Key points

- Many corporations and governments around the world have promised to end deforestation in commodity supply chains, with beef a recognised priority.
- Despite tightening of the law in 2018, land clearing and deforestation is widespread, with almost all being for livestock and within that for beef.
- Industry representatives deny or downplay this reality.
- Queensland producers risk being excluded from emerging markets for deforestation-free beef.
- A comparatively small number of beef producers account for a “lion’s share” of deforestation.
- In contrast, nine large beef producing companies accounted for very little deforestation. It could be relatively easy for these large companies to act as a flagship for marketing of “deforestation-free” beef in Queensland.

Executive summary

Internationally, governments, corporations and consumers are pushing for deforestation-free products, including for commodities like beef.

Queensland outpaces all other Australian jurisdictions combined in annual bulldozing of forests primarily for beef and is the primary reason why Eastern Australia is listed as a global deforestation front.

Despite tightening of laws in 2018, the latest state government data shows substantial increases in clearing of both remnant (primary or mature) and regrowing (secondary or immature) forests and woodlands.

Some of this increase is a result of actual increased clearing and some attributed to better monitoring methodology. However, the recent increase due to better methodology also means that tree clearing in previous years has been substantially under-estimated.

Of 2.1 million hectares of all woody vegetation cleared in Queensland over a five year study period 2014/15 to 2018/19 (the latest year for which government clearing data has been published):-

- 93% was for livestock pasture development of which 73% was for pastures on beef properties;
- 71% was clearing of forests of any age and 60% was clearing of either remnant (intact or mature) forests or "high value regrowth" forests (more than 15 years old).

Almost all clearing of "high value regrowth" forests over 15 years of age -- totalling over 760,000ha over the five year period -- had previously been "locked-in" as exempt on property maps of assessable vegetation (PMAVs) and so could be cleared without restraints.

- Of all deforestation of endangered regional ecosystems, 78% was for pasture development on beef properties.
- Of all deforestation for pasture development on beef properties 24% was of regional ecosystems deemed endangered due to past land clearing.
- And another 24% of those deemed as of-concern under the *Vegetation Management Act* in Queensland.

Deforestation for beef pastures destroyed habitats for 388 nationally threatened species and 14 threatened ecological communities over the five year study period.

- The then vulnerable, now endangered Koala lost 0.65% of its entire "likely-to-occur" habitat to beef pasture deforestation over the five year study period, representing 73% of all Koala habitat deforestation statewide.
- The endangered Brigalow ecological community lost 2.34% of its entire "likely-to-occur" habitat to beef pasture deforestation over the five year study period, representing 83% of all Brigalow deforestation statewide.

Ongoing widespread deforestation for livestock production in Queensland is a serious barrier to the ability of Queensland's red meat industry to meet growing market demand for deforestation-free products.

Industry representatives publicly deny deforestation stating, "*there has been no significant clearing of trees in Queensland.*"

Although deforestation is widespread, a relatively small number of livestock producers have a disproportionate contribution to deforestation. An estimated 334 beef property owners account for half of all deforestation for pastures on all beef properties over the period.

Conversely, 36% of livestock production capacity in Queensland was deforestation-free over the five year study period, although that could change in future unless there are changes to industry and government policies.

Although deforestation is widespread, a relatively small number of livestock producers have a disproportionate contribution to deforestation. An estimated 334 beef property owners account for half of all deforestation for pastures on all beef properties over the period.

Ending deforestation should not present a significant hurdle for these nine large beef companies, since all deforestation over the five year study represents a tiny fraction of 0.1% of the vast land area they hold, and 97% of the land area is still in uncleared remnant condition. Ceasing all deforestation and allowing endangered forests to regrow naturally would allow recovery to take place.

There is a remarkable opportunity for large beef producers to act as a flagship for their industry and become the first in Australia to offer the first verified and trustworthy deforestation-free beef to the growing numbers of retailers who have committed to selling only deforestation-free products.

Glossary

Vegetation - any woody vegetation including forest.

Land clearing - the partial or total removal of woody vegetation.

Forest - that component of woody vegetation with greater than 20% canopy cover composed of trees that exceed 2m in height, over patches of at least 0.2ha.

Deforestation - the partial or total removal of trees from a forest to the point it is no longer the same forest or is non forest.

SLATS - the Queensland Government's "Statewide Land and Tree Study" eco-sciences unit.

VMA - *Vegetation Management Act 1999* (Queensland).

EPBCA - *Environment Protection and Biodiversity Conservation Act 1999* (Federal).

Introduction

Many promises to end deforestation

At CoP26 of the United Nations Framework Convention on Climate Change (UNFCCC), 137 parties including Australia committed to “working collectively to halt and reverse forest loss and land degradation by 2030”.²

In 2010, the Consumer Goods Forum, a peak body for major global and Australian food corporations like Woolworths and McDonald’s committed to removing deforestation from supply chains and net zero deforestation by 2020.³ They were later joined by many other major brands.⁴

Recently, the European Union introduced laws to prevent import of products that involve deforestation. Importation of goods including beef and lamb from areas deforested after January 2020 would be banned.⁵

Australia’s Red Meat Advisory Council has committed to carbon neutral production by 2030, and Meat and Livestock Australia has released a roadmap to get there. However the need to halt ongoing deforestation to reduce emissions is not mentioned in that roadmap.⁶

Livestock the driver of almost all deforestation in Queensland

Queensland is the main beef producing state in Australia.⁷ However, ongoing high levels of deforestation for beef presents a major barrier to the ability of the Queensland industry to meet the growing demand for verified deforestation-free beef.

Ongoing high levels of deforestation undermines the promises of the red meat industry to be carbon neutral by 2030.

Queensland accounts for more tree clearing than all other jurisdictions combined. The majority (73%) of this destruction of forests and woodlands is to develop pastures for beef production.⁸ Land clearing in Queensland happens widely

throughout the state, although it is concentrated in the central belt of *Acacia*-dominated forests.⁹

Tree clearing for pasture development is widespread and has resurged in recent years due to weakening of state laws in 2013, pervasive failure by pastoralists clearing forests to observe national conservation law, and a corresponding failure of the national regulator to enforce the law.¹⁰

Misleading national statistics

The National Greenhouse Gas Inventory (NGGI) suggests that deforestation has declined dramatically in Queensland since a ban on broadscale clearing for agriculture came into force in December 2006 and has stayed at a low level. But this is contradicted by the more accurate figures derived from Queensland Government SLATS spatial data which show a dramatic upward resurgence of land clearing after the broadscale clearing ban was mostly overturned in 2013 (Fig. 1).

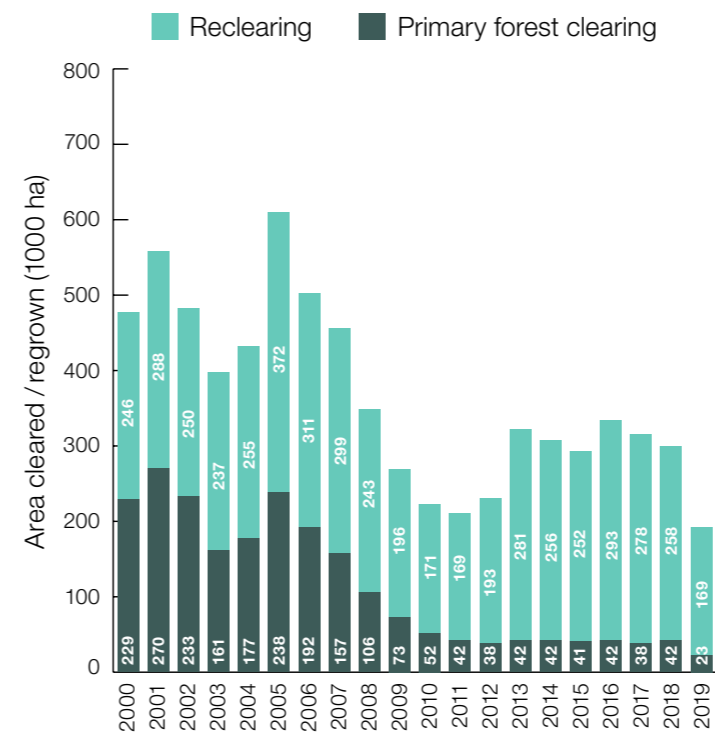

Comparative analysis reveals that the NGGI forest cover detection is inaccurate and as a result, NGGI figures for deforestation in Queensland may have been underestimated by as much as half in 2018/19. Moreover, the more accurate SLATS detection method used in 2018/19, led to a significant boost in detection of land clearing by as much as 30% (Fig. 1). This suggests that land clearing areas in years prior to 2018/19 were underestimated by SLATS.¹¹

NGGI statistics reported to the UN suggest that there is “net forest gain” for the entire country and for Queensland. The Activity Tables for Land Use, Land Use Change and Forestry (LULUCF) Table 1a reports 11,800 ha of primary (remnant or mature) forest cleared and 112,900 ha of regrowth forest re-cleared in Queensland in 2020. Table 1b reports 167,500 ha of new forest. On this basis, NGGI reports a “net forest clearing” of negative 42,800 ha, that is, a “net forest gain”.¹² These statistics are used by industry representatives to deny that there is any “significant” land clearing at all in Queensland.¹³

National LULUCF activity table

Queensland SLATS

Fig. 1. Reported areas of deforestation of primary and secondary forests in Queensland according to NGGI Activity Tables (left) and clearing of all woody vegetation (including forests) according to the Queensland Government’s Statewide Land and Tree Study (SLATS, right). Note: SLATS division into clearing of remnant and re-clearing of non-remnant for 2018-19 are not from the published SLATS report. We extrapolated from the SLATS comparison in the Brigalow Belt using the new SLATS method which found a 58% increase in remnant and 14% increase in non-remnant re-clearing from 2017/18 to 2018/19 to derive the figures shown for 2018/19 of 117,000 and 363,000 ha respectively. The hatched bar shows the 202,000 ha additional clearing detected by SLATS in 2018/19 which is therefore the best estimate of the improved detection of clearing using the new methodology. SLATS data for 18/19 are based on a new methodology using Sentinel-2 10m imagery whereas in previous years Landsat 30m imagery was used. SLATS has not released any statistics for areas of regrowth as yet.¹⁴

NGGI claims of “net” forest gain are erroneous, ecologically meaningless and misleading.

A pixel may move from “non-forest” to “forest” in NGGI land cover maps¹⁵ simply because an automated classifier of Landsat satellite photos tips the pixel above 20% canopy cover.

- Trees may have just put out more foliage in response to rain, tipping a pixel over 20%, with no real change in numbers of trees on the ground.
- Low resprouting or coppicing of foliage from seeds, stumps and root stocks left after recent clearing, may also tip a pixel over 20%, but this is not yet a forest in any meaningful ecological sense.

Such “new forest” pixel counts cannot legitimately be used in “net” calculations to cancel out destruction of forests which may be ecologically very different, or be decades or centuries old, tens of metres high and full of wildlife.

Any claim to be deforestation-free, must mean there is zero absolute deforestation, regardless how much regrowth there might be elsewhere. The only question to be answered is if an area cleared constituted a native forest at the time of clearing.

Despite recent tightening of laws, land clearing widespread

The state law regulating tree clearing in Queensland, the *Vegetation Management Act 1999* (VMA), was greatly weakened by the short-lived Newman - LNP state government (2012-2015). Weakened laws in Queensland and later, in New South Wales, led to an explosion of forest and woodland destruction that placed Eastern Australia on WWF's list of global deforestation “fronts”.¹⁶

It was not until 2018 that the VMA was amended again.¹⁷ It came as a shock therefore, to see that despite the 2018 tightening of the VMA, clearing rates went up not down, and quite substantially for remnant clearing as opposed to non-remnant (Fig.1).¹⁸

While state legislation was tightened to protect Queensland's forests and threatened species habitat, significant loopholes in that legislation mean deforestation remains widespread in Queensland. The state government admitted that something has obviously “gone wrong” and promised a review which at time of writing was still in progress.¹⁹

Impacts of land clearing on biodiversity are severe

The recent Australian State of the Environment report found *“Industry pressures [on biodiversity] are highest from extensive agriculture and land clearing, which continues to remove or fragment native ecosystems.”*²⁰

Queensland Government scientists report that land clearing ²¹:-

- *“causes species death and habitat loss [and fragmentation]...”*
- *“Reduces the resilience of threatened species populations to survive future perturbations such as climate change...”*
- *“[has] Significant negative impacts offsite e.g. (sediment runoff into streams, rivers, wetlands and the Great Barrier Reef marine lagoon)...”*
- *“[is] A major contributor to climate change...”*
- *“[is] Directly responsible for two plant species becoming extinct in the wild...”*
- *“[is a] threatening process for many of the 739 threatened flora species and 210 threatened fauna species in Queensland...”*

In this report, we use the most recent SLATS data to quantify the deforestation due to beef production in Queensland and profile nine of the biggest known beef producers in Queensland, updating an earlier analysis.²²

Results and discussion

Land clearing in Queensland has increased, but was also underestimated in the past

From 2014/15 to 2018/19, 2,121,857 ha of woody vegetation was cleared in Queensland (“land clearing”). This analysis removed repeat clearing events within the five year period in the Queensland Government SLATS spatial data to avoid double counting. Of this nearly a third, 32% happened in the most recent year of record 2018/19, representing a significant increase on previous years (Figs 1,2).

Fig. 2. Clearing of woody vegetation and in the five years from 2014/15 to 2018/19 derived from Queensland Government SLATS spatial data, broken down by vegetation type and contributions from livestock pasture development, within that for beef, and within that for nine large beef producing companies.²³

²² The Wilderness Society (2019). Drivers of Deforestation and land clearing in Queensland (<https://www.wilderness.org.au/qlddeforestation>).

²³ There are some minor divergences from official SLATS figures due to pixellation of polygon source files and due to removal of overlaps by SLATS polygons in later years to prevent double counting of areas cleared within the 5 year period.

SLATS applied the same new methodology comparing clearing detections for 2017/18 and 2018/19 but only for the Brigalow Belt bioregion. SLATS reports a 58% increase in remnant clearing and 14% increase in regrowth (“non-remnant”) clearing between these two years. Based on extrapolation of these results statewide, as much as 30% of the clearing detected by SLATS in 2018/19 may be attributable to improved methods newly adopted for that year (Fig. 1 hatched bar).²⁴

But this also suggests that clearing in foregoing years was substantially underestimated. Unfortunately, SLATS has announced no plans to apply the new method to prior years to enable estimation of how much past clearing was under-estimated. However, actual clearing has genuinely increased in 2018/19 relative to previous years in the five year period (Fig. 1), despite the VMA having been tightened again in mid 2018.

Most land clearing is of forests

Woody vegetation clearing is not the same as deforestation, and not all deforestation is necessarily of remnant forest.

Forest is taken to be woody vegetation with 20% or higher canopy cover, over a minimum patch size of 0.2ha, following the national definition of forest as used by the National Carbon Accounting System.²⁵

Using the whole SLATS woody vegetation clearing and Foliage Projective Cover (FPC) layers, we broke woody vegetation clearing down into four classes mapped at 30m pixel scale²⁶:-

1. non-forest whether remnant or non-remnant,
2. non-remnant forest less than 15 years old,
3. non-remnant forest 15+ years old (“high value regrowth” forest),
4. remnant forest.

Of a total of 2,121,798 ha of woody vegetation clearing over the five year period 2014/15 to 2018/19, 22% was of remnant forest, 38% of high value regrowth forests 15+ years old and 11% of young regrowth forests less than 15 years old, a total of 71% forest clearing (Fig. 2).

Clearing of remnant or high value regrowth forests accounted for 60% of all woody clearing (Fig. 2).

Tree clearing in Queensland is mostly exempt from any restrictions

The 2018/19 SLATS report found that 70% of all land clearing is exempt under the state VMA, but provides no breakdown into forest and non-forest, nor of forest age.²⁷

Clearing of regrowth forests, even high value regrowth forests (15+ years of age), is almost entirely exempt from restrictions on the relevant state regulated vegetation map (Category X, Fig. 3).

Under the VMA, category C “high value regrowth” means regrowth 15 years and older. However, almost all such regrowth has already been “locked-in” as exempt on PMAVs and remains exempt despite it having regrown towards or even if it has returned to mature forest. Most non-forest vegetation cleared is also exempt because much of it is previously cleared non-remnant (Fig. 3).

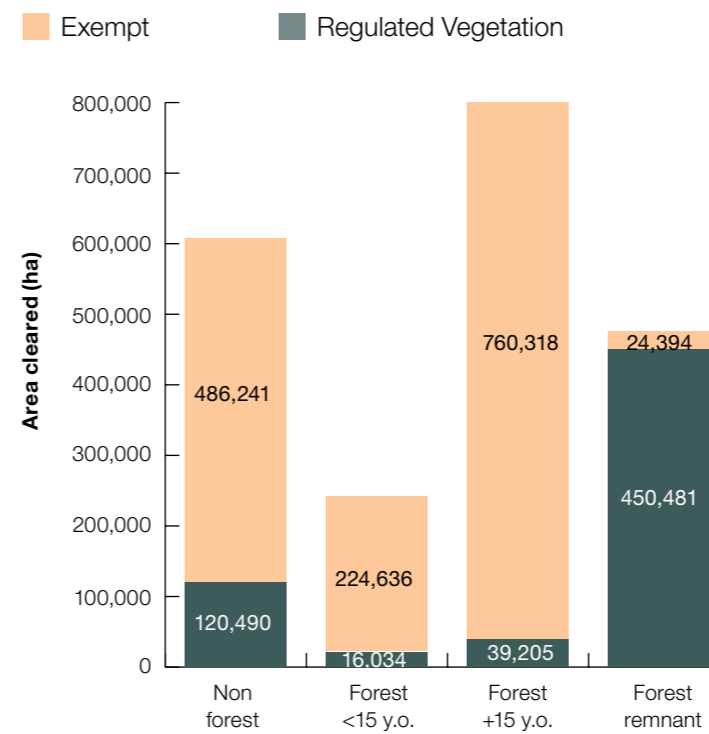

Fig 3. Woody vegetation cleared in Queensland, 2014/15 - 2018/19, classified by vegetation type and whether of regulated or exempt vegetation under the *Vegetation Management Act 1999*²⁸
Note: Non-forest includes both remnant and regrowth. Regulated vegetation could be any category B, C or R. Category A is banned to all clearing and is not included in these figures.

²⁵ “forest is defined as woody vegetation with a minimum 20 per cent canopy cover, at least 2 metres high and a minimum area of 0.2 hectares.” from Australian Government Department of Climate Change, Energy, the Environment and Water (2021) *National Forest and Sparse Woody Vegetation Data (Version 5.0 - 2020 Release)* (<https://data.gov.au/dataset/ds-dga-69d09a6c-df77-439f-8bc7-87822cd520fd>)

²⁶ in 2013 for forest cleared 2014/15 to 2017/18, but in 2017 for forest cleared in 2018/19.

²⁷ Queensland Government (2021) *2018/19 SLATS Report* (cited above).

²⁸ Note that regulated vegetation map used was current for April 2014 for any clearing over the 2014/15 to 2017/18 period. In mid 2018 there were significant amendments to the regulatory map. Clearing in 2018/19 is therefore referenced against the regulated vegetation map as updated in June 2018. Some of the clearing in the 2017/18 year will have fallen into the post-amendment regulatory map, not the 2014 map to which it is ascribed, leading to possible underestimation of clearing of regulated vegetation in that year.

92% of all forest clearing is for livestock pasture

Pasture clearing (including thinning²⁹) accounted for 93% of all woody vegetation clearing in the five year study period and 92% of all forest clearing (Fig. 2). All other clearing purposes combined (forestry, crops, infrastructure, mines and settlements) accounted for a small fraction (7%) of all woody vegetation clearing (Fig. 2).

73% of forest clearing for pasture is for beef

We identified 54,485 land parcels where the primary or secondary land use was beef production as of 2018 according to PriceFinder land sales data. Deforestation just for pasture purposes on these properties represented 73% of all deforestation (Fig. 2), as also found in an earlier analysis.³⁰

This is subject to both underestimation and overestimation errors.

Underestimation error derives from the fact that land parcels below 30ha may also be used for beef production, and land parcels which are actually used for beef production may have been missed or mis-attributed to other purposes in the database search.

Overestimation errors derives from the fact that the areas cleared include many isolated forest fragments less than 0.2ha in size, and so do not meet patch size thresholds to be considered forest prior to clearing. Applying this patch size restriction to deforestation we found that “strict” deforestation for pasture on beef properties was less than shown in Fig. 2, at 960,423 ha, representing 45% of all woody vegetation clearing for any purpose, and 67% of deforestation for all purposes of 1,428,159 ha (Table 1).

Another over-estimation error source comes from the reliance here on SLATS attribution of clearing instances to specific “replacement land cover classes”. Clearing instances attributed to pasture may in fact have been for crops on a number of properties subject to clearing under former High Value Agriculture permits over the five year period. However, this error is less of concern because it is known that the crops listed as to be planted under these permits are primarily stock feed for beef cattle.

²⁹ Thinning was categorised as such in SLATS prior to 2018/19. In 2018/19 SLATS the categories changed to *Partial clearing major - Pasture and Partial clearing minor*. Although the latter was not attributed to pasture by SLATS, pasture is the overwhelmingly dominant purpose of partial clearing and both categories were attributed to pasture.

³⁰ The Wilderness Society, 2019, *Drivers of Deforestation and land clearing in Queensland* (<https://www.wilderness.org.au/qlddeforestation>).

Beef deforestation is widespread in Queensland

Deforestation for pastures for beef production is widespread in Queensland, with 960,423ha attributed to an estimated 7,757 of a total of 20,202 known owners of beef producing properties.³¹

Most of these owners are individuals or partnerships of named individuals (68%), and only 13% are corporate entities (Fig. 4). Properties engaging in deforestation (a minimum 0.2ha patch size per property), are widespread except in the arid west of the state (Fig. 5).

As noted above properties mapped as deforested for pasture (according to SLATS) on beef properties (according to PriceFinder data) may nonetheless include clearing for cropping especially in the lower Cape York area, although this was primarily for livestock feed crops like sorghum (Fig. 5). Both attribution sources (SLATS and PriceFinder) attribute the majority land use to pasture and beef respectively.

Weed management negligible as a driver of deforestation for pasture

It has been claimed that land clearing is necessitated by weed management.³²

Since 2014, clearing codes³³ have allowed clearing of native vegetation incidental to removing woody weeds like prickly acacia. From the online register of code notifications³⁴ we found that weed management code clearing intentions were notified on 1,356 land parcels from 2014 until August 2019 over the study period.

Of 27,893 of all statewide land parcels with some deforestation for pasture (not confined to beef) over the period, only 582 had a weed management notification matching the land parcels descriptors listed in the notification register. At most only 25,000 ha -- 2% of all pasture deforestation over the study period -- might have been associated with woody weed control.

Fig. 4. Types of beef property landowners clearing forests for pasture 2014/15 - 2018/19 by property area: (LEFT) all beef producers and (RIGHT) the minority of known landowners accounting for half of all deforestation.

Fig. 6. Beef properties that had no deforestation, that fell in the majority lower half or in the minority upper half of total area deforested for pasture in Queensland from 2014/15 to 2018/19 showing (LEFT) areas of properties (units million hectares) and (RIGHT) estimated stock capacity (units million beef yearling steers) (see map Fig 5).

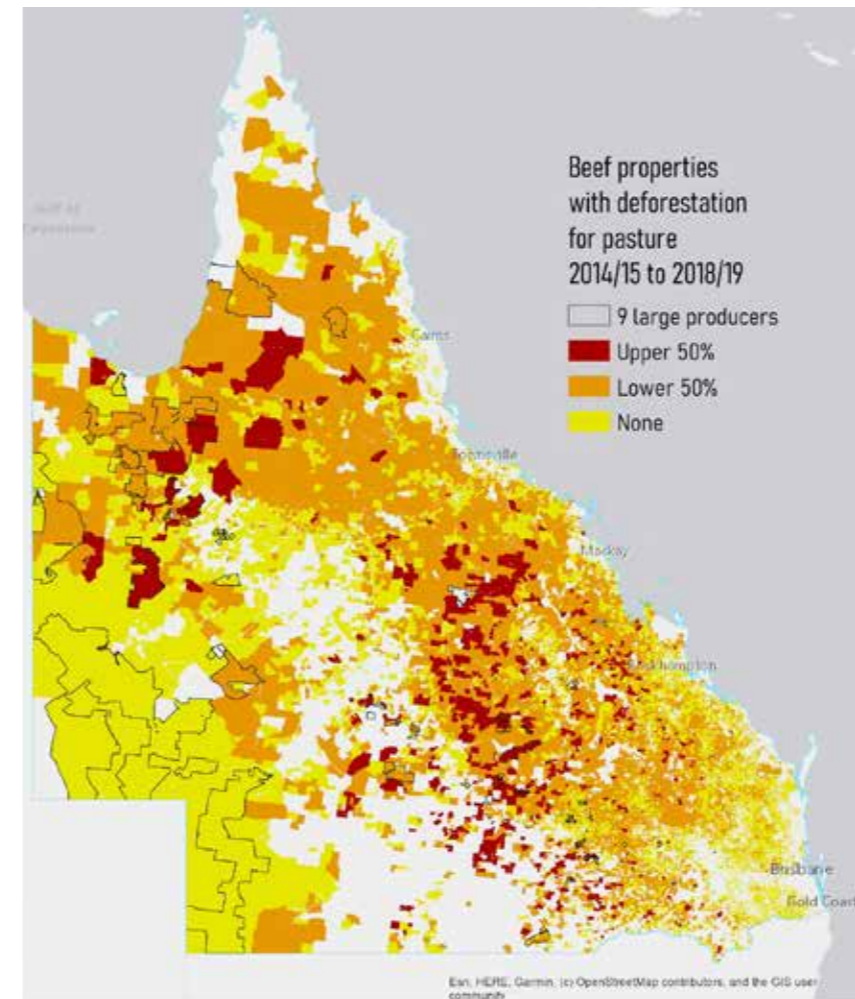

Fig. 5. Beef properties that had no deforestation, that fell in the majority lower half or in the minority upper half of total area deforested for pasture in Queensland from 2014/15 to 2018/19 (see also Fig 4). Overlaid are the properties of nine large beef producing companies. Note that these are whole properties shown, not the areas deforested.

³¹ Note as described in Methods and Caveats there are inevitable under- and over-estimation errors in counting beef property owners, despite efforts made to identify properties with the same or overlapping owners.

Nine large beef companies account for relatively little deforestation

A total of 265 land parcels could be attributed to nine major beef producing companies in Queensland, covering a combined area of 16.7 million ha, nearly 10% of the entire state land area (Fig 5).

These properties have a modelled beef capacity of 0.93 million yearling steers which represents 7.8% of the whole of state beef capacity of 11.9 million yearling steers (Figs. 5,6). The modelled capacity is close to the actual Queensland cattle herd, estimated at 10.5 million by Meat and Livestock Australia. Differences between the estimates arise due to the diversity of actual cattle age structure. Not all cattle are yearling steers. Note also that dairy herds are excluded from this analysis.³⁵

Most of the properties of the nine large companies are situated in far western arid woodlands and grasslands (Fig. 5).

Over the five years 2014/15 to 2018/19, only 1.8% of all deforestation for beef pasture fell on these properties, a total of 17,974 ha (Fig. 2), of which 48% was high value regrowth and 38% was remnant forest.

Nonetheless, some of these properties also fell within the minority accounting for 50% of beef deforestation (overlaps in Fig. 5).

These large companies usually have properties ranging right across the state and may also have properties in other states (Fig. 5). A common pattern is to have grazing lands in the western and northwestern savannahs, and higher productivity coastal or near coastal properties that may include cropping and feedlots (Fig. 7).

Intersecting the 2019 Regional Ecosystems map with the map of these properties, we found that 97% of total land area of these properties is remnant vegetation, and most of it non-forest vegetation.

A minority of properties account for most beef deforestation

Most deforestation for beef involves relatively small areas. A minority of only 276 individual and 58 corporate beef producers accounted collectively for half of all deforestation on beef properties over the five year period with properties being concentrated in central Queensland and the Gulf catchments (Figs 4, 5). These properties account for 10% by area of all beef production properties and 11% of all beef capacity in the state (Fig. 6).

Nonetheless, the majority of properties accounting for half of all deforestation, accounted for nearly half of all beef production area and 53% of beef capacity (Fig.6).

Only 36% of total beef capacity in the state did not involve deforestation over the five year period (Fig. 6).

O-subdom	68,667	26,233	6,225	101,125
LeastC	502,165	189,615	52,863	744,643
Total	960,423	351,779	115,957	1,428,159

Fig. 8 and Table 1. Threat status of regional ecosystems deforested for beef and other purposes (% and ha). Note the x-axis area scale is broken between 0.5 and 1 million ha deforested. Key: E-dom = endangered REs 100% or dominant in area deforested, E-subdom = endangered REs sub-dominant, O-dom = of-concern REs 100% or dominant, O-subdom = of-concern REs sub-dominant, LeastC = only least concern REs deforested.

Beef dominates deforestation of Queensland threatened regional ecosystems

Deforestation for beef doesn't just impact common forest ecosystems. Threatened ecosystems comprised 48% of the area deforested for pasture on beef properties (Fig. 8, Table 1).

These regional ecosystems are listed (as of 2019) under the VMA as Endangered or Of-Concern, with endangered ecosystems comprising a quarter of beef deforestation (24%) (Fig. 8). Note that deforestation includes both remnant and non-remnant regrowth forests.

Proportions of threatened ecosystems deforested for beef were similar to those for other pasture clearing and clearing for other purposes (Fig. 8). However, just as beef pasture dominated all clearing (Fig. 2), it also dominated the deforestation of threatened ecosystems, with 78% of all deforestation of Endangered ecosystems and 59% of Of-concern ecosystems attributed to pasture on beef properties over the five year study period (Table 1).

Beef dominates deforestation of threatened ecological communities

Deforestation of ecological communities and species listed as threatened under the national *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act), was also dominated by deforestation for pastures on beef properties.

For four of fourteen endangered ecological communities experiencing deforestation over the period in Queensland, proportions due to beef deforestation were over 80% (* in Table 2). All others ranged from 8 to 76% (Table 2).

Table 2. Areas of “likely-to-occur” distributions of threatened ecological communities (TECs) deforested 2014/15 to 2018/19 in Queensland.

Beef dominates deforestation of threatened species habitats

Deforestation destroyed “likely-to-occur” habitat for 388 terrestrial plants and animals listed as threatened by the Australian Government under the *Environment Protection and Biodiversity Conservation (EPBC) Act 1999* (Table 3). This included 37 critically endangered species and 124 endangered species. Threatened plants dominated the list of species affected (280 out of 388 or 72%) (Table 3). The 388 species and areas of habitat deforested are listed in Appendix 1.

Extracted from this list in Table 4 are 58 species (41 plants, 17 animals) for which beef pasture deforestation comprised at least half of all deforestation of their “likely-to-occur” habitat, and for which in addition, the loss of total “likely-to-occur” habitat to beef pasture exceeded 0.5% (5 ha/1000ha).

- The then vulnerable, now endangered Koala lost 0.65% of its entire “likely-to-occur” habitat to beef pasture deforestation in just this five year study period, representing 73% of all deforestation statewide (Table 4).
- The critically endangered Northern Hairy Nosed Wombat has a tiny area of “likely-to-occur” habitat mapped around and including its last wild refuge of Epping Forest National Park in central Queensland. Regardless how endangered this rare animal is, patches of “likely-to-occur” habitat were cleared nearby over the period (Table 4, Fig 9).

These figures are the areas of overlap with publicly available maps of “likely-to-occur” habitats as published by the Australian Government. Because these maps are not ground-truthed the resulting figures are subject to over-estimation and under-estimation errors.

Underestimation errors occur for the proportions of total “likely-to-occur” habitat deforested because not all “likely-to-occur” habitat on the maps is or was actually forested, meaning that the areas of total “likely-to-occur” forest habitat are overestimated at the time of clearing. This is evident in Fig 9 where the “likely-to-occur” habitat for Northern Hairy Nosed Wombat includes areas long deforested surrounding the national park. Also this is the only habitat patch mapped by the Dept as habitat. Large areas of remnant forest known to be suitable for the wombat are not included, and neither is the habitat occupied by the colony established further south near St George in 2009.³⁸

Conversely, due to the generic and often crude nature of the habitat maps, a patch of forest that was cleared in a given location may not necessarily represent occupied, actual or even potential habitat for that species or community, leading to over-estimation of the areas of habitat deforested. This is also evident in Fig 9 where “likely-to-occur” habitat for Northern Hairy Nosed Wombat consists of large blocks, with very coarse resolution.

Elsewhere it has been shown that in the two years prior to release of the 2018/19 SLATS data:³⁹

“Habitats for 265 EPBC Act-listed threatened species covering almost 250,000 hectares were destroyed between 2016 and 2018 in Queensland, with no evidence of any referral and approval under the EPBC Act, including 50,000 hectares of koala habitat.

Of this destruction, 94% was for livestock pasture development, and 79% fell in just two bioregions: Brigalow Belt and Mulga Lands.”

This analysis suggests that harm to matters of national significance may be continuing on these beef properties at significant scales.

Table 3. Numbers of nationally threatened species losing at least 1ha of “likely-to-occur” habitat to deforestation in Queensland 2014/15 to 2018/19 by taxon group and current status under the EPBC Act.

Non-forest species and ecosystems also impacted by clearing

Although we have focussed on impacts of deforestation in this analysis, there is also extensive clearing of non-forest ecosystems negatively affecting grassland and savannah threatened species such as the Gouldian Finch, the Night Parrot and Bluegrass.

Ending deforestation

These results suggest that major steps toward ending deforestation in Queensland and the harm to native species and ecosystems that results, could be made by a relatively small number of actors changing their behaviour:- the minority responsible for the "lion's share" of deforestation and those few large producers.

Of total deforestation for pasture on beef properties, half was attributable to a minority of just 334 landholders. If just these producers committed to deforestation free-production, a very substantial reduction in statewide deforestation would result.

Nine large beef producing companies are responsible for a relatively small amount of overall deforestation compared with the huge scale of their property portfolios. It should therefore be a relatively minor task for these companies to commit to halting all future deforestation, a commitment readily open to third party auditing using freely available spatial data such as that provided by SLATS.

Reversing deforestation

By ending deforestation, including regrowing forests previously cleared, beef producers would also be making a major contribution to reversing deforestation.

Most regrowth forest is exempt under the Queensland VMA and can be, and is, recleared at any time without restraint. By halting re-clearing once regrowth retains forest status, a massive reversal of deforestation would ensue with many if not most threatened regional ecosystems unique to Queensland recovering and eventually coming off the threatened list.

Replanting should be unnecessary because there is usually already abundant regrowth of brigalow in particular, which will grow back if allowed to do so (Fig. 10).

Fig. 10. Vegetation composition in Queensland, 2017-18. Note that a portion of what was non-forest at the time of this analysis may also regrow to forest if allowed to do so. At the time of analysis canopy cover had not reached the 20% threshold to be considered forest.

Methods

1. Beef properties layers

A set of 54,485 land parcels were identified from earlier work as being for beef production either as the primary or the secondary land use. Ownership was duplicated or similar for many properties. We removed punctuation and standardised spellings and abbreviations to reveal identities otherwise not evident. To get a more accurate picture of true ownership and control we lumped together properties with same person or corporation including where multiple people or corporate names were listed against the same parcel usually family members or family companies. Owners were classified as individuals (including partnerships) or corporations, otherwise unknown.

A further 269 land parcels in Queensland were identified as being owned or managed by one of nine large beef producers who have significant operations in Queensland.⁴⁰

2. Vegetation type layer

To classify clearing over the four years 2014/15 to 2017/18 by type of vegetation, we constructed a raster layer of four classes:

1. Non-forest in 2014, identified as any pixels less than 11% Foliage Projective Cover (FPC) in the FPC product for that year produced by SLATS (11% is the SLATS FPC equivalent of 20% canopy cover).⁴¹
2. Forest in 2014 (all pixels other than in 1 above), non-remnant but younger than 15 years. Pixels were non-remnant if mapped as such in archived Queensland Government's Regional Ecosystems version 9 (REs v9) which was current to 2013. Some unmapped blank spots in version 9 in western Queensland had to be backfilled from the more complete archived RE version 10 current to 2015. If a pixel fell within any of the footprints of woody cover loss from the 15 SLATS layers from 1999/2000 to 2013/14 they were deemed to be less than 15 years old.
3. Forest in 2014, non-remnant but 15 years or older. Any other non-remnant pixels other than in 1 or 2 above.

4. Remnant forest in 2014, where pixels overlapped areas deemed remnant in REs v9 as described above. However, if pixels were cleared at any time in the entire SLATS record, we reclassified them as either 2 or 3 above depending when the most recent clearing event happened.

We did not attempt to derive a similar age class and type layer for vegetation as it was prior to each of the four years simply because suitable FPC and regional ecosystem layers of the right time currencies were not available to do so.

To classify clearing over the most recent 2018/19 SLATS period, by type of vegetation, we constructed a similar raster layer for 2018 of the same four vegetation age and type classes, but using instead the 2018 FPC layer and the REs v11 layer current to 2017, the closest available.

All rasters were 30m x 30m pixel size in the Albers Conical Equal Area projection aligned to the same template.

3. Clearing by vegetation type

We converted SLATS polygons for each of the five years 2014/15 to 2018/19 to rasters aligned to the template with values aligned to the same 8 level purpose types (0 natural loss, 1 pasture, 2 pasture thinning (partial clearing), 3 forestry (including partial forestry clearing), 4 crops, 5 Infrastructure, 6 Mining and 7 Settlements). We combined these rasters into single raster classified by year of clearing and purpose.

For pixels cleared a second time within the five year study period, we assigned the first year of clearing to the pixel to avoid double counting.

Using raster arithmetic we summed areas cleared in each year in each of the four vegetation classes derived above on each lot.

⁴⁰ The Wilderness Society (2019) Drivers of Deforestation and land clearing in Queensland (<https://www.wilderness.org.au/qlddefforestation>).

⁴¹ Scarth P (2012) On the relationship between crown cover, foliage projective cover and leaf area index. *figshare. Journal contribution*. <https://doi.org/10.6084/m9.figshare.94249.v1>

4. Deforestation layer

We then extracted just the areas of forest cleared over the 5 year period condensed into two classes: pasture clearing and other clearing purposes. This raster we converted back to polygons, and excluded all isolated fragments less than 0.2ha. By unioning this with the beef property layer, we classified areas deforested into three categories: a) clearing for beef pasture, b) for other pasture and c) other non-pasture clearing.

5. Beef properties by beef pasture deforestation

We intersected a) beef pasture clearing from (4) above with the property layers of all beef properties and the properties of the nine large producers and calculated areas of forest cleared for pasture on both sets.

From this we were able to classify each beef property as a) not deforesting at all, b) belonging to the minority of owners responsible for half of all beef pasture deforestation or c) belonging to the majority of smaller scale clearers responsible for the other half.

6. Deforestation of threatened ecosystems and species

We dissolved the Queensland Regional Ecosystems version 12.2 current to 2019,⁴² by the VMpoly field which lists the status of each polygon by current Vegetation Management

Act threatened status whether least concern, endangered or of concern, within those whether dominant or sub-dominant. For non-remnant areas on the present day layer, we substituted in the pre-clearing VMpoly values.

We then intersected these by the deforestation layer from (4) above and tabulated areas.

Finally, we intersected the Australian Government's "likely-to-occur" maps for threatened species and ecological communities by deforestation layer (4) and tabulated areas of habitats deforested.⁴³

7. Estimating cattle production capacity

To estimate cattle production capacity for all beef properties or for the properties of the nine companies, we downloaded a layer of beef stocking densities from the portfolio of layers used in the Multi-Criteria Analysis Shell for Spatial Decision Support and served on the Terrestrial Ecosystem Research Network portal.⁴⁴ Units are in "dry sheep equivalents" per hectare and pixel sizes 1km x 1km. We converted these to yearling steer equivalents per 1000 ha using an average of 8 DSEs per yearling steer.⁴⁵ We used the 2012-2017 Queensland Land Use layer⁴⁶ to clip this layer only to land uses that are relatively undeveloped but excluding all protected areas. We used this layer to sum the totals of predicted yearling steer capacities for the whole state within the footprints of beef producing properties as classified in (5) above.

Caveats

No implication is made from this analysis that any landholder the subject of this study has cleared unlawfully or improperly. No analysis of the legal authorities for the tree clearing observed was conducted for this report.

In ascribing land parcels to particular owners, errors may result from the passing of time. Landholders may have sold off properties since this search was conducted and may have purchased others not shown in this analysis.

Areas derived for clearing after conversion from polygons to rasters are subject to minor inaccuracies due to pixelation of more precise polygon boundaries.

Whether areas are accurately described as forest on the basis solely of FPC is also subject to errors. The FPC product is itself subject to error in modelling actual foliage cover from satellite imagery⁴⁷. Also some areas in the arid woodlands and savannahs in particular can fluctuate around the 11% FPC (20% canopy cover) threshold from year to year between nominal "forest" and "non-forest" on the basis of fire, drought or other natural fluctuations alone, with no change in numbers of live standing trees. Also FPC contains no information about species or vegetation height. So it is possible that areas deemed to be forest based on FPC alone, may in fact be low woody shrubland.

Similarly it is possible that some areas, including those cleared, may have included non-native woody weeds like prickly acacia. There is no way available to a desktop analysis to estimate this error. However by quantifying which properties notified for woody weed control under the relevant code we determined that this contribution must be low. In any case, the whole point of notification under the weed management code is that native vegetation would be cleared or killed in the process of killing exotic weeds.

Grey-headed flying fox
© Martin Taylor.

By age-classifying the vegetation we hoped to reduce some of the uncertainty about whether regrowth cleared was in fact a genuine forest. For ages below 15 years, uncertainty is relatively high. For ages 15 and above however, confidence that the area cleared was genuine forest is high.

All errors and omissions are the author's own.
