Supplement 2. Environmental factors that have been reported in the science literature as selecting for certain sponge morphologies, or accounts of sponge distribution patterns in relation to environmental parameters. To facilitate information retrieval and locating different growth forms, the main function categories [encrusting](#), [massive](#), [cup-like](#) and [erect](#) have been highlighted in colour to match colours used in the scheme overview and to visualise strong patterns (e.g. “laminar flow” is yellow-dominated = (2D-)erect dominated). Please note that the terms for the morphologies used in the cited publications do not exactly correspond to the presently proposed sponge classification scheme. Especially definitions for “massive” sponges differ widely, and 2- and 3-dimensionally branching sponges were almost never differentiated (see [Suppl. 1](#)).

Environmental condition	Sponge morphologies	Reference
Hydrodynamics		
Strong, turbulent flow with high drag force of unpredictable direction	<p>Calcified sclerosponges of low relief live at exposed sites at the reef edge but also often occur at deeper sites to about 100 m with reduced water movement. Their overall shape was described as massive, encrusting and tabular, but similar to corals they have only a thin veneer of living tissue on top of the skeleton they form and often function as encrusting sponges, depending on the overall shape.</p> <p>In a reef environment, no sponges were found at the shallowest sites, and endolithic-bioeroding sponges were detected at slightly deeper sites (in SCUBA diving depth).</p> <p><i>Halichondria panicea</i> develops a higher structural rigidity in times and at sites with stronger turbulent flow. At exposed sites this species also has a more massive, more compact body shape compared to in reduced flow. At low-energy sites the morphology is more delicate and can tend towards more branching shapes, including raised oscules that attain a fistular function. In general, oscules were at the outer edges of the sponges, where maximum flow was achieved.</p> <p>Jackson (1979) ranked expected success of sessile marine invertebrates in strong flow as creeping, encrusting, massive (here including cups) > rope sponges that are here understood as creeping (his “vines”) > tabular, erect-branching. “Maintenance of relatively large areas of attachment [...] should make mounds [= simple-massive] more resistant to strong water movements”.</p> <p>Encrusting sponges are resistant to turbulent flow, cup-like, simple-erect and erect-branching sponges less so.</p> <p>Strong, unpredictable flow conditions select against more delicate and erect morphologies by causing damage, dislodgement, fragmentation, scouring and abrasion. As good mixing guarantees a good food supply, sponges do not have to spatially separate their in- and exhalants. Risk of smothering and clogging is reduced by strong flow, so that low-relief forms that are less feeding-efficient can settle under these conditions, and often encrusting forms dominate.</p> <p>The encrusting to massive <i>Pachymatisma johnstonia</i>, <i>Thymosia guernei</i>, <i>Tethyspira spinosa</i> and <i>Myxilla (Myxilla) rosacea</i> predominantly occurred at wave-swept sites.</p> <p>As a general rule, organisms in wave-swept or strong-current environments either reduce the effects of the fluid-dynamic forces by being small, having a low profile and large attachment area, or they are flexible and move with the forces. Some avoid wave force by seeking out concave shelters (e.g. sea urchins, snails; note by Schönberg: see also sponge balls). Morphologies may vary from crusts in the surf zone to erect forms in deeper water (e.g. <i>Millepora complanata</i>).</p> <p>In less than 10 m depth in a reef environment, sponges were generally smaller than fist-size, with the exception of some larger endolithic-bioeroding sponges.</p> <p>At sites in shallow water, the effect of turbulence, waves and storms was most pronounced and selected for a predominance of encrusting and endolithic-bioeroding sponges. The ball-shaped <i>Tectitethya crypta</i> (as <i>Tethya</i>) and the encrusting morphology of the rope sponge <i>Clathria (Thalysias) virgultosa</i> (as <i>Rhaphidophylus juniperinus</i>) were more common in the shallow water.</p>	<p>Hartman and Goreau, 1970</p> <p>Rützler, 1972</p> <p>Vogel 1974; Peattie and Hoare, 1981; Palumbi, 1984, 1986; Barthel, 1991; Schönberg and Barthel, 1997</p> <p>Jackson, 1979</p> <p>Trammer, 1979</p> <p>Hiscock, 1983</p> <p>Hiscock et al., 1984</p> <p>Denny et al., 1985; Denny, 1988</p> <p>Alcolado, 1990</p> <p>Schmahl, 1990</p>

Environmental condition	Sponge morphologies	Reference
Ctd.: Strong, turbulent flow	<p>The erect-branching, “ropy” <i>Agelas sceptrum</i> suffered a large rate of fragmentation during a hurricane, but many fragments also quickly re-attached and recovered.</p> <p>Simplified summary: In experiments using objects of different shapes placed broadside to the tested current, a plate (erect-laminar) experienced higher drag forces than a cylinder (tube or barrel), than a shallow cone (mound, simple-massive), than a ball.</p> <p>In erect-branching sponges a high spongin content safeguards against physical tearing and fragmentation.</p> <p>In comparison between an exposed and a sheltered reef site, the proportional distributions of sponge morphologies did not much vary between the two, but at both sites encrusting sponges dominated. The ball-shaped <i>Cinachyrella arabica</i> (as <i>C. voeltzkowii</i>) was the only sponge present and abundant on the upper shore.</p> <p>The authors’ exposed site had poor diversity of sponge morphologies, mostly reduced to encrusting and well-attached simple-massive sponges, lacking sponges with small attachment area. This was true for inclined, as well as for vertical surfaces.</p> <p><i>Cliona</i> cf. <i>celata</i> was encrusting and ridge-like simple-massive in strong, turbulent flow</p> <p>The ball-shaped <i>Cinachyrella australiensis</i> was larger and rounder in stronger flow and had a higher content of inorganic skeleton, as well as thicker spicules.</p> <p>The ball-shaped <i>Tetilla</i> sp. had larger bodies in stronger, turbulent flow, a higher content of inorganic skeleton, and longer spicules.</p> <p>When transplanted from 3 to 1 m, the thickly encrusting to creeping to tubular <i>Haliclona</i> (<i>Soestella</i>) <i>caerulea</i> developed a larger attachment area, smaller, but more oscules, a higher density, and a higher inorganic content (spicules, but also algal partner scaffold).</p> <p>Compared to sheltered embayments, survey sites with ocean swells were dominated by encrusting morphologies (by % cover), with low diversity, but variability over time.</p> <p><i>Aplysina cauliformis</i> commonly occurs in areas with strong waves, frequent exposure to storms and sedimentation. It is erect-branching, but it also has a high spongin content and is flexible. It furthermore tends to be repent. The broad base of the barrel-shaped <i>Sphaciospongia vesparium</i> provides a good attachment and protection against storm damage.</p> <p>The often sack-like glass sponge <i>Aphrocallistes vastus</i> had a smaller, more compact morphology at more exposed sites.</p> <p>Rocky substrate at an exposed coast was predominately covered by encrusting sponges.</p> <p>Ordination on a sponge community associated the thickly encrusting sponge <i>Placospongia melobesioides</i> and the fistular species <i>Oceanapia sagittaria</i> and <i>Coelocarteria singaporensis</i> with exposure, the thickly encrusting to creeping to erect-branching <i>Neopetrosia chaliniformis</i> (as <i>N. exigua</i>) with offshore habitats.</p> <p>Globular sponges were more prevalent with exposure (stronger flow). Creeping, massive-creeping (with upright branches, i.e. in function fistular or erect-branching?) and thickly encrusting to massive sponges were found at shallow depth (where flow would be more turbulent than at depth).</p> <p>Dislocated sponges that washed up on the beach by waves were mostly branching, massive and cushion-shaped. Encrusting species were never found washed up. While sponges with high spongin content occurred in the area, they were not found washed up.</p> <p>Exposed coral reef sites with turbulent flow had more sponges with “irregular-massive” growth forms.</p> <p>New Zealand intertidal sponges were dominated by encrusting, fistular and ball-shaped forms.</p>	<p>Fenner, 1991</p> <p>Denny, 1994</p> <p>Wulff, 1997</p> <p>Barnes, 1999</p> <p>Bell and Barnes, 2000a, 2000b</p> <p>Bell et al., 2002b</p> <p>MacDonald et al., 2002</p> <p>Meroz-Fine et al., 2005</p> <p>Carballo et al., 2006</p> <p>Roberts et al., 2006a</p> <p>Alcolado, 2007</p> <p>Austin et al., 2007</p> <p>Carballo and Nava, 2007</p> <p>Cleary and de Voogd, 2007</p> <p>De Voogd and Cleary, 2007</p> <p>Ávila et al., 2011</p> <p>Hadi et al., 2015</p> <p>Rush et al., 2017</p>

Environmental condition	Sponge morphologies	Reference
Strong, laminar flow	<p>“There is a possibility that [fan-shaped sponges] are found always in a permanent current, on which they depend for subsistence. [...] It is possible that the fan-shaped form only occurs in response to the stimulus of a constant current [...] across which its plane is extended.” Bidder (1923) hazarded that cups result from constant flow that changes across all directions.</p>	Bidder, 1923
	<p>“Plates [= tabular sponges] cannot usually grow as high as trees [= erect-branching sponges] and thus may have less access to the water column [= resource limitation]. Depending on their orientation, however, their large, flattened surfaces may be more effective than the branches of trees in obtaining resources in unidirectional water regimes. A potential cost is a greater vulnerability to strong water movements.” But such sponges usually have a high spongin content, see other listings.</p>	Jackson, 1979
	<p>Passive suspension feeders with erect-laminar bodies orient themselves at right angle to the predominant current.</p>	Hiscock, 1983
	<p>The thickly encrusting to branching <i>Halichondria panicea</i> and <i>Amphilectus fucorum</i> occurred at strong-current sites exposed to tidal flows.</p>	Hiscock et al., 1984
	<p>Erect, branching parts of the freshwater <i>Spongilla lacustris</i> could not be maintained when stream flow seasonally increased. Branches were detached, and crusts of the sponge remained behind.</p>	Manconi and Pronzato, 1991
	<p><i>Spongia (Spongia) agaricina</i> had a cup-like to erect-laminar form and preferentially occurred at sites with laminar flow.</p>	Pronzato et al., 1998
	<p>Branching sponges have a higher branch complexity and more branches in stronger flow.</p>	Abraham, 2000; Lawler and Osborn, 2008
	<p>“The orientation of an individual sponge to the direction of the [tidal] current was [...] dependent on its morphology, with [2-D and 3-D branching, flexible] species orientated across the current.” More rigid, massive sponges were at right angle to the prevailing currents at lower flow speed and parallel to the current at high flow speeds. Encrusting sponges were less clearly oriented but mostly extended parallel to the current.</p>	Ginn et al., 2000
	<p><i>Cliona</i> cf. <i>celata</i> was encrusting and ridge-like, simple-massive in strong flow and had more oscules per area than in low flow.</p>	Bell et al., 2002
	<p>In strong tidal currents <i>Spongia</i> sp. oriented itself with the broad face across prevailing currents. It grew faster in that orientation than when placed in parallel with the currents. This was explained as an optimisation for feeding by separation of in- and exhalant streams.</p>	McDonald et al., 2003
<p>Erect-laminar Axinellidae were reported for northern Australian sites with strong tidal currents.</p>	Alvarez and Hooper, 2009	
<p>Predominant morphologies in elongated valleys between scarps were erect-branching (here: “arborescent”), fistular (“digitate”) and erect-laminar (“pedunculate”). Geomorphology may suggest laminar flow.</p>	Ruzicka and Gleason, 2009	
<p>Laminar flow favours a high frequency of erect-laminar and palmate sponges, situated at right angle to the predominant flow direction; these sponges have a high spongin content and are flexible to bend in strong flow regimes.</p>	Schönberg and Fromont, 2012	
<p>The flexible, erect-laminar sponge <i>Ianthella flabelliformis</i> had “positive affinities for seabed current stress” at a northern Australian site with strong tidal currents (Torres Strait). The area also had a high frequency of ball-shaped sponges.</p>	Pitcher et al., 2007	
Strong to moderate, but predictable, steady flow	<p>Sponges adapted to stronger flow with increased wall thickness (in tubes) or overall reinforcement.</p>	Schmahl, 1990
	<p>Modelling and transplantation showed that the branching, mostly erect-palmate sponge <i>Haliclona (Haliclona) oculata</i> produced thinner branches in reduced flow, and wider, more flattened branches under increased flow. With stronger flow the variation in branch spacing and the chance of branch fusion also grew.</p>	Kaandorp, 1991; Kaandorp and de Kluijver, 1992; Kaandorp, 1999
	<p>Crusts were by far most dominant overall, and especially in shallow water between ca. -90 and -170 m. All morphologies were most abundant in -90 m, with cups also being common around -370 m and dominant at about -520 m (here: astrophorines), which the authors interpreted as an adaptation to maximize feeding and sediment avoidance (presumably in reduced flow). Massives were dominant around -480 m. Erect, whip-like (simple-erect) and branching sponges only occurred to -140 m.</p>	Maldonado and Young, 1996
	<p>Of 3 local <i>Spongia</i> species, <i>S. (Spongia) officinalis</i> displayed the most variability in morphology and occurred across the widest range of habitats. It is mostly massive, but it has a slight separation of in- and exhalants (side and top, respectively). The distribution peak of <i>S. officinalis</i> did not match the highest sedimentation peak.</p>	Pronzato et al., 1998

Environmental condition	Sponge morphologies	Reference
Ctd.: Strong to moderate flow	Branching sponges have an increased branch complexity and more branches in higher flow.	Abraham, 2000; Lawler and Osborn, 2008
	The predominantly massive <i>Rhopaloides odorabile</i> occurred at more exposed locations with stronger flow. This is here interpreted as a necessity arising from its surface with mixed in- and exhalants that require good flow in order to prevent re-inhalation of exhaled water. Cups were found at offshore sites with high wave energy and exposed to oceanic swells. [... At sites] “where the current is strong and constant, tube- and vase- shaped sponges dominate.”	Bannister et al., 2007 De Voogd and Cleary, 2007 Díaz, 2012
Reduced flow	In the encrusting sponge <i>Ophlitaspongia papilla</i> (as <i>O. seriata</i>) the “membranous contractile oscular papillae [...] are much more strongly developed” at a flow-reduced than at a “hydrodynamically more violent” site. Sponges at the former site had a cuticle, at the latter not. Simple-erect and erect-branching sponges are more in danger of fragmentation in stronger, turbulent currents than other forms, but they reach into the water column to enter a better flow regime to transport nutrients to them. They require moderate flow regimes.	Fry, 1971 Trammer, 1979
	Weak water movement prevents physical damage and enables the survival of delicate and erect morphologies and selects against the usually strong space competitors with encrusting habit. Enhanced sedimentation leads to clogging and smothering and to the exclusion of morphologies with large horizontal surface area such as encrusting sponges, instead selecting for erect forms raised above the sediments or those with parts above the sediments (e.g. with fistules). Reduced mixing causes food and oxygen limitation, favouring erect forms. In fistular sponges, the exhalant fistules are well above inhalant structures to afford spatial separation (see Suppl. 4 and 5.2H, I and P – in clionids the inhalant fields are usually at the bases of the closed fistules, the exhalants are usually bundled together and raised above the sponge’s surface; Schönberg, pers. obs.).	Hiscock, 1983
	The ball-shaped <i>Suberites carnosus</i> and the ball-shaped to massive <i>Suberites ficus</i> were restricted to wave-sheltered sites. Larger and erect sponges such as axinellids and poecilosclerids were found at wave-sheltered sites or microhabitats and in the circalittoral at depths deeper than -10 m, where flow was reduced in comparison to shallower sites. Encrusting sponges were rare.	Hiscock et al., 1984
	Erect sponges in shallow water were more abundant at sheltered than at exposed sites. Some common tubular and more delicate cup-like sponges and barrels were restricted to deeper sites in 13 m.	Schmahl, 1990
	Hexactinellida can develop a symmetry in accordance to the predominant flow: “The dermal surface of these sponges is exposed to the water current, while the atrial surface is at the lee side.” This means that these sponges are arranged so that the inhalants point into the arriving current, the exhalants are aligned with the leaving current, and the wastewater can be carried away more efficiently.	Tabachnick, 1991
	In a comparison between low-profile (“ encrusting ”) and higher profile (“ erect ”, here including e.g. cups) sponges, the latter became much more prevalent with depth (= reduced flow, finer sediments), while encrusting morphologies became less common.	Roberts and Davis, 1996
	Branching sponges have fewer branches in reduced flow.	Abraham, 2000; Lawler and Osborn, 2008
	Sponge morphological diversity increased with depth, sedimentation and with reduced flow (in shallow depths), the frequency of more delicate erect-branching forms increased; settling on vertical surfaces generated refuge for other forms. In three-dimensionally erect-branching sponges branching complexity was reduced with reduced flow.	Bell and Barnes, 2000a, 2000b; Bell et al. 2002a
	The simple-massive <i>Cliona</i> cf. <i>celata</i> produced the largest individuals in stable, low flow conditions.	Bell et al., 2002b
	Tubular individuals of <i>Callyspongia (Cladochalina) aculeata</i> (as <i>Callyspongia vaginalis</i>), <i>Agelas conifera</i> and <i>Aplysina fistularis</i> grew to higher total heights at deeper depth with reduced flow (25 m) compared to a site in shallower water (14 m). However, growth rates at depth were also higher due to a higher nutrient concentration.	Lesser, 2006; Trussell et al., 2006
Compared to sites exposed to ocean swells, sheltered survey sites were dominated by “ erect ” morphologies (here including massives), with higher diversity and less variability over time (by % cover).	Roberts et al., 2006a	

Environmental condition	Sponge morphologies	Reference
Ctd.: Reduced flow	<p>Ordination on a sponge community associated <i>Clathria (Wilsonella) mixta</i> (erect?) and the thickly encrusting or creeping species <i>Iotrochota baculifera</i> with sheltered sites. The ball-shaped <i>Melophlus sarassinorum</i> that is slightly removed from the substrate by foot-like little stalks, and the ball-shaped <i>Diacarnus megaspinorhabdosa</i>, the creeping <i>Pseudoceratina verrucosa</i>, <i>Xestospongia mamillata</i> (thick crust? Species was originally described as fragment) and the tubular sponges <i>Haliclona (Reniera) fascigera</i> and <i>Niphates olemda</i> were found in deeper water with presumably reduced flow.</p> <p>Barrels such as <i>Xestospongia testudinaria</i> and larger massive sponges occurred in deeper water, where wave energy would be reduced. Balls are smaller with reduced flow.</p> <p>The thickly encrusting to composite-massive to tubular <i>Dysidea avara</i> became increasingly less compact and more erect and branching with water depth and reduced flow speed. At a calm-water site the oscules were particularly large, and the erect branches tube-like, achieving the best separation between inhaled and exhaled water and becoming more fistule-like. During intermittent high-flow periods, these large oscules were closed.</p> <p>Occurrence of erect sponges in soft bottom environments moderately correlated with reduced clay in the substrate, suggesting that they required slightly elevated flow conditions. This was explained in a need for being provided adequate nutrients for filter feeding. The weak correlation of <i>Xestospongia</i> sp. barrels with mud was explained with their tolerance to reduced flow conditions.</p> <p>The morphologically variable <i>Halichondria (Halichondria) melanadocia</i> had larger volumes and much larger oscules in the more sheltered seagrass environment than in the mangrove system with slightly more flow. Larger oscules allow stronger exhalant flow, which reduces the risk of re-inhaling wastewater under stagnant conditions (Bidder, 1923). Both sites had similar sedimentation conditions. Sponge height was similar in both habitats.</p> <p>Coral reef sites with reduced flow had more sponges with delicate (erect?) growth forms, including “breakable” ones.</p> <p>The massive <i>Coscinoderma matthewsi</i> was more abundant and had larger individuals in 12 than in 6 m, where flow was halved; it had a simple-massive morphology in 6 m, and a more “lobed” composite-massive, or more erect morphology in 12 m, which was explained as an adaptation to increase access to food.</p>	<p>Cleary and de Voogd, 2007</p> <p>De Voogd and Cleary, 2007</p> <p>Lawler and Osborn, 2008</p> <p>Mendola et al., 2008</p> <p>Kelly and Przeslawski, 2012</p> <p>Ávila and Ortega-Bastida, 2015</p> <p>Hadi et al., 2015</p> <p>Duckworth, 2016</p>
Low flow to stagnant water	<p>Encrusting forms are very much governed by near-substrate conditions and cannot reach beyond that. Boundary layer resources are often restricted, while at the same time a comparatively large tissue area is exposed to possible disturbance.</p> <p>At greater depth [= with finer sediments and reduced flow], sponges develop special morphological structures such stalks to be distanced from the substrate. While such stalks appear of similar length between younger and older sponges, the body size increases with age. This may relate to the need to reach a layer in the water column where flow regime is more favourable.</p> <p>The morphologically variable sponge <i>Halichondria panicea</i> develops an increasingly more tubular structure in more sheltered environments and is more encrusting and compact (=simple-massive) where it is more exposed.</p> <p>Larger encrusting sponges are not usually found in “continuously still water”. Separation of their in- and exhalants was assumed to be insufficient to prevent re-inhalation and thus to prevented them from growing into larger specimens.</p> <p>According to Trammer (1979), tubular and cup-shaped sponges can tolerate strongly reduced flow, as their inhalant and exhalant structures are separated. However, this does not yet take into account that reduced flow means increased sediment deposition and finer sediments, which will be a trade-off for these forms.</p> <p>With distance into caves, flow reduction and darkness resulted in food limitation. Here, thin crusts “with a more efficient filtration surface ratio” dominated.</p> <p>Fragile Hexactinellida cannot tolerate high-energy hydrodynamic conditions. To compensate for reduced filter-feeding efficiency, they have switched to osmotrophy, i.e. they are feeding on dissolved or colloidal materials and enhance absorption in stagnant waters by developing thin-walled morphologies with a high surface : volume ratio. Spicular veils can supplement the diet by becoming habitats for microbial communities.</p>	<p>Jackson, 1979</p> <p>Burton, 1928</p> <p>Burton, 1928</p> <p>Fry, 1979</p> <p>Trammer, 1979</p> <p>Bibiloni et al., 1989</p> <p>Leinfelder, 1996; Krautter, 1998</p>

Environmental condition	Sponge morphologies	Reference
Ctd.: Low flow to stagnant water	<p>With bathymetry and reducing flow, incidence of erect-branching forms increases, including forms with short stalks. <i>Haliclona caerulea</i> transplanted from 3 to 5 m developed a larger surface area by growing many little erect extensions or branchlets (only in cages, which may have created stagnant and nutrient limited conditions).</p>	<p>Bell and Barnes, 2000a Carballo et al., 2006</p>
Substrate/sediment quality		
Prevailing hard = rocky or coral substrate	<p>Even though creeping forms are probably the most versatile in using different substrates or even altering the growth direction from horizontal into a more vertical aspect, Jackson (1979) identified them as most vulnerable to substrate-related factors. He however allowed that possible damaging effects will rarely kill the entire animal, and regeneration will occur. Erect forms and cup-like forms with small attachment areas are most removed from substrate effects. He ranked expected success on instable substratum as creeping, encrusting, vines (= creeping rope sponges potentially with erect elements) > massive (including cup-like forms) > tabular, erect-branching.</p> <p>Comparing Antarctic sponge communities, on muddy substrate Demospongiae with fistules or surface cleaning capability prevailed, while on hardground stalked Demospongiae and cup- and sack-like Hexactinellida dominated.</p> <p>Hard bottom had higher total, erect and massive or thickly encrusting sponge densities than cobble or gravel.</p> <p>Morphological and species richness were correlated, but in the reef environment taxonomic diversity increased stronger with morphological diversity than in a soft sediment environment.</p> <p>Rocky substrate at an exposed coast was predominately covered by encrusting sponges. Apart from that, bedrock (stable, in 2-3 m depth) was dominated by the massive <i>Haliclona caerulea</i>, and endolithic bioeroders were more common on boulders (occasionally overturned by storms? in 4-6 m).</p> <p>[... In the present study] “there is a clear dominance of tubular, creeping, and massive sponges among conspicuous coral reef species, whereas thin and massive crusts predominate among mangrove species. [...] On open reef habitats, the most conspicuous species are the massive large, creeping, tubular, fan, or vase sponges.”</p> <p>Sponge morphological and taxonomic diversity were correlated and increased with availability of dead coral substrate and decreased with abundance of coral rubble.</p> <p>On elevated, hard-bottom ridges the predominating sponges were encrusting and simple-massive. On the sandy valleys in between sponges were endopsammic (= fistular), erect-laminar or erect-palmate. Presumably the tops of the ledges represented a hydrodynamically exposed habitat, whereas the flow between the ledges valleys was reduced and predominantly laminar. In this case the distribution of sponge morphologies thus appeared to be more strongly influenced by currents than by substrate.</p> <p>The bioeroding-endolithic to simple-massive sponge <i>Cliona</i> cf. <i>celata</i> was more abundant on bottoms with low silt-clay content and a mean grain diameter in the medium sand range. The simple-massive form was most abundant on bottoms poor in dead shell material and more abundant on coarser sediments where stronger currents were assumed to provide nutrients.</p> <p>In a field survey, the fistular <i>Spheciospongia florida</i> (cf. <i>Spheciospongia vagabunda/inconstans</i> species complex) was only found on sand. <i>Spheciospongia</i> spp. are often endopsammic and tend to develop fistular morphologies (Schönberg, 2016). The ball-shaped <i>Cinachyrella arabica</i> and the fistular <i>Ciocalypta</i> sp. were only found on sand.</p> <p>The endopsammic, fistular sponges <i>Oceanapia amboinensis</i>, <i>Biemna fortis</i>, <i>Spheciospongia solida</i> (as <i>Spirastrella</i>) and <i>Siphonodictyon mucosum</i> (as <i>Aka mucosa</i>) live (half-)buried in sediment, anchor themselves by being attached to or inhabiting buried rock and have erect parts or fistules that emerge from the sediment.</p> <p><i>Coscinoderma matthewsi</i> was more abundant in 12 than in 6 m, where sediment occurrence was doubled, covering surfaces; the sponge has a simple-massive morphology in 6 m, and a more “lobed”, more erect morphology in 12 m, which could be a reaction to sediment deposition.</p>	<p>Jackson, 1979</p> <p>Barthel and Gutt, 1992</p> <p>Ginn et al., 2000</p> <p>Bell and Barnes, 2002</p> <p>Carballo and Nava, 2007</p> <p>Díaz, 2012</p> <p>Hadi et al., 2015</p> <p>Freeman et al., 2007</p> <p>Driscoll, 1967</p> <p>Barnes and Bell, 2002</p> <p>Cerrano et al., 2002</p> <p>Duckworth, 2016</p>
Environment with rocky outcrops		
Sediment-dominated environment, sandy bottom		

Environmental condition	Sponge morphologies	Reference
Fine sediments in the environment, soft bottom	<p>At greater depth [= with finer sediments and reduced flow], sponges, especially hexactinellids, develop special morphological structures such as basal spicule tufts for anchoring in fine sediments and stalks to be distanced from the substrate and avoid burial.</p>	Burton, 1928; Tabachnick, 1991; Schönberg, 2016
	<p>Fistular sponges such as <i>Ciocalypta penicillus</i> and <i>Polymastia mamillaris</i> were associated with soft sediments and were often partially buried in them.</p>	Hiscock et al., 1984
	<p>The often fistular sponge <i>Tedania (Tedania) ignis</i> was observed to occur in areas with soft, muddy bottom sediments.</p>	Alcolado, 1990
	<p>The fistular species <i>Tentorium papillatum</i> and <i>Polymastia invaginata</i> can survive in very muddy areas as long as there are boulders for initial settlement. Another species at this site, <i>Mycale acerata</i>, forms tube clusters. The most common species found at this site keep their surfaces sediment-free or have erect structures.</p>	Barthel and Gutt, 1992
	<p>The stalked glass sponge <i>Caulophacus (Caulophacus) arcticus</i> was found in deep sea mud environments, was usually fixed on stones in the mud, had a stalk and a disc-shaped, elevated body, on which inhalants pointed downwards and exhalants were on the upper surface. <i>Forcepia (Forcepia) topsenti</i> was small, spherical sponge that was observed to have endosammic tendencies (= fistular), at times half buried in the sediment and agglutinating particles. <i>Forcepia</i> spp. were encrusting to massive and have been observed to develop fistular structures (see also van Soest, 2002; Lim et al., 2012). The thinly encrusting-creeping sponge <i>Hymedesmia (Hymedesmia) stylata</i> had 2 mm long, fistule-like papillae and appeared to have surface-cleaning capability. <i>Sycon abyssale</i> was tubular and had a short stalk.</p>	Barthel and Tendal, 1993
	<p><i>Thenea</i> spp. often inhabit fine sediments. They are functionally between globular sponges and barrels by being small and rounded, but also separating in- and exhalants. Oscules can be extended into fistular structures. The spicule-anchored lower part of the body can be embedded in sediment, the spicule-screened inhalants are lateral, just above the sediment surface, the exhalant is apically, on the top of the sponge. <i>Tentorium semisuberites</i> has a very similar functional biology. Occurring in the same habitat as <i>T. semisuberites</i> was the ball-shaped <i>Radiella sol</i> (as <i>Trichostemma</i>).</p>	Barthel and Tendal, 1993; Cárdenas and Rapp, 2012
	<p>No stalked sponges were seen, but the morphology was interpreted as adaptations to soft abyssal bottoms.</p>	Maldonado and Young, 1996
	<p>Morphological and species richness were correlated, but in the reef environment taxonomic diversity increased stronger with morphological diversity than in a soft sediment environment.</p>	Bell and Barnes, 2002
	<p>The erect, tubular sponge <i>Liosina granularis</i> was able to live at a site with fine sediments and siltation. Its outer walls can be covered with a fine layer of silt.</p>	Bell and Smith, 2004
	<p>The often sack-like glass sponge <i>Aphrocallistes vastus</i> occurs at sites with soft sediments and sedimentation.</p>	Austin et al., 2007
<p>Erect-branching sponges formed a significant part of the community where fine sediments were present, at the expense of encrusting and massive sponges. Overall sponge height was larger with fine sediments.</p>	Lawler and Osborn, 2008	
<p>Prevalence of muddy substrate correlated with the occurrence of erect-palmate sponges. Large erect-laminar sponges such as <i>Ianthella</i> spp. and barrels such as <i>Xestospongia</i> spp. were also common.</p>	Kelly and Przeslawski, 2012	
<p>An environment dominated by fine sediments, high turbidity and strong tidal flow supported a sponge community dominated by erect (50%, >30% 2D-erect) and fistular sponges (22%). Wide cups, barrels and crusts were each only around 5% of the counts.</p>	Fromont et al., 2013; Schönberg pers. obs. 2013	
<p>Many endolithic-bioeroding sponges can be smothered by fine sediments and do not well in muddy environments.</p>	Schönberg et al., 2017; Schönberg pers. obs. 2013; Abdul Wahab pers. comm.	
Biotic substrate	<p>Sponges colonising living surfaces of other invertebrates are often encrusting.</p>	e.g., Davis et al., 1996; Calcinai et al., 2013; Voultziadou et al., 2010

Environmental condition	Sponge morphologies	Reference
Turbidity/sedimentation	<p>“Foliose”, wide, shallow cups to erect-laminar sponges, with large horizontal surface area were the dominant sponge morphologies on clear-water coral reefs and most common between 10 and 30 m, and most were photosymbiotic. They were missing from more turbid inshore reefs with higher sedimentation rates and elevated nutrient concentration.</p>	Wilkinson, 1988
Clear water without much sedimentation, potentially nutrient-poor water	<p>The low-relief, composite-massive <i>Axinella damicornis</i>, the encrusting <i>Scopalina lophyropoda</i>, the thickly encrusting to composite-massive sponge <i>Aplysilla rosea</i>, the thickly encrusting <i>Crambe crambe</i>, the thinly encrusting <i>Timea unistellata</i> and the endolithic-bioeroding <i>Pione</i> (as <i>Ciona</i>) cf. <i>vastifica</i> only occurred at sites with low levels of siltation, or on vertical surfaces and under stones or overhangs. The ball-shaped <i>Tethya aurantium</i> also appeared to prefer reduced sedimentation.</p>	Carballo et al., 1996
	<p>The pink vase sponge <i>Niphates digitalis</i> (cup) is usually associated with deep water and high water clarity.</p>	Reeson et al., 2002
	<p>Despite its tubular shape, <i>Aplysina fistularis</i> appears to prefer high water clarity.</p>	Alcolado, 2007
	<p>In clear water, massive, cup-shaped, massive-encrusting and tubular sponges were common. The cups were often photosymbiotic and had a higher proportion of horizontal surface.</p>	De Voogd and Cleary, 2007
Turbid water	<p>The ball-shaped <i>Cinachyrella australiensis</i> (as <i>Cinachyra porosa</i>) and the fistular sponges <i>Axinyssa mertoni</i> (as <i>Pseudaxinyssa pitys</i>) and <i>Biemna fortis</i> occurred in turbid water, also suggesting sedimentation pressure.</p>	De Laubenfels, 1954
	<p>Barrels of the genus <i>Xestospongia</i> (as <i>Sigmatocia</i>) were often observed to be more common in turbid water.</p>	De Laubenfels, 1954; Wilkinson and Cheshire, 1989
	<p>Ball-shaped, globular sponges have often been found in turbid waters with high sedimentation rates, e.g. <i>Tethya aurantium</i> and the Tetillidae in general.</p>	Bell and Barnes, 2000b; van Soest and Rützler, 2002
	<p>Ordination on a sponge community associated the sediment-resistant and ball-shaped species <i>Paratetilla bacca</i>, the creeping <i>Gelliodes fibulata</i> and the erect-laminar sponge <i>Lissodendoryx (Acanthodoryx) fibrosa</i> with turbidity, whereas e.g. the rope-like erect-branching to creeping <i>Callyspongia (Euplacella) biru</i> needed clearer water and stronger flow.</p>	Cleary and de Voogd, 2007
	<p>With reduced water transparency near human settlement, the abundance of globular, fistular and fan-shaped sponges increased.</p>	De Voogd and Cleary, 2007
	<p>Changes in predominant sponge morphologies were related to seasonal changes (mostly turbidity and temperature); encrusting sponges were more abundant in winter (was explained by competition with algae in summer), abundance of erect-branching sponges was consistent, apart from a peak in October (explained by reproduction); overall predominance of erect and fistular sponges across seasons suggested high sedimentation at site. Seasonal differences were most apparent through encrusting, erect-branching and tubular sponges</p>	Berman et al., 2013
	<p>At a highly turbid, high-sedimentation site with fine sediments and strong tidal currents wide cups were rare (5% of all sponge individuals scored*). The few wide cups that occurred often displayed necrotic or dead parts or had parts missing that presumably had previously died*. Barrels were also uncommon, but conspicuous (6%*). They usually had coarse sediments in their apical, concave part (Fig. 8), with fine sediments having been washed out by the exhalant stream*. While Abdul Wahab et al. (2017b) stated encrusting and massive sponges to be predominant, the other two sources found the sponge community was dominated by erect forms (ca. 50%*) and endopsammic, fistular forms (22%*). Massives together contributed only 30%*. Data in Abdul Wahab (2017a) suggest that scoring may have been incorrectly applied.</p>	Fromont et al., 2013*; Schönberg pers. obs. 2013*; Abdul Wahab et al., 2017b
	<p>In a before-after sediment-impact study by capital dredging at a turbid site with fine sediments, fistular, erect-branching forms and barrels increased in abundance after the impact, which are all morphologies with strategies to deal with sedimentation.</p>	Abdul Wahab et al., 2017b
	<p>Many bioeroding sponges can tolerate high levels of turbidity and moderately high sedimentation. However, endolithic-bioeroding sponges can be smothered by fine sediments and do not well in muddy environments.</p>	Schönberg et al., 2017; Schönberg pers. obs. 2013; Abdul Wahab pers. comm.

Environmental condition	Sponge morphologies	Reference
Ctd.: Turbid water	At the study's clear-water site cups were 1.5 x as abundant than at the turbid site. Erect forms were 13 x as abundant at the turbid site. No differences were found for crusts and massives .	Abdul Wahab et al. 2018
	Despite shown sediment-clearing abilities, <i>Crella incrustans</i> developed fistule -like appendages in an experiment applying high suspended sediment concentration to resemble fistular sponges	Cummings et al., 2020
High sedimentation rate	When <i>Hymeniacion perlevis</i> occurred in areas with high sedimentation and became covered in mud, it displayed fistular projections, raising the oscules above the sediments.	Stone, 1970
	In a reef environment, at a sheltered site below 6 m depth and with high rates of sedimentation, only few sponge species were found. These were "tall or massive " and half-buried in sediment (fistular). Encrusting sponges occurred on vertical surfaces where they had enough flow, but were at the same time at safe distance from the sediment and avoided sediment deposition.	Rützler, 1972
	Based on approximated calculations, Jackson (1979) ranked expected success of sessile marine invertebrates in high sedimentation as erect-branching > tabular , massive (here including cup-like forms), vines (= rope sponges that Jackson described as creeping) > encrusting , creeping .	Jackson, 1979
	The amphora - or tube -shaped <i>Varongia aerophoba</i> grew faster when sedimentation was excluded with a transparent roof.	Wilkinson and Vacelet, 1979
	The ball-shaped <i>Cinachyrella</i> (as <i>Cinachyra</i>) <i>apion</i> survived > 15 days of burial in ventilated reef sediment.	Rice, 1984
	The erect-reticulate <i>Echinodictyum pulchrum</i> (as <i>E. cancellatum</i>) occurs on "shallow coastal and shallow offshore rock reefs, in mud or areas with high sedimentation". Erect-branching <i>Raspailia</i> spp. can tolerate extremely high sedimentation levels.	Hooper, 1991; Bell and Barnes, 2000b, 2000c
	The freshwater <i>Spongilla lacustris</i> developed erect parts to avoid burial.	Manconi and Pronzato, 1991
	The encrusting sponges <i>Crambe crambe</i> , <i>Scopalina lophyropoda</i> and some <i>Hymedesmia</i> spp. were less common or excluded from sites with high levels of siltation and rather occurred on vertical surfaces, under overhangs or on the underside of stones. Simple-massive <i>Sarcotragus</i> spp. were excluded from high sedimentation sites.	Carballo et al., 1996
	At depth crusts were more common on vertical surfaces (presumably avoiding sedimentation and moving into levels with higher flow than in the boundary layer). Predominance of cups at about -520 m (here: astrophorids) was interpreted as an adaptation to maximize feeding and sediment avoidance. No stalked sponges were seen, but the morphology was interpreted as adaptations to soft abyssal bottoms.	Maldonado and Young, 1996
	Tabular Hexactinellida are very sensitive to sedimentation and will perish under such conditions.	Leinfelder, 1996
Moderate sedimentation selects for tubular sponge morphologies, as these create bundled exhalant jets suited to prevent sediment entering or collecting in the concave parts of the body.	Krautter, 1998	
In comparison to other local <i>Spongia</i> species, <i>S. (S.) agaricina</i> was most tolerant to high levels of sedimentation, and its peak in occurrence matched the sedimentation. While it most commonly had an incomplete or complete cup-like morphology with clear separation of in- and exhalants, the local sediments were mostly coarse, and the sponge incorporated sediments into its fibres.	Pronzato et al., 1998	
In contrast to other local <i>Spongia</i> species, <i>S. (S.) virgultosa</i> only occurred in sheltered, shallow waters of 3-10 m, where it formed crusts with small fistules . The abundance of this species was similar to sedimentation levels. This species did not incorporate sediment grains in its fibres and needed the erect structures to deal with potential sediment deposition and with observed overgrowth by epibiotic organisms.		
The thickly encrusting or low-relief massive sponge <i>Cliona (Spheciaspongia? – published as Anthosigmella) varians</i> produces erect branching structures at sites with higher sedimentation, becoming more fistular .	Hill, 1999	

Environmental condition	Sponge morphologies	Reference
Ctd.: High sedimentation rate	<p>With reduced flow and higher rates of sediment settlement erect-branching forms, morphologies with short stalks, and cryptic-massive forms with fistules emerging from the sediment increased in frequency (e.g., <i>Polymastia</i> spp.); encrusting forms were lacking or grow on vertical surfaces. The simple-massive sponge <i>Cliona</i> cf. <i>celata</i> occurred at high sedimentation sites, growing on inclined (fewer, larger specimens) and on vertical surfaces (more, smaller specimens).</p> <p>Ball-shaped, globular sponges have often been found in turbid waters with high sedimentation rates, e.g. <i>Tethya aurantium</i> and the Tetillidae in general.</p> <p>With increased water depth and sedimentation and decreased flow branching complexity was reduced in three-dimensionally erect-branching sponges.</p> <p>Encrusting and endolithic growth forms of <i>Cliona</i> cf. <i>celata</i> were more common at sites with reduced flow and higher sedimentation, as well as developing fistules, except for one site they had also more oscules per unit surface area.</p> <p>The ball-shaped <i>Cinachyrella australiensis</i> was adapted to high sedimentation levels and occurs in high turbidity and strong flushing. The sponge formed thicker spicules in environments with the coarser sediment, and a flattened growth form with finer sediments.</p> <p>The ball-shaped <i>Cinachyrella barbata</i> occurred on “sediment-rich bottoms”.</p> <p><i>Haliclona</i> (<i>Haliclona</i>) <i>urceolus</i> is a tubular sponge with an apical water jet protecting the oscular opening; it was common in sedimented habitats.</p> <p>Seasonal sediment deposition events reduced the diversity of the coastal sponge community by smothering larger sponges (massive and branching), but endolithic-bioeroding, encrusting clionoids and <i>Clathria</i> (<i>Microcionia</i>) sp. survived. It was not explained whether the encrusting species were located on horizontal surfaces and how they survived being covered, but they have a micro-hispid ectosome that may help in keeping their surfaces clean (Schönberg, 2015). Overall, the habitat was described as high-energy, with turbulent flow.</p> <p>Sedimentation can select for some clionoid, endolithic-bioeroding sponges.</p> <p>Experiments creating elevated levels of suspended sediments proved lethal for cup-shaped <i>Callyspongia confederata</i> and caused necrosis in other sponges with much horizontal surface area (massives, encrusting sponges, wide cups).</p> <p>The wide cup-shaped and photosymbiotic sponge <i>Cymbastela concentrica</i> did not tolerate sedimentation or shading very well.</p> <p>The barrel-shaped <i>Sphaciospongia vesparium</i> and the composite-massive to fistular, sediment-incorporating <i>Tectitethya crypta</i> are tolerant to sedimentation.</p> <p>The ball-shaped <i>Paratetilla corrugata</i> (as <i>P. bacca</i>) was adapted to perturbed sites and high sedimentation levels, and displayed a bristly surface that caught sediments and kept pores free.</p> <p><i>Dysidea avara</i> became increasingly less compact and more erect and branching with water depth and increased sedimentation. At the deepest site, where the sponge was covered with a film of sediments, the apical oscules were smaller than at intermediate depth, where intermittent flow occurred.</p> <p>Highly turbid and sedimented reef areas in Singapore were dominated by globular, fistular, fan-shaped and creeping sponges. Cup-shaped and photosymbiotic sponges were absent.</p> <p>The ball-shaped <i>Paratetilla</i> sp. is a heterotrophic globular sponge with a natural crust of sediments and algae, and it occurred in very shallow depths on sandflats. In an 8 d flow-through tank experiment sponges were subjected to daily application of a handful of mud or sand onto the sponges. In <i>Paratetilla</i> sp. mud and sand treatments had no visible effect at all. Most sediment slid off and what remained on top of the sponge did not cause any change. The control sponges did not show any signs of tank effects.</p>	<p>Bell and Barnes, 2000a, 2000b, 2000c</p> <p>Bell and Barnes, 2000b; van Soest and Rützler, 2002</p> <p>Bell et al., 2002a</p> <p>Bell et al., 2002b</p> <p>McDonald et al., 2002</p> <p>Van Soest and Rützler, 2002</p> <p>Bell, 2004</p> <p>Carballo, 2006</p> <p>Carballo et al., 2006</p> <p>Pineda et al., 2006</p> <p>Roberts et al., 2006b</p> <p>Alcolado, 2007</p> <p>De Voogd and Cleary, 2007</p> <p>Mendola et al., 2008</p> <p>De Voogd and Cleary, 2009</p> <p>Büttner and Siebler 2013 (incl. Schönberg pers. obs. 2013)</p>

Environmental condition	Sponge morphologies	Reference	
Ctd.: High sedimentation rate	At a highly turbid, high-sedimentation site with fine sediments and strong tidal currents wide cups were rare (5% of all sponge individuals scored*). The few wide cups that occurred often displayed necrotic or dead parts or had parts missing that presumably had previously died*. Barrels were also uncommon, but conspicuous (6%*). They usually had coarse sediments in their apical, concave part, with fine sediments having been washed out by the exhalant stream*. While Abdul Wahab et al. (2017b) stated encrusting and massive sponges to be predominant, the other two sources found the sponge community was dominated by erect forms (ca. 50%*) and endopsammic, fistular forms (22%*). Massives together contributed 30%*. Data in Abdul Wahab (2017a) suggest that scoring may have been incorrectly applied.	Fromont et al., 2013*; Schönberg pers. obs. 2013*; Abdul Wahab et al., 2017b	
	In a before-after sediment-impact study by capital dredging at a turbid site with fine sediments, fistular , erect-branching forms and barrels increased in abundance after the impact. During the construction work the proportion of finer sediments increased at the site.	Abdul Wahab et al., 2017b	
	<i>Biemna fortis</i> developed a fistular or cryptic-massive morphology at a site with higher levels of suspended particles (and presumably high rates of sedimentation), whereas at a site with less suspended material, the sponge had a simple-massive growth form	Dahihande and Thakur, 2017	
	Many endolithic-bioeroding sponges can tolerate high levels of turbidity and moderately high sedimentation. However, they can be smothered by fine sediments and do not well in muddy environments.	Schönberg et al., 2017; Schönberg pers. obs. 2013; Abdul Wahab pers. comm.	
Other parameters			
Bathymetry	[Apart from rare exceptions, keratose sponges] are never found at greater depths than [ca. 180 m], and seldom go down so far as that even". On the other hand, the "Hexactinellida, typical deep-sea animals, are but rarely found at depths less than [ca. 180 m]".	Burton, 1928	
	In the deep sea, morphology per species becomes more uniform, and forms become more symmetrical.	Burton, 1928	
	At greater depth [= with finer sediments and reduced flow], sponges develop special morphological structures such as spicule tufts for anchoring in mud and stalks to be distanced from the substrate. While such stalks appear of similar length between younger and older sponges, the body size increases with age.	Burton, 1928	
	Clustering of Antarctic sponge associations related to substrate properties and sedimentation, not depth.	Barthel and Gutt, 1992	
	The erect, carnivorous sponge <i>Cladorhiza gelida</i> was found on rock and muddy bottom in 780-2800 m depth.	Barthel and Tendal, 1993	
	Low-profile forms such as encrusting , massive and creeping dominated in shallower water, erect and fistular forms increased in frequency at deeper sites. This was mainly discussed in the context of flow.	Bell and Barnes, 2000a	
	Comparing intertidal and subtidal sites, tubular and branching forms were missing at the former site (but site-relevant covariables possibly affecting result were not discussed; branching sponges were observed in the intertidal in NW Australia, Schönberg pers. obs.).	Barnes and Bell, 2002	
	Demospongiae and Homoscleromorpha remained largely confined to shelf habitats between 0 and 200 m with dSI concentrations of <150 µM. Hexactinellida mostly required high-silica conditions >100 µM and extended down to 6000 m, and the Calcarea had another peak between 1500 and 3000 m. However, the paper did not investigate and differentiate growth forms.	Alvarez et al., 2017	
	Light/shade	Calcified sclerosponges that function as encrusting sponges often prefer shaded environments.	Hartman and Goreau, 1970
		Based on approximated shape parameter calculations, Jackson (1979) ranked expected success under an abundance of food and light as encrusting , massive (including cup-like forms) ≥ vines (= creeping rope sponges) ≥ tabular , erect-branching > creeping . Under food/light limitation this ranking changed to: erect-branching , tabular > massive , vines (creeping rope sponges) > encrusting > creeping .	Jackson, 1979
With distance into caves, flow reduction and darkness resulted in food limitation. Here, thin crusts "with a more efficient filtration surface ratio" dominated.		Bibiloni et al., 1989	
	The encrusting <i>Crambe crambe</i> had an irregular outline in light (shallow) and a more directional growth at sciaphilous locations. This was thought to be more likely due to lack of space competition at the shallow sites, rather than a light effect.	Becerro et al., 1994	

Environmental condition	Sponge morphologies	Reference
Ctd.: Light/shade	When the photosymbiotic massive sponge <i>Ircinia felix</i> was transplanted from 4 m depth to 100, 200 and 300 m, it lost its cyanobacteria and developed fistule -like processes in 200 m. None survived in 300 m. The tubular <i>Aplysina fistularis</i> only survived in 100 m, did not lose the photosymbionts and did not develop fistules .	Maldonado and Young, 1998
	Exposure to strong light was interpreted as stressful for sponges, and those exposed to light were observed to have a cortex or had lacunae to trap water when exposed, or they were partially buried. Encrusting and tabular forms were found more commonly in shaded environments. The authors' views on light effects may perhaps be too simplified, ignoring other factors that may have had a stronger influence on the morphology.	Barnes, 1999
	Endolithic-bioeroding and endopsammic- fistular bioeroding sponges such as <i>Siphonodictyon</i> spp. and some <i>Spheciospongia</i> spp. are relatively resistant to exposure to air, and some species occur in the upper intertidal, where they would also be exposed to high UV irradiation during low tide.	Rützler, 1971; Schönberg, 2000, 2001; Schönberg and Tapanila, 2006; Schönberg pers. obs. 1996-2013
Exposure to air	The wide cup-shaped and photosymbiotic sponge <i>Cymbastela concentrica</i> did not tolerate sedimentation or shading very well.	Roberts et al., 2006b
	Frequency of photosymbiotic sponges decreased with water depth, but this was not related to morphology.	Bell, 2007a
	The encrusting <i>Hymeniacion perlevis</i> (as <i>H. sanguinea</i>) can survive exposure to air in the upper intertidal, but exposure often results in partial tissue death and fragmentation of the specimens, leading to smaller individuals.	Burton, 1928
Climate, temperature, heat events	Endolithic-bioeroding and endopsammic- fistular bioeroding sponges such as <i>Siphonodictyon</i> spp. and some <i>Spheciospongia</i> spp. are relatively resistant to exposure to air, and some species occur in the upper intertidal, where they would also be exposed to high UV irradiation during low tide.	Rützler, 1971; Schönberg, 2000, 2001; Schönberg and Tapanila, 2006; Schönberg pers. obs. 1996-2013
	The intertidal site of this study lacked tubular and branching sponges. Supposedly, these were at larger risk of desiccation due to the comparatively large surface area and the proportionally longer exposure being erect.	Barnes and Bell, 2002
	Keratose sponges are excluded from cold waters. [...] "formation of spongin can usually only take place in moderate temperatures[, and keratose sponges] are confined, for the most part, to the seas between 45° of latitude north and south of the Equator and are pre-eminently abundant in the warm shallow waters of the Mediterranean and Gulf of Mexico. Outside this area their occurrence is extremely rare."	Burton, 1928
Anoxia	Photosymbiotic sponges often have a wide cup-shaped growth form that provide the sponge with more horizontal surface area for light harvest, erect-branching sponges are not as likely to be photosymbiotic. E.g. encrusting , low-profile sponges near the substrate surface with reduced flow are more likely to bleach and to die than erect sponges that reach into layers with stronger currents, or larger sponges with large canal system and oscules that can produce a cooling effect with the pumping currents they produce.	Bell, 2007a
	The subtropics and tropics have a more morphologically and taxonomically diverse sponge fauna than temperate waters. The authors found more erect-branching and palmate sponges at their tropical sites than at their subtropical sites (but site-relevant covariables affecting result were not discussed).	Barnes and Bell, 2002
	Morphological and species richness were correlated, but unlike for bottom characteristics, the correlation slopes of taxonomic diversity versus morphological diversity did not differ with climate.	Bell and Barnes, 2002
Anoxia	The encrusting sponge <i>Hemimycale columella</i> tended to fission in the colder season.	Garate et al., 2017
	Endolithic-bioeroding sponges appear to be more heat tolerant than many other benthic organisms	Schönberg et al., 2017
	The ball-shaped <i>Cinachyrella</i> (as <i>Cinachyra</i>) <i>apion</i> survived > 15 days of burial in ventilated reef sediment.	Rice, 1984

Environmental condition	Sponge morphologies	Reference
Nutrients	<p>Individuals of <i>Grantia compressa</i> were larger in estuarine environments rich in detritus than in other marine environments.</p> <p>Erect forms of sessile marine invertebrates have an advantage against low-relief forms in terms of resource and nutrient access in higher layers of the water column. Their disadvantage is a small basal attachment area. Vines (= creeping forms) can bridge between low-relief encrusting and erect-branching forms by often forming erect branches. Based on his approximated shape parameter calculations, Jackson (1979) ranked expected success under an abundance of food and light as encrusting, massive (including cup-like forms) ≥ vines (= creeping rope sponges) ≥ tabular, erect-branching > creeping. Under food/light limitation this ranking changed to: erect-branching, tabular > massive (incl. some cup-likes), vines (creeping rope sponges) > encrusting > creeping.</p> <p>Encrusting sponges have openings at an angle to prevailing flow that may induce passive flow through the sponge (Vogel, 1974, 1977), while this is not the case in erect sponges. The latter employ a different strategy, i.e. they extend into the water column, moving away from the nutrient-depleted boundary layer.</p> <p>During aquarium experiments the form-variable sponges <i>Haliclona (Halichoelona) fistulosa</i>, <i>H. (Reniera) cinerea</i> (as <i>H. elegans</i>), <i>H. (Gellius) rava</i>, <i>H. (Rhizoniera) rosea</i>, <i>Amphilectus fucorum</i> and <i>Halichondria (Halichondria) bowerbanki</i> reacted to starvation with process formation. The author interpreted this observation as an attempt to increase feeding efficiency by increasing the surface : volume ratio and as a means to spread out into other microhabitats. All these sponges range in nature from encrusting to fistular and erect-branching.</p> <p>Hydrodynamic conditions have an impact on the growth form of sessile animals such as sponge and corals. Fractal modelling showed that this process is strongly linked to the nutrient distribution. “[...] sensitivity to the amount of contact with the environment, for example by a relatively low contribution of translocation of nutrients from the place of absorption to more remote sites, could play a role in the formation of branches.” A more open branching pattern assures a better nutrient distribution to all branches. Branching asymmetry suggests that arriving nutrients are depleted when passing through the branch structure. Highest nutrient access is upstream and near the tips, where the most intensive growth proceeds.</p> <p>Experimentally changed nutrient conditions did not seem to have a significant effect on the cup-shaped and photosymbiotic sponge <i>Cymbastela concentrica</i>.</p> <p>Near human settlement, the abundance of globular, fistular and fan-shaped sponges increased.</p> <p>Bioeroding sponge abundances increase with eutrophication (evidence mostly for endolithic-encrusting sponges, but likely also valid for fistular forms). Although, this is probably also true for a vast range of different sponges with different morphologies.</p>	<p>Burton, 1928</p> <p>Jackson, 1979</p> <p>Trammer, 1979</p> <p>Jones, 1994</p> <p>Kaandorp and Sloot, 2001</p> <p>Roberts et al., 2006b</p> <p>De Voogd and Cleary, 2007</p> <p>Schönberg, 2008; Schönberg et al., 2017</p> <p>Alvarez et al., 2017</p>
Silica	<p>Sponge distributions could not conclusively be correlated to certain silica concentrations, except that the Hexactinellida largely required high-silica conditions >100 µM and extended down to 6000 m, and the Calcarea had another peak between 1500 and 3000 m. The Demospongiae and Homoscleromorpha remained mostly confined to shelf habitats between 0 and 200 m with dSi concentrations of <150 µM. The paper did not investigate and differentiate growth forms.</p>	<p>Alvarez et al., 2017</p>
Salinity	<p>Individuals of the amphora-like <i>Grantia compressa</i> were larger in estuarine than in marine environments.</p> <p>The wide cup-shaped sponge <i>Cymbastela concentrica</i> did not tolerate lowered salinity.</p>	<p>Burton, 1928</p> <p>Roberts et al., 2006b</p>
Heavy metals	<p>The encrusting <i>Crambe crambe</i> developed increased shape irregularity and fission at a contaminated site and accumulated lead, copper and vanadium, and survival, growth rates and fecundity were reduced. The polluted site had also finer sediments.</p>	<p>Cebrian et al., 2003</p>
Ocean acidification	<p>In areas of low pH only encrusting sponges were found.</p> <p>At a CO₂ seep site, the sample location with the lowest pH had a x40 increase in ambient abundance of the fistular <i>Coelocarteria singaporense</i> and the ball-shaped <i>Cinachyra</i> sp. The composite-massive <i>Stylissa massa</i> was less common near the high-CO₂ site.</p> <p>Sponge cover in general was reduced with decreasing distance to a vent site and a lowered pH in the field.</p>	<p>Goodwin et al., 2013</p> <p>Morrow et al., 2015</p> <p>Fabricius et al., 2011</p>

Environmental condition	Sponge morphologies	Reference
Predation, spongivory	<p>Predation is thought to act more general, unlikely to affect different morphologies to different levels, apart from targeting more conspicuous forms more strongly. Jackson (1979) listed reactions of sessile marine invertebrates to predation to include distribution and abundance patterns, and structural, chemical or behavioural mechanisms. However, survival, recovery and regrowth may differ between different growth forms. He ranked expected success with high predator abundance as creeping, encrusting, vines (= creeping rope sponges potentially with erect elements) > massive (including cup-like forms) > tabular, erect-branching.</p>	Jackson, 1979
	<p>The branching (fistular?) morph of the thickly encrusting <i>Cliona varians</i> (<i>Sphaciospongia?</i> – published as <i>Anthosigmella</i>) developed a higher spicule content and became encrusting when subjected to real or simulated spongivory, but the encrusting morph did not develop branches when fish was excluded.</p>	Hill and Hill, 2002
	<p>Grazers that can ingest sponge tissue appear to suppress bioeroding sponges (here largely endolithic-bioeroding forms).</p>	Carreiro-Silva and McClanahan 2012; Schönberg et al., 2017
Space competition	<p>Due to the way they occupy available space and substrate, encrusting sessile marine invertebrates are superior space competitors. The author hypothesised that creeping forms may be “escapists incapable of confrontation” and that they would exhibit greater growth rates than other morphologies, possibly at the expense of sexual reproductive output (but cited evidence pointing in the opposite direction). This competition strategy would strongly separate creeping from more typically encrusting forms that are otherwise morphologically similar. For epibiosis he ranked forms creeping (his runners and vines) > encrusting > massive (including some cups), tabular, erect-branching.</p>	Jackson, 1979
	<p>The encrusting <i>Crambe crambe</i> had an irregular outline in light (shallow) and a more directional growth at sciaphilous locations. This was thought to be more likely due to lack of space competition at the shallow sites, rather than a light effect. The sponges were more toxic at depth.</p>	Becerro et al., 1994, 1995
	<p>In field surveys encrusting and massive sponges were better competitors against corals than erect morphologies (more contact area).</p>	Aerts and van Soest, 1997
	<p>Under intense space competition, there is selection for erect and tubular morphologies as they require less area to attach to and can make use of small patches of substratum.</p>	Krautter, 1998
	<p>“Sponges which exhibited thick (>2 mm) crusts were, in the majority of interactions, superior competitors compared to the thin (<1 mm) crusts.”</p>	Bell and Barnes, 2003
	<p>At coral reef sites with a mix of live and dead coral and sponges, latter had predominantly growth forms that required little attachment space, such as cups, fans and columnar (= 1D-erect) sponges. A similar situation emerged on dead coral in competition with turf algae, however, here thick crusts or fast-growing creeping sponges emerged. Balls were also observed.</p>	Hadi et al., 2015
Disease	<p>2006a: In a long-term study sponge community changes were observed that differed by growth form. “No erect-branching species were lost, 40% of encrusting species were lost, and 80% of massive species were lost.” Changes were discussed as natural fluctuations or being due to disease. 2006b: During a more targeted investigation massive (mound-shaped) sponges suffered higher losses from mortality due to disease than branching sponge. Latter had a higher incidence of disease but were more likely to recover. Branching sponges were rope sponges with fast growth rates and tendency to have creeping parts. (Note: Wulff’s 2006a, 2006b definitions differed from the present one, as both erect and massive forms included cup-like morphologies. See Suppl. 1 for a comparison of approaches to the uses of sponge morphologies.)</p>	Wulff, 2006a, 2006b
	<p>Comparing resistance/recovery properties of two halicionid species, the more tubular (“massive”) one was more fragile, and unattached fragments would likely perish, but remaining sponges healed fast. The cushion-shaped species with raised papillae to produce a fistular appearance (“submassive”) and resisted physical damage, but was more vulnerable to necrosis.</p>	Abdo et al., 2008

Environmental condition	Sponge morphologies	Reference
Physical damage due to e.g. dredging, fishing, storms	<p>Encrusting and creeping sessile marine invertebrates were modelled to exhibit a low feeding and reproductive potential compared to other morphologies. Especially mound-shaped (simple-massive) forms can increase these potentials with size. In contrast, in erect forms attachment area decreases with size and makes them more vulnerable to physical damage. After disturbance, Jackson (1979) expected a succession from creeping, encrusting to massive (incl. cups) – when food supply is high, or to erect forms – when food supply is low.</p>	Jackson, 1979
	<p>Erect-branching rope sponges with tendencies to have creeping parts such as <i>Amphimedon</i> spp. and <i>Aplysina cauliformis</i> and <i>Aplysina fulva</i> have a very high growth rates and can quickly recover to original or even increased abundance after physical damage. However, <i>Aplysina</i> spp. are also flexible and resist drag forces and may not suffer much damage.</p>	Wulff, 1994, 2005; Alcolado, 2007; Biggs, 2013
	<p>Sponges with a higher spongin content are more resistant to physical damage such as during storms.</p>	E.g., Wulff, 1995
	<p>Scallop dredging reduced the overall sponge biodiversity and may select for certain morphologies. Massive and erect forms were more affected by dredging than creeping forms. Endolithic-bioeroding sponges were removed together with the substrate. Encrusting and cushion-shaped (simple-massive) sponges were turned over with their substrate and died. The abundance of the morphologically variable <i>Suberites massa</i> increased after dredging.</p>	Kefalas et al., 2003
	<p>After experimental damage tubular sponges healed faster than vasiform, cup-shaped sponge.</p>	Walters and Pawlik, 2005; Wulff, 2006c
	<p>Comparing resistance/recovery properties of two halicionid species, the more tubular (“massive”) one was more fragile, and unattached fragments would likely perish, but remaining sponges healed fast. The cushion-shaped species with raised papillae to produce a fistular appearance (“submassive”) and resisted physical damage, but was more vulnerable to necrosis.</p>	Abdo et al., 2008
	<p>Sponge recovery potential may vary with morphology. The creeping sponge <i>Neopetrosia</i> (as <i>Xestospongia</i>) <i>subtriangularis</i> increased after a storm. Balls were not affected by the observed disturbances. Simple-massive, barrel-shaped and tubular species mostly recovered after a bloom-induced mortality event, but some at a slower rate, or they deteriorated or vanished due to further disturbance.</p>	Stevely et al., 2010
<p>Sponges washed up on the beach by waves were mostly branching, massive and cushion-shaped. Encrusting species were never found washed up. While sponges with high spongin content occurred in the area, they were not found washed up.</p>	Ávila et al., 2011	
<p>Storm surges removed almost 40% of the erect sponges, followed by an almost 25% increase of encrusting sponges.</p>	Gochfeld et al., 2020	

Supplement 3. List of species names used in the publication and its supplements, together with taxonomic affiliations, taxon authors and predominantly seen (but occasionally variable) growth forms. The latest formats and taxonomic agreements were checked in the World Register of Marine Species ([WoRMS, 2020](https://www.marinespecies.org/woRMS)), where original descriptions are also deposited. Figure references are for images displayed in the main publication.

Class	Subclass	Order	Family	Genus	Species	Taxon author	Morphologies

Demospongiae	Heteroscleromorpha	Axinellida	Axinellidae	<i>Dragmacidon</i>	<i>reticulatum</i>	(Ridley and Dendy, 1886)	composite-massive
Demospongiae	Heteroscleromorpha	Axinellida	Axinellidae	<i>Pararhaphoxya</i>	<i>sinclairi</i>	(Gray, 1843)	erect-branching in three dimensions
Demospongiae	Heteroscleromorpha	Axinellida	Axinellidae	<i>Phakellia</i>	-	Bowerbank, 1862	variable, flabellate to cups
Demospongiae	Heteroscleromorpha	Axinellida	Axinellidae	<i>Phakellia</i>	<i>ventilabrum</i>	(Linnaeus, 1767)	incomplete cups to erect-laminar fans
Demospongiae	Heteroscleromorpha	Axinellida	Axinellidae	<i>Pipestela</i>	<i>candelabra</i>	Alvarez et al., 2008	tube cluster
Demospongiae	Heteroscleromorpha	Axinellida	Axinellidae	<i>Reniochalina</i>	<i>stalagmitis</i>	Von Lendenfeld, 1888	erect-palmate
Demospongiae	Heteroscleromorpha	Axinellida	Raspailiidae (Echinodictyinae)	<i>Echinodictyum</i>	<i>clathroides</i>	Hentschel, 1911	cup
Demospongiae	Heteroscleromorpha	Axinellida	Raspailiidae (Echinodictyinae)	<i>Echinodictyum</i>	<i>mesenterinum</i>	(De Lamarck, 1814)	cup
Demospongiae	Heteroscleromorpha	Axinellida	Raspailiidae (Echinodictyinae)	<i>Echinodictyum</i>	<i>pulchrum</i>	Brøndsted, 1934	erect-reticulate
Demospongiae	Heteroscleromorpha	Axinellida	Raspailiidae (Raspailiinae)	<i>Ectyoplasia</i>	<i>frondosa</i>	(Von Lendenfeld, 1887)	fan to cup
Demospongiae	Heteroscleromorpha	Axinellida	Raspailiidae (Raspailiinae)	<i>Ectyoplasia</i>	<i>tabula</i>	(De Lamarck, 1814)	palmate
Demospongiae	Heteroscleromorpha	Axinellida	Raspailiidae (Raspailiinae)	<i>Raspailia (Raspaxilla)</i>	<i>topsenti</i>	Dendy, 1924	erect-branching in three dimensions
Demospongiae	Heteroscleromorpha	Axinellida	Stelligeridae	<i>Acanthoclada</i>	<i>prostrata</i>	Bergquist, 1970	thick crust
Demospongiae	Heteroscleromorpha	Axinellida	Stelligeridae	<i>Halicnemis</i>	<i>patera</i>	Bowerbank, 1864	thin crust
Demospongiae	Heteroscleromorpha	Biemnida	Biemnidae	<i>Biemna</i>	<i>fortis</i>	(Topsent, 1897)	fistular to massive, endopsammic
Demospongiae	Heteroscleromorpha	Bubarida	Dictyonellidae	<i>Acanthella</i>	-	Schmidt, 1862	variable, often composite-massive
Demospongiae	Heteroscleromorpha	Bubarida	Dictyonellidae	<i>Acanthella</i>	<i>pulcherrima</i>	Ridley and Dendy, 1886	composite-massive
Demospongiae	Heteroscleromorpha	Bubarida	Dictyonellidae	<i>Tethyspira</i>	<i>spinosa</i>	(Bowerbank, 1874)	encrusting to simple-massive
Demospongiae	Heteroscleromorpha	Clionaida	Clionaidae	<i>Cliona</i>	-	Grant, 1926	endolithic-bioeroding
Demospongiae	Heteroscleromorpha	Clionaida	Clionaidae	<i>Cliona</i>	<i>caribbaea</i>	Carter, 1882	endolithic-bioeroding (Fig. 4C)
Demospongiae	Heteroscleromorpha	Clionaida	Clionaidae	<i>Cliona</i>	<i>celata</i>	Grant, 1926	variable, can be endolithic-bioeroding or simple-massive or fistular (but is published as a species complex, so different morphologies can refer to different species)
Demospongiae	Heteroscleromorpha	Clionaida	Clionaidae	<i>Cliona</i>	<i>orientalis</i>	Thiele, 1900	endolithic-bioeroding
Demospongiae	Heteroscleromorpha	Clionaida	Clionaidae	<i>Cliona</i>	<i>patera</i>	(Hardwicke, 1820)	stalked or cup
Demospongiae	Heteroscleromorpha	Clionaida	Clionaidae	<i>Cliona</i>	<i>varians</i> ¹	(Duchassaing and Michelotti, 1864)	thickly encrusting, can have erect portions, basally eroding
Demospongiae	Heteroscleromorpha	Clionaida	Clionaidae	<i>Cliona</i>	<i>viridis</i>	(Schmidt, 1862)	variable, can be endolithic-bioeroding or fistular (but is published as a species complex, so different morphologies can refer to different species)
Demospongiae	Heteroscleromorpha	Clionaida	Clionaidae	<i>Cliothosa</i>	-	Topsent, 1905	endolithic-bioeroding
Demospongiae	Heteroscleromorpha	Clionaida	Clionaidae	<i>Cliothosa</i>	<i>deltrix</i>	(Pang, 19730)	endolithic-bioeroding (Fig. 5E)
Demospongiae	Heteroscleromorpha	Clionaida	Clionaidae	<i>Pione</i>	-	Gray, 1867	endolithic-bioeroding
Demospongiae	Heteroscleromorpha	Clionaida	Clionaidae	<i>Pione</i>	<i>vastifica</i>	(Hancock, 1849)	endolithic-bioeroding
Demospongiae	Heteroscleromorpha	Clionaida	Clionaidae	<i>Spheciospongia</i>	-	Marshall, 1892	often fistular, but can be simple-massive or barrels (Fig. 4F)
Demospongiae	Heteroscleromorpha	Clionaida	Clionaidae	<i>Spheciospongia</i>	<i>florida</i> ²	(Von Lendenfeld, 1897)	fistular

¹ This sponge is more likely a *Spheciospongia* species (C. Schönberg unpubl. data).

² This species strongly resembles *Spheciospongia inconstans* and is part of the *Spheciospongia vagabunda* species complex (C. Schönberg unpubl. data).

Class	Subclass	Order	Family	Genus	Species	Taxon author	Morphologies	
Demospongiae	Heteroscleromorpha	Clionaida	Clionaidae	<i>Sphaciospongia</i>	<i>inconstans</i>	(Dendy, 1887)	mostly fistulate (Fig. 1C), occas. simple-massive	
Demospongiae	Heteroscleromorpha	Clionaida	Clionaidae	<i>Sphaciospongia</i>	<i>solida</i>	(Ridley and Dendy, 1886)	fistular	
Demospongiae	Heteroscleromorpha	Clionaida	Clionaidae	<i>Sphaciospongia</i>	<i>vagabunda</i>	(Ridley, 1884)	fistular	
Demospongiae	Heteroscleromorpha	Clionaida	Clionaidae	<i>Sphaciospongia</i>	<i>vesparium</i>	(De Lamarck, 1815)	barrel	
Demospongiae	Heteroscleromorpha	Clionaida	Placospongiidae	<i>Placosphaera</i>	<i>micraster</i> ³	(Lehnert and Heimler, 2001)	thick crust (Fig. 7A)	
Demospongiae	Heteroscleromorpha	Clionaida	Placospongiidae	<i>Placospongia</i>	-	Gray, 1867	thick crust	
Demospongiae	Heteroscleromorpha	Clionaida	Placospongiidae	<i>Placospongia</i>	<i>melobesoides</i>	Gray, 1867	thick crust	
Demospongiae	Heteroscleromorpha	Clionaida	Spirastrellidae	<i>Spirastrella</i>	-	Schmidt, 1868	thin crust	
Demospongiae	Heteroscleromorpha	Haplosclerida	Callyspongiidae	<i>Callyspongia</i>	-	Duchassaing and Michelotti, 1864	variable, often creeping	
Demospongiae	Heteroscleromorpha	Haplosclerida	Callyspongiidae	<i>Callyspongia</i>	<i>confederata</i> ⁴	(sensu Ridley, 1884)	cup	
Demospongiae	Heteroscleromorpha	Haplosclerida	Callyspongiidae	<i>Callyspongia</i>	<i>fallax</i>	Duchassaing and Michelotti, 1864	creeping	
Demospongiae	Heteroscleromorpha	Haplosclerida	Callyspongiidae	<i>Callyspongia</i>	<i>aculeata</i>	(Linnaeus, 1759)	tube	
Demospongiae	Heteroscleromorpha	Haplosclerida	Callyspongiidae	<i>Callyspongia</i>	<i>tenerrima</i>	Duchassaing and Michelotti, 1864	creeping	
Demospongiae	Heteroscleromorpha	Haplosclerida	Callyspongiidae	<i>Callyspongia</i>	<i>biru</i>	De Voogd, 2004	erect-branching in three dimensions, but can also be creeping	
Demospongiae	Heteroscleromorpha	Haplosclerida	Chalinidae	<i>Haliclona</i>	-	Grant, 1841	variable, can be creeping or low-relief	
Demospongiae	Heteroscleromorpha	Haplosclerida	Chalinidae	<i>Haliclona</i>	<i>koremella</i>	De Laubenfels, 1954	erect-branching in three dimensions, but can also be simple-erect and tends to creeping	
Demospongiae	Heteroscleromorpha	Haplosclerida	Chalinidae	<i>Haliclona</i>	<i>Gellius</i>	(Esper, 1806)	creeping	
Demospongiae	Heteroscleromorpha	Haplosclerida	Chalinidae	<i>Haliclona</i>	<i>Gellius</i>	<i>rava</i>	(Stephens, 1912)	thick crust
Demospongiae	Heteroscleromorpha	Haplosclerida	Chalinidae	<i>Haliclona</i>	<i>fistulosa</i>	(Bowerbank, 1866)	thick crust to low cushion, with fistular tendencies (= for large, slightly tubular oscules or slim, erect-branching processes)	
Demospongiae	Heteroscleromorpha	Haplosclerida	Chalinidae	<i>Haliclona</i>	<i>oculata</i>	(Linnaeus, 1759)	mostly erect-palmate, but can be erect branching in three dimensions	
Demospongiae	Heteroscleromorpha	Haplosclerida	Chalinidae	<i>Haliclona</i>	<i>urceolus</i>	(Rathke and Vahl, 1806)	tubular	
Demospongiae	Heteroscleromorpha	Haplosclerida	Chalinidae	<i>Haliclona</i>	<i>(Reniera)</i>	<i>cinerea</i>	(Grant, 1826)	thick crust to low cushion, with fistular tendencies (= for large, tubular oscules or sometimes for slim, erect-branching processes)
Demospongiae	Heteroscleromorpha	Haplosclerida	Chalinidae	<i>Haliclona</i>	<i>(Reniera)</i>	<i>fascigera</i>	(Hentschel, 1912)	mostly tubular, but can vary into erect-branching and cup-shaped
Demospongiae	Heteroscleromorpha	Haplosclerida	Chalinidae	<i>Haliclona</i>	<i>rosea</i>	(Bowerbank, 1866)	thick crust, can have pronounced to elevated oscules	
Demospongiae	Heteroscleromorpha	Haplosclerida	Chalinidae	<i>Haliclona</i>	<i>(Soestella)</i>	<i>caerulea</i>	(Hechtel, 1965)	variable, mostly thickly encrusting with almost fistule like, raised oscules
Demospongiae	Heteroscleromorpha	Haplosclerida	Niphatidae	<i>Amphimedon</i>	-	Duchassaing and Michelotti, 1864	can be creeping	
Demospongiae	Heteroscleromorpha	Haplosclerida	Niphatidae	<i>Amphimedon</i>	<i>paraviridis</i>	Fromont, 1993	creeping to erect-branching	
Demospongiae	Heteroscleromorpha	Haplosclerida	Niphatidae	<i>Cribrachalina</i>	<i>vasculum</i>	(De Lamarck, 1814)	cup (Fig. 7K)	
Demospongiae	Heteroscleromorpha	Haplosclerida	Niphatidae	<i>Gelliodes</i>	<i>fibulata</i>	(Carter, 1881)	creeping	
Demospongiae	Heteroscleromorpha	Haplosclerida	Niphatidae	<i>Niphates</i>	<i>erecta</i>	Duchassaing and Michelotti, 1864	creeping	
Demospongiae	Heteroscleromorpha	Haplosclerida	Niphatidae	<i>Niphates</i>	<i>digitalis</i>	(De Lamarck, 1814)	cup	
Demospongiae	Heteroscleromorpha	Haplosclerida	Niphatidae	<i>Niphates</i>	<i>olemda</i>	(De Laubenfels, 1954)	tubular	
Demospongiae	Heteroscleromorpha	Haplosclerida	Petrosidae	<i>Xestospongia</i>	-	De Laubenfels, 1932	genus contains e.g. barrels and thickly encrusting or massive species	
Demospongiae	Heteroscleromorpha	Haplosclerida	Petrosidae	<i>Xestospongia</i>	<i>mamillata</i>	Pulitzer-Finali, 1982	? taxon author described a flat fragment	
Demospongiae	Heteroscleromorpha	Haplosclerida	Petrosidae	<i>Xestospongia</i>	<i>testudinaria</i>	(De Lamarck, 1815)	barrel (Fig. 2B, 5F-G, 8)	
Demospongiae	Heteroscleromorpha	Haplosclerida	Petrosidae	<i>Neopetrosia</i>	<i>chaliniformis</i>	(Thiele, 1899)	variable, can be creeping, thickly encrusting to erect-branching	
Demospongiae	Heteroscleromorpha	Haplosclerida	Petrosiidae	<i>Neopetrosia</i>	<i>subtriangularis</i>	(Duchassaing, 1850)	variable, can be creeping or low-relief (Fig. 7E)	
Demospongiae	Heteroscleromorpha	Haplosclerida	Petrosiidae	<i>Petrosia</i>	<i>(Petrosia)</i>	<i>ficiformis</i>	(Poiret, 1789)	creeping
Demospongiae	Heteroscleromorpha	Haplosclerida	Phloeodictyidae	<i>Oceanapia</i>	-	Norman, 1869	fistular (Fig. 10E)	
Demospongiae	Heteroscleromorpha	Haplosclerida	Phloeodictyidae	<i>Oceanapia</i>	<i>ambainensis</i>	Topsent, 1897	fistular	
Demospongiae	Heteroscleromorpha	Haplosclerida	Phloeodictyidae	<i>Oceanapia</i>	<i>sagittaria</i>	(Sollas, 1902)	fistular	
Demospongiae	Heteroscleromorpha	Haplosclerida	Phloeodictyidae	<i>Siphonodictyon</i>	-	Bergquist, 1965	smaller species and individuals: endolithic-bioeroding, larger species and individuals: fistular	
Demospongiae	Heteroscleromorpha	Haplosclerida	Phloeodictyidae	<i>Siphonodictyon</i>	<i>coralliphagum</i>	Rützler, 1971	mostly fistular (Fig. 7G), or when smaller: endolithic-bioeroding, occasionally thickly encrusting	
Demospongiae	Heteroscleromorpha	Haplosclerida	Phloeodictyidae	<i>Siphonodictyon</i>	<i>mucosum</i>	Bergquist, 1965	fistular	
Demospongiae	Heteroscleromorpha	Poecilosclerida	Acarnidae	<i>lophon</i>	<i>minor</i>	(Brøndsted, 1924)	erect-reticulate	
Demospongiae	Heteroscleromorpha	Poecilosclerida	Chondropsidae	<i>Chondropsis</i>	-	Carter, 1886	variable (Fig. 4A)	
Demospongiae	Heteroscleromorpha	Poecilosclerida	Cladorhizidae	<i>Abyssocladia</i>	-	Lévi, 1964	carnivorous	
Demospongiae	Heteroscleromorpha	Poecilosclerida	Poecilosclerida	<i>Chondrocladia</i>	<i>grandis</i>	(Verrill, 1879)	carnivorous (Fig. 3E)	
Demospongiae	Heteroscleromorpha	Poecilosclerida	Cladorhizidae	<i>Chondrocladia</i>	<i>(Chondrocladia)</i>	<i>lyra</i>	Lee et al., 2012	carnivorous (Fig. 3D)
Demospongiae	Heteroscleromorpha	Poecilosclerida	Cladorhizidae	<i>Chondrocladia</i>	<i>(Symmetrocladia)</i>	<i>Cladorhiza</i>	-	carnivorous

³ The genus change from *Timea* to *Placosphaera* is presently not implemented in van Soest et al. (2020), but is explained in the Sponge Guide (Zea et al., 2014)

⁴ See taxonomic remarks in van Soest et al. (2020).

Class	Subclass	Order	Family	Genus	Species	Taxon author	Morphologies
Demospongiae	Heteroscleromorpha	Poecilosclerida	Cladorhizidae	<i>Cladorhiza</i>	<i>gelida</i>	Lundbeck, 1905	carnivorous
Demospongiae	Heteroscleromorpha	Poecilosclerida	Coelosphaeridae	<i>Forcepia (Forcepia)</i>	<i>topsenti</i>	Lundbeck, 1905	endopsammic, likely fistular
Demospongiae	Heteroscleromorpha	Poecilosclerida	Coelosphaeridae	<i>Lissodendoryx (Acanthodoryx)</i>	<i>fibrosa</i>	(Lévi, 1961)	erect-laminar
Demospongiae	Heteroscleromorpha	Poecilosclerida	Crambeidae	<i>Crambe</i>	<i>crambe</i>	(Schmidt, 1862)	thick crust
Demospongiae	Heteroscleromorpha	Poecilosclerida	Crellidae	<i>Crella</i>	<i>incrustans</i>	(Carter, 1885)	variable, often encrusting, but can develop fistules
Demospongiae	Heteroscleromorpha	Poecilosclerida	Desmacididae	<i>Desmacidon</i>	-	Bowerbank, 1861	variable
Demospongiae	Heteroscleromorpha	Poecilosclerida	Esperiopsidae	<i>Amphilectus</i>	<i>fucorum</i>	(Esper, 1794)	thickly encrusting to erect-branching, can have fistular tendencies
Demospongiae	Heteroscleromorpha	Poecilosclerida	Hymedesmiidae	<i>Hemimycale</i>	<i>columella</i>	(Bowerbank, 1874)	encrusting
Demospongiae	Heteroscleromorpha	Poecilosclerida	Hymedesmiidae	<i>Hymedesmia</i>	-	Bowerbank, 1864	often encrusting
Demospongiae	Heteroscleromorpha	Poecilosclerida	Hymedesmiidae	<i>Hymedesmia (Hymedesmia)</i>	<i>stylata</i>	Lundbeck, 1905	thin crust, creeping over particles, but functionally fistular
Demospongiae	Heteroscleromorpha	Poecilosclerida	Hymedesmiidae	<i>Hymedesmia (Stylapus)</i>	<i>coriacea</i>	(Fristedt, 1885)	thin crust
Demospongiae	Heteroscleromorpha	Poecilosclerida	Hymedesmiidae	<i>Phorbas</i>	-	Duchassaing and Michelotti, 1864	variable, often thickly encrusting
Demospongiae	Heteroscleromorpha	Poecilosclerida	Hymedesmiidae	<i>Phorbas</i>	<i>fictitius</i>	Bowerbank, 1866	thick crust
Demospongiae	Heteroscleromorpha	Poecilosclerida	Isodictyidae	<i>Coelocarteria</i>	-	Burton, 1934	fistular
Demospongiae	Heteroscleromorpha	Poecilosclerida	Isodictyidae	<i>Coelocarteria</i>	<i>singaporensis</i>	(Carter, 1883)	fistular
Demospongiae	Heteroscleromorpha	Poecilosclerida	Istrochotidae	<i>Istrochota</i>	<i>baculifera</i>	Ridley, 1884	thickly encrusting
Demospongiae	Heteroscleromorpha	Poecilosclerida	Microcionidae (Microcioninae)	<i>Clathria</i>	-	Schmidt, 1862	variable, can be composite-massive
Demospongiae	Heteroscleromorpha	Poecilosclerida	Microcionidae (Microcioninae)	<i>Clathria (Clathria)</i>	-	Schmidt, 1862	variable
Demospongiae	Heteroscleromorpha	Poecilosclerida	Microcionidae (Microcioninae)	<i>Clathria (Clathria)</i>	<i>hjorti</i>	(Arnesen, 1920)	erect-reticulate
Demospongiae	Heteroscleromorpha	Poecilosclerida	Microcionidae (Microcioninae)	<i>Clathria (Microcionina)</i>	-	Bowerbank, 1862	variable
Demospongiae	Heteroscleromorpha	Poecilosclerida	Microcionidae (Microcioninae)	<i>Clathria (Microcionina)</i>	<i>aceratoobtusa</i>	(Carter, 1887)	thin crust
Demospongiae	Heteroscleromorpha	Poecilosclerida	Microcionidae (Microcioninae)	<i>Clathria (Thalysias)</i>	<i>coppingeri</i>	Ridley, 1884	erect-reticulate (Fig. 10C)
Demospongiae	Heteroscleromorpha	Poecilosclerida	Microcionidae (Microcioninae)	<i>Clathria (Thalysias)</i>	<i>costifera</i>	Hallmann, 1912	erect-laminar
Demospongiae	Heteroscleromorpha	Poecilosclerida	Microcionidae (Microcioninae)	<i>Clathria (Thalysias)</i>	<i>fusterna</i>	Hooper, 1996	erect-stalked
Demospongiae	Heteroscleromorpha	Poecilosclerida	Microcionidae (Microcioninae)	<i>Clathria (Thalysias)</i>	<i>lendenfeldi</i>	Ridley and Dendy, 1886	usually erect-laminar
Demospongiae	Heteroscleromorpha	Poecilosclerida	Microcionidae (Microcioninae)	<i>Clathria (Thalysias)</i>	<i>major</i>	Hentschel, 1912	erect-palmate
Demospongiae	Heteroscleromorpha	Poecilosclerida	Microcionidae (Microcioninae)	<i>Clathria (Thalysias)</i>	<i>placenta</i>	(De Lamarck, 1814)	erect-laminar
Demospongiae	Heteroscleromorpha	Poecilosclerida	Microcionidae (Microcioninae)	<i>Clathria (Thalysias)</i>	<i>procera</i>	(Ridley, 1884)	erect-branching in three dimensions, but can also be simple-erect and tends to creeping
Demospongiae	Heteroscleromorpha	Poecilosclerida	Microcionidae (Microcioninae)	<i>Clathria (Thalysias)</i>	<i>spinifera</i>	(Lindgren, 1897)	erect-palmate
Demospongiae	Heteroscleromorpha	Poecilosclerida	Microcionidae (Microcioninae)	<i>Clathria (Thalysias)</i>	<i>virgultosa</i>	(Esper, 1806)	creeping, rope sponge that can also be erect-branching in three dimensions (Fig. 7D)
Demospongiae	Heteroscleromorpha	Poecilosclerida	Microcionidae (Microcioninae)	<i>Clathria (Wilsonella)</i>	<i>mixta</i>	Hentschel, 1912	erect
Demospongiae	Heteroscleromorpha	Poecilosclerida	Microcionidae (Microcioninae)	<i>Echinocalina (Protaphlitaspongia)</i>	<i>isaaci</i>	Hooper, 1996	tube cluster
Demospongiae	Heteroscleromorpha	Poecilosclerida	Microcionidae (Ophlitaspongiinae)	<i>Ophlitaspongia</i>	<i>papilla</i>	Bowerbank, 1866	encrusting
Demospongiae	Heteroscleromorpha	Poecilosclerida	Mycalidae	<i>Mycale (Aegagropila)</i>	-	Gray, 1867	often creeping or thickly encrusting
Demospongiae	Heteroscleromorpha	Poecilosclerida	Mycalidae	<i>Mycale</i>	<i>laxissima</i>	(Duchassaing and Michelotti, 1864)	amphora
Demospongiae	Heteroscleromorpha	Poecilosclerida	Mycalidae	<i>Mycale (Arenochalina)</i>	-	(Carter, 1882)	thick crust (insinuating) or creeping
Demospongiae	Heteroscleromorpha	Poecilosclerida	Mycalidae	<i>Mycale (Oxymycale)</i>	<i>acerata</i>	Kirkpatrick, 1907	tube cluster
Demospongiae	Heteroscleromorpha	Poecilosclerida	Myxillidae	<i>Myxilla (Myxilla)</i>	<i>rosacea</i>	(Lieberkühn, 1859)	encrusting to simple-massive
Demospongiae	Heteroscleromorpha	Poecilosclerida	Podospongiidae	<i>Diacarnus</i>	<i>megaspinothabdosia</i>	Kelly-Borges and Vacelet, 1995	ball
Demospongiae	Heteroscleromorpha	Poecilosclerida	Podospongiidae	<i>Podospongia</i>	<i>virga</i>	Sim-Smith and Kelly, 2011	erect-stalked
Demospongiae	Heteroscleromorpha	Poecilosclerida	Raspailiidae (Cyamoninae)	<i>Trikenrion</i>	<i>flabelliforme</i>	Hentschel, 1912	erect-palmate
Demospongiae	Heteroscleromorpha	Poecilosclerida	Raspailiidae (Echinodictyinae))	<i>Echinodictyum</i>	<i>pulchrum</i>	Brøndsted, 1934	erect-reticulate
Demospongiae	Heteroscleromorpha	Poecilosclerida	Raspailiidae (Raspailiinae)	<i>Ectyoplasia</i>	<i>tabula</i>	(De Lamarck, 1814)	erect-palmate
Demospongiae	Heteroscleromorpha	Poecilosclerida	Raspailiidae (Raspailiinae)	<i>Raspailia (Raspaxilla)</i>	-	Topsent, 1913	usually erect, often branching
Demospongiae	Heteroscleromorpha	Poecilosclerida	Tedaniidae	<i>Tedania (Tedania)</i>	<i>ignis</i>	(Duchassaing and Michelotti, 1864)	can be fistular
Demospongiae	Heteroscleromorpha	Polymastiida	Polymastiidae	<i>Polymastia</i>	-	Bowerbank, 1862	fistular
Demospongiae	Heteroscleromorpha	Polymastiida	Polymastiidae	<i>Polymastia</i>	<i>grimaldii</i>	(Topsent, 1913)	fistular
Demospongiae	Heteroscleromorpha	Polymastiida	Polymastiidae	<i>Polymastia</i>	<i>hemisphaerica</i>	(Sars, 1872)	fistular
Demospongiae	Heteroscleromorpha	Polymastiida	Polymastiidae	<i>Polymastia</i>	<i>invaginata</i>	Kirkpatrick, 1907	fistular
Demospongiae	Heteroscleromorpha	Polymastiida	Polymastiidae	<i>Polymastia</i>	<i>mamillaris</i>	Bowerbank, 1862	fistular
Demospongiae	Heteroscleromorpha	Polymastiida	Polymastiidae	<i>Radiella</i>	<i>sol</i>	(Schmidt, 1870)	ball
Demospongiae	Heteroscleromorpha	Polymastiida	Polymastiidae	<i>Tentorium</i>	<i>papillatum</i>	(Kirkpatrick, 1908)	fistular
Demospongiae	Heteroscleromorpha	Polymastiida	Polymastiidae	<i>Tentorium</i>	<i>semisuberites</i>	(Schmidt, 1870)	fistular
Demospongiae	Heteroscleromorpha	Scoplainida	Scopalinidae	<i>Scopalina</i>	<i>lophyropoda</i>	Schmidt, 1862	encrusting

Class	Subclass	Order	Family	Genus	Species	Taxon author	Morphologies
Demospongiae	Heteroscleromorpha	Scoplainida	Scopalinidae	<i>Stylissa</i>	<i>flabelliformis</i>	(Hentschel, 1912)	erect-laminar
Demospongiae	Heteroscleromorpha	Scoplainida	Scopalinidae	<i>Stylissa</i>	<i>massa</i>	(Carter, 1887)	variable, often composite-massive
Demospongiae	Heteroscleromorpha	Spongillida	Spongillidae	<i>Spongilla</i>	<i>lacustris</i>	(Linnaeus, 1759)	thickly encrusting to erect-branching
Demospongiae	Heteroscleromorpha	Suberitida	Halichondriidae	<i>Ciocalypta</i>	-	Bowerbank, 1862	fistular
Demospongiae	Heteroscleromorpha	Suberitida	Halichondriidae	<i>Ciocalypta</i>	<i>penicillus</i>	Bowerbank, 1862	fistular
Demospongiae	Heteroscleromorpha	Suberitida	Halichondriidae	<i>Halichondria</i> (<i>Halichondria</i>)	<i>bowerbanki</i>	Burton, 1930	thin to thick crust that can develop pronounced, fistule-like oscules and fine erect-branching processes
Demospongiae	Heteroscleromorpha	Suberitida	Halichondriidae	<i>Halichondria</i> (<i>Halichondria</i>)	<i>melanadocia</i>	De Laubenfels, 1936	variable, can be encrusting, simple-massive to branching or even
Demospongiae	Heteroscleromorpha	Suberitida	Halichondriidae	<i>Halichondria</i> (<i>Halichondria</i>)	<i>panicea</i>	(Pallas, 1766)	fistular, or can function as creeping
Demospongiae	Heteroscleromorpha	Suberitida	Halichondriidae	<i>Hymeniacion</i>	<i>perlevis</i>	(Montagu, 1814)	variable, can be encrusting, simple-massive to branching or even
Demospongiae	Heteroscleromorpha	Suberitida	Stylocordylidae	<i>Stylocordyla</i>	<i>chupachups</i>	Uriz et al., 2011	erect-stalked
Demospongiae	Heteroscleromorpha	Suberitida	Suberitidae	<i>Caulospongia</i>	-	Kent, 1871	erect, ranging in function from simple-erect to three-dimensionally branching to stalked (Fig. 4G)
Demospongiae	Heteroscleromorpha	Suberitida	Suberitidae	<i>Rhizaxinella</i>	-	Keller, 1880	erect-stalked
Demospongiae	Heteroscleromorpha	Suberitida	Suberitidae	<i>Suberites</i>	-	Nardo, 1833	variable, small species can behave as balls
Demospongiae	Heteroscleromorpha	Suberitida	Suberitidae	<i>Suberites</i>	<i>carnosus</i>	(Johnston, 1842)	ball
Demospongiae	Heteroscleromorpha	Suberitida	Suberitidae	<i>Suberites</i>	<i>ficus</i>	(Johnston, 1842)	variable, can be simple-massive, or
Demospongiae	Heteroscleromorpha	Suberitida	Suberitidae	<i>Suberites</i>	<i>massa</i>	Nardo, 1847	thickly encrusting or ball-shaped
Demospongiae	Heteroscleromorpha	Suberitida	Suberitidae	<i>Terpios</i>	-	Duchassaing and Michelotti, 1864	variable, can be thickly encrusting to composite-massive to fistular
Demospongiae	Heteroscleromorpha	Tethyida	Hemiasterellidae	<i>Adreus</i>	<i>axiferum</i>	(Hentschel, 1912)	thin crust
Demospongiae	Heteroscleromorpha	Tethyida	Hemiasterellidae	<i>Axos</i>	-	Gray, 1867	palmete or 3D erect-branching can be erect-palmete (Fig. 14A)
Demospongiae	Heteroscleromorpha	Tethyida	Hemiasterellidae	<i>Axos</i>	<i>cliftoni</i>	Gray, 1867	erect-palmete
Demospongiae	Heteroscleromorpha	Tethyida	Hemiasterellidae	<i>Axos</i>	<i>flabelliformis</i>	Carter, 1879	erect-palmete (cliftoni, flabelliformis)
Demospongiae	Heteroscleromorpha	Tethyida	Hemiasterellidae	<i>Liosina</i>	<i>granularis</i>	Kelly-Borges and Bergquist, 1988	tubular
Demospongiae	Heteroscleromorpha	Tethyida	Hemiasterellidae	<i>Liosina</i>	<i>paradoxa</i>	Thile, 1899	tubular
Demospongiae	Heteroscleromorpha	Tethyida	Tethyidae	<i>Tectitethya</i>	<i>crypta</i>	(De Laubenfels, 1949)	
Demospongiae	Heteroscleromorpha	Tethyida	Tethyidae	<i>Tethya</i>	-	De Lamarck, 1815	ball (Fig. 1C)
Demospongiae	Heteroscleromorpha	Tethyida	Tethyidae	<i>Tethya</i>	<i>aurantium</i>	(Pallas, 1766)	ball
Demospongiae	Heteroscleromorpha	Tethyida	Tethyidae	<i>Tethycometes</i>	<i>radicosa</i>	Lim and Tan, 2008	erect-stalked
Demospongiae	Heteroscleromorpha	Tethyida	Tethyidae	<i>Xenospongia</i>	<i>patelliformis</i>	Gray, 1858	is an unattached disc, but is adapted to sandy habitats similar as fistular sponges (Fig. 6)
Demospongiae	Heteroscleromorpha	Tethyida	Timeidae	<i>Timea</i>	<i>unistellata</i>	(Topsent, 1892)	thin crust
Demospongiae	Heteroscleromorpha	Tetractinellida (Astrophorina)	Ancorinidae	<i>Asteropus</i>	<i>niger</i>	Hajdu and van Soest, 1992	simple-massive (Fig. 7F)
Demospongiae	Heteroscleromorpha	Tetractinellida (Astrophorina)	Ancorinidae	<i>Stelletta</i>	<i>clavosa</i>	Ridley, 1884	ball
Demospongiae	Heteroscleromorpha	Tetractinellida (Astrophorina)	Geodiidae (Erylinae)	<i>Melophlus</i>	<i>sarassinorum</i>	Thiele, 1899	ball, but on "feet", short stalks that slightly elevate it
Demospongiae	Heteroscleromorpha	Tetractinellida (Astrophorina)	Geodiidae (Erylinae)	<i>Pachymatisma</i>	<i>johnstonia</i>	(Bowerbank in Johnston, 1842)	encrusting to simple-massive
Demospongiae	Heteroscleromorpha	Tetractinellida (Astrophorina)	Geodiidae (Geodiinae)	<i>Geodia</i>	<i>neptuni</i>	(Sollas, 1886)	barrel
Demospongiae	Heteroscleromorpha	Tetractinellida (Astrophorina)	Theneidae	<i>Thenea</i>	-	Gray, 1867	often fistular, but can be balls or
Demospongiae	Heteroscleromorpha	Tetractinellida (Astrophorina)	Theonellidae	<i>Theonella</i>	<i>swinhoei</i>	Gray, 1868	barrels in function
Demospongiae	Heteroscleromorpha	Tetractinellida (Spirophorina)	Tetillidae	<i>Cinachyra</i>	-	Sollas, 1886	amphora
Demospongiae	Heteroscleromorpha	Tetractinellida (Spirophorina)	Tetillidae	<i>Cinachyra</i>	<i>barbata</i>	Sollas, 1886	ball
Demospongiae	Heteroscleromorpha	Tetractinellida (Spirophorina)	Tetillidae	<i>Cinachyrella</i>	-	Wilson, 1925	ball
Demospongiae	Heteroscleromorpha	Tetractinellida (Spirophorina)	Tetillidae	<i>Cinachyrella</i>	<i>apion</i>	(Uliczka, 1929)	ball
Demospongiae	Heteroscleromorpha	Tetractinellida (Spirophorina)	Tetillidae	<i>Cinachyrella</i>	<i>arabica</i>	(Carter, 1869)	ball
Demospongiae	Heteroscleromorpha	Tetractinellida (Spirophorina)	Tetillidae	<i>Cinachyrella</i>	<i>australiensis</i>	(Carter, 1886)	ball
Demospongiae	Heteroscleromorpha	Tetractinellida (Spirophorina)	Tetillidae	<i>Cinachyrella</i>	<i>kuekenthali</i>	(Uliczka, 1929)	ball (Fig. 7H)
Demospongiae	Heteroscleromorpha	Tetractinellida (Spirophorina)	Tetillidae	<i>Paratetilla</i>	-	Dendy, 1905	balls
Demospongiae	Heteroscleromorpha	Tetractinellida (Spirophorina)	Tetillidae	<i>Paratetilla</i>	<i>bacca</i>	(Selenka, 1867)	ball
Demospongiae	Heteroscleromorpha	Tetractinellida (Spirophorina)	Tetillidae	<i>Paratetilla</i>	<i>corrugata</i>	Dendy, 1922	ball
Demospongiae	Homoscleromorpha	Homosclerophorida	Plakinidae	<i>Plakortis</i>	-	Schulze, 1880	variable, OTU species in paper was basically ball-shaped (Fig. 4D)
Demospongiae	Homoscleromorpha	Homosclerophorida	Plakinidae	<i>Plakortis</i>	<i>simplex</i>	Schulze, 1880	thin crust
Demospongiae	Keratosa	Dendroceratida	Darwinellidae	<i>Aplysilla</i>	<i>rosea</i>	(Barrois, 1876)	composite-massive
Demospongiae	Keratosa	Dendroceratida	Darwinellidae	<i>Darwinella</i>	<i>australiensis</i>	Carter, 1885	thin crust (Fig. 4B)
Demospongiae	Keratosa	Dictyoceratida	Dysideidae	<i>Dysidea</i>	-	Johnston, 1842	variable
Demospongiae	Keratosa	Dictyoceratida	Dysideidae	<i>Dysidea</i>	<i>avara</i>	(Schmidt, 1862)	variable, can be simple-massive to more tubular or erect-branching

Class	Subclass	Order	Family	Genus	Species	Taxon author	Morphologies
Demospongiae	Keratosa	Dictyoceratida	Dysideidae	<i>Lamellodysidea</i>	<i>herbacea</i>	(Keller, 1889)	variable, creeping, but can have a significant erect portion of finger-like or little flabellate projections cup (Fig. 7J)
Demospongiae	Keratosa	Dictyoceratida	Irciniidae	<i>Ircinia</i>	<i>campana</i>	(De Lamarck, 1814)	composite-massive
Demospongiae	Keratosa	Dictyoceratida	Irciniidae	<i>Ircinia</i>	<i>felix</i>	(Duchassaing and Michelotti, 1864)	
Demospongiae	Keratosa	Dictyoceratida	Irciniidae	<i>Ircinia</i>	<i>strobilina</i>	(De Lamarck, 1816)	barrel
Demospongiae	Keratosa	Dictyoceratida	Irciniidae	<i>Psammocinia</i>	<i>bulbosa</i>	Bergquist, 1995	fistular, endopsammic
Demospongiae	Keratosa	Dictyoceratida	Irciniidae	<i>Sarcotragus</i>	-	Schmidt, 1862	often simple-massive
Demospongiae	Keratosa	Dictyoceratida	Spongiidae	<i>Coscinoderma</i>	<i>matthewsi</i>	Von Lendenfeld, 1886	simple-massive
Demospongiae	Keratosa	Dictyoceratida	Spongiidae	<i>Rhopaloeides</i>	<i>odorabile</i>	Thompson et al., 1987	variable, commonly simple-massive
Demospongiae	Keratosa	Dictyoceratida	Spongiidae	<i>Spongia (Spongia)</i>	-	Linnaeus, 1759	variable, commonly simple-massive
Demospongiae	Keratosa	Dictyoceratida	Spongiidae	<i>Spongia (Spongia)</i>	<i>agaricina</i>	Pallas, 1766	variable, can be cup-like to erect-laminar
Demospongiae	Keratosa	Dictyoceratida	Spongiidae	<i>Spongia (Spongia)</i>	<i>officinalis</i>	Linnaeus, 1759	simple-massive (Fig. 1B, 5A-D), can function as creeping
Demospongiae	Keratosa	Dictyoceratida	Spongiidae	<i>Spongia (Spongia)</i>	<i>virgultosa</i>	(Schmidt, 1868)	crusts with small fistules
Demospongiae	Keratosa	Dictyoceratida	Thorectidae (Phyllospongiinae)	<i>Carteriospongia</i>	<i>foliascens</i>	(Pallas, 1766)	cups, incomplete cups to erect-laminar fans (Fig. 9)
Demospongiae	Keratosa	Dictyoceratida	Thorectidae (Thorectinae)	<i>Aplysinopsis</i>	-	(Von Lendenfeld, 1888)	variable, mostly simple-massive or low-relief
Demospongiae	Keratosa	Dictyoceratida	Thorectidae (Thorectinae)	<i>Cacospongia</i>	-	Schmidt, 1862	mostly simple-massive
Demospongiae	Keratosa	Dictyoceratida	Thorectidae (Thorectinae)	<i>Fascaplysinopsis</i>	<i>reticulata</i>	(Hentschel, 1912)	simple-massive
Demospongiae	Keratosa	Dictyoceratida	Thorectidae (Thorectinae)	<i>Hyrtios</i>	<i>cavernosus</i>	Vacelet et al., 1976	simple-massive (Fig. 7B)
Demospongiae	Keratosa	Dictyoceratida	Thorectidae (Thorectinae)	<i>Hyrtios</i>	<i>erectus</i>	(Keller, 1889)	creeping
Demospongiae	Verongimorpha	Verongiida	Chondrillidae	<i>Thymosia</i>	<i>guernei</i>	Topsent, 1895	encrusting to simple-massive
Demospongiae	Verongimorpha	Verongiida	Aplysinidae	<i>Aplysina</i>	-	Nardo, 1834	creeping
Demospongiae	Verongimorpha	Verongiida	Aplysinidae	<i>Aplysina</i>	<i>aerophoba</i>	(Nardo, 1833)	tube
Demospongiae	Verongimorpha	Verongiida	Aplysinidae	<i>Aplysina</i>	<i>archeri</i>	(Higgin, 1875)	variable, e.g. erect-branching (Fig. 7C)
Demospongiae	Verongimorpha	Verongiida	Aplysinidae	<i>Aplysina</i>	<i>cauliformis</i>	(Carter, 1882)	tube (Fig. 7L)
Demospongiae	Verongimorpha	Verongiida	Aplysinidae	<i>Aplysina</i>	<i>fistularis</i>	(Pallas, 1766)	tube
Demospongiae	Verongimorpha	Verongiida	Aplysinidae	<i>Aplysina</i>	<i>fulva</i>	(Pallas, 1766)	erect-branching in three dimensions, but can also be simple-erect and tends to creeping
Demospongiae	Verongimorpha	Verongiida	Aplysinidae	<i>Verongula</i>	<i>reiswigi</i>	Alcolado, 1984	barrel or cup (Fig. 7I), or even tube
Demospongiae	Verongimorpha	Verongiida	Ernstiliidae	<i>Ernstilla</i>	<i>lacunosa</i>	(Hentschel, 1912)	erect-palmate (Fig. 10B)
Demospongiae	Verongimorpha	Verongiida	lanthellidae	<i>lanthella</i>	-	Gray, 1869	mostly erect-laminar, but can form functionally intermediate forms towards cup-like morphologies
Demospongiae	Verongimorpha	Verongiida	lanthellidae	<i>lanthella</i>	<i>basta</i>	(Pallas, 1766)	often tubular (Fig. 2B, 4H-I), small specimens can be erect-laminar
Demospongiae	Verongimorpha	Verongiida	lanthellidae	<i>lanthella</i>	<i>flabelliformis</i>	(Linnaeus, 1759)	erect-laminar (Fig. 10A)
Demospongiae	Verongimorpha	Verongiida	Pseudoceratinidae	<i>Pseudoceratina</i>	<i>purpurea</i>	(Carter, 1880)	creeping
Demospongiae	Verongimorpha	Verongiida	Pseudoceratinidae	<i>Pseudoceratina</i>	<i>verrucosa</i>	Bergquist, 1995	creeping
Hexactinellida	Amphidiscophora	Hyalonematida	Hyalonematidae	<i>Hyalonema</i>	-	Gray, 1832	erect-stalked
Hexactinellida	Hexasterophora	Lyssacinosida	Euplectellidae (Bolosominae)	<i>Bolosoma</i>	-	Ijima, 1904	erect-stalked
Hexactinellida	Hexasterophora	Lyssacinosida	Euplectellidae (Euplectellinae)	<i>Docosaccus</i>	-	Topsent, 1910	tabular
Hexactinellida	Hexasterophora	Lyssacinosida	Euplectellidae (Euplectellinae)	<i>Euplectella</i>	-	Owen, 1841	tube to amphora
Hexactinellida	Hexasterophora	Lyssacinosida	Euplectellidae (Euplectellinae)	<i>Euplectella</i>	<i>aspergillum</i>	Owen, 1841	tube to amphora
Hexactinellida	Hexasterophora	Lyssacinosida	Rosellidae (Lanuginellidae)	<i>Caulophacus</i>	-	Schulze, 1886	erect-stalked
Hexactinellida	Hexasterophora	Lyssacinosida	Rosellidae (Lanuginellidae)	<i>Caulophacus</i>	<i>arcticus</i>	(Hansen, 1885)	erect-stalked
Hexactinellida	Hexasterophora	Lyssacinosida	Rosellidae (Rosellinae)	<i>Anoxycalyx (Scolymastra)</i>	<i>jaubini</i>	(Topsent, 1916)	amphora
Hexactinellida	Hexasterophora	Lyssacinosida	Rosellidae (Rosellinae)	<i>Bathydorus</i>	-	Schulze, 1886	tabular
Hexactinellida	Hexasterophora	Lyssacinosida	Rosellidae (Rosellinae)	<i>Rosella</i>	-	Carer, 1872	amphora
Hexactinellida	Hexasterophora	Sceptrulophora	Aphrocallistidae	<i>Aphrocallistes</i>	<i>vastus</i>	Schulze, 1886	amphora
Hexactinellida	Hexasterophora	Sceptrulophora	Euretidae (Chonalesmatinae)	<i>Chonelasma</i>	-	Schulze, 1886	erect-stalked to erect-palmate
Asciacea	-	Stolidobranchia	Pyuridae	<i>Pyura</i>	<i>spinifera</i>	(Quoi and Gaimard, 1834)	stalked (but not a sponge)
Anthozoa	Hexacorallia	Scleractinia	Dendrophylliidae	<i>Turbinaria</i>	-	Oken, 1815	shallow complete cup to tabular (but not a sponge)
Hydrozoa	Hydroidolina	Anthoathecata (Capitata)	Milleporidae	<i>Millepora</i>	<i>complanata</i>	De Lamarck, 1816	3D or 2D branching to composite-massive (but not a sponge)

Supplement 4. Cheat sheet. Print, trim off white frame, laminate, bring for fieldwork or as reference

1-2 FUNCTIONAL CRUST (EN)		3-6 MASSIVE IN FUNCTION (M)	7-9 CUP-LIKE FUNCTION (C)	10-14 ERECT IN FUNCTION (E)
1 – Crust (EN-lat) <i>sensu lato</i>	1.1 – true crust (EN-cr), thin (few mm; thn , showing substrate contours) and thick crusts (few cm; thc); none or low surface relief	3 - simple-massive (M-s), about as wide as high, inhalants and exhalants scattered across same surface	7 – Wide cups (C-w) apical diameter > body diameter	10 – 1D-erect, simple-erect (E-1D), columns, rods, whips, usually in- & exhalants, +/- round in cross section
	1.2 - endolithic, bioeroding (EN-be), tissue dots or as crust, difficult to recognise as non-expert, but very similar to above	4 - balls (M-bl), small body, more or less globular, in- and exhalants mixed or separate		7.1 – tables, or very shallow cups (C-tab), can easily be covered by sediments
2 - creeping, repent (EN-rep), branches follow ground, can have erect parts, multiple attachm., easy to detach		5 - composite-massive (M-c), overall body shape and function massive, but body composed of densely merged or meshed subunits	7.2 - incomplete cup (C-inc), intermediate form to erect-laminar, but body curled to funnel	11.1 - erect-laminar, spatulas, fans (E-lam), flabellate, flat-upright, can have a short stalk or stem
 	 	6 - fistular-massive (M-f), more or less embedded in the sediment, usually with elevated fistules, often with (hidden) anchoring structures	7.3 – complete cup (C-cmp), concave, catch sediment that is more difficult to be washed out	11.2 - erect-palmate, hand-shaped, flat bush (E-pal), small base or stalk, with round or flat branches fanning out in 1 plane
			8 – Narrow cups (C-nr)	8.1 – tube or chimney (C-t), apical diameter = body diameter
		CHEAT	9 – barrels or “massive” cups (C-b), lateral inhalants, central-apical exhalant or exhalant cluster, usually with barrel, high mound or cone shape	12 – 3D-erect, erect-branching (E-3D), arborescent, bush or otherwise irregularly branching, in different planes
			SHEET v. 2020-04	Sponge functional growth forms (<i>sensu</i> Schönberg 2020)
Can be used for classification without taxonomy and to generate (limited) information about environmental conditions. Four main functional categories are further subdivided – for environmental surrogacy, distinguish morphologies at integer level. All morphologies are steps in a continuum, and intermediate forms occur. <u>Always decide by function in preference to shape.</u>				14 – carnivorous (E-c), usually delicate, usually stalked or branching from central axis
<i>Body width significantly greater than height, extending across substrate surface. Typical for high-velocity, turbulent flow. Partly vulnerable against sedimentation.</i>		<i>Body width and height roughly similar, various forms. Usually mixed in- and exhalants. Fistular-massive forms and many balls sediment specialists.</i>	<i>Apically concave or hollow forms, in- and exhalants usually spatially separated. Sediment-vulnerable unless with bundled exhalant jet. Many photosynthetic species.</i>	<i>Body and branches longer than wide, solid in cross section. 1D and 2D typical for strong, laminar flow. Sediment-tolerant and implying nutrient limitation.</i>

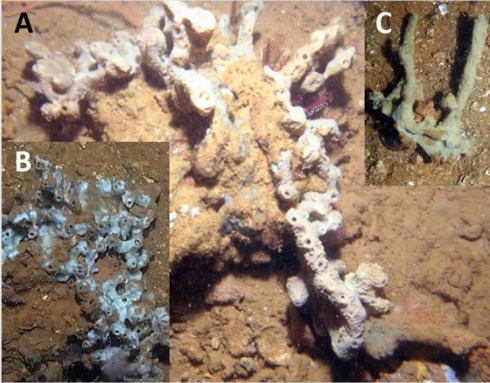

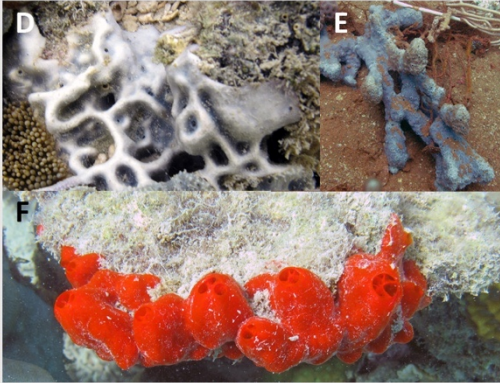

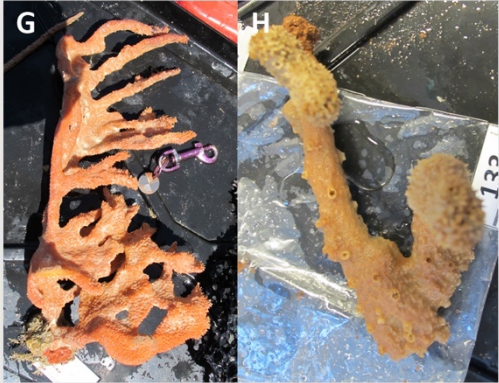

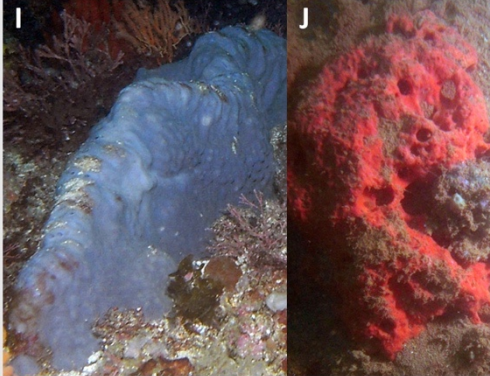

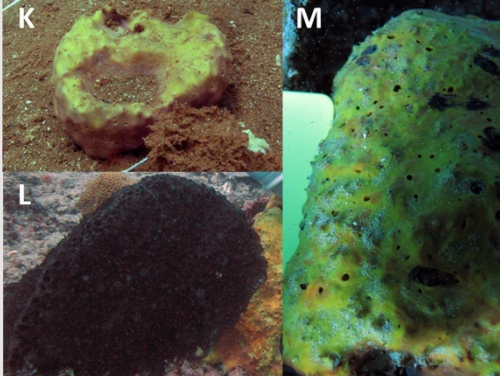

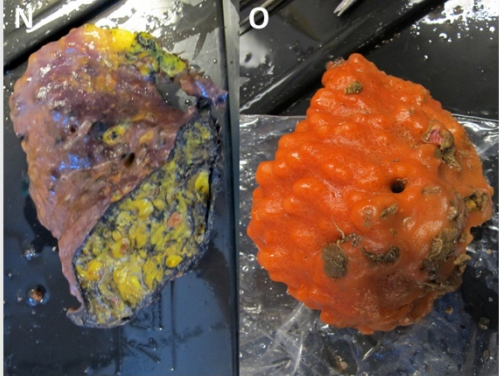

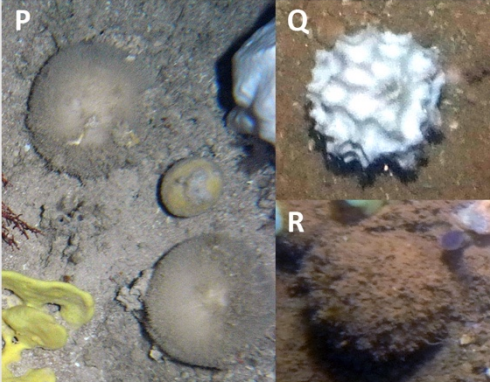

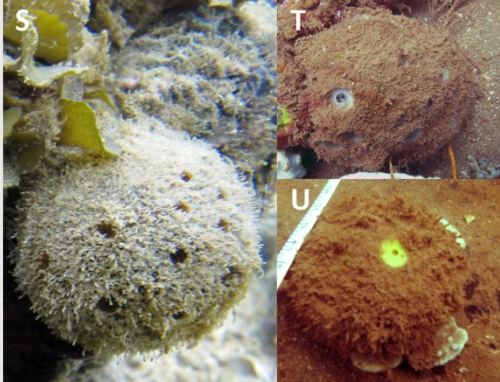

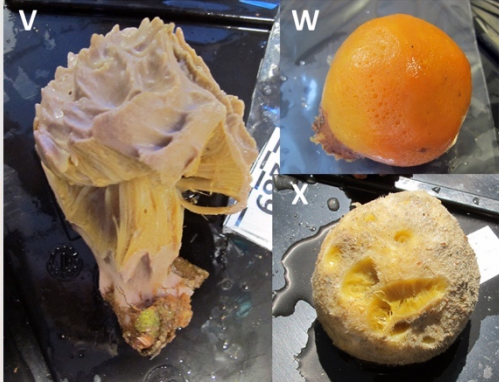

Examples. Photographs from the central Pacific (NOAA; <https://oceanexplorer.noaa.gov/>), SE Australia (JT; <https://www.flickr.com/photos/johnwturnbull/>), NW Australia and the central Great Barrier Reef (CS, EB, FS; AIMS). © AIMS, NOAA or photographer: CS – Christine Schönberg, EB – Evy Büttner, FS – Flora Siebler, JT – John Turnbull, with friendly permission. Sources for Images in Supplement 5

The above images come from different sources. Except for the carnivorous sponges all depict Australian sponges. Towed imagery was collected during surveys that were funded by the Western Australian Marine Science Institution (WAMSI) as part of the WAMSI Dredging Science Node Theme 6.3 (<https://www.wamsi.org.au/dredging-science-node>), a project made possible through investment from Chevron Australia, Woodside Energy Limited, BHP Billiton as environmental offsets and by co-investment from the WAMSI Joint Venture partners. Other significant sources of above images were the “Surrogates for Biodiversity” project of the Commonwealth Environmental Research Facilities (CERF) Marine Biodiversity Hub in partnership between Geoscience Australia and the Australian Institute of Marine Science (<https://www.nespmarine.edu.au/project/improvement-existing-and-development-new-surrogacy-relationships-between-physical-variables>), various AIMS research projects led by Christine Schönberg and from specimens in her reference collection, and from publicly accessible Flickr albums collated by John Turnbull (<https://www.flickr.com/photos/johnwturnbull/albums/72157672870310525>). These and other sources are listed below as per-image information. Collection abbreviations: AIMS – Australian Institute of Marine Science, CERF – Commonwealth Environmental Research Facilities (samples stored at WAM), KIM – Kimberly collection (samples stored at WAM), WAM – Western Australian Museum, ZMB – Berlin Museum of Natural History. When identifications are unsure, the qualifiers “cf.” and “aff.” are used in the sense of “looks like, could be” and “looks similar, but unlikely to be”, respectively.

Supplement 5.1: Thin and thick crusts, and endolithic-bioeroding sponges

- A Red encrusting sponge, shelf habitat at Carnarvon Shelf, NW Australia. Photograph AIMS.
- B Blue-grey encrusting sponge in -8 to -15 m, Onslow, NW Australia. Photograph AIMS, WAMSI Dredging Science Node.
- C-D Patches of encrusting sponges, North Bondi, Sydney, SE Australia. From <https://www.flickr.com/photos/johnwturnbull/albums/72157672870310525>, accessed March 28, 2020. Photographs John Turnbull, with friendly permission.
- E Unidentified thin crust from -21 m, S Montgomery Reef, N Australia. Sample KIM_1_1_49. Photograph Christine Schönberg.
- F *Clathria (Microciona)* sp. from -45 m, Mandu, Carnarvon Shelf, NW Australia. Sample CERF 1_009_1_14. Photograph Christine Schönberg, CERF project (Schönberg et al., 2006).
- G Thickly encrusting sponge at Bare Island, Botany Bay, Sydney, SE Australia. From <https://www.flickr.com/photos/johnwturnbull/albums/72157672870310525>, accessed March 28, 2020. Photograph John Turnbull, with friendly permission.
- H Thickly encrusting blue-grey sponge in -4 m, Sandy Bay, Carnarvon Shelf, NW Australia. Photograph Christine Schönberg.
- I Thickly encrusting grey sponge in the intertidal, Montgomery Reef, N Australia. Photograph Janett Voigt.
- J Thickly encrusting purplish grey sponge in -4 to -5 m, Sandy Bay, Carnarvon Shelf, NW Australia. Photograph Christine Schönberg.
- K-M Thickly encrusting sponges from -26 m, NE Montgomery Reef, N Australia. Photographs Christine Schönberg. K – *Xestospongia* sp., sample KIM_2_1_6. L – Unidentified grey sponge, sample KIM_2_1_13. M – *Placospongia* sp., sample KIM_2_1_12.
- N *Cliona orientalis* in -4 m, Orpheus Island, central Great Barrier Reef. Photograph Christine Schönberg.
- O *Cliona* sp. in -8 to -15 m, Onslow, NW Australia. Photograph AIMS, WAMSI Dredging Science Node.
- P *Cliona* aff. *viridis* at Rhodes Island in shallow water. Photograph Max Wisshak, Senckenberg, with friendly permission.
- Q *Cliona* cf. *orientalis* in -1 m, One Tree Island S Great Barrier Reef. Photograph Christine Schönberg.
- R *Cliona orientalis* in -6 m, Orpheus Island, central Great Barrier Reef. Photograph Christine Schönberg.

- S *Cliona* sp. from -12 m, Onslow, NW Australia. Sample WAMSI_315 = WAM Z65318. Photograph Flora Siebler, WAMSI Dredging Science Node.
- T *Cliona* cf. *celata* from Sylt Island, E North Sea. Sample ZMB1518. Photograph Christine Schönberg.

Supplement 5.2: Thin and thick creeping, simple-massive and ball-shaped sponges

- A-C Repent sponges in -8 to -15 m, Onslow, NW Australia. Photographs AIMS, WAMSI Dredging Science Node.
- D Cf. *Lamellodysidea herbacea* in the intertidal, Montgomery Reef, N Australia. Photograph Christine Schönberg.
- E Cf. *Amphimedon paraviridis* in -10 to -15 m, Onslow, NW Australia. Photograph Christine Schönberg, WAMSI Dredging Science Node.
- F Unidentified red sponge from -3 m, Orpheus Island, central Great Barrier Reef. Photograph Christine Schönberg.
- G Unidentified orange sponge from -23 m, S Montgomery Reef, N Australia, sample KIM_1_2_1. Photograph Christine Schönberg.
- H *Amphimedon* cf. *paraviridis* from -11 m, Onslow, NW Australia. Sample WAMSI_133 = WAM Z65173. Photograph Flora Siebler, WAMSI Dredging Science Node.
- I Shelf habitat at Gnaraloo, Carnarvon Shelf, NW Australia. Photograph AIMS.
- J Unidentified red sponge in -10 to -15 m, Onslow, NW Australia. Photograph AIMS, WAMSI Dredging Science Node.
- K Aff. *Pseudoceratina verrucosa* in -12 m, Onslow, NW Australia. Photograph Christine Schönberg, WAMSI Dredging Science Node.
- L-M Unidentified massive sponges in -13 m, Gnaraloo, Carnarvon Shelf, NW Australia. Photographs Jamie Colquhoun, AIMS.
- N *Pseudoceratina* cf. *verrucosa* from -12 m, Onslow, NW Australia. Sample WAMSI_328 = WAM Z65328. Photograph Flora Siebler, WAMSI Dredging Science Node.
- O *Mycale (Aegogropila)* sp. from -14 m, Onslow, NW Australia. Sample WAMSI_111 = WAM Z53919. Photographs Flora Siebler, WAMSI Dredging Science Node.
- P Unidentified tetractinellid sponges in -95 m, Point Cloates, Carnarvon Shelf, NW Australia. Photograph AIMS (Brooke et al., 2008).
- Q-R Spirophorine sponges in -8 to -15 m, Onslow, NW Australia. Photographs AIMS, WAMSI Dredging Science Node. Q – *Cinachyra* sp. R – Unidentified.
- S Unidentified spirophorine sponge in the intertidal, Montgomery Reef, N Australia. Photograph Christine Schönberg.
- T Unidentified spirophorine sponge in -12 m, Ashburton Island, NW Australia. Photograph Christine Schönberg, WAMSI Dredging Science Node.
- U Unidentified spirophorine sponge in -11 m, Onslow, NW Australia. Photograph Evy Büttner, WAMSI Dredging Science Node.
- V *Cinachyra* sp. from -11 m, Ashburton Island, NW Australia. Sample WAMSI_289 = WAM Z65296. Photograph Flora Siebler, WAMSI Dredging Science Node. The sponge ruptured after sampling and was globular *in situ*.
- W *Cinachyrella* cf. *australiensis* from -12 m, Onslow, NW Australia. Sample WAMSI_156 = WAM Z53985. Photograph Flora Siebler, WAMSI Dredging Science Node.
- X *Cinachyrella* sp. from -21 m, S Montgomery Reef, N Australia. Sample KIM_1_1_24. Photograph Christine Schönberg.

Supplement 5.3: Composite-massive, fistular and table-shaped sponges

- A Cf. *Pseudoceratina verrucosa* in -8 to -15 m, Onslow, NW Australia. Photograph AIMS, WAMSI Dredging Science Node.
- B Unidentified sponge in -11 m, Onslow, NW Australia. Photograph Christine Schönberg, WAMSI Dredging Science Node.
- C Lobed sponge at Middle Head, Sydney Harbour, SE Australia. From <https://www.flickr.com/photos/johnwturnbull/albums/72157672870310525>, accessed March 28, 2020. Photograph John Turnbull, with friendly permission.
- D *Stylissa* cf. *flabelliformis* in -11 m, Onslow, NW Australia. Sample WAMSI_178 = WAM Z65220. Photograph Evy Büttner, WAMSI Dredging Science Node.

- E** *Clathria* (cf. *Clathria*) sp. from -30 m, Point Cloates, Carnarvon Shelf, NW Australia, sample CERF 2_047_1_27A. Photograph Christine Schönberg, CERF project (Schönberg et al., 2006).
- F** *Dysidea* sp. from -72 m, Point Cloates, Carnarvon Shelf, NW Australia, sample CERF 2_031_1_04. Photograph Christine Schönberg, CERF project (Schönberg et al., 2006).
- G** *Raspailia* (*Raspaxilla*) sp. from -60 m, Point Cloates, Carnarvon Shelf, NW Australia, sample CERF 2_049_1_13. Photograph Christine Schönberg, CERF project (Schönberg et al., 2006).
- H-J** Fistular sponges in 8-15 m, Onslow, NW Australia. Photograph Australian Institute of Marine Science, WAMSI Dredging Science Node. Please note oscule plates in **H** and **I** (arrow).
- K** *Oceanapia* sp. in -11 m, Onslow, NW Australia. Photograph Evy Büttner, WAMSI Dredging Science Node.
- L** *Oceanapia sagittaria* in -2 m, Orpheus Island, central Great Barrier Reef. Photograph Flora Siebler.
- M-N** Fistular sponges at Ashburton Island, NW Australia. Photographs Christine Schönberg, WAMSI Dredging Science Node. **M** – *Psammodinia* cf. *bulbosa* in -11m. **N** – *Sphaciospongia* sp. in -12 m.
- O** *Xestospongia* sp. from -12 m, Onslow, NW Australia. Sample WAMSI_097 = WAM Z65140. Photographs Flora Siebler, WAMSI Dredging Science Node.
- P** *Sphaciospongia* sp. from -41 m, Gnaraloo, Carnarvon Shelf, NW Australia, sample CERF 3_086_2_33. Photograph Christine Schönberg, CERF project. Please note oscule plate (arrow).
- Q** *Oceanapia* sp. from -28 m, Montgomery Reef, N Australia, sample KIM_2_3_36 = WAM Z29296. Photograph Christine Schönberg.
- R-T** Tabular sponges in SE Australia. From <https://www.flickr.com/photos/johnwturnbull/albums/72157672870310525>, accessed March 28, 2020. Photograph John Turnbull, with friendly permission. **R, T**: Dee Why Wide, Curl Curl Beach, N Sydney. **S**: -18 m, Henry Head, Botany Bay, Sydney.
- U-V** Tabular sponges in -1 m, Fantome Island, central Great Barrier Reef. Photograph Flora Siebler. **U** – *Cymbastela coralliophila*. **V** – *Carteriospongia foliascens*.
- W** *Cymbastela coralliophila* from -1 m, Fantome Island, central Great Barrier Reef. Photograph Evy Büttner.
- X-Z** *Phakellia* sp. from -36 m, Point Cloates, Carnarvon Shelf, NW Australia. Sample CERF_2_53_1_15. Photographs Christine Schönberg, **X** – bottom, **Y** – top, and **Z** – side views, CERF project (Schönberg et al., 2006).

Supplement 5.4: Incomplete and complete wide cups and tubular sponges

- A** Yellow incomplete cup sponge in -95 m, Point Cloates, Carnarvon Shelf, NW Australia. Image AIMS.
- B** Cf. *Stylissa flabelliformis* in -8 to -15 m, Onslow, NW Australia. Photograph AIMS, WAMSI Dredging Science Node.
- C** Incomplete cup sponge at North Head, Sydney Harbour, SE Australia. From <https://www.flickr.com/photos/johnwturnbull/albums/72157672870310525>, accessed March 28, 2020. Photograph John Turnbull, with friendly permission.
- D** *Ectyoplasia frondosa* in -12 m, Ashburton Island, NW Australia. Sample WAMSI_327 = WAM Z65327. Photograph Christine Schönberg, WAMSI Dredging Science Node.
- E** *Cymbastela stipitata* from -11 m, Onslow, NW Australia. Sample WAMSI_208 = WAM Z65188. Photograph Flora Siebler, WAMSI Dredging Science Node.
- F** Macerated spongin skeleton of a keratose sponge, beach find, Ashburton Island, NW Australia. Photograph Christine Schönberg,
- G** *Clathria* (*Thalysias*) cf. *lendenfeldi* from -11 m, Onslow, NW Australia. Sample WAMSI_333 = WAM Z65297. Photograph Flora Siebler, WAMSI Dredging Science Node. This sponge can be either interpreted as a fan or due to the slight rounding as a cup-like form.
- H-K** Different cup-shaped sponges in -8 to -15 m, Onslow, NW Australia. Photographs AIMS, WAMSI Dredging Science Node.
- L** *Ectyoplasia frondosa* in -12 m, Onslow, NW Australia. Sample WAMSI_123 = WAM Z65146 (same as **P**). Photograph Evy Büttner, WAMSI Dredging Science Node.
- M** Cf. *Cymbastela stipitata* in -12 m, Ashburton Island, NW Australia. Photograph Christine Schönberg, WAMSI Dredging Science Node.
- N** *Carteriospongia foliascens* in -1 m, Fantome Island, central Great Barrier Reef. Photograph Flora Siebler.
- O-P** Cup-like sponges from -12 m, Onslow, NW Australia. Photographs Flora Siebler, WAMSI Dredging Science Node. **O** – *Echinodictyum clathrioides*. Sample WAMSI_155 = WAM Z53966. **P** – *Ectyoplasia frondosa*. Sample WAMSI_123 = WAM Z65146 (same as **L**).

- Q-S Tubular sponges in -8 to -15 m, Onslow, NW Australia. Photographs AIMS, WAMSI Dredging Science Node.
- Q-R – Unidentified sponges, their habit and location in fine sediments possibly suggesting that they are fistular, rather than tubes. The scoring context sometimes needs to be decided from what is known about the sample area. S – *lantella basta*.
- T Sponge tube cluster at Port Stephens, New South Wales, SE Australia. From <https://www.flickr.com/photos/johnwturnbull/albums/72157672870310525>, accessed March 28, 2020. Photograph John Turnbull, with friendly permission.
- U Unidentified sponge in -12 m, Ashburton Island, NW Australia. Photograph Christine Schönberg, WAMSI Dredging Science Node.
- V Sponge tube cluster at Kurnell, Whale Watch Platform, Botany Bay, Sydney, SE Australia. From <https://www.flickr.com/photos/johnwturnbull/albums/72157672870310525>, accessed March 28, 2020. Photograph John Turnbull, with friendly permission.
- W Macerated spongin skeleton of a tubular sponge, beach find, Fowlers Bay, S Australia. Photograph Christine Schönberg.
- X Dried tubular sponge, beach find, Ashburton Island, NW Australia. Photograph Christine Schönberg.

Supplement 5.5: Amphoras, barrels and 1D-erect sponges

- A *Euplectella* sp. in -810 to -830 m, Ocean Explorer dive 05-2019, Stetson Mound Field, waters off E Florida, USA. From <https://oceanexplorer.noaa.gov/oceanos/explorations/ex1907/logs/photolog/welcome.html#>, accessed April 25, 2020. Photograph US National Oceanic and Atmospheric Administration, creative commons.
- B Hexactinellid sponge in -750 to -830 m, Ocean Explorer dive 02-2019, Stetson Mesa, waters off E Florida, USA. From <https://oceanexplorer.noaa.gov/oceanos/explorations/ex1907/logs/photolog/welcome.html#>, accessed April 25, 2020. Photograph US National Oceanic and Atmospheric Administration, creative commons.
- C Amphora-like cluster of a sponge in -10 to -15 m, Onslow, NW Australia. Photograph AIMS, WAMSI Dredging Science Node.
- D Sponge amphora cluster at Bare Island, Botany Bay, Sydney, SE Australia. From <https://www.flickr.com/photos/johnwturnbull/albums/72157672870310525>, accessed March 28, 2020. Photograph John Turnbull, with friendly permission. Due to the density of this cluster, this could possibly alternatively be interpreted as a composite-massive sponge.
- E Macerated spongin skeleton of an amphora-shaped sponge, beach find, Rossiter Bay, Cape Le Grand, SW Australia. Photograph Christine Schönberg.
- F Barrel-shaped sponge in -8 to -15 m, Onslow, NW Australia. Photograph Australian Institute of Marine Science, WAMSI Dredging Science Node.
- G Barrel- or cup-like white sponge in an outer-shelf seabed habitat at the Muiron Islands, NW Australia. Photograph AIMS (Brooke et al., 2008).
- H Barrel-like sponge in -8 to -15 m, Onslow, NW Australia. Photograph AIMS, WAMSI Dredging Science Node.
- I Aff. *Pseudoceratina verrucosa* in -11 m, Onslow, NW Australia. Photograph Evy Büttner, WAMSI Dredging Science Node.
- J-K Barrel sponges at Onslow, NW Australia. Photographs Christine Schönberg, WAMSI Dredging Science Node. J – Cf. *Sarcotragus* sp. in -14 m. K – *Xestospongia testudinaria* in -12 m.
- L *Sphaciospongia vesparium* from the W Atlantic. Sample ZMB1518. Photograph Christine Schönberg.
- M *Sphaciospongia* sp. of unknown origin. Sample ZMB0037. Photograph Christine Schönberg.
- N Geodiid sponge from -108 m, Mandu, Carnarvon Shelf, NW Australia. Photograph Matthew McArthur, CERF project. Geoscience Australia, with friendly permission.
- O-P One-dimensionally erect sponges in a shelf habitat at the Muiron Islands, NW Australia. Photographs AIMS.
- Q Mostly one-dimensionally erect sponge in -10 to -15 m, Onslow, NW Australia. Photograph AIMS, WAMSI Dredging Science Node.
- R One-dimensionally erect branch of an orange sponge at Bare Island, Botany Bay, Sydney, SE Australia. <https://www.flickr.com/photos/johnwturnbull/albums/72157672870310525>, accessed March 28, 2020. Photograph John Turnbull, with friendly permission.
- S-T One-dimensionally-erect sponges in -12 m, Onslow, NW Australia. Photographs Christine Schönberg, WAMSI Dredging Science Node. S – *Reniochalina* cf. *stalagmitis*. Sample WAMSI_239 = WAM Z65235. T – *Ernstilla lacunosa*.

U-W One-dimensionally-erect sponges from -21 m, Montgomery Reef, N Australia. Photographs Christine Schönberg. **U** – *Triaktrion flabelliforme*, sample KIM_1_1_89 = WAM Z29040 (with zoanths). **V** – Unidentified sponge, sample KIM_1_1_93. **W** – Unidentified poecilosclerid sponge, sample KIM_1_1_74.

Supplement 5.6: 2D-erect sponges – laminar, palmate and reticulate erect sponges.

- A-B** *Ianthella* sp. -8 to -15 m, Onslow, NW Australia. Photographs AIMS, WAMSI Dredging Science Node.
- C** *Triaktrion flabelliforme* in -11 m, Onslow, NW Australia. Sample WAMSI_303 = WAM Z65303. Photograph Evy Büttner, WAMSI Dredging Science Node.
- D-E** Erect-laminar sponges in -11 m, Onslow, NW Australia. Photographs Christine Schönberg, WAMSI Dredging Science Node. **D** – Cf. *Axinella aruensis*. **E** – *Clathria (Thalysias) major*, sample WAMSI_201 = WAM Z65164.
- F-G** Erect-laminar sponges from -35 m, Red Bluff, Carnarvon Shelf, NW Australia. Photographs Christine Schönberg.
- H-J** Erect-palmate sponges in -8 to -15 m, Onslow, NW Australia. Photographs AIMS, WAMSI Dredging Science Node.
- K** *Ernstilla lacunosa* in -12 m, Onslow, NW Australia. Photograph Evy Büttner, WAMSI Dredging Science Node.
- L-M** Erect-palmate sponges in -12 m, Ashburton Island, NW Australia. Photographs Christine Schönberg, WAMSI Dredging Science Node. **L** – *Ectyoplasia tabula*. **M** – *Triaktrion flabelliforme* with white zoanths, sample WAMSI_317 = WAM Z65319.
- N** *Ectyoplasia tabula* from -41 m, Gnaraloo, Carnarvon Shelf, NW Australia, sample CERF 3_086_1_28. Photograph Andrew Heyward, CERF project (Schönberg et al., 2006).
- O** *Phorbas* sp. from -35 m, Red Bluff, Carnarvon Shelf, NW Australia. Photograph Christine Schönberg.
- P** *Desmacidon* sp. from -45 m, Gnaraloo, Carnarvon Shelf, NW Australia, sample CERF 3_088_2_15. Photograph Andrew Heyward, CERF project.
- Q** Erect-reticulate sponge in -10 to -15 m, Onslow, NW Australia. Photograph AIMS, WAMSI Dredging Science Node.
- R** Cf. *Echinodictyum pulchrum* in -12 m, Onslow, NW Australia. Sample WAM Z65183. Photograph Christine Schönberg, WAMSI Dredging Science Node. The discolouration suggests that the sponge was diseased, compare to **T**.
- S** *Axos flabelliformis* in -11 m, Onslow, NW Australia. Sample WAMSI_253 = WAM Z65218. Photograph Christine Schönberg, WAMSI Dredging Science Node.
- T** *Echinodictyum pulchrum* in -11 m, Onslow, NW Australia. Sample WAMSI_166 = WAM Z65183. Photograph Evy Büttner, WAMSI Dredging Science Node.
- U** Unidentified sponge from -39 m, Gnaraloo, Carnarvon Shelf, NW Australia, sample CERF 3_101_2_P8. Photograph Andrew Heyward, CERF project.
- V** *Clathria (Thalysias) coppingeri* from -21 m, Montgomery Reef, N Australia. Photographs Christine Schönberg.

Supplement 5.7: 3D-erect branching, stalked and carnivorous sponges.

- A-B** Three-dimensionally erect-branching sponges in 10-15 m, Onslow, NW Australia. Photographs AIMS, WAMSI Dredging Science Node. **A** – Cf. *Cacospongia* sp. **B** – Unidentified.
- C** Cf. *Axos cliftoni* in -11 m, Onslow, NW Australia. Photograph Christine Schönberg, WAMSI Dredging Science Node.
- D** Cf. *Adreus axiferum* in -8 to -15 m, Onslow, NW Australia. Photograph AIMS, WAMSI Dredging Science Node.
- E** Cf. *Cacospongia* sp. in -11 m, Onslow, NW Australia. Photograph Christine Schönberg, WAMSI Dredging Science Node.
- F** Three-dimensionally erect-branching sponge at North Head, Sydney Harbour, SE Australia. From <https://www.flickr.com/photos/johnwturnbull/albums/72157672870310525>, accessed March 28, 2020. Photograph John Turnbull, with friendly permission.
- G** *Axinella aruensis* in -11 m, Onslow, NW Australia. Sample WAMSI_277 = WAM Z65289. Photograph Christine Schönberg, WAMSI Dredging Science Node.
- H** *Callyspongia* sp. from -21 m, S Montgomery Reef, N Australia. Photographs Christine Schönberg.
- I** Undetermined three-dimensionally erect-branching sponge from -37 m, Gnaraloo, Carnarvon Shelf, NW Australia, sample CERF 3_089_1_7. Photograph Andrew Heyward, CERF project (Schönberg et al., 2006).

- J *Haliclona* sp. from -41 m, Gnaraloo, Carnarvon Shelf, NW Australia, sample CERF 3_086_1_20. Photograph Andrew Heyward, CERF project (Schönberg et al., 2006).
- K Cf. *Aplysinopsis* sp. in -8- to 15 m, Onslow, NW Australia. Photograph AIMS, WAMSI Dredging Science Node.

Photograph US National Oceanic and Atmospheric Administration/Arctic Net, creative commons.

Supplement 6. Scoring examples for towed imagery captured with a stills camera pointing downwards, in -8 to -15 m at Onslow, NW Australia. Images were contrast-enhanced, but not otherwise changed. When zooming into images, corallite structure in most shallow cups confirmed that they were *Turbinaria* corals (in **A**, **D** – here one was bleached or dead, **E**). Mottled appearance of dark blue structures and translucent appearance of grey globular structures was suggestive of ascidians. Some sponges were recognised by finding pores on their surfaces (e.g. for *E-pal* in **D**). *C-b* – barrel, *C-cmp* – complete cup, *E-lam* – erect-laminar, fan, *E-pal* – palmate, *E-3D* – three-dimensionally erect-branching, *EN-rep* – here functioning as creeping, repent (dark grey patch, may become a barrel when growing up, may consist of two different sponges), *M-bl* – ball, *M-f* – fistular and endopsammic sponge, *M-s* – simple massive sponge.
