PREFACE

Since Barnard's 1925 revision of the Anthuridean isopods (Crustacea), there have been considerably advances in our knowledge of this group, stemming from almost world-wide research work mainly in taxonomy. At present 65 genera and 502 species in three families are known. Most species live in tropical and subtropical shallow-water environments, few are known from the Arctic and Antarctic area. That means, this group of conspicuous isopods is often present in benthic samples taken in shallow waters in the course of ecological studies.

A great deal of systematic work has been published the past three decades, and this has often confronted me with problems in the field of nomenclature, due to the often quite different opinions of certain authors. On the one hand it would be unwise, in a catalogue of these crustaceans designed as a source of worldwide information, to adopt without question suggested schemes of classification which had not yet been subjected to criticism and discussion. On the other hand I do not wish to seem to have ignored any of the important taxonomic work which has been published as a consequence of the greatly increased interest now being shown in the Anthuridea. I have therefore given the most careful consideration to this question of names and have exercised my best judgement.

I'm strongly in favour of a stable nomenclature, and my general policy in this book has been not to change names (genera or species) except where very good reasons for doing so appear to exist. A particular problem arises with decisions on genera, since different authors have differing views on the importance of the various criteria for defining a supraspecific taxon, and in consequence such definitions contain a considerable subjective element, characterized by the well-known taxonomic habits of "splitting" and "lumping". Because of this subjective element, it must be admitted that I may not have been entirely consistent in all cases in my choice of the generic name to be employed. A stable nomenclature has certainly not yet arrived, and further name changes will surely occur. Moreover, most of the species described, even in the more recent literature, are incompletely characterized. Considering the more active authors in anthuridean taxonomy, the most detailed descriptions are undoubtedly presented by Wägele, while those given by Kensley and Poore (et al.) are partly incomplete with sometimes erroneous assignments of developmental stages. The descriptions of species published by Nunomura, mainly on the Japanese fauna, are superficial sketches throughout, contribute very little to the understanding of anthuridean systematics and require redescriptions.

Some years ago I started with this compilation as an aid for myself to seize the information available for Anthuridea as the needed background for systematic, faunistic and ecological research programs already carried out

or planned in the near future. It may help taxonomists and ecologists to obtain information about "what was made" in this group in the past decades and curators of museums to manage their collection of anthuridean isopods. Old literature is sometimes ignored, when more recent publications provide detailed redescriptions, or a summary of the data for the respective genus and species exists.

HOW TO USE THIS CATALOGUE IN YOUR COMPUTER

With the search key of "Word Perfect" you have easy access to the respective taxa, even when only older names/synonyms are available.

Users should keep in mind, that we have a considerable steady increase of information within a short time. Thus, to avoid unnecessary inflation of the volume of this catalogue, I tried to include only substantial new information. For example, when a species is mentioned only in a key in a certain paper, this is not always noted in the list of references under the respective species. When you are searching for keys to genera or species, you should check the information given for the subfamily, or genera to determine species.

Typewrite Shift-F6, followed by the name of the family, genus or species, to move to the chapter of the respective taxon. When you ignore Shift-F6 and typewrite only the name of a certain taxon, the search key will stop everywhere in the text, where the respective name is mentioned, i.e. also in relation with other facts, discussions or missplacements in older literature.

For locating certain countries use only the current name, i.e. Sri Lanka instead of Ceylon, Kenya instead of British East Africa. I found it too problematic in this catalogue to summarize in each case the species known from a certain country, because many species are widely distributed in the Indo-Pacific and often can not be assigned to a certain country, when they have been caught offshore.

Remarks: Considerable confusion exists regarding the status of the genera *Apanthura*, *Amakusanthura* and *Apanthuretta*. The latter has been considered a junior synonym of *Amakusanthura* by Poore & Lew Ton (1988). The distinguishing features for *Amakusanthura* and *Apanthura* given by Poore & Lew Ton (1988: 109, in key) are as follows: *Apanthura*. - "Pleonites 1-5 indistinguishable dorsally (except in some males); male antenna 1 flagellum of about 10 articles". *Amakusanthura*. - Pleonites, except 4-5, distinguished by dorsal grooves (rarely 1-5 indistinguishable), male antenna 1 flagellum of at least 15 (usually about 20) articles".

Considering these characters, it becomes evident that this delimitation is premature. As mentioned by Poore and Lew Ton, the presence of dorsal pleonal grooves is not a constant feature in "*Amakusanthura*", and species with dorsally unfused pleonites occur in "*Apanthura*" too. Moreover, the ill-fated attempt to distinguish these genera through the number of the male antennular articles should be ignored, because this is not an apomorphic feature, and therefore unsuitable to distinguish taxa on genus level.

Due to the fact that most species of the complex "*Apanthura*" are incompletely described and the separation of *Amakusanthura* and *Apanthuretta* is poorly definable, I keep herein all nominal species described in these genera provisionally under *Apanthura*. A complete revision is needed to understand the interrelationships of this complex of species. The splitting into genera with the present meagre base of information is surely the wrong

way how taxonomy should be and leaves nothing but confusion.

Distribution: W-Atlantic. - Canada to the Gulf of Mexico; Cuba.

Depth range: 0-35m.

Habitat: fresh and brackish water; in estuaries and tidal marshes; among vegetation, on sand and mud bottoms with detritus; is a tubicolous species.

Size: 15mm.

Remarks: In tidal marshes of Cape Cod, Massachusetts, the detritus-feeding *C. polita* species was collected in substrate depths of 5-8cm. 108-1080 specimens/m² were found in this sandy, brackish water location under tidal influence (Burbanck, 1961: 29-30). The breeding cycle in a *Juncus roemerianus* marsh in northern Florida has been studied by Kruczynski & Subrahmanyam (1978). Reproduction occurred in April, and, because ♂♂ matured first, there may be some evidence for a protogynous hermaphroditism.

1989 *Leptanthura*, - Wägele, Zoologica, 140: 159, fig. 76 (remarks on phylogeny).

Remarks: The genus *Leptanthura* has a predominantly southern distribution, with most species reported from the Indo-West Pacific. *Leptanthura*-species inhabit a wide variety of substrates from the intertidal zone to the deep sea. Although there are still many gaps concerning the world-wide distribution of the genus, it appears that *Leptanthura* is not present along the North-American east-coast south to the Caribbean and along the westcoast

of the American continent. The genus is also unknown from the entire Central and East Pacific area.
