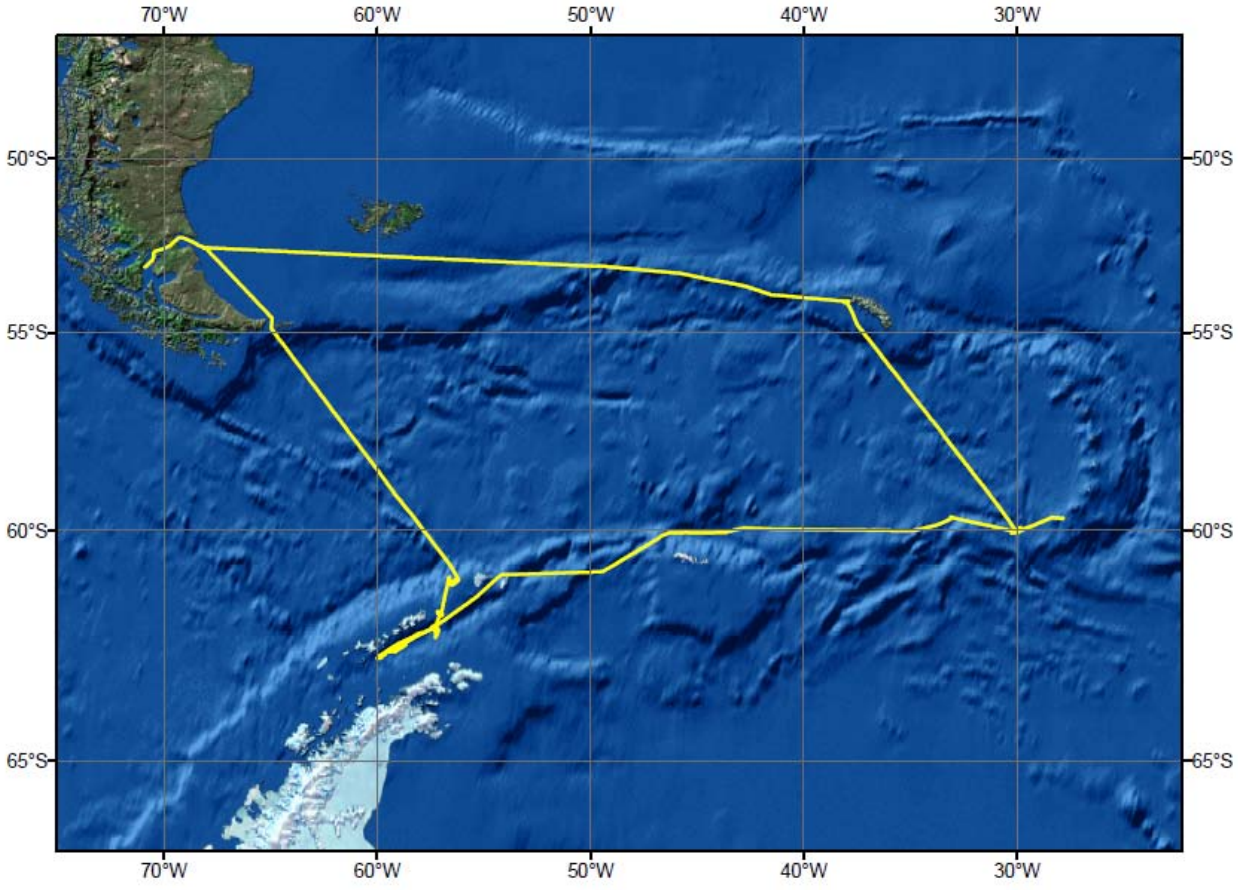
RRS *James Cook* Cruise JC55

Bransfield Strait, the East Scotia Ridge and the Kemp Seamount Calderas

Cruise 3 of the NERC Consortium Grant 'Chemosynthetically-driven ecosystems in the Southern ocean: Ecology and Biogeography' (ChEsSo)

13 January to 22nd February 2011



Contents

Abstract

The whole programme of JC55 changed with the extensive damage to the ROV *Isis* on day 5 of the 42-day cruise. As a result Plan B, an over-the-side science programme was put in place and sampling with CTD/SAPs, Megacore, gravity cores and SHRIMP. This limited a number of aspects of the sampling and visual observation of the seabed but resulted in a programme that achieved a remarkably high proportion of the objectives of the cruise. In the Bransfield St some hydrothermal activity was observed at Hook Ridge, together with areas of reducing sediment but no areas of extensive hydrothermal activity. A Middle Sister a small anomaly in the Eh readings on the CTD suggested hydrothermal release but visual observation of the seabed showed only sedimented and old areas of pillow lava. At the Axe (aka Edifice A), despite extensive CTDs, there was no evidence of any modern hydrothermal activity. At the three sites we did obtain excellent samples for geochemical and water analysis, as well as samples for microbial analysis, macrofaunal and isotope analysis. Megafauna and mosaic analysis was not possible because of the loss of use of *Isis*. On moving to the East Scotia Ridge at E9 we were able to use SHRIMP to locate the Twin Peaks area (first sighted in 2009) and obtain a third annual set of images over a specified area. Additional exploration did not find any additional vents to those found on JC42. Water column sampling in the plume for chemistry and microbiology was successful. At the Kemp seamount crater there were successful stations for water chemistry and microbiology. A long SHRIMP transect over the venting area within the caldera was particularly successful and this together with fine scale mosaicking gave a clear map of this venting field. Planned fine scale sampling and ROV swath could not be completed. A SHRIMP transect at the nearby recently-mapped Adventure caldera discovered a small vent site on the southern side of the crater. Lastly, we returned to the putative cold seep site off the southwestern end of South Georgia. High CH_4 levels in the water column and reduced sediment in cores suggested methane release but two SHRIMP surveys revealed no evidence of surface expression of a cold seep.

To summarise on the effects of the loss of use of *Isis* on JC55.

Despite the loss of use of *Isis* we were able to obtain very good samples for water column for chemistry and microbiology and complete our sampling programme. This completed the fieldwork for one of the PhD studentships. We were also able to get good sedimentary cores from surface deployment and this completed the field aspect for one of the tied studentships. We obtained good HD imagery of the seabed in some locations but this was not controlled as it would have been by the ROV.

However, the damage to *Isis* prevented us completing the following:

1. Collecting megafauna for molecular analysis, isotope and reproductive analysis
2. Deploying traps for larger species of megafauna and fish for isotope analysis
3. Collecting end member fluids for chemical analysis
4. Collecting diffuse flow fluids for chemical and microbial analysis
5. Completing ROV swath at fine scale over vent areas
6. Collecting cores in the crater for geochemical analysis
7. Continuing the fine-scale video mosaicking of the vent fields

Acknowledgements

We wish to thank the Master, Ships officers and crew for all their support during JC55. We also thank the continuing support of the technical staff from NMF. This research cruise was part of the consortium grant ‘Chemosynthetic ecosystems south of the Polar Front: Ecology and Biogeography’ (NE/D01249X/1) from NERC which is gratefully acknowledged.

Executive Summary and Objectives of the 'ChEsSo' programme

Chemosynthetically-driven Ecosystems South of the Polar Front: Biogeography and Ecology (ChEsSo)

Executive Summary

We propose a consortium of UK marine scientists to investigate the chemosynthetic environments and associated ecosystems south of the Polar Front. Sites in the East Scotia Sea (East Scotia Ridge, South Sandwich Arc and forearc) will be compared with chemosynthetically-driven communities in the Bransfield Strait, and north of King George Island, Antarctica. The primary objective of this work is to evaluate whether these sites, collectively, represent a Southern Ocean "gateway" to enable gene-flow of chemosynthetic fauna from the Southern Pacific Ocean to the South Atlantic Ocean. To address this issue our consortium of PIs will collectively conduct a detailed investigation and analysis of four contrasting types of chemosynthetically-driven communities, together with their regional tectonic setting, and the specific hydrothermal vent and cold seep environments they inhabit. The communities chosen for our investigation comprise: those associated with high-temperature, bare-rock hydrothermal vents on the East Scotia Ridge, high-temperature, sediment-hosted hydrothermal activity (Bransfield Strait), mud volcanoes (South Sandwich forearc basin) and methane hydrates (north of King George Island). To achieve these aims, we propose a three-cruise (involving international collaboration) and laboratory-based programme. Cruise 1 will be to the East Scotia Sea where we will locate vent and seep sites, using existing evidence for active plumes, examine their tectonic setting and sample the discharge at hydrothermal and cold seep sites. This cruise will rely primarily on proven water-column survey techniques, combined with very high resolution bathymetric mapping and video/image capabilities provided by WHOI's ABE autonomous underwater vehicle. These methods will locate precisely and begin to characterise individual vent and seep environments on the deep sea-floor. Cruise 2 will be to the same area and will use the UK's Remotely Operated Vehicle (ROV) Isis to dive on, sample and thoroughly characterise the biological, chemical and physical environment surrounding vent and seep sites identified during Cruise 1. Cruise 3 will be a combined geophysical, chemical and biological cruise, using the ROV Isis to dive upon and examine hydrothermal vent and cold seep environments, at least some of which have been closely spatially-constrained already, both north and south of King George Island, Antarctic Peninsula. Subsequent analysis of geological, chemical and biological (both microbial and metazoan) samples will allow us to compare the hydrothermal and seep communities among these four sites. We will also use morphological, molecular, lipid and stable isotope analyses to determine the phylogeography of species, and understand their food web processes. In concert, our programme will determine whether colonisation of vents

and seeps, in these most isolated of chemosynthetically-driven ecosystems, is driven by oceanographic or geologic processes or, instead, whether any site has hosted completely isolated evolution.

Specific Objectives and Deliverables

*Our **single specific objective** is to investigate contrasting chemosynthetically-driven ecosystems south of the Polar Front, Antarctica and their relation to their geological, oceanographic and chemical environments. We will determine whether these ecosystems represent one or more unique biogeographic provinces, separated from the Global Ocean by the Polar Front or CDW, or instead are related to vent and seep ecosystems in the Pacific and Atlantic Oceans providing 'stepping stones' between the two. Detailed objectives include:*

1. *to locate individual vent and cold seep sites using a combination of the deep-tow vehicle BRIDGET and the Autonomous Benthic Explorer (ABE), and to use the sampling/deployment capabilities of ROV Isis to investigate these sites in detail (see subsequent objectives 2 to 6)*
2. *to sample and analyse focussed and diffuse vent fluid compositions (temperature, pH, sulphide, methane concentrations, metals and other redox-active elements) to evaluate the contribution of the reduced chemicals supplied to the overall energy budget within the chemosynthetic food-web, and to ascertain if there are any systematic geochemical differences in the detected chemosynthetically-driven ecosystems.*
3. *to sample the vent and seep sites for metazoan organisms, and for micro-organisms using standard techniques*
4. *to compare the biota of the examined vent and seep sites, using both morphology and molecular techniques, and determine their place in the global biogeographic context for both hydrothermal vent and cold-seeps.*
5. *to determine whether the fauna of any or all the four study sites are inter-related due to migration along the seafloor (eg via volcanic or tectonic links) or by hydrographic controls.*
6. *to elucidate food-web structures using state of the art techniques of stable isotope and lipid analyses, and to compare these chemosynthetic-community types and locations both within the chosen region and outside it.*

This report is a description of Cruise 3 of the ChEsSo programme

JC55 Cruise narrative

(All times Ship time GMT-3)

Station planning will be found in Appendix A; Station numbers in electronic Appendix B and Waypoints in electronic Appendix C

Daily narrative (see Figures 1 to 5)

January 12 All scientific party on board and ship has completed demob from JC54 and mobbing for JC55 underway. Social and political unrest has started in Punta Arenas over fuel prices and some roads are blocked causing delay in delivery of provisions.

January 13 Continue to mob JC55. Safety briefing

January 14 JC leaves berth and stands off Punta Arenas. Later in the morning agent's boat comes alongside with galley provisions for loading. JC then cleared for departure and leaves Punta Arenas at 17.00 steaming eastward down the Magellan St.

January 15 JC proceeding down Magellan St and out into South Atlantic to cross Mar Argentino towards Estrecho de la Maire and the Drake Passage (Fig. 1A)

January 16 Continued in a southeasterly direction across the Drake Passage in moderate seas

January 17 Passage continued with short hove to pay out 3000m of ROV tether at 10.00 to stream. Passage continued to WP1

January 18 On arriving over the BSR site we commenced EK60 survey and continued this for 20h but failed to recognise any flare patterns (JC55-001_EK60#1). On completion of the EK60 survey a CTD with SVP was deployed in 2200m water at 21.15 to obtain water samples for analysis and experimentation and conduct the sound velocity profile necessary for the position fixing of the ROV (JC55_002_CTD1). On completion JC steamed towards the ACES6 site arriving early on 19th January

January 19 *Isis* was prepared for deployment at 09.00 (JC55_003_Dive181). On deployment there was a serious incident in which *Isis* was drawn into the port propeller and very severely damaged. The rest of the day was spent ensuring recovery of the remains of the vehicle and the floating debris and reporting to NMF and starting an investigation into the causes of this disaster. All scientific activity was halted. At 15.00 the ACES6 whale bone lander was contacted by pinger and released but could not be found at the surface (JC55_004_ACES6). Late in the evening JC steamed to the Hook Ridge site

January 20 The PSO requested that we start the contingency plan for science and the CTD was deployed on tow-yo mode SE to NW over the Hook Ridge site locating the hydrothermal plume first discovered by Gary Klinkhammer 10 y ago. However, NMF were asking the STO Jez Evans, the Master and the ROV team leader

for copious amounts of information and the decision was taken to suspend all science so shipside and tech-side could concentrate on reporting to NMF.

January 21 In calm conditions the PSO requested that whilst we were stood down from active science we could use the ship's swath to get detailed charts of the Hook Ridge site (Fig. 1B). The Hook Ridge area was swathed by JC starting at 12.00 and completed at 20.00 (JC55_006_EM120#1). We then established a series of CTD tow-yo transects from SE to NW across the Hook Ridge site and occupied transects into 22nd January.

January 22 The transects completed over night showed evidence of light scattering and Eh values indicative of hydrothermal plumes south of the main ridge at Hook Ridge. CTD tow-yos continued throughout the day and were completed by 06.30 on January 23rd (JC55_007_CTD to JC55_010_CTD).

January 23 JC steams to station JC55_011_MC#1 on the shelf to the east of Hook Ridge that will act as a control station for experimental and macrofaunal studies. First megacore completed by 10.00 ship time (JC55_011_MC#1). Five additional megacores were taken for background macrofauna and chemical and isotope analysis (JC55_011to 16_MC#2 to 6). On completion of this series of cores (18.00), JC steamed back to Hook Ridge arriving about 19.30 and deploying SHRIMP on a grid pattern survey of part the main ridge at Hook Ridge (JC55_017_SHRIMP#1). This deployment continued overnight.

January 24 SHRIMP remained deployed and seabed video showed a thin later of sediment overlying a hard base with most obvious fauna being ophiuroids and holothurians. The lower slope showed no evidence of hydrothermal activity but at 62º11.858S; 57º 17.699W single 1m high chimney with very diffuse flow was found. SHRIMP deployment continued overnight

January 25 SHRIMPing continued until 07.00 by which time the weather had deteriorated rapidly and SHRIMP could not be safely recovered. Operations were suspended with SHRIMP being held at 1000m depth. Weather downtime 10 hrs. SHRIMP was retrieved at 17.00 after weather had moderated. In the evening and during the night a series of megacores (JC55_18 to 26_MC#) were taken over a reducing site to the SE of the crater area.

January 26. Megacoring continued until 0.900. JC then repositioned at the northern end of the next CTD tow-yo transect (JC55_027_CTD). The tow-yo continued throughout the day moving towards the SE and showing increasing evidence of a hydrothermal plume. Water samples were taken at 500m on retrieval. The CTD was back on deck at 17.30. At 18.10 the CTD was redeployed (JC55_028_CTD#192) over the putative vent seepage site and water samples for microbiology collected just above the seabed. On recovery of the CTD, the gravity core was prepared for deployment and lowered over the side at 20.45 and recovered 21.30. JC was then manoeuvred towards WP 60 for deployment of the megacores in the crater at Hook.

January 27 Megacoring continued throughout the night with at least five of the eight barrels in each core containing good cores of the seabed (JC55_30_MC#16 to JC55_35_#21). On completion of the megacores a spade box core was taken (JC55_036_SBC#1). The JC then moved to a track south of, and parallel to, Hook

Ridge and successfully completed an Agassiz Trawl between 12.00 and 17.00 at 1600m depth. The fauna collected was limited but contained bivalves and ophiuroids. The Hook Ridge programme was completed with a second spade box core (JC55_038_SBC#2) to ground truth the ophiuroid fauna seen in the SHRIMP video. JC was then programmed to steam overnight to Threes Sisters site stopping for CTDs in deep water (JC55_039_CTD) and at Orca volcano. The latter could not be completed at a very large iceberg was sat in the water column immediately above Orca volcano!

January 28 JC arrived at the Three Sisters (Fig. 2A) site early in the morning (06.00) and proceeded to swath in increasing fog (JC55_040_Swath#2). Speed was reduced to 2 knots and after a short time it was decided this was uneconomical with time and time would be better used conducting a tow yo CTD survey (JC55_041_CTD) over the three linear structures of the Three Sisters site. This was an 8 km long transect and took about 24h.

January 29 On completion of the tow yo transect it was apparent only a small section of the ridge was showing hydrothermal activity. The remainder of the day was spent completing the swath (JC55_042_Swath#3) in variable visibility conditions and at variable speeds. At 23.30 a second short tow-yo CTD transect across part of the Middle Sister was started (JC55_043_CTD). The tow yo continued overnight

January 30 Tow-yo (JC55_043_CTD) continued throughout the morning with very limited evidence of hydrothermal activity. At 19.30 an up and down CTD (JC55_046_CTD) was taken close to the area selected for survey. At 21.00 Shrimp was deployed to survey a box area and this continued overnight. The box was extended to cover part of the top of the ridge. Considerable heterogeneity of the seabed was found but no evidence of recent hydrothermal activity.

January 31 The SHRIMP deployment continued throughout the day until terminated on orders from the bridge because of an increase in wind speed and concerns over safe recovery. SHRIMP was on board by 19.50. At 21.00 the first of a series of four megacores was deployed (JC55_048_MC#22) in a sedimentary area near the crest of Middle Sister.

February 1 On completion of the megacores in early morning JC steamed towards the Axe as different speeds to allow the engineers to assess the vibration caused by the damaged port propeller. This was completed by midday and a series of CTDs and concomitant Swath was made along the axis of the Axe to look for hydrothermal activity. CTDs continued all day and through the night into the following morning (Fig. 2B)

February 2 CTDs continued until the last one, WP145, in the centre of the Axe (JC55_076_CTD) was completed by 13.00. JC moved to the north of the Axe to deploy the megacorer (JC55_077_MC#26) at a background site. A magnificent 8 cores were obtained. It was now apparent that there was no obvious hydrothermal activity that we could trace at the Axe. There had been no response to either lss or Eh probes and those changes observed in the CTD profiles could be attributed to water mass variation. The decision was

taken to return north, sampling in the Orca crater and again at Hook with the CTD. After discussions with the Master and NMF in Southampton it was agreed we could proceed to the East Scotia Ridge and South Sandwich Islands to continue our study at sites discovered there in 2009 and 2010. At 15.00 JC started to steam to Orca Crater.

February 3 JC steamed northward taking a CTD in the Orca crater (JC55_078_CTD) before steaming on to Hook Ridge and taking two CTDs (JC55_079/080_CTD) and a successful megacore (JC55_081_MC#27). This completed our work in Bransfield St and at 10.00h the JC set sail for the East Scotia Ridge passing the Elephant Island archipelago and the South Orkneys on the way.

February 4 and 5 Steaming to ESR

February 6 Steaming to ESR. En route we stopped at an off site station (WP181) to carry out a CTD (JC55_082_CTD) over 2500m water depth and collect water well off site to give background chemical and microbial data. The station was completed successfully and JC proceeded to station E9 on the East Scotia Ridge.

February 7 After steaming through rough seas and a strong headwind, JC arrived on station E9 on the East Scotia Ridge (~2500m depth)(Fig. 3) at 7.00h in decreasing wind speeds and a moderate swell. CTD (JC55_083_CTD) was deployed at E9 immediately. A very well structured hydrothermal plume was found ~300m above the seabed with low Eh values and high lss. The CTD was recovered and redeployed armed with a SAPs (JC55_083_SAPs#1). However the wind speed was increasing and after 25 mins deployment sampling at depth the Master called time and the CTD was recovered at 13.30. Weather deteriorated fast and ship work stopped until 03.00.

February 8 At 03.00 it was considered prudent to deploy the CTD again (JC55_086_CTD) followed by a CTD plus SAPs (JC55_087_CTD) at 06.00. The weather was improving slowly but no yet good enough to deploy SHRIMP. Two deployments of SAPs were made, one for chemical particles and one for vent/water column larvae (JC55_088_SAPs#3 and JC55_089_SAPs#4). These were completed by 14.30 and the decision was taken to deploy SHRIMP (JC55_090_shrimp#3) although there was still some swell running. The first part of the deployment over the Twin Peaks site was very successful but the second part that was more exploratory did not find evidence of additional venting. SHRIMP was recovered by 09.00 on 9th February

February 9 On completion of SHRIMP JC steamed towards the Kemp Seamount crater conducting shaft tests required by NMF on the way. JC arrived at the crater at 14.00 (Fig. 4A, B). Deployment was delayed to allow completion of the shaft tests. At 15.00 a CTD (JC55_091_CTD) was deployed that gave low Eh and high lss reading below the lip of the crater. Water samples collected at depth smelled of hydrogen sulphide. At 16.30 at megacore was deployed (JC55_092_MC#28) but retrieved only about 4cm of lithified crust. At 18.30 a second CTD was deployed (JC55_093_CTD). This had trouble finding the exact location for sampling the buoyant plume and was completed at 23.30

February 10 During the early hours there was a series of 3 megacores to try and obtain sediments from within the crater. Although some small sediment samples were recovered no decent cores were obtained. We attribute this to the very small patches of corable sediment in the crater and the inability to locate the megacore precisely. After damage to two cores coring was suspended at 05.00 and a sub-bottom profile run to try and locate patches of sediment (JC55_100_SBP#1). At 08.00 a CTD was deployed (JC55_101_CTD). Again there was difficulty finding the buoyant plume. On completion of this station (09.10) JC steamed to a newly-discovered crater, Adventure Crater, 17miles to the east (WP228)(Fig. 5A). We started a SHRIMP survey (JC55_102_SHRIMP#5) at 12.00 and found a typical Antarctic fauna from the deepest part of the crater up to 500m depth. As we modified the track of the SHRIMP we discovered a new small hydrothermal vent system at 538m. With very careful manoeuvring of the ship by the bridge we were able to spend an hour carefully video documenting this new site to the great delight of all on board. SHRIMP was recovered at 20.30. It was then decided to try and sample this hydrothermal fluid with a CTD rosette (JC55_104_CTD) and this was deployed and successfully sampled warm water above the vents site.

February 12 JC steamed back to the main caldera and deployed a CTD to sample the buoyant plume (JC55_105_CTD). After successful samples were retrieved the gravity corer was deployed 3 times (JC55_106/107/108) in the centre of the caldera WP 196-198) to try and obtain some samples of the sub-seabed, but with only limited success, although a small sample of siboglinid tubeworms was obtained. The CTD was again deployed over the main venting area (WP207) and samples recovered (JC55_109_CTD). A short delay occurred as the CTD was serviced and the bottles emptied and their contents treated before the CTD was lowered over the site at 10.30 (JC55_110_CTD). Once again the buoyant plume proved difficult to locate but samples were taken above the seabed and the CTD retrieved by 14.00. At this point the work at the crater was complete with the equipment available and the JC steamed for E9 on the East Scotia Ridge in worsening weather. JC arrived at E9 in very rough conditions and winds at almost 40knots. On the advice of the bridge no CTD was deployed and for potential medical reasons as well JC proceeded to South Georgia.

February 13 Steaming towards South Georgia in decreasing seas.

February 14 Arrived off South Georgia (WP237) at 19.00. Water depth ~250m. JC completed three successful megacores and two gravity cores at WPs 237, 238 and 239 (Fig. 5B).

February 15 At 00.00 started an EK60 survey looking for gas bubbles. This continued until 07.00 and putative sites of gas bubbling were observed. At 07.00 a megacore was deployed at WP 247 for geochemistry and microbiology (JC55_117_MC#35). 5 subsequent megacores were taken for macrofaunal and microbial analysis. At 12.00 Shrimp was deployed over a putative cold seep site, and at 18.00 redeployed over a second site. SHRIMP was recovered at 22.00 having observed only sedimentary surfaces. This completed the science programme of JC55. At 22.30 JC set steam towards Punta Arenas.

February 16 to 21 Steaming to Punta Areanas, arriving **February 22**nd

JC55 Scientific Reports

Water column Chemistry

Douglas Connelly , Jeff Hawkes, Cathy Cole and Darryl Green

Following the success of finding new vent sites in 2010 the first part of the work moved to looking for evidence of hydrothermal venting in the Bransfield Strait. There was prior evidence of hydrothermal activity here from work by Klinkhammer and others from a series of cruises in the late 1990s early 2000s. The areas are discussed earlier in this report of this cruise report, all of the locations and sampling data for the CTD sampling programme can be found in electronic Appendix D. The majority of the water samples collected were taken using a Seabird CTD. The CTD system used is a Seabird +911 on a titanium frame with up to 24 externally sprung Niskin bottles. This is a clean system, specifically designed for the sampling of waters with low levels of trace metals and nutrients. The bottles are Teflon lined, with Teflon taps and non-metallic parts, any metallic components are titanium or high quality stainless steel. In addition to the standard CTD sensors there was an addition light scattering sensor (LSS) and bespoke Eh sensor provided by Prof Koichi Nakamura a geologist at the National Institute of Advanced Industrial Science and Technology in Tsukuba, Japan.

There was previous evidence for the existence of a BSR (Bottom simulating reflector) in an area to the north of King George Island. Since these data often indicate the presence of not only free gas but also gas hydrate deposits a series of EK60 lines were run over the deeper areas and extended up onto the shelf to look for gas bubble streams in the water column, such as those found in the Arctic (Westbrook et al. 2009). This investigation proved fruitless with no sign of active gas venting in any of the areas studied over a period of 14 hours. All station data are in electronic file JC055_APPENDIX_D_geochemStations

We then proceeded to the Bransfield Strait and commenced work over the Hook Ridge, and area identified by Klinkhammer et al. (2001) as having sediments with temperatures in excess of 40°C. We performed a series of 5 TowYo's across Hook Ridge. There was unusual signals evidenced at a number of places across and along the ridge, these were mainly Eh (redox potential, negative signals indicate the presense of reducing species in the water column) signals and were unsupported by either LSS (Light Scattering Sensor) or the transmissometer. This indicates that the source of the Eh anomaly is not a classical black or white smoker vent site. We feel it is more likely to be a seep site with little buoyancy. The best area located was actually to the south of the Ridge and this was re-occupied later in the cruise and a series of samples collected. CTD 192 was the main sampling CTD for this stage of the survey.

Following from Hook Ridge we proceeded to the Three Sisters area in the Strait. At this site we deployed the CTD on 4 TowYos and 3 vertical casts, there was no evidence of a plume on any of these casts

indicating that the site is not active with regard to hydrothermal activity. We took samples for salinity checks to calibrate the CTD.

We the moved onto the most southerly of our sites, and area known as the Axe. This has not previously been explored for hydrothermal activity. Our plan involved a combined CTD survey with a swath survey to map the area. A series of 22 full ocean depth vertical CTD casts were performed; none of these produced any evidence of hydrothermal or seep activity. A single Niskin was fired at the bottom of each cast for a salinity measurement to check the CTD drift.

We went to the Orca Crater and dropped a CTD in the centre to determine if there was any hydrothermal activity, this showed that there was no activity. We completed our studies in the Bransfield Strait by a further 2 CTDs over the Hook Ridge in the area we had collected core samples that showed unusual chemical anomalies. The first CTD (CTD420) showed 3 large Eh anomalies in the water column and was sampled and sub-sampled for nutrients, metals, microbiology and methane. The second CTD in the series at Hook Ridge did not show an Eh anomaly and we departed the site.

After leaving the Bransfield Strait we proceeded back to our study areas from JC044, E9 on the East Scotia Ridge and the newly discovered site in the Kemp caldera to the west of the Kemp seamount.

Hydrothermal vent sites at E9

CTD casts were made over the 'Black and White' Smoker (at 60°02.557, 29°58.900) to sample the buoyant and neutrally buoyant plume. Five casts were undertaken, including one blank station at 59°40.898, 33°06.181.

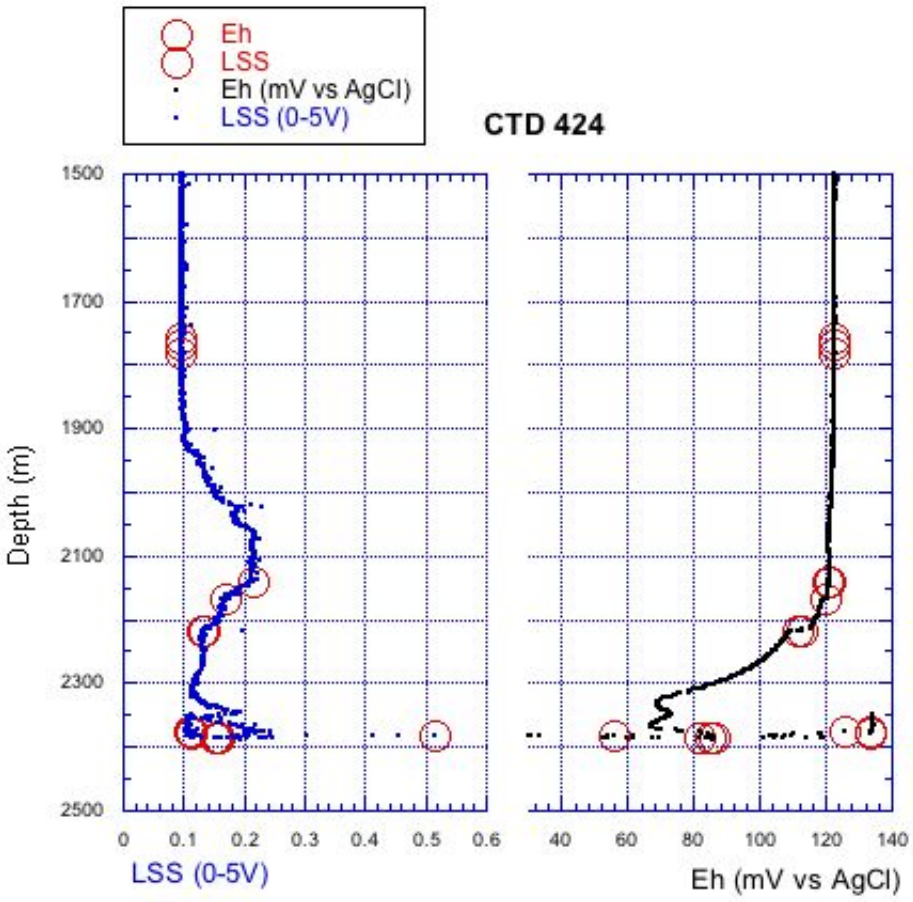

Fig. 6. - Example up-cast CTD cast at Black and White smoker. The neutrally buoyant plume is between 1900-2200m - as visible in the Light Scattering Sensor (LSS) signal. The buoyant plume occurs at ~2375m. Both LSS and Eh are activated here, and the Eh takes ~200m of clean water to equilibrate to background levels. Niskin firing positions are indicated by red circles.

The bottles were fired in groups of three or four at depths of interest, and each group was sampled for some or all of the following:

Methane, nutrients, dissolved inorganic carbon (DIC), dissolved and total organic carbon (DOC/TOC), dissolved and total metals, Rare earth elements (REEs), iron isotopes, metal speciation and metal particle analysis. Total numbers of samples can be found in Table.1. Additionally a series of samples were collected which then were left on the CTD carousel and sampled at various time intervals to provide a time-series study for both metals and REEs.

Kemp Caldera

CTD casts were made over the 'Great Wall', which is a diffusing system that appears to effuse sulphur-rich fluids. A neutrally buoyant plume was sometimes observed ~200m above the Great Wall, which is thought not to be associated with the Wall itself, as the fluids emanating from the Wall are only about 40°C (As

sampled in 2010 on JC042). These temperatures are not typically high enough to account for such a plume rise. An additional plume of particulate matter was often observed (to varying degrees) at ~950m depth. This is of unknown origin. Particle analysis should shed some light on the origin of both neutrally buoyant plumes.

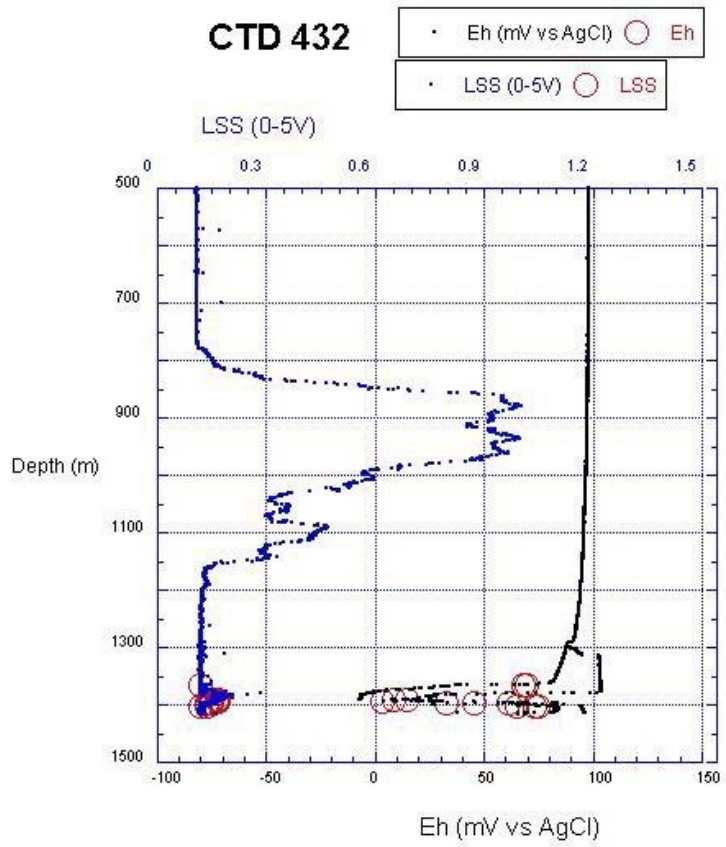

Fig. 7. - Example CTD up-cast at the Great Wall. The narrow plume at 1100m (visible in LSS) is thought to be associated with either the 'Winter Palace' or 'Toxic Castle' white smokers. The wide plume at ~950m is of unknown origin. It coincides with the height of the rim of the Kemp crater, so may be water mass related. The reducing fluids from the Great Wall are responsible for the low Eh signal between 1350-1400m. Niskin firing positions are indicated by red circles.

In total, six profiles were taken in the Kemp Caldera - five over the Wall and one background (59°42.000, 28°19.000). Total numbers of samples can be found in Table1.

In addition, two CTD casts were undertaken in the 'Adventure Crater', which was recently discovered on the Kemp Seamount. Neither cast detected any signals, though a chimney effusing shimmering water was observed with the SHRIMP camera system on the seafloor, at a shallow depth of ~500m.

Table 1. list of samples collected on JC055 for Water Geochemistry.

Sediment Geochemistry

Bransfield Strait Geochemistry Coring Activity

Alfred Aquilina, Cathy Cole, Doug Connelly, Jeff Hawkes, Laura Hepburn, Darryl Green, Rachel Mills

The Bransfield Strait is a 400 km-long sedimented marginal basin between the South Shetland Arc and the Antarctic Peninsula. Hydrothermal activity in this basin has been inferred from water column anomalies and sulfidic deposits dredged from volcanic highs. Our working area was within the Central Basin between the two subaereal volcanic islands Bridgeman and Deception. Seafloor spreading rates in this basin are ~1cm yr^{-1} (Peterson et al., 2004). The volcanic highs within the Central Basin strike parallel to the South Shetland Arc.

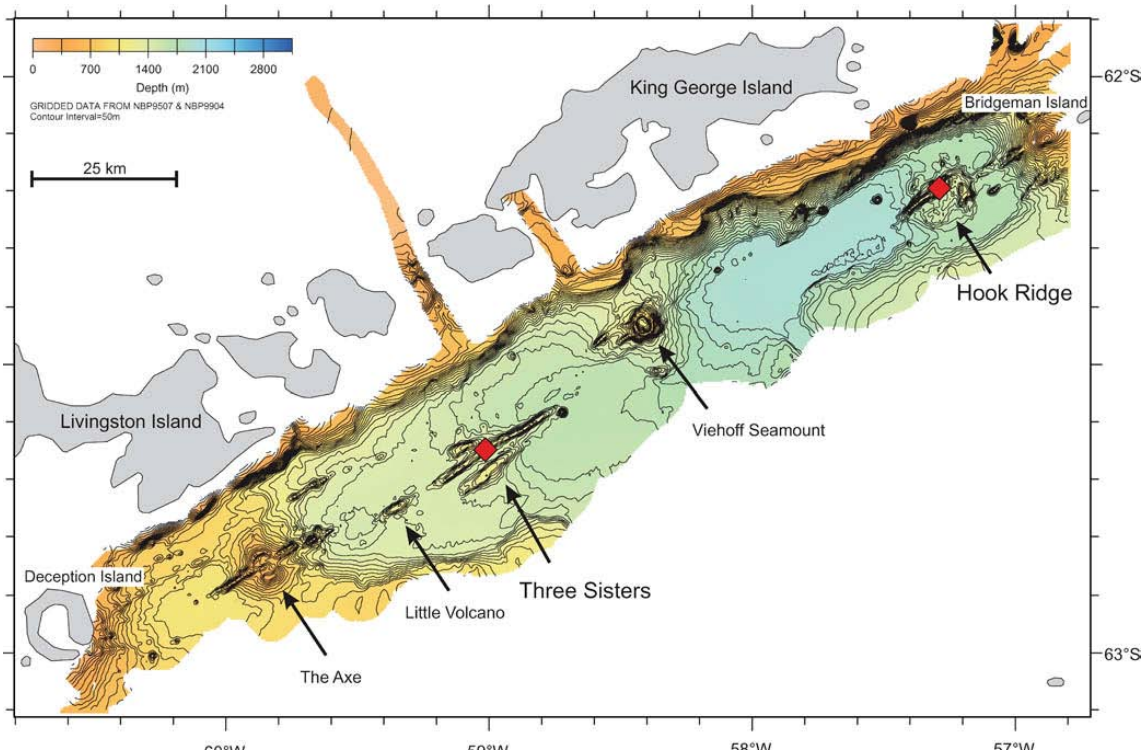

Fig. 8: Bathymetric map of Central Basin (from Peterson et al. 2004). Red diamonds indicate areas of known hydrothermal activity.

Hook Ridge

Plume distribution over the Hook Ridge has previously been used to identify likely locations of hydrothermal discharge (Klinkhammer et al. 2001) and hot sediments have been collected along the southeast side of the crest of the Ridge (Dahlmann et al. 2001). Pore fluids extracted from the hot (up to 50^{o}C) cores imply upwelling (18-40 cm/yr; Sahling et al. 2005) of low-pH, low-chlorinity, low-sulfate, high-sulfide, high-methane and high-ammonia fluids. The hydrothermal precipitates collected include polymetallic sulfides,

barite, pyrite, marcasite mixed with lithified diatomaceous and volcaniclastic sediment (Peterson et al. 2004). Native sulfur and opaline silica are common infilling minerals.

Coring locations

We identified two main coring targets at Hook Ridge (see Figure 9) which were occupied from JD23 to JD27 and on JD34 in 2011. SHRIMP survey indicated the presence of shimmering water, mineralized substrate and sediment cover suitable for core deployment.

	Statio	Long	Lat	Long	Water Depth

Table 2 Coring loc

**Background Site*

The Background core site was on the adjacent shelf region at an equivalent depth (1150 m). Note that this site is ~3km from the wreck of the *MV Explorer* which sank in 2007 (62° 24'S, 57° 12'W in 1130 m water)

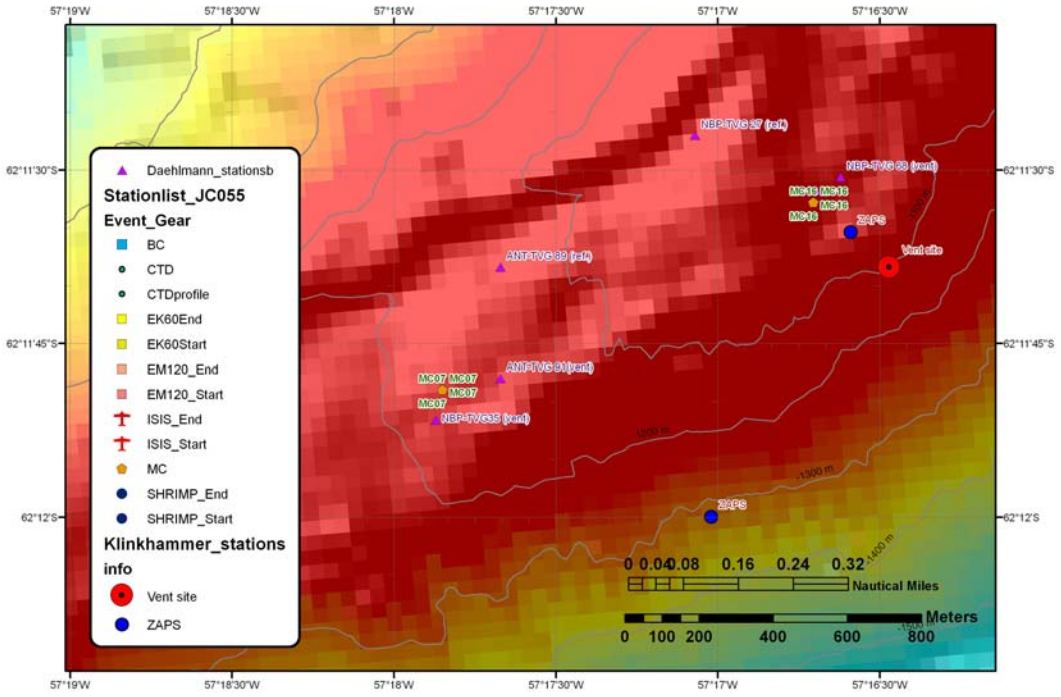

Figure 9: Map showing crest of Hook Ridge with coring sites from JC055. Klinkhammer et al. (2001) and Dahlmann et al. (2001) coring sites are shown for comparison.

Onboard Chemistry: Results

Stations 11-13: Background shelf site

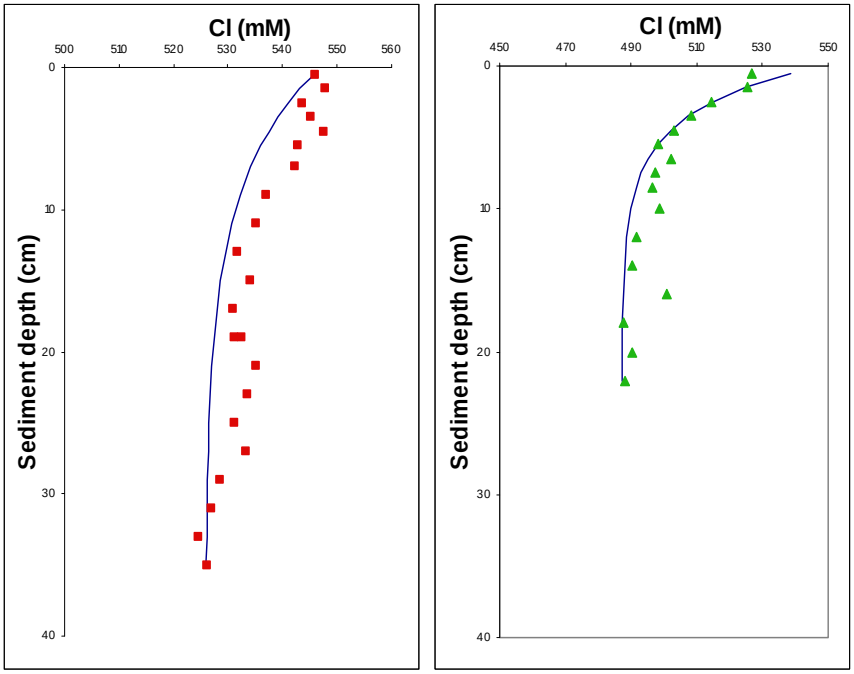
The oxygen penetration depth at this site is inferred to be ~2.5 cmbsf (based on extrapolation of oxygen probe data). Pore fluid ammonium is high in the oxygenated zone (up to ~285 µM), dropping sharply to values of 70-180 µM throughout the rest of the core (to 32 cmbsf). H_2S is below detection limit throughout the core and methane content is low (~0.15 µM) in the lower core (25-35 cmbsf). Alkalinity determinations indicate significantly enhanced values over seawater below 13 cmbsf (3-4 mM) and there is evidence for sulfate depletion below sea water values (sulfate reduction) at depth.

Stations 18 (MC7), 30 (MC16) and 81 (MC27): Hook Ridge

MC7 (and the replicate biology deployments) was collected close to TVG site 35 (Dahlmann et al. 2001). This area is characterized by pyrite/marcasite crusts with areas of silicified sediment (Peterson et al. 2004). 3 sub cores were taken from MC7, one for oxygen analysis, one for pore fluid extraction and solid phase storage (freeze dried on board) and one frozen at -20^{o}C for biomarker analysis. A 4.5 m Gravity Core was also collected from this site, sectioned, split, photographed, logged and stored on board.

MC16 (and the replicate biology deployments) was collected close to TVG site 68 (Dahlmann et al., 2001) where ~50^{o}C cores were collected (Klinkhammer et al., 2001). Solid phase samples from this region have been described as silica crusts, native sulfur and sulfide/sulfate talus (Peterson et al. 2004). 3 sub cores were taken from MC16, one for oxygen analysis, one for pore fluid extraction and solid phase storage (freeze dried on board) and one frozen at -20^{o}C for biomarker analysis. Two subcores from MC27 were collected from the TVG site 68 position.

Seawater anions (Cl, Br and SO_4) are all depleted relative to sea water below surface at both sites; core top values are close to seawater values. Advection rates at Hook Ridge can be modelled using the high-resolution pore water profiles by fitting a one-dimensional transport-reaction model. Chloride is chosen as it behaves conservatively in this environment and, therefore, the reaction term can be ignored (Dahlmann et al., 2001). The inferred hydrothermal end-member fluids are depleted in chloride due to phase separation at high temperatures and relatively low pressure (subcritical phase separation). The Br/Cl ratios are close to sea water values throughout indicating no fractionation of these two elements during phase separation.



MC7: v = 21 cm yr^{-1} MC16: v = 48 cm yr^{-1}

Fig.10: Downcore plots of pore water chloride at the two hydrothermal sites. Blue line is the modelled fit to the data indicating upward advection of low chlorinity fluids at rates of 20-50 cm yr^{-1}. Note the background core has seawater chloride content throughout.

Oxygen penetration depths over the Hook Ridge are 1.5-5.5 cmbsf. Ammonium increases with depth below the depth of oxygen penetration at both sites to values of 226 µM (MC7) and 400 µM (MC16) which are significantly higher than the background site but somewhat lower than published values. Ammonium increases are associated with organic matter remineralisation in suboxic sediments and upwards advection of hydrothermal fluids through these cores. Hydrogen sulfide increases from zero at 10 cmbsf to ~150 µM at 35 cmbsf in core MC7. H_2S in core MC16 remains close to zero throughout the core. Alkalinity increases to maximum values of 4-5.5 mM with depth and are significantly higher than background values in MC16.

.

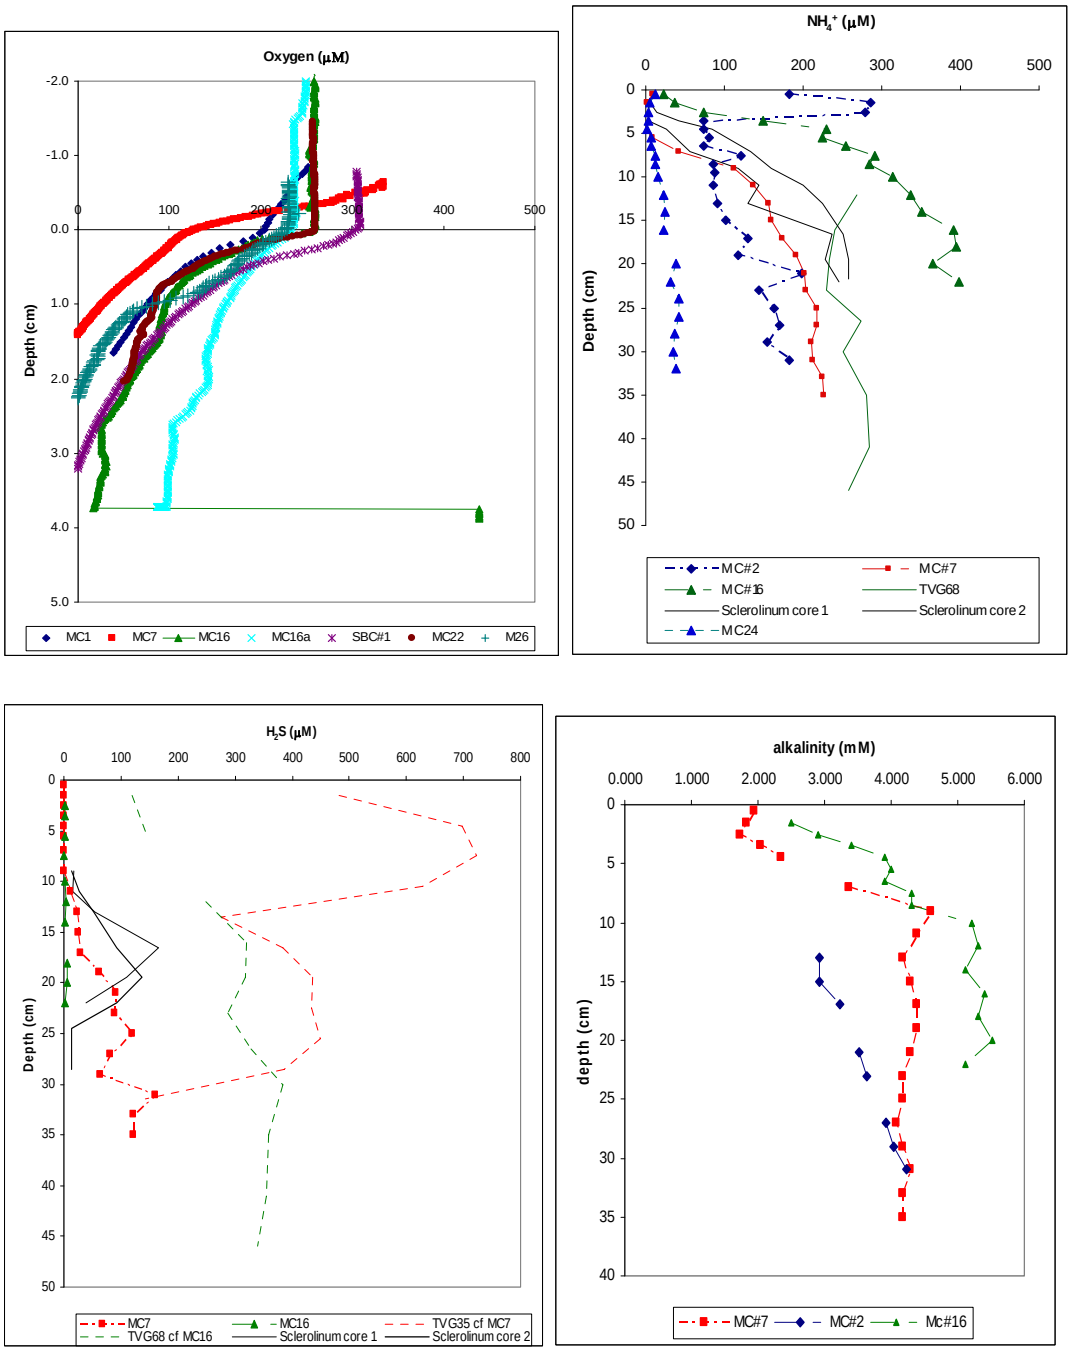


Fig. 11: Down core plots of (a) oxygen, (b) ammonium, (c) hydrogen sulfide and (d) alkalinity in pore fluids extracted from the sediments at the background and hydrothermal sites.

Chloride is inferred to behave conservatively within the hydrothermal sediments at Hook Ridge (Dahlmann et al., 2001). Sulfate shows slight depletion relative to the mixing line between the sea water end member and the inferred low salinity phase separated end member fluid. For MC7 core top values fall on the mixing line, whereas samples from deeper than 5.5 cmbsf show slight sulfate depletion (0.2 to 1.1 mM). Core MC16

shows sulfate depletions of 0.3-1.7mM. Sulfate reduction occurs either via oxidation of organic matter in sub/anoxic environments or via the anaerobic oxidation of methane (AOM).

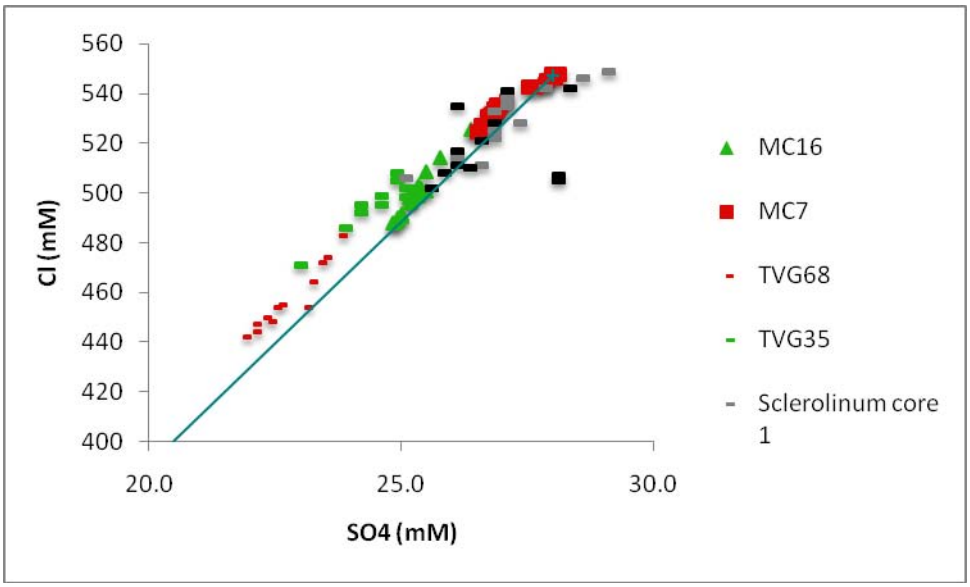

Fig. 12: Plot of chloride against sulfate content for Hook Ridge cores. The blue line indicates linear mixing of sea water with a fresh water vapour phase derived from subcritical phase separation at shallow depths.

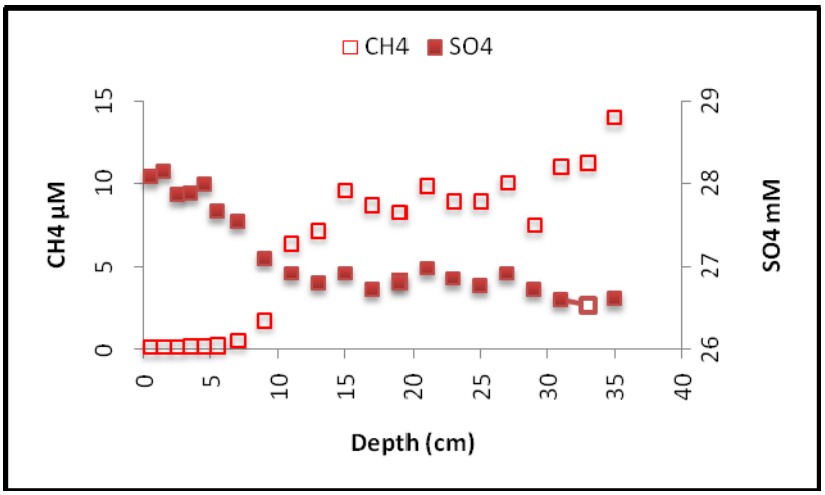
Methane increases below the surface in both Hook Ridge cores with the highest values observed in MC7 (up to 15 µM; data need correcting for shore-based porosity measurements). In both cores, the increase in methane concentrations is concomitant with a decrease in sulfate, suggesting the occurrence of anaerobic oxidation of methane by sulfate (AOM). This is consistent with the occurrence of hydrogen sulfide at this depth. The occurrence of AOM will be assessed on-shore using stable isotope/organic geochemical techniques.



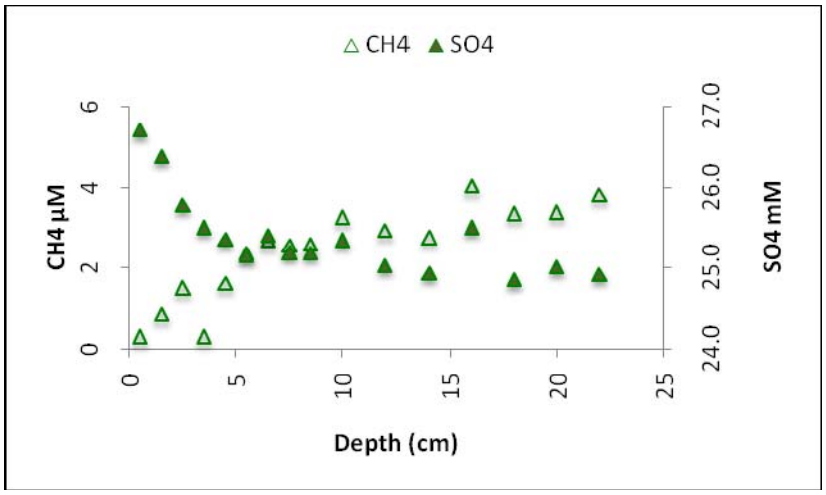


Fig. 13: Down core plots of (a) sulfate and methane in MC7 and (b) sulfate and methane in MC16 for Hook Ridge

Overall core MC7 shows close similarities to the *Sclerolinum* hosting sediments described by Sahling et al. (2005). The core base temperature was ~2^{o}C above the core top temperature on recovery indicating marginally warmer water was present at the seafloor (c.f. temperatures of ~4.5^{o}C measured by Sahling et al., 2005). The 4.5 m gravity core collected at this site is dominantly olive green diatomaceous ooze intermixed with coarse grained intervals of sulfide/sulfate debris. No significant or measurable temperature anomaly was observed during any of the replicate biology deployments at this site.

There is little detectable H_2S throughout MC16 though there is relatively rapid advection of low-chlorinity fluid through the sediment. There is significant alkalinity increase, and sulfate decrease with depth. No temperature anomalies were observed in this core deployment or any of the subsequent biology replicate coring deployments.

Three Sisters

Klinkhammer et al. (2001) described small dissolved Mn and particulate Fe anomalies above the Middle Sister ridge crest. Peterson et al. (2004) dredged hydrothermal crusts and other precipitates from the ridge crest.

We cored at two sites on the Middle Sister on JD31; one near the ridge crest, the second in deeper (1300 m) water between the volcanic edifices.

	Static	Leng	Lat	Long	Water Depth
Mega Core	48	15.5-17	62º 39.21	59º 01.8	1150
Mega Core	50	27-39	62º39.31	57º03.01	1311

The ridge crest core site (MC22) led to shallow core recovery. One subcore was analysed for oxygen (penetration depth ~2 cmbsf) and one subcore was frozen for biomarker analysis.

The deeper coring site (MC24) recovered longer sediment subcores (up to 40 cm) which were sampled for oxygen, pore fluid extraction and frozen for biomarker analysis.

The oxygen penetration depth at MC24 was similarly shallow (~2.5 cmbsf). Alkalinity was constant downcore and similar to seawater values. Ammonium was close to zero at the core top increasing to ~40 µM by 30 cmbsf. No hydrogen sulfide or methane measurements were made.

The Axe

The Axe volcanic edifice swath and sub-bottom profiling indicates that the sediment cover is negligible. One mega core deployment was made on the flanks of the edifice in 1024 m of water.

	Static	Leng	Lat	Long	Water Depth
Mega Core	78	36-38	62º 47.26	59º 45.9	1024

Three subcores were taken: one for oxygen measurements, one for pore fluid extrusion and one frozen for biomarker analysis. Ammonium shows little variation with depth and values of up to 45mM were observed at 33 cmbsf.

Kemp Caldera Coring Activity

Alfred Aquilina, Cathy Cole, Doug Connelly, Jeff Hawkes, Laura Hepburn, Darryl Green, Rachel Mills

Kemp Caldera is a submarine feature that lies to the west of Kemp seamount at the southern tip of the South Sandwich Island arc. In 2009, SHRIMP discovered the potential presence of hydrothermal activity during the *JCR224* cruise. This was confirmed in 2010 when *JC42* returned to the site with the ISIS ROV and discovered a number of different chemosynthetic habitats, including: white smoker vent fields, extensive areas of diffuse-flow, and a whale fall to the NE of a small sub-cone in the centre of the crater (see inset of Figure 1).

During *JC42*, ISIS-mounted push cores retrieved a total of 24 samples from each of these areas (19 of these were extruded successfully). The single successful 2 m gravity core (undertaken > 200 m to the east of the

surveyed sub-cone) sampled just 20 cm of sediment from the centre of the caldera. No megacores were taken from the crater.

This cruise revisited the whale fall and 2 diffuse-flow sites (Snowfield and Toxic Castle). Without ISIS we were unable to obtain push core samples, so these areas were sampled using the gravity core and megacore.

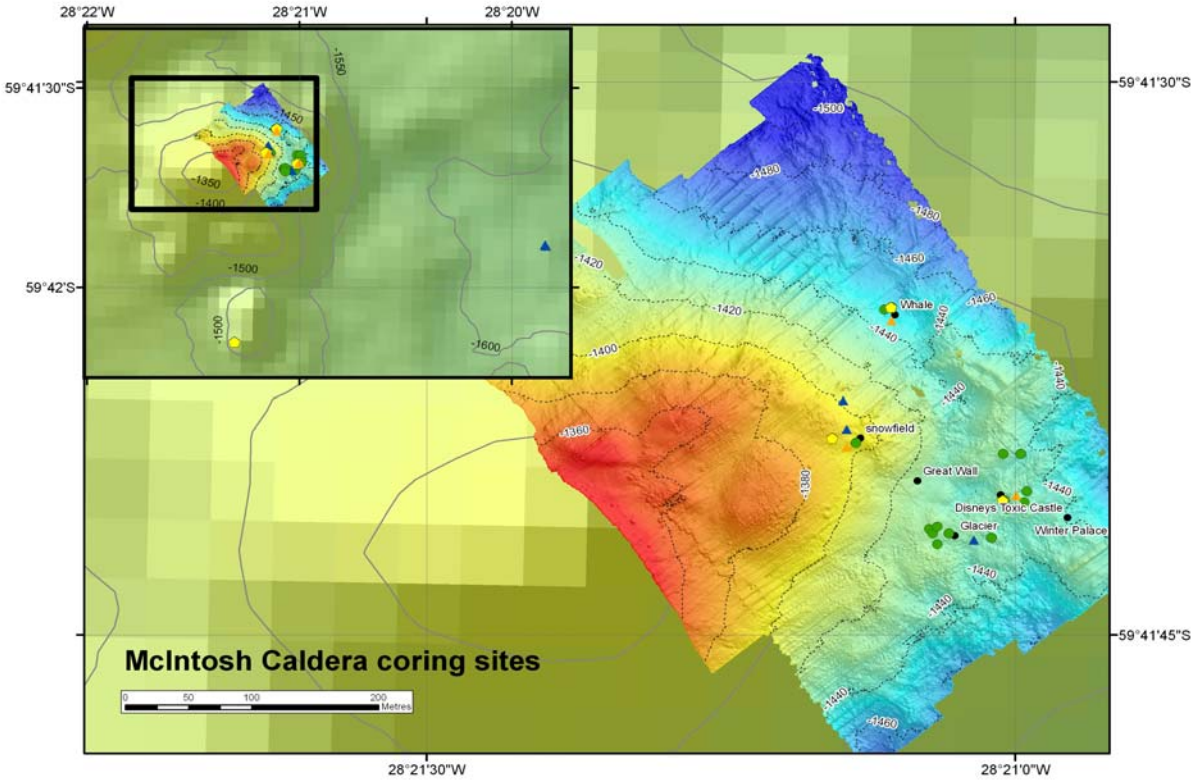

Fig. 14. Main coring activity on the Kemp (McIntosh) Caldera subcone during *JC42* and *JC55*. Inset frames the entire coring area to include a gravity core and megacore taken from the centre of the caldera. Gravity cores, megacores and push cores are represented by triangle, circle and pentagon icons respectively. Stations marked by dark blue and dark green icons were conducted during *JC42*, while those in orange and yellow were sampled on *JC55*. The southernmost megacore shown on the inset was taken for biological sampling only.

All JC42 and JC55 coring sites are shown in the SWATH diagram in Figure 14.

Sediment cover within the Kemp Caldera is thin and coring attempts at each of the hydrothermally-active sites yielded short cores comprised mainly of rubble and broken *Calyptogena* (clam) shells. A brief description of all sediment sampled via gravity coring and megacoring at the caldera for *JC55* is given in Table 3. All samples have been bagged and stored cold; they will be transported back to NOCS where they will be analysed for their geochemical and mineralogical composition.

Core ID	Length	Lat	Long	Comments
JC055_092_MC28	4 cm	59° 41.68915	28° 21.0102	Circular chunk of hard, light grey rock with thin, white layer of anhydrite / microbial mat

TABLE 3. Megacore (MC) and gravity core (GC) sediment description and location information. JC055_092_MC28 and JC055_106_GC2 are from Toxic Castle; JC055_097_MC29 and JC055_108_GC4 are from the Whale Fall; and JC055_098_MC30 and JC055_107_GC3 are from Snowfield (see Figure 14).

South Georgia coring activity

The continental shelf near South Georgia is characterised by substantial sediment cover. Relatively high methane concentrations have been measured in the water column (JR224) and in sediments (up to 1.5mM, JC42-GC02). Putative methane seeps were, however, not observed using visual surveying of the region during expeditions JC42 and JC55. EK60 echo-sounder surveys carried out during JC42 and JC55 suggested the potential presence of gas bubbles emanating from the seafloor on the continental shelf near South Georgia; subsequent SHRIMP surveys did not confirm the presence of gas plumes at the sea floor.

Coring locations

Coring activity near South Georgia was carried out during JD45 and JD46 (Figure 15; Table 4). Megacores were used to measure oxygen profiles (on-board), to extract pore fluids (on-board) and for lipid biomarker analysis (on-shore). Gravity cores were cut into sections and stored with no further processing. Note that coring stations 111,112 and 117 coincide with two of the three stations at which the EK-60 surveys suggested the potential presence of gas plumes.

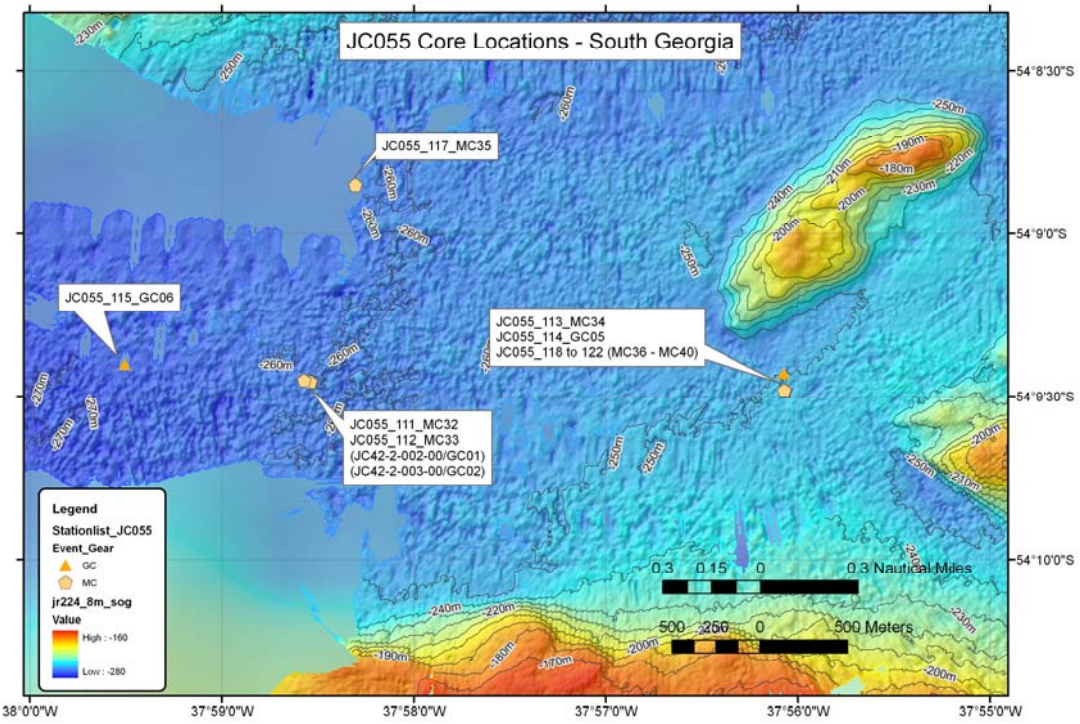

Fig. 15. Locations of cores collected from near South Georgia for geochemical analysis.

JC55_118_M	1	36	54° 9.4	37° 56.0	247

On board chemistry: Results

Station 112 (MC33)

The oxygen penetration depth at this site is approximately 1.5 cm (MC32). Pore fluid ammonium concentrations increase with depth to more than 700 µM at 27 cm depth. Concentrations of methane increase to 2µM in the top 20cm and further to 7µM at 27cm. Pore water sulphate concentrations decrease from 27.5

mM at the surface to 22.9mM at 27cm. H_2S concentrations of <2µM occurred in the top 13cm, these subsequently increased to 0.288mM at 27cm. Alkalinity increased from near seawater values (2.305mM) at the surface of the core to 10.508mM at 27cm. Chloride concentrations varied between 535mM at the core top to 531mM at the bottom.

Station 113 (MC34)

Down-core oxygen concentrations were not measured at this site. Pore fluid ammonium concentrations increased to >500µM in the deepest sample at 17.5cm. Concentrations of methane were low throughout the core, reaching 0.6µM at 18cm. Pore water sulphate concentrations decrease from 27.4mM to 25.8mM at 18cm. H_2S concentrations too were relatively low, and did not exceed 0.003mM. Alkalinity increased with depth from seawater values (2.325mM) at the top to 5.762mM at 18cm. Chloride concentrations varied between 531mM and 533mM.

Note: This coring location is the only one of the described in this section at which no putative gas signals were detected by the EK60-echosounder.

Station 117 (MC35)

The oxygen penetration depth at this site is approximately 2.0cm (MC35). Pore fluid ammonium concentrations increased to >800µM at 29cm depth. Concentrations of methane increased from 0.06µM at the surface to 9.8µM at 29cm. Pore water concentrations decrease from 27.3 to 21.2mM at 29cm. H_2S concentrations were low (<0.002mM) in the top 15cm. Alkalinity increased from 2.123mM at 0.5cm to 11.9mM at 29cm. Chloride concentrations varied between 530mM and 524mM.

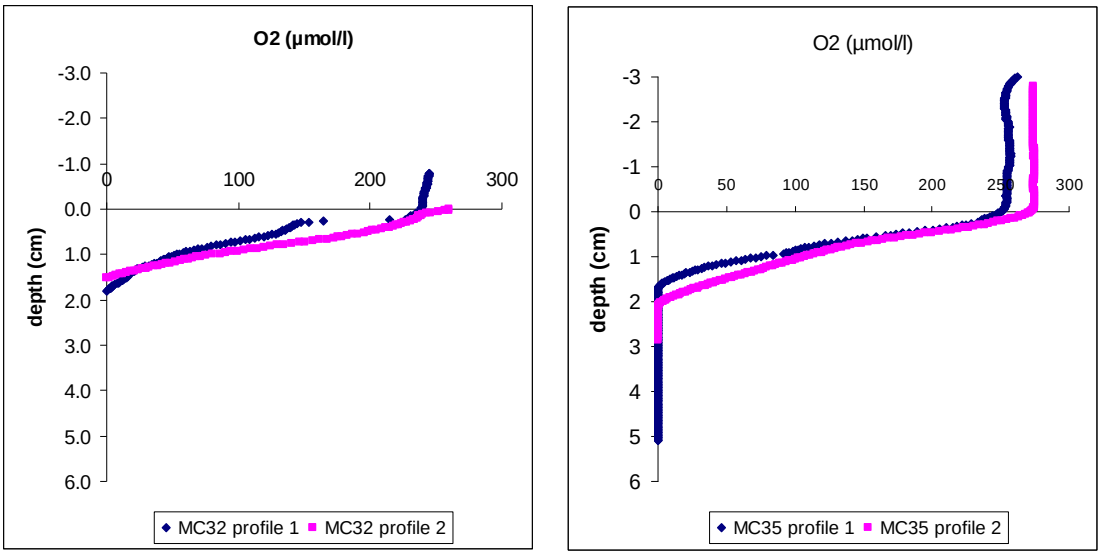

Fig. 16. Oxygen depth profiles for MC32 (station 111) and MC35 (station 117).

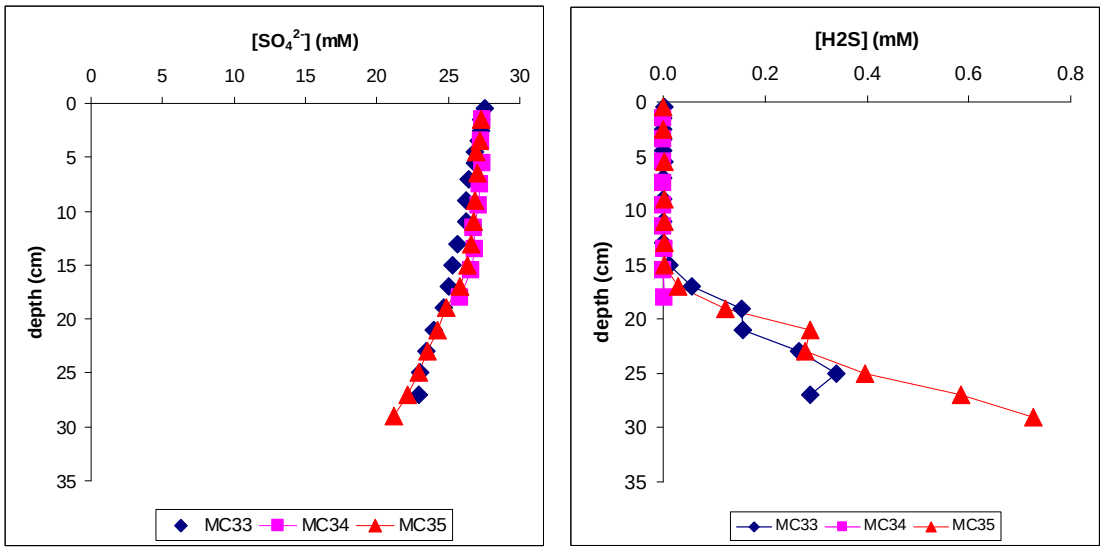

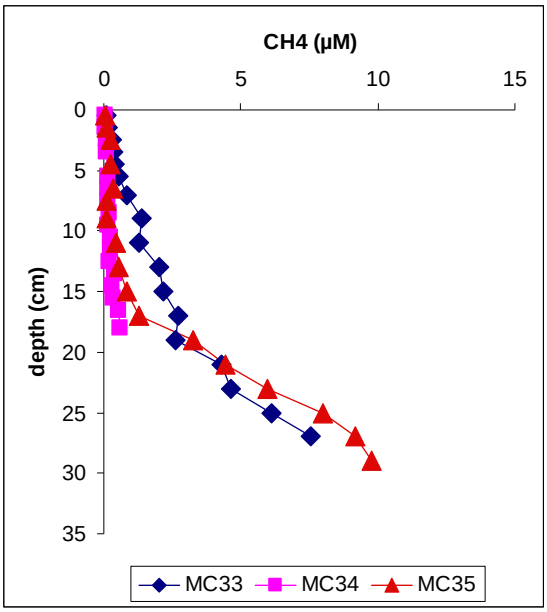

Fig. 17. Down-core pore water sulphate, sulphide and methane concentrations.

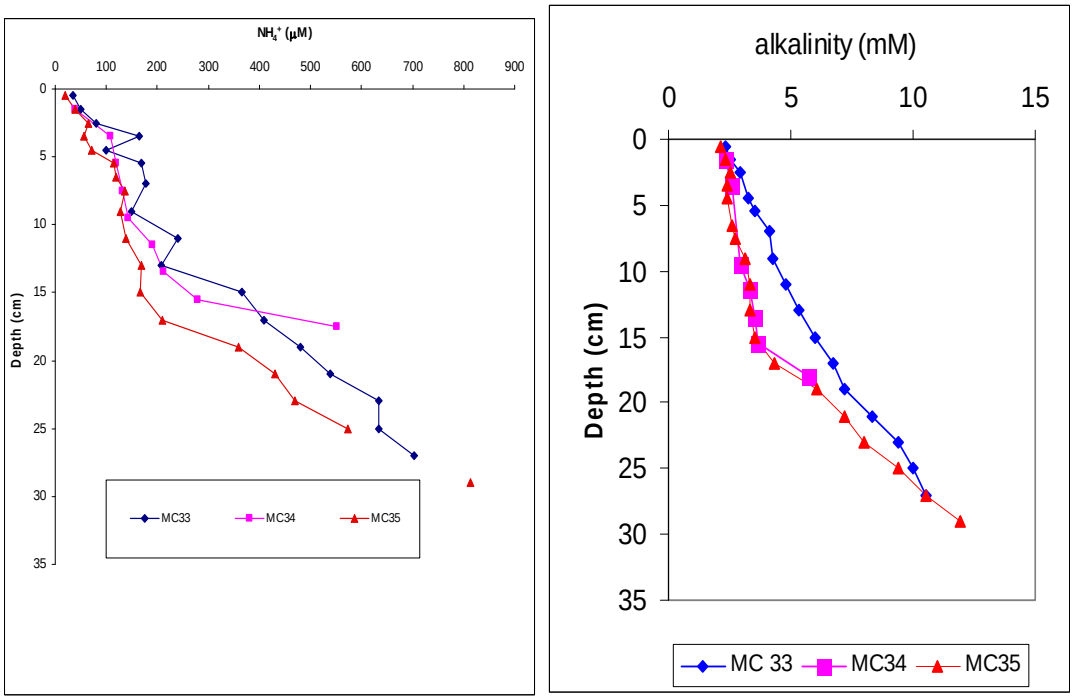

Fig. 18. Concentration depth profiles of ammonium and alkalinity

JC42 South Georgia gravity core GC02

Pore water profiles from gravity core GC02 (collected in 2010 during expedition JC42) are provided here to allow comparison with the megacore pore water profiles measured during JC55. Note that the coring location of JC42-GC02 coincides with JC55 coring stations 111 and 112.

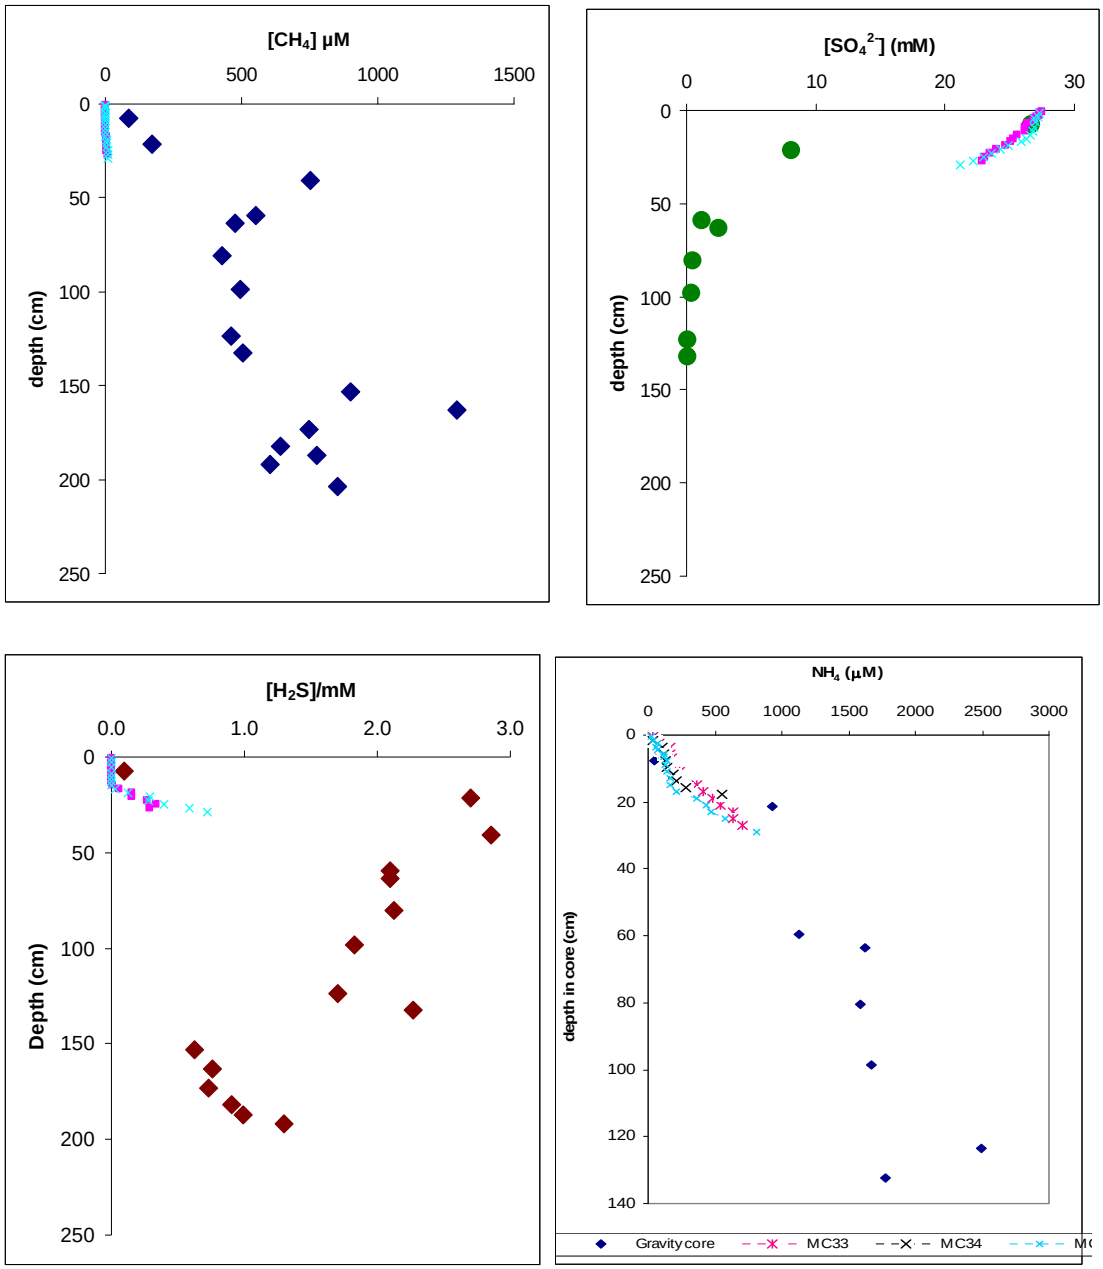

Fig. 19. Down-core concentrations of methane (blue diamonds), dissolved sulphate (green circles), sulphide (brown diamonds) and ammonium (blue diamonds) in gravity core JC42-GC02. Corresponding values for JC55 megacores 33 and 35 are included for reference.

The sulphate-methane transition occurs at around 50cm in GC02. At this depth sulphate concentrations <2.5mM occur, coinciding with an increase in methane content. Similarly, sulphide concentrations above 2 mM occur at this depth.

It must be noted that gravity cores (unlike megacores) are susceptible to significant (~50%) compression when extracted from the seafloor and, therefore, caution needs to be exercised when comparing depth profiles between the two types of cores.

Microbiology

Katrin Zwirglmaier, David Pearce

Hydrothermal vents provide a wide range of habitats for micororganisms and the diversity of microbial communities can vary from one or two species in the case of endo- or episymbionts to diverse communities of Archaea and bacteria and their viruses, as well as single cell eukaryotes. Organisms may be attached to substrata, form microbial mats, live as endo- or episymbionts, or occur as free cells in venting fluids, buoyant and neutrally buoyant plumes above the vents and in the sediment. The main aim of the microbial studies is to elucidate the diversity of a variety of biotopes in vents and compare this diversity to that known from comparable environments in the Pacific and Atlantic Oceans as well as non-venting areas near the sampling sites. This will include studies on both prokaryote and eukaryote microbial communities as well as bacteriophage.

Defining the microbial taxa that inhabit Southern Ocean chemosynthetic environments will help to determine what elements of primary production and carbon cycling are present and in which biotopes or habitats they are occurring. This work is directly linked to biomarker and isotope studies (Chris Sweeting/Will Reid, Newcastle, Clare Woulds, Leeds) and to the physical and geochemical background in which samples are taken (Doug Connelly/Jeff Hawkes/ Cathy Cole/Darryl Green/Rachel Mills/Alfred Aquilina/ Laura Hepburn, NOC).

On JC42 (2010), a range of vent fauna samples was collected at the ESR sites E2, E9 and the Kemp caldera. Analysis of the endo- and episymbionts of these samples is still ongoing. In addition, water samples from CTDs and ROV Niskins were collected at selected sites. Only one sediment sample (from South Georgia) was obtained, as the seafloor at the other sites proved to be unsuitable for coring.

On JC55, due to the loss of ROV ISIS, no vent fauna samples were obtained for microbiology. Instead, this provided the opportunity for extensive CTD sampling of the water column, as well as a large number of sediment samples. CTD samples were taken at five sites in the Bransfield Strait (BSR, Hook Ridge, Three Sisters, Orca, The Axe). At ESR, E9 and the Kemp caldera were re-visited and sampling there focussed on buoyant and neutrally buoyant plume the Black & White smoker (E9) and Great Wall (Kemp). Both Black & White and Great Wall had been sampled on JC42, therefore allowing comparison of microbial diversity in the 2010 (JC42) and 2011 (JC55) samples.

Transmission electron microscopy (TEM) of selected CTD samples from JC42 has revealed a number of bacteriophages with previously undescribed morphology. The literature on bacteriophage diversity in hydrothermal vents is still very limited and this presents the first study of this kind in Antarctic vent systems. Due to the limited number of CTD casts on JC42, the volume for most of these samples was not large enough

to allow DNA extraction and further analysis of the bacteriophage community. Therefore, on JC55 special emphasis was placed on obtaining larger volumes (>100L) and concentrating bacteriophage through tangential flow filtration.

1. Water samples

Sampling

Samples were taken with a CTD with 24 10L Niskin bottles. The sample volume varied between 80-220L (see sample list). The water was drained from the Niskin bottles into 50L plastic barrels that had been rinsed with MQ water. The samples were stored in the CTD hangar (ambient temperature <10°C) until processing.

Processing of samples

Water samples were processed for 5 different types of analysis: 1. Flow cytometry, 2. Fluorescence in situ hybridisation (FISH) filters, 3.phage counts, 4. DNA (bacterial, archaeal and eukaryotic) and 5. tangential flow filtration (TFF) to concentrate phage. Sample types 1-3 were processed immediately after the CTD came on deck, processing for DNA extraction, especially for volumes >100L, took up to 48h.

1. Flow cytometry

1ml sample was transferred to an Eppendorf tube and fixed with 0.5% glutaraldehyde. Samples (in triplicate) were stored at -80°C.

2. FISH filters

50ml sample was filtered onto a 0.2µm 25mm diameter black polycarbonate filter using a glass filtration unit and a hand pump. Filters were air-dried and then fixed in 4% paraformaldehyde for 1-6h at 4°C. After that, filters were briefly dipped in MQ water and then dehydrated in 50, 80 and 100% ethanol for 3min each. Filters were air-dried and stored at -80°C. For each sample 10 filters were used.

3. Phage counts

a) unfiltered sample was stored at 4°C in 4x50ml tubes

b) 0.2µm filtered sample was stored at 4°C in 4x50ml tubes

c) unfiltered sample was stored at -80°C in 4x50ml tubes

4. DNA extraction (bacterial, archaeal, eukaryotic)

The entire remaining volume of the sample (between 80-220L) was filtered onto 0.2um filters for DNA extraction. Filtration was done with a vacuum pump connected to a filtration manifold with 10 Sartorius filtration towers. Whatman GF-D glass fibre filters were used as support for the 0.2um, 47mm diameter cellulose nitrate filters (Whatman). The filters were frozen at -20C and then stored at -80C. The filtrate was

collected and used for the tangential flow filtration for bacteriophage/ virus concentration.

5. Tangential flow filtration

Bacteriophage and viruses in the 0.2um filtrate were concentrated using a peristalitic pump (Millipore Masterflex) and a Pellicon cross-flow filtration unit (Pellicon 2 cassette, Biomax-10, 0.5 m2 surface, 10kDa cut-off). The final sample volume after the concentration was 150-400ml, which was frozen at -80C.

Analysis

All analysis will be done back on land. The main focus will be on the DNA samples, i.e. pyrosequencing of 16S/18S rDNA PCR products to determine bacterial, archaeal and eukaryotic diversity, potentially metagenomic sequencing to determine functional capacities of the microbial population, as well as FISH analysis to complement and confirm the sequence data. For bacteriophage/viruses, further TEM will be done to compare phage morphology and abundance at different sites, as well as some pyrosequencing of structural phage genes to assess phage diversity.

2. Sediment samples

Aim: To assess the microbial biodiversity of previously identified Southern Ocean chemosynthetic communities and to use the biodiversity so obtained to conduct a biogeographic comparison with chemosynthetic communities described from other parts of the world. The hypothesis under investigation was that the chemosynthetic communities of the Southern Ocean harbour a unique microbial biodiversity, which differs significantly from those found elsewhere.

Methods: The microbial community will be accessed through direct culture on both selective and non-selective media, extraction of DNA from both seawater filtrate (see above) and sediment and direct sampling of microbial mats. General microbial biodiversity will be assessed through a combination of microscopy, community profiling and 454 sequencing. Specific groups / microorganisms will be targeted through FISH and using specific PCR primers. Comparison of selected common groups will be achieved through multi locus sequence typing (MLST) where a culture is obtained and sequence alignment for DNA only uncultivated samples. Specifically targeted groups are: bacterial mats, extremophiles (and in particular thermophiles) and the fungi. Samples collected will also be used to determine detection limits for the various techniques, for subsequent cross comparison with other sites.

Results: Sediment cores were obtained in triplicate with the mega-corer at Hook Ridge (both over the site of activity and a control site), at Three Sisters, and only one at the Axe in the Bransfield Strait, and three at South Georgia. Sections were cut at intervals of 0-1, 1-2, 2-3, 3-4, 4-5, 10-11, 15-16 and 20-21 cm. These sections were frozen at -80C in independently sealed plastic bags. Water samples were obtained from CTD drops as described by Katrin Zwirglmaier.

Discussion: We will not be in a position to extract and examine the samples until they are returned to the UK. It was not possible, without the use of an ROV to sample bacterial mats directly, take push cores in specific locations or select material that is likely to harbour extremophilic microorganisms. It was also only possible to sample vent water in the plume from a distance using a CTD. Although we have a large number of samples, it remains to be seen whether they can provide the basis for a comprehensive biodiversity / microbial biogeography assessment, and much reliance will have to be placed on samples returned from JC42.

Potential co-ordination opportunities: Sediment samples were taken to coincide with chemical / geological analyses. Sediment will be co-extracted for biodiversity and functional analysis studies. Sub-samples from stable isotope experiments could be analysed for the microbial contribution.

Samples sought but not obtained: Bacterial mat samples, high temperature porous rock fragments, push cores and pore fluids.

Isotope tracing experiments: Clare Woulds

Introduction

Chemosynthetic ecosystems represent interesting and new setting for studies of benthic food webs, sedimentary carbon cycling, and microbiology. The presence of in situ carbon fixation, conducted by diverse assemblages of microbes, via unusual redox reactions, clearly has implications for ecosystem C sources and flow pathways. However, chemosynthetic settings have not yet been fully characterised, and questions remain regarding the functioning of many/most of the organisms found there. Specifically, it is not clear to what extent chemosynthetic ecosystems rely on in situ production, versus phytodetritus from the water column, nor which microbial processes are most active and important.

Therefore, this study aims to conduct isotope tracing experiments to characterise and quantify C and N flow through chemosynthetic ecosystems.

Objectives

1) To contrast in situ production and phytodetritus as C and N sources for chemosynthetic communities.
2) To identify the main bacterial groups responsible for in situ production.
3) To characterise and quantify the short-term fate of organic C and N in chemosynthetic sediments.
4) To establish the role of archaea in benthic C and N cycling in both chemosynthetic and regular sedimentary environments.

Approach

Experimental

Isotope tracing experiments were conducted at four sites: Hook Ridge (JC55_30), Middle Sister (JC55_51), South Georgia (JC55_111), and an off vent background site (JC55_11), in the Bransfield Strait. The experimental protocol at each site was as follows:

1) Four replicate megacores were collected from a single deployment.
2) Isotopically labelled substrate was added to each core. Two of th four cores received ^{13}C and ^{15}N labelled algal cells (dead), which were allowed to settle onto the sediment surface (dose = 435 mg C m^{-2}). The other two cores received ^{13}C bicarbonate (dose = sufficient to make surface 3 cm of porewater 1 mM labelled bicarbonate) and ^{15}N ammonium (dose = sufficient to make surface 3 m of porewater 7 M labelled ammonium). In this case the solutions were injected into the porewaters of the surface 3cm.
3) Cores were then left in a cold environment (in the hanger) for 2 hours for the algae to settle.

4) Cores were sealed using custom built core tops (Fig. 20), which are equipped with magnetic stirrers and sampling ports.
5) Cores were incubated at in situ temperature, with stirring of core top water, for ~48 hours.
6) Every 12 hours a sample of core top water was withdrawn. The samples were preserved for isotopic analysis of DIC (in crimp-cap vials, poisoned with $HgCl_2$) and NH_4^+(by freezing).
7) Experiments were terminated by extruding and sectioning the cores. Half of each slice was frozen (-80°C), and half was preserved in formalin for subsequent extraction of macro and meio fauna.

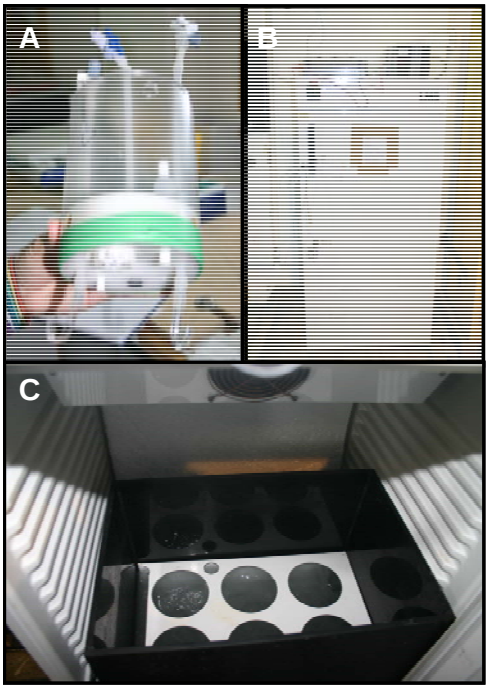

Fig. 20. A. Incubation core caps with sampling ports and magnetic stirrer. B. Refrigerated incubator. C. Incubator interior with water tank and core rack.

Sample processing

A significant proportion of the preserved sediment samples were sieved. Macrofauna was extracted from them as follows:

1) Sediments were wet sieved on a 250μm screen.
2) The fine fraction which passed through the sieve was sieved again to 63 μm, and the 63-250 μm fraction was preserved in formalin.
3) The >250μm fraction was picked through under x12 magnification.
4) Organisms were extracted, identified (to family level for polychaetes), and stored frozen in pre-weighed, ultra-clean silver boats.

Notes on Approach

- The relatively short experiment duration was chosen to limit re-cycling of fixed carbon in the cores labelled with bicarbonate. This would complicate interpretation of results. It also meant that cores

could be capped and sealed from the start without becoming significantly hypoxic. This eliminated the possibility of labelled bicarbonate leaking into the algae experiment, which could happen in an open bath setup.

- Glucose was not used due to reports of it being directly assimilated by metazoans, as well as a desire to label autotrophic bacteria rather than heterotrophic ones.

Observations

- The only site which showed visual evidence of chemosynthesis was Hook Ridge. At this site Siboglinid polychaetes were present, and the sediment exhibited an iron rich band, and sulphide deeper in the core.
- The off-vent site was also reported to host Siboglinid polychaetes, thus perhaps it was not completely free of chemosynthesis.
- The middle Sister site may not have been chemosynthetic, however the bioloy is still interesting. Mudballs were present on the sediment surface, and large (visible) polychaetes were also present.
- The South Georgia site features methane rich porewaters, and evidence of anaerobic oxidation of methane at 10-15 cm. It therefore seems likely that it will show evidence of chemosynthesis in isotope tracing experiments.

Analytical Plans

Fauna

Macrofaunal extraction will be completed when the samples arrive in Leeds. Samples will be analysed for ^{13}C and ^{15}N at the Macaulay Institute. It is hoped that meiofauna will be extracted, identified, and analysed by MRes students at NOC, in collaboration with John Copley.

Overlying Water

Time-series samples of overlying water will be analysed for ^{13}C in DIC, either at NERC LSMSF (Lancaster), following a NERC facility application, or at KU Leuven, Belgium (lab of Dr Stephen Bouillon). The decision will be driven by funding availability, and the methods used at the LSMSF.

Frozen water samples may also be analysed for ^{15}N in NH_4^+, in collaboration with Dr Dalsgaard (Denmark), or at NIOO (the Netherlands), depending on progress with method development.

Sediment

Phospholipid fatty acids will be extracted from sediment samples and subjected to compound-specific isotope (^{13}C) analysis, preferably at Bristol, following a NERC LSMSF application. The application will also include a proposal to conduct compound specific isotope analysis on a range of microbial biomarkers, including archaeal markers. This work will be in collaboration with Rich Pancost.

Sediment samples will also be subjected to DNA extractions, for tracing of ^{13}C into microbial DNA. This work will be in collaboration with David Pearce, and Colin Murrell at Warwick.

Table 6 Sample List

Sample Type	Number	Treatment
Experimental sediment	12 cores (6 half-sections per core)	Frozen
Experimental sediment	12 cores (6 half-sections per core)	Formalin
Overlying water DIC	59	$HgCl_2$ + refrigerated
Overlying water NH_4^+	59	Frozen
Experimental fauna	56	Frozen in Ag boats
Background sediment	2 cores (6 sections per core)	Frozen

Macrofauna

Sampling of macrobenthic fauna

Katrin Linse, Jon Copley, Adrian Glover, Santiago Herrera, Leigh Marsh, Will Reid, Nicolai Roterman, Chris Sweeting, Paul Tyler

One of the main objectives for the third ChEsSO cruise to the Bransfield Strait and East Scotia Ridge is to sample the macrofauna organisms from hydrothermally active sites (vents, seeps) and the neighbouring non-vent organisms for later taxonomic (morphological and molecular), biogeographic, phylogenetic and ecological studies. The macrofaunal collection and sample distribution protocol followed the one developed for JC42. During JC55 three areas had been planned for ISIS collection dives: the Bransfield Strait (Hook Ridge, Three Sisters, Edifice A), the East Scotia Ridge E9 and the crater near the Kemp seamount.

Work at sea:

After the loss of ISIS for macrofaunal sampling, the Hook Ridge site (Bransfield Strait) was sampled for macrofauna with a spate box core (SBC) and a 3-m wide Agassiz trawl (AT). The AT was “flown in” with 1kn and 2.2 times cable length to water depth to ensure that the AT had reached the seafloor as not signal was seen on the tension meter. The collected macrofauna was low in numbers and diversity (Table 7). The collected species were photographed and fixed for further studies.

Loss of science because ISIS damage:

The collection of macrofauna was severely hindered by the damage to ISIS. We were unable to collect any vent/seep site fauna as well as off-site hard-bottom fauna. The way the AT was deployed ("flown in" to avoid contact with ship's propellers) prevented the deployment of the AT in the craters to collect off-site fauna.

Megacoring for quantitative macrofauna

Sediment macrofaunal biodiversity, taxonomy, food-web structure and carbon cycling

Adrian Glover, Chris Sweeting, Will Reid, Clare Woulds

With acknowledgement to Alex Tate, Leigh Marsh and Veerle Huvenne for assistance with sample processing, and in particular to Jez Evans and the deck team for their help and expertise with the megacore deployments.

Background

This collaborative project was developed during the JC55 cruise in response to the inability to sample using the ROV and the nature of the sedimented habitats of the Bransfield Strait. The overall aim was to collect quantitative infaunal sediment samples using the megacore from putative hydrothermal vent sites in the

Bransfield Strait, with control samples taken 'off-vent' for comparison. These would then be studied with the following objectives in mind:

1. A comparison of macrofaunal biodiversity and community structure at vent and off-vent settings (led by Adrian Glover)
2. A study of macrofaunal food-web structure at the species level (led by Chris Sweeting)
3. A study of carbon cycling in the benthic food-web at chemosynthetic ecosystems (led by Clare Woulds)
4. Taxonomy and molecular phylogenetics of novel annelid species (led by Adrian Glover)

Sampling

The sampling part of this project was highly successful. A total of 102 megacore tube samples were taken using quantitative methods (Table 8). An additional 7 tubes were taken, at least 1 from each site, and live-sorted on the ship to make an initial examination of macrofaunal community composition, as well as live-specimen photography (Figs. 22-25). This allowed us to adjust our sampling strategy as needed on the cruise. A number of interesting taxonomic discoveries were also made.

Grand Total	

At each site, replicate drops of the megacore were made, ideally a minimum of 5 separate drops, in some cases more and in some a little less. The Axe site was not sampled quantitatively but will be available for taxonomic comparison. From each drop, between 2 and 6 core tubes were taken and sliced into 0-5cm and 5-10cm layers using a core extruder. The top water was added to the 0-5cm fraction. Thus from each drop, two sample jars were created, one for the 0-5cm layer and one for the 5-10cm layer from a varying number of tubes. The combined cores, making up the individual sample, were then sieved on a 300 micron mesh held under the water to carefully prevent damage to the specimens. All sieving took place in ambient temperatures, of about 2-5ºC. Samples were fixed in both 99% ethanol (for DNA) and formaldehyde (4%).

Although the number of core tubes per sample varied, the data can be normalized to a unit area in later analyses as the samples were all treated quantitatively. This has become standard practice in many deep-sea studies of infaunal diversity.

For the cores treated for live sorting, a similar protocol was followed although in some cases residues with stones, gravel etc were discarded to enable rapid assessment and picking of individuals in cold temperatures while still alive. Picking was done under a dissecting microscope held in a tray of ice to keep specimens cool. Live specimens were observed from all samples and photographed using a Lumix G2 camera with Leica 45mm f2.8 Lumix macro lens held on a Benbo Mini-Trekker tripod. Specimens for imaging were illuminated with a fibre optic lamp (not strobes) and prior to imaging they were cleaned and relaxed in 7% Magnesium chloride solution. Black cotton fabric was placed under petri dishes and small tubs to create black backgrounds. Very small specimens (less than 3mm) were imaged using a Nikon Coolpix 4500 camera with Optem Instruments microscope eyepiece coupler and a Wild M5 dissecting microscope. Lighting was also with the fibre optic lamp.

Preliminary observations

At all sites, macrofaunal abundance was high and it is likely that subsequent analyses of these cores will reveal many thousands of individuals. We expect good statistical replication, possibly several hundred specimens per sample. Many months to years work will be required to sort and identify the specimens to species-level, but based on the live sorting we can provide some preliminary observations.

There was a reasonable degree of homogeneity between samples from a site, but a great deal of heterogeneity between sites.

The Bransfield off-vent site (Figure 22) was dominated by deposit feeders, in particular a very abundant species of oligochaete, preliminarily identified as *Torodrilus lowryi* by Christer Erseus of Göteborg University, an oligochaete expert. Samples will be provided to Christer Erseus for further taxonomic study. The site was also marked by the presence of patches of siboglinid polychaetes, a putative chemosynthetic species. The largest patch of specimens was recovered in the megacore tube-closing mechanism (non-quantitative sample), although specimens were also observed in the other cores. The specimens appear to be a species of *Siboglinum*, which are known to exist in sulfide or methane-rich sediments in shelf settings.

The Hook ridge putative vent site was dominated by patches of a different species of siboglinid chemosynthetic polychaete, *Sclerolinum* sp. (Figure 23). These animals have quite different tubes and internal morphology. Rather little is known about their biology but it is likely that they contain sulfophilic symbiotic bacteria. The animals were observed with parts of their tubes buried in red-coloured sediments presumed indicative of the presence of iron oxides. It will be extremely interesting to compare the geochemisty (led by Rachel Mills) of the Hook Ridge and off-vent sites with the presence/absence of these two species of siboglinid polychaete. At the Hook Ridge site, abundant deposit-feeding species were also observed, for example terebellid and chaetopterid tube-dwelling annelids living in the pelagic sediments that overlie the red layers. It is thus probable that this site represents a balance between chemosynthetic fauna living off enriched sediments, presumably quite patchy, and an upper layer of typical Antarctic shelf deposit-feeders.

The Three Sisters and Axe sites were dominated by typical deposit feeders, such as ampharetid and onuphid polychaetes (Figure 3). No chemosynthetic species were observed. Abundant mud-balls (Figure 24) were observed on the surface of the cores, and these were also noticed on SHRIMP survey tows. We are not yet sure which species is creating them, or if they are a protozoan such as a Foraminifera.

A final site off the south-west tip of South Georgia was sampled quantitatively for macrofauna towards the end of the cruise (Figure 25). The site was much shallower and thought from previous cruises to be the site of putative cold seeps. Two sites were initially selected as potential core sites (corresponding to JC55 stations 111 and 113). Site 111 was heavily dominated by capitellid polychaetes, deposit feeders in organic-rich settings. The second site (113) was more species-rich but still showed dominance, this time by cirratulid polychaetes. The abundance of the fauna was extraordinary, with all specimens observed having extremely full guts and ripe with gonads. It is probable that this corresponds with a strong seasonal phytoplankton

bloom. No chemosynthetic species were observed in the initial sort, although the sediments below about 10cm depth were blackened and sulfidic. The second site (around station 113) was sampled quantitatively (5 replicate drops) on the last science day of the cruise, with many hands helping to get the sieving done as the cores came quickly onto the deck from this shallow site.

Fig. 22 Fauna at the Bransfield off-vent site: (a) Annelida, Oligochaeta, *Torodrilus lowryi*, (b) and (c) Annelida, Siboglinidae, *Siboglinum* sp.

Other interesting taxonomic finds

During the cruise visits were made to the E9 and Caldera sites sampled by ROV during JC42. Although these sites were not suitable for megacore work (being essentially hard-substrate), a remarkable discovery was made from a gravity core taken at the Caldera site.

The gravity core (JC55_106) had most likely toppled over on the seabed and during the recovery process, the lip of the upper weighted section had scraped over some of the seafloor. A small chunk of white matter was observed in this section and recovered by Rachel Mills and the deck crew on the deck.

The white matter appeared to be a lump of sulphurous sediment or even almost pure sulfur, and was riddled with black tube worms (Figure 26). It smelt very strongly of hydrogen sulfide. On examination, the tube worms were found to be alive and are most likely another species of siboglinid polychaete, quite different to those found at Hook Ridge and the Bransfield. The worms were extremely thin and showed very little internal morphology, DNA work will be carried out to determine them.

The find is significant as it shows the potential for a macrofauna to exist in areas of the white sulfurous Caldera perhaps previously thought to be too toxic for large metazoans (these animals were not observed on JC42). It will also be very interesting to study the general geochemical milieu of these various siboglinid species from the Antarctic.

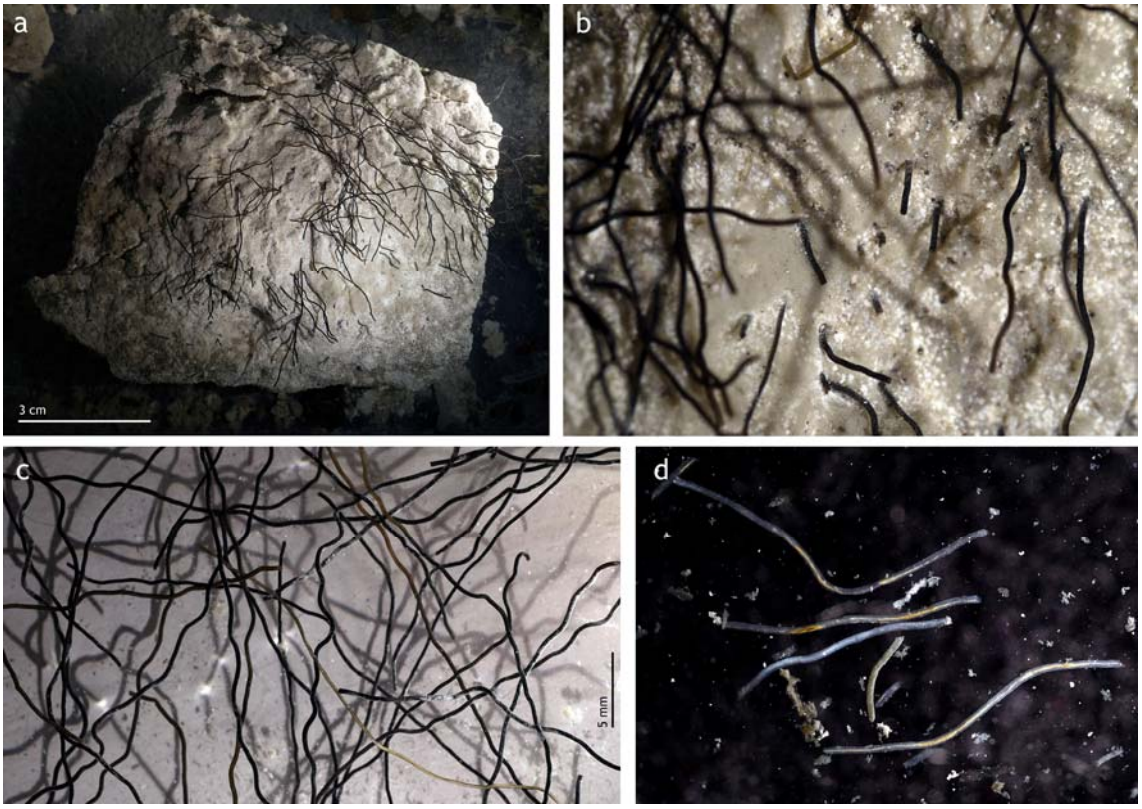

Fig. 26 Annelida, Siboglinidae recovered from a piece of white sulfurous matter at the Caldera site, South Sandwich Arc: (a) lump of white sulfurous matter with worm tubes, (b) detail of surface, (c) worm tubes after dissection from the soft white matter, (d) sections of live worms removed from inside tubes (with great difficulty).

Further work

The samples will be returned to the Natural History Museum, London for initial sorting and species-level ID subject to staff-time being available as no funding has yet been earmarked for this project. One possibility is that the entire sample set would make an excellent PhD project. Adrian Glover and Chris Sweeting will explore the possibility of a joint studentship.

The stable isotope work will potentially be carried out in Newcastle (Chris Sweeting to lead) on specimens identified to species level at the NHM London, and these data will then be fed into the project led by Clare Woulds.

For the siboglinid work, funding is available to undertake molecular analysis of the DNA and undertake taxonomic descriptions and phylogenetic analysis. This will be led by Adrian Glover and PDRA Dr Helena Wiklund funded under a recent EU Marie-Curie award.

Outside of the annelids, there is a wide range of material potentially available from these samples for taxonomic projects (including DNA-fixed material) and the PIs would welcome enquiries by those interested to study them.

Isotopic analysis

Sampling for Food Web Analyses

Chris Sweeting, Will Reid

Objectives

A primary objective for the third ChEsSo cruise to the Bransfield Strait and East Scotia Ridge was to sample the macrofauna organisms from hydrothermally active sites (vents, seeps) and the neighbouring non-vent organisms to understand the ecological structure and function of these systems. Within this, the food-web package had specific objectives to assess spatial and temporal variations in sources of production and trophic structure at these sites and to assess intra-population trophodynamics of the dominant macrofauna.

Work at Sea

We sought macrofaunal samples for stable isotope analysis of trophic structure and sediments for characterisation of bacterial communities via hopanoid and 16S DNA markers to identify potential bacterial food web production sources within and away from chemosynthetic sites.

Macrofauna

The loss of the ROV Isis was a severe impediment to macro- and mega-faunal collection. This was compounded by the inability to use Azimuth thrusters which impacted Agassiz trawling. Other gears such as box core or mega core did not yield adequate sample numbers for macrofaunal food web analyses such that no samples were collected from any chemosynthetic site. Limited macrofauna were collected from non-chemosynthetic sites through the single Agassiz trawl (off Hook Ridge, Bransfield Straight – included Table 9) and opportunistically from the CTD (Salps collected over Hook Ridge) and the ships water intake filters (mainly krill over E9 – East Scotia Ridge). Macrofaunal samples were freeze dried for return to the UK.

Bacterial communities

The revised sampling programme allowed for more extensive coring in Bransfield Strait and additional sampling off South Georgia. This achieved satisfactory sample numbers for analysis of bacterial production through DNA and hopanoid analyses to identify bacterial functional groups. Sediment samples were collected

in conjunction with the microbiology work package (16S DNA) and sediment geochemistry (hopanoids) and methodologies for collection and sample lists are detailed more comprehensively there.

Infaunal food webs

Coring allowed for the assessment of infaunal food web trophodynamics as an alternative objective in the absence of macrofaunal sampling. This work was conducted in collaboration with Dr Adrian Glover (Natural History Museum) and Dr Clare Woulds (University of Leeds). Methodologies for collection and sample lists are detailed in Macrofauna above. It has been agreed that A Glover will arrange for specimen identification, these will be passed to C. Sweeting for stable isotope analysis to construct infaunal food webs. Isotope data will then be given to C. Woulds for deduction from enrichment experiments for nutrient cycling modelling.

A summary of sampling sites and samples collected is given in Table 1 below. As all sampling required either coreable or trawlable sediment, no samples were taken from E9, Mackintosh crater or Adventure crater.

Table 9. Summary of samples collected on JC055 for food web analysis and associated gear, depth and habitat type. MC = mega core, AGT =Agassiz trawl, SIA = stable isotope analysis, HOP = bacterial hopanoids analysis, MIC = bacterial DNA analysis.

Site and location (Decimal lat/long)	Chemosynthetic / Depth	Gear	Sample Summary and analyses
Hook Ridge	Weak	MC	SIA - 5 drops of 3-6 cores each
-62.1924	1054m		HOP - 1 drop of 1 core
-57.2783			MIC – 3 drops of 1 core each
Hook Ridge	Weak	MC	SIA - 6 drops of 2-5 cores each
-62.1969	1174m		HOP - 1 drop of 1 core
-57.2975			MIC – 3 drops of 1 core each
Hook Ridge	None	AGT	SIA - 34 samples over 5 species of macrofauna
-62.2203	1647m		
-57.3173			
Bransfield Slope	None	MC	SIA - 5 drops of 2-4 cores each
-62.3842^{o}	1148m		HOP - 1 drop of 1 core
-57.2440^{o}			MIC – 3 drops with 1 core each
Three Sisters	None	MC	SIA - 2 drops of 3,5 cores respectively
-62.6552	1311m		HOP - 1 drop of 1 core
-59.0502			MIC – 1 drop of 1 core each
Three Sisters	None	MC	SIA - 1 drop of 2 cores
-62.6539	1121m		HOP - 1 drop of 1 core
-59.0326			MIC – 1 drop of 1 core
Edifice A	None	MC	SIA - 1 drop of 4 cores
-62.7866	1024m		HOP - 1 drop of 1 core
-59.7616			MIC – 1 drop of 1 core
South Georgia	None	MC	SIA - 2 drops of 2-4 cores each

-54.1575	243m		HOP - 1 drop of 1 core
-37.9756			MIC – 1 drop of 1 core
South Georgia	None	MC	SIA - 1 drop of 3 cores
-54.1475	254m		HOP - 1 drop of 1 core
-37.9717			MIC – 1 drop of 1 core
South Georgia	None	MC	SIA - 5 drops of 4 cores each
-54.1580	247m		HOP - 1 drop of 1 core
-37.9344			MIC – 1 drop of 1 core

Note: Samples of infauna for stable isotope analysis will initially be handled by A. Glover, those for Hopanoids will be the responsibility of Rachael Mill until transfer to Richard Pancost and samples for microbiology will be dealt with by David Pearce.

Shrimp dives

SHRIMP observations (Tables 10 and 11)
Jon Copley, Leigh Marsh, Paul Tyler

Hook Ridge, Bransfield Strait

Based on information from CTD tow-yos, SHRIMP dive #1 (JC55-017) surveyed the seafloor of the southern slope of Hook Ridge, and the central crest of the ridge. SHRIMP undertook a series of contour-parallel survey lines stepping upslope on the southern face of the ridge, and continued this pattern of lines across the ridge crest. These survey lines were followed by closer inspection of an area of venting at the western end of the survey area on the ridge crest, and a final line extending along the ridge crest further to the west.

The seafloor on the southern slope of the ridge was comprised of fine but possibly only shallow sediments, with occasional basalt outcrops forming slope-perpendicular fissures. The crest of the ridge is marked by a graben-like depression with sheer basalt walls. The seafloor within this crest feature is similarly comprised of areas of fine sediment and basalt outcrops.

Several apparent assemblage biotopes were observed during the dive. "General background fauna" in sedimented areas consisted of holothurians (including *Peniagone*-type), echinoids, enteropneusts, and *Umbellula* pennatulids. "Rich echinoderm fauna" areas contained a higher density of holothurians, echinoids, and asteroids. "Brittle star beds" were dominated by ophiuroids, with few other species present. Within the ridge crest depression, areas dominated by *Anthomastus*-type soft corals were present along northernmost survey lines. Patches of "burrow fields", and indeterminate polychaete tubes, and depauperate areas of sediment, were all present around the main area of hydrothermal venting (described below), along with areas dominated by

microbial mats. Rocky outcrops observed during the dive were occupied by anemones, octocorals, and solitary scleractinians.

Hydrothermal activity, in the form of shimmering water issuing from depressions in the seabed and also from some small (less than 2 m high) mineral chimneys, was observed in the SW corner of the survey area at the ridge crest (e.g. chimneys at 62º 11.8573' S, 57º 17.7628' W, depth ~1200 m). Mats of filamentous bacteria were observed around these sources, but no specialist vent fauna were observed. Microbial mats and shimmering water were also observed in a more limited area in the NE corner of the crest survey area (e.g. at 62º 11.549' S, 57º 16.708' W, depth ~1030m).

A whale skeleton (skull and vertebrae; Fig. 27A) was observed near the main ridge crest vent area, at 62º 11.8617' S, 57º 17.8910' W, depth ~1200 m. It was not possible to obtain close-up footage of the bones from SHRIMP to examine possible whale-fall fauna.

Three Sisters, Bransfield Strait

SHRIMP dive #2 (JC55-047) surveyed the northern slope of the central ridge in the Three Sisters feature, undertaking a series of contour-parallel lines moving downslope. SHRIMP then moved south to the crest of the ridge to undertake a further series of lines to the SE of the original survey box.

Exposed basalt, including eroded and sedimented pillows, characterise the crest and slope the ridge, giving way to sedimented seafloor to the north. Fauna occupying rock substratum was dominated by sponges and anemones on the slope of the ridge, with octocorals and solitary corals more abundant on the ridge crest. Sedimented seafloor to the north of the survey area was dominated by ophiuroids and 8-armed asteroids. "Mud balls" characterised the surface of the sediment on several survey lines.

No indications of any hydrothermal activity (e.g. shimmering water or bacterial mats) were observed during the dive.

E9 segment, East Scotia Ridge

SHRIMP dive #3 (JC55-090) began by repeating a survey line from the north of the E9 vent field, along which SHRIMP first observed the Twin Peaks area during January 2009. The ship was then manoeuvered to tow SHRIMP across the Twin Peaks area several times, to obtain imagery of

features observed in 2009 and 2010 (Fig. 27B). Some growth (~1 to 1.5 m) of vent chimneys was apparent at Twin Peaks compared with the ROV observations in 2010, but little change in faunal composition, apart from an apparent increase in the abundance of seven-armed asteroids in the periphery of the assemblage. The Black & White chimney structure was observed using the low-light pan-and-tilt camera, with no obvious gross change in morphology of its structure.

Having revisited the Twin Peaks area of the E9 vent field, SHRIMP then undertook a series of ridge-axis parallel survey lines south of the Twin Peaks and Garden area, examining seafloor not visited by the Isis ROV in 2010. No further active venting structures were discovered in this survey area, although extinct sulfides were observed towards the southern end of the survey lines, close to the edge of the "Devil's Punchbowl" caldera.

The fauna observed on the sheet basalts that characterised the majority of the substratum type along transects was dominated by brisingids on upstanding features, ophiuroids, holothurians, gorgonians, and enteropneusts.

Kemp Caldera, South Sandwich Islands

SHRIMP dive #4 (JC55-094) began by repeating the survey line undertaken by SHRIMP in 2009 from the centre of the caldera to the top of the volcanic knoll. Fauna observed here was very similar to that seen in 2009: holothurians dominating sedimented areas in the centre of the caldera, and abundant ophiuroids on basalt outcrops. The dominant type of holothurian also changed as depth decreased up the volcanic knoll, as observed previously.

SHRIMP then surveyed the northern slope of the knoll, traversing east across the area where wood and shell colonisation experiments were deployed by the ROV in 2010. No new areas of hydrothermal activity were encountered in this area. There were also no obvious signs of invertebrate colonisation on the experimental wood panels, although the view of them was limited from the SHRIMP cameras.

SHRIMP then crossed the main vent field on the eastern slope of the volcanic knoll, observing the same biotopes found in 2010, with little apparent change in faunal composition: clam beds in sedimented areas, anemones and limpets dominating on basalts, and an extensive sponge zone towards the periphery of the assemblage.

After transiting the main vent field, SHRIMP undertook a survey line south across the second small knoll to the south of the main knoll, passing over "Clam Road", in search of other loci of hydrothermal activity. None were found on the southern knoll, although sediments resembling oxidised sulfides were observed on the western slopes of the southern knoll during the west-east line across it.

SHRIMP then returned to the main vent field to repeat E-W and N-S transect lines undertaken by the ROV in 2010, followed by an extensive series of NW-SE lines to constrain the entire extent of the vent field (Figure 4B). These lines revealed abundant possible sipunculans beyond the "sponge zone" around the vents, particularly in the southern side of the vent field.

During these survey lines, SHRIMP also revisited the whalefall found in 2010, where the bones were observed to be undisturbed in the same orientation seen in the previous year (Fig. 27C)

Adventure Caldera, South Sandwich Islands

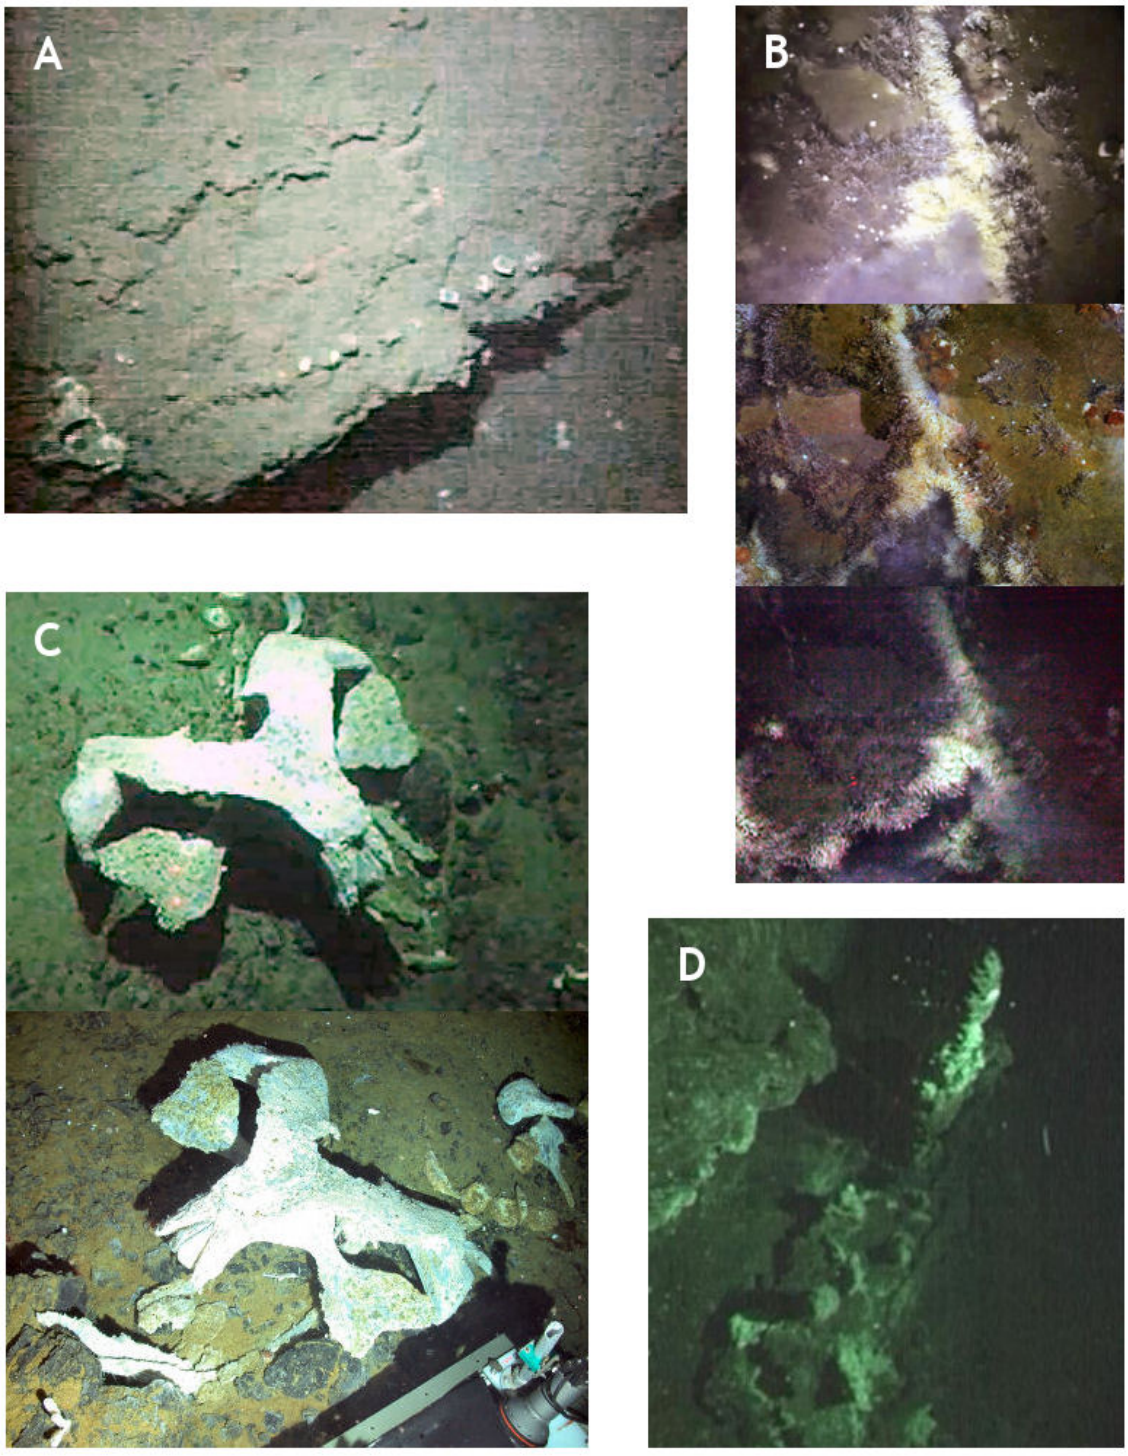
SHRIMP dive #5 (JC55-103) surveyed the seafloor of Adventure Caldera, conducting a transect from the centre of the caldera up volcanic knolls on its southern edge, and then back into deeper water to the west of those knolls.

Along the initial transect, the seafloor was dominated by bivalve shells (*Linopsis mariantatus*), with asteroids (e.g. *Labidiaster*), ophiuroids, holothurians, sponges, bryozoans, *Umbellula*, *Anthomastus*- and *Xenia*-type soft corals, and ophiuroids gave way to bivalve beds on the slopes of the knolls, with sponges and bryozoans also present towards the upper margin of the slope. Bivalve shells gave way to sedimented seafloor at the top of the first knoll, which was dominated by abundant comatulid crinoids and ophiuroids.

On the survey line west into deeper water, faunal abundance decreased as the seafloor changed to sulfide rubble. Sulfide chimney venting shimmering water were found at 59°43.262S, 27°51.428W (Fig. 27D). The chimneys were up to 3 metres high and surrounded by extensive microbial mats, but no specialist vent fauna were observed. However, ophiuroids were present in close proximity to active vent sources and on disturbance of microbial mats *Tomopteris* sp. (Tomopteridae) were observed in the water column.

South Georgia shelf

SHRIMP dives #6 and #7 (JC55-123 and JC55-124) examined the seafloor of the South Georgia shelf, where megacoring recovered hydrocarbon-smelling sediments and EK60 echosounder survey lines suggested possible methane bubble sources. Two areas approximately 1 km apart were surveyed in detail through closely-spaced SHRIMP lines. No evidence of focussed seepage or bubbling was observed in either area. The seabed was fine mud throughout, with occasional pits and hollows. Fauna included Scotia Sea Icefish, Marbled Rock Cod, anemones, and asteroids. Kelp detritus was also observed. On the northernmost line of dive 6 long and continuous net and roller marks as a result of trawling were observed.



Fig, 27: A - Whale skeleton encountered during SHRIMP dive #1 on Hook Ridge, Bransfield Strait; B - imagery of seafloor feature at Twin Peaks area of E9 vent field, East Scotia Ridge, visited in 2009 (top panel), 2010 (middle panel), and SHRIMP dive #3 (lower panel); C - skull of whalefall at Kemp Caldera, South Sandwich Islands, seen during SHRIMP dive #4 (top panel) and in 2010 (lower panel); D - vent chimney observed in Adventure Caldera, South Sandwich Islands, during SHRIMP dive #5.

Outreach

Public outreach during JC55

The programme of public engagement undertaken during the cruise included cruise blogs hosted on www.thesearethevoyages.net (produced by Jon Copley with contributions from Chris Sweeting, Jeff Hawkes, Clare Woulds and Cathy Cole), www.rrsjamescook.com (produced by Clare Woulds and Leighton Rolley) and noc.ac.uk (produced by Rachel Mills). Doug Connelly, Jon Copley, Rachel Mills and Clare Woulds also undertook microblogging during the cruise via Twitter.

Adrian Glover delivered two live links to public audiences in the David Attenborough studio at the Natural History Museum, and Clare Woulds undertook a live chat with Calder High school in West Yorkshire. We also received and answered questions from school pupils in Hampshire, Berkshire and Cambridgeshire via www.thesearethevoyages.net

On 14th February we issued a press release via the NOC press office, describing the discovery of vents in the Adventure Caldera. The story was covered by outlets including MSNBC, sciencedaily.com and in several blogs.

Webpage statistics for www.thesearethevoyages.net

Between 14th January and 16th February, there were 6964 unique visits to the www.thesearethevoyages.net website. Visitors came from at least 34 countries (top ten in rank order: US, UK, Germany, Canada, Cayman Islands, Sweden, Russia, Australia, Norway, France). Numbers of visitors to the site peaked after issuing the press release on 14th February, which carried a link to the website:

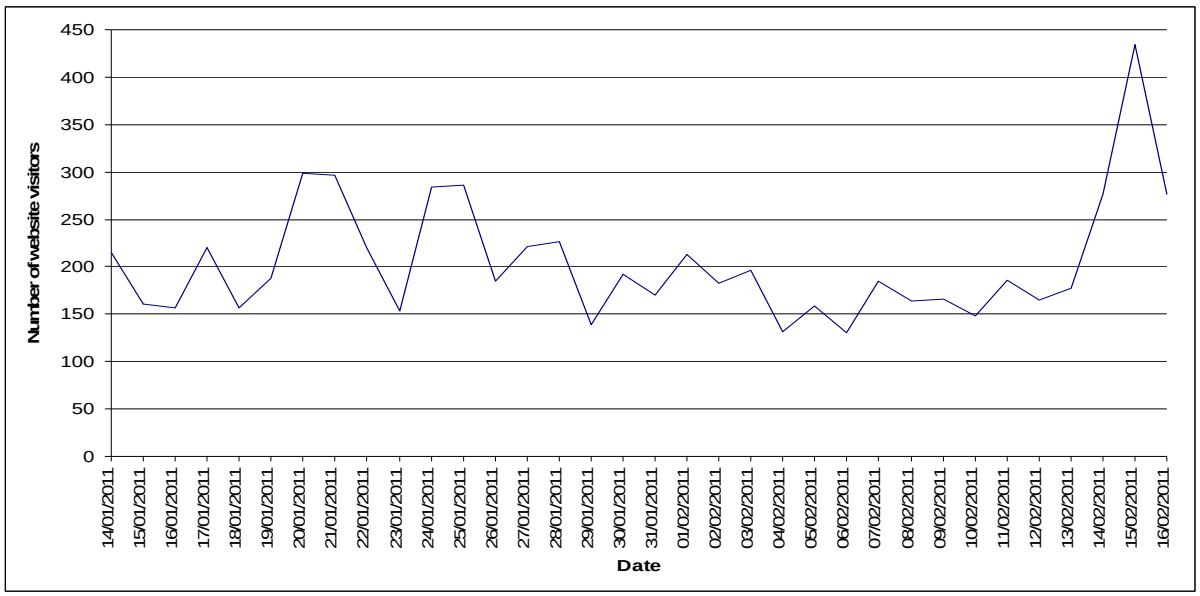

Fig. 28 Number of website visitors

Most of the trackable referrals to www.thesearethevoyages.net were received from the NOC webpages (22%), followed by Facebook (8%) and Twitter (7%), demonstrating the reach of those social media websites. Visitors also arrived at the webpages from the University of Southampton and University of Leeds webpages, following the posting of news items on those pages on 14th February. Coverage of our press release in physorg.com and seadiscovery.com also brought visitors to the site, as did social linksharing via stumbleupon.com

The most visited pages at www.thesearethevoyages.net were the daily diary page (12%) and the homepage (12%). The most popular individual blog entry was for 24th January, which contained excerpts from the dive log of the first SHRIMP dive, with seafloor photographs. Bandwidth limitations in the ship's internet link prevented publishing of video material for public engagement from the cruise.

Sampling equipment

The damage to Isis is being reported elsewhere as an independent enquiry and will not be addressed here. All other over the side equipment worked well including the megacorer, spade box corer, CTD and Agassiz trawl. The SHRIMP was not functioning when initially brought into use by the ROV team prepared a very acceptable SHRIMP capable of taking three different videos including HD and concomitant temperature.
