---

### **ABSTRACT**

Based on published literature, preserved lichen specimens at lichen herbarium in National Botanical Research Institute, Lucknow (LWG) and recent collections of lichens from different regions of Kumaun Himalaya is provided. The Pithoragarh district exhibits the occurrence of 246. The available information regarding bark inhabiting lichen will be useful for conducting future biomonitoring studies in the area.

**Key Words:** Corticolous lichen diversity, Western Himalaya, Uttarakhand.

### **INTRODUCTION**

The Indian Himalayan lichen flora has been documented several times and included repeatedly in different monographic and revisionary studies. The lichen diversity in the Himalayas was first described by Babington (1852) who mentioned the occurrence of 44 species of which 4 species were new from the lichens collected by Strachey & Winterbottom (1846-49) in Kumaun Himalayas. Stirton (1879) reported 98 lichen taxa based on the collection of G. Watt, A. Watt, King and Thomson from Kumaun Himalayas and some states of east Himalayan region. Kashyap, 1925; Chopra, 1934; Quarashi, 1928 were some other early explorer of the Himalayas for lichen collection. Awasthi (1975) provided the floristic account based on the lichens of Pindari Glacier catchment area from Kapkote to Pindari glacier and enumerated 122 species of lichens belonging to 38 genera and 18 families. Subsequently, Awasthi and Joshi, 1977, 1978; Awasthi and Singh, 1978; Negi and Gadgil, 1996, 1997; Upreti and Negi, 1998; Negi, 1999, 2000, 2001; Upreti and Divakar, 2003 provided assorted account on lichens of Garhwal Himalayas

along with some other contributors (Kumar, 2008 ; Rawat, 2010). Pant (2002) enumerated 203 lichen species belonging to 64 genera and 32 families from Askote-Sandev and Gori-Ganga, the two botanical 'Hot Spot' of Pithoragarh district. Joshi *et al.*, (2008 a,b) described lichen species from Munsiyari area and have thrown some light on the impact of climate on lichen flora of Pindari. Earlier Upreti (1997; 2001) explored the lichens from Indian Himalayas. In higher altitudes area of the region Pindari and Milam Glacier region explored of lichens carried out by Joshi (2010). In Kumaun Himalaya the major localities were exhaustively explored for lichen collections. Based on the altitudinal variations, Kumaun Himalaya lichens can be divided into subtropical, temperate and alpine region. The temperate and alpine regions exhibit luxuriance and rich diversity of foliose lichens. The temperate region shows diversity of different phorophytes which provides suitable condition for a large number lichens genera to grow colonize epiphytically on them. The trees provide varied niches for the lichens to grow as at the base which is laden with soil and mosses, upper trunk with rough bark higher trunk with smooth bark

branches and twigs with varied pH and texture. The alpine region exhibit luxuriance of lichens grows on soil and rock. Both moist habitats along the rivers and dry exposed areas provided varied climatic conditions for foliose and other lichen taxa on rock and soil. Earlier Upreti and Chatterjee (1999a,b) studied the distribution of epiphytic lichen in Kumaun Himalaya and reported 64 lichen species of lichen on *Quercus* trees. Similarly in the year 1975 Awasthi studied Pindari Glacier lichen flora and recorded 122 species belonging to 38 genera and 18 families. Furthermore in the Kumaun region floristic and revisionary studies of lichen from India carried out by various workers (Divarkar & Upreti 2005, Nayaka 2005, Joshi 2010, Kumar et al. 2011, Mishra et al. 2010, Kholia et al. 2012, Mishra et al. 2011 & Mishra 2012). But so far not a single foliose floristic account of Kumaun Himalayas is available. Thus the present study is carried out with an aim to list the epiphytic lichen from Kumaun Himalaya together with their distribution pattern in different districts.

## MATERIALS AND METHODS

The dried samples were packed on hard card sheets inside a lichen herbarium packet (17cm X 13 cm) with details of the locality, date of collection, substratum and are preserved at the lichen herbarium of National Botanical Research Institute, Lucknow (LWG). The study is based on the lichen material collected from the region and the specimens collected earlier and preserved in the lichen herbarium of National Botanical Research Institute, Lucknow (LWG), lichen herbarium of Lucknow University, Lucknow (LWU) and personal herbarium of Dr. D.D. Awasthi (AWAS).

The specimens were identified by studying their morphology, anatomy and chemistry. The morphology of the taxa was studied under stereozoom binocular microscope. The details of thallus anatomy and fruiting bodies were studied by compound microscope. The colour test were carried out on cortex and medulla with usual chemical regents such as aqueous potassium hydroxide (K), Steiner's stable paraphenylenediamine (PD) and aqueous calcium hypochlorite (C). Thin layer chromatography was performed for identification of the lichen substances in solvent system A (Toluene 180: 1-4 Dioxane 60: Acetic acid 8) following the techniques of Walker & James (1980) and Orange et al., (2001). For authentic identification of different lichen taxa literature of Awasthi (1988, 1991, 2000 and 2007), Divakar and Upreti (2005), Nayaka (2004) and Joshi (2008) were consulted for the identification of specimens up to species level.

## RESULTS AND DISCUSSION

Among the different habitats of lichens the corticolous species (bark inhabiting) dominates with 429 species belonging to 90 genera and 36 families. The probable reason for luxuriant growth of corticolous lichens in the region may be due to the rich diversity of phorophytes at different altitudinal gradients. A number of tree species such as *Syzygium cumini*, *Shorea rubusta*, *Quercus leucotrichopora*, *Quercus floribunda*, *Quercus semecarpifolia*, *Pinus wallichiana*, *Pinus roxburghii*, *Rhododendron arboreum*, *Cedrus deodara*, *Alnus nepalensis* and *Betula utilis* trees growing in moist, shady and open areas both in subtropical and temperate areas provide suitable substrate to various lichen forms to colonize on them. The corticolous lichen taxa of the lichen family Parmeliaceae with 103 species under 21 genera followed by 67 species of 14 genera of Physciaceae are the dominant lichens in the area. Among the different growth form the foliose form of corticolous lichens exhibit their dominance by 189 species followed by 187crustose, 32 fruticose, 12 squamulose and 5 leprose species. The different districts of the Kumaun exhibit a great variation in altitude, topography and climate. The lichen diversity of each district is provided separately as following (Table 1):

**Almora district** - Almora district shows occurrence of 80 species of corticolous lichens. The lichen family Parmeliaceae dominates the district represented by 8 genera and 26 species followed by Physciaceae with 5 genera and 17 species of lichens. The lichen genera *Heterodermia*, *Lecanora*, *Parmotrema* and *Usnea* are the dominant genera in the. The lichen species *Parmotrema tinctorum* (Despr. ex Nyl.) Hale, *Phaeophyscia hispidula* (Ach.) Moberg and *Usnea eumitrioides* Motyka are widely distributed and recorded from most of the localities of the district.

**Bageshwar district**- Among the different districts of the Kumaun the Bageshwar district exhibit maximum diversity of corticolous lichens represented by 235 species. Parmeliaceae with 18 genera and 58 species and Physciaceae with 6 genera and 29 species are the dominant families in the study area. The lichen genera *Lecanora* with 16 species and *Cladonia* with 11 species dominate the district. The rich diversity of phorophytes and different altitudinal gradients support luxuriant growth of corticolous lichens.

**Champawat district**- The Champawat district is represented by the occurrence of 129 species of corticolous lichens. The member of lichen family Parmeliaceae dominates with 25 species followed by 8 Physciaceae and 5 Lecanoraceae species respectively. The lichen genera *Heterodermia*, *Caloplaca*, *Parmotrema* and *Lecanora* are the dominant genera of the district.

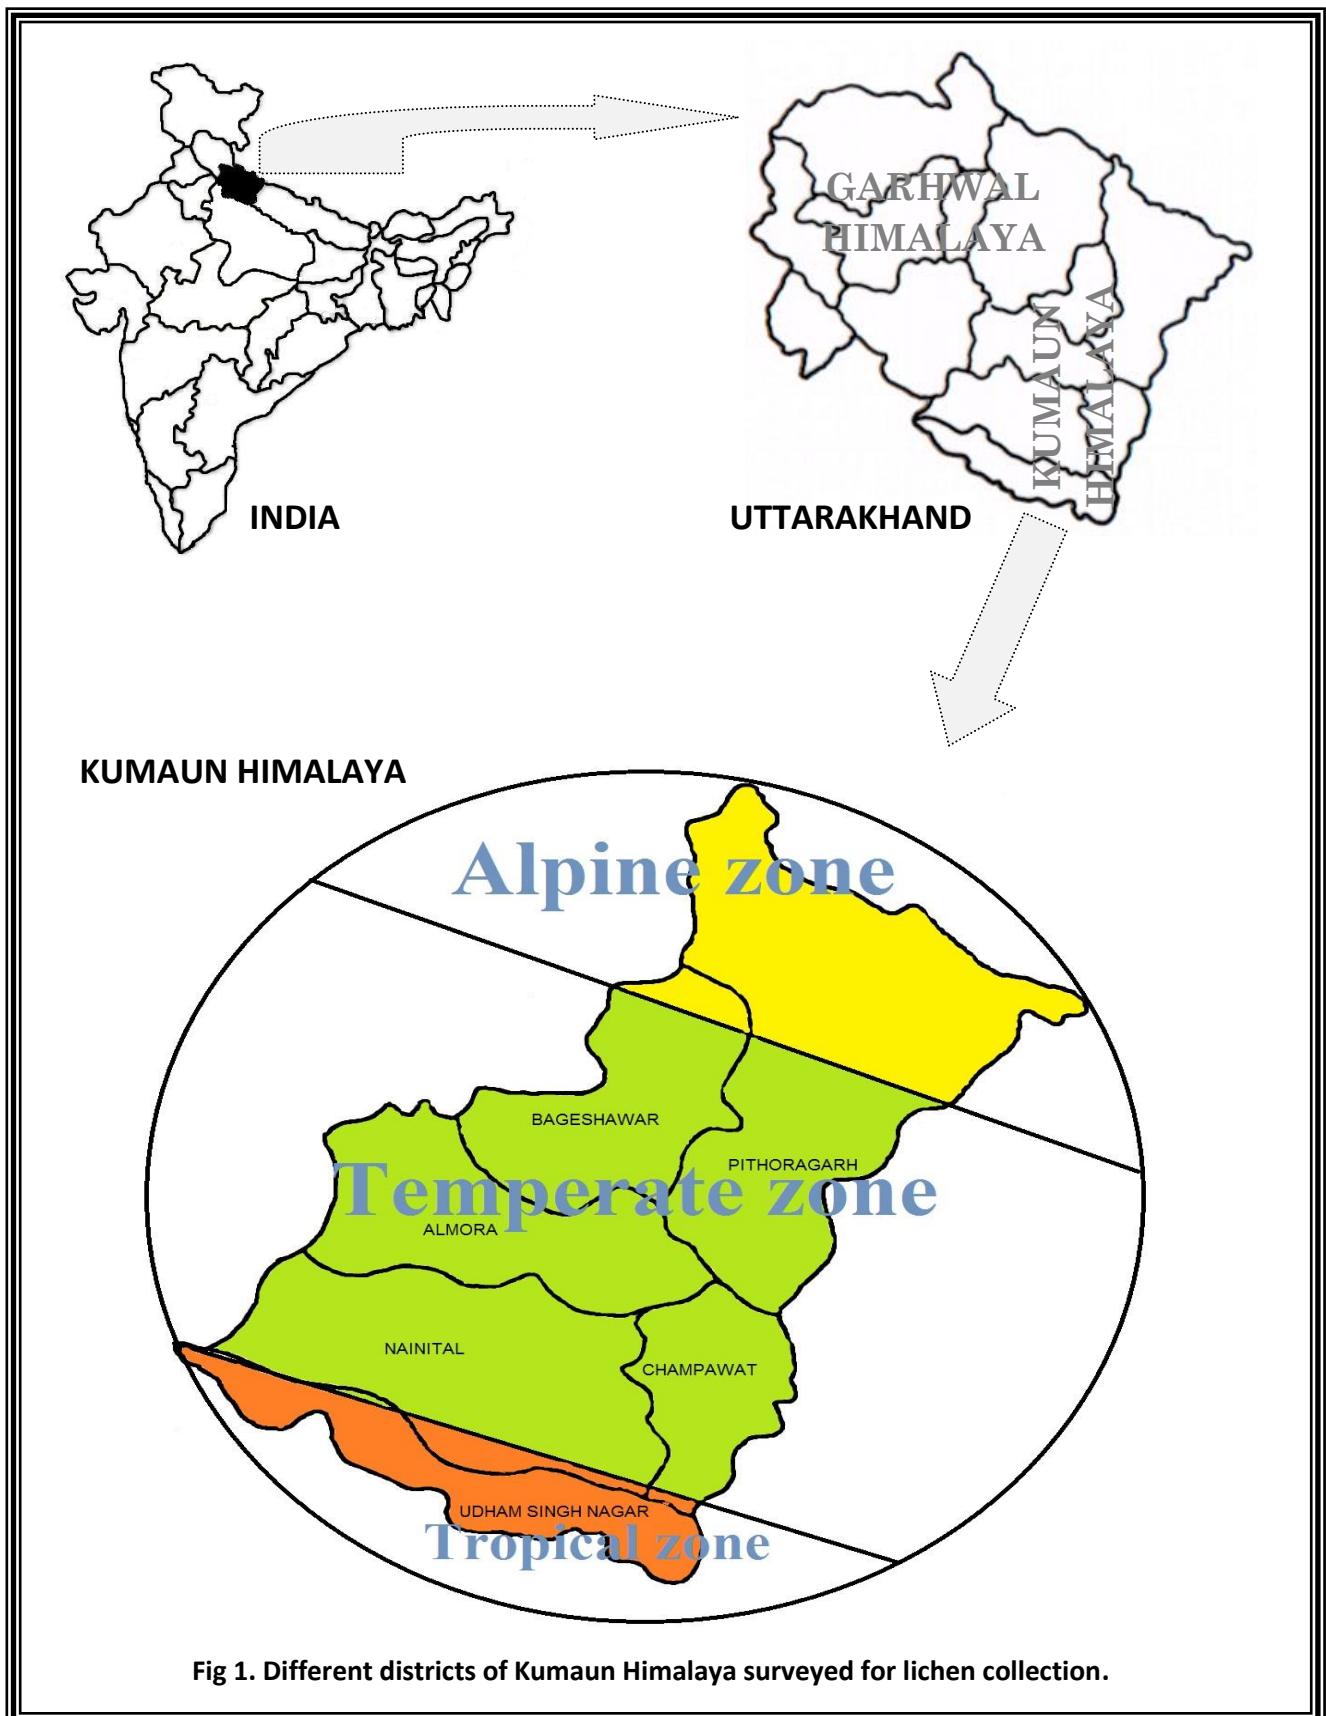

Fig 1. Different districts of Kumaun Himalaya surveyed for lichen collection.

**Table 1.** Distribution of corticolous lichens in different districts of Kumaun Himalaya and their growth forms.

**Abbreviations:** Sub. - Substrate, + Present, - Absent, F-, Foliose, Fr-Fruticose, Cr-Crustose, Sq- Squamulose, Di- Dimorphic

**Nainital district** - The Nainital district represented by the occurrence of 92 species of epiphytic lichens. The members of lichen family Parmeliaceae with 26 species under 6 genera followed by Physciaceae with 6 genera and 18 species exhibit their dominance in the area. The epiphytic lichens grow luxuriantly on *Quercus* and other coniferous trees of *Cedrus deodara* and *Abies*. Among the different tree *Quercus semecarpifolia* bears the maximum diversity of lichens.

**Pithoragarh district** - Pithoragarh district is represented by the occurrences of 246 bark inhabiting lichens species. The lichen family Parmeliaceae dominates the district with 16 genera followed by Physciaceae with 9 genera. Among the different phorophyte the *Quercus* trees bear the maximum diversity of lichens. The forest of *Quercus semecarpifolia* between altitudes of 2500-3000m are preferred by a number of lichen species while *Q. leucotrichophora* in lower temperate areas (1500-2000m) also provide excellent substratum for many taxa of lichens to colonize. *Alnus nepalensis* a smooth barked tree in temperate areas also provide suitable habitat for colonization of Pyrenocarpous and Graphidaceous lichens which prefers the smooth bark. The *Pinus roxburghii* trees

having thick rough bark are mostly preferred by the members of Parmelioid lichen genera and other rough barked loving lichens. More than 30 lichen species are recorded on *Pinus roxburghii* trees. The *Rhododendron campanulatum* trees in higher temperate and bushy *Rhododendron* species in alpine regions also provide suitable substrate for many lichens taxa to colonize. Mostly the species of *Opegrapha*, *Pertusaria* and *Lecanora* prefers to grow on such bark. *Phaeophyscia hispidula*, *Heterodermia diademata*, *Parmotrema reticulatum*, *Bulbothrix setschwanensis*, *Physcia dilatata*, and *Everniastrum cirratum* are the most common and widely distributed lichen taxa found growing on various substrates both in tropical and temperate areas of the district.

**Udham Singh Nagar district** - Udham Singh Nagar district is represented by the occurrences of 28 species. The Physciaceae is the dominant family in the study area represented by 6 species belonging to 4 genera. The lichen genera *Bacidia* exhibits its dominance as represented by 4 species followed by *Pyxine* and *Parmotrema* with 3 species each. *Caloplaca bassiae* (Willd. ex Ach.) Zahlbar., *Dirinaria appalanata* (Fée) D. Awasthi and *Pyxine coeces* (Swartz) Nyl., are the common lichen species of the district. Among the different phorophytes in all three localities of the district,

*Mallotus philippensis* exhibits maximum diversity of lichens represented by 13 species. Lichens prefer *Shorea robusta* trees to grow luxuriantly on trunk at base and up to chest height and above branches and twig.

Out of the six districts of Kumaun the Pithoragarh district exhibit the maximum diversity of epiphytic lichens because of varied altitudinal variations and the presence of diverse phorophytes that provides a wide range of substratum to different lichen communities to colonize. Bageshwar district also exhibit rich diversity of lichens as the district has diverse altitudinal gradients, rich diversity of phorophytes together with thick undisturbed forest areas. The forest area in Almora, Champawat, Nainital and Udham Singh Nagar districts experience tremendous pressure of human activities. Local population is dependent on the forest resources for their daily need, this dependence induce some activities such as lopping and pruning of twigs, bark wood for fodder and kitchen fuel. Besides these activities, the local population is also indulged in collection of medicinal herbs and shrubs along with lichens which are sold to big markets in the foothill areas of Kumaun Himalaya. The agriculture practise, urbanization, construction of roads and other anthropogenic activities leads to the destruction of forest in and around village and other human settlements. The thinned out forest do not support many lichen taxa to colonize thus resulted in the loss of lichen diversity. In alpine region, *Rhododendron* and shrubs destroyed by tourists for bonfires and other activities also cause damage to number of lichen species. The grazing of sheep and goat in alpine meadow destroy many soil lichens in alpine areas.

## ACKNOWLEDGEMENTS

We are thankful to the Director, Birbal Sahni Institute of Palaeobotany, Lucknow for providing necessary laboratory facilities to work.
