## LIST OF TABLES

### Table

- 1 Locations (latitudes, longitudes) of sampling sites.
- 2 Site sampling dates and physical parameters. '--' indicates no weight obtained. The distance from the sample site to the lowest extent of the *Fucus* sp. boundary is also given for intertidal locations.
- 3 Presence (+) and absence of taxa recorded in the survey. See Table 5 for confirmed identifications of *Mytilus* sp.
- 4 Number of invertebrate taxa found in the Burrard Inlet survey categorized by major taxonomic group.
- 5 Identification of *Mytilus* sp. hybrids using GLU-5' enzyme marker (Rawson 1996). Samples from Sites 1 (West Vancouver Lab (tire)), 19 (Cates Tugs (float)), and 20 (Cates Tugs (piling)). Mg = *Mytilus galloprovincialis*; Mt = *Mytilus trossulus*; Me = *Mytilus edulis*. Mt/Mg and Mt/Me indicate hybrids of *M. trossulus* with *M. galloprovincialis* and *M. edulis*, respectively.
- 6 Preliminary list of non-indigenous and cryptogenic species reported from Vancouver harbour in present survey and the literature. '\*' indicates cryptogenic species.

## LIST OF FIGURES

### Figure

- 1 Location of sampling sites in Burrard Inlet, Vancouver, British Columbia.
- 2 Dendrogram for hierarchical clustering of benthic samples using group-average linking of presence/absence similarities. Group a – qualitative samples from floating structures; Groups b, c, d (intertidal and piling quadrat samples (except Site 2, obtained on a floating dock at West Vancouver Laboratory, West Vancouver)).

## **ABSTRACT**

Richoux, N.B., Levings, C.D., Lu, L. and Piercey, G.E. 2006. Preliminary survey of indigenous, non-indigenous and cryptogenic benthic invertebrates in Burrard Inlet, Vancouver, British Columbia. Can. Data Rep. Fish. Aquat. Sci. 1183: 20 pp.

In a preliminary investigation into the presence of non-indigenous invertebrates in Burrard Inlet, Vancouver, British Columbia, qualitative sampling on rocky shores, pilings and floating docks was conducted in July and August 2004. Twenty-nine sites were established, 34 samples were analysed, and 103 different taxa were identified. Data were also obtained on habitat characteristics including substrate type, salinity and temperature. Identification of polychaetes, mussels from four sites, all amphipods, isopods and patellogastropods have been confirmed by taxonomic specialists.

## **RESUME**

Richoux, N.B., Levings, C.D., Lu, L. and Piercey, G.E. 2006. Preliminary survey of indigenous, non-indigenous and cryptogenic benthic invertebrates in Burrard Inlet, Vancouver, British Columbia. Can. Data Rep. Fish. Aquat. Sci. 1183: 20 pp.

Des échantillonnages qualitatifs sur des berges rocheuses, des empilements et des quais flottants ont été effectués en juillet et août 2004 dans le cadre d'une enquête préliminaire sur la présence éventuelle d'invertébrés non indigènes dans l'inlet Burrard, à Vancouver (Colombie-Britannique). Vingt-neuf sites ont été établis, 34 échantillons ont été analysés et 163 taxa différents ont été identifiés. Des données ont également été recueillies sur les caractéristiques des habitats, notamment le type de substrat, la salinité et la température. La présence de polychètes, de moules provenant d'autres sites, d'amphipodes, d'isopodes et de patellogastropoda a été confirmée par des taxonomistes.

## INTRODUCTION

Vectors for invasion by non-indigenous marine species into coastal regions include transfer via ballast water, ship hulls and introduced aquaculture organisms (Levings et al. 2002). Habitats in Vancouver harbour and Burrard Inlet are subject to varying degrees of past and present ship traffic. We hypothesize that habitats nearest the location of the former Burrard Dry Dock (BDD), which operated from 1906 to 1992 (Anon. 2005) are characterized by the highest risk for exposure to non-indigenous species (NIS). A small dry dock operation continues adjacent to the location of the BDD. Locations near dry docks are considered high risk areas for NIS exposure as ships are routinely emptied of ballast water to raise them in the dock. In addition fouling organisms are likely to be scraped off ships' hulls during maintenance and subsequently introduced to the harbour when a ship is refloated. To test this hypothesis, benthic invertebrates were collected from boulders and floating docks along the northern coastline of Burrard Inlet to determine the natural species composition and the presence of non-indigenous and cryptogenic species. Particular attention was focused on taxa with direct development (e.g. amphipods and isopods) as species without planktonic larval stages might be expected to show a relationship with distance from a target source such as a dry dock.

With the aim of developing a comprehensive list of NIS in Vancouver harbour, a literature search was conducted to retrieve past records of NIS in this region. As noted in Levings et al. (2002) information on invertebrate communities in the harbour is almost entirely lacking, and therefore data on NIS are not readily available.

## METHODS AND DATA PRESENTATIONS

### Study Area Boundary

Literature records from locations east of a line from Point Atkinson to Point Grey were considered, and the boundaries of the present study extend from outer Burrard Inlet (north shore only) to outer Indian Arm (Figure 1).

### Sample Collection

Twenty-nine sites were established on the north shore of the Inlet. Thirty-four non-replicated samples were collected on hard substrates from these sites between July 28 and August 18 2004 (Figure 1). Sample locations for each site were determined with a Garmin GPS 76 (Table 1).

Whenever possible, intertidal sampling protocols for baseline port surveys used by Hewitt and Martin (2001) were employed. A 0.25m x 0.25m (0.06 m<sup>2</sup>) quadrat was used when collecting 29 of the 34 samples from above the water line. Quadrats were placed on boulders, wooden creosoted pilings, concrete slabs or rip rap and organisms removed using a household scraper. The remaining five samples (Sites 1, 19, 23, 31 and 32) were qualitative, removed by hand from under the water on floats or chains without the use of the quadrat.

Sampling was conducted on an ebbing tide at mid-tide level, and apart from the float collections, recently exposed benthic fauna were collected whenever possible. Digital photographs of the general landscape at each site and the specific quadrat placements are on file at CAER (formerly the West Vancouver Laboratory) for most of the sites.

Live samples were placed in 2L plastic jars and stored in an ice-filled cooler for subsequent transport to the laboratory.

Water temperatures were measured at the shoreline with a hand-held thermometer. Salinity samples were collected, stored on ice and determined several hours later using a refractometer. Time of day, air temperature, general weather characteristics, any details of interest regarding the site, and the distance of the quadrat to the tide line of attached *Fucus* sp. algae (when possible/applicable) were recorded for each site (Table 2).

### **Preliminary Sample Analysis**

Upon return to the laboratory, tared sample jars were weighed to provide an approximation of the wet biomass collected at each site (Table 2). Samples were spread onto a large enamel pan and rinsed with fresh seawater. Preliminary live sorting of delicate specimens such as polychaete worms, in addition to any visible specimens of interest, were separated into smaller jars containing seawater. The remaining samples were returned to the 2L containers and topped with seawater to a known volume. Small amounts of a 33% stock solution of magnesium chloride were added to the sample jars to narcotize and relax any remaining delicate specimens. Buffered formaldehyde (37.5% solution) was added to all sample jars within 1-3 hours of the preliminary live sorting process, resulting in a 10% formalin fixative solution. Within two weeks of collection, all samples were rinsed thoroughly in fresh water over a 355µm sieve and transferred to a 70% isopropyl alcohol solution for storage.

Samples were then sorted into the various taxonomic groups using a Wild M5 dissecting microscope where appropriate. Individual organisms were not counted. Samples have been archived at CAER for future analyses or verification of identifications.

### **Identification of Polychaeta Specimens**

All polychaetes were identified by L. Lu. Polychaetes from Site 19 were also identified by Sheila Byers, ScByers Environmental Services (202-1024 West 7<sup>th</sup> Ave., Vancouver, B.C. V6H 1B3) to provide additional verification. Samples at Site 19 were chosen for this additional step owing to its close proximity to BDD and the high diversity of specimens found.

### **Identification of Amphipoda, Isopoda and Mesogastropoda Specimens**

All amphipods, isopods and mesogastropods were identified by Phil Hoover, Biologica Environmental Services Ltd.

### **Identification of *Mytilus* sp. Specimens**

As species of *Mytilus* (*edulis*, *trossulus*, and *galloprovincialis*) are not readily distinguishable morphologically, two specific sampling excursions (Cates Tugs on October 21 2004; West Vancouver Lab on January 5 2005) were undertaken to obtain additional *Mytilus* individuals. These samples were identified using the GLU-5' enzyme marker (Rawson et al. 1996) by Dr. Dan Heath at the University of Windsor, Windsor, ON. At the Cates Tugs site, 10 mussels were collected from a piling near the end of the float and 10 were collected from below the water level along the side of the float. At the West Vancouver Lab site, 10 mussels were taken from a submerged tire on the float, and 10 others were collected from the styrofoam of the float. Samples were kept on ice during transport, and the mantle tissue was removed and stored in separate vials containing 100% anhydrous ethyl alcohol. The remaining tissue and shell samples were fixed in 10% formalin and stored in 70% isopropyl alcohol.

### **Statistical Methods**

Hierarchical agglomerative clustering, based on presence/absence similarities, was used to analyse differences in community structure of the benthic invertebrates found in the survey. A group-average linked method was used in clustering, and a Tukey multi-comparison of all clusters was performed using Primer-E (Clarke and Warwick 2001). For consistency, the data set that was analysed did not include the polychaete identifications from Sheila Byers.

### **Literature Searches**

Standard scientific bibliographic search engines (BIOSIS, ASFA, Google Scholar) were used in the literature search. Staff at the Royal BC Museum, the National Museum of Canada and the UBC herbarium were also consulted in addition to the literature collections of the authors. Computer based searches were completed up to August 31 2005.

## **RESULTS AND DISCUSSION**

A total of 103 taxa, primarily polychaetes, amphipods and cirripeds, were found in the survey (Tables 3 and 4). Confirmation of the status of these species will require further taxonomic investigations using classical or contemporary methods. In addition, there are a large number of unidentified specimens that need detailed examination to complete the survey. Since only one NIS (*Ampithoe valida* (Amphipoda) at three sites) with direct development was found, the relationship between NIS and distance from BDD could not be tested using the present data set. Results in Table 3 (polychaetes, amphipods, isopods, and mesogastropods excepted) should be considered preliminary as they have not been verified.

Including the two hybrids of the *Mytilus* species (Table 5), a total of 16 aquatic non-indigenous and cryptogenic species have been found in Vancouver harbour (Table 6). The summarized list includes macroalgae species in addition to invertebrate taxa from

habitats that were not surveyed in the present study, such as intertidal and subtidal soft sediments, and hard substrate organisms (e.g. Pacific oyster) that were not found at the locations we sampled. By comparison, 89 species of non-indigenous algae and invertebrates were noted by Levings et al. (2002) in the entire Strait of Georgia, including the estuary of the Fraser River where numerous NIS have been found.

Results of the cluster analysis showed that invertebrate communities from the qualitative samples obtained on floating structures were separated from those on the intertidal zone and pilings. An exception was the quadrat sample from Site 2 (West Vancouver Lab floating dock) which clustered with the intertidal and piling sites. More taxa were found in the float samples (Figure 2, Group A—31 taxa) relative to the intertidal grouping (Group B—13 taxa; Group C—18 taxa; group D—15 taxa (all expressed as mean number of taxa per site),  $p < 0.001$  in all comparisons), therefore the floating habitats appear to be more suitable for NIS surveys owing to their inherent species richness. In addition, unlike intertidal habitats that are exposed for sampling by foot only during low to mid tide, the floating habitats are available at any time during the tide cycle for quantitative work or qualitative "directed searches" for NIS (e.g. Cohen et al. 2005).

Biologica Environmental Services (2000) also sampled the fouling community on floats or floating structures at our Site 2 (West Vancouver Laboratory) and at a Lonsdale Quay location near our Site 19. Only ten taxa were found in these two samples, although the data sets are not strictly comparable as the Biologica Environmental Services (2000) study was done during late winter when populations are reduced. One cryptogenic species, *Neanthes succinea*, was found in the Biologica Environmental Services (2000) study, but not in the present survey.

In addition to unidentified NIS, it is possible there are as yet unidentified species in Vancouver harbour, particularly of the poorly known taxa. An example is the nemertean *Callinera zhirmunskyi* recently described by Chernyshev (2002) that was found at several subtidal stations (B-49, B-38, B-48, B-3A, B-11B; see Levings et al. (2003)) in the harbour by Chernyshev (2002).

## **ACKNOWLEDGEMENTS**

We thank Sheila Byers (ScByers Environmental Services, Vancouver) for the detailed identification of polychaetes and Phil Hoover (Biologica Environmental Services Ltd., Victoria) for detailed identification of amphipods, isopods and mesogastropods. Dr. Dan Heath and his staff at the Department of Biological Sciences and Great Lakes Institute for the Environment, University of Windsor, identified the mussels. Brianne Addison assisted in the laboratory. Appreciation is also extended to Mr. Phil Lambert, Royal British Columbia Museum, Victoria, B.C. and Drs. Kathy Conlan and Jean-Marc Gagnon, Canadian Museum of Nature, Ottawa, Ontario, for searching computer data bases at their respective museums. Funding was provided by DFO Science Branch, NCR.

<i>Strongylocentrotus droebachiensis</i> (O.F. Muller, 1776)												
<b>Miscellaneous</b>												
MOLLUSCA: BIVALVIA - clam shells							+					
ARTHROPODA: DIPTERA: CHIRONOMIDAE							+	+	+	+	+	+
ARTHROPODA: DIPTERA								+	+	+	+	+
algae - <i>Fucus</i> sp.										+		+
algae - other							+	+	+	+	+	+
MONOCOTYLEDONEAE (sea grasses)												
eggs												

Table 4. Number of invertebrate taxa found in the Burrard Inlet survey categorized by major taxonomic group.

Taxa	No. of Taxa
Porifera	1
Cnidaria: Hydrozoa	3
Platyhelminthes	1
Nemertea	3
Nematoda	1
Annelida: Polychaeta: Capitellida	1
Annelida: Polychaeta: Opheliida	2
Annelida: Polychaeta: Phyllodocida	18
Annelida: Polychaeta: Sabellida	1
Annelida: Polychaeta: Spionida	5
Annelida: Polychaeta: Terebellida	1
Annelida: Oligochaeta	1
Mollusca: Gastropoda: Nudibranchia	3
Mollusca: Gastropoda: Mesogastropoda	4
Mollusca: Gastropoda: Patellogastropoda	3
Mollusca: Bivalvia	2
Arthropoda: Pseudoscorpionida	1
Arthropoda: Ararida	1
Arthropoda: Crustacea: Copepoda	2
Arthropoda: Crustacea: Ostracoda	1
Arthropoda: Crustacea: Cirripedia	5
Arthropoda: Crustacea: Isopoda	5
Arthropoda: Crustacea: Amphipoda: Gammaridae	17
Arthropoda: Crustacea: Amphipoda: Caprellidae	4
Arthropoda: Crustacea: Decapoda: Anomura	1
Arthropoda: Crustacea: Decapoda: Brachyura	2
Bryozoa	5
Echinodermata: Asteroidea	1
Echinodermata: Echinoidea	1
Miscellaneous	7

Table 5. Identification of *Mytilus* sp. hybrids using GLU-5' enzyme marker (Rawson 1996). Samples from Sites 1 (West Vancouver Lab (tire)), 19 (Cates Tugs (float)), and 20 (Cates Tugs (piling)). Mg = *Mytilus galloprovincialis*; Mt = *Mytilus trossulus*; Me = *Mytilus edulis*. Mt/Mg and Mt/Me indicate hybrids of *M. trossulus* with *M. galloprovincialis* and *M. edulis*, respectively.

Site No.	Site Name	Sample No.	Sample Date	Identification	Shell Length (cm)
20	Cates Tugs (piling)	1	Oct 21 04	Mt	4.7
20	Cates Tugs (piling)	2	Oct 21 04	Mt	3.5
20	Cates Tugs (piling)	3	Oct 21 04	Mt	4.0
20	Cates Tugs (piling)	4	Oct 21 04	Mt	4.1
20	Cates Tugs (piling)	5	Oct 21 04	Mt	4.5

1	West Vancouver Lab (tire)	40	Jan 05 05	Mt	3.4

Table 6. Preliminary list of non-indigenous and cryptogenic species reported from Vancouver harbour in present survey and the literature. '\*' indicates cryptogenic species.

Species	Group	Common Name	Recorded Locations	Reference
<i>Antithamnionella spirographidis</i> (Schiffner) E.M. Wollaston, 1968	Algae	None	Stanley Park	Lindstrom, 1999 (record also in UBC herbarium)
<i>Sargassum muticum</i> (Yendo) Fensholt	Algae	Japanese weed	West Vancouver, North Vancouver floats; likely widespread	Present study; Lindstrom 1999 (records in UBC herbarium)
<i>Tubificoides benedii</i> (d'Udekem, 1855)	Oligochaete	None	Subtidal in central Vancouver harbour	Burd and Brinkhurst 1990
* <i>Boccardia columbiana</i> Berkeley, 1927	Polychaete	None	See Table 3	Present study
* <i>Nereis zonata</i> Malmgren, 1867	Polychaete	None	See Table 3	Present study
* <i>Platynereis</i> cf <i>bicanaliculata</i> (Baird, 1863)	Polychaete	None	See Table 3	Present study
<i>Polydora cornuta</i> Bosc, 1802	Polychaete	None	See Table 3	Present study
* <i>Typosyllis</i> cf <i>pulchra</i> (Berkeley and Berkeley, 1938)	Polychaete	None	See Table 3	Present study
<i>Ampithoe valida</i> S.I. Smith, 1873	Amphipod	None	See Table 3	Present study
<i>Nuttallia obscurata</i> (Reeve, 1857)	Bivalve mollusc	Varnish clam	Widespread in the harbour on intertidal soft sediment	Larson et al. 2003
<i>Crassostrea gigas</i> (Thunberg, 1793)	Bivalve mollusc	Pacific oyster	Second Narrow and Indian Arm on hard substrates	unpublished observations by GP 2001
<i>Mya arenaria</i> Linnaeus, 1758	Bivalve mollusc	Soft shell clam	Indian Arm on intertidal soft sediment	Horiguchi et al. 2003
<i>Mytilus trossulus</i> Gould, 1850 hybrids with <i>M. galloprovincialis</i> Lamarck, 1819 and <i>M. edulis</i> Linnaeus, 1758	Bivalve mollusc	Foolish mussel	West Vancouver, North Vancouver floats	Present study
<i>Venerupis philippinarum</i> (A. Adams and Reeve, 1850)	Bivalve mollusc	Japanese littleneck	Port Moody on intertidal soft sediment	Horiguchi et al. 2003
<i>Spartina anglica</i> C.E. Hubbard	Vascular plant	Cordgrass	North Vancouver (Maplewood mud flats); Port Moody (southwest shore); intertidal soft sediment	Williams 1999 in Levings et al. 2002

Figure 1. Location of sampling sites in Burrard Inlet, Vancouver, British Columbia.

Figure 2. Dendrogram for hierarchical clustering of benthic samples using group-average linking of presence/absence similarities. Group a – qualitative samples from floating structures; Groups b, c, d (intertidal and piling quadrat samples (except Site 2, obtained on a floating dock at West Vancouver Laboratory, West Vancouver)).
