## Fernandina ODMDS Status and Trends August 2005

**THIS PAGE INTENTIONALLY LEFT BLANK**

## ACKNOWLEDGEMENTS

Samples were collected August 8-10, 2005 from the Fernandina Ocean Dredged Material Disposal Site (Christopher McArthur, Site Manager; Gary W. Collins, Chief Scientist). Sample tracking and custody were performed by Phyllis Meyer. On-board sample processing on the invertebrate samples was led by the Chief Scientist, along with the assistance of Christopher McArthur and Drew Kendall. Processing of the chemical samples and the sediment particle size samples was performed by Phyllis Meyer and Mel Parsons. Water quality profiling and sampling were led by Christopher McArthur.

The Region 4 Oceans Protection Team would like to express their sincere appreciation to Ken Potts, along with Craig Vogt and Dave Redford for all the sacrifices they made to acquire the new vessel, OSV Bold, for EPA. This survey effort could not have been possible without their efforts and that of Captain Dave Sullivan and the entire crew of the Bold.

## INTRODUCTION

Ocean disposal of dredged materials can affect the environment of a disposal site by disturbing the benthic community and potentially causing long-term reduction of oxygen in the pore waters of the sediments and the overlying waters. Natural oceanographic processes can also be responsible for transporting disposed materials offsite into nearby habitats.

As part of Region 4's strategy to monitor the effects of dredged material disposal within the marine environment, routine surveys of the benthos and water column within and adjacent to our sites are conducted so that their status may be assessed. In addition, the data is archived so that over time, trends which may occur can be observed. These status and trends surveys are consistent with the requirements of 40 C.F.R. 228.9. The present study being discussed was conducted aboard the Ocean Survey Vessel (OSV) Bold between August 8-9, 2005.

## BACKGROUND

The Fernandina Beach ODMDS was designated by EPA in 1987. The ODMDS received over 6 million cubic yards of dredged material from new work at the Kings Bay Entrance Channel in 1988. Since then it has received annual maintenance material from the channel of up to 1 million cubic yards per year with periodic disposal events from the Fernandina Harbor Inner Channel and Turning Basin on the order of 1 million cubic yards.

A Site Management and Monitoring Plan was developed for the Fernandina Beach ODMDS in 1998 and amended in 2001. Annual bathymetry surveys have been conducted at the site by the Corps of Engineers. The last status and trends survey conducted at this ODMDS was in September, 1989.

### **Survey Area and Location**

The study area is within and surrounding the Fernandina, FL ODMDS located offshore Amelia Island. The survey area is approximately 3 X 4 nautical miles (nmi) in area. Twelve stations were selected in order to analyze the sediment grain size, chemical, and biological characteristics of two areas – one where disposal has occurred and the other one undisturbed by disposal. Of these 12, four (4) received water quality sampling. Depths in this area range from 30 to 60 feet. The ODMDS boundary corner coordinates are:

30 33.00' N/081 16.86' W  
30 31.00' N/081 16.86' W  
30 31.00' N/081 19.13' W

The ODMDS, survey area and station locations are shown in Figure 1.

## **METHODS AND MATERIALS**

Method Rationale: Characterization of the benthic community and sediment size/chemistry at selected stations, followed by analysis of community parameters via statistical treatment, allows for identification and interpretation of changes in the community structure. Such community statistics can be used to draw inferences regarding perturbations to the benthic macroinvertebrate community and subsequently allow for judgments regarding the likelihood of impact from dredged material disposal.

### **Sampling Stations**

The boundaries of the Fernandina ODMDS measure approximately 2 X 2 nmi. Twelve stations (see Table 1 and Figure 1) were established by selecting half within and half outside of the site. Past locations (1989) were used when their locations were appropriate to provide an even distribution of sites, relative to those areas in which past dumping has occurred. Only two of the twelve stations from 1989 were not used again in 2005. Table 1 lists which stations from 1989 were re-sampled and the previous nomenclature used to identify them. The two most distant stations within each treatment (within vs. outside the site) were selected for water quality sampling.

### **Water Quality**

To characterize the general water quality associated with the dump site, the following water column parameters were sampled: conductivity, dissolved oxygen (DO), salinity, temperature, density, turbidity, % light transmission and Chlorophyll a.

All measurements were accomplished utilizing the ship's CTD. At the surface and bottom, Go Flow<sup>®</sup> bottles attached to the CTD/rosette frame were deployed to obtain grab samples for the laboratory analysis. Once the rosette was back aboard the ship, the bottles were emptied directly into the appropriate sample containers, labeled, and refrigerated until demobilization. Laboratory analysis of the water includes nutrients, metals, PAHs, PCBs and pesticides.

### **Seafloor Sampling**

Bottom sampling at all twelve stations was accomplished by deployment of a Young grab (surface area = 0.04 m<sup>2</sup>; depth of 10 cm) from the stern of the ship. After retrieval of the grab and confirmation of an adequate sample, the device was sub-sampled in order to

obtain discrete samples for sediment particle size analyses, sediment chemical analyses, and benthic macroinvertebrate identification. The sampling device and handling/preservative protocol for each type of sample follows below:

#### Sediment Particle Size

Two separate samples for particle size were collected from the Young grab by acrylic 5 cm diameter coring tubes. The subsamples were placed into whirl packs, labeled, and frozen for return to the lab. Two replicate samples were obtained at each station; one was analyzed at SESD by laser defraction (USEPA, 2001a) and the other was analyzed by Vittor and Associates by using the wet sieve method (ASTM D-422). In addition, SESD provided data from three stations by wet sieving the fraction of the sample larger than 2 mm (USEPA, 2001b).

#### Sediment Chemistry

Analyses for the following parameters were conducted at the SESD lab in Athens, Georgia: heavy metals scan, nutrients which includes total phosphorous (TP), NO<sub>2</sub>+NO<sub>3</sub>, NH<sub>3</sub>, and TKN, extractable organic compounds, pesticides, and PCBs. The sample was transferred to a glass pan and thoroughly mixed. The sample was alloquated into two 236.6 ml. glass containers and preserved by storing at 4 C until analyzed. One container was analyzed for extractable organic compounds and the other was analyzed for metals and nutrients

#### Benthic Macroinvertebrate Infauna

Sediment from a separate deployment of the grab were collected to obtain benthic macroinvertebrate organisms. On-board processing involved washing the sample through a #35 screen (0.5mm). The sample retained on the screen after washing was preserved in 10% seawater formalin with staining solution. Benthic containers were labeled both internally and externally and stored for transfer to contract lab facilities. The details of sorting and identification of infaunal taxa are described in Vittor, 2006.

All sampling procedures and sample preservation for analyses were according to the Science and Ecosystem Support Division (SESD) Standard Operating Procedures (SOP), (US EPA 1996, 2002).

## **RESULTS AND DISCUSSION**

### **Water Quality**

The results of the water quality profiles are summarized in Table 2. Although the data showed the site's water column to be fairly well-mixed, there was a sharp enough change to discern a small-scale pycnocline.

Turbidity across the survey area ranged from 0.34 to 2.25 NTUs, with nearly all maximum numbers occurring right above the pycnocline (see Fig. 2, Tables D4-D7).

Dissolved oxygen (DO) readings also showed a narrow range (see Fig. 3, Tables D4-D7), from 5.53 mg/L (typically near the bottom) to 6.46 mg/L (typically just above the pycnocline).

Temperature (Fig. 4, Tables D4-D7) and salinity (Fig. 5, Tables D4-D7) profiles also showed that the waters within and around the Fernandina ODMDS are fairly well-mixed. Temperatures ranged from 29.46 to 30.58 °C; salinities ranged from 32.65 to 35.58 ppt.

Although these profiles show the column to be fairly well mixed, it also shows that complete mixing has not occurred. This is particularly evidenced in the turbidity and DO profiles, but also demonstrated in the temperature and salinity profiles.

Chemical analyses of the water samples collected as part of this study showed all analytes to be at or below the detection limit with one exception. For all but one of the samples collected, bis(2-Ethylhexyl) Phthalate was shown to be present, ranging from 58 ug/l at the F10 Top station to 230 ug/l at the F12 Bottom station (see Table D2).

### **Seafloor Sampling**

#### Sediment Particle Size.

The results of the sediment particle size analyses are given in Table 3. The most remarkable feature within the data set is the substantial presence of gravel (18- 39 %) at several stations within the ODMDS. The overall percentage of fine-grained material at any of the sampling locations is extremely low. Obviously, the disposal of dredged material within the Fernandina ODMDS is not resulting in an increase in overall fine-grained material being found in the offshore sediments.

#### Sediment Chemistry.

The sediment chemistry showed most contaminants to be below detection limits. The seven exceptions were arsenic, cadmium, chromium, copper, iron, lead and manganese. Table 4 shows the results of these metals analyses, comparing stations from within the ODMDS to those outside the ODMDS. With the exception of manganese, all metals show mean concentrations within the ODMDS as being lower than those outside the ODMDS. Because this data showed levels associated with dredged material disposal to be lower than ambient levels, no attempt was made to determine whether a statistical difference could be found between treatments. In the case of manganese, a quick look at

the standard deviations of the two groups (see Table 4) shows the absence of a significant difference between inside vs. outside the ODMDS.

### Benthic Macroinvertebrate Infauna.

The benthic infauna data is detailed and summarized in “Fernandina Beach, Florida ODMDS 2005 Benthic Community Assessment “(Vittor, 2006). Polychaetes dominated the total assemblage (58.9%), and also ranked first in number of taxa (45.1%) represented. In terms of abundance, the polychaetes were followed by bivalves (13.3%), malacostracans (10.2%) and gastropods (6.0%): by taxa, the polychaetes were followed by malacostracans (23.5%), bivalves (11.4%) and gastropods (9.0%). In general, the stations representing inside the ODMDS were dominated by a variety of polychaetes, while stations outside the ODMDS were dominated by a mixed assemblage of polychaetes, bivalves and gastropods.

The dominant taxa were the polychaete *Bhawania heteroseta* (5.2 %), the polychaete family Maldanidae [LPIL] (4.9%) and the polychaetes *Prionospio cristata* (4.6%), *Mediomastus* [LPIL] (3.9%) and *Polygordius* [LPIL] (3.1%).

Mean densities ranged from 625 organisms/m<sup>2</sup> at Station F07 to 3800 organisms/m<sup>2</sup> at Station F01. Although densities averaged 2025 outside the ODMDS compared to 7354.2 inside the ODMDS, there was not a significant difference in densities between stations inside vs. outside (Vittor, 2006).

The mean number of taxa ranged from 20 taxa/station at Stations F03 and F08 to 88 taxa/station at Station F05. Again, although taxa richness averaged 34.0 outside the ODMDS compared to 54.0 inside the ODMDS, there was not a significant difference in mean number of taxa between stations inside vs. outside (Vittor, 2006).

The results of cluster, ANOSIM and SIMPLER analyses are discussed in detail within Vittor, 2006. In summary, these results indicate that assemblages inside and outside the ODMDS are similar. Table 5 lists the infaunal community parameters by station.

## CONCLUSIONS

When comparing the various study parameters between stations located within the ODMDS and those outside the ODMDS, no significant differences can be found. Table 6 summarizes the main parameters of this study, demonstrating that no physical, chemical nor biological difference can be seen.

When comparing this data to data collected from the 1989 study (see Vittor, 2006), the most significant differences seen through time are in the biological parameters. Taxa

richness within the site was 29.5 taxa/station in 1989 vs. 54.0 taxa/station in 2005. Outside the site, taxa richness was 19.6 taxa/station in 1989 vs. 34.0 taxa/station in 2005. Densities within the ODMDS changed from 19152.2 in 1989 to 7354.2 in 2005. Outside the ODMDS, densities went from 7746 (1989) to 2025 (2005). However, as pointed out by Vittor, 2006, these differences are most likely due to a significant reduction in the number of samples collected from 1989 to 2005. Biological parameters from the 1989 data set were based on a total of 147 replicate samples (diver-collected hand-held cores; 0.0079 m<sup>2</sup>) whereas the 2005 data set were based on a total of 12 replicate samples.

One important note omitted in Vittor, 2006 (most likely unknown) was the fact that those samples were collected Day 1 and 2 post passage of Hurricane Hugo over the area. Divers reported near zero visibility and being tossed about while attempting to collect the benthic cores. Obviously, the bottom sediments at that time were exposed to rare dynamic stresses that calls into question how useful the data from 1989 might be in comparing communities between the treatment areas.

In conclusion, the data shows that benthic communities within the disposal footprint of the Fernandina ODMDS compare favorably with those adjacent to the dump site, and at the most basic levels of comparison, no long term adverse impact from dumping of dredged material has occurred.

NOTE: all values reported, unless otherwise flagged, were flagged with 'U'.

U-Analyte not detected at or above reporting limit. The number is the minimum quantitation limit.

UJ-Analyte not detected at or above reporting limit. Reporting limit is an estimate.

J- Identification of analyte is acceptable; reported value is an estimate

N-Presumptive evidence analyte is present

\* Numbers in bold type were non-detects that exceeded the target detection limit.
