

ANALYSIS AND VALIDATION OF THE D.M.A. GRAVIMETRIC DATA OF THE MEDITERRANEAN SEA

Miguel J. Sevilla

Instituto de Astronomía y Geodesia
Facultad de Ciencias Matemáticas
Universidad Complutense. 28040 MADRID

1. INTRODUCTION.

In agreement with the decisions made in Trieste in 1992, on occasion of a meeting help by the GEOMED Group, with Prof R.H.Rapp, I was charged to contact with the USA Defense Mapping Agency (DMA) in order to exchange gravity data in the Mediterranean area. The contact was made at the end of 1992 and now we dispose of new gravimetric material to include in the GEOMED Gravity Data Bank.

These DMA gravimetric data have been analyzed and the marine data corresponding to the Mediterranean Sea have been validated following the standard procedure used by the Madrid Geomed Group. In the following I present the computations made and the results obtained.

2. D.M.A. DATA.

The following material has been received from the DMA (Doodson, 1992):

- a) A magnetic tape containing 249511 point gravity anomaly records within the coordinates 25°N to 45°N; 12°W to 40°E.
- b) Source File listing.
- c) References Base Station Data Format.
- d) WGS 84 Ellipsoidal gravity formula and gravity anomaly conversion equations.

GEOMED people have the compromise of not disseminate the data external to GEOMED.

The observed gravity values are adjusted to the International Gravity Standardization Net of 1971. The theoretical gravity is the reference gravity value obtained from the gravity field of the World Geodetic System (WGS 84) reference ellipsoid of revolution. As the WGS 84 Earth's gravitational constant includes the mass of the atmosphere, the atmospheric gravity correction has been added to observed gravity. As the GEOMED Group works in the GRS 80 no system transformations are needed.

The DMA point gravity file data format has 80 characters by record and has been changed to the GEOMED format (Sevilla et al, 1991) with the following information: order number, latitude, longitude, depth, free air anomaly, observing error, and finally the validation flag; (the format is: I10, 2F12.6, 3F8.2, I3). Figure 1 shows the distribution of the DMA available gravity data in the whole area, Figure 2 shows the blocks of $1^{\circ} \times 1^{\circ}$ with DMA data in the Mediterranean Sea, and Figure 3 shows de previous GEOMED data for comparison.

D.M.A. DATA

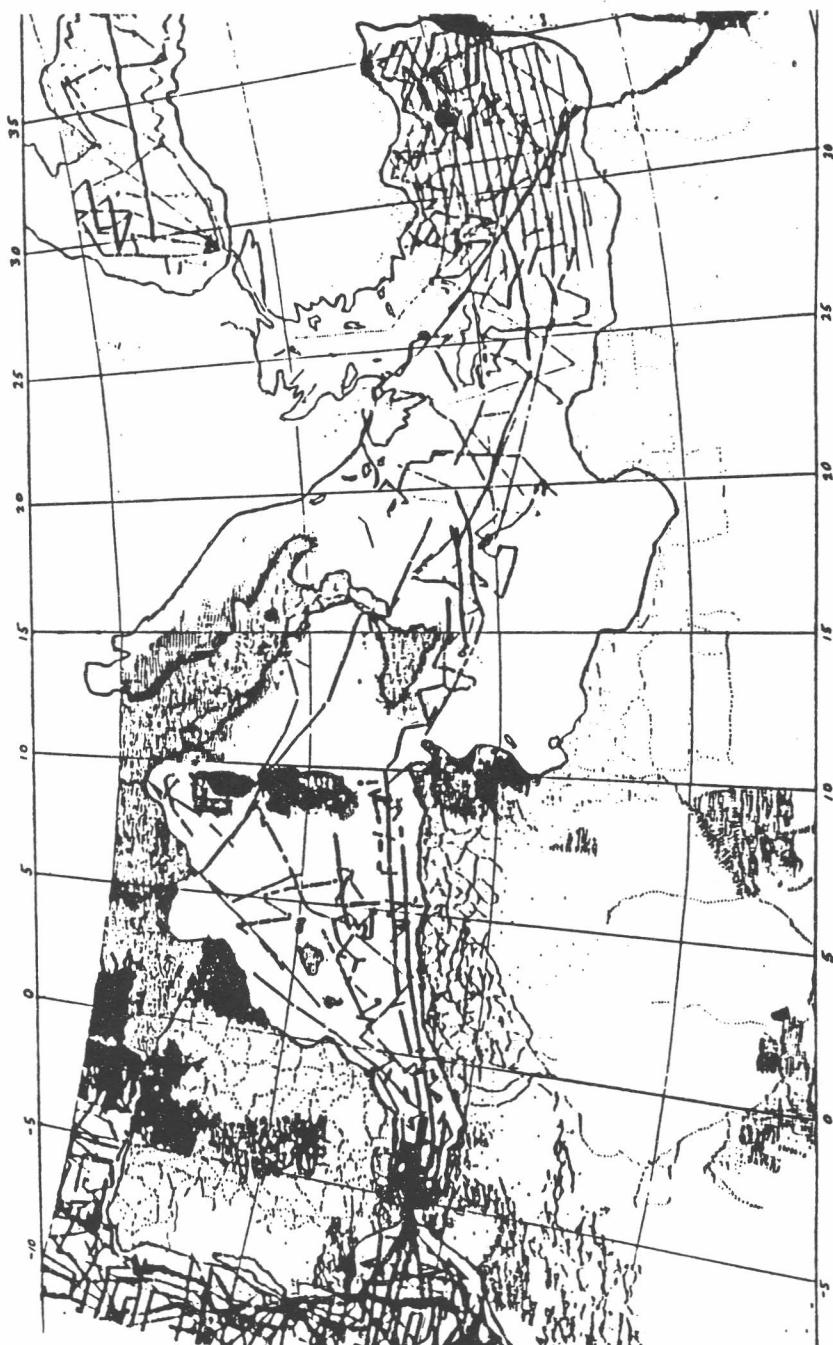

Figure 1. Distribution of the DMA gravity data

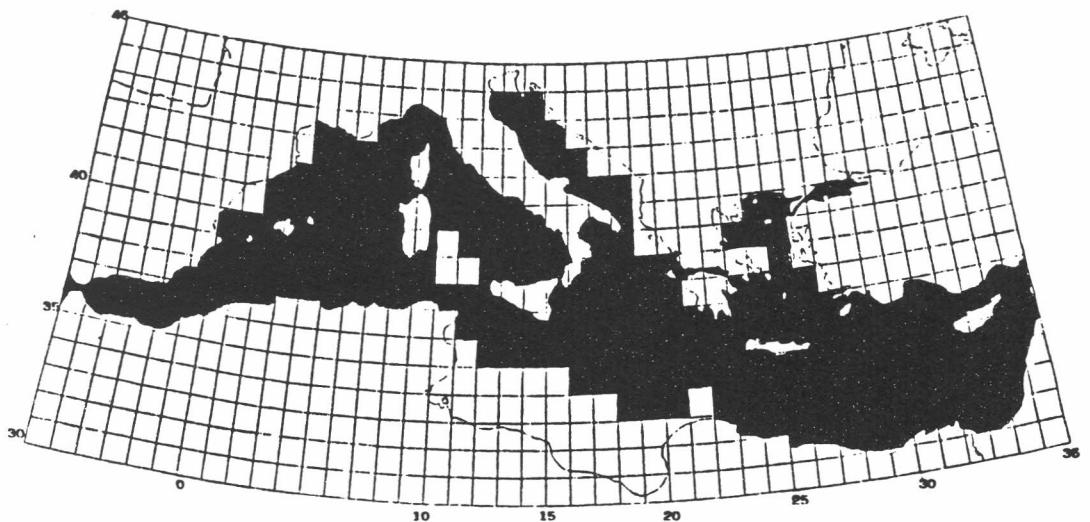

Figure 2. Blocks of $1^\circ \times 1^\circ$ with DMA data in the Mediterranean Sea

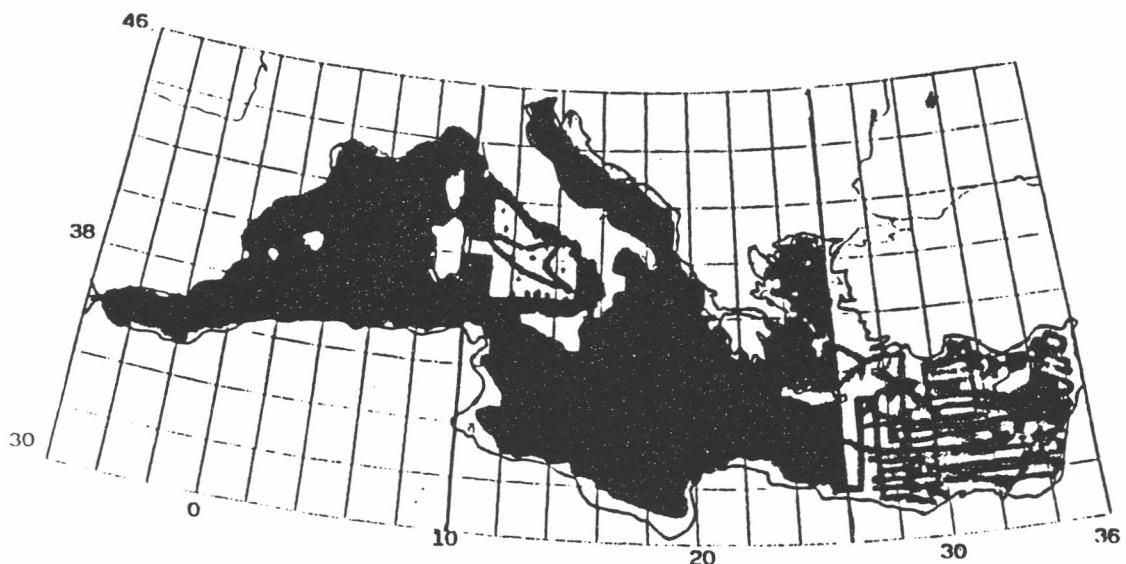

Figure 3. GEOMED data in the Mediterranean Sea

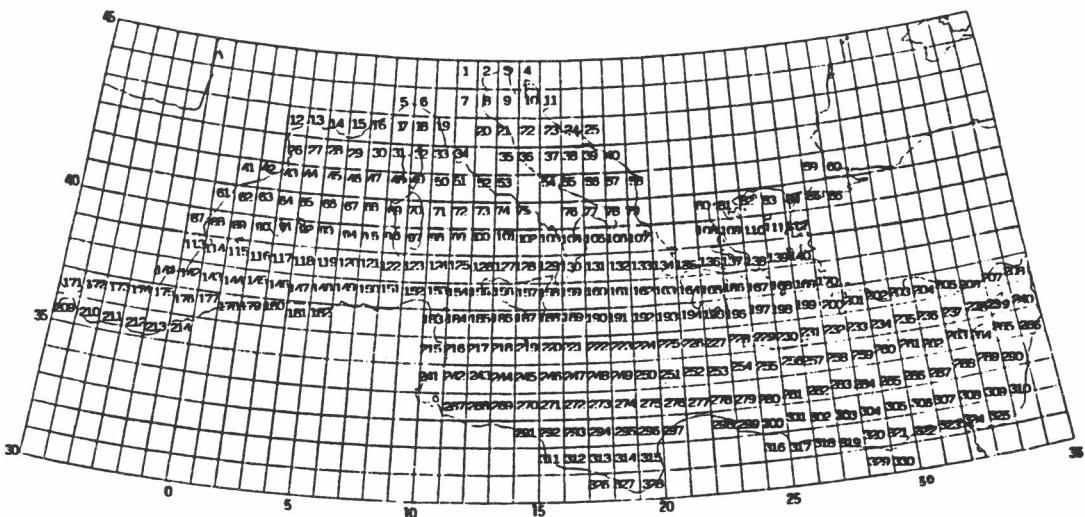

Figure 4. Distribution and numbering of the $1^\circ \times 1^\circ$ zones in the Mediterranean

2.1 Data distribution: The DMA data are distributed as follows:

59.364 land data
190.147 marine data (48.160 mediterranean data)

Following the initial classification of the Mediterranean Sea in three blocks, namely East, Central and West, and recalling also the GEOMED data, we have the result shown in Table 1.

Table 1. Summary of gravimetric data in the Mediterranean Sea

BLOCK	AREA	GEOMED DATA					DMA DATA		
		(1)	(2)	(3)	(4)	(5)	(1)	(4)	(5)
G1MED ($26 < \lambda < 36$)		4244	3652	2587	2583	2566	16175	16048	15761
G2MED ($10 < \lambda < 26$)		15972	15905	14995	15688	15633	16870	16597	16125
G3MED ($-6 < \lambda < 10$)		8390	8457	8457	8392	8376	15115	15033	14642
MEDIGRA 1+2+3		28606	28014	26039	26663	26575	48160	47678	46528

(1) = Original data, (2) = Transformed GRS80 data, (3) = Gridded data, (4) = Validated (flag 1), (5) = Validated (flag 1+2).

• This number must be supplemented in 910 point data (BGI data added to G2MED) no gridded, having a total of 26949 points in the whole raw GEOMED data file (MEDIGRA92).

2.2 Data preprocessing

First of all a comparison of the DMA data with GEOMED gravity data to find repeated points is made. The result is: No common points are detected.

3. VALIDATION PROCEDURE

The procedure applied to validate the DMA data is the following

1.- The data are classified in $1^\circ \times 1^\circ$ zones, the same zones that used in the computations of MEDIGEO92 geoid (Sevilla et al. 1992a). The distribution of these zones is shown in Figure 4 and the number of points in each zone (DMA and GEOMED) is given in Appendix A.

2.- Least squares predictions of gravity anomalies, Δg_{pre} , in the same points in which there are DMA anomalies, Δg_{DMA} , are made by using the covariance functions and the validated data used in the calculation of MEDIGEO92 in each zone (data of $2^\circ \times 2^\circ$ zones with the $1^\circ \times 1^\circ$ zones in the middle), and the prediction error is also calculated.

3.- Residual anomalies are calculated by the difference

$$\Delta g_{res} = \Delta g_{DMA} - \Delta g_{pre}$$

4.- The limit of tolerance is fixed in 20 milligals (the observing error in the DMA data run from 3 to 15 milligals).

5.- Criterion:

If $\Delta g_{res} < 20$ the point is considered good,

If $\Delta g_{res} > 20$ the point is analyzed by taking into account several circumstances:

- a) The number and the distribution of the bad points is checked in the zone. If there is a majority of bad points it is possible that the prediction is false. Then the prediction data and the covariance function are checked. This testing produces a revalidation of the GEOMED data with external sources, mainly in conflictive zones (Sevilla et al. 1992b). In some zones the validation using this procedure is not possible
- b) If the bad points are a minority, their distribution and position in the zone are studied. Normally, these points are isolated with large Δg_{res} and immediately a gross-error in the Δg_{DMA} is detected by inspection and comparison with the neighboring points (See Table 2).
- c) Sometimes, the bad points are arranged in a particular way (See Table 3). In this case the data source is the same and there can be problems with the datum definition or the datum transformation; this is not so easy to check up and these data are considered as bad data. (Really a validation procedure of marine data, as the ones published in the BGI Bulletin No 71 (Dec-92), must be applied).

Table 2. Example of accumulated bad point (DMA: Zone 019)

faa = free-air anomaly, ra = residual anomaly, pe = prediction error

6.- When there is an island in the zone, the prediction is made with the data and the covariance on the same island side on which the DMA data are located.

7.- Finally, for bad points a flag is associated in the following way:

If $20 < \Delta g_{pre} < 30$ the flag is 1

If $\Delta g_{pre} > 30$ the flag is 2

If the point has been not validated, the flag is 9

8-. The DMA Zones that cannot be validated with this procedure are show in Figure 5. This zones are: 82, 84, 85, 86, 97, 111, 139, 166, 167, 168, 195, 196, 197, 199, 200, 201, 203, 207, 229, 231, 232, 233, 234, 257, 258, 263, 275, 290e, 298, 324, 325, 325e.

9.- In all these calculations we have used the GEOCOL10 program (C.C. Tscherning).

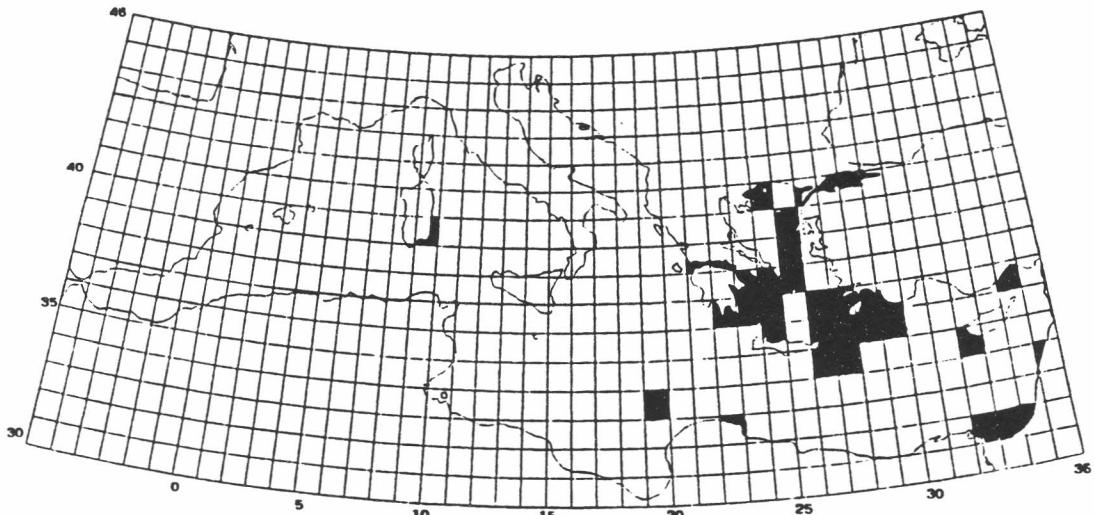

Figure 5. DMA Zones no validated

4.- STATISTICAL ANALYSIS OF THE GRAVIMETRIC DATA

4.1. Geopotential model comparison

The first step in the statistical analysis is the calculation of model anomalies with three geopotential models: IFE88E2, OSU89B and OSU91AIF; then a comparison with the observed anomalies is made to establish the model that better suits the gravity field in the area. In Appendix A we have the results of these calculations, considering separately each block of Table 1 and also

the sum blocks 1+2 and 1+2+3, i.e. the whole Mediterranean Sea. As sight these results we can conclude that in all the cases the model that best fits the gravity field in the Mediterranean Sea is the IFE88E2 one, and the rejected points in validation have not influence on this conclusion.

4.2. Comparative analysis between GEOMED data and DMA data

From Appendix A we select the GEOMED and DMA observed anomalies and the respective IFE88E2 reduced anomalies, both without having rejected any point as Table 4 shows.

For the raw data, a systematic difference is detected, especially in BLOCKS 1 and 3. The DMA anomalies are greater than the GEOMED anomalies, the standard deviations are also greater. This seems a consequence of the smoothing. The geopotential models fits better the GEOMED data, i.e. the standard deviations are minor.

Table 4. Statistical parameters of the raw data

STATISTIC OF THE OBSERVED FREE-AIR ANOMALIES

	NUMBER	MEAN	SD	MINIMUM	MAXIMUM	RANGE
GMG BLOCK 1	2587	-45.95	53.24	-216.31	96.78	313.09
DMA BLOCK 1	16175	-52.50	62.11	-239.10	147.30	386.40

DMA BLOCK 1+2+3	48160	-3.78	22.10	-129.11	117.23	246.34

As the rejected points in validations do not have influence in these differences, and to make a further analysis, a new calculation using the DMA data excluding the points with flag 9, (i.e. the no validated points) is made. Now we get the Appendix B and the Table 4.

In BLOCKS 1 and 2 the large differences in reduced anomalies have disappeared and the values become very similar to the GEOMED data. This is not the result for the BLOCK 3. As to get this results has been needed to reject 4836 points in BLOCK 1 and 1904 in BLOCK 2, and only 39 in BLOCK 3, a further analysis must be done. A proposition is clear: Do not work with no validated raw data.

4.3. Gridding effect in the G1MED block.

The original G1MED block consists on 4244 gravity points irregularly distributed in the interval $31.1^\circ\phi<37.6$, $16.6^\circ\lambda<35.6$. These points have been classified in two blocks with the actual limits of G1MED and G2MED; The result is 3652 gravity points in the interval $26^\circ\lambda<36$ (G1MEDINI) and 592 in the interval $16^\circ\lambda<26$ (G2MED SUP).

The statistical analysis of these blocks is shown in Appendix C and Table 3. We can see the variations of the statistical parameters: the block G1MED(3652 points) fits the IFE88E2 model better than the block G2MED(592 points). These 592 points have been rejected from the MEDIGRA92 FILE.

If we compare the GIMED(3652 points) with the GIMED(2587 gridded points) we see the effect of gridding that reduce the mean and the standard deviations of the free air gravity anomalies due to the missing of extreme values. Therefore, a smoothing has been produced in the data bank and it is possible that some high frequency of the gravity field has been lost.

Table 5. Gridding effects on the free-air anomalies in the GIMED block

STATISTIC OF THE OBSERVED FREE-AIR ANOMALIES

5. ANALYSIS OF THE MEDIGEO92 THROUGH EXTERNAL GRAVIMETRIC CONTROL

In Section 3 we have mentioned that using the DMA data it is possible to revalidate the GEOMED data through external control. The GEOMED and the DMA data are completely independent, the former are taken by digitization of appropriate cartography (or by gridding) and the later are directly points of measurements. The correct prediction of DMA anomalies with GEOMED data and covariances is an indicative of a correct prediction of geoid undulations, therefore, having made these predictions in all the zones, when a prediction is not correct we change the data and covariance till getting success in the task or to mark the zone as no valuable. After this, we have the conclusions shown in Table 4 (Compare with the conflictive zones in Sevilla et al. 1992b).

6. ACKNOWLEDGEMENTS

This work is a contribution to the GEOMED Project sponsored by European Community contract No. sci*-ct92-0808. I am gratefully acknowledge the support of Professor C.C. Tscherning who has provided the main software package. I thank Dr. L.L. Dootson from DMA who has provided the gravimetric data. Also I thank the Centro Informático de Somosaguas (UCM Madrid) the facilities in the use of the CONVEX-210 Computer.
