Abstract

Based on morphology and phylogeny of samples from Asia Pacific, two new species of *Ceriporia*, *C. eucalypti* sp. nov. and *C. sino-viridans* sp. nov., are described. *C. eucalypti* is characterized by resupinate and snow white fresh basidiocarps, abundant crystals and oily substances present in subiculum and trama, distinct allantoid basidiospores measuring 4–4.4 × 1.1–1.4 µm, and growing on wood of *Eucalyptus* in Australia. *C. sino-viridans* is characterized by white to flesh-pink fresh pores, ellipsoid to lunate basidiospores measuring 3–3.5 × 1.7–2.2 µm, and occurring in tropical China. Phylogenetically *C. eucalypti*, *C. sino-viridans*, *C. aurantiocarnescens* and *C. viridans* are related, but they can be distinguished by size of basidiospores. A key to accepted species of *Ceriporia* in China is provided.

Introduction

Ceriporia Donk, belonging to the Irpicaceae Spirin & Zmitr. of Polyporales (Justo et al. 2017), was established by Donk (1933) with *Polyporus viridans* Berk. & Broome ($\equiv C. viridans$ (Berk. & Broome) Donk) as the type species. It is a poroid genus comprises species with seasonal, thin and resupinate basidiocarps which are soft when fresh and variable colors and fragile when dry. Microscopically species in the genus has a monomitic hyphal structure with simple septa on generative hyphae in most species, subicular hyphae usually distinctly thicker than tramal hyphae, lacking of cystidia in most species, and hyaline, thin-walled basidiospores which are negative in Cotton Blue and Melzer's reagent, and causing a white rot (Gilbertson and Ryvarden 1986; Jia et al. 2014; Ryvarden and Melo 2017; Chen et al. 2020).

The genus was at first considered monophyletic based on five sequences of mitochondrial small subunit rDNA (Kim and Jung 1999). Recently, more molecular data of *Ceriporia* were provided by phylogenetic analyses and the genus was treated as sensu lato (s.l.) based on the internal transcribed spacer (ITS) regions and nuclear large subunit (nrLSU) ribosomal RNA gene regions (Jia et al. 2014; Floudas and Hibbett 2015; Miettinen et al. 2016; Spirin et al. 2016; Justo et al. 2017; Yuan et al. 2017; Chen et al. 2020). Based on sequences from ITS, nrLSU, and the gene encoding the RNA polymerase II largest subunit (rpb1), three species of *Ceriporia* addressed in the Phanerochaetaceae Jülich were transferred to the recently proposed genera *Emmia* Zmitr. et al. (*E. lacerata* (N. Maek. et al.) F. Wu et al. $\equiv C. lacerata$ N. Maek. et al.), *Phanerina* Miettinen (*P. mellea* (Berk. & Broome) Miettinen $\equiv C. inflata$ B.S. Jia & B.K. Cui) and *Riopa* D.A. Reid. (*R. metamorphosa* (Fuckel) Miettinen & Spirin $\equiv C. metamorphosa$ (Fuckel) Ryvarden & Gilb.) (Miettinen et al. 2016; Wu et al. 2017). With the aid of three loci (ITS, 28S, and rpb1), Chen et al. (2020) revised the part species concept of *Ceriporia* s.l. and *Meruliopsis* Bondartsev, resulting four new combinations: *M. albomellea* (Yuan Yuan et al.) C.C. Chen & Sheng H. Wu ($\equiv C. albomellea$ Yuan Yuan et al.), *M. crassitunicata* (Y.C. Dai & Sheng H. Wu) C.C. Chen & Sheng H. Wu ($\equiv C. crassitunicata$ Y.C. Dai & Sheng H. Wu), *M. nanlingensis* (B.K. Cui & B.S. Jia) C.C. Chen & Sheng H. Wu ($\equiv C. nanlingensis$ B.K. Cui & B.S. Jia), and *M. pseudocystidiata* (B.S. Jia & Y.C. Dai) C.C. Chen & Sheng H. Wu ($\equiv C. pseudocystidiata$ B.S. Jia & Y.C. Dai). For the being now, approximately 54 *Ceriporia* species have been recorded worldwide including 18 species from China (Jia et al. 2014; Spirin et al. 2016; Ryvarden and Melo 2017; Yuan et al. 2017; Ryvarden 2018, 2020; Chen et al. 2020).

During a study on wood-decaying fungi from Asia Pacific area, three specimens have seasonal and thin basidiocarps, a monomitic hyphal structure with simple septa on generative hyphae, and hyaline, thin-walled, ellipsoid or lunate to allantoid basidiospores. These characteristics correspond definition of *Ceriporia*, but no existing names are suitable for them. After phylogenetic analyses, these samples formed two independent lineages in *Ceriporia* clades. Based on both morphology and phylogeny, we describe them as two new species of *Ceriporia*, one is from tropical China and another from Australia.

Materials And Methods

Morphological studies

Specimens examined were deposited in the herbaria of the Institute of Microbiology, Beijing Forestry University (BJFC). Australian specimen will forward to Royal Botanic Gardens Victoria, Australia (MEL). Morphological descriptions are based on field notes and herbarium specimens. Microscopic analyses follow Dai (2010). In the description: KOH = 5% potassium hydroxide, IKI = Melzer's reagent, IKI- = neither amyloid nor dextrinoid, CB = Cotton Blue, CB+ = cyanophilous in Cotton Blue, CB- = acyanophilous, L = mean spore length (arithmetic average of all spores), W = mean spore width (arithmetic average of all spores), Q = variation in the L/W ratios between the specimens studied, n (a/b) = number of spores (a) measured from given number (b) of specimens. Colour terms are cited from Petersen (1996).

Molecular studies and phylogenetic analysis

A cetyl trimethylammonium bromide rapid plant genome extraction kit (Demeter Biotechnologies Co., Ltd, Beijing) was used to extract total genomic DNA from dried specimens, and performed the polymerase chain reaction (PCR) according to the manufacturer's instructions with some modifications (Cui et al. 2019). Two DNA gene fragments, ITS and nrLSU were amplified using the primer pairs respectively ITS5/ITS4 (White et al. 1990) and LR0R/LR7 (Vilgalys and Hester 1990). The PCR procedures for ITS and nrLSU followed Shen et al. (2019) in the phylogenetic analyses. DNA sequencing was performed at Beijing Genomics Institute, and the newly generated sequences were deposited in the GenBank database. Besides the sequences generated from this study (Table 1), other reference taxa for our phylogenetic analysis were selected from GenBank, Jia et al. (2014), Miettinen et al. (2016), and Chen et al. (2020). Sequences were aligned with BioEdit (Hall 1999) and ClustalX (Thompson et al. 1997). Alignment was manually adjusted to allow maximum alignment and to minimize gaps. Sequence alignment was deposited at TreeBase (<http://purl.org/phylo/treebase/>; submission ID 27658).

Maximum parsimony analysis was applied to the combined dataset of ITS and nrLSU sequences with PAUP* version 4.0b10 (Swofford 2002). The sequences of *Hyphoderma litschaueri* (Burt) J. Erikss. & Å. Strid and *H. setigerum* (Fr.) Donk were used as the outgroups (Chen et al. 2020). All characters were equally weighted, and gaps were treated as missing data. Trees were inferred using the heuristic search option with TBR branch swapping and 1,000 random sequence additions. Max-trees were set to 5,000, branches of zero length were collapsed and all parsimonious trees were saved. Clade robustness was assessed by bootstrap analysis with 1,000 replicates (Felsenstein 1985). Descriptive tree statistics, tree length (TL), consistency index (CI), retention index (RI), rescaled consistency index (RC), and homoplasy index (HI) were calculated for each maximum parsimonious tree generated.

Maximum likelihood (ML) analysis and Bayesian inference (BI) methods were also used to analyze the combined ITS and nrLSU dataset. Substitution models suitable for each partition in both datasets were determined using Akaike Information Criterion implemented in MrMODELTEST2.3 (Nylander 2004). The General Time Reversible + proportion Invariant + Gamma (GTR + I + G) was the selected substitution model for each partition. RAxML v7.2.6 (Stamatakis 2006) was used for ML analysis. All parameters in the ML analysis used the default setting, and statistical support values were obtained using nonparametric bootstrapping with 1000 replicates. A Bayesian tree was inferred using MrBayes3.1.2 (Ronquist and Huelsenbeck 2003), with a general time reversible model of DNA substitution and an invgamma distribution rate variation across sites. Four Markov chains were run for two runs from random starting trees for 2,500,000 generations for ITS + nrLSU, and trees were sampled every 100 generations. The first one-fourth of the generations were discarded as burn-in. Majority rule consensus

tree of all remaining trees was calculated. Branches that received bootstrap values for MP, ML, and bayesian posterior probabilities (BPP) greater than or equal to 75% (MP), 75% (ML), and 0.90 (BPP) were considered as significantly supported. Tree was visualized in TreeView 1.6.6 (Page 1996).

Results

Molecular phylogeny

The ITS + nrLSU dataset included sequences from 81 fungal specimens representing 64 taxa. The dataset had an aligned length of 1,613 characters, of which 810 characters are constant, 170 are variable and parsimony-uninformative, and 633 are parsimony-informative. Maximum parsimony analysis yielded six equally parsimonious trees (TL = 4,324, CI = 0.329, RI = 0.652, RC = 0.215, HI = 0.671). BI, ML and MP analyses yielded similar tree topologies with an average standard deviation of split frequencies = 0.009281 and only the MP tree is shown (Fig. 1). Both bootstrap values ($\geq 50\%$) and BPPs (≥ 0.90) are shown at the nodes (Fig. 1).

The sequences of *Ceriporia eucalypti* clustered together with *C. aurantiocarnescens* (Henn.) M. Pieri & B. Rivoire with high support (76% ML and 0.99 BPPs, Fig. 1), then formed a distinct supported clade together with *C. sino-viridans* and *C. viridans* with modest support (67% ML and 1 BPPs).

Taxonomy

***Ceriporia eucalypti* Y.C. Dai & Jia J. Chen, sp. nov.** (Figs. 2–3)

MycoBank no.: MB 838617

Ceriporia eucalypti is characterized by its annual, resupinate, snow white fresh basidiocarps, generative hyphae with simple septa, allantoid basidiospores measuring $4.0 - 4.4 \times 1.1 - 1.4 \mu\text{m}$ and a distribution in Australia.

Type. AUSTRALIA. Melbourne, Dandenong Ranges Botanical Garden, on rotten wood of *Eucalyptus*, 12.V.2018, Dai 18675 (holotype BJFC027144, isotype in MEL).

Etymology. *Eucalypti* (Lat.) referring to the host tree of *Eucalyptus*.

Rotting type. White rot.

Basidiocarps. Basidiocarps annual, resupinate, very soft when fresh, brittle when dry, up to 3 cm long, 1 cm wide, and 1.1 mm thick at center. Pore surface snow white when fresh, curry-yellow when dry; pores angular, 3–5 per mm; dissepiment thin, lacerate. Margin thin, cream to buff, cottony, up to 1 mm wide. Subiculum white, fragile when dry, up to 0.1 mm thick. Tubes concolorous with pore surface, brittle when dry, up to 1 mm long.

Hyphal structure. Hyphal system monomitic; generative hyphae with simple septa, IKI-, CB+; tissues unchanged in KOH.

Subiculum. Generative hyphae hyaline, thin- to thick-walled, frequently branched, interwoven, 4–6 µm in diam; abundant crystals and oily substances present among hyphae.

Tubes. Generative hyphae hyaline, thin-walled, frequently branched, subparallel along tube to loosely interwoven, slightly gelatinized, usually incrusted with irregular crystals, 2–4 µm in diam; cystidia and cystidioles absent; basidia barrel-shaped, with four sterigmata and a simple basal septum, 12–14 · 3–4 µm; basidioles in shape similar to basidia, but slightly smaller.

Spores. Basidiospores allantoid, hyaline, thin-walled, smooth, IKI-, CB-, sometimes bearing one or two guttules, (3.8–)4–4.4(–4.6) · 1.1–1.4(–1.5) µm, L = 4.2 µm, W = 1.2 µm, Q = 3.5 (n = 30/1).

Ceriporia sino-viridans Y.C. Dai & Jia J. Chen, sp. nov. (Figs. 4–5)

Mycobank no.: MB 838618

Ceriporia sino-viridans is distinguished from other species in the genus by its annual, resupinate, white to flesh-pink fresh basidiocarps, generative hyphae with simple septa, ellipsoid to lunate basidiospores measuring 3.0 – 3.5 × 1.7 – 2.2 µm and a distribution in China.

Type. CHINA. Hainan Prov., Baoting County, Diaoluoshan Forest Park, on dead basidiocarp of *Physisporinus vinctus*, 14.VI.2014, Dai 13617A (Holotype BJFC017356).

Etymology. *Sino-viridans* (Lat.) referring to the Chinese specimens similar to *Ceriporia viridans*.

Rotting type. White rot.

Basidiocarps. Basidiocarps annual, resupinate, very soft when fresh, brittle when dry, up to 8 cm long, 4 cm wide, and 1 mm thick at center. Pore surface white to flesh-pink when fresh, pinkish buff when dry; pores more or less circular, 4–6 per mm; dissepiment thin, lacerate. Margin thin, buff, cottony, up to 1 mm wide. Subiculum cream, fragile when dry, less than 0.1 mm thick. Tubes concolorous with pore surface, brittle when dry, up to 0.9 mm long.

Hyphal structure. Hyphal system monomitic; generative hyphae with simple septa, IKI-, CB+; tissues unchanged in KOH.

Subiculum. Generative hyphae hyaline, thin- to slightly thick-walled, frequently branched, interwoven, 6–8 µm in diam; irregular crystals present among hyphae.

Tubes. Generative hyphae hyaline, thin-walled, frequently branched, subparallel along tube or loosely interwoven, 3–5 µm in diam; cystidia and cystidioles absent; basidia short clavate to barrel-shaped, with

four sterigmata and a simple basal septum, $10\text{--}12 \cdot 4\text{--}4.5 \mu\text{m}$; basidioles in shape similar to basidia, but slightly smaller.

Spores. Basidiospores ellipsoid to lunate, hyaline, thin-walled, smooth, IKI-, CB-, (2.9-)3-3.5(-3.8) · (1.4-)1.7-2.2(-2.3) μm , L = 3.21 μm , W = 1.93 μm , Q = 1.66 (n = 60/2).

Additional specimen examined (paratype). CHINA. Hainan Prov., Baoting County, Diaoluoshan Forest Park, on rotten angiosperm wood, 14.VI.2014, Dai 13621A (BJFC017360).

Discussion

Phylogenetically *Ceriporia eucalypti* is related to *C. aurantiocarnescens*, *C. sino-viridans* and *C. viridans*, but the latter three species have wider basidiospores ($4\text{--}4.4 \cdot 1.1\text{--}1.4 \mu\text{m}$ in *C. eucalypti*, $3.5\text{--}4 \cdot 1.8\text{--}2 \mu\text{m}$ in *C. aurantiocarnescens*, $3\text{--}3.5 \cdot 1.7\text{--}2.2 \mu\text{m}$ in *C. sino-viridans* and $4\text{--}6 \cdot 1.5\text{--}2 \mu\text{m}$ in *C. viridans*, Ryvarden & Melo 2017). *C. sino-viridans* differs from *C. aurantiocarnescens* and *C. viridans* by its shorter basidiospores (see above data).

Ceriporia eucalypti is similar to *C. alba* M. Pieri & B. Rivoire by sharing snow white pore surface and almost the same size of pores, but the latter species has bigger basidiospores ($5.5\text{--}7 \times 2\text{--}2.5 \mu\text{m}$, Pieri and Rivoire 1997). Among species of *Ceriporia*, *C. eucalypti* resembles *C. albobrunnea* Ryvarden & Iturr. and *C. arbuscula* C.C. Chen & Sheng H. Wu by thin basidiospores (<1.5 μm wide). However, *C. albobrunnea* is different from *C. eucalypti* by its bigger pores (2–3 per mm), thick dissepiments and occurring in Venezuela (Ryvarden and Iturriaga 2003); *C. arbuscula* differs from *C. eucalypti* by its shorter basidiospores ($3\text{--}3.5 \times 1\text{--}1.5 \mu\text{m}$, Chen et al. 2020).

Ceriporia sino-viridans is very similar to *C. viridans*, the latter species was originally described from UK and has a highly variable in micromorphology (Ryvarden 1984). However, *C. viridans* differs from *C. sino-viridans* by longer basidiospores ($4\text{--}6 \cdot 1.5\text{--}2 \mu\text{m}$, Ryvarden and Melo 2017). The fresh basidiocarps of *C. sino-viridans* remind of *C. xylostromatoides* (Berk.) Ryvarden, but the latter species has subglobose basidiospores ($4\text{--}5 \cdot 3.5\text{--}4.5 \mu\text{m}$, Ryvarden and Melo 2017).

Two specimens of *Ceriporia alachuana* (Murrill) Hallenb. respectively from Maryland (FP-103881-Sp) of United States and Singapore (Dai 17769), formed a lineage within the Meruliaceae Rea (Fig. 1). This lineage seems to represent *C. alachuana* because the species was originally described from United States. In our phylogeny, the sequences of the specimen Li 1011 which was originally identified as Chinese *C. alachuana* clustered together with that of *Meruliodiplosis leptocystidiata* with high support (100% MP, 1 BPPs). The ITS sequences of the specimen Li 1011 (GenBank Accession No. MG572749) showed 99.83% identity to that of the holotype *M. leptocystidiata* LC427013. Therefore, the Chinese samples previously treated as *C. alachuana* seem to be *M. leptocystidiata*.

Our phylogenetic tree is overall consistent with that presented by Miettinen et al. (2016) and Chen et al. (2020). Judging from our molecular analysis, *Ceriporia* is still a heterogeneous assemblage. It seems

more taxa are existed in the so-called ‘*C. spissa* (Schwein. ex Fr.) Rajchenb.’. Moreover the taxonomic status of some *Ceriporia* species nested in Meruliaceae (e.g. *C. alachuana*) or the other genera (e.g. *C. cystidiata* Ryvarden & Iturr.) is needed to be confirmed. Therefore, a fully resolved phylogeny for *Ceriporia*, *Meruliopsis*, *Emmia* and their related genera requires evolutionary information from wider taxa samplings and more conserved gene markers. The studies on these taxa will be done in the coming papers.

Key to species of *Ceriporia* in China

1 Hyphal system dimitic————— *C. totara* (G. Cunn.) P.K. Buchanan & Ryvarden

1 Hyphal system monomitic————— 2

2 Cystidia present————— 3

2 Cystidia absent————— 6

3 Pores 6–8 per mm————— 4

3 Pores 1–5 per mm————— 5

4 Cystidia tubular and encusted————— *C. bubalinomarginata* B.S. Jia & Y.C. Dai

4 Cystidia clavate and non-encusted————— *C. cystidiata*

5 Cystidia present at the bottom of tube only; basidiospores > 2.9 µm wide—————

————— *C. mellea* (Berk. & Broome) Ryvarden

5 Cystidia present in all parts of the hymenium; basidiospores mostly < 2.9 µm wide—————

————— *C. purpurea* (Fr.) Donk

6 Basidiospores allantoid————— 7

6 Basidiospores oblong-ellipsoid to cylindrical, or cylindrical but a little curved————— 10

7 Pores brown, orange-brown to reddish-brown; basidiospores mostly > 5 µm long—————

————— *C. spissa*

7 Pores cream, buff, cinnamon, salmon, clay-pink or brownish vinaceous; basidiospores mostly < 5 µm long————— 8

8 Pores 5–8 per mm————— *C. aurantiocarnescens*

8 Pores 3–6 per mm————— 9

9 Basidiospores 4.0–4.4 × 1.1–1.4 µm	<i>C. eucalypti</i>
9 Basidiospores 4–6 × 1.5–2 µm	<i>C. viridans</i>
10 Basidiospores mostly > 5 µm long	11
10 Basidiospores mostly < 5 µm long	12
11 Pores 2–3 per mm; tramal hyphae thin-walled	<i>C. reticulata</i> (Hoffm.) Domański
11 Pores 3–4 per mm; tramal hyphae thin- to slightly thick-walled	<i>C. camaresiana</i> (Bourd. & Galzin) Bondartsev & Singer
12 Tramal hyphae interwoven	<i>C. sulphuricolor</i> Bernicchia & Niemelä
12 Tramal hyphae parallel or subparallel along the tube	13
13 Subicular hyphae thick-walled	14
13 Subicular hyphae thin- to slightly thick-walled	15
14 Basidiospores > 3.5 µm long	<i>C. tarda</i> (Berk.) Ginns
14 Basidiospores < 3.5 µm long	<i>C. arbuscula</i>
15 Pores 2–3 per mm	<i>C. excels</i> Parmasto
15 Pores 3–6 per mm	16
16 Basidiospores > 4.2 µm long	<i>C. davidii</i> (D.A. Reid) M. Pieri & B. Rivoire
16 Basidiospores < 4.2 µm long	17
17 Pores white to cream when dry	<i>C. humilis</i> Spirin & Miettinen
17 Pores pinkish buff when dry	<i>C. sino-viridans</i>

Declarations

Acknowledgments

The research was supported by the National Natural Science Foundation of China (Project No. 31870007).

Declarations

Funding:

The National Natural Science Foundation of China (Project No. 31870007)

Conflicts of interest/Competing interests:

The authors declare that there are no conflicts of interest.

Availability of data and material:

All data generated or analysed during this study are included in this published article and its supplementary information files.

Code availability: Not applicable.

Authors' contributions:

Jia-Jia Chen, Wang Ya-Rong, Wang Chao-Ge performed the experiment, the data analyses and wrote the manuscript. Yu-Cheng Dai designed the experiments and helped perform the analysis with constructive discussions.
