Eelpouts are a group of about 240 valid species of perciform fishes. They are the most diverse family of the suborder Zoarcoidei and exhibit a greater degree of character plasticity than the other families. Species of some Northern Hemisphere zoarcid genera, especially *Bothrocara*, *Gymnelus*, and *Lycodes*, appear to exist as polymorphic populations. Body elongate, dorsal and anal fins confluent with caudal. Basisphenoid bone, swim bladder, posterior nostrils, and supramaxilla absent. Pelvic fins, lateral lines, pseudobranchia, and pyloric caeca rudimentary or absent. Scales minute, imbedded, cycloid; or absent. Branchiostegal rays 4–8, usually 6. Ovary single. Vertebrae 58–150. Maximum adult size range about 12–110 cm (5–43 in) total length. Eelpouts inhabit primarily the outer shelves to upper slopes of the North Atlantic and North Pacific, but there have been significant radiations into the Arctic, southern South America, and Antarctica. Two genera (*Lycodapus* and *Melanostigma*) are meso- or benthopelagic. A few genera (e.g., *Dieidolycus*, *Lycenchelys*, and *Pachycara*) have abyssal benthic species. The classification follows Anderson (1994 [ref. 21438]), who provided a phylogenetic analysis of the whole family, with four subfamilies recognized.

**Subfamily Lycozoarcinae Andriashev 1939**

Body and tail relatively stout, vertebrae 65–71. Branchiostegal membranes free of isthmus. Interorbital pore present. Two epurals, with 2–3 rays. Caudal fin rays 13–15. Suborbital bones 5–6, forming semicircle around eye. No fin spines. Marked sexual dimorphism in the single species. Outer shelf depths of the Okhotsk Sea.

**Genus *Lycozoarces* Popov 1935**

*Lycozoarces* Popov 1935:303 [ref. 3546]. Type species *Lycozoarces hubbsi* Popov 1935. Type by monotypy.

REMARKS: Appeared first in Popov (1933:151 [ref. 6535]) as a nomen nudum with a new species *regani*, but without qualifying as a combined description, so the genus is unavailable from 1933; the species is available, however, since the genus does not have to be an available name (Art. 11.9.3.1 of the International Code of Zoological Nomenclature). In 1935 *Lycozoarces* was described as was *hubbsi*, and *regani* was mentioned as a second species in the genus. The title includes the statement, "... *Lycozoarces hubbsi*, Gen. N. Sp. N...."; this qualifies as a combined

description (see Art. 13.4) since only one new nominal species is included (although a second available species was included); under these circumstances the type is *hubbsi* by monotypy.

***Lycozoarces regani* Popov 1933**

*Lycozoarces regani* Popov 1933:151, Fig. 1 [labeled 2 on plate] [ref. 6535] (Tatar Strait, 50°36.7'N, 140°53.6'E, Russia, n. Japan Sea, 70 m). Holotype (unique): ZIN 29987.

**Subfamily Zoarcinae Swainson 1839**

Body and tail elongate, vertebrae 101–146. Branchiostegal membranes attached to isthmus. Interorbital pore present. Single epural, with two rays. Caudal fin rays 9–11. ### Subfamily Gymnelinae Gill 1863

Body and tail elongate, vertebrae 76–150. Branchiostegal membranes broadly fused to isthmus, gill slit usually extending to about mid-pectoral base, or is a small pore well above pectoral fin (fin absent in *Andriashevia*). Interorbital pore usually present. Single epural, sometimes absent, with 0–2 rays. Caudal fin rays 5–12. Suborbital bones 4–8, usually 5–6, forming semicircle around eye. No fin spines except in *Krusensterniella*, which has a variable series of pungent spines in the dorsal fin preceded by flexible spines. About 35 species, most in the North Pacific. Several species apparently exist as polymorphic populations. *Melanostigma* is a cosmopolitan, mesopelagic genus, and *Seleniolyicus* is endemic to the Southern Ocean.\*
