Abstract

Orobanche haenseleri var. *deludens* Beck (Orobanchaceae), a problematic taxon described from Algeciras (Cádiz, S Spain) is here identified after studying the original material of Wolley-Dod (BM 4476). It is considered to be the same as *O. austrohispanica* M.J.Y. Foley and better included, as a variety, under *O. gracilis* Sm. The new combination *O. gracilis* var. *deludens* (Beck) A. Pujadas is consequently proposed. It mainly parasites *Ulex* (Fabaceae) in the western Mediterranean Region (Iberian Peninsula and NW Africa).

Key words: broomrape, *Flora iberica*, Iberian Peninsula, nomenclature, NW Africa, *Orobanche*, parasitic plants, taxonomy.

Resumen

Se identifica *Orobanche haenseleri* var. *deludens* Beck (Orobanchaceae), un taxón conflictivo descrito de Algeciras (Cádiz, sur de España), a partir del análisis del material original de Wolley-Dod (BM 4476). Se considera que es lo mismo que *O. austrohispanica* M.J.Y. Foley, y se incluye en *O. gracilis* Sm. con rango varietal. Se propone la nueva combinación *O. gracilis* var. *deludens* (Beck) A. Pujadas. Parasita principalmente a especies del género *Ulex* (Fabaceae) en la Región Mediterránea Occidental (Península Ibérica y noroeste de África).

Palabras clave: *Flora iberica*, jopo, nomenclatura, noroeste de África, *Orobanche*, Península Ibérica, plantas parásitas, taxonomía.

Introduction

Beck (1922: 38) described *Orobanche haenseleri* var. *deludens* on the basis of the material collected by Wolley-Dod near Algeciras. The following description was provided: "Validissima. Scapus 11-16 cm longus, crassus, copiose squamatus, bracteis ovalibus triangularibus copiose glandulosis. Spica -36 cm longa, densa in parte inferiore laxiflora. Calyxis segmenta libera. Laciniae labii inferioris rotundatae, eae labii superi truncatae, dentatae et dente major apiculatae, omnes copiose glanduloso pilosae. Filamenta 1-2 mm supra basim corollae inserta, infra pilosa supra parce glanduloso pilosa. Stylus copiose glanduloso-pilosus. - Hispania ad aquas cadentes prope Algeciras m. Martio 1912 (Wolley-Dod)".

The taxon has been largely ignored by subsequent authors. Only Foley (2001b: 54), after studying the original material, concluded that it was impossible to identify the specimen accurately, although he also stated that it did not fit *O. haenseleri* Reut. It is clear that *Orobanche haenseleri* var. *deludens* Beck constitutes a problematic taxon that remains as an unidentified en-

try in the current edition of *Flora iberica*. "*Deludens*", from the latin verb "*deludo*" meaning to mock, to cheat, to simulate, to do trap, to be deceptive, is a very adequate name for this taxon, since it has been a confusing case during many years.

Material and methods

The original material of *O. haenseleri* var. *deludens* (Wolley-Dod 370, BM) was studied and contrasted against Beck's description. This specimen was compared with *Orobanche* specimens from ABH, ARAN, ALME, BC, COA, G, GDAC, JACA, La Salle Almería, LEB, LISI, LISU, LOU, MA, MAF, MGC, MPU, MUB, SALA, SANT and SEV.

Results

Type description and status

Leaves 14-16 × 9-11 mm, ovate to ovate-deltate, dense. Bracts 15-20 × 7-9 mm, ovate-lanceolate. Calyx (13)15-17 mm, unequally bipartite, densely glandular pubescent, veined. Corolla 20-25 mm, campanulate,

glandular pubescent, glabrescent at base, with lip margins clearly glandular ciliate (hairs 0.2-0.6 mm), ochre with reticulate veins externally and ochre or reddish -in some flowers- internally when dry. Filaments inserted very near the corolla base (adaxial filaments inserted 1.5-2 mm above the corolla base, abaxial filaments inserted at 1-1.5 mm), filaments very narrow, abruptly dilated at base, minutely pubescent only in the lowest part, with very few eglandular hairs (c. 0.5 mm) and with sessile glandular hairs (<0.1 mm) at the apex; anthers c. 2.5 mm. Ovary glabrescent. Style with glandular hairs.

The type of *O. haenseleri* var. *deludens* is similar to *O. gracilis* in calyx shape, hairy calyx and corolla, clearly ciliate corolla lip margins, and the insertion of the staminal filaments close to the corolla base. However, the ovate to ovate-deltate leaves, the ochre to (occasionally) reddish internal corolla when dry, and the narrow staminal filaments pubescent at the base, make it also similar to a taxon, relatively abundant in

the southern Iberian Peninsula, which has yellowish-brown corolla often reddish inside. This taxon was first recognized by Haenseler (1837), who found it growing on *Ulex baeticus* ("*Ulex australis*") in Carratraca (Malaga, S Spain). Subsequently, it was included in *O. cruenta* Bertol. (Boissier, 1839: 475), *O. reticulata* Wallr.? [sic.] (Reuter, 1847: 16), *O. reticulata* sensu Reut. (including *O. cruenta*) (Willkomm, 1870: 621), *O. gracilis* var. *spruneri* sensu Willk. (non *O. spruneri* F.W. Schultz 1843) (Willkomm, 1893: 186), or even described as a new species, *O. ulicis* Haens. ex Willk., non Des Moul. (Willkomm, 1846: 313). In recent treatments it has been included in *O. gracilis* var. *spruneri* (F.W. Schultz) Beck (Pujadas-Salvà & Lora-González 1996: 218; Pujadas-Salvà 2002: 431), or considered conspecific with *O. austrohispanica* M.J.Y. Foley (Foley 2001a: 226).

Based on the similarity of morphological characters, the taxon in question, in our opinion, should be subordinated to *O. gracilis* at the varietal rank. Accordingly, the new combination is proposed here:

Identification key

The var. *deludens* can be separate from the typical variety with the following key:

1. Upper leaves 3-7(9) mm width, lanceolate to ovate, scattered. Bracts 2.5-4(6) mm width. Calyx without conspicuous veins. Corolla yellow or yellowish-brown, rarely with reticulate veins, with red apex externally, dark shining red internally. Adaxial filaments inserted (1)2-4(6) mm above the corolla base, abaxial filaments inserted (0.5)1-2.5(3) mm the corolla base; filaments progressively wider to the base, more or less long hairy below var. **gracilis**
1. Upper leaves (5)8-12(16) mm width, ovate to ovate-deltate, dense, sometimes subimbricate. Bracts (4)7-12 mm width. Calyx with conspicuous veins. Corolla yellowish-brown with reticulate veins (rarely with reddish apex or without reticulate veins) externally, yellowish-brown to reddish internally. Adaxial filaments inserted 1-2(3) mm above the corolla base, abaxial filaments inserted 0.5-1.5(2) mm the corolla base; filaments narrow, abruptly dilated below, minutely pubescent, sometimes glabrescent below var. **deludens**

Note.—In *Orobanche gracilis* var. *deludens* the pigmentation of the corolla is very variable even in the same population as shown in Figs. 2 and 3.

Geographical distribution and habitat

Orobanche gracilis var. *deludens* is distributed in the western Mediterranean Region (Fig. 4). It grows in three discontinuous regions: NW Iberian Peninsula, with just a few populations; S Spain, where it seems to be relatively abundant; and NW Africa, in the Rif and High Atlas mountains of Morocco, where it seems to be undercollected. It grows in rocky areas, often on dry grasslands or degraded scrubland. It parasites perennial Fabaceae, namely species of *Ulex* (*U. parviflorus*

Fig. 4. Distribution of *Orobanche gracilis* var. *deludens*.

Pourr. and *U. baeticus* Boiss.), but sometimes on *Anthyllis cytisoides* L. or *Dorycnium pentaphyllum* Scop. Flowering from February to June (July). Fructification from April to July. Altitudinal range from 200-1400 m.

Relationships with Orobanche gracilis

Orobanche gracilis var. *deludens* has often been confused with *O. gracilis* var. *gracilis*, to which it is very close morphologically. We believe that the varietal rank –the same established by Beck– is the more appropriate for this plant because there is no clear-cut geographical separation between both varieties. In addition, the two are linked by forms intermediate in leaf width, corolla color, and hairiness and width of the staminal filaments.

Biomolecular analyses further justify the use of the varietal rank for this taxon and its subordination to *O. gracilis*. Thus, RAPD analysis (Román & al., 2003) revealed very short genetic distances among the four *O. gracilis* populations studied. The first population of *O. gracilis* to appear in the dendrogram sequence corresponded to var. *deludens* from Sierra de Cabra (Córdoba, Spain, COA 29293) and the other three to var. *gracilis* (Román & al., 2003: 640). Likewise, results by Schneeweiss & al. (2004), repeatedly included var. *gracilis* and var. *deludens* (as *O. austrohispanica*) within the same small clade based on the short genetic distances found.
