Canadian Data Report of Fisheries and Aquatic Sciences

These reports provide a medium for filing and archiving data compilations where little or no analysis is included. Such compilations commonly will have been prepared in support of other journal publications or reports. The subject matter of Data Reports reflects the broad interests and policies of the Department of Fisheries and Oceans, namely, fisheries management, technology and development, ocean sciences, and aquatic environments relevant to Canada.

Numbers 1-25 in this series were issued as Fisheries and Marine Service Data Records. Numbers 26-160 were issued as Department of Fisheries and the Environment, Fisheries and Marine Service Data Reports. The current series name was changed with report number 161.

Data Reports are not intended for general distribution and the contents must not be referred to in other publications without prior written clearance from the issuing establishment. The correct citation appears above the abstract of each report.

Rapport statistique canadien des sciences halieutiques et aquatiques

Ces rapports servent de base à la compilation des données de classement et d'archives pour lesquelles il y a peu ou point d'analyse. Cette compilation aura d'ordinaire été préparée pour appuyer d'autres publications ou rapports. Les sujets des Rapports statistiques reflètent la vaste gamme des intérêts et politiques du Ministère des Pêches et des Océans, notamment gestion des pêches, techniques et développement, sciences océaniques et environnements aquatiques, au Canada.

Les numéros 1 à 25 de cette série ont été publiés à titre de Records statistiques, Service des pêches et de la mer. Les numéros 26-160 ont été publiés à titre de Rapports statistiques du Service des pêches et de la mer, Ministère des Pêches et de l'Environnement. Le nom de la série a été modifié à partir du numéro 161.

Les Rapports statistiques ne sont pas préparés pour une vaste distribution et leur contenu ne doit pas être mentionné dans une publication sans autorisation écrite préalable de l'établissement auteur. Le titre exact paraît au haut du résumé de chaque rapport.

ABSTRACT

Wacasey, J. W., E. G. Atkinson, and L. Glasspoole. 1980. Zoobenthos data from inshore stations of upper Frobisher Bay, 1969-1976. Can. Data Rep. Fish. Aquat. Sci. 205:42 p.

Data on marine zoobenthic invertebrates of upper Frobisher Bay, Baffin Island, were obtained from grab samples collected periodically from 1969 to 1976 from stations located along a 3.5 km track in water depths extending from 9 to 43 m. Methods of collecting and processing samples, and directions for the presentation of data are given.

Results are presented in tabular form and consist of density and biomass of species by station, and values of elements in sediments. Associated collecting data together with some data on benthic macrophytes and detritus are included.

Key words: Benthos: invertebrates, biomass, density, sediments, Arctic, Canada, Frobisher Bay.

RESUME

Wacasey, J. W., E. G. Atkinson, and L. Glasspoole. 1980. Zoobenthos data from inshore stations of upper Frobisher Bay, 1969-1976. Can. Data Rep. Fish. Aquat. Sci. 205:42 p.

Des données relatives aux invertébrés benthiques ont été obtenues dans le haut de la baie de Frobisher, Terre de Baffin; les échantillons ont été prélevés à la benne périodiquement de 1969 à 1976 à partir de stations situées le long d'un transect de 3.5 km, à des profondeurs variant de 9 à 43 m. On retrouve la description des méthodes de prélèvement et de préparation des échantillons ainsi que des directives sur la présentation des données.

Les résultats, présentés sous forme tabulaire, comprennent la densité et la biomasse des espèces par station et les valeurs des éléments dans les sédiments. Les autres données associées à l'échantillonnage de même que des données sur les macrophytes benthiques et les détritus sont incluses.

INTRODUCTION

Zoobenthic studies were initiated in 1967 in upper Frobisher Bay, southern Baffin Island, as part of a multidisciplinary program devised by the Biological Oceanography Section of the Arctic Biological Station. The objective of these continuing studies is to determine the nature and magnitude of the role of benthic invertebrates in an arctic marine ecosystem.

In a previous report Wacasey *et al* (1979) presented data from stations that were quantitatively sampled in a 1.2 km² area of upper Frobisher Bay in depths of water from 26 to 90 m. The present report includes data on zoobenthos collected from 5 inshore stations located along a 3.5 km track in water depths extending from 9 to 43 m (Fig. 1). These stations were sampled by grab periodically from 1969 to 1976. Samples were not taken in 1971, 1974, and 1975. Station 5b was sampled 10 times from 1969 to 1976; station 25 was sampled once in 1973 and once in 1976; stations 26, 27, and 28 were sampled only once in 1973.

The data, presented in tabular form, consist of density and biomass estimates of each species by station, and the totals for the stations. Although these totals pertain to the primarily infaunal component of the community, they reflect the largest proportion of the density and biomass of the community. A list of species from all stations is also given.

Sediment samples were usually collected when benthic samples were taken. Sediment data consist of values of particle-size distribution, pH, nitrate-nitrogen, ammonia-nitrogen, total nitrogen, organic carbon, carbon-nitrogen ratio, calcium, potassium, magnesium, phosphorus, iron, manganese, zinc, copper, and silicon.

Associated collection data, biomass of algae, and biomass of detritus are included.

DESCRIPTION OF STUDY AREA

The settlement of Frobisher Bay is located at the head of Koojesse Inlet in upper Frobisher Bay, Baffin Island (Fig. 1). A causeway built of rocks and boulders in the early fifties and now in disrepair is located along the eastern shore of the inlet 2 km south of the settlement. The study area, starting at a point immediately south of the end of the causeway, extends for 3.5 km to a point off Monument Island. Five stations (5b, 25, 26, 27 and 28) were sampled by grab in depths of 9 to 43 m along or near this 3.5 km line.

At all stations the predominant fraction of the sediments is sand. At the shallowest station, 5b, the sand fraction is variable suggesting

that the bottom in this area is patchy. Bottoms at the deeper stations are more uniform with the sand fraction of the sediments decreasing with depth.

Temperatures of water near the bottom vary from -1.8 to 1.5°C with positive temperatures occurring at the shallower stations from August to September. Salinities of water near the bottom vary from 31.0 to 33.6‰ and are uniformly maintained by the mixing effect of the large tides in the area.

The tides in upper Frobisher Bay are semi-diurnal with a mean range of 7.3 m and a large range of 11.6 m.

Ice which begins to form in late November or early December, depending upon the year, gradually increases in thickness to approximately 2 m by late May or early June when the snow cover melts and ice breakup commences.

METHODS

ASSOCIATED DATA

Associated data, mostly self-explanatory, are presented in Tables 1 and 2. The listed water depth of a station is that recorded at the time of sampling. Temperature and salinity values are available only from some of the stations. Calibrated reversing thermometers were used to determine temperatures. Prior to 1973 salinity values of water samples taken near the bottom were determined at Bedford Institute in Dartmouth, Nova Scotia. Subsequently, salinity values were determined on water samples at the Arctic Biological Station using a Bissett-Berman model 6230 laboratory salinometer. Temperature and salinity values apply to depths within 5 m of the bottom.

ZOOBENTHOS

A "Petterson" grab (Foerst, Chicago) was used to collect samples from the 15 m M. V. *Calanus* during the open water season, and from the surface of the ice in winter. This grab samples an area of 0.065 m² and has a volume of 5 L. A sample consisted of 4 to 6 grabs giving a total sampled area of 0.25 to 0.39 m². On soft bottoms the volume of a grab is governed by the depth of penetration which ranges from 4 to 10 cm depending upon the nature of the substrate. Grabs with less than 2 L of sediment or with rocks wedged in the jaws were not retained.

Following the collection of grabs at a station, sediments and contained organisms were washed on a stainless steel screen with a mesh size of 0.5 mm. Retained invertebrates and debris were preserved in formalin (1 part

formaldehyde with 9 parts water) for transporting to the Arctic Biological Station where they were processed.

Processing consisted of sorting, identifying, counting, and weighing the specimens in each sample. Organisms in each sample were sorted by hand using a Wild M5 dissecting microscope. Specimens were identified to species in most cases and representatives of the species were counted. Identification of species was not attempted on specimens in the taxa of nematodes, nemerteans, hydroids, bryozoans, and sponges, and although several species were represented, they were listed by taxon on a collective basis. In a similar manner sponges, bryozoans, hydroids, and other colonial forms were regarded as one individual or their presence was indicated by an "X". Names of some species may not be the most recent. Names which were used when the animals were initially identified have been retained to permit consistent referral to the species at different localities in the Canadian Arctic. Protozoans have been arbitrarily excluded from this report.

Following sorting and identification, specimens were oven-dried at 100°C overnight, then weighed on a Sartorius gravimetric balance in grams to four decimal places. The dry weights exclude tubes of polychaetes and shells of molluscs, but due to the difficulty of separating organic and inorganic fractions, the skeletal spicules of sponges and calcareous parts of echinoderms are included in the dry weights of these organisms. No effort was made to eliminate the gut contents of any of the organisms.

Data are presented on a m^2 basis. These values were derived by multiplying the number and weight of individuals of each species by a factor proportional to the area sampled for that station. For example, data from a sample of five "Petterson" grabs with a sampled area of 0.33 m^2 was multiplied by a factor of 3 to obtain the m^2 values. Most species collected by grab were considered to be representative and the sample values were uniformly converted to m^2 equivalents. In a few cases, as indicated, sample values were used without converting, because representation of large epifaunal species, which were infrequently collected, was not determined.

Species from all stations are listed in Table 3. Number of species, density, and biomass values for each station are summarized in Table 4. Density and biomass of species by station are presented in Tables 5 to 8. Biomass values for algae and organic debris (of terrestrial origin) were determined in the same way as the biomass values for the invertebrates and are listed by station or collection in Table 5.

SEDIMENT ANALYSIS

Samples of sediment were obtained from some of the collections made at Station 5b, and from stations 25, 26, 27 and 28. Approximately one litre of substrate, collected by grab from the station, was frozen for transportation to and storage at the Arctic Biological Station pending analysis.

Mechanical and chemical analyses of sediments were made by the Macdonald College Soil Testing Laboratory under the supervision of Dr. A. F. MacKenzie. Synoptic procedures and references provided by Dr. MacKenzie have been presented in Data Report No. 164 (Wacasey *et al*, 1979). Where applicable, values are related to 1 g of oven-dried sediment. In most cases the values of the determined substances are presented as levels of the substances in forms that are available to zoobenthos and phytobenthos; however, the significance and relationship of the substances to the biota remain to be evaluated. Data from sediment analyses are presented in Tables 10 to 13.

ACKNOWLEDGEMENTS

We thank B. Emmett, E. H. Grainger, J. Lovrity, B. Marchant, J. Negrijn, B. Petolas, G. Sleno, and D. Weston who, at different times, provided assistance during the collecting and processing of samples in the field, and to summer university students C. Lewis, M. Lines, and S. Starr who sorted the samples in the laboratory and made some of the identifications and counts.

Of our colleagues at the Arctic Biological Station we are grateful to E. H. Grainger and J. Lovrity for providing some of the temperature and salinity data, and to A. Mohammed for identifying the amphipods.

Appreciation is extended to L. McMullan and F. Reid for typing and preparing the manuscript for the printer, and E. Krivanek for making the illustration.
