11. Monograph on the Anguillulidx, or Free Nematoids, Marine, Land, and Freshwater, with Descriptions of 100 New Species. By M. Cifarlton Bastlan, M.A., M.B. Lond., F.L.S.
page 73
1II. Description of some New and Remarkable Species of Aristolochia from Western Tropical Africa. By Jos. D. Hooker, M.D., F.R.S., V.P.L.S., \&c. . . . 185
IV. On the Anatomy of Doridopsis, a Genus of the Nudibranchiate Mollusca. By Albany Hancock, F.L.S.

189
V. A List of the Exogenous Plants found in the Anamallay Mountains, in Southern India, with Descriptions of the New Species. By Capt. R. H. Beddome, Officiating Conservator of Forests in the Madras Presidency. Communicated by Dr. T. Thomsox, F.L.S.

209
VI. On Gripidea, a New Genus of the Loasacex, with an account of some Peculiarities in the Structure of the Seeds in that Family. By John Miers, F.R.S. \& L.S., Commend. Ord. Imp. Bras. Rosa

227
VII. Supplementary Observations on the Sphæriæ of the Hookerian Herbarinm. By Frederick Currey, M.A., F.R.S., Sec. L.S. 239
VIII. On the Asymmetry of the Pleuronectidx, as elucidated by an Examination of the
Skeleton in the Turbot, Halibut, and Plaice. By Ramsay H. Traquatr, M.D.,
Demonstrator of Anatomy in the University of Edinburgh. Communicated by Pro-
fessor Hcxley, F.R.S. \&L.S. . . . . . . . . . . . . . . . . 263
IX. Description of some New Genera and Species of Tropical Leguminosæ. By George
Bentham, P.L.S. . . . . . . . . . . . . . . . . . . . 297

1. Descriptions of Fifty-two New Species of Phasmidæ, from the Collection of Mr. W. Wilson Saunders, with Remarks on the Family. By Henry Walter Bates, Esq.
certain minute microseopie Nematoids found in fresh or salt water, and amongst Conferrex, by other naturalists, the principal of whom are Bory ${ }^{1}$, Stcinbuch ${ }^{2}$, Dugès ${ }^{3}$, Ehrenberğ and Hempriel ${ }^{4}$, Nordmann ${ }^{5}$, Dujardin ${ }^{6}$, Oken ${ }^{7}$, Quatrefages ${ }^{5}$, Grube and Leuckart ${ }^{9}$, Diesing ${ }^{10}$, Max Schultzo ${ }^{11}$, Leidyy ${ }^{12}$, Kühn ${ }^{13}$, Carter ${ }^{14}$, and Eberth ${ }^{15}$. The labours, in this direction, of these scientific obserrers have resulted in the discorery of about cighty species of free Nematodes found in various parts of the world. It is, however, to the researches of Dujardin, Eberth, Cartcr, and Diesing that we have been principally indebted for our knowledge of this group. Dujardin was the first who seemed to entertain comprehensive notions as to the extent and probalble diffusion of these animals, and, besides the discorery of screral new species, added more precise descriptions of them than the extremely scant details concerning the anatomy of the carlier forms furnished by Otto Müller, Ehrenberg, Hemprich ${ }^{16}$, and others. Carter, besides the discovery of ten new species, has contributed many interesting anatomical details; and Eberth, in his recent valuable memoir ${ }^{17}$, has added much to our knowledge of their anatomy, in addition to the descriptions and beautiful figures which he has given of twenty-three new speeies; though he, like his predecessors, has tended to create great confusion in the nomenclature, by deseribing under the same generic name species differing notably in the anatomical arrangement of important parts, as I shall hereafter endeavour to explain. It is by his writings, rather than by special anatomical examinations of his own, that Diesing's name is associated with this group, since he has not only treated of them in his 'Systema,' but also has lately made the classification of the Nematodes, both free and parasitic, the sulject of a special communication ${ }^{18}$.

The writings of Carter afforded the stimulus which induced me to inquire into this subject; for, like himself, having been intcrested in the anatomy of the Dracunculus ${ }^{19}$, my attention was arrested by his interesting paper on the "Microscopic Filaridæ in the Island of Bombay" "80, and my search for similar free Nematoids in this country has been

[^0]rewarded by the most gratifying results-more especially as, with the exception of the "Paste" and "Vinegar Eels," the Tibrio tritici, and one or two unknown species always alluded to by the same name of Auguillula fluviatilis, no representatives of this group have, I believe, yet been described as existing in Great Britain: hitherto the harvest has been with the continental naturalists, with Dr. Leidy in America, and with our own countryman Carter in India.

As a result of my investigations, I am inclined to believe that these free Nematodes will be found to constitute one of the most widely diffused and numerically abundant groups in the whole animal kinçdom, rivalling, in the first respect at least, the almost ubiquitous Diatomacere. A statement of some of the principal situations in which I have met with these animals will best illustrate this proposition. Thus, beginning with the land- and freshwater-species, I have found them in all the specimens of soil examined, in moss, various species of lichen, about the roots of fungi ${ }^{1}$, also the roots of grasses, and between the sheaths of their leaves, amongst the mud of ponds and rivers, on the freshwater Algæ, amidst decaying liverworts and mosses, and on submerged aquatic plants. The marine species exist in great abundance in the surface-mud of rivers and estuaries ${ }^{2}$, in the sand, and among'st the small stony débris under the shelter of rocks, as well as in the tide-pools, where they swarm about the roots of the corallines and on some of the smaller and finer sea-wceds, especially those having a dingy appearance from the presence of Diatomaceæ. And, lastly, two or three species I have found in the greatest abundance, as pseudo-parasites, within the sulbstance of some of the softer sponges. So numerous are they in these latter situations, that it is rather surprising they should have so long escaped the attention of marine zoologists. From the transparency of their integuments, they are not only beautiful microscopical objects, but also admirably adapted for anatomical rescarch; and Dr. Eberth and myself have already worked out so many interesting structural details, that I have no doubt, should the investigation be followed up by other observers, the question of the anatomy and real affinities of the Nematoids, at present so doubtful, would be soon placed upon a satisfactory footing.

The specimens I have examined have varied in length from $\frac{1}{70}{ }^{\prime \prime}$ to nearly $\frac{3^{\prime \prime}}{4}$, almost all the larger forms being marine, though Dorylainurs stagnalis, Dujard., is about $\frac{1}{3}$ " long, and far excceds in size any of the other land or freshwater species I have met with. In their various habitats individuals of all ages may be seen, from the young, immature and non-sexual embryo just emerged from the egg or its parent, up to the adult condition; and frequently the ova of species infesting a particular sea-weed may be seen attached to it, whilst the parent worms are gliding and twining, serpent-like, amongst its branches. This fact alone would induce one to believe that these animals are never parasites at any stage of their existence, even if this view were not-confirmed by the existence of anatomical peculiarities which seem to distinguish them as a group from the parasitic forms

[^1]in gencral. Since, however, the amomement of the discovery of so many free Nematoids is likely to suggest to the minds of many the belief that these are identical with the parasites, being merely the revelation of another stage of their life-history, which has hitherto been hidden from us, it seems desirable to bring forward some evidence to disprove such a supprosition, and establish the claim of these minute creatures to a distinet and independent place in the animal kingdom-and more especially so since precisely such a view has been taken ly one of the principal writers on these free Nematodes. For', at the conclusion of his paper before mentioned, Carter, speaking of the uncertainty still cxisting with regard to the carly history of the Dracunculus, adds, "It remains a subject for future and interesting inquiry, but not more so than the still further elucidation of the Filaridec generally, both free and parasitic; for when we consider that the former abound in species, and are spread in myriads probably all over the world, where there is regetable matter for them to feed upon, in salt as well as in fresh mater, in the sea and on the land, while the latter inhahit all amimals, perhaps, more or less, down to the lowest worms; that many of the former ${ }^{1}$ leave their habitat and vegetable food for a temporary residence in animals, to live thus on animal food, and that therefore the whole of the parasitic forms may be originally derived from the free ones"; for these, and other reasons, he says, "these worms, at first apparently insignificant from their thread-like form and scarcity, are secn to assume an importance in organic creation which calls for a much more extended study of them than they lave as yet received " (p. 112).

With the view of investigating this question, I made a careful analysis of the anatomical details and plates given by Dujardin, in his ' Histoire naturelle des Helminthes,' of the Nematoid Entozon, -selecting this writer, not only on account of the more complete descriptions found in his work, but also in deference to his extensive practical acquaintance with this particular branch of his subject. The result of this examination has sufficed to convince me that the nearly constant combination of several important characters-so universal as to be typical of these free Nematodes-are only probably present in two or perhaps thee of the parasitic genera. These distinct characters are furnished by the male and female genital organs, - the males having two equal subterminal intromittent spicules, with or without accessory pieces, whilst the females have the vulva situated at about the middle of the body, a short vagina, with a symmetrical double uterus, whose branches lic on opposite sides and are connected with a short and simple reflexed ovarian tube-the only exception to this arrangement being in a few gencra, in which, the females having the vulva situated some way behind the middle of the hody (about the commencement of the posterior third), the hinder segment of the uterus remains abortive and undeveloped (Pl. X. fig. 113), whilst the anterior segment retains its characteristic form.

On referring to Dujardin's classification ${ }^{2}$, it will be secu that he has ranged the Nematoids into seven sections, together with an appendix containing the little-known or anomalous forms. The anatomy of the animals included in his first section, comprising the genera Trichocephalus and Trichosoma, is totally distinct as regards the arrangement

[^2]of the genital organs from that above mentioned; those of his second, including Filaria, Spiropterch, dec., are distinguished "par la présence de deux organes copulatoires, ou pénis, inégaux," whilst of his third section, containing the genera Strongylus, Leptodeva, Dicclis, \&c., the members of which do possess two equal spicules, with or without accessory picces, the genus Leptodera is the only one affording also the character of a uterus divided into two equal and opposite branches, with the vulva occupying a median position. This genus contains one species ${ }^{1}$, the L. flexilis, found in the vas deferens of Limax cinereus. In his fourth section, comprising the Ascarides, the members of the second subgentus, Ascaridia, including several species found in the intestines of birds, comply with the requirements so far as the male intromittent organs and double uterus are concerned, but differ by the presence of the three prominent cephalic lobes and the filiform ovaries characteristic of the genus Ascaris. In his fifth group, Dujardin places these frec Nematodes together with certain other genera. The sixth section, containing Sclerostoma, Syngamus, \&c., contains only one genus, Angiostomum, having the beforementioned arrangement of the male and female sexual organs; but the figures giren by Dujardin of the only two species of this genus-one found in the lungs of Anguis fragilis ${ }^{2}$, and the other in the intestine of a pulmonate Gasteropod-seem to indicate a totally different formation of the ovarian tubes. The individuals of the seventh and last section, including the genera Dacnitis, Ophiostoma, \&c., are out of the question, from their not possessing a terminal mouth; and those of the appendix do not comply with other conditions ${ }^{3}$.

This cvidence seems a sufficient warrant for the belief in the non-parasitic nature of the animals in question, since it could scarcely happen, if these forms were ever parasitic, that they should not some of them-or, at all events, species of the same genera -have been met with in this condition, so as to cnable us to include in the same genus parasitic and non-parasitic types. To me, indeed, it seems clear that these free Nematoids themselves, which can be detected in all stages of growth in external media, are not likely, as a rule, to be capable of existing also as parasites. Then comes the question, are they as a group distinguished by any particular characters from the parasitic forms? To which I think we are fairly entitled to return an answer in the affirmative, after the statements that have just been made, and from a consideration of other facts to be presently mentioned ${ }^{4}$. So far, too, this is in accordance with the views held by the
${ }^{1}$ Another and much larger species has since been found by Dr. Baird in the abdominal carity of Siredon mexicanus (Proc. Zool. Soc. 1858, p. 225, (Annulosa) pl. 52. f. 6, 7.
= This species, Angiostomum entomelas, I have lately discovered, and have satisfied myself, not only that it does not belong to any of the genera of free Nematodes at present known, but that it is distinguished from the members of this group generally by the form of its ovaries and the extreme thimness of its integument.
${ }^{3}$ The genus Odontobius being the only one concerning which there is any doubt, the nature of which will be explained in the systematic portion of this memoir.
${ }^{1}$ It is true that a fex of thesc free Nematodes have been found within the intestines of other animals by Dujardin; but in all the cases related by him, their presence within the intestinal camal may be looked upon as accidental rather than necessary, they having been swallowed, as he suggests, by these animals either with or as food. Thus, Dorylaimus stagnalis was found by him in the intestinc of the Carp. He has found species of the genus Rhabditis within the intestine of small slugs and of the common Frog (which, in its turn, swallows the slug), as well as in the stomach of sercral fishes, and the general carity of the body of the Earth-worm. It would be desirable to have additional obser-
leading helminthologists of the present day, who are almost all now disposed to believe that the parasitic Nematoids exist in an asexual condition within the body of an intermediate host, before host and gruest are swallowed by those animals destined to harbour the sexually mature Entozon-the conditions essential to their development seeming to necessitate this intermediate state, instead of that direct and continuous method of evolution from the egge to the adult animal which I have recognized in all the free Nematodes in their various halsitats. Our knowledge of the life-history of the parasites is extremely defective; but what we do know concerning the so-called Filaria piscium, Trichince spirctis, and other immature Nematodes is confirmatory of this belief. Moreorer, in his recent work on "Entozoa," Dr. Cobbold, speaking of the Asearides, remarks, "In all situations where there is an abundant water-supply these parasites are more particularly common; and it is well known that the lowlands of Holland and the lake distriets of Sweden are cminently farourable to their existence. All this is explicable enough from what we now know respecting the conditions which are essential for the rearing of the larre; but, as I have before obscred, it is almost certain that the human body becomes infested, not by the drinking of water whieh may eontain the sexually immature cmbryos, but by fecding upon the flesh of some quadruped, fish, or fowl which happens to represent the so-called intermediate host" (p. 313).

Some additional points in the anatomy of the members of this group, to which I will briefly allude, seem to strengthen the view I have been endeavouring to enforce. In the first place, the integuments hare a greater proportional thickness than in the recognized parasitic forms; and in the next, there is a marked difference in the number of ova or youngi produced: whitst the entozoid species are most prolifie, furnishing offspring by hundreds, thousands, or even millions, in these frec Nematoids the ova are relatively rery large and few in number, being easily countal)le, and, for the most part, scen in single
rations concerning the animals found in this last habitat, before we can be certain that they belong to any of the genera of free Nematoids, since it is perfectly certain that in his gemus Rhabditis Dujardin ineludes many and most diverse types. Speaking of these Nematoids aud the Earth-worm, he says, "Je l'ai ru plusieurs fois, soit it Paris, soit i Rennes, se développer en quantité prodigieuse, et former des amas blanehâtres dans des rases où j’avais conservé des lombries arec de la mousse et de la terre humide." Moreorer it appears from the interesting experiments of Davaine ('Recherches sur l'Anguillule du blé niellé,' Paris, 1857, p. 6-1) upon the young of the Fibrio tritici, that their chitinous integument effectually protects then from injury within the alimentary canal of the cold-blooded aminals. This was aseertained by experiments upon the Frog, the Triton, the Salamander, and a fish (Cyprimus auratus) belonging to the same gemus as that in which the Dorylaimi were found by Dujardin. Davaine says, "Ingérués dans l'estomae de ces animaux, soit sèches, soit humides et virantes, les anguillules de la nielle ont parcouru tout le tube digestif, sans avoir subi d’altération; elles ont été éracućes ou retrourćes dans le rectum, privées de monrements, mais non de la vie, dont elles n'ont par tardé à reprendre les manifestations, après aroir été placées dans l'eau pure." This seems to afford a rery probable explanation of the aceidental presence of these free Nematodes uninjured within the alimentury canals of certain of the lower anmals, though it does not at all aceount for their presence within the general cavity of the body of the earth-worm, as reported by Dujardin, or of Naïs albida, as related by Carter. It should be remembered, howerer, that the geveral carity of the body in these animals is not a shut sac, since it communientes with the exterior by means of certain ciliated tubes, called by Dr. Williams (Phil. Traus. 1858, p. 93) "segmental organs.". In these tubes of the earthworm a parasitic Nematoid (llicelis filaria, Duj.), is known to exist in great abundance. The young of this anmal might work their way through the patent terminations of the tubes into the abdominal cavity of their host; and it is eren possible that minute free Nematoids might also work their way inwards, through these tubes, into the aldominal cavity of both Nais aud Earthworm.
file within the genital tubes, though often occupying the whole width of the body. This is a condition of things quite in harmony with the several requirements of animals dependent upon such totally different conditions. The free Nematodes produce their ova or young at once in that environment which they are destined to inhahit, whereas the parasitic progeny are subjceted to a multiplicity of chances and contingencies before they meet with the necessary conditions suitable for their development: there must be many blanks in order to ensure a few prizes. It is but another instance of the harmony subsisting between the observed biological history of an organized being and the physical conditions to which it is suljeeted and surrounded; and the difference in this respect between the two divisions of the order Nematoidea may not inaptly be compared to that existing between the predaceous eartilaginous fishes, on the one hand, and the ordinary osseous species on the other. We may note the same limited number of progeny in those forms whose young are most likely to survive, owing to their being produced viviparously or else with the egg enclosed in a coriaceous cnvelope, which, for additional security, becomes fixed by means of its tendrils to some rock or larger seaweed. Whilst the ova or young of such species may be numbered by units, for those of the majority of osseous fishes tre may substitute, instead of units, millions or even billions.

Then many of the free Nematoids, more especially of the marine species, are provided with such rudimentary sensc-organs as would be useless to a parasite. These exist in the form of distinct, reddish, conical and cireumseribed masses of pigment, with the addition oceasionally of transparent lens-like bodies, situated on the anterior part of the œsophagus, which doubtless'subserve the purpose of rudimentary visual organs. And, lastly, almost all the free Nematodes are furnished with a eandal sucker, most highly developed in the marine species, to whom its utility is obvious, by enabling their smooth and polished bodies to adhere to the particular weeds which they infest, whilst these are swayed to and fro by the currents of the flowing and receding tide.

These varions considerations lead me to believe that the free Nematoids constitute a group absolutely distinet from the parasitic forms; and I have dwelt upon this point, not only because it has not been cuforced by previous writers, but also with the view of slowing the untenability of the opposite hypothesis, advanced, perhaps somewhat hastily, by a most aecurate observer, and one whose opinions generally are so worthy of credit. On this account, too, it does not seem to me desirable to associate with these animals, as Dujardin has done in his fifth section, "Enopliens," the two parasitic genera, Pussalur"us and Atractis-and this not simply on the arbitrary ground of their being parasitic, but because they neither of them comply with those structural conditions which were stated to obtain almost universally in the group in question. They appear to have been so placed by Dujardin, from the simple fact of their possessing a mouth armed with three teeth or jaws, which he took to be the typical character of this group, as shown by the name he applied to them. But a reference to the figures and deseriptions of the species discovered by Dr. Eberth and myself will show that this is a structure quite exceptional -only met with in one or two genera, and therefore untenable as a family distinction. Diesing, also, in his recent communication on the elassification of the Nematoids, has associated with these animals certain parasitic genera; and in this paper, as well as in his
'Systema,' under Ehrenberg's genus Anguillula (which is characterized in such general terms as to be perfectly capable of including the most diverse types) he places sereral species of mimite Nematodes fomd in the intestines of insects, myriapods, and other animals, which were, for the most part, named hy their original discoverers either Ascerides or Oxyurides. An examination of the extremely imperfect descriptions giren by him, as well as of the figures by their original discoverers ${ }^{1}$, scem rather to confirm the former position assigned to them; and from a consideration of the facts before mentioned, I certainly should not be disposed to place in the same genus parasitic and non-parasitic forms without more distinct evidence of their identity in anatomical details than we at present possess ${ }^{2}$.

Since the classification of the Nematoids generally is in such a confessedly unsatisfactory condition, it is quite impossible to indicate the precise position or affinitics of these non-parasitic forms. It seems, however, most desirable to retain for this group the family name of Angutlutlide, proposed by Gervais and Van Beneden ${ }^{3}$, which is not only generally suitable, but is also recommended by the fact of the most fimiliar and first-discorered species having still retained for them the generic name of Angritlula.

In the description of species and genera, and the arrangement of the former into the lattcr groups, an extreme amount of confusion prerails concerning almost all the forms hitherto discorcred. This scems to hare arisen partly from the meagre descriptions and indefinite figures giren, and partly, with morc accurate and precise observers such as Eberth, from their not haring definitely settled what should be looked upon as points of generic importance. Some of this confusion I hope to be able to clear up in the more special portion of this memoir, and also to indicate, as far as my observation has exterded, the value of different anatomical peculiarities as guides to classification.

IIaving thus sketched the history of our knowledge concerning this group of animals, I will now add a few details regarding their structure, habits, and mode of life. I shall merely give a bricf outline, howerer, of their anatomy, as I intend to make this the subjeet of another communication.

The integment is mostly very transparent and hyaline in appearance, of a chitinous composition, and presenting sometimes transverse lines or dots, at others longitudinal markings ${ }^{4}$, either alone or with trausrerse also; whilst in the remainder the integument appears perfoctly plain, with no striae of any liind. I have discovered numerous fine capillary canals through the integument, cstalblishing a communication, apparently, between the exterior element and the peculiar lateral and median lines of these animals. These minute channels vary much in their number and arrangement in different genera, and promise to throw considerable light upon the nature of the curious lateral

[^3]lines which hare so long been a puzzle to anatomists. I have also detected these cutancous pores in several of the parasitic Nematoids. In many species the integument is provided with sete around the head, and more sparingly on other parts of the body; occasionally it is developed into papille around the mouth; and, besides the caudal sucker before alluded to, many of the males are furnished with a rarying umber of rentral suckers. Ehrenberg records the fact of his having observed Anguillula recticauda cast its skin. I have seen evidences of the same thing in many species, and suspect that, during the period of growth of the free Nematodes, it is the rule. In some few species, the integument appears to be glutinous. Thus Oncholaimus vulgaris, from marine mud, has always adhering to its surface minute particles of sand and Diatomaced, and in one case I saw two or three Torticella. In Spira parasitiferca I have frequently found specimens of a stalked fan-shaped diatom, probably belonging to the genus Echinella, as well as Torticella, attached to the integument. Some fer species, too, of the genus Chromadorc, from marine mud, hare been found enclosed in a tube like that of the Sabella, composed of agglutinated sand-particles.

The alimentary canal commences wih a terminal rounded mouth, either opening into a dilated pharyngeal cavity or commmicating at once with the cesophagus. This latter is often distinctly muscular, and has sometimes a pretty equal calibre thronghout, whilst at others it is provided with one or tro rounded or oval muscular swellings. The posterior one is occasionally provided with a few horny plates in its centre, and has generally been described as a stomach, though, I think, crroncously, since it secms to perform none of the functions of a stomach: it is not a receptacle for food, and the swelling is due to an increased muscularity of the walls of the œsophagus at this point, rather than to a dilatation of its central cavity. The structure seems to me to partake more of the nature of a valvular apparatus, partly facilitating the swallorring of food, and partly preventing the regurgitation of the frecly moving and fluid contents of the intestine proper, during the rapid movements of the animal. This osophagus is clivided by a well-marked constriction from the intestine, which continues nearly uniform in size throughout the remainder of its course, terminating by a curved anal cleft on the ventral surface of the body at a variable distance from the posterior extremity. It is made up of a central tube and a mesenteric envelope, between which is situated a uniform layer of cells, containing light or olive-coloured fat-particles, probably having' a rudimentary hepatic function. The arrangement of these cells and their contained granules is sometimes so regular as to give a distinctly tessellated appearance to the structure; whilst, at others, the intestine merely appears covered with a layer of irregularly disposed fat-particles, the containing cells being invisible, and their contained particles not definitely aggregated.

Some of the free Nematodes are viviparous; but, as before stated, most are oviparous, the ova being large and proportionally fer in number. In many species they are so large as singly to distend the body; and in Leptosomatum figuratum I have measured one of this character of an elongated oval form, whose length was three times the breadth of the parent body. In Dorylaimus stagnalis, Dujardin, however, they are much smaller, admitting two or even three abreast within the uterus. In most of the

VOL. Exv.
genera the uterus and oraries are formed upon the same type; and in those exceptional eases where the posterior segment remains undereloped, it may still be seen in a rudimentary condition in the gemus Tylelenchus (Pl. X. fig. 113), whilst in others little or no trace of it can be recoguized in the adult animal. The male organs consist usually of a long tube proceeding from the junction of two clongated sacs or testicles, which occupies the ventral aspect of the hody, and terminates at the anal cleft, or, as in Bronhysterce ambigua and M. disjuncle (Pl. IX. figs. 12, 13), a little anterior to it. In two species, $J I$. ambigua and Diplogaster filiformis, I have failed to detect any horny intromittent spicules, whilst in the remainder I have always found two equal spicules, either alone or with one, two, or four accessory picces.

The glauduler and voater-ucescular systems are so intimately connected with one another, that it seems best to include in the same notice what little I have ascertained concerning their relations. The whole inner surface of the body is lined by a glandular substance, more lighly dereloped in some species than in others, similar to what I described in the Guineaworm, and to what has been met with in some of the parasitic Nematoids by Eberth and other observers. In addition, in several species there are ore or two pyriform glandular masses connected with the ragina (Pl. XI. fig. 147 ; Pl. XIII. figs. 189, 192), and also others near the anal cleft (Pl. XI. fig. 143 ; Pl. XIII. fig. 226), which have already been obscrved by Eberth, and termed by him "raginal" and " anal glands" respectively. He has also described and figured two or three clongated sacs proceeding from the posterior extremity of the body, and has termed them tail-glands (Schwanzdrüsefi) : these I had observed also, but, from the fact of their being most developed in those species in which the caudal sucker is largest, and from their not presentiug the usual granular appearance of the other unmistakeable glands, I have alwars looked upon them rather as contractile saes in some way comected with the operation of the sucker, and shall speak of them henceforth as sucker-tubes (Pl. XI. figs. 126, 151). In nearly all the marine species, I have recognized a glandular excretory organ, "opening by means of a long duet on the abdominal aspect of the esophameal portion of the body (Pl. XI. fig. 151; Pl. XII. fig. 161), but have found no structure precisely answering to this in the land and freshwater species, though in four of these gencra, Tylelenchus, Plectus, Aphelenchus, and Cepheclolus-the members of which all possess the same remarkable tenacity of life-a modification of the same organ eridently exists. In these genera I hare failed litherto to detect the entire structure, and hate only suceceded in recognizing the curved, more slender, and rigid duct with which it terminates (Pl. X. figs. 79, 97, 101, 112). Two lateral cellular canals, essentially similar to the peculiar fat-camals or lateral lines of the parasitic Nematoids, are met with, well developed, in many species, between which and the external medium I hare been enabled to detect numerous communications by means of a raviable number of integumental pores ${ }^{1}$. In three of the four land and freshwater genera above mentioned I have

[^4]detected, instead of these canals, two lateral, doulle-outlined, colourless ressels, somewhat similar to what I described in Dracunculus ${ }^{1}$, and which are most apparent in Tylelencluts tritici. In this species, from their beinç longer than the body, they are wayy or even convoluted, and I have sereral times succeeded in isolating them completely from other structures ${ }^{2}$. These seem to correspond to the axial ressels contained within the lateral lines ${ }^{3}$ of Ascaris lumbricoides, A. mergalocephala, and other parasitie Nematoids.

I hare met with no distinct traces of a nervous system in these animals, the only thing which might be at all mistaken for a portion of such a system being the peculiar ring (also observed by Eberth) sutrounding the osophagus in some of the marine genera ${ }^{4}$, concerning the nature of which we have both arrived, independently, at the same conclusion, that its connexions and structural peculiarities rather point to its affinity with the grlandular than the nervous system (Pl. XI. fig. 126). The absence of any traces of nervous filaments in connexion with the well-dereloped ocelli of so many of the marine species affords also strong negative evidence of the absence of such a system in the Nematoids.

The muscles of the body seem to be, the same as in other Nematodes, composed of four longitudinal bundles, two dorsal and two rentral, with an interspace on either side. 'In neither free nor parasitic have I been able to recognize the circular fibres spoken of by some anatomists.

Much difference exists as to the museular power and activity of different species. The Dorylaimi and Tylelenchi, for instance, are very slow and tardy in their movements; Spherolaimus hirsutus is remarkable both for its activity and power; whilst the differont species of the genera Theristus and Tachyhodites are distinguished by rapidity of movement. The mode of locomotion of all is indeed most characteristic, being effected by eel-like undulations of the body, which at onee distinguish these animals from the Naï-
${ }^{1}$ Liun. Traus. rol. xxiv. p. 113, pl. 21. fig. 266.
${ }^{2}$ Although not yet detected, I bave little doubt that similar ressels will be found to exist in the fourth and nearly allied genus Cephalobus.
${ }^{3}$ Siuce this paper was read, I bave ascertained that not only the lateral lines, but also the mid rentral and dorsal lines of the two dscarides abore mentioned are only local developments in these situations of a fibro-cellular layer lining the whole interual surface of the chitinous integument, and separating it from the four great lougitudinal muscles. These developments (occupying the muscular interspaces) differ notably from one another, inasmuch as those iu tbe lateral regions, besides being much larger and more prominent than the dorsal and rentral cords, contain each a well-marked axial ressel. Whether this vessel exists in all the Nematoids seems very doubtful, as in some of the parasitic, and in nearly all the free species, in which the lateral lines can be detected, they appear to be simple aggregations of large cells, bounded, iutcrnally at least, by a limitiug membrane-though I think we may fairly look upon these lateral lines of the free Nematoids as homologous with the lateral lines of the dscarides, and consequently iufer that they are also integral parts of $\mathfrak{n}$ general subcntaneous cellular layer. In this cellular layer of $A$. lumbricoides and A. megalocephala I have also detected a serics of delicate trausverse vessels, mostly in pairs, extending from the mid dorsal to the mid ventral line, and much more uumerous on the right than on the left side of the body. These, I fancy, open externally by means of minute pores through the iutegument, though hitherto I have been unable thoroughly to satisfy myself of the fact.
${ }^{4}$ As yet I have only met with it distinctly in some of the marine genera, and, curiously enough, in those species only whicl have a plane or longitudinally striated integument, and never in those with transverse markiugs.
dince, with whom they are frequently associated, and also from the Amelids generally. Other morements of the aquatic species may be well seen if these animals are placed in a wateh-glass and cramined by a low power of the microscope, when they may be observed twining amongst the branches of the aquatic plants or algese which they frequent, their gliding morements suggesting a resemblance to tiny serpents, till the delnsion is banished by a sudden change in their method of proceeding, when, anchoring themselves firmly lyy means of their caudal sucker, they continue for some minutes swaying atont with the greatest rapidity, darting their bodies hither and thither, and bending in all directions.

With respect to food, the free Nematodes scem to be almost exclusively vegetable feeders, though it is not often easy to recognize anything definite within their alimentary canal-the usual contents being a kind of granular déloris, and in sereral species large oil-globules. In individuals of the genera Cyatholaimus and Spilophora, however, I hare frequently seen the intestine filled with large Diatomaceer, whilst in species of other genera I have occasionally made out a few cells of algae. The quantity of large fat-globules often seen within the intestinal canal is remarkable, and also interesting in a physiological point of riew, as an excmplification of the almost direct conversion of cellulose into fat and other products. In Dorylaimus stagnalis these large beads of fat are gencrally of a bright yellow, whilst in other species I hare occasionally found them of a pure emerald-green colour, and in one instance even of a distinct magenta hue; but in the majority of species the fat is colomless. I have never yet seen one of these animals swallow a particle of food; but what they do take appears to remain a long time within the intestinal canal, becoming slowly and almost entirely metamorphosed into fat, as the primary stage of assimilation. In this respect they differ notably from the Naïdince, with which they are usually associated in both fresh- and salt-water mud; for with these, as with their near ally the Earthworm, the intestinal canal may be considered as little else than a highway road along which extrancous matter, containing organie particles, is continually passing. These latter animals are less fastidious in their appetites, swallowing at random, and appropriating the organic material only when within the alimentary tube; whilst the Nematodes are selective from the first, taking nothing but such vergetable substances as constitute their particular food. Their powers of prehension seem very limited; and I believe, from what I have seen, that their food is taken partly by suction, this being effected by the sudden dilatation of the otherwise habitually closed triquetrous canal of the cesophagus, by means of the radiating transverse muscular fibres of which its walls are composed. This rapid dilatation canses an inrush of fluid, with any particles that may be in front of the mouth; and I have several times obscrved air-bubbles and fluid enter and pass aloug the cosophagus in this way. How or of what nature is the food taken ly individuals of the genera Dorylaimus, Tylelenchus, and Cephalobus, having a sharp, exsertile, spear-like commencement of the cesophagus, I cannot say: it scems difficult to account for the presence of such a structure, unless it were destined to pierce animal or vegetable tissues, and thus enable them to suck the organic juices-a supposition which seems horme out also by the thread-like dimensions of the œsophageal canal in the genus Tylelenchus. The so-called gastric teeth met with in some of the free as well as the parasitic Nematodes, in the terminal dilated portion of
the osophagus, constitute also, I believe, in reality, a valvular apparatns, probably connected with this same process of snction.

The power of repairing injuries possessed by these animals seems to be very low. In a specimen of Oncholuimus vulgaris, the head and œesophageal part of the body were severed from the remaining portion; and during the three days that the pieces were observed, although both portions continued to more about with tolemble activity, not the slightest attempt at repair was seen-no contraction even or closing up of the cut ends, such as almost instantly occurs when a Neïs is similarly injured. The chitinous nature of the integument in the Nematoids almost precludes contraction, and nothing like circular muscles seems to exist. On another occasion I found the anterior half of an individual of the same species moving about freely a fortuight after scetion of its body, but presenting no attempt at repair. Similar results have been arrived at with one or two other species, and with seetions made in various parts of the body.

I have not yet obtained much positive information with regard to their duration of cxistence, but, from what I hare scen, suspect it rarely exceeds from six to ten months ${ }^{1}$. In Mononchus truncatus I have ascertained that in about two months the embryos had attained two-thirds of their adult size, and were only then beginning to emerge from their asexual condition, the very first rudiments of a genital apparatus being just perceptible. The rate of growth after this seems to be still slow and gradual; and the females appear to dic after the production of a single brood or batch of ova. Sueh is certainly the case with the Vibrio tritici; and, as pointed out by Davaine ${ }^{2}$, the total duration of the active life of this animal is about nine or ten months.

The different members of this group rary mmeh as to their tenaeity of life. As a rule they are frail and delicate, and do not recover even after a slight desiceation of five or six minutes, thus difforing remarkally from what I have at present observed with members of the four land and freshwater genera, T'ylelenchus, Plectus, Aphelenchus, and Cephulobus: with all these there is a remarkable tenacity of life and power of recovery after what seems to be complete desiccation. This power of revivification, now so well known to be possessed by the young of the Fibrio tritici, was first ascertained by its discoverer, Turberville Needham, in 1743; and afterwards the same property was recognized by Spallanzani in eertain species of minute Nematoids found in tufts of moss; and a series of experiments were instituted by him with the view of estimating the cxtent of this power. These experiments have been repeated and extended in the most careful and conclusive manner by MM. Davaine ${ }^{3}$, Doyere ${ }^{4}$, and Gavarret ${ }^{5}$; and the remarkable advantages proved to be possessed by these minute animals have been erroneously supposed by most writers to he characteristic of the whole group ${ }^{6}$. I hope to make more extended observations on this head, and to he ahle to point out more fully hereafter the particular genera in which this capability of resisting desiccation exists, with the ana-

[^5]tomical peculiaritics which distinguish them from their less fortunate allics. It is an established fact that the young of the so-called Tibrio tritici are capable of resuming their activity, by immersion in water, after having remained dormant within their scedlike gall for a period of twenty-seren years, since Baker. was enabled to establish this fact in $17 \bar{\prime} 1$ with specimens given to him by Needham in $1744^{\prime}$; and I have lately been informed by one of the Fellows of this Society ${ }^{2}$ that he has suceceded in restoring. them after" a period of "about twenty years," though it was stated by Bancr in lis wellknown paper in the 'Philosophical Transactions' for $1822^{3}$, and by other observers, that from five to eight years was the limit; whilst lately, in his valuable work on 'Entozoa,' Dr. Cohbold has reported the perind to be no more than "four or even fire years." These diserepancies depend doubtless to a certain extent upon the manner in which the gall has been preserved during the interval, and upon certain differences in the hygrometrical conditions to which it has been subjected, just in the same way as sceds retain their power of germination for a variable period under the influence of different methods of preservation. I have been able to verify the observations of Spallanzani, Dujardin, and others, regarding the degree of vitality of the Nematodes found in tufts of moss, though they do not in reality belong to the gem Rikebditis, 'as reported by Dujardin, but are distinct forms, which I have inchuded in the gencra Plectus and Aphelenchus. And, more marvellous still, I took, this summer, during the long-continued drought of months, from the top of a slate roof with a sonthern aspect, and fully exposed to the direct rays of the sun, a patch of the yellow lichen, Parmelia parietina, for the purpose of examination-though more with a view of making quite sure that there were no Nematoids in it than with the expectation of finding any-when, after placing a small portion with some water in a watch-glass, I was extremely surprised on looking at it with a lens about two hours afterwards, to see forty or fifty of these little Nematodes in the full swing of life and activity. But with these other Nematoids of moss and lichen it is not as with the Tibrio tritici, that this remarkable power is possessed only by young and immature indiriduals, since it is enjoyed also by adults haring fully developed ova within them. I have fomd no representatives of these particular types in salt water; and, as far as my experience groes, those found in this situation are all incapalule of being revired? after haring remained without water, on a slip of glass, for a fow minutes. A statement apparently in direet opposition to this was made by Otto Müller in his 'Animalia Infusoria.' 'Two marine species, named by him Vibrio gordius and $T$. anguillula marina respectively, were stated to revive after desiceation by the addition of spring water ; but, since lie does not make any definite statements concerning the length of time during which the morements continued, I suspect that what he observed may be nothing more than what I have myself scen very frequently, mamely, two or three tolcrably brisk contractions immediately on the addition of the water, gradually becoming less marked, and finally ceasingr altogether in less than a minute. This offect I imagine to be physical

[^6]rather than vital, and due to the rapid imbibition of water by the previously dried animal.

With respect to the Tibrio tritici, I may state that this yoar I suceeeded in infecting some wheat with young spocimens taken from a gall sereral years old. As my stock was small, the method followed was that adopted by Bauer-that is to say, the placing some of the young Nematodes within the cleft of the seed, allowing them to dry in this situation, and then consigning the seeds to the earth in the ordinary way. This was done in the end of February last, when eighty seeds so infected were sown in a box containing ordinary soil ; and on the 8th of July I diseovered one plant evidently diseased. It was extremely stunted, being only about five inehes in height; and the whole specimen was dry and withered, with the exception of the small and abortive ear. This eontained no healthy florets, the diseasod ones being about fourteen in uumber, each being composed of the slightly altered glumes and palere surrounding a gall of the usual size and oroidal shape, instead of a germen. In confirmation of this view of the gall-like nature of the growth, as ascertained by Davaine', I may state that at the time when these bodies had attained their full size and maturity, the other healthy plants were only just flowering, the germens in them being minute and undeveloped. I am also able to testify to the probability of the correetness of Davaine's description of the precise method in which the disease is produeed, and the young worms come in contact with the growing flower. Before his time the only observers who had attempted to explain the mamer in which the young Vibrios reach the ear were Roffredi ${ }^{2}$ and Bauer; and both these investigators imagined the little Nematodes obtained an entry to the vessels of the plant, and were so transmitted to the germen. Bauer, indeed, whose paper, apart from the special subject on which he wrote-namely, the degree of vitality of these animals-is full of inaccuracies, and whose figure and description of the adult animal is utterly unlike the original, imagined that the young, found in what he considered to be the diseased grain, were the products of a third generation in this spot, the two others having taken place within the ressels of the stem of the plant during the progress of the animals towards the flower. But the real process, aceording to Davaine, seems to be this:-When the infeeted galls are sown together with healthy seeds ${ }^{3}$, the young in a week or so, aecording to the degree of moisture of the soil, make their way out of the softened gall, and, diffusing themselves in all directions, some come at last into contact with the budding plant just

[^7]sprouting from the healthy seed, and then insert themselves between the sheaths of its leaves, gradually working their way round till they come to the imnermost of these, where they remain for' a variable time, without increasing much in size, till the rudiment of the future ear begins to form. The length of time during which they remain in this situation, and their degree of activity, depend upon the rapidity of growth of the plant and the moisture of the scason. The remainder of the process may be best described in Daraine's orn words; he says:-"L'épi du blé, avant de paraître au dehors, se forme et reste longtemps renfermé dans les gaines des dernières feuilles. Les anguillules, libres dans ces gaines, le rencontrent et peurent s'introduire cutre les parties qui le composent. Pour que l'invasion des anguillules soit suivie de la production de la nielle, il faut que la rencontre ait licu à une époque très-rapprochée de la formation de l'épi. Lorsque celui-ci n'a encore que quelques millimètres de longueur, que les paléoles, les étamines et l'ovaire, ayaut la forme d'écailles, ne sont point distincts les uns des autres, ces écailles sont constituées par des cellules naissantes très-molles, pulpeuses, qui se laissent pénétrer facilement, et c'est ì cette époque que les anguillules en contact avee l'épi déterminent la production de la nielle, en s'introduisant dans leur pareneliyme. Mais, lorsque ces écailles acquièrent la forme des diverses parties qui constituent la fleur du blé, lorsque le pistil bificle devient distinct, les anguillules ne pénètrent plus dans leur parenchyme, trop consistant sans doute, et la nielle ne peut plus être produite; c'est un fait que j"ai constaté par plusicurs expéricnces" (p. 18). This picreinğ and occupation of a part of the rudimentary flower arrests its derelopment, though it stimulates growth. A gall-like body is more rapidly produced in the site which should have been occupied by the germen, whilst the young worms soon become perfectly dereloped males and females. These vary in number from two to ten or twelve in each gall, and, after producing an enormous number of ora containing fully formed young-which speedily liberate themselves, though they afterwards undergo little change-themselves die and wither, at the time when the gall begins to assume its characteristic purplishbrown or black appearance.

In harmony with this method of infcetion of the wheat by the Tibrio tritici, as revealed by Davaine, I may state that in several grasses I have found different species of these free Nematodes, lying hetween the imner sheaths of the leares, near the bottom of the culm. In Festuca elatior I met with no less than fire species in this situation, belonging to the genera Doryluimus, Mononchus, and Plectus; and in the stalks of wheat and oats remored from stubble-fields I have frequently found specimens cither of these genera or of Rhubditis, Aphelenchus, or Cephelobus. In addition to a malady of oats and maize similar to that of the wheat, and said to be produced by the same animal, Stcinbuch ${ }^{1}$, nearly a century ago, recognized a disease somewhat similar to the "purples" in two of the bent-grasses (Agrostis); and, from the frequent presence of these Nematoids in the situation named, I suspect such discases of grass will be found more frequent, if specially looked after. As another instance of disease induced in plants by these animals may be mentioned the discovery of Kïln², who has ascertained that a long-known and recognized discase of the common teasel (Dipsacus fullonmm) is owing to the presence of a number

[^8]of these minute Nematodes, which gives some parts of the flower a white filamentary appearance. They seem to be endowed with the same tenacity of life as Tylelenchus tritici, and, from their correspondence in anatomical details, evidently belong to the same genus. Whilst speaking of these parasites of vegctables, I may again mention the fact that two or three of the most highly organized species of the free Nematoids I have met with, all the specimens of which are provided with well-developed ocelli, have been found infesting some of the British marine Sponges. Although there can be no doubt of the animal nature of these latter, still the organization of Sponges is so peculiar that the conditions of existence of these minute Nematoids within their interstices may, on the whole, be considered much more nearly allied to those of the non-parasitic Nematoids in general than to those to which the parasitic forms are subjected within the various organs of more highly developed members of the animal kingdom. There would seem to be no more reason why these animals should be considered parasites on account of their habitat, than that those Annelids with which they are often associated in the Spongiade should, for a like cause, be brought under the same designation.

## Classification.

The only two writers who have attempted to classify the free Nematoids are Diesing and Eberth; and since the opinions of both are so much entitled to respect, it will be only right for me to consider their respective schemes of classification, and point out, not only the nature of these schemes, but also in what way they appear to me to be defective.

Diesing's most recent communication is to be found in a paper entitled "Revision der Nematoden", in which he treats of the classification of the Nematoids generally. I shall, of course, confine my attention to what he has to say on the free Nematoids. These, with one or two other genera of a doubtful nature, he includes under two families, the distinguishing characters of which he considers to be the presence or absence of cirrhi or setæ around the mouth. His arrangement is as follows :-

Family I. Cirrhostomea. Corpus capillare. Os terminale cirrhatum. Ocellata vel cæca. Penis haud vaginatus v . vagina tubulosa exceptus. Papilla suctoria caudalis nulla v. unica terminalis. Animalcula ut plurimum microscopica. Aquarum dulcium vel maris incolæ.

* Ocellata.

Family II. Anguillulidea. Corpus capillare, inerme vel armatum. Os terminale sessile, v. in apice tubuli protractilis, inerme aut denticulatum, nudum vel papillis cinctum. Cæca, rarius ocellata. Pcnis haud vaginatus aut vagina dipetala inclusus. Papilla suctoria caudalis nulla vel unica terminalis vel duæ marginales. Animalcula minora. Aquarum dulcium vel maris incolæ, aut in animalibus variis endoparasita, nonnulla migratoria.

$$
\begin{aligned}
* \text { Odontostomata. } & \text { Os dentatum. Ceca vel ocellata. } \\
& \dagger \text { Ocellata. } \\
& \text { 5. Enoplus. }
\end{aligned}
$$

[^9]VOL. XXV.
$\dagger \dagger$ Cecea.
6. Oncholaimus.
7. Dorylaimus.
8. Odontobius.
9. Diplogaster.
** Anoplostomata. Os elentatum.
10. Dicelis. 11. Anguillula. 12. Angiostomum. 13. Leptodera. 14. Isacis.
Genera inquirenda.
15. Phacelura. 16. Potamonema. 17. Nema.

More extended observation has convinced not only myself, but also Dr. Eberth, that this character, derived from the presence or absence of cirrhi, selected by Diesing as a family distinction, is altogether too inconsistent and variable. Several of the genera placed by Diesing in that family the members of which are supposed by lim to have no eirrhi contain species which are abundantly furnished with these appendages, such as Enoplus, Oncholaimus, and Odontolius; and, moreover, their presence or absence is not always a character of sufficient importance to be employed even as a generic distinction. Five of these genera too, Dicelis, Angiostomum, Leptodera, Isacis, and Phacelura, are composed of species which are not free Nematodes at all, hut parasitic forms infesting various kinds of insects, mollusks, myriapods, \&c., concerning which I have already expressed my unwillingness to admit their identity with the free Nematoids till such a relation shall be fully established by a more accurate and precise knowledge of their anatomy than we at present possess.

Dr. Eberth also rejects this arrangement of the free Nematoids by Diesing as unsatisfactory, and offers in its place a readjustment of his own. He divides them into two principal families, but is doubtful and uncertain about some genera, such as Dorylaimus, Diploguster, Phanoglene, and Pontonema. His main divisions are as follows :-

1. Anguillula.
a. Nematodes with an unarmed mouth, with a cylindrical œesophagus, and well-marked stomach; without tail-glands or ocelli; partly free and partly parasitic.
$b$. Nematodes with an unarmed mouth and simple œesophagus, without stomach and without tail-glands.
2. Urolabes. Nematodes without well-defined stomach, partly with and partly without cirrhi around the mouth; with or without occlli, but provided with well-defined tail-glands. Habitat, fresh and salt water.
a. Apharyngea.

Amblyura. Phanoglene. Enchelidium.
j. Pharyngea.

> * Cæca. Oncholaimus. Odontobius.
> ** Ocellata. Enoplus.

This classification is also extremely defeetive, though based upon characters haring real importanee, instead of such mere individual peculiarities as were adopted by Diesing. Eberth has also unfortunately attempted to range all the twenty-three new marine species discovered by himself under five of the old genera, with the result of greatly con-
fusing the nomenclature, since I feel quite convinced, from an examination of the beautiful figures he has given of these forms, that they cannot properly be included under less than from eight to twelve distinct genera.

So far as my own experience goes, I feel assured that even now, with the accession of new forms brought to light by myself, it is altogether premature to attempt anything like a philosophical classification; we are as yet but on the threshold of our knowledge of the multiplicity of types which will doubtless soon be revealed if the investigation is taken up by naturalists at home, and à fortiori if the subject enlists the attention of scientific observers in various quarters of the globe. In this memoir I have accordingly not ventured upon what may be called a classification, though I have carefully drawn up tables presenting a differential analysis of the characters of those of the genera whose anatomical details are sufficiently known. This has been done principally with the view of assisting in the identification of the species already described. On looking over these tables, one cannot but be struck with the fact of the almost universal distiuctness of the land and freshwater from the marine types. In only one undoubted instance have I met with representatives of the same genus inhabiting both fresh and salt water (Rhabditis), since the marine species Monhystera ambigua and M. disjuncta, at present placed in this freshwater genus, will in all probability ultimately be found to belong to a distinct type, by virtue of certain auatomical peculiarities which distinguish them from other species of that genus in which they have been temporarily placed. One species of the freshwater genus Dorylaimus is also reported to have been found in salt water by Dujardin.

The ventral gland, or excretory organ, does not appear to be so common in the freshwater as in the marine gencra; and, as far as I have recognized it in the former, it presents certain structural peculiarities. The peculiar "osophageal ring," too, I have only met with as unmistakeably existing in some of the marine genera, and in these, curiously enough (though in this respect my experience appears to be contrary to that of Dr. Eberth), only amongst such as have either longitudinal or no perceptible strie of the integument, as I have never once met with it in any species presenting well-marked transverse striæ. The ocelli are much more marked and more frequent in the marine species, though even the possession of such a well-marked appendage as this is not a character of constant generic importance. In the genera DIonhystera, Cyathotaimus, and Chromadora, for instance, certain species are provided with ocelli, whilst others are without them; and their presence or absence seems frequently to be connected with the nature of the habitat. The degree of complexity of the male intromittent organs is also increased in the marine genera, since in these as many as two or even four accessory pieces may exist, whilst in the land and freshwater types the spicules are either solitary or provided with one single, posterior, median accessory piece. The shape and number of these organs afford excellent generic characters of a most constant kind, with the exception that occasionally, in genera whose species have spicules only, representatives will be met with presenting also a single posterior accessory piece. Such is the case in the genera Oncholaimus, Comesoma, and Monhystera. It may be, it is true, that this accessory piece exists in a membranous and undeveloped condition in the other species, and so is not
readily recognizable. The exact structure of the pharynx and cesophagus, the nature of the integumental markings or strix, and the position and character of the duct of the ventral gland seem to me the other characters which, from their constaney, should be most relied upon in the construction of genera. The necessity of absolute accuracy concerning these details cannot be too strongly enforced, in view of the crude generalities which have been offered by some preceding observers as specific descriptions, many of which are absolutely useless as a means of identification, and serve only to swell the number of synonyms and uselessly perplex subsequent workers in the same field of research ${ }^{1}$.

## Family ANGUILLULIDæ, Gervais \& Van Beneden.

Free Nematoids.-Body cylindrical, tapering more or less at either extremity. Inlegument transparent, striated or plain; naked, or provided with papillæ or setæ; traversed by capillary pores; shed and renewed at intervals. Candal sucker mostly present. Glanduler system well developed; often single excretory organ in anterior part of ventral region. Lateral lines existing as cellular canals communicating with the exterior, with or without a central chamnel; in others replaced by distinct vessels. Median lines indistinct. Nervons system, nouc. Ocelli, when present, aggregations of reddish pigment on anterior part of osophagus, with or without transparent lens-like bodies. Generative organs-female, composed of double symmetrical uteri and short reflexed ovarian tubes, with vagina near centre of body; vagina occasionally more posterior, with posterior uterine segment and ovary undeveloped ; ova few, large: male, consisting of an almost simple seminal tube, and two equal horny spicules, either alone or with one or more accessory pieces.

[^10]
## TABULAR LIST OF GENERA.

## I. LAND AND FRESHWATER.

Spicules two, equal, with or without a single posterior median accessory piece.

* Integument plain, or with longitudinal narkings. Ventral excretory gland wanting.
$\dagger$ Caudal sucker small.

1. Monhystera. Integument with lateral circular mark anteriorly. Ocellus single, often absent. Pharyngeal cavity none. Esophagus cylindrical. Uterus unsymmetrical.
2. Trilobus. Pharyngeal cavity cup-shaped; no teeth. Esophagus having three lobes at termination. Males with well-developed suckers in middle line above anal cleft.
3. Mononchus. Pharynyeal cavity large, oval, having one upper tooth-like projection. Canal of cesophagus indicated by three bright lines.
$\dagger \dagger$ Caudal sucker absent.
4. Ironus. Pharyngeal cavity small, long, and narrow. EEsophageal canal bounded by three bright lines.
5. Dorylaimus. Spear exsertile, at commencement of esophagus, whose canal is indicated by three bright lines. Males having oblique integumental markings on posterior extremity, with or without small median suckers above anal cleft.
6. Anguillula. Pharyngeal cavity very small. Esophagus having oval swelling at termination, containing a simple valvular apparatus. Uterus unsymmetrical. Spicules long and narrow. Accessory piece single, distinct.
** Integument with transverse stria. Ventral excretory gland present or absent.
$\dagger$ Caudal sucker present.
7. Tripula. Strice well marked. Pharyngeal cavity none. Esophagus with constricted portion at termination. Three large pores through integument in anterior part of ventral region.
8. Diplogaster. Strice transverse and longitudinal. Pharyngeal cavity cup-shaped, with small horny plates at bottom. Esophagus having large muscular swelling at middle of length. Sucker very minute. Accessory portion of penis well marked.
a9. Plectus. Pharyngeal cavity long and narrow. Esophagus having oval swelling at termination, provided with a complex valvular apparatus. Ventral gland having twisted duct opening near midldle of cesophagus. Uterus symmetrical.
a10. Aphelenchus. Spear simple, at commencement of asophagus, which terminates in a large rounded muscular swelling. Ventral yland-opening posterior to termination of cesophagus. Uterus unsymmetrical. Spicules simple, without accessory piece.
[^11]
## $\dagger \dagger$ Coudal sucker absent.

a11. Celualobus. Strice well marked. Head slightly bilobed. Plarynyeal carity none, or small. Esophagus having rounded swelling posteriorly, containing a simple valvular apparatus. Veutrat gtand-opening opposite posterior part of cesophagus. Uterus unsymmetrical.

Males having caudat ala.
${ }^{\text {a }}$ I2. T'yelenchus. Spear with trilobed base. Cesophagus having a rounded muscular swelling about its middle. Ventral gland-opening opposite posterior part of esophagus. Uterus unsymmetrical, Caudal ale narrow, unsupported.
13. Radbditis. Strice transverse and longitudinal. Pharynyeal cavity cylindrical. Esophagus having clongated swelling at middle, with rounded one at termination, containing a simple valvular apparatus. Uterns symmetrical. Caudal ala large, supported by rays.

## II. MARINE.

Spicules two, equal, solitary, or with one, two, or four accessory pieces. Occasionally a single supplemental organ in ventral region, above amus. Ventrul excretory gland present in all (?). Caudal sucker universal.

* Inteyument plain, or with longitudinal markings. Assophagus embraced by glandular (?) ring. $\dagger$ Spicules solitary, or with a single posterior median piece.

14. Sxaplocostoma. Pharyngeal cavity elongated, oval, complex, crossed by lines or bars, and having a funnel-shaped body on its inferior aspect. Ocelli present or absent. Spicules long, solitary.
15. Oncholanus. Pharyngeal cavity large, oval, provided with three tooth-like projections. Ocelli none (?). Uterus symmetrical or unsymmetrical. Spicules solitary, or with a single accessory piece.
16. Enchelidium. Pharyngeal cavity none (?). Ocellus mostly large and single. Spicules long, narrow, with or without a single median accessory portion.
${ }^{\text {b }} 17$. Anticoma. Integument having a row of opposite seta on dorsal and ventral surfaces. Ocelli none. Vuginal glends two, equal. Spicules solitary. Supplementary organ small.
bis. Phanoderma. Pharynyeal cavity small. Ocelli distinct, lateral. Spicules long, solitary. Supplementary organ small.
$\dagger \dagger$ Spicules having two equal accessory pieces.
${ }^{\text {b }}$ 19. Leptosomatum. Pharyngeal cuvity none. Ocelli distinct, dorsal, occasionally coalescing. Excretory glandular organs two, laterat, opening on either side of head. Supplementary organ a small sucker-like prominence.
b20. Enoplus. Pharyngeal cavity indistinct, surrounded by three separate teeth or jaws. Ocelti not distinct from surrounding pigment. No cesophageal ring, and integument with delicate transverse as welt as longitudinal strice.
cュ1. Linhomomius. Plaryngeal cavity cup-shaped. Wsophagus enlarged behind pharynx and also at posterior extremity. Essophageal ring (?). Anal glands large. Accessory pieces recurved.
a All the animals belonging to the genera having this mark affixed to then have a modification of the ventral gland, and are endowed with a remarkable tenacity of life.
b The species belonging to the genera having this mark aftixed to them are all distinguished by the males bciug provided with a supplementary organ.
c The males of the species belonging to these three genera present the common character of reflexed accessory pieces.
** Integument will transverse stria or dots. Esophageal ring alsent.
$\dagger$ Ocelli absent.
$\ddagger$ Uterus unsynmetrical.
cog. Tachyhodites. Plaryngeal cavity absent. Two peculiar colourless bodies on dorsal surface near anterior extremity. Vaginal glands wanting. Accessory pieces recurved.
c23. Tineristus. Pharyngeal cavity hemispherical. Vaginal glands two, unequal. Accessory pieces recurved.
17. Spherolaimus. Pharyngeal cavity large, somewhat spherical. Esophayeal canal bounded by three longitudinal bands. Vayinal gland single, posterior. Spicules long, narrow, with a single posterior shield-shaped accessory piece.
$\ddagger \ddagger$ Uterus symmetrical.
18. Comesoma. Integument having lateral circular depressions near head. Pharyngeal cavity very small. Spicules long, narrow, with or without a very small posterior accessory piece.
19. Spira. Integument having lateral, convex, circular proninences near head. Pharyngeal cavity none. Esophagus having a slight rounded swelling posteriorly. Spicules stout, curved, with two accessory pieces.
20. Odontobius. Pharynyeal cavity none. Teelh doubtful. Spicules stout, curved, with two accessory pieces.
$\dagger$ Ocelli present or alsent.
21. Cyatholamus. Integunent with transverse strix or rows of dots. Pharyngeal cavity cupshapcd, with longitudinal markings. CEsophayus cylindrical. Accessory pieces strong, four, in two pairs. Coudal sucker elongated, cylindrical.
22. Spilophora. Integument with transverse rows of dots or striæ. Pharyngeal cavity cup-shaped, with longitudinal markings, and threc processes extending backwards. Accessory pieces two, rather indistinct. Caudal sucker elongated, cylindrical. Esophayus having well-marked swelling posteriorly.
23. Chromadora. Integument with transverse and longitudinal striæ. Pharyngeal cavity rather indistinct, three cuneiform processes extending backwards and in contact. Accessory pieces two, strong, hooked. Caulal sucker clongated, pointed.

## GENERA WHOSE CHARACTERS ARE INSUFFICIENTLY KNOWN

31. Amblyura, Hemprich and Ehrenberg.
32. Hemipsilus, Quatrefages.
33. Pifanoglene, Nordmann.
34. Pontonema, Leidy.
35. Potamonema, Leidy.
36. Nema, Leidy.
37. Urolabes, Carter.

## SYNONYMS OF PREVIOUSLY DISCOVERED SPECIES.

[^12]
## LAND AND FRESHWATER ${ }^{1}$.

## 1. MONHYSTERA ${ }^{2}$, Bastian.

Gen. Char. Body mostly tapering considerably posteriorly. Caudal sucker small, somewhat pointed. Integnment unstriated; setic very fers; lateral circular mark on either side near anterior extremity. Pharyngeal cavity none. Esophagus uniform, cylindrical. Intestinal cells not tessellated. Fulva about posterior third of body. Uterus unsynmetrical. Tiviparous or oviparons. Spicules long and narrow. Accessory piece, when present, single, small. Ocellus single, often absent.
In ail probability, the two species which I have named M. disjuncta and M. ambigua will hereafter be found to belong to a distinct genms; but, not liaving seen the females of either, I was mwilling to describe them apart, and have therefore placed them temporarily in that genus to which they secmed to be the most nearly allied.

1. M. stagnalis, n. sp. (Plate IX. figs. 9-11.)

Female, length $\frac{1}{15}$ ", breadth $\frac{1}{2 \frac{1}{50}}{ }^{\prime \prime}$.
External Characters.-Body opaque-white in part, tapering considerably at extremities, especially towards the posterior, which is long and filiform. Head truncatcd, having a circlet of 4-6 short sete. Integument plain.

Esophayus about $\frac{1}{8}$ th of whole length. Intestine narrowed where encronched upon by genital tube, but widening considerably behind vulva. Anus $\frac{1}{11 \frac{11}{\prime \prime}}$ from posterior extremity. Tulva behind commencoment of posterior third of body. Fiviparous; young numerous. Ocellus bright red, on sheath of œesophagus.

MLule, length $\frac{1}{22}{ }^{\prime \prime}$, breadth $\frac{1}{45 \frac{1}{4}}$. Anus $\frac{1}{1+\frac{1}{2}}{ }^{\prime \prime}$ from posterior extremity. Spicules $\frac{1}{250} \sigma^{\prime \prime}$ long. Accessory piece small, somewhat triangular. Spermatozoa having slight vibratile movements, of an clongated oval form, $\frac{1}{5000}{ }^{\prime \prime}$ long.

Hab. Mud from ponds, Falmouth and Easthampstcad.
2. M. dispar, n. sp. (Plate IX. figs. 1, 2.)

Female, length $\frac{1}{23} 3^{\prime \prime}$, breadth $\frac{1}{555}{ }^{\prime \prime}$.
External Characters.-Body scarcely tapering at all anteriorly, but abruptly behind vulva, and then gradually narrowing so as to terminate with a filiform extremity and minute pointed sucker. Head truncate, provided with 2-4 short setæ. Integument hyaline.

Esophagus $\frac{1}{5}$ th of total length. Intestinal cells containing rather large dark-coloured particles, having indistinctly tessellated arrangement. Anus $\frac{1}{143}{ }^{\prime \prime}$ from posterior extremity. Fillva about commencement of postcrior third of body.

Male, not seen.
Ha乙. In moss, Falmouth.
3. M. rivularis, n. sp. (Plate IX. figs. 3, 4.)

Mrale, length $\frac{1}{28}{ }^{\prime \prime}$, breadth $\frac{1}{66} \overline{6}^{\prime \prime}$.
${ }^{1}$ Three exceptions to this,-Rhabditis marina, Monhystera ambigua, and M. disjuncta being marine, and found amongst the sand of tide-pools. 2 $\mu$ óras, single, and ivrépa, the uterus.

Exterual Characters.-Body tapering slightly anteriorly, but gradually to a point posteriorly. Head truncate; no setre.

Cesophagus $\frac{1}{6}$ th of total length. Inlestine rather thinly corcred with fat-particles. Auns $\frac{1}{200}{ }^{\prime \prime}$ from posterior extremity. S'picules slightly enlarged at upper extremities, $\frac{1}{235}{ }^{\prime \prime}$ long.

Female, not seen.
Hab. Sandy mud from stream, Falmouth.
4. M. longicaudata, n.sp. (Plate IX. figs. 5, 6.)

Female, leugth $\frac{1}{11}{ }^{\prime \prime}$, breadth $\frac{1}{250} 0^{\prime \prime}$.
External Characters.-Body tapering slightly anteriorly, more considerably behind rulva, and terminating in a very long filiform extremity. Head truncate; no setæ.

Esophagus about $\frac{1}{6}$ th of total length. Intestine rather thinly covered with fat-particles, having indistinct tessellation. Aurs $\frac{1}{71^{\prime \prime}}$ from posterior extremity. Tulva near middle of body. Uterus unsymmetrical.

MIale, not seen.
Hab. Fine sedimentary sand, pond, Tunbridge Wclls.
5. N. flliformis, n. sp. (Plate IX. figs. 7, S.)

Female, length $\frac{1}{44}{ }^{\prime \prime}$, breadth $\frac{1}{1111^{\prime \prime}}$.
External Characters.-Body long and narrow, scarcely tapering at all anteriorly, but narrowing behind rulva, and thence onwards, so as to terminate in a long filiform extremity. Head truncate; no sete.

Gesophagus $\frac{1}{5}$ th of total length. Intesine sparingly covered with fat-particles. Anus $\frac{1}{160}{ }^{\prime \prime}$ from posterior extremity. Vulva considerably behind middle of body.

Mrale, not seen.
Hab. About liverwort, from pier of bridge just above water-lerel, river Blackwater.
6. M. disjuncta, n. sp. (Plate IX. figs. 12, 13.)

Male, length $\frac{1}{20}$ ", breadth $\frac{1}{435}$ ".
Erterual Characters.-Body tapering slightly anteriorly, and also gradually to a point posteriorly. Terminal sucker small; another large and prominent in the mid-ventral region, $\frac{1}{1000}{ }^{\prime \prime}$ from posterior extremity. Head rounded; no setre. Integument plain, having a circular depression on each side of head $\frac{1}{10000}$ " in diameter.

Plaryngeal catily very small, conical. Esophayus about $\frac{1}{9}$ th of total length. Intestine having a sphincter with traces of a valvular apparatus occupying its commencement, which is devoid of granules; remaining portion covered by very large cells, apparently arranged in two rows. Auts $\frac{1}{312}$ from posterior extremity. Genital duct opening scparately $\frac{1}{2000}$ "above anus. Spicules at anal cleft, slightly curved, $\frac{1}{666}{ }^{\prime \prime}$ in length, with two (?) small triangular accessory pieces. Spermutozoa linear, $\frac{1}{1000}{ }^{\prime \prime}$ long, having slowly undulating morcment.

Fcmale, not scen.
Mab. Miarine, in sand from tide-pool, Falmouth.
7. M. ambigua, n. sp. (Plate IX. figs. 14, 15.)

Male, length $\frac{1}{17}{ }^{\prime \prime}$, breadth $\frac{1}{400^{\prime \prime}}$.
Eaternal Characters.-Body narrowing gradually anteriorly, but tapering to a point abruptly behind orifice of genital tubc. Sucker small, pointed. Head obtusely rounded, naked. Integument plain, having circular depressions on each side of head $\frac{1}{7000}{ }^{\prime \prime}$ in diameter.

Esophagus about $\frac{1}{8}$ th of total length. Intestine having a lind of sphincter, with traces of a valvular apparatus at commencement; otherwise covered with very large eells appearing in two rows, and containing rather light-coloured particles. Auus $\frac{1}{250}{ }^{\prime \prime}$ from posterior extremity. Genilal tube containing very large and distinct granular cells, opening $\frac{1}{1000}$ " above amus. No spicules visible either there or at anal cleft.

Female, not seen.
Hab. Marine, in sand from tide-pool, Falmouth.

## 2. TRILOBUS ${ }^{1}$, Bastian.

Anguillula, Leidy.
Gex. Cifar. Body tapering considerably posteriorly. Caudal sucker small. Integument plain, or with longitudinal strix; setæ scarce. Pharyngeal cavity rather largc, cup-shaped. Teeth nonc. Gesophagus cylindrical, having three lobes at termination. Intestinal cells liaving pale-eoloured fat-particles, more or less distinctly tessellated. Tulva about middle of body. Uterus bifid, segments symmetrical. Spicules solitary. Males having well-developed ventral suckers. Movements moderately active, frequently coiling when touched.

1. T. gracilis, n. sp. (Plate IX. figs. 20-22.)

Female, length $\frac{1}{12}{ }^{\prime \prime}$, breadth $\frac{1}{263} 3^{\prime \prime}$.
External Characters.-Body pale white, tapering slightly anteriorly, and gradually narrowing to a point posteriorly. Head bluntly rounded, provided with 4-6 stout, short setæ. Integument rathcr thick, but very transparent, with longitudinal striæ $\frac{1}{10000}{ }^{\prime \prime}$ apart.

Pharyngeal cavity distinct, cup-shaped. Gesophagus $\frac{1}{6}$ th of total length, having three oval lobes at termination, each about $\frac{1}{770} 0^{\prime \prime}$ long. Intestinal cells containing almost colourless fat-particles, not having distinct tessellation. Anus $\frac{1}{108}$ " from posterior extremity. Vulva rather anterior to middle of body; whole of uterus and ovaries very readily seen.

Male much smaller than female, length $\frac{1}{17}{ }^{\prime \prime}$, breadth $\frac{1}{476}{ }^{\prime \prime}$. Anus $\frac{1}{18 玉^{\prime \prime}}$ from posterior extremity. Spicules solitary, segments narrow, nearly straight, about $\frac{1}{666}{ }^{\prime \prime}$ in length. Transverse striæ, as well as longitudinal, for some distance above the genital cleft of male; also in mid-ventral region a row of six large sacculi (suckers), in two sets of three, each sacculus about $\frac{1}{2500^{\prime \prime}}$ deep.

Hab. About the roots of Ruppia maritima from brackish water, Falmouth.
2. T. pellucidus, n. sp. (Plate IX. figs. 23, 24.)

Female, length $\frac{1}{9}{ }^{\prime \prime}$, breadth $\frac{1}{22} \frac{1}{2}^{\prime \prime}$.
Externat Characters.-Body white, tapering slightly anteriorly, more considerably posteriorly, where it terminates in a rather long filiform extremity, with a minute pointed sucker. Head truncate, provided with four short, spreading setre. Integument transparent; no strice visible.

Phrayngeal cavity enp-shaped. Esophagus about $\frac{1}{6}$ th of total length, having three pear-shaped lobes at termination, each about $\frac{1}{500}{ }^{\prime \prime}$ long. Intestine well covered with light-coloured fat-particles tessellated in arrangement. Anus $\frac{1}{66}$ from posterior extremity. Tulva slightly anterior to middle of body ; genital organs very visible.

Male, not seen,
Hab. Mud from bottom of ponds, Falnouth. Has a habit of coiling itself into a circle when touched.
3. T. hongus.

Anyuillula longa, Leidy, Proceed. of Acad. of Philad. v. p. 205.
"Body cylindrical, translucent, colourless. Mouth round ; buceal cavity inverted, campanulate ; œsophagus and intestine cylindrical, cqual in diameter, the former $\frac{1}{25}$ " long.
"Female, 2 to 3 lines long; anteriorly $\frac{1}{333}$ " broad, middle $\frac{1}{285}$ ". Tail narrow, acute, $\frac{1}{11 \frac{1}{1}}$ " to $\frac{1}{75}$ " long from anus.
" Male, $1 \frac{1}{2}$ to 2 lines long, posteriorly dilated, obtusely rounded, curved, with three slight tubercular thickenings of the integument ventrally; $\frac{1}{285}{ }^{\prime \prime}$ broad, at middle $\frac{1}{370}{ }^{\prime \prime}$ broad. Penis a curved spiculum, $\frac{1}{2 \delta 0}{ }^{\prime \prime}$ long.
"IHab. Found in very great abundance, wriggling about the surface of soft mud, in stagnant ditches in the neighbourhood of Philadelphia."

## 3. MONONCHUS ${ }^{1}$, Bastian.

Oncholaimus, Dujardin ; Enoplus?, Dujardin.
Gen. Cirar. Body tapering to a point posteriorly. Caudal sucker small, not pointed. Integument plain, or with longitudinal strix; no setæ; papillx present or absent around the month. Pharyngeal cavity large, oral, having one hook or tooth-like projection from the upper surface. Gisophagus cylindrical, canal indicated by three bright lines; transverse museular fibres not distinct. Intestine well covered with hepatic cells; fat-particles light-coloured, having tessellated arrangement. Trulva about middle of body. Uterus bifid, segments symmetrical. S'picules _? Lateral canals rery indistinct, having a slightly cellular appearance. Movements active.

Dujardin appears to me to have included in his genus Oncholaimus tro distinet types, which, as far as I have yet ascertained, are exclusively denizens of fresh and salt water respectively. Since he has described a marine representative as his typical species, I have retained the old generic name with a more limited definition for the animals of

[^13]this type, whilst I have transferred the freshwater members to my new genus Blononchus. The species of this latter genus differ from those of the former in having one pharyngeal hook only instead of three; in having the head sometimes furnished with papille, but never, as far as I have seen, with setce; by the different structure of the œsophagus, and absence of the peculiar œsophageal ring; and, lastly, by the comparatively undeveloped condition of the caudal sucker and its appendages.

The males of this genus must be either very minute or very scarce; for though I have seen nearly one hundred female representatives of the different species, I have never met with a siugle specimen of the opposite sex.

1. M. truncatus, n. sp. (Plate IX. figs. 25, 26.)

Female, length $\frac{1}{15}{ }^{\prime \prime}$, breadth $\frac{1}{285}{ }^{\prime \prime}$.
External Characters.-Body tapering slightly anteriorly, but more considerably posteriorly. Head truncate ; no papillæ. Integument with lomgitudinal striæ, $\frac{1}{7500}{ }^{\prime \prime}$ apart.

Pharyngeal cavity oval, $\frac{1}{585}{ }^{\prime \prime}$ in length, with a single hook projecting from upper surface. GEsophagus about $\frac{1}{4}$ th of total lengtlı. Intestinal cells with light-coloured particles, having distinctly tessellated arrangement. Anus $\frac{1}{110}{ }^{\prime \prime}$ from posterior extremity. Vulva slightly posterior to middle of body. Lateral canals broad, rery indistinct, only recognizable behind intestine; no cells apparent-merely a few light-coloured scattered granules.

Male, not seen.
Hab. Small pool amidst decaying moss and liverwort, Falmouth.
2. M. papillatus, n. sp. (Plate IX. figs. 27, 28.)

Female, length $\frac{1}{11}$ ", breadth $\frac{1}{25} \mathbf{a}^{\prime \prime}$.
External Characters.-Body opaque-white in colour, tapering slightly anteriorly, but gradually to a point posteriorly. Head truncate; month surrounded by four wellmarked papillæ. Integument with longitudinal striæ, about $\frac{1}{10000}{ }^{\prime \prime}$ apart.

Pharyngeal cavity a little removed from anterior extremity, proportionally rather small, $\frac{1}{71 t^{\prime \prime}}$ long; tooth single. Wesoplugus $\frac{1}{4}$ th of total length. Intestinal cells containing yellowish-coloured granules. Anus $\frac{1}{160 "}$ from posterior extremity. Tulva at commencement of posterior third of body. Uterus bifid.

Male, not seen.
Hub. Between the sheaths of the leaves, at the lower part of culm of Festuca elatior, Broadmoor, Berks.

## 3. M. macrostoma, n. sp. (Plate IX. figs. 29, 30.)

Female, length $\frac{1}{10}{ }^{\prime \prime}$, breadth $\frac{1}{294}{ }^{\prime \prime}$.
External Characters.-Body tapering rery slightly towards head, more considerably posteriorly, where it is filiform for a short distance. Head obtusely rounded, with two papillie, upper and lower. Integument with longitudinal striæ.

Pharyngeal cavity large, $\frac{1}{588^{\prime \prime}}$ long; hook single, $\frac{1}{1000^{\prime \prime}}$ long. Wisophagus about $\frac{1}{4}$ th of total length; very slightly increased in size posteriorly, where also there is a di-
rergence of the bright lines representing the lumen. Intestinal cells well marked. Anus $\frac{1}{11}$ " from posterior extremity. Tulva at middle of body.

Male, not seen.
Hab. Small freshwater pool, in boggy ground, amidst decaying moss and liverwort, Falmouth.
4. M. tunbridg ensis, n. sp. (Plate IX. figs. 31, 32.)

Femule, length $\frac{1}{23}{ }^{\prime \prime}$, breadth $\frac{1}{416}{ }^{\prime \prime}$.
External Characters.-Body searcely tapering at all anteriorly, except quite at the extremity, opposite the pharyugeal cavity, where it becomes suddenly diminished in size; posteriorly it narrows rather abruptly behind anus, and then terminates in a curved filiform extremity. Head small, romded; no papillæ. Integument laving longitudinal strice $\frac{1}{7500}$ " apart.

Pharyngeal cavity elongated, somewhat narrowed in the middle, $\frac{1}{1 \pm 28^{\prime \prime}}$ long. CEsophagrs $\frac{1}{5}$ th of total length, uniform in size. Intestinal cells containing yellowish-coloured granules, and having a tessellated arrangement. Amus $\frac{1}{250}$ " from posterior extremity. Tulve slightly posterior to middle of body.

Mralc, not scen.
Hab. In fiue sedimentary sand of small poud, Tumbridge Wells '.
5. M. cristatus, n. sp. (Plate IN. figs. 33, 34.)

Female (immature), length $\frac{1}{23}{ }^{\prime \prime}$, breadth $\frac{1}{416}{ }^{\prime \prime}$.
External Characters.-Body tapering very slightly anteriorly, but more considerably posterior to the anus, where it gradually narrows to a point, and is provided on the dorsal surface with an integumental prolongation or crista, whose greatest breadth is $\frac{1}{1060}{ }^{\prime \prime}$. Head truncate, provided with a minute papilia above and below. Integumental strie invisible.

Plaryngeal catity large, oral, with one hook-like projection. Esophagus between $\frac{1}{3} \mathrm{rcl}$ and $\frac{1}{4}$ th of total length, uniform in size. Intestinal cells not distinetly tessellated, containing small pale granules. Amus $\frac{1}{133}$ " from posterior extremity. Tulve considerably posterior to the middle of body.

Mrale, not scen.
Hub. In moss, Falmontli.

## 6. M. foveatum.

Oncholaimus forearum, Dujard. Hist. Nat. des Helminthes, p. 236.
"Corps trente à trente-trois fois aussi long que large ; tête un peu anguleuse ; carité buceale oblongruc, armée de deux ou trois pièces étroites, portant chacune (?) une forte deut en arant du milieu; œsophage long de 0 mm. 37 .
"Femelle lougue de $2^{\text {min }} 5$, large de $0^{\text {mum. }} 07$, ì queue amincie, assez longuc, conservant une même longueur de $0^{\text {man }} 0011$ dans sa dernière moitié, et terminće par une

[^14]sorte de ventouse (?) ; anus ì $0^{\mathrm{mm}} \cdot 18$ de l'extrémité ; vulve située au milieu de la longueur' ; utérus divisé en doux branehes opposées, eonteuant une seule sćrie d'œufs.
"Je l'ai trouvé à Rennes, au mois de Septembre, dans un fossé rempli par les eaux pluviales, et contonant des Branchipus, divers Eutomostracés, des hydatides et des Euglena."

## 7. M. nuscorun.

Oncholaimus muscorum, Dujard. Hist. Nat, des Helminthes, p. 2.37.
"Corps trente-deux fois aussi loug que large; tête rendue anguleuse par six ou liuit papilles opposées, large de $0^{\text {mm. }} 046$; cavité buceale ovale, armée de trois pic̀ees longitudinales arquées, dont une seule porte une forte dent en avant du milieu, tandis que les deux autres sont finement denticulées ou en peigue; oesophage long de $0^{\mathrm{mm}} 55$, large de $0^{\text {mum }} 04$.
"Femelle longue de $2^{m n \cdot 56}$, large de $0^{\text {min. }} 08$; queue amiucic, recourbée en erochet; anus ì $0^{\mathrm{mm}}$. 11 de l'extrémité; vulve saillante, située au tiers postérieur de la longueur'; œufs longs de $0^{\text {mim•0 }} 035$.
" Il a été trouvé assez abondamment ì Paris par mon ami M. Doyère, en 1839, dans les touffes de mousses (Bryumz) des allées du Jardlin des Plantes.
"J'ai depuis lors, en janvier 1844, trouvé à Rennes des Oncholaimes presque semblables dans l'intestin des Gasterosteus lcevis, qui probablement les avaient avalés avee
 la cavité buecale également longue de $0^{\mathrm{mm}} \cdot 046$."

## 8. M. crassiusculus.

Enoplus crussiusculus, Dujardin, Hist. Nat. des Helminthes, p. 235.
"Corps long de $0^{m m} 60$ à (?), large de $0^{\text {mm. }} 026$ à (?), vingt-trois fois sculement aussi long que large ; tête large de 0 mm. 015 , hérissée de quelques soies roides; bouche montrant une armure interne; œsophage museuleux, épais, long de $0^{\mathrm{mm} \cdot} \cdot 112$, large de $0^{\mathrm{mm} \cdot 02}$.
"Femelle à queue allongée, amincie peu à peu; anus à $0^{\mathrm{mm}} 12$ de l'extrémité; vulve située vers le tiers postéricur.
"J'ai trouvé dans l'eau de la Vilaine, à Rennes, cet Helminthe, qui pourrait bien appartenir ì un autre geure-i l'Oncholaime ou au Selérostome, car il paraît avoir une cavité buceale distincte."

As it seems very doubtful to what geuns this species really belongs, I have merely acted upon the suggestion of Dujardin, as expressed above, by transferring it to this group, in which are included the freshwater representatives of lis genus Oncholaimus.

## 4. IRONUS ${ }^{1}$, Bastian.

Gen. Char. Body long and narrow, tapering at extremities. Caulal sucker absent. Integument with delicate longitudinal markings; cephalic setæ present. Pharyngeal cavity long and narrow, having three small, moveable, rounded projections

[^15]near commencement. Wisophagus cylindrical, canal indicated by three bright lines; transterse muscular fibres not distinct. Intestine moderately well covered with hepatic cells containing light-coloured fat-particles indistinctly aggregated. Trulua about the middle of the body. Uterus bifid, segments symmetrical. Spicules -? Lateral canals - ? Morements very slugrgish.
I. IGNavus, n. sp. (Pl. TX. figs. $34 a, 3 \pm$.)

Female, length $\frac{1}{13}$ ", breadth $\frac{1}{555^{\prime \prime}}$.
External Characters.-Body long and slender, tapering very gradually at both extremities, till, at the posterior, it terminates in a long filiform portion. Head bluntly rounded, provided with a circle of four very short setæ. Integument having almost imperceptible longitudinal striee, about $\frac{1}{30000}$ " apart.

Pharyngeal cacity long and narrow, having three small, rounded, ralve-like plates near commencement. Wsophurges $\frac{1}{4}$ th of total length. Intestinal cells containing lightcoloured, non-tessellated particles. Anus $\frac{1}{100}{ }^{\prime \prime}$ from posterior extremity. Tulve slightly anterior to the middle of body.

Mlale, not scen.
Hab. Stagnant water of Easthampstead Plain, amongst Diatomacere and decaying Algie; also about the decaying submerged leaves of a species of Diyriophyllum from the lake, Sundhurst.

## 5. DORYLAIMIUS, Dujardin.

Urolabes, Carter; Anyuillulu, Grube.
Gen. Char. Body sometimes blunt and rounded, sometimes filiform posteriorly. Caudal sucker absent. Integument having longitudinal markings, more or less risible, and a scries of minute pores on each side of body ; setex none; cephalic papillæ prescnt or absent. Plarymx indistinct, but somewhat cup-shaped, having a long, horny and hollow exscrtile spear projecting into and through it, which is renewed twice or oftener during the period of growth. Esophagus having the posterior half, or onethird, of increased size ; canal indieated by three bright lines; transverse muscular fibres not distinct. Intestine mostly well corcred with hepatic cells containing fatparticles having a tessellated arragement. Tulve about the middle of body. Uterus bifid, segments symmetrical. Spicules solitary, glaive-shaped; males haring sometimes a variable number of linear ventral suckers in mid line above anal cleft, and also oblique markings of the integmment. Lateral canals well dereloped and distinctly cellular.
The Nematoid (D. stagnalis) found by Dujardin at Remes, within the stomachs of certain fish, appears to me identical with that form which I have met with so abundantly in mud from the bottom of freshwater ponds. Dujardin also appears to have found a marine representative of this genus, though I have searched for such in vain. Curiously enough, the form which Carter has taken as typieal of his provisional genus Urolabes is undoubtedly a member of the genus Dorylaimus; and, from the absence of the caudal sucker amongst these, its habits would probahly not be of the nature indicated by

Carter's generic name. Carter is inclined to believe that this Urolabes palustris may be the antecedent condition of the Dracunculus, or Guinea-worm, which is so prevalent as a parasite in the island of Bombay. But my investigations have almost convinced me that this is impossible, and principally for a reason which also occurred to Mr. Carter, but of the precise importance of which he does not seem to have been aware. He knew that the integument of the Dracunculus presented transverse strise (most casily recognizable in the young), but could not succeed in demonstrating such strix in U. palustris: to him its integument appeared plain. I have since ascertained that the integument in Dorylaimus stagnalis and others of the same genus not only has no transverse striæ, but is undoubtedly furnished with longitudinal ones '; and all my experience goes to prove that the nature of the integumental markings affords a constant character, not only of specific, but even of gencric importance. Independently of this, there is the difficulty that no horny spear, such as exists in U. palustris, can be detected in the Dracunculus, and also the fact that nothing answering to the peculiar lateral sacculi discovered by myself ${ }^{2}$ in the young Guinea-worms can be recognized in this, or has yet been found in any other species of Nematode, so far as I am aware, with the exception of Dicelis filaria, Dujardin. I may state, however, that from what I have seen of the anatomy of the Dracumenlus and other members of the Nematoid order, I feel quite disposed to believe that its affinities are with these free Nematodes, and fully expect that one day this will be an established fact. I cannot but consider the step which Dr. Cobbold has taken in his recent work, of placing the Guinea-worm amongst the Gordiide, and constituting these a merc family of the order Nematoider, as altogether a retrograde movement, and one almost in direct opposition to the existing state of our knowledge ${ }^{3}$.

We are much indebted to Carter for his descriptions of the male and female genital organs of $U$. palustris, as wcll as for his account of the development of the spermatozoa. There appears to be no other representative of this genus Dorylaimus amongst the ten species described by him-five of which were marine, and five from fresh water.

In all the Dorylaimi examined, which had not yct attained their full development, I observed a second and somewhat larger spear a short distance belind the one in situ, and contained within the walls of the œesophagus. In due time this moves upwards in some obscure way, and finally displaces the other, just as the deciduous is replaced by the

[^16]permanent tooth. It is not the whole of the rigid spear, however, that is renewed in this manner, lout only what appears to be the anterior half of it.

1. I). stagnalis, Dujardin. (Plate IX. figs. 35-37.)

Dujardin, Hist. des Helminthes, p. 231, pl. iii. fig. C.
Female. Length $\frac{1{ }^{\prime \prime}}{4}$, breadth $\frac{1}{111^{\prime \prime}}$.
Erternal Characters.-Body dark-coloured, tapering gradually anteriorly, but more abruptly posteriorly, where it terminates in a pointed filiform extremity. Head truncate; no papillæ. Integument thick, with longitudinal markings $\frac{1}{2000}{ }^{\prime \prime}$ apart; lateral pores easily recognizable, and about $\frac{1}{1428^{\prime \prime}}$ apart.

Spear $\frac{1}{357} 7^{\prime \prime}$ long. Esophagus $\frac{1}{5}$ th of total length, posterior half enlarged. Intestinal cells having a tessellated arrangement, and containing dark-olive-coloured fat-particles. Posterior portion of intestine for about $\frac{1}{50}{ }^{\prime \prime}$ narrower, and very scantily covered with cells and granules. Alus $\frac{7^{\frac{1}{4}}}{}{ }^{\prime \prime}$ from posterior extremity. Tulua slightly anterior to middle of body. Oca lying two or three abreast, within uterus.

DIale. Length $\frac{1}{5}$ ", breadth $\frac{1}{125}{ }^{\prime \prime}$.
Gsophagus proportionally longer than in the female. Anus $\frac{1}{666}{ }^{\prime \prime}$ from posterior extremity. Spicules solitary, $\frac{1}{25} 0^{\prime \prime}$ long. Oblique integumental strise well-marked.

ILub. Mud from freshwater ponds, Falmouth; and New Cross, Kent.
Individuals of this species were found by Dujardin in the stomachs of the Carp (Cyprinus carpio) and of Gasterosteus lavis; which specimens, he conjectures, had been swallowed aecidentally by these voracious fish.
2. D. Carteri ${ }^{1}$, n. sp. (Plate IX. figs. 38-40.)

Female. Length $\frac{1^{\prime \prime}}{1{ }^{\prime \prime}}$, breadth $\frac{1}{290}{ }^{\prime \prime}$.
Externcl Characters.-Body tapering towards either extremity, especially posteriorly, where it is acuminated. Head truneate; no papillæ. Integument thick.

Spear $\frac{1}{450}{ }^{\prime \prime}$ long. Asophagus about $\frac{1}{5}$ th of total length. Hepatic or intestinal cells well marked. Anus $\frac{1}{455}{ }^{\prime \prime}$ from posterior extremity. Vulva in the middle of body. Oca large.

Male, same size as female.
Werophayus longer. Spicules $\frac{1}{500}{ }^{\prime \prime}$ long by $\frac{1}{2000^{\prime \prime}}$ broad. Oblique markings of integument for some distance above spicules; also S-11 minute suckers communicating with corresponding slanting channels through the integument, about $\frac{1}{1+28^{\prime \prime}}$ apart, in the midventral region.

Hub. Stagnant water, with decaying liverwort and moss: Falnouth.
3. D. obtusicaudatus, n. sp. (Plate IX. figs. 41, 42.)

Female. Length $\frac{1^{\prime \prime}}{9}$, breadth $\frac{1}{175}{ }^{\prime \prime}$.
External Characters.-Body tapering considerably for some distance from anterior extremity, but not at all posteriorly, where it is blunt and rounded. Head truncate,

[^17]marked off by a constriction from the rest of the body. Integument with longitudinal striæ $\frac{1}{10000}{ }^{\prime \prime}$ apart.

Spear $\frac{1}{400}{ }^{\prime \prime}$ long. Csophagus about $\frac{1}{5}$ th of total length; anterior half narrow, posterior much wider. Intestinal cells not having tessellated arrangement, but well filled with rather small fat-particles. Amus $\frac{1}{500^{\prime}}{ }^{\prime \prime}$ from posterior extremity. Tulva slightly posterior to middle of body.

Male not seen.
Hab. Amidst rich mould and decaying leaves, from a damp and shady wood, Falmouth.

## 4. D. tenuicaudatus, n. sp. (Plate IX. figs. 43, 44.)

Female. Length $\frac{1}{14}{ }^{\prime \prime}$, breadth $\frac{1}{360^{\prime \prime}}$.
External Characters.-Body tapering very gradually anteriorly, but rapidly behind anal cleft, where it terminates in a long filiform extremity. Head truncate, furnished with two small papille. Integument with longitudinal markings.

Spear $\frac{1}{66 \sigma^{\prime \prime}}$ long. Esophagus about $\frac{1}{7}$ th of total length, posterior half enlarged. Intestinal cells well marked. Anus $\frac{1}{100}{ }^{\prime \prime}$ from posterior extremity. Fulva slightly posterior to the middlle of body.

Male not seen.
Hab. Fine sandy mud from pond, Tunbridge Wells.

## 5. D. tritici, n. sp. (Plate X. figs. 45-47.)

Female. Length $\frac{1}{13}{ }^{\prime \prime}$, breadth $\frac{1}{357^{\prime \prime}}$.
Extemal Characters.-Body white, tapering very slightly anteriorly, and not at all posteriorly, where it is blunt and rounded. Head bluntly rounded, marked off by a constriction; no papillæ. Integumental markings not apparent.

Spear $\frac{1}{3}^{33}{ }^{\prime \prime}$ long. Esophagus rather less than $\frac{1}{3} \mathrm{rd}$ of total length, posterior half enlarged. Intestizal cetls having a tessellated arrangement, and containing light-coloured fat-particles. Anus $\frac{1}{83} \bar{"}^{\prime \prime}$ from posterior extremity. Fulva slightly posterior to middle of borly; segments of uterus very short, extending only about $\frac{1}{154}{ }^{\prime \prime}$ on either side of vagina.

Mrale. Length $\frac{1}{17}{ }^{\prime \prime}$, breadth $\frac{1}{500}{ }^{\prime \prime}$.
Esophagus mach shorter than in female. Anus $\frac{1}{1000}$ " from posterior extremity. Spicules $\frac{1}{666^{\prime \prime}}$ long. Suckers 9, mid-ventral, the first boing $\frac{1}{400^{\prime \prime}}$ above anus, and the others being equidistant and $\frac{1}{2000}{ }^{\prime \prime}$ apart.

Hab. About the roots of wheat growing in a sandy soil, and also between the lower sheaths of its leaves: Broadmoor, Berks.
6. D. filiformis, n. sp. (Plate X. figs. $48,49$. )

Female. Length $\frac{1}{10}{ }^{\prime \prime}$, breadth $\frac{1}{590}{ }^{\prime \prime}$.
External Characters.-Body very long and slender, tapering only slightly anteriorly, but considerably posteriorly, where it terminates in a fine point. Fead truncate; no papillæ. Integumental markings not visible.

Speax $\frac{1}{590}{ }^{\prime \prime}$ long. Esophagus $\frac{1}{6}$ th of total lengtl, posterior third cnlarged. Intes-
tinal cells not distinctly tessellated, and containing light-coloured fat-particles. Anus $\frac{1}{133}{ }^{\prime \prime}$ from posterior extremity. Trelea in the middle of body.

Mrale not seen.
Mab. With Diatomacea, on the decaying lower leaves of Myriophyllum verticillatum from pond, Bagshot.
7. D. polyblastes, n. sp. (Plate X. figs. 50, 51.)

Male. Length $\frac{1}{13}{ }^{\prime \prime}$, breadth $\frac{1}{500}{ }^{\prime \prime}$.
Extermal Characters.-Body long and thread-like, tapering but very slightly at either extremity. Head rounded; no papillæ.

Spear $\frac{1}{1000}{ }^{\prime \prime}$ long. Esophagus $\frac{1}{7}$ th of total length; postcrior half enlarged. Intestinal cells moderately developed, and containing light-coloured fat-particles. Anus $\frac{1}{77} \frac{11}{}{ }^{\prime \prime}$ from posterior extremity.

Spicules $\frac{1}{588}{ }^{\prime \prime}$ long. Suckers 16-20, in mid-ventral region, commencing at $\frac{1}{417^{\prime \prime}}$ above anus, and occupying a space of about $\frac{1}{2} \frac{1}{50}{ }^{\prime \prime}$.

Female not seen.
Hab. With Tylclenchus Davaineii, from moss coating a large boulder in freshwater stream, Falmouth.
8. D. papllatus, n. sp. (Plate X. figs. 52, 53.)

Female. Length $\frac{1}{10}{ }^{\prime \prime}$, breadth $\frac{1}{22} \frac{1}{2}$.
Exterual Characters.-Body opaque-white, tapering gradually anteriorly, but not posteriorly, where it is blunt and rounded. Head truncate, provided with a coronet of six large papillx. Integument with longitudinal strice $\frac{1}{4000}$ " apart.

Spear $\frac{1}{500}{ }^{\prime \prime}$ long. Esophagus $\frac{1}{4}$ th of total length, gradually midening posteriorly. Intestinal cells abundant, tessellated, containing light-olive-coloured particles. Amus $\frac{1}{666}{ }^{\prime \prime}$ from posterior extremity. Tulva near the commencement of middle third of body. Uterus symmetrical. Lateral cell-canals very distinet, owing to their contained granules being of a light olive-colour.

Movements very sluggish.
Male not seen.
Hab. Between the lower sheaths of the leaves of the Giant Feseue (Festuca elatior), Broadmoor, Berks.
9. D. torpidus, n. sp. (Plate X. figs. 54-56.)

Female. Length $\frac{1}{15}{ }^{\prime \prime}$, breadth $\frac{1}{285}{ }^{\prime \prime}$.
External Characters.-Body tapering gradually anteriorly, but more suddenly at postcrior extremity, which is acuminated. ILead truncatc, provided with four small crucial papillæ. Integumental markings not apparent.

Spear $\frac{1}{400}{ }^{\prime \prime}$ long. Esophagus about $\frac{1}{4}$ th of total length ; posterior half enlarged. Intestinal cells having a tessellated arrangement. Anus $\frac{1}{250}{ }^{\prime \prime}$ from posterior extremity. Vulva slightly posterior to middle of body.

Mrale. Length $\frac{1}{17}{ }^{\prime \prime}$, breadth $\frac{1}{500}{ }^{\prime \prime}$. Esophagus shorter. Anus $\frac{1}{400}{ }^{\prime \prime}$ from posterior extremity. Spicules $\frac{1}{66 i}{ }^{\prime \prime}$ long. Suckers none.
\#ab. Same as last species.
10. D. iners, n. sp. (Plate X. figs. 57-59.)

Female. Length $\frac{1}{13}{ }^{\prime \prime}$, breadth $\frac{1}{285}{ }^{\prime \prime}$.
External Characters.-Body tapering slightly anteriorly, but suddenly towards posterior extremity, which is acuminated. Head bluntly rounded. Integumental mark_ ings not visible.

Spear $\frac{1}{1000}$ " long. Esophagus $\frac{1}{4}$ th of total length, posterior third enlarged. Intestinat cells not well marked, and containing light-coloured granules. Anus $\frac{1}{3} 3{ }^{\prime \prime}$ from posterior extremity. Fulva at middle of hody.

Mrale. Length $\frac{1}{18}{ }^{\prime \prime}$, breadth $\frac{1}{500}{ }^{\prime \prime}$.
Esopluagus only half as long as that of female. Anus $\frac{1}{434}$ " from posterior extremity. Spicules $\frac{1}{588}$ " long. Suckers 5, mid-ventral, commencing about $\frac{1}{3} \frac{1}{30}$ " above anus; distance between first two $\frac{1}{1000}{ }^{\prime \prime}$, between the others gradually increasing.

Hab. Same as that of D. polyblastus.
11. D. palustris.

Urolabes palustris, Carter, Ann. of Nat. Hist. 1859, 3 ser. vol. iv. p. 33, pl. ii. figs. 7, 9.
"Female. Length (max.) $\frac{1}{6}$ ", breadth $\frac{1}{370}$ ". Linear, cylindrical, smooth, white or colourless, unstriated transversely, gradually diminishing towards the head, which is obtuse and terminated by a distinct labiate portion, furnished with at least two, if not four, indistinet papillæ; diminishing abruptly towards the tail, whieh is attenuated and whip-like. Mouth in the centre of the anterior extremity. Fulva a little in front of the middle of the body. Anus at the root of the tail." . . . "Esophagus commencing with a cup-like or buccal cavity, into the posterior part of which projects a sharp-pointed, horny, narrow tube (fig. 11 cl ), which is continued backwards in a straight line to the intestine, and is exsertile at the oral orifice."
"Male the same as the female, but smaller, and with the tail truncated almost close to the anus."
"Hab. Fresh water, in tanks and dirty drains wherever there is vegetable matter, mud, and putrescency, and in the gelatinous algæe during the 'rains:' Island of Bombay." 12. D. Linea, Diesing.

Gordius lacteus, Müller ?, Hist. Verm. terr. et fluv. i. ii. 32.
G. linea, Oken ?, Lehrb. d. Naturg. Zool. i. Abtheil. 192.

Anguillula linea, Grube, Wiegmann's Arch., 1840, i. 367-368, tab..vii. figs. 15-17; Diesing, Syst. Helminth. p. 557.
Dorylaimus linea, Diesing, Sitzungsber. der kais. Akad. der Wissen. xlii. Bd. p. 626.
"Corpus intestino nigro percursum utrinque parum attenuatum, antice truncatum, margine paulo incrassato. Cauda subulata, fere $\frac{1}{12}$ longitudinis corporis. Apertura genitalis feminea subcentralis supera. Longit. fem. $2-8^{\prime \prime \prime}$, crassit. ad $\frac{1^{\prime \prime \prime}}{}$.
" Esophagus postice bulbosus, denticulo solummodo retracto viso.
"Hab. In fondo aquarum cum Sanuride variegata, haud raro Dorpati."-Grube.
13. D. mirinus, Dujardin.

Hist. Nat. des Helminth. p. 23I, pl. iii. fig. D.
 stylet protractile, continué par un long tube flexible et par le canal triquètre de l'œsophage ; tégument lisse.
"Femelle ayant la queue longne, cfficéc, la vulve au milieu de la longueur, et les ceufs oblongs, longs de 0 mm• 07 ; larges de $0^{\mathrm{mm}} 027$.
"Je l'ai trouvé dans l'eau de mer, parmi les algues, ì l'Orient."

## 6. ANGUILLULA, Ehrenberg.

Vibrio, Müller ; Ascaris, Goeze; Rhabditis, Dujardin.

Gen. Char. Body long, narrow, and tapering at extremities. Caudal sucker absent. Integument thin, presenting neither transverse nor longitudinal markings; setre none (?) ; papille none (?). Pharyngeal caxity very minute. Wsophagus cylindrical, with rounded swelling posteriorly containing a simple horny valvular apparatus. Intestine sparingly covered with large colourless gramules, presenting no appearance of tessellation; distinct cells not recognizable. Tulce posterior to the middle of body. Uterus mensymmetrical. Oviparous or viviparous. Spicules long, narrow, curved. Accessory piece single, posterior, somewhat fan-shaped. Fentral gland wanting. Floating gland-cells abundant. Lateral canals not recognizable.
Movements active.
Under the old imperfcetly defined gemus Anguillula have been ranged, from time to time by various observers, the most heterogeneons types; but the name has become so familiar, and to some extent distinctive of these free Nematoids, that I have thought it better to retain it with a limited signification, than to cast it aside altogether. This I have aecordingly done, taking as a type Anguillula aceti, since this appears to have been so regarded by Ehrenberg, and modifying the general terms in which he formerly described the genus by the substitution of more exact statements, founded on the anatomical characters of that species ${ }^{1}$. This will undoubtedly exclude many of the other forms hitherto located in this gemus, and amongst them the so-called Auguillula tritici, which I have now placed, with other allied species, in the new genus Tylelenchus. Sereral of the species also that I have (from ignorance of their real characters) still retained under this generic name will, I have little doubt, have to be weeded out by subsequent observers, and transferred to other genera as more precise information is obtained concerning their anatomy.

I hare already expressed my reluctance to assent to Diesing's arrangement when he places in this genus many parasitic forms found in beetles, myriapods, and other animals. Some of these species, which, in his 'Systema Melminthmm,' Diesing had included in the

[^18]genus Anguillula, he has now, in his more recent 'Revision der Nematoden,' transferred to the genus Isacis of Lespés; whilst he includes, as subsections of the former genus, certain other of these parasitic forms, mostly discovered by Dr. Leidy, of Philadelphia, and placed by him, rightly enongh, in distinct genera-Streptostoma, Thelastoma, and Mystrignathus.

For many of the descriptions and references concerning old species placed in this and other genera I have freely availed myself of Diesing's admirable work.

Diesing, Syst. Helminth. ii. p. 128 ; et Sitzungsb. ais. Akad., Bd. xii., No. 28, p. 627.
Female (size very variable). Length $\frac{1}{13}$ ", breadth $\frac{1}{555}{ }^{\prime \prime}$.
External Characters.-Body white, much obscured by colourless granules within integument; long and narrow, tapering very much posteriorly, and terminating in a long pointed extremity. Head rounded, unarmed. Integument thin, showing no striæ.

Pharyngeal cavity very minute, cup-shaped. Csophagns $\frac{1}{9}$ th of total length, having a rounded swelling at termiuation, containing valvular apparatus. Iutestine covered with coarse colourless granules; no sort of tessellation. Anus $\frac{1}{80}$ " from posterior extremity. Vitva somewhat posterior to middle of body. Uterus unsymmetrical. Small floating gland-cells numerous in cavity of body.

Mrale. Length $\frac{1}{21}{ }^{\prime \prime}$, breadth $\frac{1}{850}$ ".
Esophagus $\frac{1}{7}$ th of total length. Anus $\frac{1}{133}$ " from posterior extremity. Spicules narrow, having a double curve, $\frac{1}{714}{ }^{\prime \prime}$ long. Accessory piece about $\frac{1}{3}$ rd as long as spicules, rather thick externally, but expanding inwards into a thinner fan-shaped portion.
"Hab. In fæcihus aceti (Borellus, MÄller, © ©c.) ; in aceto communi cerevisise et vinf, in aqua cum farina, in aqua cocta, et in fiecibus cerevisier, Moscovie ( $C z=1 n a y$ ) ; in aceto e pomis parato, frequenter Philadelphiæ (Leidy)."
"Nota 1. Larvas musca cujusdam (Mosilli eellarii?) in aceto obvias cum hac specie confundit Spallanzani (Microsc. Beobacht. 176).
"Nota 2. Probabiliter e Mosilli cellarii intestinis in acetum translata."-Diesing.
If the drawings are accurate (Pop. Sc. Rev. Jan. 1863) of the animal discovered, by Mr. Jabez Hogg, about portions of the common truflle left for some days moisteued with vinegar, I am rather inclined to believe that this will prove to be a distinct species, and not the real $A$. aceli, since it differs in several respects, more especially as regards the male spicules, from the animals examined by myself, conceruing which there can be little doubt, seeing that they swarm in a specimen of pure vinegar, kindly sent to me by M. Davaine.

Anyuillula glutinis, Ehrenberg, Infusionsth. 8?.
Rhabditis glutinis, Dujardin, Hist. Nat. des IIelminthes, 243.-Leidy, in Procced. Acad. Philad. viii. (1856) 49.
"Corps filiforme, assez épais, long de 1 mm. 68 ; vingt fois environ aussi long que large, amincic en arrière et terminé par une pointe fine allongée; vulve située au ticrs postérieur; œufs grands (de $0^{m m \cdot 09) ~ i t ~ c o q u e ~ m e m b r a m e u s e ~ e t ~ c o n t e n a n t ~ u n ~ c m b r y o u ~ r e p l i e ́ . " ~}$ -Dıjardin.
"Mub. Tn glutine farine (Baker, Alïller, ©c.) ; in glutine tritici, secalis, tragacanthi, ctc., fiequenter Philadelphire (Leidy)."—Diesing.

In the paper hefore alluded to, Mr. Mogg seems to doubt the fact of any specific difference existing between this form and Anguillula aceti; but, from the deseriptions of Dujardin, there appears to be a great discrepancy in the comparative dimensions of the two. Thus, speakingr of A"guillula aceti, he reports it as, "trente it quarante-cinq fois aussi long que large," and so making the body much narrower than in A. glutinis. M. Davaine believes them to be distinct species, and says, in a letter lately received, "D'après quelques recherches que j'ai faites, il y a quelques années, je pense que les vers de la colle de pâte viement de la terre, où elles rivent normalement dans les grains ou dans les racines qui contiemnent de la féculc."

All my attempts to procure these animals in ordinary wheaten paste have been unsuccessful, though I have taken every precaution to ensure the purity of the flour.

## 3. A. fluviatilis, Hemprich \& Ehrenberg.

Ferskounds Aal, Strackker, in Nye SammI. of Dansk. Vid. Selsk. Skr. iii. D. 33.
? Corculum vermiculo simile, Linné, Amœn. Acad. (mundus invis.).
Vibrio anguillula, $\gamma$. Anguillula fluviatilis, Müller, Anim. Infusor. 65. tab. ix. 5-8. (Reliqua synon. Mülleri vel incerta, vel ad Anguillulam tritici aut Lumbrici pertinent.)
Vibrio fluviatilis, Bory, in Encycl. Méth. 1824, 1. 777 , tab. iv. 20-23.-Idem in Dict. Class. d'Hist. Nat. xvi. 586 (les Oxyurides), tab. v. A, 39.-Blainville in Dict. des Sc. Nat. lvii. 537, ct lviii. 71.

Anguillula fluviatilis, IIcmprich et Ehrenberg, Symb. Phys. Phỵtoz. Entoz. tab. ii. 8 et 13 (libyca).-Ehrenberg, Organ. Syst. u. geogr. Yerb. d. Infusionsth. 1830, pp. 10, 15, 68, 105, tab. vii. 5 ; ejus Infusionsth. S2.-Dujardin, Hist. Nat. des Helminthes, 244.-Diesing, Syst. Helminth. ii. 130.
"Cauda recta brevi conica, subulata, baseos crassitie triplo quadruplove longior.
Longit. $\frac{1}{8}-\frac{1}{3}{ }^{\prime \prime \prime}$."-Dicsing.
"Corpus subtilissime transverse striolatum, subannulatum. Tubus cibarius hine ore illine ano terminatus, simplex, cum strictura cardiaea. Os terminale, anus ad caude basim lateralis. Teminarum apertura genitalis in medio eorpore. Uterus bicornis. Ova ovata. Fotus maturus bis complicatus. Feminæ maribus majores. Maris penis simplex nee vaginatus. Ita in speciminibus Berolinensibus."-Ehrenberg, Symb. Phys. l.c.
"Hab. In aqua dulci in Dania (O. F. Meilller).—Tnter Confervas, in aqua Oascos Jovis Hammonis Sirre, nee non pagi Tor in Arabia.-In Sibiria prope Tobolsk, in montibus altaicis prope Semimogorsk et prope Berolinum (Ehrenberg)."—Diesing.

The few definite characters given abore, such as "corpus subtilissime transverse striolatum" and "uterus bieornis," seem pretty positively to indicate that this species does not in reality belong to the genus Anguillula. Any free Nematodes other than the "paste-" or " vinegar-eels," or the Tylelenchus tritici, which have been aecidentally met with or referred to by most English writers hitherio, have been provided with the convenient name of Anguillulce fluwialitis; so that the altogether doubtful animal to which this eognomen rightly belongs has been invested with a pseudo-popularity for which, in all probability, it could make but little valid claim. It may perhaps belong to the genus Plectus, judging from the eharacters above mentioned, as well as the abundance and wide distribution of the animals of this type.
4. A. inflexa, Hemprieh \& Ehrenberg.

Anguilluta inflexa, Hemprich et Ehrenberg, Symb. Phys. Phytoz. Entoz. tab. i. 12 (Vibrio fluviatilis niloticus).-Dujardin, Hist. Nat. des Helminthes, 244.—Diesing, Syst. Helminth. ii. 131.
"Cauda longiore subulata, maris inflexa, baseos crassitie plus decuplo longiore, corporis fere octavam partem equante. Longit. mar. $\frac{1}{8}-\frac{1}{4}{ }^{\prime \prime \prime}$, crassit. $\frac{1}{64}$; fem. $\frac{1}{4}-1^{\prime \prime \prime}$, crassit. $\frac{1}{38}{ }^{\prime \prime \prime}$.
"Hab. Inter Confervas aquæ Nili in provincia Dongola Nubie eandem formam cepisse monet eel. Ehrenberg, quam scrius in aqua salsa prope Petropawlofsk in Sibiria et prope Berolinum reperït."

## 7. TRIPYLA ${ }^{1}$, Bastian.

Gen. Char. Body tapering at extremities. Caudal sucker large, well developed. Integument thick, having well-marked transverse striæ, with lateral and ventral pores; setæ none (?); cephalic papillæ present or absent. Pharyngeal cavity none. EEsophagus cylindrical, distinctly muscular; postcrior part scparated by a constriction, but not containing any valvular apparatus. Intestine rather sparsely covered with coarse granules, their arrangement in cells not being visible. Valva at about the middle of body. Uterus bifid, segments symmetrical. Spicules of an elongated cuneiform shape. Accessory piece posterior, very small. Lateral canals indistinct, having a faintly granular appcarance. No regular ventral duct, but three large integumental canals in same region, close to anterior extremity.
Movements active, often forming into a coil when touched.

1. T. glomerans, n. sp. (Pl. IX. figs. 16, 17.)

Male, length $\frac{1}{11}{ }^{\prime \prime}$, breadth $\frac{1}{256^{\prime \prime}}$.
External Characters.-Body whitc, cylindrical, tapering slightly forward, but more backwards, where it gradually narrows to the well-developed sucker. Head bluntly

[^19]rounded; no papille. Integument thick; transverse strice very distinct, $\frac{1}{7500}{ }^{\prime \prime}$ apart, laving lateral pores and three larger equidistant channcls opening through anterior part of rentral recgion.

Esophagus about $\frac{1}{5}$ th of total length; constricted portion $\frac{1}{1428}$ " long. Intestine sparsely covered with light-coloured fat-particles. Anus $\frac{1}{69}$ " from postcrior extremity. Spicules cmnciform, slightly curved, $\frac{1}{333}{ }^{\prime \prime}$ long. Accessory piece small and indistinct, somewhat triangular.

Female, not seen.
Hab. 'Mud from freshwater ponds, Falmouth ; and Easthampstead, Berks.
2. T. salsa, n. sp. (Plate IX. figs. 18, 19.)

Female, length $\frac{1}{8}$ ", breadth $\frac{1}{208}$.
External Characters.-Body cylindrical, tapering much the same as last. Head more rounded, provided with two papillæ, lateral (?). Integument thinner; transverse striæ not so well marked.

Esophagus $\frac{1}{6}$ th of total length; constricted portion large, $\frac{1}{83}{ }^{\prime \prime}$ long. Intestine covered with rather large, light-coloured fat-particles. Aure $\frac{1}{65}$ " from postcrior extremity. Tutlea posterior to the middle of body. Uterus bificl. Lateral canals indistinct, $\frac{1}{1000}$ " broad.

Male, not scen.
Hab. Abont the roots of Rüppia maritina, brackish mater', Swanpool, Falmouth.

## 8. DIPLOGASTER, Max Schultze.

Gen. Char.-Body tapering at extremities, especially at posterior. Caudul suctier very small, scarccly recognizable. Integument having longitndinal and also delicate transverse markings ; setæ none (?) ; papillæ none (?); small lateral cervical markings. Pharyax emp-shaped, laving two homy valvular plates at the bottom. OEsophagus having a well-marked muscular swelling about its middle; canal of anterior half indicated by three bright lines; not so, however, posterior to muscular swelling. Intestine moderatcly covered with fat-particles, having a more or less tessellated appearance. Tulva about the middle of body. Uterus bifid, segments symmetrical. Spicules two, cmrved, barbed. Accessory piece single, posterior, casily recognizable. Ventrat excretory gland wanting. Lateral canals . . .
Movements very active.

1. D. fictor, 11. sp. (Plate X. figs. 71-73.)

Female, length $\frac{1}{15}$ ", breadth $\frac{1}{500}{ }^{\prime \prime}$.
External Characters.-Body white, slender, tapering very slightly anteriorly, but considerably posteriorly, where it gradually tapers to a fine point; sucker not recognizable. Head truncate, unarmed. Integument with longitudinal strie $\frac{1}{10000}{ }^{\prime \prime}$ apart, and almost imperceptible transverse strix $\frac{1}{20000}{ }^{\prime \prime}$ apart.

Pharyngeal cavity $\frac{1}{3333}$ " deep. Esophagus $\frac{1}{6}-\frac{1}{7}$ th of total length, swelling in the middle, $\frac{1}{81 t^{\prime \prime}}$ long. Intestinal cells containing a moderate number of light-coloured par-
ticles, tessellated. Anus $\frac{1}{125}$ " from posterior extremity. Vulva slightly anterior to middle of body.

Mrale rather shorter, more slender, and transparent breadtl being $\frac{1}{833} 3^{\prime \prime}$. Anus $\frac{1}{1+3}{ }^{\prime \prime}$ from posterior extremity. Spicules curved, $\frac{1}{1111^{\prime \prime}}$ long. Accessory portion well marked, $\frac{1}{1666^{\prime \prime}}$ long.

Hab. With Diatomaceæ from the decaying lower leaves of Myyriophyllum verticillatum, pond, Bagsliot.

Has a hahit, when touched, of straightening itself, and remaining perfectly still for a fer seconds.
2. D. asbus, n. sp. (Plate X. figs. 74, 75.)

Female, length $\frac{1}{42^{\prime \prime}}$, breadth $\frac{1}{555}{ }^{\prime \prime}$.
Exterval Characters.-Body white, rather stout, tapering very slightly forwards, but considerably backwards, where it terminates in a short filiform extremity. Head bluntly rounded. Integument having longitudinal and transverse strix.

Plaryngeal cavity large, cup-shaped, with valvular plates at bottom. Esophayus $\frac{1}{6}$ th of total length, having the usual median swelling $\frac{1}{1250}{ }^{\prime \prime}$ long. Intestine slightly covered with light-coloured fat-particles. Anus $\frac{1}{28} 5^{\prime \prime}$ from posterior extremity. Vulve in middle of body.

Mrale, not seen.
Hab. About rootlets of wheat from sandy soil, Broadmoor, Berks.
3. D. filiformis, n. sp. (Plate X. figs. 76-78.)

Female, length $\frac{1}{41}{ }^{\prime \prime}$, breadth $\frac{1}{1000}{ }^{\prime \prime}$.
External Characters.-Body white and rery slender, tapering very slightly anteriorly, but very considerably behind, where it terminates in a long filiform extremity. Integument witl longitudinal strix $\frac{1}{10000^{\prime \prime}}$, and transerse $\frac{1}{20000 "}$ apart.

Pharyngeal cavity cup-shaped, with horny plates at bottom. Esophayus about $\frac{1}{6}$ th of total length, with usual sweliing of mid portion. Inlestine covered sparingly with light-coloured granules. Auus $\frac{1}{222^{\prime \prime}}$ from posterior extremity. Vulva at middle of body.

Male, length $\frac{1}{44} \mathbf{t}^{\prime \prime}$, breadth $\frac{1}{1250 "}$.
Anus $\frac{1}{180} 0^{\prime \prime}$ from posterior extremity, which is longer than in female. Spicules could not be detected, though the genital tube could be readily seen in front of the anus.

Hab. Same as last.
I could detect no sucker with the microscope, though I feel confident that such a structure, however minute, must exist, since $I$ have seen the male of this species swaying violently about in all directions, the extremely fine extremity of thread-like tail only remaining in a fixed position.

## 4. D. micans, Max Schultze.

Hab. Unknown.

## 9. PLECTUS ${ }^{1}$, Bastian.

Enoplus?, Dujardin.
Gen. Char. Body tapering at either extremity. Caudal sucker pointed. Integument having transverse strix; sete or papille around head occasionally present. Pharyngeal cavity slightly dilated at first, then narrow and elongated; commencement of cesophagus marked by $4-6$ bright slightly curved lines. Esophagus cylindrical, but having an oval swelling posteriorly, in which is contained a horny valvular apparatus of the same shape. Intestinal cells mostly containing rather few palecoloured fat-particles. Trulve about middle of body. Uterus bifid; segments short, symmetrical. Onarian tubes short, broad, reflexed. Spicules
Excretory gland having linear duct twisted round osophagus, and opening nearly opposite its middle in length. Lateral vessels with distinct double outline, commencing at latcral circular markings of integument, opposite pharyngeal region of body, and terminating posteriorly.
Movements active.
I have little doubt that the Nematoids found by Spallanzani in tufts of moss, and ascertained lyy him to possess the remarkable power of resuming all the functions of life after prolonged periods of torpidity and more or less complete desiccation, belonged to this genus; and it secms probable also that Dujardin, in his obscrvations, has confounded together such forms as the members of this, and those corresponding to the type of his genus Rhabditis. I have found individuals of this genus in specimens of lichen brought by my fricud Howard Fox, Esq., from Norway, and which had been lying in his cabinct for four years; none of the animals, however, exhibited signs of life after prolonged immersion in water. In these specimens of lichen, as well as in the fresh patches of Parmelia parietina which I have examined in this country, I have found the Nematoids associated with two or three species of Rotifera, as well as the peculiarly slow-moring little animals designated "Sloths" by the Abbe Spallanzani ${ }^{2}$, and belonging, I believe, to the genera Emydium and Beacrobiohers-all possessing about the same tenacity of life.

## 1. P. parietinus, n. sp. (Plate X. figs. 79, 80.)

Female, length $\frac{1}{2} 3^{\prime \prime}$, breadth $\frac{1}{400}{ }^{\prime \prime}$.
Externat Characters.-Body white, tapering at cither extremity, more especially posteriorly. Head truncate, provided with a circle of four large rounded papillæ. Integumental strix transrersc, $\frac{1}{18000^{\prime \prime}}$ apart.

Pharyngeat cavity $\frac{1}{6+3}{ }^{\prime \prime}$ long. Wesophagus about $\frac{1}{4}$ th of total length. Intestinal cells indistinetly tessellated, containing rather few light-coloured fat-particles. Amus $\frac{1}{250}{ }^{\prime \prime}$ from posterior extremity. Tulce at middle of body. Excretory ventral gland having twisted duct opening at $\frac{1}{13 \frac{1}{3}}{ }^{\prime \prime}$ from anterior extremity. Lateral vessels commencing at

[^20]circular markings of integument $\frac{1}{1250}{ }^{\prime \prime}$ from anterior extremity, by narrowed portions $\frac{1}{1333}$ " in length, with delicate vessels from $\frac{1}{10000}{ }^{\prime \prime}$ to $\frac{1}{5000}$ " broad.

Dale, not seen.
Mab. Hemispherical tufts of moss (Tortula) on the roofs of old houses or walls, and also from the yellow lichen (Parmelia parietina), Broadmoor, Berks.
2. P. cirratus, n. sp. (Plate X. figs. S1, 82.)

Femate, length $\frac{1}{16}$ ", breadth $\frac{1}{43} \frac{1}{5}^{\prime \prime}$.
External Characters.-Body slender, tapering at both extremities, especially posteriorly. Head rounded, provided with a cirele of four very short cirri, about $\frac{1500}{15000}$ long. Integumental strie $\frac{1}{20000^{\prime \prime}}$ apart, transverse.

Pharyngeal cavity slightly dilated at first, then long and narrow, length being about $\frac{1}{666}{ }^{\prime \prime}$. Esophagus less than $\frac{1}{4}$ th of total length. Intestinal cells not well marked, and containing but few fat-particles. Auus $\frac{1}{15 \frac{1}{4}}$ from posterior extremity. Tulva slightly posterior to the middle of body. Duct of excretory gland opening opposite middle of œsophagus. Lateral vessels commencing at $\frac{1}{1250}{ }^{\prime \prime}$ from anterior extremity.

Male, not seen.
Mab. About lower decaying leaves of Myriophyllum verticillatum, pond, Bagshot.
3. P. tevuis, n. sp. (Plate X. figs. 83, 84.)

Femule, length $\frac{1}{33}{ }^{\prime \prime}$, breadth $\frac{1}{1000}{ }^{\prime \prime}$.
E.cterwal Characters.-Body white, slender, tapering very slightly anteriorly and posteriorly. Head rounded, naked. Integumental striæ transverse, almost imperceptible, $\frac{1}{30000}{ }^{\prime \prime}$ apart.

Pharyngeal cavity $\frac{1}{7 \overline{0}}{ }^{\prime \prime}$ long. Esophagus more than $\frac{1}{4}$ th of total length. Intestinal cells containing but few light-coloured fat-particles. Anus $\frac{1}{2} \frac{1}{70}$ from posterior extremity. Trulva at the middle of body. Excretory duct opening at $\frac{1}{188}$ " from anterior extremity. Lateral ressels commencing at circular markings $\frac{1}{2000}{ }^{\prime \prime}$ from anterior extremity.

Mirle, not seen.
IIab. In transparent gelatinous matter, with Vorticella chlorostigma, from the shady margin of a lake, Sandhurst.
4. P. velox, n. sp. (Plate X. figs. 85, 86.)

Female, length $\frac{1}{26}{ }^{\prime \prime}$, breadth $\frac{1}{50} 0^{\prime \prime}$.
External Characters.-Body white, tapering anteriorly and posteriorly, especially in the latter direction. Head rounded, unarmed. Integumental striæ transverse, $\frac{1}{20000}{ }^{\prime \prime}$ apart.

Pharyngeal cavity $\frac{1}{1000^{\prime \prime}}$ long. Gesophaghs $\frac{1}{4}$ th of total length. Intestinal cells indistinetly marked, containing very few light-coloured particles. Auns $\frac{1}{250}$ " from posterior extremity. Vulve slightly posterior to the middle of body. Excretory duct opening at $\frac{1}{182}{ }^{\prime \prime}$ from antcrior extremity. Lateral vessels commeneing at $\frac{1}{1666}$ "from anterior extremity.

Mrale, not seen.
Mab. From moss with T. Davaineii, Falmouth.
5. P. acuminatus, n. sp. (Plate X. figs. S7, 88.)

Female, length $\frac{1}{30}$ ", breadth $\frac{1}{666} \sigma^{\prime \prime}$.
Extemul Characters.-Body white, tapering at both extremities, especially at posterior, which is narrow and acmminated. Head rounded, unarmed. Integumental strix transverse, $\frac{1}{20000}{ }^{\prime \prime}$ apart.

Pharyngeal cavity narrow, clongated, $\frac{1}{111}$ long. FEsophagus about $\frac{1}{4}$ th of total length. Intestinal cells very indistinct, from their containing rery few light-coloured fat-particles. Anus $\frac{1}{280}{ }^{\prime \prime}$ from posterior extremity. Tule a in middle of body. Exeretory duct opening opposite the middle portion of ossophagus. Lateral ressels commencing in the usual way, at $\frac{1}{2000}{ }^{\prime \prime}$ from anterior extremity.

Mrale, not seen.
ITub. In moss.
6. P. paryus, n. sp. (Plate X. figs. 89, 90.)

Female, length $\frac{1}{47}{ }^{\prime \prime}$, breadth $\frac{1}{1000}{ }^{\prime \prime}$.
Erternal Characters.-Body white, tapering anteriorly and posteriorly, especially in the latter direction. Head romded, marmed. Strix transrerse, $\frac{1}{30000}{ }^{\prime \prime}$ apart.

Phargngeal cavity $\frac{1}{1 \pm 25}{ }^{\prime \prime}$ long. Esophagus about $\frac{1}{4}$ th of total length. Intestinal cells rery indistinct. Anus $\frac{1}{500}$ " from postcrior extremity. Trulea at middle of body. Eacretory dluct opening opposite middle of oesophagus. Lateral vessels commencing at integumental circles $\frac{1}{2000}$ " from anterior extremity.

Mlale, not seen.
ILab. With $P$. velox, from moss covering stone lying in a freshwater stream, Falmouth.
7. 1’. tritici, 11. sp. (Plate X. figs. 91, 92.)

Female, length $\frac{1}{10}$ ", breadth $\frac{1}{154} 4^{\prime \prime}$.
External Characters.-Body white, tapering slightly anteriorly, but more posteriorly. Head rounded, unarmed. Transverse striee readily seen, $\frac{1}{15000}{ }^{\prime \prime}$ apart.

Phanyngeal cavity $\frac{1}{66} \overline{6}{ }^{\prime \prime}$ long. Wisophagus only $\frac{1}{8}$ th of total length. Intestinal cells containing few light-coloured fat-particles. Anus $\frac{-1}{2} \frac{1}{5}{ }^{\prime \prime}$ from posterior extremity. Trelece about the centre of body. Everctory duct opening at $\frac{1}{133}{ }^{\prime \prime}$ from anterior extremity. Lateral vessels commencing in usual way, at $\frac{1}{1606}$ " from head.

Male, not scen.
IIrib. Between the lower part of the sheaths of leaves of wheat-stalks taken from a stubble-ficld with sandy soil, Broadmoor, Berks.
S. P. granulosus, n. sp. (Plate X. figs. 93, 91.)

Femate, length $\frac{1}{2} \frac{1}{0}$, breadth $\frac{1}{550} 0^{\prime \prime}$.
External Characters.-Body opaque-white, narrow at anterior extremity, but not tapering in either direction so much as usual. Head rather truncate, unarmed. Strix transverse. Whole body much obscured by a number of rather large colourless granules.

Pharyngeal cavity $\frac{1}{1+28^{\prime \prime}}$ long. Cesophagus $\frac{1}{5}$ th of total length. Intestinal cells indistinct. Anus $\frac{1}{40 \bar{\prime}}$ from posterior extremity. Tulva about middle of body. Excretory duct opening near middle of cesophagus. Lateral cessels commencing at $\frac{1}{1250}$ " from anterior extremity.

DIcle, not seen.
Ifab. About the rootlets of oats from sandy soil, Broadmoor, Berks.
9. P. fusiformis, n.sp. (Plate X. figs. 95, 96.)

Female, length $\frac{1}{27} 7^{\prime \prime}$, breadth $\frac{1}{526}{ }^{\prime \prime}$.
Esternal Charecters.-Body tapering considerably, both anteriorly and posteriorly. Head truncate, leaving no papillæ, but provided with four small sctr. Integument with transrerse strixe, $\frac{1}{20000}{ }^{\prime \prime}$ apart.

Pharyngeal cavity long and narow. Esophagus $\frac{1}{4}$ th of total length. Intestinal cells containing few light-coloured granules. Auus $\frac{2}{50}$ " from posterior extremity. Vulva slightly posterior to the middle of body. Excrelory duct opening opposite commencement of posterior $\frac{1}{3}$ rd of osophagns. Lateral ressels commencing at $\frac{1}{1250}{ }^{\prime \prime}$ from anterior extromity.

Mule, not scen.
IIct. Tuft of bright-green moss from thatehed roof, Sandhurst.
10. P. rivalis, Dujardin.

Enoplus rivalis, Dujardin, IIst. Nat. des IIelminthes, p. 235.
"Corps blane, filiforme, aminci on arrière, long de $2^{\text {mm. }} 23$, large de $0^{m m}$, quarante fois aussi long que large; tête large de $0^{m m \cdot 28}$, trouquée en avant et hérissée de quelques soies roides; bouche armée intériourement de trois pièces ćtroites, arquées, qui sc réunissent à l'entrée de l'ocsophage; oesophage musculeux, cylindrique, longrg de $0^{\text {mm. }} 34$, terminé par un petit ventrieulc, que précède un léger étranglement.
"Femelle longue de $2^{\text {mm. }} 23$ à $3^{\text {mun }}$, large de $0^{\text {mm. }} 055$ ì $0^{\text {mm. }} 00$, ì queuc insensiblement amincic, et terminée par un petit renflement d'où part une soie courte; vulve située un peu en avant du milicu; ntérus divisé en deux branches opposécs, qui, arrivées à $0 \cdot \mathrm{~mm} 30$ ou $0^{\mathrm{mma}} \cdot 45$ en avant et en arrière de la valve, se recourbent pour se continuer avec les ovaires correspondants qui reviennent de part et d'autre jusqu'au-dessus de la vulve commes deux larges tubos contenant une pile d'œufs comprimés; œufs elliptiques, longs de $0^{\mathrm{mm}} \cdot 06$."
"Je l'ai trouvé dans l'eau de la Scine, à Paris, et dans l'ean courante d'une fontaine à Blagnac, près de Toulouse, ainsi que dans la Vilaine, à Rennes."

I cannot feel certain about the genus to which this animal belongs, but have placed it in that to which the nature of its oesophagus allies it most: it is evidently not an Enoplus.

## 10. APHELENCHUS ${ }^{1}$, Bastian.

Gen. Char. Body tapering more or less at extremities; posterior pointed, or blnnt and rounded. Caudal sucker, if present, very small. Integument having transverse

[^21]VOL. EXV.
striie; sete none; papillæ none (?). Pharyngeal cavity modified into a simple hollow exscrtile (?) spear. Cisophagus having a distinct rounded muscular swelling at termination; lumen of oesophagus thread-like. Intestine not distinctly defincd, from extremely small number and colourless nature of hepatic granules; internal or intestinal tube proper often very distinct. Trulea at about the commencement of posterior third of hody. Uterus unsymmetrical. Spicules simple, slender, curved. Accessory piece nonc. Exceretory glend having rather rigid, curved duct, opening posterior to junction of ocsophagus with intestinc. Lateral vessels
Movements sluggish.
In a member of this genus, Aphelenchus parietimus, I have rery frequently met with certain bodies such as I have also recognized once in a species of the genus Plectus, and two or threc times in Tyleuchus Davainio. In these specimens a remarkable condition has been met with, in which, beneath the integument of the whole animal, in the general carity of its body, and, in A. parietinus, also within the intestinal canal, there have becn a large number of small spherical cellular bodies, simply granular-looking in this last species, but in the two others presenting the appcarance of small hyaline cells, each of which contains a large, highly refracting, spherical central body.or nucleus. What is their precise nature secms difficult to say at present. That their occurrence is exceptional, as well as other considerations, rather inclines me to the opinion that they are distinct organisms, perhaps belonging to the family Gregarinide, "a group of animals of very simple structure, met with in the intestine and other parts of many insects and Annelids" ${ }^{1}$. Whatever be their nature, they seem to correspond pretty closely to what Dujardin and other helminthologists have obserred in certain parasitic Nematoids. Speaking of Ascuris trumata, this distinguished naturalist says ${ }^{2}$ : -"Tontes les cavités interviscérales sont occupées, chez les mâles comme chez les femelles, par des vésicules indépendentes qui ont attiré l'attention de tous les helminthologistes, mais dont on n'a point indiqué la nature. Il semble qu'on ne peut dire autre chose, sinon que ce sont des productions prasites analogues aux acéphalocystes des mamuifères." And a little further on (p. 220), after describing' A. maculose from the Common Pigeon, speaking of Rudolphi's obscrrations, he adds:- " Il signale aussi dans le tégument des corpuseles orbiculaires diaphanes, beaucoup plus grands que les ocufs, et qui rendent le corps presque tacheté, d’où le nom spécifique de maculosa. En disséquant ces ascarides, on voit en effet flotter avec les cufs, dans le liquide, des résicules larges de $0^{\mathrm{mm}} \cdot 14$ à $0^{\mathrm{mm}} \cdot 30$, sur la nature desquelles il est difficile d'être fixé. Ce sont les mêmes que l'on trouve aussi dans l'ascaride du Perroquet, et que je crois analogucs à des acéphalocystes."

1. A. AYEN.e, n. sp. (Plate X. figs. 97, 9S.)

Female, lengeth $\frac{1}{20}{ }^{\prime \prime}$, breadth $\frac{1}{454}$ ".
External Characters.-Body white, tapering very slightly at cither extremity, hoth of
${ }^{1}$ "On our Present Knowledge of the Gregarinide," Sc., by E. Kay Lankester, Journ. of Microsc. Soc., new scries, rol. iii. p. 83.
= 1List. Nat. des llelminthes, p. 215.
of which are rounded. Head having no setæ or papillæ. Caudal sucker none. Integumental strix transverse, $\frac{\frac{1}{10000}}{}$ " apart, easily visible.

Dart $\frac{1}{1666}{ }^{\prime \prime}$ long, simple, not knobbed at the base. Esophagus $\frac{1}{14}$ th only of total length, having' a globular and distinctly muscular terminal swelling, $\frac{1}{1000}$ " broad. Intestinc, portion next cesophagus very indistinct; gramules seattered, rather coarse and colourless. Anus $\frac{1}{606}$ " from posterior extremity. Fulva posterior to commencement of hinder third of body, $\frac{1}{77}$ " from posterior extremity. Excretory duct opening slightly posterior to commeucement of intestine.

Male, not seen.
Hab. Between the lower sheaths of leaves of oats from stubble-field, Broadmoor, Berks.
2. A. villosus, n. sp. (Plate X. figs. 99-101.)

Female, length $\frac{1}{51} 1^{\prime \prime}$, breadth $\frac{1}{1000}$ ".
External Characters.-Body tapering very slightly anteriorly, but narrowing to a point posteriorly ; shaggy from the presence of a lair-like fungus (?) growing on integument. Sucker (?). Head rounded, naked. Striee transverse.

Spear $\frac{1}{2500} "$ long, simple. Esophagus $\frac{1}{10}$ th of total length; terminal muscular swelling $\frac{1}{2000}$ " in diameter. Intestine sparingly covered with granules. Anus $\frac{1}{1000}$ " from posterior extremity. Vulva at commencement of posterior third of body. Excretory duct opening at $\frac{1}{200}$ " from anterior extremity.

Mrale, length $\frac{1}{60}{ }^{\prime \prime}$, breadth $\frac{10-\overline{\prime \prime}}{100}$.
Anus about the same position as in female. Spicules $\frac{1}{1666}{ }^{\prime \prime}$ long, narrow, curved, slightly knobbed at upper extremities.

Hab. With Plectus parictinus, in tufts of moss (Tortula), Broadmoor, Berks.
3. A. Parietinus, n. sp. (Plate X. figs. 102, 103.)

Female, length $\frac{1}{36}{ }^{\prime \prime}$, breadth $\frac{1}{8} \frac{1}{3} 3^{\prime \prime}$.
External Characters.-Body pellucid, tapering very slightly forwards, but to a point backwards, where it appears to terminate in a sucker. Head almost truncate. Transverse strix $\frac{1}{30000}{ }^{\prime \prime}$ apart.

Spear simple, $\frac{1}{2000}$ " long. Cesophagus $\frac{1}{11}$ th of total length; terminal swelling $\frac{1}{2000}{ }^{\prime \prime}$ in diameter. Intestine covered by a fer scattered granules; internal tube well seen. Anus $\frac{1}{770}{ }^{\prime \prime}$ from posterior extremity. Tulva at commencement of posterior third of body. Excretory duct opening at $\frac{1}{266}$ " from anterior extremity.

Male, not seen.
Hab. With Plectus parietinus, in patches of yellow lichen (Parmelia parietina), Broadmoor, Berks.
4. A. pyri, n. sp. (Plate X. figs. $103 a-103 c$.)

Female, length $\frac{1}{43}{ }^{\prime \prime}$, breadth $\frac{1}{1250}{ }^{\prime \prime}$.
External Characters.-Body naked, pellucid, filiform, tapering slightly at both extremities; sucker doubtful. Head narrowed, rounded. Integrmental striæ not visible.

Spear simple, $\frac{1}{2500}$ " long. Esophagus $\frac{1}{10}$ th of total length; terminal swelling large, $\frac{1}{2000}$ " in diameter. Intestine very sparingly covered with a few light-coloured granules.

Anus $\frac{1}{8} 8^{\prime \prime}$ from posterior extremity. Excretory duct opening opposite cesophageointestinal junction (\%). Laterat vessels straight, not convoluted. Trulva at commencement of posterior third of body.

Alule, about same size as female.
Auns $\frac{1}{666}$ from posterior extremity. Spicules solitary, large, curved, $\frac{1}{1250 "}$ long, somewhat knobbed at upper extremitics.

Ital. Found by Dr. Cobbold in the decaying pulp of pears ${ }^{1}$.

## 11. CEPIIALOBUS ${ }^{2}$, Bastian.

Gen. Cifar. Body tapering slightly at extremities. Head somewhat lobed. Caudal suclier none. Integument haring well-marked transverse strix; no seta or papilla. Pharyngeal cavity indistinet. EEsophagus narrowed prerionsly to its termination in a rounded swelling containing a simple valvular apparatus. Intestine sparingly corered with light-coloured fat-particles; intestinal tube proper easily seen. Tulea at commencement of posterior third of body. Uterus unsymmetrical. Spicules slightly curved, somewhat fusiform. Accessory piece posterior, median, easily recognizable. Excretory rentral gland having a somewhat rigid, eurved duct, opening opposite posterior third of osophagus. Lateral ressels straight; terminations uncertain.
Morements slugrish.

1. C. persegnis, n. sp. (Plate X. figs. 104-106.)

Female, length $\frac{1}{34}{ }^{\prime \prime}$, breadth $\frac{1}{555}{ }^{\prime \prime}$.
External Churacters.-Body white, tapering slightly anteriorly, and also posteriorly, where it is blunt and rounded. Head bilobed. Strixe transrerse, distinct, $\frac{1}{10000 " ~ a p a r t . ~}$
 few light-coloured hepatic particles. Auus $\frac{1}{625}{ }^{\prime \prime}$ from posterior extremity. Trulve at posterior third of body. Eucretory duct opposite narrowed portion of oesophagus.

[^22]Male, longer than female, but narrower; length $\frac{1}{31}{ }^{\prime \prime}$, breadth $\frac{1}{625}{ }^{\prime \prime}$.
Auns $\frac{1}{5} \frac{1}{5}{ }^{\prime \prime}$ from posterior extremity, which is altogether narrower than in the female. Spicules not distinctly visible, slightly eurved, $\frac{1}{1000}{ }^{\prime \prime}$ long. Accessory piece more distinct, straight, $\frac{1}{2000}{ }^{\prime \prime}$ long.

Hab. Between the sheaths of leaves of wheat-stalks, from stubble-ficlds, Broadmoor, Berks.
2. C. striatus, n. sp. (Plate X. figs. 107, 108.)

Femule, length $\frac{1}{45}$ ", breadth $7 \frac{1}{4}^{\prime \prime}$.
Extemal Cherracters.-Body white, tapering anteriorly and posteriorly; posterior extremity proportionally narrower than in last species. Head bilobed. Strix transverse, very distinct, $\frac{1}{10000}{ }^{\prime \prime}$ apart.

Esophagus $\frac{1}{4}$ th of total length. Intestine sparingly covered with light-coloured hepatic particles. Amus $\frac{1}{500}{ }^{\prime \prime}$ from posterior extremity. Tulce slightly anterior to posterior third of body. Excretory duch readily visible, $\frac{1}{270}$ " from anterior extromity.

Mrale, not seen.
Hab. Sandy soil, about rootlets of wheat, Broadmoor, Berks.

## 12. 'IYLENCIIUS ${ }^{1}$, Bastian.

-Vibrio, Müller; Anguillula, Hemprieh \& Ehrenberg; Rhabditis, Dujardin.
Gen. Char. Body tapering at extremities. Caudel sucker, nonc. Integument having distinet transrerse strice; no setac or papillec. Pharym. modified into an exsertile spear, with a trilobed basc. Esophagus laving a rounded muscular swelling about its middle; canal thread-like, continuous with spear, most distinct in anterior half. Intestine rather indistinet, sparingly covered with coarse, colourless fat-granules; intestinal tube proper easily recognizable. Tiulva considerably posterior to middle of body. Uterus unsymmetrical; traces of abortive posterior median segment. Spicules rather stont, gencrally united to the posterior accessory piece. Caudal alce in males membranous and unsupported by rays. Duct of excretory rentral gland lincar, rigid, and curved at termination. Lateral vessels distinct, oceasionally flexuous; terminations uneertain.
Movements sluggish.
The tenacity of life possessed by the members of this genns, as well as those of Plectus, Aphelenchus, and Cephalobus, is a most remarkable peeuliarity, which may perhaps, in some slight degree, be accounted for by the strueture of the integument, which seems calenlated to enable them to resist actual desiceation and the evaporation of the natural moisture from their tissues for a much longer period than could bo the case with other species, whose tegumentary organs are construeted upon a different principle. I have demonstrated by actual microseopical obscrvation the presence of a plurality of integumental pores in the species of many gencra; and all these amimals (as well as many others, in which such pores have not been recognized, owing to the smallness of their size and the intrinsic difficulty of the investigation), when immersed in a dense medium,

[^23]such as glycerine, almost immediately shrivel up, owing to the rapid osmosis of fluids from within; or, when placed in a colouring solution of magenta, the whole of their tissucs become speedily and uniformly dyed of the same lue. But if a species of either of these four land and freshwater genera be submitted to the same conditions, they exhibit totally different results: they will continue to more about in glycerinc for about fifteen or twenty minutes before commencing to shrivel, and will remain nearly as long in a strong magenta solution with the body uncoloured, save for a very short distance from the mouth and anus. Both these experiments seem to indicate that there is not such a free communication through the integument, in these species, between tlie internal parts of the body and the external medinm, and that the integument is hermetically sealed, excepting at such natural apertures as mouth, anus, and vulva. This property may be one of the factors concerned in producing the extraordinary tenacity of life ohserved in these animals,-one of small significance, howerer, when we attempt to explain the very prolouged periods of suspended animation, extending over a series of years. This power of remaining for lengthened periods to all intents and purposes dead, inasmuch as there is a negation of all that we are apt to consider as the characteristic attributes of life, sare that, like seeds, they still retain the potentiality of resuming their rital manifestations under the influence of suitable extcrnal conditions, must, doubtless, depend upon inherent peculiarities of the tissues themsetres, beyond the reach of detection by optical instruments even of the lighest power.

Another peculiarity of these four genera is the fact that they all possess the exeretory gland in a modified condition, though I have not met with it at all in any of the other land and and freshwater types.

1. T. Davalnil, n. sp. (Plate X. figs. 100-111.)

Female, length $\frac{1}{27}{ }^{\prime \prime}$, breadth $\frac{1}{770} 0^{\prime \prime}$.
Erternal Characters.-Body tapering at both extremitics, especially towards posterior. Head narrowed, truncate. Integument thick; strixe transverse, distinct, $\frac{1}{1500}{ }^{\prime \prime}$ apart.

Spear large, $\frac{1}{1428}{ }^{\prime \prime}$ long. Esophagus $\frac{1}{5}$ th of total length ; posterior part, bohind median swelling, gradually widening. Intestine not very distinct from body generally, being obscured by large, coarsc, colourless granules. Auzs $\frac{1}{200}$ " from posterior cxtremity. Tulca considerably behind middle of body, $\frac{1}{40}$ " from anterior extremity. Exeretory duct distinct, opening opposite posterior part of osophagus, and extending backwards for about $\frac{1}{250} 0^{\prime \prime}$, where it terminiates in an oroid sac.

Male, same size as female.
Esoplugus shorter. Amus $\frac{1}{182}{ }^{\prime \prime}$ from posterior extremity. Spicules rather narrow, $\frac{1}{81} \mathbf{i}^{\prime \prime}$ long; accessory piece of about half this length. Alse transparent, narrow, extending, on either side, from slightly above to a little below the anus.

Mat. From sheet of moss corering large boulder lying in a freshwater stream, Falmoutl.

Female ${ }^{1}$, length $\frac{1^{\prime \prime}}{}{ }^{\prime \prime}$, breadth $\frac{1}{117^{\prime \prime}}$.
Extermal Cheracters.-Body yellowish white, tapering rather abruptly forwards, but nore gradually towards posterior extremity. Head rounded ; no setæ or papillac. Transverse strix of integument not very distinct, $\frac{1}{20000}{ }^{\prime \prime}$ apart.

Spear small, ouly $\frac{1}{2500}$ " long. CEsophagus about $\frac{1}{24}$ th of total length; middle of swelling $\frac{1}{400}$ " from anterior cxtremity. Intestine much obscured by genital tubes, covered with irregularly arranged fat-particles. Anus $\frac{1}{250}$ " from posterior extremity. Tuloce rather prominent, $\frac{1}{6 a^{\prime \prime}}$ from posterior extremity. Anterior uterine segments and oxary largely developed. General cavity of body filled with delicate parenchymatons or hyaline cells. Excretory duct opening at $\frac{1}{182}$ " from anterior extremity, and, in favourable specimens, visible for about $\frac{1}{80}$ " as a somewhat rigid, almost linear, curved tube. Lateral vessels most distiuct, about $\frac{1}{3330}{ }^{\prime \prime}$ in breadth, often much convoluted anteriorly ${ }^{2}$. Male, length $\frac{1}{11}$ ", breadth $\frac{1}{31} \frac{1}{2}$.
Anus $\frac{1}{285}$ " from posterior extremity. S'picules rather broad, $\frac{1}{833}{ }^{\prime \prime}$ long. Accessory piece comncted with spicules, $\frac{1}{1+28^{\prime \prime}}$ long. Alce narrow, transparent, extending from斋" ${ }^{\prime \prime}$ above anus to posterior extremity.

Hab. In gall-like growths, replaeing germens in certain ears of wheat, also more rarely in those of oats and ryc.
3. T. terricola, n. sp. (Plate X. figs. 115, 116.)

Female, length $\frac{1}{47}{ }^{\prime \prime}$, breadth $\frac{1}{1250}{ }^{\prime \prime}$.
External Characters.-Body pellucid, tapering slightly forwards, but more posteriorly. Striæ of integument transverse.

[^24]Spear $\frac{1}{2500}{ }^{\prime \prime}$ long. Gisophagus $\frac{1}{6}$ th of total length; centre of globate swelling $\frac{1}{454}$ " from anterior extremity. Intestine corered with rather coarse, seattcred granules. Anus $\frac{1}{7}{ }^{\prime \prime}$ " from posterior extremity. Tulte slightly posterior to anterior $\frac{2}{3}$ rels of body. Excretory duct opening opposite commencement of posterior third of oesophagus.

Male, not scen.
ILab. From sandy soil, adhering to rootlets of wheat-plant, Broadmoor, Berks.
4. T. obtusus, n. sp. (Plate X. figs. 117, 118.)

Fomale, length $\frac{1}{2} y^{\prime \prime}$, breadth $\frac{1}{770} 0^{\prime \prime}$.
Externel Characters.-Body tapering very slightly anteriorly, and still less posteriorly, where it is blunt and rounded. Head rather truneate. Strie transrerse, $200^{1} \overline{00}{ }^{\prime \prime}$ apart.

Spear $\frac{1}{1+\frac{1}{2} 8^{\prime \prime}}$ long. Esophagus $\frac{1}{14}$ th of total length, having a globate swelling about its middle. Intestine sparingly covered with light-colomed gramules. Lums $\frac{1}{435}$ " from posterior extremity. Tulca near commeneement of posterior third of body. Exceretory duct opening slightly posterior to middle of cesophargus.

Male, length $\frac{1}{33}$ ", breadth $\frac{1}{770}{ }^{\prime \prime}$.
Amus $\frac{1}{500}{ }^{\prime \prime}$ from posterior extremity. Spicules $\frac{1000 "}{1000}$ long. Accessory piece about half as long, posterior, median. Ale membranous and transparent, extending on either side from a little above anus to posterior extremity.

Irub. Sandy soil, abont the rootlets of oats, Broadmoor, Berks.
5. T. dlpsacl, Külhn.

Anynillula Dipsaci, J. Kühn, in Sehles. Jahresher. 1857, pp. 50-53.-Idem, in Zeitseh. für Wissenselı. Zool. ix. (1857) 199-137, tab. vii. C.-Diesiug, Sitzungsb. der Ǩiis. Akad. Bd. xlii. (1S61) p. 6²s.
"Corpus antrorsum attenuatum transparens. Caput obtusum, rotundatum. Caude sensim acuminata recta $v$. paulo incurvata. Apertura gonitalis feminea retrorsum sita. Ovipure. Longit. corp. $\frac{1}{2}-\frac{2^{\prime \prime \prime}}{}{ }^{\prime \prime}$, crassit. $\frac{1}{8}-\frac{1}{6}{ }^{\prime \prime \prime}$; longit. candic maris (a pene) $\frac{1}{15}$, femina (a vulva) $\frac{1}{5}$ corporis longitudinis."
"Esophagus postice bulbosus."
"Mab. In anthodiis depravatis Dipsaci fullonum, Junio (Kïhn)."
6. T. agrostidis.

Vibrio graminis, Steinbueh, in Naturf. xxriii. St. p. 233, tab. v., et cjus Analeeten, 97, 135, tab. ii. figs. 1-6. Anyuillula graminearum (in part), Diesing, Syst. Helminth. ii. p. 13 .

It seems to mo most probable that this species is distinct from Tylenchus tritici; the determination of this question, however, must be left to future observers.

## 13. RHABDI'TIS, Dujardin.

Anyuillula, Grube.
Gen. Char. Body tapering at extremitics. Cuudal sucker none. Integument liaving longitudinal as well as transverse strie; sete none; papillie none. Pharynyeal covity long cylindrical. Esophayus distinctly muscular, having two swollings,
one elongated near its middle, and the other terminal, rounded, and containing a simple valvular apparatus. Intestine rather sparsely eovered with fat-particles, the large eontaining cells of which can sometimes be recognized. Vulva near the middle of body. Uterus bifid, segments symmetrical. Oviparous or viviparous. Spicules of moderate size, slightly eurved. Accessory piece single, posterior, median, about half as long. Caudal ale lateral, membranous, supported by sets of rays. Ventral gland wanting. Lateral vessels or cellular canals not seen.
Movements active.
Although I have looked very carefully for them, I have been unable to distinguish either lateral vessels or the ventral excretory gland in any of the representatives of this genus.

The typical Rhabditis tervicola of Dujardin seems undoubtedly to correspond as regards structural details with the other species that I have placed in this genus; and, since it is now evident that Dujardin associated with this animal others of such diverse types as Anguillula uceti and Tylelenchus tritici, we shall have the less difficulty in imagining that he may have confounded with them also members of the genus Plectus, not only because they seem to be much more abundant than are the proper representatives of the genus Rhabditis, but also because he speaks of the latter as possessing that remarkable tenacity of life which belongs to species of the two former genera, when, as far as my experience gocs, it is not possessed by the real allies of the typical Rhabditis terricola.

1. R. marina, n. sp. (Plate X. figs. 60-62.)

Female, length $\frac{1^{\prime \prime}}{}{ }^{\prime \prime}$, breadth $\frac{1}{161}{ }^{\prime \prime}$.
External Characters.-Body tapering considerably anteriorly, but more posteriorly, where it narrows to a point. Head truneate, naked. Integument having transverse and longitudinal striæ, those of each set being about $\frac{1}{10000}{ }^{\prime \prime}$ apart.

Pharyngeal cavity cylindrical, $\frac{1}{1111}$ " long. Esophagus $\frac{1}{9}$ th of total length, eontaining in its terminal enlargement a valvular apparatus, which may be seen to open and shut with spring-like rapidity for the passage of fluids. Posterior part of cesophagus and anterior portion of intestine fixed to parictes by distinct muscular retinacula. Intestine much larger at commencement than terminal part of cesophagus; covered sparsely with fatpartieles, the containing cells of which can occasionally be recognized. Anus $\frac{1}{166}$ " from posterior extremity. Fulva slightly posterior to middle of body. Uterus bifid; segments symmetrical, large, and densely distended with freely moving young and ova in all stages of development. Ova $\frac{1}{400}{ }^{\prime \prime}$ long, by $\frac{1}{666}{ }^{\prime \prime}$ broad. Gland-system very slightly developed; but numerous floating gland- or blood-cells in cavity of body, the maximum size being about $\frac{1}{1666^{\prime \prime}}$ in diameter ${ }^{1}$.

Male, length $\frac{1}{12}{ }^{\prime \prime}$, breadtl $\frac{1}{200}{ }^{\prime \prime}$.
Anus $\frac{1}{285}$ " from posterior extremity. Genital tube consisting of a single testicle,

[^25]divided by a narrow constricted portion from the broad vas deferens. Spicules and accessory piece united together; segments of former $\frac{1}{45 \frac{1}{4}}$ long. Spermatozoa eylindrical, $\frac{1}{5000}{ }^{\prime \prime}$ long, having slow oscillating movement. Ale two, eomposed of a hyaline membrane extending on each side from $\frac{1}{285}$ " abore anus to posterior extremity, supported by nine rays in sets of one, two, and three.

Hab. Marine, in sand from tide-pools, Falmouth.
2. R. longicaudata, n. sp. (Plate X. figs. 63, 64.)

Female, length $\frac{1}{14}$ ", breadth $\frac{1}{22^{2}}{ }^{\prime \prime}$.
Externat Characters.-Body white, tapering gradually anteriorly, but more abruptly towards the posterior extremity, which is long and filiform. Head truneate, naked. Integument with longitudinal striæ, $\frac{1}{10000}{ }^{\prime \prime}$ apart ; transverse not recognized.

Pharyngeal cavity cylindrical, $\frac{1}{1000}$ " long by $\frac{1}{5000}$ " broad. Esophagus $\frac{1}{7}$ th of total length. Intestine very broad at eommeneement, before it is compressed by genital organs; covered by only a very few scattered fat-partieles. Anus $\frac{1}{100}{ }^{\prime \prime}$ from posterior extremity. Tulra very slightly anterior to middle of body.

Male, not seen.
Hab. Sandy soil about roots of wheat, Broadmoor, Berks.
3. R. ornata, n. sp. (Plate X. figs. 65-67.)

Female, length $\frac{1}{22}{ }^{\prime \prime}$, breadth $\frac{1}{500}{ }^{\prime \prime}$.
External Characters.-Body white, tapering anteriorly, but more posteriorly, where it is filiform. Head truncate, naked. Integument very transparent, with transverse strix $\frac{1}{20000}$ " apart; longitudinal not recognized.

Plaryngeal cavity $\frac{1}{1111}{ }^{"}$ long. Esophagus about $\frac{1}{6}$ th of total length. Intestine, just at commencement, devoid of hepatic granules; remaining portion sparingly covered with large and rather dark-coloured particles. Anus $\frac{1}{200}{ }^{\prime \prime}$ from posterior extremity. Tulva exactly in centre of body.

Male, length $\frac{1}{2} \frac{11}{3}$, breadth $\frac{1}{555}$ ".
Amus $\frac{1}{400}{ }^{\prime \prime}$ from posterior extremity. Spicules not very broad, slightly curved, $\frac{1}{588}{ }^{\prime \prime}$ long, and connected with a posterior median accessory portion of one-half the length. Ale lateral, same as in $R$. marina.

Hab. Between sheaths of leaves, stalks of wheat in stubble-fields, Broadmoor, Berks.
4. R. ACRIS, n. sp. (Plate X . figs. $68-70$.)

Female, length $\frac{1}{35}$ ", breadth $\frac{1}{666}{ }^{\prime \prime}$.
External Characters.-Body white, tapering forwards and also towardis posterior extremity, which terminates in a sharp point. Head truneate. Integument with transverse strixe, $\frac{1}{20000}{ }^{\prime \prime}$ apart; longitudinal not seen.

Pharyngeal cavity $\frac{1}{2000}{ }^{\prime \prime}$ long. Esophagus about $\frac{1}{5}$ th of total length. Intestine covered with few but large and dark-coloured hepatic granules. Anus $\frac{1}{\underline{944}}{ }^{\prime \prime}$ from posterior extremity. Tulue slightly posterior to middle of body.

Ifale, length $\frac{1}{41}$ ", breadth $\frac{1}{909^{\prime \prime}}$.
Aurs $\frac{1}{714}$ " from posterior extremity. Spicules double, $\frac{1}{1250}{ }^{\prime \prime}$ long, united to a post-
median accessory piece of one-half the length. Ala on each side of tail, supported by nine minute rays, same as in other species ${ }^{1}$.
$H a b$. Sandy soil about the rootlets of wheat, Broadmoor, Berks.

## 5. R. terricola, Dujardin.

Angiostomum terricola, Diesing, in Syst. Helminth. ii. p. 139.
"Corps blanc, fusiforme, allongé, quinze fois environ aussi long que large; tête large de $0^{\text {mm. }} 016$; bouche suivie d'un pharynx prismatique, long de $0^{\text {mm. }} 03$; œesophage long de $0^{\mathrm{mm} \cdot 13}$ à $0^{\mathrm{mm} \cdot 2 \text {, renflé en fuseau, large de } 0^{\mathrm{mm}} \cdot 033 \mathrm{au} \text { milieu, élargi de nouveau en }}$ arrière pour se continuer avec le ventricule beaucoup plus large (de $0^{\text {min }} \cdot 04$ à $0^{\mathrm{mm}} \cdot 045$ ).
" Mâle long de $0^{\mathrm{mm}} 50$ à $1^{\mathrm{mm} \cdot 05}$, large de $0^{\mathrm{mm} \cdot 025}$ à $0^{\mathrm{mm} \cdot 07 \text {; queue courte, un peu }}$ courbée, terminée en pointe fine, et munie en dessous de deux ailes latérales, soutenues par sept à huit côtes chacuue; anus à $0^{\mathrm{mm} \cdot 04}$ de l'extrémité; deux spicules, longs de $0^{\text {ma }} 06$.
 prolongé en pointe fine plus ou moins longue; auus ì $0^{\mathrm{mm}} \cdot 14$, au moins, de l'extrémité; vulve située vers le milieu; utérus très-large, musculeux au-dessus de la vulve, puis divisé en deux branches opposées; œufs elliptiques, lougs de $0^{\mathrm{mm} \cdot} \cdot 05$ à $0^{\mathrm{mm} \cdot 06 \text {, contenant }}$ un embryon replié trois fois.
"Cet helminthe, si remarquable par sa structure, ne l'cst pas moins par son habitatiou dans la terre humide et parmi les mousses, où il peut subir une dessication complète sans périr, et d'où il est entraîné par la pluie dans les fossés et les rivières. Il passe ensuite commc nourriture dans l'intestin des limaces, et de là dans l'intestin de la grenouille rousse, qui dévore ces mollusques; ou bien il est avalé dans les eaux par les gastérostés et divers petits poissons. On le trouve enfin aussi dans les lombrics; mais lì il parait avoir pris naissance dans des masses de parenclyyme, libres entre l'intestin et l'enveloppe musculeuse. Je l'ai vu plusieurs fois, soit à Paris, soit à Rennes, se développer en quantité prodigieuse et former des amas blanchâtres dans des vases où j'avais conservé des lombries avec de la mousse et de la terre humide ${ }^{2}$. Je l'ai trouvé communément dans les plaques d’oscillaires qui se développent sur la terre humide et dans les touffes de monsses (Bryum) qui se trouvent sur le sol et même sur les murs."
"Les exemplaires que j'ai recueillis dans l'intestin des Gasterosteus sont longs de $1^{\mathrm{mm}} \cdot 55$; leur queue est plus brusquement amincie ou subulée, longue de $0 \mathrm{~mm} \cdot 07$; les œufs sont longs de $0^{\mathrm{mm} \cdot 062 . " ~}$
"J'ai trouvé fréquemment, soit dans la terre humide ou dans les eaux vaseuses, ou dans l'intestin des batraciens et des mollusques, divers Rhabdites qui diffèrent du précédent par leur œesophage eylindrique et non renflé en fuseau. Ce sont, $1^{\circ}$, des vers filiformes, longs de $0^{\text {max }} \cdot 25$, larges de $0^{\text {mm. }} 016$, dans les oscillaires à Paris; $2^{\circ}$ des vers fusiformes, longs de $0^{\mathrm{mm} \cdot} 5$, larges de $0^{\mathrm{mm} \cdot 026 \text {, parmi les conferves, sur' les murs humides des }}$ fontaines à Toulon; $3^{\circ}$ des vers longs de $0^{\text {mm }} \cdot 6$, larges de $0^{\mathrm{mm}} \cdot 3$, à queue obtuse, et ayant

[^26]l'œsophage étroit, long de $0^{\mathrm{mm} \cdot} 15$, parmi les oscillaires; 4" un ver long de $0^{\mathrm{mm} .53,}$
 de $0^{\mathrm{mm} \cdot 08}$, dans l'intestin du Triton varicgatus, etc."

I have thought it best to give Dujardin's description and remarks concerning this species entire. From the great difference between the measurements giveu of this Rhabditis terricola, I think it very probable that Dujardin may not clearly have distinguished between two or more different species of this genus; whilst the animals referred to in his subsequent remarks, I have little doulb, belong to several totally distinct genera.

## 6. R. mucronata.

Anguillula mucronata, Grube, in Wiegmann's Archiv, 1849, i. 361-365, tab. vii. 11-14 (cum anatom.).Diesing, Syst. Helminth. ii. p. 557.
"Extremitate corporis antica lentius attenuata, truncata, bifariam e longitudine erenata, postica vix attenuata, fomina rotundata, mucronata, maris in paleam maxime excavatam (costulis sustentam) desinente; asophago postice bulboso, vulva in medio corpore sita. Tivipara. Longit. vix $\frac{1_{2}^{\prime \prime \prime}}{}$; crassit. vix $\frac{1}{24}{ }^{\prime \prime \prime}$."
"Hab. In terra humida cum lumbricis servata (Grube)."

## MARINE. <br> 14. SYMPLOCOSTOMA ${ }^{1}$, Bastian.

Enoplus, Eberth; Urolabes, Carter.
Gen. Char. Body tapering at extremities. Cuudal sucker well developed. Integument plain, or with longitudinal markings; setæ none (?). Pharyngeal cavity clongated, somewhat fiddle-shaped, having a peculiar funnel-shaped body lying along its inferior aspect, and an appearance of three or more circular lines around the parietes. Esophagus gradually widening posteriorly, not distinctly muscular, embraced in some part of middle third by glandular ring. Intestinal cells large, well filled with dark-coloured granules; often very irregularly disposed in adult specimens. Tulva about middre of body. Uterus bifid; segments symmetrical. Spicules long, narrow. Accessory piece wanting. Ocelli present or absent. Glandular system well developed, especially at anterior and posterior extremities. Excretory ventral gland opening near anterior extremity; duct containing a granular fluid, and much contracted just before termination. Lateral canals . . . . . .
Movements active.
I have temporarily placed in this genus three species, which will, in all probability, have to be removed hereafter : the first is S.vivipara, about the exact structure of whose pharynx I have not had sufficient opportunity of satisfying myself; and the other two, evidently very elosely allied, are Enoplus ornatus of Eberth and Urolabes barbata of Carter. These would appear not exactly to belong to this gemus, but to a type very similar. Future observation must decide this point.

1. S. longicollis, n. sp. (Plate XI. figs. 119-122.)

Female, length $\frac{1^{\prime \prime}}{8}$, breadth $\frac{1}{250}$.
External Characters.-Body smooth; anterior extremity tapering much, long, and narrow; posterior tapering more quickly. Caudal sucker well developed. Head truncate, naked. Integument with an appearance of longitudinal markings, $\frac{1}{6000}{ }^{\prime \prime}$ apart.

Pharyngeal cavity somewhat fiddle-shaped, length $\frac{1}{142} \overline{8}^{\prime \prime}$, having funnel and three circular markings. Two circular, highly refracting, colourless bodies (on œesophagus?) near termination of pharyngeal cavity. Gesophagus $\frac{1}{5}$ th of total length. Intestinal cells large, from $\frac{1}{1000}$ " to $\frac{1}{500}$ " in diameter, containing an abundance of dark fawn-coloured granules, sometimes varying in shade in contiguons cells, and these themselves often very irregularly disposed. Anus $\frac{1}{118}{ }^{\prime \prime}$ from posterior extremity. Fulva slightly posterior to middle of body. Ocelli none. Glandular system around middle third of œsophagus highly developed, and also at posterior extremity behind anus. Excretory ventral duct opening at $\frac{1}{300}$ " from anterior extremity.

Male, slightly larger than female.
Anus $\frac{1}{100}$ " from posterior extremity. Spicules long and narrow, very slightly curved, length $\frac{1}{172} 2^{\prime \prime}$.

Hab. From tide-pools, on Cladophora rupestris and other fine green and brown weeds on which Diatomacex abound, Falmouth and Brighton.

## 2. S. tenuicollis.

Enoplus tenuicnllis, Eberth, Untersuch. über Nematoden, 1863, p. 41, tab. iv. fig. 16, tab. v. figs. 1 \& 2.
"Körper fast gerade, cylindrisch, gegen beide Enden ziemlich gleich stark verschmälert. Hinterende bei dem Weibchen gerade, bei dem Männchen eingerollt. Kopf quer abgestutzt. Schwanz mit einer grösseren Papille versehen."
"Länge des Weibehens 6 Mm ., Breite $0 \cdot 15 \mathrm{Mm}$.
"Länge des Männchens 4.5 Mm ., Breite 0.09 Mm .
"Oesophaguslänge $=\frac{1}{5}$ der Körperlänge " ${ }^{1}$.
3. S. vivipara, n. sp. (Plate XI. figs. 123-125.)

Female, length $\frac{1}{12}{ }^{\prime \prime}$, breadth $\frac{1}{294}{ }^{\prime \prime}$.
External Characters.-Body tapering considerably at extremities, especially at posterior, which is long, filiform, and terminates with a minute sucker. Head slender, rounded, provided with a circlet of $6-8$ spreading setr. Integument, with longitudinal markings about $\frac{1}{10000}{ }^{\prime \prime}$ apart.

Pharyngeal cavity of a somewhat elongated-oval shape, containing no funnel or circular markings (?), $\frac{1}{1666 "}$ in length. CEsophagus about $\frac{1}{6}$ th of total length, gradually widening posteriorly, and embraced by a glandular ring at about its middle. Intestine irregularly and rather sparsely covered with somewhat large fat-particles. Anus $\frac{1}{117^{\prime \prime}}$ from posterior extremity. Vulva in centre of body. Uterus bifid. Segments symmetrical. Tiviparous. Excretory ventral gland . . . . . .?

[^27]Male, length $\frac{1}{17} 7^{\prime \prime}$, breadth $\frac{1}{370^{\prime \prime}}$.
Auns $\frac{1}{154}$ " from posterior extremity. Spicules $\frac{1}{400}{ }^{\prime \prime}$ long, solitary, very slender, and slightly eurved.

Hab. Fine surface-mud from marine estuary, Falmouth.
4. S. olinata.

Enoplus ornatus, Eberth, Untersuch. ïber Nematod. 1863, p. 40, tab. iv. figs. 13-15, tab. v. figs. 5 \& G.
"Körper fadenförmig, gegen beide Enden versehmälert. Vorderleib gerade, Hinterleib bei beiden Geschlechtern cingerollt, stärker bei dem Männchen als bei dem Weibchen. Kopf fast quer abgestutzt. Schwanz stumpfspitz mit feiner terminaleu Oeffnung. Hinter dem Munde ist der Körper leicht eingeschnürt.
"Länge des Weibchens 4 Mm ., Breite 0.125 Mm .
"Länge des Männchens 5 Mm ., Breite 0.1 Mm .
"Verhältuiss der Oesophaguslänge zur Körperlänge wic 1:4."

## 5. S. barbata.

Urolabes barbatu, Carter, Ann. of Nat. Hist. ser. 3, vol. iv. (1859) p. 43, pl. iii. fig. 32.
"Female. Body the same as the last (U. ocellata), but much longer. Head furnished with four linear, short cirri. Tail short, somewhat curved, furnished with a short, pointed, digital termination. Mouth and anus the same. Vulva situated much posteriorly to the middle of the body, about the junction of the middle with the anterior third of the posterior half."
"Alimentary canal the same as in the foregoing species, but the intestinal sheath terminating less abruptly upon the commencement of the reetum. Hepatic organ the same. Organs of generation double, occupying the middle part of the body; their form undetermined. Ocelli at some distance from the head, of the same colour as in $U$. infiequens."
"Size $\frac{1}{7}$ th inch long, and $\frac{1}{600}$ th of an inch broad."
" Male, the same as the female; but with a large, thiek, curved tail, obtuse at the extremity, tuberculated in its inner curvature, and furnished on each side with a row of short setre, extending from above the anus towards the tip; also three or four setie on the outer curvature. Testes and penis the same as in the foregoing species; form of the testes undetermined."

Hab. "Silty clots of Oscillatoria floating in the salt-water main drain of the town of Bombay."

## 15. ONCHOLATMUS, Dujardin.

## Enoplus, Diesing \& M. Schultze.

Gen. Char. Body often elongated; posterior extremity blunt- or sharp-pointed. Caudal sucker variable, sometimes well developed, with 2 or 3 distinct sucker-tubes. Integument plain or with longitudinal markings; cephalic sete generally present, and occasionally a few seattered over other parts of the body; cephalic papillæ wanting ; integumental pores most distinet iu mid-dorsal and ventral regions. Pharyngeal cavity large, ovoid, bounded by horny parietes, and having three longitudinal, slightly
curved, tooth-like projections from its inner surface. Esophagus not distinctly museular, cylindrical, and almost uniform in size ; surrounded by a distinet asophageal ring. Intestine mostly covered with olive-eoloured particles, having a tessellated arrangement. Vulva at centre of body, or oceasionally at posterior third. Uterus symmetrical or unsymmetrical. Spicules two, with or without a single accessory piece. Ocelli mostly wanting. Excretory ventral gland simple, tubular, extending from the anterior third nearly to the termination of œsophagus. Lateral canals often distinctly cellular.
Movements active.
This is not quite so natural an assemblage as those presented by some of the other genera, even after the freshwater species formerly included by Dujardin have been transferred to the genus Mononchus. In some members of this.genus Oncholaimus the vulva is posterior, and the uterus unsymmetrical; and in some males also the spiculcs are solitary, whilst in one at least, $O$. vulgaris, there is a large and well-developed accessory piece. Owing to my not having found in several eases both the male and female representatives of the same species, I am unable to say, from my own observation, whether these alterations in the male and female organs are generally coincident, and constant enough to enable the species to be ranged under two distinct subgenera; and, unfortunately, the details concerning the anatomy of those discovered by other observers are too scanty to afford any assistance in the solution of this question. In two species also, $O$. fuscus and O. albidus, I have been unable to detect the usual œesophageal ring.

1. O. vulgaris, n. sp. (Plate XI. figs. 126-128 a.)

Female, length $\frac{1_{2}^{\prime \prime}}{2}$, breadth $\frac{1}{143}{ }^{\prime \prime}$.
External Characters.-Body elongated, eylindrical, tapering very slightly at extremities. Sucker well developed, with three large sucker-tubes occupying nearly the whole of the eavity of body posterior to anus. Head truncate, with a circlet of 4-6 short, stout setæ, and a few smaller ones seattered over anterior part of body. Integument thick, with an appearance of longitudinal markings $\frac{1}{5000}$ " apart; integumental pores distinet in mid-dorsal and ventral regions.

Pharyngeal cavity $\frac{1}{285}$ " long by $\frac{1}{666}$ " broad, having three strongly marked, slightly curved teeth projecting into cavity. Esophagus about $\frac{1}{9}$ th of total length, nearly uniform in size, having three longitudinal rows of pigment-granules; embraced at termination of anterior third by an cesophageal ring. Intestine broad, having a thick coating of olivecoloured hepatic granules, enclosed in cells, and presenting a distinct tessellated arrangement. Anus $\frac{1}{154}$ " from posterior extremity. Tulva slightly posterior to middle of body. Uterus bifid. Excretory ventral gland opening close to the cesophageal ring. Lateral canals distinct, cellular.

Male, length $\frac{4}{10}{ }^{\prime \prime}$, breadth $\frac{1}{91}{ }^{\prime \prime}$.
Anus $\frac{1}{250}$ " from posterior extremity. Spicules rather wider at middle, and tapering towards extremities, $\frac{1}{190}{ }^{\prime \prime}$ long. Accessory piece single, somewhat triangular, $\frac{1}{454}{ }^{\prime \prime}$ long by $\frac{1}{666}$ " broad at the base. A large mid-ventral prominent sucker $\frac{1}{154}$ " above anal eleft.

Hab. Amongst half-tide sand and stony débris very abundant, and also found once on a bright grass-green filiform weed (free from Diatomacex) from tide-pool, Falmouth.
2. O. Glaber, n. sp. (Plate XI. figs. 129, 130.)

Female, leugth $\frac{1}{25}{ }^{\prime \prime}$, breadth $\frac{1}{833}{ }^{\prime \prime}$.
Extermal Characters.-Body tapering slightly forwards, but considerably towards posterior cxtremity, which is long, narrow, and pointed, and terminates with a minute sucker. Head rounded, naked. Integument plain or with longitudinal markings.

Pharyngeal cavity $\frac{1}{1666}{ }^{\prime \prime}$ long. CEsophagus about $\frac{1}{4}$ th of total length, embraced obliquely, near its middle, by an cesophageal ring. Intestine thinly covered with hepatic partieles. Anus $\frac{1}{160} \sigma^{\prime \prime}$ from posterior extremity. Vulva about middle of body. Excretory ventral duct

Male, not seen.
Hab. Marine surface-mud from estuary, Falmouth.
3. O. viscosus, n. sp. (Plate XI. figs. 131-133.)

Female, length $\frac{1}{13}{ }^{\prime \prime}$, breadth $\frac{1}{114^{\prime \prime}}$.
External Charucters.-Body long and filiform, scar ${ }^{\ddagger}$ cely at all narrowed anteriorly, but tapering gradually to a point at posterior extremity, which terminates with a minute sucker. Head bluntly rounded, provided with a circlet of four setre. Integument plain or with longitudinal markings, having numerous fine particles of sand and diatoms adhering to its external surface.

Pharyngeal cavity $\frac{1}{1111^{\prime \prime}}$ long. Esophagus $\frac{1}{7}$ th of total length, embraced obliquely, near its middle, by an cesophageal ring. Intestine sparsely covered with hepatic particles. Aurs $\frac{1}{222^{\prime \prime}}$ from posterior extremity. Vulva at middle of body. Uterus bifid.

Male, the same length as female, breadth $\frac{1}{83} \frac{1}{3}^{\prime \prime}$.
Anus $\frac{1}{285}{ }^{\prime \prime}$ from postcrior extremity. Spicules solitary, of an clongated wedge-shaped form, and $\frac{1}{1000}{ }^{\prime \prime}$ long.

Hab. Marine surface-mud from estuary, Falmouth.
When a thin layer of mud is spread out with water on a slip of glass, I have met with this species geuerally floating on the surface, appearing under a liand-lens as a slowly moring pellucid filament.
4. O. fuscus, n. sp. (Plate XI. figs. 139, 140.)

Mralc, length $\frac{1}{7}^{\prime \prime}$, breadth $\frac{1}{166}{ }^{\prime \prime}$.
External Characters.-Body stout, of a brownish colour, tapering slightly forwards, but abruptly posterior to aus. Terminal sucker minute. Head narrow, rounded, having a circlet of $6-8$ short, thick sete at $\frac{1}{1250}{ }^{\prime \prime}$ from anterior extremity. Integument having longitudinal markings; slightly tinged of a blackish colour at posterior extremity.

Pharyngeal cavity $\frac{1}{450}{ }^{\prime \prime}$ long, large, elongated-oval; one tooth much larger than either of the other two. Esophagus about $\frac{1}{6}$ th of total length; slightly eularged posteriorly; no ring visible. Intestine thickly covered with dark-brown hepatic particles; tesscllation indistinct. Anus $\frac{1}{154}{ }^{\prime \prime}$ from posterior extremity. Spicules long and narrow,
very dark in colour, hollow, $\frac{1}{143}{ }^{\prime \prime}$ long; accessory piece wanting. Excretory ventral gland not recognized.

Female, not seen.
Hab. Marine surface-mud of estuary, Falmouth.
5. O. albidus, n. sp. (Plate XI. figs. 141, 142.)

Female, length $\frac{1^{\prime \prime}}{4}$, breadth $\frac{1}{160^{\prime \prime}}$.
External Characters.-Body elongated, whitish in colour, tapering anteriorly, but more towards posterior extremity ; terminating in a moderate-sized sucker. Head truneate, provided with a circlet of four short, stout setre, and a few smaller ones scattered over anterior part of body. Integument having longitudinal markings.

Pharyngeal cavity broadly ovate, $\frac{1}{588^{\prime \prime}}$ long. (Esophagus short, about $\frac{1}{10}$ th of total length; enlarging slightly posteriorly; no ring seen. Intestine moderatcly well covered with rather light-coloured hepatic particles tessellated in arrangement. Anus $\frac{1}{100}$ " from posterior extremity. Vulua considerably behind middle of body, $\frac{1}{15}$ " from posterior extremity. Uterus unsymmetrical. Ova very large, in single file, occupying the whole width of the body, and somewhat flattened against its parietes. Excretory ventral gland opening far forward, at $\frac{1}{285}$ " from anterior extremity.

Male, not seen.
Hab. Amongst small stones and sand in tide-pools, Falmouth.
6. O. viridis, n. sp. (Plate XI. figs. 137, 138.)

Female, length $\frac{l^{\prime \prime}}{9}$, breadth $\frac{1}{333}{ }^{\prime \prime}$.
External Characters.-Body of a light-greenish hue, tapering very slightly forwards, but somewhat abruptly behind ams, where it terminates with a pretty distinct sucker and sucker-tubes. Head truncated, provided with a circlet of 4-6 setre; a few other smaller ones seattered over anterior part of body. Integument having longitudinal markings.

Pharyngeal cavity broad anteriorly, $\frac{1}{83}{ }^{\prime \prime}$ long. (Esophagus about $\frac{1}{6}$ th of total length, uniform in size, embraced obliquely by ring near its middle; having a collection of pigment immediately behind pharynx somewhat resembling an ocellus. Intestine well covered with hepatic partieles having a distinctly tessellated arrangement. Anus $\frac{1}{285}{ }^{\prime \prime}$ from posterior extremity. Vulva prominent, considerably behind middle of body, $\frac{1}{31}^{\prime \prime}$ from posterior extremity. Uterus unsymmetrical.

Male, not seen.
Hab. Small filamentous green weed from tide-pool, Falmouth.
7. O. attenuatus, Dujardin. (Plate XI. figs. 134-136.)

Enoplus attenuatus, Diesing, Syst. Helminth. ii. p. 125.
Female, length $\frac{1}{10}{ }^{\prime \prime}$, breadth $\frac{1}{435}{ }^{\prime \prime}$.
External Characteis.-Body long and slender, tapering very slightly at extremities, though most at posterior, which is somewhat blunt, and terminated by a well-marked sucker, with which are connected sucker-tubes. Head bluntly rounded, provided with a circlet of 6-8 setæ. Integument having longitudinal markings.

Pharyngeal cavity elongated, $\frac{1}{66}{ }^{\prime \prime}$ in length. Esophagus about $\frac{1}{8}$ th of total length, VOL. XXV.
uniform in size, embraced by a ring near its middle, having three longitudinal lines of pigment more or less distinct, and two distinct local aggregations immediately behind pharynx (pseudocelli), varying in colour from brown to carmine. Intestine covered with hepatic particles having a tessellated arrangement. Anus $\frac{1}{285}{ }^{\prime \prime}$ from posterior extremity; posterior boundary of anal cleft rather prominent. Vulva prominent, some distance behind middle of body. Uterus unsymmetrical. Floating gland-cells numerous, large, about $\frac{1}{3000}$ " in diameter. Excretory ventral duct opening far forwards, only $\frac{1}{400}{ }^{\prime \prime}$ from anterior extremity, by a very narrow portion immediately following a small pyriform dilatation. Latercl canculs of a green colour and granular, with the appearance of an axial chanuel.

Male, length $\frac{1}{11}{ }^{\prime \prime}$, breadth $\frac{1}{50} \overline{0}^{\prime \prime}$.
Posterior extremity curved, shorter, more abruptly narrowed, and laving two median sete immediately above anal cleft. Eesophagus about $\frac{1}{5}$ th of total length. Anus $\frac{1}{590}{ }^{\prime \prime}$ from posterior extremity. Spicules almost straight, slender, $\frac{1}{83}{ }^{\prime \prime}$ " long; accessory piece wauting.

Mab. Found, with Chromadora vulgaris, C. filiformis, and Cyatholaimus ocellatus, on a stunted and dingy specimen of Cladophora rupestris from half-tide pool, Falmouth.

The specimens found by myself seem to agree so closely with the short description Dujardin has left us of his Oncholaimus attenuatus, as to make me think they must belong to the same species. The principal difference is that he mentions a " série de soies roides" above the auus in the male, whilst I have only recognized a single pair in this situation. His description is as follows:-"Corps filiforme, très-mince, cinquante fois aussi long que large; tête munie latéralement de deux ou quatre soies courtes; cavité buccale alongée, armée de trois pièces longitudinales, étroites, portant chacune une forte dent au milieu ; deux taches rouges contiguées près du pharynx ; œsophage loug de $0^{\text {mm. }} 4$, large de $0 \mathrm{~mm} .025 .{ }^{\text {." }}$
" Mále, long de $2^{\mathrm{mm} \cdot} 4$, large de $0^{\mathrm{mm} \cdot 0.45}$; quene brusquement rétrécie en arrière de l'anus, lecourbée en crochct et terminée par une sorte de papille (ou ventouse ?) ; anus à $0^{\mathrm{mm}} \cdot 033$ de l'extrémité, accompagné d'une double série de soies roides; spicules longs de $0 \mathrm{~mm} \cdot 03$."
"Dans l'eau de mer, entre les algues, à Lorient." (Hist. Nat. des Helminth. p. 236.) 8. O. papillosus, Eberth.

Untersuch. über Nemat. p. 26, tab. i. figs. 13-17.
"Körper gestrickt, das Vorderende wenig versehmälert, quer abgestutzt. Das Hinterende des Weibehens gerade, in eine lange Spitze ausgezogen. Bei dem Männehen macht das Hintertheil einc leichte Krümmung gegen den Rücken, biegt sich aber dann mit der äussersten Spitze wieder gegen den Bauch.
"Länge des Weibchens 3 Mm ., Breite 0.075 .
"Oesophagus=cin Viertel der Körperlänge."
9. O. megastona, Eberth.

Untersuch. über Nemat. p. 26, tab. i. figs. 18-20.
"Körper fast gerade, fadenförmig, gegen dca Vorderleib wenig versehmälert Mund-
ende abgerundet, Schwanzende beim Männchen stark verdünnt, weniger bei dem Weibchen, leicht eingebogen."
"Weibchen 3 Mm . lang, 1 Mm . breit.
" Männchen $5-6 \mathrm{Mm}$. lang.
"Oesophagus=ein Sechstel der Körperlänge."
I have retained this species provisionally in the genus Oncholaimus, where it was placed by Eberth, though the representation he has given of this animal seems to indicate that it possesses a form of pharynx different, not only from that characteristic of the genus Oncholaimus, but also from that possessed by any other type that I have yet examined.
10. O. Echini, Leydig.

Müller's Archiv, 1854, p. 291.—Diesing, Sitzungsb. der Kais. Akad. Bd. xlii. (1861) p. 626.—Eberth, Untersuch. über Nemat. p. 25.
"Corpus utrinque attenuatum. Os dentibus pluribus instructum. Ovipara. Longit. 4"'".
"Hab. Echinus esculentus, in intestinis (Leydig)."
Probably swallowed accidentally; and it seems doubtful whether it really belongs to this genus.
11. O. rivalis, Leydig.

Müller's Archiv, 1854, p. 291, tab. xi. 89.-Diesing, Sitzungsb. der Kais. Akad. Bd. xlii. (1861) p. 626. -Eberth, Untersuch. über Nemat. p. 25.
" $O s$ dentibus duobus lateralibus et tertio intermedio denticulato instructum. Vivipara. Longit.
"Hab. Sub saxis Meni frequenter (Leydig)."
If this really belongs to the genus Oncholaimus, it is the only freshwater species yet discovered.

## 16. ENCHELIDIUM, Ehrenberg.

"Body often 3-6 mm. long, straight or slightly curved. Head blunt, rounded off or' truncate. Postcrior extremity pointed, provided with a perforated sucker. Mouth plain, or with four small punctiform papillæ.
"Skin consisting of two or three layers, having, especially on fore part of body, several hairs implanted in its substance; larger cirrhi around the mouth. Behind the pharynx there opens on the ventral surface either a small gland or a tube reaching to commencement of intestine.
"An agglomeration of small cells in the place of tail-glands.
" Lateral lines simple, narrow, cellular cords.
"Organs of Digestion.-No pharynx. (Esophagus cylindrical, widening posteriorly; the external sheath finely granular, or transversely striped. Anus at the base of tail.
"Organs of Generation.-Two spicules, or a larger and a smaller pair, the latter being rather posterior.
"Bright ring around the œesophagus, which in one case appeared to be incomplete.
"Ocelli.-One large, ring-formed mass surrounding œsophagus, and having several lenses auteriorly."-Eberth, Unters. über Nemat. p. 23.

1. E. marinum, Ehrenberg.

Enchelidium marinum, Ehrenberg, Die Akaleph. d. roth. Meer, u. d. Organism. d. Medus. 1836, pp. 41, 57.-Dujardin, Hist. Nat. des Helm. p. 238.-Diesing, Syst. Helminth. ii. p. 127 (partim).-Oersted, De regione marinis, 1844, p. 69.
"Corpus capillare, extremitate caudali subulata. Caput corpore continuum, trmencatum. Os terminale, orbiculare, cirrhatum? Ocellus pone os. Penis ....; feminæ apertura genitalis . . . . Longit. . . . .
"Hab. Iuter mucosa palos marinos obvesticutia, et in aqua marina servata frequentissime."
2. E. Tenuicolle, Eberth.

Unters. über Nemat. p. 23, tab. iii. figs. 1-3.
"Körper des Männchens fast gleichmässig cylindriseh, mit Ausnahme des verdünnten Kopf- und Schwanzendes. Ersteres besonders im Cerviealtheile sehr dünn, nach vorn wieder etwas anschwellend, quer abgestutzt endigend. Das Hinterende zugespitzt mit durchbohrter Papille."
"Auge im Cervicaltheil kurtz hinter der Mundöffnung, schcint ringförmigg den Oesosophagus zu umgeben, von schön brauner Farbe, enthält zwei kleine runde Linsen.
" Länge des Männchens 5 Mm., Breite 0.10.
"Ocsophagus=cin Fünftel der Körperlänge."
3. E. acuminatum, Eberth.

Unters. über Nemat. p. 24, tab. iii. figs. 4, 5.
"Körper des Mänucheus fast gerade, cylindrisch, nach unten wenig an Dicke zunehmend, wenig verschmälert gegen das Vordereude, das Hinterendc leicht eingebogen, in cine feine Spitze auslaufend, die in eine durchbohrte Papille endigt. . . . . Hinter den Pharynx ein schwarzbrauner birnförmiger Pigmenthaufen, dessen vorderer verschmälerter Partic drei grössere runde Linsen aufliegen . . . .
"Lünge des Mäuncheus 3 Mm ., Breite $0 \cdot 1$.
"Oesophagus=ein Fünftel der Körperlänge."
4. E. subrotundum.

Enoplus subrotundus, Eberth. Unters. über Nemat. p. 33, tab. ii. figs. 11, 12.
" Körper des Männchens fadenförmig, Hinterende zugespitzt mit fciner durchbohrter Endanschwellung, Vorderende wenig verschmälert, abgerundet, in cinen rundlichen, vom übrigen Körper leicht abgesetzten Kopf geendigt.
"Auge gross länglichruud, hinter dem Pharynx gelegen, schön braun, mit einer grösseren kugligen centralen Linse.
"Länge des Männchens $5 \frac{3}{4} \mathrm{Mm}$., Breite 0.1 Mm .
"Oesophaguslänge verlält sich zur Körperlänge wie 1 : 6."

## 5. E. Grubif.

Grube, Ausflug nach Triest und dem Quarnero, 1861.-Eberth, Unters. über Nemat., p. 22.

## 17. ANTICOMA ${ }^{1}$, Bastian.

Odontobius, Eberth.
Gen. Char. Body tapering at extremities. Caudal sucker rather small; sucker-tubes undeveloped. Integument plain; short rows of opposite setæ on lateral aspects of anterior extremity; also cephalie setæ, and others more or less seattered over posterior part of body of males; papillæ absent. Pharyngeal cavity none. Gesophagus not distinetly muscular, widening posteriorly, surrounded by ring near its middle. Intestine mostly covered with rather pale granules having a tessellated arrangement. Vulva about middle of body. Uterus bificl. Spicules two, curved. Accessory piece wanting. Supplementary organ small, simple, tubular. Ocelli absent. Taginal glands two, pyriform, equal; anal two, medium-sized, nucleated. Excretory ventral gland opening opposite anterior of œsophagus. Lateral canals narrow, cellular.
Movements moderately aetive.

1. A. Eberthi, n. sp. (Plate XI. figs. 143-145.)

Female, length $\frac{1_{4}^{\prime \prime}}{4}$, breadth $\frac{1}{166^{\prime \prime}}$.
External Characters.-Body whitish, slender, tapering considerably at extremities, especially at posterior, which is filiform. Head bluntly rounded, provided with a circlet of $6-8$ well-marked setæ, whilst laterally, at a distance of $\frac{1}{666}$ " from anterior extremity, on each side, there is a row of 5 or 6 setæ extending at right angles from body. Integument plain.

Esophagus $\frac{1}{8}$ th of total length, gradually widening posteriorly, embraced by ring near its middle. Intestine well covered with light-coloured tessellated fat-particles. Anus $\frac{1}{91}$ " from posterior extremity. Tulva considerably anterior to middle of body, $\frac{1}{10}$ " from anterior extremity. Uterus bifid; segments symmetrical. Anal glands two. Excretory ventral duct opening opposite termination of anterior $\frac{1}{3} \mathrm{rd}$ of œesophagus.

Male, length $\frac{1^{\prime \prime}}{}{ }^{\prime \prime}$, breadth $\frac{1}{200}$.
Posterior extremity having a well-marked row of seta in mid-abdominal region, above and below anus. Anus $\frac{1}{13} 3^{\prime \prime}$ from posterior extremity. Spicules curved, pointed, enlarged at upper extremities. Supplementary organ $\frac{1}{285}{ }^{\prime \prime}$ above anal cleft, oblique, simple, tubular, $\frac{1}{1666}{ }^{\prime \prime}$ long.

Hab. About the roots of Corallina officinalis, tide-pools, Falmouth.
2. A. Limalis, n. sp. (Plate XI. figs. 146-148.)

Female, length $\frac{1}{10}{ }^{\prime \prime}$, breadth $\frac{1}{227^{\prime \prime}}{ }^{\prime \prime}$.
External Characters.-Body whitish, tapering considerably anteriorly, and also at posterior extremity, which is rather long and filiform. Head slightly rounded, provided

[^28]with a circlet of 4-6 spreading sete; opposite cervical hairs not recognized. Integument plain or with the appearance of longitudinal markings about $\frac{1}{9000}$ " apart.

Esophagus $\frac{1}{5}$ th of total length, gradually widening posteriorly, embraced by ring slightly in frout of middle. Intestine covered with pale, regularly tessellated fat-cells. Auus $\frac{1}{11-8}$ "from posterior extremity. Fulva slightly posterior to middle of body. Uterus bifid. Taginal glands two, equal, pyriform. Excretory ventral gland opening close to anterior extremity, at a distance from it of only $\frac{1}{1666}$ ".

Male, not seen.
Hab. Narine surface-mud of estuary, Falmouth.
Not having seen the male of this species, I do not feel quite certain that it belongs to this genus.
3. A. Pellucida, n. sp. (Plate XI. figs. 149, 150.)

Female, length $\frac{1}{9}{ }^{\prime \prime}$, breadth $\frac{1}{222}{ }^{\prime \prime}$.
Exterwal Characters.-Body tapering considerably forwards, posterior extremity long and filiform. Head slightly rounded, provided with 4-6 sete; whilst laterally, at $\frac{1}{666}{ }^{\prime \prime}$ from anterior extremity, on each side, is a row of six short equidistant setæ. Integument with an appearance of longitudinal markings $\frac{1}{8000^{\prime \prime}}$ apart.

Esophagus about $\frac{1}{5}$ th of total length, widening posteriorly, and embraced by ring slightly anterior to its middle. Intestine covered with light, distinctly tessellated hepatic particles. Anus $\frac{1}{105}{ }^{\prime \prime}$ from posterior extremity. Tulva slightly anterior to middle of body. Anal glands two. Excretory ventral duct . . .

Male, not scen.
Hab. Small green weed from tide-pools, Falmonth.

## 4. A. acuminata.

Oduntobius acuminatus, Eberth, Unters. über Nemat. p. 28, tab. i. figs. 6-9.
"Körper des Wiebchens weisslich, gerade. Vorderende stark verschmälert, Mund leicht abgerundet, Hinterende stark verdïnnt, in einen geraden pfriemenförmigen Schwanz auslaufend.
"Kürper des Männchens, Hinterende wie beim Weibchen. Zwei paarige, gekrümmte, leicht blassgelbe Spicula, davor cin unpaares, stabförmiges, accessorisches Glied. . . . . .
"Weibchen 2.5 Mm . lang, 0.1 Mm . breit.
"Männchen 2 Mm . lang, 0.075 Mm . breit.
"Oesophagus=ein Drittel der Körperlänge."

## 18. PHANODERMA ${ }^{1}$, Bastian.

Enoplus, Eberth.
Gen. Char. Body tapering at extremities. Caudal sueker well developed; sucker-tubes three, rather short. Integument plain, or with longitudinal markings, very transparent; cephalic sete present; integumental pores well marked anteriorly, lateral.

[^29]Plaryngeal cavity indistinct, with obscure indications of three slightly coloured pharyngeal plates. Esophagus not distinctly muscular, widening posteriorly, surrounded by a ring, and in its latter half having circular contractions of its sheath at intervals, giving its border a regular crenated appearance; three longitudinal rows of orange- or other coloured pigment-granules moro or less marked along its whole extent. Intestine covered with somewhat olive-coloured fat-particles, having a tessellated arrangement. Tulva about middle of body. Uterus bifid; segments symmetrical. Spicules two, long and narrow; accessory piece wanting. Supplemental organ small, obliquely situated, tubular. Ocelli two, large, conical, bright red, situated laterally. Parietal glands, on muscles, well developed. Excretory ventral gland consisting of a short tube, with a blind dilated extremity, and opening by an abruptly narrowed duct near anterior extremity. Lateral canals distinctly cellular,
Movements active.

1. P. Cocksi ${ }^{1}$, n. sp. (Plate XI. figs. 151-153.)

Female, length $\frac{1}{4}{ }^{\prime \prime}$, breadth $\frac{1}{144}$ ".
External Characters.-Body tapering very gradually forwards, but narrowing quickly to a point behind, where it terminates in a well-dcveloped sucker. Head narrow, rounded, provided with a circlet of 6-8 setæ; a few others scattered over anterior part of body. Integument hyaline, with an appearance of longitudinal markings $\frac{1}{12000}$ " apart.

Pharyngeal cavity indistinct. Esophagus about $\frac{1}{5}$ th of total length, embraced by ring at termination of anterior third; having three rows of pigment, varying from orangecolour to olive-green, along its whole length; constrictions of posterior half at regular intervals, giving a crenated appearance to borders. Intestine well covered with a tessellation of hepatic particles. Auns $\frac{1}{143}$ " from posterior extremity. Fiulou slightly posterior to middle of body. Parietal glands in œsophageal part of body very abundant. Ocelli two quite lateral, conical, bright-red pigment-masses. Excretory ventral gland opening by narrow duct, only $\frac{1}{250}$ " from anterior extremity, and terminating in a dilated extremity near the middle of œesophagus.

Male, length $\frac{1}{7}^{\prime \prime}$, breadth $\frac{1}{222^{\prime \prime}}$.
Anus $\frac{1}{200}$ " from posterior extremity. Spicules long, narrow, solitary; length $\frac{1}{125}$ ". Supplementary organ tubular, not very distinct, slightly curved, $\frac{1}{666}{ }^{\prime \prime}$ in length, and situated $\frac{1}{66}{ }^{\prime \prime}$ above anus.

Hab. About the roots of Corallines in tide-pools, Falmouth.
2. P. albidum, n. sp. (Plate XI. figs. 154, 155.

Female, length $\frac{1}{7}{ }^{\prime \prime}$, breadth $\frac{1}{250}$.
External Characters.-Body white, tapering gradually at extremities, not suddenly at posterior, as in last; terminating in distinct suckcr, with which are connected three sucker-tubes. Head narrowed, rounded, having a circlet of $6-8$ spreading cirri. Integument very hyaline and transparent.

[^30]Pharyngeal cavity indistinct. Gesophagus $\frac{1}{5}$ th and $\frac{1}{4}$ th of total length, embraced by a ring; border of posterior half crenated. Intestine well covered with fat-particles, arranged in a tessellate manner. Auus $\frac{1}{154^{\prime \prime}}$ from posterior extremity. Tulva somewhat posterior to middle of body. Ocelli lateral, bright red, situated about $\frac{1}{666}$ " from anterior extremity. Parietal glands well developed. Excretory ventral duct . . . . . .

Male, not seen.
Hub. Small green sea-weed from tide-pools, Falmouth.
3. P. tuberculatum, Eberth.

Enoplus tuberculatus, Eberth, Untersuch. uber Nemat. p. 38, tab. iv. figs. 1-5.
"Körper fast gerade, naeh hinten ansehwellend, nach vorn sich allmählich versehmälernd, mit quer abgestutztem Kopf. Schwanz kurz, wenig spitz, in eine durehbohrte Papille endigend. Das Mïnnchen vor Beginn des Schwanzes stärker anschwellend
"Länge des Weibchens 5 Mm ., Breite 0.2 Mm .
"Länge des Mäunchens $4 \frac{1}{2}$ Mm., Breite 0.125 Mm .
"Oesophaguslänge verhält sich zur Körperlänge wie $1: 3$. ."

## 19. LEPTOSOMATUM ${ }^{1}$, Bastian.

Phanoglene, Eberth; Enoplus, Eberth.
Gen. Char. Body elongated, filiform; posterior extremity blunt and rounded. Caudal sucker not prominent, provided with two or three long sucker-tubes. Integument plain or with longitudinal markings; lateral integumental pores well marked; setre absent, or very few in mmber; eephalic papillæ wanting. Pharyngeal cavity wanting. Esophugus not distinetly muscular, almost uniform in size, and surrounded anteriorly by an osophageal ring. Intestine very seantily covered with small light-coloured fit-particles, sometimes almost altogether wanting. Trulva considerably posterior to middle of body. Uterus bifid; segments symmetrieal (?). Spicules two, rather broad, but tapering at extremities. Aecessory pieces two, posterior, somewhat cuneiform. Supplementul argan occasionally present. Suckers also occasionally present in male, above anus. Ocelli two, conical, red, almost lateral, having occasionally a transparent lens-shaped body imbedded in their substance anteriorly. Excretory glands two, lateral, opening on either side close to anterior extromity, and reaching nearly to posterior part of oesophagus. Lateral canals
Movements mostly slow and tardy.
I feel by no means certain that the animals here placed in this genus all really belong to the same type, and may not later require a rearragement. The three species found by me undoubtedly present certain common characters, the most notable of whieh are the similarity in the shape of the male spicules and aceessory pieces, as well as in the nature of the ocelli; but I have unfortunately been unable to ascertain whether Leplosomatum gracile and L. figuratum have the same double excretory glands as I have un-

[^31]mistakeably made out in the typical species L. elongatum; in both these other two species I have as yet failed to detect any structure, either simple or double, answering to the excretory gland.

After a careful examination of Eberth's figures, however, I feel almost sure that his Phanoglene punctata presents the same type of structure ${ }^{1}$ as my L. elongatum, and still more convinced that his $P$. bacillata is intimately allied to L. gracile. Whether belonging to this or more correctly to another, it is also evident that his Enoplus coronatus and my L. figuratum must be included in the same genus.

I have constituted this new genus, and removed from the genus Phanoglene the species placed in it by Eberth, on account of the improbability that these marine forms would agree in structure with the freshwater type of Nordmann's genus.

1. L. elongatem, n. sp. (Plate XII. figs. 156, 157.)

Male, length $\frac{2^{\prime \prime}}{5}$, breadth $\frac{1}{200}{ }^{\prime \prime}$.
External Characters.-Body cylindrical, filiform, tapering but very slightly at extremities. Sucker not prominent; sucker-tubes two, long, tubular, the terminations being blont and rounded. Head slightly narrowed, rounded, naked. Integument plain; no strire visible.

Esophagus $\frac{1}{7}$ th of total length, slender, ncarly uniform in size, and free from pigment, surrounded by ring near end of anterior third. Intestine scarcely recognizable, from the almost total absence of hepatic particles. Anus $\frac{1}{28} \frac{5^{\prime \prime}}{}$ from posterior extremity. Spicules $\frac{1}{25}{ }^{\prime \prime}$ long, broad in the middle, but tapering at extremities; accessory pieces $\frac{1}{1000}{ }^{\prime \prime}$ long. Ocelli two conical carmine-coloured masses on dorsum of cesophagus, $\frac{1}{285}{ }^{\prime \prime}$ from anterior extremity. Ercretory glauds two, tubular, extending along anterior two-thirds of cesophagus, and opening one on each side of head, $\frac{1}{1000}$ " from level of anterior extremity.

Female, not seen.
Hab. In a small dull-reddish sponge between crevices of stones from estuary, Falmouth.

## 2. L. punctatum.

Phanoglene punctata, Eberth, Untersuch. über Nemat. p. 20, tab. ii. figs. 5-7.
"Körper überall von fast gleicher Dicke, stärker verschmälert nach vorn, hinten in eine stumpfe Spitze auslaufend, leicht gegen den Bauch concav, mitunter auch stärker cingerollt. Das terminale Ende hicr und da leicht nach unten cingebogen. Hinterende des Männchens etwas schmäler als das vom Weibchen. Mundöffnung einc leichte Grube, kurz hinter ihr auf der Bauch- und Rückenfläche zwei klcine Haare
"Weibchen 4.5 Mm , lang, $0 \cdot 10 \mathrm{Mm}$. breit. Männchen $7 \cdot 5-8 \mathrm{Mm}$. lang, $0 \cdot 1 \mathrm{Mm}$, breit.
"Oesophagus=ein F'ünftel der Körperlänge.
"Hab. Villafranca, unter Seepflanzen."
3. L. gractle, n. sp. (Plate XII. figs. 158-160.)

Female, length $\frac{1^{\prime \prime}}{2}$, breadth $\frac{1}{133}{ }^{\prime \prime}$.

[^32]VOL. XXV.

Extemal Characters.-Body white, long, thread-like, tapering very slightly at extremities. Head rounded and, as well as rest of body, naked. Integrument plain; pores very numerous and easily recognizable, especially in lateral regions of anterior extremity.

Esophagus $\frac{1}{9}$ th of total leugth, embraced by ring anteriorly, very slightly pigmented, and almost uniform in size. Intestine sparingly covered with small light-coloured granules more or less tessellate in arrangement. Aluis $\frac{1}{182}$ " from posterior extremity. Vulva posterior to middle of body. Uterus lifid; segments symmetrical. Ova very large, ocempying whole width of body. Excretory glands . . . . . . Ocelli two, bright red, conical, on dorsum of cosophagus, $\frac{1}{2 \frac{1}{2}}{ }^{\prime \prime}$ from posterior extremity.

Male, length $\frac{1^{\prime \prime}}{3}$, breadth $\frac{1}{182^{\prime \prime}}$.
Amus $\frac{1}{18 \frac{1}{2}}$ " from posterior extremity. Spicules $\frac{1}{3} \frac{1}{3}{ }^{\prime \prime}$ long, same shape as in L. elongatum; uccessory pieces about half as long as spicules.

Hab. Same as L. elongatum.

## 4. L. bacillatum. •

Phanoglene bacillata, Eberth, Unters. über Nemat. p. 19, tab. ii. figs. 1-4.
"Körper des Weibchens gerade, gegen die Mitte wenig anschwellend, beide Enden fast gleichmässig verdünnt, Vorderende leicht gerundet, quer abgestutzt, Hiuterende stumpf, mit terminaler Oeffnumg für die Schwanzdrüse. . . . . . .
"Weibchen S-9 Mm. lang, 0.1 Mm . breit.
"Ocsophaguslänge $=$ cin Fünftel des Körpers.
"Hrab. Unter Corallen im Hafeu von Nizza."
5. L. figuratum, n. sp. (Plate XII. figs. 161-163.)

Female, length $\frac{1^{\prime \prime}}{}{ }^{\prime \prime}$, breadth $\frac{1}{166^{\prime \prime}}$.
External Characters.-Body long, cylindrical, scarcely tapering at all at extremities, the posterior being blunt and rounded. Sucker well developed; sucker-tubes large. Head bluntly rounded, of a light yellowish colour for about $\frac{1}{666}{ }^{\prime \prime}$ of an inch, and figured in a regular manner by bright lines; provided with a circlet of four short conical setre. Integument with an appearance of longitudinal markings; integumental pores lateral.

Csophagus about $\frac{1}{5}$ th of total length, nearly uniform in size, embraced by ring about the termination of anterior third. Intestine rather slightly covered with light fatparticles not tessellately arranged. Anus $\frac{1}{28} 5^{\prime \prime}$ from posterior extremity. Tulva at commencement of posterior third of body. Ulerus bifid; segments short, symmetrical. Ocelli two lateral, reddish brown, conical pigment-masses, each having a transparent lens-like body imbedded anteriorly. Floating gland-cells very large, oval, nucleated, often at regular distances on either side of body. Excrelory glands indistinct; appearanee of lateral openings at either side of head; nothing else recoguized.

Mrale, very slightly smaller than female.
Auns $\frac{1}{285}$ " from posterior extremity. Spicules $\frac{1}{200}$ " in length; accessory pieces $\frac{1}{285}{ }^{\prime \prime}$ long. Supplementary organ in the form of a horny sucker-like body, $\frac{1}{333}$ " above anus.

A series of nine hemispherical prominences above anus, on either side of middle line (suctorial papillæ).

Hab. About the roots of Corallina officinalis, and in sponge with L. elongatum and L. gracile, Falmouth.
6. L. coronatum.

Enoplus coronatus, Eberth, Unters. über Nemat. p. 37, tab. iii. figs. 13-19.
"Körper bei dem Weibchen fast gerade, stärker versehmälert gegen das Kopfende, weniger gegen den Schwanz.
"Kopf leicht abgerundet mit einer kleinen centralen Vertiefung, die zum Pharynx führt. Hinterende stumpf spitz, bei dem Mäunchen leicht eingerollt.
"Länge des Weibchens 5 Mm ., Breite 0.20 Mm .
" Länge des Mänuchens 4-5 Mm., Breite 0.2 Mm .
"Oesophaguslänge verhält sich zur Körperlänge wie 1:5.
"Hab. Unter Corallen im Hafen von Nizza."
7. L. Longissimum.

Phanoylene longissimum, Eberth, Unters. über Nemat. p. 21, tab. ii. fig. 8 .
"Körper des Weibchens eingerollt, nach unten ansehwellend, Vorderende ziemlich schmal, Hinterende wenig verschmächtigt, stumpf.
"Simesorgane. In der Cervicalgegend zwei viercekige hellbraune Pigmentfleeke olme deutliche Linse.
"Weibehen 15 Mm . lang, $\frac{1}{4} \mathrm{Mm}$. breit.
"Oesophagus verhält sich zur Körperlänge wie 1:15.
"Hab. Unter Corallen im Hafen von Nizza."

## 8. I. subulatum.

Phanoglene subutata, Eberth, Unters. über Nemat. p. 21, tab. ii. figs. 9 \& 10.
"Körper des Weibehens in der äussern Form der vorigen Art (L. longissimum), mit Ausnahme des Sehwanzes, ganz ähnlich. Dieser war hier sehr lang, pfriemenförmig und endete in eine schmale durchbohrte Papille.
"Länge etwa 8 Mm .
"Hab. Nizza."
This species seems to differ considerably from the others; and the form of the tail, with the presence of anal glands, as represented by Eberth, are sufficient to indicate the improbability of its really belonging to this genus.
20. ENOPLUS, Dujardin.

Lineola, Kölliker.
Gen. Char. Body tapering at extremities, especially towards posterior, which is more or less eonical. Caudal sucker of moderate size, generally provided with three short sucker-tubes. Integument having transverse and longitudinal markings; pores most visible in mid-dorsal and ventral region; eephalic setæ generally present, and
others frequent about posterior extremity, especially in the male; ceplaalic papille often present. Pharyngeal cavity none or indistinct, but in its situation three distinct horny jaws or teeth, more or less bilobed at their extremities. Wsophagus not distinctly muscular, nearly uniform in size, often much stained with pigment, especially at the anterior part; no distinct œesophageal ring. Intestine well covered with dark pigment-granules often distinetly tessellate in arrangement. Trulva about middle of body. Cterus bifid; segments symmetrical. Spicules large, curred, and, together with two strong lateral accessory pieces, of a yellowish-brown colour. Supplemental organ of same colour, large, oblique, funnel-shaped. Ocelli (pseud.) occasional, owing to more distinet aggregation of the usual pigment-matter of oesophagus; sometimes on or external to cesophageal sheath (?). Excretory rentral gland tubular, opening about the termination of anterior third of cesophagus. Lateral canals distinctly cellular.
Morements moderately active.
This is a very interesting genus, inasmuch as it appears to reveal to us the most rudimentary condition of the ocelli, which are found more specially developed in the species of other genera, such as Phanoderma and Leptosomatum. Here we find, in several species, a simple local increase in the aggregation of the pigment, in two or three patches, on the anterior part of the cesophagus, it being also more or less scattered over its whole extent, whilst in Enoplus inermis it is wanting in all parts of the œesophagus, save in two rather distinctly defined ocelli-like masses, which seem, however, to be still situated bencath instead of on the sheath of the oesophagus, as is so evidently their situation in the genera above named.

In this genus also are included many species of free Nematodes which have been discovered by other observers, but whose real position and nature are still very doubtful, either from the insufficient or unsatisfactory nature of the details concerning them.

1. E. communts, n. sp. (Plate XII. figs. 164-166.)

Female, length $\frac{1^{\prime \prime}}{4}$, breadth $\frac{1}{120}{ }^{\prime \prime}$.
External Characters.-Body tapering slightly forwards, but considerably behind, where it terminates in a rather long pointed extremity, with a rounded sucker and three small divergent setæ. Head rounded, narrowed, provided with four crucially arranged papille, and behind them a circlet of 8-10 long patent setre; a few small setie scattered over anterior part of body also. Integument with almost imperceptible transverse striec, about $\frac{1}{30000}{ }^{\prime \prime}$ apart, and with an appearance of longitudinal markings atso at a distance of $\frac{1}{8000}{ }^{\prime \prime}$.

Pharynx indistinct. Teeth three, equal-sized, of a light fawn-colour, $\frac{1}{1000}{ }^{\prime \prime}$ long, marked with minute longitudinal lines, and having their upper extremities somewhat bilobed. CEsophugus about $\frac{1}{8}$ th of total length, having its eanal indicated by a sinuous line, with irregular transverse markings of its walls at intervals, and a more or less abundant arrangement of minute olive-coloured pigment-granules, mostly collected in three longitudinal lines, with short irregular transverse offshoots or separate masses, most marked anteriorly just behind pharynx. Intestine thickly corered with darkcoloured fat-particles contained in rather large cells, the tessellated appearance beins
distinct. Anus $\frac{1}{77}$ " from posterior extremity. Fulva slightly posterior to middle of body. Excretory ventral glend tubular, extending from posterior part of cesophagus to about the termination of anterior third.

Male, length $\frac{1^{\prime \prime}}{4}$, breadth $\frac{1}{100}$ ".
Rather stonter than female, especially at-posterior extremity; tail tapering more abruptly behind anus; small setze scattered over posterior part of body; helow anal eleft are two strong setæ, one on each side of middle line; and above, between it and supplementary organ, is a single median row of about sixteen louger and more slender bristles. Strong obliquely transverse markings of integument $\frac{1}{3500}$ " apart for some distance above anal eleft.

Spicules brownish yellow, strong, curved, $\frac{1}{100}$ " in length; accessory pieces of sante colour, $\frac{1}{2} \frac{1}{2}{ }^{\prime \prime}$ long, slightly curved, and somewhat wedge-shaped. Supplementary organ $\frac{1}{66}{ }^{\prime \prime}$ above anus, brownish yellow, large, infundibuliform, $\frac{1}{200}{ }^{\prime \prime}$ long; internal expanded portion becoming thin and rather indistinet.

Hab. About the roots of Corallina officinalis from tide-pools, Falmouth.

## 2. E. Dujardinit, n. sp. (Plate XII. figs. 168-170.) <br> Female, length $\frac{1^{\prime \prime}}{4}$, breadth $\frac{1}{100}{ }^{\prime \prime}$.

Exterial Characters.-Body very pellucid, tapering slightly auteriorly, but considerably behind anus. Head narrowed, rounded, having four crucially arranged papillæ around mouth, and behind these a circlet of $10-12$ strong patent seta; no other setæ visible. Integument very transparent, with almost impereeptible transverse and also longitudinal markings.

Teeth three, same as in last. Esophagus between $\frac{1}{6}$ th and $\frac{1}{7}$ th of total length; pig-ment-lines and markings well developed anteriorly, but no very distinct local aggregations. Intestine broad, densely covered with small, dark-coloured, tessellate aggregations of fat-partieles only about $\frac{1}{2000}$ " in diameter. Auus $\frac{1}{60}$ " from posterior extremity. Vulva very slightly posterior to the middle of body. Excretory ventral duct opening opposite termination of anterior third of œesophagus.

Male, about same size as female, but slightly narrower. Posterior extremity terminating with three minute setre; single median row of long narrow setre between anus and supplementary organ; the two posterior to anus not present, neither were any small ones scattered over posterior part of bodly recognized.

Spicules brownish yellow, strong, curved, $\frac{1}{125}{ }^{\prime \prime}$ long; accessory pieces about half as long. Supplementary organ $\frac{1}{77}^{\prime \prime}$ above anus, much longer, as compared with breadth of body, than in last species.

Hab. In sand and about roots of Algre from tide-pools, Falmouth.
3. E. pigmentosus, n. sp. (Plate XII. figs. 171, 172.)

Female, length $\frac{1^{\prime \prime}}{}{ }^{\prime \prime}$, breadth $\frac{1}{100}{ }^{\prime \prime}$.
External Characters.-Body tapering slightly forwards; posterior extremity behind anus elongated, conical, terminating with distinct rounded sucker, but no setæ. Head bluntly rounded ; mouth surrounded by four rather smaller papillæ; and behind them is
a circlet of about six strong spreading sctre; no setae recognized on other parts of body. Integument transparent ; strize not recognized.

Teeth three, large, $\frac{1}{666}$ in length. Esophagus about $\frac{1}{7}$ th of total length, abundantly marked with pigment arranged in three prineipal rows. Iutestine densely covered with rery dark-coloured and almost black pigment-granules; tessellate arrangement not very distinct. Anuis $\frac{1}{160}{ }^{\prime \prime}$ from posterior extremity. Tagina anterior to middle of body. Ova large. Excretory rentral duct opening opposite termination of anterior third of oesophagus.

Mate, not seen.
Hab. About roots of Alge and Corallines from tide-pools, Falmouth.
-
4. E. inernis, n. sp. (Plate XII. figs. 173-175.)

Fcmale, length $\frac{1}{3}$ ", breadth $\frac{1}{187^{\prime \prime}}$.
External Characters.-Body naked, tapering but very slightly anteriorly, thongh in the usual way towards posterior extremity, which terminates in a rather undeveloped sucker, in connexion with which the usual sucker-tubes were not recognized. Head bluntly rounded, or eren somewhat angular; no papillie; no sete. Integument with faint transverse strixe, $\frac{1}{10000}$ " apart, and also indistinct longitudinal markings.

Teeth three, small, $\frac{1}{3333}{ }^{\prime \prime}$ long, very close to month. Qsophagus about $\frac{1}{7}$ th of total length, almost free from pigment, except anteriorly, where it is principally collected into two reddish-brown occlli-like masses, about $\frac{1}{33} 3^{\prime \prime}$ from anterior extremity. Iutestine well corered with dark pigment-granules; tessellation indistinct. Auus $\frac{1}{6}$ " from posterior extremity. Tulva posterior to middle of body. Excretory ventral gland could not be detected.

Murc, lengeth mearly the same as that of female, lreadth $\frac{1}{1+3}$ ". Head provided with four indistinct papillic ; posterior extremity broader than in female, and tapering more abruptly behind anus; two sete below anus, small; no other seen.

Spiculcs brownish yellow, curved, obtuse at points, $\frac{1}{166}{ }^{\prime \prime}$ long; accessory pieces of about half the length. Supplementary organ rather narrow, $\frac{1}{80}$ " abore anus, and $\frac{1}{200} 0^{\prime \prime}$ in length.
\#ub. In small red sponges from crevices of rock, Falmouth.
5. E. Bleevis, n. sp. (Plate XII. figs. 176,177 .)

Feualc, length $\frac{1}{5}{ }^{\prime \prime}$, breadth $\frac{1}{143}{ }^{\prime \prime}$.
External Churacters.-Body scarcely tapering at all anteriorly, but considerably towards the posterior extremity, which is rather long and pointed, teminating in a distinct sucker; sucker-tubes mot recognized. Head rounded, having no papilla, but provided with a cirelet of $10-12$ setre. Integument transparent, with very delieate transverse and longitudinal markings.

Teeth three, large, $\frac{1}{16} \bar{\sigma}^{\prime \prime}$ in length. Esophagus between $\frac{1}{5}$ th and $\frac{1}{6}$ th of total length; pigmentary deposits distinct almost to termination. Intestine well eovered with darkcoloured fat-particles, having a tessellate arrangement. Anus $\frac{1}{80}{ }^{\prime \prime}$ from posterior
extremity. Vulva posterior to middle of body. Excretory ventral duct opening at $\frac{1}{100}{ }^{\prime \prime}$ from anterior extremity.

Male, not seen.
Hab. About roots of small Algac and Corallines from tide-pools, Falmouth.
6. E. tridentatus, Dujardin.

Hist. Nat. des Helminthes, p. 233.
"Corps filiforme, gris-brunâtre, long de 3 à $7^{m m}$, large de $0^{m m} \cdot 11$ à $0^{\mathrm{mm} \cdot 23}$, trente à
 ment quelques soies roides, opposées; bouche ronde, entourée par le tégunent mou, et armée intérieurement de trois mâchoires cornées, symétriques; mandibules longues de $0^{\mathrm{mm}} .046$, formées d'une apophyse postérieure, plus étroite, ćlargies et bilobées en avant, où elles se terminent par une dent erochue interne; œesophage musculeux, long de $0^{\mathrm{mm} \cdot 9} 9$, large de $0^{\text {mm. }} 063$, avec des bandes transverses de pigment brun-rougeâtre; deux amas de pigment rouge (taches oculiformes ?) ì l'origine de l'œsophage; eanal œsophagien triquêtre, à bord flexueux ; intestin revêtı de plaques aréolées brunâtres (foie ?) ; tégument
 diaphane élastique.
"Mâle ayant la partie postérieure du corps hérissée de quelques soies éparses; queue assez brusquement amincie, large de $0^{\mathrm{mm}} 02$, à l'extrémité ; orifice génital (et anal ?) à $0^{\mathrm{mnn}} 31$ de l'extrémité; un autre orifice (anus ou ventouse?) situé à $0^{\mathrm{mm}} 35$ en avant; spicules épais, longs de $0^{\mathrm{mm}} \cdot 15$, courbés en faucille et dentelés vers l'extrémité; pièce accessoire longue de $0 \mathrm{~mm} \cdot 048$, embrassant l'extrémité des spicules.
"Femelle à queue plus longue et moins brusquement amincie; anus à $0^{\text {nam. }} 47$ de l'extrémité; vulve orbiculaire, située eu avant du milieu.
"Je l'ai trouvé fréquemment entre les algues marines à Toulon, et à Cette dans la Méditerranée, et dans l'étang de Thau, et à Saint-Malo dans l'Océan."
7. E. stenodon, Dujardin.

Hist. Nat. des Helminthes, p. 234.
"Corps long de $2^{\text {mm }}$ ì (?), large $0^{m m} 04$ à (?), cinquante fois environ aussi long que large; tête large de $0^{\mathrm{mm}} .013$, munie de quelques soies roides, latérales; bouche armée intérieurement de trois dents étroites, sinueuses, longue de $0^{\mathrm{mm}} 012$ : une tache rouge bien nette sur l'œosophage, à $0^{\mathrm{mm} .03}$ de la bonche; quene épaisse, amincie peu à peu; anus à $0^{\mathrm{mm} \cdot 07}$ de l'extrémité.
"Dans l'eau de mer entre les algues, à Lorient."
8. E. elongatus, Dujardin.

Hist. Nat. des Helminthes, p. 234.
"Corps long de $18^{\mathrm{mm}}$, large de $0^{\mathrm{mm} .2 \text {, quatre-vingt-dix fois aussi long que large; tête }}$ large de $0^{\mathrm{mm}} \cdot 06$, tronquée et munie de soies latérales roides, assez longues; bouche armée intérieurement de deux ou trois pièces (mâchoires) coudćes, à angle droit en avant et en dedans, et dentelées en avant.
"Dans l'eau de mer, à Saint-Malo."

## 9. E. microstonus, Dujardin.

"Corps proportionnellement assez épais, long de 2 mm. 6 , large de $0^{m m} \cdot 10$, vingt-six fois aussi long que large, auinci seulement anx extrémités; tête amincie brusquement et large $0^{\mathrm{mm}} \cdot 016$ en avant, et entourée de quelques soies roides; bouehe armée intćrieurement de trois pièces (mâchoires ?) prolongées par des apophyses étroites en arrière ; deux taches rouges bien nettes et bien séparées, à $0^{\mathrm{mm} .06 \text { de la bouche; queue courte, assez }}$ brusquement amincie.
"Dans l'eau de mer, à Lorient."
10. E. macropitilalius, Eberth.

Unters. über Nemat. p. 35, tab. ii. figs. 23, 24, tab. iii. fig. 6.
"Körper des Weibchens fast gerade, gegen das Vorderende wenig verschmälert, das Schwanzende stärker zugespitzt und in eine kleine durehbohrte Ansehwellung endigend.
"Kopf abgerundet mit einem mittleren rundlichen Vorsprung und 2 kleinen seitlichen Papillen.
"Zwei grosse braune Pigmentflecken hinter dem Pharynx.
"Weibchen 5 Mm . lang, 0.20 Mm . breit.
"Oesophaguslänge $=\frac{1}{5}$ Körperlänge."
11. E. obtusicaudatus, Eberth.

Untersuch. über Nemat. p. 36, tab. iii. figs. 7 \& 8.
" Nörper des Weibchens.-In seiner äusseren Form ist er von dem vorigen versehieden dureh die allmähliche und geringe Verschmälerung des Vorderendes und durch den stumpfen Schwanz, weleher nach oben eine mehr concave und nach unten eine mehr convexe Fläche bildet. Am Schwanze eine terminale nur leicht proninirende Mündung der Schwanzdrüse.
"Hinter dem Pharynx zwei quergelagerte dunkelbraune Augenfleeke.
"Länge des Weihchens 3 Mm ., Breite $0 \cdot 125 \mathrm{Mm}$.
"Oesophaguslänge $=\frac{1}{6}$ der Körperlänge."
12. E. striatus, Eberth.

Unters. über Nemat. p. 36, tab. ix. figs. 9-12.
" Körper fast gerade, fadenförmig, in der Nitte angesehwollen, gegen die beiden Enden verschmälert, stärker gegen den Schwanz; dieser bei dem Mäunchen leicht eingebogen. Vorderende stumpf abgerundet, mit einem kleinen trichterförmigen Mund. Der Körper hinter dem Pharynx auf eine kurze Strecke leieht eingesehnürt
" Hinter dem Pharynx zwei braune nierenförmige Pigmenthaufen.
"Länge der Männchen 3 Mm ., Breite 0.125 Mm .
"Oesophaçuslänge $=\frac{1}{6}$ der Körperlänge."

## 14. E. Leydigit, Eberth.

Müller's Archiv, 1851, p. 292.-Eberth, Unters. über Nemat. p. 32.
"Der Wurm ist fadenförmig, $1 \frac{1}{2}-2^{\prime \prime \prime}$ lang, das Kopfende breiter als das Schwanzende. Die cutieula stark quergeringelt, besonders im vorderen Drittheil des Körpers, und jeder Ring erscheint wieder für sich längsgestrichelt.
"Kopf querabgestutzt, vorderer Rand wie lippenartig, mit mehren seichten Einkerbungen und mit vereinzelten blassen Borsten besetzt. Der Lippentheil des Kopfes ist hell, sonst hat der Wurm bei durchfallendem Lichte eine bräunliche Farbung. Die Mundhöhle hat innen zwei seitliehe gezähnelte Leisten und eine unpaare mittlere kleinere. Schundröhre naeh hinten leicht kolbig angeschwollen, diekwandig, quergestreift mit innerer Cutieula. Darm gerade. Anus an der Schwanzbasis. Im Anfang des Oesophagus zwei rothbraune augenähnliche Flecke. Zwei entgegengesetzt verlaufende Eierstöcke, gemeinsamer Uterus, Vagina in der Mitte des Körpers. Das Männchen vor dem Sehwanzende auf dem Rüeken mit Borsten besetzt. Es scheinen zwei Spicula vorhanden. Schwanzdrüse bei beideu Geschlechtern dureh ein kurzes Röhrchen mïndend." - Eberth.
15. E. Sieboldif, Eluerth.

Untersuch. über Nemat. p. 31.
Lineola Sieboldii, Kölliker, Abdrück aus den Verhand. d. Naturf. Gesellch. 1845.
"Der Leib ist bräunlich, vorn und hinten weiss, $3-5$ " lang. Von den Fühlern vier sehr kurtz, zwei etwas länger, alle endständig. Mundhöhle mit kleinen zahnartigen Hervorragungen besetzt; am Kopfe dieht am Oesophagus zwei oder drei Flecken (Augen ?). Seheideöffnung mit zwei oder drei kleineı zahnartigen Vorsprüngen versehen. Schwanz $0 \cdot 1^{\prime \prime \prime}$ lang; Penis $0 \cdot 1^{\prime \prime \prime}$ lang."
16. E. cirrhatus, Eberth.

Untersuch. über Nemat. p. 34, tab. ii. fig. 20-22, tab. iv. fig. 17, \& tab. v. fig. 4.
" Körper: bei dem Weibchen am Hinterleib gegen den Bauch leicht eingebogen, stärker eingerollt bei dem Männehen, beide Enden verschmälert, der Schwanz zugespitzt, das Vorderende etwas abgerundet. Schwanz in eine kurze durehbohrte Spitze auslaufend
"Länge des Weibehens 4 Mm ., des Männchens $3 \frac{1}{2}$ Mm.
"Breite des Weibehens 0.12 Mm ., des Männchens 0.1 Mm .
"Oesophaguslänge $=\frac{1}{6}$ der Körperlänge."
This ecrtainly is not an Enoplus; the type is distinct, though unknown to me.
17. E. ceruleus, Eberth.

Untersuch. über Nemat. p. 39, tab. iv. fig. 6-12, \& tab. v. fig. 3.
"Körper von bläulicher Färbung, cylindrisch, gegen das Vorderende leicht verschmälert und stumpf eonisch geendet, das Hinterende wenig verjüngt, stumpf; beim Weibehen gegen deu Bauch eingekrïmmt, beim Männehen stärker eingerollt. Die Gestalt des Schwanzes bei beiden Gesehlechtern gleieh. An ihm findet sich terminal eine zeimlich grosse runde Oeffnung für die Schwanzdrüse. Kurz vor der Mündung liegen noch drei kleine hornige zahnartige Klappen. Die Drïse besteht aus einem grösseren, von einer gemeinsamen Membran eingesehlossenen Zellenaggregat
vol. xxv.
"Am untercu Ende des Pharynx licgen auf diesem zwei schönblaue nierenförmige Augen.
"Länge des Wreibchens 6 Mm ., Breite 0.2 Mm .
"Länge des Männchens 4 Mm ., Breite 0.2 Mm .
"Oesophagnslänge verhält sich zur Körperlänge wie 1 : 5."
This also camot belong to the genus Enoplus. The first glance at Eberth's figures reveals a large pharyngeal cavity with no teeth or jaws, a distinct cosophageal ring, and an absence of the characteristic supplementary male organ, which at once negative its really belonging to this genus. It seems to be a most remarkable and interesting type, but one with which I am quite unfamiliar.
18. E. quadidentatus, Berlin.

Müller's Archiv, 1853, p. 431.-Eberth, Untersuch. über Nemat. p. 31.
Under this name Berlin appears to have inclucled two or three forms which are perfectly distinct from one another. From his drawings, one of these animals is undoubtedly an Enoplus, whilst another appears to be a Leptosomatum.
19. E. -, n. sp., M. Schultze.
V. Carus, Icones Zootomicæ, pl. vii. fig. 3.

No description.
This animal is evidently not an Enoplus.

## 21. LINHOMCEUS ${ }^{1}$, Bastian.

Gen. Char. Body linear, cylindrical, scarcely tapering at all at the extremities, which are blunt and rounded. Caudal sucker small, very slightly prominent; suckertubes two, short and broad. Integument plain or with longitudinal markings; lateral cervical mark circular, small, with a dot in the centre; setre more or less abmudant in auterior part of body; no cephalic papillw. Pharyngeal cavity of morlerate size, cup-shaped, naked. Csophagus distinctly muscular, swollen slightly behind pharyox and again at termination. Intestinal cells containing rather lightcoloured particles more or less tessellate. Tulva about the middle of body, with minute eminences (suckers?) in median line in front and behind it. Uterus lifid, segments symmetrical. Spicules curved, pointed. Accessury picces two, thin and reflexed. Ocelli none. Glandular system parietal, not much developed; floating cells in general cavity of body large ; anal glands well dereloped. Excretory rential glame consisting of a broad duct opening near middle of oesophagus, and a terminal dilated portion pressing upon first part of intestine. Lateral canals indistinet.
Movements rather slow.

1. L. imissutus, n.sp. (Plate XII. figs. 178, 179.)

Female, length $\frac{1}{6}{ }^{\prime \prime}$, breadth $\frac{1}{303}{ }^{\prime \prime}$.
External Characters.-Body tapering scarcely at all at extremities, but rather more

[^33]posteriorly than anteriorly. Head truncated or obtusely rounded, surrom some directed formards and others spreading, the latter continuing for some distance over anterior part of body. Integument very thin; no markings visible.

Pharyngeal cavity eup-shaped, $\frac{1}{2000}{ }^{\prime \prime}$ deep. Esophagus $\frac{1}{11}$ th of total length. Intestine well covered with cells presenting a tessellate arrangement, and containing lightcoloured granules. Fulva slightly anterior to middle of body; seven minute suctorial eminences in median line before and behind it, about $\frac{1}{1000}{ }^{\prime \prime}$ apart. Anal glands consisting of four distinct masses. Excretory dluct opening near middle of cesophagus. Lateral canals faintly granular, occupying about $\frac{1}{6}$ th of circumfereuce of body.

Male, not seen.
Hab. In sand at roots of sea-weed from tide-pools, Falmouth.
2. L. elongatus, n. sp. (Plate XII. figs. 180, 181.)

Male, length $\frac{3}{10}$ ", breadth $\frac{1}{53}-{ }^{\prime \prime}$.
External Characters.-Body very long and filiform, not tapering at all anteriorly, and but very slightly immediately before termination. Head bluntly rounded, furnished with a circle of eight setie, direeted forwards. Integument thin, presenting longitudinal markings $\frac{1}{12000}{ }^{\prime \prime}$ apart.

Pharyngeal cavity nearly rectangular, depth $\frac{1}{150}{ }^{\prime \prime}$, having three thin horny lamine continued backwards (into substance of cosophagus), with rounded and minutely serrated edges. Esophagus about $\frac{1}{6}$ th of total length. Intestine covered with cells having a tessellate arrangement; individual eclls containing rather few granules. Auts $\frac{1}{55}$ " from posterior extremity. Spicules of moderate length, curved; accessory pieces thin, flat, blade-like. Aucl gtands four large, somewhat quadrate, gramular bodies, lying between anal cleft and sucker-tubes. Excretory duct opening near middle of œesophagus.

Female, not seen.
Hab. With Symplocostoma tenuicollis and Chomadora vulgaris on fine filamentous green weed from tide-pools, Falmouth.

## 22. TACHYHODITES ${ }^{1}$, Bastian.

Gen. Char. Body tapering at extremities. Caudal sucker very small; no sucker-tubes visible. Integument having transverse strie ; cephalic setæ preseut; papillie absent. Pharyngeal cavity very small, indistinct. Esophagus almost cylindrical. Intestine rather sparingly covered with light olive-coloured hepatic granules. Vulva posterior to centre of body. Uterus unsymmetrical. Spicules rather narrow, curved. Accessory pieces nearly straight, pointed, and directed backwards. Ocelli(?) two bright colourless bodies on upper surface of œesophagus. Excretory ventral gland

Lateral canals
Movements very rapid.

1. T. natans, n. sp. (Plate XIII. figs. 182-184.)

Female, length $\frac{1}{33}{ }^{\prime \prime}$, breadth $\frac{1}{666}{ }^{\prime \prime}$.
Extemal Characlers.-Body tapering towards either extremity, but principally towards

[^34]the posterior, which is sharp and filiform. Head bluntly rounded, furnished with a circlet of 4-6 short setre. Integument having very fine transverse strix, about $\frac{1}{300000^{\prime \prime}}$ apart.

Pharyngeal carity very small, conical. Esophagus about $\frac{1}{6}$ th of total length, enlarging very slightly backwards. Intestine sparingly covered with non-tessellate hepatic granules. Auns $\frac{1}{200}$ " from posterior extremity. Ocelli two highly refraetive yellowish bodies, with a dark central spot on dorsal aspect at $\frac{1}{2000}$ " from anterior extremity.
Fulvea behind centre of body.
Male, length $\frac{1}{41}$ ", brearth $\frac{1}{909}{ }^{\prime \prime}$.
Esophayus relatively shorter. Amms $\frac{1}{22} \frac{1}{2}$ from posterior extremity. Spicules barbed at upper extremity, curved, $\frac{1}{1000}{ }^{\prime \prime}$ long ; accessory pieces lying nearly at right angles to spicules, pointed.

Hab. Small green filamentons weed from tide-pools, Falmouth. Also observed in a small aquarium for two or three weeks, feeding on minute vegetable spores near the surface of water.
2. T. parvus, n. sp. (Plate XIII. figs. 185, 186.)

Female, length $\frac{1}{45}{ }^{\prime \prime}$, breadth $\frac{1}{125} 5^{\prime \prime}$.
External Characters.-Body tapering at both extremities, especially at posterior, commencing behind vulva. Head truncate, naked. Strix of integument impereeptible.

Pharyngeal cavity indistinct. Esophagrs about $\frac{1}{7}$ th of total length. Intestine sparingly covered with hepatic particles. Anus $\frac{1}{3} \frac{1}{5}{ }^{\prime \prime}$ from posterior extremity. Vulva posterior to middle of body. Ocelli . . . . . .

Male, not scen.
IIab. Small green weed from tide-pools, Falmonth.
23. THERISTUS ${ }^{1}$, Bastian.

Gen. Char. Body tapering at extremities. Caudal sucker small; sucker-tubes not visible. Integument having transverse strix; lateral, eircular, convex prominences close to anterior extremity; cephalic setre, but no papille. Pharyngeal carity moderately large, rounded; parictes membranous, not horny. Gesophagus distinctly muscular, nearly cylindrical. Iutestine plentifully eovered with hepatic particles, more or less tessellate, and of a brownish colour. Fulva at commencement of posterior third of body. Uterus unsymmetrical. Spicules shaped like a reaper's hook. Accessory picces two thin rounded plates directed backwards. Ocelli none. Vaginal glands two, unequal, pyriform. Excretory ventral gland . . . . Lateral canals . . . . Movements very active.

1. T. acer, n. sp. (Plate XIII. figs. 187-188.)

Male, length $\frac{1}{15}$ ", breadth $\frac{1}{434}{ }^{\prime \prime}$.
External Characters.-Body tapering at extremities, slightly forwards, but gradually narrowing to a point posteriorly. Head rounded, furnished with about eight spreading setse, arising from swollen bases. Integument having transrerse striæ, $\frac{1}{12000}{ }^{\prime \prime}$ apart; conical projections $\frac{-1}{3}-\frac{1}{33} \overline{3}^{\prime \prime}$ in diameter, at $\frac{1}{1250}{ }^{\prime \prime}$ from anterior extremity.

[^35] tine abundantly covered with fat-particles laving no distinct tesscllate arrangement. Amus $\frac{1}{1+3}{ }^{\prime \prime}$ from posterior extremity. Spicules $\frac{1}{606}{ }^{\prime \prime}$ from point to point; accessory pieces curved backrards, and pyriform in shape.

Female, not seen.
Hab. Marine surface mud from estuary, Falmouth.
2. T. velox, n. sp. (Plate XIII. figs. 189-191.)

Female, length $\frac{1}{18}{ }^{\prime \prime}$, breadth $\frac{1}{45 \frac{1}{4}}{ }^{\prime \prime}$.
External Characters.-Body tapering slightly forwards, but rather abruptly behind vulva, and thence gradually to pointed posterior extremity. Head rounded, provided with 4-6 setr, which are rather long, and directed forwards. Tramsverse striæ well marked, $\frac{1}{12000}{ }^{\prime \prime}$ apart ; convex lateral prominences of intcgument $\frac{1}{5000}$ " in diameter, at $\frac{1}{1000}$ " from anterior extremity.

Pharyngeal cavity rounded, $\frac{1}{2500^{\prime \prime}}$ deep. Esophagus about $\frac{1}{5}$ th of total length, ncarly cylindrical. Intestine moderately well covered with olive-brown fat-particles, having a tessellate arrangement. Anus $\frac{1}{160}{ }^{\prime \prime}$ from posterior extremity. Tulver at commencement of posterior third of body. Taginal glands pyriform granular bodies, unequal, the posterior leing much the larger and $\frac{1}{1250}{ }^{\prime \prime}$ long.

Male, not seen.
Hab. About roots of small green sea-wecd from tide-pools, Falmouth.

## 24. SPH $\mathbb{R}$ OLAIMIUS ${ }^{1}$, Bastian.

Gen. Char. Body tapering at extremities. Caudal sucker minute; sucker-tubes not visible. Integument having transverse and longitudinal markings; setæ abundant; cephalic papillæ abscnt. Pharyngeal cavity large and somewhat spherical, having peculiar sets of parictal linear markings. Esophugns distinctly muscular, canal defincd by three rather bright bands. Intestine rather densely covered with darkcoloured hepatic particles. Tutua considerably posterior to middle of body. Uterus unsymmetrical. Spicules long and marrow. Accessory piece single, posterior, somewhat shield-shaped. Ocelli none. Taginal gland single, pyriform, posterior. Excretory ventral gland tubular, opening near middle of œsophagus. Lateral canals
Movements rapid, powerful.
S. Hirsutus, n. sp. (Plate XIII. figs. 192-194.)

Female, length $\frac{1}{10}{ }^{\prime \prime}$, breadth $\frac{1}{133}{ }^{\prime \prime}$.
Extermal Characters.-Body thick in proportion to length, tapering slightly anteriorly, but more considerably towards posterior extremity, which is slightly swollen and rounded at termination; covered with rather long setæ, which are largest and nost numerous about anterior extremity. Head rounded, somewhat conical. Integument having transverse striæ $\frac{1}{150.00}{ }^{\prime \prime}$ apart, and an appearance of longitudinal also, $\frac{1}{10000}{ }^{\prime \prime}$ apart.

[^36]Pharyngeal cacity somewhat globular, about $\frac{1}{400}{ }^{\prime \prime}$ in depth, surrounded about middle by a dark band, apparently due to markings of its walls, whilst anteriorly more delicate lines are seen converging towards the mouth. Esophagus about $\frac{1}{3}$ rd of total length. Intestine densely covered with fat-particles of a dark colour, obscurely tessellate. Anzs $\frac{1}{87}$ " from posterior extremity. Tulva considerably posterior to middle of borly, $\frac{1}{100}$ " in front of anal cleft. Traginal gland single, brownish, pyriform, projecting backwards, $\frac{1}{33}{ }^{\prime \prime}$ long, by $\frac{1}{500}$ " wide. Excretory ventrul gland tubular, not dilated at extremity, extending from posterior part to a little in front of middle of cesophagus, where its duct opens.

Male, length $\frac{1}{10}$ ", breadth $\frac{1}{154} "^{\prime \prime}$ Esophagus shorter than in fomale. Anus $\frac{1}{91}{ }^{\prime \prime}$ from posterior extremity. Spicules long, rather narrow, and moderately curved, $\frac{1}{115}$ " in length; accessory piece single, shield-shaped, with two grooves, along which the spicules glide, $\frac{1}{1000}{ }^{\prime \prime}$ long, by $\frac{1}{1250}{ }^{\prime \prime}$ broad.

IIub. Marine surface-mud from estuary, Fahmouth.

## 25. COMESOMA', Bastian.

Gen. Cuar. Body tapering at extremities. Caudat sucker moderately distinct; suckertubes none (?). Integument having transverse and longitudinal striæ, spiral lateral cervical markings, setæ more or less abundant abont anterior and posterior extremities, papillæ none. Pharyngeal cuvity small, cup-shaped. (Esophagus muscular, more or less swollen posteriorly. Intestine inoderately well covered with hepatic particles, mostly having a tessellate arrangement. Tulou about the middle of body. Uterus bifid; segments symmetrical. Spicules very long and narrow. Accessory pieces none, or, if present, single, small, and indistinct. Ocelli none. Anal glazds (?). Excretory rentral gland consisting of a slightly dilated posterior portion and a wide duct extending from commencement of intestine to about middle of ocsophagus. Latercel canals having a faintly grannlar appearance.
Morements moderately rapid, frequently forming body into a circular coil.

1. Comesona vulgaris, n. sp. (Plate XIII. figs. 195-197.)

Female, length $\frac{1}{7}$ ", breadth $\frac{1}{22 \frac{1}{2}}$ ".
External Characters.-Body opaque white, tapering slightly towards head, but more considerahly towards posterior extremity, which is long and marrow, but slightly swollen at termination. Head rounded, provided with two eirclets of setre, the anterior (four) being very long, but those forming the posterior, from six to eight in number, being much shorter. Other sete scattered over anterior part of body. Integument with longitudinal warkings $\frac{1}{7500}$ " apart, and more delicate transverse striæ $\frac{1}{15000}{ }^{\prime \prime}$ apart; lateral spital marking at same level as second circlet of sete.

Pharyngeal carity small, eup-shaped. Esophagus $\frac{1}{11}$ th of total length. Intestine covered with light-coloured hepatic particles, having a tessellate arrangement. Auzs $\frac{1}{71}$ from posterior extremity. Vulva at middle of body. Excretory duct opening opposite middle of cesophagus.

Ifale, same size as female. Posterior extremity having setre scattered over its surface,

[^37]especially in rentral regiou before and behind anus, where there is a linear scries. Anus $\frac{1}{77}$ " from posterior extremity. Spicules very long and narrow, but slightly rounded and enlarged at points, length $\frac{1}{128}$ "; accessory piece none.

Hab. Small green sea-weeds from tide-pools, Falmouth.
2. C. profundi, n. sp. (Plate XIII. figs. 198-200.)

Female, length $\frac{1}{9}{ }^{\prime \prime}$, breadth $\frac{1}{250}{ }^{\prime \prime}$.
External Characteis.-Body light-coloured, slender, tapering gradually forwards, but more notably towards posterior extremity, which is rather long and filiform, having two small setre at its termination. Head truncate, furnished with a circlet of six stout and long, spreading setze. Integument having longitudinal markings, transverse not visible; two circular(?) depressions, one on each side of head, and about $\frac{1}{3333}$ " in diameter.

Pharyngeal cavity very small, almost wanting. Esophegus about $\frac{1}{9}$ th of total length, gradually widening towards termination. Intestine covered with pale-coloured hepatic particles, having a tessellate arrangement. Anus $\frac{1}{100}$ " from posterior extromity. Tuluca about the middle of body. Uterine segments rather short. Excretory duct opening opposite middle of ocsophagus.

Male, length $\frac{1^{\prime \prime}}{9}$, breadth $\frac{1}{333}{ }^{\prime \prime}$.
Anus $\frac{1}{100}$ " from postcrior extremity. Spicules very long, slightly curved, length $\frac{1}{143}$ ", apparently not tubular, but grooved from angular bending. Accessory piece small, indistinct.

Hab. In mud dredged up from a depth of 20 fathoms, Falmouth Harlour.

## 26. SPIRA ${ }^{1}$, Bastian.

Gen. Char. Body tapering at extremitics. Caudul sucher very small and indistinct; sucker-tubes absent. Integument having transverse strie; two small, lateral, circular, convex prominences or depressions of integument in cervical region; seta not abundant, principally cephalic; cephalic papillæ wanting. Pharyngeat cavity wanting. EEsophagus short, distinctly muscular, with a simple terminal swelling. Intestine modcrately well covered with rather large, light-coloured hepatic particles. Tulva at middle of body. Uterus bifid; segments symmetrical. Spicules curved, moderately broad, cnlarged at upper extremities. Accessory pieces two, nearly straight. Ocelli none. Ercretory ventrul gland . . . Lateral canuls . . . .
Movements active.

1. S. parastitifera, n. sp. (Plate XIII. figs. 201-203.)

Female, length $\frac{1}{10}{ }^{\prime \prime}$, breadth $\frac{1}{333}{ }^{\prime \prime}$.
External Characters.-Body opaque white, tapering anteriorly and also gradually to a point posteriorly. Head rounded, provided with a circlet of 4-6 short setr. Integument with faint transverse striæ $\frac{1}{20000}$ " apart; small lateral hemispherical prominences close to anterior extremity.

Esophagus about $\frac{1}{17}$ th of total length; terminal swelling nearly globular. Intestine
rather narrow, moderately well covered with rather large particles having a tessellate arrangement. Anus $\frac{1}{200}$ " from posterior extremity. Tuluce near middle of body.

Mule, about same size as female. Alus about $\frac{1}{20 \bar{u}}$ "from posterior extremity. Spicules rather short, curved, $\frac{1}{455}{ }^{\prime \prime}$ in length; accessory pieces short, horizontal; proximal extremity curved and pointed.
\#ab. Amongst sand and small stones from tide-pools, Falmouth.
Body often more or less covered with minute tufts of hair-like algæe, whilst to the posterior extremities of two specimens I have seen groups of Forticella attached.
2. S. L.evis, n. sp. (Plate XIII. figs. 204-206.)

Female, length $\frac{1^{\prime \prime}}{6}$, breadth $\frac{1}{200}{ }^{\prime \prime}$.
Extermal Characters.-Body light-coloured, tapering slightly anteriorly, and gradually narrowing to a point posteriorly. Head most distinctly rounded. Integument smooth; no striae visible; a few small setæ seattered over antcrior extremity; lateral cervical depressions (slightly raised in centre) $\frac{1}{3333}{ }^{\prime \prime}$ in diameter, close to anterior extremity.

Esophagus between $\frac{1}{18}$ th and $\frac{1}{19}$ th of total length; terminal swelling nearly globular. Intestine sparingly corered with light-coloured hepatic particles having a somewhat tessellate arrangement. Anus $\frac{1}{166}{ }^{\prime \prime}$ from posterior extremity. Tulva anterior to middle of body, $\frac{1}{15}$ " from anterior extremity. Uterus bifid; segments symmetrical. Oca large, occupying whole breadth of body. Genital tube containing large, spherical, finely granular cells, about $\frac{1}{1000}$ " in diameter.

Male, length $\frac{1}{7}$ ", breadth $\frac{1}{285}{ }^{\prime \prime}$.
Esophagus about $\frac{1}{2}-$ th of total length. Anus $\frac{1}{18} \frac{1}{1}$ from posterior extremity. Spicules large, curved, $\frac{1}{333}{ }^{\prime \prime}$ in length; accessory pieces straight, rather narrow, and half the length of spicules.

IIub. In sand from roots of small algre, tide-pools, Falmouth.
3. S. tenuicaudata, n. sp. (Plate XIII. figs. 207-209.)

Female, length $\frac{1}{10}{ }^{\prime \prime}$, breadth $\frac{1}{285^{\prime \prime}}$.
External Characters.-Body white, tapering gradually anteriorly, but more abruptly towards posterior extremity, which is long and filiform. Head truncate, provided with a circle of $4-6$ seta. Integument with transverse strix, pretty well marked, $\frac{1}{20000}{ }^{\prime \prime}$ apart; two lateral circular depressions close to anterior extremity, $\frac{1}{3333}$ " in diameter; when looked down upon, a small central circle is seen $\frac{2}{3}$ rels less in diameter than that which contains it.

Esophagus about $\frac{1}{9}$ th of total length; posterior enlargement not nearly globular. Intestine covered pretty uniformly with pale small-sized granules. Anus $\frac{1}{133}$ " from postcrior extremity. Iruluc about middle of body.

Mrale, length $\frac{1}{12}$ ", breadth $\frac{1}{335}$ " ; having a few short seta seattered orer posterior extremity. Auus $\frac{1}{15 \Psi^{\prime \prime}}$ from posterior cxtremity. Spicules narrow, curred, $\frac{1}{500}$ " long; accessory pieces reflexed, curved, almost linear, $\frac{1}{608}{ }^{\prime \prime}$ long.

Hab. In sand from tide-pools, Fahmouth.
The different shape and length of the cesophagus, as well as the difference in form of the spicules and accessory pieces, lead me to suspect that this species will hereafter re-
quire to be transferred to a distinct though nearly allied genus. Its present position may be looked upon merely as provisional.

## 27. ODONTOBIUS, Roussel.

Gen. Char. "Body thread-like; anterior extremity more or less narrowed; posterior obtusely or sharply pointed, ending in a small papilla. Around the mouth and on anterior part of body are several cirri. On the hinder part of the body of the male, around the genital opening, are oue or two rows of roundish integumental prominenees.
"Skin colourless or of a yellowish-green colour, occasionally iridesecnt. External integument smooth or transversely striped. EEsophagus cylindrical, widening slightly posteriorly ; external layer or sheath composed of a finely granular mass, or cylindrical cells.
" Vagina variable in position. Lateral lines present. Gland (ventral?) of anterior part of body doubtful. Tail-glands consisting of an agglomeration of cells.
"Two spicules, with an anterior accessory organ', or two pairs of spicules, one large and one sinall."-Eberth, Unters. über Nemat. p. 27.

This description is the one given by Eberth, which I have inserted rather than that of Roussel, from its containing more details, though even these are insufficient accurately to characterize and fix the position of the genus. Eberth naturally enough objects to Diesing's having in his recent "Revision der Nematoden" placed this genus among'st his subfamily Anguillulidre, since Roussel's Odontobius was distinctly stated to be provided with cirri aromnd the month. Eberth is, however, himself uncertain what systematic place to assign to this genus, but says that he includes in it several free Nematoids which, from the appearance of small teeth ${ }^{2}$ in the mouth, are distinguished from those of Amblyura, Phanoglene, Enchelidium, and Oncholaimus, and, through the want of ocelli, from those of Enoplus.

Whether the original animal described by Ronssel de Vauzème, and found by him in or on the mucous membrane abont the basc of the whalebone in Balcou Australis, is * rightly included amongst the free Nematodes is a point about which I am still doubtfiu; but, as it seems quite possible that one of these animals might be met with in such a situation, I have retained it amongst them, and have refrained from altering the designation of three of the species placed by Eberth in this genus, though one of them seems to differ in some important respects from the other two.

" Körper bei beiden Geschlechtern ziemlich gleich, fadenförmig, gegen den Bauch eingekrïmmt, in der Mitte stärker anschwellend, an beiden Enden verschmälert. Vorderende fast quer abgestutzt, um die Mundöffnung und hinter dieser mit kurzen Härchen besetzt. Schwanzende abgerundet, mit eincr spitzen durchborten Papille versehen.
"Länge des Weibchens 3 Min., Breite 0.175 Mm.
"Länge des Männchens 2 Mm ., Breite $0 \cdot 1 \mathrm{Mm}$.
"Oesophaguslänge $\frac{3}{4}$ Mm."

## 28. CYATHOLAIMUS ${ }^{1}$, Bastian.

Gex. Char. Body mostly of a brownish colour, tapering at extremities; posterior conieal. Caudat sucker mostly well marked, cylindrical; sucker-tubes occasionally present. Integument having transverse striæ or rows of dots; small, lateral, circular, convex prominenees in cervical region, and occasionally others over posterior part of body ; eephalie setæ generally present, papille occasionally. Pharyngeal carity cup-shaped, with slight longitudinal rib-like markings. Eesophagus nearly uniform and cylindrieal; central canal broad. Intestine moderately well covered with large and

[^39]generally dark fawn-coloured hepatic particles. Tulce about the middle of body. Uterus bifid ; segments symmetrical. Spicules rather thick and solid, of a yellowish colour. Accessory pieces four, in two pairs, the longer being somewhat lamelliform, whilst the external pair are thick and quadrilateral. Ocelli, two aggregations of brownish pigment on dorsum of œesophagus; not present in some species. Glandular system well developed; subcutaneous, glandular, cell-like bodies numerous; anal glands three, occasioual. Excretory ventral gland terminating in moderatesized cluct, opening opposite middle of œesophagus. Lateral canals . . . .
Movements moderately active.

## * Candal sucker well markied, cylindrical.

1. C. ocellatus, n. sp. (Plate XIII. figs. 210-212a.)

Female, length $\frac{1}{17}{ }^{\prime \prime}$, breadth $\frac{1}{460}{ }^{\prime \prime}$.
External Characters.-Body tapering slightly forwards, but much more towards posterior extremity. Head rounded, provided with a circlet of four small setre. Integument with delicate transverse striæ, faintly visible, $\frac{1}{20000}{ }^{\prime \prime}$ apart; slureds easily peeling off under pressure.

Pharyngeal cavity $\frac{1}{2500^{\prime \prime}}$ deep. Esophagus rather less than $\frac{1}{7}$ th of total length. Intestine thinly covered with fat-particles, non-tessellated. Auus $\frac{1}{215}$ "from posterior extremity. Vulva slightly anterior to middle of body. Ocelli, two small greenish-brown masses of pigment, $\frac{1}{900}$ " from anterior extremity. Subcutaneous gland-cells numerous, rounded, granular, giving the animal a peculiar maculated appearance.

Male, length $\frac{1}{22}{ }^{\prime \prime}$ breadth $\frac{1}{535}{ }^{\prime \prime}$.
Auns $\frac{1}{32} \frac{1}{8}$ from posterior extremity. Spicules curved, somewhat wedge-shaped, $\frac{1}{500}{ }^{\prime \prime}$ long; accessory pieces four; principal pair rather long, narrow, and united in middle line; external pair rounded.

Hab. About Cladophora rupestris from tide-pools, Falmouth.
2. C. ceecus, n. sp. (Plate XIII. figs. 213, 214.)

Female, length $\frac{1}{15}{ }^{\prime \prime}$, breadth $\frac{1}{333}{ }^{\prime \prime}$.
External Characters.-Body tapering slightly forwards, but gradually narrowing to a point posteriorly. Head broad, truncate, having a circlet of four small setæ. Integument with almost imperceptible transverse striæ, about $\frac{1}{30000^{\prime \prime}}$ apart.

Pharyngeal cavity cup-shaped. Esophagns about $\frac{1}{7}$ th of total length. Intestine sparsely covered with large, coloured hepatic particles. Anus $\frac{1}{238}$ " from posterior extremity. Vulva anterior to middle of body. Ocelli wanting. Subcutaneous gland-cells round or oval, granular, about $\frac{1}{2000}{ }^{\prime \prime}$ in diameter.

Male, not seen.
Hab. Marine surface-mud from estuary, Falmouth.
3. C. ornatus, n. sp. (Plate XIII. figs. 215, 216.)

Female, length $\frac{1}{27}{ }^{\prime \prime}$, breadth $\frac{1}{357}{ }^{\prime \prime}$.
External Characters.-Body stout, light fawn-coloured, tapering slightly forwards, but gradually to a point posteriorly, where it terminates in an elongated sucker; sucker.
tubes two, short, distinct. Head truncate, provided with $8-10$ short setæ directed forwards. Integument with transverse strie scarcely perceptible, $\frac{1}{20000}$ " apart.

Pharyngeal cavity eup-shaped, $\frac{1}{2000}$ " deep. Esophagus rather less than $\frac{1}{4}$ th of total length. Intestine well covered with brownish fat-particles having a tessellate arrangement. Amus $\frac{1}{250}$ from posterior extremity. Tulva slightly posterior to middle of body. Ocelli, two aggregations of brown pigment, at $\frac{1}{1000}$ " from anterior extremity. Subcutuncous gland-cells aluundant. Anal glands three, large. Excretory ventral gland opening opposite middle of cesophagus; duct rather narrow, uniform in size.

Male, not seen.
Hub. Small green sea-weed from tide-pool, Falmouth ${ }^{\text {'. }}$
** Caudal sucker small, indistinct.
4. C. punctatus, n. sp. (Plate XIII. figs. 217, 218.)

Mrale, length $\frac{1}{12}{ }^{\prime \prime}$, breadth $\frac{1}{263}{ }^{\prime \prime}$.
External Characters.-Body powerful, tapering very slightly anteriorly, but gradually to a point posteriorly. Head obtusely rounded, provided with a cirelet of $6-8$ small spreading setæ; other small setæ scattered over posterior part of body. Integument having rows of dots arranged in transverse series $\frac{1}{15000}$ " apart; two lateral convex prominences of integument in cervieal region nearly opposite base of pharyngeal cavity, $\frac{1}{3333}{ }^{\prime \prime}$ in diameter.

Pharyngeal cavity eup-shaped. Esophagus about $\frac{1}{10}$ th of total length. Intestine sparsely and irregularly covered with large brownish-coloured fat-particles. Anus $\frac{1}{117}{ }^{\prime \prime}$ from posterior extremity. Spicules $\frac{1}{333}{ }^{\prime \prime}$ long. Ocelli two, greenish brown, large, $\frac{1}{1428}{ }^{\prime \prime}$ from anterior extremity. Subcutancous gland-cells wanting.

Femule, not seen.
Hab. Marine surface-mud from estuary, Falmouth.
5. C. striatus, n. sp. (Plate XIII. figs. 219, 220.)

Mule, length $\frac{1}{1 \frac{1}{2}}{ }^{\prime \prime}$, breadth $\frac{1}{285}{ }^{\prime \prime}$.
External Characters.-Body tapering slightly anteriorly, but gradually to a point postcriorly. Head obtusely rounded, provided with two small papillæ, upper and lower, and a circlet of about six setze directed forwards. Integument with very distinct transverse strise $\frac{1}{12000}$ " apart; a few scattered setac over antcrior part of body, but numerous others posteriorly behind anal cleft.

Pharyngeal cavity cup-shaped, $\frac{1}{2000}{ }^{\prime \prime}$ deep. Wsophagus $\frac{1}{11}$ th of total length. Intestine well covered with hepatie particles having a tessellate arrangement. Anns $\frac{1}{125}{ }^{\prime \prime}$ from posterior extremity. Spicules thick, strong, slightly curved, $\frac{1}{400}{ }^{\prime \prime}$ long: accessory pieces four; two median lanceolate, thin; two external stout, quadrilateral. Ocelli wanting. Subcutaneous gland-cells plentiful.

Female, not scen.
Hab. Marine surface-mud from estuary, Falmouth.

[^40]
## 6. C. gracilis.

Enoplus gracilis, Eberth, Unters. über Nemat. p. 34, tab. ii. figs. 13-19.
"Körper in der Mitte leicht angeschwollen, Vorderende verschmälert, Kopf abgerundet, leicht vom übrigen Körper abgeschnürt. Hinterende beider Geschlechter zugespitzt und gegen den Bauch eingebogen. Der Schwanz in cinen kleinen durchbohrten zierlichen Fortsatz ausgezogen
"Länge des Weibchens $3 \frac{1}{4}$ Mm., Breite 0.15 Mm .
"Länge des Männchens 2 Mm ., Breite 0.1 Mm .
"Oesophaguslänge verhält sich zur Körperlänge wie 1 : 6."
I have placed this animal in the genus Cyatholaimus, because it seems more nearly allied to the representatives of this type than to any others that I have met with. It is most certainly not an Enoplus, and will hereafter, I suspect, be found to belong to a genus distinct from, though closely allied to, the one in which I have now temporarily located it.

## 29. SPILIPHERA ${ }^{1}$, Bastian.

Gen. Char. Body tapering at extremities, conical posteriorly. Caudal sucker elongated, cylindrical; sueker-tubes undeveloped. Integument having transverse rows of dots or striæ, and two longitudinal rows of dots close together in each lateral region, as well as a spiral cervical marking on each side, close to the head; cephalic setre mostly present; no papillæ. Pharyngeal cavity cup-shaped, having longitudinal rays or rib-like markings and three horny apophyses spreading from its base. Cesophagus frequently enlarged behind pharynx, and generally terminating in an ovoid swelling. Intestine mostly pretty well covered with large, coloured hepatic particles. Tulva about middle of body. Uterus bifid; segments symmetrical. Spicules curred, narrow. Accessory pieces two, somewhat ovate, indistinct. Ocelli absent. Anal glands three, sometimes absent. Excretory ventral gland opening near middle of œesophagus. Lateral canals . . . . . .
Movements moderately active.

1. S. elegans, n.sp. (Plate XIII. figs. 221, 222.)

Mate, length $\frac{1}{17}{ }^{\prime \prime}$, breadth $\frac{1}{250} 0^{\prime \prime}$.
External Characters.-Body tapering most at posterior extremity. Head bluntly rounded, provided with $2-4$ minute setæ, directed forwards. Integument having transverse rows ( $\frac{1}{7500}{ }^{\prime \prime}$ apart) of minute rectangular dots, and two longitudinal rows of larger ones, $\frac{1}{5000}{ }^{\prime \prime}$ apart, on each side of body.

Pharyngeal cavity somewhat infundibuliform, $\frac{1}{200}{ }^{-\prime \prime}$ deep; three curved equal-sized apophyses extending backwards into substance of cesophagus, $\frac{1}{1428}{ }^{\prime \prime}$ in length. Esophagus $\frac{1}{6}$ th of total length ; swollen opposite apophyses, and again very distinctly at termination. Intestine covered irregularly with large-sized, greenish-yellow hepatio particles. Anus $\frac{1}{200}{ }^{\prime \prime}$ from posterior extremity. Spicules narrow, slightly curved, $\frac{1}{454}{ }^{\prime \prime}$

[^41]long; accessory pieces ovate, leaf-like, about $\frac{1}{3} \mathrm{r}$ d as long, rather indistinct. Anal glentls . . . . . . Excretory ventiat duct . . . . . .

Fenale, not seen.
Hab. Marine surface-mud from estuary, Fahmouth.
2. S. inequalis, n. sp. (Plate XIII. figs. 223-225.)

Female, length $\frac{1}{28}{ }^{\prime \prime}$, breadth $\frac{1}{50} 0^{\prime \prime}$.
Ectermal Characters.-Body tapering as in last species. Head slightly rounded, provided with $2-4$ spreading sete. Integument with well-marked transverse strie, $\frac{1}{15000}$ " apart, and two longitudinal lines of dots, about $\frac{1}{5000}$ " apart, ou each side of the body.

Pharyngeal cavity cup-shaped, rather indistinct, having two apophyses extending backwards for about $\frac{1}{1666} 6^{\prime \prime}$, the third being small and abortive. Esophagus $\frac{1}{5}$ the of total length, with post-pharyngeal and terminal swellings. Intestine covered pretty uniformly with large olive-yellow-coloured fat-particles. Amus $\frac{1}{200}$ " from posterior extremity. Tulcu slightly posterior to middle of body. Excretory ventral duct . . . . . .

Male, about same sizc or rather larger.
Anus $\frac{1}{2} \frac{1}{2}{ }^{\prime \prime}$ from posterior extremity. Spicules narrow, slightly curved, $\frac{1}{1000}{ }^{\prime \prime}$ long; accessory pieces indistinct. In mid-ventral region, anterior to anal cleft, is a linear series of about fifteen small, bright, rectangular spots, equidistant and $\frac{1}{2000}$ " apart.

Hab. Marine surface-mud of estuary, Falmouth.
3. S. robusta, n. sp. (Plate XIII. figs. 226, 227.)

Female, length $\frac{1}{12}{ }^{\prime \prime}$, breadth $\frac{1}{22_{2}^{2}}$ ".
External Characters.-Body stout, of a brownish-yellow colour, scarcely tapering at all anteriorly, but rery abruptly posterior to anus. Head rounded, naked. Integument with rows of clots, transverse, and $\frac{1}{12000}$ " apart.

Pharyngeal cavity large, $\frac{1}{1000}{ }^{\prime \prime}$ deep, longitudinal ribs well marked; three very thick and nearly straight apophyses exteuding backwards for $\frac{1}{1000} \overline{0}^{\prime \prime}$. Csophagus $\frac{1}{6}$ th of total length, cylindrical, and nearly uniform in size. Intestine covered with large, yellowish granules haring a tessellate arrangement. Auus $\frac{1}{222}{ }^{\prime \prime}$ from posterior extremity. Tulva slightly anterior to middle of body. Uterus bificl. Excretory rentral gland extending from about middle of oesophagus to commencement of intestine. Anal glands three, large, occupying nearly the whole of space posterior to anal cleft.

Male, not scen.
Hub. Marine surface-mud of estuary, Falmouth.
The very large size of the apophyses, the miform calibre of the cesophagus, and the apparent absence of the lateral lougitudinal rows of dots are all divergences from the typical characters of this genus, whose value it is at present difficult to estimate, and more particularly so since the characters of the male are as yet unknown.
4. S. costata, n. sp. (Plate XIII. figs. 228, 229.)

Male, length $\frac{1}{19}$ ", breadth $\frac{1}{435}$ ".
External Characters.-Body rather dark in colour anteriorly; tapering conically at posterior extremity. Sucker cylindrical, well marked. Head truncate, having a circlet
of four strong patent setr. Integument with most marked transverse strixe, $\frac{1}{10000}$ " apart, and equidistant longitudinal ridges, very obvious in the middle portions of body, but less evident towards cxtremities.

Pharyngeal cavity indistinct. Esophagns about $\frac{1}{7}$ th of total length, with post-pharyngeal aud terminal swellings. Intestine undistinguishable, from the total absence of the usual hepatic cells and contained fat-particles. Anus $\frac{1}{200}{ }^{\prime \prime}$ from posterior extremity. Spicules slightly curved and rather broad, $\frac{1}{166}{ }^{\prime \prime} \operatorname{lon}$; acecssory pieces not recognized.

Female, not sceu.
Hab. Marine surface-mud from estuary, Falmonth.
Having only scen two specimens of this species, I am not quite certain about the exact structure of its pharynx, and the presence or absence of accessory pieces to the spicules. The almost uniform light colour of, and absence of pigment from its internal parts, combined with a somewhat opaque integument, was the canse of my failure in ascertaining these points.

## 30. CEROMADORA ${ }^{1}$, Bastian.

Rhabditis, Max Schultze; Enoplus, Diesing.
Gen. Char. Body tapering at extremities; conical posteriorly. Caudal sucker elongated, pointed; sucker-tubes not developed. Integument having transverse and longitudinal strix, frequently somewhat clonded and opaque anteriorly; cephalic setre generally present, papille not. Pharyngeal cavity small and indistinct, with three cunciform horny apophyses (apices downwards) extending backwards, and in contact. Esopliagus having a more or less distinct swelling posteriorly; muscular tissue not well developed. Intestine mostly covered with irregularly arranged, large-sized, coloured hepatic particles. Tulvo at middle of body. Uterus bifid; segments symmetrical. Spicules two, somewhat narrow, curved. Accessory pieces well marked, about half as loug as spicules. Ocelli two masses of reddish pigment on dorsum of anterior part of œsophagus; sometimes wanting. Glandular system not much developed. Excretory ventral glend opening by a rather small duct nearly opposite middle of œesophagus (?). Lateral canals . . . . . .
Movements active.

1. C. volgaris, n. sp. (Plate XIII. figs. 233-235.)

Female, length $\frac{1}{10}{ }^{\prime \prime}$, breadth $\frac{1}{250}{ }^{\prime \prime}$.
External Characters.-Body clouded anteriorly, tapering from near the middle to either extremity, but somewhat widening again at head, which is truncated and provided with small seta. Integument with vcry distinct transverse strize at interrals of $\frac{1}{5000}$ ", which are crossed by delicate lougitudinal lines $\frac{1}{30000}{ }^{\prime \prime}$ apart; small longitudimal ridge on either side of body ${ }^{2}$.

[^42]Pharyngeal carity shallow and indistinet; apophyses well marked, $\frac{1}{1000}{ }^{\prime \prime}$ long. Esophogus about $\frac{1}{7}$ th of total length, with a large ovoid swelling at termination, and provided with two rows of brownish pigment extending backwards on either side from two local reddish-brown aggregations $\frac{1}{666}$ " from the anterior extremity and within the sheath of cesophagus. Intestine covered with fat-particles, laving a more or less tessellate arrangement. Anus $\frac{1}{100}$ from posterior extremity. Tiulua at middle of body. Ocelli as above.

Mrule, length $\frac{1}{13}{ }^{\prime \prime}$, breadth $\frac{1}{285}{ }^{\prime \prime}$.
Auns $\frac{1}{13} \frac{1}{}{ }^{\prime \prime}$ from posterior exterior extremity. Spicules eurved, $\frac{1}{333}{ }^{\prime \prime}$ loug; accessory pieces two, strong, broad, $\frac{1}{588}{ }^{\prime \prime}$ long.

Hub. Very abundant about Cladophora rupestris and some other small green weeds from tide-pools, Falmouth.
2. C. nudicapitata, n. sp. (Plate XIII. figs. 230-232.)

Femate, length $\frac{1}{33}{ }^{\prime \prime}$, breadth $\frac{1}{666}{ }^{\prime \prime}$.
Extermal Characters.--Body tapering very slightly forwards. Head rounded, naked. Integument with delieate transverse strixe, $\frac{15}{15000}{ }^{\prime \prime}$ apart; longitudinal not recognized.

Pharyngeal cavity shallow and indistinct; apophyses $\frac{1}{2500}$ " long. Esophagus about $\frac{1}{7}$ th of total length; rounded swelling at termination. Intestine sparingly covered with hepatic particles. Amus $\frac{1}{220}$ " from posterior extremity. Tutva slightly anterior to middle of body. Occlli two, reddish brown, at $\frac{1}{1000}$ " from anterior extremity; oceasionally one only, in'middle line.

Hale, length $\frac{1}{33}{ }^{\prime \prime}$, breadth $\frac{1}{83} 5^{\prime \prime}$.
Auus $\frac{1}{330}$ " from posterior extremity. Spicules slightly eurved, $\frac{1}{833}{ }^{\prime \prime}$ long; accessory pieces narrow, and curved at inner extremities, abont $\frac{1}{1200 "}$ long. In mid-central region above anus, within the substance of the integument, are five disk-shaped, highly refractive bodies, about $\frac{1}{5000}{ }^{\prime \prime}$ in diameter, whose distances apart gradually diminish anteriorly.

Hab. On small, stunted, greyish speeimens of Cladophora rupestris from tide-pools near high-water mark, Falmouth.
3. C. Natans, 11. sp. (Plate XIII. figs 236-238.)

Femule, length $\frac{1}{2}{ }^{\prime \prime}$ ", breadth $\frac{1}{500}{ }^{\prime \prime}$.
Extemal Churacters.-Body tapering very slightly towards anterior extremity, but as usual at posterior. Head rounded, provided with four spreading setre. Integument very transparent, not darkened anteriorly, having transverse striæ $\frac{1}{12000}$ " apart; longitudinal not recoguized.

Pharyngeat cavity indistinet; apophyses $\frac{3}{1606}$ " in length. Gsophagus $\frac{1}{7}$ th of total length. Iutestine well covered with large-sized greenish-yellow granules, having no distinct arrangement. Amus $\frac{1}{18 \frac{1}{2}}$ from postcrior extremity. Tulea at middle of body. Ocetli two distinct conical aggregations of red pigment, situated almost laterally on the oesophagus, which is somewhat narrower at this point.

Malc, length $\frac{1}{23}{ }^{\prime \prime}$, breadth $\frac{1}{55} 5^{\prime \prime}$.
Anus $\frac{1}{211}$ " from posterior extremity. Spicules rather narrow, curved, $\frac{1}{714}$ " long;
accessory pieces $\frac{1}{909}$ " long. In mid-ventral region, above anus, is a linear series of five highly refraetile roundish bodies, similar in kind to those of C. nudicapitata.

Hab. Found swimming near the surface of the water in a small aquarium containing weeds from tide-pools, Falmouth.
4. C. СєСА, n. sp. (Plate XIII. figs. 239-241.)

Female, length $\frac{1}{30}$ ", breadth $\frac{1}{500}{ }^{\prime \prime}$.
External Characters.-Body tapering considerably at both extremities. Head truncate, provided with four setæ directed forwards. Integument having well-marked transverse strize at $\frac{1}{20000}$ " apart, and with the appearance of longitudinal also.

Pharyngeal cavity small, indistinet; apophyses three. .Esophagus about $\frac{1}{7}$ th of total length; posterior swelling distinct. Intestine sparsely and irregularly covered with fatgranules of large size. Anus $\frac{1}{238}{ }^{\prime \prime}$ from posterior extremity. $l^{r} u l v a$ about the middle of body. Ocelli wanting.

Male, length $\frac{1}{37}$ ", breadth $\frac{1}{500^{\prime \prime}}$.
Anus $\frac{1}{2} \frac{1}{85}$ from posterior extremity. Spicules slender, curved, $\frac{1}{1000}{ }^{\prime \prime}$ long; accessory pieces two, nearly half as long.

Hrib. Marine surface-mud from estuary, Falmonth.
5. C. filiformis, n. sp. (Plate XIII. figs. 242-244.)

Female, length $\frac{1}{30}{ }^{\prime \prime}$, breadth $\frac{1}{666}{ }^{\prime \prime}$.
External Characters.-Body very slender, tapering most notably towards extremities, so as to appear somewhat spindle-shaped. Head bluntly rounded, provided with 2-4 setæ. Integument with transverse striæ $\frac{1}{15000}{ }^{\prime \prime}$ apart.

Pharyngeal cavity indistinct; length of apophyses $\frac{1}{2000}$ ". Esophagus about $\frac{1}{6}$ th of total length; posterior swelling not very distinet. Intestine thinly covered with irregularly disposed hepatic particles. Anus $\frac{1}{22^{2}}{ }^{\prime \prime}$ from posterior extremity. Vulva slightly posterior to middle of body. Ocelli two, reddish brown, $\frac{1}{1250}$ " from anterior extremity:

Male, longer, though more slender, than female; length $\frac{1}{22}{ }^{\prime \prime}$, breadth $\frac{1}{1000}{ }^{\prime \prime}$.
Anus $\frac{1}{18} \frac{1}{2}$ from posterior extremity. Spicules rather short, eurved, $\frac{1}{1250}$ " in length. Accessory pieces about half as long.

Hab. Small green sea-weeds from tide-pools, Falmouth.
6. C. sabellotdes, n. sp. (Plate XIII. figs. 245, 246.)

Male, length $\frac{1}{31}{ }^{\prime \prime}$, breadth $\frac{1}{666^{\prime \prime}}$.
External Characters.-Body tapering very slightly anteriorly, but in usual manner at posterior extremity. Head rounded, provided with four moderately long setæ. Integument with transverse strix $\frac{1}{15000}{ }^{\prime \prime}$ apart; longitudinal not recognizable.

Pharyngeal cavity indistinct; apophyses about $\frac{1}{3333}{ }^{\prime \prime}$ in length. Esophagus about $\frac{1}{5}$ th of total length ; posterior third forming an elongated terminal swelling. Intestine thinly covered with hepatic granules. Anus $\frac{1}{2} \frac{1}{85}$ from posterior extremity. Spicules slighty curved, $\frac{1}{1000}{ }^{\prime \prime}$ long. Accessory pieces $\frac{1}{1666}{ }^{\prime \prime}$ long.

Female, not seen.
Hab. Marine surface-mud, Falmouth. Found in the mud, moving about with a tube VOL. XXV.
like that of a Sabella, composed of the finest particles of sand and Diatomacere agglutinated together. Tube longer than worm, but embracing its body pretty closely.
7. C. paplllata, n. sp. (Plate XIII. figs. 247, 248.)

Male, lengtl $\frac{1}{15}{ }^{\prime \prime}$, breadth $\frac{1}{3} \frac{1}{33}$ ".
External Characters.-Body tapering slightly anteriorly; posterior extremity rather narrower, and more elongated than usual. Head rounded, provided with two (upper and lower) horn-like papillæ in front, and four rounded ones (crucially arranged) behind them; also four setæ arising close to these posterior papillæ. Integument brittle, clouded anteriorly, having well-marked transverse strix $\frac{1}{7000}{ }^{\prime \prime}$ apart, and longitudinal ones at a distance of $\frac{1}{30000^{\prime \prime}}$.

Pharyngeal cavity and apophyses . . . . . . Esophagus $\frac{1}{6}$ th of total length, slightly swollen posteriorly. Intestine moderately well covered with light-coloured hepatic particles. Anus $\frac{1}{1} \frac{1}{3}{ }^{\prime \prime}$ from postcrior extremity ; posterior boundary of anal cleft rather prominent, and containing a small horny body within its substance. Spicules curved, rather narrower at upper extremities, $\frac{1}{357} 7^{\prime \prime}$ long; accessory pieces strong, hook-like, $\frac{1}{6} \frac{1}{5}{ }^{\prime \prime}$ long. Ocelli wanting. Excretory ventral duct rather narrow; opening opposite middle of oesophagus.

Female, not seen.
Hub. Marine surface-mud from estuary, Falmouth.
The nature of the head and pharynx in this species differs somewhat from the strict type of this genus, though, in other important points, the characters are identical.
S. C. bioculata.

Rhabditis bioculata, M. Schultze.-V. Carus's Icones Zootom. tab. viii. 2.
Enoplus bidentatus, Diesing, Sitzungs. der Kais. Akad. der Wissen. xlii. Band (1860), p. 625.
No description.
9. C. ocellata.

Urolabes ocellatu, Carter, Ann. of Nat. Hist. ser. 3. vol. iv. p. 43.
Phanoglene ocellata, Eberth, Unters. über Nemat. p. 21, pl. iii. fig. 31.
"Female, linear, cylindrical, unstriated ', ocellated, diminishing gradually towards the head, whieh is obtuse and provided witl four short, linear cirri ; also diminishing gradually towards the tail, which is short, somewhat curved, and furnished with a pointed digital termination. Mouth, vulva ${ }^{2}$, and anus situated as in the foregoing species.
" Alimentary canal the same, but with the osophageal sheaths more bulbous posteriorly, and no globular dilatation of the intestinal sheath posterior to it."
"Sizc. About $\frac{1}{32}$ nd of an inch long."
"Mfale, the same as the female, with the exception of the difference in the generative organs."
" Hab. Silty clots of Oscillatoria floating in the salt-water main drain of the town of Bombay."

[^43]
## GENERA IMPERFECTLY DESCRIBED.

31. AMBLYURA, Hemprich and Elurenberg.

Enchelis, Hill; Vibrio, Müller; Enoplus?, Dujardin; Anguillula, Leidy.
Gen. Char. "Corpus capillare, extremitate caudali subulata, papilla suctoria subclavatum. Caput corpore continuum, truncatum. Os terminale, orbiculare, cirrhatum. dcelli nulli. Penis simplex, nec vaginatus; apertura genitalis feminea . . . . . . Aquarum dulcium et maris incola; natatoria."

1. A. serpentulus, Hemprich and Ehrenberg.

Amblyura Serpentulus, Hemprich et Ehrenberg, Symb. Phys. Phytoz. Entoz. tab. ii. 14 (omissis cirrhis). —Ehrenberg, Infusionsth. 82.-Lamarck, Anim. sans Vert. $2^{\text {nde }}$ édit. iii. 663.—Dujardin, Hist. Nat. des Helminthes, 237.
Anguillula longicauda, Leidy, in Proc. Acad. Philad. v. (1851) 225.
Amblyura serpentulus?, Leidy, ibid. viii. (1854) 49.
"Cauda elongata, clavata. Longit. $\frac{1}{8}$ "."
"Hab. In infusione vegetabili plurium septimanarum et in palustribus, in Dania raro (AIiiller). In montibus Sinaiticis cum Confcrvis e rivulo vallis Wadi Esle prope Tor, et Berolini (Ehrenberg). Inter fila Lyngbya muralis aliarumque Confervarum in aquæductu, Philadelphix (Leidy ${ }^{1}$ )."

Nota. "De Amblyura Serpentulo Berolinensi præterea sequentia valent:-Corpus subtilissime, transverse striolatum, subannulatum. Tubus cibarius hinc ore, illinc ano terminatus simplex, strictura cardiaca insignis. Os terminale, anus ad caudæ basin lateralis. Feminarum apertura genitalis in medio corpore. Uterus bicornis. Feminæ maribus majores." -Hemprich ct Ehrenberg.

## 2. A. Gordius, Hemprich et Ehrenberg.

Vibrio Gordius, Müller, Anim. Infus. 60, tab. viii. 13, 14.
Amblyura Gordius, IIemprich et Ehrenberg, Symb. Phys. Phytoz. Entoz.—Ehrenberg, Insfusionsth. 82.Lamarck, Anim. sans Vert. 2 ${ }^{\text {nde }}$ édit. iii. 663.-Dujardin, Hist. Nat. des Helminthes, 238.
Enoplus elongatus, Dujardin ?, Hist. Nat. des Helminthes, 238.
${ }^{1}$ Dr. Leidy's description, collected from the two notices, is as follows :-
"Amblyura serpentulus.-Body cylindrical, colourless, hyaline; anteriorly obtusely rounded; posteriorly attenuated, with a long, delicate, flexible, subulate tail ; suctorial disk exceedingly minute, clavate. Mouth with cirri; œesophagus cylindrical, often with the appearance of a globular bulb at its lower end; intestines cylindrical. Anus indistinct. Generative apparatus?
"Length of largest $\frac{1}{40}$ "; breadth $\frac{1}{1000 "}$; length of tail $\frac{1}{2000^{\prime}}{ }^{\prime \prime}$. Smallest, length $\frac{1}{160 "}$; breadth $\frac{11}{2000^{\prime}}$; length of tail $\frac{1}{80} 0^{\prime \prime}$. In an individnal $\frac{1}{10} \overline{0}^{\prime \prime}$ long, the cosophagns measured $\frac{1}{5800^{\prime \prime}}$ long.
"Hab. Fonnd under Lyngbya muralis and other Confervæ about gutters and water-spouts in the City of Philadelphia. This species is very active in its morements, and appears to have the power of fixing itself by the end of the tail to surrounding objects."
"Cauda brevis, globifera. Longit. . . . . . ."
"Mab. In infuso marino (O. F. Mïller, Ehrenberg)."
3. A. mucronata, Diesing ${ }^{1}$.

Czernay, in Bullet. de Moscou, xxvi. (1853) 205 (cum icone xylogr.).
"Os cirrhis brevibus quatuor cinctum. Cauda papilla suctoria subglobosa mucrone brevi aucta. Longit. fem. ad $\frac{3^{\prime \prime \prime}}{4}$.
"Mab. Prope Charkoviam."-Czernay.

## 32. HEMIPSILUS, Quatrefages.

Gen. Char. "Corpore fere cylindrico; caudla acuta, nuda; capite truncato, rotundato, setis circumdato; parte anteriore corporis setarum paribus lateralium retro decrescentium armata."

1. H. -_, Quatrefages.

Ann. des Sc. Nat. 3e sér. tom. vi. (1846) p. 131.
"Un peu obtus en avant, le corps se renfle très-légèrement dans son milieu, et se termine en pointe aiguë. Près de l'extrémité antéricure se trouvent six soies placées en cercle d'unc manic̀re symétrique autour du corps . . . . . .
"La trompe est forte et musculeuse; elle occupe environ le quart de la cavité du corps. Au point où se joignent la trompe et l'intestin, on trouve quatre corps glandulaires qui semblent déboucher dans l'œsophage.
"L'appareil genital s'ouvre à peu près vers le milieu du corps. La verge est formée par un spicule unique recourbé. À sa base sont quatre poches ì parois épaisses, deux grandes et deux petites; des muscles très-apparents servent à le mouvoir."
2. H. trichodes, Leuckart.

Leuckart, Archiv für Naturgeschichte, 1849, Band i. p. 157.
Eberth, Untersuch. über Nemat. p. 16.
3. H. amphacanthus, Grube.

Grube, Archiv für Naturgeschichte, 1855, Jahrg. 21, Bd. i. p. 153.
Eberth, Untersuch. über Nemat. p. 17.

## 33. PHANOGLENE, Nordmann.

Gen. Cbar. "Corpus capillare, retrorsum acuminatum. Caput corpore continuum, truncatum. Os terminale, bilabiatum, cirrhis 2-4. Ocelli ruberrimi in cervice. Penis filiformis, vagina tubulosa exceptus; feminæ apertura genitalis . . . ."
"Aquarum dulcium incolæ."

1. P. barbiger, Nordmann.

Phanoglene barbiger, Nordmann, in Lamarck's Anim. sans Vert. 凤de édit. iii. 664.—Dujardin, Hist. Nat. dcs Helminthes, 238.

[^44]"Os cirrhis quatuor instructum. Ocelli duo discreti. Longit . . . ."
"Hab. In aqua stagnante prope Berolinum (Nordmann)."

## 2. P. micans, Nordmanm.

Phanoylene micans, Nordmann, in Lamarck's Anim. sans Vert. 2te édit. iii. 664.-Dujardin, Hist. Nat. des Helminthes, p. 238:
"Os cirrhis duobus instructum. Ocelli coaliti. Longit . . . ."
"Hab. In larva Neuropteri (Nordmann)" ${ }^{1}$.
In all probability, this was a mere accidental tenant of the intestine of the Ncuropterous larva in which it was found by Nordmann-having been swallowed with its food. The presence of ocelli renders it almost certain that it could not be an habitual parasite; and the experiments of Davaine (Recherches sur l'Anguillule du Blé niellé, p. 64) have demonstrated that these Nematodes pass uninjured through the intestinal canal of inany of the invertebrate and cold-blooded vertebrate animals.
The only freshwater genus in which I have yet met with species possessing ocelli has been Monlystera.
The threc following marine specics I am very uncertain about, and have thercfore merely followed Eberth in allowing them to remain in this genus.
3. P. rosea, Eberth.

Lineola rosea, Kölliker, Verhandl. d. Naturforsch. Gesell. in Zürich, 1845.-Eberth, Untersuch. über Nematod. p. 18.
" Rosenrothe Farbe, Kopf dreilappig, stumpf, Mundhöhlc unberwaffnet, Fühler gleich lang, an der basis der Kopflappen; seitlich an der Speiserölhe zwei braune viereckige Flecken."-Eberth.
4. P. obtusicaudata, Ebcrth.

Lineola obtusicaudata, Kölliker, Verhandl. d. Naturf. Gesell. in Zürich, 1845.-Eberth, Untersuch. über Nematod. p. 18.
" Kopf noch stumpfer, und die braune Flecken noch einmal so gross, von 0.066 "', Fühler sehr kurz, 0.001-0.0013"' lang, vier fast ganz vorn, zwei etwas weiter hinten, alle mit dicker in der hant steckender Basis, Schwanz stumpf, kurz, $0.0033^{\prime \prime}$ lang. Penis sehr kurz, von $0.015^{\prime \prime \prime}$. -Eberth.

## 5. P. Flustre, Eberth.

Eberth, Untersuch. über Nematod. p. 18.
Ascaris Flustre, Dalyell, 'The Powers of the Creator displayed in the Creation,' vol. ii. 1853, p. 92, pl. x. fig. 27.-Leuckart, Archiv für Naturges. 1859, Jahrg. 25, Bd. ii. S. 101 u. 146.
"Length half a line; body slender, nearly cylindrical; extremities acute. Colour dark grey or brownish, with a darker line in the centre of the anterior extremity, denoting an internal organ. Two very conspicuous black specks, resembling eyes, are seated just at the origin of the anterior pellucid part.

[^45]"Some of these animals appeared among a number of the decaying corpuscula from the Flustra carbasea, which they frequently penetrated as if in quest of food."-Dalyell.

## 34. PONTONEMA, Leidy.

## Proceed. of Acad. of Philad. vol. viii. (1856) p. 49.

Gen. Ciar. "Body capillary, narrowing towards the extremities. Head continuous with the body, truncated or obtuse, and surmounted with angular papillæ, cirrated. Eyes none. Tail obtuse. Generative aperture ventral, near the middle of the body. Esophagus long, cylindro-clarate; gizzard none, intestine straight, capacious; anus ventral and posterior."

## 1. P. vactllatum, Leidy.

Journ. Acad. Philad. 2nd ser. iii. 144, et in Proceed. Acad. Philad. viii. (1856) p. 49.
"Body eylindroid anteriorly, with longitudinal rows of short cirri in addition to those of the head; posteriorly incurved; tail short, thiek, conical, obtuse. Length to 9 lines; breadth to $\frac{1}{5}$ th of a line."
"Hab. Found on the sea-shore of Rhode Island, beneath stones, between tides."

## 2. P. marinuif, Leidy.

Journ. Acad. Philad. 2nd ser. iii. 144, et in Proceed. Acad. Philad. viii. (1856) p. 49.
"Body eylindroid; head convex ; mouth surrounded with angular papillæ. Cirri 4, at the side of the head. Tail long, narrow, conical, obtuse. Length to 3 lines."
"IIab. Found at the bottom of a sound on the coast of New Jersey."

## 3. P. Mülleri, Diesing.

Vibrio Anguillula d. Anyuillula marina, Müller, Anim. Infus. 66, Taf. ix. 9-11.
Vibrio marina, Bory, in Encycl. Méth. (1824) 778, tab. xxiv. 26.-De Blainville, in Dict. d. Sc. Nat. lvii. 537, et lviii. 71.

Anguillula marina, Oerst. De region. marin. 1844, 63 \& 69.
Enchelidium marinum, Ehrenb.-Diesing, Syst. Helm. i. 127 (partim).
"Corpus subæquale, retrorsum acutatum. Caput truncatum. Os cirrhis . . . Longit. ad $1^{\prime \prime \prime}$."
" IIab. Inter mucosa palos marinos obvestientia, et in aqua marina servata frequentissime (O. F. Mïller). In profunditate 0-8 orgyiarum, æstate, in fretu Oeresund (Oersted)."
"Cum Vibrio marina, Müller, ocellis omnino destituta sit, cum Enchelidio marino, Ehrenberg, identica esse non potest (Oersted, l. e.)."-Sitzungsb. der Kais. Akad. 1861, (Bd. xlii.) S. 623.

## 35. POTAMONEMA, Leidy.

Proceed. of Acad. of Philad. viii. (1856) 49.
Gen. Cirar. " Body filiform, narrowing towards the extremities. Head eontinuous with the body, slightly dilated, obtuse. Mouth large, infundibuliform, unarmed. EEsophagus narrow, flexuous, membranous, gradually expanding into a capaeious, straight,
cylindrical intestine; anus none (?) or exceedingly indistinct. Caudal extremity obtuse. Generative aperture of the female near the middle of the body."

## P. nitidum, Leidy.

"Body cylindroid, most narrowed anteriorly. Head without appendages. Caudal extremity broad, obtusely conical. Length 5 lines; breadth $\frac{1}{5}$ th of a line."
"An active, wriggling, glistening-white worm, found among beds of Vallisneria americana growing in the river Schuylkill, near Philadelphia."

## 36. NEMA, Leidy.

Proceed. of Acad. of Philad. viii. (1856) 49.
Gen. Char. "Body ascaridiform. Head without appendages. Mouth unarmed, large, infundibuliform ; œsophagus tubular, membranous, expanding into a simple, straight intestine; anus ventral. Tail conical, acute, recurved. Gencrative aperture near the middle of the body."
N. vacillans, Leidy.
"Body white, glistening. Length $1 \frac{1}{2} \mathrm{~mm}$; breadth $\cdot 050^{\mathrm{mm}}$. Tail $\cdot 115^{\mathrm{mmn}}$ long."
"An active, wriggling worm, found about some dead specimens of a black Phryganec, which was infested with a fungous parasite, and attached to stones at the water's edge of a small brook near Philadelphia."

## 37. UROLABES, Carter.

"The generic name of Urolabes, which I have employed, should only be viewed as provisional. It has been chosen from the striking habit which all these worms lave of attaching themselves to some object by the tail, whether it be by embracing it or by adhering to its surface. Hence the tail would appear to be both prehensile and adhesive, if not suctorial. Having once fixed themselves in this way, they keep up an undulating movement from the tail forwards, which, in the absence of any evident purpose, seems more for respiration than anything else." -Ann. of Nat. Hist. ser. iii. vol. iv. p. 99.

Amongst the ten species described by Carter, there are representatives of several genera; and I have been able to assign positions to three of the species-one in the genus Dorylaimus, one in Chromadora, and one in Symplocostoma. Of the remainder, three ( $U$. gloocapsarum, $U$. labiata, and $U$. tentaculata) seem, by the form of their œesophagus, almost to belong to the genus Rhabditis, although this is somewhat negatived by the absence of caudal alæ in the male of U. gloocopsarum, the males of the other two species not having been discovered.

1. U. gleocapsardim, Carter.

Loc. cit. p. 40, pl. iii. fig. 25.
"Female, linear, cylindrical, striated transversely, gradually diminishing towards the head, which is obtuse and without papillx; also towards the tail, which is long and furnished with a digital termination. Vulva a little anterior to the middle of the body."
" Esophagus commencing with a cup-like buccal cavity, from which a narrow straight tube extends back to the intestine. Intestine much larger than œesophagus. Muscular sheath of oesophagus commencing a little distance from the buccal dilatation, leaving a portion of cesophagus naked, and then having two swellings in its course, one oval and the otler terminal and bulbous. Hepatic organ consisting of a layer of brownish oilglobules, occupying the interval between the intestine and its sheath throughout."
"Organs of generation double, occupying middle third of body."
"Size, $\frac{1}{54}$ " long, and $\frac{1}{376}$ " broad."
"Dfale, somewhat smaller than the female; tail somewhat shorter and thicker."
" Hab. The Gloocapsa which grows on walls and on the sides of gutters during the 'rains,' Island of Bombay."
2. U. labtata, Carter.

Loc. cit. p. 41, pl. iii. fig. 26.
" Female, linear', cylindrical, unstriated, gradually diminishing towards the head, which is labiated and furnished with two papillx; also towards the tail, which is conical and elongated. Vulva much behind the centre of the body, about the point of union of the posterior two quarters."
"Alimentary canal and ocsophageal and intestinal sheaths, with hepatic organ, the same as in the foregoing species; but no buccal dilatation. Organs of generation probably unsymmetrical, from backward position of vulva."
"Size, about $\frac{1}{40}$ " long, and $\frac{1}{774}$ " broad."
"Mrale, unseen."
"ILab. The Glooocapsa of the walls, \&c., during the 'rains,' Island of Bombay."

## 3. U. tentaculata, Carter.

Loc. cit. p. 41, pl. iii. fig. 27.
"Female, linear, cylindrical, unstriated, gradually diminishing towards the head, which is obtuse and furnished with two short, thick, conical tentacular prolongations closely approximated at their base and turned outwards; also diminishing gradually towards the tail, which is conical and elongated. Vulva just behind the middle of the body."
"Alimentary canal and hepatic organ much the same as in the two preceding species, but having no buccal dilatation. Organs of generation double, occupying the central portion of the body ; their form undetermined."
"Size, about $\frac{1}{23}$ " long, and $\frac{1}{26}$ " [?] broad."
"Jrale, unseen."
"ILab. The same as the two preceding species."
4. U. cirrata, Carter.

Loc. cit. p. 41, pl. iii. fig. 28.
"Female, linear', cylindrical, unstriated, gradually diminishing towards the head, which is obtuse and furnished with two linear, short cirri, widely separated; also diminishing
gradually towards the tail, which is somewhat curved and obtuse at the extremity. Vulva considerably posterior to the middle of body."
"Alimentary canal the same as in the foregoing species, but without buecal dilatation. Organs of generation undetermined."
"Size $\frac{1}{73}$ " long, and $\frac{1}{1080}$ " broad."
"Male, unseen."
"Hab. Same as foregoing."
5. U. parasitica, Carter.

Loc. cit. p. 44, et vol. ii. pl. iv. fig. 50.
"Female, linear, cylindrical, unstriated; gradually diminishing towards the head, which is obtuse and without papillæ, and also towards the tail, which is long and conical. Vulva a little in front of the middle of the body."
" Esophagus commencing in an expanded oral orifice, immediately becoming narrowed into a straight, uniform tube, naked at the eommencement, but soon surrounded by a sheath, which goes on increasing in width to the point of union of the œsophagus and intestine, after which it continues of uniform calibre to the termination of the latter. Organs of generation double, occupying the middle third of body."
"Size, $\frac{1}{43}$ " long."
"Male, unseen."
"Hab. Peritoneal cavity' of Nais albida; in more or less abundance during the ' rains,' when this Nais makes its appearance in the Gloeocapsa mentioned, Island of Bombay.
6. U. erythrops, Carter.

Loc. cit. p. 42, pl. iii. fig. 29.
"Female, linear, cylindrical, minutely striated transversely, ocellated; gradually diminishing towards the head, which is obtuse and without papillæ, also towards the tail, which is long and conical. Vulva just about the middle of body. Esophagus commencing with a cup-like followed by a globular dilatation, after which it becomes narrow, uniform in width, and pursues a straight course back to the intestine. Intestinal sheath presenting a constriction just after its commencement, which gives it a globular form, part of which only is lined with the hepatic organ. Organs of generation clouble, occupying the middle third of the booly."
"Ocelli consisting of tro globular bodies, situated a short distance from the head, and between (?) the peritoneal and muscular sheaths of the eesophagus, opake, of a rich carmine colour in their posterior three-fourths, and the anterior fourth or corneal portion bluish opalescent."
"Size $\frac{1}{20}$ " long, and $\frac{1}{470}$ " broad."
" Ilale, the same as the female, but with the posterior part of the body terminating more abruptly, and the tail more attenuated."
"Hab. Silty clots of Oscillatoria floating in the salt-water main drain of the town of Bombay."
7. U. infrequens, Carter.

Loc. cit. p. 43, pl. iii. fig. 30.
"Female, the same as the foregoing species, but a little larger in every way."
"Alimentary canal and organs of generation the same generally. Ova undergoing segmentation; and the embryo developed in the ovisac, but not liberated there."
"Ocelli, the same in situation, but semi-opake and of a yellowish eolour throughout."
"Size, undetermined."
" Ifale. Same as the female, but with a short curved tail, presenting on eaeh side of the inner curvature a membranous expansion supported on setaceous ribs, which extends from the tip of the tail to some little distance above the anus. Organs of generation the same as in the foregoing species; form of testis undetermined."
"Hab. The same as last."

Note appended on June 17, 1865.-Whilst this memoir has been going through the press, I have eompletcly satisficd myself of the general correctness of Schneider's views (Reich. and Du Bois-Reym. Archiv, 1863) regarding the nature and arrangement of the nervous system in Ascaris megalocephala; and in another memoir, laid before the Royal Society of London on the 15 th of this month ("On the Anatomy and Physiology of the Nematoids, Parasitic and Free; with observations on their Zoological Position and Affinities to the Echinoderms"), I have deseribed and figured this system as it exists in A. lumbricoides, $A$. osculata, and $\mathcal{A}$. marginata. The arrangement which has now been recognized in these and other species, either by Schneider or myself, will, I believe, prove to be the typical condition of the nervous system in the Nematoids generally, although the difficulty of actually demonstrating it is often extreme. I am still of opinion, however, that the so-called "œsophageal ring" met with oceasionally in both free and parasitic species is not to be considered a portion of the nervous system of these animals. Reasons for this belicf, as wcll as many new facts and views eoneerning the anatomy of this interesting group of animals, are contained in my last memoir above mentioned.

Most of the figures are representations of the object drawn to a scale of $150: 1$, i.e. are representations magnified 150 diameters--the exceptions being figs. 126-128 and figs. 151-177, all of which are only magnified 100 diameters.

Unless stated to the contrary, the drawings represent the anterior and posterior extremities from a lateral aspect--the animal lying on its side.

Where transverse integumental striæ exist, they are only represented on the anterior extremity.

    ${ }^{20}$ Loc. cit.

[^1]:    ${ }^{1}$ I hare not been rery successful in finding these animals on or in fungi, though Carter has discorered them in abundance at Bombay projecting from the conceptacles of a large species of the genus Xylaria, growing on the decayed trunk of a tamariud-tree. (Trans. of Med. and Phys. Soc. of Bombay, 1861, App. p. 1.)
    ${ }^{2}$ I have found six different species existing, more or less abundantly, in a small portion of mud that could be held on a shilling piece.

[^2]:    ${ }^{1}$ Not strictly speaking Nematoids; the animals referred to, constituting the genera Gordius and Mermis, be.ong in :eality to a nearly allied order, Gordiacea.-II. C. B.
    = Loc. cit. p. 2.

[^3]:    ${ }^{1}$ For references, see Diesing's 'Syst. Ifelminth.' vol. ii. pp. 132-136.

    * Diesing's Anguillula macrura I have lately fomed in the intestines of Alatta orientalis, and hare ascertained that it has no resemblance to any of the free Nematodes at present known. Its anatomical characters are totally distinct from those of Anyuillula aceti; and it seems best to place it in a distinct genus (Streptostoma), as was done by Dr. Leidy (Smithson. Cont. 1853, v. p. 46, tab. 7. f. 6, 7). $\quad{ }^{3}$ Zoologie Médiea'e.
    ${ }^{\text {a }}$ These mus. ot be confounded with the longitnd nal muscular bundles seen through an unstriated integument.

[^4]:    ${ }^{1}$ These pores seem evidently to have been recognized by Eberth at the anterior and posterior extremities of his Phanoderma bacillatum, though he put a totally different interpretation upon the appearances he observed, since he considers and speaks of them as skin-glands (IIcutdriisen), loc. cit. p. G.

[^5]:    ${ }^{1}$ The period of those species capable of revivification is, of course, altogether a variable quantity ; and I speak more particularly concerning the active life of the other members of the family.
    ${ }^{2}$ Recherches sur l'Anguillule du Blé niellé. Paris, 1857.
    ${ }^{4}$ Ann. des Sc. Nat. $2^{e}$ sér. t. xiv., xuii. \& xviii.
    ${ }^{6}$ Davaine's observations come very near to the truth in this respect (Ann. des Sc. Nat. sér. 4, 1858, tom. x. p. 335.)

[^6]:    ' Lettre de Needham en réronse au mémoire de Roffredi, dans le Journ. de Phys. de l'Abbé Rosier, t. r. p. ํㅡㄴ, $1 \% \%$
    = W. II. Iuce, Esq.
    ${ }^{3}$ "Microscopical Observations on the Suspensinn of the Muscular Motion of the Vibrio tritici."

[^7]:    ${ }^{1}$ Davaine has occasionally found a small abortive germen within the same floral envelopes with the gall; and in this case the gall is most likely to have been produced in one of the rudimentary scales, which would have gone to form a stamen. He believes it may be formed out of any of the scales belonging to the central parts of the flower; and although, as a rule, all these parts participate in the formation of a single central gall, still occasionally as many as three growths of this kind develope within the same pair of glumellce. On one occasion he found a growth of a similar nature, aud with the same kind of contents, growing from one of the leaves of the wheat. After this, additional proof as to the nature of the growth is almost superfluous. All interested in this remarkable disease of wheat should consult M. Davaine's admirable memoir on the subject.
    ${ }^{2}$ Obscrvations sur la Physique, t. v. p. 1, 1775.
    ${ }^{3}$ That the disease may be produced artificially, by placing the young within the cleft of a healthy seed, after the method of Bauer, I can have little doubt, after the result of my own experiment, though Davaine seems to be rather incredulous concerning this mode of its production (loc. cit. p. 16).

[^8]:    ${ }^{1}$ Naturforsch. xxviii. S. 233, tab. v.
    = Zeitsch. für wissen. Zoolog. 185̄, t. ix. p. 189.

[^9]:    ${ }^{1}$ Sitzungsb. der Kais. Akad. der Wissensch., slii. Band, No. 28, p. 595.

[^10]:    ${ }^{1}$ The best method of detecting and capturing these animals I have found to consist in separating with ordinary microscopical teasing-needles the specimens of algæ or coralliue into small fragments, on the surface of a square piece of glass covered with a thin stratum of fluid, the glass being laid either upon a black surface or, better still, upon a small mirror, when the larger species may be recognized with the naked eye, and the smaller with an ordinary watchmaker's lens. They are best captured by taking them up upon the pointed extremity of a feather. I have employed an ordinary quill pen, with its upper extremity cut off obliquely. In the case of marine or freshwater mud, it should be sprcad out with a little water into a very thin stratum, when, in a minute or so, various spots of disturbance will indicate the position of these or other minute animals.

    I am indebted to the kindness of my friend Howard Fox, Esq., of Falmonth, for being able to pursue in this inland locality (Broadmoor, Wokingham) researches concerning the marine Nematoids commenced at Falmouth, since he has abundantly supplied me at various times with mod, sand, aud algre from the estuaries and tide-pools of that place.

[^11]:    a All the animals belonging to the genera having this mark affixed to them have a modification of the ventral gland, and are endowed with a remarkable tenacity of life.

[^12]:    * The first name, in italics, is that under whieh the speeies has been previously described, whilst the second, in ordinary roman type, is that under whieh it is deseribed in the present nemoir.
    $\dagger$ The first figures refer to the number of the geaus, the second to that of the speeies.

[^13]:    ${ }^{1}$ Hóros, single, and üzons, a hook.

[^14]:    'This species was very abundant in the specimen of mud selected; nnd as it was the first example of one of the free Nematoids that was carefully submitted to examination by me, in May 1863, I have retained the name of the place where it was found as a specific appeliation.

[^15]:    ${ }^{1}$ From eif $\omega r$, a dissembler, on account of its habits of straightening itself and remaining still for a short time, as if dead, when touched.

[^16]:    - It is from my observations on the anatomy of D. slagnalis that I bave become perfectly convinced that the integument does present longitudinal, but no transverse markings. In this species I have frequently examined portions of integument freed from all other structures. But in the members of some other genera of free Nematoids not presenting trausverse striæ, I am in many cases donbtful whether the integument is perfectly plain or has longitudiual markings-and this not only on account of the greater difficulty of recognizing such strix, but also from the danger of confounding the appearance of the longitudinal muscles as seen through the integument with actual markings of this structure.
    ${ }^{2}$ Transactions of the Linnean Society, vol. xxiv. pl. 22. figs. 57-60.
    ${ }^{3}$ Nearly all the anatomical details of Dracunculus, so far as they are known, are in harmony with those of many typical Nematoids, whilst they differ considerably fron those stated to obtain amongst the Gordiidce. And if we may rely upon existing information, the difference as regards important anatomical characters is infinitely greater between these animals and the Nematoids generally than between any two of the families composing this latter order.

[^17]:    ( Named after Mr. Carter, so as to connect his name with a species of that genus many of the details of whose anatomy were first carefully recorded by himself.

[^18]:    ${ }^{1}$ I am indebted to the kindness of Dr. Daraine for the opportunity I hare had of examining these animals myself. Before obtaining a supply from him, I had in rain endeavoured to procure them. They are much less frequent than is generally imagined, at all events in England; and this may be dne in great measure to the adulteration of our vinegar with sulphurie acid.

[^19]:    ${ }^{1}$ Tpeis, three, and $\pi \dot{u} \lambda \eta$, an orifice, in allnsion to the three well-marked integumental openings.

[^20]:    ${ }^{1}$ חौekròs, twisted, in allusion to the particular character of the duct of its ventral gland.
    ${ }^{2}$ Tracts on the Nat. 1list. of Anim. and Veget., translated by Graham Dalyell, ed. 』, rol. ii. pp. 129-160.

[^21]:    

[^22]:    ${ }^{1}$ In his work on "Entozoa," Ir. Cobbold, speaking of Oxyuris vermicularis, remarks:-" liespecting the migrations of the larvæ, I am not aware that anything very definite is yet known. I have introduced the eggs containing embryos into various animals, but have not yet suceeeded in rearing young Oxyurides. I have also introduced them into the pulpy parenchyma of pears; but I have not been able to satisfy myself that any of the young Nematodes which I subsequently proeured, by thousands, in oue or two of the pears were the result of these experiments. I showed some of these living larver to Lenekart, who thought they might be Anyuilhule; and certainly I never saw the tadpole-like larvæ, as such, out of their shells. The young Nematodes in question displayed a very different form. As my experiments are in the aet of being repeated, I will now say no more on this hend " (pp. 369, 370).

    I am indebted to the kindness of Dr. Cobbold for the opportunity of examining these animals, when I at onee recognized two distinct species, belonging respectively to the genera Aphclenchus and Plectus. The representatives of the former genus, constituting the speeies above deseribed, were by far the most numerous, thongh those of the genns l'lectus were larger and much more aetive in their movements. The portion of pear-pulp sent to me was quite dry; but, after immersion in water for a few hours, I lad no difficulty in verifying Dr. Cobbold's previous observations, and recognizing the little Nematodes in full aetivity, showing that they also are endowed with the same property of recovering after desiceation as are the other species of these genera. Dr. Cobbold did not recognize two distinct species; and thinking all the animals found in the pear-pulp werc individuals of the sanse speeies, he proposed for it the name of Anguillula pyri, in a communication read before the last meeting of the BritishAssociation at Bath.
    = кeфadi, the head, and dopòs, a lobe.

[^23]:    ${ }^{1}$ rúdos, a linob, and $\check{\epsilon} \gamma \chi^{o s}$, a spear.

[^24]:    ${ }^{1}$ Absolute measurements of both male and female rather variable; the relative measurements, however, remain pretty constant.

    - These are not fixed to the parietes of the body in the same way as the axial tubes or vessels of the lateral lines in certain parasitic Nematoids, but float freely in the cavity of the body. When the integument of one of these animals is ruptured by pressure of the covering-glass under the microscope, I have several times scen whole coils of the ressels slip, entirely out of the cavity of the body.

[^25]:    ${ }^{1}$ I have observed (in the female only) what appear to be two lateral apertures through the integument, connected with an obscure appearance of oval vesicles or dilatations internally, situated exactly midway between the anus and posterior extremity.

[^26]:    ${ }^{1}$ In the only male of this species observed by myself, there was a swelling or development of the iutegument around the head for a distance of $T_{T+\frac{1}{28}}{ }^{\prime \prime}$, somewhat similar to what is met with in Oxyuris vermicularis. Whether this will prove to be a constant character I cannot say.
    ${ }^{2}$ Vide note, p. 77.

[^27]:    ${ }^{1}$ Unless specified to the contrary, Eberth's species have been found at Nizza, amongst Algæ and Sertulariæ. In the description of this, as well as other species discovered by him, I have merely given the external characters. In his memoir, in addition to beautiful coloured drawings of each species, will be found lengthy descriptions, including many interesting and accurate anatomical details. It should be consulted by all interested in this subject.

[^28]:    ${ }^{1}$ àrios, opposite, and кóp $\eta$, hair, on account of the opposite rows of setæ on the lateral aspects of the cervical region.

[^29]:    ${ }^{1}$ pavos, bright or clear, and $\delta \dot{f} p \mu a$, skin.

[^30]:    ${ }^{1}$ Named after my dear and valued friend, W. P. Cocks, Esq., to whom science is much indebted for his researches into the marine zoology of Falmouth, resulting as they did in the discovery of so many new species of animals.

[^31]:    ${ }^{1} \lambda_{\epsilon \pi \tau \grave{s}}$, slender, and $\sigma \hat{\omega} \mu a$, a body.

[^32]:    ${ }^{1}$ Although he merely represents a terminal portion of one excretory gland, and does not depict its commencement anteriorly, I think he has very possibly overlooked the other, and also the lateral openings so close to the anterior extremity. This very unusual arrangement seems not to have been detected by him.

[^33]:    ${ }^{1}$ Xivov, a line, and öpoos, like, in allusion to the thread-like nature of the body.

[^34]:    ${ }^{1}$ raxis, swift, and $\dot{\text { éiórns, }}$ a traveller.

[^35]:    ${ }^{1}$ 日epeoris, a reaper, on account of the shape of the spicules.

[^36]:    ${ }^{1}$ oфalpa, a globe, and datuos, the throat.

[^37]:    ${ }^{1}$ ゥón $\eta$, huir, and $\sigma \bar{\omega} \mu u$, body.

[^38]:    ${ }^{1}$ This seems only to have been met with in Odontobius acuminatus, which I have transferred to the genns Anticoma, so that the latter part of this sentence only must now be considered as applicable to the genus Odontobius.
    ${ }^{2}$ He omits to mention these in his generic description given above.

[^39]:    ${ }^{1}$ sua $\begin{gathered}\text { os a cup, and } \lambda a u \dot{s}, \text { the throat, in allusion to the shape of the pharyngeal cavity. }\end{gathered}$

[^40]:    ${ }^{1}$ Or else from marine surface-mud of estuary. I am not quite certain which, as the habitat was unfortunately not entered at the time when the species was discovered and described.

[^41]:    ${ }^{1} \sigma \pi i \lambda o s, a$ spot, and $\phi \hat{\rho} \rho \omega$, to bear, in reference to the integumental markings.

[^42]:    ${ }^{1} \chi^{\rho} \bar{\omega} \mu a$, pigment, and $\delta o \rho a$, skin, on account of the frequency with which the transparency of the integument of the anterior part of the body is obscured by a dark tinge of colour.
    \& About anterior part of body the markings of integument seem almost more dotted than linear.

[^43]:    ${ }^{1}$ Perhaps striæ fiue, and not recognized. $\quad$ In middle of body.

[^44]:    ${ }^{1}$ This account of the genus and species of Amblyura has been taken from Diesing's Syst. Helminth. vol. ii. p. 126, and his 'Revision der Nematoden," loc. cit. p. 624.

[^45]:    ${ }^{1}$ The account of this genus, so far, has been taken from Diesing's 'Syst. Helminth.' p. 128.

[^46]:    Page 73, 1 omitted before first footnote.
    78, note, line 12, instead of par read pas.
    " 82, line 22, instead of (Sehwanzdrüsefi) read (Sehwanzdrïsen).
    ," 82, line 31, instead of Tylelenchus read Tylenchus; and the same in pp. 83 (twice), 84 (twice), 85, 89, 94, 96 (four times), 110, 113.
    93, instead of 7. Tripula read 7. Tripyla.
    ", 94, instead of c 21 . Linhomomius read c 21. Linhomeus.
    " 148, line 27, instead of 166 read 167.
    " 165 , line 15 , instead of Spilipieera read Spilophora.
