FOREWORD

This document, *Benthic Community Condition at Ambient Toxicity Program Sites, 2001*, was prepared by Versar, Inc. at the request of Mr. Bruce Michael of the Maryland Department of Natural Resources under Cooperative Agreement CA-02-01/07-4-30722-3734 between Versar, Inc., and the University of Maryland Center for Environmental and Estuarine Studies. The report assesses the status of Chesapeake Bay benthic communities at sites in four Maryland eastern shore tributaries.

1.0 INTRODUCTION

In September 2001, the Maryland Department of Natural Resources conducted a study to assess water quality, sediment quality, and the quality of biological resources at 20 sites in the tidal Chesapeake Bay. These sites were located in four tributaries of the eastern shore of Maryland: Wye River, Wicomico River, Manokin River, and Big Annemessex River. Water quality, sediment chemistry, sediment toxicity, and benthic invertebrate data were collected at each site. This document presents the results of the benthic portion of the study.

2.0 METHODS

2.1 SAMPLE COLLECTION

Benthic samples for the Ambient Toxicity study were collected at twenty sites on 26 to 28 September 2001. Five sites were sampled in the mesohaline portion of each tributary. Sampling locations are provided in Table 2-1 and Figures 2-1 and 2-2.

Table 2-1. Sampling locations. NAD83 datum.

Tributary	Station	Latitude	Longitude
Wye River	WY-112	38.8807733	76.1585083

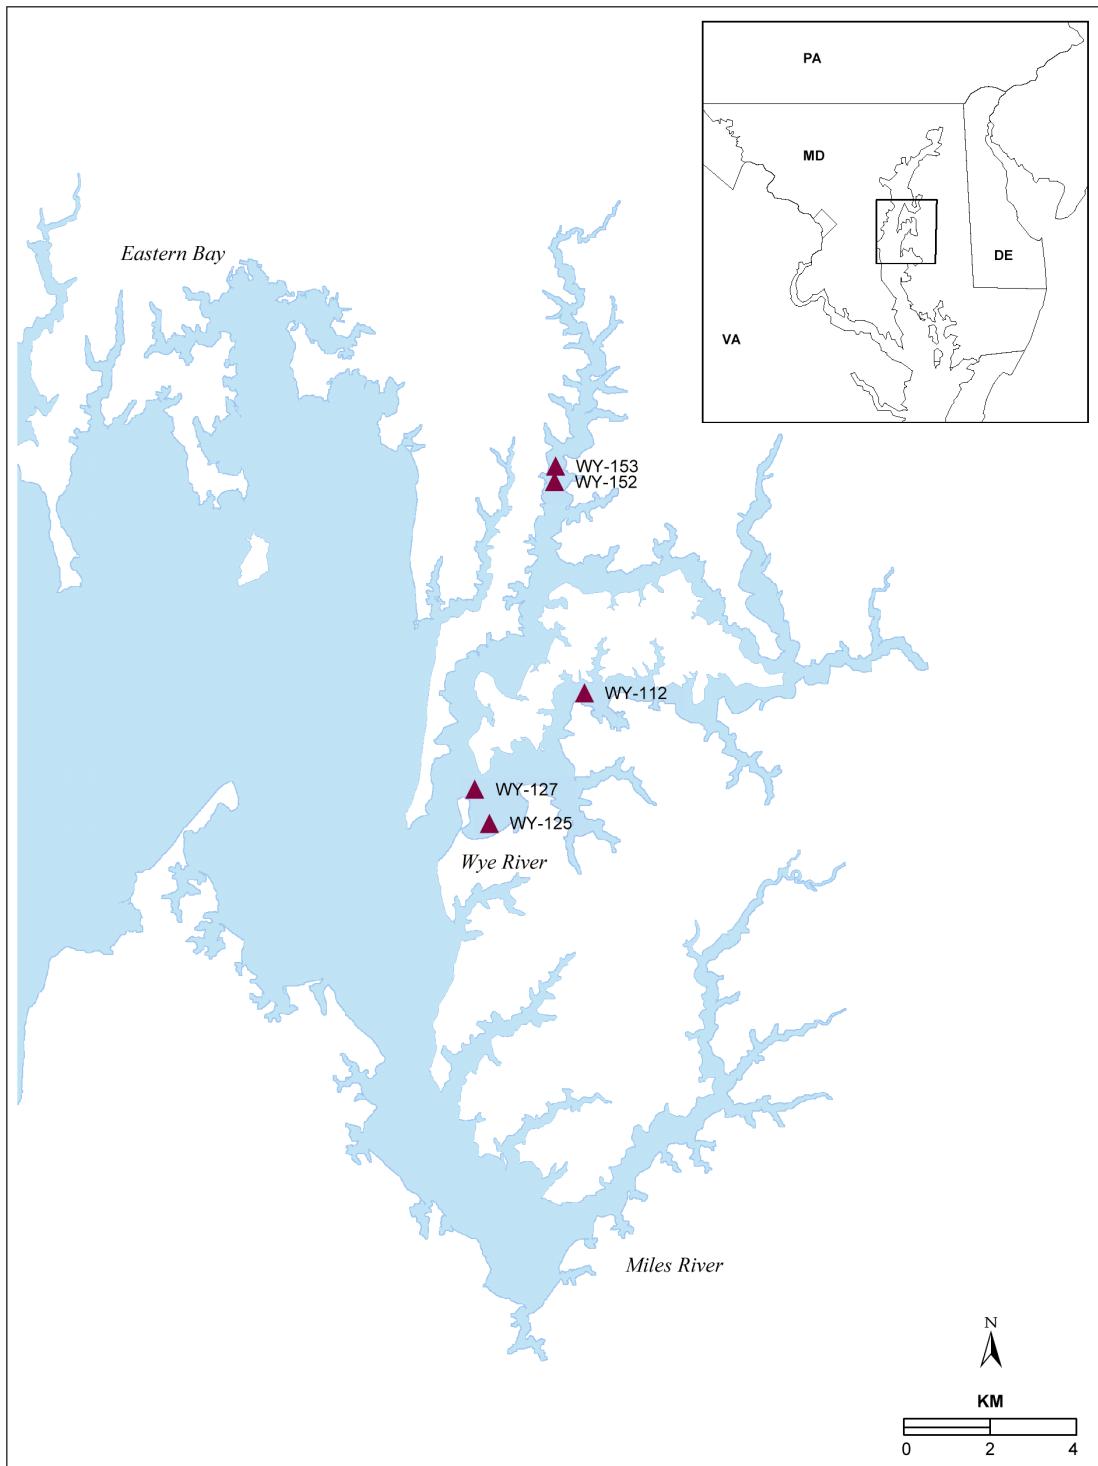

Figure 2-1. 2001 Ambient Toxicity Program sampling locations in the Wye River.

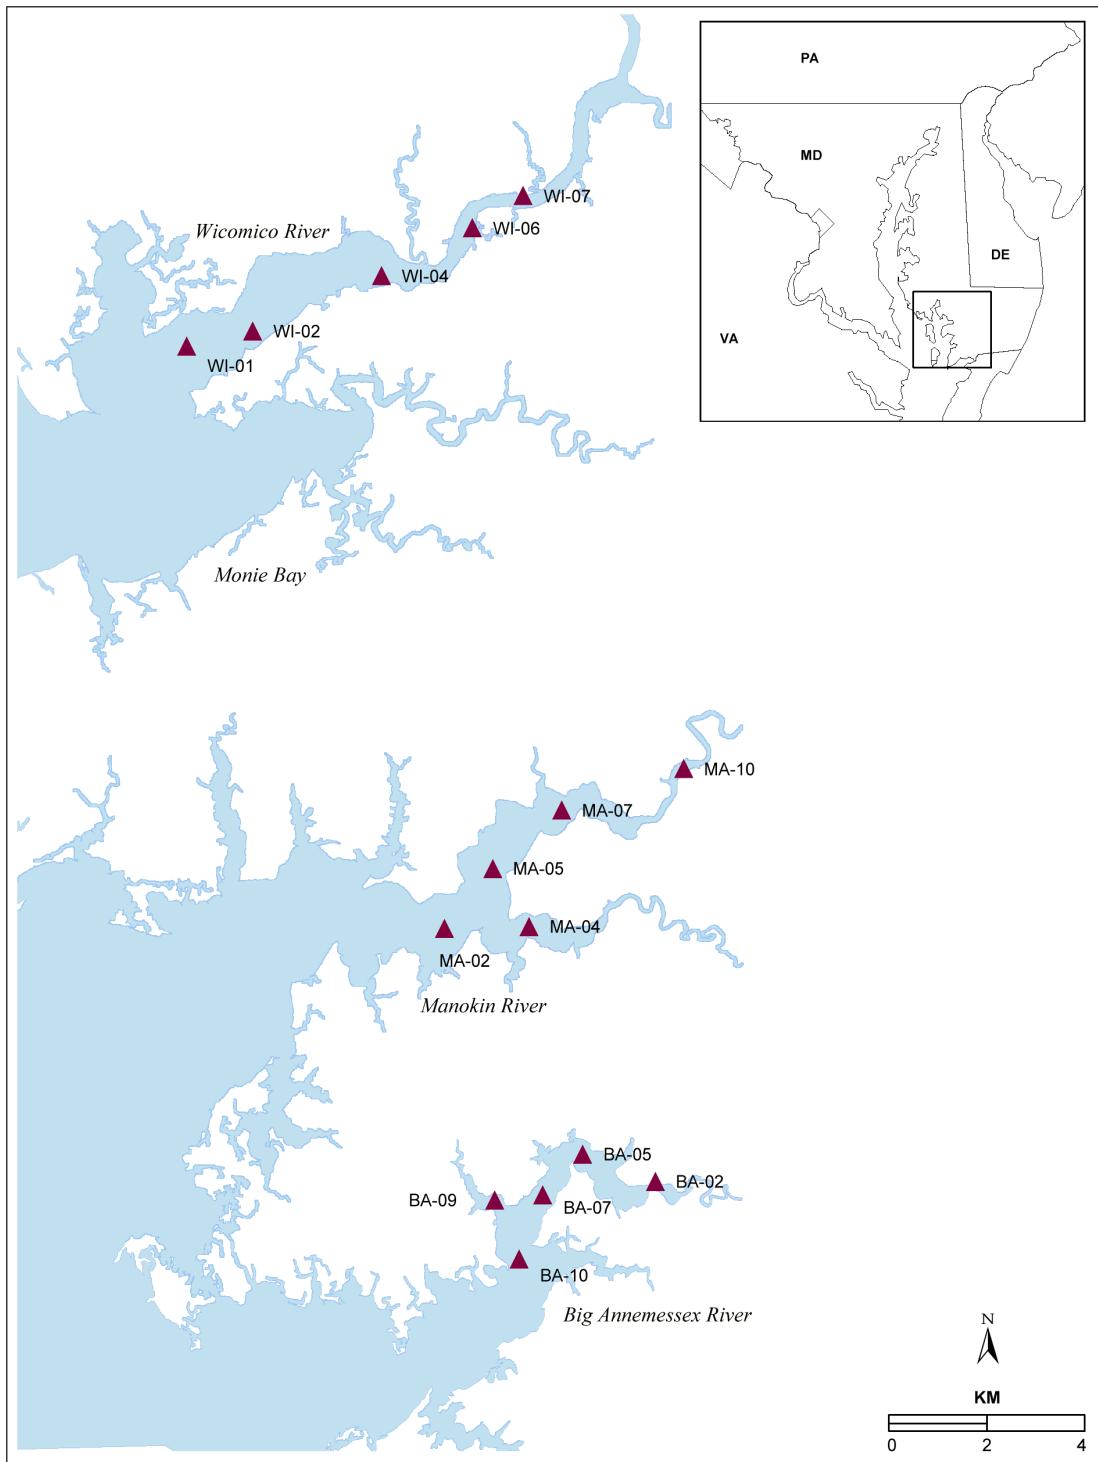

Figure 2-2. 2001 Ambient Toxicity Program sampling locations in the Wicomico, Manokin, and Big Annemessex Rivers.

Benthic samples were collected with a Young Grab, which samples an area of 440 cm² to a depth of 10 cm. One benthic grab sample was collected at each site and all samples were sieved through a 0.5-mm screen using an elutriative process. Organisms retained on the screen were transferred to labeled jars and preserved in 10% buffered formalin stained with Rose Bengal (a vital stain used to aid separation of organisms from sediment and detritus). One additional grab sample was collected from each site for percent silt/clay and total organic carbon (TOC) analysis of sediments. Two surficial sediment samples (approximately 120 ml each) from this grab were frozen until processed in the laboratory. Bottom water temperature, conductivity, salinity, dissolved oxygen concentration (DO), and pH were measured at each site with a Hydrolab DataSonde 3 unit.

2.2 LABORATORY PROCESSING

Organisms were sorted from detritus under dissecting microscopes, transferred to 70% ethanol, identified to the lowest practical taxonomic level, and counted. Ash-free dry weight biomass was measured for each species by drying the organisms to a constant weight at 60 °C followed by ashing in a muffle furnace at 500 °C for four hours.

Oligochaetes and chironomid midges were mounted on microscope slides, examined under a compound microscope, and identified to genus and species following procedures based upon currently accepted practices in benthic ecology. The protocol is as follows. If the number of oligochaetes or chironomids in a sample is over 20 individuals, the sample is split and 50% of the specimens are mounted. The remaining portion is saved and used for biomass determinations. The sample is split by evenly spreading the specimens in a gridded tray and selecting half of the total number of grids at random. Total taxonomic counts for each oligochaete or chironomid species are adjusted by the proportion of the total number of specimens mounted in the sample. Total oligochaete or chironomid biomass is estimated by weighing the unmounted specimens and multiplying by 2. Because most species of oligochaetes and chironomids need to be slide-mounted for identification, species-specific biomass cannot be provided except for *Tubificoides* spp. and *Coelotanypus* spp., which do not need slide mounting for identification.

Sand and silt-clay particles were separated by wet-sieving through a 63: stainless steel sieve and weighed using the procedures described by Plumb (1981) and Buchanan (1984). Total organic carbon (TOC) was analyzed on an Exeter Analytical Inc., Model CE-440 Analyzer by the Analytical Services Department of Chesapeake Biological Laboratory. The TOC is determined by performing separate total carbon (TC) and total inorganic carbon analyses (TIC) and subtracting the results. TC is analyzed by high temperature combustion and subsequent measurement of the carbon dioxide produced by thermal conductivity detection. TIC is analyzed by first ashing the sample in a muffle furnace at low temperature to remove the organic carbon, and then applying high temperature combustion to the remaining inorganic carbon in the ash.

2.3 DATA ANALYSIS

Analyses were performed in the context of the Chesapeake Bay Program Benthic Community Restoration Goals, which use the Benthic Index of Biotic Integrity (B-IBI) to measure goal attainment. The Chesapeake Bay B-IBI is described in Weisberg et al (1997) and Alden et al. (2002). A detailed account of the procedures used in the calculation of the B-IBI can be found on the World Wide Web at the following address:

<http://www.baybenthos.versar.com/results/sampback.htm>.

2.3.1 The B-IBI and the Chesapeake Bay Benthic Community Restoration Goals

The B-IBI is a multiple-attribute index developed to identify the degree to which a benthic assemblage meets the Chesapeake Bay Program Benthic Community Restoration Goals. The Restoration Goals are quantitative thresholds based on reference data distributions (Weisberg et al. 1997). The B-IBI provides a means for comparing the relative condition of benthic invertebrate assemblages across different habitats. It also provides a validated mechanism for integrating several benthic community attributes indicative of "health" into a single number that measures overall benthic community condition.

The B-IBI is scaled from 1 to 5. Sites with values of 3.0 or more are considered to meet the Restoration Goals. The index is calculated by scoring each of several attributes as either 5, 3, or 1 depending on whether the value of the attribute approximates, deviates slightly from, or deviates strongly from values at the best reference sites in similar habitats, and then averaging these scores across attributes. The criteria for assigning these scores are numeric and habitat-dependent.

Benthic community condition was classified into four levels based on the B-IBI. Values less than or equal to 2.0 were classified as severely degraded; values from 2.0 to 2.6 were classified as degraded; values between 2.7 and 3.0 were classified as marginal, and values of 3.0 or more were classified as meeting the goals.

3.0 RESULTS

For each of the 2001 Ambient Toxicity Program sites, B-IBI values and the corresponding benthic community condition are presented in Table 3-1 and Figures 3-1 and 3-2. Station-specific water quality measurements and sediment composition are provided in Table 3-2. Details of the water quality measurements, sediment composition, species abundance and biomass, and metric scores are provided in the Appendix.

Table 3-1. B-IBI values and benthic community condition at 2001 Ambient Toxicity Program sites.

Tributary	Station	B-IBI Value	Benthic Community Condition	Metrics Scoring 1
Wye River	WY-112	4.3	Meets Goal	none
	WY-125	3.7	Meets Goal	none
	WY-127	1.0	Severely Degraded	All metrics
	WY-152	4.0	Meets Goal	none
	WY-153	4.0	Meets Goal	none
Wicomico River	WI-01	2.7	Marginal	Pollution-sensitive sp. biomass
	WI-02	3.4	Meets Goal	Pollution-sensitive sp. biomass
	WI-04	3.0	Meets Goal	Total biomass, pollution-indicative sp. abundance
	WI-06	4.6	Meets Goal	none
	WI-07	2.6	Degraded	Total biomass, pollution-indicative sp. abundance
Manokin River	MA-02	3.3	Meets Goal	Pollution-sensitive sp. biomass
	MA-04	4.0	Meets Goal	none
	MA-05	3.3	Meets Goal	Total abundance
	MA-07	3.0	Meets Goal	Diversity, Carnivore/Omnivore abundance
	MA-10	3.8	Meets Goal	none
Big Annemessex River	BA-02	2.7	Marginal	Diversity, Total abundance, Carnivore/Omnivore abundance
	BA-05	3.7	Meets Goal	Pollution-sensitive sp. biomass
	BA-07	3.0	Meets Goal	Pollution-sensitive sp. biomass
	BA-09	3.7	Meets Goal	none
	BA-10	3.7	Meets Goal	none

For all sites, salinity was in the low (5-12 psu) or high (12-18 psu) mesohaline range (Table 3-2). Bottom water temperature was typical of late summer conditions in shallow water tributaries of the Chesapeake Bay, fluctuating between 20 and 23 °C. Dissolved oxygen concentrations in the water column indicated oxygen saturated or super-saturated conditions. Total organic carbon in sediments ranged from 1.1 % at Station 5 in the Manokin River to 4.7 at Station 2 in the Big Annemessex River, with no indication of organic enrichment being a problem. Except for the Manokin River (Stations 5 and 10), the substrate was muddy (> 40% silt/clay).

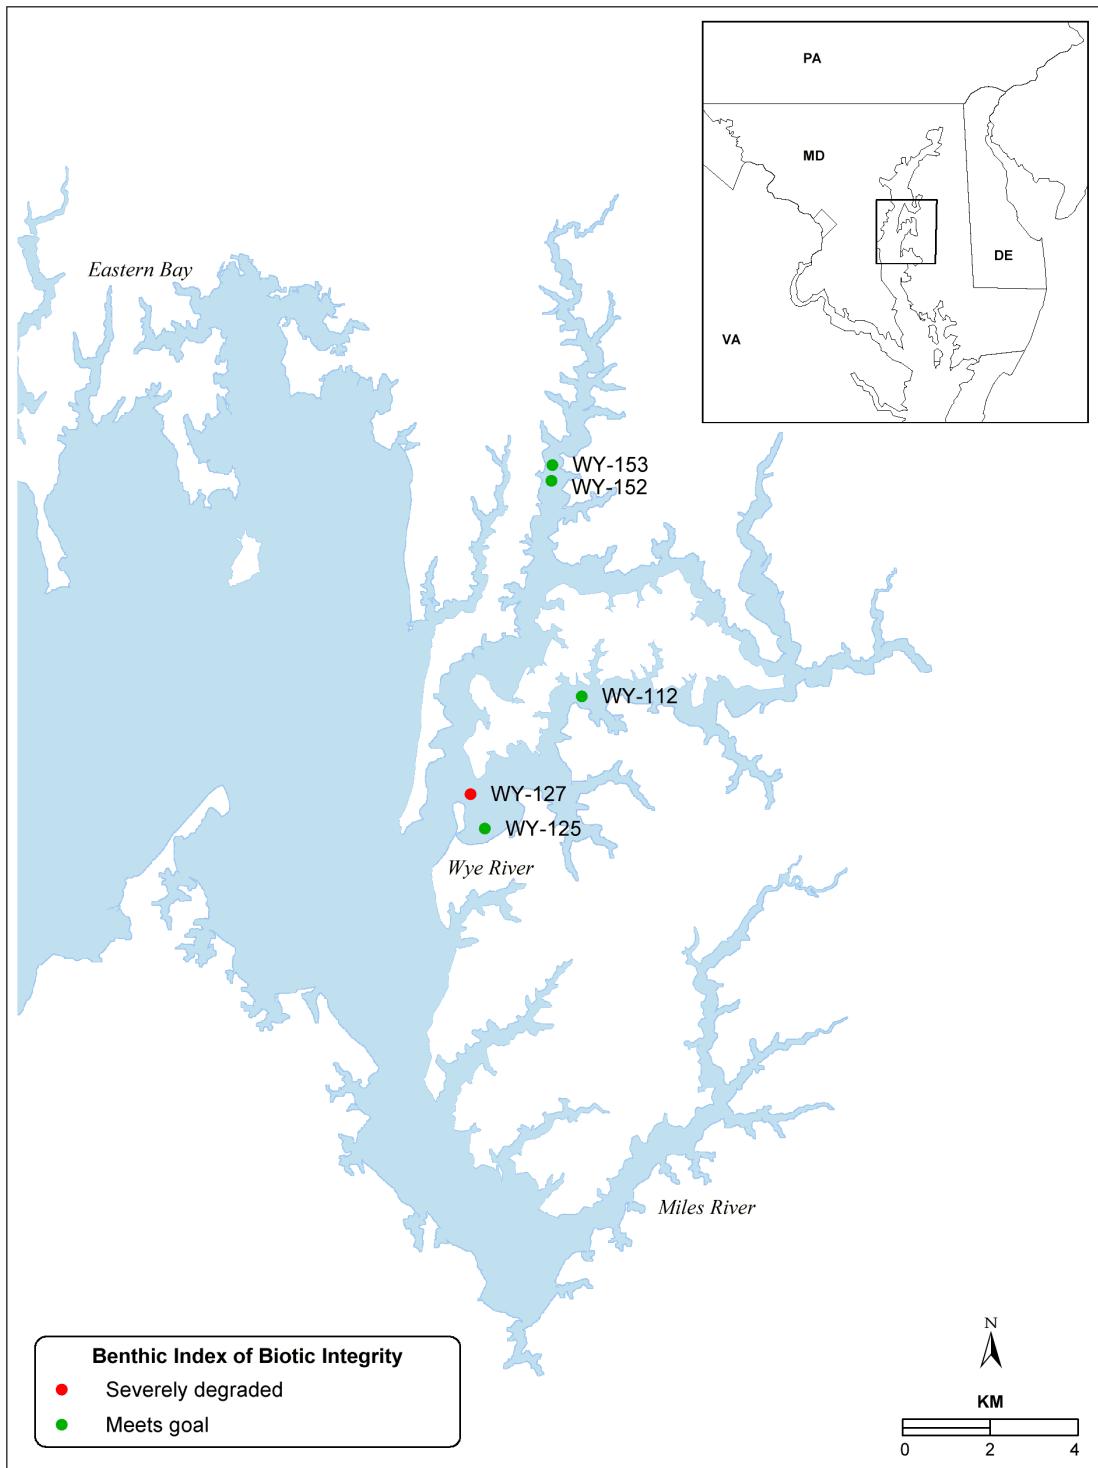

Figure 3-1. Benthic community condition at the 2001 Ambient Toxicity Program sites in the Wye River.

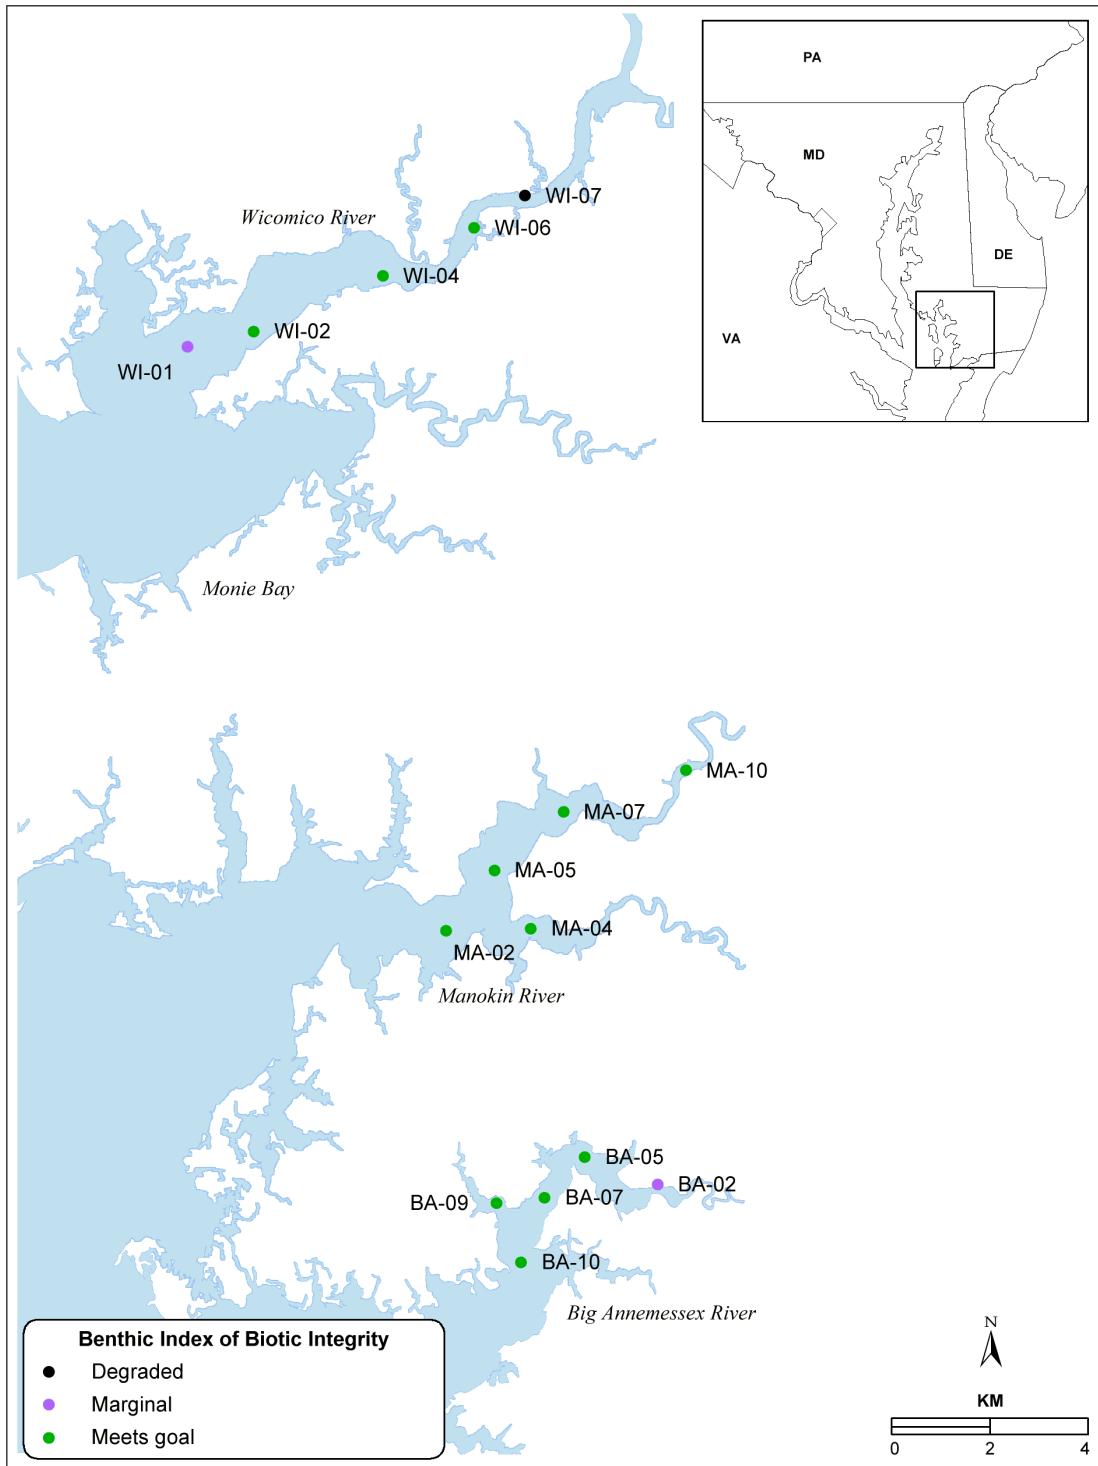

Figure 3-2. Benthic community condition at 2001 Ambient Toxicity Program sites in the Wicomico, Manokin, and Bay Annemessex Rivers.

Table 3-2. Site-specific water quality measurements near the bottom and sediment composition.

Sixteen sites met the Benthic Community Restoration Goals for Chesapeake Bay and four sites failed the goals (Table 3-1, Figure 3-1). Of the four sites that failed, two were classified as marginally degraded, one was classified as degraded, and one was classified as severely degraded.

Benthic community condition in the Wye River was best overall, except for Site 127, which was severely degraded (Table 3-1). All benthic community attributes at this site indicated severe impairment. Site 127 had few species and the community was numerically dominated by the opportunist polychaete annelid *Streblospio benedicti* (see Appendix). Some community attributes at sites in the Manokin River were below Chesapeake Bay reference values; however, the B-IBI indicated good benthic community condition at all sites in this tributary. Two sites in the Wicomico River failed the B-IBI, but these sites were only marginally or moderately degraded, within the range of error typically associated with the B-IBI. Likewise, one site failing the B-IBI in the Big Annemessex River was only marginally degraded. This last site (Site BA-02) indicated over-abundance with numerical dominance of the oligochaete annelid *Tubificoides* sp. While excess abundance of *Tubificoides* may be

indicative or organic pollution, this small organism is usually found in high numbers in natural situations near marshes and small creeks.

Overall, and except for Site 127 in the Wye River, benthic community condition in the mesohaline portion of the Maryland eastern shore tributaries here studied was good indicative of good sediment quality. No interpretation is possible with these data as to the causes of severe impairment at Site 127.
