Two new species of *Lichenostigma* (*Lichenotheliaceae*, lichenicolous fungi) from Iran

Abstract

Valadbeigi T. & Brackel W. von: Two new species of *Lichenostigma* (*Lichenotheliaceae*, lichenicolous fungi) from Iran. – Willdenowia 41: 191–195. – Online ISSN 1868-6397; © 2011 BGBM Berlin-Dahlem.
doi:10.3372/wi.41.41122 (available via <http://dx.doi.org/>)

Two species of *Lichenostigma*, both from Iran, are described as new to science: *L. iranicum*, growing on *Lobothallia praeradiosa*, is characterised by rounded to elongate ascocarps, sparse hyphal strands, 6(–8)-spored ascospores and the almost complete absence of pigmentation in the lower ascocarpal wall; *L. verrucosum*, growing on *Pleopsidium gobiense*, is distinguished by rounded to irregular ascocarps with radiating superficial hyphae, verrucose brown ascospores and by the complete absence of pigmentation in the lower ascocarpal wall.

Additional key words: *Ascomycota*, *Acarosporaceae*, *Aspiciliaceae*, biodiversity, taxonomy

Introduction

In 1982 Hafellner introduced the genus *Lichenostigma* for the single species *L. maureri* from Austria, growing on *Usnea* spp. and *Pseudevernia furfuracea*. This species, which is now known from various fruticose lichens, is characterised by the following combination of features: rounded ascocarps, fissitunicate ascospores, absence of hamathecial filaments but with more or less spherical cells filling the interascal spaces and 1-septate, brown ascospores with the upper cell broader than the lower one (Hafellner 1982). Later, two subgenera were recognised: *L. subg. Lichenostigma* with cushion-like ascocarps not connected to dark superficial hyphal strands, and *L. subg. Lichenogramma* Nav.-Ros. & Hafellner with sack-shaped superficial ascocarps connected to superficial stromatic or simple hyphal strands (Calatayud & al. 2002; Ihlen 2004).

Material and methods

The study is based on specimens collected by the first author in 2004 and 2008 in Iran. The morphological and

anatomical observations were made using standard microscopic techniques. Microscopic measurements were made with an accuracy of up to 0.5 µm on hand-cut sections mounted in water. Measurements of ascospores are recorded in the descriptions as (minimum–) $\bar{X} - \sigma_x - \bar{X} + \sigma_x$ (–maximum) followed by the number of measurements.

Lichenostigma iranicum Brackel & Valadbeigi, sp. nov.

MycoBank: 518508

Holotype: Iran, Gilan, c. 6 km on the road from Masouleh to Majalan village, siliceous rocks, on *Lobothallia praeradiosa*, c. 1600 m, 2004, T. Valadbeigi 9061 (TARI; isotype: herb. Valadbeigi).

Fungus lichenicola in thallo lichenis *Lobothallia praeradiosa* vigens. Filamenta superficialia rara, curta, fusca-olivacea, aspera. Ascomata superficialia, rotunda vel elongata, dispersa, pulla, ad 100–110 µm crassa, cellulis subglobosis composita; filamenta interascalia nulla. Paries ascomatis in partem inferiorem hyalinus. Ascii obovati, fissitunicati, 6(–8)-spori, 25–30 × 14 µm, iodo

non reagentes. Ascosporae $10\text{--}11.5 \times 5.5\text{--}6 \mu\text{m}$, uniseptatae, canae mox fuscae, tenue verruculosae.

Description. — Vegetative hyphae rare, superficial on the host thallus, short, single-stranded, unbranched, brownish olive, slightly constricted at the septa, hyphal cells $4\text{--}7 \mu\text{m}$ in diam., surface rugose. Ascomata superficial, scattered, not connected by vegetative hyphae, rounded to elongate, dark brown, shiny, $100\text{--}110 \mu\text{m}$ diam. and up to $70 \mu\text{m}$ high; ascomatal wall in section in the upper and lateral part distinctly brown, in the lower part (part connected to the host thallus) not continuous, hyaline or single cells pale brown; outermost cells brown, subglobose, $6\text{--}10 \mu\text{m}$ diam., on the outside covered by a granular brown pigment; internal cells subglobose to somewhat irregular, hyaline, $4\text{--}8 \times 3\text{--}5 \mu\text{m}$; centrum I+ yellow to pale orange, K/I-. Asci obovate, $25\text{--}30 \times 14 \mu\text{m}$, fissitunicate, 6(-8)-spored, apically thickened, I-. Ascospores ovoid to oblong-ovoid, grey to dark brown, finely verruculose, 1-septate, slightly constricted at the septum, lower cell narrower and shorter than upper cell, $(10\text{--})10.5\text{--}11(-11.5) \times 5.5\text{--}6 \mu\text{m}$ ($n=30$), perispore I+ slightly blue.

Habitat and distribution. — *Lichenostigma iranicum* is so far known from one locality in Iran. It was found on *Lobothallia praeeradiosa* (Nyl.) Hafellner (*Aspiciliaeae*) on horizontal and inclined faces of siliceous rock.

Etymology. — The new species is named after Iran, the native country of the first author and the country of the type locality. As the Greek word “stigma” and following the genus name is neuter, also the epithet has to get the neutral form.

Observations. — Growing on species of *Aspicilia*, five species of *Lichenostigma* are reported, *L. canariense* Etayo & Van den Boom, *L. elongatum* Nav.-Ros. & Hafellner, *L. radicans* Calat. & Barreno, *L. triseptatum* Halıcı & D. Hawksw. and *L. supertegentis* Ihlen & R. Sant., while the genus *Lobothallia* is reported as a host for *L. elongatum* (Navarro-Rosinés & Hafellner 1996; Calatayud & al. 2002; Calatayud & Barreno 2003; Ihlen 2004; Boom & Etayo 2006; Kukwa & Czarnota 2006; Halıcı & Hawksworth 2007; Kukwa & Jabłońska 2008).

The distinguishing features of *Lichenostigma* species growing on *Aspicilia* and *Lobothallia* are summarised in Table 1. The new species differs from all other species of *Lichenostigma* living on *Aspicilia* or *Lobothallia* in the almost complete lack of pigmentation in the lower ascromatal wall; only some single cells show a slight tinge of brown colour and darkened outer walls. The border between the ascoma and the host cells is not clearly distinguishable (Fig. 1D, 1E). Moreover, the aforementioned five species differ in the following characters:

Lichenostigma elongatum has larger ascospores ($9\text{--}13 \times 6\text{--}8.5 \mu\text{m}$) with granular ornamentation, 8-spored

asci, distinct and ramifying dark superficial hyphae and always elongate ascomata. *L. canariense* has smaller ascospores ($8.5\text{--}10.5 \times 5\text{--}6 \mu\text{m}$) and ascomata ($25\text{--}80 \mu\text{m}$) and no superficial mycelium. *L. radicans* has pale brown inner ascromatal cells and a penetrating, not superficial mycelium without ornamentation. *L. iranicum* is more similar to *L. triseptatum*, with subglobose to elongate-ellipsoid ascomata, intermediate between the subgenera *Lichenogramma* (elongate ascomata connected to simple or plurihyphal strands of vegetative hyphae, growing superficially on the host thallus and ascomata) and *Lichenostigma* (rounded ascomata without connection of superficial hyphal strands). However, *L. triseptata* has mostly 3-septate, larger ascospores and asci, and red-brown to black or dark reddish brown ascospores. *L. supertegentis* differs from *L. iranicum* in the larger ascospores ($16\text{--}25 \times 7\text{--}12 \mu\text{m}$) and asci ($40\text{--}50 \times 25\text{--}35 \mu\text{m}$) as well as in the absence of a superficial mycelium.

***Lichenostigma verrucosum* Brackel & Valadbeigi, sp. nov.**

Mycobank: 518509

Holotypus: Iran, Azarbayjan, Arasbaran protected area, top mountain to Mazgar, siliceous rocks, on *Pleopsidium gobiense*, $38^{\circ}40'N$, $47^{\circ}00'E$, c. 2200–2600 m, 1.2.2008, T. Valadbeigi 6525 (TARI; isotype: herb. Valadbeigi).

Fungus lichenicola in thallo lichenis *Pleopsidium gobiense* vigens. Filamenta superficialia, ramosa, fusca, aspera. Ascomata superficialia, rotunda, dispersa vel aggregata, ad $120\text{--}130 \mu\text{m}$ crassa, cellulis subglobosis composita; filamenta interascalia nulla. Paries ascomatis in partem inferiorem hyalinus. Asci saccati, fissitunicati, octospori, $3\text{--}45 \times 25\text{--}33 \mu\text{m}$, iodo non reagentes. Ascosporae $12\text{--}14(-16) \times (5.5\text{--})6\text{--}7.5(-9) \mu\text{m}$, uniseptatae, fuscae, verrucosae.

Description. — Vegetative hyphae radiating from the ascromata, superficial on the host thallus, sometimes penetrating into the thallus, near the ascromata plurihyphal, then single, branched, dark brown, slightly constricted at the septa, hyphal cells $5\text{--}10 \mu\text{m}$ in diam., suborbicular to irregular, surface rugose, later cracked. Ascomata superficial, loosely aggregated, not connected by vegetative hyphae, rounded to irregular, black, matt, $120\text{--}130 \mu\text{m}$ in diam. and $40\text{--}80 \mu\text{m}$ high; ascomatal wall in section in the upper and lateral part distinctly brown, in the lower part (part connected to the host thallus) not visible, hyaline; outermost cells brown, subglobose, $5\text{--}8 \mu\text{m}$ diam., covered by a granular brown pigment; internal cells subglobose to somewhat irregular, hyaline, $3\text{--}8 \mu\text{m}$ in diam.; centrum I+ pale blue, K/I-. Asci saccate, $30\text{--}45 \times 25\text{--}33 \mu\text{m}$, fissitunicate, 8-spored, apically thickened, I-. Ascospores ovoid to oblong-ovoid, pale to dark brown, distinctly verrucose, 1-septate, constricted at the septum, easily splitting into two single cells, lower

Table 1. Main distinguishing features of *Lichenostigma* (L.) species growing on *Aspicilia* (A.) and *Lobothallia* (Lo.).

Species	Host	Spores Size [µm]	Colour	Ornamentation	Cells	Size [µm]	Spores / ascus	Ascomata		Mycelium	Strands	Colour and ornamentation	Basal acoma wall

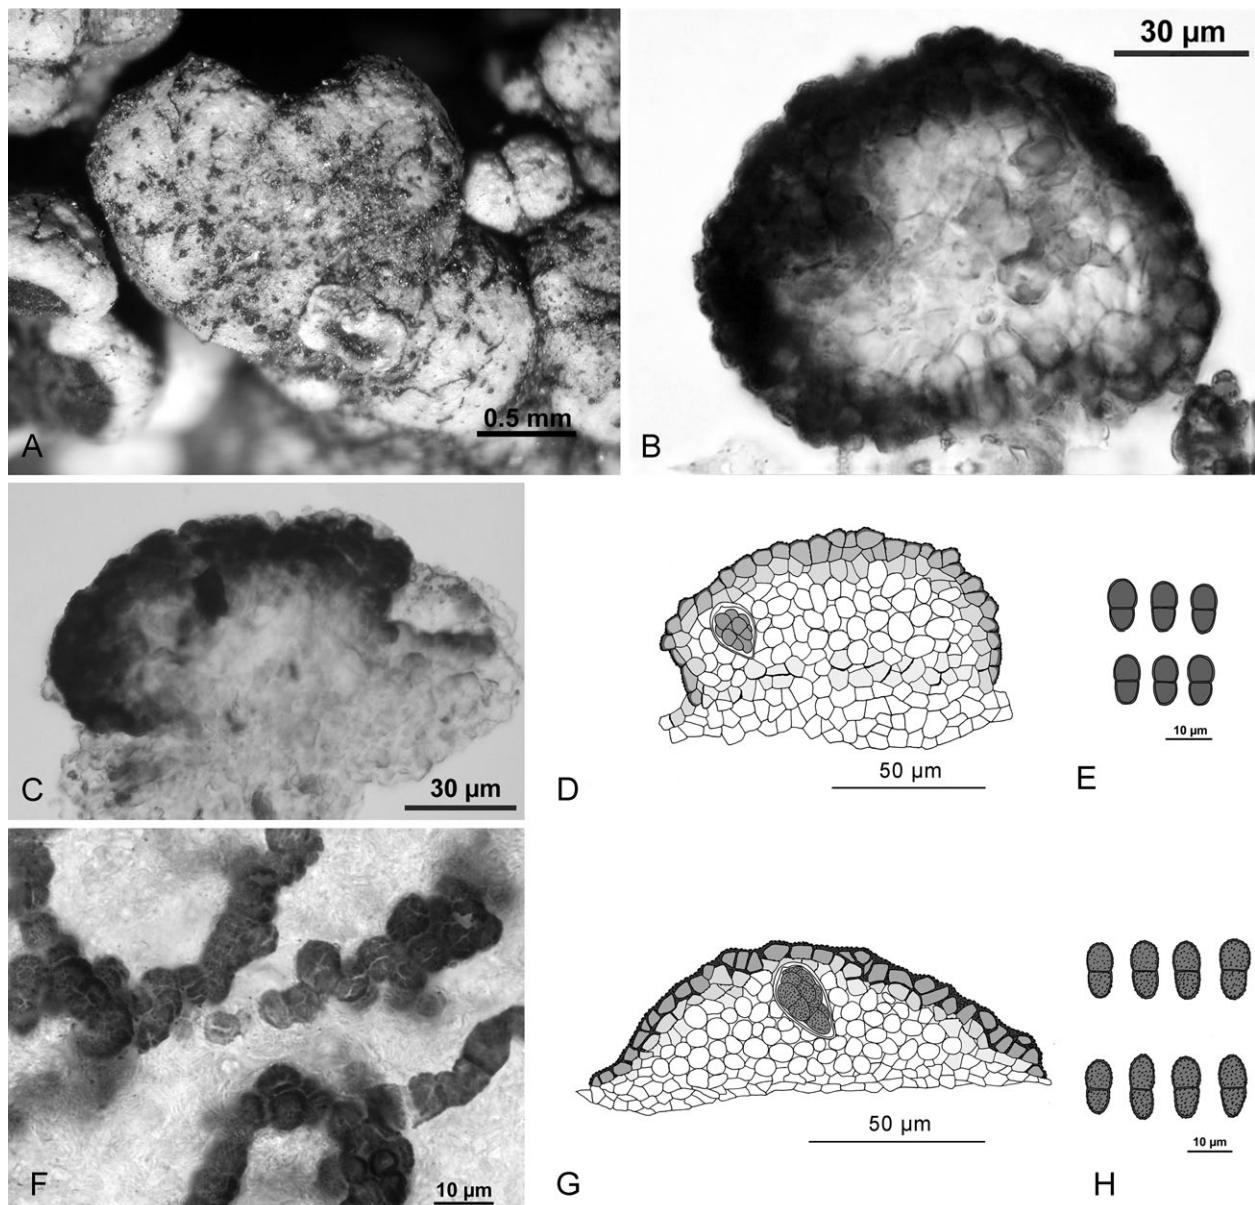

Fig. 1. A, C–D: *Lichenostigma iranicum*: on *Lobothallia praeradiosa*, habitus (A); ascoma without basal wall (C) and section through an ascoma (D); ascospores (E). – B: *L. elongatum*: ascoma with basal wall. – F–H: *L. verrucosum*: vegetative hyphal strands (F); section through an ascoma (G); ascospores (H). – A, C, F = photographs from the type collections; B = photograph from a specimen from Italy, Sicily, Prov. Palermo, on *Aspicilia calcarea* agg. (herb. IVL 3943); D, E, G, H = drawn from the type collections.

cell narrower and shorter than upper cell, $12\text{--}14(16)\times(5.5\text{--})6\text{--}7.5(9.5)\text{ }\mu\text{m}$ ($n=32$), perispore hyaline, $1\text{--}1.5\text{ }\mu\text{m}$, I+ slightly blue.

Habitat and distribution. — *Lichenostigma verrucosum* so far is known only from the type locality in Iran. It was found on *Pleopsidium gobiense* (H. Magn.) Hafellner (Acarosporaceae), on siliceous rock.

Observations. — Until now no species of *Lichenostigma* was known on hosts of the genus *Pleopsidium*. On *Acarospora*, which belongs to the same family as *Pleopsidium* (Acarosporaceae), four species of the genus have

been described: *L. subradians* Hafellner & al. on yellow and rarely on brown species of *Acarospora*, *L. gracile* Calatayud & al. on *A. fuscata*, *L. anatolicum* Halıcı & Kocakaya on an unidentified species of *Acarospora* and *L. svndae* Vondrák & Soun on *A. cervina*. The first three have clearly smaller ascospores ($9\text{--}10\times5\text{--}6\text{ }\mu\text{m}$, $9\text{--}12\times5\text{--}6\text{ }\mu\text{m}$, and $9.2\text{--}11.8\times5.5\text{--}7\text{ }\mu\text{m}$, respectively) than the new species. *L. svndae* is similar to the new species in several features, but distinguished by root-like coloured hyphae penetrating the host thallus below the ascomata and an I+ centrum. From all mentioned species *L. verrucosum* is distinguished by the easily splitting spores.

Acknowledgements

The first author expresses her gratitude to Gisela von Brackel (Röttenbach, Germany) for her encouragement and Dagmar Triebel and Andreas Beck who allowed her to visit the Botanische Staatssammlung München (M). She was financially supported by a grant from Shahid Beheshti University, Tehran, awarded to Dr H. Riahi. M. Darabi (Tehran, Iran) and Harrie Sipman (Berlin, Germany) kindly checked the manuscript. Dagmar Triebel (München, Germany) supported our work greatly by her hospitality and extensive discussions.
