Dear Dr. Zelaya

It is my pleasure to confirm that your manuscript, “Marine bivalves from the Argentine coast and continental shelf: Species diversity” has been accepted (18 February 2015) for publication in the *American Malacological Bulletin* as part of the Proceedings of the Symposium “Bivalvia of the Americas” presented at the 79th Annual Meeting of the American Malacological Society, in conjunction with the Society of Malacology of Mexico, the Latinoamerican Society of Malacology, and the Western Society of Malacologists on June 24–25, 2014 in Mexico City, Mexico.

Your manuscript is currently being processed and is expected to be published in AMB 33(2) in September 1st, 2015.

Sincerely,

A handwritten signature in black ink, appearing to read "Fabio Moretzsohn".

Fabio Moretzsohn

**Marine bivalves from the Argentine coast and continental shelf:
Species diversity and assessment of the historical knowledge**

Diego G. Zelaya

Key words: Argentina, Biodiversity, Bivalvia

Running title: Argentine marine bivalves

Abstract: Bivalves are one of the most abundant groups of invertebrates in many benthic communities. From 1817 to date, numerous contributions have dealt with the Argentine fauna of marine bivalves. Despite this, at present, there is no a text summarizing the currently available information on this group in Argentine waters. The present contribution aims to provide a synthesis of the current state of knowledge of systematics, geographic distribution, biology, and ecology of the living marine and estuarine species of bivalves from the Argentine coast and its shelf and, based on this information, to analyze the species diversity of these areas. For that, 225 publications, including results of scientific expeditions, systematic revisions, description of new species, new distributional records, check-lists, compilations on the diversity for particular areas, and contributions dealing with biological and ecological information, were surveyed. As part of this study, 277 nominal species of bivalves were found reported for the study area, although only 169 of them are currently regarded as valid. The analysis of the available bibliography makes evident that the Argentine bivalves have been overlooked throughout the years. This fact results in several limitations and gaps in the current knowledge of this fauna, which are highlighted in the present revision.

The Argentine coastline, of about 6,800 km length, extends in a predominantly north to south direction along 21 degrees of latitude, and is associated with an extensive continental shelf, up to 850 km wide, which covers a total surface of *ca.* 1,000,000 km². The study of the marine bivalves from this area started with the pioneer contribution of Dillwyn (1817), who described the first species: *Venus exalbida* (currently in the genus *Retroapes* del Río, 1997). A subsequent (and greater) contribution was made by d'Orbigny (1834-1847), who provided information on the bivalves collected during his *Voyage dans l'Amérique Méridionale*. Since then, several expeditions collected bivalves from the Argentine shelf, providing information from more than 400 stations. In addition, a number of contributions provided new information on species diversity and geographic distributions. The information at hands suggests, at first, that the Argentine bivalves are relatively well-known. However, this body of information has never been comprehensively or critically reviewed. In fact, information on the Argentine bivalves appears widespread in the literature and there is at present no compilation referring to the total number of species present in this area.

The aim of this contribution is to determine what is (un)known at present on systematics, geographic distribution, biology, and ecology of the living marine and estuarine species of bivalves from the Argentine coast and its shelf and, based on this information, to analyze the species diversity of these areas.

MATERIALS AND METHODS

The area considered in this study comprises the Argentine coast (including the estuarine environments) and the continental shelf, from the mouth of the Rio de la Plata River (at about 35°30'S) to Tierra del Fuego (55°S), including the Isla de los Estados archipelago and Malvinas / Falkland Islands (Fig. 1). The Argentine waters also comprise part of the Beagle Channel (south of Tierra del Fuego), although this fauna will be considered separately.

Published literature dealing with Argentine bivalves was compiled and assigned to one of the following six thematic categories, based on to the main subject of the publication: 1) results of scientific expeditions (“expeditions”); 2) systematic revisions of particular genera / families or insights on the identity of particular species, already known for the area (“systematics”); 3) description of new species (“new species”); 4) first records in Argentine waters of species previously known from other geographic areas (“new localities”); 5) check-lists or compilations on the diversity of particular areas (“catalogs”); and 6) information on biological or ecological aspects of species (“biology / ecology”). Often, the two first categories also provide new localities or describe some new species, although even in these cases the contributions were assigned to “expeditions” or “systematics”, according to the previous criteria. Following this criterion, there were no great difficulties to assign each publication to only one of the above-mentioned categories, with the exception of six publications: Dall (1900) and Dell (1964), who provided the results of expeditions but also performed systematic revisions for some particular taxa; Scarabino (1977), who provided information on the material coming from an expedition, but the publication also represents a catalog of the fauna from the San Matías Gulf; Roux *et al.* (1993), who provide information on expeditions but also on the faunistic assemblages (the latter belonging to

“biology / ecology”); and Zelaya and Ituarte (2012, 2013) in which new species were described and information on biological aspects of the species was provided. These five publications were consequently considered twice when analyzing the subject of publication (although only once when counting the total number of published papers). “Gray” literature (*i.e.*, non-peer-reviewed reports, unpublished dissertations, abstracts of meetings or symposia, and technical reports) were excluded from the present compilation, as well as those papers dealing with physiology, fisheries, natural predation, parasites, and the use of bivalves as substrata for non-molluscan taxa. As this contribution deals with living species of bivalves, publications on fossils / subfossils were also disregarded, except for five articles that described fossil species regarded as reaching to (and living in) the Recent: d'Orbigny 1835-1847; Farinati 1978; Ihering 1907; Philippi 1893; and Wahnish 1939 (in these cases, only those species reaching to the Recent were considered).

With a view to evaluate the temporal variation in the number of publications on Argentine bivalves, the period between the first report (1817) and the present (December 2014), was divided in 20-calendar-year intervals. In the case of contributions that were published as separate issues in different years, only that / those section(s) involving the Argentine species were considered for the year(s) of publication(s). This is the case of d'Orbigny (1834-1847), whose contribution extends over two different periods; however, all Argentine bivalve species were published after 1842, and the publication is consequently here considered as belonging to a single period. In the case of Lamy's (1936-1937) systematic revision of living Mytilidae, the publication was assigned to two different periods, due to the fact that different sections (corresponding to different temporal intervals) refer to Argentine species. The average number of publications per period was

calculated as the ratio of the total number of publications in a period and the total number of years comprising that period.

For the purposes of this contribution, the term species “described from Argentine waters” refers to those taxa whose original locality(ies) being listed as located on the Argentine shelf or coast. The “valid names” of the species follow Huber (2010), except for the Mactridae and Carditidae / Condylocardiidae, for which the subsequent local revisions by Signorelli and Pastorino (2011, 2012) and Güller and Zelaya (2013), respectively, were followed. In the current compilation, synonymies are based on the available literature, and encompass only those records coming from Argentine waters (*i.e.*, names currently regarded as synonyms but not mentioned from the studied area are not considered herein).

RESULTS

Publications dealing with Argentine bivalves

From the first publication by Dillwyn (1817) to December 2014, after nearly two centuries, a total of 225 publications dealing with Argentine bivalves, were issued. This means a general average of one publication per year. However, the rate of publication was not the same over time, and there is a fluctuation in the number of publications when comparing different periods (Fig. 2). In fact, in the 80 years between 1817 and 1896, the number of publications was extremely low, with a maximum of eight publications between 1877 and 1896, but with seven or less publications in the remaining periods. Between 1897 and 1916, the number of publications reached a peak, with a threefold increase when compared with the previous period; although this value decreased in the next period. However, it is

interesting to note that since 1917, there is a clear tendency to increase the number of publications per period (Fig. 2). In fact, in the present period (1996-2014) the average number of publications per year is 3.8.

Regarding the subject of these publications, it is noted that: 1) most papers belong to the categories “systematics” and “biology / ecology”, which account for 67 % of the total publications; 2) although “systematics” contributions are represented since the 1850s, “biology / ecology” contributions began in the 1960s, and are restricted to the last three periods, when they show a fast increase in number; and 3) both “systematics” and “biology / ecology” categories reach the maximum number of publications in the current period, when the latter category represents the main subject of publications (Fig. 3).

Most of the contributions in “biology / ecology” deal with reproductive aspects or other life history traits (see appendix, SM1). Studies addressing reproduction at the population level are currently available for 23 species, including venerids (Schuldt 1975; Verdinelli and Schuldt 1976; Morsan and Kroeck 2005), pectinids (Christiansen and Olivier 1971; Christiansen *et al.* 1974; Lasta and Calvo 1978; Calvo *et al.* 1998; Narvarte and Kroeck 2002; Ciocco *et al.* 2006; Campodónico *et al.* 2008), ostreids (Morriconi and Calvo 1979, 1980, 1989; Calvo and Morriconi 1978; Pascual *et al.* 1989; Castaños *et al.* 2009), mytilids (Penchaszadeh 1971, 1980; Barrionuevo *et al.* 1976; Vinuesa 1977, 1979, 1981; Vinuesa and Tortorelli 1980; Amor 1981; Gray *et al.* 1997), the geoduck *Panopea abbreviata* Valenciennes, 1839 (van der Molen *et al.* 2007; Zaidman *et al.* 2012), the pinnid *Atrina seminuda* (Lamarck, 1819) (Soria *et al.* 2002), the tellinid *Tellina petitiana* d'Orbigny, 1846 (Barón and Ciocco 2001), the glycymerid *Glycymeris longior* (G. B. Sowerby I, 1833) (Ituarte, 1979), the mesodesmatid *Amarilladesma mactroides* (Reeve, 1854) (Olivier *et al.*,

1971; Herrmann *et al.* 2009, 2011), the corbulid *Erodona mactroides* Bosc, 1801 (Pujals, 1986), the wedge clam *Donax hanleyanus* Philippi, 1847 (Herrmann *et al.* 2010), and the razor clams *Ensis macha* (Molina, 1782) (Barón *et al.* 2004) and *Tagelus plebeius* (Lightfoot, 1786) (Cledón *et al.* 2004). Reproductive aspects of small-sized bivalves were reported for only three taxa: *Tellimya tehuelcha*: Zelaya and Ituarte 2012; and *Waldo digitatus* and *W. paucitentaculatus*: Zelaya and Ituarte 2013 (in each case, the information was provided in the context of the original description). Information on the habitat of the species is restricted to a reduced number of contributions (Ringuelet *et al.*, 1962; Olivier *et al.*, 1968; Otaegui and Zaixso 1974; Zaixso 1975, 1996a, 1999; Escofet *et al.* 1978; Layerle and Scarabino 1984; Ciocco 1988; Bremec 1990; Roux *et al.*, 1993; Zaixso *et al.*, 1998; Bremec *et al.* 2008; Zelaya and Ituarte 2012, 2013).

The articles on “systematics” include the revision of species diversity of ten families (Ungulinidae, Tellinidae, Teredinidae, Pectinidae, Ostreidae, Thyasiridae, Mytilidae, Mactridae, Carditidae, and Condylocardiidae) and 19 genera (*Pododesmus*, *Limopsis*, *Philobrya*, *Cyclocardia*, *Cyamium*, *Tellina*, *Strigilla*, *Semele*, *Lithophaga*, *Crassinella*, “*Chlamys*”, *Yoldia*, *Adrana*, *Neolepton*, *Thaysira*, *Parathyasira*, *Sphenia*, *Lyonsia*, and *Brachidontes*); as well as the redescription, generic reallocation or study of intraspecific variability for 17 species: *Glycymeris longior* (G. B. Sowerby I, 1833), *Amarillodesma mactroides* (Reeve, 1854), *Aulacomya atra* (Molina, 1782), *Pitar patagonicus* (d'Orbigny, 1842), *Plicatula gibbosa* Lamarck, 1801, *Acesta patagonica* (Dall, 1902), *Limea pygmaea* (Philippi, 1845), *Asthenothaerus rushii* (Pilsbry, 1897), *Malletia subaequalis* (G. B. Sowerby II, 1870), *Sphenia hatcheri* Pilsbry, 1899, *Neilonella sulculata* (Gould, 1852), *Hiatella meridionalis* (d'Orbigny, 1846), *Perrierina crassilabrum* (Dell, 1964), *Ensis*

macha (Molina, 1782), *Tawera elliptica* (Lamarck, 1818), *Mactra isabelleana* d'Orbigny, 1846, and *Panopea abbreviata* Valenciennes, 1839 (for references see appendix, SM2). Only nine of the publications at generic / family level focus particularly on Argentine species (Ihering 1902; Parodiz 1948; Ageitos de Castellanos 1957, 1968; Castellanos 1957, 1971b; Ituarte 1998; Pastorino and Bagur 2011; Adami *et al.* 2013). On the contrary, most of the papers on systematics also include faunas from the Uruguayan or Chilean waters (*e.g.*, Carcelles 1941a; Waloszek 1984; Zelaya and Ituarte 2004; Signorelli and Pastorino 2011, 2012; Trovant *et al.* 2014), the Southern Ocean (Dell 1964; Rabarts and Whybrow 1979; Jonkers 2003; Zelaya 2009), the Western Atlantic (Dall 1899, 1900; Turner and Boss 1962; Boss 1966, 1969, 1972; Pimenta and Oliveira 2013; Trovant *et al.* 2013), or even wider geographical areas (Dall 1899, 1900; Lamy 1923, 1924, 1925–1926, 1927, 1929a, 1929b, 1931a, 1931b, 1934, 1936–1937, 1941; Reeve 1952–1953; Turner 1966; Sowerby 1871a, 1871b). Curiously, only eleven new species were described in the context of such “systematics” contributions.

Despite the numerous expeditions that historically surveyed the Argentine shelf (for a review, see Angelescu and Sánchez 1997, information on bivalves comes from only 29 expeditions, comprising 41 publications (see appendix, SM3). Some of these expeditions were specifically conducted in Argentine waters, such as those performed by the *R.Vs.* Shinkai Maru, Cruz del Sur, El Austral, Oca Balda and the “Mar del Plata” (I-V), “Goyena II” and “SAO” (I-V) campaigns; others, instead, obtained samples from this area during their cruises to Antarctica (*e.g.*, Schwedischen Südpolar Expedition, Scottish Antarctic Expedition, and Expéditions Antarctique Française), or as part of trips throughout the world (*e.g.*, the expeditions of the H.M.S. Challenger, Calypso, and Vema). The results (or at least

some of the results) on the study of bivalves collected during these expeditions were frequently published in the years immediately posterior to the end of the expedition; but for six of the expeditions, publication of the results was delayed for more than ten years; the case of the Schwedischen Südpolar-Expedition being particularly curious, for its results on bivalves were not published until 90 years later (Table 1).

Based on published information, ten of these expeditions sampled bivalves in less than five stations, and collected less than ten species of bivalves (Table 1). The expeditions that sampled bivalves in the greatest number of stations were those performed by the *R.V. William Scoresby* (66 stations), and the SAO (70 stations) and Mar del Plata (82 stations) campaigns; the two first provided information for about 40 species each and the last for 20 species. The expeditions “San José I and II” also intensively sampled the area, but the total number of stations in which bivalves were present is unknown (see comment 2 in Table 1). A similar number of species of that collected by the *R.V. William Scoresby* and the SAO campaign is reported from the collections made by the Scottish Antarctic Expedition and the *Voyage dans l'Amérique Méridionale*, however, in only 15 and 9 stations, respectively (Table 1). Eleven expeditions include the description of new species, being the reports of the *Voyage dans l'Amérique Méridionale*, which described the greatest number of new species.

Only six contributions are here classed in the category “new localities” (see appendix, SM4). It is noted that the results of these expeditions usually also provided new localities for previously known species along the Argentine coast or shelf, and reported for the first time in Argentine waters species previously known from other geographic areas.

Twelve publications comprise the category “catalogs” (see appendix, SM5). In general, these publications provide information from small geographic areas, usually a particular site or locality, and consequently refer to a relatively low number of species. This is not the case of Carcelles (1944) who, despite dealing with the fauna from a single locality (Puerto Quequén), reported a total of 64 bivalve species; and the contributions by Carcelles (1950), Carcelles and Williamson (1951), Castellanos (1970), and Scarabino (1977), which encompass larger geographic areas (“Patagonia”, the Magellan Region, the coast and shelf of Buenos Aires Province, and the San Matías Gulf, respectively), and consequently encompass a higher number of species. The above mentioned “catalogs” sometimes included the descriptions of new species: nine new species were described in these publications (Castellanos 1970; Melvill and Standen 1898, 1914; Pilsbry 1899; Smith 1905).

In addition to the species described in “expeditions”, “catalogs” or “systematics” contributions, the description of new species was the subject of other 23 papers (see appendix, SM6). Most of these papers described only one or two species, although some of them also included simultaneously the description of species from other areas or even other molluscan groups. Only three papers, each published between 1910 and 1913, described more than two species (Cooper and Preston 1910; Preston 1912, 1913), with Preston (1912) being the contribution with the greatest number of new bivalve species(6).

It should be noted that almost none of the above-mentioned publications provide information on the live / dead state of collected / reported specimens.

Current knowledge on bivalve diversity

Of the 277 nominal species currently reported from the considered area, 11 “mentioned” species were excluded from the present study: *Cytherea patagonica* Philippi, 1844, originally described from “Patagonia”, although this locality was considered in error by Huber (2010) who, in addition, regarded this species as a synonym of *Dosinia concentrica* (Born, 1778); *Chlamys argentinensis* Castellanos, 1973 and *Chlamys lahillei* Castellanos, 1973 described on the basis of isolated valves collected at “Puerto San Antornio, Golfo San Matías” and “Santa Cruz”, respectively, for which the living / fossil status remains uncertain (Castellanos, 1973; Waloszek, 1984); and the records of eight species, native from other parts of the world, whose reports from Argentine waters seem based on misidentifications: “*Pholas costata*” and “*Mactra fragilis*” reported by d’Orbigny (1834–1847); “*Cardium edule*”, “*Tellina squalida*”, “*Anomia ephippium*”, and “*Cryptogramma subimbricata*” reported by Melvill and Standen (1914); “*Arca (Anadara) chemnitzii*” mentioned by Smith (1915); and “*Crasinella martinicensis*” mentioned by Penchaszadeh (1973). In the case of “*Arca (Anadara) chemnitzii*”, it should be noted that even Smith doubted whether the material was actually collected in Rio de Janeiro, Brazil. Out of the remaining 266 species (listed in Table 2), 114 species were described from the Argentine shelf and coast (see appendix, SM7), and 152 species were described from other geographic areas, and reported for the Argentine waters.

The new species accumulation curve versus time shows two main peaks: one between 1837 and 1856, and the other between 1897 and 1916, each of them accounting for the description of 38 new species (Figs. 4, 5). For any other period (including the present period) the number of new species is considerably smaller, each with seven or fewer new

species (Fig. 5). The high number of new species described between 1837 and 1856 mostly comes from the results of the *Voyage dans l'Amérique Méridionale* (32 new taxa described), whereas in the 1897-1916 new taxa come from the results of several surveys of the Malvinas / Falkland Islands fauna, from which 29 new species were described.

Of the 114 species described from Argentine waters, 44 species are currently regarded as synonyms, one species is a *nomen dubium* (*Cardita malvinae*), one “species” is an unnecessary replacement name (*Venus tehuelcha*), and one species is a misidentification (*Modiolus darwinianus*) (for further information see appendix, SM7). The greatest number of synonyms comes from the species described between 1837 and 1856 (13 synonyms) and between 1897 and 1916 (21 synonyms), coinciding with the high number of new species described during these periods (Fig. 5). Synonyms include both small-sized species (such as *Neolepton* and *Cyamium* species) and large-sized species, such as the edible Patagonian Scallop, *Zygochlamys patagonica* King, 1832, for which four different names were proposed.

Of the 152 species described from other geographic areas, only 102 species are currently regarded as valid and the remaining 50 names are synonyms, misidentifications or *nomina nuda*.

When considering both the species described from Argentine waters and those described from other areas and reported from this area, the total number of valid bivalve species is 169 species (Table 2). These species belong to 109 genera corresponding to 51 families plus the superfamily Galeommatoidea (Galeommatidae + Lasaeidae + Montacutidae), the latter with several uncertainties at family and genus levels. To date, 50% of the families are

represented by only one or two species; only 7 families (Cyamiidae, Tellinidae, Mactridae, Veneridae, Mytilidae, and Philobryidae), and the superfamily Galeommatoidea, show more than 6 species each. The high diversity of these families is determined either by the presence of a high number of genera per family (such as in the Cyamiidae, Mytilidae and Veneridae), the presence of numerous species per genus (such as in the Philobryidae and Mactridae, with 7 and 5 species into the genera *Philobrya* and *Mactra*, respectively), or the presence of several genera with several species each (Tellinidae and Galeommatoidea). However, as a general trend, Argentine bivalve fauna shows a low number of species per genus and a low number of genera per family.

DISCUSSION

In the last years, an increasing number of publications dealt with Argentine bivalves. Such an increment mostly comes from an explosive number of contributions referring to “biology / ecology” of the species that, in only 45 years (from the 1960s to the present), represented a 40% of the total number of contributions on diversity and geographic distribution of the species published since 1817. Taking into account the recent nature of this research subject, it is easy to understand that these contributions have addressed at present only a small fraction of the total Argentine bivalve fauna; and, not surprisingly, the studied taxa mainly comprise the large and commercially valuable species.

The contributions dealing with the diversity and geographic distribution of Argentine bivalves (*i.e.* those belonging to the categories “systematics”, “new species”, “expeditions”, “catalogs”, and “new localities”) started much earlier than those on “biology / ecology” and, although with several fluctuations along the timeline, also showed a consistent

tendency to the increase in number toward the present. Taking into account the extended period and the numerous publications dealing with bivalves, a relatively good knowledge of these issues would be expected to date. However, this is far from being so: the identity of several taxa still requires revision, the ranges of geographic distribution of most the species needs to be improved, and extensive areas of the Argentine coast and shelf still remain undersampled (*i.e.* with records of an extremely low number of bivalves or without records at all). These facts make evident that the Argentine bivalve fauna has been neglected along the time. The oversight of bivalves started with the first expeditions; in this way, despite the numerous trips performed to Argentine waters, information on the diversity and geographic distribution of bivalves was only provided by a reduced number of cases. Clearly, this fact is not a consequence of bivalves not being present in the samples obtained by these expeditions, but to a lack of expertise or interest in their study. The contribution by Dell (1990) is an example of this: the author reported the first information on the bivalves collected during the Schwedischen Südpolar Expedition [between 1901 and 1903], and during the expeditions of the *R. R. S. Discovery* [between 1926 and 1938], the *U. S. N. S. Eltanine* [between 1961 and 1966], and the *R. V. Hero* [in 1970 and 1971]. Usually, published information on the bivalves collected by the expeditions refers to a low number of species coming from a reduced number of sampling stations, and lacking of figures of the collected specimens.

More evidence of the oversight of the Argentine bivalve fauna becomes evident when considering the low number of comprehensive revisions at generic and family levels. In this regard, only 10 families (of the 51 present in the area) and 18 genera (of the 109 currently reported) have been systematically revised; and even in these cases —and not

infrequently—several Argentine species were not considered therein. The local diversity of the families Malletiidae, Nuculidae, Philobryidae, and Thraciidae, and of the genera *Gaimardia*, *Mysella*, *Kellia*, *Corbula*, and *Yoldia* are clear examples of taxa still imperfectly known. In other cases, such revisions need to consider not only the local area, but also wider geographic areas, *e.g.*, the identity of several Antarctic species reported as present in Argentine waters [*i.e.*, *Cuspidaria kerguelensis* (Smith, 1885), *Cuspidaria tenella* Smith, 1907, *Cyamiocardium denticulatum* (Smith, 1907), *Cyamiomactra laminifera* (Lamy, 1906), *Pseudokellya cardiformis* (Smith, 1885), *Limopsis marionensis* Smith, 1885], the identity of 18 species currently regarded as widely distributed from Florida (U.S.A.) or the Caribbean to Argentina (see appendix, SM8), or even some “worldwide distributed” taxa (such as “*Kellia suborbicularis*”, “*Ostrea stentina*”, *Hiatella* and *Lasaea* species).

From the described scenario, it is clear that the current knowledge on diversity and geographic distribution of Argentine bivalves is far from being complete or even adequate; this fact, together with the historical absence of local researchers specifically working on this group, results in the absence of a complete catalog (or even a previous check-list) addressing the total species diversity occurring in the extensive area comprised by the Argentine coast and the associated continental shelf (thus far restricted to local / regional catalogs / check-lists, previously mentioned). With these limitations in mind, the present study seeks to provide the first compilation of the currently available information on the bivalves occurring in this area, as a first step toward a better knowledge of this fauna.

ACKNOWLEDGEMENTS

The author expresses his gratitude to C. Ituarte, M. Güller, P. Mikkelsen, and F. Scarabino for providing valuable suggestions and discussions, while drafting this MS. This study was partially funded by PICT 2011-2182. The author is member of the Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Argentina.

FIGURE AND TABLE CAPTIONS

Figure 1. Location map: The area considered in this study is highlighted in grey.

Figure 2. Total number of publications on Argentine bivalves per 20-year interval.

Figure 3. Main subject of the publications on Argentine bivalves versus time. The five contributions of fossils that reach the Recent are not included in this graph.

Table 1. Expeditions (“Exp.”) conducted to the Argentine shelf and coasts for which information on bivalves was published. Expeditions (chronologically arranged) are referred by their name (when using “ ”) or the name of the ship. In the case of expeditions that extended for several years, the “year(s)” here indicated correspond to the moment of sampling in Argentine waters; the number of stations and number of species collected also refer to the information from Argentine waters.

Figure 4. Special accumulation curve of bivalves described from Argentine waters.

Figure 5. Number of new species described from Argentine waters. Black bars: total number of species; gray bars: species currently regarded as valid.

Table 2. Species of bivalves currently known from Argentine waters (families arranged alphabetically). Species considered as valid are aligned to left in the second column; taxa considered as synonyms or wrong identifications are indented, below the corresponding valid name of the species. Synonyms are mentioned by using the original name of the species; if different combinations were locally used to refer to these taxa, such information is indicated with “[]”. “=?”: before a species name refers to possible synonyms, here suggested by first.

R.V. Puerto Deseado	2009	32	1	Signorelli <i>et al.</i> 2013

¹ Penchaszadeh (1973) only detailed the species found in station 3 of the expedition Mejillón I. This fauna corresponds to gut content of the sea star *Astropecten brasiliensis* Müller and Troschel, 1842.

² Although a total of 75 stations were sampled as part of the R. V. Shinkai Maru expeditions along the Argentine shelf, information on bivalves was provided for only 19 stations.

³ A list of the species collected by the R. V. Shinkai Maru was also given by Bastida *et al.* (1992) although this contribution does not provide information on the provenance of each species.

⁴ According to Zaixso (1997) 181 stations from these expeditions contained samples of mollusks. However, the author did not indicate how many of these stations actually sampled bivalves.

Table 2. Species of bivalves currently known from Argentine waters (families arranged alphabetically). Species considered as valid are aligned to left in the second column; taxa considered as synonyms or wrong identifications are indented, below the corresponding valid name of the species. Synonyms are mentioned by using the original name of the species; if different combinations were locally used to refer to these taxa, such information is indicated with “[]”. “=?”: before a species name refers to possible synonyms, here suggested for the first time.

	<i>Transenpitar keenae</i> Fischer-Piette & Testud, 1967
Yoldiidae	<i>Yoldia eightsii</i> (Jay, 1839)
	<i>Yoldia woodwardi</i> Hanley, 1860
	<i>Yoldia abbreviata</i> G. B. Sowerby II, 1871
	<i>Yoldiella valettei</i> (Lamy, 1906)

[1] To this species are assigned the previous records of "*Trachycardium muricatum*" from Argentine waters. Huber (2010) also mentioned *T. manueli* from Argentina, Uruguay and south of Brazil, and restricted *T. muricatum* to Caribbean waters.

[2] The actual identity of the specimens identified as *Corbula caribaea* from Argentine waters deserves further study. They do not seem to correspond to *C. swiftiana* Adams, 1852, currently regarded as a senior synonym of *C. caribaea*.

[3] A worldwide study of this genus is needed to clarify the actual status of the different names applied to Argentine specimens.

[4] Historically reported for the studied area either under *Limatula* or *Antarctolima*.

[5] Huber (2010) reported this species as a synonym of *Mulinia edulis* forma *epidermia* (Reeve, 1854).

- [6] Assigned to the genus *Spisula* by Huber (2010).
- [7] The species was reported under the genus *Tumbeziconcha* by Huber (2010).
- [8] The species was regarded as a synonym of *Mulinia edulis* forma *levicardo* (E. A. Smith, 1881) by Huber (2010).
- [9] Argentine records were previously assigned to either the genus *Nuculana* or *Tindariopsis*.
- [10] Argentine records were historically reported under the genus *Mesodesma*.
- [11] The species was historically reported in Argentine waters under the genus *Lithophaga*.
- [12] Scarabino *et al.* (2006) regarded this species as a distinct from *E. puelcha*, although the diagnostic characters for each taxon are still unknown.
- [13] Scarabino *et al.* (2006) suggested that *Flexopecten felipponei* could be a morphological variant of *Aequipecten tehuelchus*.
- [14] The species name was misspelled in the original description as "thuelcha".
- [15] d'Orbigny mentioned the species as *vilardeboana* when illustrating the species (*i.e.*, plate 84: figs. 14, 15).
- [16] The name here used to refer to this species follows Scarabino *et al.* (this volume) instead Malchus (2010), who regarded *Tivela isabelleana* as a junior synonym of *T. dentaria* (Lamarck, 1818).
- [17] The inclusion of *Petricola* in the Veneridae follows Mikkelsen *et al.*'s (2006) criteria, although some subsequent authors (*e.g.*, Huber, 2010) still regarded Petricolidae as a distinct (valid) family.
- [18] The Argentine records were historically assigned to *Pitar* or *Pitaria*.
- [19] All published Argentine records were referred to as *Tawera* (or *Clausinella*) *gayi*.
