26 Abstract

27

28 Although studies show that Antarctic mega- and macrofauna are highly diverse, little is known 29 about meiofaunal biodiversity in sediment communities, which are a vital part of a healthy and functional ecosystem. This is the first study to analyse community DNA (targeting meiofauna) 30 31 using metabarcoding to investigate biodiversity levels in sediment communities of the Antarctic 32 Peninsula. The results show that almost all of the meiofaunal biodiversity in the benthic habitat has 33 yet to be characterised, levels of biodiversity were higher than expected and similar to temperate regions, albeit with the existence of potentially new and locally adapted species never described 34 35 before at the molecular level. The Rothera meiofaunal sample sites showed four dominant eukaryotic groups, the nematodes, arthropods, platyhelminthes, and the annelids; some of which 36 37 could comprise species complexes. Comparisons with deep-sea data from the same region suggest 38 little exchange of Operational Taxonomic Units (OTUs) between depths with the nematodes 39 prevalent at all depths, but sharing the shallow water benthos with the copepods. This study provides a preliminary analysis of benthic Antarctic Peninsula meiofauna using high throughput 40 sequencing which substantiates how little is known on the biodiversity of one of the most diverse, 41 42 vet underexplored communities of the Antarctic: the benthos.

43

44

46 Introduction

Much recent effort has been expended into characterising Antarctic marine biodiversity and it is 47 clear that it is significantly higher than was thought in previous decades, particularly in relation to 48 marine invertebrates^{1,2}. An increasing number of cryptic species are being discovered³ and in some 49 50 invertebrate groups, such as pycnogonids and polychaete worms. Antarctica has significantly higher diversity than the global averages⁴. However, even the most recent reviews of marine biodiversity 51 in Antarctica have concentrated on marine mega- and macrofauna with relatively little discussion 52 on endemic meiofauna, particularly those metazoans inhabiting marine sediments⁵. In a recent UN 53 54 Assessment of the State of the Ocean I (http://www.worldoceanassessment.org/), meiofauna and the 55 poles were highlighted as being of particular importance for future research. There is currently very limited knowledge on polar meiofauna; the extent of their biodiversity and their contribution to 56 57 polar ecosystem functioning

58

59 Marine sediments are some of the most species-rich habitats on Earth. They are one of the main contributors to ocean health and functioning, but one of the least studied habitats in the biosphere⁶. 60 61 Within marine sediments, the meiofauna (the microscopic taxa generally between 45-500µm) are important members of the benthic ecosystem, playing a critical role in carbon transfer and nutrient 62 cycling⁶. They participate in ecosystem energy flows via the consumption of dissolved organic 63 carbon and from grazing on primary producers and bacteria⁷. In addition they play important roles 64 in the consumption of detritus and predation. They excrete nutrients which can be used by 65 66 phytobionts, bacteria and associated meiofauna, but they also act as a food source for benthic invertebrates and higher predators⁶. Thus, evaluations of benthic meiofauna biodiversity are of 67 critical importance for understanding ecosystem functioning, sustainability and resilience, as well as 68 69 understanding carbon cycling in the largest part of the World, the seabed⁶. In addition meiofauna represent useful tools for studying change within an ecosystem and could be particularly useful for 70 understanding the effects of anthropogenic impacts and climate change⁶. 71

One region of particular note with respect to environmental change is the Western Antarctic 73 74 Peninsula, some areas of which, particularly in the north west, are regarded as experiencing the most rapid rate of climate warming on the Antarctic continent⁸. However, the situation is complex 75 76 and exacerbated by the lack of high density measurements. Recent analyses suggest that the atmospheric warming along the Peninsula has ceased⁹, but there is uncertainty whether this trend 77 78 will continue, what the drivers are, and whether this cessation of warming is reflected in oceanographic data which is still showing changes in sea ice and retreat of glaciers¹⁰. What is clear 79 is that this is still a region in transition and highly vulnerable¹¹. Surface ocean temperatures rose by 80 more than 1°C in the second half of the 20th Century and the deeper layers have also warmed due to 81 increased upwelling of warm Upper Circumpolar Deep Water. Sea ice duration has reduced 82 83 significantly in the past few decades (by 100 days since 1978), which impacts not only on primary production and water column stratification, but also on the frequency of iceberg scouring^{11,12}. About 84 80% of glaciers along the Peninsula are in retreat, which has increased the amount of sediment and 85 fresh-water in the system¹⁰. Given the huge uncertainty concerning climate trends in this region, 86 87 continued monitoring is vital, as is the evaluation of the potential impact on the endemic fauna. The Southern Ocean fauna have evolved to life in freezing seas in relative isolation for the last 15Myr¹³ 88 89 and as a consequence have evolved a series of physiological and biochemical adaptations to life in the cold, are highly stenothermal and poorly adapted to rapid change¹⁴. 90

91

Advances in molecular and sequencing methodologies now enable us to evaluate biodiversity levels from even the most remote habitats, in a way, not previously possible. Large-scale environmental DNA (eDNA) approaches using high throughput sequencing (shortly referred to as metabarcoding) have recently been applied to examine biodiversity levels at the poles. To date polar marker gene studies have mainly focussed on microbial communities within soil, ice cores, microbial mats and melt water^{15,16}, marine viruses¹⁷, freshwater picoplankton¹⁸ and more recently, microbial

⁷²

biodiversity, on the shelf and the deep-sea^{19,20}. These studies have provided intriguing pilot data on 98 99 micro- and meiofaunal biodiversity in this largely understudied and extreme environment. Whilst 100 there is a long history of biological sediment analyses at research stations along the Peninsula, these have been based on either taxonomic identification or stable isotope analyses²¹⁻²⁵. High throughput 101 102 sequencing of DNA derived from community environmental samples provides a powerful tool with 103 which to complement existing approaches and provides a timely opportunity to gain insight into 104 alpha and beta-diversity of Antarctic meiofauna and start to assess their likely resilience in the 105 context of climate change.

106

107 The first aim of this study was to provide a global description of marine Antarctic meiofaunal 108 diversity and community structure in shallow waters, using high throughput sequencing approaches 109 on community DNA. Secondly, to compare Antarctic shallow-water datasets with deep-sea samples 110 taken in the same area (both published and un-published) to identify general diversity trends in 111 freezing habitats and potential depth gradients. A third aspect was to compare the data generated 112 here with those of another metabarcoding study on meiofaunal samples from a mid-temperate region using the same 18S rRNA region to identify relative levels of biodiversity and whether these 113 114 were markedly reduced in the Antarctic samples.

115

116

117 **RESULTS**

118 The total number of reads derived from the 454 FLX sequencing platform from the Antarctic

119 Peninsula sampled sites was 61,057; which was reduced to 49,655 reads after filtering and chimera

120 removal. This level of reduction in read numbers was comparable with previous 454 eDNA

121 studies^{26,27}. This particular chemistry introduces higher error rates than the Illumina platform within

- 122 homopolymer regions due to accumulated light intensity variation, but these reads can be identified
- 123 and removed *in silico*. Additional reads were removed as they were only present in singletons and

124	through the application of UCHIME, which is known to be a stringent filtering step ²⁷ . Metazoan
125	OTU numbers varied moderately between sample sites with a mean number of 90 OTUs in Hangar
126	Cove (stdv \pm 36.09), 48.7 OTUs in Rothera Point (stdv \pm 26.05), 87 OTUs in Islands (stdv \pm 60.65)
127	and South Cove with mean OTUs number of 47 (stdv \pm 24.24). A major proportion of the OTUs
128	from each site (16-31%) were not assigned to any annotated taxa in SILVA database (Table 1). In
129	terms of those taxa with matches in SILVA, the nematodes had the highest OTU numbers among
130	the main phyla, with 92 OTUs followed by the arthropods and platyhelminthes represented by 47
131	and 37 OTUs respectively (Figure 1). More detailed taxonomy assignments retrieved for each
132	clustered OTU (using a cut-off of 90% to any reference nSSU) showed that the majority (95-98%)
133	of platyhelminth, arthropod and nematod OTUs were not present in the SILVA database (Figure 1).
134	In total this represented 171 OTUs (30% of OTUs comprising 37671 individual sequences) which
135	may represent un-sampled diversity. The annelids and molluscs, however, had 23% and 50%
136	respectively, of their OTUs with a 100% identity to previously sequenced taxa. The Brachiopoda,
137	Echinodermata, Cnidaria, Gastrotricha and Bryozoa were grouped as BECGB with a total of 9
138	OTUs where 11% of which had 100% identity matches to previously annotated sequence data.
139	Sampling saturation profiles showed that the sequencing effort was not sufficient to determine the
140	full extent of the diversity for any of the four sampled sites (Figure 2). The slope of the OTU
141	rarefaction curves did not approach saturation at 97% cut-off for all the meiobenthic phyla and
142	more specifically for the nematodes, arthropods and even for the platyhelminthes which comprised
143	a low abundance phylum where rarefaction curves tend to converge and reach an asymptote ^{28}
144	(Supplementary Figure S1) and therefore the data described here are underestimates.
145	

Community composition by number of OTUs did not show significant differences between the
sites, with the nematodes totalling ca 30-50 OTUs (Kruskal-Wallis, p=0.189) followed by the
arthropods with ca. 20-30 OTUs (Kruskal-Wallis, p=0.901), the platyhelminthes with ca. 10-20
(Kruskal-Wallis, p=0.494), OTUs and the annelids with ca. 3-9 OTUS (Kruskal-Wallis, p=0.110),

150	found in the Antarctic meiobenthic samples (Supplementary Figure S2). In fact, the majority of the
151	samples showed that 90-100% of the OTUs were shared between sites, with the exception of one of
152	the triplicates of the Islands sample that had approximately 30% of unique OTUs (Figure 3). Whilst
153	all sites showed globally very similar communities, cluster analysis for taxonomic patterns of
154	meiofaunal communities based on Sørensen similarities of OTU presence/absence data for the
155	combined sites showed two well-defined groups within the Antarctic Peninsula sampling sites
156	(Supplementary Figure S3). The Islands and Hangar Cove were more similar to each other, sharing
157	approximately 20% more OTUs than with South Cove and Rothera Point (data not shown).
158	
159	Graphical representation of community composition from all sample sites was visualized with the
160	Krona chart (Figure 4a). Here, the eukaryotic taxonomic composition of all sites combined showed
161	that the nematodes comprised 32% of the total eukaryotic OTUs. Followed by the arthropods,
162	platyhelminthes and annelids with 18%, 12% and 4% representing the total eukaryotic biodiversity,
163	respectively. Within the nematodes two taxonomic classes predominated: the Chromadorea (80%
164	OTUs) and the Enoplea (20% OTUs) (Figure 4b, Supplementary Table S1.1 – S1.3, Supplementary
165	Material S1). Within these two taxa, Monhysterida (37% OTUs) and Enoplida (19% OTUs)
166	comprised the major proportion of the identifications respectively (Figure 4b, Supplementary Table
167	S1.1 - S1.3). Copepoda dominated the arthropods with 87% of the identified OTUs. The
168	Harpacticoida were particularly abundant at 76% of the Copepoda (Figure 4b, Supplementary Table
169	S1.1 - S1.3, Supplementary Material S1). Outside of the crustaceans, the Acari represented 2% of
170	the arthropod OTUs. The platyhelminthes were mainly represented by with the Rhabditophora
171	(97%) with predominance of the orders Rhabdocoela (62%) and Macrostomida (31%) (Figure 4b,
172	Supplementary Table S1.1 – S1.3, Supplementary Material S1). The annelids were mainly
173	composed of the Polychaeta (85%) and the Haplotaxida (15%). The Polychaeta were dominated by
174	the subclass Palpata (31%) and infraclass Scolecida (54%). The Palpata comprised the Phylodocida
175	order (23%) and taxa with uncertain taxonomic position (Incertae Sedis) (8%). The Scolecida

176 covered five distinct families with the Spionida (15%), Orbibidae (15%), Terebellida (8%),

177 Ophellidae (8%) and the Capitellida (8%) (Figure 4b, Supplementary Table S1.1 – S1.3,

178 Supplementary Material S1), identifications which have been further substantiated by 18s rRNA

179 molecular barcoding of polychaete samples from shallow-water hard and soft sediment

- 180 communities near Rothera (Clark, unpublished data).
- 181

182 The shallow-water comparisons with deep-water samples taken from along the Antarctic Peninsula 183 showed very different community compositions (Supplementary Figure S4). Although the annelids 184 and nematodes were found at both depths, they were particularly dominant in the deep-water 185 samples. Shallow-water samples had a much higher percentage of arthropods (or more precisely, 186 copepods). The Nemertea and Hemicordata were essentially only found in the deep samples, with 187 the Cnidaria, Echinodermata and Mollusca more common in the shallows. The difference in 188 community composition was further substantiated by pairwise comparisons of the number of shared OTUs between the different deep-water samples with the combined shallow samples, with the 189 190 shallow-water sites sharing on average ca. 15% of OTUs with the different deep-water sites 191 (Supplementary Figure S5). It should be noted that comparisons of two of the deep-water sites taken 192 at a similar depth (CTD, 515m and Laubeuf, 500m) showed only 20.4% shared OTUs, indicating 193 the patchiness of distributions (similar shallow-water comparisons between the Islands (13m) and 194 Rothera Point (15m) showed 26.7% shared OTUs) (data not shown).

195

196 **DISCUSSION**

197 This study shows interesting insights into levels of meiofaunal biodiversity in Antarctic sediments, 198 suggesting similar levels of meiobenthic diversity when compared to other marine studies carried 199 out in more temperate regions using the same nSSU gene region²⁶, which is higher than expected. 200 Such evidence emerges when comparing the incomplete slopes of the rarefaction curves and OTU 201 numbers obtained here with a previous study on a Scottish temperate benthic ecosystem²⁶ using an

identical 18S rRNA gene region, a 97% identity cut-off and the same number of replicates, showing
both sites to be very similar (e.g. 540 Antarctic and 650 Scottish meiofauna total OTUs). This
evidence is not in line with paradigms of reducing diversity with latitude²⁹. It also suggests that
Antarctic meiofaunal biodiversity could be as rich and diverse as that found in temperate areas.

207 This preliminary study reveals that almost all of the main meiobenthic biodiversity is yet to be 208 described, particularly with regard to taxonomic identification and development of associated 209 barcodes, since only 1-4% of our taxa had a full taxonomy match against public databases (Figure 210 1). Such low levels of taxonomy assignments are almost certainly the result of the lack of Antarctic 211 species in eukaryotic sequence databases, limited and patchy sampling regimes and the almost total absence of knowledge of Antarctic meiobenthic biodiversity in many taxa³⁰. Studies on the benthos 212 213 around the Antarctic Peninsula have found more than 20% of new families, genera and species, 214 which emphasizes that these habitats contain not only new species records but previously undescribed taxa^{3,31}. For example, more than half of the known gastropods and bivalve mollusc 215 species in the Antarctic have only been found once or twice³⁰. Although this level of novelty might 216 217 seem atypical for such an extensive but harsh environment, it is somehow reasonable that a 218 topographically complex and remote area such as the Antarctic would be bound to contain new 219 species due to the long period of biogeographic isolation via the Antarctic Circumpolar Current, especially if some of these areas have been little or never sampled before³². 220

221

In this study, the phylogenetic analysis and the taxonomic assignments retrieved from the SILVA database produced four dominant taxonomically distinct metazoan groups, the nematodes, arthropods, platyhelminthes and the annelids (Figure 4a and b, Supplemental Material S1). These results are supported by previous studies showing that nematodes and Harpaticoid copepods dominate the Antarctic benthos^{33, 34}. Additionally, very few studies describe platyhelminthes living within Antarctic sediments possibly because they are commonly known to live in the sea-ice and

feed on sea ice diatoms³⁵ but may also be explained by a likely high destruction rate of their soft 228 229 bodies when sampled for physical taxonomic studies. Most annelids found in this study, were 230 dominated by the polychaetes, which tend to be transient meiofauna associated with Antarctic sediments³⁶. These data are supported by a macrofaunal (>1mm) taxonomic study in the same 231 232 region, which showed a predominance of Arthropods and Annelids (polychaete worms) in the sediments³⁷. The more fragile nematode samples were largely identified using molecular 233 techniques, which showed them to be the dominant microtaxa, followed by Arthropods and 234 Platyhelminthes³⁷. In our study there were also some identified phyla with very few assigned OTUs 235 236 (Mollusca, Brachiopoda and Echinodermata). However, given the size fractionation methodology 237 used in this study (<500um, >45um), these low abundant OTUs would be either traces of larval or very early post-settlement stages or more likely, gut contents of detritivores, cell debris, faeces, 238 239 pieces of dermis etc. from adult benthic colonisers. Indeed the macrofaunal study showed that 240 molluscs were highly represented, particularly by Mysella charcoti and Aequivoldia eightsi, which would have been largely excluded in meiofaunal fractionation³⁷. Taxonomy studies in the Southern 241 Ocean^{1,2} have described a greater number of species than presented in this data set here (for 242 example 524 nematode species compared with our estimate of 140 OTUs). However the fact that 243 we identified such a number of OTUs in shallow waters at four sampling sites, some of which are 244 geographically close (rather than the whole of the Southern Ocean for the 524 species²) 245 (Supplementary Figure S2) validates the conclusion that there is still much to discover, especially in 246 the sediments. 247

248

While, the four meiobenthic phyla described here are the main representatives found in the benthos anywhere in the world, there will be taxonomic differences in community structures at the species level. This is reflected in trophic features and reproductive strategies, which in the case of the shallow-water meiofauna in Antarctica are adjusted to a cold, highly disturbed and food limiting environment. Stable isotope analyses of meiofaunal communities in Potter Cove, Antarctic

254 Peninsula (latitude -62.235, longitude -58.663) have shown relatively small food webs, based 255 mainly on non-selective deposit feeders, epistrate feeders and a higher proportion of predators²². 256 This was substantiated in our study where the taxonomic assignment within the nematodes were 257 dominated by the Neochromodora, Desmolaimus and Sabieteria genera, suggesting that nematode 258 assemblages were mainly composed of deposit feeders and epistrate feeders, which can minimize 259 interspecific competition. There was also a proportion of Enoplea nematodes that are known to be 260 predators/omnivores. Such different feeding strategies will alleviate species competition to available food^{38,39}. Molecular analyses, such as metabarcoding used here, allow the identification of 261 previously unknown levels of biodiversity²⁰ and enable studies that would otherwise not be possible 262 263 in such detail using other methodologies. In this study, for each of the main meiobenthic phyla 264 (nematodes, arthropods, platyhelminthes and annelids) (Supplemental Material S1) there were some 265 well-supported clades, particularly in the nematodes and nematodes, where OTUs assigned to the 266 same genus, could potentially comprise species complexes. However without further molecular and taxonomic analysis, these would be difficult to define, but would be highly likely⁴⁰. 267

268

Clustering of sites according to community composition similarity revealed two well-defined 269 270 groups (Supplementary Figure S3). The first composed of South Cove (8m depth) and Rothera 271 Point (15m depth), represented virtually adjacent sites and thus their clustering confirmed the 272 similarity of their meiobenthic community assemblages. The second cluster was comprised of Hangar Cove (18m depth) and the Islands (13m depth). This is substantiated by the macrofaunal 273 274 study which showed significant patchiness and differences between different coves³⁷. South Cove and Rothera Point are more exposed areas with smaller levels of sediment than Hangar Cove or the 275 Islands and likely subject to different current patterns within Ryder Bay and also increased iceberg 276 277 scour. Generally, replicates of each ecological location always clustered together and thus the 278 combined replicate meiobenthic samples accurately reflected alpha diversity from the Antarctic Peninsula, as shown previously in similar studies in more temperate areas^{41,42}. Meiobenthic 279

community composition can be extremely variable even within small spatial scales^{21,26,43-46}. Local 280 patchiness and structure within these communities is probably a consequence of a combination of 281 several biotic and abiotic factors^{41,42}. Similar to global observations, sediment type and grain size 282 play large roles in structuring Antarctic communities^{21,23,37}, with the additional factors of food 283 supply, which influences species richness and ice disturbance²³. Glacial retreat, ice shelf collapse 284 285 and the increasing frequency of iceberg scour are significantly impacting the Antarctic benthos, particularly the more shallow waters^{12,21-23,47}. Species return is largely dictated by motility, with the 286 three main methods of return being locomotion, advection by storms and larval re-colonisation⁴⁸. 287 288 Overall, only the most resilient animals (probably r-selection species) are able to regularly resist 289 such local impacts and prosper in these harsh environments⁴⁹. Studies on Antarctic sediments have shown that nematodes are able to resist and survive in such harsh conditions, namely after ice 290 disturbance nematode communities are very little impacted³³, which again reflects their dominance 291 292 within the benthos described here.

293

294 The shallow-water data were also compared to six deep sea samples from the Peninsula region 295 (Supplementary Figures S4 and S5). There was a clear difference in phyla composition with the 296 deep sea sites dominated by nematodes and the shallow by both nematodes and arthropods (or more 297 specifically copepods). These data confirm existing published information on the differences between shallow and deep meiofauna and fit with previous analyses showing biodiversity patterns 298 299 associated with sediment type and grain size. The shallow samples comprised coarser grains, which 300 are a more favourable habitat for copepods, whilst the deeper sites comprised more fine sediments (mud) suitable for nematodes, as noted in previous studies 20,23,37 . What was interesting to note was 301 the relatively small overlap in shared OTUs between the shallow and deep samples (Supplementary 302 303 Figure S5). Because of the way the OTUs were clustered at 97% similarity, "same OTU" in these 304 comparisons may represent the same genus or family, but is unlikely to be the same species in all OTUs^{50,51}. However, the 97% cut-off for OTU clustering is a known proxy for most meiofaunal 305

studies. Although the physical processing of the shallow and deep samples was slightly different, the rest of the process was identical (primers used in the initial amplification reactions and processing of the data such as removal of non-metazoan OTUs from the comparisons between the two studies) and contributed to standardising the data comparison. Moreover, the higher sensitivity for extracellular DNA of the methods used in the deeper sediments should have actually increased the amount of overlap between shallow and deep due to sedimentation, yet very limited overlap was observed.

313

314 This lack of overlap between shallow and deep sites is particularly interesting as the deep CTD 315 samples were quite close to all the shallow sites (Figure 5) and the CTD sampling site was at the 316 bottom of the Marguerite Bay trough. One could expect all the OTUs from the shallow sites to passively sink/disperse to the deepest point and this clearly does not happen or the conditions at 317 depth select against shallow dwelling species. This depth zonation has been shown previously^{20,34} 318 and as yet, there is not a clear answer as to whether there is true depth zonation of meiofauna or 319 whether the shallow DNAs are simply too diluted or degraded by the time they reach the deep. 320 Further to this, more sampling effort would be needed to clarify meiofauna zonation patterns since 321 322 the rarefaction curves for the sampled Antarctic areas remained incomplete and thus community composition and diversity levels are yet to be determined. The question of faunal exchange between 323 deep and shallow waters is the subject of much debate and may vary according to species ecology, 324 but is a clear area for further research²³. Interestingly even after five years, the meiofaunal 325 326 communities of the innermost embayments of Larsen B (at 242-427m depth) were still much more similar to those from the deep sea (800-4000m), than shallow shelf communities suggesting that 327 perhaps such zonation does exist. In addition these data show that recolonisation and restructuring 328 329 of meiofaunal communities is not rapid and less likely to be subject to the rapid shifts as seen in motile megabenthic communities^{21-23,52}. Because they are less motile, they may be forced to adapt 330 and thus the signals of change may be clearer in these smaller species⁶. However, what is clear in 331

both shallow and deep-sea Antarctic samples is the high levels of undiscovered taxa and potentially

high levels of biodiversity, in what are often described as species-poor regions of the globe.

334

335 Conclusions

336 Our results suggest that meiofaunal biodiversity in the shallow waters of the Antarctic is at least 337 similar to that of temperate regions. The Antarctic comprises ca. 10-11% of the World's 338 continental-shelf-area and the total number of validated marine species (mega- and macrofauna) 339 described for the Southern Ocean exceeds 8,000 species, with at least as many more expected^{1,2}. 340 Antarctic meiofaunal descriptions are relatively few to date and have concentrated on taxonomic 341 characterisation. Taxonomically classification of all species is often not practical due to the lack of 342 suitably qualified taxonomists and the sheer volume of work required, thus environmental high throughput sequencing enables faster surveys into understanding biodiversity, albeit providing a 343 slightly different type of data. It also facilitates studies that would otherwise be impossible 344 particularly when applied to bulk environmental samples containing small and easily damaged taxa 345 obtained from inhospitable regions²⁷. The study described here showed that much of the Rothera 346 meiofaunal biodiversity is yet to be described, as no plateau was reached from the rarefaction 347 348 curves and most OTUs could not be annotated with confidence using the public databases. It also 349 shows that the genomic variability of the 18S rRNA gene can effectively be used to reflect the high 350 but also intangible level of biodiversity even in such a relatively small dataset used in this study and that the methodology is highly tractable for more detailed samplings in the future. These will enable 351 us to gain a more accurate understanding of patchiness and adaptation of meiobethic communities 352 to different environments. This approach may be particularly useful for detecting molecular 353 354 taxonomic signatures of response to climate change not only in terms of gradual sea warming and 355 acidification, but also the emergence of new habitats resulting from anthropogenic change.

356

357 MATERIAL AND METHODS

358

359 Sample collection

360 Sediment samples were collected in triplicate at different depths in four different sites near Rothera 361 Station, Adelaide Island on the Antarctic Peninsula (Figure 5). Sampled areas comprised the Islands 362 (67°35.6' S, 68°15.1' W, 13m depth), Hangar Cove (67°33.8' S, 68°07.6' W, 18m depth), South Cove (67°34.2' S, 68°7.9' W, 8m depth) and Rothera Point (67°34'19'S, 68°6'44'W, 15m depth). 363 364 Samples were collected using a standard corer methodology. All samples were immediately fixed in 365 500 ml storage pots containing 300 ml of DESS (20% DMSO and 0.25 M disodium EDTA, saturated with NaCl, pH 8.0)⁵³. The meiofaunal size fraction was mechanically separated from the 366 367 sand and concentrated by decanting five times with filtered tap water through a 45 µm filter. 368 Subsequent separation from fine silt was achieved by repetitive centrifugation in 1.16 specific gravity (sg) LUDOX-TM solution⁵⁴. Following centrifugation, each sample was retained on a 369 370 distinct mesh sieve which was then folded, sliced and placed in a 15 ml falcon tube and kept at -371 80°C until DNA extraction. Samples were lysed overnight at 55°C in lysis buffer (100 mM Tris-372 HCl, pH7.5; 100 mM NaCl; 100 mM EDTA; 1% SDS, 500 µg/ ml proteinase K), assisted by 373 spinning wheel mixing, and DNA extracted with the QIA amp DNA Blood Maxi Kit (Qiagen) following the manufacturer's protocol²⁶. 374

375

376 **Primer design and PCR**

Due to the extreme sensitivity of this methodology, all PCR and DNA extractions were carried out
in separate rooms and recommended eDNA practices were applied to avoid cross-contamination
between samples. The primers were SSU_F04 primer (GCTTGTCTCAAAGATTAAGCC) and
SSU_R22mod (5'- CCTGCTGCCTTCCTTRGA -3') were used to amplify approximately 450 bp of
the V1–V2 regions of the nuclear small subunit rDNA (18S rDNA)²⁰. Fusion primers, PCR
amplification and 454 Roche sequencing were performed as described previously^{26,27}. Specifically,
PCR amplification of the specified nSSU region was performed using 1 µl of genomic DNA

384	template (1:500 dilutions) in $3x40 \ \mu$ l independent reactions with Pfu DNA polymerase (Promega).
385	PCR conditions involved a 5 min denaturation at 95 °C, then 35 cycles with 1 min at 95 °C, 45 s
386	57 °C, 3 min 72 °C and a final extension of 10 min at 72 °C. Negative controls (ultrapure water
387	only) were included for all amplification reactions. Subsequently, triplicates of PCR products were
388	visualized and the expected 450 bp fragment was purified (QIAquick Gel Extraction Kit, Qiagen) in
389	an agarose gel and quantified using the Agilent Bioanalyser 2100. All purified PCR products were
390	diluted to the same concentration, pooled together to create one metagenetic sample/ library and
391	sequenced in one direction (A-Amplicon) on half a plate of a Roche 454 GSFLX platform (2x250
392	bp) at the Centre for Genomic Research, Liverpool. For full details of replicated PCRs and
393	associated MID tags, see Supplementary Table S2.

Data analysis and generation of OTUs

Raw sequence reads were filtered and denoised using FlowClus⁵⁵. The filtering criteria included 397 truncating reads prior to the first ambiguous base, the reverse primer, or a window of 50bp whose 398 399 average quality score was less than 25.0. Any reads shorter than 200bp or longer than 600bp were 400 eliminated. For the denoising step, in which pyrosequencing errors were corrected by clustering the flowgrams, a constant value of 0.50 was used for the denoising distance⁵⁶. After denoising, PCR 401 chimeras were removed using UCHIME⁵⁷ (Supplementary Table S2). The remaining reads were then 402 analysed using QIIME⁵⁸. They were clustered into OTUs at 97% sequence similarity using 403 UCLUST⁵⁹ (pick otus.py), and taxonomic assignment was performed using the Silva 111 database⁶⁰ 404 (assign taxonomy.py), which uses uclust. The uclust consensus taxonomy assigner retrieves the 405 406 maximum assigned matches for each query sequence. It then assigns the most specific taxonomic 407 label that is associated with at least min consensus fraction of the matches. It is acknowledged that 408 the threshold used for the OTU clustering at 97% similarity might cluster genus or family from the 409 same taxa, as intra-specific variability will differ across many taxa/ species. However, this cut-off is

410 known as proxy for most meiofauna species⁵⁰, but cut-offs such as 99% have also been justified as a 411 proxy for some nematode species in more targeted studies⁵¹. For direct ecological comparisons among 412 samples with different read numbers, the percentage of reads in each sample was used instead of read 413 counts and downstream analyses targeted main representatives within meiofauna phyla occupying 414 the Antarctic Peninsula sediment habitats⁴².

415

416 Data Deposition: All sequence reads have been deposited in the European Nucleotide Archive
417 (ENA) with accession number ENA: PRJEB1952.

418

419 **Diversity and community analysis**

Rarefaction curves were generated with EstimateS 8.2.0 software⁶¹ using the Chao1 richness 420 421 estimator; nonetheless other richness estimators were tested (ACE, Chao1, Jackknife1 and 422 Bootstrap) and yielded similar results. Sørensen's similarity coefficient among samples was computed based on a presence/absence similarity matrix and was used to create cluster 423 dendrograms with 50 random starts, using primer 6^{62} . Using the same software, a similarity profile 424 ('SIMPROF') permutation test, was performed on group-average cluster analysis to test whether the 425 meiobenthic samples differ from each other. In order to further test for significant differences in 426 community composition among sampling sites, a permutational multivariate analysis of variance 427 ('PERMANOVA') was performed. Analyses were based on Sørensen's similarity coefficient on 428 429 untransformed data of an OTU presence/absence matrix over the four sampled sites, with 1000 permutations. Further comparisons between the Antarctic and a Scottish study²⁶ were performed to 430 illustrate possible differences between the numbers of meiofauna OTUs found per phyla in the two 431 432 habitats. In order for the two studies to be as comparable as possible, all analysis were performed 433 using triplicated samples, similar 18S gene regions and using the same OTU clustering threshold of 97%. Antarctic eukaryotic OTUs retrieved from the data analysis were used in a Neighbour-Joining 434 (NJ) phylogeny reconstruction to confirm the taxonomic assignments (Supplemental material S6). 435

436 Taxonomic contributions using total OTU proportions were visualized using Krona graphs, plotted

437 using the Krona web interface software⁶³ and a non-parametrical statistical test was performed

438 (Kruskal-Walis) to check if number of OTUs per replicated sample site were significantly different

439 Taxonomic assignment for this purpose was also performed using SILVAngs 1.5 database at

440 https://www.arb-silva.de/ngs/.

441

442 Comparison with deep sea samples

443 Comparisons of OTUs were made with deep sea meiofaunal data from samples taken along the Antarctic Peninsula²⁰ and comprise SED 415 (Laubeuf Fjord) (500m) (67°52.583S 68°5.842'W), 444 445 SED 390 and SED 410 (duplicate CTD samples at the same site and depth) (515m) (67°35'6.57S 68°12'17.38W), SED385 (390m) (67°35'6.16"S 68°8'35.42"W), SED395 (off Anchorage Island) 446 (290m) (67°36'5.23"S 68°13'29.75"W) with an additional sample denoted Adria2 (1120m) 447 (74°29'.00S 104°25'.00W) kindly provided by Holly Bik and Adrian Glover (data unpublished) 448 449 (Figure 5). Published data were obtained from direct extractions of minimal amounts of frozen sediments²⁰ while the data from the additional sample "Adria2" was processed using the same 450 451 methodology (DESS fixed samples, meiofauna isolated from sediments and then DNA extraction) 452 as the shallow-water data presented here.

453

454 Acknowledgements

The authors would like to thank both Holly Bik and Adrian Glover for allowing us to use the data from their deep-sea Peninsula sediment sample in our analyses. We would also like to thank the Rothera Dive Team for help in collecting core samples, Susannah Pereira for meiofaunal decantation and molecular technical assistance and Laura Gerrish for producing the maps. The NERC National Facility for Scientific Diving (Oban) provided overall diving support. This paper was financed by NERC core funding to BAS within the Polar Sciences for Planet Earth Programme (MSC and LSP) and a NERC Antarctic Funding Initiative Collaborative Gearing Scheme to SC (No

462 57). VGF and DMP were supported by CCMAR core funding from the Portuguese Science

463 Foundation (FCT.UID/Multi/04326/2013). VGF would like to thank the Portuguese Foundation for

- 464 Science and Technology (FCT) for a post-doctoral grant (SFRH/BPD/80447/2014). FS was
- 465 supported by the European Community FP7 Marie Curie International Incoming Fellowship project

466 MARMEDIV (no. 253251).

467

468 Author Contributions

469 VGF performed most of the shallow-water bioinformatics analyses, interpreted the data and wrote 470 the first draft of the paper. FS was involved in collecting the samples, advised on the bioinformatics 471 analyses, supplied the deep-sea data, performed the deep-sea analyses and contributed to the paper. 472 JMG and CQ both performed some of the shallow-water bioinformatics analyses and provided 473 bioinformatics advice. SC jointly conceived the project with LSP, supervised sample collection and 474 the molecular extractions, provided metagenomics advice and contributed to the paper. DMP supervised the biological interpretations and the production of the manuscript. LSP jointly 475 476 conceived the project with SC, managed the Antarctic fieldwork, provided advice on Antarctic ecology and contributed to the paper. MSC supervised the project and the analyses and wrote the 477 478 final draft of the paper.

479

480 **Competing Financial Interests**

481 The authors state that they have no conflicts of interest.

648	Figure 1 - Percent identity to known sequences and number of OTUs found for the main meiofauna
649	phyla retrieved from the Antarctic Peninsula sampled sites. The red full line represents the total
650	number of OTUs found per phyla and the blue bar represents the percentage identity BLAST match
651	against the SILVA 111 nucleotide database. OTUs percentages of BLAST match identity against
652	SILVA database are shown black (100% BLAST), dark to light grey (100-97% BLAST), light to
653	dark blue (97-93%) and light to dark orange (93-90% BLAST). BECGB: Brachiopoda,
654	Echinodermata, Cnidaria, Gastrotricha, Bryozoa.
655	
656	Figure 2 - Operational taxonomic unit saturation profiles at 99% sequence similarity level, for the
657	Antarctic samples collected. Hangar Cove (HC), Islands (I), Rothera Point (RP) and South Cove
658	(SC), where 1-3 represent each sample replicate.
659	
660	Figure 3 – Venn diagram depicting OTUs that are shared or unique to each of the four
661	sampling sites found in the Antarctica meiofaunal shallow waters. Numbers in the diagram
662	represent the number of total OTUs found in the different samples, South Cove (blue), Islands
663	(Red), Rothera Point (yellow) and Hangar Cove (green).
664	
665	Figure 4 – Krona graphical representation of the relative taxonomic contributions (OTU

666	percentages) of the main eukaryotic (a) and meiofauna representatives (b) found at Rothera
667	Peninsula sampled sites, using taxonomic assignment from SILVAngs 1.5 database at
668	https://www.arb-silva.de/ngs/. Depicted are also OTU percentages of four of the main meiofauna
669	phyla found, the nematodes, arthropods, platyhelminthes and the annelids.
670	
671	
672	Figure 5 – Map showing the main sampling sites along the Antarctic Peninsula, with finer detail of
673	the deep-water sites in Ryder Bay. SED 385 is closest to Rothera Research Station and the sites of
674	the four shallow-water sediment-sampling sites (not shown at this scale). Maps made in-house at

675 BAS using ArcGIS v10.1 by the Mapping and Geographical Information Centre (MAGIC).

676 **Table 1:** Summary data for the sampled areas Hangar (HC), Rothera point (RP), Islands (I) and

677 South Cove (SC) at Rothera in the Antarctic Peninsula. The number of reads before (No reads) and

after denoising (QC/CC): QC: quality score; CC: chimera check) and total OTU numbers are

shown. OTUs numbers were taxonomically assigned to the eukaryotes and unknown. The latter

680 samples comprised both sequences with no matches in the SILVA reference database and also

- 681 matches to unannotated environmental samples.
- 682
- 683

Location	Depth (m)	No Reads	QC/CC	Number of OTUs

Supplementary Figure S1: Rarefaction curves of the Chao 1 diversity estimator. Plots are shown for all phyla, Nematoda, Arthropoda and Platyhelminthes at 97% identity OTU cut-off for all the Antarctic Peninsula sampled sites samples. Curves were estimated from 100 randomizations, without replacement, using EstimateS, version 8.2.0.

Supplementary Figure S2: Community composition for the Antarctic sampled areas Hangar Cove (HC), Rothera Point (RP), Islands (I), South Cove (SC) and also for the Scottish sampled site²⁶. Taxonomy assignment was performed using the SILVA database and the number of total OTUs for each sample site is shown (triplicates were merged per sample site).

Supplementary_Figure_S3: Cluster analysis for taxonomic patterns of meiofaunal communities based on Sørensen similarities of OTU presence/absence data for the combined sites. In the dendrogram, black solid lines represent samples sharing a significant similarity profile with a SIMPROF analysis.

Supplementary Figure S4: Community composition for the shallow and deep-water samples. The shallow-water samples are highlighted within a border. Taxonomy assignment was performed using the SILVA database with the percentage of OTUs per phyla shown in all sample sites.

Supplementary Figure S5: Overlap of metazoan OTUs between merged shallow samples and deep samples (individual and merged). Values are based on presence/absence data, with a total of 203 distinct metazoan OTUs found in all shallow samples and between 54 and 136 distinct OTUs in each of the deep samples for a total of 228 different deep metazoan OTUs.

Fonseca et al. "**Revealing higher than expected meiofaunal diversity in Antarctic sediments: a metabarcoding approach**"

Supplementary analysis

Method

All Eukaryotic OTUs retrieved from the data analysis were used to confirm the taxonomic position and community composition within the main eukaryotic metazoan found, using a Neighbour-Joining (NJ) phylogeny reconstruction, 500 bootstrap replications and the Kimura 2-parameter pairwise distance model. The analysis was performed using the software Mega7 (Kumar *et al.*, 2016) and illustrated via a phylogenetic tree produced using the Interactive Tree of Life iTOL tool (Letunic & Bork, 2007).

Result

Phylogenetic analysis of the total Eukaryotic OTUs further confirmed the presence of five taxonomically distinct phyla groups, the Nematoda, Arthropoda, Platyhelminthes, Annelida and the SAR supergroup (Starmenopiles, Alveolata and Rhizaria) and all phylogenetic clusters were supported by strong to moderate bootstrap values (Figure S1). OTUs assigned to Fungi were removed from the analysis and the Chloroplastida OTUS (ALGAE) were used as an outgroup (Figure S1). The Arthropoda cluster had a strong bootstrap support but it also showed a smaller independent cluster comprised mainly of the Ostracoda class (Figure S1). Here, three Echinodermata OTUs, two Kynorincha OTUs and one Mollusca OTU also sub-clustered. The Mollusca (7 OTUs) and Gastrotricha (4 OTUs) clustered inside the Annelida phyla. Within the SAR supergroup the Rhizaria (Cercozoa) also showed an independent phylogenetic sub-cluster, whereas the Stramenopiles and Alveolata clustered concurrently (Figure S1).

Supplementary Table S1.1- Closest BLAST matches of Operational Taxonomic Units (OTUs) retrieved from Rothera sample sites, assigned to Nematoda, up to genus or species levels (Description) using SILVA 1.11 database. Depicted are the public accession numbers (AcNumber), BLAST identity percentage against SILVA (BLAST % ID), Phylum and other Taxa ranking.

Supplementary Table S2: Overview of the Antarctic sampled sites *in silico* statistics for the NGS of 18S rRNA gene region used. Each replicated sampled site had a 8 nucleotide multiplex-identification tag (MID), depth in meters (m), abbreviated description of the sample, post-quality control and chimera checked number of reads and total number of OTUs at the 97% threshold.

Location	MIDTag	Depth (m)	Description	No Reads	QC/ Chimera check reads	Total OTUs
