## Infaunal and PSA analyses of benthic samples collected from around the Isle of Arran, Loch Fyne and Orkney in July and August 2015

**Commissioned Report No. 945**

**Project No: 015846**

**Contractor: Precision Marine Survey Limited**

**Year of publication: 2017**

### **Keywords**

Marine survey; MPA; South Arran; Loch Fyne; Wyre Sound; protected features; PMF; seabed habitats; infauna; PSA.

### **Background**

Provisions to designate new Marine Protected Areas (MPAs) within Scottish waters have been introduced through the Marine (Scotland) Act 2010 and the UK Marine and Coastal Access Act 2009. Management measures were announced by Marine Scotland in 2015 covering 11 MPAs designated under the Marine (Scotland) Act 2010, and nine Special Areas of Conservation (SACs), designated under the EU Habitats Directive. Sampling at South Arran and Upper Loch Fyne and Loch Goil Nature Conservation MPAs was undertaken in 2015 because they support a wide range of protected features, including those with a 'Recover' conservation objective.

Seabed surveys were conducted using drop down video, grab sampling and diver cores. This report presents the analysis of the grab samples collected during research cruises conducted by SNH during July and August 2015 on board the vessel *MRV Seol Mara*. In total 36 grab samples were collected from South Arran and 17 grab samples collected from Loch Fyne along with 28 core samples from flame shell beds in Loch Fyne. Subsequently, additional core samples from maerl beds in Wyre Sound (16 samples) were added to the project specification. Precision Marine Survey Ltd. were commissioned to undertake faunal analysis and particle size analysis (PSA) of the samples and produce a brief interpretative report to characterise the benthic infaunal communities.

### **Main findings**

- PSA of the seabed samples highlighted a variety of sediment types ranging from sandy-muds through to mixed gravelly-sands and sandy-gravels with the muddiest habitats located in the upper reaches of Loch Fyne and off the coast of Arran.
- Species diversity was also highly variable (for example, between 13 and 103 taxa per  $0.1\text{ m}^2$  in Loch Fyne). Highest diversities and species richness were recorded in the coarse/mixed sediments off Arran (up to 101 taxa per  $0.1\text{m}^2$ ) and in flame shell (*Limaria hians*) beds in Loch Fyne (up to 103 taxa per  $0.1\text{m}^2$ ). High diversities were also recorded in the Wyre Sound maerl cores (up to 86 taxa per sample).

- The Arran benthic samples were dominated by taxa such as nematode worms, *Abra alba*, *Owenia fusiformis*, juvenile Amphiuridae spp., *Gouldia minima*, *Galathowenia oculata* and *Mediomastus fragilis*. The Loch Fyne benthic grab samples were dominated by species including *Nereimyra punctata*, *Nematoda*, *Spirobranchus triqueter*, *Ophiothrix fragilis*, *Onoba semicostata*, *Ophiocomina nigra*, *Pholoe inornata*, juvenile *Modiolus modiolus*, *Gouldia minima*, *Sphaerodorum gracilis* and *Limaria hians*.
- The Loch Fyne diver core samples from the Otter Narrows *Limaria* bed were dominated by Nematoda spp., *Balanus balanus*, *Ophiocomina nigra*, *Onoba semicostata*, *Pholoe inornata*, *Verruca stroemia*, juvenile *Modiolus modiolus*, *Alvania punctura* and *Thracia villosiuscula*. *Limaria hians* were recorded in 11 of the 28 samples.
- The maerl bed diver cores in Wyre Sound, Orkney, were dominated by *Leptochiton cancellatus*, juvenile *Modiolus modiolus*, Nematoda spp., *Amphipolis squamata*, *Socernes erythrophthalmus*, *Vaunthompsonia cristata*, *Uromunna petiti*, *Animoceradocus semiserratus* and *Caprella acanthifera*.
- A variety of biotopes were recorded from the surveys including **SS.SMu.CFiMu**, **SS.SCS.ICS**, **SS.SMx.IMx**, **SS.SMx.CMx** and **SS.SMu.CSaMu.AfilMysAnit** at Arran and **SS.SMu.CFiMu**, **SS.SMx.IMx.Lim**, **SS.SMx.IMx** and **SS.SMx.CMx.OphMx** in Loch Fyne.
- Examples of **SS.SMu.CFiMu** (Circalittoral fine mud) from Arran and Loch Fyne are likely to include examples of burrowing mud biotopes (e.g. **SS.SMu.CFiMu.MegMax** or **SS.SMu.CFiMu.SpnMeg**) although video data would be required to confirm this. Burrowed mud is a protected feature in the South Arran Nature Conservation MPA and the Upper Loch Fyne and Loch Goil NC MPA. The flame shell biotope **SS.SMx.IMx.Lim** is also a protected feature of the Upper Loch Fyne and Loch Goil NC MPA and five additional records for this biotope were recorded in Loch Fyne during the benthic survey.
- Additional information on the species composition and variability within the *Limaria* beds at Otter Spit in Loch Fyne were obtained from diver cores, which highlighted the high levels of diversity associated with this habitat. Length, width and height of *Limaria* collected from the permanent dive transects were also recorded.
- Specimens of maerl (a red seaweed with a hard, chalky skeleton) were collected at 30 stations/samples. Abundances of live maerl were too low to qualify as records of maerl bed biotopes at Arran and Loch Fyne whilst maerl bed biotopes (**SS.SMp.Mrl**) were recorded in Wyre Sound. Measurements of live maerl fragments in the benthic grab and diver core samples were also undertaken.
- The ocean quahog *Arctica islandica* (a protected feature within both of the NC MPAs sampled within the Clyde Sea in this study) was recorded at five stations off Arran.

## **1. INTRODUCTION**

In July and August 2015 SNH undertook a survey to improve knowledge of the occurrence and distribution of protected seabed habitats within the South Arran (ARR) and Upper Loch Fyne and Loch Goil (LFG) Nature Conservation MPAs. A survey was also carried out in the waters around Wyre and Rousay in Orkney for a Heriot-Watt University PhD project where SNH are the case studentship partner.

Provisions to designate new Marine Protected Areas (MPAs) within Scottish waters have been introduced through the Marine (Scotland) Act 2010 and the UK Marine and Coastal Access Act 2009.

New fisheries management measures were announced by Marine Scotland in 2015 covering 11 NC MPAs designated under the Marine (Scotland) Act 2010 and nine Special Areas of Conservation (SACs) designated under the EU Habitats Directive. The South Arran and Upper Loch Fyne and Loch Goil NC MPAs were chosen for survey in 2015 because they support a wide range of protected features, including those with a 'Recover' conservation objective. The primary aim of the 2015 survey was to establish current baseline conditions for a range of the features present within the sites, against which future change can be determined.

Precision Marine Survey Limited were contracted by SNH to undertake the analyses of 53 grab samples which were collected on board the vessel *MRV Seol Mara* and 28 core samples collected during an SNH diver survey. In total 36 grab samples were collected from South Arran and 17 samples collected from Loch Fyne along with 28 core samples from flame shell (*Limaria hians*) beds in Loch Fyne. Subsequently, additional core samples from maerl beds in Wyre Sound and off Tingwall in Orkney (16 samples) were added to the project specification. Analyses included infaunal identification, particle size analysis (PSA) and the assignment of a biotope to each sample. The location of the survey areas for the 2015 surveys is provided in Figure 1.

In addition to the collection of infaunal samples, divers assessed the extent of the flame shell bed at Otter Spit in Loch Fyne and permanent transects were established in five locations to enable relocation of the stations. It is expected that the data presented here will be used for comparison with data collected in the future.

Drop down video and still photographic imagery were also collected during the survey, and results of their analysis will be reported separately.

## **2. METHODS**

### **2.1 Infaunal grab sample collection**

The Clyde Sea grab sampling was undertaken between the 12<sup>th</sup> - 21<sup>st</sup> of July 2015 around the Isle of Arran and in Loch Fyne, off western Scotland (Figures 2 and 3). Water depths at the benthic grab stations ranged from 3.9 m to 91.9 m BCD. Infaunal and PSA samples were collected from 53 stations at South Arran and Loch Fyne, and at each station a single grab sample was collected using a 0.1 m<sup>2</sup> Day grab. PSA samples were not collected from three sites in Loch Fyne (FG10, FG24 and FG28) resulting in a total of 53 infaunal samples and 50 PSA samples.

Stations in South Arran were randomly selected within depth and habitat stratified sampling boxes (see clustered stations in Figure 2) to allow for a mixed model approach to analysis in the future, where the sample box can be used as a random factor to account for spatial autocorrelation (Millar and Anderson, 2004). Similarly, stations in Orkney were selected

where abiotic data such as flow rate are also available. The biological community data will feed into models to show the relationship between flow rate and diversity which is beyond the scope of this report.

Grab sample station positioning in Loch Fyne was informed by the results of previous studies and designed to increase confidence in our knowledge of feature extent and to validate biotopes assigned to towed video in the same area. Grab sampling was targeted outside the previously mapped boundaries of the flame shell bed in Otter Narrows to minimise disturbance to the bed (where diver cores were used). It is hoped that potential recovery of the bed here can be monitored using grab sampling techniques to register sparse *Limaria* presence in the sediment (and derive measures of *Limaria* abundance and size frequency) prior to the development of a conspicuous byssal carpet. Monitoring of the return of adult *L. hians* and the associated byssal turf development would subsequently be carried out by diving (Moore, 2014). For the purposes of this report some statistical analysis of community measures was carried out to describe similarity between sites and to help assign biotopes, however, given that no true replicates were taken, the conclusions regarding differences between sites are limited.

Once the grab was recovered on board a small sub-sample was removed for separate particle size analysis (PSA) and stored in a plastic bag before being frozen. Each infaunal sample was passed through a 1 mm mesh sieve. The sieve residue was retained and fixed using buffered formalin. A summary of the sampling details for the survey is provided in Annex 1 and maps showing the locations of the sampling stations are given in Figures 2 and 3.

## 2.2 Diver sample collection

Diver core samples were collected from the *Limaria* bed in Loch Fyne from the 10<sup>th</sup> to the 12<sup>th</sup> of August 2015 at 6.8 m to 10.7 m BCD. Core samples were collected by divers along five 25 m transects at Otter Sound (Table 2) using a standard diver core (110 mm diameter cores driven in to 20 cm depth of sediment). Three permanent transect markers (yellow steel posts - see Figure 1) were hammered into the seabed at the start, middle and end of the transects. The posts were marked with 1, 2 and 3 horizontal black stripes to represent their position along the transect. Six replicate core samples were taken at intervals along the transects (at 2.75, 6.75, 10.75, 14.75, 18.75 and 22.75 m) unless core lids were broken at the surface in which case less replicates were used. In addition to the core samples, divers carried out cell frequency counts of *Limaria* nest material from 0.25 m<sup>2</sup> quadrats at 1 m intervals along the transects. Divers also estimated *Limaria* nest percentage cover at eight spot dives. Sample locations are provided in Figure 4 and Annex 1.

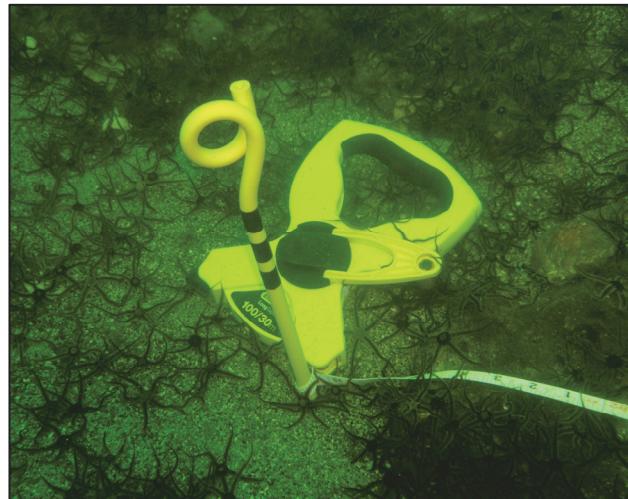

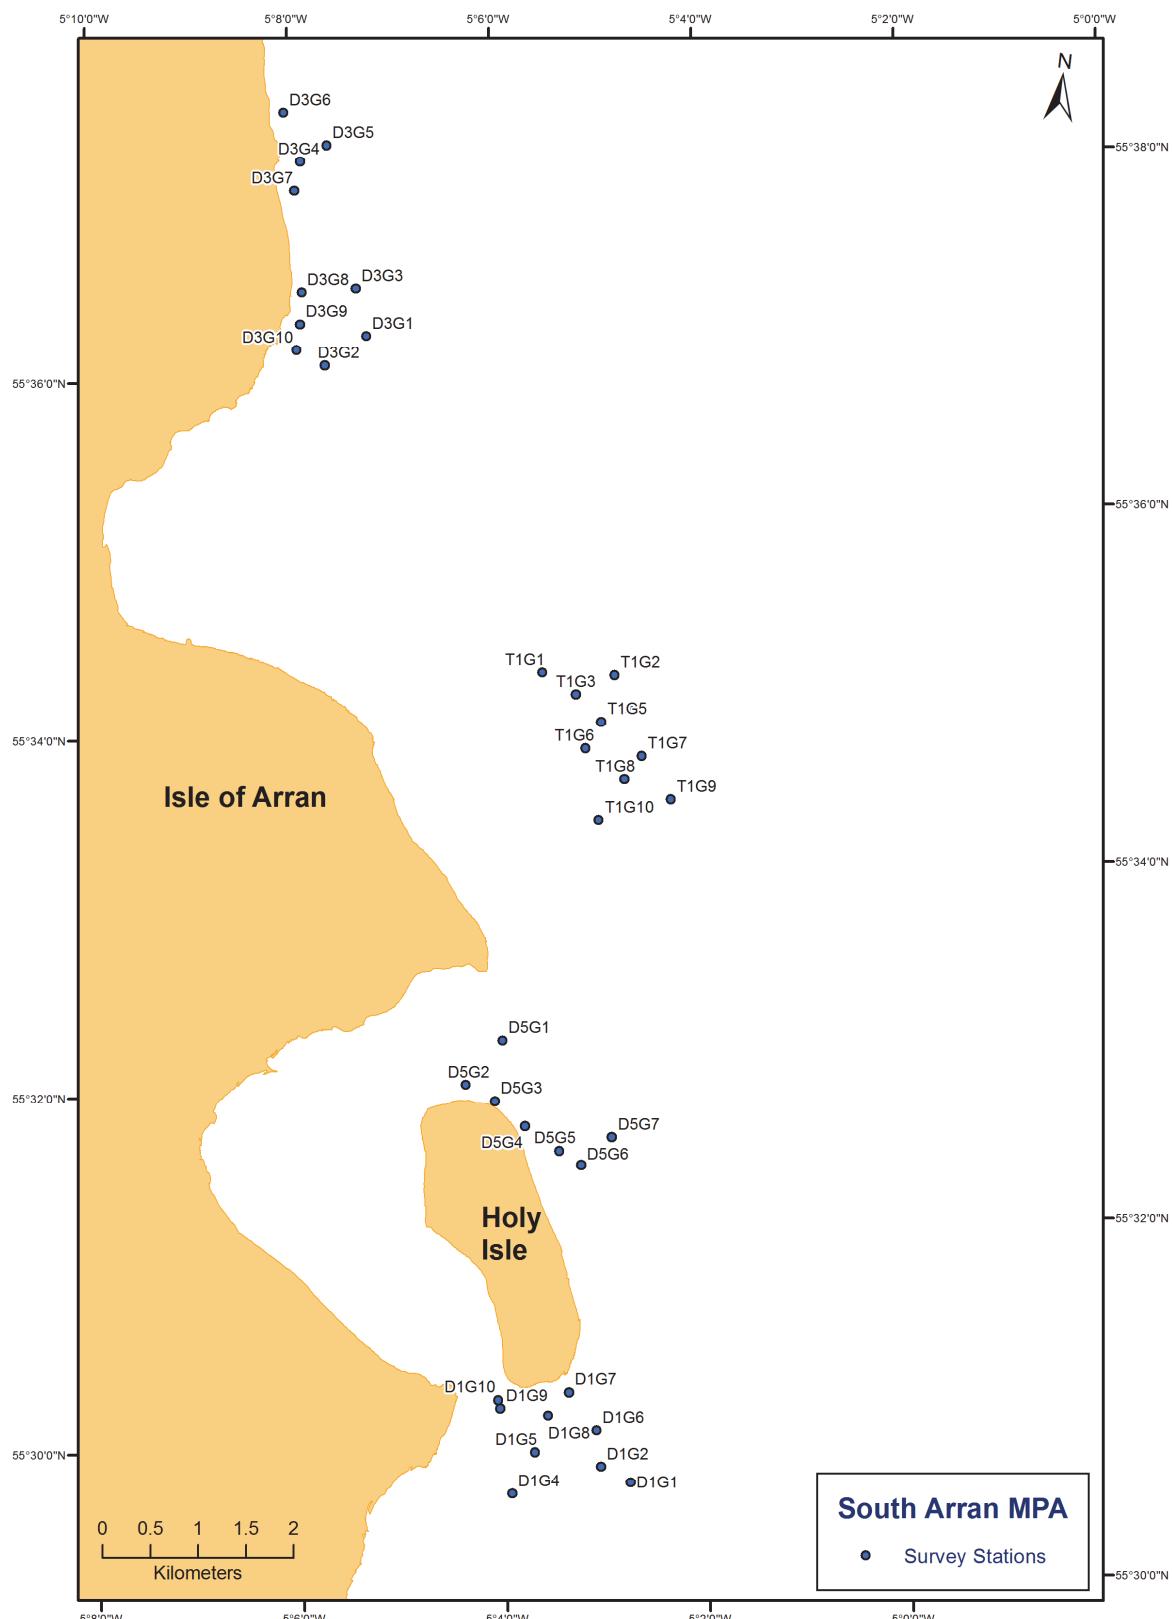

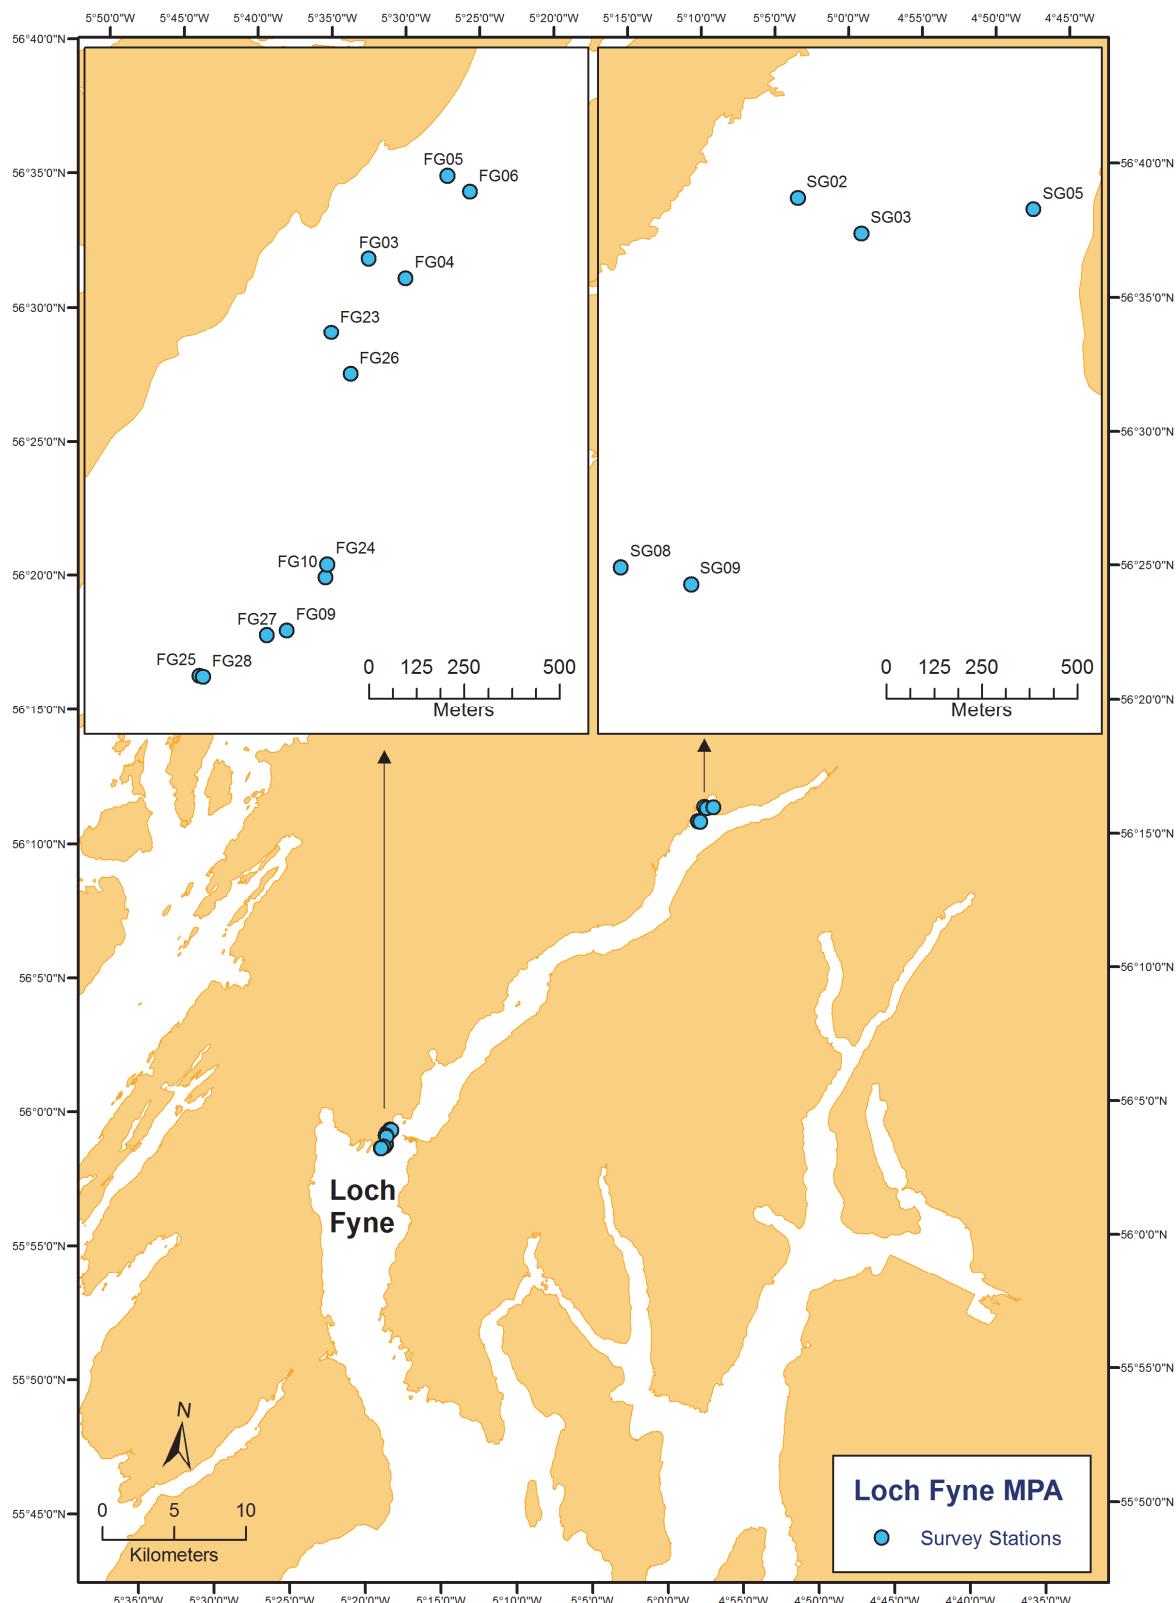

Figure 1. Example of a transect marker at the end of a transect.

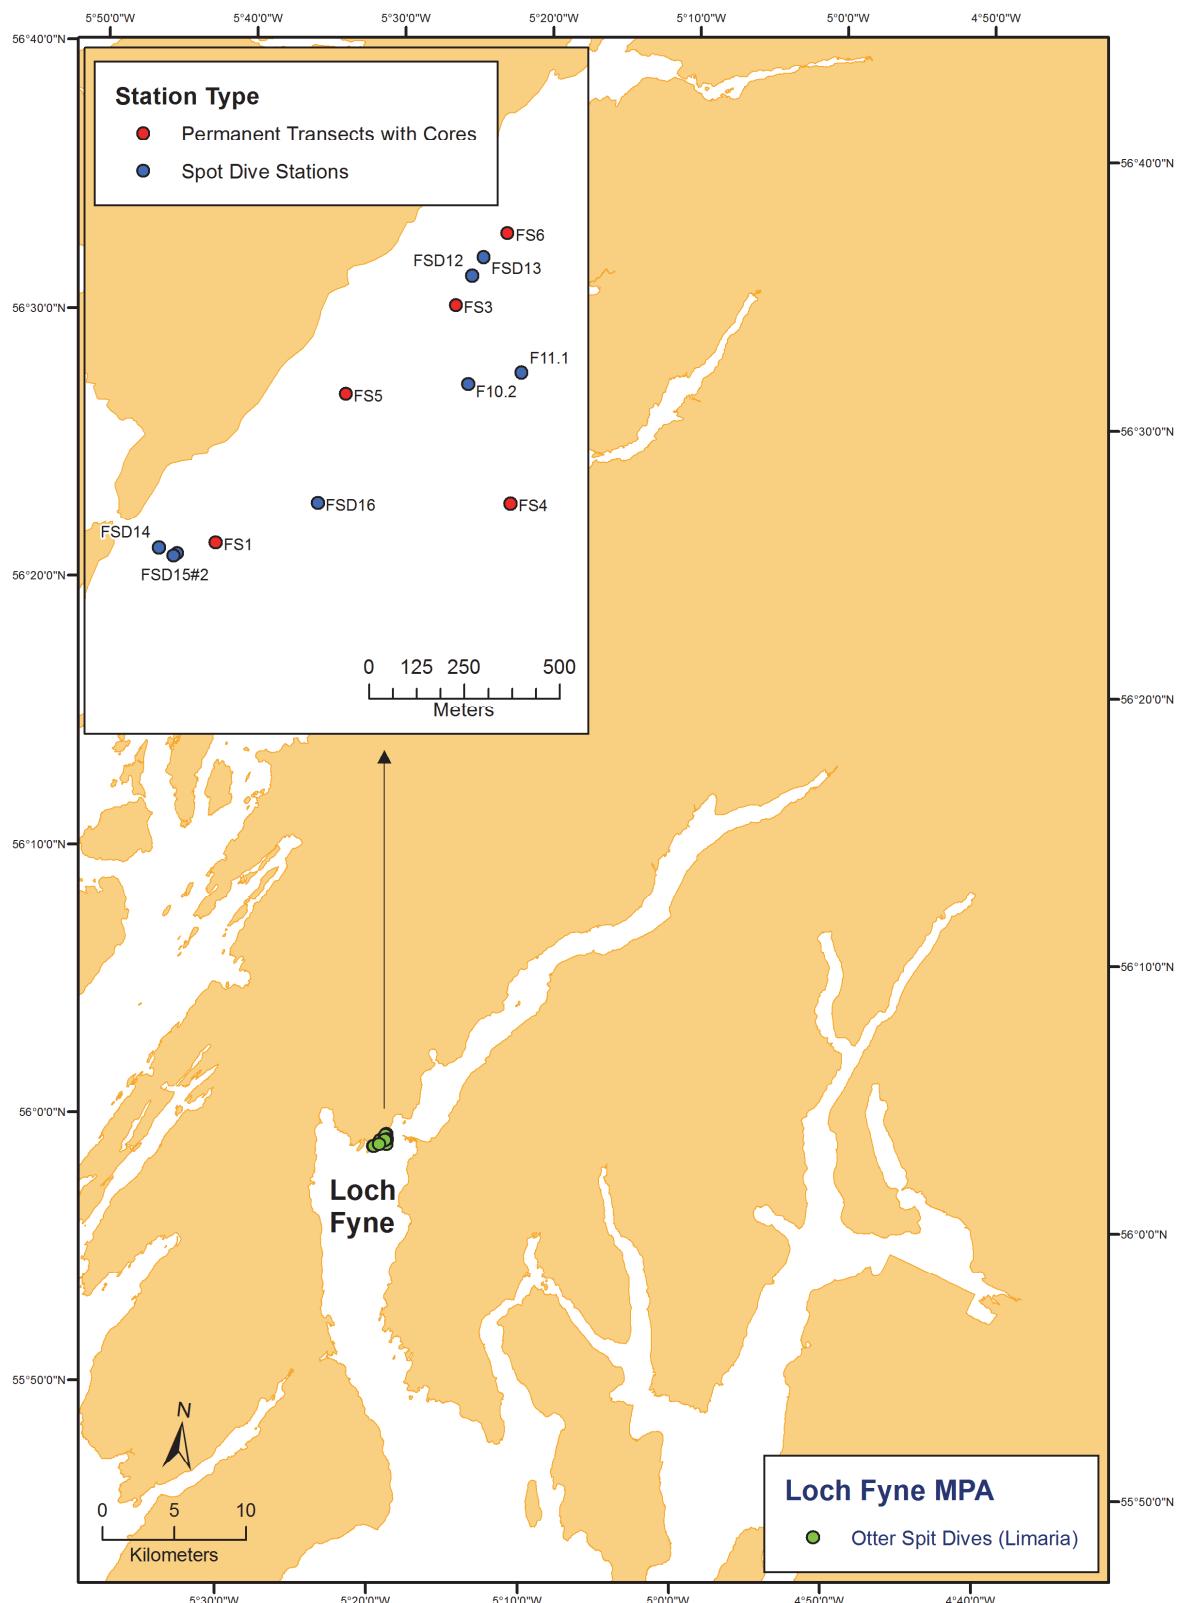

The additional core samples collected in Wyre Sound for processing under this project were collected using standard 110 mm diameter diver core (20 cm depth). Four replicate cores were taken at three sites in Wyre Sound and one off Tingwall in Orkney (Figure 5 and Annex 1). Sample locations were haphazardly selected on the top of a maerl wave formation where live maerl had accumulated.

## 2.3 Laboratory Processing

All laboratory methodologies were based on best practice (Thomas, 2001; Rees *et al.*, 1990; Rees 1999; Cooper & Rees 2002; Worsfold & Hall, 2010; Ware & Kenny, 2011). In addition Precision Marine Survey Limited is a member of the National Marine Biological and Analytical Quality Control scheme (NMBAQC). Two experienced members of staff undertook all the sieving, sorting work and sample description with a further member of staff carrying out standard sorting quality control. Experienced taxonomists carried out the identification of the sorted fauna, with an additional member of staff carrying out quality control for faunal identification. A standard sample tracking procedure was followed throughout the analysis period.

Prior to species identification each sample was washed through a nest of sieves to remove the preservative and partition the sample for ease of sorting. The smallest mesh aperture was 1 mm and larger sieves (5 mm or 10 mm) were also used as required to separate larger animals or coarser sediment residue. The residue from each sieve was then gently washed into separate 100 mm petri dishes for subsequent identification. For larger samples the sieve residue was put into a separate bucket or white tray with water and the contents agitated. Immediately after agitation, the light fraction was decanted to another container. The light fraction was then decanted into petri dishes and the remaining residue put into a separate container.

The sample containers / petri dishes were marked with the appropriate sample code (relating to the client, date, specific station, sample and replicate no.). All fractions were then decanted into separate 100 mm petri dishes and examined under a stereoscopic microscope. The fauna derived were then split by phyla and placed in glass vials with 70% IMS and stored ready for identification. Each petri dish was then checked for a final time by another member of staff.

Identification was carried out using Olympus SZ40 zoom microscopes with 10X and 20X eyepieces, giving a maximum magnification of up to 80X. An additional 2X objective was occasionally used to increase the potential magnification to 160X. Olympus BX41 compound microscopes were used for further magnification, up to 800X. Identification of infaunal samples was to the lowest possible taxonomic level (i.e. species), and during identification, all individuals were initially separated into families, with part animals being assigned to families where possible. The macrofaunal specimens were identified to species level using standard taxonomic keys, low and high power stereoscopic microscopes and dissection, when necessary, for identification. Incomplete animals without anterior ends were not recorded as individuals to be included in the quantitative dataset. However, they were identified where possible and recorded as present.

The taxonomic literature used was that as detailed in Rees *et al.* (1990) which includes the most recent updates in the scientific literature and newer keys provided by groups such as the NMBAQC and species reporting nomenclature used WoRMS standards (WoRMS editorial board, 2016) and the WoRMS MSBIAS subset (UK Marine Environmental Data and Information Network, 2011).

Measuring of live maerl fragments were undertaken for 30 samples from Arran, Loch Fyne and Wyre Sound and this was undertaken by extracting live maerl fragments from sieve residue on a 5mm sieve and measuring the maximum length of each fragment. Specimens of *Limaria hians* were also measured from samples collected from Loch Fyne with length, width and breadth measured to the nearest mm for each specimen.

The particle size analysis was carried out by a combination of dry sieving and laser particle size analysis (for the fraction <1 mm) using a Malvern Mastersizer 3000 following the latest

NMBAQC guidance (Mason, 2016 v18\_01\_2016). Prior to analysis, photographs were taken of all samples. The sediment samples were then split with one sub-sample being passed through a 1mm sieve to remove the larger size classes of sediment if required and the <1 mm fraction of the sub-sample analysed using the Malvern Mastersizer 3000. If the PSA sample contained any material above 1mm the remainder of the PSA sample was wet sieved through a 1mm sieve. Each fraction, including the <1 mm fraction was then oven dried at 100°C for 12 hours and weighed with the >1mm fraction passed through a nest of sieves at 0.5 phi intervals. Coarse and fine fractions were combined following NMBAQC guidelines and the data derived from PSA were then used to derive statistics including mean grain size, bulk sediment classes (% silt, sand & gravel), skewness and sorting coefficient using the program Gradistat. These methods are consistent with the procedures identified at the recent NMBAQC PSA workshop on laboratory methods, which was held at the Cefas Lowestoft laboratory in 2014.

## 2.4 Analysis of Biological Data

### Univariate Analysis

A number of primary and derived biological parameter values were calculated from the species data which were subsequently tabulated and input into GIS. A variety of standard biological parameters are routinely utilised for benthic analysis which summarise the species richness and diversity of the benthic communities and may subsequently be used for management purposes to monitor temporal/spatial trends and allow further statistical testing. The following biological parameters have been used in the current study as these are widely reported in the industry and therefore allow comparison with other surveys and were also used for a number of recent SNH surveys in the Clyde Sea area (Allen, 2013, 2014).

- The total number of species at each station (S)
- The total abundance of individuals at each station (A)
- Margalef's index of species richness (d)
- Shannon's diversity index ( $H'$ ) - This index is a univariate measure of diversity which incorporates both the number of species and the distribution or equitability of individuals between species. High values of  $H'$  indicate a more diverse community whilst low values indicate low diversity.
- Pielou's evenness (J) - This index is a univariate measure of evenness or equitability which describes the distribution of individuals between species. High values of J (approaching 1) indicate that the abundance of animals are evenly spread between species whilst low values of J (approaching 0) indicate that the majority of animals comprised a few species, a situation which often occurs in low diversity areas subject to disturbance or organic enrichment.

### Multivariate Analysis

Multivariate analysis of the abundance data was carried out in order to describe the main patterns and assemblages within the area following standard methodologies (Clarke and Warwick, 2001; Clarke and Gorley, 2006). The samples were analysed for each area (Arran, Loch Fyne and Orkney) to simplify interpretation of biotopes within each MPA and given that habitat types and communities were quite distinct. The differing sampling techniques and sample sizes utilised for the dive core surveys (Loch Fyne and Orkney) in contrast to the grab sampling surveys also required that these samples were analysed separately. Classification (cluster analysis) of the data was undertaken using the Bray-Curtis similarity coefficient and grouped average (UPGMA) clustering technique followed by a non-metric MDS (multi-dimensional scaling) ordination both using the PRIMER package. Cluster analysis is used to display graphically the similarity between stations based upon their

species composition whereby the similarity between stations is calculated (in this case using the Bray-Curtis similarity coefficient) to produce a similarity matrix showing the percent similarity of stations (0% indicating no species in common and 100% indicating an identical community).

These values are then used to plot a dendrogram or tree diagram in which stations are linked at their respective similarity to other stations and consequently it is possible to define groups of stations with similar species composition at a predefined level of similarity. This information along with available environmental data can subsequently be used to assist in the assignation of biotopes.

Non-metric MDS graphically displays the (rank) similarity between stations as a 2 dimensional plot in which the distances between stations indicates the level of similarity between them. The station groupings derived from cluster analysis were subsequently superimposed onto the MDS plots and input into GIS, with the dominant species and mean environmental and biological parameters calculated for each group. Station groupings were derived using the similarity profile test (SIMPROF) within the PRIMER package.

Characteristic taxa within each group were assessed using calculations of mean abundance and the percentage of stations at which the species occurred, and by using the SIMPER routine within PRIMER. The most characteristic taxa for each cluster group derived from SIMPER analysis have been presented along with available environmental data in tabular form to provide a summary of the biological and environmental characteristics of each group of stations which can then be used to assist in the derivation of biotopes.

Correlations between species data and sediment parameters were undertaken using the BEST routine within PRIMER which derives a non-parametric Spearman correlation between the similarity matrices derived from the biological and environmental data. The results of this procedure give the statistic  $r$  which gives an indication of the strength of the relationships between the environmental parameters and community structure with higher values (approaching 1) indicating a strong positive correlation. This technique also derives a subset of the best combination of environmental parameters which give the highest correlation in similarity.

### **3. RESULTS - ARRAN & LOCH FYNE GRAB SAMPLING**

#### **3.1 Sedimentary parameters (South Arran and Loch Fyne)**

The results of particle size analysis are provided in Annex 2 with a summary of key parameters provided in Annex 3. The spatial distribution of sediment types is illustrated in Figures 6 and 7 which highlight bulk sediment classes (% sand, gravel and mud) for the Arran and Loch Fyne sampling stations respectively.

At South Arran sediments are predominantly gravelly or slightly gravelly sandy muds/muddy sands with a few sites characterised by cleaner gravelly sands, sandy gravel or gravel. In Loch Fyne sediments were either gravelly muddy sands or (slightly gravelly) sandy mud. Quantities of gravel at the survey stations were highly variable and ranged from < 1% (predominantly at the T1 stations in South Arran and the SG stations in Loch Fyne) to 89% at station D5G3. Gravel content tended to be highest at inshore sites to the north at South Arran (stations D3) or inshore around Holy Isle. Mud content was also highly variable at South Arran with values ranging from 1.62% (station D5G3) to 83.8% (station T1G4) with relatively few stations having less than 10% mud (D5G3, D5G4, D1G7, D3G4, D5G1 and D3G9). In Loch Fyne sediments tended to be muddier with mud contents ranging from 9.11% at station FG09 to 68.14% at station SG02. This variability was reflected in the values of sediment sorting coefficients with all samples poorly or very poorly sorted.

### 3.2 Primary and derived biological parameters

The samples collected from South Arran during the survey varied considerably in terms of species richness, densities, diversity and evenness and these parameters have been summarised in Table 3 with the spatial distribution of the number of species, abundance and Shannon's diversity provided in Figures 8 to 10. Overall the Arran survey stations were considered to exhibit moderate to very high levels of diversity whilst the densities (abundances) of infaunal organisms were moderate to low (Table 3). The numbers of species recorded per sample station ranged from 11 taxa per 0.1 m<sup>2</sup> at T1G3 and T1G4 to 101 taxa per 0.1 m<sup>2</sup> at D5G4, and aside from the T1 stations the majority of samples had over 50 taxa per 0.1m<sup>2</sup>. Figures 8 and 9 highlight lower numbers at the offshore T1 stations whilst higher numbers tend to occur at the most inshore stations.

The abundances of invertebrates ranged from low to moderately high with numbers ranging from 18 individuals at station T1G4 up to 778 individuals per 0.1 m<sup>2</sup> at station D3G9. The majority of stations had between 150 to 400 individuals per 0.1 m<sup>2</sup> with lower densities recorded at the offshore T1 stations of which the majority had fewer than 100 individuals. Densities at the other stations were more variable but with slightly higher numbers closer inshore. Diversity indices were also quite variable but generally showed moderate to high levels of diversity and evenness. With the exception of stations D1G10 and D5G6 the inshore stations all had H' values above four with many exhibiting high values above 5. The offshore stations (T1 samples) tended to have somewhat lower values of Shannon's H' ranging from 2.58 to 4.06. All stations with the exception of D1G10, D5G6 and T1G1 and exhibited evenness values above 0.7 with most showing values above 0.8. As described for numbers of taxa and abundance lower diversity metrics were generally recorded at the offshore stations.

*Table 3. Primary and derived biological parameters at South Arran.*

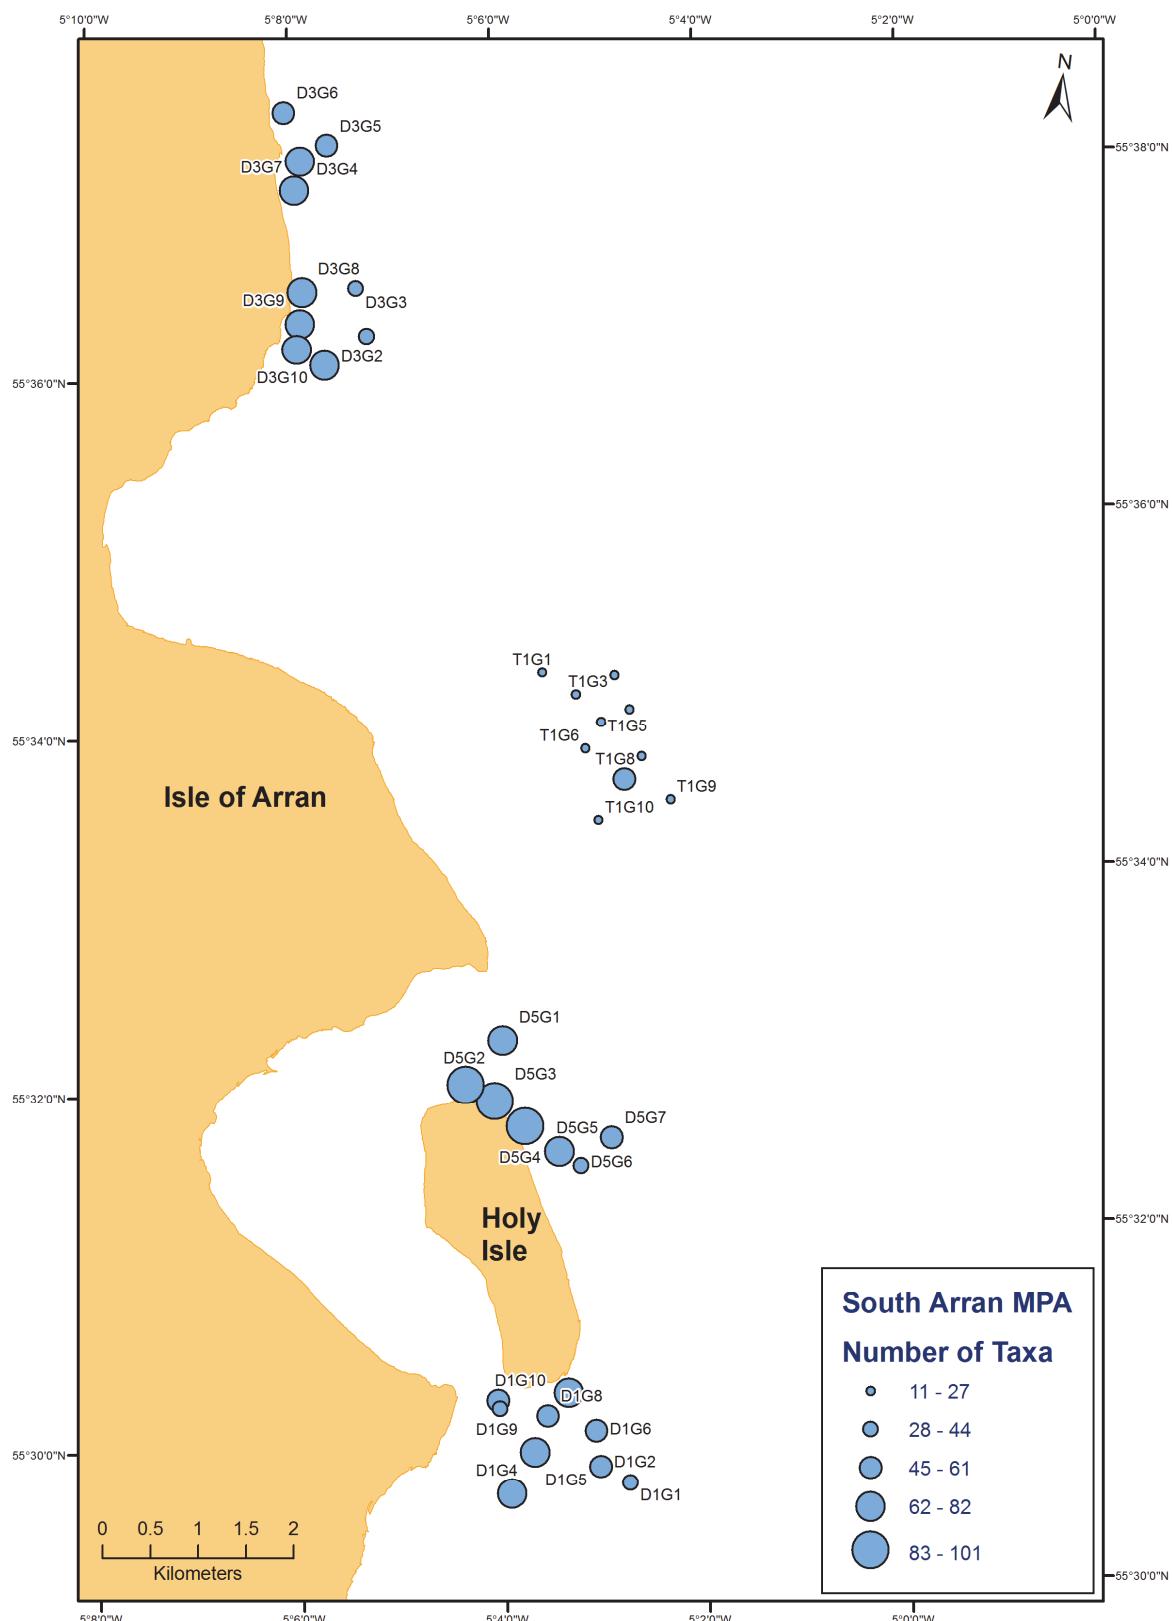

Station	Number of Species per 0.1m <sup>2</sup>	Total Abundance (A) per 0.1m <sup>2</sup>	Margalef's d	Pielou's Evenness J	Shannon's Diversity H'
D1G1	38	70	8.71	0.94	4.91
D1G2	49	242	8.74	0.81	4.55
D1G4	75	309	12.56	0.82	5.10
D1G5	74	257	12.98	0.89	5.52
D1G6	60	241	10.76	0.87	5.12

The primary and derived biological parameters recorded at Loch Fyne (Table 4 and Figures 11 to 13) highlight the presence of a varied and often diverse range of benthic communities with the numbers of taxa per 0.1m<sup>2</sup> ranging from 13 (SG02 and SG09) to 103 (FG27). Lowest numbers of species were recorded in the muddier upper Fyne samples (SG02 to SG09) whilst samples in the lower loch were generally characterised by high numbers of taxa with most stations having in excess of 50 taxa. A similar pattern was evident with regards to the numbers of animals recorded (abundance) which were relatively low (<70 per 0.1m<sup>2</sup>) in the upper loch and moderate to high in the lower loch with abundances ranging from 33 (SG09) to 1318 (FG27) individuals per 0.1m<sup>2</sup>. Diversity and evenness metrics also highlighted higher levels of diversity in the lower loch compared with the upper reaches with values of Shannon's H' diversity for example ranging from 2.3 to 3.08 at stations SG02 to SG09 in upper Loch Fyne whilst the remaining stations in the lower loch all had values of H' greater than 4 with some stations having particularly high H' values above 5 (FG27 and FG23). Pielou's evenness (J) ranged from moderate to high with values ranging 0.6 (SG05) to 0.86 (FG25 and FG26).

### 3.3 Species composition

In total 438 taxa were recorded from the 36 Arran samples collected and whilst many of these were present in low abundances or at relatively few stations it highlights the relatively high diversity and variability of the South Arran survey area with regard to infaunal communities. A list of taxa ranked by abundance (taxa which account for 50% of total abundance) is provided in Table 5 and the full species dataset is provided in Annex 4. In terms of abundance, nematode worms along with *Abra alba*, *Owenia fusiformis*, juvenile Amphiuridae spp., *Gouldia minima*, *Galathowenia oculata* and *Mediomastus fragilis* were most abundant and together accounted for just under over 23% of the animals collected. These species were present in 36% to 61% of the samples. Other taxa with moderate abundances included *Verruca stroemaria*, *Lumbrineris* agg., *Leptochiton asellus*, *Aonides paucibranchiata*, *Spirobranchus triqueter*, *Dosinia exoleta*, *Balanus crenatus*, *Nemertea* spp., *Echinocyamus pusillus*, *Scalibregma inflatum*, *Amphiura filiformis*, *Ennucula tenuis*, *Leptochiton cancellatus*, *Nucula nucleus*, *Glycera lapidum* agg., *Edwardsia claparedii*, *Abra nitida*, *Spiophanes kroyeri*, *Pholoe baltica* and *Thracia villosiuscula* which together with the previously mentioned species accounted for 50% of the total abundance.

Table 5. Dominant taxa (by abundance) recorded at the South Arran survey stations.

Taxa (Sth Arran)	Total Abundance	Mean Abundance	Cumulative% of Total Abundance	No. of Samples	% of Samples
Nematoda spp.	497	13.81	5.44	13	36
<i>Abra alba</i>	377	10.47	9.56	22	61
<i>Owenia fusiformis</i>	281	7.81	12.64	20	56
Amphiuridae spp. (juvenile)	264	7.33	15.53	18	50
<i>Gouldia minima</i>	259	7.19	18.36	16	44
<i>Galathowenia oculata</i>	225	6.25	20.82	17	47
<i>Mediomastus fragilis</i>	201	5.58	23.02	20	56
<i>Verruca stroemaria</i>	182	5.06	25.01	4	11
<i>Lumbrineris</i> agg.	179	4.97	26.97	24	67
<i>Leptochiton asellus</i>	167	4.64	28.80	13	36
<i>Aonides paucibranchiata</i>	165	4.58	30.61	9	25
<i>Spirobranchus triqueter</i>	160	4.44	32.36	13	36
<i>Dosinia exoleta</i>	153	4.25	34.03	18	50
<i>Balanus crenatus</i>	146	4.06	35.63	7	19
<i>Nemertea</i> spp.	132	3.67	37.07	26	72
<i>Echinocyamus pusillus</i>	131	3.64	38.51	17	47
<i>Scalibregma inflatum</i>	130	3.61	39.93	24	67
<i>Amphiura filiformis</i>	129	3.58	41.34	14	39
<i>Ennucula tenuis</i>	115	3.19	42.60	9	25
<i>Leptochiton cancellatus</i>	113	3.14	43.83	11	31
<i>Nucula nucleus</i>	106	2.94	44.99	13	36
<i>Glycera lapidum</i> agg.	103	2.86	46.12	18	50
<i>Edwardsia claparedii</i>	95	2.64	47.16	14	39
<i>Abra nitida</i>	93	2.58	48.18	12	33
<i>Spiophanes kroyeri</i>	87	2.42	49.13	22	61
<i>Pholoe baltica</i>	80	2.22	50.01	16	44
<i>Thracia villosiuscula</i>	79	2.19	50.87	7	19
<i>Kurtiella bidentata</i>	78	2.17	51.72	18	50
<i>Lysianassa plumosa</i>	75	2.08	52.54	9	25
<i>Sosane sulcata</i>	71	1.97	53.32	8	22

A wide range of other polychaete, bivalve, crustacean and echinoderm taxa were also recorded in very low numbers with the majority of taxa recorded at fewer than three stations. Specimens of live maerl were recorded at a number of the shallower stations off Arran albeit in relatively low densities. In the muddier sediments further offshore (stations T1) low

numbers of larger crustacea were recorded at some stations including burrowing megafauna such as *Calocaris macandreae* and *Nephrops norvegicus*. A few examples of the PMF species *Arctica islandica* were also recorded.

The Loch Fyne benthic samples recorded a total of 279 taxa (Annex 5) with a diverse variety of faunal groups predominantly polychaetes, echinoderms (notably ophiuroids) and bivalve molluscs. Five samples included *Limaria hians*, a habitat forming species and a protected feature in the Upper Loch Fyne and Loch Goil NC MPA.

The most dominant taxa recorded within the Loch Fyne grab samples (Table 6) included *Nereimyra punctata*, Nematoda, *Spirobranchus triqueter*, *Ophiothrix fragilis*, *Onoba semicostata*, *Ophiocomina nigra*, *Pholoe inornata*, juvenile *Modiolus modiolus*, *Gouldia minima*, *Sphaerodorum gracilis*, *L. hians*, *Leptochiton asellus* and *Polycirrus* spp. which collectively accounted for 51% of the total abundance. These taxa were often patchily distributed and occurred in 29% to 71% of the samples with the most ubiquitous taxa including *Polycirrus* spp., Nemertea, *S. triqueter* and *S. gracilis* which were recorded in over 70% of the samples. A wide range of other polychaete, bivalve, crustacean and echinoderm taxa were also recorded in very low numbers with the majority of taxa recorded at fewer than 15% of stations. Occasional fragments of live maerl (*Phymatolithon calcareum* or *Lithothamnion* sp.) were recorded at a number of the shallower stations in Loch Fyne albeit in low densities.

Table 6. Dominant taxa (by abundance) recorded at the Loch Fyne survey stations.

Taxa (Fyne)	Total Abundance	Mean Abundance	Cumulative % of Total Abundance	No. of Samples	% of Samples
<i>Nereimyra punctata</i>	397	23.35	7.73	9	53
Nematoda	288	16.94	13.34	8	47
<i>Spirobranchus triqueter</i>	270	15.88	18.60	12	71
<i>Ophiothrix fragilis</i>	254	14.94	23.55	7	41
<i>Onoba semicostata</i>	234	13.76	28.11	6	35

<i>Ennucula tenuis</i>	44	2.59	68.25	10	59
<i>Ophiopholis aculeata</i>	43	2.53	69.09	4	24
<i>Glycera lapidum</i> agg.	40	2.35	69.87	8	47
<i>Moerella donacina</i>	40	2.35	70.65	6	35

### 3.4 Multivariate analysis (Arran)

The results of multivariate analysis on the benthic samples are provided in Figure 14. Similarities between samples range from 10% to just over 60% highlighting a quite varied benthic assemblage which is likely to reflect (in part) the high numbers of taxa occurring in low numbers at few stations. The SIMPROF routine identified 14 groups of samples as highlighted in Figure 14 although these included five groups containing a single sample. The main divisions split the majority of the offshore T1 samples in groups a and b from the remaining samples at around 10% similarity whilst the other main division splits groups c to g from groups h to m at around 20% similarity. The results of the BEST routine (Table 7) highlight the correlation between the environmental parameters and species similarity data. Correlations ranged from 0.114 (sediment kurtosis) to 0.857 (water depth) with mud content and median/mean phi grain size also exhibiting relatively high correlations around 0.7 or above. The remaining parameters exhibited somewhat lower correlations. The best combination of parameters was water depth and median phi grain size which gave a combined correlation of 0.865. These results reflect the correlation between water depth and mud content/median grain size with the deeper sites over 40m water depth (SG stations) having mud contents in excess of 60% whilst shallower inshore stations tended to have a lower mud content. However, there was also considerable differences in mud content at the shallower stations which was not depth dependent. Such trends could be examined further in the future using additional analysis e.g. Permanova.

The characteristic taxa derived from SIMPER which accounted for the bulk of the similarity within sample groups (typically the top 70%) are provided in Annex 6 which also includes the list of samples and a summary of the sediment types and water depth (m CD) to aid in biotope assignments. For groups with just a single station (groups d, e, j, k and l) just the most dominant taxa are shown. Group a includes four stations in the offshore T1 area in deep sandy muds with a very low gravel content. These stations are characterised by taxa such as *Abra alba*, *Mediomastus fragilis*, *Spiophanes kroyeri*, *Chaetoderma nitidulum*, *Scoletoma fragilis*, *Glycera unicornis*, *Nucula nucleus* and *Nephtys incisa*. A number of stations in this group also included burrowing megafauna such as *Nephrops norvegicus* and *Calocaris macandrea*. Group b comprised on the majority of the remaining offshore stations in similar sediments but with a somewhat lower mud content and variable but higher gravel content. These stations were characterised by taxa such as *A. alba*, *S. kroyeri*, *Abra nitida*, *Ennucula tenuis*, *Dasybranchus* spp., *Turritella communis* and *N. incisa* and also occasionally included examples of burrowing megafauna.

Group c comprised samples from D3 stations in shallow water whilst group d was represented by a single station (D1G8). These shallow water stations were typically characterised by mixed muddy sandy gravel or gravelly muddy sand with taxa such as *Scalibregma inflatum*, *Gouldia minima*, *Lysianassa plumosa*, *Vaunthompsonia cristata*, *Leptochiton asellus*, *Echinocyamus pusillus*, *Tectura virginea*, *Nereimyra punctata* and *Spirobranchus triqueter* (group c) or *Mediomastus fragilis*, *Leptochiton cancellatus*, *Lumbrineris* agg., *Aonides paucibranchiata*, *Glycera lapidum* agg., *Scalibregma inflatum* and *Echinocyamus pusillus* (group d).

Group e comprised a very gravelly site (D5G3) which was characterised by Nematoda spp., Amphiuridae spp. (juvenile), *Gouldia minima*, *Malmgrenia mcintoshii*, *Leptochiton asellus*, *Leptochiton cancellatus*, *Ophiocomina nigra* and *Spirobranchus triqueter*. Group f included stations D3G8 and D3G9 in shallow mixed sediment habitats with sandy gravels with a moderate silt content and taxa including Nematoda spp., *M. fragilis*, *Aonides paucibranchiata*, *Grania* spp., *Glycera lapidum* agg., *S. triqueter* and juvenile Amphiuridae spp.

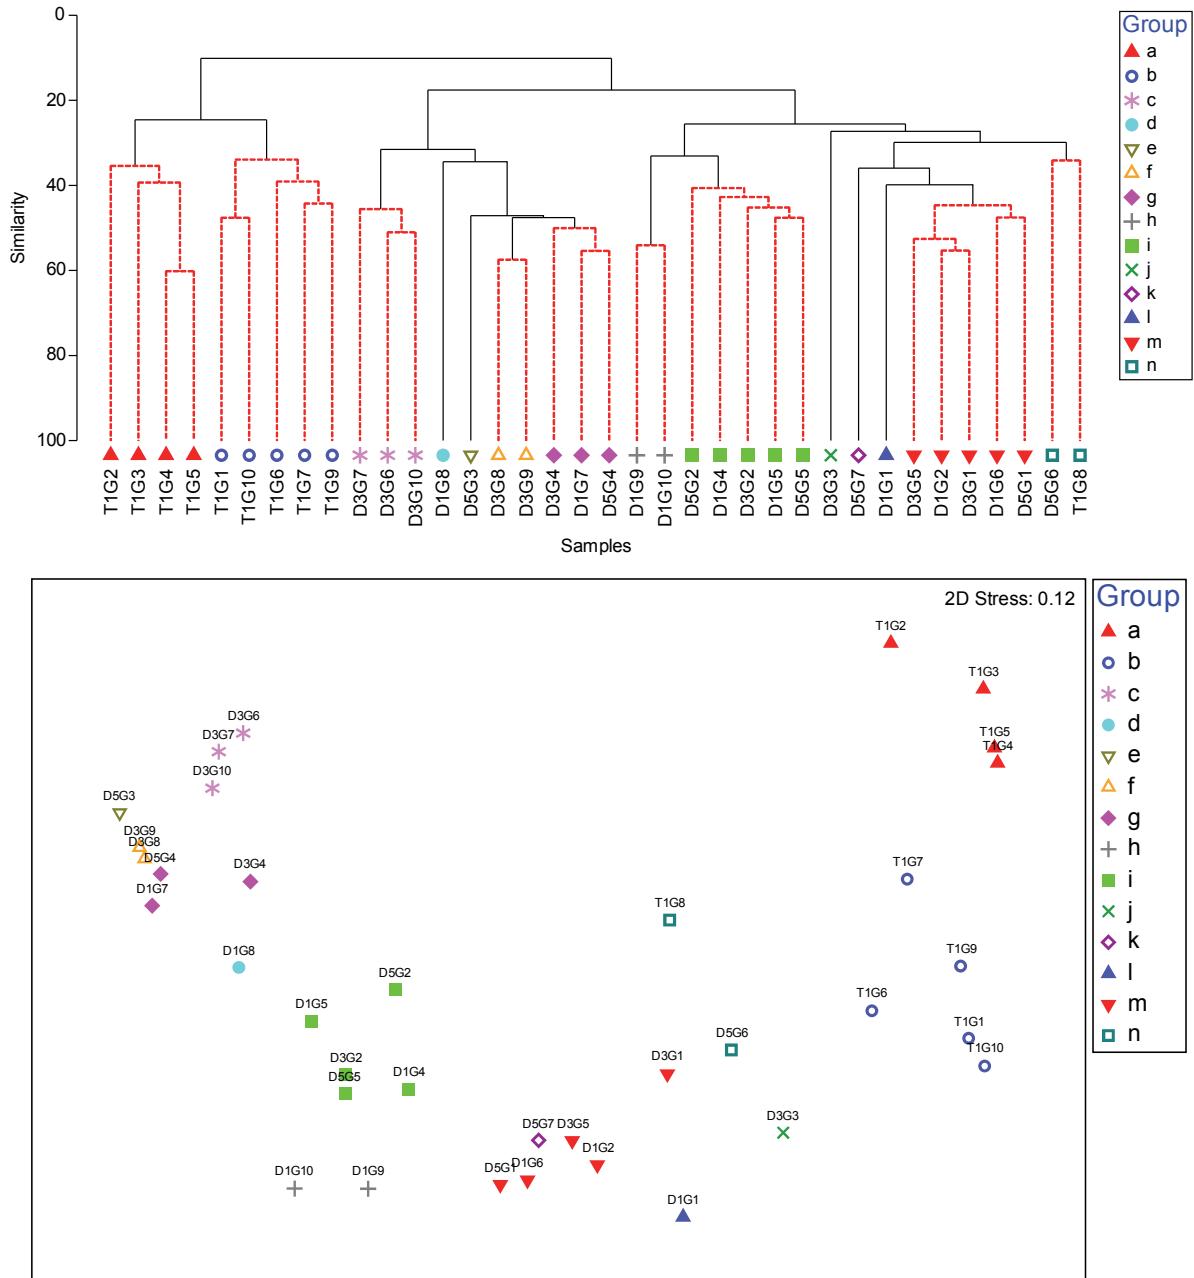

Figure 14. Results of cluster analysis and MDS.

Group g included stations D1G7, D3G4 and D5G4 which were also relatively shallow inshore habitats but with somewhat cleaner sandy gravel or muddy sandy gravel sediments. This group of stations was characterised by taxa including *G. minima*, *Leptochiton asellus*, *Aonides paucibranchiata*, *Dosinia exoleta*, *Leptochiton cancellatus*, *M. fragilis*, *Echinocyamus pusillus*, *Thracia villosiuscula*, *S. triquetus*, Macrochaeta spp. and *Clausinella fasciata*. Many of the stations from groups c to g were found in areas with maerl gravel and occasional live fragments of maerl were often recorded at these stations with high numbers of invertebrate taxa.

Groups h and i were clustered together at around 30% similarity and included a number of stations in slightly deeper water in mixed gravelly muddy sand. These were typically characterised by taxa such as *Sosane sulcata*, *Owenia fusiformis*, *Lumbrineris agg.*, *Kurtiella*

*bidentata*, *Polycirrus* spp., *Balanus balanus* and *Goniada maculata* (group h) or *Owenia fusiformis*, *Balanus crenatus*, *Lumbrineris* agg., *Nemertea* spp., *Galathowenia oculata*, *Amphictene auricoma* and *Terebellides stroemii* (group i).

Groups j and k were associated with groups l and m both included a just single station (D3G3 and D5G7 respectively) in deeper slightly gravelly sandy muds. These were characterised by lower numbers of taxa such as *Abra* spp., *Chaetozone setosa*, *A. alba*, *Nucula hanleyi*, *Spiophanes kroyeri*, *Notomastus* spp. and *Amphiura filiformis* (group j) or *Amphiuridae* spp. (juvenile), *G. oculata*, *O. fusiformis*, *Kurtiella bidentata*, *Nemertea* spp., *Amphiura filiformis*, *Spio* spp. and *Spiophanes kroyeri* (group k). Group l also consisted of a single station (D1G1) in slightly gravelly muddy sand characterised by *G. oculata*, *A. alba*, *A. filiformis*, *Polycarpa* spp., *Amphiuridae* spp. (juvenile) and *Timoclea ovata*. Group m included a range of stations in moderately deep circalittoral (slightly gravelly) muddy sands with moderately high mud content and taxa including *Galathowenia oculata*, *A. filiformis*, *O. fusiformis*, *Amphiuridae* spp. (juvenile), *A. alba*, *Edwardsia claparedii*, *Diplocirrus glaucus*, *Nemertea* spp., *Nucula hanleyi*, *Lumbrineris* agg., *Phaxas pellucidus*, *Polycirrus* spp., *Ampelisca tenuicornis*, *Phoronis* spp., *Nephtys hombergii* and *Dosinia exoleta*.

Group n included two stations a circalittoral inshore site in (slightly gravelly) muddy sand (D5G6) and an offshore deeper sandy mud site (T1G8). These stations were characterised by high numbers of *A. alba* along with *Amphictene auricoma*, *Abra nitida*, *Nucula nucleus*, *Nemertea* spp., *G. oculata* and *Spiophanes kroyeri* with the offshore site also including a single *Nephrops norvegicus*.

*Table 7. Results of the BEST routine. Parameters with ticks highlight those parameters which in combination produced the highest correlation with species similarity data.*

Parameter	Correlation (r)	Best Combination (r=0.865)
Depth	0.857	✓
Median Phi	0.734	✓
Mud	0.708	
Mean Phi	0.697	
Gravel	0.374	
Sand	0.343	
Skewness	0.164	
Sorting	0.127	
Kurtosis	0.114	

### 3.5 Multivariate analysis (Loch Fyne)

The results of multivariate analysis on the benthic samples are provided in Figure 15. Similarities between samples range from around 5% to just below 70% highlighting a quite varied benthic assemblage which is likely to reflect (in part) the high numbers of taxa recorded in low numbers at relatively few stations and also the variations in habitat type. The SIMPROF routine identified 8 groups of samples as highlighted in Figure 15 although these included four groups containing a single station. The results of SIMPER analysis on the cluster groups derived from SIMPROF which highlights characteristic taxa along with environmental parameters are provided in Annex 7.

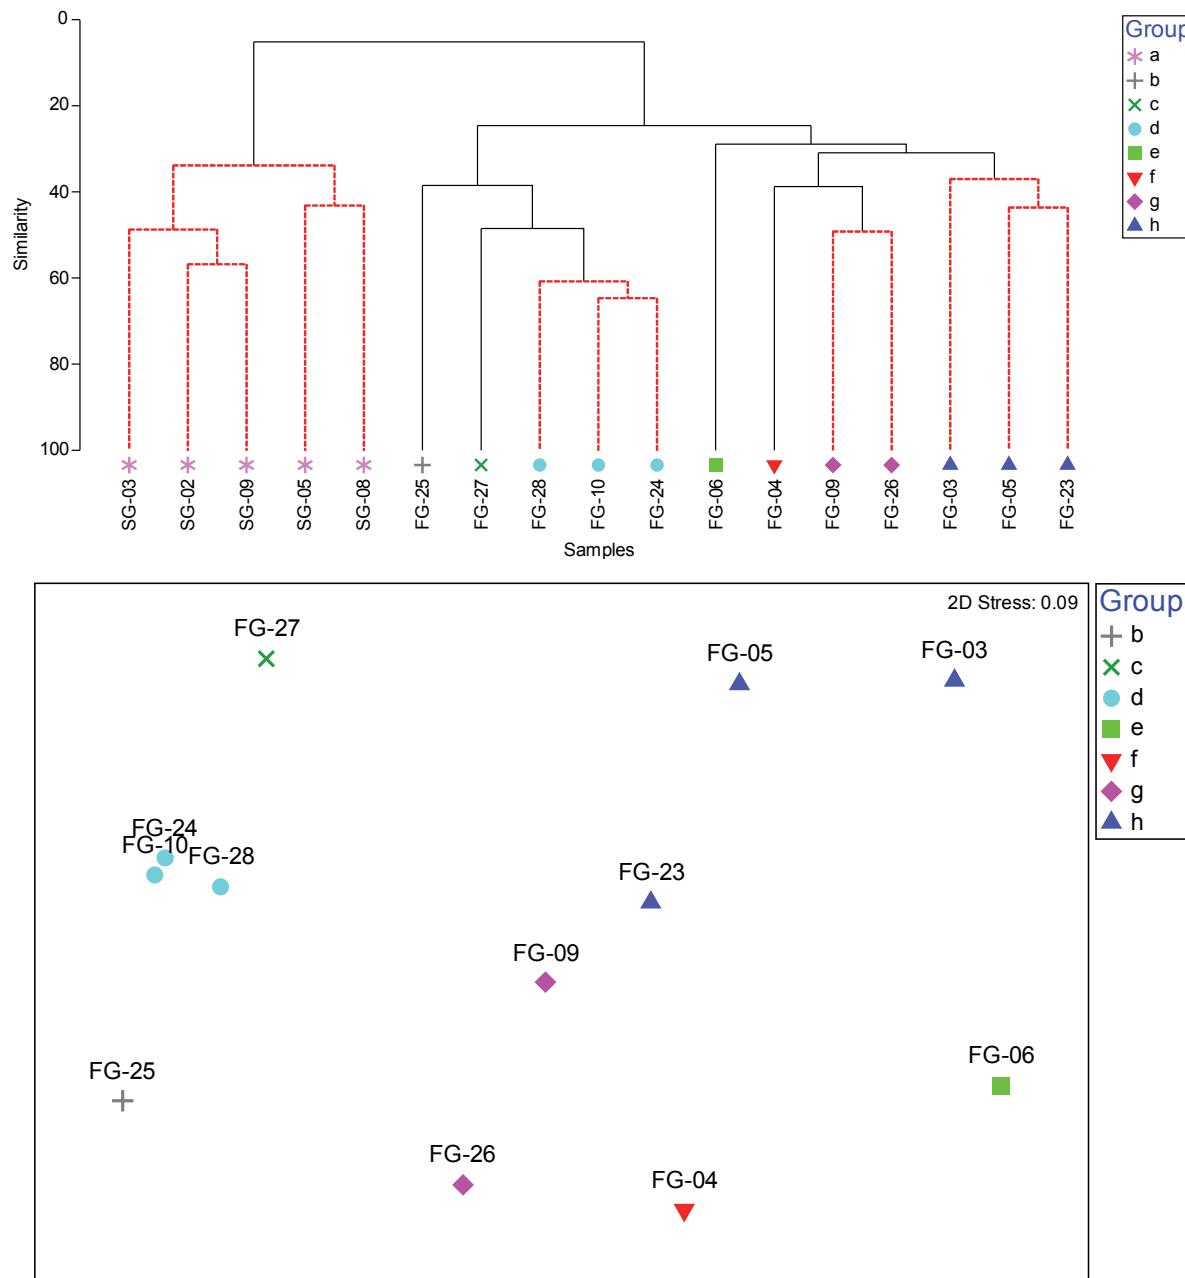

Figure 15. Results of cluster analysis and nMDS (SG stations from group a omitted).

Group a consists of all the SG stations located in deeper water in (slightly gravelly) sandy mud which were separated from the remaining stations at around 5% similarity. These

stations were characterised by *Amphiura chiajei* and *Diplocirrus glaucus* along with a variety of other less frequently recorded taxa with lower densities such as *Cylichna cylindracea*, *Spiophanes kroyeri*, *Chaetozone setosa*, *Ennucula tenuis*, *Scalibregma inflatum* and *Nemertea* spp. Groups b and b comprised single stations (FG25 and FG27 respectively) in shallow gravelly muddy sand characterised by either *Ophiothrix fragilis*, *Nereimyra punctata*, *Ophiopholis aculeata*, *Ophiocomina nigra*, *Harmothoe* spp., *Ensis ensis*, *Onoba semicostata*, *Lumbrineris* agg. and *Mya arenaria* with occasional flame shell (*Limaria hians*) in group b, or *Onoba semicostata*, *Nematoda*, *Nereimyra punctata*, *Modiolus modiolus*, *Pholoe inornata*, *O. fragilis*, *L. hians*, *Spirobranchus triqueter*, *Sphaerodorum gracilis* and *Ophiocomina nigra* in group c. Both of these stations were loosely associated with stations FG10, FG24 and FG28 in group d which were taken from *Limaria* nest material and along with moderately high numbers of *Limaria* included taxa such as *Nereimyra punctata*, *Nematoda*, *Pholoe inornata*, *O. fragilis*, *M. modiolus*, *Polycirrus* spp., *Onoba semicostata*, *Sphaerodorum gracilis*, *Hiatella arctica*, *S. triqueter*, *Ennucula tenuis* and *Ophiocomina nigra*.

Groups e and f consisted of single stations FG06 and FG04 which were loosely associated with groups g and h at around 30 to 40% similarity which were all characterised by somewhat mixed sediments (gravelly muddy sand) in shallow water. Group e was characterised by taxa such as *Pseudopolydora pulchra* along with *Phaxas pellucidus*, *Mya truncata*, *Thyasira flexuosa*, *Dosinia lupinus*, *Nemertea*, *Ampelisca tenuicornis*, *Thracia villosiuscula* and *Pholoe inornata* whilst group F was characterised by moderate numbers of the ophiuroid *O. nigra* and the encrusting polychaete *S. triqueter* along with *Lysianassa plumosa*, *Dosinia lupinus*, *Glycera lapidum* agg., *Balanus balanus* and *Moerella donacina*.

Group g (FG09 and FG26) was also characterised by quite high numbers of *O. nigra* along with polychaetes such as *Sphaerodorum gracilis*, *Lumbrineris* agg. and *Mediomastus fragilis* with other taxa including *Leptochiton asellus*, *S. triqueter*, *G. lapidum* agg. and *Gouldia minima* also present. The stations in group H were also characterised by shallow gravelly muddy sand and whilst ophiuroids were present in somewhat lower numbers (including a variety of *Ophiothrix* species or *O. nigra*) these stations were also characterised by bivalves such as *G. minima*, *Thyasira flexuosa*, *Moerella donacina* and *Thracia villosiuscula* along with a variety of other taxa such as *Leptochiton asellus*, *S. triqueter*, *Lysianassa plumosa* and *Photis longicaudata*.

The results of the BEST routine (Table 8) indicated that sedimentary parameters and water depth were well correlated to patterns in species similarity with most parameters exhibiting correlations above 0.5 with sand content, mud content and depth all having correlations above 0.7. Sediment skewness and kurtosis had rather low correlations (<0.2) and the best combination of parameters were sand content, water depth, median phi grain size and sediment sorting with a correlation of 0.856.

*Table 8. Results of the BEST routine on the Loch Fyne data. Parameters with ticks highlight those parameters which in combination produced the highest correlation with species similarity data.*

### 3.6 Biotope composition (Arran)

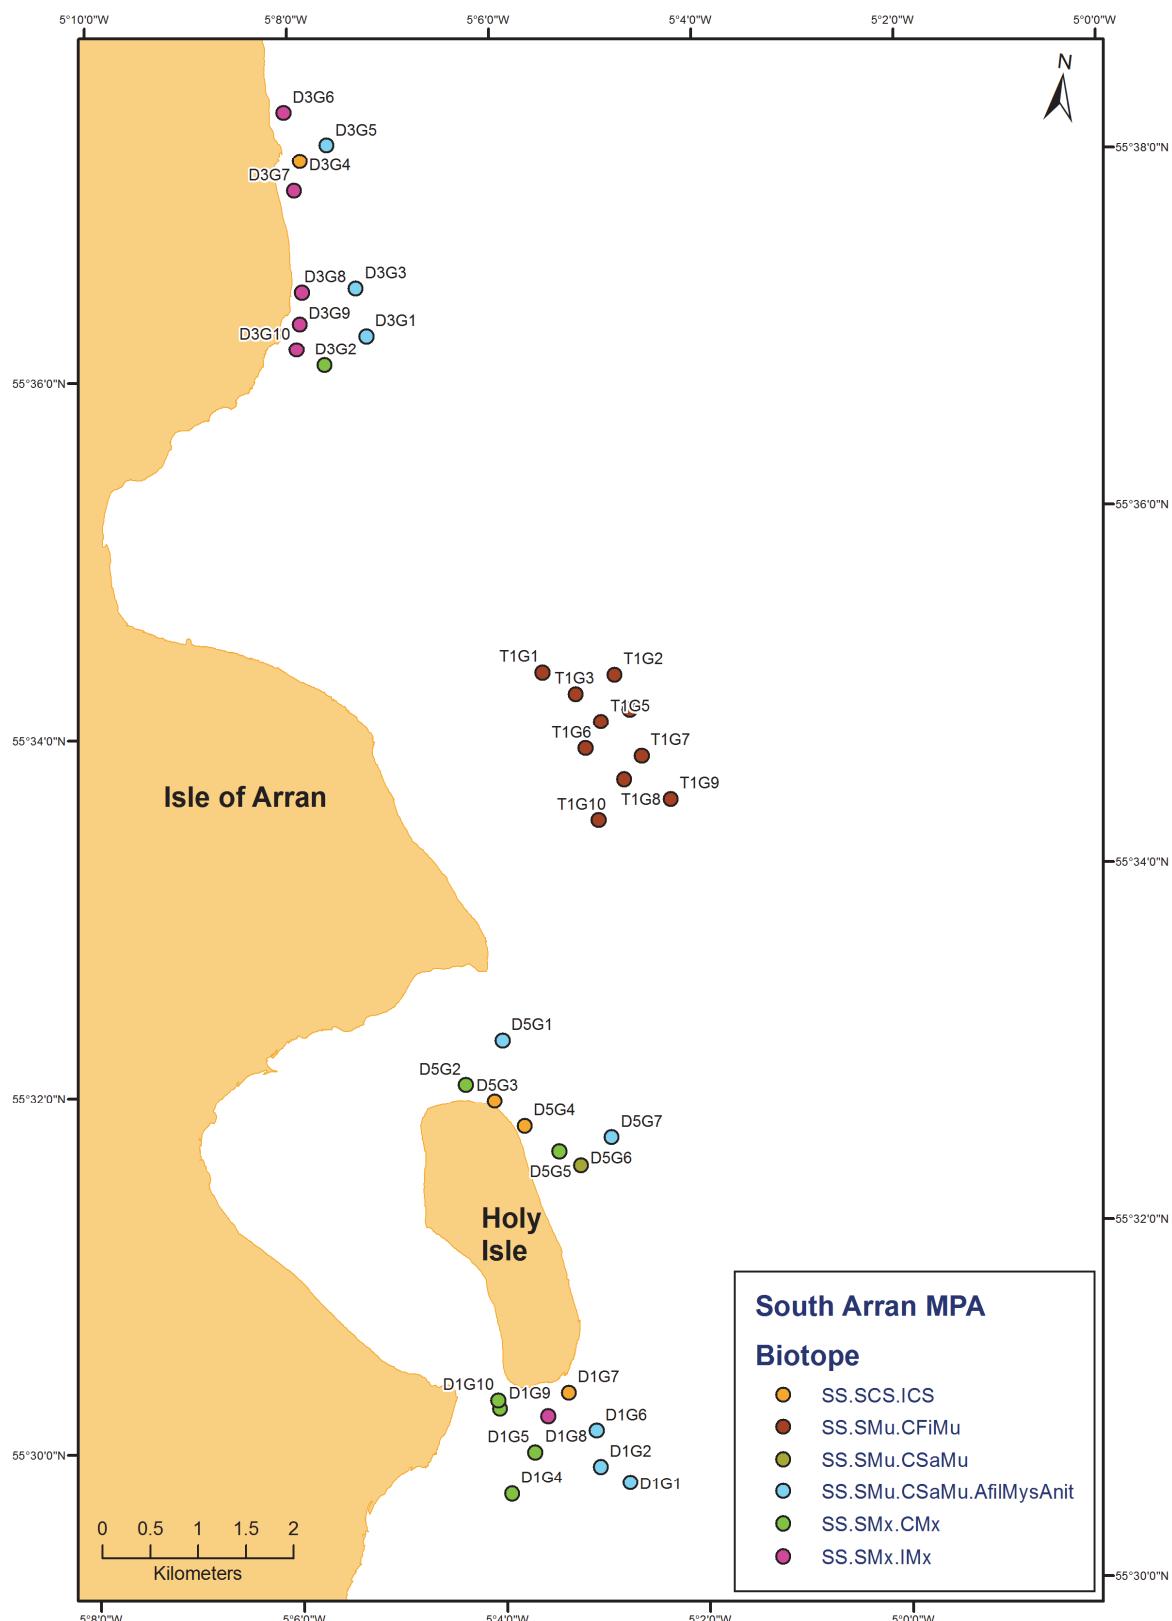

Biotopes were assigned to each station on the basis of species composition, sedimentary parameters, water depth and the results of multivariate analysis. A number of the stations exhibited somewhat poorly defined or intermediate infaunal communities notably from coarse or mixed sediment communities which are rather poorly defined by the current version of the UK biotope classification (Connor *et al.*, 2004). A summary of biotope codes for stations in each of the groups derived by cluster analysis with sediment descriptions and characteristic taxa is provided in Table 9. A number of stations had rather uncertain biotope classifications as described below and have been recorded with the appropriate qualifier for entry into Marine Recorder. The spatial distribution of biotopes around South Arran is provided in Figure 16.

The stations within groups a and b are typically deep mud or sandy mud habitats with a comparatively impoverished infaunal community (in relation to the inshore stations) which resembles that recorded in burrowed mud communities and occasional megafauna were recorded in the grabs at some stations in these groups. Whilst these have been assigned **SS.SMu.CFiMu** (Circalittoral fine mud) this area are likely to include examples of **SS.SMu.CFiMu.MegMax** (Burrowing megafauna and *Maxmuelleria lankesteri* in circalittoral mud) or possibly **SS.SMu.CFiMu.SpnMeg** (Seapens and burrowing megafauna in circalittoral fine mud). Characterisation of such biotopes from grab samples is problematic given that they typically under sample larger taxa and video footage would be required to be certain of any finer resolution biotope assignment.

Groups c to g include the samples from shallow inshore mixed muddy sandy gravels around Arran. These groups included muddier and cleaner variants of shallow infralittoral mixed or coarse sediment biotopes with the coarser fraction often comprising maerl gravel and live specimens of maerl were also recorded in low densities. The maerl fragments recorded in the grab sample residues were not present in sufficient densities to be classified as a maerl biotope. However, video data would be required to confirm the presence of maerl biotopes in the general vicinity of these stations. Such habitats were often extremely diverse and supported a range of taxa including robust venerid bivalves and a range of other bivalves such as *Moerella* spp. (albeit in low numbers). Whilst these biotopes are somewhat poorly defined and currently classified as **SS.SCS.ICS** (Infralittoral coarse sediment) and **SS.SMx.IMx** (Infralittoral mixed sediment) these stations show some resemblance to coarse gravel or sand biotopes such as **SS.SCS.CCS.MedLumVen** (*Mediomastus fragilis*, *Lumbrineris* spp. and venerid bivalves in circalittoral coarse sand or gravel) (Connor *et al.*,

2004) and **SS.SCS.ICS.MoeVen** (*Moerella* spp. with venerid bivalves in infralittoral gravelly sand). It is possible that such habitats are shallow, slightly silty, maerl influenced variants of these biotopes.

Groups h and i include moderately deep circalittoral mixed sediments (typically gravelly muddy sands) which are quite diverse but poorly defined in terms of the biotope classification and have subsequently been assigned **SS.SMx.CMx** (Circalittoral mixed sediment). Groups j, k, l and m are closely associated in the cluster analysis and include stations characterised by circalittoral muddy sands with quite high mud content usually with moderate numbers of *Abra* spp., brittlestars such as *Amphiura filiformis* and Oweniidae polychaetes along with a wide range other bivalves and polychaetes. These have tentatively been assigned the biotope **SS.SMu.CSaMu.AfilMysAnit** (*Amphiura filiformis*, *Mysella bidentata* and *Abra nitida* in circalittoral sandy mud) although this classification is rather uncertain as species composition is quite variable and these communities also resemble other circalittoral muddy sand/sandy mud biotopes such as **SS.SMu.CSaMu.AfilNten** (*Amphiura filiformis* and *Nuculoma tenuis* in circalittoral and offshore sandy mud) or **SS.SMu.CSaMu.ThyNten** (*Thyasira* spp. and *Nuculoma tenuis* in circalittoral sandy mud). This group also shows some similarity to offshore biotopes such as **SS.SSa.OSa.OfusAfil** (*Owenia fusiformis* and *Amphiura filiformis* in offshore circalittoral sand or muddy sand) so perhaps represent an intermediate variant. The two stations in group n are rather poorly defined circalittoral muddy sand or sandy mud habitats classified as **SS.SMu.CSaMu** and **SS.SMu.CFiMu** although the latter (station T1G8) in deeper water included a specimen of *Nephrops norvegicus* so as described for groups a and b could include burrowing megafauna biotopes such as **SS.SMu.CFiMu.MegMax** or **SS.SMu.CFiMu.SpnMeg**.

### 3.7 Biotope Composition (Loch Fyne)

The groups defined from cluster analysis have been tabulated with biotope, sediment type, water depth and dominant taxa in Table 10 and the spatial distribution of biotopes mapped in Figure 17 along with the *Limaria* bed boundary defined from surveys undertaken in 2012 (Moore *et al.* 2013). The stations labelled “SG” in the upper loch are not particularly well defined in terms of biotope but the infauna in this area are similar to those often recorded in burrowed mud communities. Whilst these have been assigned **SS.SMu.CFiMu** (Circalittoral fine mud) this area may include examples of **SS.SMu.CFiMu.MegMax** (Burrowing megafauna and *Maxmuelleria lankesteri* in circalittoral mud) or possibly **SS.SMu.CFiMu.SpnMeg** (Seapens and burrowing megafauna in circalittoral fine mud). Characterisation of such biotopes from grab samples is problematic given that they typically under sample larger taxa and video footage would be required to be certain of specific biotope or sub-biotope classification.

The stations in groups b, c and d in the lower loch all include moderate densities of the flame shell, *Limaria hians*, and have therefore been classified as **SS.SMx.IMx.Lim** (*Limaria hians* beds in tide-swept sublittoral muddy mixed sediment). The single station in group e (FG-06) is not particularly well defined so on the basis of its environmental characteristics has been assigned the biotope **SS.SMx.IMx** (Infralittoral mixed sediment). The stations in groups f, g and h are all gravelly muddy sands often dominated by brittlestars (notably *Ophiocomina nigra* or *Ophiothrix* spp.) so have been classified as **SS.SMx.CMx.OphMx** (*Ophiothrix fragilis* and/or *Ophiocomina nigra* brittlestar beds on sublittoral mixed sediment). Stations in Group h generally exhibit lower numbers of brittlestars so the biotope determination of **SS.SMx.CMx.OphMx** is uncertain and these stations could represent an intermediate community or reflect patchiness in brittlestar distribution. As such the stations in group h could also be grouped at a higher level e.g. **SS.SMx.IMx** (Infralittoral mixed sediment).

## 4. LOCH FYNE (OTTER SPIT) LIMARIA CORE SAMPLING

### 4.1 Primary and derived biological parameters

The biological parameters derived for each core sample from the permanent dive transects in Loch Fyne are provided in Table 11 and highlight a high level of variability both between and within the survey transects. *Limaria* density ranged from zero to eight individuals with highest numbers generally recorded at transects FS1 and FS5 and no *Limaria* present at transect FS4. Whilst variable the other biological parameters generally correlated to *Limaria* density with highest species richness, density and diversity recorded in samples with higher densities of *Limaria*. The number of species recorded ranged from 5 taxa (FS6.1 and FS4.5) to 64 taxa (FS1.3), with transects FS1 and FS5 which had greater numbers of *Limaria* generally having the highest number of taxa but all transects were highly variable. Transect 4 (no *Limaria* present) consistently had the lowest number of taxa ranging from 5 to 22 taxa. Total abundance was also highly variable and exhibited similar patterns to the number of taxa with abundances ranging from 5 (FS6.1) to 418 taxa (FS5.6). The majority of samples had fewer than 100 animals with over 50% of the samples having fewer than 50 individuals. Highest abundances tended to occur at samples along transects FS1 and FS5 which had higher *Limaria* densities. Pielou's evenness ranged from moderate to high with values ranging from 0.59 (FS4.5) to 1 (FS6.1) and this parameter was less correlated to *Limaria* density. Shannon's diversity ranged from rather low to moderately high with values ranging from 1.37 (FS4.5) to 4.85 (FS1.1) and as described for other parameters highest levels of Shannon's diversity tended to occur in samples with higher densities of *Limaria*.

*Table 11. Primary and derived biological parameters recorded at the Loch Fyne Limaria stations.*

Station	Number of Species	Total Abundance (A)	Margalef's d	Pielou's Evenness J	Shannon's Diversity H'	Limaria Density
FS1.1	52	217	8.92	0.86	4.85	8
FS1.2	12	20	3.67	0.94	3.38	0
FS1.3	64	370	9.98	0.76	4.47	6
FS1.4	14	24	4.09	0.94	3.57	0

## 4.2 Species Composition

The diver cores collected in Loch Fyne collected a total of 200 taxa (Annex 8) although many of the taxa recorded were present in relatively low numbers. The benthic communities were typified by a range of invertebrates including barnacles, bivalve molluscs, ophiuroid echinoderms and a variety of polychaetes. Flame shells were present at all bar one transect (FS4) and were present at 11 of the 28 sample stations. Dominant taxa recorded during the survey included Nematoda spp., *Balanus balanus*, *Ophiocomina nigra*, *Onoba semicostata*, *Pholoe inornata*, *Verruca stroemia*, *Modiolus modiolus*, *Alvania punctura* and *Thracia villosiuscula* which accounted for 51% of the total abundance although the majority of taxa occurred in fewer than 50% of the samples with *Thracia villosiuscula*, *Ophiocomina nigra*, *Gouldia minima*, juvenile/immature *M. modiolus* and *Spirobranchus triqueter* the most ubiquitous taxa recorded at 50% to 85% of samples. Fragments of live maerl were also recorded at a few of the sample locations albeit in low quantities.

*Table 12. Dominant taxa (by abundance) recorded at the Loch Fyne Limaria survey stations.*

Taxa	Total Abundance	Mean Abundance	Cumulative % Abundance	No. of Samples	% of Samples
Nematoda spp.	452	16.14	15.25	12	43
<i>Balanus balanus</i>	212	7.57	22.41	9	32
<i>Ophiocomina nigra</i>	188	6.71	28.75	22	79
<i>Onoba semicostata</i>	149	5.32	33.78	9	32
<i>Pholoe inornata</i>	148	5.29	38.78	12	43
<i>Verruca stroemia</i>	107	3.82	42.39	9	32
<i>Modiolus modiolus</i> (juv.)	101	3.61	45.80	14	50
<i>Alvania punctura</i>	79	2.82	48.46	8	29
<i>Thracia villosiuscula</i>	78	2.79	51.10	24	86
<i>Hiatella arctica</i>	73	2.61	53.56	8	29
<i>Spirobranchus triqueter</i>	70	2.50	55.92	14	50
<i>Flabelligera affinis</i>	66	2.36	58.15	10	36
<i>Nereimyra punctata</i>	62	2.21	60.24	11	39
<i>Gouldia minima</i>	58	2.07	62.20	17	61
<i>Polycirrus</i> spp.	50	1.79	63.89	10	36
<i>Limaria hians</i>	49	1.75	65.54	11	39
<i>Psamathe fusca</i>	46	1.64	67.09	9	32
<i>Sphaerodorum gracilis</i>	44	1.57	68.58	12	43
<i>Pherusa plumosa</i>	37	1.32	69.83	5	18
<i>Nucula nucleus</i>	35	1.25	71.01	7	25

#### 4.3 Multivariate Analysis

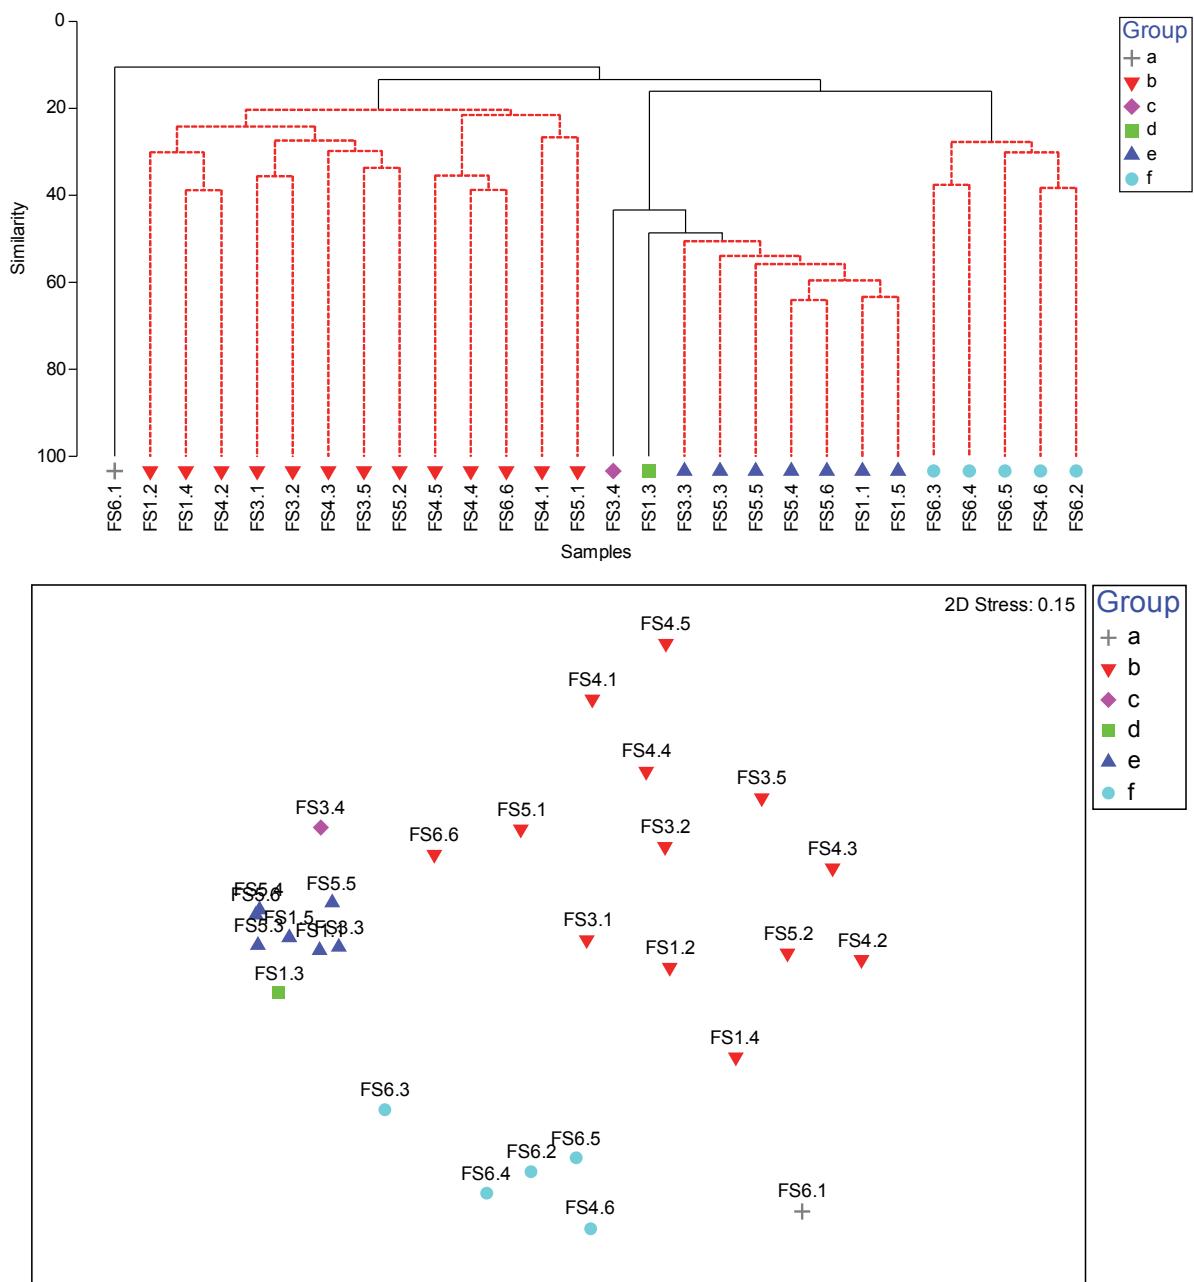

The results of cluster analysis and nMDS on the Loch Fyne diver core samples are provided in Figure 18. Similarities between samples range from around 10% to just below 70% highlighting a quite varied benthic assemblage. The SIMPROF routine identified six groups of samples as highlighted in Figure 18 although these included three groups containing a single station. The results of SIMPER analysis on the cluster groups derived from SIMPROF which highlights characteristic taxa are provided in Annex 9 whilst a summary of the groups with top 10 most abundant taxa for each sample and biotope type is provided in Table 13.

Group a comprises of a single sample from transect FS6 (sample FS6.1) which was relatively impoverished with only five taxa present in low numbers namely juvenile *Polydora* sp., *Macrochaeta* spp., juvenile *Dosinia* spp., *Gouldia minima* and *Thracia villosiuscula*. Group b was separated from the remaining samples at around 15% similarity and included a variety of samples from transects FS1, FS3, FS4 and FS5 which were dominated by the ophiuroid *Ophiocomina nigra* along with lower numbers of taxa such as *Thracia villosiuscula*, *Moerella donacina*, *Cerianthus lloydii*, *G. minima*, *Ophiothrix fragilis*, *Timoclea ovata* and *Lumbrineris* agg. Samples within this group (and group f described below) exhibited relatively low levels of similarity highlighting a relatively varied assemblage in contrast to the *Limaria* samples in group e which exhibited a more consistent benthic community.

Groups c and d were closely associated to group e and each comprised of a single sample (FS3.4 and FS1.3 respectively). Both of these samples had moderate numbers of the flame shell *Limaria hians* along with taxa such as Nematoda spp., *Flabelligera affinis*, Ascidiacea, *Sphaerodorum gracilis*, *Psamathe fusca*, *Modiolus modiolus* and *O. nigra* (FS3.4) or Nematoda spp., *Alvania punctura*, *Onoba semicostata*, *Pholoe inornata*, *Nereimyra punctata*, *Flabelligera affinis*, *Pherusa flabellata*, *T. villosiuscula* and *M. modiolus* (FS1.3). Group E comprised of a number of samples from transects 1, 3, 5 and 6 with relatively high levels of similarity (above 50% similarity) which also had varying densities of *L. hians* along with Nematoda spp., *M. modiolus*, *Onoba semicostata*, *Balanus balanus*, *Pholoe inornata*, *O. nigra*, *Polycirrus* spp., *F. affinis* and *Verruca stroemii*.

Group f included a number of samples from transect 6 and one sample from transect 4 which were characterised by the bivalves *G. minima* and *T. villosiuscula* along with a variety of other taxa in lower numbers including *Spirobranchus triqueter*, juvenile *Dosinia* spp., *Photis longicaudata*, *Terebellides stroemii*, *Lysianassa plumosa*, Nemertea spp., *M. modiolus* and *Nereiphylla rubiginosa*.

The groups defined from cluster analysis have been tabulated with biotope and dominant taxa in Table 13. The sample in group a (FS6.1) is rather impoverished and poorly defined in terms of biotope and has been classified as **SS.SMx.IMx** (Infralittoral mixed sediment). Samples in group b are generally dominated by brittlestars (notably *O. nigra*) so have been classified as **SS.SMx.CMx.OphMx** (*O. fragilis* and/or *O. nigra* brittlestar beds on sublittoral mixed sediment). Groups c, d and e all include samples with moderate densities of *L. hians* and have therefore been classified as **SS.SMx.IMx.Lim** (*Limaria hians* beds in tide-swept sublittoral muddy mixed sediment). Samples in group f (primarily transect 6) are not particularly well defined and been assigned the biotope **SS.SMx.IMx** (Infralittoral mixed sediment) although they are associated with the *Limaria* biotope samples in groups c to e (albeit at a lower level of similarity) so may represent a similar but less diverse infaunal community which lacks significant numbers of *Limaria*.

## 5. WYRE SOUND MAERL BED CORE SAMPLING

### 5.1 Primary and derived biological parameters

The biological parameters recorded from diver cores taken in maerl beds in the Wyre Sound and off Tingwall (Table 14) tended to be quite variable but generally exhibited moderate to high levels of species richness and diversity. Multiple core samples were collected per station which was not the case for the grab samples. Numbers of species ranged from 28 taxa at TW1B to 86 taxa at WYS11B with lower numbers of taxa recorded at the station off Tingwall (TW1) which had 28 to 35 taxa. Stations in Wyre Sound generally had over 50 taxa per core. A similar pattern was evident with regard to abundance which ranged from 70 (TW1A) to 510 individuals (WYS11B) with the Tingwall samples exhibiting lower abundances. Pielou's evenness values were moderate to high ranging from 0.67 (WY10B and D) to 0.91 (TW1B) with slightly lower values recorded at station WYS10 whilst Shannon's diversity were generally quite high (>4) and ranged from 3.45 (WYS10B) to 4.8 (WYS12C) with stations WYS11 and WYS12 generally having slightly higher diversity values.

*Table 14. Primary and derived biological parameters at Wyre Sound.*

Station	Number of Species	Total Abundance (A)	Margalef's d	Pielou's Evenness J	Shannon's Diversity H'
TW1_A	29	70	6.36	0.87	4.17
TW1_B	28	72	6.08	0.91	4.33
TW1_C	35	114	6.97	0.87	4.41
TW1_D	29	84	6.32	0.86	4.19
WYS10_A	54	398	8.35	0.70	3.96

WYS12_C	53	240	8.94	0.85	4.80
WYS12_D	43	115	8.01	0.89	4.68

### 5.2 Species Composition

A wide variety of taxa were recorded from the maerl bed dive cores at Wyre Sound with 270 taxa recorded in total (Annex 11). The most dominant taxa are provided in Table 15 which shows those taxa which account for 70% of the total abundance. The most dominant taxa included a range of crustacea (predominantly amphipods and isopods) along with a variety of molluscs, echinoderms and polychaetes. Taxa such as *Leptochiton cancellatus*, *Modiolus modiolus*, *Nematoda* spp., *Amphipholis squamata*, *Socarnes erythrophthalmus*, *Vaunthompsonia cristata*, *Uromunna petiti*, *Animoceradocus semiserratus* and *Caprella acanthifera* accounted for around 50% of the total abundance and were recorded at the majority of stations. Aside from maerl fragments which were recorded in all samples, the most widespread taxa was *Caprella acanthifera* which was recorded in all samples along with *Nematoda* spp., *Onoba semicostata*, *Nemertea* spp., *Modiolus modiolus* and *Amphipholis squamata* which were recorded in over 80% of the samples.

Large quantities of live maerl were recorded in the cores, particularly within the Wyre Sound samples. The maximum length of live maerl fragments (>5 mm) from this survey (and maerl samples from Arran and Loch Fyne) are recorded in Annex 14.

*Table 15. Dominant taxa (by abundance) recorded at the Wyre Sound survey stations.*

Taxa (All Wyre Sites)	Total Abundance	Mean Abundance	Cumulative % Abundance	No. of Samples	% of Samples
<i>Leptochiton cancellatus</i>	477	29.81	11.21	8	50
<i>Modiolus modiolus</i>	397	24.81	20.54	13	81
Nematoda spp.	321	20.06	28.08	14	88
<i>Amphipolis squamata</i>	205	12.81	32.89	13	81
<i>Socarnes erythrophthalmus</i>	187	11.69	37.29	8	50
<i>Vaunthompsonia cristata</i>	150	9.38	40.81	12	75
<i>Uromunna petiti</i>	144	9.00	44.20	11	69
<i>Animoceradocus semiserratus</i>	131	8.19	47.27	10	63
<i>Caprella acanthifera</i>	109	6.81	49.84	16	100
<i>Onoba semicostata</i>	93	5.81	52.02	14	88
<i>Golfingia vulgaris vulgaris</i>	93	5.81	54.21	8	50
<i>Urothoe elegans</i>	91	5.69	56.34	7	44
<i>Grania</i> spp.	89	5.56	58.44	10	63
<i>Leptocheirus pectinatus</i>	84	5.25	60.41	12	75
<i>Rissoa parva</i>	64	4.00	61.91	10	63

<i>Tubificoides benedii</i>	60	3.75	64.78	4	25
<i>Onoba aculeus</i>	59	3.69	66.17	9	56
<i>Othomaera othonis</i>	49	3.06	67.32	10	63
<i>Gibbula cineraria</i>	49	3.06	68.47	9	56
<i>Crenella decussata</i>	46	2.88	69.55	8	50
<i>Hiatella arctica</i>	43	2.69	70.56	12	75

### 5.3 Multivariate Analysis

The results of cluster analysis and nMDS on the Wyre Sound and Tingwall maerl bed diver core samples are provided in Figure 20. Similarities between samples range from around 20% to just below 60% and the SIMPROF routine identified five groups of samples as highlighted in Figure 17 although this included two groups each containing a single sample. The results of SIMPER analysis on the cluster groups derived from SIMPROF which highlights characteristic taxa are provided in Annex 12 whilst a summary of the groups with the top 10 most abundant taxa for each sample and biotope type is provided in Table 16.

Group a includes all the Tingwall samples which were separated from the remaining samples at around 20% similarity. These samples were characterised by the oligochaete *Tubificoides benedii* along with moderate numbers of other taxa including *Caprella acanthifera*, *Othomaera othonis*, *Amphipolis squamata*, *Nemertea* spp., *Phtisica marina*, *Pusillina sarsii*, *Modiolus modiolus*, *Hiatella arctica*, *Onoba semicostata* and *Flabelligera affinis*. Group b includes all the samples from station WYS12 in Wyre sound which were characterised by amphipod, cumacean and caprellid crustacea namely *Urothoe elegans*, *Vaunthompsonia cristata* and *Caprella acanthifera*. A variety of other taxa characterise this group, including *Rissoa parva*, *Prionospio* spp., *Leptocheirus pectinatus*, *Gibbula cineraria*, *Onoba semicostata*, *Socarnes erythrophthalmus*, *Nematoda* spp., *Amphiuridae* spp. (juvenile), *Animoceradocus semiserratus*, *Nemertea* spp. and *Philine* spp.

Groups c, d and e were broadly similar and separated at around 40% similarity and contained all the samples from stations WYS10 and WYS11 with groups c and d each comprising a single sample (WYS10\_B and WYS11\_C respectively). Group c (WYS10\_B) was characterised by species such as *Leptochiton cancellatus*, *Nematoda* spp., *Animoceradocus semiserratus* and juvenile *M. modiolus* whilst group d (WYS11\_C) was

characterised by juvenile *M. modiolus* along with *Uromunna petiti*, *Leptocheirus hirsutimanus*, *Othomaera othonis* and *Amphipholis squamata*. Group e includes the remaining samples from stations WYS10 and WYS11 which were dominated by high numbers of juvenile/immature *M. modiolus* along with Nematoda spp., *Leptochiton cancellatus*, *Golfingia (Golfingia) vulgaris vulgaris*, *A. squamata*, *Grania* spp., *A. semiserratus*, *Leptocheirus pectinatus*, *Uromunna petiti*, *Sphaerodorum gracilis*, *Cymodoce truncata* and *Polygordius* spp.

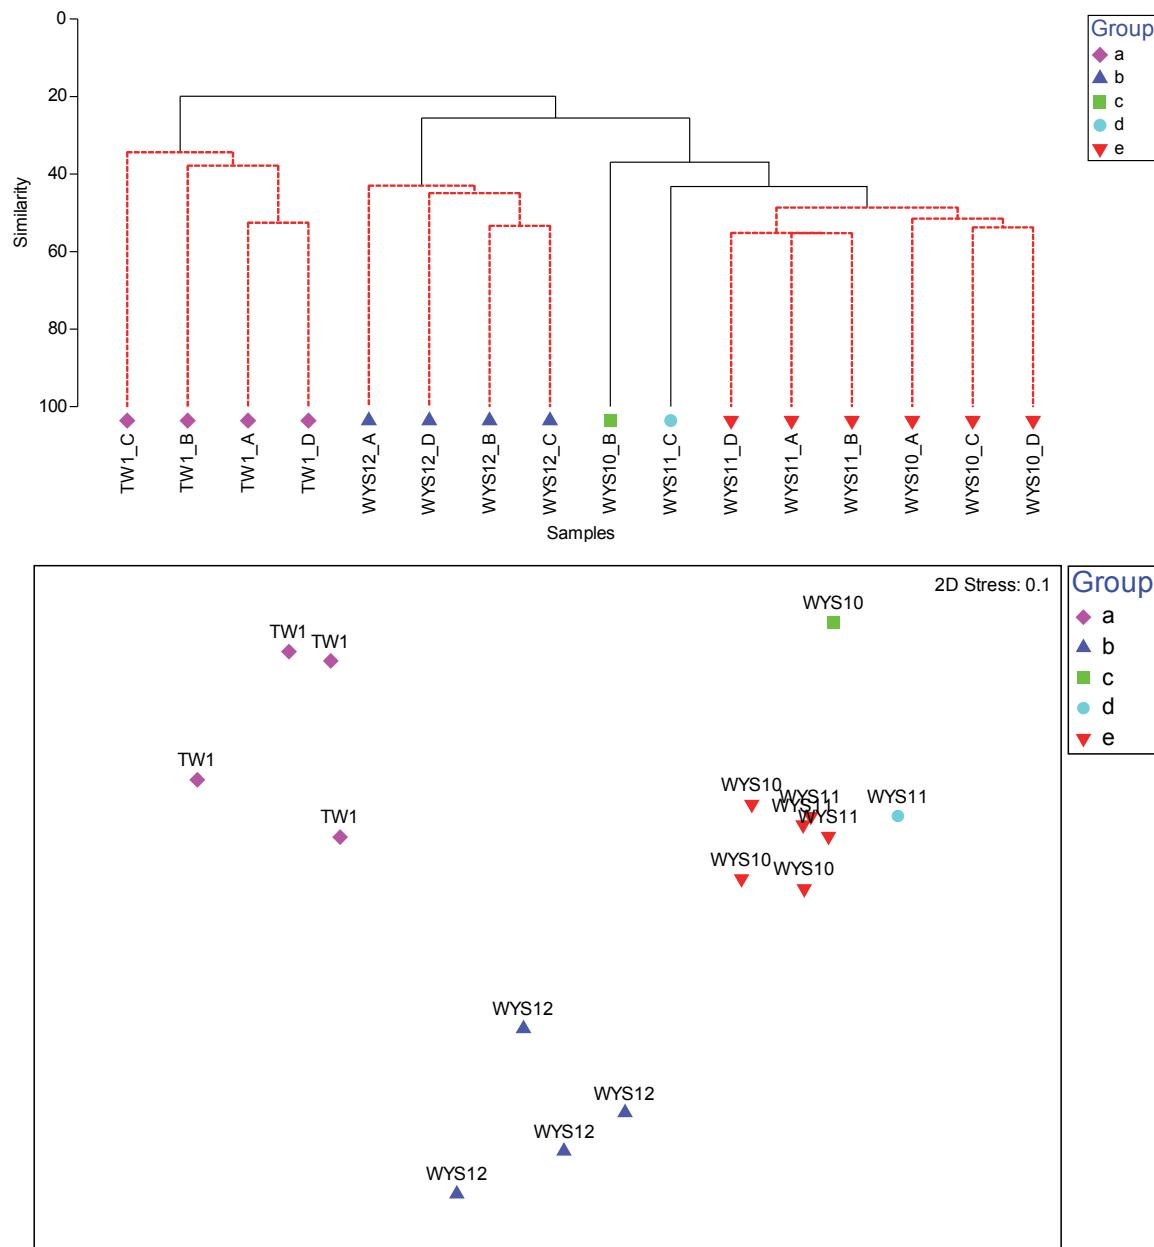

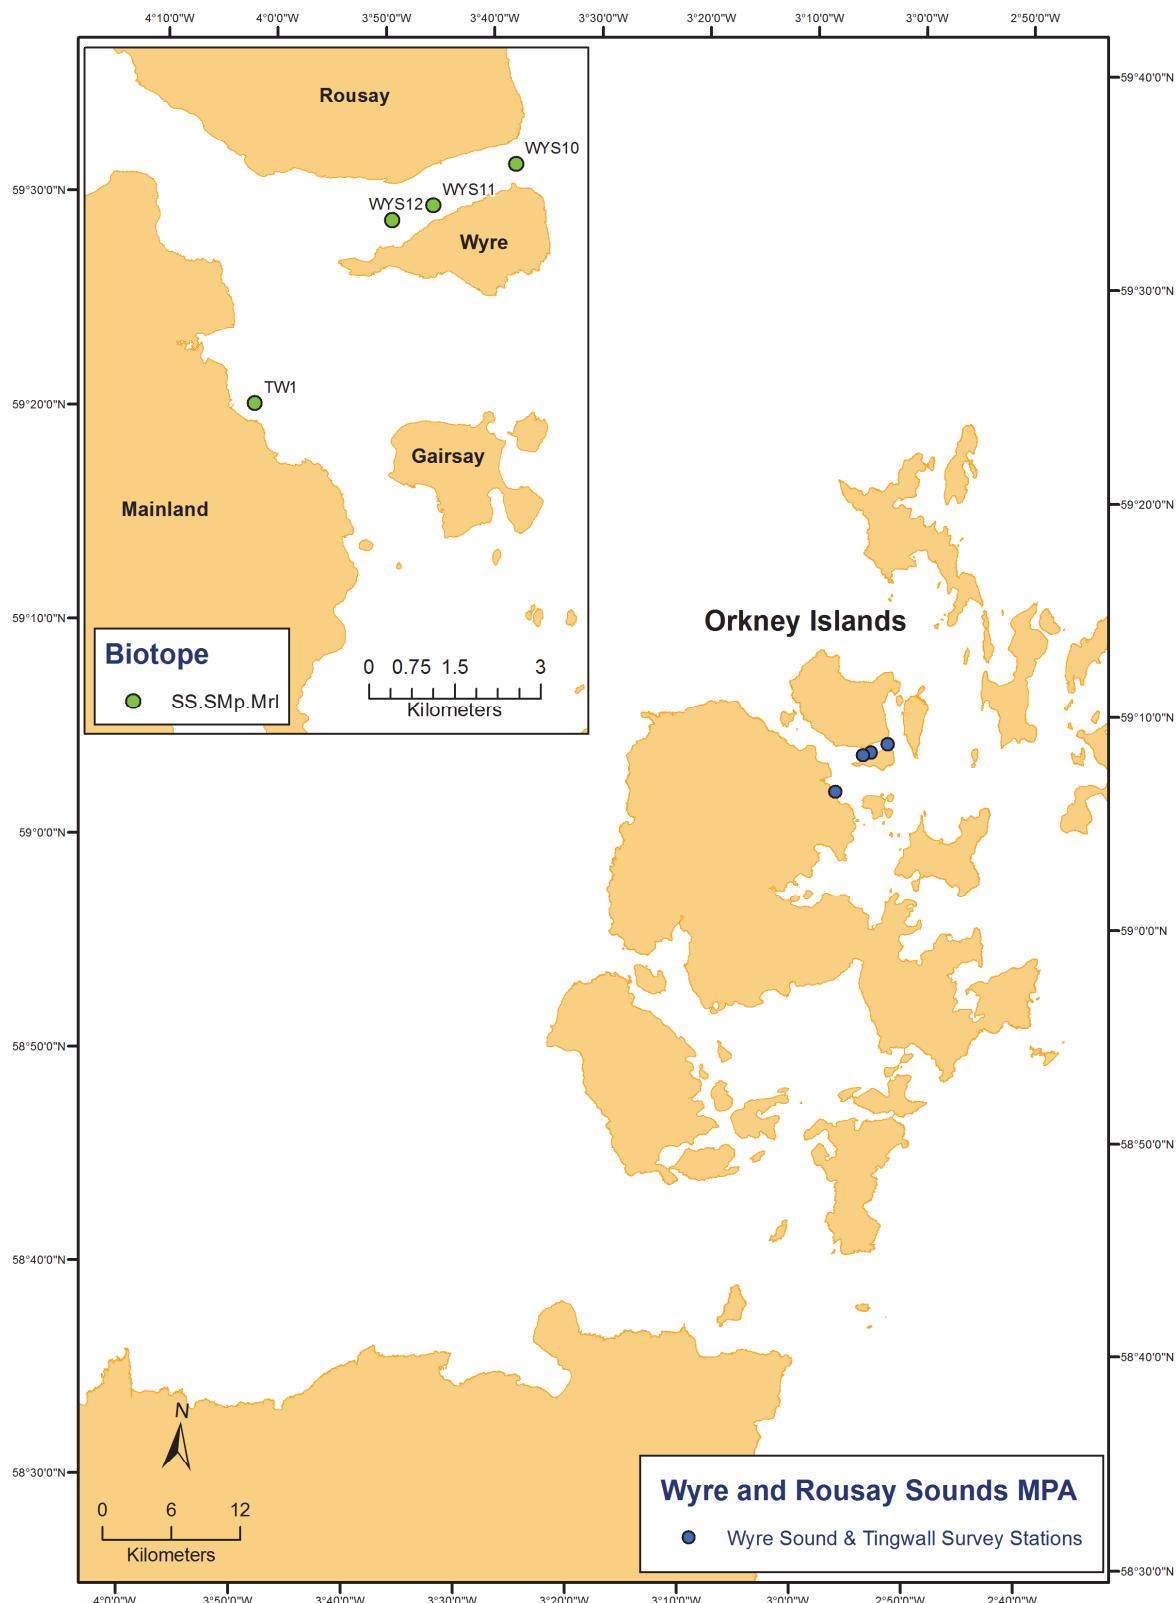

Figure 20. Results of cluster analysis and nMDS for the Wyre Sound maerl samples.

The groups defined from cluster analysis have been tabulated with biotope and dominant taxa in Table 16 and Figure 17. Given the high quantity of live maerl at these stations they have all been assigned **SS.SMp.Mrl** (Maerl beds). The different infaunal assemblages recorded during survey and illustrated above presumably reflect differences in environmental conditions and these communities may also include different maerl species and/or biotopes but information from video or diver observations would be required to confirm this.

## 6. DISCUSSION

The sampling stations surveyed in the Clyde Sea area in 2015 covered a range of habitats off Arran and in Loch Fyne, including gravelly sands, gravelly sandy muds/muddy sands or cleaner sands. A large number of taxa were recorded from the survey with 438 taxa identified off Arran and 279 taxa recorded in Loch Fyne. Polychaetes, ophiuroid echinoderms (brittlestars) and bivalves were most characteristic off Arran with taxa such as nematode worms, *Abra alba*, *Owenia fusiformis*, juvenile Amphiuridae spp., *Gouldia minima*, *Galathowenia oculata* and *Mediomastus fragilis* particularly abundant. In Loch Fyne, five grab samples and 11 diver core samples included *Limaria hians*, a habitat-forming species and protected feature in the Upper Loch Fyne and Loch Goil NC MPA. Other key taxa included *Nereimyra punctata*, Nematoda, *Spirobranchus triqueter*, *Ophiothrix fragilis*, *Onoba semicostata*, *Ophiocomina nigra*, *Pholoe inornata*, *Modiolus modiolus*, *Gouldia minima* and *Sphaerodorum gracilis*. Live maerl was also recorded at a number of the grab sites off Arran and in Loch Fyne albeit in low densities and five stations off Arran included the species *Arctica islandica* (ocean quahog), a protected feature of the South Arran NC MPA.

Multivariate analysis indicated significant variability across the survey area with a large number of discrete groups derived. However, many of these groups comprised few stations and could be loosely aggregated into broader groups with similar environmental conditions which could be correlated to biotope complexes. An assessment of the main communities in relation to the UK biotope classification (Connor *et al.*, 2004) indicated the presence of a number of biotopes, although as in previous surveys in the Clyde Sea area biotopes were often rather poorly defined or included intermediate forms. Analysis of video footage in these locations would allow biotope assignment at a finer resolution. For example, sites that have been assigned circalittoral fine mud are likely to include examples burrowing megafauna or possibly seapens and burrowing megafauna in circalittoral fine mud. Characterisation of such biotopes from grab samples is problematic given that the technique typically under samples larger taxa (e.g. seapens and other megafauna), which may otherwise be revealed by video surveys.

Off Arran the variable slightly muddy sandy gravels included muddier and cleaner variants of shallow infralittoral mixed or coarse sediment biotopes with the gravel fraction often comprising of dead maerl fragments with low densities of live maerl. The live maerl recorded in the grab sample residues off Arran and in Loch Fyne were not present in sufficient densities to be classified as a maerl biotope. Video data would be required to determine the presence and distribution of maerl biotopes in relevant parts of the MPAs.

Typical biotopes off Arran included somewhat poorly defined examples of **SS.SCS.ICS** (Infralittoral coarse sediment) and **SS.SMx.IMx** (Infralittoral mixed sediment) which exhibited some resemblance to coarse gravel or sand biotopes such as **SS.SCS.CCS.MedLumVen** (*Mediomastus fragilis*, *Lumbrineris* spp. and venerid bivalves in circalittoral coarse sand or gravel) and **SS.SCS.ICS.MoeVen** (*Moerella* spp. with venerid bivalves in infralittoral gravelly sand). **SS.SCS.ICS.MoeVen** is a Priority Marine Feature (PMF) in Scottish waters (see Tyler-Walters *et al.*, 2016) and it is possible that habitats classified as **SS.SCS.ICS** here are shallow, slightly silty, maerl influenced variants of these biotopes. Coarse mixed sediment communities is an area of the biotope classification which (along with offshore biotopes) is currently less well defined and subject to an ongoing review by JNCC. As such, examples of these coarse sediment habitats within the Clyde Sea area are likely to be under-reported and would benefit from additional data to improve the knowledge-base of such communities in this region.

Other biotopes off Arran included **SS.SMx.CMx** (Circalittoral mixed sediment) and rather variable forms of sandy mud biotopes such as **SS.SMu.CSaMu.AfilMysAnit** (*Amphiura filiformis*, *Mysella bidentata* and *Abra nitida* in circalittoral sandy mud) whilst deeper muddy

habitats were classified as **SS.SMu.CSaMu** (Circalittoral sandy mud) or **SS.SMu.CFiMu** (Circalittoral fine mud) with the latter including occasional stations with specimens of burrowing megafaunal crustacea such as *Nephrops norvegicus*. Muddy habitats in upper Loch Fyne were also classified as **SS.SMu.CFiMu** (although burrowing megafauna were less evident) and similar rather impoverished habitats were recorded offshore from Arran and in Loch Goil in the 2012 and 2013 Clyde Sea surveys (Allen, 2013; 2014 and Moore, 2013). Given that some of these deeper muddy stations (particularly off Arran) included occasional examples of burrowing megafauna it is likely that such areas may include burrowed mud biotopes such as **SS.SMu.CFiMu.SpnMeg** (Seapens and burrowing megafauna in circalittoral fine mud) or **SS.SMu.CFiMu.MegMax** (Burrowing megafauna and *Maxmuelleria lankesteri* in circalittoral mud) although video data would be required to confirm this. Similar habitats from the 2012 Clyde Sea survey were classified as **SS.SMu.CFiMu.SpnMeg** or in some cases **SS.SMu.CFiMu.MegMax** from video data collected at the same locations (Moore & Atkinson, 2012). It is likely that grab sampling will underestimate species richness in such areas particularly where stations lack replication, although burrowing megafaunal communities with relatively impoverished infauna have also been recorded previously in the Clyde area (Allen, 2013). The muddier habitats recorded off Arran and in Loch Fyne tended to be less diverse or in some cases rather impoverished but it is uncertain whether this is indicative of moderate disturbance relating to natural or anthropogenic factors such as physical disturbance or variation in water quality. Biotopes recorded in Loch Fyne included very diverse communities in mixed sediments with flame shell beds - **SS.SMx.IMx.Lim** (*Limaria hians* beds in tide-swept sublittoral muddy mixed sediment). Other biotopes in Loch Fyne included those characteristic of mixed sediment with abundant brittlestar communities such as **SS.SMx.CMx.OphMx** (*Ophiothrix fragilis* and/or *Ophiocomina nigra* brittlestar beds on sublittoral mixed sediment).

Diver cores in the vicinity of the *Limaria* beds at Otter Spit in Loch Fyne exhibited a varied but often very diverse community with highest diversities recorded in samples with moderate densities of *Limaria* (**SS.SMx.IMx.Lim** biotopes). These communities were broadly similar to the grab samples in Loch Fyne containing *Limaria* located approximately 500m offshore from the diver transects although a wider range of taxa were often recorded in the grab samples which reflects the larger sample size. Characteristic taxa in the diver samples which contained *Limaria* included Nematoda spp., *Balanus balanus*, *O. nigra*, *Onoba semicostata*, *Pholoe inornata*, *Verruca stroemia*, juvenile/immature *M. modiolus*, *Alvania punctura* and *Thracia villosiuscula*. Moderately high densities of *Modiolus* were often recorded in these samples although the specimens recorded during the grab and diver core surveys were predominantly juveniles or small/immature forms. As such these communities were not deemed to form *Modiolus* biotopes and accompanying diver observations also indicate that these areas represent *Limaria* biotopes rather than *Modiolus* beds.

It is uncertain at present whether samples with high numbers of juvenile *Modiolus* represent short term increases following recruitment or if they will develop into more mature populations and compete with *Limaria*. Previous surveys in Loch Alsh and Loch Fyne (Moore *et al.* 2013) have highlighted areas where *Modiolus* and *Limaria* biotopes are in close proximity or interspersed/overlap with potential competition for spaces/resources between the two species. This does not appear to be the case based on the samples analysed here with predominantly juvenile *Modiolus* but further clarification of this may be gained from analysis of the video data or in future surveys. Most transects from the diver core survey included some samples which lacked *Limaria* (highlighting the inherent patchiness of the biotope) but notably from transect FS4. These samples tended to include biotopes such as **SS.SMx.IMx** (Infralittoral mixed sediment) whilst those dominated by brittlestars (notably *Ophiocomina nigra*) were classified as **SS.SMx.CMx.OphMx** (*Ophiothrix fragilis* and/or *Ophiocomina nigra* brittlestar beds on sublittoral mixed sediment).

Diver cores in Wyre Sound and off Tingwall in waters around the Orkney Islands were characterised by maerl beds (**SS.SMp.Mrl**) with high frequencies of live maerl along with a diverse species assemblage characterised by a range of amphipod and isopod crustacea along with a variety of molluscs, echinoderms and polychaetes. Typical taxa include species such as *Leptochiton cancellatus*, *M. modiolus*, Nematoda spp., *Amphipholis squamata*, *Socernes erythrophthalmus*, *Vaunthompsonia cristata*, *Uromunna petiti*, *Animoceradocus semiserratus* and *Caprella acanthifera*. Such taxa are typical for these habitats and a number of polychaete and amphipod species have a high specificity to maerl beds (BIOMAERL team, 1999) including amphipod taxa such as *A. semiserratus* which was commonly recorded in Wyre Sound along with a variety of other amphipods, cumaceans, polychaetes and bivalves.

Maerl beds are often highly diverse which reflects their complex structure and the relatively high levels of diversity (up to 86 taxa per core) recorded here are not uncommon in maerl habitats which often exhibit increased diversity in relation to adjacent areas (Lancaster *et al.*, 2014; Birkett *et al.*, 1998). Maerl beds are a protected feature of the Wyre and Rousay Sounds NC MPA and the results from the present study illustrate the high diversity associated with maerl beds in the MPA and surrounding area. A number of separate communities were recorded within the maerl beds with differences most evident between those off Tingwall and those in Wyre Sound which may reflect differences in habitat/sediment type or other environmental factors. Information from video or diver observations would be required to confirm the presence of specific maerl biotopes.

Overall the results from the 2015 Clyde Sea survey highlighted a diverse range of communities and included some especially diverse benthic communities particularly in areas of coarse/mixed sediment and specific features of conservation interest such as flame shell beds. The findings of the current survey confirm the presence of a number of biotope complexes recorded in Loch Fyne and inshore around Arran which broadly agree with those recorded previously (Allen, 2013; 2014 and Moore, 2013) and as in previous surveys highlights a range of rather intermediate forms of mixed sediment and shallow coarse sediment biotopes which often exhibit high levels of diversity. A number of additional records of flame shell beds (**SS.SMx.IMx.Lim**) were recorded in this survey including several grab samples located just outside (to the south-east) of the *Limaria* bed boundaries derived from the 2012 surveys. Drop down video data from this area is yet to be published and these records may help further define the extent of the bed. Additional information on the size distribution of *Limaria* and more detailed community assessment by diver core sampling was also undertaken within the Otter Narrows flame shell bed within Upper Loch Fyne which represents the most southerly significant example of this seabed habitat in Scotland and the third largest known bed in Scotland (Moore *et al.*, 2013). The diver cores collected within the flame shell beds here were often highly diverse in comparison to adjacent habitats highlighting their importance from a biodiversity perspective which reflects the increased structural complexity of such habitats.

Other features of interest during the current survey include records of **SS.SMu.CFiMu** (Circalittoral fine mud) which were recorded in Loch Fyne and off Arran as such habitats are likely to include examples of the burrowed mud protected feature of the MPAs although video data would be required to confirm this. The somewhat muddy examples of infralittoral coarse sediments (**SS.SCS.ICS**) recorded off Arran may represent muddier, intermediate variants of biotopes belonging to the Shallow tide-swept coarse sands with burrowing bivalves protected feature of the MPA.

Overall the findings of the current study improve the resolution of data and increase our understanding of the extent and distribution of seabed habitats in these MPAs. In addition, the data presented here can provide baseline information such as *Limaria*/maerl size distribution, which could be used to inform future management of these areas in the context of the Scottish MPA Programme.

<i>Ampelisca</i> spp. (juvenile)												
<i>Ampelisca diadema</i>												
<i>Ampelisca spinipes</i>												
<i>Ampelisca tenuicornis</i>												
<i>Ampelisca typica</i>												
<i>Ampithoe ramondi</i>												
<i>Aora typica</i>												
<i>Microdeutopus</i> spp. (female)											1	
<i>Microdeutopus versicolatus</i>												
<i>Aoridae</i> spp. (female)												
<i>Atylus vedloensis</i>												
<i>Apherusa bispinosa</i>												
<i>Caprella fretensis</i>												
<i>Parvipalpus capillaceus</i>												
<i>Phtisica marina</i>												
<i>Pseudoprotelli phasma</i>	4											
<i>Cheiocratus</i> spp. (female)												
<i>Cheiocratus sundevalli</i>												
<i>Corophium</i> spp.												
<i>Crassicornophium crassicornis</i>												
<i>Leptocheirus</i> spp.												
<i>Leptocheirus hirsutimanus</i>												
<i>Leptocheirus pectinatus</i>											1	
<i>Leptocheirus pilosus</i>												
<i>Dexamine</i> spp.												
<i>Dexamine spinosa</i>												
<i>Dexamine thea</i>												
<i>Dulichia tuberculata</i>	2											
<i>Jassa falcata</i>												
<i>Lepidepecreum longicornis</i>												
<i>Lysianassa ceratina</i>												
<i>Lysianassa plumosa</i>												
<i>Socarnes</i> spp. (juvenile)	1											
<i>Socarnes erythrophthalmus</i>												
<i>Animoceradocus semiserratus</i>												
<i>Othomaera othonis</i>												
<i>Abulomedes obtusa</i>												
<i>Micropotopus</i> spp. (female)												
<i>Monoculodes carinatus</i>												
<i>Pontocrates altamarinus</i>												
<i>Westwoodilla caecula</i>	1	4										
<i>Gammaropsis</i> spp.												
<i>Gammaropsis maculata</i>		3										
<i>Megamphopus cornutus</i>												
<i>Photis longicaudata</i>												
<i>Harpinia antennaria</i>												
<i>Parametaphoxus fultoni</i>												
<i>Stenotheo monoculoides</i>												
<i>Amphipoda</i> spp.												
<i>Iphinoe serra</i>												
<i>Vaunthompsonia cristata</i>	1											
<i>Diastylis lucifera</i>		2										
<i>Diastylis rathkei</i>												
<i>Diastylis rugosa</i>	1	1										
<i>Diastylis tumida</i>		1										
<i>Hemilamprops roseus</i>		1										
<i>Eudorellopsis deformis</i>												
<i>Calocaris macandreae</i>				1	1							
<i>Galathea intermedia</i>												
<i>Macropodia rostrata</i>												
<i>Eury nome</i> spp.												

Taxa	D5G6	D5G7	T1G1	T1G2	T1G3	T1G4	T1G5	T1G6	T1G7	T1G8	T1G9	T1G10
<i>Nephrops norvegicus</i>			1				2			1		
<i>Anapagurus chirocanthus</i>												
<i>Anapagurus hyndmanni</i>		1										
<i>Paguridae</i> spp. (juvenile)												
<i>Liocarcinus</i> spp.												
<i>Liocarcinus corrugatus</i>												
<i>Pisidia longicornis</i>												
<i>Processa nouveli holthuisi</i>					1							
<i>Anomura</i> spp. (zoea larvae)												
<i>Brachyura</i> spp. (zoea larvae)												
<i>Anthura gracilis</i>										1		
<i>Conilera cylindracea</i>												
<i>Eurydice pulchra</i>	1											
<i>Gnathia</i> spp. ( <i>praniza</i> )												
<i>Gnathia oxyuraea</i>												
<i>Dynamene bidentata</i>												
<i>Nebalia bipes</i>												
<i>Mysida</i> spp.												
<i>Akanthophoreus gracilis</i>												
<i>Tanaidacea</i> spp.												
<i>Malacostraca</i> spp. (larvae)												
<i>Ostracoda</i> spp.												
<i>Anoplodactylus petiolatus</i>												
<i>Balanus balanus</i>												
<i>Balanus crenatus</i>												
<i>Verruca stroemia</i>												
<i>Bugula</i> spp.												
<i>Bugulina flabellata</i>												
<i>Scrupocellaria scruposa</i>												
<i>Electra pilosa</i>												
<i>Celleporella hyalina</i>						p						
<i>Membranipora membranacea</i>												
<i>Crisia eburnea</i>												
<i>Tubulipora</i> spp.												
<i>Cyclostomatida</i> spp.												
<i>Chaetognatha</i>												
<i>Ascidiella aspersa</i>												
<i>Ascididae</i> spp.

## ANNEX 5: SPECIES DATA - LOCH FYNE GRAB SAMPLES

Taxa	FG-03	FG-04	FG-05	FG-06	FG-09	FG-10	FG-23	FG-24	FG-25
<i>Grania</i> sp.					3				
<i>Limnodriloides scandinavicus</i>									
<i>Protodrilus kefersteini</i>		1	2	1	5				
<i>Lysidice unicornis</i>									
<i>Lumbrineris</i> agg.	1	4	1		9	4	4		6
<i>Aphrodita aculeata</i>		1					1		
<i>Glycera alba</i>									
<i>Glycera lapidum</i> agg.		5			5		4	1	4
<i>Glycera unicornis</i>					2				
<i>Goniada maculata</i>	1	3	3				4		
<i>Gyptis propinqua</i>									
<i>Nereimyra punctata</i>			4		1	111	1	96	20
<i>Oxydromus flexuosus</i>									
<i>Psammathe fusca</i>				2		17			2
<i>Nephthys hombergii</i>	1								
<i>Nephthys incisa</i>									
<i>Nephthys kersivalensis</i>		4							
<i>Nereis zonata</i>									1
<i>Nereididae</i> sp. (juvenile)									
<i>Pholoe baltica</i>				2		4	4	7	4
<i>Pholoe inornata</i>				5		67	4	20	2
<i>Eteone flava</i>					1				
<i>Eulalia bilineata</i>				1					
<i>Eulalia viridis</i>					3		1		
<i>Eumida bahusiensis</i>									2
<i>Eumida sanguinea</i>	1				1				
<i>Nereiphylla rubiginosa</i>							2		
<i>Notophyllum foliosum</i>				1			1		
<i>Phyllocoelus longipes</i> cf.	1								
<i>Phyllocoelus</i> sp.									
<i>Pseudomystides limbata</i>					1				
<i>Ancistrosyllis groenlandica</i>									
<i>Pilaris verrucosa</i>									
<i>Acantholepis asperrima</i>									
<i>Subadyte pellucida</i>									
<i>Aleutia gelatinosa</i>									1
<i>Antinoella finmarchica</i>									
<i>Harmothoe</i> spp.							7	7	11
<i>Lepidonotus squamatus</i>		3				3		7	2
<i>Malmgrenia marphysae</i>		2	1				1		
<i>Malmgrenia mcintoshii</i>		3					4		
<i>Malmgrenia</i> sp.							1		
<i>Polynoidae</i> ( <i>Neoplynoidae paradoxa</i> )		3							
<i>Sphaerodorum gracilis</i>	4	1	1	18	18	6	15	1	
<i>Exogone verugera</i>							1		
<i>Plionosyllis</i> sp.									
<i>Sphaerosyllis taylori</i>					1

**ANNEX 9: CHARACTERISTIC TAXA FROM SIMPROF GROUPS - *LIMARIA* DIVER CORES LOCH FYNE**

Group A (Sample 6.1)			
Taxa	Abundance	Cum. %	
<i>Polydora</i> sp. (juvenile)	1	20	
<i>Macrochaeta</i> spp.	1	40	
<i>Dosinia</i> spp. (juvenile)	1	60	
<i>Gouldia minima</i>	1	80	
<i>Thracia villosiuscula</i>	1	100	

Group B (Average similarity: 23.52%) (samples 1.2, 1.4, 3.1, 3.2, 3.5, 4.1, 4.2, 4.3, 4.4, 4.5, 5.1, 5.2, 6.6)				
Dominant Taxa	Av. Abund	% of Sites	Contrib%	Cum.%
<i>Ophiocoma nigra</i>	8.15	100.00	53.18	53.18
<i>Thracia villosiuscula</i>	1.46	76.92	17.73	70.9
<i>Moerella donacina</i>	0.92	38.46	5.33	76.24
<i>Cerianthus lloydii</i>	0.54	30.77	3.23	79.47
<i>Gouldia minima</i>	0.38	38.46	2.68	82.14
<i>Ophiothrix fragilis</i>	1.08	23.08	1.94	84.08
<i>Timoclea ovata</i>	0.31	30.77	1.68	85.76
<i>Lumbrineris</i> agg.	0.38	30.77	1.6	87.36
<i>Spirobranchus triqueter</i>	0.77	23.08	1.33	88.7
<i>Dosinia</i> spp. (juvenile)	0.46	23.08	1.21	89.91
<i>Strongylocentrotus droebachiensis</i>	0.23	23.08	1.08	90.99

Group C (Sample 3.4)		
Dominant Taxa	Abundance	Cum. %
<i>Nematoda</i> spp.	11	11.34
<i>Flabelligera affinis</i>	9	20.62
<i>Ascidiae</i>	9	29.90
<i>Sphaerodorum gracilis</i>	8	38.14
<i>Psamathe fusca</i>	6	44.33
<i>Modiolus modiolus</i>	6	50.52
<i>Ophiocoma nigra</i>	5	55.67
<i>Limaria hians</i>	5	60.82
<i>Onoba semicostata</i>	4	64.95
<i>Glycera lapidum</i> agg.	3	68.04
<i>Nereimyra punctata</i>	3	71.13
<i>Pholoe inornata</i>	3	74.23
<i>Trichobranchus glacialis</i>	3	77.32

Group D (Sample 1.3)		
Dominant Taxa	Abundance	Cum. %
<i>Nematoda</i> spp.	59	15.95
<i>Alvania punctura</i>	52	30.00
<i>Onoba semicostata</i>	46	42.43
<i>Pholoe inornata</i>	44	54.32
<i>Nereimyra punctata</i>	11	57.30
<i>Flabelligera affinis</i>	11	60.27
<i>Pherusa flabellata</i>	11	63.24
<i>Thracia villosiuscula</i>	11	66.22
<i>Modiolus modiolus</i>	10	68.92
<i>Psamathe fusca</i>	9	71.35
<i>Amphipholis squamata</i>	7	73.24
<i>Mediomastus fragilis</i>	6	74.86
<i>Limaria hians</i>	6	76.49
<i>Ophiocoma nigra</i>	5	77.84
<i>Nephasoma (Nephasoma) minutum</i>	5	79.19

Group E (Average similarity: 23.52%) (samples 1.1, 1.5, 3.3, 5.3, 5.4, 5.5, 5.6)				
Dominant Taxa	Av. Abund	% of Sites	Contrib%	Cum.%
<i>Nematoda</i> spp.	54.00	100	12.03	12.03
<i>Modiolus modiolus</i>	10.86	100	6.19	18.22
