Abstract: Information about trichomes diversity and distribution of the family Caryophyllaceae is rare and the present work is intended to fill this knowledge lacuna. In the present work 62 taxa belonging to 19 genera were studied. For the analysis of trichomes diversity and vestiture type, dried plant specimens were rehydrated with water. The final illustrations of trichomes were made by using camera lucida. Six types of trichomes viz., Unicellular eglandular, Unicellular glandular, Multicellular uniseriate glandular, Multicellular uniseriate eglandular, Multicellular eglandular bifurcate and Multicellular multiserrate eglandular trichomes reported in the studied taxa. Diversity of trichome and their distribution does not play any significant role in the taxonomic delimitation either generic or tribal level of the family Caryophyllaceae. Although, few closely allied species can be distinguished from each other either on the basis of the presence of trichomes or vestiture patterns.

Keywords: *Arenaria* - *Silene* - *Stellaria* - Taxonomy -Vestiture.

INTRODUCTION

Caryophyllaceae Juss. is known as pink family or carnation family, and ranked as 24th largest family of Angiosperms with 93 genera and 2395 species (Thorne & Reveal 2007). Though, number of species and genera of the family varies from different sources as: The plant list (2013) reported 88 genera with 2295 species and Mabberley (2017) reported 96 genera with 2500 species. The family is worldwide in distribution with exception in the wet tropics. Members of the family Caryophyllaceae often have distinctive swollen nodes; simple opposite leaves; dichasial cymes inflorescence or solitary flowers; flower usually actinomorphic; pentamerous with distinct clawed petals; stamens obdiplostemonous, ten or lesser; ovary superior; placentation free-central; and fruit capsule opening by teeth or valves (Bitrich 1993a, b).

On the basis of stipulate or exstipulate leaves, free or connate sepals, styles fused at base or free, the family is further subdivided by Bitrich (1993b) into three subfamilies Paronychioideae (tribe: Polycarpeae, Paronychieae and Corrigoleae), Alsinoideae (tribe: Alsineae, Pycnophylleae, Geocarpeae, Habrosieae and Sclerantheae and Caryophylloideae (tribe: Caryophylleae, Drypidae and Sileneae). Harbaugh *et al.* (2010) proposed a new classification for tribes of the family on the basis of monophyly and abandoned traditional three subfamily classification of family. They proposed eleven tribes namely Corrigoleae, Paronychieae, Polycarpeae, Sperguleae, Saginaeae, Sclerantheae, Arenarieae, Alsineae, Eremogoneae, Caryophylleae, and Sileneae for the family.

Recently, some large genera (*Arenaria*, *Minuartia*, etc.) of the family have undergone splitting on the basis of molecular data. Dillenberger & Kadereit (2014) divided genus *Minuartia* s.l. into eleven genera *i.e.* *Cherleria*, *Eremogone*, *Facchinia*, *Mcnillia*, *Minuartia* s.s., *Minuartiella*, *Mononeuria*, *Pseudocherleria*, *Rhodalsine*, *Sabulina* and *Triplateia* on the basis of monophyly. New generic delimitation for *Arenaria* s.l. was

proposed by Harbaugh *et al.* (2010), Greenberg & Donoghue (2011), Dillenberger & Kadereit (2014), Sadeghian *et al.* (2015), and Pusalkar & Singh (2015). In the revised circumscription *Arenaria* s.l. is divided into five genera *i.e.* *Eremogone*, *Odontostemma*, *Shivparvatis*, *Himgiria*, and *Arenaria* s.s.

Trichomes are epidermis originated cells found on the plant surface. There is amazing variability of trichomes in the form of variation in shape, size and structure. For the delimitation and differentiation of certain taxa variability of trichomes is used (Werker 2000). Information about trichomes diversity and distribution of the family is little known. Metcalfe & Chalk (1950) studied trichomes diversity in some species and genera of the family. Bittrich (1993b) compiled morphological characteristics of the family and also focused on trichome diversity of some species. Some other workers Solereder & Scott (1986), Cowie (1994), Shamsabad *et al.* (2013), Selvi *et al.* (2014), Bozchaloyi & Keshavarz (2014) tried to document trichome diversity of the family but their study either focused on several genera or particular subfamily. Thus, present work intends to illustrate trichomes diversity and distribution in the family Caryophyllaceae and evaluate the relevance of this information for the family's taxonomy.

MATERIALS AND METHODS

Plant material

Trichome diversity and distribution were studied in 62 taxa including 58 species and four varieties belonging to 19 genera during present work. Plant specimens of 46 taxa were collected from the Western Himalaya, India during the year July 2012 to 2016 and specimens deposited in the herbarium of Govind Ballabh Pant University of Agriculture and Technology Pantnagar, Uttarakhand, India (GBPUH). Most of the specimens were collected from Uttarakhand Himalaya. Remaining taxa studied from specimens housed in herbaria of Botanical Survey of India Northern Circle Dehradun (BSD), Hemvati Nandan Bahuguna Garhwal University Srinagar Garhwal (GUH), Forest Research Institute Dehradun (DD) and Kumaon University Nainital (KUH).

Light microscopy

For the analysis of trichomes diversity and vestiture type, dried plant specimens were rehydrated with water. Trichomes from stem were obtained through scraping. Other plant parts as leaves, bracts and floral parts were observed under the light microscope and freehand horizontal and longitudinal sections were made to study trichomes morphology. The final illustrations of trichomes were made by using camera lucida. About 5–6 specimens for each taxa and 3–5 plant parts for each specimens were studied to assess the trichome diversity and distribution.

Trichomes classification

Payne (1978), Prabhakar & Leelavathi (1989), Krak & Mraz (2008) and de Andrade *et al.* (2014) were followed for classification, identification and characterization of trichomes in the present work. The vestiture types were determined following Lawrence (1951) and Simpson (2010).

RESULTS

Trichomes diversity

Six types of trichomes were recorded in the studied taxa; (1) Unicellular eglandular trichomes, (2) Unicellular glandular trichomes, (3) Multicellular uniseriate glandular trichomes, (4) Multicellular uniseriate eglandular trichomes (5) Multicellular eglandular bifurcate trichomes and (6) Multicellular multiseriate eglandular trichomes (Fig. 1). Apart from above mentioned categories stellate trichomes are also reported in *Stellaria vestita* Kurz, *Cerastium mollissimum* Poir., *Polycarpon loeflingiae* (Wall. ex Wight & Arn.) Benth. & Hook.f. (Solereder & Scott 1986, Majumdar 1993). However, these species were not included in the present work.

On the basis of trichomes types, all the studied taxa (62 taxa) can be categorized into five groups. *Stellaria depressa* Em. Schmid, *Spergula fallax* (Lowe) E.H. Krause and *Cerastium davuricum* Fischer were completely glabrous and constitute the first group. Second group possess unicellular trichomes and represented by *i.e.* *Drymaria cordata* (L.) Willd. ex Schult. and *Herniaria cachemiriana* J. Gay. *Drymaria cordata* possess both unicellular eglandular and capitate unicellular glandular trichomes, while *Herniaria cachemiriana* possess unicellular hairs on all plant parts except ovary. In the ovary of *Herniaria cachemiriana* multiseriate multicellular eglandular trichomes were found.

The third group of the plants contains strictly eglandular trichomes. This group further divided into two subgroups *i.e.* bifurcate eglandular trichomes and uniseriate multicellular eglandular trichome. *Polycarpon prostratum* (Forssk.) Asch. & Schweinf. possesses eglandular bifurcated trichomes and also possesses simple

multicellular uniseriate eglandular trichomes. The taxa i.e. *Silene baccifera* (L.) Roth, *S. caespitella* F. Williams, *S. kumaonensis* F. Williams, *S. moorcroftiana* Wallich ex Benth., *S. nepalensis* Majumdar, *S. vulgaris* (Moench) Garcke, *Stellaria decumbens* var. *decumbens* Edgew., *S. decumbens* var. *polyantha* Edgew. & Hook.f., *S. congestiflora* H. Hara, *S. himalayensis* Majumdar, *S. patens* D. Don, *S. semivestita* Edgew., *S. umbellata* Turcz., *S. uliginosa* Murray, *Thylacospermum caespitosum* (Cambess.) Schischk., *Cherleria* sp., *Drymaria villosa* Cham. & Schlecht., *Dianthus angulatus* Royle ex Benth., *D. barbatus* L., *D. chinensis* L., *Arenaria thangoensis* W.W. Sm., *Stellaria depauperata* Edgew., *Arenaria bhutanica* Majumdar & Babu, *Eremogone ferruginea* (Duthie ex F. Williams) Pusalkar & D.K. Singh, *E. curvifolia* Kar. & Kir., *E. kumaonensis*, *Shivparvatia ciliolata* var. *ciliolata* (Edgew.) Pusalkar & D.K. Singh, *S. ciliolata* var. *pendula* (Duthie ex F. Williams) Pusalkar & D.K. Singh, *Gypsophila cerastioides* D. Don, *Sagina saginoides* (L.) Karsten of this group possess only simple uniseriate multicellular eglandular trichomes. Only eglandular trichomes present on at least one plant part of this group.

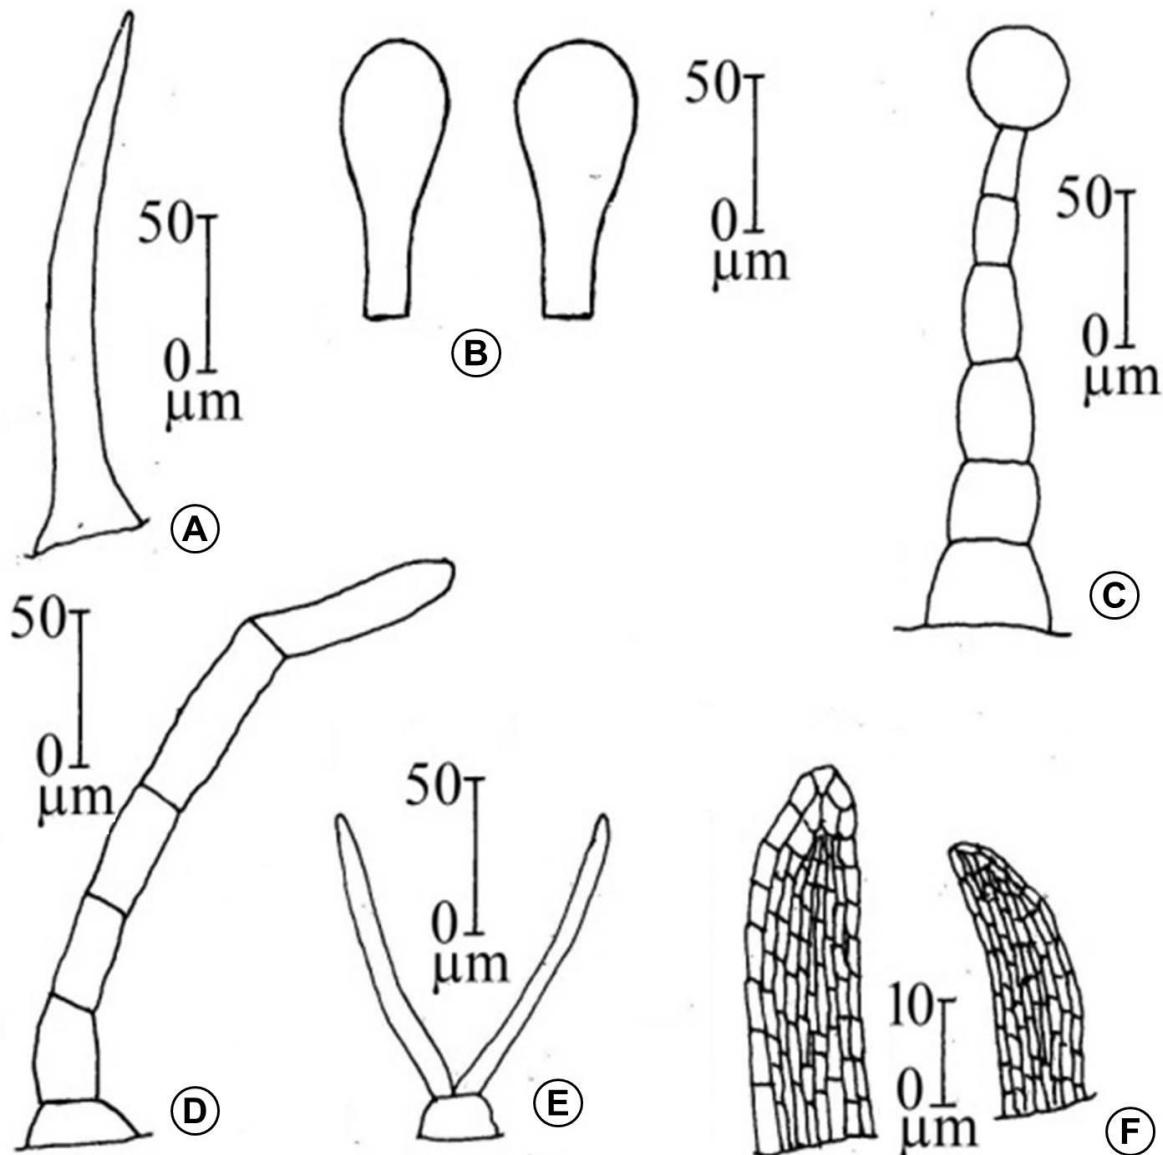

Figure 1. Different types of trichomes in family Caryophyllaceae: **A**, Unicellular eglandular trichome (*Herniaria cachemiriana*); **B**, Unicellular glandular trichome (*Drymaria cordata*); **C**, Multicellular uniseriate glandular trichome (*Shivparvatia glanduligera*); **D**, Multicellular uniseriate eglandular trichome (*Arenaria bhutanica*); **E**, Multicellular eglandular bifurcate trichome (*Polycarpon prostratum*); **F**, Multicellular multiseriate eglandular trichome (*Herniaria cachemiriana*).

The forth group of the plants bore only uniseriate multicellular glandular trichomes and represented by *Polycarpaea corymbosa* (L.) Lam. and *Spergularia rubra* (L.) J. & K. Presl. The fifth group include *Silene falconeriana* Royle ex Benth., *S. conoidea* L., *S. gangotriana* Pusalkar, D.K.Singh & Lakshmin., *S. indica* var. *indica* Roxb. ex Otth, *S. indica* var. *edgeworthii* (Bocquet) Y.J. Nasir., *S. incurvifolia* Kar. & Kir., *S. viscosa* (L.) Pers., *Stellaria aquatica* (L.) Scop., *S. media* (L.) Villars, *S. monosperma* var. *monosperma* D.Don, *S.*

monosperma var. *paniculata* (Edgew.) Majumdar, *S. webbiana* (Benth. ex G. Don) Edgew. & Hook. f., *Cerastium cerastioides* (L.) Britton, *C. fontanum* Baumg., *Odontostemma glandulosum* Benth. ex D. Don, *Eremogone festucoides* (Benth.) Pusalkar & D.K. Singh, *Shivparvatica glanduligera* (Edgew.) Pusalkar & D.K. Singh, *Arenaria neelgherrensis* Wight & Arn., *A. serpylifolia* L., *Lepyrodiclis holosteoides* (C. A. Meyer) Fenzl ex Fischer & C. A. Meyer and *Sagina apetala* Ard., which possessed both uniseriate multicellular glandular and eglandular trichomes at least at some plant parts.

Presence of trichomes in different plant parts

Trichomes in all plants are not uniform in length and distribution. Hence, the presence of trichomes in different plant parts and different types of vestiture can also be used for categorization of taxa. The presence of trichomes in different plant parts of studied taxa is shown in table 1. *Stellaria depressa*, *Spergula fallax* and *Cerastium davuricum* were completely glabrous nature. *Dianthus barbatus* L., *D. chinensis* and *Silene vulgaris* (Moench) Garcke had trichomes only at calyx teeth apex, otherwise these were glabrous plants. In *Thylacospermum caespitosum* trichomes were found only at abaxial surface of leaf, while in *Stellaria uliginosa* Murray, *S. umbellata* trichomes were found at abaxial surface of leaf toward leaf base and leaf base of upper few leaf pairs respectively. In *Polycarphaea corymbosa* trichomes found only upper parts of stem and pedicel. Among all species, only *Herniaria cachemiriana* had trichomes on the ovary surface, while in all other taxa ovary were glabrous.

Table 1. Presence of trichomes on different plant parts of the studied taxa.

Vestiture Type

Different types of vestiture depict relative length and pattern of trichome and hence can be used for further categorization of taxa. Different arrangements of trichomes on the stem surface were studied. In the plants under study, eight different types of vestitures were recorded viz. (1) Pubescent- more or less straight, short, soft, somewhat scattered, slender trichomes, (2) Puberulent- minutely pubescent with very short scattered trichomes, (3) Tomentose- plant parts covered with very dense interwoven trichomes, (4) Villous- long, soft, highly twisted trichomes, (5) Scabrous- rough trichomes, as of sandpaper, (6.) Hirsute- long stiff trichomes, (7) Strigose- dense coarse, bent and flat trichomes often with bulbous base, and (8) Strigulose- minutely strigose.

Stellaria monosperma var. *paniculata* and *S. monosperma* var. *monosperma*, *S. media*, *S. aquatica*, *Shivparvatis ciliolata* var. *ciliolata*, and *Shivparvatis ciliolata* var. *pendula* had tomentose vestiture. But, these were further differentiated on the basis of single line of trichomes, two lines of trichomes or diffused trichomes

throughout the stem. *Stellaria monosperma* var. *paniculata* and *S. monosperma* var. *paniculata* both possess trichomes in one line; *Stellaria media* has two lines of trichomes or sometimes diffused, *Shivparvatia ciliolata* var. *ciliolata*, *Shivparvatia ciliolata* var. *pendula* has two lines of trichomes. *Arenaria orbiculata* Royle ex Edgew. & Hook.f. and *Stellaria aquatica* both possess two lines of trichomes, but in *Arenaria orbiculata* vestiture is scabrous, while in *Stellaria aquatica* vestiture is tomentose. *Shivparvatia glanduligera*, *Silene conoidea*, *S. falconeriana*, *S. nepalensis*, *Stellaria depauperata* and *Arenaria bhutanica* had pubescent vestiture. *Stellaria depauperata* and *Arenaria bhutanica* are distinguished due to presence of only one line of trichomes in *Arenaria bhutanica* and both one and two lines of trichomes are present in *Stellaria depauperata*. *Shivparvatia glanduligera* possess trichomes either in two lines or in diffused manner and hence separated from the rest of taxa. The species *Silene conoidea*, *S. falconeriana*, *S. nepalensis* and rest of the species possess trichomes in diffused manner. The presence of different types of vestiture in studied taxa is summarized in table 2. In figure 2, representatives of aforementioned eight categories are depicted.

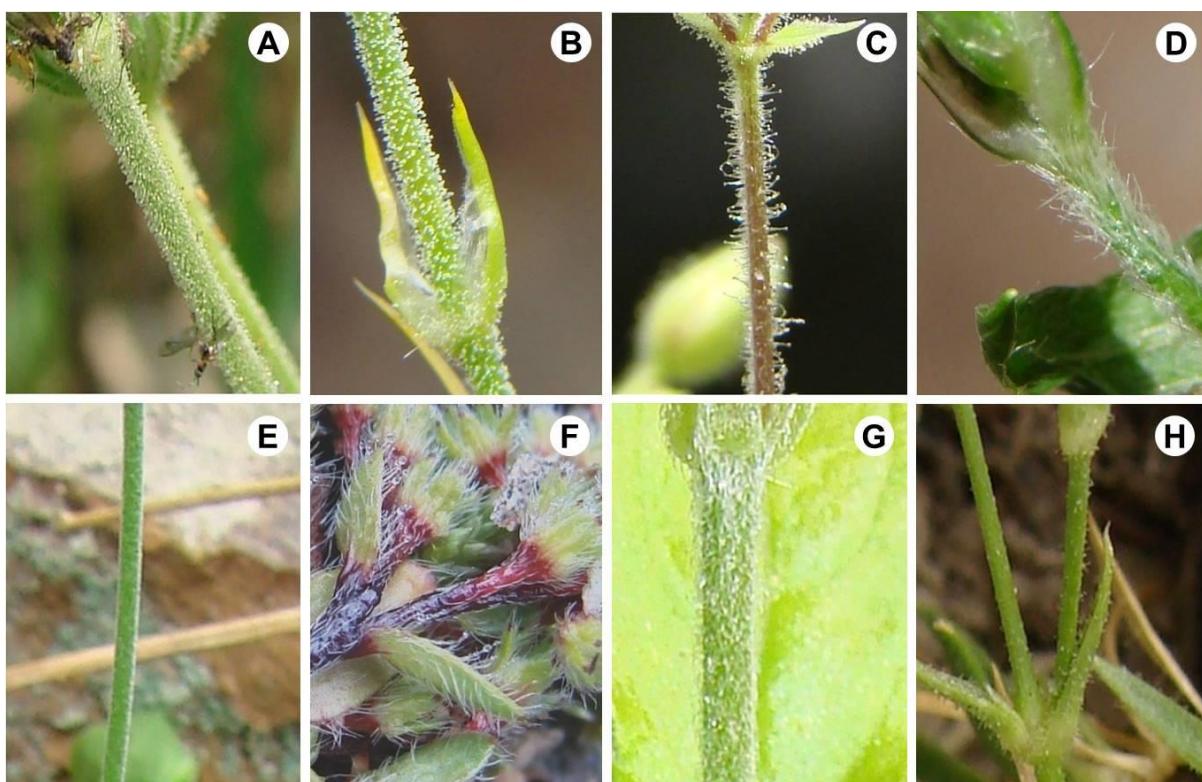

Figure 2. Different types of vestiture: **A**, Pubescent (*Silene conoidea*); **B**, Puberulent (*Eremogone curvifolia*); **C**, Tomentose (*Stellaria monosperma* var. *monosperma*); **D**, Villous (*Stellaria patens*); **E**, Scabrous (*Drymaria cordata*); **F**, Hirsute (*Herniaria cachemiriana*); **G**, Strigose (*Silene baccifera*); **H**, Strigulose (*Stellaria webbiana*).

DISCUSSION

Some of the investigated species had peculiar trichome morphology which can be used to distinguish them from the rest of the allied species. Moreover, trichome morphology and distribution do not play any significant

role in separation of genera. *Herniaria cachemiriana* has long unicellular stiff eglandular trichomes on different plant parts and multiseriate multicellular eglandular trichomes on the ovary. Metcalfe & Chalk (1950) also mentioned unicellular trichomes in *Herniaria*, *Paronychia*, *Anychia* and *Siphonochia* genus. Multiseriate trichomes are also reported from *Achyronichia* spp., *Cerastium* spp., *Pollichia* spp., *Polycarpon* spp., *Polycarpaea* spp., *Polytepalum* spp., *Krauseola* spp. and *Stipulicida* spp. (Bittrich 1993b). But the species of *Cerastium*, *Polycarpon* and *Polycarpaea* studied in the present work does not contain multiseriate trichomes. *Drymaria cordata* is characterized by presence of unicellular capitate glandular trichomes on stem, pedicel and sepal abaxial surface. Metcalfe & Chalk (1950) and Keshavarzi & Bozchaloyi (2014) also reported similar type of unicellular sessile capitate glandular trichomes in *Viscaria* spp. and *Silene propinqua* Schischk. *Polycarpon prostratum* possesses multicellular eglandular bifurcate trichomes and same type of trichomes also known in *Pollichia campestris* Aiton (Solereder & Scott 1986). Solereder & Scott (1986) reported eglandular trichomes containing two or more arms in *Cerastium dicrotrichum* Fenzl ex Rohrb., *Polycarpaea* spp. including *P. teneriffae* Lam. and *Stipulicida* spp.

Uniseriate multicellular eglandular or glandular trichomes are present in the *Silene*, *Stellaria*, *Arenaria*, *Odontostemma*, *Cherleria*, *Dianthus*, *Drymaria*, *Eremogone*, *Gypsophila*, *Lepyrodiclis*, *Polycarpaea*, *Sagina*, *Shivparvatis*, *Spergularia* and *Thylacospermum* possess. Similar uniseriate glandular or eglandular trichomes are also reported from *Acanthophyllum* spp., *Stellaria* spp., *Agrostemma* spp. (Shamsabad et al. 2013, Keshavarzi & Bozchaloyi 2014, Selvi et al. 2014). Keshavarzi & Bozchaloyi (2014) examined some taxa of subfamily Alsinoideae and found simple eglandular uniseriate trichomes in most of the taxa. Genera of subfamily Alsinoideae included in the present study are *Stellaria*, *Arenaria*, *Odontostemma*, *Cherleria*, *Eremogone*, *Lepyrodiclis*, *Sagina*, *Shivparvatis* and *Thylacospermum* which show similar morphology of trichomes as reported by Keshavarzi & Bozchaloyi (2014) in the subfamily.

Uniseriate multicellular eglandular and glandular trichomes present in all species of *Silene* understudy. Yildiz & Minareci (2008), Kilic (2009), Sahreen et al. (2010), Khan et al. (2013), Bagci & Bicer (2015) have also reported similar type of trichomes in different *Silene* species. All *Stellaria* species understudy possess uniseriate multicellular glandular or eglandular trichomes which correspond well with the results of Bozchaloyi & Keshavarzi (2014) who reported similar type of trichomes in different *Stellaria* species. During the present study uniseriate multicellular glandular and eglandular trichomes were found in *Cerastium fontanum* and *C. cerastioides*. Arcus et al. (2012) have also reported similar trichomes in *Cerastium bulgaricum* Uechtr., *C. tomentosum* L., *C. brachypetalum* Desp. ex Pers. and *C. glomeratum* Thuill. *Gypsophila cerastioides* possess only uniseriate multicellular eglandular trichomes but uniseriate multicellular glandular trichomes also were found in *G. lepidiooides* Boiss. (Ozdemir et al. 2010).

In the most of the genera understudy uniseriate multicellular trichomes with the glandular cell at apex along with unicellular eglandular trichomes were found. Species of *Silene*, *Shivparvatis*, *Stellaria*, *Cerastium*, *Odontostemma*, *Eremogone*, *Arenaria*, *Lepyrodiclis* and *Sagina* studied during present study possess both uniseriate glandular and eglandular trichomes. Metcalfe & Chalk (1950) mentioned presence of uniseriate multicellular trichomes with glandular cell at apex in the species of *Dysphania* (*D. myriocephala* Benth.), *Habrosia*, *Silene*, *Spergula*, *Spergularia* and *Loeflingia*. Al-Saadi & Al-Taie (2014) reported presence of uniseriate multicellular glandular and eglandular trichomes in different *Minuartia* species. Some completely glabrous species *Stellaria depressa*, *Spergula fallax* and *Cerastium davuricum* reported during present work *Corrigiola* sp., and *Telephium imperati* L. also show similar pattern (<https://www.infoflora.ch/fr/flore/339-telephium-imperati.html>, <https://florabase.dpaw.wa.gov.au/browse/profile/22402>).

In Caryophyllaceae, trichome presence and diversity can be used for delimitation of certain species i.e. *Spergula fallax* can be distinguished from morphologically similar *Spergularia rubra* due to having fully glabrous plant body. *Drymaria villosa* has strictly long multicellular uniseriate eglandular trichomes while its allied species *D. cordata* has unicellular glandular and eglandular trichomes. *S. incurvifolia* possess both multicellular uniseriate glandular and multicellular uniseriate eglandular trichomes while allied *S. incurvifolia* due to the presence of only multicellular uniseriate eglandular trichomes. Thus, *Silene moorcroftiana* can also be distinguished from former due to presence of the trichomes. *Silene kumaonensis* can also be distinguished from closely related *S. indica* by presence of only multicellular uniseriate eglandular trichomes, while both multicellular uniseriate glandular and multicellular uniseriate eglandular trichomes are found in *S. indica*. *Shivparvatis ciliolata* can be distinguished from *S. glanduligera* due to presence of only multicellular uniseriate eglandular trichomes, while *S. glanduligera* possess both multicellular uniseriate glandular and multicellular uniseriate eglandular trichomes. *Eremogone kumaonensis* and *E. festucoides* can also be distinguished by due to

presence of trichomes. *E. kumaonensis* contains multicellular uniseriate eglandular hairs and in *E. festucoides* both multicellular uniseriate glandular and multicellular uniseriate eglandular hairs present. *Sagina apetala* and *S. saginoides* also show same pattern. In *S. saginoides* only multicellular uniseriate eglandular trichomes are found, while both multicellular uniseriate glandular and multicellular uniseriate eglandular trichomes are found in *S. apetala*. Vestiture type can also be used to differentiate closely allied *Stellaria congestiflora* and *S. decumbens*. *Stellaria congestiflora* has villous vestiture while *S. decumbens* has strigulose vestiture. Similarly, *Silene indica* var. *indica* and *S. indica* var. *edgeworthii* can also be distinguished due to presence of tomentose vestiture in first and strigulose vestiture in later. Closely allied *Arenaria serpylifolia* and *A. neelgherrensis* can be distinguished on the basis of hairy leaf surface and sepal in first and glabrous leaf surface and sepal in the second. *Shivparvatia ciliolata* var. *ciliolata* and *Shivparvatia ciliolata* var. *pendula* also differ due glabrous leaf surface in the first variety and hairy leaf surface in second variety.

Trichome diversity and distribution in some angiosperm family as Asteraceae (Krak & Mraz 2008, Angulo & Dematteis 2014, de Andrade Wagner *et al.* 2014), Brassicaceae (Abdel 2005, Beilstein *et al.* 2006), Cucurbitaceae (Ali & Al-Hemaid 2011) Ranunculaceae (Hoot 1991), and some genera as *Colquhounia* (Hu *et al.* 2012), *Teucrium* (Navarro & El Oualidi 1999) of Lamiaceae has taxonomic significance and can be used for delimitation of tribes, genera, sections and series. But in the family Caryophyllaceae trichomes diversity and distribution does not have such significance.

After perusing literature and present work trichome types of 33 genera belonging to all eleven tribes of the family analysed and summarized in table 3. Interestingly, glabrous plants present in all tribes of the family. Further, it is concluded that trichome diversity and distribution does not play any significant role in the taxonomic delimitation neither generic nor tribal level of the family. Although, few closely allied species can be distinguished from each other either on the basis of presence of trichomes or vestiture pattern.

Table 3. Tribes and trichome types of the family Caryophyllaceae (after pursuing literature and present study).

S.N.	Tribe	Genera studied	Trichomes
1.	Sclerantheae	<i>Cherleria</i>	Uniseriate multicellular eglandular and glandular trichomes
2.	Saginae	<i>Sagina</i> and <i>Habrosia</i>	Uniseriate multicellular eglandular and glandular trichomes
3.	Spergulae	<i>Spergula</i> and <i>Spergularia</i>	Uniseriate multicellular eglandular trichomes
4.	Polycarpeae	<i>Drymaria</i> , <i>Polycarpaea</i> , <i>Polycarpon</i> , <i>Loeflingia</i> , <i>Achyronichia</i> , <i>Stipulicida</i> and <i>Krouseola</i>	Uniseriate multicellular glandular and Eglandular
	Exceptions	<i>Drymaria cordata</i> <i>Polycarpon prostratum</i> , <i>Polycarpaea</i> sp. and <i>Stipulicida</i> sp	Capitate glandular Bifurcate eglandular
		<i>Krouseola</i> sp. and <i>Achyronichia</i> sp. <i>Polycarpon loeflingiae</i>	Eglandular multiseriate Stellate
5.	Paronychieae	<i>Herniaria</i> , <i>Paronychia</i> , <i>Siphonochia</i> and <i>Pollichia</i>	Unicellular eglandular trichomes
	Exception	<i>Pollichia compestris</i> <i>Herniaria cachemiriana</i>	Bifurcate eglandular Multiseriate eglandular
6.	Corrigioleae	<i>Corrigiola</i> and <i>Telephium</i>	Glabrous
7.	Alsineae	<i>Cerastium</i> , <i>Lepyrodiclis</i> , <i>Odontostemma</i> , <i>Shivparvatia</i> and <i>Stellaria</i>	uniseriate multicellular eglandular and glandular trichomes
	Exceptions	<i>Stellaria vestita</i> and <i>Cerastium mollissimum</i> <i>Cerastium dicrotrichum</i>	Stellate eglandular bifurcate
8.	Arenarieae	<i>Arenaria</i>	Uniseriate multicellular eglandular and glandular trichomes
9.	Eremogoneae	<i>Eremogone</i> and <i>Thylacospermum</i>	Uniseriate multicellular eglandular and glandular trichomes
10.	Sileneae	<i>Agrostemma</i> , <i>Silene</i> and <i>Viscaria</i>	Uniseriate multicellular eglandular and glandular trichomes
	Exceptions	<i>Viscaria</i> sp. and <i>Silene propinqua</i>	Capitates glandular trichome
11.	Caryophylleae	<i>Acanthophyllum</i> , <i>Dianthus</i> , <i>Gypsophila</i> and <i>Vaccaria</i>	Uniseriate multicellular eglandular and glandular trichomes

ACKNOWLEDGEMENTS

Authors are thankful to Herbarium curator of Botanical Survey of India Northern Circle Dehradun (BSD), Forest Research Institute Dehradun (DD), H.N.B. Garhwal University Srinagar Garhwal (GUH), Kumaon University Nainital (KUH) and Wildlife Institute of India Dehradun for providing access to their herbaria and libraries. Authors also extend thanks to the anonymous reviewers for their suggestions and critical comments.
