KEY TO THE GENERA OF OCTOCORALLIA EXCLUSIVE OF PENNATULACEA (COELENTERATA: ANTHOZOA), WITH DIAGNOSES OF NEW TAXA

Frederick M. Bayer

Abstract.—A serial key to the genera of Octocorallia exclusive of the Pennatulacea is presented. New taxa introduced are Olindagorgia, new genus for Pseudopterogorgia marcgravii Bayer; Nicaule, new genus for N. crucifera, new species; and Lytreia, new genus for Thesea plana Deichmann. Ideogorgia is proposed as a replacement name for Dendrogorgia Simpson, 1910, not Duchassaing, 1870, and Helicogorgia for Hicksonella Simpson, December 1910, not Nutting, May 1910. A revised classification is provided.

Introduction

The key presented here was an essential outgrowth of work on a general revision of the octocoral fauna of the western part of the Atlantic Ocean. The far-reaching zoogeographical affinities of this fauna made it impossible in the course of this study to ignore genera from any part of the world, and it soon became clear that many of them require redefinition according to modern taxonomic standards. Therefore, the type-species of as many genera as possible have been examined, often on the basis of original type material, and a fully illustrated generic revision is in course of preparation as an essential first stage in the redescription of western Atlantic species. The key prepared to accompany this generic review has now reached a stage that would benefit from a broader and more objective testing under practical conditions than is possible in one laboratory. For this reason, and in order to make the results of this long-term study available, even in provisional form, not only to specialists but also to the growing number of ecologists, biochemists, and physiologists interested in octocorals, the key is now presented in condensed form with minimal illustration.

In using the key, it must be kept in mind that some common species have been repeatedly described under different names, and many others have been assigned to the wrong genera. The key cannot reconcile the generic identification reached for any given specimen with the existing literature. One cautionary example, perhaps a typical one, is the genus *Heterogorgia*. None of the species described in that genus by Nutting (1910) in his *Siboga* monograph will key out to the genus *Heterogorgia*, because most of them

are species of *Echinogorgia*—some of them valid species by default, others already described by earlier authors. Other species of *Echinogorgia* were described in still other genera in the same paper, and most of those placed in *Echinogorgia* actually belong in such genera as *Villogorgia* and *Menella*.

Although the key includes all common and well-known genera, some that may be valid are omitted for the present owing to incomplete information about them. Three new generic taxa are introduced, and one very common genus is included even though no available name applicable to it has yet been found in the literature. It is probable that some poorly-known genus established with inadequate description and no illustration will be found to apply to it. Several genera that have been treated as junior synonyms or as subgenera by previous authors are here restored to valid generic status on the basis of characters that warrant recognition, and it is possible that several more will be validated when comparative studies have been completed.

The serial key format employed here is a departure from the usual practice in octocorals, and was selected because morphologically similar forms are more closely grouped than is the case in the usual dichotomous format. It is essentially an outline key with the character statements serially numbered and printed without indentation, with the number of the alternate character statement appearing in parentheses. The key has been composed in a single long series not only to accommodate investigators with a limited working knowledge of octocoral systematics, but also because several of the traditional families are so ambiguous that it is impossible to break the key up by families in any defensible way. Where families are sufficiently well defined, they are noted at appropriate points in the key, but several are not mentioned.

Because the pennatulacean material available to me for study is not adequate for improving the summary of that order published by Kükenthal (1915), those genera are not included. I have, however, with considerable misgivings included the "soft coral" genera even though I have not had access to original type-material, because there is no comprehensive review of them comparable to Kükenthal's accounts of the gorgonians (1924) and sea pens (1915). My sources have been the original descriptions and later amplifications chiefly of Kükenthal, Tixier-Durivault and Utinomi, together with such collections as are at my disposal. This part of the key will no doubt be found full of faults, but if it serves to stimulate a reappraisal and a redescription of the "alcyonacean" genera it will have served a useful purpose.

It was not originally my intention to include illustrations in this preliminary version of the key, as the expanded version will be accompanied by diagnoses, synonymies, and scanning electron micrographs of sclerites and other skeletal structures and, wherever necessary, drawings of anthocodial armature and other features not adaptable to portrayal by SEM. As the

project progressed, however, it became clear that at least some illustrations would be necessary to clarify verbal statements. Accordingly, some figures have been inserted at various points in the key. In selecting them, I have no doubt erred in the direction of scantiness, as it is not possible to illustrate every point where the user might go astray. In some major taxa where the characters seem quite straightforward, there are no illustrations at all, and in others I may have illustrated the obvious, but I have tried to illustrate those key statements that seemed most likely to prove troublesome to investigators not familiar with the organisms and with the rather subjective terminology that has been traditional in their description. The inconsistent appearance of the figures results from their selection from diverse sources. Some are from my own published papers, some from the work of other authors, and some drawn especially for this paper. In the interests of economy, pen and ink drawings have been used throughout in preference to scanning electron micrographs.

Key to Genera

1(4). Skeleton primarily non-spicular aragonite, formed as distinct corallites containing polyps, united by ribbonlike stolons or common coenosteum (HELIOPORACEA). 2(3). Corallites connected basally only by ribbonlike stolons, skeleton not massive, white; mesogloea of polyps containing sparsely distributed sclerites of calcite (Lithotelestidae) Epiphaxum Lonsdale, 1850 Corallites united by massive coenosteum, blue; mesogloea of 3(2). polyps without sclerites (Helioporidae) 4(1). Skeleton when present primarily spicular calcite, sometimes with a more or less calcified scleroproteinous axial support. 5(8). Solitary octocorals, polyps never forming colonies by vegetative budding. 6(7). Polyps large, up to 3.5 cm tall (Fig. 1); sclerites are spindles (Taiaroidae) Taiaroa Bayer & Muzik, 1976 Polyps smaller, less than 2 cm tall; sclerites are radiates and

8(5). Polyps forming colonies by vegetative budding.

9(22). Filaments of all septa but the asulcal pair rudimentary or absent in adult polyps; tentacles with pinnules in multiple

¹ This genus may have been based upon a founder polyp of *Sarcodictyon* (pers. comm., Mr. R. L. Manuel).

rows on each side; sclerites, if present, minute (mostly 0.02-
0.03 mm, rarely up to about 0.1 mm), flattened, ovate rods
or disks, often absent altogether (Xeniidae).
Polyps retractile.
Polyps dimorphic Fungulus Tixier-Durivault, 1970
Polyps monomorphic.
Colonies membranous Sympodium Ehrenberg, 1834
Colonies forming upright, digitate lobes
Efflatounaria Gohar, 1934
Polyps not retractile.
Colonies membranous
Colonies forming upright lobes.
Lobes digitate, polyps generally distributed, not limited to
terminal capitulum
Lobes capitate, polyps concentrated on well-defined capitu-
lum. 1980 vali minorangui De espeka olima bisada (Arabain abaka e CC) AC
Polyps always monomorphic Xenia Lamarck, 1816
Polyps dimorphic, at least when breeding
Heteroxenia Kölliker, 1874
Filaments fully developed and permanently retained on all 8
septa; tentacles with pinnules in a single row on each side;
sclerites usually present, of diverse form.
Colonies usually firmly attached to solid substrate by a
spreading holdfast, sometimes anchored in soft substrate by
rootlike projections of axial skeleton or of colonial coenen-
chyme; polyps monomorphic or dimorphic.
Skeleton consists only of sclerites, free or more or less
firmly cemented together by horny or calcareous material, but
sometimes absent entirely.
. Colonies with no internal axial support, or one of loosely
bound sclerites.
Polyps connected only at their bases, neither immersed in
common coenenchyme nor joined to one another laterally.
Calcareous skeleton lacking; stolons and polyps invested by
thin, horny perisarc (Cornulariidae) Cornularia Lamarck, 1816

29(56). Proximal part of gastric cavity open to base of polyps, not filled with mesogloea containing sclerites ("intrusion tissue").

28(27). Calcareous skeleton composed of sclerites present in addition

to horny perisarc.

30(53). Colonies arise from stolons that are ribbonlike or simple sheets not divided into two coenenchymal layers.

31(48). Sclerites of stolons and anthosteles not inseparably fused but may form clumps locally.

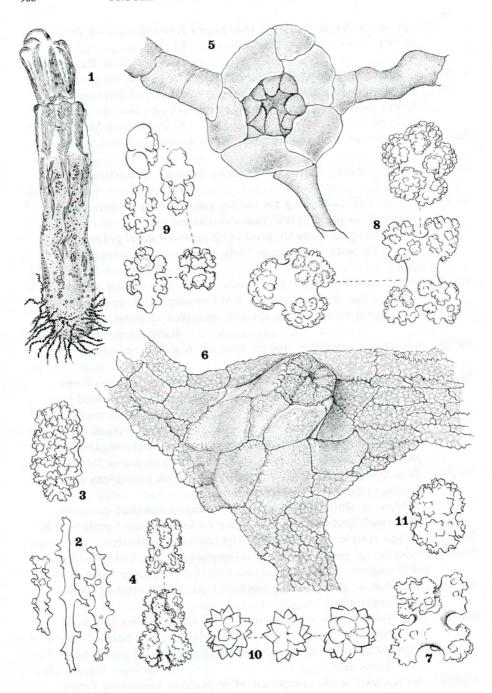

32(41).	Anthocodiae retractile into tall, cylindrical anthosteles arising from ribbonlike, often anastomosing stolons.
33(34).	Polyps simple, not producing lateral daughters, arising from stolons usually of ribbonlike or reticular form
34(33).	Tall axial polyps produce numerous daughters from their lateral walls.
35(36).	Anthocodiae not retractile, oral region covered by infolded tentacles during contraction; colonies richly arborescent, polyps of last order very short; white
	Coelogorgia Milne Edwards & Haime, 1857
36(35).	Anthocodiae fully retractile into anthosteles.
37(38).	Sclerites of body walls slender, often branching and inter-
	locking, sometimes fusing into smaller or larger clumps, or-
	namented with thorns and prickles; white (Fig. 2)
	Carijoa F. Müller, 1867
38(37).	Sclerites of body walls coarse, blunt spindles, sculpture of
	outer surface often rounded, smoother and coarser than that
	of inner surface; red, orange, rarely white (Fig. 3).
39(40).	Wall of axial polyp with multiple rings of solenia
40(39).	Wall of axial polyp with one ring of solenia
, ,	
41(32).	Polyps retractile directly into stolons, producing at most only
	low, conical or short, cylindrical anthosteles.
42(45).	Sclerites are tuberculate rods or spindles.
43(44).	Sclerites are blunt spindles or rods of moderate size (less than
	0.5 mm) with complex tubercles, more or less clearly derived
	from 6- and 8-radiates (Fig. 4); anthocodiae with few or no sclerites, fully retractile into scarcely projecting anthosteles
	in ribbonlike stolons that occasionally form a wide membrane; red, pink or yellow Sarcodictyon Forbes, 18472
44(43).	Sclerites are spindles of large size (1 mm) with small and
	rather simple tubercles or thorns; anthocodiae armed with
	distinct transverse crown and 8 points of converging spindles
	below the tentacles, retractile into low but distinct antho-
	steles, often preserved exsert; stolons commonly membra-
	nous; white Trachythela Verrill, 1922
45(42).	Sclerites are large, flattened plates.
46(47).	Calices bluntly conical, walls covered by few large plates,

² Synonym: Rolandia Lacaze-Duthiers, 1900.

	apertures closed by triangular plates forming distinct oper- culum; stolons thin, ribbonlike; red (Fig. 5)
47(46).	Calices bluntly conical, or short cylinders with walls covered by numerous plates of decreasing size but not forming differentiated operculum; stolons ribbonlike or sheetlike; white (Fig. 6)
48(31).	Sclerites of stolons and anthosteles rigidly and inseparably fused.
49(50).	Polyps short, simple, with low, conical anthosteles; red
50(49).	Polyps tall, producing secondary polyps more or less abundantly from high, cylindrical anthosteles.
51(52).	Axial polyps commonly producing shorter lateral polyps; anthocodiae with sclerites in both rachis and pinnules of tentacles
52(51).	Axial polyps infrequently producing shorter lateral polyps; anthocodiae with sclerites below tentacles in 8 septal and 8
	interseptal rows, tentacles and pinnules without sclerites
53(30).	Colonies arise from stolons forming multilayered sheets or platforms.
54(55).	Sclerites solidly fused except in anthocodiae; colonies forming rounded clumps of large size, transversely partitioned by stolonic platforms; red
55(54).	Sclerites not fused; colonies matlike, spreading, stolons composed of multiple irregular layers but not regularly successive platforms; purple or violet Pachyclavularia Roule, 1908
56(29).	Proximal part of gastric cavity filled in with mesogloea containing sclerites.
57(58).	Polyps producing daughters to form sympodial colonies (Pseudocladochonidae) Pseudocladochonus Versluys, 1907
58(57).	Polyps simple or producing daughters monopodially.
59(60).	Sclerites of polyp walls not inseparably fused. Color, white
,	or brownish Telestula Madsen, 1944
60(59).	Sclerites of polyp walls rigidly fused. Color, red or pink, sometimes white.
61(62).	Anthostelar walls composed of fused spindles <i>en chevron</i> in 8 longitudinal tracts; anthocodial sclerites in 8 points; mesogloeal intrusion tissue confined to basal part of gastric cavities. Color red

62(61). Anthostelar walls composed of irregularly branching forms

interlocked and rigidly fused; anthocodial sclerites not form-

- ing 8 points; basal spicular intrusion of gastric cavities more extensive. Color, white or pinkish ... Scyphopodium Bayer, 1981
- 63(26). Polyps either partially united laterally or immersed in common coenenchyme.
- 65(64). Polyps immersed in extensive common coenenchyme, forming membranous, lobate or arborescent colonies that may be large or massive.
- 67(66). No dominant axial polyp, regardless of colonial shape.
- 68(97). Coenenchyme divided into inner (medullar) and outer (cortical) layers, gastric cavities of polyps chiefly confined to cortical layer, not extensively penetrating medulla.³
- 69(94). Polyps monomorphic.
- 70(73). Colonies forming thick, encrusting sheets without conspicuous upright lobes or branches.
- 71(72). Sclerites predominantly 6-radiates (Fig. 7); surface of coenenchyme purplish red Erythropodium Kölliker, 1865
- 73(70). Colonies producing upright lobes or digitate processes, or arborescent structures.

³ Forms with this array of characters comprise the greater part of the suborder Scleraxonia in the system of Kükenthal.

Figs. 1-11. 1, Taiaroa tauhou Bayer & Muzik, polyp, ×3; 2, Carijoa riisei (Duch. & Mich.), sclerites, ×105; 3, Telesto sanguinea Deichmann, sclerite, ×105; 4, Sarcodictyon catenatum Forbes, sclerites, ×140; 5, Tesseranthelia rhodora Bayer, calyx, ×25; 6, Scleranthelia rugosa (Pourtalès), calyx, ×25; 7, Erythropodium caribaeorum Duch. & Mich., sclerite, ×275; 8, Titanideum frauenfeldii (Kölliker), sclerites, ×275; 9, Paragorgia spp., sclerites, ×275; 10, Asterospicularia randalli Gawel, sclerites, ×275; 11, Minabea sp., sclerite, ×250.

74(75).	Colonies lobate or digitate; medulla penetrated by solenia throughout but not separated from cortex by longitudinal boundary canals, sclerites coarse spindles sometimes branched as tripods, purple in medulla, white and/or purple in cortex
75(74).	Colonies digitate or arborescent, medulla little penetrated by solenia, chiefly proximally, separated from cortex by boundary canals.
76(77).	Medullar sclerites smooth, fusiform, branching, often anastomosing; colonies arborescent, fanshaped or bushy (Subergorgiidae)
77(76).	Medullar sclerites mostly long spinous rods or needles, in- termixed with more or less abundant tuberculated spindles or rods that may have processes more or less branched; sclerites may fuse in larger or smaller clumps, but not throughout length of medulla.
78(83).	
79(80).	Cortical sclerites are exclusively radiates (Fig. 8)
80(79).	Cortical sclerites include blunt, closely tuberculate spindles or oval bodies as well as radiate forms.
81(82).	Non-radiate sclerites of cortex are stubby, oval bodies about 0.15 mm long
82(81).	Non-radiate sclerites of cortex are blunt tuberculate spindles or rods up to 0.5 mm long Diodogorgia Kükenthal, 1919
83(78).	No radiate sclerites in cortex.
84(85).	Colonies digitate, clavate, rarely if ever branching; cortex highly vesicular <i>Tripalea</i> Bayer, 1955
85(84).	Colonies branched, often richly so; cortex not vesicular.
86(87).	Trunk and/or main branches hollow, tubular; colonies either affixed to hard substrate by spreading holdfast, or anchored in soft substrate by spatulate expansion of trunk
	Solenocaulon Gray, 1862
87(86).	Trunk and branches not hollow, tubular.
88(89).	Polyps widely scattered on all sides, forming distinctly projecting but short, cylindrical calices, anthocodiae commonly preserved exsert; branches round, slender, producing tangled
00/00	colonies often without evident main stem

89(88). Polyps crowded, fully retractile into coenenchyme or forming at most only low, bluntly conical or hemispherical calices; branches more or less flattened, colonies arborescent, with conspicuous main stem.

90(91).	Polyps fully retractile into edges of conspicuously flattened terminal branches; branch tips not fistulose
91(90).	Polyps usually forming inconspicuous or low hemispherical calices; branch tips fistulose.
92(93).	Polyps crowded on three sides of branchlets and on front of large branches and trunk Semperina Kölliker, 1870
93(92).	Polyps biserial, generally absent from front and back of colony <i>Iciligorgia</i> Duchassaing, 1870
94(69).	Polyps dimorphic. Colonies upright, arborescent; cortical sclerites 6-, 7- and 8-radiate capstans, often more or less strongly modified as double clubs or "opera glasses" (Fig. 9) medullar sclerites long, spinose, branching rods (Paragorgi-
05(00)	idae). I man ha an
95(96).	Cortex separated from medulla by a distinct ring of boundary canals; sclerites colorless Sibogagorgia Stiasny, 1937
96(95).	Cortex not separated from medulla by a ring of boundary canals; cortical sclerites commonly pink or red, medullar sclerites colorless or pink
97(68).	Coenenchyme not divided into inner and outer layers, gastric cavities of polyps extending throughout.
98(105).	Polyps arranged in clusters or on branches that are retractile within common coenenchymal trunk.
99(100).	Polyps in small clusters retractile within short, cylindrical trunks united in series by ribbonlike stolons
100(99).	Polyps on branches retractile within stout columnar trunk attached to or embedded in substrate; trunks solitary (Fig. 12).
101(102).	Polyps widely spaced on ends of twigs comprising a loosely branched polyparium; trunk soft-walled (Fig. 12a)
102(101).	Polyps crowded on numerous fingerlike branches and retractile within well-defined calices strengthened by abundant sclerites.
103(104).	Polyps monomorphic. Sclerites predominantly spindles Studeriotes Thomson & Simpson, 1909
104(103).	Polyps dimorphic. Sclerites predominantly capstans (Fig. 12b)
105(98).	

106(171). Polyps scattered or in clusters on branchlets or lobes of arborescent or lobate but not massive colony. 107(108). Sclerites are small, stellate bodies similar to those of didemnid tunicates (Fig. 10) Asterospicularia Utinomi, 1951 108(107). Sclerites of various shapes but not stellate, or absent altogether. 109(134). Colonies capitate or digitate, branching little or not at all. 110(123). Polyps monomorphic. 111(112). Anthosteles distally flared to form a broad, octagonal collar into which the anthocodiae can be withdrawn (Fig. 13); sclerites are spiny spindles Agaricoides Simpson, 1905 112(111). Anthosteles not flared to form wide collar. 113(114). Polyps not retractile, with supporting bundle of spindles along one side, forming cluster at top of undivided trunk Coronephthya Utinomi 114(113). Polyps retractile, without supporting bundle, generally distributed on distal part of trunk. 115(120). Colonies digitate. 116(117). Colonial stalk covered by distinct horny cuticle; sclerites are minute oval or rounded platelets . Ceratocaulon Jungersen, 1892 117(116). Colonial stalk without conspicuous cuticle; sclerites not minute platelets. 118(119). Sclerites are thorny spindles, sometimes clubbed Bellonella Grav, 1862 119(118). Sclerites are double spindles Metalcyonium Pfeffer, 1888⁴ 120(115). Colonies capitate. 121(122). Sclerites are coarse, tuberculate spindles; polyps retract into conical calices formed by converging sclerites 122(121). Sclerites are capstans or thorny spheres Metalcyonium Pfeffer, 1888 123(110). Polyps dimorphic. 124(125). Colonies consist of a single large, cylindrical autozooid with many siphonozooids embedded in its wall Bathyalcyon Versluys, 1906 125(124). Colonies consist of many autozooids and siphonozooids in a capitulum borne on a sterile stalk. 126(127). Sclerites totally absent Malacacanthus J. Stuart Thomson, 1910

⁴ Utinomi (1964, JARE Sci. Rept. (E)23:7) recognized *Metalcyonium* only for capitate forms, considering Pfeffer's digitate type to be *Alcyonium*.

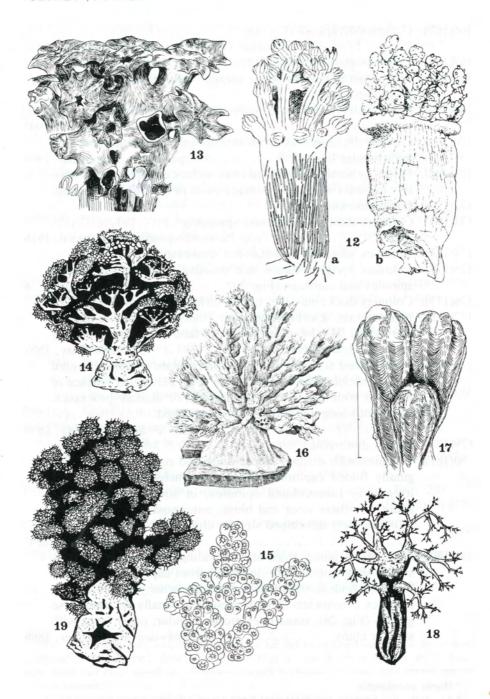

127(126).	Sclerites always present in coenenchyme.
128(131).	Capitulum digitate; polyps without sclerites.
	Sclerites are clubs about 0.25 mm long
,	Acrophytum Hickson, 1900
130(129).	Sclerites are capstans up to 0.1 mm long (Fig. 11)
	Minabea Utinomi, 1957
131(128)	Capitulum rounded or spheroidal, not digitate; polyps with
101(120).	sclerites.
132(133)	Sclerites are capstans, double stars and thorny spindles; ca-
132(133).	pitulum mushroom-shaped, sharply delimited from sterile
	stalk Anthomastus Verrill, 1878
133(132)	Sclerites are large, tuberculate spindles; capitulum not sharp-
155(152).	ly delimited from sterile stalk Nidaliopsis Kükenthal, 1906
134(100)	Colonies repeatedly branching or multilobate.
	Polyps retractile.
	Colonies low, branches lobate; polyps weakly armed
130(137).	Gersemia Marenzeller, 1877
127(126)	Colonies tall, branches slender; polyps strongly armed with
137(130).	well-formed crown and points Siphonogorgia Kölliker, 1874
129(125)	Polyps not retractile.
	Polyps without supporting bundle of spindles.
	Colonial form umbellate (Fig. 14).
141(142).	Polyps with strong armature of spindles <i>en chevron</i> forming
	8 points but without transverse collaret; sclerites of coenen-
	chyme few to many, either abundant small capstans or sparse
	spindles about 2.5 mm long, sometimes totally absent
1.42(1.41)	Umbellulifera Thomson & Dean, 1936
142(141).	Polyps weakly armed with blunt, flattened rods in converging
	double rows; coenenchymal sclerites are capstans and tuber-
	culate rods of small size (up to 0.12), rather sparse
1.12(1.10)	Duva Koren & Danielssen, 1883
	Colonial form not umbellate.
144(147)	Polyps situated on small terminal twigs ("lappets" or "cat-
	kins'') (Fig. 15).
145(146).	Coenenchyme with abundant leaf-clubs
	No leaf clubs Litophyton Forskål, 1775
	Polyps scattered or in clusters on twigs and branches.
148(149).	Cylindrical branches radiate outward from summit of short
	sterile stalk (Fig. 16) Daniela von Koch, 1891
149(148).	Branches not radiating outward from summit of short sterile
	stalk, but originating at various levels in colony.
150(155).	Colonies lobular, sterile trunk short, inconspicuous.

151(152).	Polyps and branches with an outer layer of small (0.05-0.12 mm, flattened, tuberculate rods overlying larger, slender
	spindles up to 0.8 mm long Scleronephthya Studer, 1887
152(151).	No outer layer of small sclerites.
153(154).	Sclerites of polyps arranged <i>en chevron</i> in 8 double rows forming conspicuous longitudinal ridges (Fig. 17); coenenchyme with capstans and clubs <i>Pseudodrifa</i> Utinomi, 1961
154(153).	Sclerites of polyps not in 8 double rows forming longitudinal ridges; coenenchyme with irregular spindles and capstans Drifa Danielssen, 1887
155(150).	Colonies not lobular.
	Sterile stems arising from common base subdivide into sterile primary and secondary branches producing slender branch-
	lets and twigs bearing scattered polyps; sclerites are curved spindles with projections taller on convex side and needles
	chiefly in twigs and branches, and small double stars, "brack-
	ets" and 4-rayed forms with 2 rays longer in basal parts;
	tentacles with small, finely granulated, lobed scales
157(156)	Starila stame origing from common base produce digitate
157(136).	Sterile stems arising from common base produce digitate branches that subdivide at most only once, bearing polyps crowded on distal parts; sclerites are spindles, some thorny,
	some nearly smooth Paralemnalia Kükenthal, 1913
158(139)	Polyps with supporting bundle of spindles.
	Polyps arise directly from summit of sterile trunk
107(100).	
160(159).	Polyps arise from branches.
, ,	Polyps in lappets (catkins) or bundles on branchlets of abun-
-1011	dantly ramified colonies.
162(163).	Polyps in lappets (catkins) Nephthea Audouin, 1826
	Polyps in bundles on branchlets.
	Form of colonies umbellate (Fig. 14)

165(164). Form of colonies not umbellate.

. Morchellana Gray, 1862

Figs. 12–19. 12, Colonies with retractile polyp-bearing branches: a, *Paralcyonium spinulosum* (delle Chiaje) (after Stiasny, 1941); b, *Carotalcyon sagamianum* Utinomi (after Utinomi, 1952); 13, *Agaricoides alcocki* Simpson, anthosteles of syntype, British Museum (Nat. Hist.), ×3; 14, Umbellate growth form, diagrammatic (after Thomson & Dean, 1931); 15, Catkins of *Litophyton*; 17, *Pseudodrifa nigra* (Pourtalès), 3 contracted polyps, scale = 1 mm; 18, Divaricate growth form, diagrammatic (after Thomson & Dean, 1931).

	C. I (Fig. 19)
166(167).	Colonies divaricate (Fig. 18)
167(166).	Colonies glomerate (Fig. 19) Spongodes Lesson, 1831
168(161).	Polyps not in lappets but scattered on branchlets of sparsely
	divided colonies.
169(170).	Canal walls in interior of stem with few sclerites
	Stereonephthya Kükenthal, 1905
170(169).	Canal walls in interior of stem with numerous sclerites form-
	ing irregular false axis ⁵ Neospongodes Kükenthal, 1903
171(106).	Polyps generally distributed over surface of spreading or mas-
	sive colonies with upper surface more or less folded or lobed.
172(179).	Polyps monomorphic.
173(174).	Colonies thin, membranous, spreading
	Parerythropodium Kükenthal, 1916
174(173).	Colonies lobate or massive, not membranous.
175(176).	Colonies upright, lobate, not massive; sclerites are thorny
175(176).	spindles and capstans (Fig. 20) Alcyonium Linnaeus, 1758
176(175)	Colonies thick, massive, upper surface plicate or lobate.
177(178)	Predominant sclerites are stout, thorny or spinose double
177(170).	stars (Fig. 21); lobes of upper surface of colonies usually
	short and rounded
178(177).	Predominant sclerites are large, tuberculate spindles covered
170(177).	by superficial layer of small clubs (Fig. 22); upper surface of
	colonies with low, complex plication, or digitate processes,
	sometimes long and more or less branched
	Sinularia May, 1898
170(172)	Polyps dimorphic.
1/9(1/2).	Colonies with distinct sterile stalk and rounded, often mar-
180(181).	ginally folded capitulum; inner coenenchymal sclerites are
	irregularly tuberculated spindles, in some species rather
	acute, in others stout and blunt; outermost sclerites weakly
	to moderately developed slender clubs (Fig. 23)
	to moderately developed stellar class (Fig. 25)
101/100	Sarcophyton Lesson, 18346
181(180).	Colonies flattened, thick and spreading, sometimes with low
	sterile stalk not sharply delimited from capitulum, which is
	lobed or folded; sclerites of inner coenenchyme are stubby
	spindles ("tonnelets") with tubercles usually in transverse
	girdles (Fig. 24), sometimes more irregular; outer layer with
	slender clubs Lobophytum Marenzeller, 1886

⁵ Highly questionable.

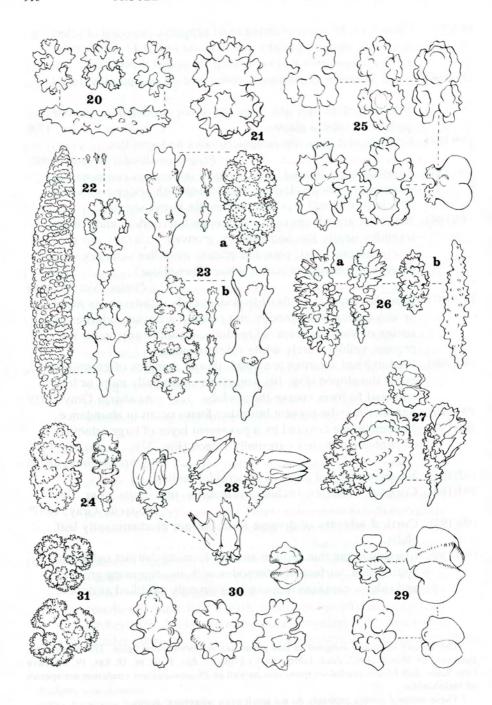

⁶ The distinction between Sarcophyton and Lobophytum is minimal.

- 182(25). Colonies with a consolidated axial support composed of sclerites firmly united by horny material and/or CaCO₃ but without a chambered central core, (except in nodes if present).
- 183(186). Axial skeleton continuous, composed of inseparably fused sclerites.
- 185(184). Sclerites of cortex are irregular plates and spindles

 Pleurocoralloides Moroff, 1902⁷
- 186(183). Axial skeleton jointed, consisting of internodes composed of inseparably fused sclerites, alternating with nodes composed of sclerites bound together by flexible horny sheaths.
- 188(187). Branches arise from flexible nodes; ends of internodes more or less conical and smooth, not radially grooved; sclerites of cortex of variable form, of medulla, smooth rods; color red, orange, yellow, rarely white (Melithaeidae).
- 189(190). Predominant sclerites are large, thorny spindles often unilaterally developed (Fig. 10), sometimes terminally more or less enlarged to form coarse thorn-clubs Acabaria Gray, 1859
- 190(189). Spindles may be present but other forms occur in abundance.
- 192(191). No pavementlike layer of spheroidal bodies.
- 194(192). Cortical sclerites of diverse form but not predominantly leaf clubs.
- 195(196). Coenenchyme thin, polyps usually forming distinct calices in contraction; surface of internodes with anastomosing grooves and ridges; capstans more or less strongly modified as double

⁷ The species originally assigned to this genus has not been found again. The illustrations published by Moroff (1902, Zool. Jahrb. (Syst.) 17:pl. 17, figs. 8, 10; pl. 18, figs. 19, 20) leave little doubt that *Pleurocoralloides formosum* as well as *Pleurocorallium confusum* are species of Melithaeidae.

⁸ These nominal genera probably do not merit even subgeneric status.

197(24). In addition to sclerites (which may be absent), colonies have a proteinous axial support more or less extensively permeated by calcium carbonate.

198(325). Axial support has a hollow, cross-chambered central core.

199(204). Chambered core surrounded by terete, smooth sclerites cemented together by conspicuous horny sheaths.

200(201). Polyps retractile into a thick common coenenchyme, not forming prominent calices; branches thick; sclerites are compact triradiates (Fig. 31); color red ... *Ideogorgia*, nom. nov.¹⁰

201(200). Polyps not retractile, forming prominent calices; branches thin; sclerites spindles or plates.

203(202). Calices cylindrical, taller than wide, margins with 8 distinct lobes filled with converging sclerites; sclerites slender, acute, prickly spindles; tentacles with small, curved spindles, no crutch-shaped bodies. White Lignella Gray, 1870

204(199). Chambered core of axis surrounded by concentric layers of

⁹ Synonyms: Melitella Gray, 1859, and Birotulata Nutting, 1911.

¹⁰ Pro *Dendrogorgia* Simpson, 1910 (type-species, *Juncella elongata capensis* Hickson, 1904), not Duchassaing, 1870.

Figs. 20–31. 20, Alcyonium digitatum Linnaeus, sclerites, ×225; 21, Cladiella krempfi (Hickson), sclerite, ×225; 22, Sinularia sp., large spindle and 3 clubs at same scale, ×30, and 2 clubs ×275; 23, Sarcophyton spp.: a, S. trocheliophorum Marenzeller, spindle and 2 clubs at same scale, ×70, and club, ×275; b, S. sp. cf. spongiosum Thomson & Dean, spindle and 3 clubs at same scale, ×70, and club ×275; 24, Lobophytum crassum Marenzeller, sclerites ×140; 25, Corallium spp., sclerites ×275; 26, Acabaria spp.: a, A. crosslandi Stiasny, sclerites ×140; b, A. erythraea (Ehrenberg), sclerites, ×140; 27, Wrightella coccinea (Ellis & Solander), sclerites, ×140; 28, Mopsella spp., leaf-clubs ×140; 29, Melithaea ocracea (Linnaeus), club and 3 birotulates, ×275; 30, Clathraria rubrinodis Gray, "leafy spheroids," i.e., capstans modified toward birotulate type, ×275. 31, Ideogorgia capensis (Hickson), sclerites, ×275.

hornlike scleroprotein that may contain calcareous deposits but not formed as sclerites.

205(218). Polyps not functionally differentiated into anthocodia and anthostele, contractile but not retractile within common coenenchyme, tentacles folding over oral disk in contraction.

206(207). Sclerites are small spindles and capstans, sometimes weakly developed as clubs, not individually conspicuous and not regularly arranged on calices Calcigorgia Broch, 1935

207(206). Sclerites are large spindles, very conspicuous on calices, where commonly arranged *en chevron* in 8 longitudinal double rows.

209(208). Distal ends of sclerites around tentacle bases not specially differentiated as spines, though the tips may project somewhat around calicular apex.

211(210). Coenenchymal sclerites with tubercles of inner and outer sides similarly developed; polyps without suture separating calicular from subtentacular sclerites.

213(212). Calices short and verruciform to tall and cylindrical, sclerites arranged more or less distinctly *en chevron* in 8 double rows, the distal ones projecting little or not at all; sclerites of calices gradually merging with those of tentacle bases, which are not abruptly smaller; inner layer of coenenchyme with more or less abundant radiates.

214(215). Calices low, verruciform Muricella Verrill, 1869

215(214). Calices prominent, tall, cylindrical.

217(216). Calices not clavate; sclerites of calicular walls en chevron in 8 longitudinal double rows Acalycigorgia Kükenthal, 1908

218(205).	Polyps functionally differentiated into anthocodia and an-
	thostele, or fully retractile into common coenenchyme; spic-
	ulation of tentacular part of polyp not continuous with that
	of proximal part but separated by neck zone with few or no
	sclerites, permitting retraction of anthocodia into anthostele
	or directly into common coenenchyme.
219(250).	Sclerites in the form of spindles with tubercular sculpture
	arranged in whorls, of moderate size (up to 0.3 mm, com-
	monly less); when present, anthocodial sclerites are tapered,
	flat rodlets with scalloped or lobed edges, not usually forming
	a crown and points; core of axis narrow, cortex dense, with
	little or no loculation (Gorgoniidae).
220(221).	The proteinous axis is flat and lamellar
	Phycogorgia Milne Edwards & Haime, 1850
221(220).	The proteinous axis is nearly or quite cylindrical, or some-
	what flattened in the basal part of colony.
	Branches of axis anastomose to form a network.
223(224).	Meshes of axial network filled in by coenenchyme, forming
	flat, more or less dissected, leaflike fronds
224(223).	Meshes of axial network not filled in by coenenchyme, form-
225(226)	ing net-like, reticulate fans.
225(226).	Scaphoids present as well as spindles and capstans (Fig. 32)
226(225)	
226(223).	Spindles and capstans only, no scaphoids (Fig. 33)
227(222)	Branches of axis not anastomosing to form a meshwork.
	Coenenchyme contains only spindles and capstans with sym-
220(229).	metrically developed tuberculation
229(228)	Many spindles and capstans modified in form or asymmetri-
227(220).	cally sculptured.
230(233)	Numerous double wheels (i.e., capstans with tubercles fused
250(255)	into disks) present as well as spindles (Figs. 35, 36).
231(232).	Double wheels large, lengths to 0.15 mm, spindles to 0.2 mm,
	some developed as leaf clubs (Fig. 35); anthocodiae weakly
	to moderately armed with flat rods 0.15–0.3 mm long
232(231).	Double wheels smaller, lengths to 0.05 mm, spindles 0.12-
Control of the later of the lat	0.18 mm, not developed as clubs (Fig. 36); anthocodiae
	unarmed Eugorgia Verrill, 1868
233(230).	No double wheels present.

234(239). Scaphoids present as well as spindles and capstans.

235(236). Polyps retractile into distinct verruciform calices; colonies small, loosely pinnate...... Olindagorgia, n. gen. 11 236(235). Polyps retract flush with coenenchymal surface, not forming calices. 237(238). Colonies dichotomously branched, bushy; polyps retracting into edges of flat or triangular branches 238(237). Colonies pinnately branched, plumose; polyps in biserial tracts, rarely all around cylindrical or weakly flattened branches, retracting flush with coenenchymal surface Pseudopterogorgia Kükenthal, 1919 239(234). No scaphoids present. 240(241). Unilaterally spinose spindles present as well as symmetrical spindles and capstans, some capstans weakly modified as disk-spindles (Fig. 39) Leptogorgia Milne Edwards & Haime, 1857 241(240). No unilaterally spinose spindles present; sclerites predominantly symmetrical spindles or capstans and small clubs. 242(245). Clubs are wart-clubs; tubercles of head prominent and set in

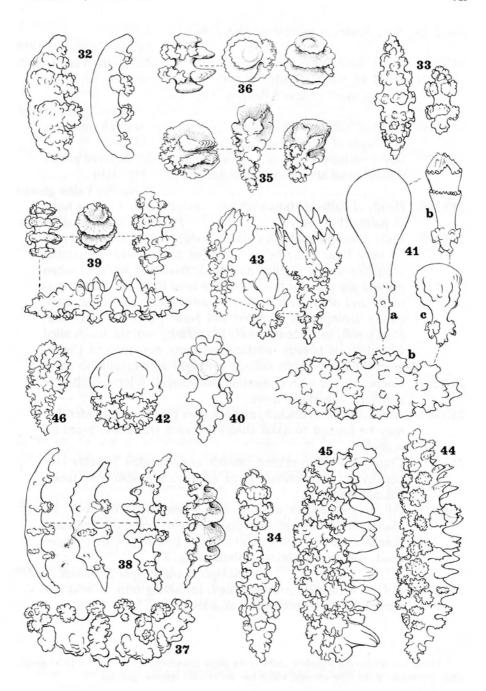

243(244). Blunt, cylindrical rods scantily distributed among tuberculate

spindles and wart-clubs Hicksonella Nutting, 1910

a regular transverse whorl (Fig. 40).

¹¹ Olindagorgia, n. gen. Small, loosely pinnate colonies under 10 cm in height; polyps biserial, usually alternate, retractile within prominent hemispherical calices, anthocodiae armed with small flat rods with more or less distinctly spatulate ends; coenenchymal sclerites consisting of acute spindles with compound tubercles in whorls, and scaphoids with surface of convex side weakly undulated. Type-species, *Pseudopterogorgia marcgravii* Bayer, 1961 [1962], Stud. Fauna Curacao 12:255, fig. 82. Holotype, USNM 50228, off Parahyba do Norte, Brazil, 6°59′30″S, 34°47′60″W, 20 fms (36.6 m), *Albatross* sta. 2758, 16 Dec. 1887.

Figs. 32–46. 32, Scaphoids of Gorgonia spp., ×275; 33, spindle and capstan of Pacifigorgia irene Bayer, ×275; 34, Spindle and capstan of Lophogorgia hebes (Verrill), ×275; 35, Double wheel, leaf-club and intermediate form, Adelogorgia phyllosclera Bayer, ×140; 36, Double wheels of Eugorgia ampla Verrill, ×275; 37, Scaphoid of Pterogorgia anceps (Pallas) ×275; 38, Scaphoids of Pseudopterogorgia spp., ×275; 39, Asymmetrical spindle, capstan and double wheels of Leptogorgia virgulata (Lamarck), ×275; 40, Wart-club of Rumphella sp., ×275; 41, Spindle and balloon-clubs of Eunicella spp.: a, E. modesta Verrill; b, E. papillosa (Esper); c, E. verrucosa (Pallas), all ×275; 42, Globular wart-club of Pseudoplexaura wagenaari (Stiasny), ×140; 43, Foliate club and torches of Eunicea spp., ×140; 44, Unilaterally spinose spindle of Muriceopsis flavida (Lamarck), ×140; 45, Unilaterally spinose spindle of Pseudoplexaura porrosa (Houttuyn), ×140; 46, Irregularly spinose club of Psammogorgia arbuscula (Verrill), ×140.

244(243).	No cylindrical rods; wart clubs abundant
245(242).	Clubs are balloon-clubs (Fig. 41) Eunicella Verrill, 1869
246(247).	Head of balloon-clubs smooth, teardrop-shaped, in some
	species more or less 3-flanged (Fig. 41a)
	Eunicella (modesta group)
247(246).	Head of balloon-clubs sculptured with low, smooth tubercles
	or whorls of small points, trigonal in cross section.
248(249).	Balloon-clubs with 2 or 3 whorls of upwardly directed points
	around head above shaft ("Dütenkeulen"; Fig. 41b)
	Eunicella (alba group)
249(248).	Heads of balloon-clubs with low, smooth warts but no whorls
	of points (Fig. 41c) Eunicella (verrucosa group)
250(219).	Fully developed sclerites usually longer than 0.3 mm and may
	be very large (lengths to 5 mm or more), with tubercular
	sculpture not in regular whorls; anthocodial sclerites when
	present are more or less curved or bent rods, sometimes flat-
	tened and often with prickly or tuberculate sculpture, com-
	monly arranged as a crown and points; core of axis wide,
	cortex soft, loculated (usually abundantly so), the loculi filled
	with delicate fibrous substance or hard, non-spicular CaCO ₃
	composed of crystals radially arranged with respect to axis.
251(264).	Coenenchyme with numerous club-shaped sclerites, often in
	a distinct superficial layer.
252(263).	At least some coenenchymal sclerites purple or lavender, but
	may be limited to axial sheath of main trunk and proximal
	branches.
253(260).	Clubs well-differentiated, mostly concentrated in outer coe-
	nenchyme; predominant large sclerites are uniformly tuber-
	culated spindles.
254(255).	Polyps unarmed or at most with a few small, flat rods, re-
	tracting flush into common coenenchyme, calicular apertures
	porelike, often gaping; clubs are wart-clubs with rounded
	head, sometimes almost globular (Fig. 42)
	Pseudoplexaura Wright & Studer, 1889 ¹²
255(254).	Polyps with numerous sclerites, retracting into distinct cal-
	ices that may be prolonged as a lower lip.

¹² Those species having abundant clubs in the outer coenenchyme may prove to be generically distinct from the type-species, which has unilaterally spinose spindles.

- 256(257). Anthocodial armature chiefly tentacular, not forming a crown and points...... Eunicea Lamouroux, 1816 (sensu stricto)
- 257(256). Anthocodial armature below tentacles forming distinct crown and points; clubs are leaf-clubs with foliate or laciniate head, often obliquely set to form "torches" (Fig. 43).
- 258(259). Pale violet or lavender interior sclerites often limited to larger branches and main trunk; coenenchyme hard; calices with falcate lower lip...... Eunicea (Euniceopsis Verrill, 1907)
- 260(253). Clubs poorly differentiated, not in a definite surface layer; spindles unilaterally spinose (Figs. 44, 45).

- 264(251). Club-shaped sclerites scarce and not concentrated in a surface layer, commonly absent altogether.
- 265(270). Predominant sclerites are stellate forms with 4 or more rays.
- 266(267). Stellate forms are 5- to many-rayed disks with central boss; outermost layer of coenenchyme filled with rosette-like "collar-button" sclerites (Fig. 47) Bebryce Philippi, 1841
- 267(266). Predominant sclerites are 4-rayed "butterflies" produced by hypertrophy of 4 rays of the 6-radiate capstans; outer layer without "collar-buttons," but small crosses with a spinose central boss may occur.
- 268(269). Colonies more or less planar or flabellate, sometimes irregularly straggling, not dichotomous, with short, crooked terminal branches bearing well-spaced polyps retracting within

¹³ Only Pseudoplexaura porosa (Houttuyn), type-species of the genus.

low, conical or hemispherical calices; rays of 4-radiate sclerites about equal in length (Fig. 48) Nicaule, n. gen. 14 269(268). Colonies robustly bushy, dichotomous, with cylindrical branches usually long and straight or nearly so, bearing crowded polyps retracting into slitlike (occasionally porelike) apertures often with a raised, bilabiate rim (or, rarely, prominent bilabiate calices); 2 rays of 4-radiate sclerites usually stronger than the others (Fig. 49) Plexaurella Valenciennes, 1855 270(265). Stellate forms not predominant. 271(276). Coenenchyme with an outer layer of large, thick plates or flattened spindles, tightly fitted as in mosaic or with smaller spindles in interstices. 272(273). Branches long and ascending (rarely unbranched); calices with 8 marginal lobes formed by converging sclerites; outer surface of coenenchymal plates with undulated or "washboard" appearance Thesea Duchassaing & Michelotti, 1860 273(272). Branches short, crooked; calices without marginal lobes.

274(275). Polyps biserial; anthocodial armature with numerous sclerites converging in each section of the points; coenenchymal sclerites without spines Scleracis Kükenthal, 1919

276(271). Coenenchymal sclerites may be large but not forming a pavementlike layer of thick plates.

¹⁴ Nicaule crucifera, n. gen., n. sp. Colony irregularly branched in one plane, about 30 cm tall, branches crooked, terminal branchlets up to 60 mm but mostly 30-40 mm long, diameter about 3 mm. Polyps on all sides, about 1.5-3.0 mm apart, retractile into low calices with 8 marginal lobes; anthocodiae occasionally preserved exsert, armature consisting of 8 points each composed of 2 bent, tuberculated rods about 0.4 mm long, above a transverse neck ring (collaret) 2-3 sclerites wide, composed of curved spindles (Fig. 48a); smaller, straight rodlets longitudinally placed extend upward from the points along the proximal part of the tentacles. Coenenchyme filled with elaborately tuberculated 6-radiate capstans (Fig. 48b) many of which develop into 4-rayed "butterflies" about 0.25 mm wide (Fig. 48c), similar to those of Plexaurella, by the suppression of 2 rays and elongation of the outer 4; a few may be 3-rayed and some approach the stellate forms of Bebryce by the development of 5 or 6 rays. Sclerites colorless. Axis with spacious central core and thin loculated cortex, soft, collapsing upon drying. Surface of coenenchyme overgrown by attached epizoa supporting a diverse community of small crustaceans. Color in life dull orange, polyps orange except for oral disk and oral surface of tentacles, which are white. Holotype, USNM 59482, Palau Islands, south point of Augulpelu Reef, 10 m, coll. Douglas Faulkner, 27 October 1971, by diving.

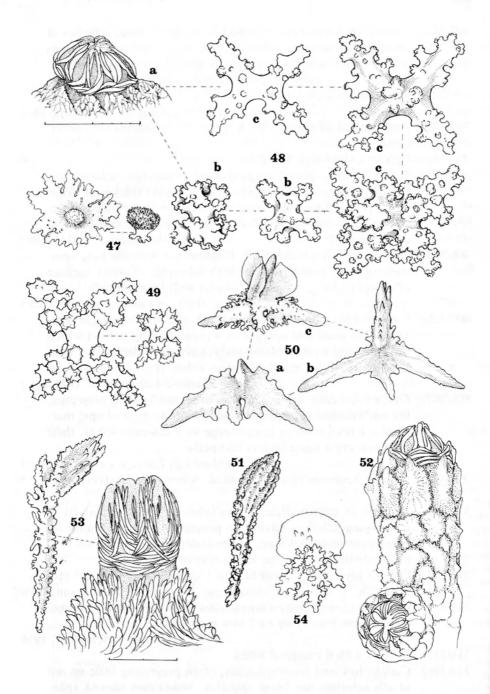

277(300).	Calicular sclerites are thorn-scales or thorn-spindles.
278(283).	Thorn-scales wider than high, consisting of two broad, di-
, ,	verging basal processes and a distal projection either foliate
	or spinose, usually strong but in some species inconspicuous;
	coenenchyme with 4-radiates having a central projection (Fig.
	50) (Villogorgia s.l.).
279(280).	Outer process an inconspicuous point, more or less flattened
,	in a plane normal to that of base (Fig. 50a)
280(279).	Outer process conspicuously projecting.
, ,	Outer process digitate or spinelike (Fig. 50b)
,	Villogorgia ("Perisceles" type)
282(281).	Outer process foliate
(/-	Villogorgia s.s. ("Acamptogorgia" type)
283(278).	Thorn-scales as high as, or higher than, wide, consisting of
()-	several diverging basal processes (sometimes only 2, but then
	not broad and flat); no 4-radiates in coenenchyme.
284(293).	Anthocodia with few, large sclerites in crown points.
	Calicular thorn-scales with rather short, blunt, serrated pro-
()	jection arising obliquely from a single, elongated root set lon-
	gitudinally in calicular wall (Fig. 51)
	Dentomuricea Grasshoff, 1977
286(285).	Calicular thorn-scales with spinelike outer projection arising
()	marginally from complex, spreading base.
287(288).	Coenenchymal sclerites elongate, without projecting spines
	Paramuricea Kölliker, 1865
288(287).	Coenenchymal sclerites with projecting spines.
	Coenenchymal sclerites not conspicuously large, projecting
	spines of only infrequent occurrence
290(289).	Coenenchymal sclerites large, platelike or scalelike, many or
, ,	all with one or more spinelike projections.
291(292)	Coenenchymal sclerites thick, coarse spindles or plates with
` ' *	one to several strong, projecting spines
•	Pseudothesea Kükenthal, 1919 ¹⁵
292(291).	Coenenchymal sclerites scalelike, with complicated margins

¹⁵ Although I have previously synonymized this genus with *Placogorgia* (Bayer, 1959, J. Wash. Acad. Sci. 49:54), it seems to be generically distinct, at least from the type-species of that genus. It may, however, be impossible to distinguish it from *Paracis*, from which it was distinguished by Kükenthal (1924, Tierreich 47:140–141, in key) on the basis of having sclerites of very diverse form, including strongly spinose, unilateral thorn-scales, but these occur in both *Pseudothesea* and *Paracis*.

	and short but stout conical spike at or near middle of outer
	surface; scales at calicular margin with spine obliquely di-
	rected at distal edge (Fig. 52)
	Lepidomuricea Kükenthal 1010
293(284).	Anthocodiae with numerous, smaller sclerites, sometimes completely unarmed.
294(295)	Base of calicular thorn-scales is a single elongated root set
27 1(275).	longitudinally in colicular well from the distance of set
	longitudinally in calicular wall, from the distal end of which
	a single stout, serrated process arises obliquely; coenen-
	chyme with thorn-spindles (Fig. 53)
295(294)	Base of calicular thorn-scales consists of diverging or branch-
275(274).	ing root-processes.
296(297)	
270(277).	Distal projection of calicular thorn-scales is a single strong
	spike; coenenchyme with thorn-spindles (Fig. 55)
297(296)	Distal projection of calicular thorn-scales is foliate or broadly
277(250).	lobate (Figs. 54, 56).
298(299)	Projection of them cooled in a law 111 1 1 111 1 111
270(277).	Projection of thorn-scales is a broad blade, thick or thin, often
	lobed marginally; coenenchyme with irregular spindles (Fig.
299(298)	54)
277(270).	Projection of thorn-scales consists of several thick, usually
	pointed lobes; coenenchyme with coarse, irregular bodies with
	serrated outer surface, sometimes unilaterally spined spindles
300(277)	(Fig. 56) Echinogorgia Kölliker, 1865
300(277).	Calicular sclerites are not thorn-scales or thorn-spindles, al-
301(324)	though marginal sclerites may have projecting edge.
JUI(J 24).	Sclerites of coenenchyme include spindles, sometimes short
	and blunt; capstans, if present, not developed as disk spin- dles.
	uics.

¹⁶ Synonym: Plexauroides Wright & Studer, 1889.

Figs. 47–54. 47, Stellate and rosette sclerites of *Bebryce cinerea* Deichmann, ×140; 48, *Nicaule crucifera* Bayer, n. sp.: a, Calyx with partly exsert anthocodia, ×25, scale = 1 mm; b, 6-radiate capstans, ×140; c, 4-rayed "butterflies," ×140; 49, Capstan and 4-rayed "butterfly" of *Plexaurella nutans* (Duch. & Mich.), ×140; 50, Calicular thorn-scales of *Villogorgia* spp.: a, "Brandella" type; b, "Perisceles" type; c, "Acamptogorgia" type, all ×105; 51, Calicular thorn-scale of *Dentomuricea meteor* Grasshoff, ×70, drawn from SEM, Grasshoff, 1977; 52, *Lepidomuricea ramosa* (Thomson & Henderson), calyx from type colony, British Museum (Nat. Hist.), ×10; 53, *Muriceides hirta* (Pourtalès), calicular thorn-scale ×70, and calyx with partly exsert anthocodia ×17; 54, Calicular thorn-scale of *Menella* sp., ×105.

302(303).	Anthocodial armature asymmetrically developed, sclerites of abaxial side, neck zone distinct only on abaxial side so polyps fold inward toward axis, obliquely placed on shelflike calices;
	coenenchymal spindles commonly reaching 4 mm in length, somewhat sinuous (Fig. 57)
303(302).	Anthocodial armature, when present, symmetrically developed.
304(309).	Calices cylindrical, tubular.
	Calices widely spaced in spiral around branches, sclerites are
().	spindles, those of calices sometimes a little thicker at distal
	end, up to 0.5 mm in length, tubercles on outer side not de-
	veloped as spines, placed en chevron in 8 double rows in
	calicular wall Anthomuricea Studer, 1887
306(307).	Calices closely crowded on all sides; sclerites are long spin-
	dles (up to 3 mm in length) with tubercles of outer surface
	often spinelike, arrange in calicular wall longitudinally
	Muricea Lamouroux, 1921(s.l.)
307(308).	Calices directed obliquely upward, the lower margin pro-
	longed outward and upward as a projecting lip behind which
	the anthocodia retracts obliquely; calicular sclerites not con-
	verging to form marginal lobes other than the lower lip
209(207)	
308(307).	lip, anthocodiae retracting vertically into truncated tips; mar-
	ginal sclerites tending to converge as 8 calicular lobes, their
	tips projecting more or less distinctly
309(304).	Calices hemispherical or conical, sometimes scarcely pro-
	jecting.
310(321).	Margins of calices divided into lobes or teeth composed of
	converging sclerites having no projecting terminal tooth; no
	outer coenenchymal layer of small capstans or spheres.
311(314).	Calices with only 2 large lobes, one on each side.
312(313).	Calices prominent; coenenchymal spindles less than 1.5 mm
	in length Calicogorgia Thomson & Henderson, 1906
313(312).	Calices not especially conspicuous (Fig. 58); coenenchymal
	spindles commonly up to 7 mm in length
214/211	
	Calices with 8 marginal lobes.
313(316).	Calices low and inconspicuous, often projecting little or not

at all; sclerites are blunt spindles, sometimes almost sphe-

	roidal, with or without median waist (Fig. 59)
	Euplexaura Verrill, 1865
316(315).	Calices hemispherical or dome-shaped, distinctly projecting;
	sclerites fusiform, more or less acute.
317(318).	Anthocodial sclerites few and small or altogether absent
	Anthoplexaura Kükenthal, 1908
318(317).	Anthocodial sclerites larger and more numerous.
319(320).	Sclerites below the 8 anthocodial points may be transverse,
	but small and numerous, not forming distinct collaret
	Astrogorgia Verrill, 1868
320(319).	Sclerites below the 8 anthocodial points large and bow-
	shaped, forming strong collaret Muricella Auct. 17
321(310).	If marginal calicular lobes present, component sclerites not
	distinctly converging; small capstans or spheres and double
	spheres in complete or incomplete outer layer of coenen-
	chyme, those surrounding calicular orifice with a terminal
	spine or tooth.
322(323).	Coenenchymal spindles overlain by a layer of capstans,
	sometimes larger at one end than the other; distal sclerites of
	calicular lobes with a strong, echinulate spine, forming a bris-
	tling barricade around calicular aperture (Fig. 60)
	Heterogorgia Verrill, 1868
323(322).	Coenenchymal spindles overlain by incomplete layer of
	small, tuberculate spheres and double spheres, often (but not
	always) with a bifurcate outer projection (Fig. 61)
	Lytreia, n. gen. 18

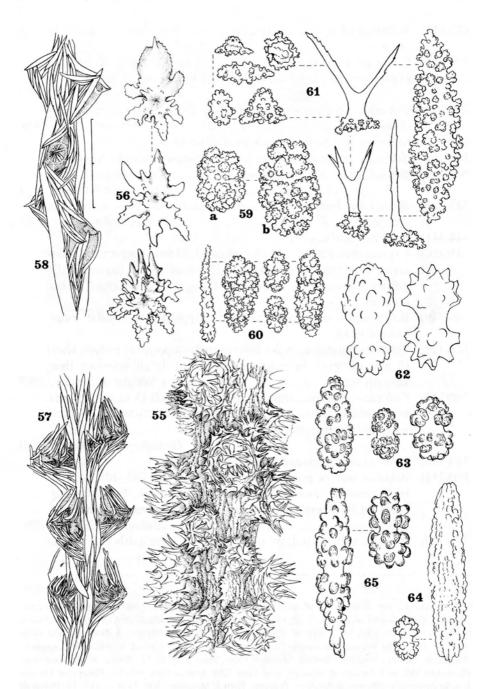

¹⁷ I have so far not been able to find a published name applicable to this generic taxon.

¹⁸ Lytreia, n. gen. Sprawling, openly bushy colonies of moderate size (up to about 20 cm tall), with crooked branches not in one plane. Polyps retractile into low, bluntly conical calices scattered irregularly on all sides of branches; calicular margins with 8 lobes, in which sclerites only irregularly and indistinctly converge, those surrounding the aperture commonly with a projecting spine. Coenenchyme containing straight or curved, irregularly tuberculate spindles overlain by a superficial layer of small, tuberculate double heads some of which have a conspicuous, forked or doubly forked spine. Anthocodiae armed with a crown of about 4–5 transversely placed bow-shaped spindles surmounted by 8 points each composed of 2–3 pairs of bent spindles en chevron. Color dirty grey, the surface conspicuously overgrown by hydroids, polychaete worms and other epizoa; sclerites colorless. Type-species, Thesea plana Deichmann, 1936 (Mem. Mus. Comp. Zool. 53:123), from west of Dry Tortugas, Florida, in 42 fathoms (76 m), MCZ 4646. Deichmann (op. cit.:124, under Thesea? sp.) foresaw the need for this genus, but overlooked the presence, in T. plana, of the "small, delicate, bi-horned deposits" characteristic of Thesea? sp., which is identical. These sclerites are of very irregular and patchy distribution and, in some colonies, may be uncommon if not altogether absent.

324(301).	In addition to spindles, sclerites of coenenchyme include capstans with warts more or less conspicuously modified as disks; calices prominent, conical or cylindrical, well separated, usually biserial; calicular margins and bases of tentacles often with stout, barlike rods; anthocodiae often preserved exsert
325(198).	Axial support does not have a chambered central core but is solid, unless the axis is jointed, in which case the calcareous internodes may be hollow, but not chambered.
326(408).	Axis continuous.
	Sclerites are tuberculate double heads or double clubs (Figs. 62–65) sometimes larger at one end (Ellisellidae).
328(329).	Cortical sclerites are clubs with distinctly enlarged head and smaller handle surrounded by a whorl of tubercles (Fig. 62)
329(328).	Cortical sclerites are double clubs with both ends roughly equal in size (Figs. 63–65).
330(331).	Branching of colony lyrate, in one plane
331(330).	Colonies not lyrate.
332(333).	Colonies profusely branched, pinnate, ultimate branchlets each terminating in a single polyp shaped like a clay pipe
333(332).	Colonies dichotomous or irregular, not pinnate, commonly unbranched.
334(337).	Sclerites of calices and coenenchyme of about equal size (Fig. 63).
335(336).	Colonies abundantly branched in one plane, terminal branches rather short and numerous
336(335).	Colonies unbranched or with few long, whiplike branches

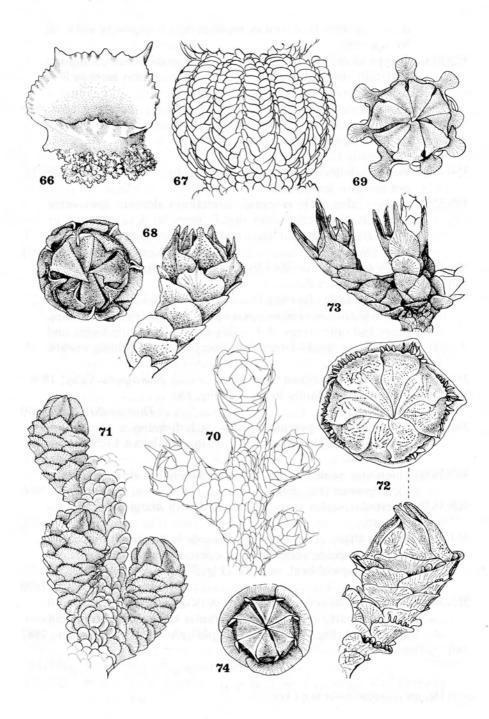

Toeplitzella Deichmann, 1936

Figs. 55-65. 55, Echinomuricea coccinea (Stimson), part of type-colony, Peabody Museum, Yale, ×17; 56, Calicular thorn-scales of Echinogorgia spp., upper ×70, lower two ×105; 57, Hypnogorgia pendula Duch. & Mich., part of branch, ×10; 58, Caliacis nutans (Duch. & Mich.), part of branch, ×10, scale = 2 mm; 59, Sclerites of Euplexaura spp.: a, E. erecta Kükenthal, ×140; b, E. capensis Verrill, type, Museum of Comparative Zoology, Harvard, ×140; 60, Sclerites of Heterogorgia verrucosa Verrill, ×105; 61, Sclerites of Lytreia plana (Deichmann), ×105; 62, Sclerites of Junceella juncea (Pallas), ×275; 63, Sclerites of Verrucella sanguinolenta (Gray), ×275; 64, Sclerites of Nicella dichotoma (Gray), type, British Museum (Nat. Hit.), ×275; 65, Sclerites of Ellisella atlantica (Toeplitz), ×275.

337(334).	Sclerites of calices distinctly longer than those of coenen- chyme.
338(339).	Colonies abundantly branched, often flattened or in one
	plane, terminal branches short and numerous (Fig. 64)
339(338).	Colonies unbranched or with few long, whiplike branches
	(Fig. 65) Ellisella Gray, 1858
` '	Sclerites not double heads or double clubs.
	Sclerites are minute disks or double disks (Ifalukellidae).
342(343).	Branching in one plane, pinnate; sclerites numerous
343(342).	Branching bushy, dense, not pinnate; sclerites extremely
	sparse Ifalukella Bayer, 1955
	Sclerites are scales.
345(386).	Crystal orientation in scales is radial, extinction pattern under
	crossed Nicols cruciform; surface of axis longitudinally
	grooved, concentric layers undulating in cross section (Prim-
	noidae).
346(349).	Body scales of fully developed polyps not in regular longi-
	tudinal rows.
347(348).	Colonies plumose, branching pinnate, opposite; polyps short
	(2 mm or less), in pairs or whorls of 3; all sclerites thin,
	smooth scales Primnoeides Wright & Studer, 1887
348(347).	Colonies whiplike, unbranched; polyps tall (3 mm or more),
	in whorls of 15 or more; sclerites thick, discoidal platelets
	with nodose or tubercular sculpture
	Ophidiogorgia Bayer, 1980
	Body scales arranged in longitudinal rows.
350(351).	Adaxial side of polyps adnate to stem, abaxial side covered
	by 2 rows of numerous sickle-shaped scales; tentacles sur-
	rounded by many small scales not differentiated as an oper-
	culum Armadillogorgia Bayer, 1980
351(350).	Adaxial side of polyps not adnate to stem (although some-

Figs. 66–74. 66, Body scale of Ascolepis nodosa (Kükenthal), ×100; 67, Primnoella australasiae Gray, whorl of polyps, ×20; 68, Polyps of Thouarella hilgendorfi (Studer), oral view ×50, lateral view ×40; 69, Polyp of Parastenella doederleini (Wright & Studer), oral view ×15; 70, Polyps of Plumarella aurea (Deichmann), ×25; 71, Polyps of Amphilaphis regularis Wright & Studer, syntype, British Museum (Nat. Hist.), ×25; 72, Polyp of Pterostenella plumatilis (Milne Edwards & Haime), oral view ×10, lateral view ×7; 73, Polyps of Dasystenella acanthina (Wright & Studer), syntype, British Museum (Nat. Hist.), ×12; 74, Polyp of Candidella johnsoni (Wright & Studer), oral view ×15.

- times appressed), naked or more or less completely covered by sclerites.
- 353(352). Polyps placed irregularly, in pairs, or in whorls, obliquely directed upward, downward, or strongly inturned, but never proximally fused.
- 354(373). Polyps completely covered all around by scales, adaxial side not more or less naked.
- 356(355). Body scales not divided by transverse crest.
- 357(366). Marginal scales 8.
- 358(361). Marginal scales forming two circles of 4 scales alternating in 2 transverse rows below operculum; opercular scales forming inner and outer rings of 4 scales each, alternating larger and smaller; marginals larger than operculars and folding inward over them.
- 359(360). Colonies unbranched (Fig. 67) *Primnoella* Gray, 1858¹⁹ 360(359). Colonies abundantly branched (Fig. 68)

...... Thouarella Gray, 1870

- 361(358). Marginal and opercular scales each forming a circle of 8 scales in a single transverse row; marginals not folding over operculars.
- 362(363). Opercular scales alternate with marginal scales; branching dichotomous (Fig. 69) Parastenella Versluys, 1906
- 363(362). Opercular scales vertically aligned with marginals; colonies pinnate.

365(364). Polyps in pairs on proximal part of twigs, irregularly scattered on distal part; inner face of opercular scales with prominent apical keel (Fig. 71) Amphilaphis Wright & Studer, 1887

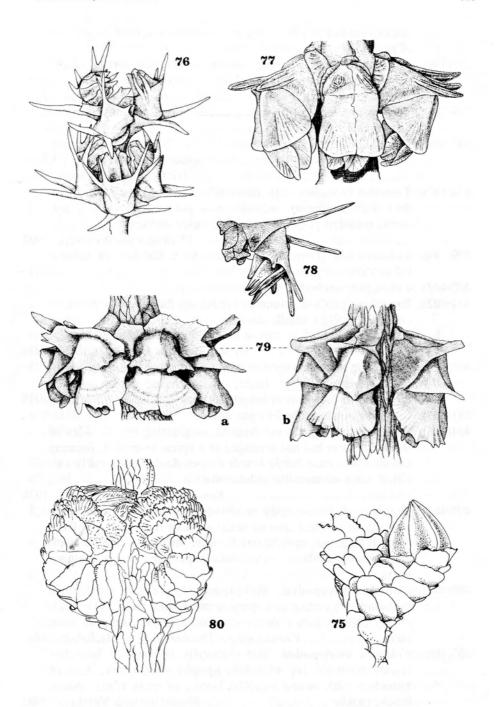

¹⁹ This genus appears twice in the key.

	Marginal scales fewer than 8. Marginal scales 5.
	Colonies pinnate, in one plane; marginal scales with short apical point but not produced as a spine (Fig. 72)
369(368).	Colonies bottle-brush shaped, branching from all sides of main stem; marginal scales with long, serrated spine (Fig. 73)
370(367).	Marginal scales fewer than 5.
	Branching dichotomous; polyps tall (2.5–7.0 mm), standing vertically or only slightly upturned, always in whorls; marginals always 4; opercular scales overlap (Fig. 74)
372(371).	Branching pinnate; polyps short (1 mm or less), set obliquely or turned inward toward axis, biserial or irregularly crowded but not in whorls; opercular scales do not overlap (Fig. 75)
373(354).	Adaxial side of polyps not covered by scales but remains partly or completely naked to accommodate strong bend inward toward stem.
374(375).	Polyps irregularly crowded all around stem and branches, not in whorls; most polyps facing downward (but occasional individuals may face upward on any colony)
375(374).	Polyps usually in distinct whorls, polyps facing either upward or downward (in a few species, verticillate arrangement is obscured by crowding, but in this case polyps face upward).
376(381).	Two pairs of abaxial body scales.
377(378).	Members of the two pairs of body scales inseparably fused to form complete rings surrounding polyp; polyps face upward (Fig. 76)
378(377).	Members of the two pairs of abaxial body scales extend nearly or completely around polyp and may meet adaxially but are not inseparably fused into rings; polyps face downward.
379(380).	Only one pair of infrabasal scales between basal body scales and stem scales; colonies dichotomous (Fig. 77)
380(379).	Several pairs of infrabasal scales between basal body scales and stem scales; colonies pinnate or dichotomous (Fig. 78)
381(376).	More than two pairs of abaxial body scales.
	Polyps face downward; only 3 or 4 pairs of abaxial body scales (Fig. 79)

383(382).	Polyps face upward; more than 4 pairs of abaxial body scales.
	Polyps strongly curved inward toward axis; opercular scales
()-	distinctly differentiated from body scales, not overreached
	by marginals which do not bend inward over them; colonies
	usually pinnate, rarely dichotomous (Fig. 80)
385(384).	Polyps strongly appressed (but not adnate) to axis; opercular
	scales poorly differentiated from body scales and more or
	less conspicuously overreached by marginals, which can fold
	over them; colonies usually unbranched, in some species di-
	chotomous with long, whiplike branches
	Primnoella Gray, 1858
386(345).	Crystal orientation in scales is predominantly longitudinal,
200(21.2).	extinction nearly complete under crossed Nicols; surface of
	axis smooth or nearly so, concentric layers not undulating
207(202)	(Chrysogorgiidae).
	Colonies unbranched, often spirally twisted.
	Polyps placed uniserially along stem Radicipes Stearns, 1883
	Polyps placed biserially along stem.
390(391).	Distal body scales of polyps forming a distinctly differentiat-
	ed operculum consisting of 8 triangular scales; abaxial body
	scales transverse Chalcogorgia Bayer, 1949
391(390).	Distal body scales of polyps not forming an operculum; abax-
	ial body scales longitudinal Distichogorgia Bayer, 1979
392(389).	Polyps closely multiserial along stem, crowded but leaving
232(203).	naked longitudinal tract free of polyps
202(297)	Colonies branched.
, ,	
3 34 (3 39).	Colonies with terminal branches long, slender and whiplike,

²⁰ Pro *Hicksonella J. J.* Simpson, 21 Dec. 1910, J. Roy. Microscop. Soc., part 6: 682 (type-species, *Juncella spiralis* Hickson, 1904, here designated); non Nutting, May 1910, Siboga-Exped. Monogr. 13b¹:14 (type-species, *Hicksonella princeps* Nutting, 1910, by original designation and monotypy).

	originating directly from main stem or after a few bifurcations
	of primary branches.
395(396).	Terminal branches simple, arising around the outside of the
	spirally coiled main stem; colonies not flabellate
	Iridogorgia Verrill, 1883
396(395).	Terminal branches originating in one plane, colonies more or
()-	less distinctly lyrate.
397(398)	Terminal branches slender and flexible. Sclerites exclusively
577(570).	in the form of small scales, or altogether absent
209(207)	Terminal branches stiff, more of less brittle. In addition to
398(397).	
	thin scales, sclerites include thick plates with closely set,
	stout, rounded projections on the outer surface
399(394).	Colonies with terminal branches short, the last of several
	bifurcations of primary branches.
` ,	Colonies branched in one plane.
401(402).	Branching profuse, pinnate, producing flabellate or plumose
	colonies, polyps small, coenenchyme extremely thin, scler-
	ites small (up to 0.15 mm in length)
	Stephanogorgia Bayer & Muzik, 1976
402(401).	Branching sparse, lateral or openly pinnate, producing loose,
	open colonies. Polyps large, coenenchyme thick, sclerites
	large (up to 0.45 mm in length) Isidoides Nutting, 1910
403(400).	Colonies not branched in one plane.
	Branches irregularly subdivided, originating on all sides of
- ()	the main stem but not arranged in a spiral around it, forming
	colonies of dense bottle-brush shape. Axis very weakly cal-
	cified, without metallic iridescence
	Xenogorgia Bayer & Muzik, 1976
405(404)	Branches dichotomously subdivided, originating either sym-
-102(+0+).	podially in a spiral around main stem or monopodially from
	the top of a tall, upright trunk. Axis strongly calcified, with
	conspicuous metallic iridescence especially in the younger
107/1050	parts.
406(407).	Colonies sympodial, dichotomously subdivided lateral
	branches originating in a spiral around main stem. Axis com-
	monly with brilliant iridescence extending even into the main
	stem Chrysogorgia Duchassaing & Michelotti, 1864
407(406).	<u>*</u>
	arising from the top of a tall, upright main trunk. Axis of
	branches with strong metallic lustre, of main trunk almost
	black, glossy Metallogorgia Versluys, 1902

408(326).	Axis consists of proteinous nodes alternating with calcareous internodes not composed of fused sclerites (Isididae).
409(414)	Polyps retractile.
	Sclerites of polyps are strongly spinose spindles; calices
.10(111).	prominent, distinctly separated
411(410).	Sclerites of polyps are small rods with transverse girdles of
().	tubercles.
412(413).	Colonies branching from internodes, bushy or planar, coe-
` ′	nenchyme thick, polyps not forming projecting calices; scler-
	ites include clubs, colorless Isis Linnaeus, 1758
413(412).	Colonies dichotomously branching from nodes, in one plane,
	coenenchyme thin, polyps forming hemispherical calices;
	sclerites chiefly radiate capstans, yellow or orange
414(409).	Polyps not retractile.
415(422).	Sclerites of polyps are large spindles, needles or rods, lon-
	gitudinally arranged, and smaller, irregularly placed rods or
	scales.
	Colonies unbranched Lepidisis Verrill, 1883
	Colonies branched.
418(419).	Branches arise from calcareous internodes
	Keratoisis Wright, 1869
419(418).	Branches arise from horny nodes.

Classification

Detailed comparative investigation of abundant specimens of many species of octocoral genera and families has eliminated more and more of the discontinuities between taxa that were the basis for classification of the subclass devised by Hickson, Kükenthal, and other students of Octocorallia, which became quite complex by the first quarter of the 20th Century. Even in the past decade, this classification was further subdivided by the addition of a new order, Gastraxonacea, by Utinomi and Harada (1973), and I, too, contributed to complexity by reviving the order Protoalcyonaria (Bayer and Muzik, 1976) proposed by Hickson (1894) but later abandoned by him. Although I must say in self defense that I still consider the introduction of vegetative reproduction to be a major step in the evolution of octocorals, I have to admit that in other coelenterate groups, such as Scleractinia, solitary forms are accepted along with colonial ones even in the same family and genus. As the solitary octocorals (other than *Taiaroa*) heretofore reported will in all likelihood prove to be founder individuals of

colonial forms, as in the case of *Hartea* suggested by Mr. R. L. Manuel (pers. comm.), the Protoalcyonaria probably does not merit ordinal recognition although it may be a nominal taxon of convenience at subordinal level.

Something similar might be said for the order Xeniacea proposed for members of the family Xeniidae by Bock (1938) and accepted by Madsen (1944). The chief distinguishing character of this order recognized by Madsen is the exclusive occurrence of small, discoidal or biscuit-shaped sclerites, but Kükenthal (1902, 1906) and Hickson (1931) emphasized the presence of only one pair of septal filaments in fully developed autozooids. As minute, discoidal sclerites occur (in addition to larger spindles) in *Clavularia* and *Tubipora*, and as *Ceratocaulon* combines the presence of small discoidal sclerites with a full complement of 8 septal filaments, and the autozooids of *Xenia* have 8 filaments in their early developmental stages, no basis remains for recognition of Xeniacea at ordinal level.

Certain species of Telestula that originally were assigned to Clavularia bridge the gap between the order Stolonifera and Telestacea, Pseudogorgia godeffrovi that between Telestacea and Alcyonacea, and Protodendron repens and Maasella radicans that between Stolonifera and Alcyonacea. The separation of Alcyonacea from Gorgonacea is challenged by the families Paragorgiidae and Briareidae as was shown by Verseveldt (1940) when he proposed to remove both from the Gorgonacea (Scleraxonia), where they traditionally had been assigned, to the Alcyonacea. The scleroproteinous axis of the gorgonacean suborder Holaxonia would seem to be an unequivocal character, but even it is compromised by the species of Keroeides, Lignella, and Ideogorgia (nom. nov. for Dendrogorgia Simpson), which combine the characteristic cross-chambered proteinous medulla of the Holaxonia with the axial cortex composed of sclerites bound together by gorgonin typical of the Scleraxonia. Moreover, the calcium-filled loculi of the axial cortex of Plexaurella are but a short step removed from the axial sclerites of the Keroeididae. Indeed, only the families Ellisellidae, Ifalukellidae, Chrysogorgiidae and Primnoidae are unequivocally separated from the remaining Gorgonacea-Alcyonacea complex by their total lack of a chambered axial medulla, and each is characterized by morphological features that are conclusive and unmistakable.

On the basis of colonial organization and skeletal structure, the only clearly discontinuous major taxa (i.e., orders) are the Pennatulacea (which are not included in the key), the Helioporacea, and the restricted "Holaxonia." The Stolonifera, Telestacea, Gastraxonacea, Alcyonacea, Scleraxonia, and medullate Holaxonia are linked by intermediate forms that preclude concise definitions of orders. These groups are comprised of an uninterrupted series from *Clavularia* to complex holaxonians such as *Paramuricea*. The traditional subdivisions might be retained as a convenience at a quasi-subordinal

level, but it must be recognized that no hard and fast boundaries can be drawn between them. In view of these considerations, a realistic classification is as follows.

Order Helioporacea (=Coenothecalia)

Lithotelestidae: Epiphaxum (=Lithotelesto)

Helioporidae: Heliopora

Order Alcyonacea

[Suborder Protoalcyonaria]²¹

Taiaroidae: *Taiaroa* [Suborder Stolonifera]

Cornulariidae: Cornularia

Clavulariidae

Clavulariinae: Clavularia (=Hicksonia), Bathytelesto, Rhodelinda,

Scyphopodium

Sarcodictyiinae: Sarcodictyon, Cyathopodium, Scleranthelia, Tes-

seranthelia, Trachythela

Telestinae: Telesto, Carijoa, Paratelesto, Telestula

Pseudocladochoninae: Pseudocladochonus Tubiporidae: Tubipora, Pachyclavularia

Coelogorgiidae: Coelogorgia Pseudogorgiidae: Pseudogorgia

[Suborder Alcyoniina]

Paralcyoniidae (= Fasciculariidae, = Viguieriotidae); Maasella (= Fascicularia, = Viguieriotes), Carotalcyon, Paralcyonium, Studeriotes

Alcyoniidae: Alcyonium, Acrophytum, Anthomastus, Bathyalcyon, Bellonella, Cladiella (=Lobularia, =Microspicularia, =Sphaerella), Lobophytum, Metalcyonium, Minabea, Malacacanthus, Nidaliopsis, Parerythropodium, Sarcophyton, Sinularia

Asterospiculariidae: Asterospicularia

Nephtheidae: Nephthea, Capnella (=Eunephthya, =Paranephthya), Coronephthya, Daniela, Drifa, Duva, Gersemia, Lemnalia, Litophyton (=Ammothea), Morchellana, Neospongodes, Paralemnalia, Pseudodrifa, Roxasia, Scleronephthya, Spongodes, Stereonephthya, Umbellulifera

Nidaliidae

Nidaliinae: Nidalia (=Cactogorgia), Agaricoides Siphonogorgiinae: Siphonogorgia (=Chironephthya)

Xeniidae: Xenia, Anthelia, Ceratocaulon?, Cespitularia, Efflatounaria, Fungulus, Heteroxenia, Sympodium

²¹ Taxa enclosed in square brackets are not considered to have taxonomic significance, but are included for convenience.

[Suborder Scleraxonia]

Briareidae: Briareum (=Solenopodium)

Anthothelidae

Anthothelinae: Anthothela

Semperiniae: Semperina (=Suberia), Iciligorgia, Solenocaulon Spongiodermatinae: Homophyton (=Spongioderma), Alertigorgia, Callipodium (=Anthopodium?), Diodogorgia, Erythropodium, Ti-

tanideum, Tripalea

Subergorgiidae: Subergorgia

Paragorgiidae: Paragorgia, Sibogagorgia

Coralliidae: Corallium (=Hemicorallium, =Pleurocorallium), Pleuro-

coralloides?

Melithaeidae: Melithaea (=Melitella, =Melitodes, =Birotulata), Acabaria. Clathraria, Mopsella, Wrightella

Parisididae: Parisis (=Trinella)

[Suborder Holaxonia]

Keroeidididae: Keroeides, Ideogorgia (=Dendrogorgia), Lignella

Acanthogorgiidae: Acanthogorgia (=Boarella), Acalycigorgia, Anthogorgia, Calcigorgia, Cyclomuricea, Muricella, Versluysia

Plexauridae (including Muriceidae, Paramuriceidae)

[Plexaurinae]: Plexaura, Anthoplexaura, Eunicea, Euplexaura, Muriceopsis, Plexaurella, Psammogorgia, Pseudoplexaura

[Stenogorgiinae (=Paramuriceinae)]: Swiftia (=Allogorgia, =Callistephanus, =Platycaulos, =Stenogorgia), Acanthacis, Astrogorgia, Bebryce, Calicogorgia, Dentomuricea, Echinogorgia (=Bovella, =Paraplexaura, =Trimuricea?), Echinomuricea, Heterogorgia, Hypnogorgia, Lepidomuricea, Lytreia, Menella (=Plexauroides), Muriceides (=Clematissa, =Trachymuricea), Nicaule, Paracis (=Discomuricea), Paramuricea, Placogorgia, Pseudothesea, Scleracis, Thesea (=Discogorgia, =Evacis, =Filigella), Villogorgia (=Acamptogorgia, =Brandella, =Perisceles)

Gorgoniidae: Gorgonia (=Rhipidogorgia), Adelogorgia, Eugorgia, Eunicella, Hicksonella (=Rhabdoplexaura), Leptogorgia (=Filigorgia), Lophogorgia, Olindagorgia, Pacifigorgia, Phycogorgia, Phyllogorgia (= Hymenogorgia), Pseudopterogorgia (=Antillogorgia), Pterogorgia (= Xiphigorgia), Rumphella

Ellisellidae: Ellisella (=Scirpearia, =Viminella), Ctenocella (=Dichotella), Junceella, Nicella, Riisea (=Herophile), Toeplitzella, Verrucella (=Phenilia)

Ifalukellidae: Ifalukella, Plumigorgia

Chrysogorgiidae: Chrysogorgia (=Dasygorgia), Chalcogorgia, Distichogorgia, Helicogorgia, Iridogorgia, Isidoides, Metallogorgia, Pleurogorgia, Radicipes (=Lepidogorgia, =Strophogorgia), Stephanogorgia, Trichogorgia (=Malacogorgia), Xenogorgia

Primnoidae: Primnoa, Ainigmaptilon (=Lycurus), Amphilaphis, Armadillogorgia, Arthrogorgia, Ascolepis, Callogorgia, Callozostron, Calyptrophora, Candidella (=Stenella), Dasystenella, Narella (=Stachyodes), Ophidiogorgia, Paracalyptrophora, Parastenella, Plumarella, Primnoella, Pseudoplumarella, Pterostenella

Isididae

Isidinae: Isis, Chelidonisis Muricellisidinae: Muricellisis

Keratoisidinae: Keratoisis, Acanella, Isidella, Lepidisis

Mopseinae: Mopsea, Chathamisis, Circinisis, Echinisis, Minuisis,

Peltastisis, Primnoisis

Acknowledgments

This paper results from research initiated at the Rosenstiel School of Marine and Atmospheric Science, University of Miami, and supported by grant DEB 75-07193 from the National Science Foundation to that institution, F. M. Bayer, Principal Investigator.²²

I am grateful to Dr. P. F. S. Cornelius of the British Museum (Nat. Hist.) for the privilege of examining type-material in his care, and to Dr. L. B. Holthuis of the Rijksmuseum van Natuurlijke Historie, Leiden, and Dr. Katherine Muzik, Museum of Comparative Zoology, Harvard University as well as many other colleagues, for stimulating discussions regarding the concept and realization of this paper. It is a special pleasure to acknowledge the helpful suggestions and criticisms of Mr. P. N. Alderslade of the Roche Research Institute of Marine Pharmacology, Dee Why, N.S.W., which have rendered the key more accurate, more complete, and more workable than it otherwise would have been. I also owe a considerable debt of gratitude to the Queen Elizabeth Fellowship Program of Australia for the opportunity to work in that country in 1980, and particularly to Drs. J. T. Baker and John Pollard.
