Abstract: A summary of the available information on stomatopod and decapod diversity of Isla del Coco and records of recently collected species during the CIMAR-MarViva expedition (January 2007) as well as the presence of yet unpublished specimens deposited in the Museo de Zoología, Universidad de Costa Rica, is reported. The material of the CIMAR-MarViva expedition comprised 23 species, including nine species new for the island. Revision of the collection of the Museo de Zoología, including two unpublished records, revealed the presence of additional 12 decapod species not previously reported for the island. Overall, a total of 135 species (6 stomatopods and 129 decapods) has been reported so far for the island, which harbors 29.5% of all decapod species known to occur along the Pacific mainland of Costa Rica, and 16.3% of all decapods reported for the Panamic Province. The most diverse families (including ≥ 10 spp.) at Isla del Coco are Xanthidae (14 spp.), Majidae and Alpheidae (each 11 spp.), and Porcellanidae (10 spp.). There is a strong affinity of the stomatopod and decapod fauna of both Isla del Coco and Islas Galápagos. Rev. Biol. Trop. 56 (Suppl. 2): 79-97. Epub 2008 August 29.

Key words: biodiversity, decapod crustaceans, Islas Galápagos, eastern tropical Pacific, zoogeography.

Decapod crustaceans are prominent members of most marine, estuarine, freshwater and terrestrial ecosystems. Thus, not surprisingly, the presence of these crustaceans is fairly well documented for Isla del Coco and surrounding waters. Despite the fact that a considerable number of scientific expeditions stopped – on their way to Galápagos Island – at Isla del Coco (see Hertlein 1963, Hogue & Miller 1981; Wehrtmann & Cortés 2008, Cortés 2008), the published results of only a few of these expeditions have contributed substantially to our knowledge regarding these crustaceans: Faxon (1895) analyzed the decapods obtained during the explorations of the U.S. Fish Commission Steamer “Albatross” in 1891; Rathbun (1902) reported on Brachyura and Macrura collected around Isla del Coco during the Stanford Galápagos Expedition,

1898-1899; Boone (1930) commented on the decapod and stomatopod species collected during the cruises of the yachts “Eagle” and “Ara”, 1921-1928; and Haig (1960) described the porcellanids based on collections made by the Allan Hancock Expeditions, 1933-38, including material from Isla del Coco. More recently, Camp & Huck (1990) provided some additional records of stomatopods from Isla del Coco, and Zimmerman & Martin (1999) published on the brachyuran crabs (Leucosiidae, Calappidae, and Parthenopidae) of the island, including the description of two new species (*Osachila kaiserae* and *Thyrolambrus verrucibrachium*). Wicksten & Vargas (2001) and Thoma *et al.* (2005) described a new species of *Thor* (Decapoda: Brachyura: Hippolytidae) and *Parapinnixa* (Decapoda: Brachyura: Pinnotheridae), respectively, from Isla del Coco.

While all of the previously mentioned studies refer to marine stomatopods and decapods, as far as we know there are only two publications specifically dealing with freshwater decapods: Villalobos (1959) and Abele & Kim (1984) reported the presence of four freshwater decapods from Isla del Coco, including the endemic *Macrobrachium cocoense*.

Here we summarize the available information concerning the diversity of stomatopods and decapods reported so far from Isla del Coco, and include records of additional species collected during the CIMAR–MarViva expedition to the island (2007). Moreover, we include new and yet unpublished records of species collected from Isla del Coco, deposited in the Museo de Zoología, Escuela de Biología, Universidad de Costa Rica. According to this inventory, a total of 133 species, 6 stomatopods and 127 decapods, are currently known to occur on and around Isla del Coco.

MATERIALS AND METHODS

The CIMAR–MarViva Expedition on board the vessel “Proteus” lasted from 10 – 22 January 2007. The collection around Isla del Coco was carried out between 13 and 16 January 2007. The material was obtained during a monitoring program of the coral reefs surrounding the island. The specimens were collected (1) by SCUBA in depths ranging from 15 – 21 m; (2) from rocky debris of coralline origin by SCUBA, which was subsequently washed and separated on board of the vessel, and (3) dredge trawling in depths from 50 – 60 m. Specimens were preserved in 70% ethanol and subsequently deposited in the Museo de Zoología, Escuela de Biología, Universidad de Costa Rica (UCR), in San José.

The other source of information was the collections of the Museo de Zoología of the UCR. Additionally, we included two more species based on unpublished material from Mary K. Wicksten (Texas A&M University, College Station, U.S.A.). We also examined the holding for stomatopods and decapods from Isla del Coco, and the present contribution includes all

those species, which were collected at the island, including those not previously published from this area.

RESULTS

A total of 23 species were collected during the expedition CIMAR–MarViva. Of these, 14 species had been previously reported from Isla del Coco, and nine species represent new records for the island (Table 1). Revision of the collection of the Museo de Zoología revealed the presence of additional 10 decapod species not previously reported for the island (Table 1). Finally, two more species were added based upon unpublished material kindly provided by Mary Wicksten.

Stomatopoda. Six species from five families have been reported from Isla del Coco (Table 2), including the endemic *Neocoronida cocosiana* (Manning, 1972). During the CIMAR–MarViva expedition, two species (*Neogonodactylus zacae* and *Pseudosquilla adiastalta*) were collected. Both species were known to occur around the island (Table 2).

Decapoda. Summarizing the available literature, a total of 106 species of decapods are known to occur at Isla del Coco and surrounding waters (Table 3). During the CIMAR – MarViva expedition, 23 decapod species were obtained of which nine species represent new records for Isla del Coco: one species of Caridea, two species of Anomura and six species of Brachyura (Table 1). Revision of the collections of the Museo de Zoología revealed 10 additional decapod species not previously reported for the island. Thus, the updated decapod species list for Isla del Coco includes now a total of 129 species, including six endemic species. The most diverse families (≥ 5 spp.) are: Xanthidae (14 spp.), Majidae (11 spp.), Porcellanidae (10 spp.), Alpheidae (11 spp.), Paguridae (7 spp.), Galatheidae and Palaemonidae (6 spp.), Diogenidae, Parthenopidae, Portunidae and Grapsidae (5 spp.).

Range extension. The brachyurans *Tetras scabripes* Rathbun, 1918, and *Pilumnus gonzalensis* Rathbun, 1893, have been reported previously only from Cerralvo Channel and other localities, south to Mita Point, Golfo de California, and from the Golfo de California to the southern mainland of Costa Rica, respectively (Hendrickx 1995c). The known geographic distribution of both species includes now Isla del Coco.

DISCUSSION

The revision of (a) the material collected by the CIMAR-MarViva expedition, (b) the collections of the Museo de Zoología, UCR, and (c) the published records revealed the presence of a total of 6 stomatopods and 129 decapods reported so far for Isla del Coco (Table 4). The number of decapod crustaceans reported for the island increased from 104 (Vargas & Wehrtmann, 2008) to 129 (25 spp.; 24%). The total number of decapods is actually slightly higher due to the discovery of several species new for the island which currently are being analyzed (R. Vargas, unpubl. data). In contrast, no stomatopods species new for Isla del Coco were found.

Isla del Coco harbors 29.5% of all decapod species reported so far from the Pacific coast of Costa Rica (437 spp.: Vargas & Wehrtmann, 2008), and 16.3% of decapod crustaceans reported for the Panamic Province (Boschi 2000). When compared to mainland Costa Rica, species diversity of stomatopods and decapods from Isla del Coco represents 20.0% (Stomatopoda) and 30.2% (Caridea) (Table 5). On the other hand, Isla del Coco shares a high percentage of species with the Pacific mainland of Costa Rica (Table 5): 80% for porcellanid crabs, and 46.6% for the brachyuran crabs.

The most diverse decapod families are the same in both Isla del Coco and the Pacific mainland of Costa Rica (Vargas & Wehrtmann, 2008): Xanthidae is the family with the highest number of species (Isla del Coco: 14 spp.;

TABLE 4

Caridea	26	1	21	12	58	86
Porcellanidae	10	1	6	8	12	41
Brachyura	58	1?	27	27	120	203

Number of shared species was computed from (Garth 1991), Harvey (1991), Wicksten (1991), and Hickman and Zimmerman (2000)

mainland: 45 spp.), followed by Majidae (11 and 43 spp.), Alpheidae (11 and 34 spp.), and Porcellanidae (10 and 44 spp.).

In comparison to Islas Galápagos, species numbers from Isla del Coco are substantially lower for caridean shrimps and brachyuran crabs (Table 5). Many of the caridean shrimps present at Islas Galápagos belong to the family Palaemonidae (Wicksten 1991), comprising relatively small and cryptic species, inhabiting rocky zones in shallow and low energy water. Many of these are known to occur in association with soft corals (e.g., *Pacifigorgia symbiotica* Williams & Breedy, 2004). In contrast, at Isla del Coco there are only a few shallow-water areas with rocky substrates, most of them characterized by high energy wave impact; and soft corals are less abundant, although soft coral diversity of deepwater areas around the islands have not been studied yet (O. Breedy, pers. comm.). These differences might explain the relatively low number of caridean species reported for Isla del Coco when compared to Islas Galápagos. Why brachyuran crabs are clearly more diverse at Islas Galápagos needs further attention, but this may be related to the greater extension and variability of habitats at Islas Galápagos. Here we report the presence of 17 crab species new for the island, and we assume that future studies, employing different sampling techniques (including rock washing), will further increase the number of crab species and reduce the difference between both oceanic islands.

The diversity of stomatopod and decapod species from Isla del Coco shows strong affinities with that from Islas Galápagos, at least for those groups, for which information is available (Table 5). Most caridean shrimps species (81% or 21 spp.), and many Brachyura (46.6%) and Porcellanidae (60.0%) occur also on Islas Galápagos. The strong faunal affinity between both oceanic islands might be related to the fact that they are located in the same oceanic current system (Chavez & Brusca 1991, Kessler 2006); these currents transport planktonic early life stages throughout the eastern tropical Pacific, and Isla del Coco and Islas Galápagos represent the first possible settlement areas on their path to the coasts of Central and northern South America (Harvey 1991, Wicksten 1991, Cortés 1997).

In summary, Isla del Coco is characterized by a high diversity of stomatopods and decapods. We are convinced that the inventory of these species is far from completed. Dredging efforts in the vicinity of the island and in deeper waters using sampling techniques designed to collect cryptic species will probably result in a considerable increase of species numbers.

ACKNOWLEDGMENTS

This is a contribution of both the Museo de Zoología and the Centro de Investigación en Ciencias del Mar y Limnología (CIMAR),

Universidad de Costa Rica. We are grateful to Juan José Alvarado (The Nature Conservancy and CIMAR), who collected the specimens during the CIMAR-MarViva expedition. We sincerely thank Michel Hendrickx for his critical reading and constructive advice. Special thanks go to Mary K. Wicksten (Department of Biology, Texas A&M University, College Station, U.S.A.) for allowing us to include her unpublished data concerning two species new for Isla del Coco. Robert Okazaki (Weber State University, Ogden, Utah, U.S.A.) revised the English, which is greatly appreciated.

RESUMEN

La presente contribución resume la información disponible sobre la diversidad de los estomatópodos y decápodos de la Isla del Coco, e incluye informes de especies recolectadas recientemente durante la expedición CIMAR-MarViva (enero del 2007) como también la presencia de especímenes de la Isla del Coco en el Museo de Zoología, Universidad de Costa Rica, no publicados. El material de la expedición CIMAR-MarViva comprendió 23 especies, incluyendo nueve especies nuevas para la isla. La revisión de la colección del Museo más la inclusión de dos especies no informadas, reveló adicionalmente la presencia de 12 especies de decápodos. En conjunto, un total de 135 especies (6 estomatópodos y 129 decápodos) ha sido informado hasta el momento para la isla, la cual contiene 29.5% de todas las especies de decápodos conocidas para la costa del Pacífico de Costa Rica y el 16.3% de todas las especies de decápodos informadas para la Provincia Panámica. Las familias más diversas (incluyendo ≤ 10 spp.) en la Isla del Coco son Xanthidae (14 spp.), Majidae y Alpheidae (11 spp. cada una) y Porcellanidae (10 spp.). Hay una fuerte afinidad de la fauna de estomatópodos y decápodos entre la Isla del Coco e Islas Galápagos.

Palabras clave: biodiversidad, crustáceos decapados, Islas Galápagos, Pacífico Tropical Oriental, zoogeografía.
