficult to access by means of working-through, unless the analyst pays special attention to the psychoanalytic setting and to the analysis of his or her counter-transference.

In “Remembering, Repeating and Working-Through,” Freud optimistically stated that symptomatic repetition compulsion could be rendered “harmless,” or even “useful,” if the analyst could bring it into the “transference as a playground in which it [the repetition compulsion] is allowed to expand in almost complete freedom and in which it is expected to display to us everything in the way of pathogenic instincts that is hidden in the patient’s mind” (1914g, p. 154), where everything is accessible to the analyst’s interpretations. He cited the example of an analysis that seemed to be stuck in one place but that was actually evolving normally. What must be remembered, he then wrote, is “that giving the resistance a name could not result in its immediate cessation. One must allow the patient time to become more conversant with this resistance with which he has now become acquainted, to *work through* it, to overcome it, by continuing, in defiance of it, the analytic work according to the fundamental rule of analysis” (p. 155).

Working-through is indeed linked to the notion of time, of duration, as is pointed out again at the end of the essay: “The working-through of the resistances may in practice turn out to be an arduous task for the

subject of the analysis and a trial of patience for the analyst” (p. 155). The theme of the length of the analysis was much more explicit, if only because of its title, in the 1937 essay “Analysis Terminable and Interminable.” The justification for prolonging the length of the analytic cure is considered relative to the “acquired . . . alterations of the ego” (1937c, p. 235) in its defensive struggle with the drives. These modifications of the ego seem like fixations, and the analyst’s task is to promote the “processes of remodeling the ego” in the patient. Moreover, it is this aspect of the work of analysis that, from the analyst’s viewpoint, supports the idea that “to analyze” is “an interminable task” (p. 249).

In “An Outline of Psycho-Analysis” (1940a [1938]), Freud put the finishing touches on his metapsychological overview. The mental apparatus with its two topographies, his two theories of the drives, and his theories on anxiety constitute a complex whole, in light of which thinking about analytic technique must remain cautious.

The notion of working-through retains its full importance, provided it is conceived in relation to the notion of drive fusion and defusion and the consequences thereof, as well as in relation to the analyst’s interpretation, whether it is explicit or latent, as Jean-Paul Valabrega proposed in *La formation du psychanalyste* (The training of the psychoanalyst; 1994).

## WULFF, MOSCHE (WOOLF, MOSHE) (1878–1971)

Mosche Wulff (or Moshe Woolf), a physician and teacher, was born on May 10, 1878, in Odessa, Russia, and died in November 1, 1971, in Tel Aviv. The son of an German retailer, after graduating from the Lycée Richelieu in Paris and finishing his studies at a business school, Wulff undertook medical studies in 1900 in Berlin. He defended his thesis in 1905 under the direction of Theodor Ziehen.

The psychiatrist Otto Juliusburger, whom he served as assistant at the Berlin-Lankwitz sanatorium, introduced Wulff to psychoanalysis. He never underwent a training analysis proper, although Karl Abraham, who worked at the sanatorium from 1908, became his teacher. In 1911 he joined the Vienna Psychoanalytic Society, and in the same year he returned to Russia, establishing himself in Odessa. When World War I began, he left Odessa for Moscow.

In 1922, after the Russian Revolution, Wulff founded, with Ivan Ermakov among others, the Moscow Psychoanalytic Society. This organization gave birth the next year to the Russian Institute for Psychoanalysis, officially recognized in 1924. From 1922 Wulff worked as a psychoanalyst at the Second Medical Clinic of the University of Moscow.

As early as 1921 Wulff participated in creating a psychoanalytically oriented children's home, which in 1923 became a polyclinic and expanded into a state institute where training programs were available. After Lenin's death, however, rejection of psychoanalysis began to spread, eventually leading to the dissolution of the all psychoanalytic institutions and organized activity. Wulff was elected president of the Russian Institute for Psychoanalysis at the end of 1924, yet after a few months it was closed.

In 1927 Wulff left the Soviet Union. Returning to Berlin, he worked at the famous Schloss-Tegel Sanitarium, founded that year by Ernst Simmel. Under financial stress, this institution closed in 1931.

Wulff emigrated to Tel-Aviv in 1933 to found, with Max Eitingon and other members of the Vienna Psychoanalytic Society, the Psychoanalytic Society of Palestine. After Eitingon's death, Wulff served as its president from 1947 to 1954 (in 1948 it became known as the Psychoanalytic Society of Israel). He remained honorary president of the society until his death, after a long illness.

Among his most remarkable works are "Beiträge zur infantilen Sexualität" (Contributions to infantile sexuality; 1912), his frequently cited 1932 paper "Über einen interessanten oralen Symptomenkomplex und seine Beziehung zur Sucht" (An interesting oral symptom complex and its relation to addiction), and "The Child's Moral Development" (1941). He wrote in Hebrew as well as in German and English. Additional articles in English include "On Castration Anxiety" (1955) and "Fetishism and Object Choice in Early Childhood" (1946).

Mosche Wulff is mainly important for his pioneering work in introducing psychoanalysis to Russia and to Israel, where he trained a generation of analysts and psychiatrists. His translations of some of Freud's works into Russian have been reprinted in recent years. He was primarily interested in the analysis of children and in psychoanalytically inspired pedagogy. Some of his works on infantile psychology became standard works of reference for training teachers and educators.

## ***YOUNG GIRL'S DIARY, A***

Probably written by Hermine von Hug-Hellmuth, a non-medical psychoanalyst who was considered a pioneer in the field of child psychoanalysis, *A Young Girl's Diary* was, upon publication, considered to be a watershed event (Sándor Ferenczi, December 26, 1919) and was highly successful. It was the first—and remained the only—book in a series entitled “Fundamental Texts on Spiritual Development,” which the new publishing company, created through the generosity of Anton von Freund, intended to publish. Because of its success the book provided considerable income.

Introduced by an anonymous “editor” who claimed to have retained the girl’s style unaltered and uncensored, it was accompanied by an enthusiastic letter from Freud, dated April 27, 1915, which stated, “This diary is a little jewel. I truly believe that we will never again penetrate with such clarity and sincerity into the movements of the soul that characterize the development of a young girl in our society in the years before puberty, in the present state of our civilization.”

The *Diary* contained the thoughts of the young “Rita,” written between the ages of eleven and fourteen and a half. Her lengthy commentary, which would be considered innocuous by twenty-first century standards, described the awakening of adolescent feelings in a girl living in Vienna at the turn of the twentieth century. The book describes, in Freud’s words, “how the secret of sexual life emerges, first obscurely, then taking complete control of the childish soul.” It is more of an interesting commentary on middle-class Viennese life and family relations during the birth of psychoanalysis.

Welcomed by Lou Andreas-Salomé (“this young girl has lifted her diary to the rank of works esteemed

for their literary value”), Stefan Zweig (“a quite remarkable document”), and the majority of critics, its authenticity was soon questioned by the psychoanalytic community. Siegfried Bernfeld began an investigation. The arguments in favor of fraud, published in August 1921 by Cyril Brut, an English critic, in the *British Journal of Psychology*, resulted in the exposure of Hermine von Hug-Hellmuth in 1922. Although she provided additional details on the presumed author, Hug-Hellmuth’s claims were not felt to be convincing, and a number of individuals—Karl and Charlotte Bühler, Josef Krug, Hedwig Fuchs—attempted to prove it was a fraud. It has come to be felt that a number of details in the diary are autobiographical.

The murder of Hermine von Heg-Hellmuth by her nephew, Rudolf Hug, on September 9, 1924, served only to intensify the swirl of rumors circulating around the work, which in spite of its success was withdrawn from publication in 1927. It was translated into English in 1927.

## YUGOSLAVIA (EX-)

Three men—Stjepan Betlheim, Hugo Klajn, and Nichola Sugar—born at the end of the nineteenth century are at the root of psychoanalysis in Yugoslavia. Having completed their medical studies and specialized in neuropsychiatry in Germany and Austria, their return to what was then the kingdom of the Serbs, Croats, and Slovenes marked the beginning of the spread of psychoanalytic ideas in this region. They had to contend with the resistance of the psychiatric milieu and the polite interest of the intellectuals, except in Belgrade where they met with great success in artistic circles.

Because they were Jews, these pioneers naturally found themselves in the Resistance during World War II. The victory over fascism and Nazism conferred an authority on them that translated into the creation of psychoanalytically informed treatment centers.

Psychoanalytic thinking spread very rapidly in Sarajevo under the impetus of Dr. Aleksandar Markovic, and in Ljubljana where a psychologist, Leopold Bregant, and a psychiatrist, Milan Kobal, played an important role.

A new generation of Slovene psychoanalysts was being trained in the neighboring Italian city of Trieste. But it was mainly in Croatia and Serbia that the development was decisive. The war (1991–1995) put an end, for the moment, to scientific exchanges between Serb and Croatian analysts. However, both of these groups managed under difficult conditions to maintain vital contact with Western analysts, particularly in France and Italy.

### Croatia

The history of psychoanalysis in Croatia is linked to the name of Stjepan Betlheim (1898–1970). He studied medicine in Graz and Vienna. After a first analysis with Paul Schilder, he completed his training with Sándor Radó, whom Abraham Arden Brill invited in 1932 to organize an institute of psychoanalysis in New York. Karen Horney in Berlin and Helene Deutsch in Vienna supervised Betlheim's first analyses. An "associate member" of the Vienna Psychoanalytic Society in 1928, he returned to Zagreb that same year. Until World War II he divided his time between a neuropsychiatric department and psychoanalysis in private practice. In 1948 his good reputation enabled him to introduce psychoanalysis in the medical faculty, and in 1953 to create a center for psychotherapeutic treatment in the framework of the neuropsychiatric clinic, thus offering the resources of psychoanalysis and its psychotherapeutic applications for individuals and

groups. In 1952 he was elected a "direct member" of the International Psychoanalytical Association (IPA). In 1963 he published *The Neuroses and Their Treatment*, while simultaneously campaigning for the creation of an Association of Yugoslav Psychotherapists. The first steps in this direction were taken in 1964 at the Congress of Neuropsychiatrists at Ohrid, and the project bore fruit in Split in 1968.

In the period after World War II Stjepan Betlheim personally psychoanalyzed his first students: Duska Blazevic, Eugenie Cividini-Stranic, and Edouard Klain. At the same time he created the Mokrice seminar, which, from 1966 until 1991, was a meeting place for therapists from the different Republics constituting the Federal Socialist Republic of Yugoslavia. Professor Maja Beck-Dvorzak organized the psychoanalytic treatment of children and adolescents, followed by Professor S. Nikolic, who introduced the technique of the psychoanalytic psychodrama after a stay in Paris in Serge Lebovici's department, while undergoing personal analysis with Jean Gillibert (1976–1979). In Zagreb Duska Blazevic and Edouard Klain created a psychoanalytically oriented review, *Psychoterapja*. It is the responsibility of the remaining members of this group to establish regular relations with the IPA, the only body authorized to recognize its training courses.

### Serbia

Two men contributed initially to opening Belgrade up to psychoanalysis. The first, Hugo Klajn (1894–1981), physician and psychiatrist, did his personal analysis in 1922 with Paul Schilder in Vienna. On his return to Belgrade his public lectures and translation of a considerable part of Freud's work met with an immediate success. He devoted himself mainly to theatre. As director of the Yugoslav dramatic theatre and Studio 122, his directing enriched the cultural domain. In 1955 he published *War Neuroses in Yugoslavs*.

Nikola Sugar (1897–1945) was the second of these founding fathers. He was analyzed in Berlin between 1922 and 1925 by Felix Boehm, then in Vienna between 1925 and 1927 by Paul Schilder. An associate member of the Vienna Psychoanalytic Society from 1925 to 1933, he was a full member from 1935 to 1938. When he returned to the city of Subotica (Vojvodina), he also became a member of Budapest Psychoanalytic Society. In 1938 he founded the first psychoanalytic association in Belgrade. Without having any formal character, it comprised nine members: six physicians, psychiatrists, and neurologists, and three philosophy professors. Meetings were held in the Belgrade Arts

Faculty and were soon forbidden under the regency of Prince Paul, who was close to Italy, Bulgaria, and Nazi Germany. Sugar was deported and died.

Two of Sugar's patients, Vladislav Klajn (1909–1984) and especially Vojin Matic (born 1911) were prolific in developing psychoanalytic activities. The IPA awarded an honorary diploma to Professor Vojin Matic at the San Francisco Congress in 1995. Vojin Matic was an assistant at the university neuropsychiatric clinic until 1952, before becoming a professor at the Arts Faculty until his retirement. In 1953 he founded the Medico-Psychopedagogical Center, the first of its kind in Yugoslavia. Ten years later the center was closed but continued to be active in the form of the Institute for Mental Health. In relation with the European Federation of Psychoanalysis, the Belgrade group organized the Seminar for Eastern Countries in 1990. The subject was "Transference and Counter-Transference." Protocols for psychoanalytic treatment were presented by S. Borovejki (Zagreb), V. Brzev (Belgrade), M. Cicek (Zagreb), I. Ivanovic and G. Marinkow (Belgrade). This seminar brought together more than eighty participants from Eastern Europe (Bulgaria, Hungary, Lithuania, Poland, Romania, Czechoslovakia, and Yugoslavia) and Western Europe (Germany, Spain, France, Great Britain, and Italy). Professors Nevenka Tadic, Ksenija Kondic-Belos, and Tamara Stajner-Popovic concentrated particularly on the development of psychoanalytic treatment for children and adolescents. The San Francisco Congress elected Stajner-Popovic and four of her colleagues direct members of the IPA. This election was the fruit of efforts by Hanna Groen-Prakken (of Holland) and John Kafka (of the United States) within the IPA. It opened the way for the constitution of a study group, then the formation of a provisional society, which could lead this group to recognition as a constituent society of the IPA.

## **ZAVITZIANOS, GEORGES (1909–1995)**

Greek physician and psychoanalyst Georges Zavitzianos was born in Corfu, Greece, in 1909 and died in North Bethesda, Maryland on December 13, 1995.

Escaping from Turks who burned the village of Zavitzia in 1700, the Zavitzianos family settled in the Ionian island of Corfu, where they produced a succession of scientists, writers, and artists.

After secondary school in Greece, Zavitzianos studied medicine at Montpellier in France. Returning to his native country in 1934, he worked as a neuropsychiatrist with a psychoanalytic orientation; he had been briefly psychoanalyzed by the early French analyst, Edouard Pichon.

During the late 1940s Zavitzianos participated in the creation of the first Greek psychoanalytic group, founded with the help and guidance of Marie Bonaparte; in 1950 he was elected a member of the Société psychanalytique de Paris. However, soon thereafter he decided to emigrate to North America. He spent some time in Montreal and eventually settled in the United States. He took part in founding several psychoanalytic societies and institutes, and taught from 1950 to 1982. Seduced by her beautiful soprano voice, he married Sylvia Filyndras. He also underwent analysis with Leo Stone.

Zavitzianos's principal works concern female perversions (1982); problems of transvestism (1977); and what he called "homeovestism" (1972)—sexual enjoyment in wearing the clothes of one's own sex. He also wrote about problems of psychoanalytic technique (1967) and the patient-therapist relationship. Before he died, in a letter to Anna Potamianou, written on December 12, 1995, he expressed what he called his only regret—the fact that he had not been able to share his great analytic experience with his Greek colleagues.

## ZEITSCHRIFT FÜR PSYCHOANALYTISCHE PÄDAGOGIK

Founded in 1926 by Heinrich Meng, a German psychoanalyst, and Ernst Schneider, a Swiss educationist, the *Zeitschrift für Psychoanalytische Pädagogik* (*Review of Psychoanalytic Teaching*) was first published in Stuttgart, then in Vienna until 1937, with a view to disseminating psychoanalytic discoveries among educators and “inventing a new way of posing problems” (Balint, 1932).

Contributors to the *Review*, many of whom were women, were recruited from among psychoanalysts and teachers from Austria (August Aichhorn, Siegfried Bernfeld, Paul Federn, Anna Freud, Melanie Klein, Wilhelm Reich, and Richard and Edith Sterba), Germany (Erich Fromm, Frieda Fromm-Reichmann, Georg Groddeck, Karl Landauer, and Nelly Wolffheim), Switzerland (Hans Behn-Eschenburg, Oskar Pfister, Ernst Schneider, and Hans Zulliger), but also from Hungary (Alice Balint and Sándor Ferenczi), Britain (Dorothy Burlingham and Mary Chadwick), France (Marie Bonaparte and René Laforgue), as well as Sweden, Poland, and Russia (Sabina Spielrein). The *Review* contained two articles by Freud, who welcomed the initiative of the founders.

Although they initially nurtured the hope of being able to avoid the neuroses with the help of an appropriate education, the so-called psychoanalytic teachers progressively yielded to disenchantment, even pessimism. In 1936 Ruth Weiss presented a critical review of the questions remaining to be treated (Vol. 10). And in 1937, the *Review* (Vol. 11) published the papers presented at the Budapest symposium concerning the “revision” of psychoanalytic teaching: it analyzed the problems of the psychoanalytic educator (Dorothy Burlingham) and the shortcomings of a pedagogy that accorded insufficient importance to group phenomena (Hans Zulliger) and gave rise to misunderstandings (S. Bornstein-Windholz). And as

a result of events at the time and the departure of many psychoanalysts into exile, the *Review* ceased to appear in 1937.

Although there was relatively little response from the teaching profession, the provocation to think differently about the field of education and the subversive potential of the *Review* were important in the history of the relationship between teaching and psychoanalysis. Each issue, first monthly then quarterly, devoted considerable space to a review of psychological, psychoanalytic, and literary publications and reviews as well as statements and reports on psychoanalytic training and congresses.

As a forum for exchanging experiences and theorizing about a new teaching practice that was at odds with a repressive education, the *Review* saw itself as the spokesperson for an education that was “enlightened” by psychoanalysis. Its feature articles were illustrated by case studies and focused on the manifestations of infantile sexuality, the role of the emotions in learning, intellectual inhibitions and academic failure, the importance of transference phenomena, and the unconscious of the adult educator. It pleaded for another type of teacher training and for a collaboration between psychoanalysts and teachers. It provided a critical analysis of the different educational institutions as well as of the ideals of the new education movement.

The study of the phenomena of group psychology, the contradictions of the educational system, the psychic and social limits to the capacity to be educated, as well as political determinism oriented the movement for a psychoanalytically informed education and a sociological critique of education.

## ZENTRALBLATT FÜR PSYCHOANALYSE

In the wake of the *Jahrbuch für Psychoanalyse*, the psychoanalytic movement published its first monthly periodical, the *Zentralblatt für Psychoanalyse* (Central review of psychoanalysis) in 1911. For the first two years Freud was the editor and Wilhelm Stekel was the chief editor. Whereas the *Jahrbuch* addressed a specialist readership close to psychoanalysis and tended to reflect the specificity and specialization of clinical and theoretical psychoanalysis, the *Zentralblatt* had a more didactic mission. It tried on the one hand to afford a view of the rapidly growing wave of analytic literature and, on the other, to provide a forum for shorter works that were more accessible for the general public. Alongside more strictly medico-psychological articles, the *Zentralblatt* focused as well on interdisciplinary approaches involving history, literature, esthetics, teaching, and popular culture. The periodical addressed itself specifically to a lay readership both as the final consumer of psychoanalytic progress and as the author, thus becoming a witness to the “progress” of psychoanalytic knowledge.

The new periodical was introduced with a contribution by Freud, “The Future Prospects of Psychoanalytic Therapy” (1910d). A considerable amount of space was reserved for brief observations in the form of examples, for the interpretation of dreams, parapraxes, and symptoms resulting from the “psychoanalysis workshop.” In addition to providing a large space for reviews, intended as a guide to the mass of psychoanalytic publications, the *Zentralblatt* also provided the earliest information on psychoanalytic associations and their calendars of activities, beginning with the report on the first private psychoanalytic meeting held in Salzburg on April, 27, 1908.

After 1912 the *Zentralblatt* also contained the “correspondence sheet” (*Korrespondenzblatt*), previously reserved exclusively for members of the International Psychoanalytical Association (IPA), and thus became its official organ. This official role provoked a conflict in 1912 between the association and the editor, Wilhelm Stekel: Freud withdrew as editor in November 1912 and Stekel, having disagreed with the master concerning the choice of Viktor Tausk to replace him, took single-handed control of the position. That same year saw the founding of a new periodical, *Imago*, which acted as an alternative spokesperson for psychoanalysis.

As a result of this tension the IPA suspended its official collaboration with the *Zentralblatt* and in 1913 it

founded its own publication, the *Internationale Zeitschrift für Psychoanalyse*, which resumed publication of the “correspondence sheets.” Following this new configuration of the market for psychoanalytic publications, the *Zentralblatt* suspended its activity in 1914.

## ZETZEL-ROSENBERG, ELIZABETH (1907–1970)

Elizabeth Zetzel-Rosenberg, psychoanalyst and physician, was born March 17, 1907, in New York and died November 22, 1970, in Scarsdale, New York. Her father, James N. Rosenberg, was a distinguished jurist and philanthropist, who led a United States committee for the passage of the Genocide Convention at the United Nations after World War II. After graduating from Smith College, Zetzel pursued her medical education at the University of London. She began her analytic training in the 1930s at the British Psychoanalytic Society where her analyst was Ernest Jones.

In a short memoir describing the years between 1936 and 1938, Zetzel (1969) recalled with pleasure her exposure to the work of Melanie Klein and her followers, Joan Riviere and Susan Isaacs. She credits Donald Winnicott, however, with most influencing her subsequent work because he was “fully alive to the

importance of the real mother-child relationship ... My first awareness of the importance of early object relations was attributable to my opportunity to work in his Clinic at Paddington Green Hospital.”

Zetzel returned to the United States in 1949 and became a leading member of the Boston Psychoanalytic Society, where she was an influential training analyst and teacher; she was also secretary of the International Psychoanalytic Association under the presidency of Maxwell Gitelson from 1961 to 1965 (Rangell, 1971). Zetzel was a prolific writer and her collected papers (1970) include contributions to psychoanalytic technique—her name is practically synonymous with the term “therapeutic alliance”—and to the psychodynamics of hysteria and depression as delineated in her seminal papers “On the Incapacity to Bear Depression” and “The So-Called Good Hysteric.” But equally important as her original contributions to the psychoanalytic literature was her sympathetic interest in the work of Melanie Klein. In an astute and generous obituary written after Klein’s death, Zetzel (1961) decried the fact that many contemporary analysts still remained unfamiliar with Klein’s work. At the same time, Zetzel was deeply skeptical of the theoretical reconstructions that Klein posited in her writings. She also chided Klein and her followers for failing to acknowledge the work of other analysts, notably Anna Freud, Willi Hoffer, Rene Spitz, Phyllis Greenacre, and Ernst Kris, whose findings on early psychic development were convergent with their discoveries.

Zetzel’s advocacy of Klein’s work had significant implications for the development of psychoanalytic theory in the United States. Conventionally, psychoanalytic theory in America in the 1950s is portrayed as dominated by the variant of theory called ego psychology. But Zetzel’s writings on Klein and her followers, and her extended contacts with other analysts interested in preoedipal development, notably Edith Jacobson and Phyllis Greenacre, suggest a more fluid and complex state of affairs. In other words, among a group of influential psychoanalytic thinkers, there was a sophisticated awareness of Klein’s work and a recognition that her clinical discoveries should be considered in their own work.

### **ZULLIGER, HANS (1893–1965)**

Hans Zulliger, a psychoanalytically oriented Swiss teacher and child psychoanalyst, was born on February 21, 1893, near Biel, Switzerland, and died in Illigen, Berne Canton, in 1965. Coming from a modest background, he was a student at the teachers school in Hofwil-Berne. The principal of the school, Ernst Schneider, taught psychology and psychoanalysis. All his life Zulliger remained a primary school teacher in Illigen-Bolligen, near Berne, continuing to teach working class, rural, and underprivileged children until 1959.

From his first early encounter with psychoanalysis, Zulliger was passionately enthusiastic about the new theory of the unconscious. He read Freud and Alfred Adler, contacted the pastor Oskar Pfister, who became his analyst, and conducted his own research with his pupils. His observations and reflections on school failure, anxiety, and other symptoms, and on the need for and difficulties of sexual education, led to a publication in 1921, a work that was favorably received by the Swiss psychoanalytic world. Freud encouraged the young author, who visited the master twice. His subversively titled *La psychanalyse à l'école* (Psychoanalysis at school) appeared in France in 1930. As a member of the Swiss Psychoanalytic Society, Zulliger also played a part in elaborating projective tests.

In addition to working as a schoolteacher, he also worked as a child psychotherapist, psychologist, and writer (in German and in dialect). He contributed many articles to the *Zeitschrift für psychoanalytische Pädagogik*, which he coedited after 1932, and he also published in other Swiss teaching journals. In 1928 the *Revue française de psychanalyse* published one of his articles, “La psychanalyse et les écoles nouvelles” (Psychoanalysis and the new schools).

Zulliger was without doubt the most popular representative of the psychoanalytic teaching propounded by the *Zeitschrift für psychoanalytische Pädagogik*. He

excelled at recounting his practice in a lively style with colorful language. His many case studies illustrate his skillful mastery of the art of dialog and his profound understanding of children, both as individuals and in groups, as well as his insight into the games they play. He had a sense of the therapeutic power of the educational milieu, where the schoolteacher mediates between children's instinctual egos and cultural values. After World War II, Zulliger's lectures in Switzerland and Germany contributed to reigniting the movement for psychoanalytic teaching, of which he was a remarkable pioneer.

## ZWEIG, ARNOLD (1887–1968)

Born to a Jewish family in Glogau, Silesia, on November 10, 1887, novelist and author Arnold Zweig died in East Berlin, almost completely blind, on November 26, 1968. At his death Zweig was the most celebrated author in the German Democratic Republic (East Germany).

Zweig was unrelated to the Austrian writer Stefan Zweig, but both men were important to Sigmund Freud, albeit in different ways. According to Ernest Jones: “Freud’s attitude toward the two men was indicated by his mode of address. Stefan was *Lieber Herr Doktor*, Arnold was *Lieber Meister Arnold*” (1957, p. 133).

Between 1927 and 1939 Zweig and Sigmund Freud conducted an exceptionally important correspondence. When it was published in 1968, Freud’s son Ernst and Arnold’s son Adam decided to withhold twenty-five letters as being too personal or of insufficient scientific value, creating an impression that they wished to conceal something in their fathers’ private lives.

Originally a saddler by trade, Adolf Zweig became a supplier to the Prussian army before anti-Semitic regulations forced him to return to his former profession, an incident that seems to have had a powerful impact on his son. Zweig was a brilliant student who matriculated at various European universities before being conscripted during World War I, a painful experience that undoubtedly played a role in his later antimilitarism.

Zweig began publishing fiction in 1911, and was a profound admirer both of Thomas Mann and of the nineteenth-century realists. Publication of *The Case of Sergeant Grischa* (1927) made him known to a wide audience and brought him to the attention of Freud.

After the National Socialists came to power in Germany, Zweig emigrated to Palestine in 1933 and lived for some years in Haifa. He traveled widely, and a trip to New York in 1939 enabled him to meet other well-known German émigrés. Zweig had long been interested in Zionism and socialism, but by the time Israel became a state he was both disillusioned and impoverished. He returned to East Germany in 1948, and was soon elected a parliament deputy in the new socialist republic. Zweig also succeeded Heinrich Mann as president of the German Academy of Arts. Henceforth, Zweig was a government-sponsored author and member of the Communist Party. For his efforts to legitimize East German literature, he was awarded the Lenin Peace Prize.

Zweig’s literary work features a severe critique of militarism and lively political and social convictions. These traits are also characteristic of his correspondence with Freud; their subjects range from incest and homosexuality to a wide variety of reflections on political, historical, and poetical issues.

In one of the most famous letters in their correspondence (May 11, 1934), Freud’s comments about Zweig’s plan for a book on Friedrich Nietzsche served as an opening for his own ideas on the problems of psychological and psychopathological biography. He wrote: “I cannot say whether these are my true reasons against your plan. Perhaps they have something to do

with the way in which you compare me to him. In my youth [Nietzsche] signified a nobility to which I could not attain” (Jones, 1957, p. 460). This passage probably reflects the character of transference love that more or less pervades the Freud-Zweig relationship. Zweig also alludes briefly in the correspondence to the difficulties he encountered in his own analysis in Berlin, by which he hoped to treat severe depression and anxiety.

The year Freud began writing *Moses and Monotheism*, he reported on the work and its difficulties in a letter to Zweig (September 30, 1934). In discussing the project with Max Eitington, Zweig remarked that he had advised Freud to publish his book in Palestine. Judaism was an important topic for both men and the subject of many of their letters. In one letter (May, 31 1936) Zweig reports on an archaeological discovery that might confirm Freud’s theory about the origins of the man Moses. In 1937, Freud, who thought that his “hereditary claim to life would run out in November,” (Jones, 1957, p. 213) asked Zweig, who was considering a visit to Europe, not to postpone it any longer.

In 1938, Zweig made a final attempt to intervene on Freud’s behalf in favor of his being awarded the Nobel Prize. Freud held out little hope for this, considering opposition to psychoanalysis and his reputation in the eyes of the Nazis. He wrote Zweig on June 28, 1938: “[I]t can hardly be expected that the official circles could bring themselves to make such a provocative challenge to Nazi Germany as bestowing the honor on me would be.” (Jones, 1957, p. 234)

Arnold Zweig was one of many celebrated literary figures whose friendship Freud cultivated. Their common interests in Judaism, pacifism, and such historical figures as Napoleon, Nietzsche, and Moses brought them particularly close.

## ZWEIG, STEFAN (1881–1942)

Stefan Zweig, an Austrian writer, was born in Vienna on November 28, 1881, and committed suicide in Petrópolis, Brazil, on February 22, 1942. From a wealthy middle-class Jewish family, Zweig enjoyed a privileged childhood. He grew up in an open-minded and multilingual home—a background that undoubtedly played a role in his subsequent commitment to humanist and supranationalist thought. While young he became a celebrated author, traveled widely, and developed friendships with a host of literary figures, among them the French novelist and playwright Romain Rolland and the Belgian poet Emile Verhaeren, whose work he translated. Zweig’s best-known works include the novels *Amok* (1922), *Beware of Pity* (1938), and *Conflicts* (1926), a collection that includes the novella *Twenty-four Hours in the Life of a Woman*. His autobiography, *The World of Yesterday*, appeared posthumously in 1943.

Zweig’s work, at once distinguished by its richness and diversity, includes poetry, plays, essays, short stories, novels, and biographies. He was one of the most prolific authors of his time and played a major role in creating a rapprochement between French and German literature.

In *Mental Healers* (1932), Zweig not only discussed Mary Baker Eddy, the founder of Christian Science, and Franz Mesmer’s animal magnetism; he also devoted an essay to Freud, for whom he expressed profound admiration and gratitude. In 1908 Zweig and Freud began a long correspondence that continued until the latter’s death in London in 1939. Zweig delivered Freud’s funeral oration.

In Zweig’s letter to Freud of September 8, 1926, he wrote, “For me, psychology is today *the* great passion of my life (as you will understand better than anyone else). . . . You still play the decisive role in the invisible struggle for the soul. You alone are always the one to explain to us, in a creative way, the mechanism of the spiritual. More than ever we need you and your activity.” Later, in his letter of October 21, 1932, he wrote, “Everything I write is marked by your influence and

you understand, perhaps, that the courage to tell the truth, probably the essential thing in my books, comes from you: You have served as a model for an entire generation.” Zweig’s interest in psychoanalysis found expression in his writings. In both his novels and fictionalized biographies, the main characters are presented in “case histories,” made more intriguing by a nostalgic evocation of a society condemned by history.

Freud recognized in Zweig an interest in, and aptitude for, psychological analysis. Although they argued several times—over errors Zweig made in translating Freud’s work and concerning Zweig’s appreciation of such detractors as Charles E. Maylan—Freud valued Zweig’s friendship until the end of his life.

After the Nazis prohibited and destroyed his books in 1933, Zweig emigrated to London in 1934. Together with Salvador Dalí, he visited Freud on July 19, 1938. Since Freud was near death, Zweig did not dare to show him the two sketches that Dalí had made of him. In his last letter to Freud, dated September, 14, 1939, nine days before Freud’s death, he wrote, “I hope that you are suffering only from the era, as we all do, and not also from physical pain. We must stand firm now—it would be absurd to die without having first seen the criminals sent to hell.”

After obtaining British citizenship in 1940, Zweig settled in Petrópolis, Brazil, in 1941. He became a symbol of the anguish of exile and the refusal to accept Hitler’s early triumphs. Despite this, in profound despair after Nazi victories early in the war,

he committed suicide together with his second wife, Lotte Altmann.

In his final declaration Zweig wrote, “It seems to me therefore better to put an end, in good time and without humiliation, to a life in which intellectual work has always been an unmixed joy and personal freedom earth’s most precious possession.” “I greet all my friends! May they live to see the dawn after the long night is over! I, all too impatient, am going on alone” (Allday, 1972, p. 238).

# FREUDIAN BIBLIOGRAPHY

## ΕΒΕΥΔΙΑΝ ΒΙΒΛΙΟΓΡΑΦΙΑ

Only those references to Freud that have been specifically cited in one form or another in the body of the dictionary itself have been included in this list of his works, which does not pretend to be exhaustive (hence the fact that the series of references using a, b, c, etc. will not all be found here). The full list, upon which this one is based, is in the *Freud-Bibliographie mit Werkkonkordanz* assembled by Ingeborg Meyer-Palmedo and Gerhard Fichtner, (S. Fischer Verlag: 1989). Each entry in this list references the text's first publication date, its publication date in the *Gesammelte Werke* (GW), and its translation in the Standard Edition of the Complete Psychological Works of Sigmund Freud (SE).

# TRANSLATION OF CONCEPTS/NOTIONS

## TRANSLATION OF CONCEPTS/NOTIONS

This glossary is a translation of most of the notions and concepts discussed in the *Dictionary* into five languages: French, German, Italian, Portuguese, and Spanish.

### **abandonment**

*Fr.*: abandon ; *Ger.*: Verlassen(heit) *It.*: abbandono; *Port.*: abandono; *Span.*: abandono.

### **abstinence/rule of abstinence**

*Fr.*: abstinence-règle d'abstinence ; *Ger.*: Abstinenz, Abstinenz Regel *It.*: astinenza-regola di astinenza; *Port.*: abstinência-regra de abstinência; *Span.*: abstinencia-regla de abstinencia.

### **act/action**

*Fr.*: acte, action ; *Ger.*: Akt, Aktion/Handlung *It.*: atto, azione; *Port.*: acto, acção; *Span.*: acto, acción.

### **action-language**

*Fr.*: langage d'action; *Ger.*: Handlungssprache; *It.*: linguaggio d'azione; *Port.*: linguagem de acção; *Span.*: lenguaje de acción.

### **acting out/acting in**

*Fr.*: acting-out/acting-in ; *Ger.*: Ausagieren/Acting-in *It.*: acting out/acting in; *Port.*: atuação-acting out/acting in; *Span.*: actuación/acting in.

### **action-(re)presentation**

*Fr.*: représentation d'action; *Ger.*: Handlungsrepräsentanz; *It.*: rappresentazione d'azione; *Port.*: representação de acção; *Span.*: representación de acción.

### **action-thought**

*Fr.*: action-pensée (H. Kohut); *Ger.*: Handlungsgedanke *It.*: pensiero-azione; *Port.*: acção-pensamento; *Span.*: acción-pensamiento.

### **active imagination**

*Fr.*: imagination active; *Ger.*: aktive Phantasie; *It.*: immaginazione attiva; *Port.*: imaginação activa; *Span.*: imaginación activa.

### **active technique**

*Fr.*: technique active; *Ger.*: aktive Technik; *It.*: tecnica attiva; *Port.*: técnica activa; *Span.*: técnica activa.

### **activity/passivity**

*Fr.*: activité/passivité; *Ger.*: Aktivität/Passivität *It.*: attività/ passività; *Port.*: actividade/passividade; *Span.*: actividad/pasividad.

### **act, passage to the**

*Fr.*: acte (passage à l'-) ; *Ger.*: Agieren *It.*: passaggio all'atto, agito; *Port.*: passagem ao ato; *Span.*: pasaje al acto.

### **actual**

*Fr.*: actuel; *Ger.*: aktuell *It.*: attuale; *Port.*: actual; *Span.*: actual.

### **actual neurosis/defense neurosis**

*Fr.*: névrose actuelle/névrose de défense; *Ger.*: Aktualneurose/Abwehrneurose; *It.*: nevrosi attuale/ nevrosi da difesa; *Port.*: neurose actual/neurose de defesa; *Span.*: neurosis actual/neurosis de defensa.

### **acute psychoses**

*Fr.*: psychoses aiguës; *Ger.*: akute Psychosen; *It.*: psicosi acute; *Port.*: psicoses agudas. *Span.*: psicosis agudas.

### **adaptation**

*Fr.*: adaptation; *Ger.*: Anpassung *It.*: adattamento; *Port.*: adaptação; *Span.*: adaptación.

### **addiction**

*Fr.*: addiction; *Ger.*: Sucht *It.*: dipendenza; *Port.*: adição a drogas, dependência; *Span.*: adicción.

**adhesive identification**

*Fr.*: identification adhésive; *Ger.*: adhäsive Identifizierung; *It.*: identificazione adesiva; *Port.*: identificação adesiva; *Span.*: identificación adhesiva.

**adolescence**

*Fr.*: adolescence; *Ger.*: Adoleszenz *It.*: adolescenza; *Port.*: adolescência; *Span.*: adolescencia.

**adolescent crisis**

*Fr.*: adolescence (crise d<sup>3</sup>-); *Ger.*: Adoleszenzkrise; *It.*: crisi adolescenziale; *Port.*: crise de adolescência; *Span.*: crisis de adolescencia.

**adoption**

*Fr.*: adoption; *Ger.*: Adoption; *It.*: adozione; *Port.*: adopção; *Span.*: adopción.

**affect**

*Fr.*: affect; *Ger.*: Affekt; *It.*: affetto; *Port.*: afecto; *Span.*: afecto.

**agency**

*Fr.*: instance; *Ger.*: Instanz; *It.*: istanza; *Port.*: instância; *Span.*: instancia.

**aggressiveness**

*Fr.*: agressivité; *Ger.*: Aggressivität; *It.*: aggressività; *Port.*: agressividade; *Span.*: agresividad.

**alchemy**

*Fr.*: alchimie; *Ger.*: Alchimie; *It.*: alchimia; *Port.*: alquimia; *Span.*: alquimia. alcoholism

*Fr.*: alcoolisme; *Ger.*: Alkoholismus; *It.*: alcolismo; *Port.*: alcoolismo; *Span.*: alcoholismo.

**alienation**

*Fr.*: aliénation; *Ger.*: Entfremdung; *It.*: alienazione; *Port.*: alienação; *Span.*: alienación.

**allergy**

*Fr.*: allergie; *Ger.*: Allergie; *It.*: allergia; *Port.*: alergia; *Span.*: alergia.

**allergic relation**

*Fr.*: allergique (relation d'objet -); *Ger.*: allergische Objektbeziehung; *It.*: relazione allergica; *Port.*: relação alérgica; *Span.*: relación alérgica.

**alpha-elements**

*Fr.*: éléments alpha; *Ger.*: Alpha-Elemente; *It.*: elementi alfa; *Port.*: elementos alfa; *Span.*: elementos alfa.

**alpha function**

*Fr.*: fonction alpha; *Ger.*: alpha Funktion; *It.*: funzione alfa; *Port.*: função alfa; *Span.*: función alfa.

**altruism**

*Fr.*: altruisme; *Ger.*: Nächstenliebe/Altruismus; *It.*: altruismo; *Port.*: altruísmo; *Span.*: altruismo.

**ambivalence**

*Fr.*: ambivalence; *Ger.*: Ambivalenz; *It.*: ambivalenza; *Port.*: ambivalência; *Span.*: ambivalencia.

**amnesia**

*Fr.*: amnésie; *Ger.*: Amnesie; *It.*: amnesia; *Port.*: amnésia; *Span.*: amnesia.

**amphimixia**

*Fr.*: amphimixie; *Ger.*: Amphimixis; *It.*: anfimissi; *Port.*: anfimixia; *Span.*: anfimixia.

**amplification**

*Fr.*: amplification; *Ger.*: Amplifikation; *It.*: amplificazione; *Port.*: amplificação; *Span.*: amplificación.

**anaclisis/anaclitic**

*Fr.*: anaclitisme, anaclitique; *Ger.*: Anaklitismus, anaklitisch; *It.*: anaclisi, anaclitico; *Port.*: anaclitismo, anaclítico; *Span.*: anaclitismo, anaclítico.

**anagogical interpretation**

*Fr.*: interprétation anagogique; *Ger.*: anagogische Deutung; *It.*: interpretazione anagogica; *Port.*: interpretação anagógica; *Span.*: interpretación anagógica.

**anal eroticism**

*Fr.*: érotisme anal; *Ger.*: Analerotik; *It.*: erotismo anale; *Port.*: erotismo anal; *Span.*: erotismo anal.

**anality**

*Fr.*: analité; *Ger.*: Analität; *It.*: analità; *Port.*: analidade; *Span.*: analidad.

**anal-sadistic stage**

*Fr.*: stade sadique-anal; *Ger.*: anal(sadistische) Phase; *It.*: fase sadico-anale; *Port.*: fase anal-sádica; *Span.*: fase sádico-anal.

**analysability**

*Fr.*: analysabilité; *Ger.*: Analysierbarkeit; *It.*: analizzabilità; *Port.*: analisabilidade; *Span.*: analisabilidad.

**analysand**

*Fr.*: analysé/analysant; *Ger.*: analysiert/analysierend, der Analysand; *It.*: analizzato/analizzando; *Port.*: analisado/analisante; *Span.*: analizado/analizante.

**analytical psychology**

*Fr.*: psychologie analytique; *Ger.*: analytische Psychologie; *It.*: psicologia analitica; *Port.*: psicologia analítica; *Span.*: psicología analítica.

**animal magnetism**

*Fr.*: magnétisme animal; *Ger.*: animalischer Magnetismus; *It.*: magnetismo animale; *Port.*: magnetismo animal; *Span.*: magnetismo animal.

**animistic thought**

*Fr.*: animique (pensée -); *Ger.*: animistisches Denken; *It.*: pensiero animistico; *Port.*: pensamento animista; *Span.*: pensamiento animista.

**annihilation anxiety**

*Fr.*: angoisses d'anéantissement; *Ger.*: Vernichtungssangst; *It.*: angoscia di annichilimento; *Port.*: angústias de aniquilamento; *Span.*: angustias de aniquilamiento.

**anorexia nervosa**

*Fr.*: anorexie mentale; *Ger.*: Anorexie; *It.*: anoressia mentale; *Port.*: anorexia mental; *Span.*: anorexia nerviosa.

**anticathexis, counter-cathexis**

*Fr.*: contre-investissement; *Ger.*: Gegenbesetzung; *It.*: controinvestimento; *Port.*: contra-investimento; *Span.*: contracarga.

**anticipatory ideas**

*Fr.*: représentations d'attente; *Ger.*: Erwartungsvorstellungen; *It.*: rappresentazioni anticipatorie; *Port.*: representação de espera; *Span.*: representaciones de espera.

**antilibidinal ego/internal saboteur**

*Fr.*: ego antilibidinal/saboteur interne; *Ger.*: antilibidinöses Ich/innerer Saboteur; *It.*: Io antilibidico/sabotatore interno; *Port.*: Eu anti-libidinal/ sabotador interno; *Span.*: Yo antilibidinal/saboteador interno.

**antinarcissism**

*Fr.*: anti-narcissisme; *Ger.*: Antinarzissmus; *It.*: antinarcisismo; *Port.*: antinarcisismo; *Span.*: antinarcisismo.

**anxiety**

*Fr.*: angoisse; *Ger.*: Angst; *It.*: angoscia; *Port.*: angústia; *Span.*: angustia.

**anxiety dream**

*Fr.*: rêve d'angoisse; *Ger.*: Angsttraum; *It.*: sogno di angoscia; *Port.*: sonho de angústia; *Span.*: sueño de angustia.

**aphanisis**

*Fr.*: aphanisis; *Ger.*: Aphanisis; *It.*: afanisi; *Port.*: afânise; *Span.*: afánisis.

**aphasia**

*Fr.*: aphasie; *Ger.*: Aphasie; *It.*: afasia; *Port.*: afasia; *Span.*: afasia.

**archaic**

*Fr.*: archaïque; *Ger.*: archaisch; *It.*: arcaico; *Port.*: arcaico; *Span.*: arcaico.

**archaic mother**

*Fr.*: mère archaïque; *Ger.*: archaische Mutter; *It.*: madre arcaica; *Port.*: mãe arcaica; *Span.*: madre arcaica.

**archetype**

*Fr.*: archétype; *Ger.*: Archetyp; *It.*: archetipo; *Port.*: arquétipo; *Span.*: arquetipo.

**arrogance**

*Fr.*: arrogance; *Ger.*: Arroganz; *It.*: arroganza; *Port.*: arrogância; *Span.*: arrogancia.

**as if personality**

*Fr.*: comme si (personnalité -); *Ger.*: Als-ob-Persönlichkeit; *It.*: personalità come se; *Port.*: personalidade como se; *Span.*: personalidad como si.

**attachment**

*Fr.*: attachement; *Ger.*: Bindung; *It.*: attaccamento; *Port.*: apego; *Span.*: apego.

**attention**

*Fr.*: attention; *Ger.*: Beachtung/Aufmerksamkeit; *It.*: attenzione; *Port.*: atenção; *Span.*: atención.

**autism**

*Fr.*: autisme; *Ger.*: Autismus; *It.*: autismo; *Port.*: autismo; *Span.*: autismo.

**autistic capsule/autistic nucleus**

*Fr.*: noyau autistique; *Ger.*: autistischer Kern; *It.*: nucleo autistico; *Port.*: núcleo autístico; *Span.*: núcleo autista.

**autistic defenses**

*Fr.*: défenses autistiques; *Ger.*: autistische Abwehr(mechanismen); *It.*: difese autistiche; *Port.*: defesas autísticas; *Span.*: defensas autísticas.

**autobiography**

*Fr.*: autobiographie; *Ger.*: Autobiographie; *It.*: autobiografia; *Port.*: autobiografia; *Span.*: autobiografía.

**autoeroticism/alloeroticism**

*Fr.*: autoérotisme/alloérotisme; *Ger.*: Autoerotismus/Alloerotismus; *It.*: autoerotismo/alloerotismo; *Port.*: auto-erotismo/alo-erotismo; *Span.*: autoerotismo/alloerotismo.

**automatism**

*Fr.*: automatisme; *Ger.*: Automatismus; *It.*: automatismo; *Port.*: automatismo; *Span.*: automatismo.

**autoplastic/alloplastic**

*Fr.*: autoplastique/alloplastique; *Ger.*: autoplastisch/alloplastisch; *It.*: autoplastico/alloplastico; *Port.*: autoplástico/aloplástico; *Span.*: autoplástico/aloplástico.

**autosuggestion**

*Fr.*: autosuggestion; *Ger.*: Autosuggestion; *It.*: autosuggerione; *Port.*: auto-sugestão; *Span.*: autosugestión.

**basic assumption**

*Fr.*: présupposé de base; *Ger.*: “basic assumption”/Grundannahme; *It.*: assunto di base; *Port.*: pressuposto de base; *Span.*: presupuesto de base.

**basic fault**

*Fr.*: défaut fondamental; *Ger.*: Grundstörung; *It.*: difetto fondamentale; *Port.*: falha básica; *Span.*: falla básica.

**belief**

*Fr.*: croyance; *Ger.*: Glaube; *It.*: credenza; *Port.*: crença; *Span.*: creencia.

**benign/malignant regression**

*Fr.*: régression bénigne/maligne; *Ger.*: benigne/maligne Regression; *It.*: regressione benigna/maligna; *Port.*: regressão benigna/maligna; *Span.*: regresión benigna/maligna.

**beta-elements**

*Fr.*: éléments bêta; *Ger.*: Beta-Elemente; *It.*: elementi beta; *Port.*: elementos beta; *Span.*: elementos beta.

**beta screen**

*Fr.*: écran bêta; *Ger.*: Betaschirm; *It.*: schermo beta; *Port.*: ecrã beta; *Span.*: pantalla beta.

**binding/unbinding**

*Fr.*: liaison/déliaison; *Ger.*: Bindung/Entbindung; *It.*: legame/slegamento; *Port.*: união/desunião; *Span.*: unión/desunión.

**biological bedrock**

*Fr.*: roc du biologique; *Ger.*: biologisches Fundament/gewachsener Fels; *It.*: roccia basilare del biologico; *Port.*: fundo biológico; *Span.*: roca de base/roca viva.

**bipolar self**

*Fr.*: Self bipolaire; *Ger.*: bipolares Selbst; *It.*: Sé bipolare; *Port.*: self bipolar; *Span.*: self bipolar.

**birth**

*Fr.*: naissance; *Ger.*: Geburt; *It.*: nascita; *Port.*: nascimento. *Span.*: nacimiento.

**mutual analysis**

*Fr.*: analyse mutuelle; *Ger.*: mutuelle Analyse; *It.*: analisi reciproca; *Port.*: análise mútua; *Span.*: análisis mutuo.

**mysticism**

*Fr.*: mysticisme; *Ger.*: Mystik/Mystizismus; *It.*: misticismo; *Port.*: misticismo; *Span.*: misticismo.

**myth**

*Fr.*: mythe; *Ger.*: Mythus/Mythos; *It.*: mito; *Port.*: mito; *Span.*: mito.

**myth of origins**

*Fr.*: mythe des origines; *Ger.*: Ursprungsmythus; *It.*: mito delle origini; *Port.*: mito das origens; *Span.*: mito de los orígenes.

**myth of the hero**

*Fr.*: héros (mythe du -); *Ger.*: Mythus des Helden; *It.*: mito dell'eroe; *Port.*: mito do herói; *Span.*: mito del héroe.

**mythomania**

*Fr.*: mythomanie; *Ger.*: Mythomanie; *It.*: mitomania; *Port.*: mitomania; *Span.*: mitomanía.

**nakedness, dream of**

*Fr.*: rêve de nudité; *Ger.*: Nacktheitstraum; *It.*: sogno di nudità; *Port.*: sonho de nudez; *Span.*: sueño de desnudez.

**Name-of-the-Father**

*Fr.*: Nom-du-Père; *Ger.*: Name-des-Vaters; *It.*: Nome del Padre; *Port.*: Nome do Pai; *Span.*: Nombre del Padre.

**narcissism**

*Fr.*: narcissisme; *Ger.*: Narzissmus; *It.*: narcisismo; *Port.*: narcisismo; *Span.*: narcisismo.

**narcissism of minor differences**

*Fr.*: narcissisme des petites différences; *Ger.*: Narzissmus der kleinen Unterschiede; *It.*: narcisismo delle piccole differenze; *Port.*: narcisismo das pequenas diferenças; *Span.*: narcisismo de las pequeñas diferencias.

**narcissistic defenses**

*Fr.*: défenses narcissiques; *Ger.*: narzisstische Abwehr(mechanismen); *It.*: difese narcisistiche; *Port.*: defesas narcísicas; *Span.*: defensas narcisísticas.

**narcissistic elation**

*Fr.*: élation narcissique; *Ger.*: narzisstische Gehobenheit; *It.*: elazione narcisistica; *Port.*: elação narcísica; *Span.*: elación narcisística.

**narcissistic injury**

*Fr.*: blessure narcissique; *Ger.*: narzisstische Kränkung; *It.*: ferita narcisistica; *Port.*: ferida narcísica; *Span.*: herida narcisista.

**narcissistic neurosis**

*Fr.*: névrose narcissique; *Ger.*: narzisstische Neurose; *It.*: nevrosi narcisistica; *Port.*: neurose narcísica; *Span.*: neurosis narcisista.

**narcissistic rage**

*Fr.*: rage narcissique; *Ger.*: narzisstische Wut; *It.*: rabbia narcisistica; *Port.*: raiva narcísica; *Span.*: furia narcisista.

**narcissistic transference**

*Fr.*: transfert narcissique; *Ger.*: narzisstische Übertragung; *It.*: transfert narcisistico; *Port.*: transferência narcísica; *Span.*: transferencia narcisista.

**narcissistic withdrawal**

*Fr.*: narcissique (repli -); *Ger.*: narzisstischer Rückzug; *It.*: ritiro narcisistico; *Port.*: retraimento narcísico; *Span.*: repliegue narcisista.

**narco-analysis**

*Fr.*: narco-analyse; *Ger.*: Narkose-Analyse; *It.*: narcoanalisi; *Port.*: narcoanálise; *Span.*: narcoanálisis.

**negative hallucination**

*Fr.*: hallucination négative; *Ger.*: negative Halluzination; *It.*: allucinazione negativa; *Port.*: alucinação negativa; *Span.*: alucinación negativa.

**negative, work of the**

*Fr.*: négatif (travail du -); *Ger.*: Arbeit des Negativen; *It.*: lavoro del negativo; *Port.*: trabalho do negativo; *Span.*: trabajo del negativo.

**negation**

*Fr.*: négation; *Ger.*: Verneinung; *It.*: negazione; *Port.*: negação; *Span.*: negación.

**need for causality**

*Fr.*: besoin de causalité; *Ger.*: Kausalitätsbedürfnis; *It.*: bisogno di causalità; *Port.*: necessidade de causalidade; *Span.*: necesidad de causalidad.

**need for punishment**

*Fr.*: besoin de punition; *Ger.*: Strafbedürfnis; *It.*: bisogno di punizione; *Port.*: necessidade de punição; *Span.*: necesidad de castigo.

**negative capability**

*Fr.*: capacité négative; *Ger.*: Fähigkeit zur Negativität; *It.*: capacità negativa; *Port.*: capacidade negativa; *Span.*: capacidad negativa.

**negative therapeutic reaction**

*Fr.*: réaction thérapeutique négative; *Ger.*: negative therapeutische Reaktion; *It.*: reazione terapeutica negativa; *Port.*: reação terapêutica negativa; *Span.*: reacción terapéutica negativa.

**negative transference**

*Fr.*: transfert négatif; *Ger.*: negative Übertragung; *Span.*: transferencia negativa; *It.*: transfert negativo; *Port.*: transferência negativa.

**neurasthenia**

*Fr.*: neurasthénie; *Ger.*: Neurasthenie; *It.*: nevrastenia; *Port.*: neurastenia; *Span.*: neurastenia.

**neuro-psychosis of defense**

*Fr.*: psychonévrose de défense; *Ger.*: Abwehr-Neuropsychose; *It.*: psiconevrosi da difesa; *Port.*: psiconeurose de defesa; *Span.*: psiconeurosis de defensa.

**neuroses**

*Fr.*: névroses; *Ger.*: Neurosen; *It.*: nevrosi; *Port.*: neuroses; *Span.*: neurosis.

**neurotic defenses**

*Fr.*: défenses névrotiques; *Ger.*: neurotische Abwehr(-mechanismen); *It.*: difese nevrotiche; *Port.*: defesas neuróticas; *Span.*: defensas neuróticas.

**neutrality/benevolent neutrality**

*Fr.*: neutralité, neutralité bienveillante; *Ger.*: Neutralität, wohlwollende Neutralität; *It.*: neutralità, neutralità benevola; *Port.*: neutralidade, neutralidade benevolente; *Span.*: neutralidad, neutralidad amable.

**nightmare**

*Fr.*: cauchemar; *Ger.*: Alptraum; *It.*: incubo; *Port.*: pesadelo; *Span.*: pesadilla.

**night terror**

*Fr.*: terreur nocturne; *Ger.*: Pavor nocturnus; *It.*: pavor nocturnus; *Port.*: terror nocturno; *Span.*: terror nocturno.

**nonverbal communication**

*Fr.*: communication non verbale; *Ger.*: nonverbale Kommunikation; *It.*: comunicazione non verbale; *Port.*: comunicação não verbal; *Span.*: comunicación no verbal.

**normality**

*Fr.*: normalité; *Ger.*: Normalität; *It.*: normalità; *Port.*: normalidade; *Span.*: normalidad.

**nostalgia**

*Fr.*: nostalgie; *Ger.*: Nostalgie, Heimweh; *Span.*: nostalgia; *It.*: nostalgia; *Port.*: nostalgia.

**nuclear complex**

*Fr.*: complexe nucléaire; *Ger.*: Kernkomplex; *It.*: complesso nucleare; *Port.*: complexo nuclear; *Span.*: complejo nuclear.

**numinous**

*Fr.*: numineux; *Ger.*: Numinose; *It.*: numinoso; *Port.*: numinoso; *Span.*: numinoso.

**object**

*Fr.*: objet; *Ger.*: Objekt; *It.*: oggetto; *Port.*: objecto; *Span.*: objeto.

**object a**

*Fr.*: objet a; *Ger.*: Objekt a; *It.*: oggetto a; *Port.*: objecto a; *Span.*: objeto a.

**object, change of/choice of**

*Fr.*: objet (changement d'-, choix d'-); *Ger.*: Objektwechsel, Objektwahl; *It.*: cambiamento d'oggetto, scelta d'oggetto; *Port.*: mudança de objecto, escolha de objecto; *Span.*: cambio de objeto, elección de objeto.

**object relations**

*Fr.*: relations d'objet; *Ger.*: Objektbeziehungen; *object relations* *Span.*: relaciones de objeto; *It.*: relazioni oggettuali; *Port.*: relações de objecto.

**obsessional neurosis**

*Fr.*: névrose obsessionnelle; *Ger.*: Zwangsneurose; *It.*: nevrosi ossessiva; *Port.*: neurose obsessiva; *Span.*: neurosis obsesiva.

**obsession**

*Fr.*: obsession; *Ger.*: Obsession, Zwangsvorstellung; *It.*: ossessione; *Port.*: obsessão; *Span.*: obsesión.

**oceanic feeling**

*Fr.*: sentiment océanique; *Ger.*: ozeanisches Gefühl; *Span.*: sentimiento oceánico; *It.*: sentimento oceanico; *Port.*: sentido oceânico.

**occultism**

*Fr.*: occultisme; *Ger.*: Geheimwissenschaft/Okkultismus; *It.*: occultismo; *Port.*: ocultismo; *Span.*: ocultismo.

**Oedipus complex**

*Fr.*: complexe d'Édipe; *Ger.*: Ödipuskomplex; *It.*: complesso di Edipo; *Port.*: complexo de Édipo; *Span.*: complejo de Edipo.

**omnipotence of thoughts**

*Fr.*: toute-puissance des pensées; *Ger.*: Allmacht der Gedanken, omnipotentes Denken; *It.*: onnipotenza del pensiero; *Port.*: onnipotência do pensamento; *Span.*: omnipotencia del pensamiento.

**ontogeny**

*Fr.*: ontogénèse; *Ger.*: Ontogenese; *It.*: ontogenesi; *Port.*: ontogênese; *Span.*: ontogénesis.

**operational thinking**

*Fr.*: pensée opératoire; *Ger.*: operatives Denken; *It.*: pensiero operatorio; *Port.*: pensamento operatório; *Span.*: pensamiento operatorio.

**optical schema**

*Fr.*: schéma optique; *Ger.*: optisches Modell/visuelles Modell; *It.*: schema ottico; *Port.*: esquema óptico; *Span.*: esquema óptico.

**oral eroticism**

*Fr.*: érotisme oral; *Ger.*: Oralerotik; *It.*: erotismo orale; *Port.*: erotismo oral; *Span.*: erotismo oral.

**orality**

*Fr.*: oralité; *Ger.*: Oralität; *It.*: oralità; *Port.*: oralidade; *Span.*: oralidad.

**oral-sadistic stage**

*Fr.*: stade sadique-oral (ou cannibalique); *Ger.*: oralsadistische Phase, kannibalistische Phase; *It.*: fase sadico-orale, fase cannibalica; *Port.*: fase oral-sádica, fase canibalística; *Span.*: fase sádico-oral (o canibalística).

**oral stage**

*Fr.*: stade oral; *Ger.*: orale Phase; *It.*: fase orale; *Port.*: fase oral; *Span.*: fase oral.

**organic psychoses**

*Fr.*: psychoses organiques; *Ger.*: organische Psychosen; *It.*: psicosi organiche; *Port.*: psicoses orgânicas; *Span.*: psicosis orgánicas.

**organic repression**

*Fr.*: refoulement organique; *Ger.*: organische Verdrängung; *It.*: rimozione organica; *Port.*: recalque orgânico; *Span.*: represión orgánica.

**organization**

*Fr.*: organisation; *Ger.*: Organisation; *It.*: organizzazione; *Port.*: organização; *Span.*: organización.

**organ pleasure**

*Fr.*: plaisir d'organe; *Ger.*: Organlust; *It.*: piacere d'organo; *Port.*: prazer de órgão; *Span.*: placer de órgano.

**orgasm**

*Fr.*: orgasme; *Ger.*: Orgasmus; *It.*: orgasmo; *Port.*: orgasmo; *Span.*: orgasmo.

**orgone**

*Fr.*: orgone; *Ger.*: Orgonenergie; *It.*: orgone; *Port.*: orgone; *Span.*: orgón.

**Other**

*Fr.*: Autre; *Ger.*: Anderer; *It.*: Altro; *Port.*: Outro; *Span.*: Otro.

**otherness/alterity**

*Fr.*: altérité; *Ger.*: Andersheit/Anderssein; *It.*: alterità; *Port.*: alteridade; *Span.*: alteridad.

**overdetermination**

*Fr.*: surdétermination; *Ger.*: Überdeterminierung; *It.*: sovradeterminazione; *Port.*: superdeterminação; *Span.*: sobredeterminación.

**over-interpretation**

*Fr.*: surinterprétation; *Ger.*: Überdeutung; *It.*: sovrainterpretazione; *Port.*: superinterpretação; *Span.*: sobreinterpretación.

**pair of opposites**

*Fr.*: couples d'opposés; *Ger.*: Gegensatzpaar; *It.*: coppia d'opposti; *Port.*: par antitético; *Span.*: par antitético.

**parade of the signifier**

*Fr.*: défilé du signifiant; *Ger.*: Engführung des Signifikanten; *It.*: défilé del significante; *Port.*: desfiladeiro do significante; *Span.*: desfiladero del significante.

**paradox**

*Fr.*: paradoxe; *Ger.*: Paradox; *It.*: paradosso; *Port.*: paradoxo; *Span.*: paradoja.

**paranoid position**

*Fr.*: position paranoïde; *Ger.*: paranoide Position; *It.*: posizione paranoide; *Port.*: posição paranóide; *Span.*: posición paranoide.

**paranoid psychosis**

*Fr.*: psychose paranoïde; *Ger.*: Paranoia; *It.*: psicosi paranoide; *Port.*: psicose paranóide; *Span.*: psicosis paranoide.

**parapraxis**

*Fr.*: acte manqué ; *Ger.*: Fehlleistung/Fehlhandlung *It.*: atto mancato; *Port.*: acto falhado/ato falho; *Span.*: acto fallido.

**paranoid-schizoid position**

*Fr.*: position schizo-paranoïde; *Ger.*: paranoïde-schizoïde Position; *It.*: posizione schizoparanoide; *Port.*: posição esquizo-paranoïde; *Span.*: posición esquizo-paranoïde.

**paraphrenia**

*Fr.*: paraphrénie; *Ger.*: Paraphrenie; *It.*: parafrenia; *Port.*: parafrenia; *Span.*: parafrenia.

**paranoid psychosis**

*Fr.*: psychose paranoïde; *Ger.*: Paranoia; *It.*: psicosi paranoïde; *Port.*: psicose paranoïde; *Span.*: psicosis paranoïde.

**parapraxis**

*Fr.*: acte manqué ; *Ger.*: Fehlleistung/Fehlhandlung *It.*: atto mancato; *Port.*: acto falhado/ato falho; *Span.*: acto fallido.

**parenthood**

*Fr.*: parentalité; *Ger.*: Elternschaft; *It.*: genitorialità; *Port.*: parentalidade; *Span.*: parentalidad.

**parricide**

*Fr.*: meurtre du père; *Ger.*: Vatemord; *It.*: uccisione del padre; *Port.*: assassinio do pai; *Span.*: asesinato del padre/parricidio.

**partial drive**

*Fr.*: pulsion partielle; *Ger.*: Partialtrieb; *It.*: pulsione parziale; *Port.*: pulsão parcial; *Span.*: pulsión parcial.

**passion**

*Fr.*: passion; *Ger.*: Leidenschaft; *It.*: passione; *Port.*: paixão; *Span.*: pasión.

**pass, the**

*Fr.*: passe (la -); *Ger.*: "Passe"; *It.*: la passe; *Port.*: o passe; *Span.*: el pase.

**penis envy**

*Fr.*: envie du pénis; *Ger.*: Penisneid; *It.*: invidia del pene; *Port.*: inveja do pénis; *Span.*: envidia del pene.

**Perception-Consciousness**

*Fr.*: Perception-Conscience; *Ger.*: Wahrnehmung-Bewusstsein; Perception-Consciousness *It.*: Percezione-Coscienza; *Port.*: Percepção-Consciência; *Span.*: Percepción-Conciencia.

**perceptual identity**

*Fr.*: identité de perception; *Ger.*: Wahrnehmungsidentität; *It.*: identità di percezione; *Port.*: identidade de percepção; *Span.*: identidad de percepción.

**persecution**

*Fr.*: persécution; *Ger.*: Verfolgung; *It.*: persecuzione; *Port.*: perseguição; *Span.*: persecución.

**perversion**

*Fr.*: perversion; *Ger.*: Perversion; *It.*: perversione; *Port.*: perversão; *Span.*: perversión.

**phallic woman**

*Fr.*: femme phallique; *Ger.*: phallische Frau; *It.*: donna fallica; *Port.*: mulher fálica; *Span.*: mujer fálica.

**phantom**

*Fr.*: fantôme; *Ger.*: Gespenst; *It.*: spettro; *Port.*: espectro; *Span.*: espectro.

**phallic mother**

*Fr.*: mère phallique; *Ger.*: phallische Mutter; *It.*: madre fallica; *Port.*: mãe fálica; *Span.*: madre fálica.

**phallic stage**

*Fr.*: stade phallique; *Ger.*: phallische Phase; *It.*: fase fallica; *Port.*: fase fálica; *Span.*: fase fálica.

**phobia**

*Fr.*: phobie; *Ger.*: Phobie; *It.*: fobia; *Port.*: fobia; *Span.*: fobia.

**phobia of committing impulsive acts**

*Fr.*: phobie d'impulsion; *Ger.*: Phobie mit Zwangsimpulsen; *It.*: fobia di impulso; *Port.*: fobia de impulsividade; *Span.*: fobia de impulso.

**phobic neurosis**

*Fr.*: névrose phobique; *Ger.*: phobische Neurose; *It.*: nevrosi fobica; *Port.*: neurose fóbica; *Span.*: neurosis fóbica.

**phylogenesis**

*Fr.*: phylogénèse; *Ger.*: Phylogenese; *It.*: filogenesi; *Port.*: filogênese; *Span.*: filogénesis.

**pictogram**

*Fr.*: pictogramme; *Ger.*: Piktogramm; *It.*: pittogramma; *Port.*: pictograma; *Span.*: pictograma.

**pleasure-ego/reality-ego**

*Fr.*: Moi-plaisir/Moi-réalité; *Ger.*: Lust-Ich/Realitäts-Ich; *It.*: Io-piacere/Io-realtà; *Port.*: Eu-prazer/Eu-realidade; *Span.*: Yo-placer/Yo-realidad.

**pleasure in thinking**

*Fr.*: plaisir de pensée; *Ger.*: Vergnügen am Denken; *It.*: piacere del pensiero; *Port.*: prazer de pensamento; *Span.*: placer de pensamiento.

**postnatal/postpartum depression**

*Fr.*: dépression postnatale ; *Ger.*: postpartale Depression; *It.*: depressione post-partum; *Port.*: depressão pós-parto; *Span.*: depresión postparto.

**preconception**

*Fr.*: préconception; *Ger.*: Präkonzeption; *It.*: preconcezione; *Port.*: pré-concepção; *Span.*: pre-concepción.

**Preconscious, the**

*Fr.*: Préconscient (le -); *Ger.*: das Vorbewusste; *It.*: il Preconscio; *Port.*: o Pré-consciente; *Span.*: el Preconsciente.

**pregenital**

*Fr.*: pré-génital; *Ger.*: prägenital; *It.*: pregenitale; *Port.*: pregenital *Span.*: pregenital.

**pregnancy, fantasy of**

*Fr.*: fantasme de grossesse; *Ger.*: Schwangerschaftsphantasie; *It.*: fantasia di gravidanza; *Port.*: fantasia de gravidez; *Span.*: fantasía de embarazo.

**prehistory**

*Fr.*: préhistoire; *Ger.*: Vorgeschichte; *It.*: preistoria; *Port.*: pré-história; *Span.*: prehistoria.

**premonitory dream**

*Fr.*: rêve prémonitoire; *Ger.*: prämonitorischer Traum; *It.*: sogno premonitore; *Port.*: sonho premonitório; *Span.*: sueño premonitorio.

**prepsychosis**

*Fr.*: prépsychose; *Ger.*: Präpsychose; prepsicosis; *It.*: prepsicosi; *Port.*: pré-psicose; *Span.*: prepsicosis.

**prereflective unconscious**

*Fr.*: inconscient pré-réfléchi; *Ger.*: präreflektives Unbewusstes; *It.*: inconscio preriflessivo; *Port.*: inconsciente pré-reflexivo; *Span.*: inconsciente prereflexivo.

**primal, the**

*Fr.*: originaire (l'); *Ger.*: originär, das Ursprüngliche; *It.*: l'originario; *Port.*: o originário; *Span.*: lo originario.

**primal fantasies**

*Fr.*: fantasmes originaires; *Ger.*: Urphantasien; *It.*: fantasmi originari; *Port.*: profantasia/fantasia primitivas, fantasias originárias. *Span.*: profantasia/fantasia originarias.

**primal repression**

*Fr.*: refoulement originaire; *Ger.*: Urverdrängung; *It.*: rimozione originaria; *Port.*: recalque (recalcamento)

primitivo/recalque (recalcamento) originário; *Span.*: represión primaria/represión originaria.

**primal scene**

*Fr.*: scène originaire (scène primitive); *Ger.*: Urszene; *It.*: scena originaria, scena primari; *Port.*: cena primitiva, cena originária; *Span.*: escena primaria, escena originaria.

**primary identification**

*Fr.*: identification primaire; *Ger.*: primäre Identifizierung; *It.*: identificazione primaria; *Port.*: identificação primária; *Span.*: identificación primaria.

**primary love**

*Fr.*: amour primaire; *Ger.*: primäre Liebe; *It.*: amore primario; *Port.*: amor primário; *Span.*: amor primario.

**primary masochism**

*Fr.*: masochisme primaire; *Ger.*: primärer Masochismus; *It.*: masochismo primario; *Port.*: masoquismo primário; *Span.*: masoquismo primario.

**primary narcissism**

*Fr.*: narcissisme primaire; *Ger.*: primärer Narzissmus; *It.*: narcisismo primario; *Port.*: narcisismo primário; *Span.*: narcisismo primario.

**primary need**

*Fr.*: besoin primaire; *Ger.*: Grundbedürfnis; *It.*: bisogno primario; *Port.*: necessidade primária; *Span.*: necesidad primaria.

**primary object**

*Fr.*: objet primaire; *Ger.*: Primärobjekt; *It.*: oggetto primario; *Port.*: objecto primário; *Span.*: objeto primario.

**primary process/secondary process**

*Fr.*: processus primaire, processus secondaire ; *Ger.*: Primärvorgang, Sekundärvorgang; *It.*: processo primario, processo secundario; *Port.*: processo primário, processo secundário; *Span.*: proceso primario, proceso secundario.

**primitive**

*Fr.*: primitif; *Ger.*: primitiv; *It.*: primitivo; *Port.*: primitivo; *Span.*: primitivo.

**primitive agonies**

*Fr.*: agonies primitives; *Ger.*: primitive Agonien; *It.*: agonia primitiva; *Port.*: agonias primitivas; *Span.*: agonias primitivas.

**primitive horde**

*Fr.*: horde primitive; *Ger.*: Urhorde; *It.*: orda primordiale; *Port.*: horda primitiva; *Span.*: horda primitiva.

**principle**

*Fr.*: principe; *Ger.*: Prinzip; *It.*: principio; *Port.*: princípio; *Span.*: principio.

**principle of constancy**

*Fr.*: principe de constance; *Ger.*: Konstanzprinzip; *It.*: principio di costanza; *Port.*: princípio de constância; *Span.*: principio de constancia.

**principle of identity preservation**

*Fr.*: principe d'identité; *Ger.*: Identitätsprinzip; *It.*: principio di identità; *Port.*: princípio de identidade; *Span.*: principio de identidad.

**principle of (neuronal) inertia**

*Fr.*: principe d'inertie (des neurones); *Ger.*: Trägheitssprinzip (Prinzip der Neuronenträgheit); *It.*: principio di inerzia (neuronica); *Port.*: princípio de inércia (neuronal); *Span.*: principio de inercia (neuronal).

**privation**

*Fr.*: privation; *Ger.*: Entbehrung/Entzug; *It.*: privazione; *Port.*: privação; *Span.*: privación.

**process**

*Fr.*: processus; *Ger.*: Prozess, Vorgang; *It.*: processo; *Port.*: processo; *Span.*: proceso.

**progressive neutralization**

*Fr.*: neutralisation progressive; *Ger.*: progressive Neutralisierung; *It.*: neutralizzazione progressiva; *Port.*: neutralização progressiva; *Span.*: neutralización progresiva.

**prohibition**

*Fr.*: interdit; *Ger.*: verboten, Verbot; *It.*: interdetto, interdizione; *Port.*: proibido, proibição; *Span.*: prohibido, prohibición.

**projection**

*Fr.*: projection; *Ger.*: Projektion; *It.*: proiezione; *Port.*: projecção; *Span.*: proyección.

**projection and "participation mystique"**

*Fr.*: projection et "participation mystique"; *Ger.*: Projektion und "participation mystique"; *It.*: proiezione e partecipazione mistica; *Port.*: projecção e "participação mística"; *Span.*: proyección y "participación mística."

**projective identification**

*Fr.*: identification projective; *Ger.*: projektive Identifizierung; *It.*: identificazione proiettiva; *Port.*: identificação projectiva; *Span.*: identificación proyectiva.

**protective shield**

*Fr.*: pare-excitations; *Ger.*: Reizschutz; *It.*: parastimoli o schermo antistimolo; *Port.*: pára-excitações; *Span.*: protector o protección contra las excitaciones o los estímulos.

**prot Thoughts**

*Fr.*: protopensées; *Ger.*: Protogedanken; *It.*: protopensieri; *Port.*: proto-pensamentos; *Span.*: proto-pensamientos.

**psyche/psychism**

*Fr.*: psychisme; *Ger.*: Psyche; *It.*: psichismo; *Port.*: psi-quismo; *Span.*: psiquismo.

**psychic apparatus**

*Fr.*: appareil psychique; *Ger.*: psychischer/seelischer Apparat; *It.*: apparato psichico; *Port.*: aparelho psíquico/mental; *Span.*: aparato psíquico.

**psychic causality**

*Fr.*: causalité psychique; *Ger.*: psychische Kausalität; *It.*: causalità psichica; *Port.*: causalidade psíquica; *Span.*: causalidad psíquica.

**psychic envelope**

*Fr.*: enveloppes psychiques; *Ger.*: psychische Hülle; *It.*: involucri psichici; *Port.*: invólucros psíquicos; *Span.*: envolturas psíquicas.

**psychic reality**

*Fr.*: réalité psychique; *Ger.*: psychische Realität; *It.*: realtà psichica; *Port.*: realidade psíquica; *Span.*: realidad psíquica.

**psychic representative**

*Fr.*: représentant psychique; *Ger.*: psychische Repräsentanz, psychische Repräsentant; *It.*: rappresentante psichico; *Port.*: representante psíquico; *Span.*: representante psíquico.

**psychic structure**

*Fr.*: structure psychique; *Ger.*: psychische Struktur; *It.*: struttura psichica; *Port.*: estrutura psíquica; *Span.*: estructura psíquica.

**psychic temporality**

*Fr.*: temporalité psychique; *Ger.*: psychische Zeitlichkeit; *It.*: temporalità psichica; *Port.*: temporalidade psíquica; *Span.*: temporalidad psíquica.

**psychoanalysis**

*Fr.*: psychanalyse; *Ger.*: Psychoanalyse; *It.*: psicoanalisi; *Port.*: psicanálise; *Span.*: psicoanálisis.

**psychoanalyst**

*Fr.*: psychanalyste; *Ger.*: Psychoanalytiker; *It.*: psicoanalista; *Port.*: psicanalista; *Span.*: psicoanalista.

**psychoanalytic technique**

*Fr.:* technique psychanalytique; *Ger.:* psychoanalytische Technik; *It.:* tecnica psicoanalitica; *Port.:* técnica psicanalítica; *Span.:* técnica psicoanalítica.

**psychoanalytic treatment**

*Fr.:* cure psychanalytique; *Ger.:* Psychoanalytische Kur; *It.:* cura psicoanalitica; *Port.:* cura psicanalítica; *Span.:* cura psicoanalítica.

**psychobiography**

*Fr.:* psychobiographie; *Ger.:* Psychobiographie; *It.:* psicobiografia; *Port.:* psicobiografia; *Span.:* psicobiografía.

**psychodrama**

*Fr.:* psychodrame; *Ger.:* Psychodrama; *It.:* psicodramma; *Port.:* psicodrama; *Span.:* psicodrama.

**psychogenesis/organogenesis**

*Fr.:* psychogenèse/organogenèse; *Ger.:* Psychogenese/Organogenese; *It.:* psicogenesi/organogenesi; *Port.:* psicogênese/organogênese; *Span.:* psicogénesis/organogénesis.

**psychohistory**

*Fr.:* psychohistoire; *Ger.:* Psychogeschichte; *It.:* psicotoria; *Port.:* psico-história; *Span.:* psicohistoria.

**psychological tests**

*Fr.:* tests psychologiques; *Ger.:* psychologische Tests; *It.:* test psicologici; *Port.:* testes psicológicos; *Span.:* tests psicológicos.

**psychological types**

*Fr.:* types psychologiques; *Ger.:* psychologische Typen; *It.:* tipi psicologici; *Port.:* tipos psicológicos; *Span.:* tipos psicológicos.

**psychoses, chronic and delusional**

*Fr.:* psychoses chroniques et délirantes; *Ger.:* chronische und wahnhafte Psychosen; *It.:* psicosi croniche e deliranti; *Port.:* psicoses crônicas e delirantes; *Span.:* psicosis crónicas y delirantes.

**psychosexual development**

*Fr.:* développement psychosexuel; *Ger.:* psychosexuelle Entwicklung; *It.:* sviluppo psicosessuale; *Port.:* desenvolvimento psicosexual; *Span.:* desarrollo psicosexual.

**psychosomatic**

*Fr.:* psychosomatique; *Ger.:* psychosomatisch; *It.:* psicosomatica; *Port.:* psicossomática; *Span.:* psicossomática.

**psychosomatic limit/boundary**

*Fr.:* limite psychosomatique; *Ger.:* psychosomatische Grenze; *It.:* limite psicosomatico; *Port.:* limite psicossomático; *Span.:* límite psicossomático.

*Fr.*: perlaboration; *Ger.*: Durcharbeiten; *It.*: rielaborazione; *Port.*: perlaboração; *Span.*: trabajo elaborativo.

# ACKNOWLEDGEMENTS FROM THE FRENCH EDITION

## ACKNOWLEDGEMENTS FROM THE FRENCH EDITION

I am indebted to Michel Prigent for giving me the idea to take part in this project to create a *Dictionary of Psychoanalysis*, as well as for giving me responsibility for its History Section. Although it was his wish to add this *Dictionary* to the diverse catalog published by Presses Universitaires de France; the vagaries of a collaboration that was difficult to establish and maintain based on divergent conceptual underpinnings led me in the end to submit on my own the very different project which these volumes represent to Éditions Calman-Levy in March 1995.

Encouraged and pursued by Isabelle Seguin until 1998, its principle form was accepted by Jean-Étienne Cohen-Séat who was the project's director at that time. After his departure Olivier Nora and Denis Bourgeois assumed responsibility for reworking it, with the assistance of Olivier Amiel after 1998. Finally Jean-Étienne Cohen-Séat closed the loop on its publication, or rather on its development into its final form after a relatively stagnant period in terms of editing. I am indeed particularly grateful to Marc Grinsztajn for his material support (to which Marie Donnet equally contributed), as well as for the moral backing he provided during the final months of this saga.

As soon as Cécile Nail became involved in the project in 2000, she was entrusted with the task of completing a critical re-reading of all the dictionary's entries, and the questions she raised led me to revisit each of the texts one by one once more, on top of the debates raised by a previous reader who was well-educated but not particularly a specialist in psychoanalysis. Besides the inevitable errors that were thereby unearthed, this work corrected certain contradictions and highly-impediment ambiguities, as well as numerous naiveties and tics in the "language" of psychoanalysis itself. Although some of these still remain, this work pruned them down vigilantly.

All this added to the timeline and entailed supplemental investments. I can not say enough times that Éditions Camann-Lévy undertook considerable financial risk by not giving up on the development of an original and voluminous work, comprising numerous translations and which paid a decent honorarium to each of its authors, all without external support, including even any reliance on the Centre National du Livre in 2001, and all this whilst their Human Sciences Division was undergoing a severe fiscal crisis. I owe them an immense personal debt of gratitude, just as I can never forget the choice Jean-Étienne Cohen-Séat made upon his return as Director in the Spring of 2000 to make the necessary sacrifices in order that the *Dictionary's* publication be continued, and that its production be as impeccable as possible.

I have never been alone in this enterprise, and I am also grateful for the adept and never-ending support provided by all the members of this sound and venerable publishing

house. They all helped me get the project off the ground and saw to its completion, but in particular I should like to mention Élisabeth Laye and Rosa Thieck, without forgetting Claire Teuwissen and Heidi Warnecke, who worked to get foreign publishers to get started on publishing this work, as well as Bernard Dobremetz and above all Bénédicte Gerber, (who invested the most faithfully of all in this work throughout all these long years, and who was my most reliable supporter), who saw to the delicate tasks of executing its actual production.

Catherine Joubaud and Éliane Rosenberg-Mounier must also be singled-out. It was their mission to “set up” the final manuscript, meaning to read all the entries a first time through after I had finished re-reading them, in order to standardize the formats, which had changed a bit over the years, and also to identify and correct stylistic and spelling errors, as well as other incoherencies which had managed to escape our previous readings—all this in addition to revising the 3,200 bibliographic references. I must also thank Jacques Sédat for the revisions he was kind enough to undertake of the proofs. *Last but not least*, Catherine Picard and Catherine Schram effected a final critical revision of all the proofs which was particularly painstaking and once again came on the heels of my own reading.

The translators were either longtime friends like Ruth Menahem, or highly-qualified professionals like Pierre-Emmanuel Duzat who had contributed some of the edition’s finest gems, like *History of Psychoanalysis* (at the Presses Universitaires de France), Dominique Lepreux, Alix Gaillard-Dermigny who, with Martine Sandor-Buthaud, assumed responsibility for all the Analytic Psychology articles, and finally Danielle Goldstein and Catherine Wieder. Other friends and colleagues contributed to the constitution of the glossary which includes the translation of a large number of concepts into five different languages: Dr. Pedro Luzes and M. Norton Godinho from the Portuguese, Dr. Roberto Goldstein and Mrs. Béatrice Marquis-Goldstein from the Spanish, Dr. Gian Franco Nicolussi and Dr. Alberto Luchetti from the Italian, Mr. Andrew Weller from the English, and Andrew Weller and Mrs. Vera Renz from the German.

It is true that 20 years of work as an editor allowed me to draw upon a wealth of friends who greatly contributed to completing a work in seven years that should have called for even more time. First of all I must thank those amongst my colleagues who spontaneously agreed to encourage this project by supporting it in various forms from the first moment it was announced. Their encouragement touched me deeply and I viewed it as a mark of confidence that was accorded to me even though everything still remained to be done. Their list is long and certain amongst them will no longer be with us at the time the book to which they attached their immediate confidence appears, but it is my duty to remember their names: Mr. André Alsteens (Belgium), Dr. Jacqueline Amati-Mehler (Italy), Professor Didier-Anzieu (France), Dr. Harold Blum (United States), Professor René Diatkine (France), Dr. Roger A. Dufresne (Canada), Dr. Horacio Etchegoyen (Argentina), Dr. Ernst Federn (Austria), Professor Gerhard Fichtner (Germany), Dr. Olivier Flournoy (Switzerland), Dr.-Professor Folch Mateu (Spain), Dr. Peter Fonagy (United Kingdom), Dr. André Green (France), Dr. León Grinberg (Spain), Mrs. Han Groen-Prakken (Netherlands), Professor André Haynal (Switzerland), Dr. Otto F. Kernberg (United States), Miss Pearl King (United Kingdom), Professor Georges Lantéri-Laura (France), Professor Serge Lebovici (France), Dr. Harald Leupold-Löwenthal (Austria), Professor Peter Loewenberg (United States), Ft/ Pedro Luzes (Portugal), Mr. Patrick Mahony (Canada), Mrs. Joyce MacDougall (France), Dr. Keigo Okonogi (Japan), Mrs. Anna Potamianou (Greece), Dr. Jean-Michel Quinodoz (Switzerland), Professor Álvaro Rey de Castro (Peru), Mrs. Anne-Marie Sandler (United Kingdom), Professor Joseph Sandler (United Kingdom), Dr. Antonio Santamaria Fernandez (Mexico), Professor Jacques Schotte (Belgium), Mr. Riccardo Steiner (United

Kingdom), Dr. Jean-Paul Valabrega (France), Dr. Robert Wallerstein (United States), Professor Daniel Widlocher (France) and Mrs. Nathalie Zaltzmann (France).

At practically the same moment in time, a certain number of other associates were asked for their scientific advice concerning the choice of entries and authors in the areas where they excelled the most. I shall recall them here more precisely by including their privileged domains: Anna Maria Accerboni and Giancarlo Gramaglia advised us concerning entries related to Italy; Jorge Luis Ahumada for Argentina, André Alsteens for Belgium, Mireille Cifali and Bernard Minder for Switzerland, Judith Dupont for Hungary, Horacio Etchegoyen for South America, Han Groen-Prakken for the Netherlands, Ludger M. Hermanns for Germany, Robert D. Hinshelwood and Riccardo Steiner for the United Kingdom, Didier Houzel for the entries on Wilfred R. Bion, Per Magnus Johansson for the Scandinavian countries, Thomas Kirsch and Christian Gaillard for Psychoanalytic Psychology, Maria Luisa Munoz for Spain, Ingrid Scholz-Strasse for Austria, Agnès Oppenheimer for Heinz Kohut, Bernard Pernot, Marie-Christine Laznik and Jacques Sédât for the entries on Lacanian psychoanalysis, Jean-François Rabain for Japan, Joseph Reppen and Paul Roazen for the United States.

I believe I sufficiently emphasized the use of the word “we” in my introductory comments to this *Dictionary* for it to be understood how indebted I have been to the members of the editorial committee for their scientific contributions and undying support. Whether it was a question of the initial choice between which articles to include and authors to use, or of assuming responsibility for writing a large number of articles and therefore taking up the slack when one or another of the former fell short, the following were in various guises the artisans of a work that without them would not exist: Sophie de Mijolla-Mellor (for writing of 96 entries and managing 165), Roger Perron (for writing 83 entries and managing 254), and Bernard Golse (for writing 40 articles and managing 194); all of whom were helped in the beginning by Jacques Angelergues. Affection, friendship and gratitude combined with the talents each of these colleagues possess resulted in a collaborative effort that rendered the management of the project far easier than I could have ever hoped for.

All that remains are the principal artisans of the work: that is the 460 authors who combined forces from all four corners of the globe into an enterprise upon which they bestowed us the pleasure and the honor of believing in, and therefore of being able to invest ourselves in, usually with great passion. Though some will never see the results of their efforts, including: André Alsteens, Didier Anzieu, Parthenope Bion Talamo, Owen Hugh D. Blomfield, Simone Decombert, Joël Dor, Serge Lebovici, Rosario Merendino, Marie-Thérèse Neyraut-Sutterman, Agnès Oppenheimer, Augusto Miguel Picollo, Helene Rank-Veltfort, Joël Sipsos and Maria Torrok; their presence remains alive and well in the texts they have written.

I do not want to close this all too brief list of acknowledgements, given the many supporters and friends I must have forgotten, without highlighting our debt to the work completed by our British and American colleagues in the development of their indispensable tool, the “P.E.P. Archives CD-ROM,” which groups together the totality of articles published by the primary English-language psychoanalytic journals from their inception dates through today. Much fact checking and supplemental information were made possible thanks this resolutely modern instrument of research.

However we shouldn’t let this homage fool us! It is mixed with equal parts envy and regret that we have not yet been able to complete a similar compendium of the French-language psychoanalytic literature. Let it express nonetheless the hope that our *Dictionary* may itself now become usable and susceptible to being regularly updated by future means of diffusion and search-engines that this 21st century, which has spawned it, has yet to develop.

ALAIN DE MIJOLLA

## INDEX

Volume 1, pp. 1–662; Volume 2, pp. 663–1344; Volume 3, pp. 1345–1892

- Biolibidio* (Levi Bianchini), 963
- Biological bedrock, **182–183**, 254, 575, 773, 1278
- “Biological Economy of Birth, The” (Greenacre), 702
- Bion, Wilfred Ruprecht, **183–184**
- on alpha-elements, 50–51, 184, 815
- on alpha function, 51–52, 121, 184, 952, 953
- analytic psychodrama and, 78
- Anzieu and, 104
- Argentinian psychoanalysis and, 118
- on arrogance, 121
- on attacks on linking, 983–984
- on attention, 127–128, 439
- on autobiography, 140
- on basic assumption, 151, 709–710, 711
- on beta-elements, 171, 184
- on beta-screens, 171–172
- on binding/unbinding, 658
- on birth, 185
- on birth trauma, 1803
- on bizarre object, 188
- Bleger and, 194
- Brazilian psychoanalysis and, 217
- British psychoanalysis and, 699
- Canadian psychoanalysis and, 244
- on castration, 1676
- on castration complex, 254
- on catastrophic change, 257, 418
- on change, 268
- on common sense, 419
- on compulsion, 323
- on concepts, 323–324
- on contact-barrier, 339–340
- on container-contained, 184, 340, 850
- Corrao and, 347
- on death instinct, 373
- on deferred action, 380
- definition of psychoanalysis and, 1363
- on disintegration anxieties, 418
- on dream-like memory, 439
- on emotions, 501
- on envy, 508–509
- on fantasy, 551
- feminist views of psychoanalysis and, 577
- Foulkes and, 601
- on frame of psychoanalytic treatment, 606
- on grids, 704, 705, 1031
- on groups, 183, 184, 601, 709, 710–711, 713, 1371
- on hallucinatory, 722
- on hallucinosis, 722–723
- on hatred, 729
- on *infans* stage, 813
- on infant development, 815
- on infant observation, 817
- on infantile psychosis, 824–825, 826
- on intergenerational phenomena, 846
- on internal/external reality, 848
- on internal objects, 849, 850
- on invariant, 871–872
- Israeli psychoanalysis and, 878
- Italian psychoanalysis and, 879, 880, 881
- on lack of differentiation, 932
- Learning from Experience*, 50, 171, 339, 704, 952–953
- on logic, 990
- Los Angeles Psychoanalytic Society/Institute and, 992
- on Love-Hate-Knowledge links, 995–996
- Main and, 1003
- on maternal, 1028
- on memoirs of the future, 1039–1040
- Money-Kyrle and, 1070
- on nameless dread, 90
- on negative capability, 1123–1124
- on nonverbal communication, 1154
- on object, 1170
- on preconception, 1299–1300
- on primal, 1312
- on primary object, 1317
- on projective identification, 1336, 1339
- on protective shield, 1340
- on proto-thoughts, 1343
- psychology and psychoanalysis and, 1398
- on psychotic defenses, 1414
- on psychotic panic, 1416
- on psychotic part of the personality, 1416–1417
- on psychotic transference, 1419
- on puerperal psychoses, 1422
- Racamier and, 1436
- on realization, 1451–1452
- Rees and, 1457
- on relations model, 1464
- on representation, 551, 782
- on resistance, 1489
- on reverie, 5, 127–128, 184, 1030–1031, 1169, 1317
- Rickman and, 183, 1502
- Second World War and, 1558
- on selected facts, 1566–1567
- on self, 1568
- on sense/nonsense, 1585
- Simmel and, 1612
- on skin, 1613
- sociology and, 1632
- on splitting, 1646
- on splitting of the object, 1642
- Swedish psychoanalysis and, 1699
- on symbiosis, 1464, 1706
- on symbolic equation, 1709
- on symbolization, 1714
- Tavistock Clinic and, 1728
- on thought-thinking apparatus, 1749–1750
- on transformations, 1790
- Tustin and, 1809
- on vertex, 1833–1834
- on work of the negative, 1130
- Bios, Psyche, Person* (Caruso), 249
- Biosocial theory, 307
- Biotrauma, 90
- Bipolar self, **184–185**
- Biro, Elisabeth, 1686
- Birraux, Annie, 1275, 1276
- Birth, 185–186, **185**, 1747
- Birth dreams, **185–186**
- “Birth of Intellect, The” (Ferenczi), 1289
- Birth trauma, 641
- anaclitic depression and, 70
- asthma and, 124
- castration complex and, 253
- Laforge on, 933
- Rank on, 124, 253, 641, 833, 834, 1802–1803
- Bisexuality, **186–187**, 1635, 1752
- aggression and, 33
- female sexuality and, 365, 571
- femininity and, 573
- homosexuality and, 757
- masculinity/femininity and, 186–187, 1019
- object-choice and, 187, 1175
- parenthood and, 1237
- pregnancy fantasy and, 1302–1303
- rejection of femininity and, 575
- rivalry and, 1506
- sublimation and, 1679
- superego and, 1691
- symbolization and, 1714
- Weininger and, 1587–1588
- Biting, 6
- Bittencourt de Martins, Zaira, 215, 217, 248
- Bitter, Wilhelm, 677
- Bizarre object, **188**, 850, 851
- Bjerre, Poul, **188–189**, 1697
- Björk, Stig, 584
- Black holes, **189–190**, 218

## INDEX

Volume 1, pp. 1–662; Volume 2, pp. 663–1344; Volume 3, pp. 1345–1892

- anti-Semitism, 291  
 anticathexes and, 94, 1309, 1478, 1482, 1492  
 antilibidinal ego and, 96  
 Aulagnier-Spairani on, 111  
 automatism and, 143  
 bisexuality and, 186  
 censorship and, 262–263  
 character and, 269  
 condemning judgments and, 900–901  
 conflict and, 325  
 consciousness and, 333  
 constructions and, 335  
 contradiction and, 341  
 dead mother complex and, 369  
 decathexis and, 374  
 defense mechanisms and, 377  
 defense neuroses and, 19  
 defenses and, 374, 375  
 deferred action and, 380  
 déjà vu and, 382  
 Deleuze/Guattari on, 98  
 depression and, 395  
 derivatives of the repressed and, 1478–1479, 1481, 1484, 1491  
 desexualization and, 398–399  
 doubt and, 435  
 dreams and, 436, 437  
 drives and, 446  
 dynamic point of view and, 451  
 ego and, 463, 464  
 erotogenic zones and, 518  
 feminist views of psychoanalysis and, 578  
 flight into illness and, 590  
 forgetting and, 596, 597  
 fundamental rule and, 656  
 German romanticism and, 673  
 history and, 750  
 hysteria and, 773  
 id and, 778  
 imago and, 800  
 incest and, 804  
 infantile amnesia and, 819  
 lifting of, 976, 977, **1486–1487**  
 memory and, 1043  
 myth of origins and, 1092–1093  
 negation and, 1122–1123  
 negative hallucination and, 1124  
 neurotic defenses and, 1141  
 organic, 1206–1208  
 paranoia and, 1229–1231  
 perception-consciousness system and, 1249  
 persecution and, 1252–1253  
 phobias and, 1273  
 primal, 1050, 1308–1309, 1308–1310, 1483, 1485  
 primary narcissism and, 1110  
 “Project for a Scientific Psychology, A” on, 1332  
 rivalry and, 1506  
 scotomization and, 1554  
 seduction theory and, 1592  
 sense of smell and, 1616  
 shame and, 1599  
 signifying chain and, 1607  
 splitting and, 1646, 1650  
 splitting of the object and, 1642  
 subject and, 1673  
 suppression and, 1693–1694  
 symbolic equation and, 1708  
 symptom-formation and, 1717  
 symptoms and, 1715  
 transgression and, 1792  
 translation and, 1797  
 word association and, 1872  
 work and, 1875  
 work of the negative and, 1129  
 working-through and, 1879
