Freshwater Mussel Survey and Comparison of Two Black River Alternative Crossings for ARDOT Job 100512  
Walnut Ridge - Missouri State Line (Future I-57) in Clay and Randolph Counties, Arkansas

### Introduction

Several endangered mussel species presently occur or have historically occurred in the Black River, Arkansas including *Epioblasma triquetra* (Rafinesque 1820), *Lampsilis abrupta* (Say 1831), *Potamilus leptodon* (Rafinesque 1820), and *Theliderma cylindrica* (Say 1817) (Harris *et al.* 2007, 2010; Bouldin *et al.* 2013, Christian *et al.* 2021).

Additionally, substantial mussel assemblages (mussel beds) are known to occur in the Black River that are extremely important to maintaining species richness and genetic diversity throughout the system (Rust 1993).

A mussel survey was performed to determine if federally protected mussel species exist within the area of potential effect for proposed four-lane highway facility alternative crossings of the Black River associated with Arkansas Department of Transportation Project 100512, Walnut Ridge - Missouri State Line (Future I-57). Two alternative river crossings, named Alternative 2 and Alternative 3, are proposed at sites on the Black River as illustrated in Figure 1. Alternative 2 is located approximately 1.6 river kilometers upstream of the confluence of Black River and Current River and approximately 3.74 air miles (6.0 air kilometers) ESE of the U. S. Hwy 63 crossing of Black River in Pocahontas. Alternative 3 is located approximately 9.55 river miles (15.4 river kilometers) downstream of and 4.57 air miles (7.35 air kilometers) SW of the U. S. Hwy 62 crossing of Black River east of Corning.

### Methods

A mussel survey of the proposed 400-foot (122-meter) wide Alternative 2 corridor was conducted during 16-17 October and 6 November 2021 and during 30-31 October 2021 for the Alternative 3 corridor. The surveyors utilized dive techniques with surface supplied air provided by a Brownies hookah rig apparatus supported from a boat mounted dive platform consisting of a 16-ft (4.9-m) Weldbilt jon-boat powered by a 30-horsepower Evinrude outboard motor. The diver was equipped with an AGA full face mask allowing diver to surface communication via Mach II-BUDS (diver) and an Ocean Tech STX 101 surface system. Communication was essential for the field assistant to direct the diver on transects in areas without current velocity and for the diver to provide

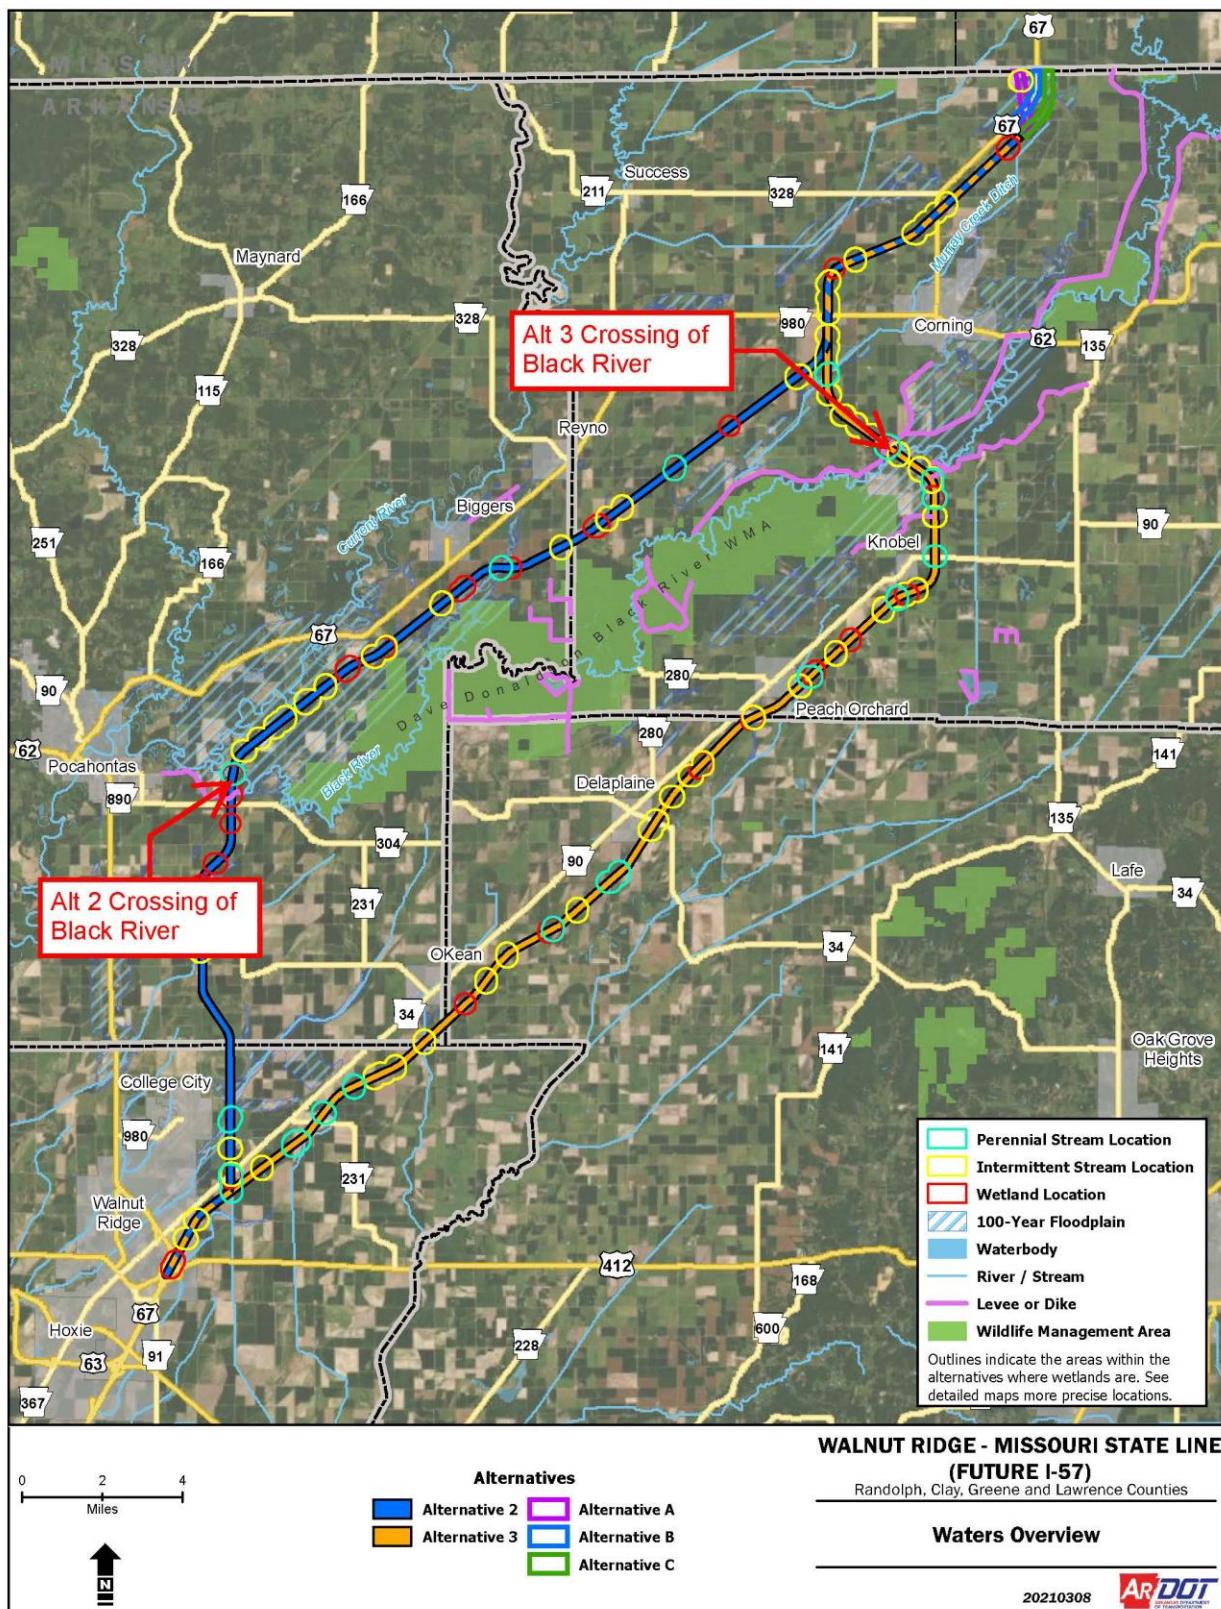

Figure 1. Mussel survey project locations.

mussel density, substrate, and river conditions data to the assistant. Water depths were determined with a Humminbird 560 Fishfinder boat mounted depth finder or a Sokkia fiberglass 25-ft (7.6-m) depth rod. Dive locations within the survey area were recorded utilizing a Garmin GPSMAP 64st global positioning satellite receiver. The diver provided substrate conditions for each search cell by estimating percent surface substrate composition using the modified Wentworth Scale.

The effort required to find protected species is often considerable, and they are rarely collected in quantitative samples (Kovalak *et al.* 1986). Overall, the qualitative timed-search approach with limited excavation may be the best for detecting mussel presence or demonstrating a reasonable probability of mussel absence (EPA 2013); therefore, our preferred survey method was qualitative timed searches.

Searches were conducted along the entire channel width of the Black River at both alternative corridor sites. The proposed alternative corridor crossings are each 400-ft (122-m) in width. Transects perpendicular to river flow were established at approximately 50-ft (15-m) intervals from the downstream to the upstream termini for each alternative. A tape measure was walked along the shoreline where feasible, and pin flags were placed at the upstream and downstream boundary for each search cell. Where vertical riverbanks prevented shoreline access, a Nikon PROSTAFF 7i laser rangefinder was used to measure distances for search cell limits. Cell boundaries in mid-river were marked by anchored buoys with their distance perpendicular from shore measured using the Nikon PROSTAFF 7i laser rangefinder from the anchored boat. GPS coordinates were recorded from the right descending bank (RDB) and left descending bank (LDB) pin flags for the transects established at 50-ft (15.2-m) intervals and at the mid-river buoys of the transects at 100-ft (30.5-m) intervals. The perpendicular transects and centerline points were used to establish 16 rectangular search cells at each alternative crossing. The search cells were abutted end to end so that the entire proposed corridor width of the Black River at each alternative crossing was surveyed.

Survey methodology consisted of tactile searches using a zigzag pattern (near shore to mid-river) from upstream to downstream within each search cell. Search cells were each approximately 50-feet (15 m) long (upstream to downstream) and ranged in width (shoreline to midchannel) from approximately 66 to 82 ft (20 to 25m) at Alternative 2 and 92 to 112 ft (28 to 34 m) at Alternative 3. Search time was recorded for each of the 16 search cells at each proposed crossing. Cell searches began at the downstream limit of the survey areas (cells 1 and 2) and proceeded upstream until completion of all cells. For

Alternative 2 and Alternative 3, all cells along the RDB (odd numbered cells) were searched on the first day at the site, and all cells along the LDB (even numbered sites) were searched on the second day. Alternative 3 required additional search time on a third day to complete the survey effort.

Mussels were identified to species, enumerated, and any federally listed species were measured for length, width, and height to the nearest 0.1 mm with digital calipers and photographed. Nomenclature generally follows Williams *et al.* (2017) except where modified by recent research as documented by the FMCS Common and Scientific Names subcommittee (FMCS 2022). Catch per unit effort (CPUE) values were calculated as the number of live mussels obtained per 10 minutes of search effort. Cumulative species richness was plotted against cumulative search time to determine where the plot reached horizontal stability signifying the majority of species were recovered. Ecological Specialists, Inc. (2006) were able to reach species richness asymptotic values in 170 minutes and 270 minutes search time during surveys of two low density mussel concentrations in the White River, DeValls Bluff, AR. Those survey conditions were similar to conditions for the Black River survey sites. Metcalfe-Smith *et al.* (2000) found that 4.5-hrs search time was generally sufficient to recover ~93% of species in their survey rivers. For our survey, three consecutive 20-minute search intervals with no additional species added (after at least 210 minutes search time) was considered the termination point for the survey.

## Results

Tables 1 and 2 summarize the results of 16 dive searches conducted during the survey at Alternative 2 and Alternative 3, respectively. Individual data sheets for each dive search at Alternative 2 and Alternative 3 are found in Appendix A and Appendix B, respectively. The locations of Alternative 2 and Alternative 3 search cells are illustrated in Figures 2 and 3, respectively.

A total of 609 live mussels representing 23 taxa were encountered during 334 minutes (~5.6 hours) of search time for Alternative 2. Alternative 2 catch per 10-minute effort ranged from 3.6 to 38.2 with a mean of 18.2. The cumulative species versus cumulative time searched is illustrated in Figure 4a, and horizontal stability (at 23 species) was reached after approximately 180 minutes search time. Mussel densities were greatest along the right descending bank in search cells 3, 5, 7, 9, 11, 13. Maximum density in the survey area was estimated at approximately 10 live mussels per square meter in search

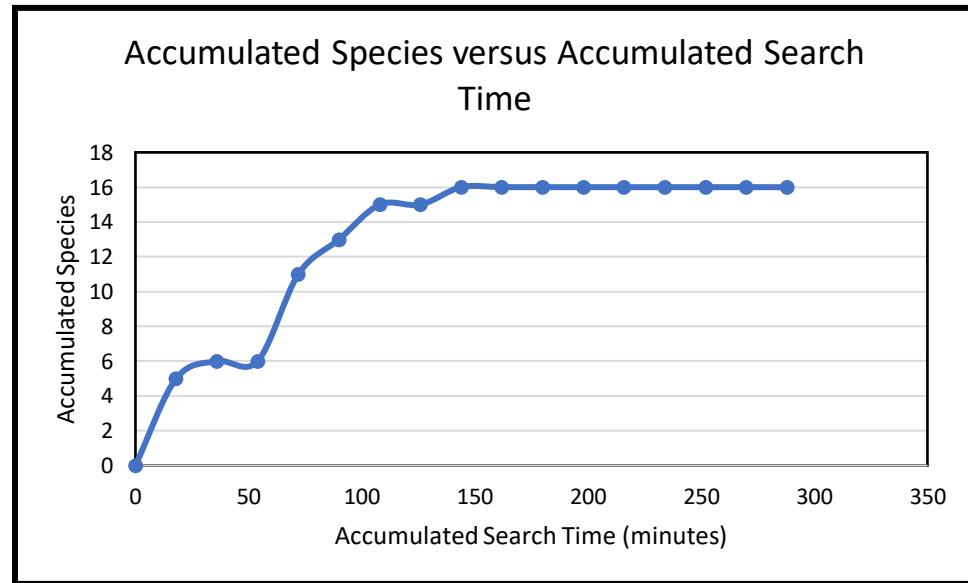

Figure 4b. Alternative 3 cumulative species versus cumulative search time.

cells 5, 7, 9, 11 along the right descending bank. The mussel assemblage at Alternative 2 was dominated by *Cyclonaias pustulosa* (302 of 609 individuals) representing 49.6% of the live mussels found. The next most abundant species was *Potamilus purpuratus* at 8.2% (50 of 609 individuals). The federally protected Rabbitsfoot (*Theliderma cylindrica*), listed as a Threatened species, was represented at Alternative 2 by two live specimens that accounted for 0.3% of the live mussels collected (Figure 5).

A total of 563 live mussels representing 16 taxa were found during 281 minutes (~4.7 hours) of dive search time at Alternative 3. Alternative 3 CPUE ranged from 4.7 to 60.0 with a mean of 20.1. Cumulative species versus cumulative time searched reached horizontal stability (16 species) after approximately 150 minutes search time (see Figure 4b). Mussel densities were greatest along the right descending bank in search cells 11, 13, 15, and maximum density was estimated at approximately 10/m<sup>2</sup> in portions of these cells. *Ambloema plicata* was the dominant species at Alternative 3 representing 48.7% (274 of 563 live individuals) of the mussel fauna, and *Potamilus purpuratus* composed 18.5% (104 of 563). Two additional species comprised >10% of live mussels encountered at Alternative 3, and these were *Obliquaria reflexa* (11.4%) and *Cyclonaias pustulosa* (10.8%).

### Discussion and Conclusions

Alternatives 2 and 3 occur in relatively different riverine habitats for mussels. Alternative 2 is in and immediately downstream of a bendway with the outside portion of the bendway possessing moderate to swift current velocities and more armored substrates composed of rock, gravel, sand, and scoured hard clay. The inside portion of the Alternative bendway has relatively slower current velocity and fine sediments (silt and sand) as the primary substrates. At the downstream terminus of Alternative 2, water depth is shallower and current velocity has moderated. In comparison with Alternative 3, Alternative 2 provides more physical habitat diversity potentially accounting for its greater species richness. Alternative 3 is in a straight reach of the river with a wider channel, slower current velocity and deeper water depth compared to Alternative 2. Alternative 3 provides less habitat diversity and is almost lentic in its physical characteristics.

Both Alternatives were dominated by mussel species that have widespread geographic distributions and are considered relatively stable from a conservation status perspective. Alternative 2 has 20 of 23 species (~87%) that are considered Secure (S5) or Apparently Secure (S4) in Arkansas (Harris and Posey 2015). The remaining three species at Alternative 2, *Pleurobema sintoxia*, *Theliderma cylindrica*, *T. nobilis*) were all ranked

Figure 5. *Theliderma cylindrica*. Upper: Alternative 2, Search Cell 2. Lower: Alternative 2, Search Cell 4.

Vulnerable (S3) (Harris and Posey 2015) and comprised 1.3% (8 of 609) of the live mussels collected. Mussels at Alternative 3 were all Secure (S5) or Apparently Secure (S4) species; therefore, all live specimens collected were from common and widespread species.

Mussel habitat at both Alternative crossings has likely been affected by anthropogenic activities. Farming occurs up to the edge of the right descending bank at Alternative 2. There appears to be ongoing bank failure which has contributed treefall and large woody debris deposition causing substrate scouring and likely displacement of mussels in the moderate to swift flow velocity of this outside bendway. This is the likely cause of large numbers of dead shells at Alternative 2 search cells 3, 5, and 7. Similarly, Alternative 3 has farming activities adjacent to the left descending bank, and a levee is present near the bank edge. Large woody debris is prevalent in the channel along the left descending bank for the length of Alternative 3 and likely contributes to sediment deposition in the extremely slow flow velocity at this site.

Design mitigation appears feasible at both proposed Alternative crossings. Spanning the right descending half of the Alternative 2 channel should minimize adverse impacts to the mussel fauna at this crossing. Spanning the right descending third to half of the Alternative 3 channel should minimize adverse effects to mussels at this crossing. Timely implementation and maintenance of effective erosion control measures during construction at either alternative will be particularly important to minimizing adverse effects to Black River mussel resources because of construction of the proposed project.

### Acknowledgements

Anna M. Pieri was field assistant for the project and is responsible for quality control and bringing the survey to completion. Ron Redman of Mitigation Surveying Services, LLC and Ryan Mountain of Garver provided administrative and logistical support.

## Arkansas Freshwater Bivalves Field Data Sheet

Date: 30 October 2021	Drainage: White River
County: Clay	Quad: NA
Substrate: silt, clay	Width: 27 - 28.5 m
Latitude: 36.36285	Longitude: -90.60875

Collectors: J. L. Harris, A. M. Pieri

Location: Black River approximately 15.4 river kilometers downstream of and 7.35 air kilometers SW of the U. S. Hwy 62 crossing of Black River east of Corning.

## ATTACHMENT E — PONDBERRY SURVEY MEMO

**Survey for Pondberry (*Lindera melissifolia*) within Suitable  
Habitat of the Preferred alternative for Future I-57**

**Lawrence, Randolph, and Clay Counties  
Arkansas**

**Prepared by Garver for the Arkansas Department of  
Transportation (ARDOT)**

**April 2022**

**Future I-57 DEIS: Pondberry Survey Memo**

# Pondberry Survey Memo

## Summary

Species: Pondberry (*Lindera melissifolia*)  
 Date(s) of Survey: April 19, 2022  
 Project Location: Future I-57 Preferred Alternative (Randolph, Clay, Greene, and Lawrence Counties, Arkansas)  
 Surveyor(s): Bill McAbee of Garver  
 Findings: No pondberry was found

## Project Description and General Project Area

The Arkansas Department of Transportation (ARDOT), in cooperation with the Federal Highway Administration (FHWA), is proposing to construct a fully-controlled access interstate facility from Walnut Ridge to the state line within Clay, Lawrence, and Randolph counties, Arkansas (ARDOT Job Number 100512). The Preferred Alternative begins at the Highway (Hwy.) 67/Hwy. 412 interchange at Walnut Ridge, Arkansas and ends on Hwy. 67 at the Arkansas-Missouri State line, a distance of approximately 42 miles. The alignment is almost entirely on new location and generally lies between Hwy. 67 and the Dave Donaldson Black River Wildlife Management Area (Black River WMA). The proposed action would involve construction of a four-lane divided highway with a depressed grass median and up to a 400-foot-wide right of way. Additionally, the proposed action would include construction of a new bridge spanning the Black River as well as several box culverts and cross drains throughout the remainder of project length to accommodate the new roadway.

The Preferred Alternative, which is comprised of Alternatives 2 and C, is located in Clay, Lawrence, and Randolph Counties in northeast Arkansas from Walnut Ridge in Arkansas to the Missouri State line. The project occurs within the Mississippi Alluvial Plain ecoregion, which is characterized as mostly a flat, broad alluvial plain with river terraces and levees providing the main elements of relief (Woods et al., 2004). Despite its length, the project limits contain a relatively homogeneous landscape due to its flat topography and abundance of agricultural practices.

## Survey and Memo Purpose

Due to the presence of potentially suitable habitat within the project limits, a survey for the Federally endangered pondberry (*Lindera melissifolia*) is required. In 2022, the U.S. Fish and Wildlife Service (USFWS) confirmed that the required pondberry survey need only be conducted in areas that have suitable habitat and that a habitat assessment can be used to rule out areas that are not suitable due to solid type, too wet, etc. Thus, a pondberry survey of the Preferred Alternative was conducted April 19, 2022 within areas identified as containing potentially suitable habitat.

The purpose of this memo is to summarize the results of the April 2022 pondberry survey.

## Species Information

### Species Description

Pondberry is a member of the Lauraceae family and is also referred to as the southern spicebush. Pondberry, *Lindera melissifolia*, is a deciduous shrub, growing from less than 1 ft. (30 cm) to,

## Future I-57 DEIS: Pondberry Survey Memo

infrequently, more than 6 ft. (2 m) in height (NatureServe, 2022). Leaves are aromatic, alternate, elliptical, somewhat thin and membranaceous, with entire margins. Shrubs usually are sparsely branched, with fewer branches on smaller plants. Plants are rhizomatous, frequently propagating by vegetative sprouts and forming clonal colonies. Plants are dioecious (each plant is either a male or a female) and produce clusters of small, yellow flowers in early spring prior to leaf development from buds on branches produced from the growth during the preceding year (NatureServe, 2022). Fruits are drupes that green when immature and ripen to red by fall.

### Life History

According to NatureServe (2022), pondberry can apparently occupy a variety of habitats as long as hydrological requirements are met. The species occurs in seasonally flooded wetlands such as floodplain/bottomland hardwood forests and forested swales, on the bottoms and edges of shallow seasonal ponds in old dune fields, along the margins of ponds and depressions in pinelands, around the edges of sinkholes in coastal areas with karst topography, and along the borders of Sphagnum bogs. Usually in shade, but tolerates full sun.

Habitat preferences for the pondberry within the project area include forested depressional wetland habitats that are seasonally flooded and that provide shade. These locations with suitable habitat are shown on Baker, B. 2018. Final report on *Lindera melissifolia* (Walter) Blume [Pondberry] survey and research work in Arkansas, 2017. Unpublished report to U.S. Fish and Wildlife Service. 60 pp.

### Status and Distribution

According to the 5-year review by USFWS (2021), the status review results indicate that of Arkansas's 24 known populations, 6 are extirpated, 1 exists only in cultivation (no longer extant in the wild), 5 (all on state- or federally owned or managed conservation lands) have been confirmed extant, and 12 (all on private lands, including 2 protected by conservation easements) are of uncertain status. Pondberry monitoring and surveys in Arkansas confirmed the continued existence of pondberry at the Stateline Sand Ponds Natural Area (NA) in Clay County (this population is shared by adjacent conservation lands in Ripley County, Arkansas), although the population is in apparent decline (Baker, 2018). Of the 12 populations found on private lands that are of uncertain status, recent aerial imagery indicates that habitat remains intact, suggesting that these populations may yet persist. These populations are found in Clay (1 population), Lawrence (2), Jackson (8), and Woodruff (1) counties.

No known pondberry occurrence records were found within the Preferred Alternative; however, known populations have been identified by the Arkansas Natural Heritage Commission (ANHC) within a forested area located approximately 1.8 miles south of O'Kean and 0.17 mile west of Lawrence

## Future I-57 DEIS: Pondberry Survey Memo

County Road 603 (Main Street). This known population is approximately 4.7 miles from the Preferred Alternative.

### **Survey Methods**

A pedestrian survey was conducted on April 19, 2022, for pondberry in 12 separate locations previously identified as possible pondberry habitat. These locations are shown on Baker, B. 2018. Final report on *Lindera melissifolia* (Walter) Blume [Pondberry] survey and research work in Arkansas, 2017. Unpublished report to U.S. Fish and Wildlife Service. 60 pp.

. Only the Preferred Alternative (Alternatives 2 and C) were surveyed per USFWS.

Survey sites were relatively small ranging for a few hundred square feet to approximately five acres. Conditions during the survey were clear and sunny with temperatures ranging from 45-65 degrees Fahrenheit. The hydrological conditions ranged from saturated soils to complete site inundation. The Black River was out of its banks at the time of the survey. One survey location north of the Black River and two survey locations just south of the Black River were inundated and survey was not possible.

## Future I-57 DEIS: Pondberry Survey Memo

Figure 1: Federally-listed Pondberry Habitat Locations

Spring growth had began and most plants were either flowering or had developed foliage to aide in species identification.

Smaller sites less than 3 acres were visually inspected up to 100% surface area. In larger tracts greater than 3 acres, the surveyor targeted depressional wetlands within forested areas and attempts were made to conduct 100% visual inspections of these depressional areas by a single observer. Thus, portions of some sites may have only been partially inspected. If any suspect plants would have been identified the location would have been documented with handheld GPS and a subsequent visit would have been conducted later in spring when additional diagnostic features of the plants could confirm species identity.

## **Survey Results**

Nine locations were surveyed within the Preferred Alternative. No populations of pondberry were observed. The survey, which investigated approximately 37 acres over a period of 8 hours, is considered thorough and had a level of effort comparable to other surveys conducted for the species.
