

A Catalogue of Tennessee Lichens, Revisited

Alex Ciegler

In 1972 Skorepa published a catalogue of the lichens reported for Tennessee; the catalogue was based primarily on a literature survey covering the years 1858 to the time of the report. Skorepa accepted 427 species in 94 genera, one subspecies, 14 varieties, and 21 forms. A perusal of his compiled data and a few studies subsequently published show that most of the species listed for Tennessee were found on the eastern Tennessee border and, in particular, in the Smoky Mountains as a result of two major studies (Degelius, 1943; Dey, 1978). A limited survey that excluded crustose lichens was conducted over a three year period in an area known as The Land Between the Lakes (Philips, 1970). This area included Steward County located in north-central Tennessee on the southern Kentucky border and Trigg and Lyon Counties in Kentucky. Only a few scientific reports have been published on a small number of species from western Tennessee (Wilhelm and Ladd, 1992; Ekman, 1996). Data from the above publications are given in Table 1. All species names have been updated to conform to the sixth lichen checklist (Esslinger and Egan, 1995). No known lichen surveys had been conducted in the central or south-central area of the state.

In 1998, Arnold Engineering Development Center (AEDC) initiated a lichen survey on Arnold Air Force Base (AAFB) as part of efforts to establish a baseline inventory of biological diversity on the base's lands. AAFB is a Department of Defense installation in Coffee and Franklin Counties, south-central Tennessee, near the city of Tullahoma. The base is located within the Highland Rim physiographic region and encompasses 39,081 acres. Topography ranges from relatively flat land with poor surface drainage in the northern portion of the base to moderate relief with defined stream channels in the southern section. About 88 percent of AEDC is undeveloped with 29,021 forested acres; the rest is comprised of open areas, open water habitat, and a little over 2,000 acres of facilities. The forested area is about 80 percent hardwoods, primarily oak, and 20 percent softwood (pine). There are approximately 1,900 acres of jurisdictional wetlands (Bingham and Winford, 1998).

Seven sites totaling 3,029 acres were selected by AEDC for the lichen survey. These sites were chosen by AEDC conservation biologists to represent the diversity of terrain and natural vegetation communities present on the base including wetland systems and localities with known occurrences of rare, threatened, and endangered (RTE) vascular plant species. An additional four sites totaling about 2,000 acres were chosen by the current investigator for added study. These additional sites included dry, oak-type forest, rolling forested hills, and marshland communities. Several small sites, each under one acre, were also sampled: an old cemetery, concrete structures still remaining on the abandoned site of the former airbase, and miscellaneous small points. The entire survey was conducted over a total of about 5,000 acres.

AEDC has an extensive concentration of karst wetlands, a component within a barrens ecosystem on the southeast region of the Eastern Highland Rim of Tennessee. Although the soils of the barrens are poor for farming, they possess an exceptionally rich and diverse assortment of disjunct plants and animal species. AAFB comprises the largest remaining undeveloped or

nonagricultural piece of land in the Tennessee barrens (De Selm, 1981, 1989, 1990). At least 68 RTE plants and animals have been identified at AAFB, most of them in or near karst formations. Additionally, several disjunct populations of Coastal Plain vascular plant species, in association with wetland communities, were reported by Clebsch and Pyne in 1995. The Barrens are characterized by highly acidic soils overlaying a cherty limestone residuum (Wolfe, 1996). Very small areas of this limestone base are exposed at various points at AAFB as a result of soil erosion. These alkaline sites were carefully examined for they often support unique lichen communities. A total of 1,342 lichen specimens were collected for identification. All specimens were deposited at the University of Tennessee Herbarium in Knoxville.

Table 1 shows a total of 567 lichen species within 156 genera as occurring in Tennessee of which 216 were found at AAFB. Of the 216 taxa comprising 79 genera, 66 taxa represent new state records; accession numbers (AAFB) are given for the latter in Table 1. Since no lichens were previously reported from Coffee and Franklin Counties, the 216 taxa found at AAFB represent a new data base for the region. The relatively large number of new state records may seem unusual but it is believed that this only reflects the previous lack of surveys in central Tennessee. The two lichens listed by the Federal government as being RTE species (*Cladonia perforata* A. Evans and *Gymnoderme lineare* (A. Evans) Yoshimura and Sharpe) were not found. This is not surprising in that physiographic conditions noted for their growth do not occur at AAFB. Some of the species found at the base may represent a disjunct population, e.g., *Parmotrema margaritatum* (Hue) Hale and *Phaeophyscia hispidula* (Ach.) Essl. occur primarily in the western part of the United States. However, until more lichen distribution studies for North America become available, a disjunct claim may be unwarranted. No strong pattern of physical or environmental selection for lichen occurrence was noted in the survey with two exceptions: ground-dwelling taxa such as *Cladonia* spp. tended not to occur in the wetlands; taxa such as *Bacidia granosa*, *B. sabulotorum*, *Caloplaca feracissima*, *Farnoldia jurana*, *Protoblastenia rupestris*, and *Sarcogyne regularis* were found on alkaline substrates such as discarded concrete blocks, concrete structures, alkaline rocks, and marble tombstones. *Candelaria concolor* and *Physcia dubia* were also found on alkaline substrates since they can tolerate alkaline conditions but normally occur on acidic substrates. No correlation was found between lichen distribution and the distribution of vascular flora particularly with respect to the high incidence of disjunct vascular plants among karst formations.

The eleven sites surveyed were, more or less, evenly distributed over the base. Although the 5,000 acres investigated represent only about 12 to 13 percent of the total acreage at AAFB, based on the pattern of lichen distribution it is believed that a good representation of the lichen population for the area was obtained.

Acknowledgement: The lichen survey at Arnold Air Force Base was carried out as part of Delivery Order No. 26 under Contract No. 40650-95-D-0006 between CH2M Hill and Arnold Engineering Development Center and was managed by Dr. Steven R. Layman of CH2M Hill. I also wish to thank Mrs. Janet Ciegler for technical assistance during the course of the survey and Mr. Geoff Call of ACS Conservation for reviewing the manuscript..

Key to lichen records:

A = Arnold Air Force Base (Ciegler, 1998)

T = University of Tennessee Herbarium

S = Smoky Mountains (Degelius, 1941)

H = High Appalachians (Dey, 1978)

L = Land between the Lakes (Phillips, 1970)

M = Miscellaneous species: Berry, 1941; Cain, 1935; Calkins, 1890; Ciegler, Unpublished Data; Ekman, 1996; Evans, 1947; Fink, 1904, 1906, 1907, 1919; Hedrick, 1933; Howe, 1910; Ihlen and Tonsberg, 1996; Magnusson, 1929, 1935; Motyka, 1964; Mozingo, 1954, 1961; Phillips, 1963; Sharp, 1930; Sheard, 1995; Sierk, 1958; Skorepa, 1972; Tuckerman, 1859; Wilhelm and Ladd, 1992

** = New state record; voucher specimens indicated by AAFB acquisition number.

Total number species reported from Tennessee: 569

Number species reported from Arnold Air Force Base (Ciegler):	215
Number species in University of Tennessee Herbarium:	207
Number species reported from Smoky Mountains (Degelius):	159
Number species reported from High Appalachians (Dey):	139
Number species reported from Land between the Lakes (Phillips):	42
Number miscellaneous species reported:	136
Number New State Records:	64
