

## Multiple Independently-targetable Reentry Vehicle (MIRV)

Multiple Independently-targetable Reentry Vehicles (MIRVs) were originally developed in the early 1960s to permit a missile to deliver multiple nuclear warheads to different targets. In contrast to a traditional missile, which carries one warhead, MIRVs can carry multiple warheads. For instance, a Russian MIRVed missile under development may be able to carry up to [16 warheads](#), each in a separate re-entry vehicle. Warheads on MIRVed missiles can be released from the missile at different speeds and in different directions. Some MIRVed missiles can hit targets as far as [1,500 kilometers](#) apart.

Land-based MIRVed missiles are considered particularly destabilizing. These missiles are a much more tempting target than traditional land-based missiles, because an attacker can take out several of their enemy's warheads at once.

Although MIRVs were not initially intended to defeat [ballistic missile defenses](#), they are much more difficult to defend against than traditional missiles and are considered effective BMD countermeasures.

### Who Has Them?

The development of MIRV technology is not easy. It requires the combination of large missiles, small warheads, accurate guidance, and a complex mechanism for releasing warheads sequentially during flight.

The United States was the first country to develop MIRV technology, [deploying](#) a MIRVed Intercontinental Ballistic Missile (ICBM) in 1970 and a MIRVed Submarine-Launched Ballistic Missile (SLBM) in 1971. The Soviet Union quickly followed suit and by the end of the 1970s had developed their own MIRV-enabled ICBM and SLBM technology.

Today, the [United States](#), the [United Kingdom](#), and [France](#) use MIRV technology on SLBMs. [China](#) has MIRVed ICBMs, while [Russia](#) deploys both MIRVed ICBMs and SLBMs. The use of MIRVs on submarines is considered less destabilizing than on land-based missiles because the difficulty of finding nuclear submarines makes strikes against them unlikely.

India and Pakistan are also experimenting with MIRV technology. In January 2017, Pakistan reportedly [tested](#) a MIRVed missile, the Ababeel. Senior Indian defense officials, meanwhile, have [indicated](#) that future iterations of the Agni-class long-range missiles will be MIRVed.
