## Abstract

Species checklists enlist the species available within the defined geographical region and thus serve as essential input for developing conservation and management strategies. The fields of conservation biology and ecology confront the challenge of inflated biodiversity, attributed to non-recognition of taxonomic inconsistencies such as synonyms, alternate representation, emendations etc. Critical review of the checklists and distributional records of Phylum Echinodermata from Indian waters and subsequent validation of species names with World Register of Marine Species (WoRMS) database, revealed that the current literature included 236 incorrect entries comprising of 162 synonyms, 15 emendations, 5 *nomina dubia*, 1 *nomen nudum*, 40 species under alternate representation, 9 species with author misnomer, 1 subspecies and 1 unaccepted. The 226 species found to be mixed with valid names and a revised checklist was prepared. The revised and updated checklist holds 741 species of echinoderms comprising of 182 asteroids (24.56%), 70 crinoids (9.45%), 138 echinoids (18.62%), 179 holothuroids (24.16%) and 172 ophiuroids (23.21%), placed under 28 orders and 107 families. This paper discusses the cause for taxonomic inflation and argues that such taxonomic inconsistencies alter our interpretations of a species including its inaccurate distribution and, could possibly impede the country's conservation and management efforts.

## Introduction

India has diverse coastal and marine ecosystems with many faunal and floral groups. The conservation, management and sustainable utilisation of natural resources depend on the qualitative and quantitative assessment of biodiversity (Narendran 2001; Prathapan *et al.* 2009). Preparation of checklist is the first step in any conservation effort, where the occurrence and distribution of the available species in the country is documented. Updating species checklists is an inherent and continuous task in biodiversity assessment. Unfortunately, most of the Indian marine taxa are not revised periodically, due to the prodigious nature of the task and lack of required experts and expertise. This impedes the conservation dependent on taxonomic checklists by conservation biologists, ecologists, and environmental managers. The glamour of taxonomy has been on a decline, and the subject is not recognized as an intellectually challenging and hypotheses-driven science, that it has become (Dayrat 2005; Padial *et al.* 2010; Haszprunar 2011). Reduction in financial support for taxonomic research, limited number of scientific journals publishing taxonomic research and editorial resistance among high impact journals to publish taxonomic data has been a significant impediment for addressing today's biodiversity crisis through scientific research (Bortolus 2008; Werner 2009; Boero 2010). This has led to lack of high quality taxonomic works and increased number of publications on taxonomic data in non-peer reviewed journals, which in turn have resulted in '*taxonomic inflation*' (Padial & Riva 2006), the increase in the number of taxa as a consequence of use of different taxonomic concepts and a visible shift from conventional taxonomy to "*cybertaxonomy*" during the last decade (Miller *et al.* 2012).

The current study critically reviews the checklists and taxonomic records of Phylum Echinodermata reported from India. Echinoderms are marine invertebrates comprised of feather stars and sea lilies, sea stars, brittle stars, sea urchins and sea cucumbers. Echinoderms are pentaradially symmetrical animals with unique features of endoskeleton and water vascular system and form a dominant group in the marine benthic environment (Brusca & Brusca 1990). This phylum has a variety of trophic groups, including detritivores, filter-feeders, grazers, scavengers and active predators (Himmelman & Dutil 1991). They are distributed from shallow to the deep,

tropical to polar and are generally benthic except the pelagic holothuroid, *Rynkattropha pawsoni* (Pawson 2007). Globally about 13,000 fossil species and 7000 living species of echinoderms have been reported (Pawson 2007). Echinoderms are deuterostomes and therefore more closely related to the Chordata than any other invertebrate phylum (Hyman 1955; Smith 2004).

Major works on echinoderm taxonomy was undertaken in the 19<sup>th</sup> century based on samples collected during the expeditions such as Challenger, Valdivia, Siboga, Albatross, etc. (James 2008). Significant collections were made during the cruise by Royal Indian Marine Survey steamer investigator (RIMS). This is substantiated in the Indian Museum deposits as reported - Crinoidea (Clark AH 1912), Asteroidea including a few echinoids (Wood-Mason & Alcock 1891; Alcock 1893, 1894; Koehler 1909, 1910), Ophiuroidea (Koehler 1897, 1898, 1899, 1900), Echinoidea (Koehler 1914, 1922, 1927) and Holothuroidea (Koehler & Vaney 1905, 1908).

Some significant contribution to the knowledge of echinoderm fauna from India were given by James (1966a, b, 1967, 1973, 1983, 1986a, b, c, d, 1987a, b, 1988, 1991, 1998, 2001, 2008), Clark & Rowe (1971), James & James (1994), Sastry (2007), Srinivasa Rao *et al.* (2009); Deepa & Kumar (2010, 2011), Stöhr *et al.* (2012) and Hegde & Rivonker (2013).-The current paper aims at updating the checklist of echinoderms from India, assessing the extent of taxonomic inflation, identifying taxonomic inconsistencies by following international nomenclatural norms.

## Methods

The records on the distribution and abundance of echinoderms in India were sourced from the existing literature, reviews, monographs, catalogues, checklists, websites and fishery reports from Indian waters. The scientific names were validated with WoRMS database for valid names of each reported species (validating unaccepted names, emendations, synonyms, alternate representations, *nomen nudum*, *nomen dubium* etc.) and all the corrected names were revised and an updated checklist has been prepared. Species under *nomen dubium* and *nomen nudum* categories were retained as such but were not included in the checklist. The species list was classified into groups with accepted names, unaccepted names, emendations and those with doubtful distribution provided as supplementary table. The contribution of different classes within the phylum echinodermata and that of various orders in each class was estimated in percentage.

## Results

A total of 741 species of echinoderms are reported from Indian waters represented by Class Asteroidea (24.56%), followed by Holothuroidea (24.16%), Ophiuroidea (23.21%), Echinoidea (18.62%) and Crinoidea (9.45%). The percentage contribution of different Orders under each of the Classes within the Phylum Echinodermata is presented in Fig.1. The status of species revised under each class was given in table 1.

A critical review of the published checklists revealed that the current literature included 236 incorrect entries comprising 162 synonyms, 15 emendations, 5 *nomina dubia*, 1 *nomen nudum*, 2 *taxon inquirendum*, 40 species under alternate representation, 9 species of misnomer, 1 unaccepted species and 1 subspecies inclusion. It was observed that over 85% inconsistencies in the checklist were due to synonyms (68.64%), and alternate representation (16.95%). The remaining were the constituents of emendations (6.36%), misnomer (3.81%), *nomen dubium* (2.12%), *taxon inquirendum* (0.85), *nomen nudum*, subspecies inclusion and unaccepted species with 0.42% each (Table 2). Synonomy was the predominant issue among all the classes (Fig. 2). The revised and updated checklist of echinoderms comprising 741 species from coastal and marine environment of India is provided in Table 3. Species with various inconsistencies and their status was shown in table 4 and the omitted species was produced in a supplementary table (table 5).

## Discussion

A comprehensive checklist on Indian echinoderms is that of Sastry (2007), who documented a total of 651 species. Prior to this, Clark & Rowe (1971) reported 191 species from the Bay of Bengal region. A total of 175 research publications from 1758 to 2016 were referred to generate this checklist. There were many inconsistencies like synonyms, *taxon inquirendum*, *nomen nudum*, *nomen dubium*, emendations etc. Most of the emendation errors were observed in many of the publications.

Asteroids are relatively easier to identify based on their body structure, colour pattern and the disc to arm ratio, which could possibly explain their higher representation among the documented echinoderms from India. Besides, relatively higher number of taxonomic experts for asteroids and holothuroids led to addition of new species during the 80s and 90s. Holothuroids (24.16%) are second to asteroids in terms of their representation to the total echinoderm diversity. Most of the species reports are from the coral reef ecosystems such as Andaman & Nicobar Islands and Gulf of Mannar, where the collection of specimens from trawl by-catch aided in effective documentation of the diversity. The under-representation of crinoids (9.45%) in the diversity of echinoderms in India could be attributed to limited expertise, difficulty in accessing their habitats and the taxonomic impediments associated with crinoid taxonomy.

The major part of inconsistencies (68.64%) in the echinoderm checklist in India was due to synonyms, emerged as a result of nomenclatural inflation caused by unwarranted descriptions of a new taxa (Padial & Riva 2006).

The second major inconsistency in the checklist is due to alternate representations with 16.95 %. The third inconsistency arose from emendations (6.36%), which are attributed to lack of expertise or oversight within the research community. Spelling changes should be made with justification in order to uphold the *nomen*'s validity.

Some inconsistencies are due to author misnomer as well as wrong year entry. Sastry *et al.* (2004) and Raghunathan & Venkataraman (2012) included the wrong author name and year Michelin, 1845 for the sea urchin *Diadema savignyi* but the authentic author & year are Audouin, 1809. Kumar (2012) reported a holothuroid *Psolidium complanatum* Cherbonnier, 1969 was author misnomer. The actual author & year for the species is *Psolidium complanatum* (Semper 1867).

Sl.No.	Omitted species names	References	Reasons
18	<i>Ophiothela venusta</i> (de Loriol, 1900)	Sadhukhan & Raghunathan (2011b)	& Expert Dr. Sabine stöhr reviewed this publication and disproved it as <i>Ophiocoma</i> sp. based on the reported key character 1 tentacle scale which conflicts with the images clearly show 2 and does not fit with <i>Ophiothela</i>
19	<i>Dougaloplus echinatus</i> (Ljungman, 1867)	Sadhukhan & Raghunathan (2011b)	& Dr. Sabine stöhr commented that this species probably of juvenile <i>Ophiocoma</i> sp. that still lacks disc granules and Tooth papillae are interpreted as infradental papillae
20	<i>Ophiopteron vitiensis</i> (Koehler, 1927)	Sadhukhan et al. (2012)	Dr. Sabine stöhr reviewed this as <i>Ophiothela</i> sp.
21	<i>Ophionereis degeneri</i> (A.H. Clark, 1949)	Sadhukhan et al. (2012)	Dr. Sabine stöhr reviewed this as <i>Ophiocoma</i> sp.
22	<i>Ophiothrix savignyi</i> (Muller and Troschel, 1842)	Sadhukhan et al. (2012)	Dr. Sabine stöhr reviewed this as <i>Ophiothela</i> cf. <i>danae</i>
23	<i>Ophiothrix (Theophrix) pusilla</i> (Lyman, 1874)	Sadhukhan et al. (2012)	Dr. Sabine stöhr reviewed this as <i>Ophiothela</i> cf. <i>danae</i>
24	<i>Heterometra crenulata</i> (P.H.Carpenter, 1882)	Sadhukhan & Raghunathan (2012b)	& Dr. Charles Messing reviewed this paper and suggested based on image that it is likely to be <i>Himerometra robustipinna</i> (Carpenter, 1881)
25	<i>Amphimetra molleri</i> (A. H. Clark, 1908)	Sadhukhan & Raghunathan (2012b)	& Dr. Charles Messing commented that this is not any species of <i>Amphimetra</i> by setting the point <i>Amphimetra</i> species have only ten arms (rarely 11 or 12) but specimen in the figure appears to have over 20 arms (with at least 7 on one ray) including division series of four ossicles.
26	<i>Cenometra bella</i> (Hartlaub, 1890)	Sadhukhan & Raghunathan (2012b)	& Dr. Charles Messing commented that this is most likely <i>Phanogenia typical</i> by setting the point lack of characteristic rounded processes on the sides of the division series ossicles, and the paired aboral tubercles on the cirri for <i>Cenometra bella</i>
27	<i>Comanthus alternans</i> (P. H. Carpenter, 1881) a synonym of <i>Clarkcomanthus alternans</i> (Carpenter, 1881)	Sadhukhan & Raghunathan (2012b)	& Dr. Charles Messing commented that this is most likely <i>Phanogenia typica</i> based on the ossicles have typical concave sides, the division series beyond the second tend to give rise to an undivided arm and another division series in alternating fashion, and the habitat described is that of <i>P. typica</i> . <i>Clarkcomanthus alternans</i> generally sits completely exposed

28	<i>Petasometra clarae</i> (Hartlaub, 1890)	Nigam <i>et al.</i> (2016)	Dr. Charles Messing commented that this appears from the images most likely <i>Cenometra bella</i> . The authors state that “The outer borders of the division series are smooth, without lateral processes.” However, lateral processes characteristic of <i>C. bella</i> are clearly visible in figure 2e.
29	<i>Ophiura</i> sp.	Stöhr <i>et al.</i> (2012)	Reported only genus level

The names of echinoid *Caenopedina depressa* Koehler, 1927, sea cucumbers *Holothuria (Stauropora) exilis* Koehler & Vaney, 1908, *Holothuria glaberrima* Risso, 1826, *Holothuria marmorata* Saville-Kent, 1893 and *Peniagone obscura* Koehler & Vaney, 1905 are *nomina dubia*. *Nomina dubia* are more problematic than synonyms and they should be either removed from the checklists or labelled explicitly so as to alert the non-taxonomic users of the checklists (Dayrat 2011).

Two species, *Pentacta quadrangularis* (Lesson) reported by Satyamurti (1976) and *Cucumaria turbinata* (Hutton, 1879) reported by Mukhopadhyay (1988) and Sastry (2007) are taxon inquirendum. Likewise, *Dictyaster wood-masoni* (Asteroidea) is an undescribed species placed under *nomen nudum* status (a non-available name). There has been a steep increase in collection and documentation of samples from voyages and research world over. A ‘taxonomic increase’ could be attributed to (i) genuine increase in knowledge because of discovery of new species or obtaining data on the known species or (ii) an artificial increase in species number due to debates in adopted methodology, disagreements or problems among taxonomists (Padial & Riva 2006). Another reason for taxonomic inflation arises from the fact that subspecies are raised to species as a result, a change in species concept rather than new discoveries occur (Nick *et al.* 2004).-

Some of the species description from India have not been revised or revisited since their original description and only changes in generic names, as reported globally, have been applied to them, thus rendering the status of such species as uncertain. The current work points out taxonomic inflation attributed primarily by synonymies, emendations and alternative representation and, provides a revised checklist updated till February 2017. An accurate checklist aids in appropriate resource allocation for conservation of the biodiversity though taxonomy has many other functions besides biodiversity conservation. Illustrating the case with diversity of echinoderms in India, the current study calls for periodic taxonomic updates and development of a national repository of chronologically updated species list for all taxa.

## Acknowledgements

The study was undertaken as a part of the study on “Coastal and Marine Biodiversity Integration Network (CoMBINe)”, by the Coastal and Marine Resources Conservation Division, National Centre for Sustainable Coastal Management, Chennai. Authors are thankful to Dr Sabine stöhr, Dr Charles G. Messing and Dr Gustav Paulay for their suggestions, comments and untiring work taken on identification of ophiuroids, holothuroids and crinoids.
