Historical Note

The demise of Archbishop Wolf Dietrich – A historical note on a fatal status epilepticus documented at Salzburg in 1617

Gudrun Kalss [a,b,*], Julia Höfler [a,b], Alexandra Rohracher [a,b], Ildiko Deak [a,b], Judith Dobesberger [a,b], Giorgi Kuchukhidze [a,b,c], Markus Leitinger [a,b], Kathrin Ogris [d], Mark Mc Coy [e], Eugen Trinka [a,b]

"...he loses consciousness. His whole body is jerked by an epileptic seizure, as he suffered from before. The symptoms are of such desperate magnitude, namely unconsciousness, salivation, breathing in a stertorously way and distortion of his face, which are pathognomonic for the disease of Hercules."

Historical Vignette

Wolf Dietrich of Raitenau ruled the archiepiscopal Salzburg from 1587 to 1611.

Died on January 16th 1617

first well-documented left hemispheric stroke in winter 1604/05 followed later by a right sided stroke:

„leva corporis pars iam pridem simili ex apoplectico assultu in paralysin resoluta"

"epileptico insultu quo etiam alias correptus est"

Kalss G, et al. Epilepsy Behav (2015), http://dx.doi.org/10.1016/j.yebeh.2015.03.024

Epidemiology of Status Epilepticus

- Incidence 10-41/100.000/a → one of the most common neurological emergencies[1]
- 70.000 - 300.000 patients in Europe
- ≈20% mortality[2]
- < 50% with preexisting epilepsy[1,2]
  - Low AED level
- 50% acute symptomatic SE[1,2]
  - Cerebrovascular diseases, traumatic brain injury, encephalitis, meningitis, alcohol related, metabolic

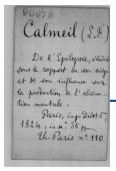
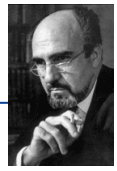
Agenda

- Definition and classification of status epilepticus
- Causes and mechanisms
- Staged Treatment approach
  - Refractory Status epilepticus
  - Super-refractory Status epilepticus
- Prognosis
- Concluding remarks



Definition of Status Epilepticus



Traditional classification:

• There were as many types of status as there were types of epileptic seizures (draft 1962; final 1967)

• SE classification mirrored the seizure classification (1964, final 1970)

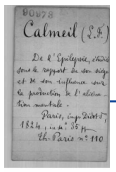
„a seizure that persists for a sufficient length of time or is repeated frequently enough that recovery between attacks does not occur“ ILAE 1981[1]

Majority of GTCS < 2-3 min[3,6]

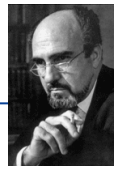
Operational definition: 5min[4,5]

…“Mechanistically, SE represents the failure of the natural homeostatic seizure-suppressing mechanisms for seizure termination.”…[2]

1: Commission on Classification ILAE, Epilepsia 1981; 2 Engel et al. Epilepsia 2006; 3 Theodore et al. 1994; 4 Lowenstein et al. 1999; 5 Trinka et al. 2015; 6: Dobesberger et al. 2015



Definition of Non Convulsive Status Epilepticus



Traditional classification:

- There were as many types of status as there were types of epileptic seizures (draft 1962; final 1967)
- SE classification mirrored the seizure classification (draft 1964, final 1970)

„enduring epileptic condition with reduced/altered consciousness, behavioral and vegetative abnormalities or merely subjective symptoms, without major convulsive movements“

NCSE Definition 30 min

NCSE Definition 10 min[5]

…“Mechanistically, SE represents the failure of the natural homeostatic seizure-suppressing mechanisms for seizure termination.”…[2]

1: Commission on Classification ILAE, Epilepsia 1981; 2 Engel et al. Epilepsia 2006; 3 Theodore et al. 1994; 4 Lowenstein et al. 1999; 5 Trinka et al. 2015

Definition of Status Epilepticus

Status epilepticus is a condition resulting either from the *failure of the mechanisms responsible for seizure termination or from the initiation of mechanisms*, which lead to abnormally, prolonged seizures (after time point t1). It is a condition, which can have long-term consequences (after time point t2), including neuronal death, neuronal injury, and alteration of neuronal networks, depending on the type and duration of seizure

Trinka et al. Epilepsia 2015 in press

Definition of Status Epilepticus

Status epilepticus is a condition resulting either from the *failure of the mechanisms responsible for seizure termination or from the initiation of mechanisms*, which lead to **abnormally, prolonged seizures** (**after time point t1**). It is a condition, which can have **long-term consequences (after time point t2)**, including neuronal death, neuronal injury, and alteration of neuronal networks, depending on the type and duration of seizure

Conceptual (="mechanistic") definition

2 Operational dimensions:
- → length of seizure (t_1)
- → time (t_2) to long term consequences

Trinka et al. Epilepsia 2015 in press

Type of SE	Time (t1), when a seizure is likely to be prolonged leading to continuous seizure activity	Time (t2), beyond which long term consequences are increasingly likely (including neuronal injury, neuronal death, alteration of neuronal networks and functional deficits)
Tonic clonic SE	5 minutes	<30 minutes
SE with impairment of consciousness	10 minutes	30-60 minutes*
Absence status epilepticus	2 minutes*	unknown*
Implications to treatment	**Time point 1 determines the earliest time when treatment should be considered or started**	**Time point 2 determines the time at which status should be controlled to prevent long term consequences**

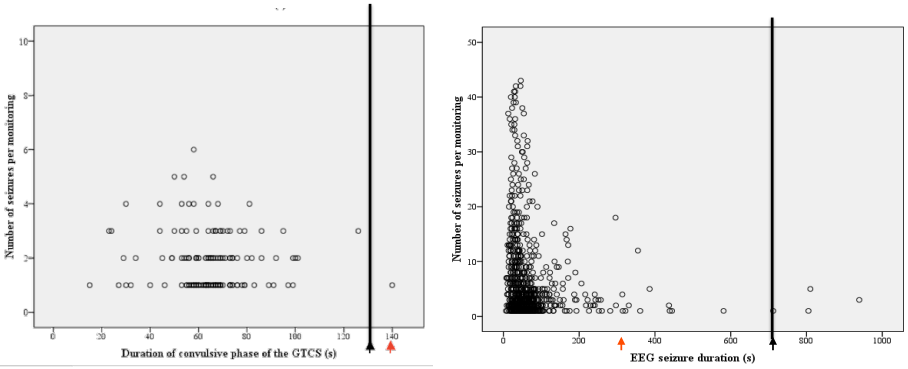
* Best available evidence, but insufficient data to give a definite timepoint

Trinka et al. Epilepsia 2015 in press

How long do seizures last in monitoring units?

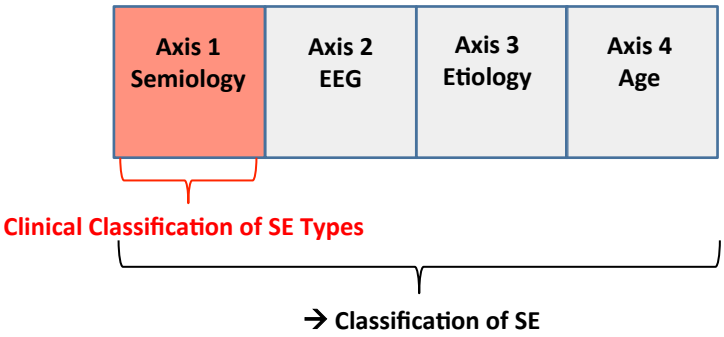
Mean seizure duration +4 SD

Cumulative 99% seizure duration of focal complex seizures



1: Dobesberger, Trinka and Ristic Epilepsy and Behavior 2015

Classification of SE



Trinka et al. Epilepsia 2015 in press

Axis 1 = semiology
Classification of SE types

Along two taxonomic criteria: motor symptoms and impairment of consciousness

A) With prominent motor symptoms

B) Without prominent motor symptoms (i.e. NCSE)

Trinka et al. Epilepsia 2015 in press

Axis 1 = semiology
Classification of SE types

Along two taxonomic criteria: motor symptoms and impairment of consciousness

A) With prominent motor symptoms

- **Convulsive SE (syn.: tonic clonic SE, CSE)**
- **Myoclonic SE** *(prominent epileptic myoclonic jerks)*
- **Focal motor** *(including EPC)*
- **Tonic SE**
- **Hyperkinetic SE**

B) Without prominent motor symptoms (i.e. NCSE)

Trinka et al. Epilepsia 2015 in press

Axis 1 = semiology
Classification of SE types

Along two taxonomic criteria: motor symptoms and impairment of consciousness

A) With prominent motor symptoms

- **Convulsive SE (syn.: tonic clonic SE, CSE)**
- **Myoclonic SE** *(prominent epileptic myoclonic jerks)*
- **Focal motor** *(including EPC)*
- **Tonic SE**
- **Hyperkinetic SE**

B) Without prominent motor symptoms (i.e. NCSE)

- **NCSE with coma**
- **NCSE without coma**
  - **Generalised**
  - **Focal**

Trinka et al. Epilepsia 2015 in press

Axis 1 = semiology
Classification of SE types

Along two taxonomic criteria: motor symptoms and impairment of consciousness

A) With prominent motor symptoms

- **Convulsive SE (syn.: tonic clonic SE, CSE)**
  - **Generalised convulsive**
  - **Focal onset evolving into bilateral convulsive SE**
  - **Unknown whether focal or generalised**
- **Myoclonic SE**
  - **With coma**
  - **Without coma**
- **Focal motor**
  - **Repeated focal motor seizures (Jacksonian)**
  - **Epilepsia Partialis Continua (EPC)**
  - **Adversive status**
  - **Oculoclonic status**
  - **Ictal paresis**
- **Tonic SE**
- **Hyperkinetic SE**

Trinka et al. Epilepsia 2015 in press

Axis 1 = semiology
Classification of SE types

Along two taxonomic criteria: motor symptoms and impairment of consciousness

B) Without prominent motor symptoms (i.e. NCSE)

- **NCSE with coma**
- **NCSE without coma**
  - **Generalised**
    - **Typical absence status**
    - **Atypical absence status**
    - **Myoclonic absence status**
  - **Focal**
    - **Without impaired consciousness (Aura continua)**
      - (With autonomic*, sensory symptoms, visual, olfactory, gustatory, emotional, auditory symptoms
    - **Aphasic SE**
    - **With impaired consciousness**
  - **Unknown**
    - **Autonomic SE***

* Differentiation between 2.b.a and 2.c.a has to be discussed

Trinka et al. Epilepsia 2015 in press

Axis 1 = semiology
Classification of SE types

Along two taxonomic criteria: motor symptoms and impairment of consciousness

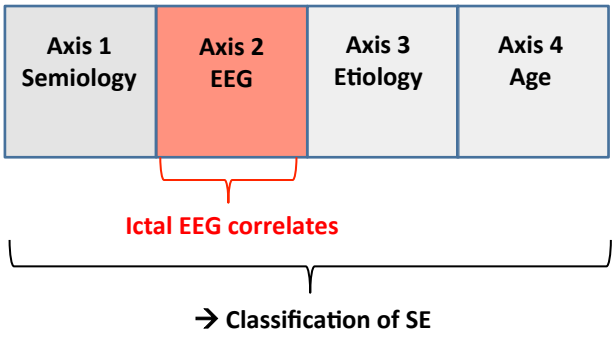
Currently indeterminate conditions**

- **Epileptic encephalopathies**
- **Coma with epileptiform EEG patterns**
- **Behavioural disturbance (e.g psychosis) in patients with epilepsy**
- **Acute confusional states (e.g delirium) with epileptiform EEG patterns**

**= Boundary syndromes

Trinka et al. Epilepsia 2015 in press

Classification of SE



Trinka et al. Epilepsia 2015 in press

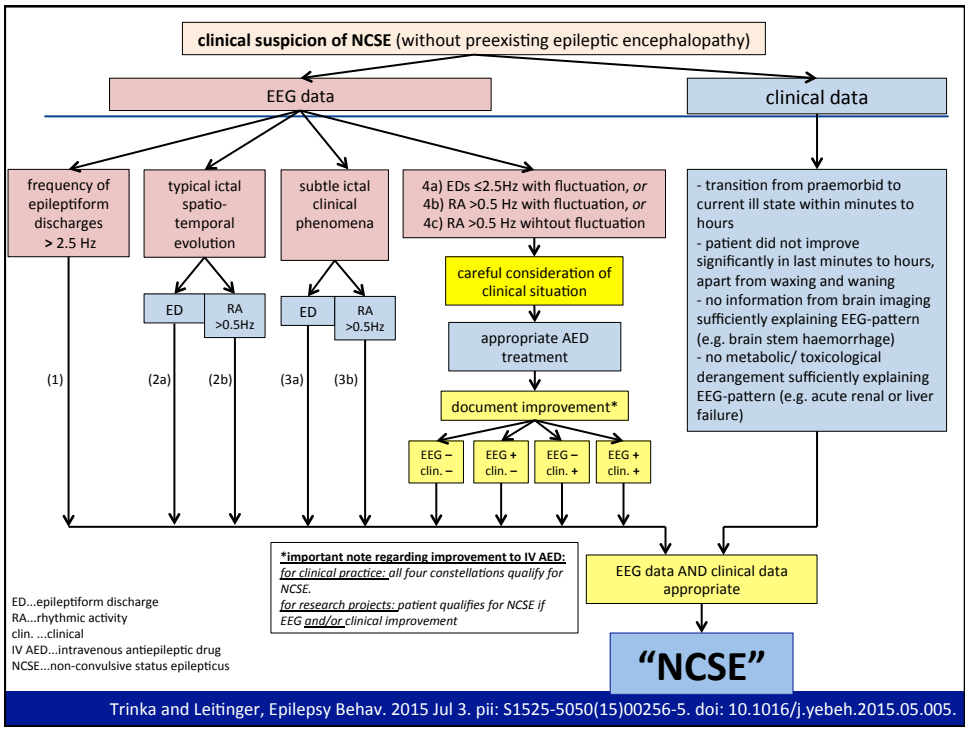
Proposed EEG Criteria for NCSE –

For patients without epileptic encephalopathies:

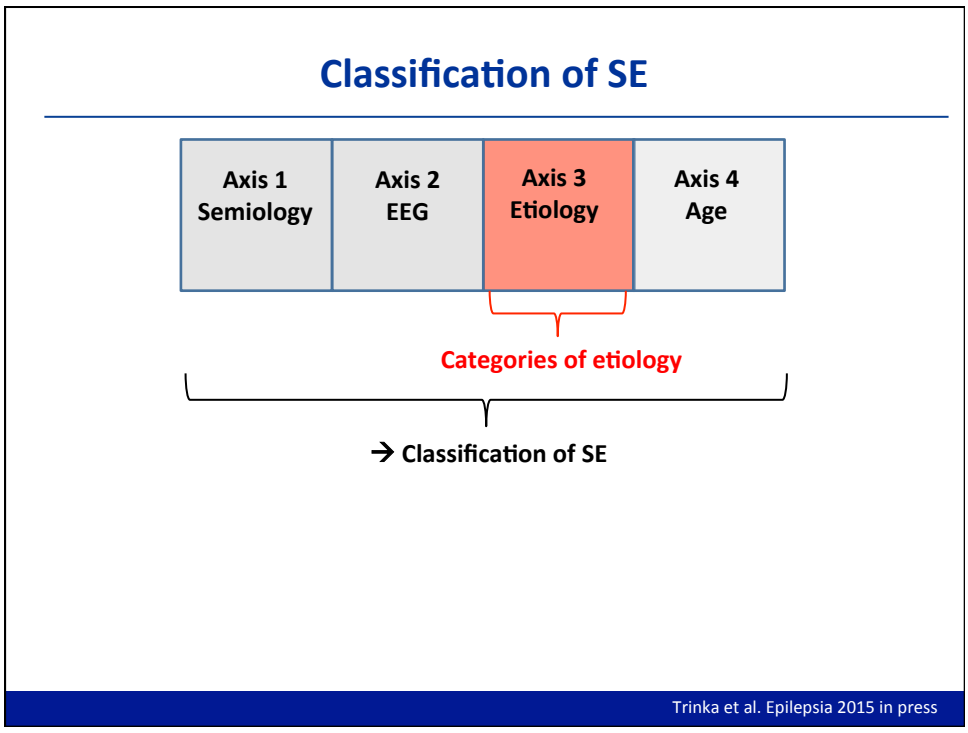
- EDs > 2.5 Hz, *or*
- EDs ≤ 2.5 Hz or rhythmic delta/theta activity (>0.5 Hz) AND one of the following:
  - EEG and clinical improvement after IV AED*, *or*
  - Subtle clinical ictal phenomena, *or*
  - Typical spatiotemporal evolution**

If EEG improvement without clinical improvement, or if fluctuation without definite evolution, this should be considered **possible NCSE.*
***Incrementing onset (increase in voltage and change in frequency), or evolution in pattern (change in frequency >1 Hz or change in location), or decrementing termination (voltage or frequency).*

Beniczky et al. Epilepsia 2013



Trinka and Leitinger, Epilepsy Behav. 2015 Jul 3. pii: S1525-5050(15)00256-5. doi: 10.1016/j.yebeh.2015.05.005.



Trinka et al. Epilepsia 2015 in press

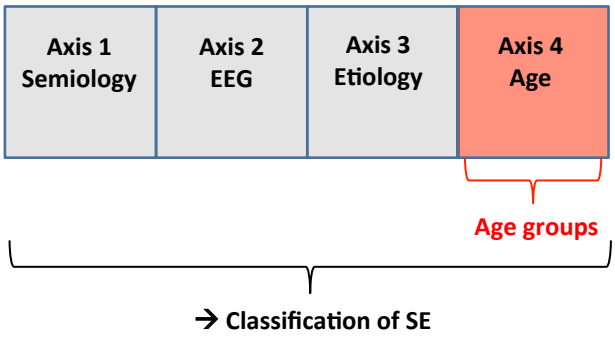
Classification of SE: Axis 3 Etiology

1. **Known** (= **symptomatic)**
   a) Acute (e.g.: stroke, intoxication, malaria, encephalitis, etc.)
   b) Remote (e.g. posttraumatic, postencephalitic, poststroke, etc.)
   c) Progressive (e.g. glioblastoma, Lafora´s disease and other PMEs)
   d) SE in defined electroclinical syndromes
2. **Unknown** (= **cryptogenic**)[1]

1: Synonymous translations germ.: ungeklärt; french: xxx, span.: yyy; ital.: zzz, russ.: aaa ...)

Trinka et al. Epilepsia 2015 in press

Classification of SE



Trinka et al. Epilepsia 2015 in press

Age Related Disorders and Electroclinical Syndromes with SE

1. **SE occurring in the neonatal and infantile epilepsy syndromes**
   a) Tonic Status in Ohtahara Syndrome
   b) Myoclonic status in Dravet´s syndrome
   c) Febrile SE
      i. With bilateral motor symptoms
      ii. With unilateral motor symptoms
2. **SE occurring predominately in childhood and adolescence**
   a) NCSE in Early-onset Childhood Occipital Epilepsy (Panayiotopoulos syndrome)
   b) NCSE in childhood epileptic encephalopathies (e.g., myoclonic-astatic epilepsy, Ring chromosome 20, Angelman syndrome → see appendix)
   c) Tonic status in Lennox Gastaut Syndrome
   d) Myoclonic Status in Down Syndrome
   e) Absence Status in Juvenile Absence Epilepsy
   f) Myoclonic Status in Juvenile Myoclonic Epilepsy
   g) Myoclonic Status in Progressive Myoclonus Epilepsies
   h) FIRES
3. **SE occurring only in adults and elderly**
   a) De Novo (or relapsing) absence status of later life

Trinka et al. *Epilepsia* 2015 in press

Clinical course of convulsive status epilepticus

Stage 1	Early phase Premonitory SE, impending SE	5-10 min
Stage 2	Established SE	10-30 min
Stage 3	Refractory SE: SE, that continues despite stage 1/2 treatment[1] subtle SE, stuporous SE	30-60 min
Stage 4	Super-refractory SE[2]: SE, that continues despite treatment with anaesthetics > 24 hours	>24h

1: Holtkamp *Lancet Neurol* 2007; 2: Shorvon and Trinka *Epilepsia* 2011;

Clinical course of convulsive status epilepticus

BUT: Most (17/29) RSE patients not in the ICU[4]

Refractory and Super-refractory SE represent 23%-43% of all status epilepticus[3,4,5]

Stage 3 — Refractory SE: SE, that continues despite stage 1/2 treatment[1]

subtle SE, stuporous SE

Stage 4 — Super-refractory SE[2]: SE, that continues despite treatment with anaesthetics > 24 hours

1: Holtkamp *Lancet Neurol* 2007; 2: Shorvon and Trinka *Epilepsia* 2011; 3: Mayer *Arch Neur* 2002, 4: Novy *Epilepsia* 2010, 5: Kellinghaus *Epil Behav* 2012

Etiology of refractory and super-refractory SE

	Refractory SE (n=29)	Non-Refractory SE (n=99)	p-value χ^2
Acute Symptomatic	19 (65.5%)	59 (59.6%)	0.667
Remote Symptomatic	5 (17.2%)	17 (17.2%)	
Progressive Symptomatic	4 (13.8%)	15 (15.2%)	
Cryptogenic	1 (3.4%)	8 (8.1%)	
Potentially fatal	**20 (69%)**	**45 (45.5%)**	**0.034**

Up to 50% without previous seizures

Causes of Super refractory SE

Fig. 1. Map of the countries where the cases have been reported.

- 488 cases from 44 countries
- **38% with Hx of epilepsy**
- First-line treatment was delayed and not in line with current guidelines
- midazolam (59%), followed by propofol and barbiturates
- **Seizure control in 74%**

Causes of status epilepticus and outcome.

Cause	Recovered	Died/therapy withdrawn
Antiepileptic drug reduction/withdrawal	28 (90%)	3 (10%)
Genetic/chromosomal	6 (86%)	1 (14%)
Cerebral tumor	18 (82%)	4 (18%)
Unknown (cryptogenic)	63 (80%)	16 (20%)
Trauma	12 (80%)	3 (20%)
Mitochondrial disease	3 (75%)	1 (25%)
Vascular (including stroke)	42 (74%)	15 (26%)
Acute meningitis	8 (73%)	3 (27%)
Other infection	23 (72%)	9 (28%)
Alcohol	12 (67%)	6 (33%)
Other toxins	2 (67%)	1 (33%)
Immunological, all	17 (65%)	9 (35%)
Acute encephalitis	32 (65%)	17 (35%)
Metabolic	13 (62%)	8 (38%)
Anoxic (including cardiac arrest)	22 (49%)	23 (51%)

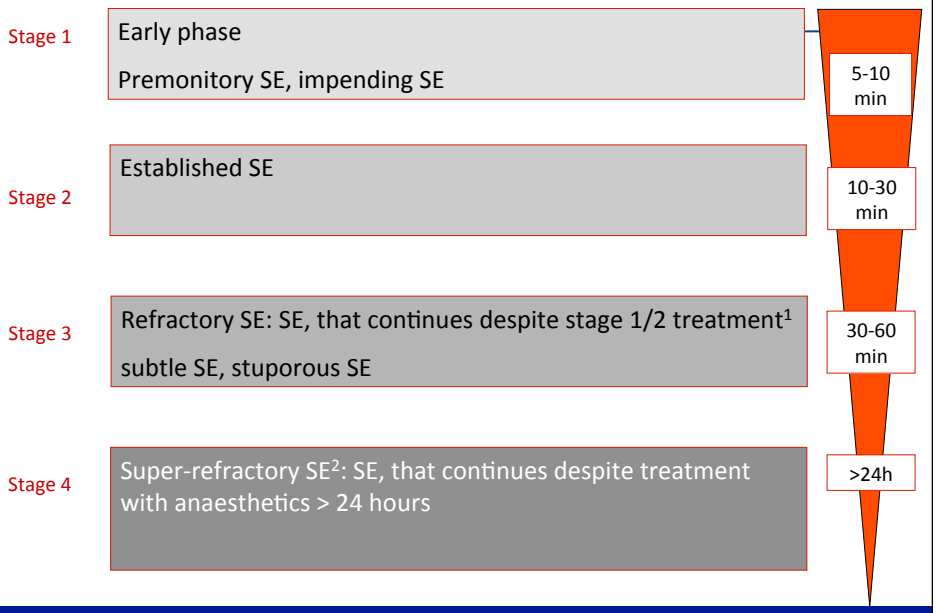
Agenda

- Definition and classification of status epilepticus
- Causes and mechanisms
- Staged Treatment approach
  - Refractory Status epilepticus
  - Super-refractory Status epilepticus
- Prognosis
- Concluding remarks

Clinical course of convulsive status epilepticus



1: Holtkamp *Lancet Neurol* 2007; 2: Shorvon and Trinka *Epilepsia* 2011;

	Diazepam	Lorazepam	Midazolam	Clonazepam
+	Rapid onset of action IV Rectal formulation available Long standing clinical experience in adults and children Widespread availability	Rapid onset of action IV Long lasting effect (>24h) after a single injection Long standing clinical experience Proven efficacy in randomised controlled trials in GCSE	Rapid onset of action with all routes Water solubility (IB, IN, IM) socially well accepted Lack of reactions at the infusion site Little risk of accumulation	Rapid onset of action IV Long lasting effect (>24h) after a single injection Long standing clinical experience
-	Short duration of action, due to rapid redistribution Accumulation with the risk of prolonged sedation and respiratory depression Adverse effects from the polypropylene solvent	Rapid development of tolerance Adverse effects from the polypropylene solvent	Short duration of action with risk of seizure relapse	-lack of RCTs Adverse effects from the polypropylene solvent

Mod. From: Trinka E and Brigo F , Benzodiazepines used primarily for emergency treatment. In: Treatment of Epilepsies, 5th Ed. Blackwell 2015

WHAT TO DO WHEN

A protocol for the inhospital emergency drug management of convulsive status epilepticus in adults

Stage I: Early Phase

Premonitory SE, impending SE

Shelley Jones,[1] Clemens Pahl,[2] Eugen Trinka,[3] Lina Nashef[4]

In-Hospital **Emergency** Drug Management of Convulsive Status Epilepticus in Adults
See page 2 for essential parallel general measures

STEP 1: benzodiazepine give if fitting for > 5 min

First choice:
Intravenous lorazepam; Usual dose bolus **2 to 4 mg** (maximum rate 2 mg/min). If necessary repeat up to a total maximum dose of 0.1 mg/kg.
OR Intravenous diazepam: Usual dose **5 to 10 mg** titrate for effect, up to 20 mg if necessary. Do not give too fast, to avoid respiratory depression (maximum rate 5 mg/min). Diazepam is rapidly redistributed and may accumulate with repeated dosing.
OR Intravenous clonazepam: Usual dose 1 mg, if necessary repeat 1 mg dose after 5 minutes (maximum rate 0.5 mg/min).
If intravenous is difficult or not possible:
- **Buccal midazolam:** Usual dose **10 mg** (Caution: Give 5 mg in the elderly or patients less than 50 kg). Repeat dose once after 10 minutes if necessary.[1] If buccal preparation not available, use 10 mg/2 mL injection via buccal route.

OR Intramuscular midazolam: Usual dose 10 mg (Caution: Give 5 mg in the elderly or patients weighing less than 50 kg). Repeat dose once after 10 minutes if necessary.
If intravenous, buccal and intramuscular are not possible:
- **Rectal diazepam:** Usual dose **10 mg** (caution: give 5 mg in elderly patients or patients weighing less than 50 kg). Repeat dose once after 10 minutes if necessary.

If seizures stop, the recurrence rate is high; most patients need an intravenous stage 2 anti-epileptic drug (see below for doses) to prevent further seizures

Jones et al. Pract Neurol 2014

Stage II: Established SE

STEP 2: If no response to step 1 WITHIN 10 min, give stage 2 agent and INFORM NEURO-INTENSIVIST or EXPERIENCED ANAESTHETIST

Second stage antiepileptic drug given **intravenously and inform neurointensivist or experienced anaesthetist**
See loading dose proformas for administration guidance

If there is no specific contraindication or a clear preference for alternative:
Phenytoin; **18 mg/kg** (range 15–20); **maximum rate 50 mg/min**. Infuse into large or central vein via filter with ECG and blood pressure monitoring (caution **hypotension, bradycardia)**. Check concomitant drugs (phenytoin is an enzyme inducer—its effect on the half-life of affected drugs is not immediate). For patients already on phenytoin, see note on page 2* before administering.
OR
Levetiracetam; 30 mg/kg (range 20–70); **infuse over 10 minutes**; no interactions; good side effect profile in this setting but comparative efficacy remains to be established; renal excretion.[2,3]
OR
Sodium Valproate; 30 mg/kg (range 15–30); **infuse over 5 minutes**
Contraindicated in mitochondrial disease. Avoid in status of unknown cause in young people. Caution: in pregnancy or acute liver failure, where an alternative is preferable. Check concomitant drugs (valproate is an enzyme inhibitor, with immediate effect on half-life of affected drugs).[4,5]
OR
Phenobarbital; 10 mg/kg (range 10–15)**; maximum rate 100 mg/min.** Monitor blood pressure, ECG and respiratory function (Caution: **respiratory depression** may occur—only give if ventilatory support can be provided). Check concomitant drugs (phenobarbital is an enzyme inducer—the effect of enzyme induction on half-life of affected drugs is not immediate).

ENSURE NEUROINTENSIVIST/EXPERIENCED ANAESTHETIST IS AWARE OF THE PATIENT
If seizures recur in patients who are haemodynamically stable, optimise dose of initial second stage intravenous antiepileptic drug and then consider another second stage intravenous antiepileptic drug.

Jones et al. Pract Neurol 2014

IV Lacosamide: safety studies

Open label multicentre trial
Patients with 1-2 AEDs (n=100, 16-60yrs)
IV loading with 200mg, 300mg, 400mg LCM over 15 min followed 12h later by PO LCM (50% of loading dose)

→400mg less well tolerated (TEAEs) than lower doses
→ small increase of PR from baseline at end of infusion (6.1, 8.6, 10.6ms)
→No prolongation of QTcF interval

Table 5. Summary of lacosamide plasma concentrations by dose group (pharmacokinetic set[a])

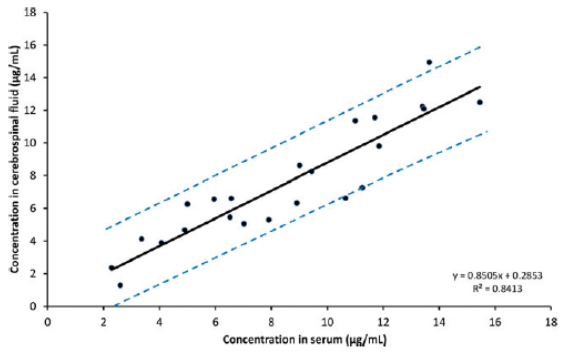
Assessment time	Statistics	LCM 200 mg n = 25	Combined LCM 300 mg[b] n = 50	LCM 400 mg n = 25
Day 1/End of infusion	n	23	45	23
	Mean (SD) (μg/ml)	6.586 (2.218)	9.319 (3.765)	12.330 (4.118)
	Min, Max (μg/ml)	3.193, 12.130	0.683, 16.017	4.779, 23.133
Day 1/Evening predose	n	23	40	19
	Mean (SD) (μg/ml)	2.927 (1.276)	3.243 (1.162)	4.500 (1.625)
	Min, Max (μg/ml)	1.612, 7.674	1.108, 8.154	2.843, 8.794
Day 2/Morning predose	n	20	45	21
	Mean (SD) (μg/ml)	3.379 (1.694)	3.844 (1.730)	4.917 (1.499)
	Min, Max (μg/ml)	1.794, 9.091	1.610, 11.067	3.384, 9.026

[a]Pharmacokinetic set = two patients in the repeat 300-mg cohort who received an infusion of 400-mg lacosamide were analyzed with assigned cohort.
[b]Combined cohort = cohort 2 and repeat cohort (300-mg LCM).

1: Fountain et al. Epilepsia 2012

CSF Concentration of Lacosamide

- 27 serum and cerebral spinal fluid (CSF) samples from 21 patients
- Lacosamide 50–600 mg/day over two or three doses
- 23 time-matched pairs of serum and CSF samples from 19 patients



Lacosamide concentration in CSF is approximately 85% of that found in serum

May et al. Epilepsia, 56(7):1134–1140, 2015

IV Lacosamide adverse events

- Studies for approval of LCM for treatment of painful neuropathy[2]
  → 1 report of atrial fibrillation correlate with LCM administration

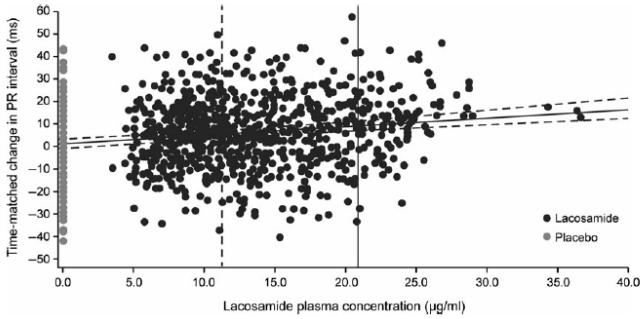
- 1 Case report[3] : 89-year-old woman –
  Medical history: heart failure, arterial hypertension, hypothyroidism

  NCSE: → LCM 400 mg within 6 hours
  Normal PQ interval before and after the first dose of LCM
  → reversible complete AV block approximately 30 minutes after the second bolus
  → caution when using high doses of LCM in patients with significant cardiac diseases

1: Biton et al. Epilepsia 2008; 2: DeGiorgio, Epilepsy Behav. 2010; 3: Krause et al., Epilepsy &Behaviour 2011;

Lacosamide cardiac safety: a thorough QT/QTc trial in healthy volunteers

LCM 400 mg/day (maximum-recommended daily dose, 6 days),
LCM 800 mg/day (supratherapeutic dose, 6 days),
PBOn (6 days)
Healthy volunteers



QTcI mean maximum difference from PBO was 4.3 ms and 6.3 ms for LCM 400 and 800 mg/day (90% confidence interval was below the 10 ms non-inferiority margin

Kropeit et al. Acta Neurol Scand 2015: DOI: 10.1111/ane.12416.

IV Lacosamide in Status Epilepticus[1-3]

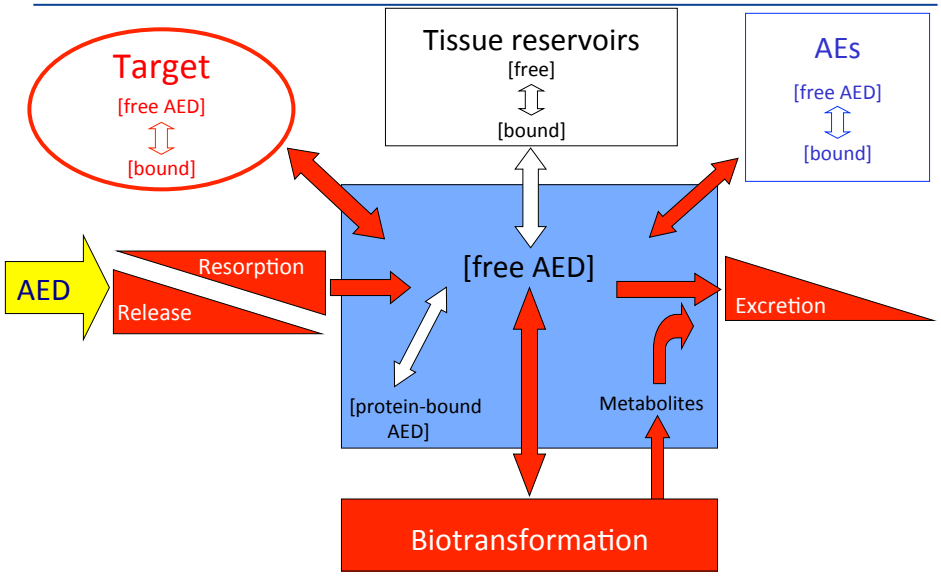
- [1-3]Overall **126 patients** with different types of SE treated with LCM
- Success rate 84/126: **66.7% [95%CI 58.4-74.9]**
- Most often used bolus: **400mg** (range 50-400mg)@ **40-80mg/min**
- No obvious CNS depressant effect, no hypotension, no ECG changes
- Angioedema (n=2), skin rash (n=1)

Open issues:

- Optimal bolus dose and rate not explored → satefty in high dose/high rate
- EEG response not well determined
- Clear order effect
- → Place in the treatment algorithm stage II or add on stage I
- **→ RCT is needed**

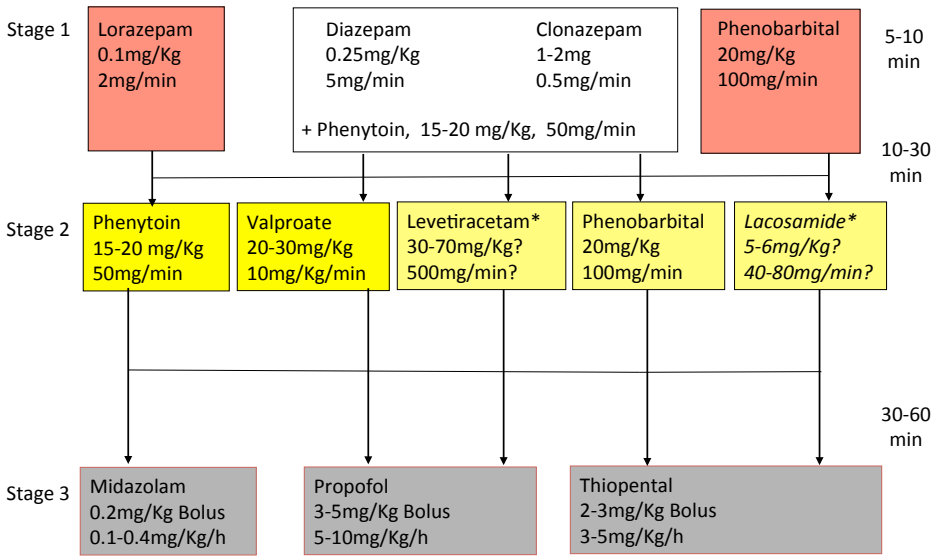
1: Höfler et al. Epilepsia 2011; 2: Trinka Epilepsia 2011; 3: Höfler and Trinka Epilepsia 2013

Interrelationship of absorption, distribution, binding, metabolism, and excretion of a drug



Modified after Buxton ILO. In Goodman and Gilman´s *The Pharmacological Basis of Therapeutics* 11th ed. 2006 p2

Staged approach to the treatment of focal NCSE without coma



Modified after: Trinka Nervenheilkunde 2007, Shorvon, Baulac, Cross, Trinka and Walker for the ILAE Task force on SE, Epilepsia 2008, Trinka E Klein Neurophysiologie 2012; Rosenow et al. Leitlinien der DGN, ÖGN, 2012

Stage III: Refractory SE

STEP 3:
If no response to step 2 within 30 minutes of onset anaesthesia and ICU admission

General anaesthesia with intubation and ventilation
Consider if haemodynamically unstable at any stage or if respiratory support is needed

- These drugs must be **administered by a neurointensivist/experienced anaesthetist in an intensive care unit (ICU) setting** as per local protocols to control clinical/EEG seizures
- *Induction* – usually propofol (1.5–3 mg/kg bolus) caution hypotension, bradycardia **OR**
  - thiopentone (usually 3–5 mg/kg bolus, additional boluses of 50 mg every 3 minutes until seizures terminated, may be given if blood pressure remains stable)
- *Maintenance* – Propofol 1–5 mg/kg/hour titrated to effect; prolonged use may lead to propofol infusion syndrome **OR**
  - midazolam if patient already ventilated, initial bolus 1 mg intravenously and titrate to effect then 0.05–0.20 mg/kg/hour titrated to effect **OR** consider propofol with midazolam **OR**
  - thiopentone 3–5 mg/kg/hour titrated to effect. Caution: hypotension, cardiac suppression, immunosuppression, hypokalaemia, pancreatitis and drug accumulation
- **EEG monitoring is indicated (continuous or minimum every 24 hours) to assess level of anaesthesia and abolition of ictal discharges.**

Over next 24-48 hours, optimise doses and levels of non-anaesthetic anti-epileptic drugs and, if no electrical or clinical evidence of ongoing seizures, withdraw anaesthesia to assess response.

Jones et al. Pract Neurol 2014

Anaesthetics: Overview

	BARB	PRO	MDZ
Mechanisms	$GABA_A$ (NMDA,Ca)	$GABA_A$ (NMDA?,Ca)	$GABA_A$
Loading dose	THP 2-7mg/kg PTB 5-15 mg/kg	2 mg/kg	0.1-0.3 mg/kg
Maintenance	THP 3-5 mg/kg/h PTB 1-5 mg/kg/h	2-5(10) mg/kg/h	0.05-0.6 mg/kg/h
Elimination $t_{1/2}$	THP 36h, PTB 22h	2h	0.5-50h
Disadvantages	Long wash-out	PRIS: check lactate, add BDZ	Increase dose with time

Kress 1987, Van Ness 1990, Parke 1992, Orser 1995, Cremer 2001, Zhan 2001, Claassen 2001 & 2002, Walder 2002, Vasile 2003, Charlesworth 2004, Marik 2004, Rogawsky 2004, Rossetti 2004, Parviainen 2006, Zarovnaya 2007, Iyer 2009

Practice Points

- Anesthetics should be initiated in
  - immediately refractory generalized convulsive SE (evolving to NCSE)
  - deferred in complex focal SE
  - never in absence SE
- Which is the preferred anesthetic?
  - Midazolam > Propofol >> Barbiturates
- How should anesthetics be used?
  - Target BS (1/10s) → 24h → weaning 12-14h → repeat
- Stop treatment?
  - only if evidence (!) that patient will not recover

Which Anaesthetic Drug?

There is no clear first choice....BUT....

Table 2 Outcome data

	Propofol	BBT	*P*
Patients	14	9	
Efficacy			
RSE controlled with first course of study drug	6 (43%)	2 (22%)	0.40
RSE treated subsequently	4/8 (50%)	5/7 (71%)	1.00
Functional outcome at 3 weeks (returned to baseline)	5 (36%)	3 (33%)	1.00
Functional outcome at 3 months (returned to baseline)	5 (36%)	4 (44%)	1.00
Mortality	6 (43%)	3 (33%)	1.00
Tolerability			
Thrombotic/embolic complication	0	0	1.00
Infections requiring antibiotics	7 (50%)	6 (66%)	0.67
Hypotension requiring specific treatment	7 (50%)	5 (55%)	1.00
Other severe complications	1 (7%)[a]	1 (11%)[b]	1.00
Study drug administration (days, median, range)	2.5 (0–7)	2 (0–4)	0.45
Intubation time in survivors (days, median, range)	4 (2–28)	13.5 (8–70)	0.03

Ketamine

- Ketamine (S-Ketamine) is a strong NMDA receptor antagonist; short t½ 1-2h
- 2 retrospective case series[1,2] and 9 single case reports[2], reporting 80 episodes of refractory status epilepticus in adults treated with ketamine:
- Largest series[2] with 46 adults and 12 children; 23 convulsive SE, 13 NCSE, 5 focal SE, 38 focal NCSE and 1 SE of infantile spasms
- The overall success rate was **56%**[2]
- Most often used bolus dose: ranging from **0.5 mg/kg to 2 mg/kg**, followed by infusion ranging from **0.6 mg/kg/h to maximal 10 mg/kg/h**
- Duration 2h to 140 days

1: Synowiec et al, Epilepsy Res 2013; 2: Gaspard et al, Epilepsia 2013; 3: Hsieh et al, Clin Neuropharmacol. 2010; 4: Ubogu et al, Epilepsy Behav. 2003; 5: Kramer et al, Neurocrit Care. 2012 ; 6: Kofke et al, J Neurosurg Anesthesiol. 1997; 6: Prüss et al, Epilepsy Res. 2008; 7: Robakis et al, Neurocrit Care. 2006; 8: Zeiler et al, Neurocrit Care 2014

Ketamine in RSE: The Salzburg Experience

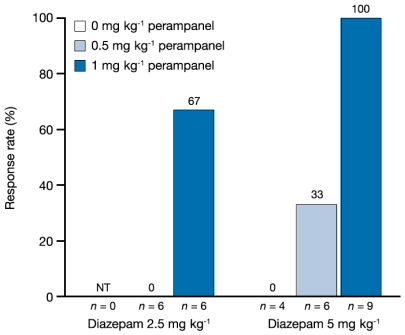
- 26/219 patients (64.5 years; range 15-80 at time of SE) with SE at the NICU
- **Causes**: 8 post-anoxic, 4 systemic infection, 4 stroke/intracerebral hemorrhage, 6 unknown, 4 pre-existing epilepsy with low AED level
- **Types of SE**: 2 myoclonic SE, 5 convulsive SE, 15 NCSE, 3 CSE→NCSE, 1 FSE

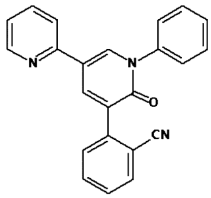
Patients	n = 26
Time of SE before KET	median 3.5 days (range 1-20)
Duration of KET treatment	median 5 days (range 1-16); 96 hours (range 8-355);
Dose of KET	median 1.91 mg/kg/h (range 0.11- 4.68); 150 mg/h (range 12.5-375)
Initial bolus of KET	6/26 patients, median 200 mg (range 200-300)
Initial continous infusion	20/26, median 200 mg/h (range 50-375)
Responder	**12/26 patients, 46%**
Mortality	**14/26 patients, 54% (due to underlying cause)**

Höfler et al. American Epilepsy Society Meeting, 2014

Perampanel in super refractory SE

- Perampanel (PER): non-competitive AMPA-antagonist;
- Lithium pilocarpine rat model of SE: efficacy of PER in termination of benzodiazepine resistant SE[4].
  - ED_{50} 1.7 mg/kg 10 minutes after SE onset; ED_{50} 5.1 mg/kg 30 min after SE onset; PER 8 mg/kg terminated SE in all rats at 10 and 30 min





PER and DZP were intravenously 30 min after seizure onset

Perampanel						
8 mg kg⁻¹	10	6/6	+			
	30	6/6	+			
GYKI52466						
50 mg kg⁻¹	30	2/4	+			
Diazepam plus perampanel						
Diazepam 5 mg kg⁻¹ Perampanel 1 mg kg⁻¹	30	9/9	+			

1 mV

4 Hanada et al. Pharmacol Res Perspect 2014

Perampanel in SRSE: The Salzburg Experience

Retrospective analysis (09/2012 - 01/2015); all in NICU

Twelve patients (75% women; median age 75 yrs [range 60-91]), with refractory and super-refractory SE received add on treatment with PER via nasogastric tube

SE type: NCSE with coma 5/12 (42%), NCSE without coma 6/12 (50%), focal motor 1/12(8 %)

Etiology:

acute symptomatic 5/12 (42%)

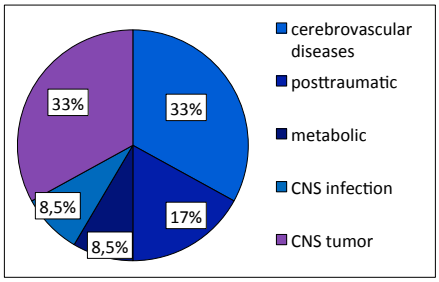
remote symptomatic 5/12 (42%)

progressive symptomatic 2/12 (16%)

SE de novo 7/12 (58%)

preexisting epilepsy 5/12

1/5 had insufficient AED levels



Rohracher A, et al, Epilepsy Behav (2015), http://dx.doi.org/10.1016/j.yebeh.2015.04.005

Perampanel in SRSE: The Salzburg Experience

AED treatment before PER:

	1st treatment	2nd treatment	3rd treatment	4th treatment	5th treatment	6th treatment	7th treatment
Lorazepam	11 (92%)	1 (8%)					
Midazolam	1 (8%)				1 (8%)		
Levetirazetam		9 (75%)	1 (8%)				
Phenytoin		2 (17%)	2 (17%)	3(25%)	1 (8%)		
Valproic acid			3 (25%)	3 (25%)			
Lacosamide			4 (33%)	1(8%)			
Topiramate				2 (17%)		2 (17%)	
Propofol					1 (8%)	1 (8%)	
Ketamine					1 (8%)	1 (8%)	
Carabamazepine							1 (8%)

83% concom EI (9/12 PHT, 1/10 CBZ)

Median number of prior AEDs: 4 [2 to 7], Median time to PER: 1.5 days [0.8 to 18.3]

Median initial dose PER: 4 mg [2 to 12], Median maximum dose PER: 12 mg [4 to 12]

Rohracher A, et al, Epilepsy Behav (2015), http://dx.doi.org/10.1016/j.yebeh.2015.04.005

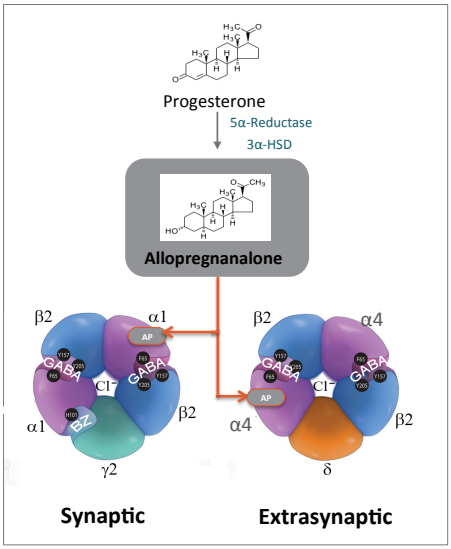
Perampanel in SRSE: The Salzburg Experience

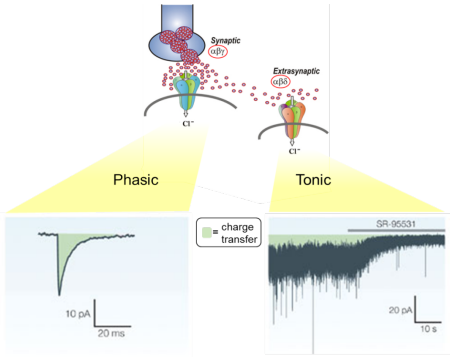
- STESS score positive (≥3 points) 8/12 pts (PPV 25%, NPV 75%)
- EMSE score positive (≥ 64 points) 8/12 pts (PPV 37.5%, NPV 100%)
- Outcome after SE (GOS):
  - good recovery 0/12 (0%), moderate disability 5/12 (42%), severe disability 2/12 (17%), persistent vegetative state 2/12 (17%), Dead 3/12 (25%)
- Median stay in the NICU 8 days [4 to 21]
- Median stay in hospital 18 days [6 to 70]
- No adverse effects regarding cardiorespiratory and laboratory parameters

→ Clinical and EEG improvement after PER in 2/12 pts. (17%)

Rohracher A, et al, Epilepsy Behav (2015), http://dx.doi.org/10.1016/j.yebeh.2015.04.005

Neurosteroids in Super-refractory SE



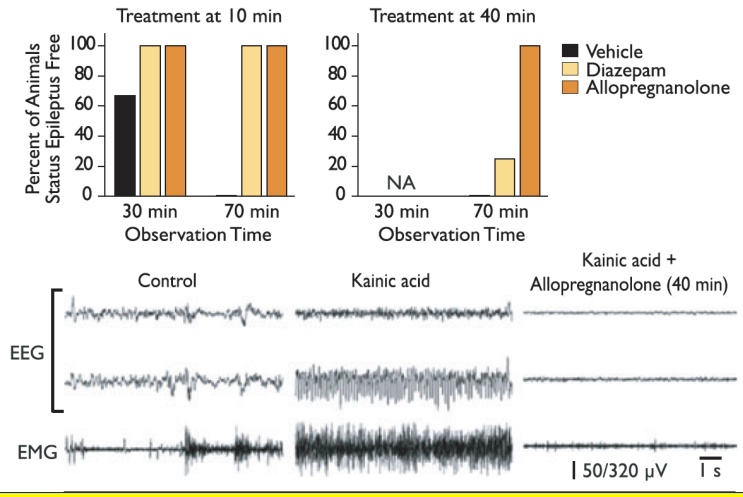


Neurosteroids modulate **synaptic** and **extrasynaptic** $GABA_A$ receptors

Benzodiazepines modulate only **synaptic** $GABA_A$ receptors

Rogawski et al. Epilepsia, 54(Suppl. 6):93–98, 2013

Neurosteroids in Super-refractory SE



Neurosteroids SGE-547 and SGE-102: in Phase II/III

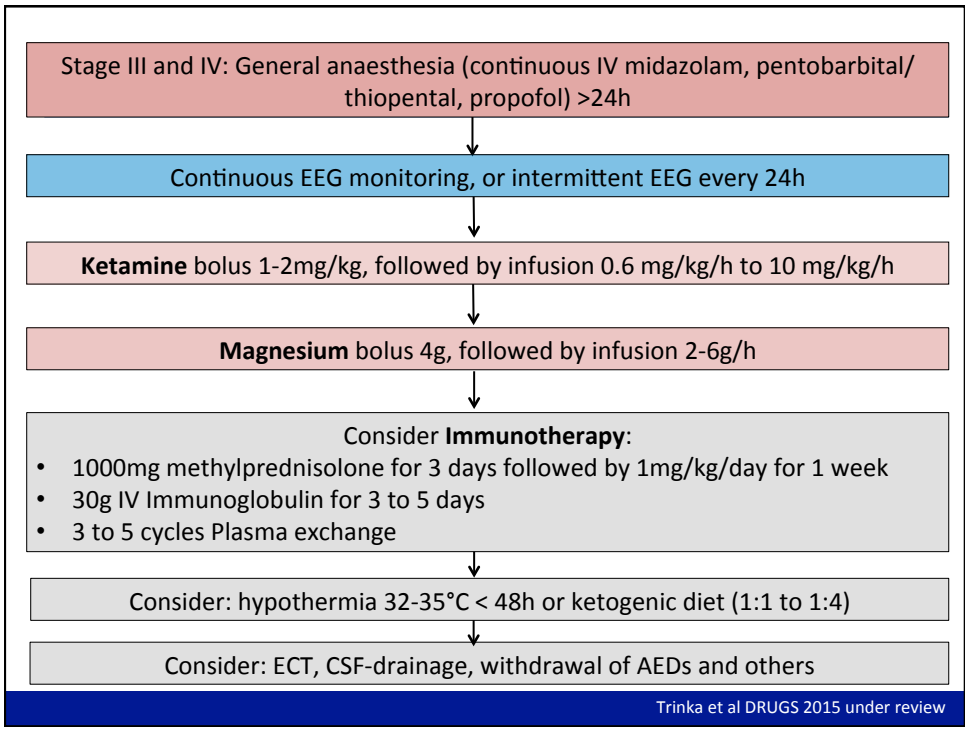
Ketogenic diet for adults in super-refractory status epilepticus

- Ten (4 woman) adult patients at 4 medical centers

median age was 33 years (IQR 21); 7 had encephalitis

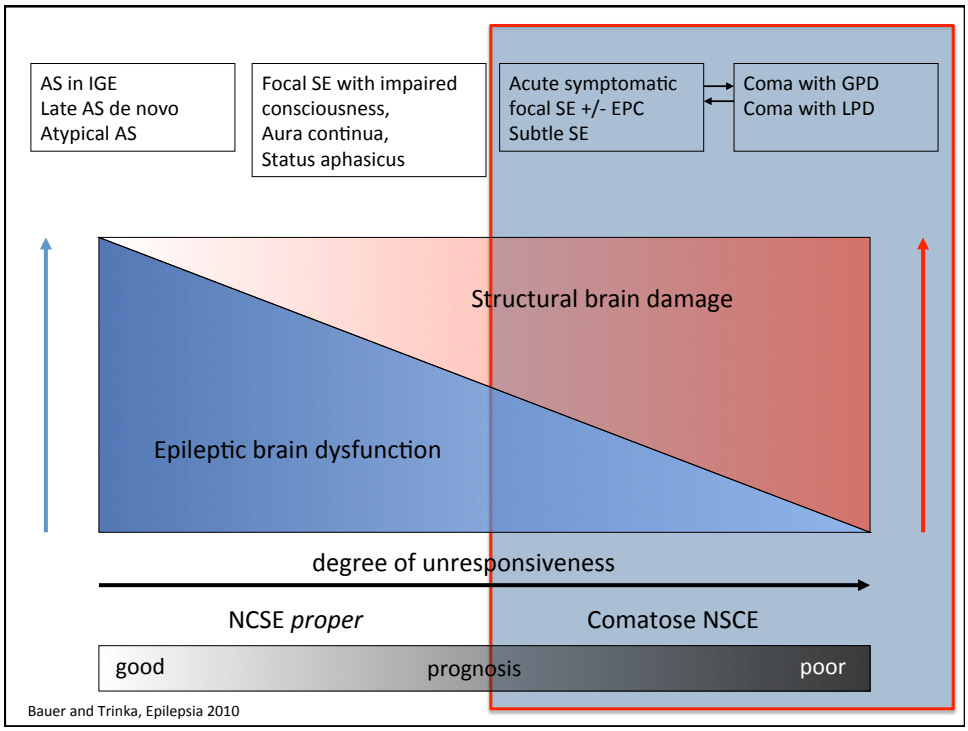
  - Median duration of SE before initiation of KD was 21.5 days (IQR 28)
  - Median number of antiepileptic medications used before initiation of KD was 7 (IQR 7)
  - Ninety percent of patients achieved ketosis
- **SE ceased in all patients achieving ketosis** in a median of 3 days (IQR 8)
- transient acidosis and hypertriglyceridemia and 2 patients ultimately died (unrelated to KD

Thakur et al. *Neurology* 2014;82:665–670



Agenda

- Definition and classification of status epilepticus
- Causes and mechanisms
- Staged Treatment approach
  - Refractory Status epilepticus
  - Super-refractory Status epilepticus
- Prognosis
- Concluding remarks



Bauer and Trinka, Epilepsia 2010

Is it comatose NCSE or coma?

1 Video was taped by Martin Soyer

Epilepsia, **(*):1–14, 2009
doi: 10.1111/j.1528-1167.2009.02297.x

CRITICAL REVIEW AND INVITED COMMENTARY

Nonconvulsive status epilepticus and coma

Gerhard Bauer and Eugen Trinka

Department of Neurology, Medical University of Innsbruck, Innsbruck, Austria

Prevalence of NCSE in comatose patients[2] n=236

8% of all patients in coma without obvious clinical signs of SE

Age: 1 mo to 87 years

Persisting NCSE after "control" of GCSE[3] n=164

24h continuous EEG monitoring

48% with ictal EEG pattern: coma without obvious signs of SE

Consequently: There is no diagnosis of coma without EEG

1: Bauer and Trinka Epilepsia 2009; 2: Towne et al Neurology 2000; 3: DeLorenzo et al Epilepsia 1998

Era of Continuous Video EEG Monitoring

537 patients with suspected SE during three comparable 9-month period
2 groups before (groups 1 and 2) and 1 (group 3) after cont-video-EEG (cvEEG) introduction

Rate on NCSE diagnosis by group

Group	Diagnosis rate	p
1	0.12 (16/129 of 754)	0.0546
2	0.14 (23/159 of 677)	
3	0.20 (49/249 of 682)	

Frequency of NCSE diagnosis increased significantly after implementation of cvEEG monitoring and was higher than the increment of performed investigations alone."

Sutter et al. *Epilepsia*, 52(3):453–457, 2011

No, some types of nonconvulsive status epilepticus cause little permanent neurologic sequelae (or: « The cure may be worse than the disease »)

Higher rate of good functional outcome in patients with normal MRI, and SE on admission

Beluzzo et al. *Epilepsy Research* 2015; 110: 179-182

Scores for outcome prediction in SE

STESS[1]

Status Epilepticus Severity Score

- parameters (4):
  - aetiology
  - age
  - seizure type
  - level of consciousness before treatment
- score points:
  - a priori assumptions
- initial study
  - retrospective evaluation prospectively tested
- prospective validation: yes[3,4]

EMSE[2]

Epidemiology Based Mortality Score

- parameters (4):
  - aetiology
  - age
  - comorbidities
  - EEG
- score points:
  - epidemiological ("real world") data
- initial study
  - explorative, hypothesis generating
  - "fitting test/score to sample"
- prospective validation: *ongoing*

1: Rosetti et al. 2006; 2: Leitinger et al. Neurocritical Care 2015; 22: 273-282; 3: Rossetti et al. 2008; 4: Sutter et al. 2013

Status epilepticus severity score (STESS)[1,3,4]

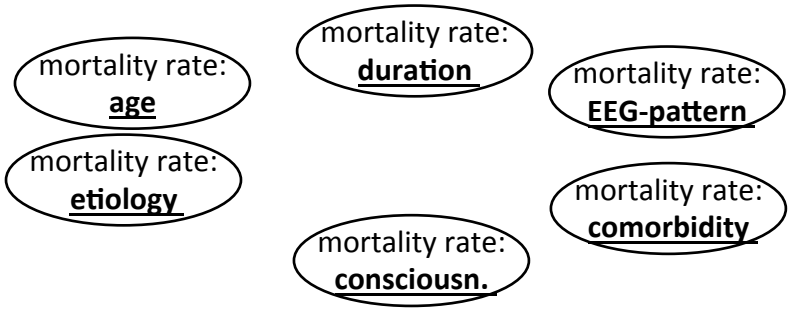
	Features	STESS
Consciousness	Alert or somnolent/confused	0
	Stuporous or comatose	1
Worst seizure type	Simple-partial, complex-partial, absence, myoclonic*	0
	Generalized-convulsive	1
	Nonconvulsive status epilepticus in coma	2
Age	< 65 years	0
	≥ 65 years	2
History of previous seizures	Yes	0
	No or unknown	1
Total		0–6

Values of 3 or higher indicate high risk of death

1: Rosetti et al. 2006; 2: Leitinger et al. Neurocritical Care 2015; 22: 273-282; 3: Rossetti et al. 2008; 4: Sutter et al. 2013

Epidemiology Based Mortality Score in SE (EMSE)[1]

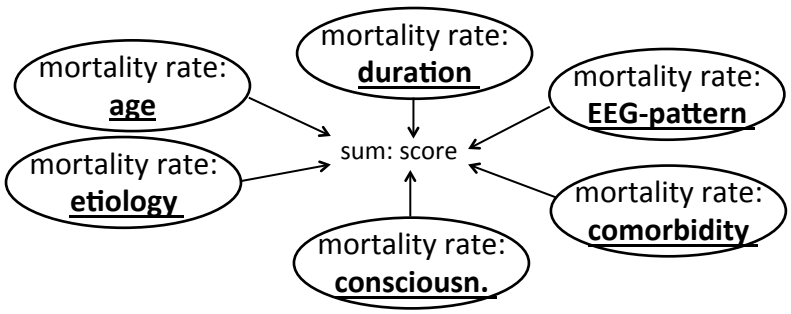
concept of EMSE:
✓ epidemiological studies present **mortality rates** for different parameters (e.g. age, aetiology,…)



1: Leitinger et al. Neurocritical Care 2015; 22: 273-282;

Epidemiology Based Mortality Score in SE (EMSE)[1]

concept of EMSE:
✓ epidemiological studies present **mortality rates** for different factors
✓ these mortality rates are taken as **points in a score** and summed up → those with many "risk points" should have a higher risk

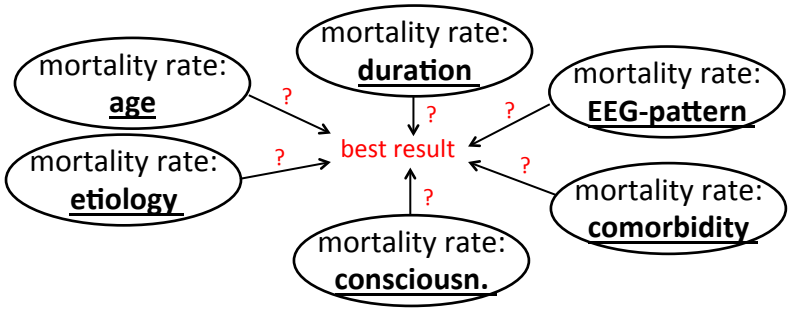


1: Leitinger et al. Neurocritical Care 2015; 22: 273-282;

Epidemiology Based Mortality Score in SE (EMSE)[1]

concept of EMSE:

- ✓ epidemiological studies present **mortality rates** for different factors
- ✓ these mortality rates are taken as **points in a score** and summed up → those with many "risk points" should have a higher risk
- ✓ test, which combination of factors yields best result



1: Leitinger et al. Neurocritical Care 2015; 22: 273-282;

Epidemiology Based Mortality Score in SE (EMSE)[1]

AETIOLOGY: score one stratum

aetiology E (reference: 1, 9)	EMSE-points
CNS-anomalies	2
drug reduction/ withdrawal, poor compliance	2
multiple sclerosis	5
remote cerebrovascular disease, brain injury	7
hydrocephalus	8
alcohol abuse	10
drug overdose	11
head trauma	12
cryptogenic	12
brain tumor	16
metabolic: sodium imbalance	17
metabolic disorders	22
acute cerebrovascular disease	26
CNS-infection: acute	33
anoxia	65

AGE: score one stratum

age A (reference: 11)	EMSE-points
21-30	1
31-40	2
41-50	3
51-60	5
61-70	7
71-80	8
>80	10

EEG: score only worst stratum

EEG E (reference 13, 14)	EMSE-points
burst suppression (spontaneous)	60
ASIDs	40
LPDs	40
GPDs	40
no LPDs, GPDs or ASIDs	0

COMORBIDITY: score each disease

comorbidity C (reference: 16)	EMSE-points
myocardial infarction, congestive heart failure, peripheral vascular disease, cerebrovascular disease, dementia, chronic pulmonary disease, connective tissue disease, ulcer disease, mild liver disease, diabetes	10
hemiplegia, moderate or severe renal disease, diabetes with end organ damage, any tumor including leukemia/ lymphoma	20
moderate or severe liver disease	30
metastatic solid tumor, AIDS	60

sum score = ___

Global Audit of Treatment of Refractory Status Epilepticus and Super-refractory Status Epilepticus

The 4th London-Innsbruck Colloquium on Status Epilepticus and Acute Seizures
4-6 April 2013
Salzburg, Austria

To all doctors treating patients with status epilepticus in the intensive care setting

Dear Colleague,

As you may know, there is no consensus about the best form of therapy for status epilepticus which has not responded to initial therapy and which requires ITU admission and intravenous anaesthetics. We invite you to join us in setting up an online global audit. The aim of this is to document what treatments of refractory status epilepticus are being used in practice around the world, and also information on aetiology and outcome.

This is an academically-driven exercise, with no external funding, and we hope this will be an important step in the road to better therapy for status epilepticus.

The audit comprises short online questionnaires to be completed for patients you treat with refractory status epilepticus. The information sheet provides further details.

We are hoping to have the initial findings discussed at the next Status Epilepticus Colloquium in Salzburg in April 2013 (www.statusepilepticus2013.eu) and all collaborators are invited to the conference to debate the findings.

Yours sincerely,

Dr. Monica Ferlisi (Italy)
Dr. Sara Hocker (US)
Prof. Simon Shorvon (UK)
Prof. Eugen Trinka (Austria)

To register for this study please enter your name and e-mail address below.

When registered for the study, you will regularly receive e-mails invitating you to report new cases of status epilepticus. There are no liabilities and you can unregister your e-mail address any time.

Please note that you receive an e-mail to confirm your address. Please click the hyperlink in this e-mail to complete registration.

All data will be entirely confidential. The e-mail address will not be handed to any third party or passed on in any way. It is requested here as all communications from the study team will be made by email.

An information sheet about the study can be downloaded here.

Global Audit of Treatment of Refractory and Super-Refractory Status Epilepticus

Online audit of the treatments being used in status epilepticus around the world and their outcome

Short and easy to complete Questionnaires

!! PLEASE REGISTER AND TAKE PART !!

Conclusions

- SE is one of the most common neurological emergencies
- Establishment of a treatment protocol is of utmost importance → Dichotomy CSE vs. NCSE
- Prognostication with scores and EEG criteria for NCSE
- Lack of RCTs in stage 2, 3, and 4 → treatment decisions are based on
  - **co-morbidity etiology of SE, guidelines, ease of use, and doctor´s habits**
- **Stage 2: ESSET-Trial 2015: LEV vs. PHT vs. VPA**
- **Stage 3/4:** TRENdS Trial (LCM vs. PHT in NCSE): recruitment stopped
- **Stage 4:** Neurosteroids in Phase III development
- Antiglutamatergic drugs: KET, PER and other (BGG492, GYKI 52466 etc.) drugs on the horizon
