The EFForTS project is a Collaborative Research Centre funded by the German Research Council (DFG) and focuses on the ecological and socioeconomic dimensions of rainforest conversion. For more information, see www.uni-goettingen.de/EFForTS.

Contributions

All 209 butterfly species were photographed by Rawati Panjaitan over the course of two field visits to EFForTS Core Plots, with the exception of *Troides amphrysus*, for which we used an image by Thomas Neubauer from the Natural History Museum Vienna, Austria. All butterflies were identified by Rawati Panjaitan under supervision of Purnama Hidayat, Djunijanti Peggie and Damayanti Buchori. The guide was compiled by Rawati Panjaitan, Stefan Scheu and Jochen Drescher.

I. Introduction

Butterflies are probably the most enigmatic insects among the arthropods. For centuries, both professional scientists and amateur enthusiasts have collected, catalogued and scientifically described butterflies from all over the world. Unsurprisingly, they belong to the most well-known insect groups in terms of taxonomy and global species record completeness. More than 17.500 described species are spread throughout the entire world, with the exception of Antarctica. Many species migrate annually to avoid unfavorable conditions in temperate regions. While most migrate only short distances of a few hundred kilometers, monarch butterflies and several other species can migrate up to thousands of kilometers, often over several generations per migration cycle.

Butterflies have the typical four-staged insect life cycle of the holometabolous insects, which includes egg, larva, pupa and adult. The larva differ greatly from the adults and are called caterpillars. Almost exclusively herbivorous, caterpillars are voracious feeders and some species can be severe agricultural pests. Larva of other butterflies are highly valued as sources of silk, food, or pest plant control. In the tropics, many butterflies have several generations per year, where the adult stage lasts about two months. Within the framework of the [EFForTS Project](#), we counted and collected butterflies in a nested replicated design in four land use systems in Jambi Province, Sumatra, Indonesia: Old growth secondary lowland rainforest, jungle rubber (a form of extensive rubber cultivation), and monoculture plantations of rubber and oil palm (Fig. 1a-d).

Figure 1. Four land use systems are investigated in EFForTS. (a) Old-growth secondary forest F, (b) Jungle rubber J (extensive rubber cultivation), (c), Rubber plantation R (*Hevea brasiliensis*) and (d) Oil Palm plantation O (*Elaeis guineensis*).

The *EFForTS* study sites are located in and around two forest reserves, i.e. the Bukit Duabelas National Park and the lowland rainforest restoration concession of PT Restorasi Ekosistem Indonesia (PT REKI), also called Harapan Rainforest. In each of the two ‘landscapes’, we established a mirrored design of four plots of each land use type in each of the two landscapes, resulting in $4 \times 4 \times 2 = 32$ ‘core plots’ (Fig. 2). Each core plot measures 50 × 50 m. Butterflies were collected between August and October 2017 using sweep netting (exception: *Troides amphrysus* CRAMER 1779, identified on sight) on three parallel transects per core plot, with two transects located on the outer borders of the core plots, and the third transect located through the center of the core plot. Sweep netting was conducted twice per day per plot, mornings (8:00 – 11:00 am) and afternoons (13:00 – 16:00 pm). All butterfly individuals were released after identification in the evenings of the sampling day, with the exception of up to two dried/mounted individuals and five individuals in 99% EtOH p.A. per species, which were kept for species ID and further analysis. Our data is based on 6653 caught and/or observed butterfly individuals that we identified to 209 species from 106 genera, 19 subfamilies and 5 families.

This guide contains a checklist and images of all 209 species observed and collected. It provides scientists working in the region with an easy to use reference, and will be updated regularly.

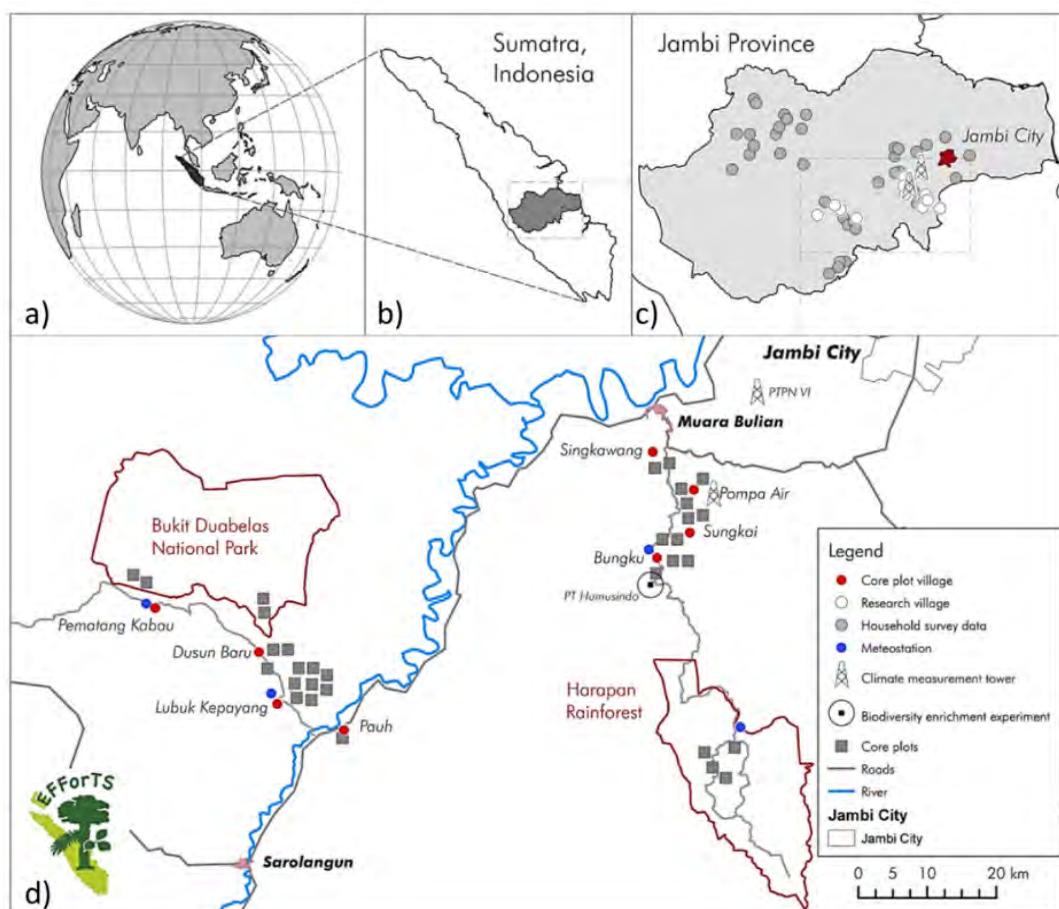

Figure 2. *EFForTS* study sites in Sumatra (a, b) and Jambi Province (c, d). The core plot design (grey squares) is mirrored in two landscapes within and adjacent to two lowland rainforests, i.e. the Bukit Duabelas National Park and the Harapan Rainforest. Circles represent study villages and sites for socioeconomic surveys (map from: Drescher et al., 2016. Ecological and socio-economic functions across tropical land use systems after rainforest conversion. *Philos. Trans. R Soc. Lond. B Biol. Sci.*).

II. Species Checklist

This is a list of the 209 species we encountered in Jambi during visits to all EFForTS core plots in Jambi dry season 2017. It contains the taxonomic resolution from family and subfamily to species, the land use systems the species were found in (, i.e. lowland rainforest F, jungle rubber J, rubber monoculture R and oil palm plantation O), and the figure numbers of the image section.

IV. Acknowledgements

We are greatly indebted to Davig Darusman, Juwita Sihombing, Norman Marbun and Somad for invaluable help in the field collecting, photographing and identifying butterflies. Images for this guide were taken during two field trips of Rawati Panjaitan to EFForTS field sites in Jambi Province, Indonesia. Both trips were funded by the Access-and-Benefit-Sharing (ABS) fund in EFForTS. Otherwise, Rawati Panjaitan is funded by an Indonesian Education Scholarship (BPI) through the use of National Trust for Education Development (DPPN), managed by the Indonesian Endowment fund for Education. The EFForTS project is funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) – project number 192626868 – SFB 990 in the framework of the collaborative German -Indonesian research project CRC990. We thank village leaders, local plot owners, PT Humusindo, Harapan Rainforest / PT REKI and Bukit Duabelas National Park for granting us access to and use of their properties.
