Received 19 October 2011; accepted 14 November 2011

Key indicators: single-crystal X-ray study: T = 293 K: mean  $\sigma(Pr-Br) = 0.001$  Å: R factor = 0.026; wR factor = 0.059; data-to-parameter ratio = 11.3.

The crystal structure of the praseodymium(III) oxide bromide, PrOBr, can be best described with layers of agglomerated square antiprisms  $[PrO_4Br_4]^{9-}$ . These slabs are stacked along the c axis and linked via two different secondary contacts between Pr<sup>3+</sup> and Br<sup>-</sup>. The Pr<sup>3+</sup> cations occupy the Wyckoff site 2c with 4mm symmetry and carry four  $O^{2-}$  anions as well as four primary Br<sup>-</sup> anions, yielding a coordination number of 8. While the Br<sup>-</sup> anions exhibit the same site symmetry as the Pr<sup>3+</sup> cations, the oxide anions are located at the Wyckoff position 2a with site symmetry  $\overline{4m2}$  and have four  $Pr^{3+}$  cations as neighbours, defining a tetrahedron.

# Pia Talmon-Gros, Christian M. Schurz and Thomas Schleid

# S1. Comment

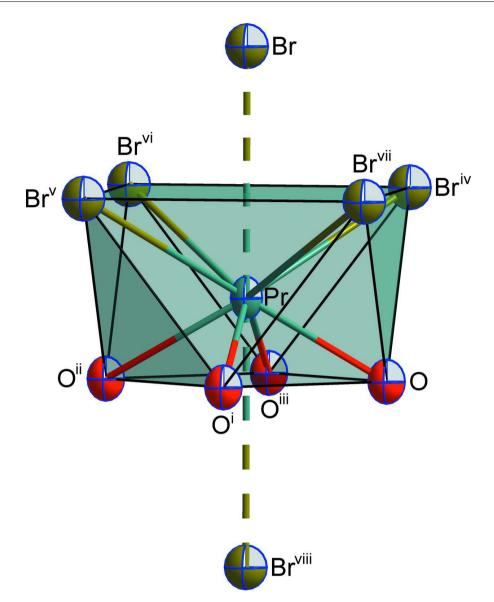

With the exception of PrOF (Baenziger et al. 1950) all praseodymium(III) oxide halides of the general composition PrOX (X = Cl - I); Zachariasen 1949, Potapova *et al.* 1977) crystallize with the *matlockite*-type structure (Nieuwenkamp & Bijvoet, 1932). The tetragonal crystal structure of the here presented praseodymium(III) oxide bromide PrOBr can be best described with layers of agglomerated square antiprisms  $[PrO_4Br_4]^{9-}$  ( $d(Pr^{3+}-O^{2-}) = 234.96$  (4) pm,  $d(Pr^{3+}-Br^{-}) = 234.96$  (4) pm,  $d(Pr^{3$ 324.57 (8) pm,  $d(Pr^{3+}...Br) = 360.8$  (1) and 385.9 (1) pm; Figure 1). These slabs are stacked along the *c*-axis and linked via two different secondary contacts between Pr<sup>3+</sup> and Br (Figure 2). According to the ionic radii ( $r_{\rm Cl} = 180$  pm,  $r_{\rm Br} = 195$ pm,  $r_1 = 220$  pm; Shannon, 1976) of the halide anions involved the expansion of the unit-cell dimensions occurs in quite an usual range, but the c-axes become significantly longer than the a-axes (a-axes: from 405.3 pm to 408.6 pm; c-axes: from 679.9 pm to 916.2 pm) along the Cl–Br–I track. The lattice parameters of single crystalline PrOBr (a = 406.71 pm, c = 746.69 pm) fit almost perfectly with that from a previous powder diffraction study (a = 407.1 pm, c = 748.7 pm; Mayer *et al.* 1965). Differences in the molar volumes of the PbFCl-type praseodymium(III) oxide halides ( $V_m$ (PrOCl) = 33.6 cm<sup>3</sup>/mol,  $V_m$ (PrOBr) = 37.2 cm<sup>3</sup>/mol,  $V_m$ (PrOI) = 46.1 cm<sup>3</sup>/mol) correspond well with the differences of the molar volumes of the respective halide anions ( $V_m(Cl^-) = 16.3 \text{ cm}^3/\text{mol}$ ,  $V_m(Br^-) = 19.2 \text{ cm}^3/\text{mol}$ ,  $V_m(I^-) = 24.5 \text{ cm}^3/\text{mol}$ ; Biltz 1934). However, the  $Pr^{3+}$  cations occupy the *Wyckoff* site 2*c* (symmetry: 4*mm*) and bond four O<sup>2-</sup> anions as well as four+one+one Br anions ending up with a total coordination number of 8+1+1 (Figure 1). While the Br anions exhibit the same site symmetry as the  $Pr^{3+}$  cations, the oxide anions are located at *Wyckoff* position 2*a* with the site symmetry 4m2. Bond-Valence and MAPLE calculations support the interpretation of one important ( $d(Pr^{3+}...Br) = 360.8$  (1) pm) and one less important secondary contact ( $d(Pr^{3+...}Br) = 385.9(1)$  pm): The valency and ECoN for the first bond amounts to values of about 0.08 (with  $R_0 = 267$  pm, b = 37 pm; Brown, 2002) and 0.12 (Hoppe, 1975), but almost *nil* for the second one, since this next nearest contact to bromide has only very low influence on the effective coordination sphere of the  $Pr^{3+}$ cations (ECoN = 0.03).

# **S2. Experimental**

Pale green, transparent, plate-shaped single crystals of PrOBr were obtained as by-product from a mixture of 0.06 g Pr, 0.38 g PrBr<sub>3</sub> and 0.01 g NaN<sub>3</sub>, along with 0.30 g NaBr added as a flux. The mixture was kept at 800 °C for 7 days in an evacuated, sealed fused-silica vessel designed to produce the praseodymium(III) nitride bromide  $Pr_3NBr_6$  in analogy with La<sub>3</sub>NBr<sub>6</sub> (Lulei, 1998) and Ce<sub>3</sub>NBr<sub>6</sub> (Mattausch & Simon, 1996).

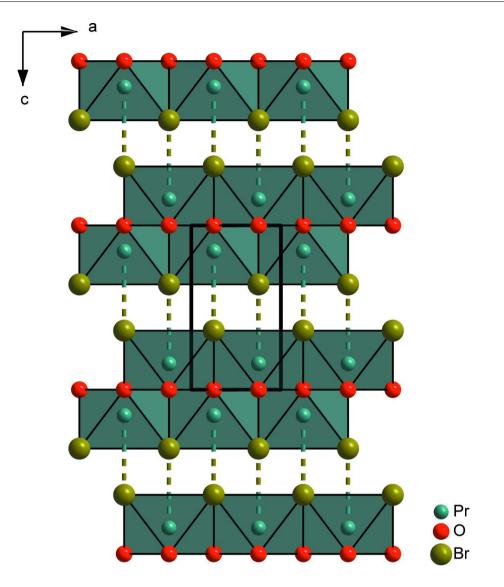

# **S3. Refinement**

The highest peak and the deepest hole in the final difference Fourier map are 95 pm and 84 pm apart from Pr.

### Special details

**Geometry**. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

**Refinement**. Refinement of  $F^2$  against ALL reflections. The weighted R-factor wR and goodness of fit S are based on  $F^2$ , conventional R-factors R are based on F, with F set to zero for negative  $F^2$ . The threshold expression of  $F^2 > 2sigma(F^2)$  is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on  $F^2$  are statistically about twice as large as those based on F, and R- factors based on ALL data will be even larger.
