BRITISH LICHENS

LONDON :
PRINTED BY WILLIAM CLOWES AND SONS, LIMITED,
DUKE STREET, STAMFORD STREET, S.E. 1, AND GREAT WINDMILL STREET, W. 1.

P R E F A C E

THE object of this Handbook is to supply a portable guide to the determination of the British Lichens. It is based on the "Monograph of the British Lichens," by the same author, which is a descriptive catalogue of all the known British species, published by the Trustees of the British Museum.*

The Handbook supplies detailed descriptions of the families and genera; the distinguishing characters of the species are indicated in a key under the genus. A typical species is figured in most of the genera; the figures have been drawn by Mr. P. Highley from the plates in the Monograph; a few are new.

INTRODUCTION

THE LICHEN-PLANT.

LICHENS are a class of thallophytes of lowly organization that inhabit soil, rock, wood, trees, etc. The vegetative thallus is of varying form and colour; the reproductive organs are akin to those of fungi. They differ from all other members of the vegetable kingdom in their composite structure, being formed from the union in intimate symbiotic relationship of two separate plants, a fungus and an alga. This can easily be demonstrated in any part of the thallus or vegetative structure; a thin section, examined under the microscope, shows a ground structure of colourless cells or hyphae, the fungal elements; and a series of green cells which are the algae. If the latter are confined to a narrow zone near the upper surface, the thallus is termed heteromerous (see figs. 5, 6), but if they are scattered more or less evenly through the thallus it is then described as homoiomerous (fig. 1).

This old division of lichens into heteromerous and homoiomerous does not entirely correspond with the modern more exact system of classification based on the reproductive organs; but the type of structure thus indicated is generally well marked, and a valuable character in identification.

Fungal elements of the thallus.—These have undergone considerable modification as lichen constituents, and cannot as a rule be traced back to any particular species or genus of fungi. The British lichens, however, are all associated with Ascomycetes, and approximate to certain groups within that class of fungi. In the tropics there are lichens in which the fungus belongs to the Hymenomycetes.

Lichen-hyphae, as they issue from the germinating spore and lay hold on the algae, are thin-walled, and similar to those of fungi (fig. 2). The various tissues are formed by the branching and septation of these hyphae. In the growing regions, at the apex or edges of the thallus, or in the gonidial region, the cells remain comparatively thin-walled; but in the other parts of the thallus, especially in the medulla, the walls become very thick, with the exception of the gelatinous lichens, in which the thickening is less marked. In the cortex of the foliose and other species, there is frequently a formation of pseudo-parenchyma (plectenchyma). It arises

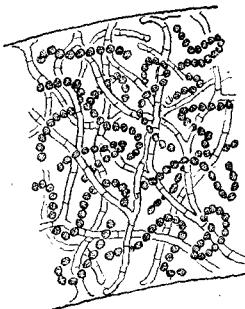

FIG. 1.—Section of homoiomeric thallus of *Collema*.
x 250.

from the vertical, multiseptate tips of the hyphae which lie closely packed together and present the appearance of cellular structure. In many cortices, more especially of crustaceous lichens, the walls

are so swollen that the cell-lumen practically disappears and the tissue becomes an amorphous gelatinized mass.

Strengthening elements are provided by the coherent parallel growth of thick-walled hyphae which form fibre-like bundles or chondroid strands that give support to the thallus.

Lichen-hyphae retain many of the characteristics of those of the higher fungi. Pure cellulose has not been found, the cell-walls being formed of various hemi-celluloses, and nearly all the cell-membranes contain more or less chitin. The cells enclose a nucleus, protoplasm, glucoses and sometimes oil-drops; glycogen occurs in the cells of the reproductive system. Sphaeroid cells filled with greenish oil are a constant feature of the lower rhizoidal layer of calcicolous lichens; oil cells also occur occasionally in other lichens.

Algal elements of the thallus.—The algal constituents of the composite thallus belong to the two classes—(1) Myxophycæ, generally termed blue-green algae, and (2) Chlorophycæ, which are referred to as bright-green. Most of them are aerial forms and, in a free condition, they inhabit moist shady situations. They multiply by division within the thallus; zoospores are never produced except in cultivation outside the thallus. *Chlorella* which resembles *Protococcus* in form and size has been proved recently* to be the gonidium of many of our common lichens. It increases within the thallus by the formation of aplanospores in the mother-cell. The sporulation stage is evident at times of special growth in spring or in rainy weather following a dry season. The determination of the genera and species to which the algae severally belong is often uncertain, but their distribution in British lichens is somewhat as follows:—

1. Myxophycæ associated with Phycolichenes, many of them gelatinous lichens (fig. 3). They are:—

Seytonema occurring in *Thermitis*, *Spilonema*, *Leptogidium*, *Gyalicta* (in part), *Placynthium*, *Polychidium*, *Porocyphus* and *Coccocarpia*.

Stigonema in *Ephebe* and *Ephebia*.

Glœocapsa in *Euopsis*, *Pyrenopsis*, *Synalissa* and *Psorotichia*.

Nostoc in *Collema*, *Leptogium*, *Peltigera*, *Pannaria* and *Parmeliella*.

Rivularia in *Lichina* and *Pterygium*.

Nylander gave the name goniinia to the blue-green algae of the thallus, retaining the term gonidia for the bright-green species. The distinction is not generally maintained.

* Paulson & Hastings in Journ. Linn. Soc. xliv, pp. 497-506, 1920.

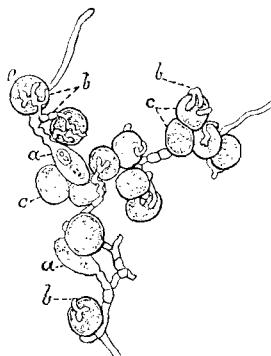

FIG. 2.—*a*, Germinating spores; *b*, clasping filaments; *c*, algal cells. (After Bonnier X 350.)

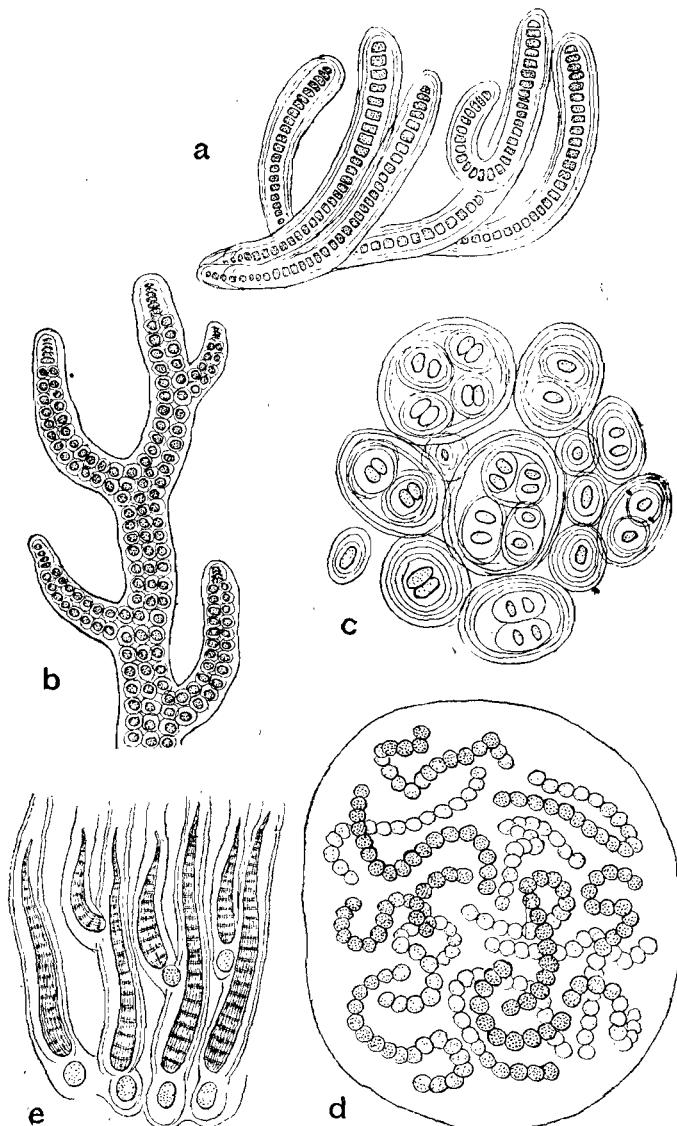

FIG. 3.—Blue-green algae that form gonidia. a, *Scytonema*; b, *Stigonema*; c, *Gloeocapsa*; d, *Nostoc*; e, *Ricularia*. (a, b, e, after Kützing, $\times 350$; c, after Cooke, $\times 400$; d, $\times 450$.)

2. Chlorophyceæ associated with Archilichenes (fig. 4) as follows :—

Protococeus (*Cystococeus*, *Pleurococeus*) or probably only *Chlorella* and *Palmella* in the greater number of the larger lichens and in many crustaceous genera, such as *Lecanora*, *Lecidea*, *Pertusaria*, *Verrucaria*, etc.

Trentepohlia in *Cænogonium*, *Dirina*, *Roccella*, *Graphidaceæ*, *Pyrenulaceæ*, and also in *Thelotrema* and *Gyalecta*, rarely in *Lecanora* and *Lecidea*.

Cladophora in *Racodium*.

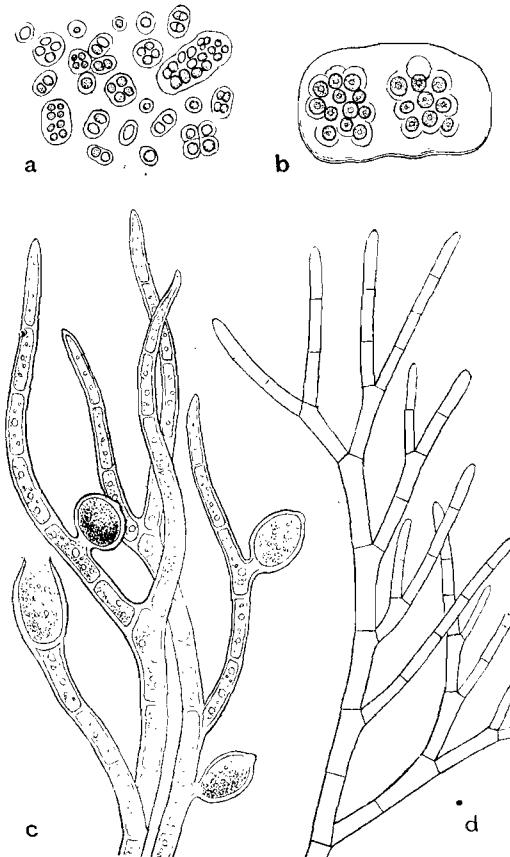

FIG. 4.—Bright-green algae that form gonia. a, *Protococcus*; b, *Palmella*; c, *Trentepohlia*; d, *Cladophora*. (a, b, $\times 250$, after Hassall; c, after Cooke, $\times 250$; d, after West, $\times 60$.)

• Though as a general rule the alga is less affected than the fungus by the symbiotic life, it also may become modified in appearance. The blue-green forms may lose their colour, as in *Gloecapsa*; or the strings of cells may be broken up, as occasionally in *Nostoc*, *Scytonema*, etc. Among the Chlorophyceæ, there is occasional change of form both in *Protococcus* and in *Trentepohlia*; they revert to their original appearance in free cultivation.

MORPHOLOGY.

- There are three principal types of development in the vegetative body or thallus of lichens :—

1. *Crustaceous*, or encrusting lichens which spread over trees, rocks or soil, with a more or less well-developed crust varying in thickness, form and colour. The thallus consists generally of an upper cortical layer of hyphae; beneath the cortex a zone of algal cells and lower still a medulla of fungal filaments, the latter resting directly on the substratum; sometimes the crust is only a thin structureless mixture of hyphae and alga. Though mostly superficial the crustaceous thallus is, in certain genera or species, partly or wholly embedded in the bark or rock on which it grows. It is thus often difficult to recognize the different tissues. The lower hyphae in many of the superficial species form a thin spreading layer called the hypothallus; it is usually dark in colour and often appears as a black border to the thallus, either as a firm limiting line or as dendritic filaments. A patch of crustaceous lichen on tree or rock may belong to one species and yet be composed of many individuals which have started from different centres, each growing centrifugally. The dark lines chiefly occur where the different individuals encounter each other. A striking instance of such intersecting lines occurs in the thallus of the well-known *Rhizocarpon geographicum*. Strong boundary lines also frequently divide different species inhabiting the same substratum.

2. *Foliose, foliaceous or leafy lichens*: as the name implies, these are spreading leaf-like expansions of one or many lobes, which adhere more or less firmly to the support on which they grow. Like the crustaceous forms, they are dorsiventral in structure; the upper surface is provided with a distinct hyphal cortex, beneath which lies the gonidial zone and the medulla. There is also a lower cortex which is frequently of a darker colour and which is mostly provided with hairs or with rhizoids formed of strands of hyphae that are chiefly organs of attachment.

3. *Fruticose or shrubby lichens*: these are upright branching forms rising from a basal point, and they are either cylindrical or strap-shaped. The structure is radial, with a central pith of fungal hyphae, a surrounding band of algae and an outer cortex of fungal elements. There is considerable variety of form in this group from the short, stiff, strap-shaped lobes of some *Ramalinae* to the long pendulous thread-like strands of *Alectoria* or *Usnea*. Intermediate forms connect these different groups. In the Cladoniaceæ there is a basal thallus, either crustaceous or of small lobes, and there is also an upright stalk called a "podetium," which in many cases opens out into a cup-like structure called a "scyphus." The podetia may be simple or branched, and as the reproductive bodies in this family are borne on the tips of the branches or on the edges of the scyphi, the upright thallus has been frequently regarded as a modified fruit-stalk.

VEGETATIVE STRUCTURES PECULIAR TO THE LICHEN-THALLUS.

Sordia.—These are small powdery bodies that consist of one or several algal cells closely surrounded by lichen-hyphae. They occur as greyish powder on trees, or on the ground, representing the first stage of thallus formation; as white or greyish granules on the squamules and podetia of many Cladoniae, or they are massed on the surface of the thallus into well-defined pustules called soralia. The sorarium is formed by an increased growth of soredial gonidia and hyphae at certain points within the thallus,

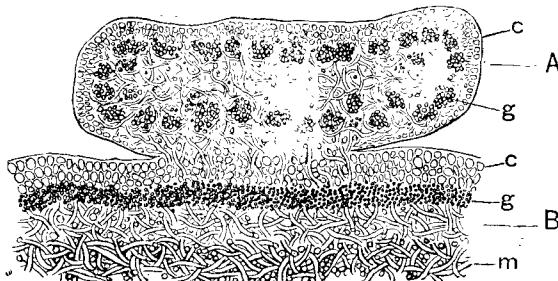

FIG. 5.—Vertical section of thallus and cephalodium of *Peltigera aphthosa*. A, Cephalodium; B, Thallus. c, cortex; g, gonidia; m, medulla. (Greatly magnified.)

the overlying tissue finally bursting and allowing the escape of the soredia. Soralia are generally constant in form and in position on the thallus. Each soredium can give rise to a new lichen-plant. It is a method of vegetative reproduction that secures a ready and wide dispersal of species.

Isidria.—The isidium is a small outgrowth from the surface of the thallus which contains both the algal and fungal constituents, but differs from the

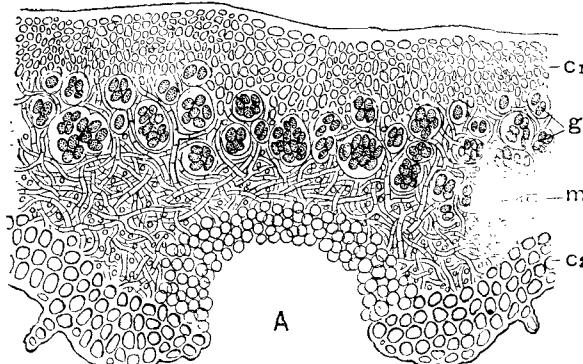

FIG. 6.—Vertical section of heteromerous thallus and cypella of *Sticta* sp. A, Cypella; c₁, upper cortex; c₂, lower cortex; g, gonidia; m, medulla. (Greatly magnified.)

soralium in being covered by a cortex. Usually the isidia are like minute cones on a narrow stalk; occasionally they are branched.

Cephalodia.—On the thallus of various lichens there are developed abnormal, and generally darker-coloured swellings, tubercles or warts, composed of the normal lichen hyphae, but containing a different algal constituent, which is almost invariably one of the Myxophyceæ (*Nostoc*, *Stigonema*, etc.). Cephalodia are constant in form and occur as flat orbicular light-coloured expansions (*Lecanora gelida*), groups of dark branchlets (*Lobaria laciniata*), or irregular warts (*Peltigera*, *Sterrocaulon*). They also form internal packets in certain species, which are termed endotrophic cephalodia. They are probably of value in retaining moisture (fig. 5).

Cyphella and *Pseudo-cyphella*.—These are small roundish bodies scattered over the lower surface, mostly in the genus *Sticta*. They are of definite form with a distinct rim (cyphellæ), or they are mere openings in the cortex through which hyphae project (pseudocyphellæ). They serve most probably as aerating organs as do the bare areas on the under surface of *Lobaria pulmonaria*, etc. (fig. 6).

Definite breathing pores have been demonstrated in only one lichen, *Parmelia exasperata*; but openings and breaks occur frequently and allow ready communication between the internal tissues and the outer air.

REPRODUCTIVE ORGANS.

Apothecia and Perithecia.—With the exception of a few tropical genera of Hymenolichenes, all known lichens belong to the subclass Ascolichenes and produce their spores in fruits—apothecia or perithecia—somewhat similar to those of the Ascomycetes.

Apothecium.—An open fruit with a more or less exposed disc, comparable to that of the Discomycetes among fungi. The simplest type of apothecium is formed solely from the fungal constituent as in the Lecideaceæ,

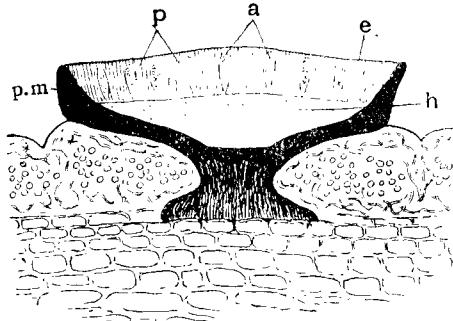

FIG. 7.—Vertical section of lecideine apothecium. a, ascii; p, paraphyses; e, epithecium; h, hypothecium; p.m., proper margin. (Greatly magnified.)

usually a round button-like disc, which is either soft and often brightly coloured (biatorine) (fig. 8), or dark and mostly hard and carbonaceous (lecidine) (fig. 7). The disc is formed of compact upright rows of ascii or theciæ (a) which contain the spores, and of simple or branched sterile threads,

the paraphyses (p), of which the tips generally project beyond the ascci and form the epithecium (e). The combined ascii and paraphyses are the hymenium. The tissue of the fruit immediately below the hymenium is

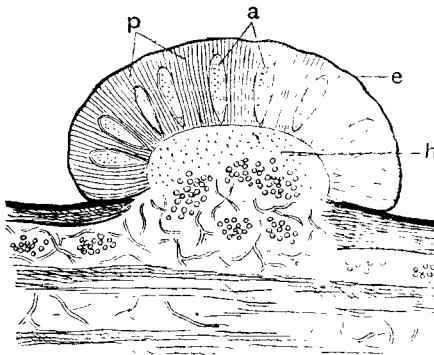

FIG. 8.—Vertical section of biatorine apothecium.
a, ascii; p, paraphyses; e, epithecium; h, hypothecium. (Greatly magnified.)

the hypothecium (h), and as continued up and round the fruit is called the parathecium or "proper margin" (p.m.). It may be formed of loosely interwoven light-coloured hyphae, or it may be dark and carbonaceous. Frequently it is excluded by the growth of the disc (fig. 8).

In the more highly developed lecanorine apothecium (fig. 9) the thalline

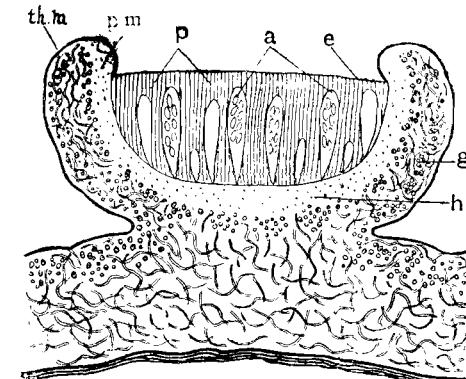

FIG. 9.—Vertical section of lecanorine apothecium.
a, ascii; p, paraphyses; e, epithecium; g, gonidia;
h, hypothecium; p.m., proper margin; th.m.,
thalline margin. (Greatly magnified.)

tissue containing gonidia develops along with the other apothecial tissues. This outer protective wall or amphitheciun is generally called the "thalline margin" (th.m.); it closely surrounds and forms an integral part of the

apothecium. Apothecia vary greatly in size from about 0·25 to 10 mm. or more in diameter.

Perithecium.—When the fruit is a closed body with only a narrow opening, or ostiole it is called a perithecium (fig. 10). Generally it is surrounded by a wall and the peritheciun is then entire (a), or the wall is absent or reduced to a thin line below the base and it is then described as dimidiate (b). Perithecia are always small bodies and usually they are partly immersed in the thallus or substratum.

As a rule lichen-fruits grow slowly. Spores may be produced almost any time in the year, but for a number of species there is a double spore-bearing season, in spring and again in autumn. The same fruits often persist for several years, new asci being continually formed. It is therefore no unusual experience to find the spores shed in seemingly well-fruited lichens.

Lichen spores vary considerably in size, form, septation and colour. Usually there are 8 in the ascus, but in some genera or species the ascus contains only one large spore, in others they are innumerable and of small dimensions.

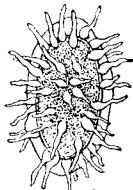

FIG. 11.—Multi-nucleate spore of *Leptidea sanguinaria* var. *affinis*, with germinating tubes. (After de Bary. X about 250.)

The largest spores are found in *Pertusaria* and in *Varicellaria*, the 1-septate spore of the latter measuring up to $350 \mu \times 115 \mu$. In the family, Physciaceae, the cross wall of the septate spore is so thickened that the lumen of each cell is reduced to a small area at the ends; hence the term polar-bilocular. This is a type of spore without any parallel among fungi. Each cell of a septate spore may give rise to a hyphal filament on germination. The large one-celled spores of *Pertusaria* and other lichens contain many nuclei and produce germinating tubes all over the surface (fig. 11). The newly formed hyphal filaments become associated with an algal cell, and development proceeds (fig. 2), or, if no alga is encountered, the hyphae in time die off. In some genera of Pyrenocarpaceae (*Endocarpon* and *Staurothecia*) gonidia

occur in the hymenium alongside of the asci. They escape from the perithecia with the spores, and together they build up a new plant.

Spermogones or Pycnidia.—These are small perithecia-like bodies which occur on many lichens, generally scattered over the thallus, but occasionally confined to definite areas: to the periphery of the lobes (*Parmelia physodes*), the margins (*Cetraria islandica*) or the tips of the podetia (*Cladonia*). They vary in form, being ovoid, globose, etc., and sometimes irregular, with folds of tissue projecting inwards thus subdividing the interior. The inner wall is lined by simple or branched hyphae, the sterigmata, or by a cellular tissue on which spermatia are borne. The spermatia are usually minute, and more or less cylindrical, and are provided with a cell-wall and contain a nucleus, etc. Many lichenologists have looked on these bodies as the male

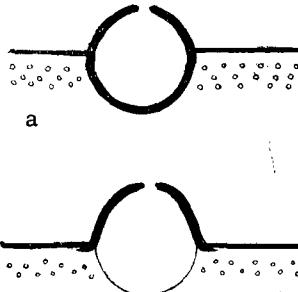

FIG. 10.—Vertical section of perithecia. a, entire; b, dimidiate. (Greatly enlarged, diagrammatic.)

organs of the plant bearing non-motile spermatia. They are largely functionless, and as germination of the "spermatia" has been observed in a number of forms, it seems probable that they should rank as secondary fruit forms or pycnidia, their contents would then be more properly described as sporophores and pycnidiospores.

The form of the sterigmata (or sporophores) varies, and the differences have been made use of in classification. Nylander divided the spermogones into two groups: those with simple "sterigmata" and those with "arthrosterigmata." In the former, the more usual type, the sterigmata are more or less upright, variously branched, and sometimes anastomosing; they are usually sparingly septate, and the spermatia are acrogenous on the tips of a secondary branch. The arthrosterigmata are divided up into short cells, each cell directly giving rise to a pleurogenous spermatium (or spore). This type of sterigma is found in *Physcia* and *Sticta*. In *Endocarpon* the arthrosterigmata form a tissue lining the wall.

The spermatia also show great variation in form. Usually they are extremely minute, or if elongate, extremely narrow and thread-like. Some undoubted pycnidia contain larger stouter spores which do not differ from the others except in size, though the term "pycniodes" was wholly reserved for these by Lindsay.

PHYSIOLOGY.

Nutrition.—In the higher plants there are green cells containing chlorophyll and colourless cells forming tissues with different functions. We find the same distinctions between the tissues in lichens, but with this great difference, that whereas, in the higher plants, all the cells have the same initial starting point, in lichens, the two kinds of cells have a widely separate origin. In lichens, as in the higher plants, the green cells—the lichen gonidia—do the work of assimilation and by photosynthesis prepare carbohydrates for the whole plant. The colourless cells or hyphae are the organs of absorption, and, in return for the algal carbohydrates in the form of sugars or glucoses, they supply water, nitrogenous substances and salts, which they have absorbed from the substratum or from the environment and converted into a state in which they can be used by the protoplasm of the green cell.

Symbiosis.—The relationship between the two organisms was at first regarded as that of algal host and fungal parasite, but further consideration showed that this view was not entirely satisfactory, and Reinke pointed out that each member of the joint thallus might be regarded as the "consort" of the other. This view was further elaborated by de Bary, who brought forward a similar theory of "symbiosis," or conjoint life with more or less advantage to each member or *symbiont* of the dual organism. The alga undoubtedly grows with great vigour in the lichen-thallus, being excited to increased vitality by contact with the fungus, or by conditions, such as increased moisture, supply of inorganic salts, shelter, etc., that are specially favourable to its growth. On the other hand, the fungus withdraws from the alga the necessary carbohydrates. The presence of hyphic within the algal cells observed in certain lichens, and of empty algal membranes in others, testify to the occasional harmful ravages of the fungus; but any theory of lichens as merely parasitic fungi is incompatible with the continuous healthy development of the lichen plant.

• *Excretory products.*—In many lichens there is an abundant formation of oxalate of lime; it is laid down in crystals on the outside of the hyphæ, medullary or cortical. In *Lecanora esculenta*, a limestone desert lichen, it has been proved that the crystals form sixty per cent. or more of the dry substance of the thallus.

There is also an enormous production of lichen acids, organic products of varying chemical formulae found only in lichens, and due undoubtedly to the peculiar symbiotic relationship of fungus and alga. Among the best known are parietin (chrysophanic acid), which gives the brilliant yellow colour to several lichens, and the valuable series of acids that produce the orchill of commerce, called also cudbear and litmus. Orchill provides a beautiful purple dye, and though it can be extracted from a number of lichens, the chief commercial source is *Roccella tinctoria* which grows in great abundance on the rocky coasts of southern Europe. The crustaceous lichen *Lecanora tartarea* also yields a purple dye.

ECOLOGY AND DISTRIBUTION.

Lichens are xerophytic in structure and well-adapted by their composite nature to withstand extreme drought and extreme weather conditions. In some cases water may be absorbed from the soil, but in most lichens the habitat precludes that possibility: they live nearly always in xerophytic conditions—on the bark of trees, on the bare rock, on acid moorland soil, on sandy wastes or by the seashore. The hyphae swell up and retain for a long time the moisture they receive mostly from mist or rain. There is no regular provision for transpiration except in a few cases. Growth is extremely slow, and there is in consequence little demand on the metabolic activity of the cells. A plant of *Parmelia saratilis* kept under observation for a considerable period was observed to increase about 1 cm. in diameter in a year. The gonidial layer is usually several cell-rows below the surface and is often obscured by pigments in the cortical cells; they require therefore abundant light and pure air, and are always most luxuriant in well-lighted situations, such as the sunny side of a wall, and on the outskirts of a wood rather than in its shady glades. They soon die out or lead an impoverished existence in the near precincts of a large town, owing to the smoke. They are the most cosmopolitan of all plants and the pioneers of vegetation, occupying great tracts of mountain and arctic regions where no other plants can live. Distribution in the case of some genera and species is limited by climate or by the nature of the substratum. On the other hand, there are species, like the mountain-loving *Rhizocarpon geographicum*, that spread almost from pole to pole.

ECONOMIC USES OF LICHENS.

In addition to their use as dye-plants, lichens are to a very limited extent valuable as a food supply. The lichenin stored in the cell-walls of *Cetraria islandica*, the Iceland Moss, can be so prepared as to be both nutritious and appetising and has been often utilised by northern peoples. Species of *Gyrophora*, "tripe de roche," have been eaten by travellers when no other food was available, but though they contain some nourishment they are too bitter for consumption. Reindeer pasture largely on *Cladonia rangiferina*, and snails, slugs, mites, etc., devour eagerly many different kinds of lichens.

In the economy of Nature a considerable part is played by crustaceous saxicolous lichens in breaking up the rock and preparing it for plants more dependent on loose soil. Calcareous and granite rocks are thus slowly but gradually disintegrated. Volcanic rocks with their smoother harder surface are less affected. Topographically as well as geographically, lichens are indispensable pioneers. Many lichens grow on trees, where they are epiphytic, though occasionally their root-bases penetrate the living tissue; only one species, a leaf-lichen in the tropics, has been recorded as constantly parasitic. Sometimes the growth of leafy and shrubby forms is so luxuriant as to cover the entire bark and thus impede the aeration of the tree. On the other hand, it is suggested that they probably protect the tree from extreme cold. They do, however, indirect harm by providing harbourage for insect pests.

PHYLOGENY AND CLASSIFICATION.

Lichens as regards both their symbionts are polyphyletic in origin, the algae which form gonidia belonging to widely separated groups, and the fungi which form lichen-hyphae being derived from the two great subclasses Basidiomycetes and Ascomycetes.

All the British lichens are derived from the Ascomycetes, and they are again polyphyletic within the subclass. They fall into two great series:—

I. *Gymnocarpeæ*, in which the fruits have more or less open discs.

II. *Pyrenocarpeæ*, with closed fruits.

Series I.—The *Gymnocarpeæ* are divided into three subseries:—

1. *Coniocarpineæ*, characterized by a "mazaedium" type of fruit, and, in most of the families, by a primitive thallus. The derivation is doubtful.
2. *Cyclocarpineæ*, with open fruits corresponding to those of the Discomycetes. Their fungal ancestors are to be sought for among the Pezizineæ and most probably in the family Patelariaceæ.
3. *Graphidineæ*. The fruits are characterized by a narrow generally elongate disc. The nearest allies among fungi are the Hysteriaceæ.

In the arrangement of the various Orders or families, special attention has been given to the development of the lichen-plant as a whole within each series.

The *Coniocarpineæ* are a subseries apart, intimately connected with fungi and have been placed first. The almost closed form of the fruit suggests, however, affinity with the *Pyrenocarpeæ*.

In the *Cyclocarpineæ*, the first group includes those families in which the fruit is highly developed, the apothecia with few exceptions having a thalline margin (lecanorine). The lichens containing blue-green algae (Myxophyceæ) have been considered first; those with a simple homoiomerous thallus being followed by those with a heteromerous thallus, reaching the highest development in the Peltigeraceæ and Stictaceæ, which include genera with both types of gonidia, blue-green and bright-green.

To avoid any break in the arrangement, the Parmeliaceæ, which are

allied to the Stictaceæ, are placed next. The gonidia in this and the following families are bright-green. Then follow the Usnaceæ, and after that family the Physciaceæ, marked by the peculiar polarilocular spores. The genera of Physciaceæ range from fruticose to crustaceous forms. The Lecanoracæ and other crustaceous families close the first group.

The second group (Cyclocarpineæ) includes those families in which the apothecia are without a thalline margin (biatorine or lecideine), the gonidia taking no part in the formation of the fruit: they are thus more primitive phylogenetically than the preceding. Beginning with the highest families of the group, we place first the Gyrophoraceæ with a well-developed foliose thallus, followed by the Cladoniaceæ, the filamentous Cænogomiaceæ—very poorly represented in northern countries—and finally the great family of Lecideaceæ with a crustaceous or, at most, minutely squamulose thallus.

In subseries Graphidinæ, the families have a crustaceous thallus, with the exception of Roccellaceæ, which is fruticose and highly developed, the gonidia are all Chlorophycæ and mostly from the genus *Trentepohlia*. The arrangement depends on the character of the fruit.

Series II. Pyrenocarpeæ.—There is a small family of Pyrenidiaceæ with blue-green gonidia (Myxophycæ), the others all contain Chlorophycæ. There is one family, Dermatocarpaceæ, which is foliose, the other families are all crustaceous and are arranged according to perithecial characters. They are derived from the Pyrenomycetes.

The metric system has been used for measurement; the Greek letter μ indicates the one-thousandth part of a millimeter. Other abbreviations which refer to chemical reagents are as follows:—+ a colour reaction, f+ a faint reaction, — no reaction. Iodine solution (I) iodine 1 grain, potassium iodide 3 grains, water $\frac{1}{2}$ oz., is used as a test for starch or glycogen; potassium hydrate (K)—caustic potash and water, calcium hypochlorite or bleaching-powder (CaCl or simply C)—1 part in half its weight of water, and Nitric acid (NO_3) indicate by colour-reactions the presence of lichen-acids in the thallus. Thus K + y indicates a general yellow reaction; K followed by C frequently gives a reaction and is expressed as:—K(C) +. The meaning of these varying reactions is that the colour of the acids is liberated by the application of an alkali alone, by bleaching-powder alone or after previous treatment with an alkali. Reactions cannot always be relied on, as the production of acids may have been inhibited by absence of light, etc.

The arrangement of species according to habitat is more or less artificial, as not a few grow on several substrata. Cross references are given to avert risk of mistakes in determination. The numbering of the species refers to the numbers in the Monograph of "British Lichens." Missing numbers are those of imperfectly known species. Descriptions have been severely curtailed in order to keep within the limits of a "Handbook."

LIST OF ABBREVIATIONS

- Apo., Apothecium.
Aren., Arenaceous (sandstone), etc.
Cal., Calcareous (limestone, mortar).
Colour reactions.—er., crimson; o., orange; p., purple; y., yellow.
Distribution.—C., common; F., frequent; S., scarce; R., rare.
Epi., Epitheciwm (generally tips of the paraphyses).
Hypo., Hypothecium.
Med., Medulla.
Mod., Moderate- or medium-sized.
Paraph., Paraphyses.
Peri., Peritheciwm.
Pod., Podetium of Cladoniaceæ.
Reagents.—C, Calcium hypochlorite; K, potash; I, iodine; NO₃, nitric acid; (followed by + or -).
Sey., Scyphus of Cladoniaceæ.
Sil., Siliceous rock
Sp., Spore.
Sq., Squamule, squamulose.
Th., Thallus.

CLASS LICHENES.

SUBCLASS ASCOLICHENES.

Series I. GYMNOCARPEÆ.—Fruit a more or less open apothecium.

Series II. PYRENOCARPEÆ.—Fruit a closed perithecium.

SERIES I. GYMNOCARPEÆ.

Subseries I. CONIOCARPINEÆ.—Apothecium partially closed; spores, when mature, a powdery mass (*mazædium*).

Subseries II. CYCLOCARPINEÆ.—Apothecium with open disc; spores ejected when mature.

Subseries III. GRAPHIDINEÆ.—Apothecium with elongate narrow disc (*lirella*); or roundish (*ardella*); spores ejected when mature.

Subseries I. CONIOCARPINEÆ.

Thallus crustaceous, wanting, or fruticose (foliose in some foreign genera). Algal cells Chlorophyceæ. Fruit a stalked or sessile apothecium or capitulum, open or partially closed; ascii usually cylindrical, dissolving early, the spores, as they mature lying loose in the apothecium, like powder or dust, forming a *mazædium*.

The Coniocarpineæ are distinguished from all other lichens by the peculiar character of the mature fruit. Species in which the thallus has become obsolete have been included by some botanists in fungi, but British species have all been retained among lichens, as they so evidently belong to one series.

Thallus crustaceous I. CALICIACEÆ

Thallus foliose or fruticose II. SPHEROPHORACEÆ.

FAMILY I. CALICIACEÆ.

Thallus effuse, thin, granular-crustaceous, often obsolete. Algal cells Protococcaceæ. Fruit usually a stalked apothecium, top-shaped or globose (capitulum), the stalk, simple or sometimes branched, without gonia;

paraphyses thread-like; the spores forming a mazedium, simple or septate, mostly dark-coloured.

The fruits are small, mostly stalked and dark in colour resembling minute nails. In one genus, *Cyphelium* (*Trachylia*), they are sessile and marginate, but are easily recognized as coniocarpous by the dark powder, mazedium.

Thallus wanting. Apothecia parasitic.

Apothecia shortly-stalked, top-shaped 1. **Sphinetrina**.
Thallus granular-crustaceous, sometimes obsolete.

Apothecia stalked.

Spores spherical, simple.

Dark in the mass 2. **Chænotheca**.

Yellow in the mass 3. **Coniocybe**.

Spores oblong, septate, dark.

1-septate 4. **Calicium**.

3- or more-septate 5. **Stenocybe**.

Apothecia sessile, with thalline margin.

Spores oblong, 1- or more-septate, dark 6. **Cyphelium**.

1. SPHINCTRINA Fr.—Thallus none. Apothecia small, top-shaped, sessile or shortly stalked, black, somewhat shining, with a thick connivent proper margin almost closing the disc; ascii suppersistent; spores simple, rarely 1-septate, blackish.

Mostly parasitic on the thallus of *Pertusaria* or other lichens. *S. microcephala* (*S. anglica*) in our specimens occurs on old rails, etc., probably on disappearing lichen thalli.

On *Pertusaria communis*. C. 1. *S. turbinata* Fr.

On *Pertusaria melaleuca*, *P. fallax*, etc. R. 2. *S. tubiformis* Massal.

On *Lecanora parella* and *L. nitens* on maritime

rocks. R. 3. *S. kylemoriensis* Cromb.

On pines and on rails, in shady places. R. 4. *S. microcephala* Koerb.

2. CHÆNOTHECA Th. Fr. (*Cyphelium* Ach.)—Thallus granular, pulverulent or evanescent. Apothecia stalked, top-shaped or subglobose, small, dark, often finely powdered, with a greyish or yellow pruina; spores globose or subellipsoid, simple dark, mostly minute.

Mostly on dead wood or on the trunks of old trees.

Apothecia black, yellow-pruinose. Th.

various.

Th. bright-yellow, thickish. F. 1. *Ch. chrysocephala* Th. Fr.

Th. grey or olive-brown. R. 2. *Ch. trabinella* A. L. Sm.

(*Ch. phaeocephalum* Th. Fr.)

Th. grey, thin; sporal mass protruding. R. 3. *Ch. acicularis* Zwackh.

Apothecia black or brown, greyish-pruinose.

Th. greyish, thin. S. 4. *Ch. trichialis* Th. Fr.

Th. greyish-green, powdery. R. 5. *Ch. aeruginosa* A. L. Sm.

Apothecia brown, not pruinose. R. 6. *Ch. brunneola* Müll.-Arg.

Apothecia black, not pruinose. Sp. 8-11 μ

diam. R. 7. *Ch. melanophœa* Zwackh.

3. **CONIOCYBE** Ach.—Effuse, thin, mostly pulverulent, sometimes obsolete. Apothecia stalked, light-coloured, the capitulum more or less globose and powdery with the protruded spores; paraphyses slender; spores spherical, simple, colourless, yellowish or pale-brownish.

On dead trunks, on twigs or on mosses, rarely on rocks.

Thallus well developed, greenish. Fruit stalks long. C. 1. C. furfuracea Ach. Thallus scanty, whitish. Fruit stalks short.

- Capitulum and sp. bright-yellow. R..... 2. C. sulphurea Nyl.
- Capitulum white or brownish, sp. up to $10\ \mu$
diam. R..... 3. C. pallida Fr.
- Capitulum white or pale-reddish, sp. up to $3\ \mu$
diam. R..... 4. C. hyalinella Nyl.

4. **CALICIUM** Pers.—Granular, pulverulent or obsolete. Apothecia stalked or almost sessile, lens- or top-shaped, brown or black, often pruinose;

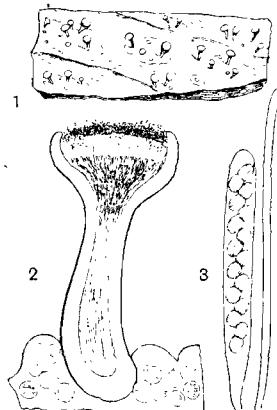

FIG. 12.—*Calicium quercinum* Pers. 1. Plant, nat. size. 2. Vertical section of thallus, stalk and capitulum $\times 25$. 3. Ascus with spores and paraphysis $\times 500$.

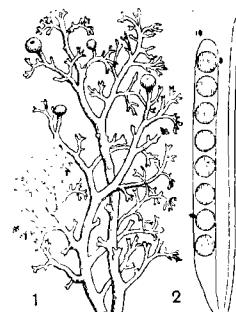

FIG. 13.—*Sphaerophorus globosus* Wain. 1. Portion of plant, $\frac{1}{2}$ nat. size. 2. Ascus with spores and paraphysis $\times 500$.

spores oblong-ovoid, 1-septate, sometimes slightly constricted at the septum, smoky- or dark-brown, from $5\ \mu$ to $16\ \mu$ in length.

On trunks of old trees or on dead wood (*C. arenarium* is parasitic). The pruina is mainly visible on the capitulum.

Capitulum yellow pruinose.

Parasitic on *Lecidea lucida*, on stones. F. 1. *C. arenarium* Nyl.

Growing on oaks, thallus grey. R. 2. *C. roscidum* Floerke.

Capitulum reddish-pruinose.

Thallus granular, bright-greenish-yellow. C. 3. *C. hyperellum* Ach.

Thallus thin, greyish-white or obsolete. C. 4. *C. sphærocephalum* Wahlenb. (*C. trachelinum* Ach.)

Capitulum whitish-pruinose. Thallus greyish.	
Stalks long. F.....	5. <i>C. quercinum</i> Pers.
Stalks short, spores protruded. C.....	6. <i>C. curtum</i> Turn. & Borr.
Capitulum not pruinose.	
Thallus whitish or absent. Apothecia minute.	
On wood. Sp. fusiform or clavate. R. 7. <i>C. pusillum</i> Floerke.	
On wood. Sp. fusiform-ellipsoid. R. 8. <i>C. debile</i> Turn. & Borr. <i>(C. paricinum Ach.)</i>	
On bark of poplars. R.....	9. <i>C. populneum</i> De Brond.
On bark of holly. R.	10. <i>C. diplocladium</i> Floerke.

5. **STENOCYBE** Nyl.—Thallus in spots (macular), thin, often obsolete or none proper. Apothecia stalked, scattered, black, minute, the capitulum top-shaped or clavate; spores ellipsoid or fusiform, large, becoming 3- (or more) septate, colourless, then brown.

On bark, or parasitic on other bark lichens.

On holly. Sp. up to $36\ \mu$ long. R.....	1. <i>S. major</i> Nyl.
On holly and on other lichens. Sp. up to $70\ \mu$ long. F. 2. <i>S. septata</i> Rehm.	
On alder bark. Sp. up to $23\ \mu$ long. R.	3. <i>S. byssacea</i> Nyl.

6. **CYPHELIUM** Ach. (*Trachylia* Fr.).—Granular or powdery. Apothecia sessile or almost immersed in the thallus, semi-globose, becoming open and plane, black, with a thin thalline margin; sporal mass plane, black; spores ellipsoid, rather large, mostly 1-septate, brownish-black.

On old palings, etc. One species is parasitic, and is found on the same habitat as the host lichen.

Spores 1-septate.

Thallus yellowish or greenish. R..... 1. *C. tigillare* Ach.

Thallus grey or greyish-white. C..... 2. *C. inquinans* Trev.

Parasitic on *Pertusaria*. R..... 3. *C. stigonellum* A. Zahlbr.

Spores pluri-septate and muriiform.

Thallus bright greenish-yellow. R..... 4. *C. Notarisii* A. Zahlbr.

FAMILY II. SPHÆROPHORACEÆ.

Thallus erect, leafy or shrubby, corticated or, in leafy forms (foreign), scarcely corticated below. Algal cells Protococcaceæ. Apothecia sessile on the tips of an upright thallus, or at the edge or underside of a leafy thallus, open from the beginning, or surrounded by a thalline covering. Spermatia oblong, on short-celled tissue-like sterigmata.

Only one genus of this family has been found, so far, in the British Isles.

The spores as in other genera of Coniocarpineæ
form a powdery mazedium.

Thallus shrubby..... 7. *Sphærophorus* Pers.

7. **SPHÆROPHORUS** Pers.—Thallus shrubby, composed of upright stalks irregularly branched, the cortical layer cartilaginous, smooth and shining, the central medullary layer white and rather soft. Apothecia terminal on the primary stalks or branches, innate in the swollen tips, globose or sub-

globose, at length bursting irregularly; paraphyses slender; spores 8, globose, simple, dark, in copious black masses.

Mostly found in regions of moorland and rocks, where they often grow in great profusion.

Main branches with short branchlets or fibrillæ.

Branches flattened. C..... 1. *S. melanocarpus* Schær.
(*S. compressus* Ach.)

Branches round. C..... 2. *S. globosus* Wain.
(*S. coralloides* Pers.)

Branches without fibrillæ. C..... 3. *S. fragilis* Ach.

Subseries II. CYCLOCARPINEÆ.

Thallus crustaceous, squamulose, foliose or fruticose. Algal cells blue-green (*Myxophyceæ*), or bright-green (*Chlorophyceæ*). Fruits a roundish apothecium open or partially open from the first, marginate or immarginate, the margin composed of hyphæ alone (*proper*) or including gonidia (thalline). Ascii and spores various.

The Cyclocarpineæ include a large and varied series of lichens that differ widely in the characters of thallus and fruit. The algæ are blue-green (*Myxophyceæ*) in a comparatively small number of families and genera; mostly they are bright-green or yellow (*Chlorophyceæ*). In the former case the thallus is frequently gelatinous when moist, as are the alge which are distributed equally through the thallus (*homoiomericous*), though also sometimes non-gelatinous, with the alge arranged in a definite zone (*heteromericous*). The thallus containing Chlorophyceæ is non-gelatinous and nearly always heteromericous.

Thallus homoiomericous, gelatinous when moist,
varying in form. Algæ Myxophyceæ.

With *Scytoneema* or *Stigonema*, crustaceous or minutely fruticose.....

With *Gloeocapsa*, crustaceous, minutely squamulose or fruticose.....

With *Rivularia*, fruticose or squamulose, small.....

With *Nostoc*, crustaceous, squamulose or foliose.....

Thallus heteromericous, not gelatinous when moist. Algæ in a definite zone. Spores simple or 1-septate.

Algæ blue-green (bright-green in *Psoroma*). Apothecia small.

Crustaceous, squamulose or subfoliose, minute.....

Algæ blue-green or bright-green. Apothecia large.

Foliose. Spores septate. Apothecia without a thalline margin,

adnate.....

Apothecia with a thalline margin, scutellate

III. EPHEBACEÆ.

IV. PYRENOPSIDACEÆ.

V. LICHINACEÆ.

VI. COLLEMACEÆ.

VII. PANNARIACEÆ.

VIII. PELTIGERACEÆ.

IX. STICTACEÆ.

Algae constantly Chlorophyceæ.	
Apothecia large, with thalline margin.	X. PARMELIACEÆ..
Foliose. Spores simple.....	XI. USNEACEÆ.. .
Fruticose. Spores simple or septate.....

Squamulose, and with upright podetia...	XVII. CLADONIACEÆ.
Filamentous.....	XVIII. CENOGONIACEÆ.
Crustaceous or minutely squamulose.....	XIX. LECIDEACEÆ.

FAMILY III. EPHEBACEÆ.

Thallus more or less gelatinous when moist, minutely fruticose, crustaceous or partly squamulose, corticated or non-corticated. Algal cells Myxophyceæ (*Scytonema* or *Stigonema*). Apothecia rather small, discoid, mostly with a proper margin only; spores 8, colourless, simple or septate. Spermogones partly immersed in the thallus, with simple or septate sterigmata and minute ellipsoid acrogenous or pleurogenous spermatia.

The algae in this family are species of *Scytonema* with uni-seriate cell-rows, or *Stigonema*, with the cell-rows in several series. The algal rows may be broken up into groups of cells.

Algal cells <i>Scytonema</i> .	
Crustaceous. Spores simple.....	8. <i>Porocyphus</i> .
Minutely fruticose.	
Fronds, without a cortex.....	9. <i>Thermutis</i> .

Apothecia minute. Spores simple	11. <i>Leptogidium</i> .
Minutely squamulose-coralloid. Spores septate.....	12. <i>Placynthium</i> .
With upright fronds. Sterile.....	13. <i>Schizoma</i> .
Algal cells <i>Stigonema</i> .	
Fronds minute. Apothecia black	14. <i>Spilonema</i> .
Fronds elongate. Apothecia pale.	
Smooth. Paraphyses absent.....	15. <i>Ephebe</i> .
Spiny. Paraphyses present	16. <i>Ephebeia</i> .

8. **POROCYPHUS** Koerb.—Crustaceous, continuous or areolate or granular, slightly gelatinous. Algal cells *Scytonema*. Apothecia small, immersed, closed then open, with a stout thalline margin; paraphyses slender, discrete; ascii usually rather irregular in form, often bent or twisted; spores 8, ellipsoid, simple, colourless.

Thallus blackish, thin. Sp. $9-16 \mu \times 8-10 \mu$. Rocks. R. P. areolata Koerb.

9. THERMUTIS Fr. (*Goniumema* Nyl.).—Minutely shrubby or felted, of thread-like, sparingly branched fronds. Algal cells *Scytonema*, a single cell-row in each filament, the lichen hyphae growing parallel within the gelatinous sheath of the alga. Apothecia small, flattened-globose, lateral on the fronds; paraphyses unbranched, slender; asci elongate; spores 8, colourless, ellipsoid or elongate, simple.

The species are all rather rare; they grow on moist rocks in upland districts. The brown filaments differ very slightly in appearance from those of *Scytonema*.

- Filaments spreading. S. 1. *Th. velutina* Th. Fr.
Filaments compact. S. 2. *Th. compacta* A. L. Sm.

10. POLYCHIDIUM S. F. Gray.—Thallus minute, foliose, with narrow laciniae or shrubby and branched, the branches terete, with a well-developed cellular cortex. Algal cells, *Scytonema*, in parallel longitudinal lines.

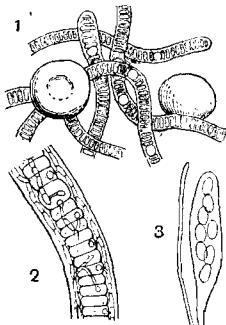

FIG. 14.—*Thermutis velutina* Th. Fr.
1. Portion of plant $\times 50$. 2. Filament $\times 150$. 3. Ascus with spores and paraphysis $\times 350$.

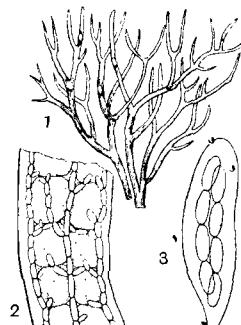

FIG. 15.—*Ephebe lanata* Wainio.
1. Portion of plant $\times 5$. 2. Portion of filament $\times 100$. 3. Ascus \times ca. 700.

Apothecia moderate in size, sessile, lateral or terminal, brown; spores 8, elongate-fusiform, 1-septate, colourless.

The single British species is not uncommon in moorland and upland districts, among mosses on rocks and walls.

Dark-brown or olive-blackish, in cushion-like tufts *P. muscicolum* S. F. Gray.

11. LEPTOGIDIUM Nyl.—Thallus minutely shrubby and tangled, the fronds terete, with a well-developed cellular cortex and a central medullary strand of hyphae. Algal cells, *Scytonema*, in parallel longitudinal lines. Apothecia small, reddish or brownish; spores 8, colourless, ellipsoid, simple.

A tropical genus of which one species occurs in S.W. Ireland. The specimens are sterile; imperfectly developed spermogones are present.

Finely filamentous, olive-greenish, on mossy trunks *L. dendriticum* Nyl.

12. PLACYNTHIUM S. F. Gray.—Granular, crustaceous and cracked-reticulate, or minutely coraloid-squamulose, almost entirely homoiomerous with a plectenchymatous cortex and usually with a well-developed hypo-

thallus of stout blackish-blue hyphae. Algal cells *Scytonema*. Apothecia sessile, plane or convex, with a proper margin only; paraphyses stoutish, unbranched, septate, thicker and dark-coloured at the tips; spores 8, elongate or ellipsoid-ovate, 1-7-septate, colourless.

Placynthium nigrum (*Pannularia nigra* Stiz.) is fairly common on calcareous rocks.

Minute coraloid, dark-coloured sq.

- Spores 1-, sometimes 3-septate. C. 1. *P. nigrum* S. F. Gray.
- Sp. more distinctly septate: f. *psotina*; crустaceous and sp. 3-septate: f. *triseptata*.
- Alpine rocks.
- Thin, crustaceous, brown. Mosses.
- Alpine. R. 2. *P. delicatulum* A. L. Sm.

13. **SCHIZOMA** Nyl.—Laciniate-linear, gelatinous when moist, non-corticate. Algal cells *Scytonema*. Apothecia unknown. Spermogones with minute cylindrical spermata slightly wider at the ends, acrogenous, on sparingly branched sterigmata.

Fronds angular, cylindrical, stoutish up to 1 cm.
long. Mosses. Alpine. R. *S. lichenodeum* Nyl.

14. **SPILONEMA** Born.—Minutely shrubby, with branching fronds. Algal cells *Stigonema*, in rows of several series of cells. Apothecia small, lenticular; paraphyses mostly thickish, septate; spores 8, simple or 1-septate, colourless.

Distinguished from the two following genera by the minute thallus and the almost black flat apothecia. The species grow in minutely felted dark-brown patches on moist rocks in subalpine districts.

In rather loose felted patches. Sp. simple. R. 1. *S. paradoxum* Born.
In small agglutinated pulvinuli.

- Sp. oblong, simple. R. 2. *S. revertens* Nyl.
- Sp. ovoid-oblong, 1-septate. S. 3. *S. scoticum* Nyl.

15. **EPHEBE** Fr.—Fruticose, slender, in spreading tufts, branched and intricate, without a cellular cortex. Algal cells *Stigonema*, the lichen hyphae external to the alga in young stages, forming central strands in the older branches. Apothecia minute, solitary or aggregate, immersed in swollen portions of the fronds; paraphyses none; spores simple or 1-3-septate.

The single species forms matted irregular tufts on moist shady rocks, especially by streams. It is fairly abundant in hilly and mountainous regions.

Dark-olive-green or brownish-black, in fairly large patches. *E. lanata* Wainio
(*E. pubescens* Nyl.)

16. **EPHEBEIA** Nyl.—Thallus similar to that of *Ephebe*. Apothecia solitary, lateral, minute; paraphyses numerous, slender, slightly clavate at the tips; spores constantly simple, colourless.

The one recorded species is rather rare on damp rocks in subalpine districts.

Dark-olive-green or brownish-black, the filaments with
stiff spiny or hispid branchlets *E. hispidula* Nyl.

FAMILY IV. PYRENOPSIDACEÆ.

Thallus gelatinous when moist, crustaceous, partly squamulose, or minutely fruticose, mostly non-corticated. Algal cells Myxophyceæ (*Glaucapsa*, *Chroococcus*, etc.). Apothecia small, open, or subimmersed and partly closed; spores 8, colourless, simple or rarely septate. Spermatogones with ovate or elongate acrogenous spermatia.

The algal cells occur in small colonies, each surrounded by mucilage. They are blue-green, or are coloured red, especially towards the surface of the thallus, by the colouring substance Glœocapsin.

Algae with reddish sheath.

Crustaceous.

- Apothecia open or plane..... 17. **Euopsis**.
- Apothecia almost closed..... 18. **Pyrenopsis**.

Fruticose, of short tufts..... 19. **Synalissa**.

Algae with yellow sheath.

Crustaceous, dark-coloured..... 20. **Psorotichia**.

17. **EUOPSIS** Nyl.—Crustaceous, granular-areolate, fragile. Apothecia small or moderate in size, discoid, with a thalline margin; paraphyses septate; spores ellipsoid, simple, colourless.

Distinguished by the reddish colour of the crustaceous thallus, more pronounced when moist. The rather rare species grow on rocks in the mountainous regions of Wales, Scotland and Ireland.

Effuse, thickish, coarsely areolate..... 1. *E. pulvinata* Wainio.
(*E. hamalea* Nyl.)

Effuse, areolate, the granules rounded 2. *E. granatina* Nyl.

18. **PYRENOPSIS** Nyl.—Crustaceous, granular, rarely subsquamulose or subfruticulose. Apothecia innate and partly closed, small or minute; paraphyses non-septate, slender; spores simple, rarely numerous.

Constantly darker than the preceding genus, though red in a thin section, and differing in the almost closed apothecia and the non-septate paraphyses. More or less rare on maritime or mountainous rocks.

Persistently dark-coloured.

Granular, thickish.

Granules in rounded groups. Alpine..... 1. *P. haematopis* Th. Fr.

Granules effuse, deeply cracked-areolate.

Alpine 2. *P. homœopsis* Nyl.

Granular, thinnish.

Granules in small aggregations or scattered. Maritime..... 3. *P. fuscatula* Nyl.

Granules effuse, in cracked-areoles. Hilly or maritime..... 4. *P. subareolata* Nyl.

Granules in flattened squamules. Alpine 5. *P. phylliscella* Nyl.

Reddish when moist.

Granules effuse, cracked-areolate. Alpine 6. *P. furfurea* Nyl.

19. **SYNALISSA** Fr.—Minutely fruticose, or partly crustaceous, dark-coloured. Apothecia terminal, partly immersed, at first closed then open, with a thalline margin; spores ellipsoid, small, simple, colourless.

The thallus is tinged red- or dark-brown on the surface by Glæocapsin. *S. intricata* from S. Scotland is of doubtful determination.

- On calcareous rocks. S..... 1. *S. ramulosa* Fr.
(*S. symphorea* Nyl.)
- On granite rocks. R..... 2. *S. intricata* Nyl.

20. PSOROTICHIA Massal.—Crustaceous, granular-areolate, more or less corticated, loosely affixed to the substratum. Algal cells *Glæocapsa*, sect. *Xanthocapsa*. Apothecia innate, urceolate, small, the margin usually tumid and connivent; paraphyses slender; spores 8, ellipsoid, simple, colourless.

Glossy, allied to *Pyrenopsis*, but differing in the yellow colour of the algal sheath. It also somewhat resembles *Parmeliella*, but is distinguished

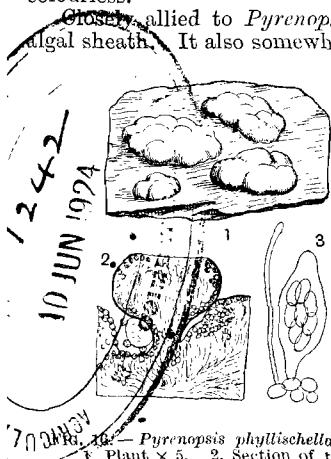

FIG. 16.—*Pyrenopsis phyllisella* Nyl.
1. Plant x 5. 2. Section of thallus
and apothecium x 50. 3. Ascus and
spores with paraphysis x ca. 350.

with paraphysis x 175.

from that genus by the absence of a hypothallus. The species are very rare with the exception of *Ps. Schæreri* and *Ps. lugubris*.

Spores ellipsoid.

On calcareous rocks, cretaceous pebbles, etc.

Thickish granular-areolate..... 1. *Ps. Schæreri* Arn.

On sandstone or schistose rocks.

Of scattered granules. Apo. black..... 2. *Ps. furfurella* Boist.

Of granular squamules. Apo. reddish... 3. *Ps. diffundens* Syd.

Spores spherical.

Thickish, squamulose-granular..... 4. *Ps. lugubris* Dalla Torre
& Sarnth. (*Lecidea lugubris* Somm.)

FAMILY V. LICHINACEÆ.

Thallus gelatinous when moist, crustaceous, sometimes lobed at the circumference, squamulose or minutely fruticose. Algal cells *Myxophycæa* (*Rivularia*). Apothecia immersed and partly closed or open and with or

without a thalline margin; paraphyses simple; spores 8, colourless, globose or ellipsoid, simple or septate. Spermogones with minute ellipsoid, acrogenous or pleurogenous spermatia.

- Minutely shrubby. Maritime..... 21. *Lichina*.
- Crustaceous or minutely squamulose..... 22. *Pterygium*.

21. **LICHINA** Ag.—Minutely fruticose, crowdedly branched, indistinctly corticated, dark-coloured. Apothecia terminal, immersed in the globose swollen tips, almost closed; paraphyses slender, sparingly branched; asci almost cylindrical; spores ellipsoid, simple.

- * A small maritime genus long regarded as brown algae. Frequent on rocks washed by the tide or by the spray from the sea.

Short flattened lobes. Below high water..... 1. *L. pygmæa* Ag.
Smaller rounded branchlets. At or above high water.... 2. *L. confinis* Ag.

22. **PTERYGIUM** Nyl.—Crustaceous, dark, granular or granular-areolate or minutely squamulose and usually somewhat lobed at the circumference. Apothecia sessile, without a thalline margin, the proper margin cellular; paraphyses septate, unbranched; spores ellipsoid or ovate, 1-3-septate.

On calcareous rocks.

- Radiate-lobed. R. 1. *Pt. filiforme* A. L. Sm.
- Not distinctly radiate. R. 2. *Pt. kismoreense* Grumb.

On schistose rocks.

- Crowded laciniae. Alpine. R. 3. *Pt. pannariellum* Nyl.
- Nodulose squamules or granules. Lake shore. R. 4. *Pt. kenmoreense* A. L. Sm.

FAMILY VI. COLLEMACEÆ.

Thallus gelatinous when moist, crustaceous, fruticose or foliaceous, usually homoiomerous, corticated or not corticated, sometimes with rhizinae. Algal cells Myxophyceæ (*Nostoc*). Apothecia partly closed or open, with reddish disc, immersed or sessile, the thalline margin present or wanting; spores usually 8, varying in form, simple, septate or muriform, colourless. Spermogones with pleurogenous or acrogenous spermatia.

In this family are found the most highly developed of the gelatinous lichens. The *Nostoc* chains retain as a rule their original form, and are scattered fairly equally through the thallus, except in some species of *Leptogium* which have more of a heteromerous character. Nearly all the species are some shade of dark-olive- or bluish-green, sometimes almost black when dry.

Non-corticated.

- Spores simple 23. *Physma*.
- Spores septate-muriform 24. *Collema*.
- Spores elongate, pluri-septate 25. *Synechoblastus*.

More or less corticated.

- Spores simple 26. *Lemmopsis*.
- Spores septate-muriform 27. *Leptogium*.

23. **PHYSMA** Massal.—Crustaceous, warted, squamulose or variously lobed or minutely fruticose, non-corticated, with or without rhizinae. Apothecia innate, with a thalline margin which is sometimes cellular;

paraphyses slender, simple; ascii clavate, often bent or twisted; spores fusiform, ellipsoid or globose, simple, colourless.

Rather rare among mosses on old walls or on the ground.

On old walls.

Spores almost globose $11-12 \mu \times 9-10 \mu$... 1. *Ph. polyanthes* Arn.

Spores ellipsoid $12-17 \mu \times 5-15 \mu$ 3. *Ph. chalazanodes* A. L. Sm.

On the ground.

Apothecia minute; sp. $20-24 \mu \times 8-13 \mu$ 2. *Ph. chalazanum* Arn.

Apothecia larger; sp. $17-23 \mu \times 8-10 \mu$... 4. *Ph. confertum* A. L. Sm.

24. COLLEMA Wigg. (emend. A. Zahlbr.).—Variously lobed or almost crustaceous, gelatinous and swollen when moist, without rhizinae, non-corticated. Apothecia with a thalline margin which is sometimes of plectenchyma; paraphyses conglutinate; spores fusiform or ellipsoid, variously septate and muriform, rather large.

On old walls, on the ground or on rocks, often among mosses, very rarely on trees. (See also *Lepfogium* (*Colleodium*)).

*Apothecial margin entire (slightly crenate in n. 3).

Indistinctly crustaceous.

On bark. R. 1. *C. terrulentum* Nyl.

On moist clay. R. 3. *C. glaucescens* Hoffm.

Thallus lobate, lobes erect, crowded.

Small, coralloid. Among mosses, alpine. R. 4. *C. ceraniscum* Nyl.

Lobes somewhat spreading, smooth.

Pulpy, often plicate. Cal. and on ground. C. 5. *C. pulposum* Ach.

More flattened, small. Rocks and wall-tops. R. 6. *C. concinnum* Flot.

Thinner, imbricate, roundish or sub-palmate. Among mosses. F.

Apo. margin subentire. On walls and ground. F.

Var. *coronatum* Koerb.

**Apothecial margin granular (entire in *C. granosum* and *C. furvum*).

Lobes not granular.

Minute and imbricate, or large at edge; rhizinoe below apo. Cal. C. 8. *C. cheileum* Ach.

Imbricate, margins erect, crisp or lacerate. Cal. C. 9. *C. multifidum* Schär.
(*C. melanum* Ach.)

Short upright. Cal. R. 10. *C. hypergenum* Nyl.

Intricate, erect, deeply crenate. Among mosses. F. 11. *C. cristatum* Hoffm.

Lobes granular. Apothecial margin granular. Granules on surface. Cal. C. 12. *C. granuliferum* Nyl.

Granules on surface and margins. Among mosses. F. 13. *C. crispum* Ach.

Lobes granular, large. Apothecial margin entire.

Laciniate, granular on upper surface. Cal. R. 14. *C. granosum* Schär.
Entire, shell-like. F. Var. *auriculatum*

A. L. Sm.

Rounded, granular on both surfaces. Cal. F. 15. *C. furvum* Ach.

• 25. **SYNECHOBLASTUS** Trev.—Thallus variously lobed, gelatinous when moist, without rhizinae, more or less appressed to the substratum, non-corticated. Apothecia with a thalline margin; spores 8, elongate-fusiform or acicular, pluriseptate.

Differs from *Collema* in the structure of the spores.

Lobes smooth, narrow. Cal. or on trees.

- Narrow. Apo. numerous, small, button-like. F. 1. S. polycarpus Dalla Torre & Sarnth.
 - Broader. Apo. numerous, small. R. 2. S. Laureri Flot.
 - Narrow, convex. Apo. few, mod. F. 3. S. multipartitus Mudd.
 - Upright, tufted. On trees. R. 4. S. fascicularis A. L. Sm.
- Lobes rather broad, often granular. Mostly on trees.

- Radiately wrinkled. C. 5. S. nigrescens Anzi.
- Smaller with irregular short wrinkles. F. 6. S. aggregatus Th. Fr.
- Large, flaccid when moist, smooth. C. 7. S. rupestris A. L. Sm.
(*Collema flacidum* Ach.)

26. **LEMMOPSIS** A. Zahlbr.—Effuse, granular-crustaceous or nodulose, corticated. Apothecia sessile, with a proper margin, spores 8, ellipsoid, simple.

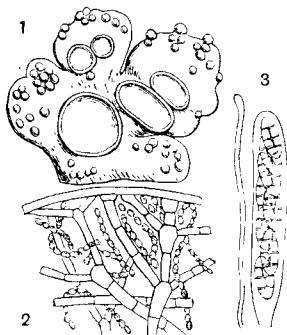

FIG. 18.—*Collema granuliferum* Nyl.
1. Part of plant. 2. Section of thallus
× 225. 3. Ascus with spores and para-physis × 150.

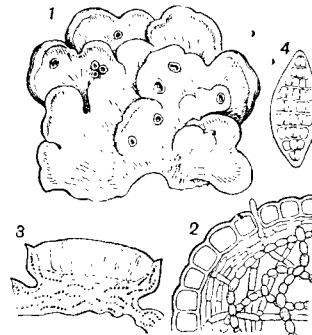

FIG. 19.—*Leptogium sinuatum* var.
scutinum Koerb. 1. Part of plant.
2. Section of thallus × 225. 3. Ver-tical section of apothecium × 15.
4. Spore × 350.

Differs from *Leptogium* in the crustaceous thallus and simple spores. The species are rare, but may have been overlooked.

- Forming a dark thin crust. Cal. 1. *L. Arnoldiana* A. Zahlbr.
- Thallus lighter in colour. Cal. soil 2. *L. oblongans* A. L. Sm.
- Thallus nodulose. Sil. 3. *L. leptogiella* A. L. Sm.

27. **LEPTOGIUM** S. F. Gray.—More or less gelatinous when moist, lobate, the lobes minute (subcrustaceous) or larger and spreading, corticate. Apothecia with a cellular thalline margin; paraphyses conglutinate; spores fusiform or ellipsoid, septate and muriform, colourless.

Differs from *Collema* in the corticate thallus, a very distinct character

in some species, in others difficult to distinguish, especially in some of those included by Nylander in the genus *Collemodium*. As a rule the thallus is less swollen than in *Collema*, the lobes being often very thin. In some species the alga tend to congregate towards the upper surface.

*Cortical cells somewhat indistinct (*Collemodium*).

Thallus of small lobes,

- On trees. (Rarely on trees *L. plicatile*).
Minute, nodulose, crowded. Apo. superficial. C. 1. *L. fragrans* Cramb.
(L. microphyllum

 Thin, crenulate. Apo. margin leafy. F. 25. *L. Burgessii* Mont.

FAMILY VII. PANNARIACEÆ.

Thallus not gelatinous, heteromerous, granular, squamulose or foliose, with hypothallus or with rhizinae. Algal cells blue-green, rarely bright-green. Apothecia with or without a thalline margin; hypothecium colourless or pale; paraphyses simple; spores 8, simple or septate, colourless or slightly brownish. Spermogones with upright, septate sterigmata and cylindrical pleurogenous spermatia.

Though containing blue-green algae, the Pannariaceæ differ from the previous families in the non-gelatinous heteromerous character of the thallus (*Pannaria nigra* is classified under *Placynthium*).

Algal cells *Nostoc*.

Apo. without a thalline margin; sp. usually simple... 28. *Parmeliella*.

Apo. with a thalline margin; sp. usually simple..... 29. *Pannaria*.

Algal cells *Scytonema*.

Apo. without a thalline margin; sp. 1-septate 30. *Massalongia*.

Algal cells bright-green (Protococeaceæ).

Apo. with a thalline margin; sp. simple 31. *Psoroma*.

28. **PARMELIELLA** Müll.-Arg. (*Pannaria* and *Coccocarpia* in part).—Squamulose or almost foliose, corticate, with a hypothallus or with rhizinae. Algal cells *Nostoc*. Apothecia sessile, rather small, without a thalline margin; spores elongate or ellipsoid, simple (rarely 1-septate), colourless.

Mostly of minute greenish or leaden-brown squamules. *P. plumbria* has a more massive, almost monophyllous thallus, with radiate-centric shell-like markings.

Thallus of small squamules.

Plane, then granular, on black hypo-thallus. Trees. C. 1. *P. corallinooides* A. Zahlbr. (*Pannaria triptophylla* Nyl.).

Inbricate, margins whitish, black beneath.

Rocks or soil. R. 2. *P. microphylla* Müll.-Arg.

Crenate, white beneath. Mosses on

ground. R..... 3. *P. lepidiota* Dal. Tor. & S.

Thallus foliose large, appressed.

Almost monophyllous, grey-brown. Trees, 4. *P. plumbea* Wain.
rocks. C. (*Coccocarpia plumbea* Nyl.).

29. PANNARIA Del.—Granular, squamulose or almost foliose, with a dark hypothallus of felted hyphae, the upper cortex a plectenchyma of vertical cell rows. Algal cells *Nostoc*. Apothecia becoming superficial, with a thalline margin; spores elongate-ellipsoid or almost fusiform, simple, colourless.

Mostly squamulose, brown, bluish- or leaden-grey, dark-green when moist. Margins of apothecia granular or pulverulent.

Squamulose. Apothecia mostly red-brown.

Sq. and apo. with silvery-white margins.

Trees. C..... 1. *P. rubiginosa* Del.

Becoming blue-grey sovediose. C..... Var. *conoplea* Koerb.

Tawny-brown, imbricate. Mosses on ground. C. 2. *P. pezizoides* Leight. (*P. brunnea* Mass.).

Leaden-grey, imbricate. Apo. blackish. Rocks. C. 3. *P. Hookeri* Nyl.
Granular, cracked.

Grey, or dark-bluish-grey. Sandy soil. C..... 4. *P. nebulosa* Nyl.

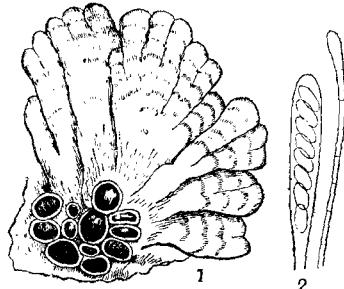

FIG. 29.—*Parmeliella plumbea* Wain.
1. Part of plant. 2. Ascus with spores,
and paraphysis $\times 250$.

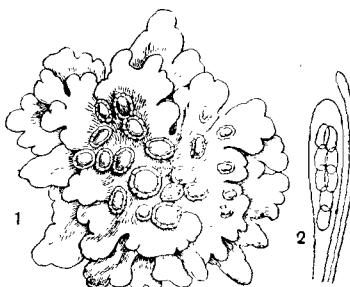

FIG. 30.—*Pannaria rubiginosa* Del.
1. Plant. 2. Ascus with spores, and
paraphysis $\times 250$.

30. MASSALONGIA Koerb.—Thallus of medium-sized squamules, the cortex of the upper surface plectenchymatous, the lower surface decorticate and with dark rhizinose hypothallus. Algal cells *Scytonema*. Apothecia plane, without a thalline margin; spores colourless or becoming brownish, 1-septate.

Apo. small, red-brown, with paler margins. Mosses
on rocks. F..... 1. *M. carnosa* Koerb.

31. PSOROMA Ach.—Minutely squamulose-granular, upper surface corticate, the lower of closely packed parallel hyphae which pass out as rhizoidal filaments. Algal cells bright-green (Protococcaceae). Apothecia with a thalline margin; spores colourless, ellipsoid or globose, simple (rarely 2-celled).

The only British species strongly resembles *Pannaria pezizoides*.

Crenate-granular, tawny-brown. Mosses on
ground. C. *P. hypnorum* S. F. Gray.

FAMILY VIII. PELTIGERACEÆ.

Thallus foliaceous or squamulose, heteromerous, corticate above, corticate or non-corticate below, and provided with a tomentum of hyphae or with rhizoids. Algal-cells blue-green (*Nostoc*) or bright-green (*Dactylococcus*). Apothecia mostly marginal, roundish, adnate on the upper or lower surface, without a thalline margin; or scattered and sunk in the thallus; spores septate, colourless or brown. Cephalodia present in some of the genera.

Apothecia marginal.

- On upper surface 32. *Peltigera*.
- On lower surface 33. *Nephromium*.
- Apothecia scattered 34. *Solorina*.

32. **PELTIGERA** Willd.—Often wide-spreading, submonophyllous or polyphylloous, corticate on the upper surface; below, tomentose or veined, and more or less rhizinose. Algal cells blue-green or bright-green. Apothecia marginal, adnate on the upper surface of the frond; spores elongate fusiform, 3- or pluri-septate, colourless or brownish. Pycnidia sometimes present with ovoid acrogenous macrospores.

In most of the species the algae are blue-green; in a few the gonidial zone is bright-green; but, in the latter, groups of *Nostoc* cells are always present in cephalodia, either superficial or within the tissue. The veining of the upper surface is due to intercalary growth of the upper cortical layers which causes a stretching of the loose tissue below.

- With blue-green gonidia § i. EUPELTIGERA.
- With bright-green gonidia, and with cephalodia § ii. PELTIDEA.

§ i. EUPELTIGERA Wain.

*Lobes downy above.

Veins of under surface white.

- Large, spreading, with long white rhizinae. C. 1. *P. canina* Willd.
- Small, ascending, with few white rhizinae. C. 2. *P. spuria* DC.

Veins of under surface dark-brown.

- Spreading, often crisp at margins. C. 3. *P. rufescens* Hoffm.
With leafy, isidioid margins Var. *prætexta* Nyl.

**Lobes pulverulent, granular or scabrid above.

- Slightly pulverulent; brown below, almost without veins. R. 4. *P. malacea* Fr.
- Granular, margins sorediate; brownish or white below. C. 5. *P. scutata* Koerb.
- Scabrid; whitish below, black at centre. R. 6. *P. seabrosa* Th. Fr.

***Lobes naked, shining above.

- Apo. oblong, on digitate lobes, revolute. C. 7. *P. polydactyla* Hoffm.
- Apo. round, constantly horizontal. F. 8. *P. horizontalis* Hoffm.

§ ii. PELTIDEA Huc.

- Th. large. Cephalodia on surface as tubercles. F. 9. *P. aphthosa* Willd.
- Th. small. Cephalodia on the veins. S. 10. *P. venosa* Hoffm.

33. NEPHROMIUM Nyl.—Lobate, horizontal, corticate on both surfaces, the under surface sometimes tomentose. Algal cells *Nostoc*. Apothecia marginal, roundish; adfixed on the lower surface of the thallus, finally directed upwards by the turning back of the fertile lobes, without a thalline margin; paraphyses simple, septate; spores fusiform, oblong, usually brownish, 1-3 septate. Spermogones with septate sterigmata and minute dumb-bell shaped pleurogenous spermatia.

Easily recognized when fertile by the position of the apothecia. If sterile it can be distinguished from *Peltigera* by the smaller more numerous lobes and by the habitat, the species growing mostly on the mossy trunks of trees, rarely on boulders. *N. lusitanicum* is the commonest.

Medulla K -.

Tomentose beneath. R..... 1. *N. resupinatum* Dalla
Torre & Sarnth.

Medulla K + purplish.

Med. yellow. C..... 3. *N. lusitanicum* Nyl.

Med. white. R..... Var. *hibernicum* Nyl.

34. SOLORINA Ach.—Foliose, fragile, the upper surface corticate, the under surface partly nervose and rhizinose. Algal cells bright-green (*Dactylococcus*), along with blue-green (*Nostoc*). Apothecia superficial or urceolate and sunk in the upper surface of the thallus, irregularly scattered, suborbicular, reddish-brown, without a thalline margin; paraphyses thickish, septate; spores 2-8 in the ascus, fusiform-oblong or ellipsoid, 1-septate, brownish or reddish-brown. Spermogones unknown.

Nostoc cells occur in all of the species, as a layer under the gonidial zone in *S. crocea*, in squamules in *S. spongiosa*, or as endogenous scattered cephalodia in the other species. The apothecia are developed before the cortex covering them is thrown off, hence the term "veiled apothecia." The species grow on soil among rocks, etc., chiefly in upland mountainous districts.

Apothecia superficial.

Th. large, saffron-yellow below. Ascus
8-spored. R..... 1. *S. crocea* Ach.

Apothecia sunk in the thallus.

Th. small. Sp. 4, smooth. R..... 3. *S. spongiosa* Carroll.

Th. small; white-pruinose. Sp. 2. R 4. *S. bispora* Nyl.

FAMILY IX. STICTACEÆ.

Thallus foliose, horizontal or somewhat ascending, corticate on both surfaces, beneath more or less tomentose. Cyphellaæ or pseudo-cyphellaæ constant on the under surface in *Sticta*. Cephalodia present in certain species. Algal cells blue-green (*Nostoc*) or bright-green (*Chlorophyceæ*). Apothecia marginal on the thallus or scattered, scutellate and sessile or shortly stalked; paraphyses simple, septate; spores elongate, 2-pluri-septate, colourless or brown. Spermogones with septate sterigmata and short straight pleurogenous spermatia.

Resembling Peltigeraceæ in that both types of gonidia, blue-green and bright-green are represented. The species with bright-green algae frequently form cephalodia. Cyphellæ are small cup-like pits with a distinct rim that occur irregularly amongst the tomentum of the lower surface; pseudo-cyphellæ are less definitely margined, and are filled with loose hyphae.

- With cyphellæ or pseudo-cyphellæ on the under surface 35. *Sticta*.
- Without these structures 36. *Lobaria*.

35. STICTA Schreb.—Variously lobate or laciniate, horizontal, sometimes slightly ascending or stalked, cortex on both surfaces of plectenchyma; beneath pale- or dark-brown tomentose, with cyphellæ or pseudo-cyphellæ. Cephalodia rarely present. Algal cells *Nostoc* or *Chlorophycceæ*. Apothecia marginal or scattered, with or without a thalline margin; paraphyses

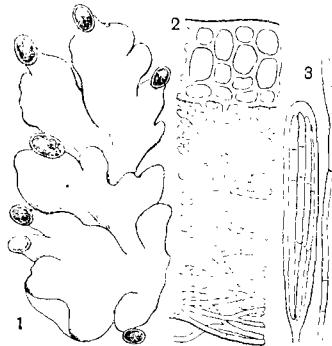

FIG. 22.—*Peltigera canina* Willd.

simple, septate; spores 8, elongate, fusiform or acicular, 1-7-septate, colourless or brown (often sterile).

The genus is distinguished from other foliose lichens by the minute round openings—cyphellæ or pseudo-cyphellæ—in the tomentose under surface. The species grow among mosses on trees or rocks.

- Algal cells *Nostoc* § i. STICTINA.

discoid, generally with a thalline margin; paraphyses simple, septate; spores 8, elongate, 1-9-septate, colourless or brown.

The British species are all very wide-spreading, green when moist and greyish-green or brown when dry. They grow mostly on the trunks of old trees, oak, etc., rarely on rocks. The genus is divided into two sections according to the algae:—

§ i. LOBARINA. Algal symbiont *Nostoc*.

Lobes irregularly pitted, with scattered soredia. C. 1. *L. scrobiculata* DC.

§ ii. RICASOLIA. Algal symbiont *Protococcaceæ*.

Pitted, bullate below, sorediate. F. ... 4. *L. pulmonaria* Hoffm.

FAMILY X. PARMELIACEÆ.

Thallus squamulose or foliose, horizontal, rarely ascending or subfruticose, corticate on one or both surfaces; beneath with rhizinae or naked. Algal cells Protococcaceæ. Apothecia sessile or shortly stalked, with a thalline margin; spores 2–8 in the ascus (rarely more), colourless, simple. Spermogones with pleurogenous or more rarely acrogenous spermatia.

Thallus rhizinose. Apothecia superficial.

- Ascus polysporous 37. Candelaria.
- Ascus 2–8-spored 38. Parmelia.

Thallus scarcely rhizinose. Apothecia marginal ... 39. Cetraria.

37. **CANDELARIA** Massal.—Minutely foliose or squamulose, corticate on both surfaces, yellow above; beneath almost colourless, rhizinose. Apothecia sessile, scattered, discoid, with a thalline margin; paraphyses discrete, simple or rarely branched, septate and clavate at the tips. Spores numerous, simple, colourless, sometimes bi-guttulate and pseudo-septate. Spermogones in small tubercles, with acrogenous ellipsoid spermatia.

The brilliant yellow colour is due to stictaurin, which gives no reaction with potash.

Squamules crenate; apothecium with granulate margin... *C. concolor* Wain.

38. **PARMELIA** Ach.—Lobate, laciniate or linear, variously coloured, generally somewhat shining; beneath more or less rhizinose or almost naked, and usually dark in colour, the rhizinae of fasciculate hyphae frequently mucilaginous at the tips. Soredia and isidia frequent. Apothecia scattered over the surface, sessile or shortly stalked, round, with a thalline margin; hypothecium colourless, with gonidia underneath; paraphyses usually branched and septate, conglutinate; spores 2–8, ellipsoid or sub-globose, small or rather large, simple, colourless. Spermogones scattered, with septate sterigmuta and minute pleurogenous spermatia.

Spores are small when 12 μ long or under; large above 20 μ long.

Normally without rhizinae, lobes narrow Subgen. i. HYPOGYNIA.
Normally without rhizinae, lobes broader, pierced

with holes „ ii. MENEGAZZIA.
More or less rhizinose, lobes various „ iii. EUPARVELIA.

Subgen. i. HYPOGYNIA Nyl.—Thallus without rhizinae on the free parts; lobes mostly narrow. Spores small.

Parmelia physodes grows mostly on trees, the other species on alpine rocks.

Glaucous-grey, spreading, tips sorediate. C. ... 1. *P. physodes* Ach.
Lobes tubular, sorediate at tips Var. *tubulosa* Mudd.
Wrinkled, almost coherent Var. *platyphylla* Ach.

Glaucous-grey, linear, black at edge, punctured below. R. 2. *P. vittata* Nyl.

Grey or dark, narrow, crowded, spathulate. R. 4. *P. alpicola* Th. Fr.

Subgen. ii. MENEGAZZIA A. Zahlbr.—Thallus without rhizinae, attached by haustoria; lobes narrow, perforate above. Spores large.

Thallus orbicular, dotted with holes, brownish.

On rocks or trees. S. 5. *P. pertusa* Schær.

Subgen. iii. EUPARMELIA Nyl.—Thallus lobes narrow or wide; beneath more or less rhizinose.

The largest number of species are included in this subgenus. There is great variation in the character of the lobes which may be almost filamentous (*P. pubescens*), divided up into narrow lobes (*P. omphalodes*), or broadly expanded (*P. cetrariooides*). Some species are almost destitute of rhizinae and suggest *Cetraria*, but in that genus the apothecia are marginal on the lobes. The thallus varies in size from small (about 2-3 cm. across) to large (up to 20 cm. or more). The species grow on trees or pales, more rarely on rocks.

A. Rhizinae very scanty.

Lobes almost black (on upland rocks; rather small).

- Suberete, slender, branched, prostrate. F. 6. *P. pubescens* Wain.
(P. lanata Wallr.)

39. **CETRARIA** Ach. (incl. *Platysma* Nyl.)—Foliaceous (*Platysma*), partly horizontal or ascending, or fruticose (*Cetraria*) with the fronds compressed, rarely cylindrical, sparingly rhizinose, or attached at the base, but soon loose from the substratum, corticate on both surfaces, the cortex mostly of small-celled plectenchyma; the under surface shining, concolorous with the upper surface or darker; pseudo-cyphella present in some species. Apothecia marginal or submarginal, sessile or shortly stalked, round, with a thalline margin; paraphyses simple or rarely branched, septate; spores 6-8.

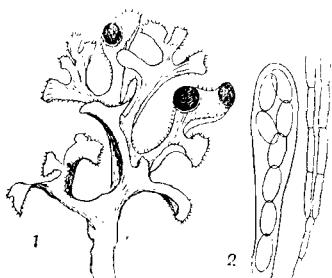

FIG. 26.—*Cetraria islandica* Ach.
 1. Plant reduced. 2. Ascus with
 spores, and paraphysis \times ca. 500.

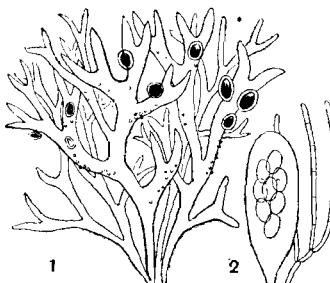

FIG. 27.—*Evernia prunastri* Ach.
 1. Plant reduced. 2. Ascus with
 spores, and paraphysis \times 500.

colourless, simple, small. Spermogones in marginal tubercles or thorn-like papillae, with pleurogenous spermatia varying in form.

Differs from *Parmelia* in the almost complete absence of rhizina, in the partly ascending or fruticose habit, and in the marginal apothecia and spermogones. The species classified by some Lichenologists under *Platysma* are of a more foliaceous character, those in *Cetraria* are fruticose, but there are intermediate connecting forms.

*Thallus foliaceous, more or less horizontal (*Platysma*). On trees, rocks or soil.

†Lobes grey (rarely brown); plants large.

FAMILY XI. USNEACEÆ.

Fruticose, attached at the base, usually radiate in structure. Algal cells Protococcaceæ. Apothecia roundish, sessile or shortly stalked, with a thalline margin; spores 1-8, colourless or rarely brown, simple or septate. Spermatogones immersed, with aerogenous or pleurogenous spermatia.

Distinguished by the fruticose thallus. Transition stages between the foliaceous and fruticose types occur in *Evernia*. *Cerania* is doubtfully included in the family.

Strap-shaped.

- Structure dorsiventral, with under surface of different colour 40. *Evernia*.
 Structure radiate, alike on both surfaces 41. *Ramalina*.

Filamentous.

- Medulla a central chondroid strand 42. *Usnea*
 Medulla of loose arachnoid hyphae 43. *Alectoria*.
 Stalk-like.
 Fronds hollow, tapering upwards 44. *Cerania*.

40. **EVERNIA** Ach.—Strap-shaped, erect or partly pendulous or decumbent, more or less divided or branched, rather soft and flaccid, differently coloured above and below, attached by a basal sheath, occasionally with a few rhizinae. Structure subdorsiventral, the gonidia mostly under the upper cortex. Apothecia lateral, or almost terminal, sessile or shortly stalked; paraphyses stoutish, simple; spores 8, small, ellipsoid, simple. Spermogones lateral, immersed, with pleurogenous straight slender spermata.

A genus intermediate between *Parmelia* and *Ramalina*, resembling the former in the almost constantly dorsiventral structure, and the latter in the fruticose habit. The fronds vary in height up to about 10 cm. or even longer. In *Evernia prunastri* var. *stictoceros* the *Ramalina*-like fronds have an *Evernia* structure. On trees, old palings, etc., *E. furfuracea* sometimes on rocks.

- Light-greenish-grey, sorediate, white beneath. C. 1. *E. prunastri* Ach.
 Yellowish-green on both surfaces Var. *stictoceros* Hook.
 Darker-grey, isidioid, black beneath. C. 2. *E. furfuracea* Mann.
 Densely isidioid: f. *scobicina*; narrow, sub-cylindrical: f. *cerata*.

41. **RAMALINA** Ach.—Fronds erect or partly pendulous, branched, compressed, strap-shaped or almost subcylindrical, attached by a basal sheath or by penetrating hyphae; structure radiate, the medulla generally of loose hyphae, the gelatinous cortex formed of thick-walled coalescing hyphae growing generally at right angles to the long axis of the plant; a system of strengthening longitudinal hyphae forming a ring or separate strands within the cortex (rarely absent). Soralia not infrequent. Air-pores occurring as breaks in the thallus. Apothecia terminal or lateral, sometimes on the angle of bent fronds (geniculate); paraphyses simple; spores 8, colourless, 1-septate, straight or curved.

The fronds vary from being almost narrowly cylindrical in some specimens of *R. calicaris* to a broad flat expansion in *R. evernioides*. The species are common unless otherwise indicated.

On trees. Without soredia.

- Long, stiff, generally narrow, often canaliculate, spores straight 1. *R. calicaris* Fr.
 Rather broad and flat, spores curved 2. *R. fraxinea* Ach.
 Rather short, rigid, fastigiate; spores curved 3. *R. fastigiata* Ach.
 Short, subpellucid, in cushion-like growths. R. 4. *R. dilacerata* Wain.
 Short, subfastigially branched, fistulose, perforated. R. 5. *R. geniculata* Nyl.

On trees. Sorediate.

- Narrow, margins sorediate. K— 6. *R. farinacea* Ach.
 Broad, farinose - sorediate, longitudinally wrinkled 7. *R. pollinaria* Ach.
 Broad, surface or margins sorediate, transversely wrinkled-reticulate 8. *R. evernioides* Nyl.

- On rocks. Without soredia.
- Narrow, rigid. Mostly maritime 9. *R. siliquosa* A. L. Sm.
(*R. scopulorum* Ach. and *R. cuspidata* Nyl.)
 - Narrow, rigid, almost round, black at base.
 - Maritime 10. *R. Curnowii* Cromb.
- On rocks. Sorediate.
- Narrow, sorediate on margins, K + y then red 11. *R. subfarinacea* Nyl.
 - Short, margins and surface sorediate 12. *R. polymorpha* Ach.
 - Short, tips sorediate 13. *R. capitata* Nyl.

42. **USNEA** Dill.—Filamentous, upright or pendulous, more or less cylindrical, variously branched, often scabrid, greyish-green or yellowish, attached at the base by a sheath or by a penetrating holdfast; structure radiate, with a firm chondroid central axis or rarely hollow, the cortical layer thin, of branching swollen hyphae. Apothecia mostly rather large,

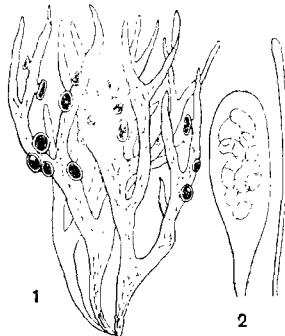

FIG. 28.—*Ramalina fraxinea* Ach.
1. Plant reduced. 2. Ascus with
spores, and paraphysis X 500.

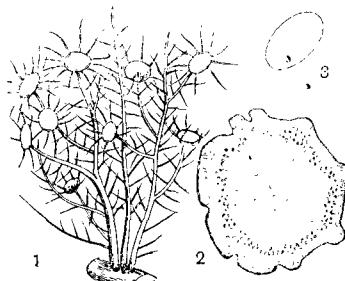

FIG. 29.—*Usnea florida* Web. 1. Plant
reduced. 2. Transverse section of
thallus X 35. 3. Spore X 750.

lateral or terminal, peltate, the disc mostly rather light-coloured, with a thalline, generally ciliate, margin; hypothecium colourless, with underlying gonidia; paraphyses concrete, branched and septate; spores 8, small, ellipsoid, simple. Spermatogones lateral, immersed or slightly protuberant, light or dark coloured with sparingly branched sterigmata and acrogenous spermatia.

The species of *Usnea* occur chiefly on trees in forests, and the pendulous forms (British) may attain a length of 1 ft. or more; occasionally they grow on rocks. Nearly all are sorediate, and, in some species, the soredia develop on the parent plant into lateral branchlets. Flesh-coloured wrinkled tubercles are frequently formed and are irregularly scattered over the filaments. They contain no gonidia and are only abortive apothecia. Reddish formis are not uncommon.

Filaments erect, branched.

- Generally with horizontal fibrils (10-12 cm. high). C. 1. *U. florida* Web.
Smaller, sorediate, non-fertile Var. *hirta* Ach.'

Erect, branches few, cornute, sorediate. R. 2. *U. cornuta* Koerb.

Sparingly fibrillose, ringed, verrucose (becoming pendulous). C. 3. *U. plicata* Web. (*U. ceratina* Ach.)

Filaments pendulous.

Long, crowded, scabrous and fibrillose. C. 4. *U. barbata* Web. (*U. dasypoga* Stiz.)

Smooth and sparingly fibrillose

Long, crowded, nearly smooth, with swollen "articulations." F. 5. *U. articulata* Hafslin.

43. ALECTORIA Ach.—Filamentous, erect or mostly pendulous, often shining, branched, cylindrical or partly compressed, attached by a basal sheath; structure radiate, the medulla of loose hyphae or partly hollow, the cortical layer formed of hyphae parallel with the long axis of the plant (fibrous). Apothecia lateral or bent, on straight branches, the margin rarely ciliate, the disc brown or blackish; hypothecium colourless, with under-

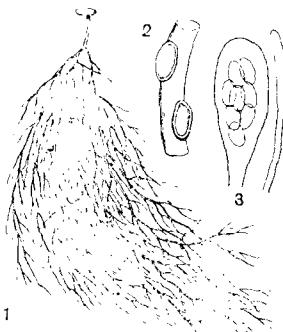

FIG. 30.—*Alectoria jubata* Ach. 1. Plant reduced. 2. Portion of filament with apothecia \times ca. 8. 3. Ascus with spores, and paraphysis \times 500.

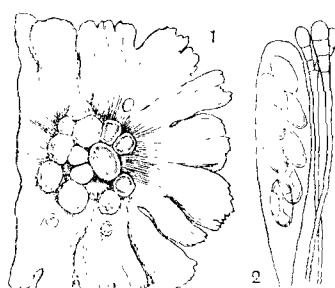

FIG. 31.—*Xanthoria parietina* Th. Fr. 1. Part of plant. 2. Ascus with spores, and paraphyses \times 350.

lying gonidia; paraphyses branched; spores 4–8, ellipsoid, simple, colourless or brownish. Spernogones in small lateral tubercles, the sterigmuta sparsely branched, with pleurogenous, short spermatia, slightly thickened at each end.

The species of *Alectoria* are confined to upland or mountainous regions where they are frequently abundant. They grow on soil, rocks or trees and they vary from light straw-coloured to brownish-black. Occasionally the filaments become free from the substratum, growth still continuing at the tips. Rare except *A. bicolor* and *A. jubata*.

Filaments mostly yellowish straw-coloured.

Erect, rigid, with tufted blackish branchlets at tips. Mossy soil..... 1. *A. ochroleuca* Nyl. Decumbent, entangled, with blackish areas Subsp. *cincinnata* Th. Fr.

Pendulous or decumbent, branches few. Mossy soil..... 2. *A. sarmentosa* Ach.

- Pendulous or decumbent, branched, sorediate at tips. Trees or rocks..... 3. *A. thrausta* Ach.
- Pendulous, long, slender, much branched. Firs 4. *A. implexa* Nyl.
- Filaments mostly dark-coloured.
- Erect, rigid, dull black, lighter at base. Rocks, etc. 5. *A. nigricans* Nyl.
 - Erect, short, densely branched, black with brownish areas. Firs..... 6. *A. bicolor* Nyl.
 - Decumbent, branches spreading, blackish-brown.
 - Mossy soil..... 7. *A. divergens* Nyl.
 - Pendulous, long, dull black, sorediate. Trees, etc. 8. *A. jubata* Ach.
 - Short greyish-coloured. Firs..... Subsp. *subeana* Nyl.
 - Subdecumbent short, very dark. Rocks..... Subsp. *chalybeiformis* Th. Fr.
44. **CERANIA** S. F. Gray (*Thamnolia* Ach.).—Fronds upright, hollow, stalk-like, sparingly branched, tapering upwards; the cortex of small cells, medulla of parallel hyphae. Apothecia not rightly known. Spermogones immersed in small warts, with pleurogenous short cylindrical straight or slightly bent spermatia.
- The position of the genus is uncertain in the absence of definite knowledge as to the reproduction of the plant. Though of upright structure it is frequently prostrate; the one known species is chalky-white, somewhat resembling white worms. On soil among mosses, etc., in mountainous regions,
- Generally up to 5 cm. in length and 1 to 2 or 3 mm. thick..... *C. vermicularis* S. F. Gray.

FAMILY XII. PHYSCIACEÆ.

Thallus fruticose, foliose, squamulose or crustaceous, yellow-coloured, grey or brown. Structure various. Algal cells Protococcaceæ. Apothecia discoid, mostly rather small, usually with a thalline margin. Spores colourless or brown, usually 1-septate, with thick outer walls and septum, the latter generally pierced by a longitudinal canal (polarilocular), rarely simple or 3-septate. Spermogones with cellular sterigmata and short pleurogenous spermatia (except in *Candelariella*).

The genera in this family are especially distinguished by the peculiar spores. The median septum develops by ingrowth from the outer wall, and though occasionally a narrow band, it broadens sometimes to such an extent that the lumen of the cells is reduced to a small space at each pole. A few species with simple or even 3-septate spores are included in the genera owing to the presence of other typical characters.

Parietin present (yellow lichen-acid colouring crimson or purple with potash).

Spores colourless, usually 1-septate, 8 in the ascus.

Fruticose, yellow 45. *Teloschistes*.

Foliose, yellow 46. *Xanthoria*.

Squamulose or crustaceous, mostly yellow 47. *Placodium*.

Parietin not present.

Spores colourless, simple at first, sometimes many in the ascus.

Crustaceous, yellow 48. *Candelariella*.

Spores brown, usually 1-septate, colour various.

- Foliose, rarely subfruticose..... 49. *Physcia*.
- Squamulose or crustaceous..... 50. *Rinodina*.

45. TELOSCHISTES Norm. (*Physcia* Schreb. pro parte).—Fruticose, brightly coloured, upright or decumbent, the fronds branched, cylindrical or compressed, attached at the base; structure radiate; cortex of longitudinal hyphae (fibrous). Apothecia discoid, sessile; hypothecium colourless with underlying goniidia; paraphyses simple or branched at the apices, septate; spores 8, polarilocular, colourless.

The genus has been separated from *Physcia* on account of the fruticose thallus and the colour of the spores. There are only two species in Britain, both of a beautiful golden colour varying to green in the shade. On trees, rocks or walls, chiefly in maritime districts.

Almost filamentous, long, bushy..... 1. *T. flavicans* Norm.

Short, strap-shaped, rigid..... 2. *T. chrysophthalmus* Th. Fr.

46. XANTHORIA Th. Fr. (*Physcia* Schreb. pro parte).—Foliose, horizontal or subascending, lobate, brightly coloured, sometimes sorediate, beneath more or less rhizinous and generally paler; cortex of plectenchyma on both surfaces. Apothecia scattered, discoid, moderate in size; hypothecium colourless with underlying goniidia; paraphyses branched and septate near the tips; spores 8, 1-septate, polarilocular, colourless. Spermogones immersed in small tubercles.

Differs from *Physcia*, in which the species have often been included, in the colour of thallus and spores. The species grow most freely in maritime districts, and are bright-yellow in the open where the acid substance parietin (K + crimson or purple) is freely formed, or almost green in the shade. The apothecial discs as in the allied genera are the most deeply coloured parts of the lichen.

- Orbicular, lobate. C. 1. *X. parietina* Th. Fr.
- More monophyllous and wrinkled, deeply coloured Var. *aureola* Th. Fr.
- More broken up, deeply coloured Var. *ectanea* Oliv.
- Poorly developed, often in masses. Apo. numerous. F. 2. *X. polycarpa* Oliv.
- Straggling, subascending, margins pulverulent. F. 3. *X. lychnea* Th. Fr.

47. PLACODIUM DC. emend Hepp.—Thallus squamulose with a definite, somewhat circular outline (effigurate) and corticate above (rarely also below), or crustaceous and effuse, mostly yellow, rarely whitish, greyish, or dark-grey, mostly K + crimson or purple. Apothecia brightly coloured, rarely dark-brown, generally with a thalline margin, in some species with a proper margin only; paraphyses slender, broader and septate and often freely branched at the tips, the epithecium generally deeply suffused with parietin; spores colourless, 1-septate (very rarely simple), polarilocular.

Parietin is produced in more or less abundance in the thallus of most species, and in the apothecia of all except *Pl. repellens*. which is probably an impoverished form. The thalline margin of the apothecium in some species is reduced to a zone of goniidia below the hypothecium; in a few others it is absent, though other characters secure their inclusion in the genus. The spores are imperfectly polarilocular in *Pl. nivea*, and simple in *Pl. fulgens* and *Pl. rupestre*.

Species with squamulose and crustaceous thalli are included in the genus as they grade into each other. Distinctive differences are indicated by the division into sections, the more highly developed forms being placed first.

Apothecia with a more or less prominent thalline margin.

Thallus squamulose-effigurate § i. EUPLACODIUM.

Thallus crustaceous § ii. CALLOPSIMA.

Apothecia without an apparent thalline margin.

Thallus crustaceous § iii. BLASTENIA.

48. **CANDELARIELLA** Müll.-Arg. (*Lecanora* subgen. *Candelaria* Nyl. pro parte).—Crustaceous, granular, sometimes lobed at the circumference (effigurate), yellow. Apothecia sessile, yellow, with a thalline margin; hypothecium colourless, with gonidia underneath; paraphyses unbranched, occasionally septate and wider towards the apex; spores 8 or many, colourless, ellipsoid, simple or becoming 1-septate and sometimes polaric-

locular. Spermogones minute, with septate forked or branched sterigmata and acrogenous spermatia.

The yellow thallus and apothecia in this genus contain no parietin and give no reaction with potash. The spores however indicate its affinity with Physciaceæ. *C. vitellina* on rocks, palings, etc., is common, the other species, on rocks or walls, are rare.

Thallus lobate at the circumference.

49. PHYSCIA Schreb.—Thallus rarely fruticose; more generally foliose and horizontal, whitish, grey, greyish-green or brown, sometimes sorediate, attached mostly by rhizine. Structure radiate, subradiate or dorsi-ventral. Apothecia discoid, small or moderate in size, blackish, with a thalline margin; hypothecium brownish or dark; paraphyses simple or branched near the brown tips; spores 8, two-celled, with a thick outer wall and thickish septum, more or less distinctly polarilocular, dark-brown.

There is considerable variation in the structure of the thallus; species of radiate structure are surrounded by a cortex which is formed of hyphae parallel with the long axis of the frond. This type of cortex termed "fibrous" occurs also in most of the horizontal species, in some being confined to the upper surface, in others to the lower, while in a few both cortices are of plectenchyma. Species with a fibrous upper cortex are placed by some authors in a separate genus, *Anaptychia*. *Physcia* with horizontal lobes are sometimes velvety or pruinose. (Fig. on p. 51.)

On trees or rocks. Colours other than greyish-green are indicated.

*Cortex fibrous above, or on both surfaces (*Anaptychia*).

Thallus fruticose or partly ascending, of narrow fronds.

Corticate on both surfaces, upright. R. ... 1. *Ph. intricata* Schær.

Corticate above, mostly decumbent, grey-ciliate. C. 2. *Ph. ciliaris* DC.

Whitish, corticate above, dark-ciliate F. in south 3. *Ph. leucomela* Mich.

Thallus horizontal, fibrous-corticate on both surfaces.

Dark-brown, narrow. Maritime. C. ... 4. *Ph. fusca* A. L. Sm.

Dark multifid laciniae, rhizinoe at
edges. R. 18. *Ph. lithotea* Nyl.

• 50. **RINODINA** Massal.—Crustaceous, rarely squamulose, non-corticulate except in highly developed species. Apothecia dark-coloured, generally with a prominent thalline margin; paraphyses slender, septate, brown and often shortly branched at the broader tips; spores 8 (rarely more), 1-septate, more or less distinctly polarilocular, brown.

The spores of this genus, as in *Physcia*, are nearly always distinctly polarilocular, with the cell-lumen however near the median wall.

- *Isidioid-squamulose, grey.
- Bluish-grey. Sp. up to $30 \times 15 \mu$. On
trees. R. 1. *R. isidioides* Koerb.

Thin, seurfy. Apo. small; sp. up to
 $35 \times 15 \mu$ (?3-septate). R. 18. *R. Conradi* Koerb.

FAMILY XIII. LECANORACEÆ.

Thallus crustaceous or squamulose, variously coloured. Structure more or less stratose, corticate above or non-corticate, attached by hyphae to the substratum. Algal cells *Protococcaceæ*, very rarely *Trentepohlia*. Apothecia superficial or sometimes immersed at first in the thallus, discoid, normally with a prominent thalline margin; spores 8, or many, in the ascus, colourless, simple or variously septate. Spermogones with acrogenous or pleurogenous spermatia.

A large and widely distributed Family. It is distinguished from the somewhat parallel *Lecideaceæ* by the character of the apothecia, in the development of which the thallus takes part and forms a protective margin generally of the same colour round the disc. The term granulate thallus indicates that the granules have become somewhat coherent and smooth, as if corticate. Warts are still larger tumid units.

- Spores simple.
8 or few in the ascus..... 51. *Lecanora*.
Many in the ascus..... 52. *Acarospora*.
Spores septate.
Elongate-ellipsoid, 1-2-septate 53. *Lecania*.
Elongate-fusiform, 1-3-septate 54. *Icmadophila*.
Elongate-acicular, pluri-septate 55. *Hæmatomma*.

51. LECANORA Ach.—Squamulose or variously crustaceous, rarely somewhat minutely fruticose, attached to the substratum by hyphae, the cortex of the upper surface of decomposed hyphae or wanting. Algal cells

Protococcaceæ. Apothecia generally superficial, discoid, with a thalline margin; hypothecium mostly colourless, generally with a layer of algae beneath; spores usually 8, simple, colourless, mostly ellipsoid.

The genus as here understood includes only species with simple colourless spores, generally 8 in the ascus (up to 32 in *L. Sambuci*); they are described as small if up to $12 \times 6 \mu$, as moderate up to $18 \times 7-10 \mu$, and as large if beyond that size.

Squamulose..... § i. SQUAMARIA.

Crustaceous or indistinctly squamulose.

• Apothecia superficial from the first.

Spores less than 40μ long..... § ii. EULECANORA.

Spores very large with thick episporule..... § iii. OCHROLECHIA.

Apothecia immersed at first..... § iv. ASPICILIA.

§ i. SQUAMARIA DC. (as genus).—Thallus more or less squamulose, imbricate, or appressed, orbicular and effigurate (with definite outline; see also

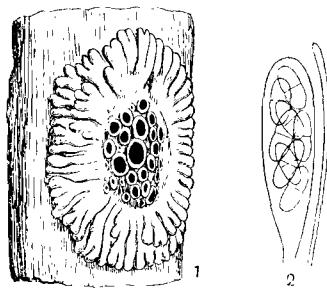

FIG. 32.—*Physcia stellaris* Nyl. var. *aipolia* Nyl. 1. Plant on bark. 2. Ascus and spores (dark-brown) with paraphysis $\times 500$.

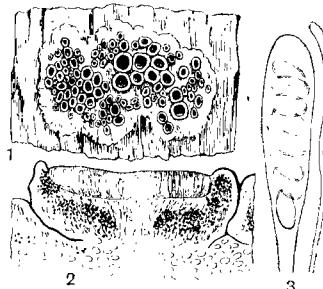

FIG. 33.—*Lecanora varia* Ach. 1. Plant on palings. 2. Vertical section of thallus and apothecium $\times 50$. 3. Ascus with spores and paraphyses $\times 500$.

L. polytropa). The species grow mostly on rocks, more rarely on soil (*L. cartilaginea* and *L. lenticula*), or also rarely on palings (*L. muralis*).

Squamules imbricate.

Spores ellipsoid. Moist rocks, Al-

derney. R. 58. *L. torquata* Nyl.

***Greyish-brown of closely packed papillæ.

Spores ellipsoid. R. 59. *L. poliophaea* Ach.

§ iii. **OCHROLECHIA** Massal. (as genus).—Thallus crustaceous, whitish, grey. Apothecia generally large (up to almost 1 cm. diam.), with a umid or prominent margin; paraphyses long, slender, branched and intricate; spores 8, usually very large. (2 in *L. geminipara*.)

The species of this section often form wide-spreading, thickish or thin rusts on rocks, trees, or mosses on the ground. *L. tartarea* and *L. parella* are well-known dye-lichens, yielding on treatment a purple dye. The former is known as the cudbear lichen.

*Grey. Apothecial disc not pruinose.

Tartareous, thick K + y, C + red. Apo.

C. + reddish. C. 61. *L. tartarea* Ach.

Mostly thin K-. Apo. disc and margin K(C) + red. Trees. R. 64. *L. pallescens* Nyl.

Continuous or scattered. Apo. K(C) -. Mosses. R. 65. *L. upsaliensis* Nyl.

§ iv. **ASPICILIA** Massal. (as genus).—Variously crustaceous.. Apothecia innate in the thallus, then usually emergent, the thalline margin persistent or disappearing, the proper margin often prominent; hypothecium generally colourless; paraphyses slender, usually densely septate, and often bead-like (moniliform) towards the tips; spores ellipsoid, rather large, or more rarely small.

The apothecia in this subgenus develop primarily as *Lecideae* with a proper margin only, the thalline margin, which is often prominent and persistent, grows up later around the apothecium. In other respects the fruits are lecanorine. *Lecanora Dicksonii* and *L. pelobotrya* are retained for convenience of reference, but belong more truly to *Lecideae*. The two groups differ in the character of the gonidia:—

A. EUASPICILIA. Algal cells *Protococcaceæ*.

B. JONASPIIS. Algal cells *Trentepohliae*.

A. Euaspicilia.—Algal cells *Protococcaceæ*.

52. **ACAROSPORA** Massal.—Squamulose or crustaceous, generally rather thick, the squamules scattered, or contiguous in areolæ, corticate above or non-corticate. Apothecia generally immersed, then plane, discoid, the thalline margin becoming indistinct; hypothecium colourless; paraphyses

FIG. 34.—*Acarospora squamulosa* Th. Fr.
Ascus with spores and paraphysis $\times 250$.

FIG. 35.—*Lecania syringea* Th. Fr.
Ascus with spores and paraphysis $\times 500$.

slender, septate; spores many in the ascus, mostly very small, oblong or ellipsoid, colourless.

Distinguished by the many-spored asci, and thus corresponding with the genus *Biatorella* (Lecideaceæ). The species *L. pruinosa*, *L. simplex*, etc., included sometimes under *Acarospora*, sect. *Sarcogyne*, have no gonidia in the fruiting body and belong to *Biatorella*. On rocks, rarely on soil. The thallus is K - C -, unless otherwise indicated.

*Squamulose, thickish.

53. LECANIA Massal.—Sometimes squamulose, imbricate or lobed at the circumference and corticate above, or variously crustaceous. Apothecia reddish-brown or blackish, marginate when young, the margin often disappearing; spores 8–16, colourless, more or less elongate and rather narrow, 1–3-septate.

In many species the thalline margin disappears at an early stage, but the presence of algae below the hypothecium indicates their position in Lecanoraceae.

Squamulose. Spermogones with pleurogenous spermatia..... § i. PLACOLECANIA.
 Crustaceous. Spermogones with aerogenous spermatia § ii. EULECANIA.

- 54. ICMADOPHILA** Massal.—Crustaceous, not corticated. Apothecia sessile or subsessile, with a thalline margin which finally disappears; hypothecium colourless, with gonidia partly below; paraphyses slender, simple, free; spores fusiform, 2-4-celled, colourless.
 The one British species is frequently classified as *Baeomyces oruginosus*. It differs from *Baeomyces* in the structure of the apothecium.
 Granular, greenish or whitish. Apothecia moderate in size or large, rose-coloured. Soil. C. I. ericetorum.

55. **HÆMATOMMA** Massal.—Crustaceous, corticate or non-corticate on the upper surface. Apothecia sessile or sometimes immersed, generally brightly coloured (red or brown); paraphyses discrete; spores 8, narrow or acicular, straight or bent, 3-many-septate, colourless.

The saxicolous species are common in upland districts, the brightly coloured apothecia conspicuous on the generally light-coloured wide-spreading thallus. *H. elatinum* grows on holly in Killarney; it occurs frequently in Scandinavia.

On rocks and boulders.

• Warted, not leprose. Apo. dark-red 1. *H. ventosum* Massal.

Often leprose. Apo. generally crimson 2. *H. coccineum* Koerb.

On holly.

Thallus thin, furfuraceous. Apo. light-brownish-red 3. *H. elatinum* Koerb.

FAMILY XIV. PERTUSARIACEÆ.

Thallus crustaceous, effuse or determinate, attached by hyphae to the substratum, corticate or non-corticate above. Algal cells Protococcaceæ. Apothecia one or several immersed in thalline protuberances (verrucæ or

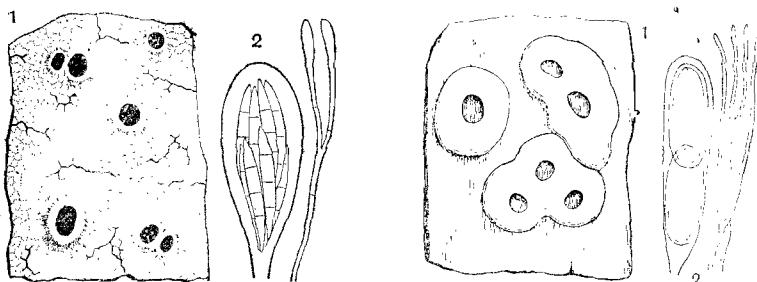

FIG. 36.—*Hæmatomma coccineum* Koerb.

|------------------------|---------------------------|
| Spores simple..... | 56. <i>Pertusaria</i> , |
| Spores 1-septate | 57. <i>Varicellaria</i> . |

56. **PERTUSARIA** DC.—Thallus continuous or cracked, varying in thickness, corticate or non-corticate above, generally superficial on the substratum, soredia often present. Apothecia generally immersed in the thalline verrucæ, the disc visible as a small point sometimes opening wider;

hypoecium colourless; spores 1-2 or 4-8, mostly colourless, simple, with a thick episore, usually very large up to 310μ long, and 100μ thick.

In *Pertusaria* the thallus is often fairly thick and the fertile verrucæ very prominent. The soredia when present appear generally in the form of "soralia," definite bodies, mostly round in outline, resembling abortive apothecia. There is great variation in the size of the spores depending on the number formed in each ascus; the predominating number is that given in the diagnosis. Unless otherwise stated the thallus is grey.

57. VARICELLARIA Nyl.—Thinly crustaceous, corticate. Apothecia immersed in convex verrucæ; spores large, ellipsoid, 1-septate, colourless. Spermogones unknown.

The thallus of the British species is whitish, smooth, though occasionally leprose. The solitary spore is up to $225-350 \mu$ long, $95-115 \mu$ thick. It is an alpine soil lichen.

Apo. disc pale-reddish..... *V. microsticta* Nyl.

FAMILY XV.—THELOTREMACEÆ.

Thallus crustaceous, thin or thickish, mostly non-corticate. Algal cells *Trentepohlia* or *Protococcaceæ*. Apothecia at first immersed and closed, then more or less open, with a proper margin generally well developed and usually surrounded by an overarching thalline margin; paraphyses simple or branched; spores 1-8, elongate-septate or muriform, rather large, colourless or dark-coloured. Spermogones with aerogenous short or long and curved spermatia.

The immersed apothecia recall those of Pertusariaceæ, but they are solitary with a more pronounced proper margin. In *Phlyctis*, however, that margin is somewhat poorly represented, while in *Conotrema* it is the thalline margin that tends to disappear.

Algal cells *Trentepohlia*.

Spores septate or muriform, large 58. *Thelotrema*.

Algal cells *Protococcaceæ*.

Spores elongate, narrow, multi-septate 59. *Conotrema*.

Spores muriform, colourless 60. *Phlyctis*.

Spores muriform, dark-coloured 61. *Diploschistes*.

(*Urceolaria*.)

58. THELOTREMA Ach.—Crustaceous, superficial or partly developed beneath the bark, non-corticate or with an anorphous cortex. Algal cells *Trentepohlia*. Apothecia at first immersed in small verrucæ, the disc half-concealed or opening out, the inner proper margin persistent, the outer margin prominent, overarching the disc; paraphyses slender, massed; spores 1-8, large, oblong or fusiform, septate or irregularly muriform colourless.

A tropical or warm-temperate genus characterised by the crater-like apothecia and by the septate or muriform spores:—

Spores elongate, 8-12-septate. Bark. C. 1. Th. lepadinum Ach.
Spores muriform, large. Bark or stone. R. 2. Th. subtile Tuckerm.

59. CONOTREMA Tuckerm.—Crustaceous, membranaceous, uniform. Apothecia immersed, becoming superficial, urceolate, the proper margin black, the thalline margin thin, soon disappearing; hypothecium blackish; spores elongate, cylindrical, slender, colourless, multiseptate (up to 30-40-septate).

A small genus, with the whitish thallus developed as a thin film on the bark. Both species are rare: No. 1, alpine, No. 2, from Killarney.

Apo. small; spores up to $160\ \mu$ long 1. C. urceolatum Tuck.

Apo. rather large; spores up to $140\ \mu$ long 2. C. hinalotropum A. L. Sm.

60. PHLYCTIS Wallr.—Crustaceous, continuous or cracked, or pulverulent, developed above or beneath the bark, light-coloured. Apothecia immersed, then scarcely emerging, the proper margin poorly developed, the outer thalline margin irregularly dehiscent or indistinct; paraphyses slender, mostly unbranched; spores 1-8, elongate or ellipsoid, muriform, colourless, with a thin episporule.

The thin effuse thallus, the immersed apothecia and muriform spores show the affinity with Thelotremae. In appearance the two species are not unlike *Pertusariae*. Both are corticolous.

Spores apiculate at each end, $45-70\ \mu \times 14-27\ \mu$. C. 1. Phl. agelaea Koerb.
Spores not apiculate, $100-140\ \mu \times 27-50\ \mu$. F. 2. Phl. argena Koerb.

61. DIPLOSCHISTES Norm.—Crustaceous, generally arcolate, sometimes with an amorphous cortex. Apothecia immersed-urceolate, with a well-developed proper dark margin, and an outer thalline margin; hypothecium dark-coloured; paraphyses slender; spores 4-8, muriform, becoming dark-brown.

A small genus, more generally known as *Urceolaria*, not unlike *Thelotrema* in the form of the apothecia. *D. seruposus* is a common rock, tree or wall lichen. In the British species there is a red reaction with CaCl.

*Apo. up to 2 mm. across; sp. up to $40 \times 20\ \mu$.

Thick, uneven, light- or dark-grey. Rocks.

C. 1. D. seruposus Norm.

Thin, pulverulent grey. Mosses. F. 2. D. bryophilus Zahlbr.

Thick, wrinkled, white. Rocks. R. 3. D. gypsaceus Zahlbr.

**Apothecia small; sp. $35 \times 16-23\ \mu$.

Thickish, smooth, areolate, light- or dark-

grey (not recorded) 4. D. actinostoma Zahlbr.

Greyish-leadened-coloured. Rocks. R. Var. cæsioplumbea

A. L. Sm.

FAMILY XV.A. CHRYSOTHRICACEÆ.

Thallus felted, spongy, of branched loosely interwoven hyphae, not corticate. Algal cells Protococcaceæ or *Trentepohlia*, generally in groups lodged among the hyphae (partly homoiomerous). Apothecia without a thalline margin, but with a double proper margin; spores colourless, simple or septate. Spermogones with simple sterigmata and small spermatia.

The Family is characterized by the byssoid structure of the thallus.

Thallus byssoid, with algal cells Protococcaceæ 62. *Crocynia*.

62. **CROCYNIA** Massal. (*Leproloma* Nyl.).—Thallus of felted intricate hyphae, spreading, non-corticate. Apothecia immersed or sessile, without a thalline margin, the disc red or blackish; paraphyses conglutinate, thickish, not branched; spores 6–8, simple or 1–3-septate, colourless.

The thallus of the single British species is orbicular, granular-pulvulent at the centre. It is sterile. A number of species, also sterile, have been recorded from France.

White or yellowish-white. Mosses on rocks. C. ... 1. *C. lanuginosa* Hue.

FAMILY XVI. GYROPHORACEÆ.

Thallus foliose, monophyllous or polyphyllous, corticate on both surfaces, attached by a central hold-fast or by rhizinae. Algal cells Protococcaceæ. Apothecia sessile or almost stalked, with proper margin only (lecidine);

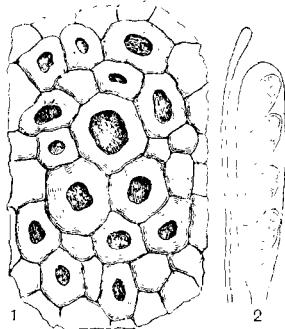

FIG. 38.—*Diploschistes scruposus* Norm.
1. Plant on stone $\times 5$. 2. Ascus and paraphysis $\times 180$.

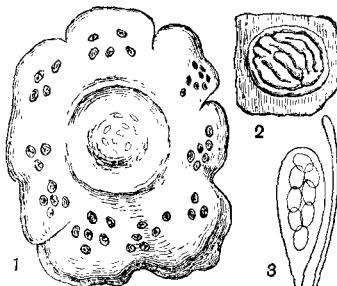

FIG. 39.—*Gyrophora proboscidea* Ach.

the disc plane or furrowed (gyrose), black; spores 1 or 8, colourless or dark-brown, simple or muriform. Spermogones with septate sterigmata and pleurogenous spermatia (in British genera).

This Family is classified with Cladoniaceæ and Lecideaceæ on account of the lecidine fruit (Order Lecideales).

Apothecia mostly gyrose; spores simple, colourless 63. *Gyrophora*.
Apothecia plane; spores muriform, dark-brown..... 64. *Umbilicaria*.

63. **GYROPHORA** Ach.—Foliose, with plectenchymatous cortex on both surfaces, attached mainly by a subcentral hold-fast, naked or rhizinose below. Apothecial disc plane or more or less concentrically furrowed, with alternate fertile and sterile tissue; hypothecium dark-coloured; paraphyses subdiscrete; asci ellipsoid-cylindrical or broadly ellipsoid; spores 8, simple (rarely septate), rather small, ellipsoid, colourless or becoming brownish.

The British species of *Gyrophora*, with one exception, have gyrose apothecia; they are saxicolous plants, and are mainly found in upland, mountainous or northern regions; they vary in colour from light cinerous-grey to brownish-black.

- Apothecial discs plane § i. AGYROPHORA.

Rhizinae dense, black, branched at tips. C. 11. *G. polyrrhiza* Koerb.

Rhizinae grey or brown, not branched at tips. R. 12. *G. cirrosa* Wain.

(*G. spodochroa* Ach.)

64. UMBILICARIA Hoffm.—Rather large, dark-coloured, leathery, with a single central or subcentral hold-fast, without rhizinae. Apothecia sessile, discoid, the disc mostly plane; hypothecium dark-coloured; paraphyses discrete; spores 1-2, ellipsoid, dark-coloured, rather large, muriform, with a thin episporite.

The single British species grows on rocks in northern or upland regions.

The upper surface frequently bears long branching isidia, and is covered by oblong-ovoid pustules with corresponding depressions or "foveolæ" below. The cortex of both surfaces is plectenchymatous. It is abundant in arctic regions and, along with species of *Gyrophora*, is known as "rock-tripe."

Thallus greyish, black, monophyllous *U. pustulata* Hoffm.

FAMILY XVII. CLADONIACEÆ.

Thallus usually of twofold character:—primary or basal, crustaceous or squamulose, often evanescent attached to the substratum by a hypothallus, by rhizinae or occasionally by a branching rhizoid, corticate or non-corticate; secondary thallus or podetium upright, varying from a short apothecial stalk to a long simple or branched structure, usually tubular, corticate or non-corticate, tapering to a point or opening above into a trumpet-shaped scyphus. Algal cells *Protococcaceæ*. Apothecia sessile on the tips of the podetia or on the margins of the scyphus, brown or red in colour, immar-

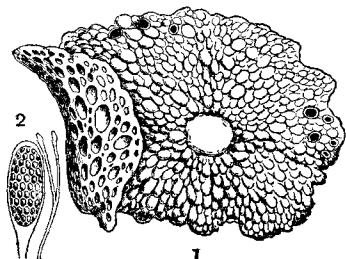

FIG. 40.—*Umbilicaria pustulata* Hoffm.

1. Plant on soil. 2. Ascus with spores and paraphysis $\times 300$.

ginate; paraphyses generally unbranched; spores 6–8, simple or variously septate, colourless. Spermogones with acrogenous spermatia.

The upright thallus in *Cladonia* is endogenous in origin and has been on that account regarded as an apothecial stalk or elongation of the conceptacle. It has become, with few exceptions, transformed to a vegetative thallus. The podetia of *Pilophorus* and *Stereocaulon* are exogenous in origin.

Podetia very short, usually simple.

Podetia glabrous.

Thallus granular. Spores simple or 1-sept. (Brit. species) 65. *Baeomyces*.

Thallus a gelatinized crust. Spores up to 100-septate 66. *Gomphillus*.

Podetia granular.

Thallus granular. Spores simple 67. *Pilophorus*.

Podetia usually well developed, often branched.

Podetia with a solid stalk. Spores 4-pluriseptate 68. *Stereocaulon*.

Podetia with a hollow stalk. Spores simple 69. *Cladonia*.

65. **BÆOMYCES** Pers.—Horizontal or primary thallus crustaceous, granular-pulverulent or squamulose. Podetia endogenous in origin, rising from the thalline granules, very short and with or without gonidia. Apothecia terminal, immarginate, dark- or light-coloured; hypothecium pale; spores usually 8, ellipsoid or fusiform, narrow, simple or 1-septate, colourless.

The British species grow on soil in moorland or upland regions, and the light-greenish thallus often spreads extensively. *B. aeruginosus* is classified under *Icmadophila* (Lecanoraceæ).

crust. Apothecia one or several at the tip of a very short stalk or podetium rising from the horizontal thallus, dark-coloured, of a horn-like consistency; spores 8, filiform, pluriseptate.

A monotypic genus most nearly allied to *Bæomyces*. It grows over mosses on the ground, trees or boulders. The long thread-like spores are about 100-septate.

Greyish or greyish-green. Apo. almost black. R. *G. calicioides* Nyl.

67. PILOPHORUS Th. Fr.—Primary thallus crustaceous, granular or minutely squamulose, non-corticated, sprinkled with flat granular olivaceous cephalodia. Podetia developed from the upward growth of the granules (not endogenous), rigid, cylindrical, simple or sparingly branched, beset with granules, non-corticated, tubular or solid, with a central strand of compact parallel hyphae. Apothecia terminal on the podetia, single or in groups, subglobose, immarginate; hypothecium thick; black; paraphyses thickish, dark at the apices; asci clavate, thickened at the apices; spores 8, elongate-ellipsoid, simple.

Differs from *Stereocaulon* in the persistent thallus and dark apothecia. There is only one British species, found on moist shady rocks, in hilly regions. The warted flattened cephalodia contain *Stigonema* algæ.

Thin, greyish-white. Pod. short, erect, simple. F. P. cereolus Stiz.

68. STEREOCAULON Schreb.—Primary thallus granular or minutely squamulose, usually soon evanescent. Podetia erect or decumbent developed from the upward growth of the primary thallus (not endogenous), much branched, solid in the centre, beset with small warts or squamules which

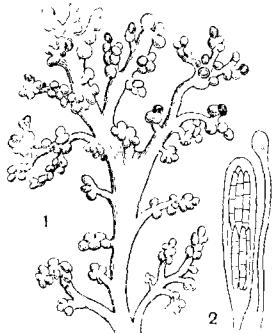

FIG. 44.—*Stereocaulon coraloides* Fr.

physis $\times 450$.

are more or less corticate. Cephalodia, as warts or tubercles, usually present on the podetia, containing *Stigonema* or *Nostoc*. Apothecia terminal or lateral, usually dark-brown, immarginate (rarely with a thalline margin); hypothecium colourless; paraphyses slender, discrete; asci cylindrical; spores 6–8, elongate, 4-pluriseptate, colourless.

The species with a persistent thallus grow usually on turf or soil, either on the ground or on walls; the others grow mostly on rocks and boulders. They are plants of hilly or upland regions.

Cephalodia dark in colour, containing *Stigonema*.

Primary thallus persistent.

69. **CLADONIA** Hill.—Primary thallus evanescent, crustaceous or squamulose; secondary thallus or podetium upright, simple or branched, ending in a point or widening to form a shallow cup or scyphus, more or less corticate, smooth, granular, pulverulent or beset with squamules, tubular and sometimes perforate at the axils or at the base of the scyphus. Apothecia terminal, at first somewhat plane and marginate, becoming convex, pale- or dark-brown or red; spores 8, simple, colourless.

Cladonia are nearly all earth lichens, and are most frequently to be found on moorland or peaty soil.

Primary thallus evanescent or persistent.

- Soon evanescent. Pod. mostly ascophous... Subgen. i. **CLADINA**.
- Crustaceous, persistent. Pod. ascophous... „ ii. **PYCNOHELIA**.
- Squamulose, mostly persistent. Pod. scy-
 phous or ascophous „ iii. **CENOMYCE**.

Subgen. i. **CLADINA** Leight.—Basal thallus granular, scanty, soon disappearing; podetia perishing at the base, with continued apical growth.

There is no visible thallus in the *Cladinae*, and no podetial squamules occur in any of the species. They are ascophous with the exception of *Cladonia amaurocraea* and *C. distracta* (occasionally). *C. rangiferina* is the well-known "reindeer moss."

*Ascophous, greenish-grey, slender, much branched.

***Seyphi occasional.

- Upright, yellowish, as in N. 4. Ground.
 R. 5. *C. amaurocerea* Schær.
 Mostly decumbent, greenish - grey.
 Moors. R. 6. *C. destricta* Wain.

Subgen. ii. PYCNOTHELIA Leight.—Primary thallus crustaceous, persistent; podetia very short, like papillæ or cones.

The single British species grows on the ground, on exposed moorlands, etc.
 Thallus effuse, granular whitish or greyish..... 7. *C. papillaria* Hoffm.
 With stouter branched podetia..... Var. *molariformis* Nyl.
 With reduced podetia Var. *apoda* Nyl.

Subgenus ii. CENOMYCE Th. Fr.—Primary thallus squamulose or foliaceous, usually persistent; podetia mostly well-developed, scyphous or ascophous. Apothecia pale- or dark-brown, or red.

The *Cladonia* of the subgenus *Cenomyce* are found mostly on undisturbed mossy earth or on sandy soil, on the ground or on rocks. In general those species with a well-developed primary thallus grow on dry exposed places; those in which the basal squamules are reduced or evanescent grow in more protected places, among heaths, etc. A few species grow by preference on old stumps or on trunks of trees, as, for instance, *C. parasitica* and *C. macilenta*. They sometimes spread widely and are often intermingled. In certain conditions the superficial granules or cortical areoleæ of the podetia grow out into squamules somewhat similar to those of the base, and thus many species have a squamulose variety or form.

In the diagnoses "large" squamules are from 1 to 3 cm. in length, with lesser width; "medium"-sized are about 1 cm. or less; and "small" about 2 to 5 mm. The podetia when "short" are a few mm. in length; medium-sized 2 to 3 cm.; and elongate or tall more than 3 cm.

Series A.—**Phæocarpeæ**.—Apothecia brown-coloured.

1. Podetia without perforations at tips or axils (*closed*), mostly scyphiferous.

*Podetia not, or only partly, corticate.

 and paraphysis × 250.

lateral, discoid, not carbonaceous; paraphyses discrete; spores fusiform or ellipsoid, simple or 1-septate.

The genus belongs almost exclusively to warm regions; it is represented in Europe by one sterile species, dark in colour owing to the brown investing hyphae; it grows in rather damp localities on rocks.

- Wide spreading. Filaments constricted at the septa of the alga..... *C. ebenum* A. L. Sm.

RACODIUM

71. **RACODIUM** Pers.—Thallus of loose branching filaments, dark-coloured. Algal cells *Cladophora*, forming a central strand. Apothecia and spermogones unknown.

Represented by one species, found on rocks in upland regions.

Filaments not constricted *R. rupestre* Pers.

FAMILY XIX. LECIDEACEÆ.

Thallus minutely squamulose or crustaceous. Algal cells nearly always *Protococcaceæ*, more rarely *Trentepohlia* or *Myxophyceæ*. Apothecia discoid or saucer-like (patellate), with proper margin only; spores usually 8 in the ascus, but sometimes fewer or more, simple or variously septate or muriform, colourless or coloured.

The family includes genera formerly classified under the large and comprehensive genus *Lecidea*. Apothecial and spore characters are the determining factors in classification.

*Apothecia urceolate or cup-like, brightly coloured,

Spores colourless, septate or muriform 72. **Gyalecta**.

**Apothecia discoid or patellate, coloured or blackish.

†Spores colourless.

§Spores simple.

8 or fewer in the ascus 73. **Lecidea**.

Many in the ascus 74. **Biatorella**.

§§Spores 1 in the ascus large.

Elongate, pluriseptate 81. **Bombyliospora**.

Ellipsoid, muriform 82. **Lopadium**.

72. **GYALECTA** Ach.—Thallus granular, pulverulent or nearly obsolete. Algal cells chiefly *Trentepohlia* (*Scytonema* in *G. exanthematica*). Apothecia brightly coloured, concave with a prominent proper margin, hypothecium colourless; paraphyses discrete, unbranched; asci 8- rarely many-spored, colourless, variously septate or muriform. Spermogones with almost simple sterigmata and rather short acrogenous spermatia.

The genus is characterized by the brightly coloured apothecia, with flesh-coloured reddish or yellowish discs and whitish margins. In the early stages there may be a surrounding growth of the thallus which is not persistent. On account of a somewhat more evident double margin *G. rubra* has been classified by authors under *Lecanora* or *Phialopsis*, and because of the *Scytonema* gonidia *G. exanthematica* has been sometimes placed in the genus *Petractus*. The thalli of the latter species, both hyphae and

algæ, are deeply immersed in the calcareous rock, only a thin film appearing on the surface.

- *Spores 8 in the ascus. Apothecial margin prominent.

 - Apo. minute; spores fusiform, 3-7-septate, $16-34 \mu \times 5-7 \mu$. On pine. R. 7. *G. corticola* A. L. Sm.

73. LECIDEA Aeli.—Thallus squamulose or crustaceous; hypothallus persistent or indistinct. Algal cells *Protococcaceae*, rarely *Trentepohlia*. Apothecia soft and more or less waxy (biatorine), or carbonaceous and black (lecidine), with a proper margin (often obliterated); spores usually 8 in the ascus, generally ellipsoid, simple, colourless; spermogones with acicular heterogenous spermatia.

A large genus mostly with a crustaceous thallus which varies in colour from white to grey, brown or black and is often subject to great alteration or to disappearance due to weathering, etc. Apothecia and spores are fairly constant in character, the latter occasionally become brown. Apothecia are distinguished as "small" when 5 mm. or less, large when more than 1 mm. in diameter. The size of the spores is given when of importance in determination. "Mod." or "Med." is used when the spores are from 12-18 μ long and up to 8 μ thick, "large" if beyond these measurements and small if of lesser size.

The characters adopted in the key—habitat, colouration, etc.—have been selected for their helpfulness in determination; certain species vary as to the substratum on which they grow or in their internal colouration, in which cases they are repeated under the different headings.

The genus is divided into four sections not always clearly delimited : -

- Thallus squamulose § i. PSORA (1-15).
Thallus variously crustaceous.

Ascus 8-spored.

- Apothecia soft, generally lighter in colour § ii. BIATORA (16-76).
Apothecia dark and carbonaceous § iii. EULECIDIA (77-200).
Ascus 1- or 2-spored.
Apothecia dark; spores very large § iv. MYCOBLASTUS (201-2).

§ i. PSORA Haller.—Thallus squamulose, the squamules appressed or imbricate, corticate above. Apothecia more or less biatorine, adnate or the squamules.

The squamules vary in size from less than 1 mm. (small) to several mm. in diameter; they are frequently rounded and crenulate.

76a. *L. pleiospora* A. L. §

§ iii. EULECIDEA Nyl.—Apothecia dark-coloured-brown or black, and more or less carbonaceous, plane with a persistent proper margin, or becoming convex and immarginate, moderate in size (about 1 mm. across), large (more than 1 mm.), small or minute (less than 1 mm.); spores usually 8 in the ascus, generally ellipsoid.

The species, as in the previous section, are grouped according to habitat, but the large majority grow on siliceous rocks, and many of those marked "rare" have only been found in hilly regions. The student is advised to refer also to § *Biatora*, as a few species that seem to belong to one group may be classified in another. In some species, as in *L. limborina*, *L. rivulosa* and *L. Kochiana*, the spores become brownish by degeneration.

A. On trees or on pales.

*Hypothecium colourless, yellowish or brownish. Thallus light, various.

- K + y, C + O. Pulverulent or smooth.
Epi. blue-green; sp. mod. F. 78. *L. dubia* Hook.
 - K + y, C + O. Yellowish, granular. Sp. small. R. 79. *L. sporodiza* Stirt.

Granulate-areolate. Apo. crowded; sp. small. R. 149. *L. nigrogrisea* Nyl.

Granular-cracked. Apo. small; sp. mod.	
F.	170. <i>L. furvella</i> Nyl.
Thin, effuse. Apo. small; sp. 18-30 μ x 11-16 μ (brown). R.	143. <i>L. limborina</i> A. L. Sm. 117. <i>L. crustulata</i> var. <i>meiospora</i> Oliv.
Apothecia sometimes in lines.....	148. <i>L. fuscoatra</i> var. <i>grisella</i> Nyl.

* § iv. MYCOBLASTUS Th. Fr.—Thallus crustaceous. Spores usually 1, rarely 2 or 3 in the ascus.

The principal British species is characterized by the blood-red colour of the medullary tissue under the apothecia, and by the large spores with a broad episporule. It grows on rocks or on mosses encrusting boulders, also on palings and on trees, chiefly firs.

K + y. Thickish, granulose, whitish. Sp.	
70-100 μ x 28-38 μ . C.	201. <i>L. sanguinaria</i> Ach.
Thin; spore smaller. R.	<i>f. microcarpa</i> Nyl.
Med, colourless. Sp. as in species. R.	Var. <i>affinis</i> Nyl.

Granulose, grey. Apo. violet within; sp.	
1-3, up to 48 μ x 22 μ . Wood. R. ...	202. <i>L. fucata</i> Stirz.

74. BIATORELLA De Not.—Thallus, effuse or determinate, rarely obsolete. Algal cells Protococcaceæ. Apothecia light-coloured (biatorine),

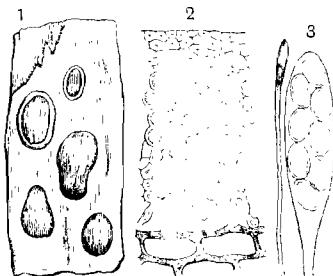

FIG. 48.—*Lecidea parasema* Ach.
1. Plant on bark x ca. 10. 2. Vertical section of thallus x 350. 3. Ascus with spores and paraphysis x 350.

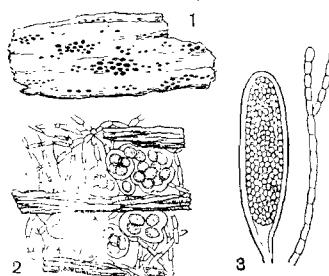

FIG. 49.—*Biatorella moriformis* Th. Fr.
1. Plant on wood. 2. Vertical section of thallus and wood fibres x 250. 3. Ascus with spores and paraphysis x 200.

or dark and carbonaceous (lecidine); asci many-spored, the spores minute, simple, oblong or round, colourless. Spermatogones with ovoid or shortly cylindrical spermatia.

The genus corresponds in spore formation with *Acarospora* (Lecanoraceæ); (compare also the polyspored *Lithographæ*); it is divided into two sections:—

- Apothecia mostly soft and pale within § i. EUBIATORELLA.
- Apothecia more or less carbonaceous § ii. SARCOGYNE.

§ i. EUBIATORELLA Th. Fr.—Thallus mostly thin or indistinct. Light or dark. Apothecia biatorine.

A. Growing on trees or on pales.

- *Apothecia light-coloured; spores globose.
Whitish. Apo. reddish-yellow, pruinose; sp. 4–5 μ . Mossy trees. R.
- Grey. Apo. reddish; sp. 3–4 μ . Resinous bark. F.

**Apothecia dark-coloured, spores globose.

- K + y, C + red. Grey or brownish. Hypo. pale; sp. 2·5–3·5 μ . Pales. F.
- Indistinct. Hypo. brown; sp. 2·5 μ . Resinous bark. R.

B. Mosses or soil (*B. Morio* on rocks).

- Greyish. Apo. red; sp. 6–12 $\mu \times$ 3–4 μ . Alpine. R.
- Grey or green, scanty. Apo. pale; sp. 7–8 $\mu \times$ 3 μ . R.
- Blackish, areolate. Apo. black; sp. 2·4 $\mu \times$ 2–3 μ . S.

§ ii. SARCOGYNE Th. Fr. Thallus superficial or immersed, light or dark. Apothecia lecideine; spores oblong or ellipsoid.

On rocks.

*Thallus evident. Hypothecium colourless or pale.

- Greyish, powdery. Apo. pruinose; sp. 4–5 $\mu \times$ 2 μ . Cal. C.
- Apo. without pruina. Cal. or Sil. F....
- Dull-green, thickish. Apo. red-black; sp. 5–6 $\mu \times$ 1–2 μ . R.
- Dull-brown, thickish. Apo. black; sp. 3 $\mu \times$ 1–2 μ . Cal. R.

**Thallus immersed or obsolete. Hypothecium pale (black in *B. clavus*). Spores minute.

- Apo. large, margin crenate. Sil. R.
- Apo. mod. irregular, margin entire. Sil. R.
- Apo. minute, plicate. Sil. or Cal. F.

10. *B. clavus* Th. Fr.
f. *nuda* A. L. Sm.

8. *B. hypophaea* A. L. Sm.

9. *B. flava* A. L. Sm.

75. BIATORINA Massal. Thallus minutely squamulose or variously crustaceous, sometimes evanescent. Algal cells Protococaceæ or rarely *Trentepohlia*. Apothecia light-coloured and biatorine or dark-coloured and more lecideine, the proper margin often obliterated; spores usually 8 in the ascus, ellipsoid or oblong-fusiform, usually 1-septate, colourless.

Trentepohlia algæ form the gonidia of *Biatorina lutea* and *B. diluta*, and these species, for that reason, and also on account of the prominent margins, have sometimes been classified under *Microphiale* (Gyalectaceæ).

The apothecia in this and the following genera are usually rather small, 1 mm. and less in diameter; the spores in *B. cyrtella* number 8 to 16, and

2. *B. ochrophora* Th. Fr.

4. *B. resinæ* Th. Fr.

3. *B. møriformis* Th. Fr.

5. *B. difformis* Wain.

1. *B. fossarum* Th. Fr.

6a. *B. campestris* Th. Fr.

6. *B. Morio* Mudd.

in that species, as well as in *B. Arnoldi*, they may be occasionally 2-septate; they are mostly narrow in proportion to their length. In light-coloured apothecia the internal tissues are light-coloured; in dark apothecia, the colour of the disc is mostly due to the dark-coloured tips of the paraphyses. Spores are reckoned "moderate" in size when they are 12 to 18 μ long, 6 to 8 μ thick, and "small" when the measurements are constantly less. There is a violet reaction with potash in the hymenium of *B. synothea*, and of *B. chalybea* subsp. *chloroscoletina*.

A: On bark, leaves or pales.

*Apothecia light in colour; spores various; hypothecium pale.

†Thallus whitish, grey or green (yellowish in *B. graniformis*).

77. **BACIDIA** De Not.—Thallus minutely squamulose or mostly thinly crustaceous. Algal cells Protococcaceæ. Apothecia pale-coloured or dark, rarely carbonaceous, moderate or rather small (less than 1 mm. in diam.), sessile or adnate and plane or convex; spores usually 8 in the ascus, elongate-acicular, straight or more or less curved, pluriseptate, colourless.

Differing from the previous genera in the acicular form and the septation of the spores; they are generally many-celled up to 16 cells or more, though in early stages the septation may be undeveloped or indistinct; they are pluriseptate unless otherwise indicated. In several species they are spirally coiled, and in *B. ascaridiella* there may be 8, 16 or 32 in the ascus. The thallus is crustaceous (squamulose in *B. pulvinata*).

A. Growing on bare or mossy trees, rarely on pales.

78. **BUELLIA** De Not.—Thallus squamulose (radiate-plicate), crustaceous, or wanting. Algal cells Protococcaceæ. Apothecia dark-coloured and carbonaceous, immarginate, or with a proper margin only; asci usually 8-spored; spores ellipsoid or oblong, usually 1-septate, dark-brown, or rarely brownish, sometimes with an episporule (halonate).

The genus is nearly related to *Rhizocarpon*. The apothecia are generally moderate in size, .5-1 mm. in diam.; the paraphyses are dark at the apices;

FIG. 52.—*Bacidia rubella*
Massal.

Ascus with spores and para-
physes $\times 200$.

FIG. 53.—*Buellia myrio-
carpa* Mudd.

Ascus with spores and para-
physes $\times 300$.

the spores bear some resemblance to those of *Rinodina*, but they have a thinner septum and no connecting channel, usually they are dark-brown or brownish; in a few species (*B. colludens*, *B. confervoides* etc.) they remain colourless for a long time. Spore sizes are indicated as in *Lecidea*. The thallus is squamulose only in *B. canescens*, which forms orbiculate, sorediate white patches on trees or rocks, about 3 or more cm. across and generally effigurate at the circumference. Species parasitic on other lichens are frequently classified under the genus *Abrothallus*.

79. **LECIOGRAPHA** Massal.—Thallus none. Apothecia parasitic on the hallus of other lichens, immersed then superficial, discoid, black and carbonaceous; hypothecium dark-coloured; spores 8, oblong-ellipsoid or fusiform, 3-septate, brown.

Frequently included among fungi (Patellariaceæ). The apothecia are generally round, but may become elongate in time. The genus is distinguished by the 4-celled brown spores. The apothecia are rather small.

- Hypo. red-brown; sp. mod. *Lecanora parella*
and *Pertusaria pertusa*. C. 1. *L. parasitica* Mudd.
- Hypo. blackish; sp. large. *Lecanora sor-*
dida. R. 2. *L. glaucomaria* A. L. Sm.
- Hypo. brown; sp. $20-35 \mu \times 3-4 \mu$. *Parme-*
liella plumbea. R. 3. *L. plumbina* Anzi.

80. **RHIZOCARPON** Ramond. Thallus crustaceous usually with a dark hypothallus. Algal cells Protococcaceæ. Apothecia usually black and carbonaceous, immarginate or with a proper margin only; ascii 8- or fewer-spored; spores ellipsoid or oblong, usually large, septate and muriform, colourless or brown, usually with a hyaline mucilaginous episporule (halonate).

Rhizocarpon species are mostly saxicolous. *Rh. geographicum* is to be found on uplands and mountains over the whole globe. The dark hypo-

physis $\times 250$.

thallus, usually well developed and visible between the areolæ or as dark lines crossing and limiting the thallus, is absent in *Rh. alboatrum* and *Rh. calcareum*. The apothecia are usually small in size, carbonaceous and adnate or plane (lighter-coloured and softer in *Rh. perlutum*), with dark hypothecium and dark tips to the paraphyses. The medulla stains blue with iodine in *Rh. Ederi* and *Rh. geographicum*. The spores are colourless at first, then generally brownish or very dark. They are more or less muriform except in *Rh. Ederi*, where they are 3-septate.

A. On trees or on wood. Thallus white or grey. Spores 3-septate and muriform.

- Areolate. Apo. sometimes pruinose; sp. brown, not halonate, $16-20 \mu \times 7-9 \mu$.

Subseries III. *GRAPHIDINEÆ*.

Thallus crustaceous or fruticose. Algal cells Trentepohliaceæ (rarely Palmellaceæ). Apothecia roundish or irregular (*ardelleæ*) or linear (*lirellæ*), immarginate or with a proper margin only.

The Graphidinea are distinguished by the almost universal presence of "chrysogonidia" (Trentepohliaceæ) in the thallus and by the form and structure of the apothecia. The structure of the thallus does not differ materially from that of the Cyclocarpineæ; in one family, Roccellaceæ, it attains to considerable fruticose dimensions. Other members of the subseries are crustaceous and, in many of those that grow on trees, the thallus is developed below the bark (hypophloedal) and appears as a dark or light stain on the surface.

The algae may retain this filamentous form or they may be broken up within the thallus into short lengths or separate cells.

Apothecia growing singly.

Thallus corticate on one or both surfaces.

Thallus crustaceous XX. DIRINACEÆ.

Thallus fruticose, strap-shaped XXI. ROCCELLACEÆ.

Thallus non-corticate.

Apothecia roundish or irregular.

With proper margin XXII. LECANACTACEÆ.

Immarginate XXIII. ARTHONIACEÆ.

Apothecia elongate

Apothecia compound in a stroma or pseudo-stroma; immersed, roundish or elongate..... XXV. CHIODECTONACEÆ.

FAMILY XX. DIRINACEÆ.

Thallus crustaceous, attached by hyphae, corticate on the upper surface, the cortex of closely packed upright hyphal branches (fastigiate). Algal cells *Trentepohlia*. Apothecia roundish or somewhat elongate, generally with proper and thalline margins; hypothecium and disc dark-coloured; spores elongate, septate. Spermogones with simple sterigmata and acicular, bent aecrogenous spermatia.

A small family represented in the British Isles by a single genus and species. It is classified under Graphidaceæ on account both of thalline and apothecial characters and is nearly allied to Roccellaceæ.

83. **DIRINA** Fr.—Thallus continuous or cracked, greyish-white, farinose and soft. Apothecia white pruinose; spores colourless.

Spores fusiform, slightly bent, 3-septate, ca. $22 \mu \times 5 \mu$... *D. repanda* Nyf.

FAMILY XXI. ROCCELLACEÆ.

Thallus mostly fruticose, of strap-shaped or rounded branching fronds, attached to the substratum by a basal sheath, corticate, with a central rather loose medulla of hyphae. Algal cells *Trentepohlia*. Apothecia roundish or somewhat elongate, usually with proper and thalline margins; spores 8 in the ascus, colourless or rarely brownish, elongate, septate. Spermogones with simple or sparingly branched sterigmata and straight or curved aecrogenous spermatia.

There is only one genus, *Roccella*, represented in Europe. The whole genus is mainly confined to the sea coasts of warm countries.

Thallus fruticose with basal sheath 84. **Roccella** DC.

84. **ROCELLA** DC.—Thallus of cylindrical or strap-shaped fronds, simple or branched, greenish- or bluish-grey, mostly sorediate; cortex of closely packed hyphal branches disposed at right angles to the surface (fastigiate); medullary hyphae more or less parallel to the long axis;

gonidia within the cortex. Apothecia lateral on the fronds, mostly discoid. with a proper margin, and with or without a thalline margin; hypothecium thick, black; paraphyses branched; spores elongate-oblong or fusiform, mostly 3-septate, colourless.

The species of *Roccella* yield in more or less abundance a purple dye, the "orseille" or orehil of commerce. *R. tinctoria*, which is not British, is the best known and was one of the earliest recorded lichens. There are two British species which grow on maritime rocks chiefly of the Southern coasts.

Fronds short, much branched, subcylindrical ... 1. *R. fucoides* Wain.

Fronds long, compressed, branched, often

proliferate 2. *R. fuciformis* DC.

FAMILY XXII. LECANACTACEÆ.

Thallus crustaceous. Algal cells *Trentepohlia*. Apothecia roundish or oblong, immersed or sessile, immarginate or with a proper margin only; paraphyses branched; spores colourless, elongate, septate.

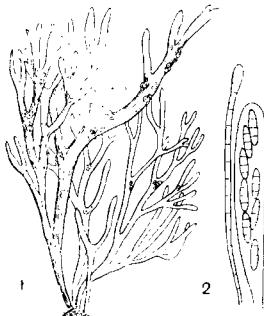

FIG. 58.—*Roccella fuciformis* DC.
1. Plant on rock, reduced ca. 1/4. 2. Ascus with spores and paraphysis $\times 250$.

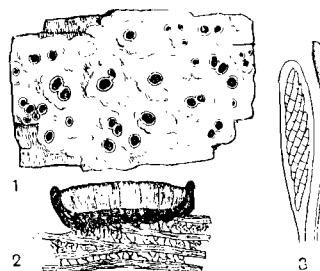

FIG. 59.—*Lecanactis premnae* Wedd.
1. Plant on bark. 2. Vertical section of apothecium $\times 18$. 3. Ascus with spores and paraphysis $\times 250$.

The family is related to Lecidaceæ by the form of the fruit, to Graphidaceæ by the internal structure of the fruit and by the algal symbiont. The genera occur more frequently in warm countries.

- Apothecia with a proper margin 85. *Lecanactis*.
- Apothecia immarginate 86. *Platygrapha*.

85. **LECANACTIS** Eschw.—Thallus crustaceous. Apothecia black, roundish, with a carbonaceous proper margin; hypothecium carbonaceous, black; paraphyses more or less confluent, ascus clavate, 8-spored; spores fusiform or acicular, 3-5-septate, colourless.

The thallus of the British species is effuse, rather thin, mostly furaceous, and light- or dark-grey. The spores resemble those of *Bilimbia*.

pothecia naked or dark-greenish-pruinose.

86. PLATYGRAPHA Nyl.—Thallus scanty or evanescent. Apothecia blackish, roundish, oblong or irregular, immarginate, but with a spurious thalline margin; spores 8 in the ascus, fusiform, septate, colourless; paraphyses slender, more or less discrete.

The genus is almost wholly confined to warm countries. The British species grow on trees.

Thallus whitish.

- Subleprose. Apo. various; sp. 3-sept., 30–
42 μ \times 3–4 μ . R. 1. *P. periclea* Nyl.
- Warted, areolate. Apo. various; sp. 3-
sept., 24–34 μ \times 3–4 μ . R. 2. *P. rimata* Nyl.

FAMILY XXIII. ARTHONIACEÆ.

Thallus crustaceous, thin, often developed beneath the bark (hypophloidal) or wanting. Algal cells *Trentepohlia* or (rarely) *Palmella*. Apothecia roundish or irregular, *ardelle*, or elongate, *lirella*; ascii short, pyriform, spores 4 to 8 in the ascus, colourless or brownish, septate or muriform; paraphyses branched above.

The family is distinguished by the flat immarginate apothecia by the short pyriform ascii, and by the epithecium formed from the branching paraphyses. Species of *Arthonia* are sometimes classified as fungi.

- Spores 1-many-septate 87. *Arthonia*.
- Spores septate and muriform 88. *Arthothelium*.

87. ARTHONIA Ach.—Thallus thin or evanescent, often hypophloidal. Algal cells *Trentepohlia* or *Palmella*. Apothecia innate, immarginate, roundish or irregular, *ardelle*, or elongate, *lirella*, plane or tumid; ascii pyriform or subglobose, rarely ellipsoid, thickened above; spores elongate-clavate, 1- or pluri-septate, colourless or brownish.

The apothecia are rather small, not prominent, and very various in form. The species are classified under three sections:—

Thallus with *Trentepohlia* gonidia.

- Apothecia more or less brightly coloured or brown § i. CONIOCARPON.
- Apothecia blackish § ii. EUARTHONIA.
- Thallus with *Palmella* gonidia § iii. LECIDEOPSIS.

§ i. CONIOCARPON A. Zahlbr.—Apothecia brightly coloured or brown becoming darker, K + violet or purple.

The species of this section grow on the bark of trees.

Spores 1-septate.

- Dark. Apo. reddish to reddish-black; sp.
10-15 μ \times 4-5 μ . C. 1. *A. lurida* Ach.
Var. *spadicea* Nyl.
- Apo. darker; sp. unequally divided.....
- Pale. Apo. vinous-red to dark; sp. 15-18 μ
 \times 6-8 μ . F. 2. *A. didyma* Koerb.
- Whitish. Apo. minute, reddish-black; sp.
12-15 μ \times 5-6 μ . R. 3. *A. atrofuscella* Nyl.

Spores 3-4-septate, the upper cell largest.

- Greyish. Apo. mostly red-pruinose; sp.
4-sept., 18-26 μ \times 7-9 μ . C. 4. *A. gregaria* Koerb.
Var. *astroides* Mudd.
Var. *kermesina* A. L. Sm
Var. *pruinata* A. L. Sm.
- Tinged purple. Apo. radiate. R.
- Th. and apo. deeply red-coloured. C.
- Th. and apo. whitish. F.
- Whitish. Apo. brown, elongate, stellate;
sp. as in *A. gregaria*. R. 5. *A. astroides* Nyl.
- Whitish. Apo. roundish, ochraceous-prui-
nose; sp. 3-sept., 15-18 μ \times 7-8 μ .
R. 6. *A. elegans* Ach.

§ ii. EUARTHONIA A. Zahlbr.—Apothecia blackish, K -.

In *Euarthonia* the thallus of the corticolous species is thin and more or less hypophloëodal. There are two saxicolous species with the thallus superficial and thicker.

*Spores 1-septate, wider at one end (corti-
colous).

- Yellowish, in patches. Apo. angular; sp.
14 μ \times 5.5 μ . R. 7. *A. aspersella* Leight.
- White. Apo. roundish or oblong; sp.
12-14 μ \times 4 μ . R. 8. *A. galactites* Duf.
- Pale spots. Apo. elongate; hym. I + blue;
sp. 10-13 μ \times 4-5 μ . R. 9. *A. dispersa* Nyl.
- Greyish. Apo. elongate; hym. I + wine-
red; sp. 16-21 μ \times 5-9 μ . R. 10. *A. excipienda* Croun.
- Filmy. Apo. roundish; sp. 29 μ \times 13 μ .
R. 11. *A. punctilliformis* Leight.

**Spores 3-6-septate, upper cell longest.

- Greyish-green. Apo. roundish or stellate;
sp. 3-sept., 13-15 μ \times 5-6 μ . Holly.
R. 12. *A. aspersa* Leight.
- Rose-cream-coloured. Apo. roundish; sp.
3-sept., 13-16 μ \times 6-7 μ . Rocks.
R. 13. *A. arthonioides* A. L. Sm.

- Greyish. Apo. radiate; sp. 2-4-sept.,
 $17-22 \mu \times 5-7 \mu$. Rocks. R. 14. *A. dendritica* A. L. Sm.
 Cream-coloured. Apo. roundish; sp. 6-
 sept., $21-36 \mu \times 9-12 \mu$. Holly.
 F. 15. *A. ilicina* Tayl.
- *** Spores 3-5-septate; cells equal in length
 (corticoloous).
- K+y, C+rose. Whitish or pale-yellow.
 Apo. pruinose; sp. 4-5-sept., $14-20 \mu$
 $\times 6-8 \mu$. F. 17. *A. pruinata* Stendel.
- Greyish. Apo. radiate or stellate; sp.
 3-sept., $12-20 \mu \times 4-6 \mu$. C. 18. *A. radiata* Ach.
 Apo. more irregular Var. *Swartziana* Sydow.
- Whitish or copper-coloured. Apo. round-
 ish; sp. 3-4-sept., $16-24 \mu \times 5-8 \mu$.
 R. 19. *A. punctiformis* Ach.
- Darker. F. Var. *melantera* Leight.
- Dark in colour. Apo. roundish; sp. 4-
 sept., $14-21 \mu \times 6-8 \mu$. R. 20. *A. insinuata* Stirton.

§ iii. LECIDEOPSIS Almq.—Algal cells Pahnellaceæ, or thallus wanting.
 Apothecia blackish.

* Thallus present.

† Spores 1-septate.

- Whitish. Apo. round or angular; sp.
 $9-15 \mu \times 3-5 \mu$. Trees. R. 21. *A. patellulata* Nyl.
 Dark-brown. Apo. roundish; sp. $11-16 \mu$
 $\times 5-6 \mu$. Cal. F. 22. *A. lapidicola* Br. & Rostr.

†† Spores 3-4-septate.

- Dark-grey. Apo. roundish; sp. large,
 $18-22 \mu \times 7 \mu$. Maritime rocks.
 R. 23. *A. paralia* Nyl.
 Pale-grey. Apo. minute; sp. small,
 $10-12 \mu \times 3-4 \mu$. Mica-schist.
 R. 24. *A. myriocarpella* Nyl.

** Thallus none (parasitic on other lichens).
 Spores often brownish.

- Apo. round, convex; sp. 1-3-sept.,
 $12-18 \mu \times 6-8 \mu$. Apothecia of
Lecanora glaucoma. F. 25. *A. varians* Nyl.
 Apo. minute, convex; sp. 1-sept.,
 $11-13 \mu \times 4-5 \mu$. Apothecia of
Lecanora glaucoma. R. 26. *A. subvarians* Nyl.
 Apo. minute, innate; sp. 1-sept., $15 \mu \times$
 6μ . *Rhizocarpon alboatrum*. R. 27. *A. punctella* Nyl.
 Apo. rather large, convex; sp. 1-sept.,
 $15-22 \mu \times 6-8 \mu$. *Peltigera* and
Solorina. R. 28. *A. peltigera* Th. Fr.

88. **ARTHOTHELIUM** Massal.—Thallus and apothecia somewhat similar
 to those of § *Euarthonia*. Spores ovate-ellipsoid or oblong, septate then
 nuriform, colourless or brownish.

The thallus of the two British species is thin and whitish; they are both corticolous, and rather rare, having been found only in southern and western districts.

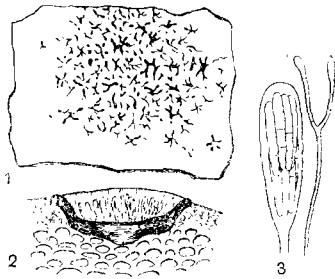

FIG. 60.—*Arthonia gregaria* var.
astroleidea Mudd.

1. Plant on bark. 2. Vertical section of apothecium $\times 40$. 3. Ascus with spores and paraphysis $\times 350$.

FIG. 61.—*Arthothelium spectabile*
Massal.

Ascus with spores $\times 350$.

- Apo. dark, small, roundish or minutely radiate;
sp. colourless, $21-27 \mu \times 10-15 \mu$ 1. *A. dispersum* Mudd.
Apo. dark, rather large, angular; sp. becoming
brown, $30-36 \mu \times 15 \mu$ 2. *A. spectabile* Massal.

FAMILY XXIV. GRAPHIDACEÆ.

Thallus crustaceous. Algal cells *Trentepohlia*, or rarely *Palmella*. Apothecia usually linear (*lirellæ*), rarely oblong or oval, simple or forked. sessile or erumpent, with a proper margin; ascii elongate-clavate; spores simple or variously septate or muriform, colourless or coloured.

Distinguished by the more distinctly lirellate marginate apothecia.

Thallus with *Palmella* gonidia. Apothecia oblong or oval.

Spores simple, colourless.

Hymenium simple.

Apothecia not carbonaceous..... 89. *Xylographa*.

Apothecia carbonaceous..... 90. *Lithographa*.

Hymenium compound 91. *Ptychographa*.

Spores 1-septate, brown..... 92. *Encephalographa*.

Thallus with *Trentepohlia* gonidia. Apothecia
elongate, rarely roundish.

Spores 1-septate, colourless or brown..... 93. *Melaspilea*.

Spores 3-pluri-septate.

Apothecia superficial 94. *Opegrapha*.

Apothecia innate-erumpent.

Spores septate, colourless 95. *Graphis*.

Spores septate, brown 96. *Phæographis*.

Spores muriform, colourless..... 97. *Graphina*.

89. **XYLOGRAPHA** Fr.—Thallus developed within the substratum. Algal cells *Palmella*. Apothecia innate-crumpent, lirelliform or irregularly oblong, not carbonaceous; the disc plane or concave; hypothecium pale; paraphyses slender; spores 8 in the ascus, simple, colourless.

Differs from other Graphidaceæ in the lighter coloured apothecia. British species grow on bark or on wood of conifers; they have only been recorded from Scottish Highland localities.

Thallus whitish, thin or evanescent.

- Scarcely visible. Apo. in parallel rows, with
 - a wide disc; hypoth. colourless; sp. $11-16 \mu$
 $\times 5-7 \mu$. S. 1. *X. parallela* Fr.
 - brown; sp. $12-15 \mu \times 7-8 \mu$. R. 2. *X. laricicola* Nyl.
 - With yellowish-green soredia. Apo. small,
 reddish; sp. $8-12 \mu \times 4-6 \mu$. R. 3. *X. spilomatrica* Th. Fr.

90. **LITHOGRAPHA** Nyl.—Thallus crustaceous, sometimes evanescent. Algal cells *Palmella*. Apothecia shortly lirellate, carbonaceous, the disc usually narrow, the margins prominent, inflexed; hypothecium usually dark-coloured; paraphyses mostly concrete; asci clavate, 8- or many-spored; spores simple, colourless.

*Spores 8 in the ascus.

Thallus light-coloured.

- K + y, then red. Th. thickish, Apo.
 rather prominent; sp. $8-15 \mu \times 5-8 \mu$.
 - Rocks. F. 1. *L. tesserata* Nyl.
 - Thickish. Apo. innate; sp. $8-9 \mu \times 5-6 \mu$. R. 3. *L. Andrewii* Stirz.
 - Thin. Apo. minute, superficial; sp. $4-6 \mu \times 2-3 \mu$. Stumps. R. 2. *L. flexella* Zahlbr.

**Spores many in the ascus.

Thallus thin, light or dark.

- Greyish. Apo. simple or furcate; sp. $5-8 \mu \times 3-4 \mu$. Trees. R. 4. *L. dendrographa* Nyl.
- Dark. Apo. congregate; sp. $3-4 \mu \times 1 \mu$. Maritime rocks. R. 5. *L. petræa* Nyl.

91. **PTYCHOGRAPHA** Nyl.—Thallus effuse. Algal cells *Palmella*. Apothecia elongate, compound, with 2-4 parallel hymenia; margins prominent, incurved; hypothecium black, carbonaceous; spores 8 in the ascus, simple, colourless.

A very rare genus, with one species, recorded only from the Scottish Highlands. It differs from *Lithographa* in the compound hymenia.

Thallus in thin greyish spots. Apo. in parallel

groups; sp. $11-14 \mu \times 6-7 \mu$.

On decorticated *Pyrus Aucuparia*. R. ... *P. xylographoides* Nyl.

92. **ENCEPHALOGRAPHA** Massal.—Thallus crustaceous. Algal cells *Palmella*. Apothecia sessile, usually in groups, elongate, roundish or angular, simple or forked, the disc usually narrow; hypothecium carbonaceous, black; spores 4-8 in the ascus, 1-septate, colourless to dark-brown.

Distinguished by the septate brown spores. The only British species is calcicolous and of rare occurrence.

Thallus thickish, tartareous, chalky-white.

Sp. $15-23 \mu \times 8-12 \mu$ *E. cerebrina* Massal.

93. MELASPILEA Nyl.—Thallus thin, sometimes immersed or wanting. Algal cells *Trentepohlia*. Apothecia black and carbonaceous, with a proper margin, roundish or elongate, simple or shortly branched, the disc narrow or flattened; hypothecium colourless or dark-coloured; paraphyses slender, free; asci elongate or narrowly clavate, 8-spored; spores ellipsoid, fusiform or ovate, usually 1-septate, colourless then brown.

The thallus is thin and often scarcely visible; the apothecia are mostly

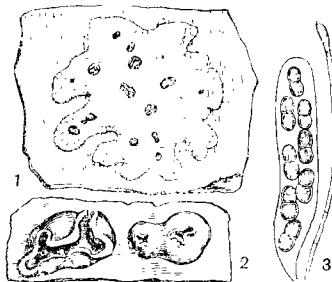

FIG. 62.—*Encephalographia cerebrina* Massal.

thallus and apothecium × 30. 3. Ascus
with spores and paraphysis × 200.

minute and irregular in form; the genus is mainly distinguished from others with *Trentepohlia* gomidia by the spores. In *M. cermifera* (parasitic on *Pertusaria globulifera*) the spores are recorded as cylindrical-vermiform and spirally arranged in the ascus; in *M. Patersoni* they are acicular-cylindrical and up to 10-septate; both seem to be aberrant species.

A. On trees.

, 94. **OPEGRAPHA** Humm.—Thallus crustaceous, developed under the bark or superficial, generally thin, sometimes wanting. Algal cells *Trentepohlia*. Apothecia (lirellae) black and carbonaceous, superficial, rarely innate, elongate or short and roundish, simple or branched with proper margins only; disc slit-like, rarely flattened: ascii broadly clavate or elongate, usually 8-spored; spores colourless or becoming brownish, linear-oblong, fusiform or acicular, 3-multi-septate.

The thallus of corticolous species is mainly developed below the bark (hypophloidal) and is generally visible as a thin film or stain of a whitish or brown colour; on rocks it often attains to greater superficial thickness. The lirellae are superficial (innate at first in *O. herpetica*), and are often variable so that spore characters are important in determination. Where not indicated the spores are fusiform.

*Spores 3- (rarely 4-) septate. Apothecia variable.

On trees, rarely on pales. Thallus immersed.

Apo. short, crowded, dilated in age; sp.
 17-27 $\mu \times 4-5 \mu$. F.

tened; sp. multi-septate. long.
Holly. R. 27. *O. involuta* Nyl.

95. **GRAPHIS** Adans.—Thallus crustaceous, developed under the bark or superficial. Algal cells *Trentepohlia*. Apothecia (lirellæ) mostly black and carbonaceous, elongate, rarely roundish, immersed then erumpent, simple or branched, the proper margins prominent, furrowed or even, hypothecium colourless or dark-coloured; asci clavate or elongate, usually 8-spored; spores colourless, elongate, pluriseptate, the cells transversely lenticiform.

The genus differs from *Opegrapha* in the generally larger lirellæ, but chiefly in the character of the spore cells. Most of the species are

corticulous. The furrows along the margins of some lirellae are due to new disc formations and become more distinct with age, they are sometimes difficult to determine. The lirellae of all the species vary in their arrangement on the thallus, in length, and in width of the disc. The spores may become brownish by degeneration.

 Thin. Apo. elongate; disc narrow; hypo. dark; sp. 30-45 μ \times 10-18 μ . F. 3. *G. Ruiziana* Muell.-Arg.

FAMILY XXV. CHIODECTONACEÆ.

Thallus crustaceous. Algal cells usually *Trentepohlia*. Apothecia aggregate in specialized prominent stroma-like portions of the thallus (verrucae), deeply immersed, immarginate, small and punctiform or elongate; asci elongate-clavate; spores elongate, pluri-septate, colourless or coloured.

Characterized by the arrangement and form of the apothecia. The family is well represented in tropical countries; in Great Britain there are only a few species in the following genera:—

- Apothecia immarginate.
 Hypothecium colourless or thinly black.
 Spores colourless 98. *Enterographa*.
 Spores brown 99. *Sclerophyton*.
 Hypothecium thick and black 100. *Chiodecton*.
 Apothecia marginate; spores colourless 101. *Glyphis*.

98. ENTEROGRAPHA Fée (*Stigmatidium*, Meyer).—Thallus crustaceous, thickish, limited by a black hypothallus. Apothecia aggregate in lines or solitary, roundish or shortly elongate, immarginate, deeply immersed in the verrucæ; hypothecium colourless or thinly black, paraphyses slender, branched; spores 8 in the ascus, elongate-fusiform, colourless, pluri-septate.

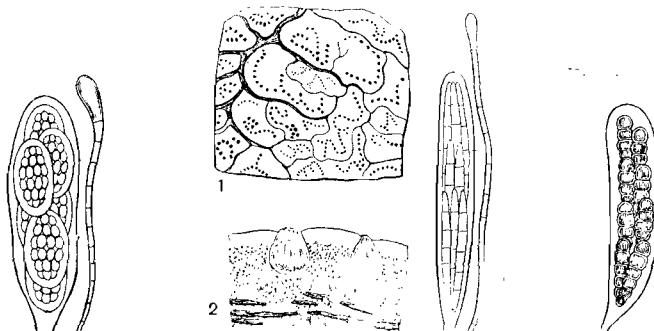

FIG. 66.—*Graphina anjuina* Muell.-Arg.
Ascus with spores and
paraphysis $\times 250$.

FIG. 67.—*Enterographa crassa* Fée.
1. Plant on bark. 2. Vertical section
of thallus and apothecia $\times 40$.
3. Ascus with spores and para-
physis $\times 375$.

FIG. 68.—*Sclerophyton cir-
cumscriptum* A. Zahlbr.
Ascus with spores
 $\times 300$.

The deeply immersed blackish fructifications sometimes resemble perithecia as the disc may be contracted to a small opening. The graphideine character is apparent in species with elongate apothecia. The species grow mostly on trees.

Thallus whitish to cream-coloured or brownish.

Verrucæ flat, wide spreading. Apo. punctiform, generally in lines; sp. 5-7-sept., $24-35 \mu \times 5 \mu$. Trees. C. 1. *E. crassa* Fée.

Thicker areolate thallus, f. *saxicola* Cromb. Rocks. R.

Verrucæ flat, small. Apo. small oblong, variable; sp. 5-7- (or more)-sept., $25-30 \mu \times 4 \mu$. Rocks, rarely trees. F. 2. *E. Hutchinsæ* Koerb.

Verrucæ thickish spreading. Apo. elongate; sp. up to 13-sept., $38-44 \mu \times 4 \mu$. Trees. R. 3. *E. venosa* Massal.

99. SCLERO PHYTON Eschw.—Thallus crustaceous. Apothecia roundish or elongate, thickly grouped, often confluent; hypothecium colourless; paraphyses slender, branched; asci clavate, 8-spored; spores elongate-clavate or fusiform, pluriseptate, brown.

Differs from *Enterographa* in the brown spores. In the single British species the fertile verrucæ are scarcely distinguishable from the thick deeply cracked thallus.

Thallus whitish, thick. Apo. punctiform, aggregate, solitary or in lines; sp. 4-7-sept. 1. *S. circumscriptum*, $20-25 \mu \times 5 \mu$. Rocks (not calcareous). F. A. Zahlbr.

100. **CHIODECTON** Ach.—Thallus crustaceous, whitish, thin or thickish. Apothecia black, immersed in the verruce, often confluent at the base; hypothecium thick, blackish-brown; paraphyses slender, branched; spores elongate, 2-pluri-septate, colourless.

Distinguished by the thick dark hypothecium. When several fruits are

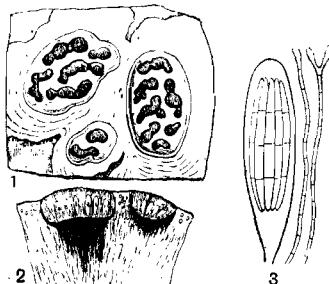

FIG. 69.—*Chiolecton albidum* Leight.

1. Plant on bark. 2. Vertical section of thallus and apothecia $\times 30$. 3. Ascus with spores and paraphysis $\times 250$.

confluent a stromatoid structure is formed. The British species are all rare, they grow in S. England, the Channel Islands or S. and W. Ireland.

On rocks.

Thin pulverulent. Sp. 3-sept., $30-40 \mu \times 5-6 \mu$... 1. *C. albidum* Leight.

Thick, cretaceous. Apo. pruinose; sp. $30-40 \mu$

$\times 3 \mu$ 2. *C. petraeum* Del.

Granular. Sp. oblong-clavate, 3-sept., $11-16 \mu$

$\times 3-5 \mu$ 4. *C. subdiscordans* Nyl.

On bark of myrtle and heath.

Granular or farinose. Sp. 2-3-sept., $36-48 \mu$

$\times 4 \mu$ 3. *C. myrticolum* Fée.

101. **GLYPHIS** Ach.—Thallus crustaceous with more or less prominent verrucæ. Apothecia immersed, roundish or elongate, simple or branched, with a dark margin; paraphyses simple; asci elongate, 4-8-spored; spores elongate, pluri-septate colourless.

Essentially a tropical genus. In the single British species (from Killarney) the thallus is whitish or brownish-olivaceous and thin, with white pulverulent verrucæ.

Apothecia slender, in reticulate lines; sp. 3-5-sept.,

$21 \mu \times 6.5 \mu$ *G. labyrinthica* Ach.

SERIES II. PYRENOCARPEÆ.

This series corresponds with Pyrenomycetes among fungi; the fruiting body is a closed peritheciun, mostly opening above by a pore or ostiole.

Perithecia solitary.

Thallus evident. Perithecia opening by a pore.

Algal cells Myxophyceæ.

Thallus minutely crustaceous, squamulose or fruticose

XXVI. PYRENIDIACEÆ.

Algal cells Chlorophyceæ.

Algeæ Protococcaceæ.

Thallus squamulose or foliose.....

XXVII. DERMATOCARPACEÆ.

Thallus crustaceous

XXVIII. VERRUCARIACEÆ.

Algeæ Trentepohliaceæ

XXIX. PYRENULACEÆ.

Thallus not evident. Perithecia without a pore

XXX. THELOCARPACEÆ.

Perithecia compound or united.

Perithecia in a common stroma

XXXI. TRYPETHELIACEÆ.

Perithecia in a common peridium

XXXII. MYCOPORACEÆ.

FAMILY XXVI. PYRENIDIACEÆ.

Thallus minutely crustaceous, squamulose or fruticose. Algal cells Myxophyceæ. Perithecia superficial or immersed; spores 4-8 in the ascus, simple or septate, colourless or coloured.

The family is poorly represented in the British Isles. *Pyrenidium* Nyl. is a doubtful genus. "*Lophothelium*" Stirt. formerly included has proved on examination to be the fungus, *Microthelia*, parasitic on the squamules of *Stercocaulon condensatum*. *Obryzum* is parasitic.

Thallus squamulose. Perithecia wanting 102. *Coriscium*.

Thallus minutely shrubby

103. *Pyrenidium*.

Thallus wanting

104. *Obryzum*.

102. CORISCUM Wainio.—Thallus squamulose, lower surface of loose straggling hyphae. Algal cells *Microcystis* (*Polycoccus* Kuetz.) occurring in compact crowded groups. Perithecia and spermogones unknown.

Formerly included in *Normandina*, but placed here because of the blue-green gonidia. There is only one widely distributed species, the thallus of which consists of crowded or scattered squamules, bluish-green, white below, rounded or neatly crenate-lobate, with pale upturned edges less or more than 2 mm. in diam.

On turf, soil, on mosses, in bogs, etc. C. C. *viride* A. Zahlbr.

103. PYRENIDIUM Nyl.—Thallus minutely fruticose, rising from a crustaceous base, with a distinct plectenchymatous cortex. Algal cells *Nostoc*. Perithecia innate, opening by a pore; spores oblong-ellipsoid, brownish, septate.

A monotypic genus recorded only from S. and S.W. England on cretaceous or calcareous pebbles. As has been suggested the peritheciun may be that of a fungus parasitic on a lichen, presumably a *Leptogium*.

Spores 3-septate, brownish, $20\text{--}24 \mu \times 8\text{--}9 \mu$... *P. actinellum* Nyl.

104. **OBRYZUM** Wallr.—Thallus none. Perithecia minute, globose, immersed in the tissue of the host-plant or almost superficial, opening above by a pore; paraphyses none; spores 8 in the ascus, fusiform, becoming 1- or more-septate, colourless.

The species of this genus are frequently classified among fungi. Abbé Vonaux has included the British species under *Sphaerulina*.

On *Leptogium*.

Perithecia immersed or superficial. Spores
guttulate, $16\text{--}21 \mu \times 5\text{--}6 \mu$ 1. *O. corniculatum* Wallr.

On *Collema*.

Perithecia projecting like minute golden
balls. Spores 3-5-sept., $23\text{--}27 \mu \times 4\text{--}5 \mu$ 2. *O. dolichoteron* Nyl.

FAMILY XXVII. DERMATOCARPACEÆ.

Thallus foliaceous, squamulose or suberustaceous, corticate on one or both surfaces, or non-corticate; under surface naked or with rhizina. Algal cells Protococcaceæ. Perithecia simple, more or less immersed in the thallus, opening by a pore at the apex. Spermatogones with short straight spermatia.

The thallus when foliose is thick and leathery. The perithecia of *Endocarpon* contain hymenial gonidia, which escape with the ascospores as in *Staurothele*.

Gonidia not present in hymenium.

Spores simple 105. *Dermatocarpon*.

Spores septate 106. *Normandina*.

Spores muriform 107. *Dacampia*.

Gonidia present in hymenium.

Spores muriform 108. *Endocarpon*.

105. **DERMATOCARPON** Eschw.—Thallus foliose or squamulose, corticate on both surfaces or on the upper surface only, sometimes with rhizina. Perithecia immersed in the thallus, globose or ovate, with a projecting ostiole: paraphyses usually mucilaginous and cohering, or sparingly developed and branched; spores 8-16 in the ascus, simple, colourless.

*Thallus foliose thickish, grey to brown.

Lobes mostly from one centre, simple or
massed. Peri. prominent. Damp
rocks. C.

1. *D. miniatum* Th. Fr.
Var. *leptophyllum* Dalla
Torre & Sarnth.

Lobes smaller. R.

Var. *complicatum* Th. Fr.

Lobes numerous, ascending. C.

Var. *variegatum* Th. Fr.

Lobes numerous, spreading. Peri. innate.

Rocks under water. F. 2. *D. aquaticum* A. Zahlbr.

Lobes minute, crisped and recurved.

Maritime rocks. R.

Var. *euploicum* A. L. Sm.

1. Plant from soil. 2. Vertical section of
thallus and perithecioid $\times 25$. 3. Ascus
with spores and paraphysis $\times 300$.

106. **NORMANDINA** Nyl.—Thallus squamulose, the squamules adnate, aised at the margins, non-corticate. Perithecia immersed; paraphyses wanting; spores cylindrical, pluri-septate, colourless, becoming brownish.

A monotypic genus, the single species being of very wide distribution but not very common. The rounded squamules, dainty and shell-like, spread over mosses on trees.

Flavous - greenish - grey. Spores 6-7-sept..

$28-40 \mu \times 6-10 \mu$ N. pulchella Cromb.

107. **DACAMPIA** Massal.—Thallus squamulose, spreading with a black ubiculum. Perithecia entire, blackish; paraphyses persistent, branched; elongate; spores ellipsoid-fusiform, variously septate and inuriform, brown.

In transverse section the white thallus contrasts strongly with the stout ark-brown hyphae of the subiculum. The perithecia rise from the subiculum. Dacampia is a mountain lichen; it is plentiful on the summit of Ben Lawers.

White, farinose, not corticate. Sp. 20-35 μ

$\times 10-12 \mu$ D. Hookeri Massal.

108. **ENDOCARPON** Hedw.—Thallus squamulose or almost crustaceous, corticate on both surfaces or on the upper only. Perithecia immersed,

containing hymenial gonidia; the ostiole more or less prominent; paraphyses mucilaginous, disappearing; spores 1-6 (usually 2) in the ascus, elongate-ellipsoid, muriform, brown.

Distinguished from *Dermatocarpon* by the hymenial gonidia and by the muriform spores which in all the species measure up to $55 \mu \times 19 \mu$. The species grow on soil or on mud walls.

Sq. brown, small, closely appressed, scattered.

Ostiole black 1. *E. pusillum* Hedw.

Sq. brown, rather larger and lobed. Ostiole powdery with soredia 2. *E. sorediatum* Hook.

Sq. pale-brown, minute, crowded imbricate. Ostiole black 3. *E. pallidum* Ach.

FAMILY XXVIII. VERRUCARIACEÆ.

Thallus crustaceous, superficial or developed within the substratum, not corticate. Algal cells *Protococcaceæ*, sometimes present in the hymenium. Perithecia simple, globose or semi-globose, more or less immersed, opening by a pore at the apex (ostiole); asci 2-8-spored; paraphyses disappearing

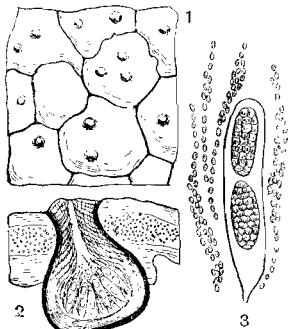

FIG. 73.—*Endocarpon pusillum* Hedw.
1. Portion of plant \times ca. 12. 2. Vertical section of thallus and perithecium \times 50. 3. Ascus with spores and hymenial gonidia \times 210.

in mucilage or persistent. Spermogones with septate sterigmata and oblong or ellipsoid pleurogenous spermatia.

Distinguished by the crustaceous thallus, bright-green gonidia and simple perithecia.

Gonidia not present in hymenium.

Paraphyses disappearing.

Spores simple, ellipsoid 109. *Verrucaria*.

Spores simple, vermiciform 110. *Sarcopyrenia*.

Spores 1-3-septate 111. *Thelidium*.

Spores muriform 112. *Polyblastia*.

Paraphyses persistent.

- Spores simple 113. *Thrombium*.
- Spores multi-septate 114. *Gongylia*.
- Spores muriform 115. *Microglæna*.

Gonidia present in hymenium.

- Spores muriform 116. *Staurothele*.

109. VERRUCARIA Pers.—Thallus crustaceous, continuous, areolate or pulverulent, sometimes developed within the substratum. Perithecia moderate in size (about .5 mm. in diam.), smaller or larger, immersed or superficial, the outer wall or peridium carbonaceous or horny, completely surrounding the perithecium (entire) or developed only over the upper part (dimidiate), frequently thickish above and thin below, opening above by a pore or slit (ostiole); paraphyses soon becoming mucilaginous and disappearing; filaments within the ostiole (periphyses) often well developed; asci 8-spored; spores ellipsoid or subglobose, colourless, rarely brownish.

The species are almost exclusively saxicolous; those on limestone or mortar penetrate the substratum more or less, and the perithecia may be formed in pits scooped out from the rock (foveolate). Many of the species grow in moist places in or near streams; others grow by the sea-shore, often within reach of the waves. The records of lignicolous species in this and the following genera are doubtful. Spore-sizes have been given, as they are helpful in determination.

A. Maritime species. Thallus more or less gelatinous when moist.

- Brownish-black, finely areolate. Peri. semi-immersed; sp. 12–17 μ \times 7–8 μ . C. 1. *V. maura* Wahlenb. •
- Th. not areolate; sp. longer and narrower.
R. Var. *memonia* Koerb. •
- Dark-olive or -green, gelatinous, thick. Peri. immersed; sp. 7–10 μ \times 5–6 μ . F. 2. *V. mucosa* Wahlenb. •
- Dark-olive, gelatinous, thin. Peri. more prominent, shining; sp. 7–10 μ \times 4–5 μ . F. 3. *V. microspora* Nyl.
- Blackish-green, thin. Peri. minute, prominent; sp. 15–18 μ \times 2–4 μ . R. 3a. *V. Lorrain-Smithiae* Knowl.
- Dark shining ridges. Peri. minute, sessile; sp. 8–9 μ \times 4–5 μ . R. 4. *V. striatula* Wahlenb.
- Th. more continuous with scattered dots and ridges f. *continua* Knowl.
- Dark-brown, scabrid. Peri. prominent; sp. 10–17 μ \times 5–9 μ . R. 5. *V. scotina* Wedd.
- Greenish-white, tartareous. Peri. prominent, large; sp. 18–20 μ \times 7–10 μ . R. 36. *V. prominula* Nyl.

B. Aquatic species growing in or near streams or lakes. Thallus sub-gelatinous.

Thallus dark, mostly olivaceous, brown or black. •

Thin, continuous. Peri. minute almost immersed; sp. subglobose, 6–8 μ \times 5–7 μ . R.

Thin or thickish, smooth. Peri. semi-immersed; sp. 19–26 μ \times 8–18 μ . S.

- 6. *V. aquatilis* Mudd. •

- 9. *V. hydrela* Ach. •

- Deeply cracked. Peri. semi-immersed; sp. $18\text{--}24 \mu \times 10\text{--}11 \mu$. F. 10. *V. levata* Ach.
 Thickish, smooth. Peri. semi-immersed; sp. $17\text{--}20 \mu \times 5\text{--}7 \mu$. R. 11. *V. degenerascens* Nyl.
 Thin, smooth. Peri. emerging; sp. $24\text{--}35 \mu \times 10\text{--}16 \mu$. S. 12. *V. margacea* Wahlenb.
 Reddish-grey, less gelatinous. Peri. almost sessile; sp. $30\text{--}35 \mu \times 12\text{--}15 \mu$. R. 13. *V. latebrosa* Koerb.
 Olive, thin, cracked when dry. Peri. entire, emerging; sp. $14\text{--}24 \mu \times 6\text{--}10 \mu$. F. 14. *V. aethiobola* Wahlenb.
 Thallus evanescent. R. Var. *acrotella* A. L. Sm.
 Greenish, then dark. Peri. dimidiate, emerging; sp. $15\text{--}24 \mu \times 6\text{--}10 \mu$. F. 15. *V. submersa* Schär.
 Greyish, areolate. Peri. on a slight elevation; sp. $18\text{--}24 \mu \times 6\text{--}10 \mu$. F. 16. *V. papillosa* Ach.

C. Species in dry situations—on mortar, walls or rocks.

- *Thallus effuse, cracked-areolate, thickish.
 Pale, or olive-brown. Peri. large, emergent; sp. $18\text{--}35 \mu \times 10\text{--}17 \mu$. C. 17. *V. viridula* Ach.
 Tawny-brown, subsquamulose. Peri. large, ostiole emergent; sp. $25\text{--}35 \mu \times 12\text{--}20 \mu$. F. 19. *V. macrostoma* DC.
 . **Thallus determinate, dark.
 Thin, cracked or uneven. Peri. emergent; sp. $15\text{--}24 \mu \times 5\text{--}9 \mu$. Mostly limestone. C. 23. *V. nigrescens* Pers.
 Very thin, subsMOOTH. Peri. small; sp. $16\text{--}22 \mu \times 8\text{--}10 \mu$. Mostly sand-stone. S. 24. *V. mauroides* Schär.
 Thickish, very dark; sp. $18\text{--}24 \mu \times 10\text{--}12 \mu$. On granite (not British). 25. *V. cataleptoides* Nyl.
 Bright ochraceous-red, areolate. Cal. R. f. *ferruginosa* Lamy.
 ***Thallus determinate, light-coloured. Calcicolous.
 Bluish, greyish or greyish-brown, thick, faintly cracked. Peri. small; sp. $14\text{--}19 \mu \times 4\text{--}7 \mu$. S. 26. *V. coerulea* DC.
 Mouse-grey, thin, determinate or effuse. Peri. small; sp. $18\text{--}24 \mu \times 6\text{--}12 \mu$. R. 27. *V. murina* Leight.
 Umber-brown, finely cracked. Peri. minute; sp. small, $12 \mu \times 4 \mu$. R. 28. *V. pinguicula* Massal.
 Greyish-brown, cracked. Peri. prominent; sp. $11\text{--}15 \mu \times 5\text{--}6 \mu$. R. 29. *V. peloclita* Nyl.
 ****Thallus determinate, with mosaic-like areole. Calcicolous.
 Lead-grey, thickish. Peri. sometimes confluent; sp. $10\text{--}20 \mu \times 5\text{--}8 \mu$. F. 30. *V. glaucina* Ach.

- Dark-greyish-brown, thickish. Peri.
scarcely visible; sp. $11-16 \mu \times$
 $4-6 \mu$. S. 31. *V. fuscella* Ach.
- ***** Thallus membranaceous, continuous,
'smooth. On calcareous rocks, flints
and stones.
Very thin, spot like, dark-brown. Peri.
small, immersed; sp. $14-24 \mu \times$ 32. *V. maculiformis* Krem-
 $6-10 \mu$. S. pelh.
- Thin, like a dark oily stain. Peri. pro-
minent; sp. $8-12 \mu \times 5-7 \mu$. R.. 33. *V. mutabilis* Borr.
- ***** Thallus tartareous, light-coloured. Cal-
cicolous.
† Perithecia not forming pits.
Thin, smooth, determinate. Peri.
prominent; sp. $15-22 \mu \times 6-10 \mu$.
F. 34. *V. Dufourii* DC.
- Tartareous, brownish (*see* maritime
species) 36. *V. prominula* Nyl.
Sp. almost globose, $10-12 \mu \times$
 $7-9 \mu$ Var. *viridans* Nyl.
Sp. $14-17 \mu \times 6-7 \mu$ Var. *minor* A. L. Sm.
- Thin, limited by wide blackish lines.
Peri. minute; sp. $12-14 \mu \times 6 \mu$.
R. 37. *V. limitata* Krempehl.
- Whitish. Peri. small, semi-im-
mersed; sp. $17-25 \mu \times 10-12 \mu$.
C. 38. *V. muralis* Ach.
- †† Perithecia forming pits in the rocks
(foveolate).
Peri. wall dimidiate; sp. $18-30 \mu \times$
 $8-13 \mu$. C. 39. *V. rupestris* Schrad.
Peri. wall entire, spreading at base;
sp. $23-32 \mu \times 10-20 \mu$. F. 40. *V. integra* Carroll.
Th. tinged rose. Peri. entire, in deep
pits; sp. $24-36 \mu \times 10-15 \mu$. S. 41. *V. dolomitica* Massal.
Th. tinged rose. Peri. emerging; sp.
 $18 \mu \times 9 \mu$ (doubtfully British) 42. *V. marinorae* Zahlbr.
Th. ashy-grey, thin. Peri. minute,
entire; sp. $12-17 \mu \times 5-7 \mu$. R. 43. *V. parva* Deakin.
Th. thin whitish. Peri. fissured
above; sp. $15-21 \mu \times 8-10 \mu$.
F. 44. *V. calcicola* DC.

110. **SARCOPYRENIA** Nyl.—Thallus crustaceous. Perithecia simple,
scattered, with a black peridium, opening by an ostiole; paraphyses dis-
appearing; asci oblong-clavate, soon disappearing, 8-spored; spores one-
celled, colourless, cylindrical-vermiform, slightly flexuose or twisted in the
middle, the ends clavate.

Only one species has been recorded:—

- Th. thin, yellowish-grey. Sp. $30-40 \mu \times 3-4 \mu$.
Sandstone. R. *S. gibba* Nyl.

III. THELIDIUM Massal.—Thallus variously crustaceous, uniform, sometimes wanting. Perithecia black, simple, superficial or immersed, entire or dimidiate, with a simple ostiole; paraphyses mucilaginous, soon disappearing; asci usually somewhat large and saccate, 8-spored; spores ellipsoid or ovoid, usually rather large. 1-3 septate, colourless or sometimes brownish.

Thallus and perithecia are similar in form and size to those of *Verrucaria*, the distinguishing feature is the septation of the spores. The species

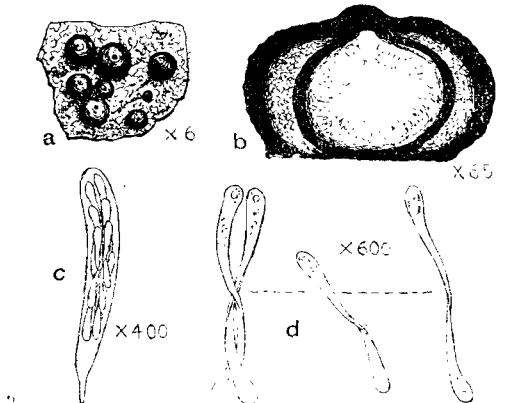

FIG. 75.—*Sarcopyrenia gibba* Nyl.
a. Plant on rock $\times 6$. b. Vertical section of perithecium $\times 65$.
c. Ascus with spores $\times 400$. d. Spores $\times 600$.

are saxicolous or terricolous, and are rather rare, or have been overlooked.

*Spores 1-septate.

On calcareous rocks.

Peri. rather large, not forming pits; sp. 1. Th. pyrenophorum
 $20-32 \mu \times 10-18 \mu$. S. Massal.

Peri. forming pits; sp. $25-38 \mu \times 12-17 \mu$.
S. 3. Th. immersum Mudd.

On siliceous rocks, perithecia rather small.
Thin, pale; sp. $12-17 \mu \times 5-6 \mu$. R. 2. Th. mesotropum A. L. Sm.

Thin, greyish green; sp. $22-30 \mu \times 9-12 \mu$.
R. 4. Th. Nylanderii Krempelh.

On soil among mosses.

Thin, green or dark; sp. $16-28 \mu \times 7-11 \mu$. R. 4a. Th. terrestre Wats.

**Spores 3-septate.

On calcareous rocks.

Peri. minute, superficial; sp. $26-32 \mu \times 7-12-14 \mu$. R. 7. Th. mierocarpum A. L. Sm.

Peri. larger, forming pits; sp. $35-53 \mu \times 12-21 \mu$. R. 8. Th. incavatum Mudd.

On siliceous rocks.

- Peri. small; sp. $21\text{--}32 \mu \times 10\text{--}15 \mu$. Stones
in streams. R. 5. *Th. cataractarum* Mudd.
- Peri. larger; sp. $35\text{--}50 \mu \times 15\text{--}20 \mu$. Damp
rocks. F. 6. *Th. papulare* Arn.

112. **POLYBLASTIA** Massal.—Thallus variously crustaceous, sometimes developed within the substratum. Perithecia simple, superficial or immersed; ostiole a simple pore; paraphyses mucilaginous, disappearing; ascii broadly clavate, 1-8-spored; spores large, ellipsoid, muriform, colourless or dark-coloured.

Resembling *Verrucaria* in thallus and perithecia, but differing in spore

FIG. 76.—*Thelidium pyrenophorum* Koerb.
Ascus with spores $\times 300$.

FIG. 77.—*Polyblastia theleoides* Th. Fr.
Ascus with spores and paraphysis
 $\times ca. 65$.

characters. The spores may vary greatly in size and form and in septation. The species grow on rock, or soil, or on mossy earth. They are all rather rare.

*Spores colourless.

On calcareous or siliceous rocks.

- Peri. moderate, prominent; sp. $24\text{--}42 \mu \times 15\text{--}21 \mu$ 1. *P. intercedens* Lönnr.
- Peri. small, crowded; sp. $18\text{--}28 \mu \times 11\text{--}16 \mu$ 3. *P. fuscoargillacea* Anzi.
- Peri. moderate; sp. $40\text{--}50 \mu \times 16\text{--}20 \mu$
(on mortar) 10a. *P. mortensis* Wats.

**Spores becoming brownish.

On calcareous rocks (forming pits).

- Peri. moderate or small; sp. $40\text{--}45 \mu \times 12\text{--}17 \mu$ 4. *P. Schraderi* A. L. Sm.
- Peri. small; sp. $22\text{--}30 \mu \times 12\text{--}15 \mu$ 5. *P. deminuta* Arn.

On siliceous rocks.

- Peri. mostly moderate, papillate; sp. $38\text{--}62 \mu \times 17\text{--}32 \mu$ 6. *P. inumbrata* A. L. Sm.

On mossy earth. Thallus variable.

- Whitish granular. Peri. minute; sp. $15\text{--}30 \mu \times 9\text{--}14 \mu$ 9. *P. Sendtneri* Krempelh.
- Dark-brown, gelatinous. Peri. prominent; sp. $30\text{--}45 \mu \times 12\text{--}21 \mu$ 10. *P. gelatinosa* Th. Fr.
- Greenish - olivaceous. Sp. $40\text{--}50 \mu \times 16\text{--}20 \mu$ 10a. *P. mortensis* Wats.
- Brown. Sp. mostly 2 in the ascus, $60\text{--}132 \mu \times 21\text{--}51 \mu$ 11. *P. tristicula* Th. Fr.

- *** Spores becoming dark-brown.
- On siliceous rocks. Perithecia rather large.
- Thickish, wrinkled. Peri. semi-immersed; sp. $60-84 \mu \times 24-45 \mu$... 12. *P. theleodes* Th. Fr.
- Thinner and gelatinous. In streams f. *inundata* Th. Fr.
- Thin. Peri. sessile; sp. $26-40 \mu \times 13-21 \mu$ 13. *P. scotinospora* Hellb.
- Th. thin. Peri. immersed; sp. $46-56 \mu \times 23-33 \mu$ 14. *P. Henscheliana* Lönne.
- On mossy earth.
- Black. Peri. small; sp. $21-36 \mu \times 9-14 \mu$ 15. *P. nigritella* A. L. Sm.
- Greenish or dark. Peri. small; sp. $18-28 \mu \times 7-9 \mu$ 16. *P. gothica* Th. Fr.

113. **THROMBIUM** Wallr.—Thallus crustaceous, uniform, sometimes developed within the substratum or altogether wanting. Perithecia simple, immersed or superficial, light- or dark-coloured, with a poriform ostiole; paraphyses persistent, slender, branched; spores 4-8 in the ascus, ellipsoid, simple, colourless or brownish.

A small genus of rare lichens, differing from *Verrucaria* in the persistent paraphyses. The spores are fairly small.

On rocks.

- Bright-green, thickish gelatinous. Peri. immersed. Maritime 1. *Thr. heterovires* A. L. Sm.
- Reddish-brown, thin. Peri. sessile. On whinstone. 3. *Thr. thelostomum* A. L. Sm.

On soil.

- Pale, gelatinous when moist. Peri. small, immersed 2. *Thr. epigaeum* Wallr.

114. **GONGYLIA** Koerb.—Thallus crustaceous. Perithecia almost sessile, soft in texture, bright- or dark-coloured, with a poriform ostiole; paraphyses slender, free; spores 4-8 in the ascus, acicular, straight or somewhat bent, colourless, multisepitate.

A small genus with few representatives in Europe. The ostiole tends to widen out at maturity so that the perithecia seem to become almost disciform.

On sandy soil.

- Bright-green. Peri. shining black; sp. $60-85 \mu \times 2-3 \mu$. R. 1. *G. viridis* A. L. Sm.

115. **MICROGLAENA** Koerb.—Thallus crustaceous. Perithecia immersed or almost free; paraphyses persistent, branched; spores 2-8 in the ascus, ellipsoid, muriform, colourless or brownish.

Similar to *Polyblastia* in spore characters but differing in the persistent paraphyses. The perithecia are black or brown above and nearly always paler below. The thallus is variable in colour and thickness. None of the species are frequent.

On trees.

- Whitish, thin. Peri. immersed; sp. $19-38 \mu \times 11-18 \mu$ 1. *M. modesta* A. L. Sm.

On rocks.

- Pale-yellow, in fragments. Peri. small, almost sessile; sp. $18-20 \mu \times 10 \mu$. 1a. *M. breadalensis* Wheld. & Wils.
- Yellowish-brown, thick. Peri. immersed; sp. $30-46 \mu \times 12-16 \mu$ 2. *M. isidioides* A. L. Sm.
- Whitish granular. Peri. immersed; sp. $18-22 \mu \times 7-11 \mu$ (alpine). 3. *M. corrosa* Arn. var. *nericiensis* A. L. Sm.
- Greyish granules. Peri. minute, sessile; sp. $16-20 \mu \times 6-8 \mu$ (on pebbles) 3a. *M. nuda* Wheld. & Trav.
- Brownish mucilaginous. Peri. immersed; sp. $50-55 \mu \times 10 \mu$. 4. *M. Larbalestierii* A. L. Sm.
- On the ground, on mosses, etc.
- Th. whitish. Peri. immersed; sp. $50-60 \mu \times 15-17 \mu$ 5. *M. Holliana* A. L. Sm.

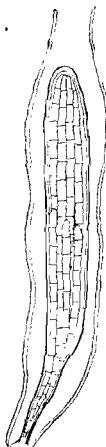

FIG. 78.—*Gongylia viridis* A. L. Sm.
Ascus with spores and paraphyses $\times 300$.

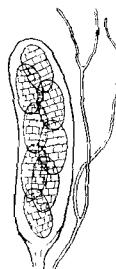

FIG. 79.—*Microglena modesta* A. L. Sm.
Ascus with spores and paraphysis $\times 300$.

116. STAUROTHELE Norm.—Thallus crustaceous, sometimes developed within the substratum. Perithecia simple, with poriform ostioles, and with hymenial gonidia; paraphyses mucilaginous, disappearing; spores 1-8 in the ascus, large, ellipsoid, muriform, colourless or brown.

Distinguished from other Verrucariaceæ by the presence of algal cells within the peritheciun alongside the ascii, in this respect resembling *Endocarpon*. The algal cells are ejected along with the spores, and a new thallus is thus readily formed. The species are saxicolous and more or less rare.

Spores colourless, 8 in the ascus. Thallus white to brown.

- Whitish. Peri. prominent; sp. $18-34 \mu \times 11-17 \mu$. Sil. & Cal. 1. *St. hymenogonia* A. Zahlbr.

Spores brown, 1-2 in the ascus.

On rocks in or near water.

Brownish, thin. Ostioles projecting; sp.

$45-50 \mu \times 18-20 \mu$ 2. *St. umbrina* A. L. Sm.

Brown, thickish. Ostioles depressed; sp.

$32-53 \mu \times 12-23 \mu$ 3. *St. elopima* Th. Fr.

Spores brown, 4-8 in the ascus.

On calcareous rocks. Perithecia in pits
(foveolate).

Whitish, bluish-grey or smoky-brown;

sp. $36-55 \mu \times 12-20 \mu$ 4. *St. rupifraga* Arn.

FAMILY XXIX. PYRENULACEÆ.

Thallus crustaceous, superficial or developed within the substratum, not corticate. Algal cells *Trentepohlia*. Perithecia simple, globose or semi-globose, more or less immersed, opening by a pore at the apex (*ostiole*). Spermogones globose or ovoid, with simple or sparingly branched sterigmata and acrogenous spermatia.

Distinguished by the yellowish filamentous gonidia and also by the more constantly persistent paraphyses. The following genera are found in the British Isles:—

*Perithecia scattered, simple.

†Paraphyses branched, entangled or rarely wanting.

Asci cylindrical; spores uniseriate.

Spores 1-septate 117. *Acrocordia*.

Asci clavate or ovate, spores more or less massed.

Spores colourless.

Spores elongate-fusiform, 1-5-septate 118. *Arthopyrenia*.

Spores acicular, multi-septate 119. *Leptorhaphis*.

Spores brown.

Spores 1-5-septate 120. *Microthelia*.

††Paraphyses unbranched, distinct.

Spores colourless, 1-5-septate.

Spores 8 in the ascus 121. *Porina*.

Spores many in the ascus 122. *Thelopsis*.

Spores brown.

Spores 1-5-septate, with short cells 123. *Pyrenula*.

**Perithecia often united.

Spores brown, muriform 124. *Anthracothecium*.

117. **ACROCORDIA** Massal.—Thallus crustaceous. Perithecia simple, globose or somewhat conical, black, semi-immersed; paraphyses persistent, slender, branched and entangled; asci cylindrical, 8-spored; spores uniseriate in the ascus, ellipsoid, 1-septate, colourless.

Distinguished by the elongate asci with the spores in a single row. The spores are broadly ellipsoid, except in *A. monensis*. The perithecia are entire or dimidiate, with the wall sometimes spreading at the base.

On trees.

- Peri. prominent, large; sp. $15-29 \mu \times 7-13 \mu$. C. 1. *A. gemmata* Koerb.
- Peri. prominent, small; sp. $12-16 \mu \times 5-7 \mu$. C. 2. *A. biformis* Oliv.
- On calcareous rocks or on mortar of walls.
- Peri. dimidiate, spreading; sp. $15-23 \mu \times 7-9 \mu$. F. 3. *A. epipokaea* A. L. Sm.
- Peri. entire; sp. $18-21 \mu \times 8-11 \mu$ 4. *A. Salweii* A. L. Sm.
- Peri. entire; sp. fusiform-ellipsoid, $20-33 \mu \times 6-10 \mu$. R. 5. *A. monensis* Wheld.

118. ARTHOPYRENIA Massal.—Thallus crustaceous. Perithecia simple, dark-coloured, mostly semi-immersed, globose or semi-globose; paraphyses branched and entangled, rarely mucilaginous and disappearing; asci elongate-ovate, 2-8-spored; spores elongate-ellipsoid, more or less constricted in the middle, 1- or more-septate, colourless.

When growing on the bark of trees the thallus is immersed (hypop-

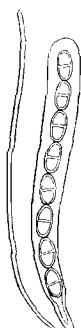

FIG. 80.—*Acrocordia gemmata* Koerb.

Ascus with spores and paraphysis $\times 210$.

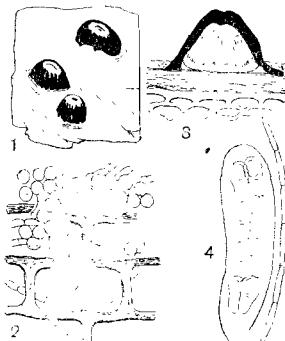

FIG. 81.—*Arthopyrenia fallax* Arn.

phloidal), appearing mostly as a stain on the surface, with the perithecia dimidiate. On rocks there is sometimes a more superficial thallus, and the perithecia may be dimidiate or entire. The species were formerly included under *Verrucaria*.

* Spores 1-septate; cells equal or unequal.

A. Growing on trees.

† Thallus mostly light-coloured. Perithecia dimidiate; paraphyses entangled, often indistinct.

Peri. scattered; sp. cells equal, $15-24 \mu \times 4-7 \mu$. C. 1. *A. epidermidis* Mudd.

- Peri. scattered; sp. cells almost equal,
 $14\text{--}17 \mu \times 3\text{--}5 \mu$. C. 2. *A. punctiformis* Arn.
- Peri. often in groups; sp. clavate, $15\text{--}25 \mu$
 $\times 4\text{--}6 \mu$. R. 3. *A. pyrenastrella* Oliv.
- Peri. immersed, pruinose; sp. cells con-
stricted, $15\text{--}22 \mu \times 5\text{--}7 \mu$. F. 4. *A. cinereopruinosa*
Koerb.
- ††Thallus light- or dark-brown. Paraphyses
various.
- Paraph. entangled; sp. cells equal,
 $16\text{--}22 \mu \times 7 \mu$. F. 5. *A. analepta* Massal.
- Paraph. distinct, free; sp. cells unequal,
 $16\text{--}22 \mu \times 7\text{--}9 \mu$. C. 6. *A. fallax* Arn.
- Paraph. indistinct; sp. often brownish,
tapering, $27\text{--}40 \mu \times 7\text{--}10 \mu$. C. 7. *A. stigmatella* A. L. Sm.
- Paraph. lax or coherent; sp. several-
guttulate, $23\text{--}35 \mu \times 6\text{--}7 \mu$. R. 8. *A. analeptoides*
A. L. Sm.
- Paraph. branched, free; sp. fusiform,
 $15 \mu \times 4 \mu$. R. 9. *A. byssacea* A. L. Sm.
- †††Thallus always rather dark-coloured.
- Smooth. Sp. cells almost equal, $20\text{--}25 \mu$
 $\times 4\text{--}5 \mu$. R. 10. *A. Laburni* Sydow.
- Filmy or rough. Sp. $13\text{--}17 \mu \times 3\text{--}5 \mu$.
On *Graphis* sp. R. 11. *A. microspila* Koerb.
- Irregular spots. Sp. $25\text{--}30 \mu \times 4\text{--}5 \mu$.
Rare. 12. *A. Taylori* Mudd.
- Definite black spots. Sp. $20\text{--}35 \mu$
 $\times 5\text{--}7 \mu$, becoming brown. R. 13. *A. aphorisasa* A. L. Sm.
- B. Growing on rocks, sand or soil or on mosses.
- Thallus superficial.
- Thin, greyish. Sp. $20\text{--}21 \mu \times 5 \mu$. Sil. R. 14. *A. saxicola* Massal.
- Thin, dark. Sp. $15\text{--}20 \mu \times 5\text{--}8 \mu$. Sil. R. 15. *A. spilobola* A. L. Sm.
- Thin, olive-green. Sp. $21\text{--}22 \mu \times 8 \mu$. Wet
sand-banks. R. 16. *A. arenicola* A. L. Sm.
- Grey, granular. Sp. broader upwards, $32\text{--}37 \mu$
 $\times 10 \mu$. Damp sandy shores. R. 17. *A. areniseda* A. L. Sm.
- Thin, blackish. Sp. $27\text{--}44 \mu \times 8\text{--}12 \mu$.
Mosses and soil. R. 18. *A. bryospila* A. L. Sm.
- Thin, black. Sp. $32\text{--}45 \mu \times 10\text{--}13 \mu$. Moss. R. 20. *A. collecta* A. L. Sm.
- Wanting. Sp. $23\text{--}37 \mu \times 7\text{--}9 \mu$. Parasitic
on *Rhizocarpon*. R. 19. *A. allogena* A. L. Sm.
- C. On rocks or shells by the sea. (Spores rarely 3-septate in *A. marina*.)
- Thallus immersed or evanescent.
- Peri. semi-immersed. Sp. $12\text{--}19 \mu \times 5\text{--}7 \mu$.
Shells or rocks. F. 21. *A. litoralis* A. L. Sm.
- Peri. leaving pits. Sp. $15\text{--}18 \mu \times 6\text{--}7 \mu$.
Shells. R. 22. *A. foveolata* A. L. Sm.
- Thallus superficial on rocks.
- Dark-green, subgelatinous. Sp. subclavate,
 $16\text{--}18 \mu \times 5 \mu$. R. 23. *A. leptotera* A. L. Sm.

- Thin, black, subgelatinous. Sp. subclavate, 24. *A. halodytes* var.
 $13\text{--}15 \mu \times 5\text{--}7 \mu$. R. *Hollii* A. L. Sm.
- Thin, pale-green. Sp. subclavate, $10\text{--}12 \mu \times 5\text{--}7 \mu$. S. 25. *A. halizoa* A. L. Sm.
- Thin, greenish. Sp. oblong, $17\text{--}19 \mu \times 6\text{--}7 \mu$. R. 26. *A. viridula* A. L. Sm.
- Dark-green, subgelatinous. Sp. 3-sept. when mature, $9\text{--}14 \mu \times 3\text{--}5 \mu$. R. 27. *A. marina* A. L. Sm.

**Spores 3-septate.

- On trees. Thallus thin. Perithecia dimidiate; paraphyses scanty or none.
- Dark. Peri. hemispherical; sp. $18\text{--}22 \mu \times 4\text{--}5 \mu$. S. 28. *A. rhypontha* Massal.
- Grey or brown. Peri. elliptical; sp. $15\text{--}25 \mu \times 4\text{--}8 \mu$. Cherry. R. 29. *A. Cerasi* Massal.
- Yellow to brown. Peri. hemispherical; sp. oblong-clavate, $20\text{--}22 \mu \times 5\text{--}6 \mu$.
- Alder. R. 30. *A. Crombiei* A. L. Sm.
- Yellow to brown. Peri. hemispherical; sp. linear, $16\text{--}22 \mu \times 4\text{--}6 \mu$. S. 31. *A. submicans* A. L. Sm.

***Spores 3-7-septate.

- On trees. Thallus various. Paraphyses scanty or none.
- Th. thin, brownish-yellow. Peri. depressed; sp. becoming brown, $23\text{--}30 \mu \times 9\text{--}11 \mu$. R. 32. *A. platypyrenia* A. L. Sm.
- Th. thickish, granular. Sp. fusiform, $30\text{--}37 \mu \times 4\text{--}5 \mu$. Mossy tree. R. 33. *A. chlorococca* A. L. Sm.
- Th. scanty. Sp. fusiform, $11\text{--}16 \mu \times 3\text{--}4 \mu$. Trees. R. 34. *A. desistens* A. L. Sm.

119. LEPTORAPHIS Koerb.—Thallus crustaceous, thin. Perithecia simple, globose or semi-globose, black, immersed; paraphyses persistent, branched and entangled; ascii cylindrical, 4-8-spored; spores acicular-fusiform, straight or bent, 1-pluri-septate, colourless.

Distinguished by the form of the spores and by the more evident paraphyses. The genus is of wide distribution, but is more fully represented in tropical regions. The species all grow on trees.

- Light-coloured. Sp. 1-5-septate. $20\text{--}37 \mu \times 3\text{--}4 \mu$. F. 1. *L. epidermidis* Th. Fr.
- Brownish. Sp. indistinctly multi-septate, $50\text{--}80 \mu \times 1\text{--}2 \mu$. R. 2. *L. Carrollii* A. L. Sm.

120. MICROTHERLIA Koerb.—Thallus crustaceous, immersed or superficial. Perithecia small, semi-immersed or superficial, semi-globose; paraphyses branched, entangled, sometimes mucilaginous and disappearing; ascii cylindrical, clavate or pyriform, 2-8-spored; spores ovate or elongate fusiform, usually 1-septate, rarely 3-5-septate, brown.

Also a widely distributed genus. The British species are very rare, except *M. micula*, which is not common. *M. exerrans* and *M. dissepula* may be fungi parasitic on lichen thalli.

Growing on trees.

Whitish-brown. Sp. oblong, upper cell longer,

$15-25 \mu \times 5-7 \mu$ 1. *M. micula* Flot.

Greyish. Sp. ellipsoid, $12-14 \mu \times 4-6 \mu$ 2. *M. atomaria* Koerb.

Growing on rocks.

Whitish, pulverulent. Sp. 2 in ascus, $25-35 \mu$

$\times 10-12 \mu$. Cal. 3. *M. dispora* A. L. Sm.

Blackish. Sp. $10-15 \mu \times 3-5 \mu$ 4. *M. exerrans* A. L. Sm.

Light-coloured, tartareous. Sp. 3-sept., $18-$

$22 \mu \times 7-10 \mu$ 5. *M. disjecta* A. L. Sm.

121. **PORINA** Ach.—Thallus crustaceous, immersed or superficial. Perithecia simple, semi-immersed or superficial, the outer wall light-coloured, darkening towards the ostiole or entirely dark-coloured, entire or dimidiate; paraphyses persistent, simple; spores 6-8 in the ascus, elongate-fusiform or clavate, 2-multi-septate, rarely with a longitudinal septum in one or more cells, colourless.

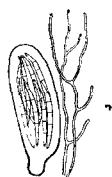

FIG. S2.—*Leptorhaphis epidermidis* Th. Fr.
Ascus with spores and
paraphyses $\times 300$.

FIG. S3.—*Microthelia micula* Flot.
Ascus with spores and
paraphyses $\times 300$.

FIG. S4.—*Porina olivacea* A. L. Sm.
Ascus with spores and
paraphyses $\times 300$.

Distinguished from *Arthopyrenia* mainly by the character of the paraphyses, but also by the more slender spores. In *P. lucens* and *P. interseptula* there is sometimes a longitudinal septum in the spores.

A. Spores septate.

*Perithecia brightly coloured; spores 3-septate (7-sept. in *P. succina*).

On trees.

Thin. Peri. minute, reddish; sp. $16-23 \mu$
 $\times 3-5 \mu$. F. 3. *P. leptalea* A. L. Sm.

On peaty earth.

Thin. Peri. reddish-brown or blackish;
sp. $24-33 \mu \times 4-5 \mu$. R. 2. *P. humicolor* A. L. Sm.

On rocks.

Thin. Peri. pale-reddish; sp. $22-32 \mu$
 $\times 4-7 \mu$. C. 1. *P. lectissima* A. Zahlbr.

Thin. Peri. amber-coloured; sp. 7-sept.,
 $16-20 \mu \times 4-6 \mu$. R. 4. *P. succina* A. L. Sm.

**Perithecia dark-coloured; spores 3-septate.

On trees.

- Thin, grey or dark. Peri. sessile; paraph. in mucus; sp. ca. $16-20 \mu \times 4-6 \mu$. C. 5. *P. carpinea* A. Zahlbr.
- Thin, light-coloured. Peri. semi-immersed; paraph. free; sp. $14-21 \mu \times 3-4 \mu$. R. 6. *P. affinis* A. Zahlbr.
- On rocks or soil.
- Thin, brown. Peri. subglobose; sp. ca. $11-20 \mu \times 4-6 \mu$. C. 7. *P. chlorotica* Wainio.
Reddish. Cal. R. Var. *persicina* A. L. Sm.
- Thin, dark. Peri. hemispherical; sp. acicular, $29-35 \mu \times 3-4 \mu$. R. 8. *P. tenuifera* A. L. Sm.
- Thin, pale. Peri. hemispherical; sp. $30-37 \mu \times 3-7 \mu$. On sandy soil. R. 9. *P. epigaeoides* A. L. Sm.

***Perithecia dark-coloured; spores 3-7- (rarely more-) septate.

On trees.

- Thin, dull-brown. Peri. immersed at base; sp. clavate, $27-40 \mu \times 5 \mu$. C. 10. *P. olivacea* A. L. Sm.
- Thin, brown. Peri. immersed at base; sp. fusiform $45-55 \mu \times 3-4 \mu$. On holly; rare 12. *P. leptospora* A. L. Sm.
- On rocks or soil.
- Thin, granulate, brown. Peri. innate; sp. $31-33 \mu \times 6 \mu$. On mossy ground; Ben Lawers 13. *P. furvescens* A. L. Sm.
- Thickish, dirty-white. Peri. in tubercles; sp. $50-67 \mu \times 11-14 \mu$. In caves. R. 14. *P. insiliens* A. L. Sm.
- Thin, brown. Peri. immersed at base; sp. ca. $52 \mu \times 3 \mu$. R. 15. *P. Curnowii* A. L. Sm.

B. Spores with occasional longitudinal septa.

On rocks.

- Thin, purplish-brown. Peri. shining; sp. clavate, $38-50 \mu \times 8-10 \mu$. F.... 16. *P. lucens* A. L. Sm.
- Thin, purplish-brown. Peri. shining; sp. fusiform $24 \mu \times 6-7 \mu$. R. 17. *P. interseptula* A. L. Sm.

122. THELOPSIS Nyl.—Thallus crustaceous, thin or scarcely visible. Perithecia immersed or becoming prominent, with poriform ostiole, the perithecial wall soft, light-coloured or dark; paraphyses slender, persistent, unbranched, free; asci many-spored; spores ellipsoid or elongate, 1-3-septate, rarely simple, colourless.

A small genus distinguished by the many-spored asci. In the two rare British species the thallus is indistinct.

Peri. pale-reddish; sp. 3-sept., $10-17 \mu \times 5-8 \mu$.

Trees 1. *Th. rubella* Nyl.

Peri. black; sp. 3-sept., $14-18 \mu \times 4-7 \mu$.

Mossy ground 2. *Th. melathelia* Nyl.

123. PYRENULA Ach.—Thallus crustaceous, superficial or immersed. Perithecia simple, variously globose, with poriform or slightly beaked ostiole; paraphyses slender, distinct; spores 8 in the ascus, elongate-ellipsoid, 2-5-septate, the spore cells lentiform or angular in shape, brown.

Distinguished by the brown septate spores and more especially by the form of the spore cells. The single British species is common on trees and of very wide distribution.

Thallus smooth, greyish-brown. Peri. prominent;

spores $14-23 \mu \times 6-9 \mu$ *P. nitida* Ach.

Peri. smaller, more immersed Var. *nitidella* Mudd.

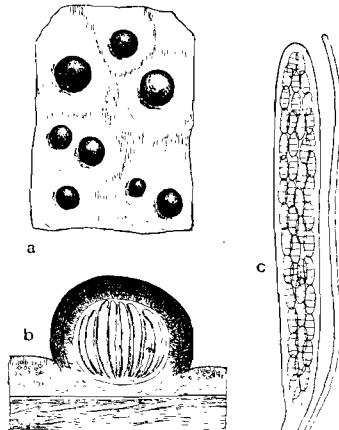

FIG. 85.—*Thelopsis rubella* Nyl.
a. Portion of plant on bark \times ca. 12. b. Vertical section of peritheciun \times 50. c. Ascus with spores and paraphysis \times 300.

124. ANTHRACOTHECIUM Hampe.—Thallus crustaceous, superficial or developed within the substratum. Perithecia simple, scattered or coherent, more or less immersed, globose or somewhat angular, entire; paraphyses unbranched, free; spores 1-8 in the ascus, elongate or ellipsoid, brown, muriform, the cells containing lentiform or angular guttæ.

A corticolous, tropical and subtropical genus. Only one species has been found in Europe, in S.W. Ireland, on hazel.

Peri. large, globose; sp. 8 in the ascus, ellipsoid. $50-110 \mu \times 20-40 \mu$ *A. hibernicum* A. L. Sm.

FAMILY XXX. THELOCARPACEÆ.

Horizontal thallus wanting. Algal cells Protococcaceæ. Perithecia superficial, surrounded by a thalline sheath, completely enclosed or opening by a pore; asci with numerous simple or septate spores. Spermogones unknown.

A peculiar family represented so far by one genus, *Thelocarpon*.

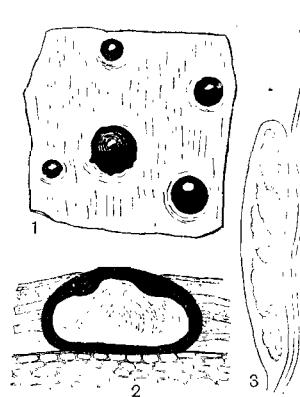

FIG. 86.—*Pyrenula nitida* Ach.
1. Portion of plant on bark \times 10. 2. Vertical section of peritheciun \times 40. 3. Ascus with spores and paraphysis \times 300.

125. **THELOCARPON** Nyl.—Thallus of small scattered or congregate verrucæ, each one enclosing a peritheciun. Perithecia almost globose, completely enclosed or opening above by a pore; perithecial wall colourless, slightly developed; paraphyses slender, simple or branched or wanting; ascii elongate, clavate or ventricose-fusiform, many-spored; spores minute, colourless, simple or pseudo-septate.

The species of *Thelocarpon* are of rare occurrence in this country. The minute tubercles constituting the thallus are yellowish-green; the ascii are

FAMILY XXXI. TRYPTHELIACEÆ.

Thallus crustaceous, superficial or immersed. Algal cells *Trentepohlia*. Perithecia united in a pseudostroma, each with a separate ostiole; spores 2-8 in the ascus, septate, colourless or brown.

A tropical or subtropical family represented in the British Isles by one genus, *Melanotheca*.

126. **MELANOTHECA** Fée.—Thallus forming spots on the bark of trees, or scarcely visible. Perithecia in confluent groups, the inner dividing walls more or less distinct, the upper common wall black; paraphyses confused or distinct; ascii usually 8-spored; spores elongate, 1- many-septate, colourless or coloured.

- Peri. many in roundish stroma; sp. 3-sept., becoming brownish, $23-27 \mu \times 7-10 \mu$. C. 1. *M. gelatinosa* Nyl.
 Peri. several in stroma; sp. 1-sept., brown, $22-26 \mu \times 5 \mu$. R. 2. *M. diffusa* Leight.
 Peri. 2-4 in a stroma; sp. 1-many-septate, colourless, $60-115 \mu \times 1-2 \mu$. R. 3. *M. ischnobela* Nyl.

FAMILY XXXII. MYCOPORACEÆ.

Thallus crustaceous, superficial or immersed. Algal cells *Palmella* or *Trentepohlia*. Perithecia compound, several united in a common outer dark-coloured wall (peridium), but with separate ostioles; spores 6-8 in the ascus, variously septate, colourless or coloured.

A small family containing only two genera.

- Algal cells *Palmella*..... 127. *Mycoporum*.
 Algal cells *Trentepohlia* 128. *Mycoporellum*.

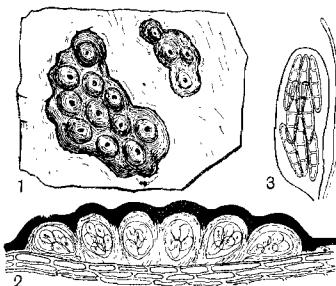

FIG. 89.—*Melanoteca gelatinosa* Nyl.
 1. Plant on bark $\times 15$. 2. Vertical section of perithecia \times ca. 65. 3. Ascus with spores and paraphysis $\times 300$.

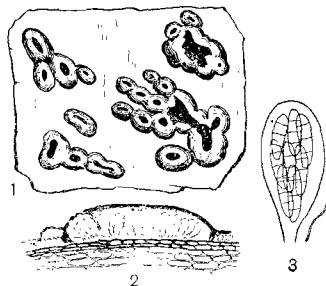

FIG. 90.—*Mycoporellum obscurum* A. L. Sm.
 1. Plant on bark $\times 10$. 2. Vertical section of perithecia $\times 50$. 3. Ascus with spores and paraphysis $\times 300$.

127. MYCOPORUM Flot.—Thallus thin or obsolete. Algal cells *Palmella*. Perithecia not well distinct from each other; asci elongate or pyriform, ellipsoid; paraphyses entangled or disappearing; spores 6-8 in the ascus, colourless, or dark-coloured, variously septate or muriform.

- Peri. 2-6 in a common peridium; sp. 3-5-sept. and muriform, $15-18 \mu \times 5-8 \mu$. Trees. F. 1. *M. miserrimum* Nyl.
 With less developed spores, $12-16 \mu \times 6-8 \mu$. Alder. B. 2. *M. ptelaeodes* Nyl.

128. MYCOPERELLUM A. Zahlbr.—Thallus thin or obsolete. Algal cells *Trentepohlia*. Perithecia not well distinct from each other; spores 8 in the ascus, colourless or brownish, elongate, septate.

- Sp. oblong-clavate, 3-sept., upper cell largest,
 $15 \mu \times 5 \mu$. Trees. R. 1. *M. obscurum* A. L. Sm.
 Sp. ovoid, 1-sept., $18-22 \mu \times 7-10 \mu$. Holly;
 in S.W. Ireland..... 2. *M. sparsellum* A. L. Sm.

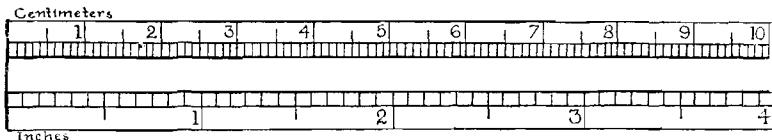

GLOSSARY

- ACERVULATE**, in small heaps.
- ACICULAR**, slender, needle-like.
- ACROGENOUS**, borne at the tips.
- ACUMINATE**, tapering gradually to a point.
- ADNATE**, adherent.
- ADPRESSED**, appressed, lying flat.
- ÆRUGINOSE**, blue-green, like verdigris.
- AGGLUTINATE**, glued together.
- AGGREGATE**, crowded but not confluent.
- AMORPHOUS CORTEX**, the cortical hyphae swollen and indistinct.
- AMPHITHECUM**, the thalline margin surrounding the apothecium.
- APOTHECIUM**, open or disc-shaped fructification.
- APPALANATE**, flattened or horizontally expanded.
- ARCHILICHENES**, lichens of which the goniidia are Chlorophyceæ (bright- or yellow-green).
- ARDELLA**, the small spot-like apothecium of Arthoniaceæ.
- AREOLA**, areolate, a small space marked out on the surface of the thallus.
- ARTHROSTERIGMA**, septate sterigma (spermatiophore).
- ASCOSPORES**, spores developed in an ascus.
- ASCUS**, enlarged cell in which the spores are developed.
- ASCYPHOUS**, without scyphi.
- BIATORINE**, apothecia that are soft or waxy, often brightly coloured and without a thalline margin, as in *Biatora*.
- BULLATE**, blistered.
- BYSSOID**, slender, thread-like, as in the old genus *Byssus*.
- CÆSPITOSE**, growing in tufts.
- CALCAREOUS**, containing lime.
- CALCICOLOUS**, living on lime rocks.
- CARBONACEOUS**, black, like charcoal.
- CARIOSE**, carious, decayed.
- CEPHALODIA**, abnormal developments upon or within the thallus, usually inducing irregular outgrowths which contain a blue-green alga.
- CHONDROID**, hard and tough, like cartilage.
- CHRYSOGONIDIA**, yellow algal cells (*Trentepohlia*).
- CILIUM**, CILIATE, marginal hair on thallus or fruit.
- CONCEPTACLE**, cavity containing reproductive cells.
- CONCRETE**, closely adhering.
- CORIACEOUS**, leathery.
- CORNEOUS**, CORNICULATE, horny.
- CORTICATE**, covered with a continuous layer of hyphal tissue.
- CORTICOLOUS**, living on the bark of trees.
- CREXATE**, CRENULATE, with rounded notches on the margin.
- CRISPATE**, curled and twisted.
- CRISTATE**, crested.
- CRUSTACEOUS**, thin closely adhering thallus.
- CUCULLATE**, hooded or hood-shaped.
- CYPHELLE**, minute cup-like depression on the under surface of the thallus (*Sticta*, etc.).
- DENDRITIC**, having a branched appearance.
- DETERMINATE**, with a definite outline.
- DIMIDIATE**, term applied to the perithecium when the outer wall covers only the upper portion.
- DISCOID**, disc-like.
- DISCRETE**, separate, loose, term applied to paraphyses.
- EFFIGURATE**, having a distinct form or figure. See placodioïd.
- EFFUSE**, indeterminate spreading thallus.
- ELLIPTICAL**, ELLIPSOID, oblong with rounded ends.
- ENDOGENOUS**, internally produced.

- ENTIRE**, term for continuous wall of the perithecium.
- EPICHLÆDAL**, thallus growing on the surface of the bark.
- EPITHECIUM**, layer covering the thecium or hymenium (best seen in section).
- ERODED**, erose, as though bitten or gnawed
- ERUPTIVE**, immersed then bursting outward.
- EXICULUM**, tissue surrounding the fruit.
- EXOGENOUS**, externally produced.
- FARINACEOUS**, **FARINOSE**, with a mealy surface.
- FASCICULATE**, growing in a bundle or cluster.
- FASTIGIATE**, with branches parallel, clustered and erect (Fastigiate cortex).
- FIBRILLÆ**, **FIBRILLOSE**, minute fibre-like strands.
- FILAMENTOUS**, slender, thread-like.
- FILIFORM**, extremely slender, thread-like.
- FIMBRIATE**, fringed.
- FLACCID**, flabby, limp.
- FLEXCOSE**, **FLEXCOUS**, wavy.
- FOLIACEOUS**, flat and leaf-like.
- FOVEOLE**, **FOVEOLATE**, pitted.
- FRUTICOSE**, **FRUTICULOSE**, having the thallus attached by a single basal point, the fronds cylindrical, filamentous or strap-shaped.
- FURcate**, forked.
- FURFURACEOUS**, scurfy.
- FUSIFORM**, **FUSOID**, elongate and tapering towards each end like a spindle.
- GENICULATE**, bent like the knee.
- GIBBOUS**, with hump-like swellings.
- GLABROUS**, with a hairless surface.
- GLAUCOUS**, sea-green or greyish-blue like the bloom on plum or cabbage.
- GLEBLOSE**, with rounded elevations on the thallus.
- GONIDIUM**, green algal cell, constituent of the lichen-thallus, term given to bright-green (*Chlorophyceæ*) and to blue-green (*Myxophyceæ*) algae.
- GONIUM**, term given to blue-green algal cells (*Myxophyceæ*) in the thallus.
- GRANULAR**, with rough irregular granules.
- GRANULATE**, with smooth granules.
- GRANULOSE**, with minute granules almost powdery.
- GRAPHIDEINE**, resembling the genus *Graphis*.
- GUTTÆ** (*guttulate*), oil-drops in spores or hyphae.
- HALONATE**, surrounded by an outer circle.
- HETEROMEROUS**, fungal and algal constituents in definite strata in the thallus.
- HOMOIOOMEROUS**, fungal and algal constituents more or less mixed in the thallus.
- HYMENIUM**, the layer of tissue in the apothecium, consisting of asci and paraphyses, cf. thecium.
- HYPHA**, a fungal filament.
- HYPOTHLEDAL**, term applied to thallus growing within the bark.
- HYPOTHALLUS**, the undergrowth of thaline hyphae often visible at the edge of the thallus.
- HYPOTHECIUM**, the layer below the thecium or hymenium.
- IMBRICATE**, overlapping like the tiles on a roof.
- IMMARGINATE**, without a margin.
- INCISE**, cut sharply into the margin.
- INNATE**, embedded in the thallus.
- INSPERSED**, interpenetrated with granules.
- INTRICATE**, entangled.
- ISIDIUM**, **ISIDIOID**, coral-like outgrowth on the lichen-thallus resembling the old genus *Isidium*.
- JOINTED**, septate.
- LACERATE**, torn or irregularly cleft.
- LACINIA**, **LACINIATE**, slender thaline lobes.
- LACUNA**, **LACUNOSE**, depressions or holes.
- LATERAL**, on or near the edge of thallus or fruit.
- LECANORINE**, term applied to apothecia with a thaline margin, as in *Lecanora*.
- LECIDINE**, apothecia that are carbonaceous, dark-coloured, and without a thaline margin, as in *Lecidea*.

LENTICULAR , LENTIFORM , lens-like.	PLACODIOID , referring to an orbicular, adpressed thallus, lobed at the circumference.
LEPROSE , mealy or scurfy like the old genera <i>Lepra</i> and <i>Lepraria</i> .	PLEUROGENOUS , borne laterally on stalk or hypha.
LIGNICOLOUS , growing on wood.	PPLICATE , folded in plaits.
LIRELLA , long narrow apothecium of Graphidaceæ.	POD ETIUM , the secondary, stalk-like thallus of Cladoniaceæ.
LOBATE , thallus divided into lobes.	POLARILOCULAR , POLARI - BILOCULAR , two - celled spores with a thick septum, and with a connecting tube between the cells.
MACULAR , applied to a thallus occurring in spots.	POLYPHYLLOUS , many-leaved or -lobed.
MARGINAL , situate on the edge or margin.	PROPER MARGIN , the rim or margin formed of hyphae that encircles the apothecium, cf. parathecium.
MARGINATE , having a margin.	PRUINA , PRUINOSE , powdery bloom on the surface of thallus or fructification.
MAZEDICUM , powdery fructification of Coniocarpineæ.	PSUDOSTROMA , not a true stroma structure.
MEDULLA , loose hyphal layer in the interior of the thallus.	PYCNDIUM , roundish fructification closed or with an ostiole, containing stylospores.
MONOPHYLLOUS , one-leaved.	
MULTI- , Latin prefix, signifying many.	RADIATE , spreading outward from a centre.
MURIFORM , term applied to multicellular spores divided like wall-masonry.	RECEPTACLE , base or surrounding tissue of the apothecium.
MYCELIUM , aggregate of fungal hyphae.	RHIZINA , root-like strands.
OBSOLETE , rudimentary or wanting.	RIVULOSE , having sinuate channels or lines.
ORBICULAR , flat, with a circular outline.	RUGOSE , wrinkled.
OSTIOLE , opening in the peritheciun through which the spores escape.	
OVAL , OVATE , Ovoid, egg-shaped.	SAXICOLOUS , growing on rocks or stones.
PALMATE , lobed in a finger-like manner.	SCYPHUS , cup-like widening of the podetium in Cladoniaceæ.
PANNIFORM , PANNOSE , felted.	SEPTATE , divided by a cell-wall.
PAPILLA , a small protuberance.	SEPTUM , wall dividing one cell from another.
PAPLOSE , beset with papillæ.	SILICOLOUS , growing on rocks containing silica.
PARAPHYSIS , sterile filament in the hymenium.	SINUATE , with a deep wavy margin.
PARATHECIUM , layer surrounding the theciun (hymenium).	SMARAGDINE , emerald or dark bluish-green.
PATELLA , PATELLATE , sessile marginate apothecia, saucer-like.	SPERMATIUM , spore-like body formed in the spermogone.
PELTATE , orbicular, like a shield or target.	SPERMOGONE , closed fructification containing spermatia.
PERIDIUM , outer wall of peritheciun.	SPORE , reproductive body which becomes free and germinates to form a new plant.
PERIPHERY , PERIPHERAL , the edge.	SQUAMULE , a small thalline lobe.
PERIPHYSSES , filaments rising near the ostiole.	STERIGMA , the stalk from which the spermatia are abjoined.
PERITHECIUM , roundish fructification closed or with an ostiole, containing ascospores.	
PERVIOUS , referring to scyphi that are open or perforate at the base.	
PHYLCOLICHENES , lichens with Myxophyceæ.	

STRATUM, a layer of tissue.	THALLUS, vegetative part of the lichen-plant.
STROMA, hyphal structure in which fructifications are developed.	THECIUM, the hymenium (asci and paraphyses).
SYMBIONT, one of two dissimilar organisms living together.	THYRSOID, with crowded dichotomous branching.
SYMBIOSIS, a living together of dissimilar organisms.	TRABECULÆ, reticulating fibrils.
TARTAREOUS, resembling tartar, having a more or less rough crumbling surface, or thickish and almost smooth.	TURGID, swollen.
TERRICOLOUS, living on soil.	URCEOLATE, pitcher-like, hollow and contracted at the mouth.
	VERRUCA, a granular wart-like part of the thallus.

Comparative scale, showing centimeters and inches.

INDEX

Specific names, along with those of varieties, genera and families, are listed. Names of genera and families are printed in capitals; synonyms are in *italics*. A figure in the text is indicated by an *.
