Canadian Industry Report of Fisheries and Aquatic Sciences

Industry reports contain the results of research and development useful to industry for either immediate or future application. They are directed primarily toward individuals in the primary and secondary sectors of the fishing and marine industries. No restriction is placed on subject matter and the series reflects the broad interests and policies of the Department of Fisheries and Oceans, namely, fisheries and aquatic sciences.

Industry reports may be cited as full publications. The correct citation appears above the abstract of each report. Each report is abstracted in *Aquatic Sciences and Fisheries Abstracts* and indexed in the Department's annual index to scientific and technical publications.

Numbers 1–91 in this series were issued as Project Reports of the Industrial Development Branch, Technical Reports of the Industrial Development Branch, and Technical Reports of the Fisherman's Service Branch. Numbers 92–110 were issued as Department of Fisheries and the Environment, Fisheries and Marine Service Industry Reports. The current series name was changed with report number 111.

Industry reports are produced regionally but are numbered nationally. Requests for individual reports will be filled by the issuing establishment listed on the front cover and title page. Out-of-stock reports will be supplied for a fee by commercial agents.

Rapport canadien à l'industrie sur les sciences halieutiques et aquatiques

Les rapports à l'industrie contiennent les résultats des activités de recherche et de développement qui peuvent être utiles à l'industrie pour des applications immédiates ou futures. Ils sont surtout destinés aux membres des secteurs primaire et secondaire de l'industrie des pêches et de la mer. Il n'y a aucune restriction quant au sujet; de fait, la série reflète la vaste gamme des intérêts et des politiques du ministère des Pêches et des Océans, c'est-à-dire les sciences halieutiques et aquatiques.

Les rapports à l'industrie peuvent être cités comme des publications complètes. Le titre exact paraît au-dessus du résumé de chaque rapport. Les rapports à l'industrie sont résumés dans la revue *Résumés des sciences aquatiques et halieutiques*, et ils sont classés dans l'index annuel des publications scientifiques et techniques du Ministère.

Les numéros 1 à 91 de cette série ont été publiés à titre de rapports sur les travaux de la Direction du développement industriel, de rapports techniques de la Direction du développement industriel, et de rapports techniques de la Direction des services aux pêcheurs. Les numéros 92 à 110 sont parus à titre de rapports à l'industrie du Service des pêches et de la mer, ministère des Pêches et de l'Environnement. Le nom actuel de la série a été établi lors de la parution du numéro 111.

Les rapports à l'industrie sont produits à l'échelon régional, mais numérotés à l'échelon national. Les demandes de rapports seront satisfaites par l'établissement auteur dont le nom figure sur la couverture et la page du titre. Les rapports épuisés seront fournis contre rétribution par des agents commerciaux.

CONTENTS

ABSTRACT

Kulka, D. W. 1986. A summary of the observed 1983-84 Greenland halibut fisheries in NAFO Subareas 0, 2 and 3. Can. Ind. Rep. Fish. Aquat. Sci. 171: iv + 240 p.

In order to determine if the Canadian offshore fleet has been exploitating the Greenland halibut resource effectively, current fishing patterns for all countries were compared against depth and area specific catch rates, and levels of by-catch. Effort location and associated catches by Canada were found to be fairly similar to those of other countries. However, an average depth of 473 m fished by Canada in 1983 and 529 m in 1984 for otter trawl gear was somewhat shallower than the area of optimum returns in terms of high catch rate and low by-catch. The most effective pattern of fishing coincided with depths greater than 400 m (550 m average) mainly in the deep trenches of unit areas 212, 213, and 216 between the months of July and December. The exception was a small area in Hawke Channel (unit areas 202 and 207) at a shallower average depth of 300 m where catch rates were high. However, excessive by-catch tended to be a problem here. For fishing grounds currently not exploited by Canada, effort along the edge of the continental shelf in unit areas 213, 216 and 219 (900-1150 m) yielded relatively good catches. It is estimated that Canada could improve its catch per unit effort by about 25% if fishing was restricted to the above mentioned effort locations.

RÉSUMÉ

Kulka, D. W. 1986. A summary of the observed 1983-84 Greenland halibut fisheries in NAFO Subareas 0, 2 and 3. Can. Ind. Rep. Fish. Aquat. Sci. 171: iv + 240 p.

Afin de déterminer si la flottille hauturière canadienne a exploité efficacement les stocks de flétan du Groenland, on a comparé les modes actuels de pêche pour tous les pays par rapport aux taux de capture selon la profondeur et le secteur et les niveaux des prises accidentelles. On a trouvé que l'endroit où s'exerce l'effort de pêche et les prises connexes par le Canada étaient assez semblables à ceux d'autres pays. Cependant, la profondeur moyenne de 473 m en 1983 et de 529 m en 1984 à laquelle le Canada a pêché avec les chaluts à panneaux était un peu plus faible que la zone de rendement optimal en termes de taux élevé de captures et de prises accidentelles faibles. Le mode de pêche le plus efficace a coincidé avec des profondeurs supérieures à 400 m (moyenne de 550 m) surtout dans les fosses profondes des secteurs 212, 213 et 216 entre les mois de juillet et de décembre. Il y a eu une exception, soit une petite zone dans le chenal Hawke (secteurs 202 et 207) où les taux de capture ont été élevés à une profondeur moyenne plus faible de 300 m. Cependent, des prises accidentelles excessives avaient tendace à constituer un probléme à cet endroit. Pour ce qui est des lieux de pêche non exploités actuellement par le Canada, l'effort de pêche en bordure de la plate-forme continentale dans les secteurs 213, 216 et 219 (900-1550 m) a permis d'obtenir des prises relativement bonnes. On estime que le Canada pourrait accroître ses prises par unité d'effort d'environ 25% si la pêche était limitée aux endroits susmentionnés où s'exerce l'effort de pêche.

INTRODUCTION

In recent years while the Greenland halibut stock seems to have increased (Bowering and Brodie 1985) it has been underutilized by the Canadian fleet. This is reflected in the substantial amount of Canadian quota that remains untaken each year. Assuming that the resource is of value to the fishing industry, then an ineffective pattern of exploitation may be contributing to its underutilization. Therefore, an examination of the 1983-84 fishery, by country, month, area, and depth was done in order to determine if the Canadian fleet was exploiting the stock effectively. To this end, examination of current fishing patterns with respect to area specific catch rates and bycatch was felt to be the best method for determining the location of the best fishing grounds. Effort locations and associated catch statistics for all countries were considered in the analysis as a more complete source of information with respect to fishable concentrations given that Canada appeared to be restricted to certain areas. Observer data were able to provide the appropriate level of detail for all countries. It contained specific effort locations for both otter trawl and gillnet gear with detailed catch composition by set. The purpose of the analysis is to put forward a more effective exploitation strategy based on observations of the whole Greenland halibut fishery.

METHODS

Detailed catch and effort data were collected on a set by set basis for 36% of the Canadian and 83% of the reported foreign fisheries in 1983 and 1984, by standard methods (Kulka and Firth 1985). From the gillnet and otter trawl directed fisheries, observed sets were separated and sorted by country, month, unit area, and 50 m depth intervals (unit areas numerically coded are illustrated in Fig. 5 and 6). For each category separately and for various amalagamated groupings, catch rates and by-catch levels were defined. Various combinations of effort location were examined to delineate areas of best fishing. Pie charts were drawn to graphically illustrate by-catch with respect to location. Plots of catch rate versus depth were used to identify optimum fishing depth for the target species in terms of catch rate, for specific areas, seasons, and combined seasons and areas. These data were then compared against actual total effort location in 1983-84 and areal charts were produced to show where "best" fishing occurred.

RESULTS AND CONCLUSIONS

Tables 1a and b for the 1983 and 1984 otter trawl fisheries and 1c and d for the corresponding gillnet fisheries list by country, month, and unit area, a detailed breakdown of observed catch and catch rates, minor species included. They also provide average bottom depth fished. N-sets, referring to the number of sets observed to contain the corresponding species provided a measure of observed effort level within each subcategory.

The offshore Greenland halibut fishery was found to extend over a wide latitude from 63°N to 48°N, and over depths ranging from 200 to 1150 m. However, 63% of the fishing effort in terms of number of sets occurred in the 300 to 500 m range for otter trawl gear and 100% in 200 to 300 m for gillnets. The latter constituted a charter fishery and was confined to a small area in NAFO Div. 2J where catch rates and by-catches (mainly cod) were relatively constant. Gillnet effort was centered in unit areas 202, 203, and 207 during the fall. The otter trawl data however, indicated considerable variation among areas with respect to amount of effort, catch composition and catch rates. Although Greenland halibut were fished by otter trawl in 17 unit areas between May and February in 1983 and 15 between May and December in 1984, only about 50% of this fishery mainly to the north, resulted in high catch rates and low by-catch.

Figures 1 and 2 for 1983 and 1984 respectively, show catch composition by country, unit area and month. For otter trawl fishery, the level and composition of by-catch was highly variable. Principal by-catches, summarized in Table 2 for both gears illustrates that problem areas were located mainly to the south and offshore with witch, cod and redfish making up the bulk. Other redfish making up the bulk. Other species such as plaice, grenadier and skate were a problem only in specific and restricted areas.

Figures 3 and 4, for 1983 and 1984 respectively show average catch rates from the directed fishery at 50 m depth intervals. The general depth related pattern that emerges regardless of area or season is a rapid drop in catch rates in fishing depths of less than 400 m. The exception, a very restricted area in Hawke Channel (unit areas 202 and 207) yielded catch rates of about 1.1 t per hour at an average depth of 300 m. This portion of the fishery conducted by Poland in 1983 constituted less than 15% of total effort in that year. With it were associated relatively high by-catches of witch and cod which may account for the relatively low effort in this area. For all other areas, particularly in NAFO Div. 2H and 2J, catch rates peaked at depths between 450 and 600 m an almost identical pattern in both years. Catch rates rose rapidly from 350 m and where fishing depths exceeded 600 m rates generally remained relatively stable but somewhat below the maximum. The deepest observed fishery, that of the USSR in 2H, indicated best catch rates between 900 and 1150 m

indicated best catch rates between 900 and 1150 m along the edge of the continental shelf. In the gillnet fishery, gear was set over a very narrow range of depths averaging around 315 m. Here, it is difficult to determine the relationship of catch rates to depth and predict what might occur on the deeper grounds not currently exploited with this gear.

By comparing areas of low by-catch and high catch rates (Fig. 1-4) with the total area fished in 1983-84 (cumulative set positions for all observed Greenland halibut directed fisheries), plots of the best fishing areas were produced. Figures 5 and 6, for each of the years indicated that for otter trawl fisheries, optimum catch rates with low or medium by-catch occurred in units areas 339, 344, 202, 203, 207, 212, 215, and 216 mainly in depths between 450 to 600 m. Although the Canadian fleet fished these locations regularly, their effort was generally spread over a wider area including shallower depths where catch rates were lower and by-catch higher. Therefore, a more appropriate strategy based on the 1983 and 1984 data is to direct for Greenland halibut mainly in June to December in the deep trenches found in the above-mentioned unit areas, particularly 212 and 216. Best catches were and would continue to be sustained at 550 m and effort would best be concentrated in depths greater than 400 m. The southern ground in 339 and 344 while yielding relatively good catches of the directed species, tended to have moderate and some time high by-catches. In the most northern area particularly unit area 212, a catch rate of about 1.5 t per hour, about 40% above average was attained at positions where depths were between 500 and 550 m. Also for these areas, level of by-catch generally remained below 15%.

A comparison of otter trawl catches between Canada and other countries indicated that Canada's catch rates were not very different from the average. In 1983, Canada fished a wide range of latitudes at an average depth of 473 m, about 75 m less than the overall average. This relatively shallow average was due mainly to a substantial spring and summer fishery in unit areas 339 and 344. An associated catch rate of 0.78 t per hour was about 10% below average and by-catch of 27% was 19% higher. However, in 1984 the pattern changed somewhat as the observed Canadian fishery shifted to the deeper more northern areas, with average 529 m. The resulting catch rate increased to 1.07 t per hour, which was slightly above average. Also, corresponding by-catch dropped to 15%. The observed shift in effort location on the part of the Canadian fleet in 1984 toward deeper, more northerly fishing locations resulted in better catches.

Particularly in 1984, Canada attained catch rates that were comparable to or exceeded those of other countries with respect to conventional fishing areas. However, USSR fished considerably deeper in NAFO Div. 2G and 2H away from the more traditional grounds. In a depth range of 900-1150 m in unit areas 219, 216, and 213 USSR sustained relatively good rates of about 1 t per hour. In the southern portion of Subarea 0A catch rates of about 0.7-0.8 t per hour were sustained. Also, when USSR was directing for roundnose grenadier in Div. 2G and 2H, Kulka (1985) indicated that high by-catches of Greenland halibut were common in 600-900 m and often dominated the catches to the north. All of these data suggested fairly extensive Greenland halibut concentrations in deep waters currently not exploited by Canada.

In summary, although Canada's offshore fishery for Greenland halibut in terms of effort location was not greatly different from those of most other countries, catch rates could be improved by restricting effort to depths greater than 400 m (550 m average) and fishing mainly in the deep trenches of unit areas 212, 213, and 216 between July to December. In terms of fishing grounds not currently exploited by Canada, effort could be expanded to the edge of the continental shelf in unit areas 213, 216, and 219 in 900-1150 m where reasonably good catch rates were observed. This adjustment should result in an improved catch per unit effort of about 25% as well as providing for expanded fishing grounds.

GENERAL NOTES

Footnotes for Table 1a-d

A) All catch data are recorded in metric tonnes.

B) Depth is recorded in metres.

C) Turbot = Greenland halibut

D) Units areas, numerically coded as illustrated in Fig. 1 and 2.

E) Tables c and d listing gillnet data represent fisheries from Canadian quota taken by chartered Portuguese vessels.

ABBREVIATIONS

1) CATCHWT = weight of catch by species (MT).

2) N-SETS = number of sets observed containing the corresponding species. Number of sets listed for the directed species are the total sets observed.

3) AVGDEPTH = average depth fished in metres corresponding to those sets observed to contain the species.

4) C-SET = Catch per set in tonnes regardless of fishing time per set.

5) NHRS = total number of hours of fishing time where each species was observed.

6) C-HR = Catch per unit effort, in this case metric tonnes per hour.

7) TOTNETS = total number of nets used to take the corresponding weight of species (catchwt). Average number of nets used per set can be calculated by dividing tot nets by N-sets.

8) C-NET = catch per unit effort in terms of average catch per net, in metric tonnes.

Table 2. Principal by-catches in the 1983-84 Greenland halibut directed fisheries.

Unit area	Percentage[a]	Species
202[b]	Medium	Cod, witch
203	High	Cod, witch, redfish, plaice
204	Medium	Witch, plaice
206	Medium	Redfish, cod
207[b]	Medium	Cod
210[b]	Low	Cod
212[b]	Low	Cod
213	Low	Redfish
215[b]	Low	Plaice
216[b]	Low	Roundnose grenadier
334	Medium	Witch, plaice, redfish
339	Medium	Witch, plaice, cod
343	Medium	Cod, witch
344	High	Witch, cod, plaice
346	High	Redfish, witch
347	High	Redfish, witch

[a]Low refers to less than 20% total by-catch for all species combined, high about 40% or more.

[b]This symbol flags unit areas with high average catch rates.
