Abstract. A revision of the wild species in the genus *Malus* Mill. (Rosaceae) is presented based on numerical analyses and specimens from herbaria around the world, while cultivated species such as *Malus domestica* (Suckow) Borkh. are not included because of their complicated domestication history. Infra- and interspecific morphological variation and species delimitation are clarified based on Principal Component Analyses (PCA) and Cluster Analyses (UPGMA). We found that several morphological characters traditionally used to distinguish species have limited taxonomic value because of high phenotypic variation or plasticity. There is a substantial conflict between traditional morphological and genetic taxonomic concepts, and as a result species lineages are often morphologically indistinguishable. None of the analyses supports the recognition of infraspecific categories in *Malus transitoria* (Batalin) C.K.Schneid. and interspecific categories between *Malus doumeri* (Bois) A.Chev. and *Malus leiocalyca* S.Z.Huang. Based on our analyses, we recognize 26 wild species in the genus, and propose seven new synonymies.

Keywords. Herbarium specimens, morphological variation, numerical analyses, revision, taxonomy.

Li J.C., Liu J.Q. & Gao X.F. 2022. A revision of the genus *Malus* Mill. (Rosaceae). *European Journal of Taxonomy* 853: 1–127. <https://doi.org/10.5852/ejt.2022.853.2019>

Introduction

The genus *Malus* Mill. (Rosaceae, *Maleae*), occurring mostly in the temperate Northern Hemisphere, is of economic and ecological importance. Some species are cultivated for their fruits such as apple (*Malus domestica* (Suckow) Borkh.) and *M. asiatica* Nakai, or as ornamentals such as *M. micromalus* Makino, *M. hupehensis* (Pamp.) Rehder, *M. spectabilis* (Aiton) Borkh., *M. yunnanensis* (Franch.) C.K.Schneid., and *M. halliana* Koehne. Species in the genus are deciduous trees or shrubs with a basal chromosome number of $x = 17$. The genus was described by Miller (1754) to include a number of species previously placed in the genus *Pyrus* L. (Linnaeus 1753). *Malus* can be distinguished from *Pyrus*, *Cydonia* Mill., and *Sorbus* L. mainly by the styles that connate at the base, the 2 ovules in each locule, the pome often

not containing the stone cells, and usually white filaments and yellow anthers in stamens. Although Christenhusz *et al.* (2018) recently suggested expanding the genus *Pyrus* s. lat. to include species of *Pyrus*, *Malus*, and other fruit crops in Rosaceae, this taxonomic proposal is not broadly accepted. The number of accepted species in *Malus* varies considerably in different studies. For example, Likhonos (1974) considered only eight species, while Ponomarenko (1986) recognized 78 species. Disagreements over species boundaries and diversity are also reflected in the recognition of various subspecies resulting from cross-compatibility in intraspecific and interspecific hybridization, and apomixis ubiquitous during the evolution of the genus (Robinson *et al.* 2001). Furthermore, a narrow species concept held by some Chinese taxonomists during the 1980s resulted in additional confusion regarding species boundaries (Hus & Gu 1986; Hus 1998).

The taxonomy of *Malus* has been revised several times (e.g., Koehne 1890; Zabel 1903; Koidzumi 1934b; Rehder 1949; Yu & Yen 1956; Chen 1959; Langenfeld 1991; Robertson *et al.* 1991; Li 1996; Qian 2005; Christenhusz *et al.* 2018). Morphological characteristics such as habit, sepals, leaf form, bud folding form, and stone cells have been mostly used in morphological classifications of *Malus*, but different researchers disagree on the categories, the taxonomic ranks, and the placement of some species. For example, *Malus* was divided into five sections, sect. *Chloromeles* (Decne.) Rehder (6 species), sect. *Docyniopsis* C.K.Schneid. (1 species), sect. *Eruolobus* (DC.) C.K.Schneid. (1 species), sect. *Eumalus* Zabel (7 species), and sect. *Sorbomalus* Zabel (8 species) (Rehder 1940). However, some important wild species such as *Malus sylvestris* (L.) Mill., *M. sieversii* (Ledeb.) M.Roem., *M. doumeri* (Bois) A.Chev., and *M. sikkimensis* (Wenz.) Koehne ex C.K.Schneid. were not included. Langenfeld (1971, 1991) presented a new taxonomic system, which is regarded as an extension of Rehder's classification. It comprises six sections including sect. *Sorbomalus*, sect. *Eriolobus* (C.K.Schneid.) Langenf., sect. *Docyniopsis* (C.K.Schneid.) Langenf., sect. *Chloromeles*, sect. *Gymnomeles* Koehne, and sect. *Malus* Langenf. Cultivars without a natural distribution area were no longer included in this system, but the addition of seven monotypic series made the system more complex. Robertson *et al.* (1991) proposed a new classification system, excluding the sections *Eriolobus* and *Docyniopsis* from the genus. Since then, a large number of new species has been described (e.g., Yu *et al.* 1980; Jiang 1991; Qian & Tang 2005; Liu *et al.* 2020), merely based on the quintessential difference between new samples and type specimens of existing species, without considering evidence from molecular, ecological or geographical data. The above mentioned taxonomic revisions lacked an evaluation of character distribution by numerical analyses, and the delimitation of some species remains unsatisfactory.

Incongruence between morphological and genetic data has been apparent in recent taxonomic studies (Yu 2000; Robinson *et al.* 2001; Forté *et al.* 2002; Huh 2007; Potter *et al.* 2007; Lo *et al.* 2012). For example, amplified fragment length polymorphism (AFLP) was employed for estimating genetic relationships within *Malus*, resulting in thirty-three species being classified into four and five groups by the UPGMA and Wanger method, respectively (Yu 2000). These results broadly support Rehder's system; however, samples of *Malus hupehensis* (Pamp.) Rehder, *M. toringo* (Siebold) Siebold ex de Vriese, and *M. baccata* (L.) Borkh. from different localities did not group together. Phylogenetic analysis based on internal transcribed spacer (ITS) and chloroplast *matK* gene sequences divided *Malus* into three clades (i.e., section *Malus* group, section *Sorbomalus* group, and basal taxa) (Robinson *et al.* 2001). Sections *Eriolobus* and *Docyniopsis* were included to ensure the monophyly of the genus. Unfortunately, the results remain ambiguous because of the low levels of sequence divergences and the incongruence between the two data sets.

Nikiforova *et al.* (2013) and Jin (2014) proposed a new molecular phylogenetic framework of *Malus*, based on chloroplast genome data. Their results indicated that *Docynia* Decne. and *Cydonia* are the closest sister genera of *Malus*. Within *Malus*, seven clades were recognized which are compatible with the geographical distribution. However, these phylogenomic results differed considerably from previous

morphological classification systems, and the authors did not offer the identifiable morphological traits of each clade. Savelyeva *et al.* (2017) reconstructed the phylogenetic relationships of species of *Malus* by sequence-specific amplified polymorphism (S-SAP), classifying 131 samples of *Malus* into three groups (Group A–C) and one subgroup (Group C1). Interestingly, two samples of *Malus florentina* C.K.Schneid. belonged to different groups, and the position of *M. sikkimensis* was unstable and dependent on the algorithm used. Overall, these studies indicate support for genetic distinctiveness of part of traditionally recognized groups, but do not find support for genetic differentiation of every currently recognized species within each group. As such, there is an urgent need to evaluate the extensive intraspecific variation within and among species.

The present study aims to: 1) analyze multivariate morphometric traits to clarify rudimentary macromorphological patterns of variation among and within the wild species of *Malus*; 2) evaluate the role of traditional taxonomic characters for identification or separation of taxa; and 3) determine relationships of species based on numerical analyses and specimens from herbaria around the world.

Material and methods

Material

This study is based mainly on digital herbarium specimens from the following herbaria (acronyms according to Thiers B. (continuously updated) <http://sweetgum.nybg.org/science/ih/>): A, AU, BJFC, BM, BNU, CAF, CCAU, CDBI, CSFI, CSH, CVH, CZH, DAO, DD, E, ECON, FI, FJSI, GFS, GH, GNNU, GNUG, GXMG, GZAC, GZTM, HBNU, HEAC, HENU, HGAS, HHBG, HIB, HIMC, HITBC, HNWP, HSIB, HTC, HUST, HWA, IBK, IBSC, IFP, IMC, IND, JIU, JFJ, JXAU, K, KUN, LBG, LE, LECB, LINN, M, MO, MW, NAS, NCU, NDG, NEFI, NKU, NO, NYA, NY, P, PAL, PE, PEY, QNUN, QYTC, RIJKS, SABG, SAU, SDFGR, SM, SXU, SYS, SZ, SZG, TASH, TCD, TIE, US, WCSBG, W, WU, WUK, XBGH, XJBI, XZ, and ZM.

Material for numerical analyses

We checked large numbers of digital specimens spanning the main distribution areas, but not all images were suitable for this study. This was mainly due to the poor resolution, missing scale bar, and folded foliage and flowers of some specimens. The present study encompassed more than 370 adult specimens from 61 wild species (including subspecies, varieties and synonyms) and subspecies of *Malus*, covering ca 87% of the known taxa in the genus. Type specimens were regarded as the standard to select samples, which would ensure taxonomic controversies observed were not caused by hybridization. The number of specimens examined for each taxon ranged from 1 to 15 depending on the availability of vegetative and reproductive characters. The names of the investigated species, specimen barcodes, and collection information are listed in Appendix 1. Most of the type specimens were also included. These specimens are preserved in the herbaria of A, BM, BNU, CDBI, CSFI, DAO, E, GH, GXMG, HENU, HNWP, HTC, IBK, IBSC, IND, IFP, JXAU, K (QIN), KUN, LBG, LINN, M, NAS, NCU, NDG, NO, NY (NYBG), P, PE, SZG, SXU, TCD, US, and WU. Most digital images were downloaded from the Chinese Virtual Herbarium (<http://www.cvh.ac.cn/>), the Muséum national d'histoire naturelle (<https://science.mnhn.fr/>), and JSTOR Global Plants (<https://plants.jstor.org/plants/browse>).

Morphological measurements

A total of 28 morphological characters, traditionally used to distinguish species (Chen *et al.* 2014; Kumar *et al.* 2018) were chosen for analysis, including qualitative and quantitative traits in mature and intact leaves, flowers and fruits. The details and definitions of the traits are presented in Table 1 and Fig. 1. For each specimen, measurements of all pomes and flowers were included, and no less than five leaves (with a few exceptions). All specimens were broadly assigned to two groups ('florescence' group, 'fruiting season' group) based on their reproductive characteristics. The 'florescence' group incorporates samples

Table 1. Description of the quantitative and qualitative morphological parameters of species of *Malus* Mill.

No. Morphological characteristics		
	Quantitative trait	Unit of measurement

	Qualitative trait	Description
24	Piliferous blade (PB)	0-Absence; 1-Partial presence; 2-Presence
25	Piliferous petiole (PP)	0-Absence; 1-Presence
26	Leaf division (LD)	0-Undivided; 1-Incised; 2-Lobed; 3-Parted; 4-Divided
27	Leaf margins (LM)	0-Edentate; 1-Erose; 2-Serrate; 3-Crenate; 4-Serrate and Crenate
28	Piliferous pedicel (Pp)	0-Absence; 1-Presence

collected from March to August with flowers, while the ‘fruiting season’ group includes samples collected from September to November with fruits. The terminology of the morphological characterization of species of *Malus* followed the works of Hickey (1973), Sun *et al.* (1997), and Harris & Harris (2001). Characters of each specimen were measured by ImageJ ver. 1.52a (<https://imagej.nih.gov/ij/index.html>).

Statistical analysis

Data from each specimen was processed with reference to Sokal & Sneath (1963) and Kumar *et al.* (2018). Data processing and analysis of the frequency distribution for each qualitative morphological parameter was prepared by R ver. 3.5.2 (<http://www.R-project.org/>) and Excel 2016. The pooled quantitative data were taken for calculating minimum, maximum, mean, standard error of the mean (SE mean), variance, standard deviation (SD), and coefficient of variance (CV) using the R package. Limited by the number of samples, Kolmogorov-Smirnov tests, Q-Q plots, and Bartlett tests of homogeneity of variances were used to verify data normal distribution after standardization. R packages were employed for one-way analysis of variance (ANOVA) followed by the LSD test (F value and p-value, package ‘agricolae’). Although the entire data is normally distributed, the simple correlation of coefficients among the studied variables using the Spearman correlation coefficient method was calculated because of the existing outliers in each variable. Cluster analysis, principal component analysis (PCA), and additional principal coordinates analysis (PCoA) were performed using both R and PAST ver. 3.21 (Hammer *et al.* 2001). The dendrogram was constructed using the UPGMA method (the Gower similarity index, Bootstrap N =

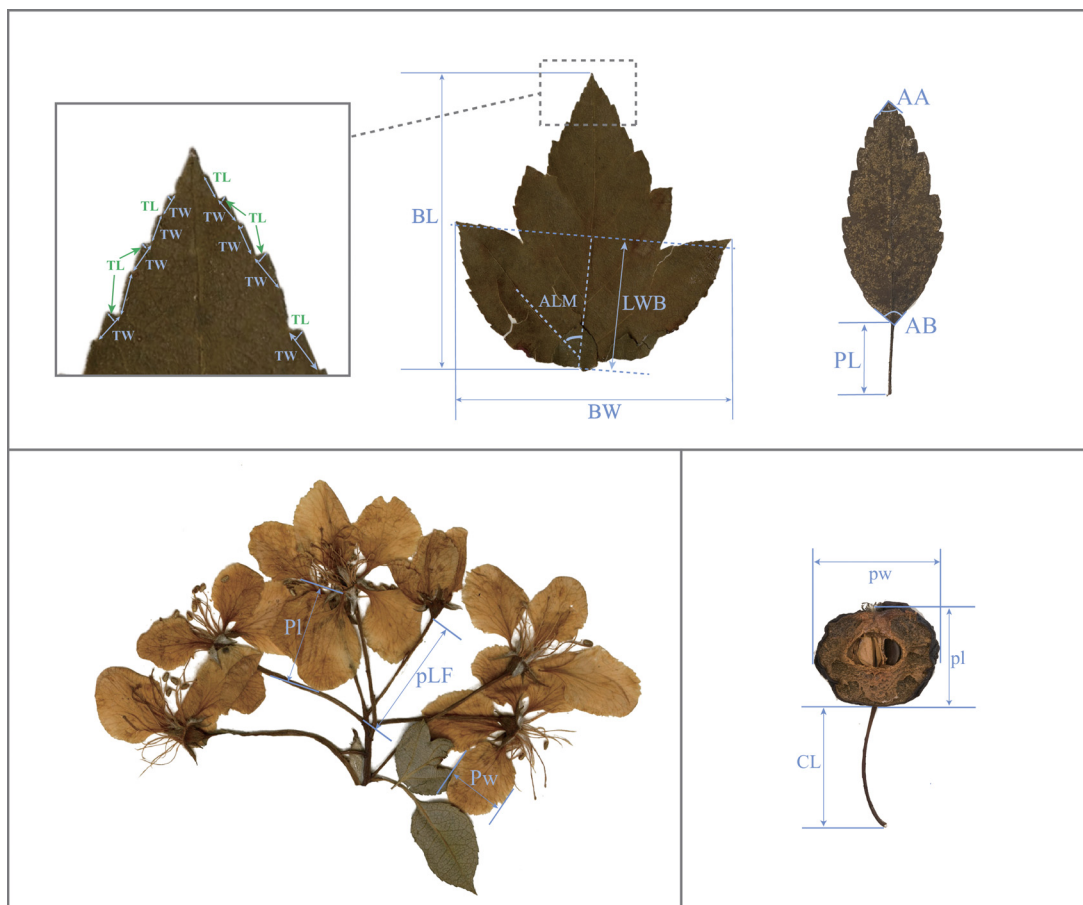

Fig. 1. Schematic for definition of morphological parameters for species of *Malus* Mill. (material from NYBG02812600, A00026590, and A00026604).

500). PCA, which won the approval of the Kaiser-Meyer-Olkin (KMO) measure and the Bartlett test of sphericity, was performed according to the correlation matrix, and factors with eigenvalues >1 were chosen in accordance with the Kaiser criteria (Kaiser 1960).

Results

Morphometric analyses

Frequency distribution of qualitative morphological parameters

Our results showed the extent of morphological variation within the distribution ranges of species. There was considerable diversity for qualitative characters related to leaf, petiole and pedicel in selected species of *Malus*, even though they showed quite distinct differences within a single species. The frequency of the abaxially glabrous leaf blade (59%) was higher than that of the abaxially piliferous leaf blade (29%), and approximately 12% of the samples had a partially piliferous blade. More than 59% of the selected species had all of the leaf traits mentioned above, and less than 41% of the species only possessed one trait. Conversely, the frequency of the glabrous petiole (42%) and pedicel (45%) was lower than the frequency of the piliferous petiole and pedicel (58% and 55%, respectively). Furthermore, 51% and 61% of species and subspecies were either glabrous or piliferous, respectively. The undivided leaves were the most common, while divided leaves were the rarest. Additionally, lobed leaves were the most common type in the species with other than the undivided leaves. The most and the least frequent types of the leaf margin were serrate and erose, respectively. See Appendix 2.

Statistics of quantitative morphological parameters

The morphology of leaves, flowers, and fruits in *Malus* presented by quantitative parameters varied significantly among different species. The coefficient of variation (CV) of all quantitative traits exceeded 10% in both ‘florescence’ and ‘fruiting season’ groups, indicating a high level of morphological variation. In line with data of the ‘fruiting season’ group, the value of CV of the pome area (PA) reaching up to 117% is the highest of all parameters, while the lowest is 13% based on the angle formed by the lateral nerve and main nerve (ALM). The largest average PA (1027.09 mm²) was observed in *Malus coronaria* var. *hoopesii* Rehder, while the smallest was in *M. muliensis* T.C.Ku (28.00 mm²). Coincidentally, the value of the CV of ALM that is presented in the ‘florescence’ group is 14%, which is only slightly more than the CV of the ratio of petal length and width (Pl/Pw, 13%). Additionally, there are two quantitative parameters called leaf area (LA) and tooth length (TL) with CV values exceeding 50%. The maximum average of these two parameters both occurs in *Malus fragrans* var. *elongata* Rehder. It is interesting to notice that *M. trilobata* (Labill. ex Poir.) C.K.Schneid. revealed the longest average petiole length (PL, 42.09 mm) in the ‘florescence’ group, but the lowest value in the ‘fruiting season’ group (8.34 mm). In contrast, the shortest average blade length (BL), length from the widest point to the base of the leaf (LWB), and the minimum average leaf area (LA) were measured in *M. transitoria* var. *glabrescens* T.T.Yu & T.C.Ku in both the ‘florescence’ and the ‘fruiting season’ groups. The remaining values of studied morphological characteristics for *Malus* and the significant differences examined by the one-way ANOVA are presented in Supp. file 1. The least significant difference (LSD) was applied to test the slight distinctions among species, particularly those that have been treated as synonyms in previous studies. Our results revealed that there is no significant difference between synonyms and their accepted species. Therefore, we follow the recognition of synonyms of previous studies.

Cluster analysis

The scores of cophenetic correlation for two diagrams are 0.76 and 0.85, respectively. The diagrams produced by the cluster analysis of the ‘florescence’ group data and the ‘fruiting season’ group data are partly similar. Eight and five main clusters were displayed by cluster analysis based on 17 and 19 quantitative morphological characteristics, respectively, although each clade was identified with poor

resolution (Fig. 2). *Malus trilobata* occupies a separate cluster both in Cluster II (BP = 25%) (Fig. 2A) and Cluster I (BP = 100%) (Fig. 2B), while *M. doumeri*, *M. leiocalyca*, and *M. melliana* (Hand.-Mazz.) Rehder gather on the same branch in the midst of Cluster III (BP = 88%) (Fig. 2B). We compared all samples of these three species and found that their positions were similar in the principal component analysis and principal coordinates analysis (Fig. 3). The information of collection location was also mapped on the dendrograms, but the results revealed no clear patterns.

Moreover, *Malus baccata* and *M. mandshurica* (synonym: *M. manshurica* (Maxim.) Kom. ex Skvortsov) grouped together not only in the cluster tree of the ‘floreescence’ group (BP = 66%) (Fig. 2A) but also in that of the ‘fruiting season’ group (BP = 73%) (Fig. 2B). Species with the status ‘unresolved’ or ‘unknown’ in Appendix 1 grouped with different species in these two cluster trees. For example, *M. xiaojinensis* M.H.Cheng & N.G.Jiang, *M. manshurica*, and *M. sylvestris* form a group in Fig. 2A (BP = 51%), while *M. xiaojinensis* groups with *M. toringoides* (Rehder) Hughes and *M. daochengensis* C.L.Li in Fig. 2B (BP = 46%).

Principal component analysis

Seventeen and nineteen quantitative characters were employed for the PCA analysis, and the result presents a similar pattern as described above. Eleven traits showed an eigenvalue > 1, which illustrates that the species are morphologically very close. The variance of eleven major traits (> 1 eigenvalue) PCs varies from 1.3% to 31.3% and 1.7% to 27.0%, respectively (Bootstrap N = 100).

Based on data of the ‘floreescence’ group, the first six principal components accounted for 84.2% of the total variance, wherein the first and second axis occupied 31.3% and 17.1%, respectively (Table 2). Factor loadings of >0.60 and <-0.60 were considered as significant. Six characters showed the highest correlation

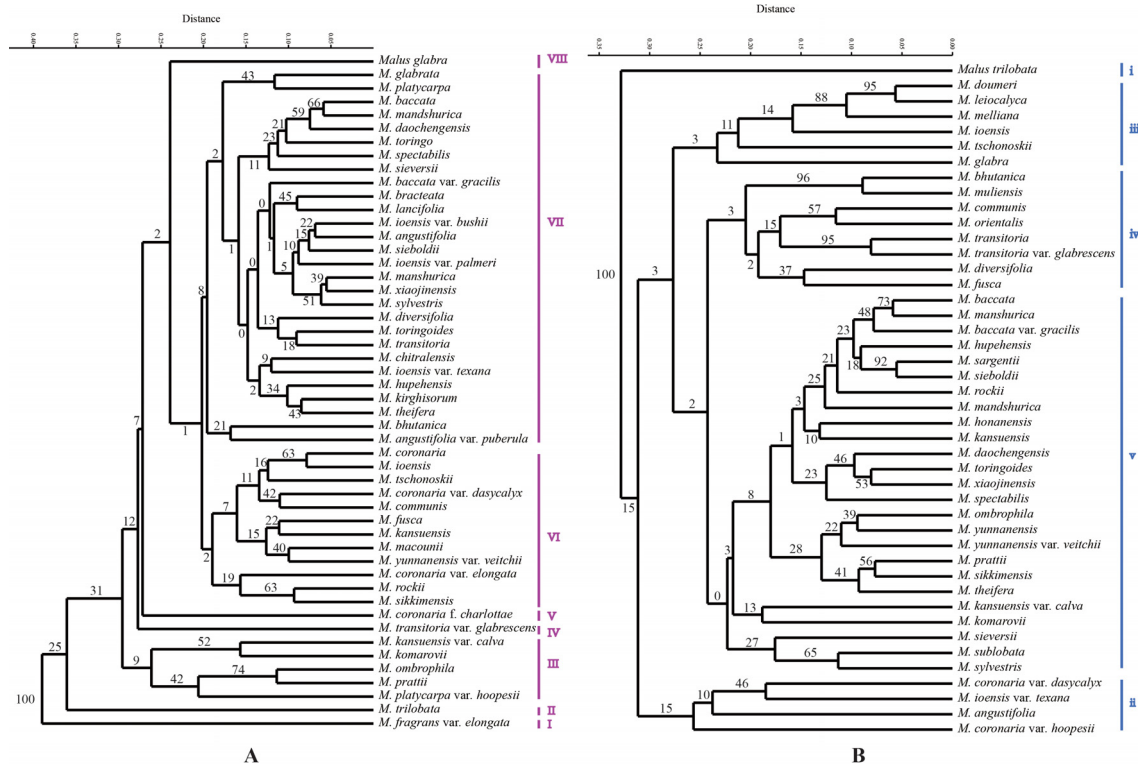

Fig. 2. Cluster analysis (UPGMA method of classification and Gower’s general similarity coefficient). **A.** ‘Floreescence’ group (17 quantitative characters). **B.** ‘Fruiting season’ group (19 quantitative characters).

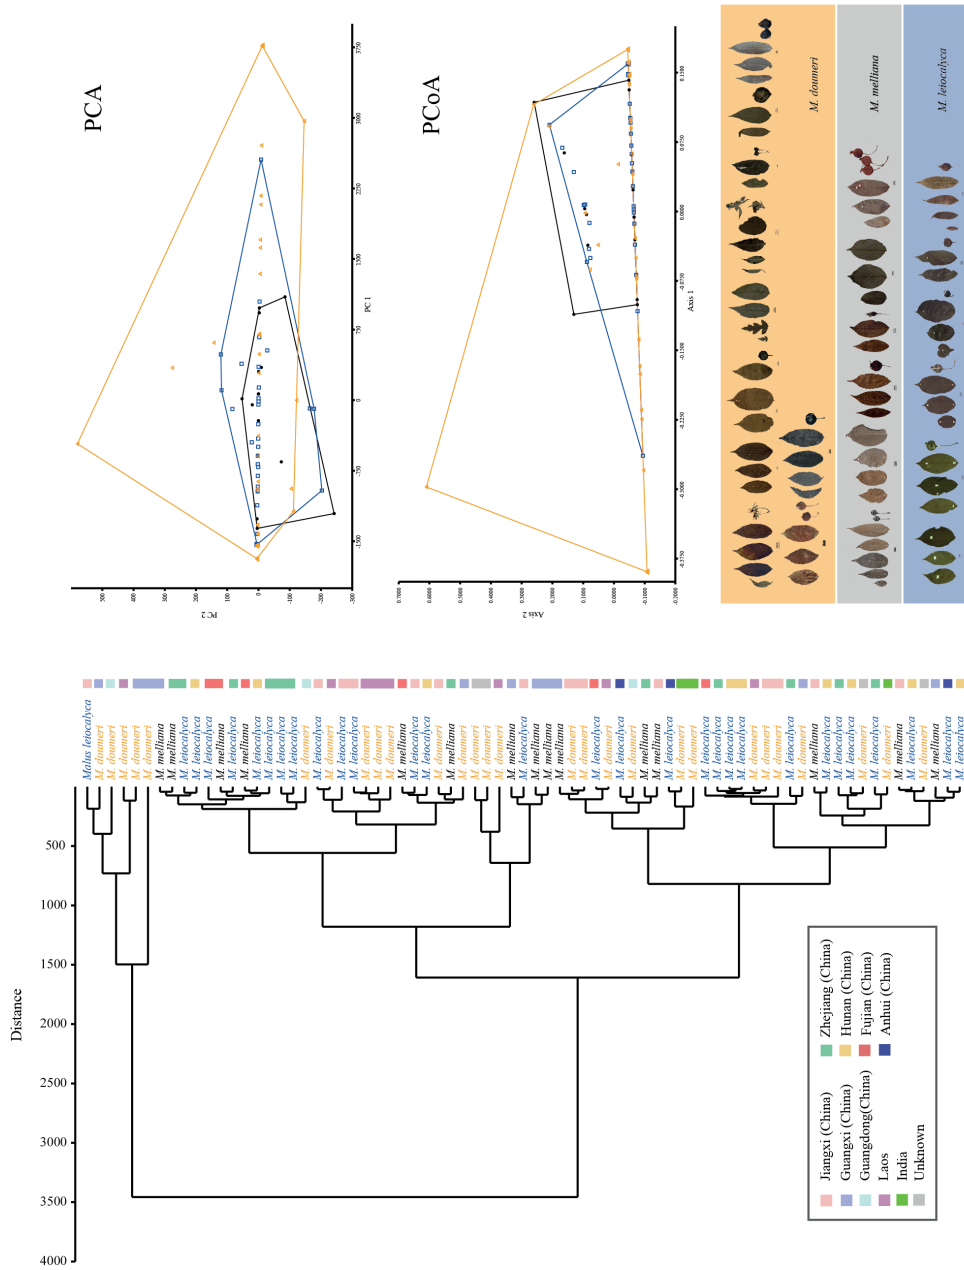

Fig. 3. Cluster analysis (UPGMA method) and PCA performed on all studied quantitative characters in *Malus doumeri* (Bois) A.Chev., *M. melliana* (Hand.-Mazz.) Rehder, and *M. leiocalyca* S.Z.Huang. The images come from the following specimens. *M. doumeri*: A00032498 (isotype of *Pyrus melliana* Hand.-Mazz.), CSFI033248, P00781055 (syntype), P00781056, P00781058 (lectotype of *Pyrus laosensis* Cardot), P03144755, P03144777, P03144789, PE00004596 (holotype of *M. asiatica* var. *argutiserrata* Hu & F.H.Chen), PE00927581, and QIN05067; *M. melliana*: P03144393, PE01460689, JXAU0004023, JXAU0004034, IBK00197341, and IBK00197343; *M. leiocalyca*: CSFI012166, CSFI012188, PE00952771, PE00952776, PE00952780 (paratype), PE00952781 (isotype), and IBK00367917.

Note: Factor loadings (>0.60 and <-0.60) are given in bold. For character abbreviations, see Table 1.

with PC1, four with PC2, three with PC3, and one each with PC4, PC5, and PC6 (Table 3). Fourteen characters had high positive factor loadings (>0.60) on the first six axes, and two had high negative factor loadings (<-0.60), which could help to distinguish between specimens of subspecies and varieties.

For data of the ‘fruiting season’ group, the first and second principal components hold 27.0% and 20.7%, respectively (Table 2). Only one factor loading exceeded 0.60. Hence factor loadings of >0.30 and <-0.30

Note: Factor loadings (> 0.30 and <-0.30) are given in bold. For character abbreviations, see Table 1.

were considered as significant in Table 4. Seventeen characters had high positive factor loadings and six had high negative factor loadings on the first six principal components. The relationship among species of *Malus* was exhibited in the scatter plot constructed by PC1 and PC2 (Fig. 4). Neighbouring species on the diagram revealed a very close relationship in morphology.

Based on the morphological information available in our study, combined with protologue, and genetic, ecological and geographical evidence for species delimitation, twenty-six wild species and two varieties are confirmed in the genus. Nonetheless, the evaluation of diagnostic characters to identify some species is still difficult due to the lack of collections from certain regions or countries. Although herbaria host rich collections of *Malus*, some species are represented by a few specimens only. For example, the Chinese endemic species *Malus muliensis* was collected only once in 1983 (19 Aug. 1983; *Expedition Qinghai-Xizang 12983*; PE[01685058] and PE[01862281]), and *M. sublobata* Rehder only has one specimen in Kew (K[000758473]) with little information. In addition, the taxonomic position of *M. daochengensis* C.L.Li is still unclear because DNA sequence data are lacking. Therefore, *M. muliensis*, *M. sublobata* and *M. daochengensis* are not involved in this revision.

Taxonomy

Class Magnoliopsida Brongn.
Order Rosales Bercht. & Presl
Family Rosaceae Juss.

Genus *Malus* Mill.

Gardeners Dictionary Abridged, 4th Ed., Vol. 2: Malus (Miller 1754).

Pyrus sect. *Malus* Tourn., *Institutiones Rei Herbariae Vol. 3: tab. 406* (Tournefort 1700). – *Pyrus* sect. *Malus* Tourn. ex DC., *Prodromus Systematis Naturalis Regni Vegetabilis Vol. 2: 635* (de Candolle 1825). – *Pyrus* subgen. *Malus* (Tourn.) Focke, *Die natürlichen Pflanzenfamilien 3rd Ed., 3 (3): 24* (Focke 1888).

Type species

Malus sylvestris (L.) Mill.

Description

Trees or shrubs, deciduous or semi-evergreen. Branches terete, generally unarmed. Leaves unifoliate, alternate, petiolate, stipular. Lamina oval to ovate, margin crenate to serrulate, serrate or lobed. Inflorescence umbellate or corymbose. Flowers usually 3–6, pedicellate. Stamens 15–50, with yellow anthers and white filaments. Hypanthium bowl-shaped, glabrous or pubescent. Petals 5, suborbicular to obovate, white to red, with 5 sepals persistent or caducous. Styles 3–5, connate at base, glabrous or pubescent. Ovary inferior, 3–5-locular, with 2 ovules in each locule. Pome stone cells present in a few species. Seeds semicircular or spindly, black or brown, 1 or 2 in each locule.

Chromosome number

x = 17, usually diploid, triploid, tetraploid, and polyploid.

Distribution

Widely distributed in North temperate zone.

Key to species

1. Microphyll (225–2025 mm²) most common 2
– Notophyll (2025–4500 mm²) most common 20
2. Insertion points of lamina base on either side of petiole are symmetrical 3
– Insertion points of lamina base on either side of petiole are asymmetrical 17
3. Leaf margin generally unlobed, or lobed in young leaves 4
– Leaf margin distinctly lobed, or divided 13
4. Lamina base cuneate or rounded 5
– Lamina base rounded, truncate, wide-cuneate or cordate 9
5. Lamina elliptic to ovate, elliptic ovate or triangular ovate 6
– Lamina obovate, oblong to oval or rotund 7
6. Tree; leaf apex retuse to caudate; abaxial blade puberulous or glabrescent; umbel
..... 1. *M. baccata* (L.) Borkh.

- Small tree or shrub; leaf apex acute, rounded or obtuse; blade glabrous or villous on midvein, sometimes lobed; corymb **20. *M. angustifolia*** (Aiton) Michx.
- 7. Young leaves piliferous, then glabrescent; small pome, with maximum diameter no more than 4.5 cm 8
 - Abaxial blade puberulous in adult leaves; sepals caducous; styles 3 or 4, with dense tomentum at base; pome ca 3.0–8.0 cm in diameter, subglobose or coniform, yellow or green **4. *M. kirghisorum*** Al.Fed. & Fed.
- 8. Small tree or shrub; hypanthium densely lanuginous; sepals densely puberulous, persistent; styles 5, rarely 4, basally densely puberulent; pome solitary, ca 2.5–4.5 cm in diameter **3. *M. sieversii*** (Ledeb.) M.Roem.
 - Tree; hypanthium glabrous; sepals abaxially puberulous or glabrous, adaxially densely puberulous, caducous; styles 3–5, glabrous; pome ca 1.0–1.3 cm in diameter **11. *M. xiaojinensis*** M.H.Cheng & N.G.Jiang
- 9. Lamina ovate, broadly ovate to elliptic ovate or rotund 10
 - Lamina ovate to oblong or triangular ovate 12
- 10. Leaf margin occasionally lobed, apex acuminate or acute; hypanthium densely lanuginous; styles 5, basally puberulous **14. *M. tschonoskii*** (Maxim.) C.K.Schneid.
 - Leaf margin unlobed, apex usually acuminate; hypanthium puberulous or glabrous; styles 5, basally glabrous 11
- 11. Small tree or shrub; lamina glabrous; umbel; pome solitary, ca 2.0–3.5 cm in diameter, subglobose, yellow **7. *M. sylvestris*** (L.) Mill.
 - Tree; lamina puberulous or glabrous; corymb; pome ca 1.0–1.5 cm in diameter, ellipsoidal, yellow to red, with fruit spots **17. *M. prattii*** (Hemsl.) C.K.Schneid.
- 12. Small tree or shrub; lamina puberulous, sometimes 3-lobed, rarely 5-lobed; umbel; hypanthium puberulous or glabrous; sepals caducous; styles 3–5, basally densely puberulent; pome ca 0.6–0.8 cm in diameter, subglobose or oblate, yellow or red **8. *M. toringo*** (Siebold) Siebold ex de Vriese
 - Small tree; lamina glabrous or puberulous, sometimes lobed; corymb; hypanthium densely puberulous; sepal persistent; styles 5, pubescent at base; pome ca 2.0–3.0 cm in diameter, subglobose, yellow..... **21. *M. ioensis*** (Alph.Wood) Britton
- 13. Lamina palmately lobed or divided 14
 - Lamina pinnately lobed or divided 15
- 14. Tree; lamina base rounded or cuneate, apex acute, pubescent on abaxial blade, lobed; sepals persistent; styles 5, pubescent at base; pome ca 1.0 cm in diameter, oval or obovate **23. *M. florentina*** (Zuccagni) C.K.Schneid.
 - Small tree or shrub; lamina base cordate or cuneate, apex acute or acuminate, puberulous, 3-lobed; sepals caducous or persistent; styles 4 or 5, glabrous; pome ca 0.8–1.0 cm in diameter, subglobose, yellow to red **26. *M. komarovii*** (Sarg.) Rehder
- 15. Lamina base usually wide-cuneate, sometimes rounded or cordate; umbelliform corymb (appearance resembles umbel) 16
 - Lamina base usually rounded or cordate, sometimes cuneate; corymb; sepals abaxially glabrous or puberulous, adaxially densely puberulous, persistent; styles 5, pubescent at base; pome ca 2.5–3.5 cm in diameter, subglobose, yellow **22. *M. coronaria*** (L.) Mill.

16. Lamina elliptic to ovate, piliferous, pubescent on midvein, usually 3-lobed or divided, sometimes unlobed; pome ca 1.0–1.3 cm in diameter, ellipsoidal to subglobose, yellow **10. *M. toringoides*** (Rehder) Hughes
 – Lamina oval to ovate, puberulous when young, then abaxially glabrescent, usually 3–5-divided; pome ca 0.6–0.8 cm in diameter, subglobose, yellow to red **12. *M. transitoria*** (Batalin) C.K.Schneid.
17. Indumentum on young leaves, then glabrescent 18
 – Indumentum on abaxial blade or midvein, sometimes glabrous 19
18. Lamina oval to ovate, usually aubergine in young leaves, base cuneate, rarely rounded, apex acuminate, rarely retuse, discolorous; umbel; styles 3, rarely 4, basally puberulent; pome ca 0.8–0.9 cm in diameter, subglobose, yellow to red **2. *M. hupehensis*** (Pamp.) Rehder
 – Lamina elliptical to oval, base cuneate or cordate, oblique, apex acuminate or acute, rarely obtuse, sporadically 3-lobed; umbelliform corymb; styles 2–5 (3–4), glabrous; pome ca 1.5–2.0 cm in diameter, coniform, yellow to red **6. *M. fusca*** (Raf.) C.K.Schneid.
19. Lamina oblong to orbicular, base cuneate; styles 5, glabrous or with dense tomentum at base, stigma clavate; pome ca 2.0–3.0 cm in diameter, subglobose or coniform, yellow or red **5. *M. orientalis*** Uglitzk. ex Juz.
 – Lamina elliptic to ovate, base rounded, cordate or cuneate; styles 4 or 5, basally crinite; pome ca 1.0–1.5 cm in diameter, subglobose, tapering, red **9. *M. rockii*** Rehder
20. Insertion points of lamina base on either side of petiole are symmetrical 21
 – Insertion points of lamina base on either side of petiole are asymmetrical; lamina oblong to ovate, base rounded or cuneate, apex acute or acuminate, pubescent when young then glabrescent, or glabrous; styles 5, pubescent at base; pome ca 2.5–5.5 cm in diameter, subglobose, yellow to red **25. *M. doumeri*** (Bois) A.Chev.
21. Leaf margin generally unlobed, sometimes lobed or divided 22
 – Leaf margin distinctly lobed, or divided, occasionally unlobed 23
22. Small tree; lamina oval to ovate, base rounded, pubescent on midvein and abaxial blade; styles 4, glabrous; pome ca 1.5–2.0 cm in diameter, subglobose or pyriform, yellow to red **13. *M. sikkimensis*** (Wenz.) Koehne ex C.K.Schneid.
 – Tree; lamina oval to oblong, base cordate, rounded or truncate, villous on abaxial blade, rarely 3–5-lobed; styles 3–5, glabrous; pome ca 1.5–2.0 cm in diameter, subglobose, red or yellow, with fruit spots **19. *M. ombrophila*** Hand.-Mazz.
23. Lamina palmately lobed or divided, ovate, base cordate, pubescent on abaxial blade; umbel; styles 5, pubescent at base; pome ca 1.0–2.0 cm in diameter, subglobose or ellipsoidal, red **24. *M. trilobata*** (Labill. ex Poir.) C.K.Schneid.
 – Lamina pinnately lobed or divided 24
24. Sepals persistent 25
 – Sepals caducous, abaxially glabrous, adaxially puberulous; lamina oval to ovate, base rounded, truncate or cordate, puberulous or glabrous, usually 3-lobed; styles 3, rarely 2 or 4, glabrous or puberulous; pome ca 1.0–1.5 cm in diameter, ellipsoidal, yellow to red, with fruit spots **16. *M. kansuensis*** (Batalin) C.K.Schneid.
25. Small tree or shrub; lamina usually oval, sometimes elliptical, base rounded, truncate or cordate, apex acute or obtuse, with dense pubescence on midvein, usually 3–6-lobed; styles 3 or 4, glabrous;

- pome ca 0.8 cm in diameter, subglobose, yellow to red, with white fruit spots 15. *M. honanensis* Rehder
- Tree; lamina oval to oblong, base cordate, rounded or truncate, apex acuminate, acute or obtuse, pubescent on abaxial blade, usually 3–5-lobed; styles 5, glabrous; pome ca 1.0–1.5 cm in diameter, subglobose, oblate or oval, red, with white fruit spots 18. *M. yunnanensis* (Franch.) C.K.Schneid.

1. *Malus baccata* (L.) Borkh.
Figs 5–6

Theoretisches-praktisches Handbuch der Forstbotanik und Forsttechnologie Vol. 2: 1280 (Borkhausen 1803).

Description

Tree or small tree. Branches terete, piliferous or glabrous. Leaves petiolate, petiole puberulous or glabrescent. Lamina oval to ovate, base cuneate, apex retuse to caudate, margin crenate to serrulate, blade abaxially piliferous or glabrescent. Inflorescence umbellate. Pedicel piliferous or glabrous. Hypanthium glabrous. Sepals lanceolate, abaxially glabrous, adaxially puberulous, caducous. Petals white, obovate. Stamens 15–20, unequal. Styles 3–5, longer than stamens, glabrous. Pome subglobose. Carpopodium piliferous or glabrous.

Distribution

Widely distributed in Asia (Fig. 5).

Chromosome number

2n = 34.

Key to varieties of *Malus baccata* (L.) Borkh.

1. Trees, 10–15 m; styles 4 or 5 2
 - Small trees, 4–6 m; branchlets pendulous; styles 3 or 4 **b. var. *gracilis*** (Rehder) T.C.Ku
2. Branchlets, leaf, sepals, pedicel and calyx tube pubescent
 - **c. var. *mandshurica*** (Maxim.) C.K.Schneid.
 - Branchlets, leaf, sepals, pedicel and calyx tube glabrous **a. var. *baccata***

Description

Tree, 10–15 m high. Leaves petiolate, petiole 1.1–4.2 cm long, puberulous or glabrescent. Lamina 3.9–9.8 × 1.6–5.2 cm, oval to ovate, base cuneate, apex retuse to caudate, margin crenate to serrulate, blade abaxially puberulous or glabrescent. Inflorescence umbellate, with 3–5 flowers. Pedicel 1.6–4.4 cm long, pubescent when young, glabrescent. Petals ca 0.9–1.8 × 0.5–1.0 cm, white, obovate. Pome ca 0.7 × 0.6 cm, subglobose, yellow to red. Carpopodium ca 3.3 cm long, glabrous.

Phenology

Flowers from April to September. Mature fruits from September to October.

Habitat

Terrestrial, seasonally green, growing in miscellaneous wood forests on slopes and in valleys; up to 1500 m a.s.l.

Distribution

Bhutan, China (Beijing, Chongqing, Fujian, Gansu, Guangdong, Guizhou, Hebei, Henan, Heilongjiang, Hubei, Hunan, Jiangxi, Jilin, Liaoning, Nei Mongol, Qinghai, Shandong, Shanxi, Shaanxi, Sichuan, Tianjin, Tibet, Xinjiang, Yunnan, Zhejiang), India (Kamoon), Japan (Aomori, Nagano), Kashmir, South Korea (Inchon, Jeollanam-do, South Gyeongsang), Mongolia, Nepal, and Russia (Siberia).

Chromosome number

2n = 34.

Description

Tree, 10–15 m high; branches terete, densely pubescent when young, glabrescent. Leaves petiolate, petiole 1.8–4.1 cm long, puberulous. Lamina ca 5.8 × 3.3 cm, oval to ovate, base cuneate, apex retuse to caudate, margin crenate to serrulate, blade abaxially puberulous or glabrescent. Inflorescence umbellate, with

Fig. 9. Distribution of *Malus baccata* (L.) Borkh. var. *mandshurica* (Maxim.) C.K. Schneid.

Fig. 10. Morphological characters of *Malus baccata* (L.) Borkh. var. *mandshurica* (Maxim.) C.K.Schneid.; BNU000964, BNU002220, GXMG0029941, NY00415893 (lectotype), P00993789, P03144392, PE02026701, SXU-SD00014341, SXU-SD00014342, SXU-SD00014343, QIN05041, QIN05042, K000758414, K000758415 / K000758416, PE00952851, PE00952873, PE00952882, PE01460677, PE01460827. Scale bars = 10 mm.

3–6 flowers. Pedicel 1.4–4.8 cm long, usually puberulous. Hypanthium glabrous or puberulous. Sepals lanceolate, abaxially glabrous, adaxially puberulous, caducous. Petals ca 1.2×6.7 cm, white, obovate. Stamens 15–20, unequal. Styles 4 or 5, longer than stamens, glabrous. Pome ca 0.7×0.6 cm, subglobose, red. Carpopodium ca 3.3 cm long, majority puberulous.

Phenology

Flowers from May to June. Mature fruits from August to September.

Habitat

Terrestrial, seasonally green, growing in mixed forest on slopes, mountain summits and in valleys; 100–2000 m a.s.l.

Distribution

China (Anhui, Beijing, Chongqing, Gansu, Guangdong, Guizhou, Hebei, Henan, Hubei, Heilongjiang, Jilin, Liaoning, Nei Mongol, Qinghai, Shandong, Shanxi, Shaanxi, Sichuan, Zhejiang), Japan (Nagano, Shinano), North Korea, South Korea, and Russia (Fig. 9).

Chromosome number

$2n = 34$.

Note

The Latin word ‘manshurica’ is used by some herbaria, but we unified it to ‘mandshurica’ according to the priority principle (i.e., *Malus baccata* var. *mandshurica* = *Malus mandshurica* = *Malus manshurica*). In addition, the lectotype designated by Langenfeld (1991: 158) (RUSSIA • Novik Bay on the Russian island, near Vladivostok; 25 May and 28 Aug. 1860; fl, fr; *Maximowicz s.n.*; lectotype: LE) is invalid, so we designated a new one here on the basis of Maximowicz’s record.

Description

Small tree or shrub, up to 8 m high. Branches terete, densely pubescent when young, glabrescent. Leaves petiolate, petiole ca 2 cm long, glabrescent. Lamina ca 6.6 × 3.6 cm, oval to ovate, usually aubergine in young leaves, base cuneate, rarely rounded, usually oblique, apex acuminate, rarely retuse, margin crenate to serrulate, blade abaxially puberulous or glabrescent, discoloured. Inflorescence umbellate, with 3–6 flowers. Pedicel ca 2.1 cm long, glabrous or puberulent. Hypanthium usually glabrous. Sepals lanceolate to ovate triangular, abaxially glabrous, adaxially puberulous, caducous, rarely persistent. Petals ca 1.2 × 0.7 cm, white to red, obovate. Stamens 15–20, unequal. Styles 3, rarely 4, longer than stamens,

Fig. 11. Distribution of *Malus hupehensis* (Pamp.) Rehder.

Fig. 12. Morphological characters of *Malus hupehensis* (Pamp.) Rehder: A00026649 (syntype), K000758418 (isolectotype of *Malus theifera* Rehder), K000758419 (isolectotype of *M. theifera*), QIN05044, QIN05045, P03144395, P03144440, P03144445, P03144446, A00026656 (lectotype of *M. theifera*), A00026658 (isolectotype of *M. theifera*), E00010837 (isolectotype of *M. theifera*), GH00026659 (isolectotype of *M. theifera*). Scale bars = 10 mm.

basally puberulent. Pome ca 0.8–0.9 cm in diameter, subglobose, yellow to red. Carpodium ca 2.9 cm long, glabrous or puberulent at base.

Phenology

Flowers from April to May. Mature fruits from August to September.

Habitat

Terrestrial, seasonally green, growing in forest on slopes or in valleys; 50–2600 m a.s.l.

Note

The syntypes of *Pyrus hupehensis* Pamp. were collected in Sian-men-kou (*Silvestri 939*) and Ma-pauscian (*Silvestri 940, 940a*), Hubei (Hupeh), China. However, there are photographs from as early as 1932 in the Biondi herbarium at the Botanical Museum in Florence according to the record of Rehder, and now a scan of *Silvestri 939* is available online in herbarium of Arnold Arboretum. Langenfeld designated a lectotype in 1991: 160 (CHINA • Fujian, Chongan, Sanghan-Tinmu-Guan; 11 Aug. 1952; *Zhou Zhenying 239*; lectotype: LE), but it is invalid because the type specimens have not been lost.

Distribution

China (Anhui, Chongqing, Fujian, Gansu, Guangxi, Guizhou, Henan, Hubei, Hunan, Jilin, Jiangsu, Jiangxi, Shandong, Shanxi, Shaanxi, HongKong, Yunnan, Zhejiang) (Fig. 11).

Chromosome numbers

2n = 34, 51, 68.

Description

Small tree or shrub, 2–8 m high. Branches terete, densely pubescent when young, glabrescent. Leaves petiolate, petiole ca 3.3 cm long, puberulous. Lamina ca 6.3 × 5.2 cm, elliptical to obovate, base cuneate, usually equilateral, apex acuminate or obtuse, margin crenate to serrulate, blade glabrescent. Inflorescence umbellate, with 3–5 flowers. Pedicel ca 3 cm long, puberulent. Hypanthium densely lanuginous. Sepals lanceolate to triangular-ovate, densely puberulous, persistent. Petals ca 1.5 × 1.0 cm, obovate. Stamens 20, unequal. Styles 5, rarely 4, as long as or longer than stamens, basally densely puberulent. Pome solitary, ca 2.5–4.5 cm in diameter, subglobose or obovate, yellow-green, red or fuchsia. Carpopodium ca 2.5–4.0 cm long, puberulent.

Phenology

Flowers from April to May. Mature fruits from August to October.

Habitat

Terrestrial, seasonally green, growing in the forest on slopes, mountaintop or in valleys near rivers; 1000–2500 m a.s.l.

Distribution

Central Asia, including China (Qinghai, Xinjiang), Kashmir, Kazakhstan, Kyrgyzstan, Russia, and Uzbekistan (Fig. 13).

Chromosome number

2n = 34.

UNITED STATES – **Illinois** • Lisle; 30 Apr. 2001; fl; *S. Packard & P. Steinhouse 9243V01*; KUN[KUN0937410]. (Seeds wild collected from Tien Shan Kirgiz, SSR, USSR, cultivated in the Morton Arboretum, Lisle, Illinois, USA.

Description

Tree, 10–14 m high. Branches terete; annotinal bud with sparse spines, pubescent when young, glabrescent. Leaves petiolate, petiole ca 0.9 cm long, puberulous. Lamina 8.0–10.0 × 4.0–6.0 cm, oblong to oval, base cuneate, equilateral, apex acuminate or obtuse, margin crenate to serrulate, blade abaxially puberulous. Inflorescence umbellate, with 3–5 flowers. Pedicel ca 3.0 cm long, pubescent when young, glabrescent. Hypanthium densely lanuginous. Sepals triangular-lanceolate to triangular, longer than calyx tube, puberulous, caducous. Petals ca 1.3 × 0.8 cm, white or light pink, obovate. Stamens 15–20, unequal. Styles 3 or 4, longer than stamens, with dense tomentum at base. Pome ca 3.0–8.0 cm in diameter, subglobose or coniform, yellow or green.

Fig. 15. Distribution of *Malus kirghisorum* Al.Fed. & Fed.

Fig. 16. Morphological characters of *Malus kirghisorum* Al.Fed. & Fed.; KUN0937410.

Phenology

Flowers from April to May. Mature fruits from July to October.

Habitat

Terrestrial, seasonally green, growing at the edge of the forest on slopes or in valleys.

Distribution

Afghanistan, Kyrgyzstan and Tajikistan (Fig. 15).

Description

Small tree or shrub, 4–10 m high, rarely 13 m. Branches terete, puberulous or glabrous when young. Leaves petiolate, petiole ca 2.5 cm long, puberulous or glabrous. Lamina 6.5 × 4.3 cm, oval to orbicular, base rounded, rarely cuneate, equilateral, apex usually acute, rarely obtuse or retuse, margin crenate to serrulate, blade glabrous. Inflorescence umbellate, with 2–5 flowers. Pedicel ca 1.9 cm long, puberulous at base. Hypanthium puberulous or glabrous. Sepals triangular, abaxially glabrous, adaxially puberulous, persistent. Petals ca 1.3 × 0.8 cm, white or pink, rarely red or mauve, obovate. Stamens ca 20, unequal, yellow. Styles 5, longer than stamens, glabrous. Pome solitary, about 20 g, ca 2.0–3.5 cm in diameter, subglobose, yellow. Carpopodium ca 1.8 cm long, glabrous.

Phenology

Flowers from May to June. Mature fruits from October to November.

Habitat

Terrestrial, seasonally green, growing at the edge of mixed forests or broad-leaf forests on south slopes or floodplains.

Distribution

Austria, Belgium, British Isles, Czechia, Denmark, France, Germany, Hungary, Italy, Moldova (Kishinev), Poland, Russia (Karel'skij peresheyek, Vologda, Perm', Ufa, Ural'sk, Volgograd), Ukraine (Mariupol), Scandinavian Peninsula, Spain, and Switzerland (Fig. 21).

Description

Small tree or shrub, 4–6 (6–8) m high. Branches terete, aculeolate and pendulous, pubescent when young, glabrescent. Leaves petiolate, petiole ca 2.3 cm long, puberulous. Lamina 5.9 × 3.0 cm, elliptic to ovate, base rounded or cuneate, equilateral, apex acute or acuminate, margin crenate to serrulate, blade puberulous, sometimes 3-lobed, rarely 5-lobed. Inflorescence umbellate, with 4–8 flowers. Pedicel ca 3.0 cm long, puberulous or glabrous. Hypanthium puberulous or glabrous. Sepals triangular, abaxially glabrous, adaxially densely puberulous, caducous. Petals ca 1.2 × 0.7 cm, pink, obovate. Stamens ca 20, unequal, yellow. Styles 3–5, longer than stamens, basally densely puberulent. Pome ca 0.6–0.8 cm in diameter, subglobose or oblate, yellow or red. Carpopodium ca 2.5 cm long, glabrous.

Phenology

Flowers from April to May. Mature fruits from August to September.

Habitat

Terrestrial, seasonally green, growing in the mixed forests or shrubs in plains or valleys, rarely in forests in mountain areas; 600–1700 m a.s.l.

Distribution

North Korea, South Korea, Japan and China (Liaoning, Shandong, Shaanxi, Gansu, Jiangxi, Zhejiang, Hubei, Hunan, Sichuan, Guizhou, Fujian, Guangdong, Guangxi, Qinghai, Zhejiang, Yunnan) (Fig. 23).

Chromosome numbers

$2n = 34, 51, 68, 85$.

Description

Tree, 8–10 m high. Branches terete, crinite when young, glabrescent. Leaves petiolate, petiole ca 2.3 cm long, crinite. Lamina 5.3–7.2 (12) × 2.9–3.7 cm, elliptic to ovate, base rounded, cordate or cuneate, oblique, apex acuminate, margin serrulate, blade puberulous abaxially or on midvein. Inflorescence umbellate, with 4–8 flowers. Pedicel ca 3.3 cm long, lanuginous. Hypanthium densely puberulous. Sepals lanceolate-triangular, abaxially puberulous or glabrous, adaxially densely puberulous, caducous. Petals ca 1.4 × 0.9 cm, white, obovate. Stamens 20–25, unequal. Styles 4 or 5, longer than stamens, basally crinite. Pome ca 1.0–1.5 cm in diameter, subglobose, tapering, red. Carpopodium ca 3.8 cm long, puberulous.

Phenology

Flowers from May to June. Mature fruits in September.

Habitat

Terrestrial, seasonally green, growing in mixed forests on slopes or in valleys; 1500–3800 m a.s.l.

Fig. 25. Distribution of *Malus rockii* Rehder.

Fig. 26. Morphological characters of *Malus rockii* Rehder. US00097446 (isotype), K000758448, K000758450, NAS00002410, NAS00002396. Scale bars = 10 mm.

Distribution

China (Chinging, Guangxi, Shaanxi, Sichuan, Tibet, Yunnan) (Fig. 25).

Chromosome numbers

$2n = 34, 51, 54, 68$.

Note

Flora of China (Ku & Spongberg 2003) considered *Pyrus baccata* var. *himalaica* Maxim. and *Malus rockii* Rehder as nomenclatural synonyms. We agree with this treatment.

UNITED STATES – **Massachusetts** • Arnold Arboretum; 17 Oct. 1973; fr; S.Y. Hu 13327; IBSC.

Description

Small tree or shrub, 3–10 m high. Branches terete, pubescent when young, glabrescent. Leaves petiolate, petiole ca 1.8–2.9 cm long, puberulous. Lamina 3.9–6.8 × 1.5–3.6 cm, elliptic to ovate, base rounded, cordate or cuneate, equilateral, apex obtuse or retuse, margin crenate, blade piliferous, pubescent on midvein, usually 3-lobed or divided, sometimes unlobed. Inflorescence umbelliform corymb, with 3–6 flowers. Pedicel ca 2.0 cm long, puberulous. Hypanthium puberulous. Sepals lanceolate-triangular or narrow-triangular, abaxially puberulous, adaxially densely puberulous, caducous, rarely persistent. Petals ca 0.7–0.9 × 0.5–0.7 cm, white, obovate, puberulous or glabrous. Stamens ca 20, unequal. Styles 3, rarely 4 or 5, shorter than stamens, glabrous. Pome ca 1.0–1.3 cm in diameter, ellipsoidal to subglobose, yellow. Carpopodium ca 2.3–2.8 cm long, puberulous.

Phenology

Flowers from April to May. Mature fruits in September.

Habitat

Terrestrial, seasonally green, growing in forests on slopes; 1500–3700 m a.s.l.

Distribution

China (Gansu, Shaanxi, Qinghai, Sichuan, Tibet) (Fig. 27).

Chromosome numbers

2n = 31, 34, 51, 54, 68.

Description

Tree, 8–12 m high. Branches terete, pubescent when young, glabrescent. Leaves petiolate, petiole ca 1.6–2.7 cm long, puberulous. Lamina 3.7–7.5 × 2.1–3.2 cm, oval, oblong or orbicular, base rounded or cuneate, equilateral, apex acuminate or caudate, margin crenate to serrulate, blade puberulous when young, glabrescent, 3–5-lobed in sapling and base of mature tree. Inflorescence umbellulate, with 3–7 flowers. Pedicel ca 2.0–3.0 cm long, puberulous. Hypanthium glabrous. Sepals lanceolate-triangular, abaxially puberulous or glabrous, adaxially densely puberulous, caducous. Petals ca 1.0–1.2 × 0.8–1.0 cm, white, obovate. Stamens ca 20, unequal. Styles 3–5, longer than stamens, glabrous. Pome ca 1.0–1.3 cm in diameter, ellipsoidal to subglobose, yellow. Carpodium ca 1.0–1.5 cm long.

Habitat

Terrestrial, seasonally green, growing at the edge of forests, river banks or gullies; 2600–3000 m a.s.l.

Distribution

China (Sichuan) (Fig. 29).

Scale bars = 10 mm.

Description

Small tree or shrub, 3–5 m high, rarely 8 m. Branches terete, pubescent when young, glabrescent. Leaves petiolate, petiole ca 0.8–1.9 cm long, densely lanuginous. Lamina 3.4–6.8 × 2.3–3.6 cm, oval to ovate, base rounded, cuneate or cordate, equilateral, apex acuminate or obtuse, margin crenate to serrulate, blade puberulous when young, then abaxially glabrescent, usually 3–5 divided. Inflorescence umbelliform corymb, with 3–6 flowers. Pedicel ca 1.7–2.0 cm long, puberulous. Hypanthium lanuginous. Sepals triangular, densely puberulous, caducous, rarely persistent. Petals ca 0.7–0.9 × 0.4–0.6 cm, white, obovate or oblong. Stamens 20–25, unequal. Styles 3–5, longer than stamens, glabrous. Pome ca 0.6–0.8 cm in diameter, subglobose, yellow to red. Carpopodium ca 2.3–2.8 cm long, puberulous.

Phenology

Flowers from April to May. Mature fruits in September.

Habitat

Terrestrial, seasonally green, growing in forests on slopes or loess hills; 1500–3900 m a.s.l.

Distribution

China (Inner Mongolia, Ningxia, Qinghai, Shaanxi, Gansu, Sichuan, Yunnan, Tibet) (Fig. 31).

Chromosome numbers

$2n = 34, 51$.

Note

There are plentiful morphological variations within this species. Varieties that have been defined on the basis of a few characters and locations are unjustified because such unique phenotypic characters have probably been affected by the environment. Therefore, three new synonyms are proposed in this study (*Malus transitoria* var. *glabrescens*, *M. transitoria* var. *calycomeles*, and *M. transitoria* var. *centralasiatica*).

The vertical vicariance of *Malus kansuensis* (distribution below 3000 m), *M. toringoides* (2600–3050 m) and *M. transitoria* (above 3000 m) is very remarkable, and there are no obvious reproductive barriers between them. As a consequence, hybrids that show characters of both parents could be found in the contact zones; for example, the specimens from Maerkang (Sichuan, China) exhibit continuous morphological variation between *M. transitoria* and *M. toringoides*.

MYANMAR – East Himalaya; Aug. 1837; fl, fr; *Griffith 2081*; K.

Description

Small tree, up to 8 m high. Branches terete, pubescent when young, glabrescent. Leaves petiolate, petiole ca 1.3–2.2 cm long, densely lanuginous. Lamina 5.6–8.3 × 2.6–4.1 cm, oval to ovate, base rounded, equilateral, apex acuminate or acute, margin serrulate, blade pubescent abaxially and on midvein. Inflorescence corymbose, with 5–8 flowers. Pedicel ca 3.7 cm long, densely lanuginous. Hypanthium densely lanuginous or glabrous. Sepals lanceolate-triangular, abaxially glabrous, adaxially densely puberulous, caducous, rarely persistent. Petals ca 1.1 × 0.9 cm, white, obovate. Stamens 25–50, unequal. Styles 4, as long as or longer than stamens, glabrous. Pome ca 1.5–2.0 cm in diameter, subglobose or pyriform, yellow to red. Carpopodium ca 2.6 cm long, lanuginous.

Phenology

Flowers in May. Mature fruits in September.

Habitat

Terrestrial, seasonally green, growing in alpine forests; 2000–3000 (3900) m a.s.l.

Fig. 33. Distribution of *Malus sikkimensis* (Wenz.) Koehne ex C.K.Schneid.

Fig. 34. Morphological characters of *Malus sikkimensis* (Wenz.) Koehne ex C.K.Schneid.; M0213776 (syntype of *Sorbus sikkimensis* Wenz.), M0213809 (syntype of *Sorbus sikkimensis*), K000758444, K000758446, K000758447. Scale bars = 10 mm.

Distribution

Bhutan, China (Sichuan, Yunnan, Tibet), India (Sikkim), Nepal and Sri Lanka (Fig. 33).

Chromosome numbers

$2n = 34, 51, 54, 68$.

Note

Sorbus sikkimensis Wenz. (including *Malus sikkimensis* (Wenz.) N.P.Balacr.) was mistakenly treated as a synonym of *Malus sikkimensis* by Hassler (2020), but it actually is a synonym of *Sorbus corymbifera* (Miq.) T.H.Nguyên & Yakovlev according to the original literature and type specimen *Sorbus sikkimensis* Wenz. *Linnaea* 38 (1): 58 (Wenzig 1874). – **Type:** INDIA • India orientalis; 1843; *Griffith 2077/1*; syntype: M[M0213809, M0213776]!; isosyntype: E[E00145673]!, GH[GH00112876, GH00135439]! (Note on the sheet: lectotype, designated by Aldasoro *et al.* 2004: 57). In addition, because the type *Hooker f. & Thomson s.n.* of *M. sikkimensis* cited by Wenzig (1874: 49) still exist, the neotype *G. King s.n.* designated by Langenfeld (1991: 129) is invalid.

Description

Tree, 10–15 m high. Branches terete, pubescent when young, glabrescent. Leaves petiolate, petiole ca 2.6–3.0 cm long, densely lanuginous. Lamina 5.7–8.7 × 3.6–6.7 cm, oval to ovate, base rounded or cordate, equilateral, apex acuminate or acute, margin crenate to serrulate, blade densely pubescent on midvein and young leaf, occasionally lobed. Inflorescence corymbose, with 2–5 flowers. Pedicel ca 1.9 cm long, densely lanuginous. Hypanthium densely lanuginous. Sepals triangular, puberulous, persistent. Petals ca 1.2 × 0.7 cm, white, obovate. Stamens 20–30, unequal. Styles 5, as long as or shorter than stamens, basally puberulous. Pome ca 1.8–2.1 cm in diameter, subglobose, yellow to red. Carpopodium ca 2.7 cm long, lanuginous.

Phenology

Flowers from April to May. Mature fruits from October to November.

Habitat

Terrestrial, seasonally green, growing in foothill forests; sea level to 1000 m a.s.l.

Distribution

Japan (Fig. 35).

Chromosome number

2n = 34.

Description

Small tree or shrub, 5–7 m high. Branches terete, pubescent when young, glabrescent. Leaves petiolate, petiole ca 1.9 cm long, densely lanuginous. Lamina ca 6.4 × 4.6 cm, usually oval, sometimes elliptical, base rounded, truncate or cordate, equilateral, apex acute or obtuse, margin crenate to serrulate, blade lanuginous, densely pubescent on midvein, usually 3–6-lobed. Inflorescence corymbose, with 5–10 flowers. Pedicel ca 2.0 cm long, pubescent when young, glabrescent. Hypanthium puberulous. Sepals triangular, abaxially glabrous, adaxially densely puberulous, persistent. Petals ca 0.8 × 0.7 cm, white, obovate. Stamens ca 20, unequal. Styles 3 or 4, longer than stamens, glabrous. Pome ca 0.8 cm in diameter, subglobose, yellow to red, with white fruit spots. Carpopodium ca 2.4 cm long, glabrous.

Phenology

Flowers in May. Mature fruits from August to September.

Habitat

Terrestrial, seasonally green, growing in forests on slopes or in valleys; 800–1000 m a.s.l.

Fig. 37. Distribution of *Malus honanensis* Rehder.

Description

Small tree or shrub, 3–8 m high. Branches terete, pubescent when young, glabrescent. Leaves petiolate, petiole ca 1.9–2.6 cm long, pubescent when young, puberulous or glabrescent. Lamina ca 4.9–5.4 × 3.6–3.9 cm, oval to ovate, base rounded, truncate or cordate, equilateral, apex acute or acuminate, margin crenate to serrulate, blade puberulous or glabrous, usually 3-lobed. Inflorescence corymbose, with 4–10 flowers. Pedicel ca 2.2–2.9 cm long, glabrous or pubescent when young then glabrescent. Hypanthium puberulous or glabrous. Sepals triangular, abaxially glabrous, adaxially puberulous, caducous. Petals ca 0.7 × 0.5 cm, white, obovate. Stamens ca 20, unequal. Styles 3, rarely 2 or 4, longer than stamens, glabrous or puberulous. Pome ca 1.0–1.5 cm in diameter, ellipsoidal, yellow to red, with fruit spots. Carpodium ca 2.6–3.6 cm long, glabrous or puberulous.

Phenology

Flowers from May to June. Mature fruits from July to August.

Habitat

Terrestrial, seasonally green, growing in mixed forests or shrubs; 1500–3300 m a.s.l.

Distribution

China (Anhui, Chongqing, Gansu, Henan, Hubei, Hunan, Jiangxi, Ningxia, Qinghai, Shanxi, Shaanxi, Sichuan, Tibet) (Fig. 39).

Chromosome number

2n = 34.

Description

Tree, 8–13 m high. Branches terete, pubescent when young, glabrescent. Leaves petiolate, petiole ca 2.0–2.5 cm long, puberulous. Lamina ca 6.0–9.5 × 3.6–5.8 cm, oval to oblong, base cordate, rounded or truncate, equilateral, apex acuminate, acute or obtuse, margin crenate to serrulate, blade abaxially pubescent, usually 3–5-lobed. Inflorescence corymbose, with 8–12 flowers. Pedicel ca 1.8 cm long, glabrous or puberulous. Hypanthium densely puberulous. Sepals triangular, puberulous, persistent. Petals ca 0.6 × 0.4 cm, white, orbicular. Stamens 20–25, unequal. Styles 5, glabrous. Pome ca 1.0–1.5 cm in diameter, subglobose, oblate or oval, red, with white fruit spots. Carpodium ca 2.3–2.8 cm long, puberulous.

Phenology

Flowers in May. Mature fruits from August to September.

Habitat

Terrestrial, seasonally green, growing in mixed forests; 1600–3800 m a.s.l.

Fig. 43. Distribution of *Malus yunnanensis* (Franch.) C.K.Schneid.

Fig. 44. Morphological characters of *Malus yunnanensis* (Franch.) C.K.Schneid.; GH00032511 (type of *Pyrus yunnanensis* Franch.), K000758438 (isotype), K000758439 (isotype), QIN05064 (type), QIN05065 (K000758437, type), P01819336 (isotype), P03240538, P03240541, P03240542, A00026642 (lectotype of *Malus yunnanensis* var. *veitchii* (Osborn) Rehder), A00106227 (isotype of *M. yunnanensis* var. *veitchii*), CDBI0043927 (*M. yunnanensis* var. *veitchii*), K000758472 (lectotype of *Pyrus veitchiana* hort.), PE00964185 (*M. yunnanensis* var. *veitchii*), PE00964192 (*M. yunnanensis* var. *veitchii*), PE00997404 (*M. yunnanensis* var. *veitchii*), PE01357615 (*M. yunnanensis* var. *veitchii*), PE01357619 (*M. yunnanensis* var. *veitchii*). Scale bars = 10 mm.

Distribution

China (Chongqing, Gansu, Guizhou, Hubei, Hunan, Shanxi, Shaanxi, Sichuan, Tibet, Yunnan) (Fig. 43).

Chromosome number

$2n = 34$.

Note

Because the syntype specimens *J.M. Delavay 2331* of *M. yunnanensis* still exist, the neotype *Handel-Mazzetti 842* designated by Langenfeld (1991: 133) is invalid.

Description

Small tree or shrub, 2–3 m or 5–7 (10) m high. Branches terete, pubescent when young, glabrescent. Leaves petiolate, petiole ca 1.0–1.2 cm long, puberulous or glabrous. Lamina ca 3.6–4.0 × 1.2–1.7 cm, oval to ovate, base cuneate or rounded, equilateral, apex acute, rounded or obtuse, margin crenate to serrulate, blade glabrous or villus on midvein, sometimes lobed. Inflorescence corymbose, with 5–8 flowers. Pedicel ca 2.2 cm long, glabrous. Hypanthium glabrous. Sepals triangular, abaxially glabrous, adaxially puberulous, persistent. Petals ca 1.1 × 0.6–0.7 cm, pink or white, obovate to oblong. Stamens ca 20, unequal, with pink anther. Styles 5, longer than stamens, pubescent at base. Pome ca 1.0–3.0 cm in diameter, subglobose, yellow. Carpodium ca 2.4 cm long, glabrous.

Phenology

Flowers from February to May. Mature fruits from August to September.

Habitat

Terrestrial, seasonally green, growing in the forests and shrubs in open areas of valleys; 10–700 m a.s.l.

Distribution

United States (Fig. 47).

Chromosome numbers

2n = 34, 68.

Note

The specimen K000758465, collected from North Carolina, conforms to the protologues of Aiton (1789: 176) and Michaux (1803: 292). We therefore consider the neotype designated by Langenfeld (1991: 152) to be incorrect.

Description

Small tree, 6–8 (10) m high, or shrub, 4–7 m high. Branches terete, pubescent when young, glabrescent. Leaves petiolate, petiole ca 1.0–3.3 cm long, puberulous. Lamina ca 3.3–8.3 × 1.9–4.6 cm, oblong to ovate, base truncate, cuneate or rounded, equilateral, apex acute, rounded or obtuse, margin crenate to serrulate, blade glabrous or puberulous, sometimes lobed. Inflorescence corymbose, with 3–5 flowers. Pedicel ca 1.7–2.2 cm long, puberulous. Hypanthium densely puberulous. Sepals triangular, puberulous, persistent. Petals ca 1.1–1.5 × 0.7–1.1 cm, white, pink or premium pink, obovate to oblong. Stamens ca 20, unequal. Styles 5, as long as stamens, pubescent at base. Pome ca 2.0–3.0 cm in diameter, subglobose, yellow. Carpopodium ca 2.1–2.5 cm long, puberulous.

Phenology

Flowers from April to May. Mature fruits from September to October.

Habitat

Terrestrial, seasonally green, growing in forests and shrubs in open areas of valleys; 100–300 m a.s.l.

Distribution

United States (Fig. 49).

Chromosome numbers

2n = 34, 68.

Description

Small tree or shrub, 5–10 m high. Branches terete, pubescent when young, glabrescent. Leaves petiolate, petiole ca 1.6–2.3 cm long, puberulous or glabrous. Lamina ca 4.6–5.6 × 2.8–3.5 cm, oblong to ovate, base cordate, rounded or cuneate, equilateral, apex acute, rounded or obtuse, margin biserrate or entire, blade glabrous or puberulous, sometimes lobed. Inflorescence corymbose, with 4–6 flowers. Pedicel ca 2.0–3.3 cm long, crinite or glabrous. Hypanthium puberulous or glabrous. Sepals triangular, abaxially glabrous or puberulous, adaxially densely puberulous, persistent. Petals ca 1.2–1.9 × 0.7–1.3 cm, white, pink or premium pink, obovate to oblong. Stamens ca 20, unequal, with pink or purple anther. Styles 5, as long as or longer than stamens, pubescent at base. Pome ca 2.5–3.5 cm in diameter, subglobose, yellow. Carpodium ca 1.2–4.0 cm long, puberulous or glabrous.

Phenology

Flowers from April to June. Mature fruits from September to November.

Habitat

Terrestrial, seasonally green, growing in forests and shrubs in open areas of valleys, beside streams or roadsides; 50–1000 m a.s.l.

Distribution

United States (Fig. 51).

Chromosome numbers

2n = 34, 51, 68.

Description

Small tree or shrub. Leaves petiolate, petiole ca 0.8–4.2 cm long, glabrous. Lamina ca 3.4–5.1 × 4.1–7.4 cm, ovate, base cordate, equilateral, apex acute, margin crenate to serrulate, blade abaxially pubescent, lobed. Inflorescence umbellate, with 6–8 flowers. Pedicel ca 3.2 cm long, puberulous. Hypanthium puberulous or glabrous. Sepals triangular, puberulous, persistent. Petals ca 1.4 × 1.0 cm, white, obovate or oval. Stamens 20–30, unequal. Styles 5, pubescent at base. Pome ca 1.0–2.0 cm in diameter, subglobose or ellipsoidal, red. Carpopodium ca 1.2–4.5 cm long, puberulous.

Phenology

Flowers in May. Mature fruits from September to October.

Distribution

Bulgaria, Greece, Israel, Lebanon, Syria, and Turkey (Fig. 55).

Chromosome number

2n = 34.

Note

The type of *Crataegus trilobata* (*La Billardièrè s.n.*) still exists, therefore the lectotype (*Juvernalk s.n.*) designated by Langenfeld (1991: 123) is invalid.

88 **Fig. 60.** Morphological characters of *Malus komarovii* (Sarg.) Rehder; K000758431 (isotype), IFP06828006y0001, PE00952717, PE00952719, PE00952721. Scale bars = 10 mm.

cordate or cuneate, equilateral, apex acute or acuminate, margin serrulate, blade puberulous, 3-lobed. Inflorescence corymbose, with 6–8 flowers. Pedicel ca 1.8 cm long, puberulous. Hypanthium puberulous. Sepals lanceolate, abaxially puberulous or glabrous, adaxially lanuginous, caducous or persistent. Petals white, ovate. Stamens 20–30, unequal. Styles 4 or 5, glabrous. Pome ca 0.8–1.0 cm in diameter, subglobose, yellow to red. Carpodium ca 1.5 cm long, puberulous.

Phenology

Flowers in May. Mature fruits in September.

Habitat

Terrestrial, seasonally green, growing in shrubs; 1100–1300 m a.s.l.

Distribution

China (Henan, Jilin), North Korea, and South Korea (Fig. 59).

Chromosome number

$2n = 34$.

Discussion

The aims of this study were to investigate morphological variation within *Malus*, reevaluate the characters traditionally used for species delimitation, and determine the morphological relationships among these species. The PCA and cluster analyses showed a high level of morphological similarity among species, and most of the clades in the diagrams were identified with a low level of resolution.

Inter- and infraspecific variation of morphometric characters

Patterns of morphological variation were found in the length of the blade, the length from the widest point to the base of the leaf, and leaf area. Characters such as petiole length, blade width, tooth length, the length and width of petal and pome, and pome area also made a high contribution in differentiating species. Thus, leaf shape and size could be used for species delimitation. This is consistent with previous studies, for instance; tree habit and the length and width of the leaf blade were indicated as the most informative characters to explain the natural variation of species of *Malus* (Kumar *et al.* 2018). Nevertheless, it is important to point out that, although pomes with approximately the same degree of dryness were selected for measurement after two-dimensionalization, the pome area as a character for classification is still questionable because it may vary depending on the time and year of collection. Chen (2014) filtered out 7 characters related to flower and leaf in spring and 9 characters related to fruit and leaf in autumn to identify species of *Malus*. Indumentum on leaf blade, pedicel and petiole, and the pattern of leaf division were treated as the most effective parameters (Chen 2014). However, these characters, which are quite possibly influenced by the environment (according to our observations), were proven to be taxonomically unstable in our study. For example, in one situation, an indumentum on blade, pedicel and petiole occurs on tender leaves rather than adult leaves (e.g., *Malus communis* Poir., *M. mandshurica*, *M. yunnanensis*). In the other situation, an indumentum could be found on the adult leaves in some specimens but not in the others (e.g., *M. angustifolia*, *M. baccata*, *M. coronaria*). As for the type of leaf division, there is only approximately one-third of wild apple species with leaves that are all lobed, whereas half of the species possess three or more forms of leaf division (e.g., *M. baccata*, *M. coronaria*, *M. daochengensis*). An interesting example is *M. xiaojinensis*, where leaves on young trees and the base branches of adult trees are often 3–5-lobed (PE[PE00964204]), but leaves of adult trees from other locations are undivided (Cheng *et al.* 1983). Moreover, *Malus baccata* and *M. mandshurica* (Maxim.) Kom. ex Juz. manifest variability among the species of *Malus*, covering all forms of leaf division from undivided to divided. The variety

of leaf margins and leaf shape presents similar results. For example, leaf margins of *M. yunnanensis* range from edentate to serrate, and leaf shape changes from cordate, elliptic to ovate in type specimens (see K[K000758438] and K[K000758439], K[QIN05064] and K[QIN05065]). Edentate, erose, serrate, crenate, and serrate-crenate blades were all found in *M. toringoides*, and 69% of the species had two or more types of leaf margin. Besides, since the angle formed by the lateral and main nerve is relatively stable both within and among species, it is unsuited for classification in *Malus*. Similarly, characters such as the ratio of tooth length and width, angle of apex, and angle of the base play a limited role in taxonomy. The above mentioned variations are not exceptions caused by specific environmental factors, but are widespread in abundant specimens that we have checked with a comprehensive sampling that covered the whole distribution area of these species. While these differences in quantitative and qualitative morphological characters could provide evidence for species delimitation, the high degree of intraspecific variation and interspecific similarity in traits remains a challenge for species delimitation.

The role of traditional delimitation traits

While subtle differences in quantitative or qualitative morphological traits can provide evidence for separate species, phenotypic variation is not always associated with genetic differentiation. Owing to the high phenotypic plasticity observed within the *Malus* group, the delimitation of some species needs to be reconsidered. For example, some taxonomists considered the presence or absence of the indumentum as a good diagnostic character to distinguish species. However, the results obtained here suggested that such characters are variable and continuous, casting doubt on their usefulness for species delimitation.

Malus leiocalyca, with characters such as the glabrous petiole, pedicel, sepals, and calyx tube, was traditionally considered as a distinct species, separate from *M. doumeri* and *M. melliana* (Huang 1989; Gu & Spongberg 2003). However, our study revealed that this species is probably not distinct. Statistical methods were employed to clarify the relationship among *M. doumeri*, *M. melliana* and *M. leiocalyca*. Our results showed that all the specimens analyzed converged with each other, representing a continuous morphological variation (Fig. 3). Although *M. melliana* was once considered a distinct species close to *M. doumeri*, the variation between these two species in leaf tooth, calyx tube, pedicel, and fruit size is found to be continuous. Therefore, *M. melliana* is here regarded as a synonym of *M. doumeri*. We have analyzed a large number of specimens (including type specimens) of *M. doumeri* and found that some individuals have one or two conditions that calyx tube, pedicel and fruit are glabrous calyx tube, pedicel and fruit. When compared with *M. leiocalyca*, there is a high level of morphological variation in *M. doumeri*. Moreover, their geographical range, which partly overlaps, increases the possibility that *M. leiocalyca* and *M. doumeri* represent two forms, rather than species. The three species are distributed in the same region from Anhui (China) through Laos to India, and prefer a warm and humid climate. Consequently, we suggest that *M. leiocalyca* is synonymous with *M. doumeri*. However, this requires future molecular evidence. A similar situation is found in *M. transitoria* var. *glabrescens*. This variety only occurs in Qamdo Xian (Tibet) (Yu *et al.* 1980), and features such as glabrous abaxial blade, sparsely pubescent pedicel and calyx tube are unsuitable for identifying as they could be a response to the local climate. Hence, *M. transitoria* var. *glabrescens* might be an ecotype, and thus a synonym of *M. transitoria*, in concordance with The World Flora Online (<http://www.worldfloraonline.org/taxon/wfo-0001015968>). There is no clear demarcation of *M. mandshurica* (*M. baccata* var. *mandshurica*) and *M. baccata* in either analysis above. The similar geographical distribution and highly similar morphology of the two species do not support the recognition of *M. mandshurica* as a separate species. In contrast to *M. baccata*, *M. mandshurica* is located at a higher altitude (up to 2100 m) and concentrated north of the Yellow River. The indumentum on the blade, flower and carpodium is likely the result of the interaction of genes and the environment to conform to the colder weather (e.g., a higher altitude and more northern distribution regions). In addition, there is a tendency in the specimens of *M. mandshurica* to have a larger size of flowers and simpler leaf architecture. Hence, *M. mandshurica* is likely an ecotype of *M. baccata*.

The characters of species of *Malus* traditionally used in taxonomy are variable within and among species, resulting in difficulties in delimiting species based on morphological criteria. Thus, morphological variation and plasticity should be seriously considered when defining species boundaries, especially when material available for species descriptions is limited.

Interspecific relationships of species of *Malus*

Our morphological clustering confirmed that the morphological traits traditionally used in taxonomy are unsuited for distinguishing the lineages identified in previous phylogenetic studies (Robinson *et al.* 2001; Nikiforova *et al.* 2013; Jin 2014). Despite differences in phylogenetic trees based on different genetic data sets, these studies broadly support a number of clades. The first clade contains *Malus baccata*, *M. baccata* var. *mandshurica* and *M. hupehensis*. The three species have a similar appearance, but the aubergine calyx, pedicel, young leaves, and a distinct red margin of the petals and flower buds can differentiate *M. hupehensis* from the other two. The second clade includes all taxa from ser. *Yunnanenses* Rehder (with the exception of *M. kansuensis*), and the third clade consists of all members of sect. *Chloromeles*. These clades are all supported by both the phylogenetic and traditional morphological classifications. However, the situation is much more complicated in *Malus* as a whole. We roughly divided the species of *Malus* into four groups related to geographical distribution according to the previous phylogenetic studies for convenience (Fig. 61).

Group A includes members from sect. *Malus* (Phipps *et al.* 1990) (with the exception of *Malus fusca*). These species share a number of morphological similarities such as umbel, undivided leaf and subglobose pome. The species are distributed in Eurasia, and are geographical replacement species of each other (i.e., Europe [*M. sylvestris*] → west Asia & Caucasus [*M. orientalis*] → Central Asia [*M. kirghisorum*] → Central Asia – east Asia [*M. sieversii*] → south of the Yellow River [*M. hupehensis*] → north of the Yellow River – Japan [*M. baccata*]). *Malus fusca* differs from the other species in its lobed leaf, oblong pome and corymb, and the pedicels that almost grow from a single point so that they look like the struts of an umbrella. It is usually classified in ser. *Kansuenses* of sect. *Sorbomalus* (e.g., Phipps *et al.* 1990; Lagenfeld 1991; Li 1996), which spreads over the western coast in North America. Our ‘fruiting season’ group data supports that *M. fusca* shares more similarities with *M. mandshurica* and *M. orientalis*, which corresponds with molecular studies (e.g., Nikiforova *et al.* 2013; Jin 2014). On the other hand, the relationships implied by the analysis of the ‘florescence’ group data are congruent with traditional morphological classification. Further investigations applying an integrative approach are needed to define boundaries and disentangle the relationships of this clade.

Group B corresponds to some species of sect. *Malus*, sect. *Sorbomalus* and sect. *Docyniopsis* (Phipps *et al.* 1990). Species in this group (*Malus tschonoskii* excluded) are characterized by polyploidy and geographical distribution ranges from China to Japan. The morphological traits traditionally used to define these sections (e.g., style characteristics) become useless. *Malus sieboldii* (revised: *M. toringo*) and *M. rockii* have umbels and a pubescent base of the styles, while *M. sikkimensis*, *M. toringoides*, and *M. transitoria* have corymbs and glabrous styles, and *M. tschonoskii* has a corymb and a pubescent base of the styles. Unfortunately, our results provide limited phenotypic support for differentiation among species within this clade. Group C is the only well-supported clade confirmed both by our morphological analyses and the previous phylogenetic analyses, containing all taxa from ser. *Yunnanenses* and one from ser. *Kansuenses* (Phipps *et al.* 1990; Lagenfeld 1991; Li 1996). The two taxa have a sympatric distribution in southern China. The basal group, Group D, is composed of all members of sect. *Chloromeles* with species restricted to North American, in addition to *M. doumeri* from sect. *Docyniopsis* (distributed in Asia) and *M. trilobata* from sect. *Eruolobus* (distributed from West Asia to Europe) (Phipps *et al.* 1990; Lagenfeld 1991; Li 1996). Contrary to the traditional taxonomic classification, our analyses show that *M. trilobata* and *M. doumeri* share many morphological characters, which is consistent with the preceding works of Nikiforova *et al.* (2013) and Jin (2014). In addition, the leaf shape of *M. tschonoskii* is more similar to

that of the members of Group C, whereas this species has a smaller leaf size. Traditionally, botanists often classified species into series and sections (Koidzumi 1934b; Rehder 1949; Yu & Yen 1956; Chen 1959; Langenfeld 1991; Phipps *et al.* 1990; Lagenfeld 1991; Li 1996; Qian 2005); however, neither our study nor the previous phylogenetic studies support these classifications.

It is very difficult to find unique morphological features characterizing the different lineages. This study and recent molecular phylogenetic studies indicate that morphological characters provide limited information on the systematic relationships among the species of *Malus*. Most species of *Malus* that clustered together on the scatter plots and are thus morphologically similar, are known to be distinct at the molecular level. As phrased by Zhang (2018), “Genotypic and phenotypic evolution could obey different laws”. Hybridization, apomixis, incomplete lineage sorting, and the effect of environmental conditions (e.g., precipitation, temperature and human activities) on morphological development could confound the boundaries and relationships of species (Miller & Spooner 1999; Robinson *et al.* 2001; Chen *et al.* 2019). *Malus* provides a good example in which evolutionary rates of morphological and genetic

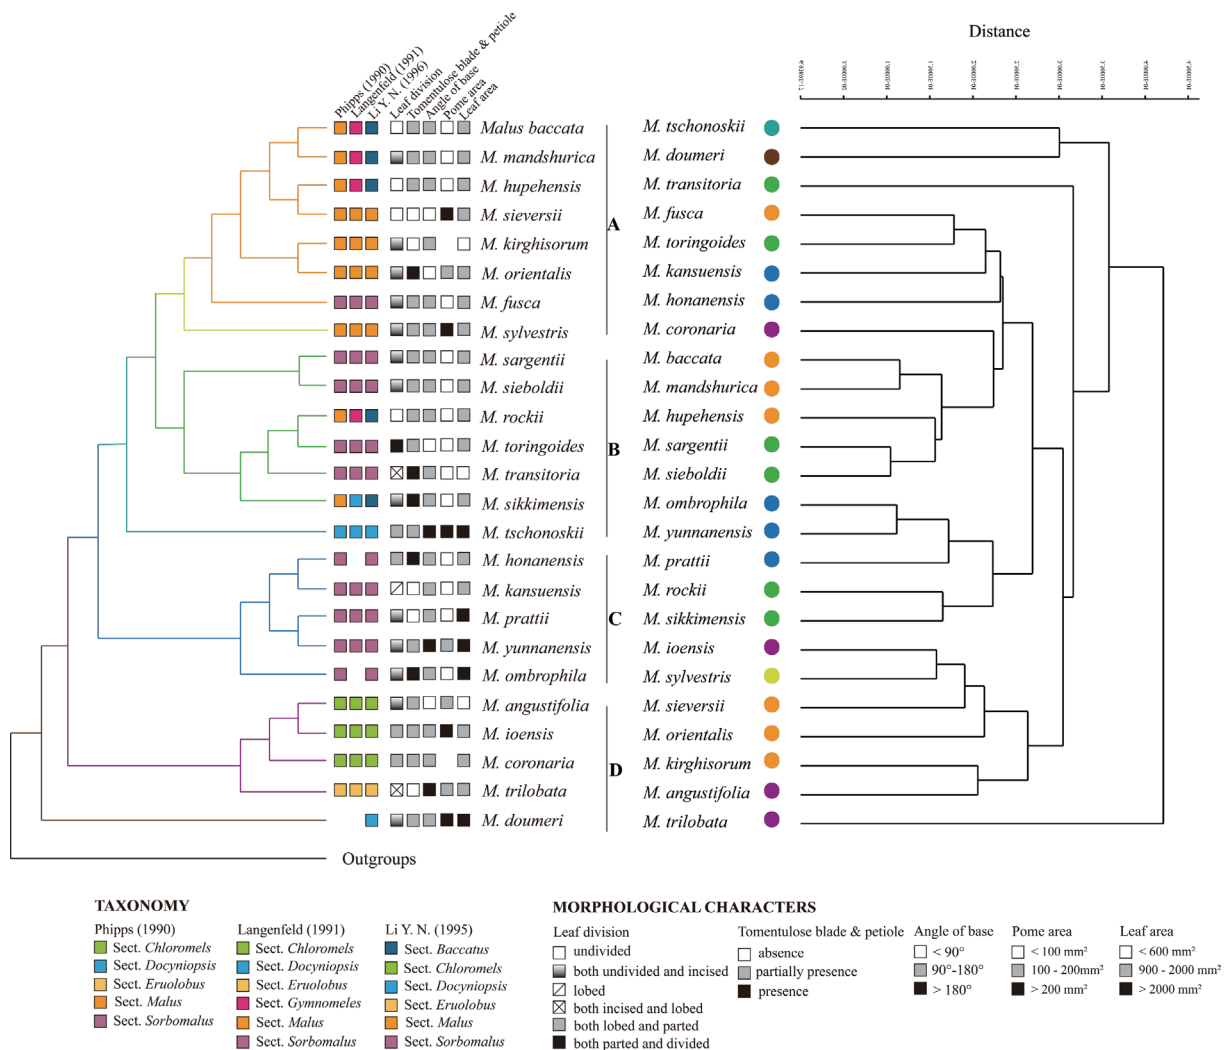

Fig. 61. Mapping the informative characters and traditional taxonomy systems by Phipps (1990), Langenfeld (1991) and Li (1996) on the most recent phylogenetic tree (adapted from Jin, 2014). The UPGMA tree used for comparison is marked with the colour of the corresponding branch. The rest of the information is presented in the legend.

characters could be decoupled. Further research on living plants at the species and population level are needed to further clarify the taxonomy of the genus.
