Abstract—This paper presents a checklist of 303 species of benthic and planktic Foraminifera from the marine waters off Guam, based on literature records and new collections. Notations on taxonomic synonymies and depositories of type and identified specimens are included in the list.

Introduction

The checklist given below is comprised of 303 species representing all of the major subclades of the clade Foraminifera (Pawlowski 2000). This species checklist was compiled from various resources in the published literature (Cushman 1917, 1932, 1933a, 1933b, 1934, 1942, Todd 1960, 1965, 1966, Matsumaru & Matsuo 1976, Lessard 1980) using the preliminary checklist of 150 species published by Clayshulte (1981a) as a foundation. In addition, several species identified from field collections by the authors were integrated into the list (Clayshulte 1981a, b, S. Richardson, unpublished observations). As much as possible, species identified in the published literature (Cushman 1917, 1932, 1933a, 1933b, 1934, 1942, Todd 1960, 1965, 1966) were checked against specimens housed in the Cushman Collection of Foraminifera, Department of Paleobiology, National Museum of Natural History, Smithsonian Institution, Washington, DC. USNM numbers are listed for those specimens housed in the Smithsonian primary and secondary type collections; however, many of specimens listed by Todd (1966) are stored on assemblage (faunal) microslides that are kept in separate slide cabinets adjacent to the type collections. These microslides are labeled with the locality numbers given in Table 4 of Todd (1966), rather than the USNM numbers assigned to individual slides in the type collections. Attempts to locate the specimens used by Lessard (1980) were unsuccessful. Accession numbers are also listed for those species for which DNA sequences have been deposited in the GenBank Database (Holzmann et al. 2001).

The 303 species of Foraminifera listed below were collected from various shallow-water habitats around Guam, including: beach sands (Todd 1966, Matsumaru & Matsuo 1976, Lessard 1980), sediments (Cushman 1917, 1932, 1933a, 1933b, 1934, 1942, Todd 1960, 1965, 1966), phytal substrata (Lessard 1980, S. Richardson, unpublished observations), and other solid substrata (Clayshulte 1981b). The foraminiferal species identified in the beach sands and sediment samples represent total (dead + live) foraminiferal populations, as no attempt was made in any of the published studies to distinguish between the tests of living foraminiferans and the empty tests of dead organisms. Field studies conducted by Clayshulte (1981b) and S. Richardson (unpublished observations); however, included observations of live individuals attached to settlement plates and other natural substrata, such as reef rock and seagrasses.

Many of the foraminiferal species identified from Guam, such as *Baculogypsina sphaerulata* (Parker & Jones, 1860) (Fig. 1), are distributed widely throughout the Indo-Pacific (Todd 1960, Langer & Hottinger 2000, Belasky 1996). Of the 303 species of Foraminifera identified from Guam, 129 are also known from Saipan (Todd 1957). In addition, several of the Recent species of large, endosymbiont-bearing foraminiferans living today in the shallow waters off Guam are also known from the fossil record (Cole 1939, 1963, Hanzawa 1957, Matsumaru 1976, Todd 1957, 1966).

Currently, the most widely used classification of Foraminifera is that published by Loeblich & Tappan (1987, 1992). In this scheme, Foraminifera is assigned the Linnaean rank of a Class within the Phylum Granuloreticulosa. More recently, molecular phylogenetic studies have challenged traditional ideas on the position of Foraminifera in the tree of life, as well as hypotheses of the evolutionary relationships within Foraminifera itself. While Foraminifera has been consistently shown to comprise a monophyletic clade of single-celled eukaryotes, the position of this clade within Eukaryota is still unresolved. In molecular studies based on 18S ribosomal DNA sequences, Foraminifera appears to be a deep-branching clade of basal mitochondrial eukaryotes, perhaps the earliest extant group with mitochondria (Pawlowski et al. 1996; Pawlowski et al. 1997; Pawlowski et al. 1999 a, b; Pawlowski 2000); however, in a recent molecular analysis based on actin gene sequences, Foraminifera emerges near the eukaryotic crown as the sister group to cercomonads and chlorachniophytes (photosynthetic amoebaflagellates) (Keeling 2001).

Molecular studies have also shed light on the taxonomic composition and relationships of the major subclades within Foraminifera, both confirming and invalidating earlier groupings. It is expected that future studies, both morphological and molecular, will result in further rearrangements. For these reasons, the checklist outlined below is organized in an untraditional manner.

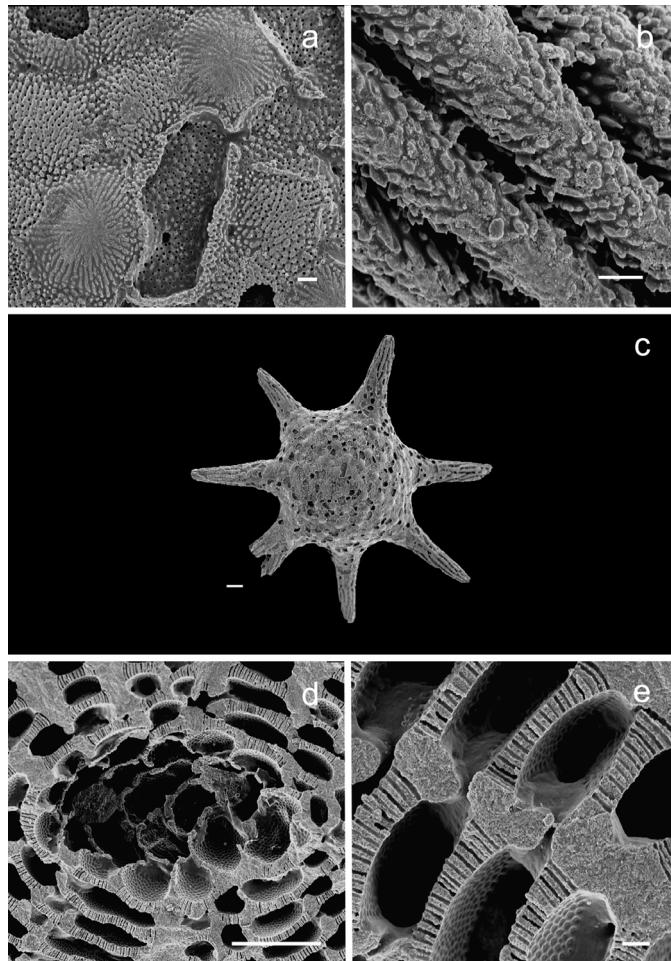

Figure 1. *Baculogypsina sphaerulata* (Parker & Jones, 1860), a benthic foraminiferal species that hosts intracellular diatom endosymbionts. All SEM images are of specimens found in beach sand collected near the entrance to Lost Pond, Guam. a close-up view of test surface, radial-patterned projections represent surface expression of imperforate conical pillars; scale bar = 10 μm . b close-up view of ornamentation on spine surface; scale bar = 10 μm . c view of whole test showing spines radiating from central body of chambers; scale bar = 100 μm . d view of early coiled chambers in sectioned test; scale bar = 100 μm . e close-up view of peripheral chambers in sectioned test showing perforated chamber walls and imperforate conical pillar; scale bar = 10 μm .

Foraminifera and its inclusive subclades (as listed in Appendix 1 below), are not assigned to traditional Linnaean ranks, but are given names based on the most recent molecular phylogeny of Foraminifera (Pawlowski 2000), as is consistent with the principles of phylogenetic taxonomy (de Queiroz & Gauthier 1990,

1992, 1994). The Linnaean system of binomial nomenclature is retained, however, for ease of information retrieval, and species are ordered alphabetically by genus and species within each subclade.

Acknowledgments

We thank John J. Lee and an anonymous reviewer for their helpful suggestions on revisions to the checklist. Susan Richardson would also like to acknowledge Marty Buzas, Mark Florence, and Jennifer Jett for their help in accessing the Cushman Collection of Foraminifera (Department of Paleobiology, National Museum of Natural History, Smithsonian Institution, Washington, DC). This is Contribution Number 532 of the Smithsonian Marine Station at Fort Pierce, Florida.

Appendix 1. Checklist of foraminiferal species

Catalogue numbers with an USNM-prefix are given for type specimens (holo=holotype, para(s)=paratypes(s)) of those species deposited in the Cushman Collection of Foraminifera, Department of Paleobiology, National Museum of Natural History of the Smithsonian Institution in Washington, DC. Accession numbers are listed for those species for which sequences have been deposited in the GenBank Database. USNM a.s.: USNM assemblage slide(s).
